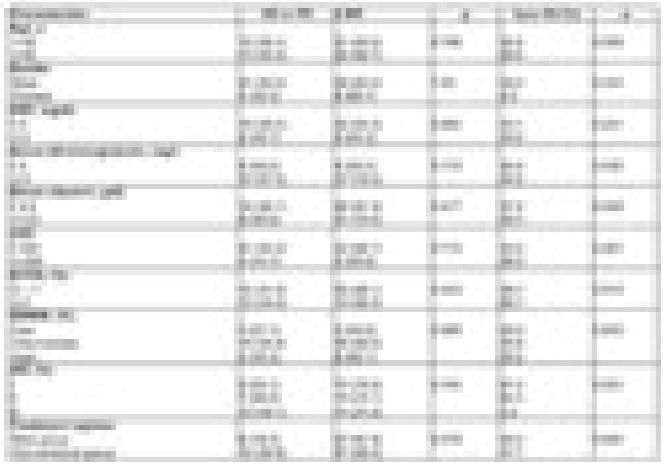
Methods: A total number of 72 patients who newly diagnosed WM and received chemotherapy at the South Korea between January 2005 and December 2012 were enrolled retrospectively in the current study. We analyzed nationwide retrospective data from sixteen university hospitals in South Korea. We divided into new group which were included patients treated by novel agents combined chemotherapy and conventional group treated by conventional chemotherapy. We analyzed overall response rates and overall survival rates in two groups.

Table 1.



Results: The median age of patients was 65.5 years (range, 37-92 years) and male to female ratio was 5 : 1. Median follow up duration was 22.6 months. Clinical features including the incidence rates of hypervisocsity syndrome, B symptoms, splenomegaly, and extranodal involvement were 11.1%, 12.5%, 25.0%, and 40.3% in our study. The analyzed patients included new group (n=33, 45.8%), and conventional group (n=39, 54.2%). New group was shown slightly higher overall response rates than those treated with conventional group (81.8% *vs* 69.2%, p=0.219). The 5 years overall survival rates were not shown differences between two groups (new group *vs* conventional group; 44.0% *vs* 47.7%, p= 0.640) (Table 1).
Summary and Conclusions: In our study, clinical features of WM were shown similar characteristics compared with western data. Patients treated with novel agents combined chemotherapy were shown a trend of higher overall response rates. But overall survival rates were shown similar between two groups. Our results were not shown significant difference of treatment outcomes between novel agents and conventional treatment because of limitation of analyzed patients number and short follow up duration. So further studies are needed to confirm efficacy of novel agents in patients with WM.

OUTCOME OF NEWLY DIAGNOSED SYMTOMATIC MULTIPLE MYELOMA IN PATIENTS AGED > 80 YEARS: SINGLE CENTRE EXPERIENCE

N Sgherza[1,*] C Minoia[1], A Iacobazzi[1], A Rana[1], A Lapietra[1], G Loseto[1], V De Fazio[1], G De Tullio[1], S Serrati[1], A Guarini[1]

[1]Haematology Unit, National Cancer Research Centre "Giovanni Paolo II", Bari, Italy

Background: Multiple Myeloma (MM) is a plasma cell neoplasm typical of the elderly, with a median age at diagnosis of 65 years. It accounts for approximately 10% of all hematologic malignancies. The increase of median age in western countries has led to an increase in the incidence of this disease; in addition the introduction of novel agents, such as the immuno-modulatory drugs thalidomide and lenalidomide, and the proteasome inhibitor bortezomib, has considerably changed the therapeutic scenario both for young and elderly patients with MM.
Aims: The purpose of this study was to evaluate the outcome of newly diagnosed symptomatic multiple myeloma in patients aged ≥ 80 years.
Methods: We report a retrospective analysis of the outcome of 15 very elderly (≥ 80 years) patients (M/F: 11/4) diagnosed and treated at our Institute from January 2008 to January 2014. Median follow-up was 16 months (range 6-49) after the start of treatment to determine the characteristics of this subset of very elderly patients.
Results: Median age at diagnosis was 83 years (range 80-89) and PS was <2 in 12 cases (80%). One or two concomitant diseases requiring specific treatments were present in 10 patients (67%), and 3 or more concomitant diseases were present in 5 patients (33%). MM was IgG lambda in 7 patients, IgG k in 4 patients, IgA k in one case, IgA lambda in 1 case, and micromolecular in 2 cases. According to the International Staging System 8 patients were classified as III stage and 7 patients as II stage. Anemia (median value: 9.8 g/dL) was present at diagnosis in 11 patients (73.3%) and was the most frequent CRAB feature. Bone lytic lesions were present in 10 patients (67%) and zoledronic acid and ibandronic acid were used in 8 and 2 patients respectively. First line therapy was bortezomib/dexamethasone in 8 patients (53.3%), and melphalan/prednisone +/- thalidomide in 7 patients (46.7%). Hematologic toxicity was infrequent but usually weak/moderate (grades 1 & 2 on the WHO scale), and was resolved only with dose delays. Six patients received erythropoiesis-stimulating agents. Extrahematologic toxicity was observed in 6 patients (40%) and neuropathy was the most common adverse event for treatment. Seven patients (47%) had at least one disease progression since diagnosis and were therefore switched to second-line therapy. The median time to first disease progression was 10 months (range 5-28). 9 patients (60%) are still alive and continuing to receive treatment. Five patients died due to disease progression. One patient died due to urinary bladder cancer.
Summary and Conclusions: A study in a larger series of patients is warranted but our experience showed that no upper age limit should be applied for the administration of new drugs with multiple myeloma; these treatments could be offered to very elderly patients, including those with severe concomitant diseases.

PB1662

TREATMENT OF BENCE-JONES MULTIPLE MYELOMA WITH CHEMOTHERAPY WITH/WITHOUT STEM CELL TRANSPLANTATION

A Zivanovic-Ivic[1,*] D Stamatovic[1], O Tarabar[1], S Marjanovic[1], L Atanaskovic[1], M Elez[1], J KnezevicBoskovic[1], Z Tatomirovic[2], O Radic-Tasic[2], B Balint[3], Z Mijuskovic[4], J Trimcev[2], L Tukic[1]

[1]Military medical academy, Clinic of haematology, [2]Military medical academy, Institut of pathology, [3]Military medical academy, Institut of transfuiology, [4]Military medical academy, Institut of medical Biochemistry, Belgrade, Serbia

Background: Bence-Jones myeloma multiplex is a progressive disease characterized by excessive numbers of abnormal plasma cells in the bone marrow and overproduction of incomplete immunoglobulins, containing only the light chain portion of the immunoglobulini.This type of myeloma occurs 15-20%.The mediana overall survival is approximately 4 years. Patient outcome in BenceJones myeloma has been remarkably improved due to the use of combination therapies including chemotherapy and stem cell transplantation.High-dose melphalan with autologus stem cell support has been an integral part of myeloma therapy for mor than 28 years.
Aims: A retrospective analysis of outcome of treatment Bence-Jones myeloma.
Methods: Since 1995. until 2013. we treated 60 pts (39 men and 21 female), average age 55,5 years (range 36-85). Regarding ISS score, the group included: ISS1 15 pts, ISS2 10 pts, ISS3 35 pts. Renal insufficiency was present in 35 pts. High risik pts was defined by the presence of following factors: b2M >5,5 mg/l,albumine<3,5gr/dl, CRP >6, high lactat dehydrogenase, renal failure, stage III.Pts treated with induction,consolidation and maintenance therapy.Conventional induction treatments were applied as following regimens:VAD(42),MP(9),CTD(3),PAD(2) and TAD(4).
Results: Conventional chemiotherapy introductory clinical response was achieved in 41pts (70%) (MR-5 pts, PR-15 pts,VGPR-21 pts), while in 19 pts (30%) established disease was resistant. Transplantation had been done with 33 pts (55%), while 27 pts (45%) were treated with conventional chemotherapy adjusted to the vital age and comorbiditity. In the group of pts with transplantation done tandem had been carried out with 11 pts and secondary SCT had been done in 4 relapsed pts. With 1 pts with tandem SCT allogenic(singen) SCT had been done. TRM is 3%. Maintenance therapy with Thalidomid had been done in 27 pts for 4-40 months, with IFN had been done in 4 pts for 6-12 months. Impact of high risk factors on outcome/PFS/OS was of no significance, except for elevated high lactat dehydrogenase values that are associated with rapid relapse. The presence of bone lesions associated with short PFS and with no difference in OS. In the group of transplanted no difference in OS with/without a response to primary therapy, but in the nontransplanted pts OS was significance shorter in patients who did not achieve a response.The transplanted patients had significantly longer PFS (mediana 14 months *vs* 8 months, p<0,05) and longer OS (mediana 50 months *vs* 20 months,p<0,001). 20 pts (33%) of treated pts are living, while 40 pts (67%) died. Univariate log. regres. analysis showed that non-transplant patients are 10,41 times more likely to terminate lethal compared to transplant patients (RR 10,41(95%C.I.43,47-2,52),p<0,001).
Summary and Conclusions: Our study showed ASCT is a more effective method of treatment of patients with BenceJones myeloma compared to the conventional chemotherapy, but the results are still unsatisfactory. Impact of high risk factors on outcome/PFS/OS was of no significance, except for elevated high lactat dehydrogenase values that are associated with rapid relapse. One of the major efforts to improve the results of intensive therapy and ASCT involves the integration of novel agents (proteasome inhibitors and immunomodulatory drugs) into the transplantation sequence.

PB1663

DIAGNOSTIC DILEMMAS AND TREATMENT DECISIONS: EXTRAMEDULLARY PLASMACYTOMA OF TESTIS AS A FIRST MANIFESTATION OF MULTIPLE MYELOMA – CASE REPORT

M Smiljanic[1,*] J Bila[1], M Perunicic[1], V Artiko[2], M Dencic Fekete[1], D Antic[1], V Vukovic[1], J Jelicic[1], V Djurasinovic[1], A Sretenovic[1], B Andjelic[1], M Todorovic[1], B Mihaljevic[1]
[1]Clinic of Hematology Clinical Centre of Serbia, [2]Center of Nuclear Medicine, Clinical Center of Serbia, Belgrade, Serbia

Background: Overall data indicates that 65-71% of patients with multiple myeloma (MM) have some form of extramedullary plasmacytoma (EMP) as well. In available literature, only 10 cases of testicular EMPs presented with simultaneous bone marrow involvement, or a diagnosed MM. Due to small patient numbers and historical retrospective analyses over many decades, no firmly established criteria for treatment exists.
Aims: The aim of our case report is to present an extremely rare case of testicular extramedullary plasmacytoma (EMP), as first manifestation of multiple myeloma (MM) with focal osteolytic lesions, in terms of diagnostic dilemmas and personalized treatment approach.
Methods: We report a case of 68-year old male with testicular plasmacytoma as a first manifestion of MM. Eight months prior to diagnosis, a swelling of a left testicle occurred and was accompanied with scrotal pain. There was no abnormalities in the initial laboratory findings, except increased serum fibrinogen (5,3g/l), ß2 microglobulin (5,6mg/l), and erythrocyte sedimentation rate (100/1h). Ultrasound exam of testicular tissue showed enlarged left testicle with hypoechoic lesions. Thoracic an abdominal CT scan did not reveal pathological findings. Subsequent total left orchiectomy was performed, and immunohistochemical profile of testicular tissue (monoclonal CD38$^+$, CD138$^+$, lambda light chain$^+$ plasma cells) indicated diagnosis of EMP. Immunoelectrophoresis of serum and urine detected high level of monoclonal (M) IgG lambda protein in serum (54,9g/l), followed with discrete Bence-Jones proteinuria (0,1g/l). There was no plasma cell infiltration in the bone marrow biopsy. Furthermore, in terms of Fluorescent in-situ hybridization (FISH) analysis of tumor cells, there were no typical or high risk cytogenetic abnormalities specific for the plasma cell disorders like del13q14; t(4;14); t(14;16); or del17. Considering current infrequent EMP localization, IgG lambda M protein above 30g/l, and absence of bone marrow infiltration with plasma cells, FDG PET-CT was performed within differential diagnostics of EMP in contrast to MM. Surprisingly, PET-CT scan revealed few scattered osteolytic lesions, in right humerus, sacral bone and left femur.
Results: Unusually, first manifestation of underlying plasma cell disorder in our patient was development of testicular EMP, without systemic symptoms of MM. In terms of diagnostic dilemmas, following confirmation of EMP and absence of medullar involvement, presence of significant concentration of IgG lambda M protein in serum, indicated further exploration with FDG PET-CT. Consequently, existence of osteolytic lesions at right humerus, sacral bone and left femur confirmed diagnosis of IgG lambda multiple myeloma in IIIA CS (Durie&Salmon criteria), ISS score 3 with testicular EMP localization. Treatment with 4 of planned 6 cycles, according to the CTD regimen was applied, followed by the achievement of very good partial remission (Blade criteria) according to patient's laboratory findings after second cycle of treatment.
Summary and Conclusions: Testicular involvement in MM is extremely rare with incidence 0,6-2,7%. FDG PET-CT scan may be obligatory diagnostic method in a case of atypical EMP localizations, with a strong impact on the treatment decision in accordance to the final diagnosis and staging.

PB1664

THE ROLE OF MERTK IN THE PROGRESSION OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE (MGUS) TO MYELOMA (MM)

KC Cheung[1,2,*]D Hewett[1,2], D Yeung[1], CW Tan[1], LB To[1], A Zannettino[1,2]
[1]Haematology, IMVS, Adelaide, [2]Myeloma Research Laboratory, Faculty of Health Science, University of Adelaide, Australia

Background: The identification of reliable biomarkers that predict which patients will progress from MGUS to MM would greatly assist treatment decision-making. In longitudinal gene expression profiling experiments, examining the transcriptome of individual patients when first diagnosed with MGUS and then subsequently MM, we identified a number of differentially expressed genes associated with the MGUS to MM transition. MERTK (c-mer proto-oncogene tyrosine kinase) was one such gene, whose expression was lost during the transition from MGUS to MM.
In this study, we performed quantitative real-time PCR (Q.RT-PCR) and immunohistochemistry (IHC) of marrow trephine biopsies recovered from patients (n=10), when first diagnosed with MGUS and subsequently MM, to confirm that MERTK was lost as a function of disease progression. In addition, we examined the prognostic significance of the loss of MERTK expression
Aims: To investigate the role of MERTK in MM progression by mean of Q.RT-PCR and IHC
Methods: Trephine biopsies were recovered from 10 patients when first diagnosed with MGUS and subsequently MM (n=20 trephines). Serial 5 µm trephine section were stained with either a MERTK-specific antibody (Abcam, UK) or an antibody to the plasma cell marker CD138 (Dako, USA). The number of CD138+MERTK+ cells in each section was assessed by 3 pathologists blinded to the level of MERTK mRNA expression in each patient. The magnitude of change in MERTK expression from MGUS to MM of each paired patient sample was expressed as ΔMERTK (defined as the ratio of the overall MERTK in MM sample compared with that in MGUS sample). A ROC curve was used to identify the best cut-off value of ΔMERTK that resolved different clinical outcomes for our cohort of patients.

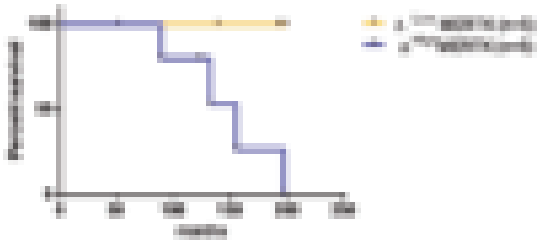

Figure 1. Kaplan-Meier curve of OS of MM patients transformed from MGUS with differential MERTK expression, p=0.33 Chi-square test.

Results: A consistent reduction in MERTK expression was observed in all patients as they progressed from MGUS to MM as evidence by a decrease in mRNA and protein expression (unpaired t-test, p=0.05). The magnitude of the

change in MERTK protein expression (ΔMERTK) in patients as they progressed from MGUS to MM varied (ΔMERTK range 0.25-0.98). A cut-off value of 0.51 for ΔMERTK was determined by ROC curve analysis and Δ^{high} MERTK was defined as <0.51 (*i.e.* greater reduction in MERTK expression from MGUS to MM). While not statistically significant, a trend towards better overall survival (OS = time of diagnosis of MGUS to death) was observed in MM patients with Δ^{low} MERTK (*i.e.* lesser reduction in MERTK expression from MGUS to MM) (Figure 1). The median OS for Δ^{low} MERTK was not reached while the median OS for Δ^{high} MERTK was 155 months from the diagnosis of MGUS. Although not statistically significant, patients with Δ^{high} MERTK had a shorter time to progression (TTP) (median 45 months) from MGUS to MM as compared to that of Δ^{low} MERTK (median 104 months).

Summary and Conclusions: The loss of MERTK expression that accompanied the transition from MGUS to MM was associated with a trend toward shorter TTP and OS in our cohort of MM patients. In view of the sample size, additional MGUS/MM paired samples are required to increase the power of study. In addition, further experiments are required to examine the biological role and prognostic value of MERTK in MM transformation.

CYTOGENETIC IMPACT ON LENALIDOMIDE TREATMENT IN RELAPSED/ REFRACTORY MULTIPLE MYELOMA: A REAL LIFE EVALUATION

R Zambello[1,*] T Berno[1], L Bonaldi[2], E Sechettin[3], E De March[1], A Branca[1], L Albana[1], C Minotto[4], C Briani[5], C Gurrieri[1], F Temporin[3], K Sammartin[1], F Piazza[1], M Cavraro[1], L Trentin[1], G Semenzato[1]

[1]Dept. Medicine, Hematology and Clinical Immunology Branch University of Padova, [2]Dept. of Oncology and Surgical Sciences, Immunology and Molecular Oncology Unit , Istituto Oncologico Veneto, [3]Dept. of Pharmaceutical and Pharmacological Sciences, University of Padova, Padova, [4]Division of Oncology, Noale (Venezia), [5]Dept. of Neurosciences, University of Padova, Padova, Italy

Background: Despite the progress obtained by the introduction of novel agents, treatment of relapsed/refractory multiple myeloma (rrMM) remains a clinical challenge. Long-term treatment aims to delay progression of MM, but there is concern regarding tolerance, especially in the non-study patient (pt) population. The mode of action of Lenalidomide (Len) as an immunomodulatory agent and the tolerability profile led to approval of the drug for continuous treatment until disease progression (PD) or unacceptable toxicity.

Aims: Due to the low number of reports assessing benefit and risk of long-term Len treatment in non-selected rrMM patients, we retrospectively analysed the long-term outcome in pts with rrMM treated with Len.

Methods: 91 pts were included in this study, treated with Len ± Dex for rrMM in the approved indication until PD or unacceptable toxicity. Median age was 70 years (range 42-85), median pretreatments were 2 (range 1–6). 40% of patients were relapsed and 60% refractory from previous therapy. 69% received prior treatment with bortezomib, 20% with thalidomide and bortezomib. High dose therapy was performed in 44%. Cytogenetic analysis and/or FISH was available in 76 pts (86%). According to time of stopping therapy for any reason (progression of disease or toxicity), patients were separated in three groups: Early Stop group (ES) (n: 23), when stop therapy occurred within 6 months from starting Len; Intermediate group (INT) (n: 23) for patients interrupting therapy between 7 to 24 months; and Long Runners group (LR) (n: 45), when patients were continuing therapy for more than 2 years.

Results: High risk cytogenetic, referring to the presence (alone or combined) of hypodiploid caryotype, del 13 in classical cytogenetic, del 17, FISH t(4;14), t(14; 16), was demonstrated in 29% of cases (53% ES, 43% INT, 21% LR). High risk cytogenetic and 1q21 gains were reported in 59% ES, 43% INT and 21% LR. Overall response rate (ORR) was 62% comprising 13 patients (14%) with VGPR and 13 patients (14%) with RC. Among the three cohorts, ≥ PR was demonstrated in 82% of LR (44% ≥ VGPR, with 20% RC), 82% of INT (26% ≥ VGPR, with RC 17%), and 4% (one PR) in ES. The median duration of treatment with Len was 20 months (range, 1-53 months). Overall, 35 patients (38%) experienced haematological (neutropenia and thrombocytopenia) and 39 (43%) non haematological adverse events (dyarrhea, rash) of clinical significance (grade 3-4) during Len treatment. Median PFS for the whole population was 2.8 years. The presence of 1q21 gains (p<0,0006), age (<65 *vs* >65) (p< 0,03), and response to therapy (ES *vs* INT *vs* LR) being statistically significant (p< 0,001). In multivariate analysis, significance was maintained for +1q21 (HR 4.105, p< 0.0001) and response to therapy (HR 0.370, p< 0,0021). OS for the whole population was 4.7 years and probability of two year OS was 74% (CI 95% 64-82%). +1q21 gains were demonstrated to negatively impact on survival (p< 0.001) maintaining its negative prognostic value in the Cox multivariate analysis (HR 2.41, p< 0.013).

Summary and Conclusions: Our study confirme that Len is safe and effective in patients undergoing long-term treatment in the setting of rrMM, leaving to a significant benefit in terms of PFR and OS for prolonged treatment. Analyzing the mechanisms impacting on the disease control mediated by Len therapy, our results suggest that 1q21 gains represent a detrimental feature in these patients, identifying a subset of patient poorly responsive to Len therapy.

PB1666

HIGH THROUGHPUT EX VIVO MONITORING OF DRUG SENSITIVITIES IN MULTIPLE MYELOMA COMBINED WITH CLINICAL TRIAL ASSESSMENT

R Silvennoinen[1,*] MM Majumder[2,3], T Lundan[4], P Anttila[5], S Eldfors[2,3], E Jantunen[1,6], T Kuittinen[1], A Kumar[2,3], J Lievonen[5], M Säily[7], K Remes[8,9], K Porkka[5,10], C Heckman[2,3]

[1]Hematology, KUOPIO UNIVERSITY HOSPITAL, Kuopio, [2]Institute for Molecular Medicine Finland FIMM, [3]University of Helsinki, Helsinki, [4]Clinical Chemistry and TYKSLAB, Turku University Central Hospital, Turku, [5]Cancer Center, Helsinki University Central Hospital, Helsinki, [6]University of Eastern Finland, Kuopio, [7]Hemato-oncology, Oulu University Hospital, Oulu, [8]Hematology, Turku University Central Hospital, [9]University of Turku, Turku, [10]Hematology Research Unit, University of Helsinki, Helsinki, Finland

Background: Treatment for multiple myeloma (MM) patients with poor prognostic markers such as the t(4;14) translocation remains a major challenge. Despite the availability of novel agents such as bortezomib and lenalidomide, these patients may be poorly responsive and could potentially benefit from a personalized approach to treatment.

Aims: To identify novel treatments for MM, we established an *ex vivo* drug sensitivity and resistance testing (DSRT) assay assessing sensitivity of patient cells to hundreds of approved or investigational oncology drugs. In addition, genomic and transcriptomic profiling were performed to better understand disease progression and drug response mechanisms.

Methods: Bone marrow (BM) aspirates and skin biopsies were collected after informed consent from newly diagnosed (10) and relapsed (26) MM patients. CD138+ cells were isolated for analyses. The DSRT repertoire includes 306 small molecule compounds, pre-plated in 384-well plates over a 10,000-fold concentration range. CD138+ cells were added and cell viability measured after a 3-day incubation. Drug sensitivities of the CD138+ cells was determined and compared to sensitivities of healthy BM mononuclear cells to identify MM specific responses. CD138+ cell and skin biopsy DNA was analyzed by exome sequencing and CD138+ cell RNA analyzed by transcriptome sequencing.

Results: The index patient was a 56-year old male with MGUS IgA-kappa since 2011. CRAB criteria were met in June 2013 and the patient was included in the Finnish Myeloma Group-MM02 trial, consisting of three induction cycles of lenalidomide/bortezomib/dexamethasone (RVD) plus randomized mobilization (Cy 2g/m2 + G-CSF 5µg/kg *versus* G-CSF 10µg/kg) followed by ASCT and then lenalidomide maintenance starting three months after ASCT. Molecular cytogenetic/FISH analysis indicated t(4;14) (FGFR3conIGH x 2) (90%), +++1q21 (CKS1B x 5) (80%), del (13q14)/-13 (13s319 x 1,13q34 x 2) (30%), (13s319 x 1,13q34 x 1) (60%). BM samples were taken for DSRT and profiling prior to treatment initiation. In agreement with the t(4;14), RNA sequence analysis revealed high gene expression levels for *FGFR3* and *MMSET*. Six compounds known to have activity against FGFR3 were tested in the DSRT assay: dovitinib, sorafenib, nintedanib, AZD4547, AZD1480 and NVP-BGJ398. The cells showed sensitivity to nintedanib and AZD1480 at high nM levels, EC50 778 nM and 568 nM, respectively, but lacked sensitivity to the other FGFR3 inhibitors (EC50 > 10 µM). The cells, however, were selectively sensitive to the BCL-2 inhibitor ABT-199 (EC50 42.5 nM), which correlated with high *BCL-2* gene expression levels. Of the RVD drugs, the cells showed very good sensitivity to bortezomib (EC50 3.1 nM), little sensitivity to lenalidomide (EC50 9.3 µM) and no sensitivity to dexamethasone (EC50 > 10 µM). With the described treatment, the patient achieved sCR/immunophenotypic remission with minimal residual disease of 0.003-0.0004% by ASO-RQ-PCR of the clonal IgH gene rearrangement before lenalidomide maintenance.

Summary and Conclusions: While t(4;14) leads to deregulated *FGFR3* expression, this may not necessarily predict for sensitivity to FGFR3 inhibitors. Recent studies suggest that MMSET is the pathogenic driver in t(4;14) MM and may therefore be a better target for treatment. Comprehensive assessment by combined *ex vivo* drug testing and deep molecular profiling may help quickly identify alternative optimal treatments such as ABT-199 for the index patient. In addition to this present patient, additional data on other newly diagnosed patients will be presented.

Hart Ziekenhuis, Roeselare, [10]Hematology, Sint-Augustinus Ziekenhuis, [11]Hematology, UZ

Antwerpen, [12]Hematology, ZNA Stuyvenberg, Antwerp, [13]Hematology, UZ Brussel, Brussels, [14]Hematology, UZ Leuven, Leuven, [15]Hematology, Clin Univ Mont-Godinne, Mont-Godinne, Belgium

Background: Bendamustine - an alkylating agent with purine-analogue like activities - shows activity in both de novo and relapsed/refractory MM patients.
Aims: The BHS MM study group initiated a study from February till December 2012 and included 20 patients with a prior history of relapse after both bortezomib and lenalidomide treatment. Other inclusion criteria were the absence of end-stage renal disease, a correct residual marrow function and the absence of plasma cell leukemia.
Methods: Twenty patients with a median age of 69 years (52y-83y) received bendamustine until disease progression. The median number of bendamustine cycles infused was 4 (1-8). Patients were heavily pretreated (mean number of prior regimens was 5, ranging from 3 to 8). Eleven patients received at least one autologous stem cell transplantation. Responses were assessed by the treating physician.
Results: The overall response rate (according to EBMT criteria) was 45% (1 very good partial response and 8 partial responses), 2 patients showed a minor response, 3 patients a stable disease and disease progression was described in 6 patients. The progression free survival (PFS) for the whole population was 90 days, but responding patients had a PFS of 133 days (compared to 60 days in non-responding patients, p=0.001). Overall survival was 350 days for responding patients compared to 137 days for non-responding patients (p=0.0006). The toxicity was mainly haematological with gr III-IV cytopenia in 50% of patients. One patient presented a septicaemia and another one a CMV infection (Figure 1).

Figure 1. Overall survival for responding *vs* non-responding.

Summary and Conclusions: In this heavily pretreated patient population, survival rates for patients responding to bendamustine salvage therapy were encouraging. We believe that well-selected double refractory patients might benefit from bendamustine as salvage treatment, but further prospective clinical trials are needed in this situation.

PB1668

USEFULNESS OF HEAVY-LIGHT CHAIN IMMUNOANALYSIS IN MULTIPLE MYELOMA PATIENTS WHO UNDERWENT ASCT. A NEW LEVEL OF RESPONSE?

I Murillo-Florez[1,*] M Andrade[1,2,3], E Colorado[1], J Quintero[1], P Giraldo[1,2,4]
[1]Hematology, [2]Traslational Research Unit, [3]Researcher Rio Hortega, Miguel Servet University Hospital, [4]CIBERER, ISCIII, Zaragoza, Spain

Background: In the last years the world of Myeloma patients has evolved, now we have many new drugs under investigation accompanied by new techniques for assessment. Currently the freelight chain immunoassay (FLC) (Bindingsite, Birmingham, UK) is part of the mandatory assessment for response according to IMWG, but the Heavy-Light-Chain (HLC) immunoassay is still under investigation with promissory results and developing a new category: immunoparesis. It seems like the recovery of uninvolved HLC (immunoparesis recovery – IR-), is the result of the immune system reconstitution.
Aims: To analyze the immunoparesis recovery (IR) in patients with MM who underwent Autologous Stem Cell Transplantation (ASCT) and correlate with outcomes.
Methods: A retrospective chart review was performed with all consecutive secretory MM patients who underwent ASCT in our institution between May 2011 and Oct 2013. Clinical, demographical and laboratory assessment before ASCT and 8-12 weeks after and outcomes were registered.
Results: A total of 42 patients were registered. Median follow-up 14 months. MF ratio: 19/23 (54.8/45.2%), mean age 58.5 y.o. (40-70). Immunoglobulin Subtype: IgG-Kappa: 38.1% (16), IgG-Lambda: 23.8% (10), IgA-Kappa: 14.3% (6), IgA-Lambda: 9.5% (4), Bence-Jones-Kappa: 4.8% (2), Bence-Jones-Lambda: 9.5% (4). Durie-Salmon Stage: IA: 14.3% (6), II-A: 31% (13), III-A: 40.5% (17), III-B: 11.9% (5), missing-data 1 case. After induction therapy (see table 1) response assessment were: minimal response: 7.9% (3), Partial Response (PR): 52.4% (22-of them 2 with IR), VGPR: 11.9% (4), SR: 9.5% (4), SR+IR: 11.9% (5), missing data: 4 cases. After ASCT, evaluation reveals 11 patients who achieved IR (8 with SR, 1 VGPR and 2 PR) the distribution according response were: stable disease: 5.2% (4), PR: 41% (16), VGPR: 28.6% (7), SR: 14.7% (6), SR+IR: 20.5% (8), missing: 3 cases. During the follow-up, a total of 16 patients who achieved at least PR after ASCT had relapsed or progressed, 11 from PR group, 4 from VGPR and 1 from SR group. Only 2 from the group of IR after ASCT (1 PR and 1 VGPR), IR were a predictor of good outcome (p= 0.032). The mean PFS was 20.7 months (16.2-25.2), median 20 months (13.7-26.3), for patients who achieved IR was 26.7 months with median not reached. The OS from ASCT was: 31.4 months (27.9-34.8).
Summary and Conclusions: Even with a small cohort, we believe the HLC analysis is a useful assessment to define patient under risk of relapse. More studies are warranted for define the role of these tests in MM patients.

PB1669

FREE LIGHT CHAIN ESCAPE REFLECT A RESISTANT RELAPSE IN MULTIPLE MYELOMA (MM), ACCOMPANIED BY DECREASED SERUM TGF-BETA1 (TGFB1); CLINICAL CORRELATIONS

E Nikolaou[1,*] E Koulieris[1], D Maltezas[1], K Sarris[1], T Iliakis[1], E Vyniou[1], I Vardounioti[1], V Karali[1], V Bartzis[1], T Tzenou[1], M Dimou[1], T Vassilakopoulos[1], M Angelopoulou[1], P Tsaftaridis[1], N Kafasi[1], P Panayiotidis[1], MC Kyrtsonis[1]
[1]Laikon General Hospital of Athens, University of Athens-Medical School, Athens, Greece

Background: Free light chain escape (LCE), defined as the occurrence of sFLC increase with stable or falling monoclonal immunoglobulin (M-Ig) concentrations was shown to reflect disease aggressive evolution in MM and to eventually reflect molecular myeloma cells changes or reveal clonal cell competition. However microenvironmental factors usually also contribute to disease evolution.
Aims: As TGF-b1, a pleiotropic cytokine that normally down-regulates B-cell proliferation and modulates Ig production, was found increased in the serum of MM patients with a better outcome, we aimed to study its levels in parallel with the prevalence and clinical impact of LCE in a series of MM patients.
Methods: We studied 234 symptomatic MM patients diagnosed and followed in our hospital. 29%, 42%, 29% and 22%, 30%, 48% were in Durie-Salmon and ISS stages I, II, III and 1, 2, 3 respectively. MM type was IgG in 138, IgA in 49, light chain only in 40, IgD in 4, non-secretory in 3 and IgM in 1 patients. As all patients were symptomatic, they all had received at least 1 treatment line (median 3). Serum TGF-b1 measurements were performed retrospectively by ELISA according to the manufacturer's instructions in frozen sera drawn at diagnosis or relapse and at the time of LCE in 10 patients.
Results: Eighteen patients presented LCE (7%). The median number of treatment lines received prior LCE was 5. Nine out of 18 LCE patients were asymptomatic and in a good performance status at the time of LCE onset and relapse would not have been obvious in the absence of free light chain (FLC) serial follow-up measurements. The median time from LCE to last follow-up or death was 2 months. 6/18 LCE patients had previously received high dose treatment and ASCT while all had received new drugs. Median TGF-b1 levels at the time of LCE was 8882 pg/ml as compared to 44196 at diagnosis or previous relapse (p<0.01).
Summary and Conclusions: LCE represent a rare form of relapse that corresponds to a very aggressive disease behavior, probably due to the emergence of a new resistant clone. In order to observe the phenomenon, regular follow –up with quantitative Ig and FLC measurements is needed. The low TGF-b1 levels observed at LCE may reflect escape from a residual immune surveillance allowing the emergence of new clones.

PB1670

FUNCTIONAL AND SEROLOGICAL RESPONSE IN PARAPROTEINAEMIC NEUROPATHY TO A STANDARDISED CHEMOIMMUNOTHERAPEUTIC REGIMEN

A Duncombe[1,*] A Publicover[1], T Burt[1], D Allen[2], M Sabah[3], A Pinto[3], N Colchester[3], H Katifi[3]
[1]Haematology, [2]Neurophysiology, [3]Neurology, UNIVERSITY HOSPITAL SOUTHAMPTON, Southampton, United Kingdom

Background: Paraproteinaemic neuropathy (PPN) is a rare disorder associated with MGUS with evidence of a pathogenetic role for the paraprotein. Many cases are associated with the presence of antibodies to myelin associated glycoprotein (MAG) and some have an underlying lymphoproliferative disorder (LPD). The natural history of the disease is of slowly progressive neurological deterioration, existing treatments have poor efficacy, and none have been proven to alter outcome. Single agent Rituximab failed in an RCT to achieve the primary endpoint

and single agent chemotherapy has produced variable results with toxicity in very small numbers of patients due to the rarity of the disorder.
Aims: The aim of the study was to evaluate the potential for combination chemoimmunotherapy similar to that used successfully in haematological malignancies to produce functional and serological responses in patients with PPN.
Methods: 12 patients with IgM PPN (7 with MGUS all of whom had anti-MAG antibodies and 5 with underlying Lymphoplasmacytic Lymphoma) were treated with a standardised chemoimmunotherapeutic regimen, comprising six cycles of Rituximab 375mg/m^2, Cyclophosphamide 750mg/m^2 and five days of Prednisolone 50mg/m^2 every 21 days, together with strict anti-microbial prophylaxis (*i.e.* 'R-CVP', with the omission of Vincristine).
Patients were assessed at baseline with bone marrow biopsy and CT scans to identify underlying LPD and with standardised neurological assessments including electrophysiology, functional MRC and Overall neuropathy limitation scores (ONLS) together with paraprotein and Anti-MAG antibody quantitation. Assessments were repeated at 3 months and 12 months post treatment.
Results: All 12 patients had an IgM paraprotein, 7 (all of whom were anti-MAG positive) had IgM MGUS and 5 had underlying lymphoplasmacytic lymphoma. At 3 months post completion of treatment, IgM paraprotein levels had fallen in all 12 patients (mean at baseline 6.24g/L, sd 4.4g/L, mean at three months post treatment 3.08g/L, sd 2.3g/L). 4/5 patients with underlying LPL achieved complete remission and the other partial remission as assessed by BM biopsy and CT scans. Functionally, the ONLS improved in 50% patients and was static in 42%. 75% of patients improved their sensory sum score, 50% by at least two points. MRC sum score of muscle power improved in 42% and remained static in 50%. Electrophysiological studies demonstrated improvements in upper limb parameters in 50% of cases and were static in the other 50%. 12 month post treatment follow up data available for 7 patients, suggests that their early response to treatment has been sustained with no functional or serological relapses to date. Furthermore 86% patients have shown falls in anti-MAG antibody titre with a mean reduction of 53% suggesting sustained immunological improvement. The treatment was generally well tolerated. There was no treatment related mortality. One patient had a mild haemorrhagic cystitis and another had influenza pneumonitis both with complete resolution.
Summary and Conclusions: This chemoimmunotherapeutic protocol (R-CP) has shown striking functional and serological responses in a cohort of patients with IgM related neuropathy in the context of a disease with a progressive neurological disabling trajectory. Patients with underlying LPD have also achieved remission and those with anti-MAG antibodies have shown ongoing fall in levels. There have been no major complications. These encouraging early results suggest the need for further evaluation in the context of a randomised clinical trial.

PB1671

PERCENTAGE OF URINARY ALBUMIN EXCRETION AND SERUM FREE LIGHT CHAIN REDUCTION AREIMPORTANT DETERMINANTS OF RENAL RESPONSE IN MYELOMA PATIENTS WITH MODERATE TO SEVERE RENAL IMPAIRMENT

H Sugihara[1,*] D Chihara[2], K Seike[1], K Fukumoto[1], M Fujisawa[1], Y Suehara[1], M Fukaya[1], Y Nishida[1], M Takeuchi[1], K Matsue[1]
[1]hematology/oncology, Kameda medical center, kamogawa city, chiba prefecture, [2]Epidemiology and Prevention, Aichi Cancer Center Reserch Institute, Nagoya, Japan

Background: Renal impairment (RI) is a major cause of morbidity and mortality in patients with multiple myeloma (MM) and approximately 50% have renal impairment and 20% of patients have acute renal failure depending of its definition. Although reversal of renal dysfunction significantly affects prognosis of MM with RI, there is no reliable test for predicting reversibility of RI in MM patients.
Aims: We postulated that MM with high albuminuria reflects glomerular disease that is difficult to reverse. We examined the impact of urinary albumin excretion percentage on renal recovery in MM patients with RI.
Methods: We retrospectively analysed 259 patients admitted to our hospital form April 2000 to September 2013.Clinical variables and laboratory data that may affect myeloma treatment response were extracted. RI was defined as an estimated glomerular filtration rate (eGFR), which was measured before treatment ≤50 ml/min/1.73 m2 by the simplified Modification of Diet in Renal Disease formula. Maximal renal response was evaluated according to the recently proposed "Criteria for the Definition of Renal Response to Antimyeloma Therapy" from IMWG working group. Patients with preexisting severe renal impairment (creatinine≥2.0 mg/dL) due to causes other than MM were excluded from the study. Extracted clinical data related to myeloma and RI included age, sex, complete blood count, urinalysis, serum protein electrophoresis, serum free light chains (FLC), serum albumin, β2-microglobulin, serum creatinine, urinary protein concentration, and urine protein electrophoresis. Reduction of involved FLC (iFLC) was checked at day 12 and at 21 after the start of anti-myeloma therapy. Percentage of urinary albumin excretion was calculated by protein electrophoresis pattern on admission. The results were examined for relationship to renal response by odds ratio (OR) using logistic regression analysis.
Results: Moderate to severe renal impairment (estimated glomerular filtration rate, eGFR≤50mL/min/1.73m2) was observed in 118 patients (46%) and renal responses of CRrenal, PRrenal, MRrenal, and no response were obtained in 42 (36%), 16 (14%), 13 (11%), and 47 (40%) patients, respectively. We examined the association between subsequent any renal response and the degree of iFLC reduction on days 12, and 21. Receiver operator curves (ROC) were constructed to determine the best cut-off% of iFLC reduction for renal recovery. From the curve, cut off point of% iFLC reduction at day 12 was identified as 81.8% with specificity 93%, sensitivity 49%, and area under the curve (AUC) of 0.73. Similarly, 95.5% reduction was identified with specificity 92%, sensitivity 49%, and AUC of 0.73 on day 21. Although renal recovery was significantly better in patients with age ≤70, myeloma response ≥VGPR, involved FLC (iFLC) reduction from baseline ≥80% on day 12, ≥95% on day 21, and urinary albumin ≤25% on univariate analysis, only reduction of iFLC ≤95% on day 21(OR: 6.26, p =0.01) and urinary albumin ≤25% (OR: 3.55, p =0.01) remained significant on multivariate analysis.
Summary and Conclusions: Urinary albumin excretion ≤25% and reduction of iFLC ≤95% on day 21 were considered as positive predictors for favorable renal response in patients with moderate to severe renal impairment. Our data will prove the important information for selecting the myeloma patients with renal impairment who will benefit from intensive antimyeloma therapy and mechanical removal of FLC.

PB1672

STRINGER RESPONSE WITH IMMUNOPARESIS RECOVERY AFTER BORTEZOMIB-BASED THERAPY IN MULTIPLE MYELOMA AND RELAPSE. USEFULNESS OF HEAVY-CHAIN-LIGHT ASSESSMENT

M Andrade[1,2,3,*] I Murillo-Florez[1], E Colorado[1], J Quintero[1], P Giraldo[1,2,4]
[1]Hematology, [2]Traslational Research Unit, Miguel Servet University Hospital, [3]Researcher Rio Hortega, IACS, [4]CIBERER, ISCIII, Zaragoza, Spain

Background: Bortezomib has proven to be one of the major advances on multiple myeloma (MM) therapy. Actually is part of the first-line standard of care therapy for patients with MM. Multiple strategies have been developed to try to predict response or improve the assessment of response and follow-up of MM patients, current International Myeloma Working Group (IMWG) criteria of response included immunophenotype and immunoparesis analysis. The Heavy Lite^{TM} and Free Lite^{TM} (Bindingsite, Birmingham, UK) permit a separate quantification of the kappa- and lambda-bounded amounts of a given immunoglobulin analysis (HFC) and the free light chains kappa or lambda amount quantification (FLC) and both are excellent tools for immunoparesis assessment.
Aims: To analyze the usefulness of immunoparesis analysis by Heavy-Lite^{TM} and Free-lite^{TM} in patients who receive bortezomib-based therapy in our institution.
Methods: A retrospective chart review was performed including the patients diagnosed of IgA or IgG secretory MM who received therapy with bortezomib even for relapsed as on first-line therapy. General clinical characteristics, schedules of therapy, number of cycles, response to therapy and relapse were recorded. For analysis only patients with at least 4 cycles of bortezomib based regimen and HLC and FLC assessment at the end of therapy or between 8-12 weeks after autologous stem cell transplantation (ASCT). Period of study: June 2004 to December 2013.
Results: At the end of study a total of 78 MM patients received bortezomib-based therapy, of them 73 complete 4 or more cycles and were included in the analysis. Male/Female ratio: 34/39, mean age: 67.3 years old (46-81), therapeutic schedules were: bortezomib-prednisone: 2 (2.7%), bortezomib-dexametasone: 36 (49.3%), bortezomib-melfalan-prednisone: 21 (28.8%), bortezomib-dexametasone-lenalidomide: 9 (12.3%) and bortezomib-talidomide-dexametasone: 2 (2.7%), bortezomib-adriamicine-dexametasone: 2 (2.7%), bortezomib-cyclophorphamide-dexametasone: 1 (1.4%). Around 70% of patients received at least 6 cycles of therapy. Immunoglobulin Myeloma type: IgAL: 20.5% (15), IgAK: 16.4% (12), IgGK: 50.7% (37) and IgGL: 12.4% (9). A total of 75.3% (46) presented an abnormal HFC ratio at diagnosis, analysis of immunoparesis before therapy revealing 79,4% (58) affected patients; a total of 76.7% (56) registered an abnormal FLC ratio at diagnosis. Response to therapy were as follows: a stringent complete response (SR) were achieved by 27.4% (20) of cases (10 associated with IR), very good partial response (VGPR): 4.1% (3), partial response (PR): 56.2% (41) patients and not-response/progressive-disease: 12.4% (9) patients. At the time of post-therapy evaluation, 35.6% (26) of patients had normalized the FLC-ratio, 20.5% (15) of the SR and, 1,4% (1) of VGPR and 10.9% (8) of PR. Normalization of HFC-ratio only occurs on patients on SR and VGPR: 20.6% (13). About immunoparesis analysis only 23.3% (17) patients presented immunoparesis recovery (IR) at the end of therapy, 16.4% (12) of SR patients and the rest on VGPR (2) and PR (4) patients. After a median follow-up of 29 months (9-94) 63% (46) of patients had relapse, mean progression free survival time (PFS) for all patients was 28.5 months (22.6-34.4) median PFS 26 months; for patients who achieve SR was 32.5 (26.6-38.5); the association of SR with IR was related to a less tendency to relapse and need of therapy, 9/10 patients who achieved this status are not-relapsed.
Summary and Conclusions: In our cohort, the patients who achieved a SR with a normalization of immunoparesis shows a clear tendency to less incidence of

relapse; probably this reflect a better response with not only an undetectable monoclonal protein but a normalization on immune system. Even in small cohorts, the immunoparesis recovery analysis through HFC quantifications seems to be an useful tool to determine a new level of response. More investigations on this field are warranted.

PB1673

A THOROUGH EVALUATION TO RULE OUT THE PRESENCE OF PLASMACYTOMAS IS OF IMPORTANCE IN PATIENTS WITH NEWLY DIAGNOSED SYMPTOMATIC MYELOMA

S Voloshin[1], A Kuvshinov[1], A Schmidt[1,*] V Shuvaev[1], A Garifullin[1], M Fominykh[1], K Abdulkadyrov[1]
[1]Russian Scientific Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Myeloma is a neoplasm of plasma cells that causes painful, bone-destructive lesions. It may present as a solitary lesion (plasmacytoma), or involve multiple sites (multiple myeloma, MM). Solitary plasmacytomas of bone or extraosseous plasmacytomas, depending on the tissue of origin, develop in isolation without systemic manifestations of MM. Some patients with MM has additional tumor masses that can affect various organs and worsen prognosis. The incidence of osseous and extraosseous plasmacytomas in MM is 7% at diagnosis and about 17% at the end stages of the disease.
Aims: To investigate possible correlations between laboratory findings and clinical outcome in patients with newly diagnosed symptomatic myeloma.
Methods: Twenty-seven adult patients (median age 56 years; male 15, female 12) with newly diagnosed MM were included. The diagnosis of active MM was made according to standard diagnostic workup (history and physical exam, serum albumin, quantitative immunoglobulins, beta-2 microglobulin, serum and urine electrophoresis, immunofixation, and free light chain assays, bone marrow (BM) aspiration and biopsy, BM multicolor flow cytometry (MFC) analysis of plasma cell (PC) population, plasmacytoma immunohistochemistry (IHC), BM routine cytogenetic and FISH). The entire patients had skeletal survey and one of the additional methods: computed tomography (CT), magnetic resonance imaging (MRI), or positron emission tomography (PET)/CT scan. MM staging assessed using Durie-Salmon and International staging systems. All the patients had primary bortezomib-based therapy. Responses were investigator-assessed and based on EBMT and IMWG response criteria.
Results: Eleven patients (40.7%) had plasmacytomas at diagnosis, which were revealed using CT, MRI, and PET/CT (4, 5, and 2 cases, respectively), six of them (55%) had no plasmacytomas at skeletal survey. 7/11 patients (64%) had symptomatic plasmacytomas. CT (7), MRI (7), and PET/CT (2) did not reveal plasmacytomas in 16 patients with bone lesions. Ten patients (37.0%) had osseous plasmacytomas, and 6/10 (60.0%) had multiple (≥2) osseous plasmacytomas. One patient had extraosseous (both breasts) plasmacytomas. 9/11 (81.8%) patients manifested with signs of vertebral column instability or spinal cord compression were operated on: 5/9 (55.5%) - before initiation of primary therapy, and 4/9 (44.5%) - between treatment cycles. During follow-up period (2 years after diagnosis) one patient was diagnosed as having new osseous plasmacytoma, which was successfully operated on. MFC was performed on 27 (100%) consecutive BM aspirates: CD38 and CD138 was expressed in all cases (100%), CD19 – 9 (33.3%), CD56 overexpression – 11 (40.7%), CD117 – 9 (33.3%). Patients' PC phenotype detected on BM MFC and results of plasmacytoma IHC were identical. 10/11 (90.1%) patients with plasmacytomas showed no CD117 overexpression on PC (results of BM MFC and IHC assays), whereas one patient was not assessed. At a median follow-up of 35 months 2-year overall survival was 77.9% (plasmacytomas at diagnosis), and 93.7% (without plasmacytomas) (*p>.05*).
Summary and Conclusions: Our study shows that the presence of plasmacytomas correlate with the absence of CD117-expression in patients with newly diagnosed symptomatic myeloma. The newly diagnosed patients with MM require a very thorough evaluation including CT, MRI and/or PET/CT (preferable diagnostic tool) to rule out the presence of plasmacytomas, especially in patients with CD117 negative PC patterns. Further studies are needed to confirm this proposal.

PB1674

COMPARISON OF RESPONSE DURATION (RPD) AFTER THALIDOMIDE, BORTEZOMIB AND LENALIDOMIDE ADMINISTRATION TO MULTIPLE MYELOMA (MM) PATIENTS; A SINGLE CENTER EXPERIENCE

MC Kyrtsonis[1,*] E Nikolaou[1], D Maltezas[1], E Koulieris[1], T Iliakis[1], K Sarris[1], E Vyniou[1], I Vardounioti[1], A Efthymiou[1], K Bitsani[1], V Karali[1], I Pessach[1], V Bartzis[1], T Tzenou[1], M Dimou[1], T Vassilakopoulos[1], M Angelopoulou[1], P Tsaftaridis[1], P Panayiotidis[1]
[1]Laikon General Hospital of Athens, University of Athens-Medical School, Athens, Greece

Background: With the introduction of novel drugs, mainly Thalidomide, Bortezomib and Lenalidomide and the enrichment of MM therapeutic armamentarium, patients' survival has improved because they produce qualitative responses accompanied by a prolonged response duration (RPD) and because a new treatment is usually more potent than the re-administration of an old one. On the meanwhile, numerous next generation new drugs are on their way. It is generally accepted that RD is longer after first response and steadily shortens with subsequent treatment lines, as new resistant clones may appear. It is however unknown if new treatments can produce long-lasting responses after multiple relapses.
Aims: To investigate RPD produced by new treatments after initial and multiple relapses.
Methods: 229 symptomatic MM patients, followed and treated in our hospital were studied; 22%, 30% and 48% of them were in ISS stages 1, 2 and 3 respectively. MM type was IgG in 62%, IgA in 22%, light chain only in 13%, IgD in 2% and non-secretory in 1% of patients. They received a total of 718 treatment lines (median 3), including various treatment combinations with or without new drugs. However, only double combinations are evaluated here in order to avoid bias. One hundred and thirty three patients received Bortezomib-Dexamethasone (VD), 81 Thalidomide-Dexamethasone (TD), and 90 Lenalidomide-Dexamethasone (RD). Median survival of the whole cohort was 48 months. Comparisons between RPD observed according to drugs administered and lines were evaluated by the chi square test.
Results: Considering all treatment lines together, patients receiving new treatments achieved better quality of response and RPD ($p<0.01$ both). As expected, TD and VD treatment produced longer RPD before than after 3rd relapse (p=0,002), while RPD did not differ among the first three treatment lines. Of the 3 drug combinations, only VD produced valuable responses at re-administration, although of shorter duration. Interestingly RD produced sustained responses with no difference in longevity at any line administered; thus median RPD after RD administration in 55 patients at 2nd and 3rd line was 10,29 months (range 1-52,2) while it was 13,21 months (1-31.48) in 35 patients treated after 3rd relapse.
Summary and Conclusions: We confirmed that better response rates and RPD were observed with novel drugs compared to conventional ones. Furthermore, we showed that sustained RPD were observed with all TD, VD and RD until 4th relapse, while RD was able to produce equally long-lasting RPD before and after 3rd relapse suggesting that the drugs ability to restore the microenvironment may delay the occurrence of new clones in responding patients, thus encouraging its administration upfront.

PB1675

IMPACT OF CUMULATIVE BORTEZOMIB DOSE ON RESPONSE TO TREATMENT AND PATIENT SURVIVAL

I Coelho[1,*] C Costa[1], M Ferreira[2], J Parreira[1], C João[1]
[1]Hematology, [2]Clinical Research Unit, Instituto Português de Oncologia Francisco Gentil, Lisboa, Portugal

Background: Multiple myeloma (MM) is an incurable plasma cell neoplasm. Newer agents in MM such as bortezomib have improved the clinical outcome of patients (pts) with this disease. Recently, it has been suggested that a higher cumulative bortezomib dose may be associated with improved response rates and even survival.
Aims: To determine if the cumulative bortezomib dose has an impact on disease response and patient outcome.
Methods: We performed a unicentric, retrospective cohort study, reviewing the clinical data of all MM pts treated with bortezomib-containing regimens between January 2012 and December 2013. The regimens included: bortezomib-cyclophosphamide-dexamethasone (VCD) in transplant-eligible pts, bortezomib-dexamethasone (VD) and bortezomib-melphalan-prednisone (VMP) in transplant-ineligible pts. We compared the planned bortezomib dose with the real delivered bortezomib dose, examined toxicities and causes for patients decreasing dose/cycles and studied the response rate, progression free survival (PFS) and treatment free interval. PFS was calculated using the Kaplan Meier method and curves were compared by log-rank test. Chi-square was used to test for differences in the proportions of responses obtained in each group.
Results: We analysed 92 pts, 59 males; median age at start of bortezomib regimen was 65 yo (min 37; max 89); main subtypes were IgGK 40, IgGL 18 and IgAK 13; ISS 1 in 34 pts and ISS 3 in 27 pts; bortezomib containing regimens were VCD in 55 pts, VMP in 19 and VD in 18; bortezomib was given intravenously (iv) in 42 pts, subcutaneously (sc) in 38 and 12 pts started iv and changed to sc during treatment. Median line of bortezomib containing regimen was 1 (range 1-8). The median number of planned cycles was 6 but only a median of 4 were performed. The median planned dose of bortezomib was 31.2 mg/m^2 (min 20.8; max 52) but the median delivered dose was 20.8 mg/m^2 (min 1.3; max 46.8). The main reasons to decrease bortezomib doses were thrombocytopenia (23 cases), polyneuropathy (19 cases) and infection (16 cases). Only patients who received a full dose of bortezomib achieved sCR (n=3). From the 11 pts achieving CR/sCR, only 2 had bortezomib dose reductions; from the 21 pts achieving VGPR, 3 had bortezomib dose reductions; from the 35 pts achieving PR, 6 had bortezomib dose reductions and from the

12 non-responders, 6 had dose reductions. We found a significant association between bortezomib doses delivered and response rate (p=0.017): the relative risk of achieving any response between patients with and without bortezomib dose reductions is 0.32 (CI95% 0.15 - 0.72). With a median follow-up of 8.4 months, PFS is associated with cumulative bortezomib dose, as pts who needed bortezomib dose reductions greater than 20% seem to have a worse PFS compared to pts treated with the planned bortezomib dose (median 23 months for pts with bortezomib dose reductions and not reached for pts without dose reduction). Median treatment-free interval was significantly longer in pts without bortezomib dose reductions (median not reached) compared to pts who needed dose reductions (median 3.4 months, p=0.0042).
Summary and Conclusions: These data suggest that a higher cumulative dose of bortezomib, reflecting prolonged treatment duration and lack of drug interruption/reduction (dose intensity), is associated with improved response rates, better PFS and longer treatment free interval.

PB1676

PRETREATMENT LYMPHOPENIA AND POOR PERFORMANCE STATUS ARE RISK FACTORS OF SEVERE BACTERIAL INFECTION IN PATIENTS WITH MULTIPLE MYELOMA DURING CHEMOTHERAPY WITH BORTEZOMIB CONTAINING REGIMENS

SY Hyun[1,*] JH Kong[1], JY Lee[2], JS Kim[2]
[1]Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Kangwondo, [2]Intermal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic Of

Background: Infection is the leading cause of morbidity and mortality in patients with multiple myeloma.
Aims: The aim of this study is to identify the risk factors associated with the development of severe infections in patient with multiple myeloma during chemotherapy with bortezomib-containing regimens.
Methods: A total of 98 patients with myeloma who were treated with bortezomib-based chemotherapy between 2006 and 2012 were examined. Using the logistic regression method, a variety of factors were analyzed for the development of severe bacterial infections (SBI) at each 427 courses.

Figure 1. Probability of severe bacterial infection according to the number or three risk factors (lymphopenia, poor performance status, early course [≤2 courser] on treatment) at each courses.

Results: Median age of patients was 62 years and 40.6% (30/98) of patients treated with bortezomib-containing chemotherapy as first-line treatment. The SBI was developed in 57% (56/98) of patients and 19% (81/427) of bortezomib courses. Of 81 SBI episodes, 42 (53%) episodes were clinically documented infection, 30 (37%) episodes were microbiologically documented infections, and 9 (11%) episodes were fever of unknown origin. The most common type of infection was pneumonia (60%), and only 6 episodes were febrile neutropenia. In univariate and multivariate analysis of the development of SBI by 98 patients, we could not find significant factors other than poor performance status (Hazard Ratio [HR] 5.365, 95% Confidence Interval [C.I.] 2.004-14.364, *P* =.001). However, in univariate analysis of the development of SBI by each 427 courses, poor performance status (ECOG ≥2) (*P* <.001), early courses of therapy (≤2 courses) (*P* <.001) and pretreatment lymphopenia (absolute lymphocyte count<1.0 × 10^9/L) (p=.043) were associated with increased risk of SBI at each courses. Multivariate analysis confirmed poor performance status (ECOG ≥2) (HR 3.920, 95% C.I. 2.305-6.666, *P* <.001), early courses of therapy (≤2 courses) (HR 2.782, 95% C.I. 1.633-4.740, *P* <.001) and pretreatment lymphopenia (HR 1.728, 95% C.I. 1.016-2.937, p=.043) as risk factors for development of SBI during the chemotherapy with bortezomib containing regimens. The probability of SBI at each course was 5.1% in courses with no risk factor, 14.9% with 1 risk factor, 23.9% with 2 risk factors and 59.5% with 3 risk factors (*P* <.001, Figure 1). In patients who were eligible for autologous stem cell transplantation (ASCT), 14 of 18 patients (77.8%) who didn't experienced SBI received ASCT, but only 6 of 26 patients (23.1%) who experienced SBI received ASCT (*P* <.001). Among these transplant-eligible patients, the patients who experienced SBI showed a significantly shorter median overall survival than patients who didn't experienced SBI (11.2 month *vs* not reached, p=.016) as well as progression free survival (6.0 months *vs* 24.4 months, p=.015). The multivariate cox analysis demonstrated that the experience of SBI was the only statistically significant factor for inferior progression free survival in patients who were eligible for ASCT (HR 2.806, 95% C.I. 1.174-6.705, p=.020).
Summary and Conclusions: In conclusion, patients in the courses with these risk factors should be more closely monitored for the development of bacterial infection and be considered to use prophylactic antibiotics.

PB1677

MONITORING OF MINIMAL RESIDUAL DISEASE (MRD) IN PATIENTS WITH MULTIPLE MYELOMA (MM) BEFORE AND AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT)

I Galtseva[1,*] L Mendeleeva[1], O Pokrovskaya[1], I Kastrikina[1], E Urnova[1], L Kuzmina[1], E Parovichnikova [1], V Savchenko[1]
[1]BMT, Research Center for Hematology, Moscow, Russian Federation

Background: According to criteria recommended by IMWG the effect of treatment of MM patients is evaluated not only by clinical, morphological, immunochemical parameters, but also by the absence of clonal plasma cells in the bone marrow in immunohistochemistry and immunofluorescence studies.
Aims: Monitoring of MRD in MM patients at the stage of high dose consolidation.
Methods: We screened 32 patients with MM (m -17, w -15), age 41-65 years (M-58). Phase of the disease after induction of bortezomib - containing regimens: CR- 12, VGPR-8, PR -12. Stem cell mobilization (SCM) included cyclophosphamide 4g/m^2 plus G-CSF 5 μg/kg/day. Prior ASCT conditioning included melphalan 200mg/m^2. After ASCT CR-19, VGPR-13. Bone marrow samples were examined by multiparameter flow cytometry (MFC) before SCM, 2-6 months after ASCT by using BD FACSCanto II flow cytometer. Myeloma plasma cells (PC) were determined according to aberrant antigens expression CD38/CD138/CD45/CD19/CD56/CD117/CD28 (A.C. Rawstron's protocol 2006). The analysis was based on at least 1000 000 CD45+ events. MRD(-)<0.01%, near-threshold amount myeloma PC was determined in amount of 0.01-0.04% residual cells.
Results: The examination of 12 patients in CR, achieved by the induction treatment, MRD (-) was detected in 6 (50%). Near-threshold amount of myeloma PC defined in the other 6 patients with CR and 1 patient with VGPR. After ASCT immunochemical CR diagnosed in 19 patients , among of them MRD (-) observed in 7 cases (37%) , while the remaining 12 patients showed near-threshold value myeloma PC.
Summary and Conclusions: MFC is the method of choice for accurate quantitation of residual myeloma PC in MM patients at different stages of therapy. Recognition of MRD after ASCT indicates the advisability of the appointment maintenance therapy.

PB1678

RESPONSE TO INDUCTION TREATMENT ADAPTED SELECTION OF MOBILIZATION REGIMEN IN MULTIPLE MYELOMA: THE G-CSF ALONE VERSUS HIGH-DOSE CYCLOPHOSPHAMIDE PLUS G-CSF REGIMEN

JY Lee[1,*] SJ Kim[1], JE Jang[1], C Suh[2], H Lee[3], HY Yhim[4], WS Lee[5], CK Min[6], JH Lee[7], JS Kim[1]
[1]Internal medicine, Severance hospital, [2]Internal medicine, Asan Medical Center, Seoul, [3]Internal medicine, National Cancer Center, Goyang, [4]Internal medicine, Chonbuk National University Hospital, Jeonju, [5]Internal medicine, Busan Paik Hospital, Inje University, Busan, [6]Internal medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, [7]Internal medicine, Gachon University Gil Hospital, Incheon, Korea, Republic Of

Background: There is no guideline for choice of mobilizing regimen for autologous stem cell transplantation (ASCT) in multiple myeloma although both of G-CSF alone regimen and cyclophosphamide plus G-CSF regimens are recommended by International myeloma working group and used most commonly.
Aims: This study was designed to evaluate the efficacy and transplant outcomes of response to therapy adapted selection of mobilization regimen.
Methods: A total of 156 patients who diagnosed with MM were admitted for peripheral blood stem cell mobilization using cyclophosphamide plus G-CSF or G-CSF alone between September 2006 and September 2012 from 7 institutions in Korea were analyzed retrospectively. The patients (N=62) who received G-CSF alone for mobilization in complete response (CR) or very good partial response (VGPR) status and the patients (N=65) who received HD-CY + G-CSF for mobilization in response less than VGPR were classed as the 'Response adapted group' (N=127). Besides, we classified the 'Random CY group' as an intended control group (N=58) with same patient composition of disease status at mobilization of half-CR + VGPR (N=29) and half-less than VGPR (N=29).
Results: In the response adapted group, the patients received G-CSF alone (G-CSF group) and the patients received HD-CY + G-CSF (CY group) were

comparable for age, sex and clinical prognostic features at diagnosis as well as previous therapies except the percentage of plasma cell in bone marrow at mobilization (CY group 4.0% *vs.* G-CSF group 0.7%, P<0.001). The total quantities of CD34+ cells collected per patients were 6.6 x10^6/kg in G-CSF group and 12.7 x10^6/kg in CY group (P <0.001). The rate of successful mobilization (≥4 x10^6/kg) tend to be higher in CY group but had no statistical difference (79% and 91%, P=0.064). Of note, requisite mobilization (≥2 x10^6/kg) was achieved in most patients of similar proportions in both groups without significant difference (97% and 97%, P>0.999). Duration of hospitalization for mobilization was longer in CY group (9 days *vs.* 17 days, P<0.001) and the treatment-related toxicity was greater in this group: 34 patients (37%) developed fever requiring antibiotics during the neutropenic period after HD-CY and 51% and 52% of patients required red cell and platelet transfusion support, respectively. After ASCT, median time to neutrophil engraftment was 10 days for G-CSF group and 11 days for CY group (P=0.004) despite the quantities of infused CD34+ cells were higher in CY group than G-CSF group (6.2 x 106/kg *vs.* 4.5 x 106/kg, P<0.001). Transplantation outcomes were compared between the response adapted group and the random CY group. The patients in two groups were comparable with each other in their demographic, clinical, and laboratory characteristics. VGPR + CR rate and CR rate tended to higher in the response adapted group than the random CY group (77.5% *vs.* 69.6% and 60.8% *vs.* 51.8%, respectively) without statistical significance. At a median follow-up of 34 months after ASCT, there were no differences in adjusted overall survival rate and progression-free survival rate (P=0.6 and P=0.635, respectively) (Figure 1).

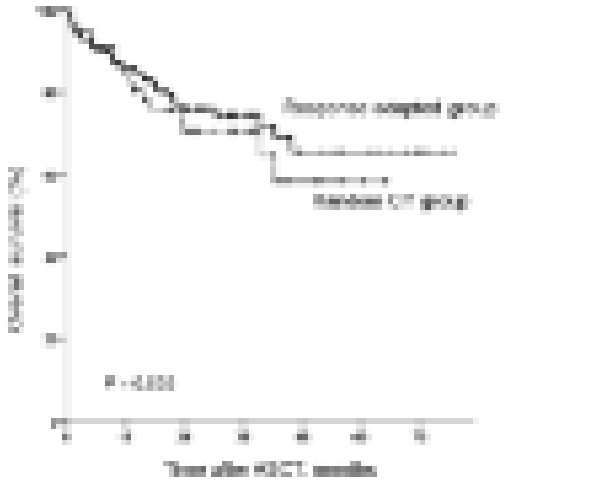

Figure 1.

Summary and Conclusions: These data suggest that the requisite CD34+ cell collections for the transplantation can be achieved with both regimens of HD-CY plus G-CSF and G-CSF alone in most MM patients. Furthermore, G-CSF alone as mobilization regimen was not only cost-effective with less toxicity, but it showed satisfactory outcomes after transplantation in the good responders to previous therapy. We suggest that risk adapted choice of mobilization regimen is appropriate and mobilization with G-CSF alone is preferred in the MM patients who achieve a good response to induction treatment.

PB1679

CYTOGENETIC RISK GROUP BY FISH IS THE MOST IMPORTANT INDEPENDENT PROGNOSTIC FACTOR TO PREDICT OUTCOMES AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN MYELOMA PATIENTS WITH EXTRAMEDULLARY DISEASE

HJ Shin[1,*] K Kim[2], JW Lee[3], MK Song[3], JJ Lee[4], JS Chung[3]
[1]Department of Internal Medicine, Pusan National University Hospital, Busan, [2]Samsung Seoul Hospital, Seoul, [3]Pusan National University Hospital, Busan, [4]Chonnam National University Hwasun Hospital, Hwasun, Korea, Republic Of

Background: Cytogenetic abnormalities are considered to have an important prognostic value in multiple myeloma (MM), helping to identify high-risk patients. Fluorescence *in situ* hybridization (FISH) is more sensitive than conventional cytogenetics for recognizing chromosomal changes. Several FISH-detected abnormalities have been associated with inferior prognosis, including deletion of chromosomes 17 and 13 and t(4;14)(p16.3;q32). However, it has been paucity data about prognostic significance of FISH abnormalities for autologous stem cell transplantation (ASCT) in MM patients with extramedullary plasmacytoma (EP).

Aims: Aim of study is to determine the prognostic impact of FISH data for ASCT in MM patients with EP.

Methods: Total forty-nine cases, whose FISH data of the bone marrow samples at diagnosis were available, were collected retrospectively.

Results: The t(11;14) cytogenetic abnormalities were seen in seven of 38 patients (14.3%). Del (13q) and t(4;14) were found in ten (20.4%) and three (6.1%) of 39 patients, respectively. No t(14;16) and del (17p) cytogenetic abnormality was detected in 38 patients. Concomitant presence of t(11;14) and del (13q) was seen in two cases and with t(4;14) in one case. Combined t(4;14) and del (13q) abnormalities was observed in one case. Three-year PFS rate was 39.5%±11.9% in patients without del (13q), 35.5%±11.1% in those without t(11;14), and 31.0%±10.0%, respectively. On the other hand, all patients were relapsed within three years after ASCT in those with del (13q) (p=0.001), t(11;14) (p=0.003), and t(4;14) (p=0.006), respectively. Patients with del (13q), t(11;14), and t(4;14) had lower OS rates than those without del (13q) (3-year OS rate, 37.5%±17.1% *vs.* 88.2%±8.0%; p=0.002), t(11;14) (3-year OS rate, 50.0%±20.4% *vs.* 80.4%±8.9%; p=0.022), and t(4;14) (3-year OS rate, 0% *vs.* 78.5%±8.6%; p=0.058). Patients without t(14;16) revealed comparative 3-year PFS (32.0%±8.5%) and OS rates (72.6%±7.9%) compared to those patients without del (13q), t(11;14), or t(4;14). Based on these FISH results, we make new FISH prognostic risk groups. Of 27 patients who had four FISH data at diagnosis, patients who were positive more than one of four FISH assigned to high-risk group (*n* = 4), those who were positive one of four FISH assigned to intermediate-risk group (*n* = 8), and patients with all negative FISH data assigned to low-risk group (*n* = 15). Median PFS of high- and intermediate-risk groups showed 28 months and 13 months, respectively. In high-risk group, median PFS duration was only 4 months (*P*<0.001). OS duration in patients with low-risk group did not reach to median value until the time of data collection. Median OS duration was 42 months in intermediate-risk group and 9 months in high-risk group (p=0.001).

Summary and Conclusions: It was suggested that FISH risk group was associated with the most important independent prognostic factor for PFS (HR, 12.228) and OS (HR, 4.528) in MM patients with EP who underwent ASCT.

PB1680

THE FREQUENCY OF GENETIC ABNORMALITIES AND THEIR IMPACT ON SURVIVAL IN PATIENTS WITH MULTIPLE MYELOMA

A Garifullin[1,*] I Martynkevich[1], S Voloshin[1], A Schmidt[1], A Kuvshinov[1], L Martynenko[1], G Salogub[2], E Karyagina[3], V Shuvaev[1], S Bessmeltsev[1], K Abdulkadyrov[1]
[1]Russian Scientific Research Institute of Hematology and Transfusiology, [2]Saint-Petersburg Pavlov State Medical University, [3]City Hospital N15, Saint-Petersburg, Russian Federation

Background: During the past decade, considerable progress has been made in our understanding of the disease process and factors that influence outcome. Overall survival in myeloma has improved significantly in with the emergence of thalidomide, bortezomib, and lenalidomide. Cytogenetic analyses, including fluorescence *in situ* hybridization (FISH), have contributed to a better understanding of the clinical implications of these chromosomal abnormalities in myeloma. Stratification of patients into various risk groups based on the chromosomal markers is being utilized by many centers for prognostic counseling, selection, and sequencing of therapy approaches.

Aims: To estimate the incidence of genetic abnormalities (GA) and their impact on overall survival (OS) in patients with multiple myeloma.

Methods: The OS was prospectively assessed in 188 patient (median age 61 years, range 28 - 93; male: female ratio – 1:1.4) with newly diagnosed multiple myeloma (NDMM). The incidences of GA were determined in all patients. Cytogenetic studies were performed on bone marrow samples using standard GTD-method. Metaphase FISH analyses were performed according to the manufacturer's protocol with use of DNA probes: LSI 13(RB1)13q14, IGH/CCND1, IGH/FGFR3, LSI TP53 (17q13.1) (Abbott).

Results: The frequency of GA in NDMM was 30.8% (58/188): 2.0% (3/152) - by conventional karyotyping, 37.1% (49/132) – by FISH analyses and 5.5% (6/108) – using both methods. GA (two aberrations) were detected in 6.4% (12/187) patients, complex abnormalities (>3 aberrations) – in 3.7% (7/187) patients. No GA were detected in 130 patients (69.2%). The frequencies of GA were similar in patients <65 years (36/121) and in patients >65 years (22/67) (29.8%, and 32.8%, respectively; *p>.05*). The incidence of GA in patients stratified according to ISS did not different significantly, but was higher in patients with ISS III at diagnosis (ISS I (n=29) – 27.6%, ISS II (n=32) – 21.9%, ISS III (n=50) – 48.0%) (*p>.05*). The estimation of the incidence of GA did not reveal any significant differences in NDMM patients depending on the type of secreting immunoglobulin: IgG (38/113) – 33.6%, IgA (10/31) – 32.3%, IgD (0/1) – 0%, Bence-Jones (3/10) – 30.0%, and non-secreting myeloma (1/5) – 20.0% (*p>.05*). Translocation t(11;14) was detected in 16.0% (30/188) of NDMM patients, del13q14 -13.8% (26/188), t(4;14) – 4.2% (8/188), del17p13.1 – 3.7% (7/188). Isolated t(11;14) was detected in 10.1% (19/188) of patients, del13q14 – 8.0% (15/188), del17p13.1 – 1.6% (3/188), t(4;14) – 0.5% (1/188). The median OS in standard-risk patients (normal

karyotype, t(11;14), hyperdiploidy) was 70 months (n=150), intermediate-risk (t(4;14), del13, hypodiploidy) – 47 months (n=25; p=*.42*), high-risk (del17, complex karyotype) – 45 months (n=13; p=*.19*) (Figure 1).

Figure 1. OS depending on molecular classification and risk stratification.

Summary and Conclusions: GA are independent prognostic factors in patients in multiple myeloma. The median OS was higher in standard-risk than in intermediate- and high-risk patients. FISH analysis increase the frequency of detection of highly specific genetic markers and should be utilized for decision making, selection, and sequencing of therapies in patients with NDMM.

LONG TERM SURVIVORS MM: MANY THANKS TO THE IMMUNE SYSTEM?

C Conticello[1],* M Cavalli[2], A La Fauci[2], A Romano[2], C Vetro[2], N Parrinello[2], G Rizzo[2], P La Cava[2], ML Consoli[2], F Di Raimondo[2]
[1]Department of Biomedical Sciences, Hematology Section, University of Catania. Via Citelli 7, 95100, Catania, Italy., [2]Department of Biomedical Sciences, Hematology Section, University of Catania. Via Citelli 7, 95100, Catania, Italy., catania, Italy

Background: MM is a plasmacellular malignancy associated with an high incidence of morbidity and mortality. Prognosis depends on a variety of factors including patient's characteristics (age, comorbidities, cytogenetics) and the old Durie-Salmon and the newer ISS (International Staging System) staging system. These prognostic systems identify patients having a better, worst or intermediate prognosis. In fact, since median survival of the best stage is about 70 months, we cannot talk about good prognosis. Over the last decade new drugs such as IMIDs and proteasome inhibitors has been introduced in treatment and favourably increased OS and PFS of MM patients but unfortunately this disease still remains an incurable disease. Numerous defects of the immune system have been described in MM, although the relative clinical importance of these remains elusive. We have examined B, T lymphocytes and neutrophils subset of 15 patients whose diagnosis was made more than 10 years ago (9 pt 13 years, 3 pt 11 years, 3 pt 10 years) by flow citometry analysis. In addition we have performed some functional experiments to evaluate the neutrophils function. Patient samples were compared with healthy donors (10), newly diagnosed multiple myeloma patients (30) and MGUS patients (20). We have observed that profile of neutrophils functional activity, the number of CD4+/CD25+CD127low/Foxp3+ T regulatory cells, the number of the recently described *exhaustive T lymphocytes and* CD19+/CD24hi/CD38hi B regulatory cells was more similar to healthy donors or MGUS patients and was different from newly diagnosed MM patients. Our data indicate a particular behaviour of immune system in long term MM patients survivors, suggesting another point of view in the evaluation of MM.

CONFOCAL MICROSCOPY IS USEFUL FOR THE DEFINITION OF THE BORTEZOMIB RELATED NEUROPATHY IN MULTIPLE MYELOMA PATIENTS

F Cocito[1],* G Ricciardelli[2], S Mangiacavalli[1], A Pompa[1], L Pochintesta[1], V Ferretti[1], R Ceccuzzi[2], M Cazzola[1], PE Bianchi[2], A Corso[1]
[1]Hematology, [2]Ophthalmology, IRCCS Fondazione Policlinico San Matteo, Pavia, Italy

Background: Painful sensory peripheral neuropathy (PN) represents the main dose-limiting toxicity of Bortezomib (Bor). Confocal microscopy (Confoscan 4, Nidek), allowing a detailed visualization of the cornea which is the most innervated tissue especially with small sensitive fibers, is used for early identification of diabetic sensory PN.
Aims: To evaluate corneal nerve sub-basal plexus in Multiple Myeloma (MM) patients (pts) treated with Bor using Confoscan 4 in order to define its possible role in the study of Bor - related neuropathy.
Methods: Corneal nerve sub-basal fibers length and number, grade of tortuosity according to Oliveira scale and Nidek index and beadings' density were evaluated with Confoscan 4. Confoscan 4 was performed in 22 MM pts under treatment or previously treated with Bor and 8 healthy controls. The distribution and the characteristics of corneal nerve sub-basal fibers of controls were similar to those of healthy population reported in the literature. In details in our controls median fibers length was 1197 µm, median fibers number 7/ field, median beadings' density 58/mm, median tortuosity grade according Oliveira scale 0.3 and according Nidek index 2.1. MM pts had a median age of 66 years (range: 44-79) and healthy controls of 63 years (range: 58-67). 16 MM pts were receiving Bor at time of evaluation (11 as first therapy line, 5 relapsed) and 6 received Bor previously; median time from the last dose was 7.5 days (range: 1 day – 35 months). Median number of Bor received doses was 16.5 (range:3-80). 9/22 pts (40.9%) presented PN at time of evaluation: 4 grade I (45%), 3 grade II (33%), 2 grade III (22%).
Results: Compared to healthy controls MM pts showed a significant reduction in terms of length and number of corneal fibers (median length 552 µm in MM *vs* 1197 µm in control p<0.001; median number 4/field *vs* 7/field p<0.001), a higher grade of tortuosity with both methods (1.5 *vs* 0.3 according to Oliveira scale, p<0.001; 3.9 *vs* 2.1 according to Nidek index p<0.001) and increased beadings' density (75/mm *vs* 58/mm, p=0.001). All MM pts have fibers' alterations even in absence of a clinical evident PN. There were not statistically significant differences in fibers' length and number among pts symptomatic and asymptomatic for PN (length 554 µm *vs* 549 µm, p=0.86; number 4/field *vs* 3/field, p=0.661). Tortuosity and beadings' density were higher in symptomatic pts, but this difference did not reach a statistical significance (tortuosity 2 *vs* 1.5 according to Oliveira, p=0.29; 4.2 *vs* 3.8 according to Nidek p=0.81; beadings' density 78/mm *vs* 73/mm p=0.27) probably due to the small number of pts studied. Patients under treatment with Bor showed a higher beadings' density with respect to those off therapy but this difference was not significant (76/mm *vs* 66/mm, p=0.14).
Summary and Conclusions: Confoscan 4 can be a useful tool for the detection of Bortezomib induced neurological damage in Multiple Myeloma patients. Prospective studies are needed to evaluate if it could also help physicians in early detecting neurological symptoms emergence.

PB1683

PULMONARY FUNCTION TEST CAN BE USEFUL TO PREDICT SEVERE PULMONARY COMPLICATIONS IN MULTIPLE MYELOMA PATIENTS TREATED WITH BORTEZOMIB

S Ferrari[1],* D Petro'[1], AM Cafro[1], M Riva[1], E Ravano[1], A Tedeschi[1], E Morra[1]
[1]Hematology, AO Niguarda Cà Granda, Milan, Italy

Background: Bortezomib is a proteasome inhibitor indicated for the treatment of Multiple Myeloma patients. Among extrahematologic adverse effects, neuropathy and gastrointestinal symptoms are the most commonly reported, whereas severe pulmonary complications have been described rarely.
Aims: To describe a possible relationship between the administration of bortezomib and the development of pulmonary complications and evaluate the predictivity of pulmonary function test (PFT).
Methods: Between January 2012 and December 2013, 115 pts affected by MM were treated with bortezomib-based therapy in our Department. Three pts developed severe pulmonary complications related to bortezomib therapy. The characteristics of the three pts are described in Table 1. All three pts had a previously untreated syntomatic myeloma, no history of pulmonary diseases and normal chest X-ray before bortezomib treatment. PFT showed medium-marked reduction of DLCO and restrictive abnormalities. After administration of bortezomib (range: 2-6 days) the three pts presented similar clinical symptoms: fever and acute impaired oxygenation followed by respiratory failure. Radiologic

manifestations were similar including: bilateral pulmonary infiltration, interstitial pneumonia and pleural effusion (Figure 1). Bacteriological blood and urine samples were negative in all pts. Bronchoalveolar lavage were performed in all of them, only the third one was positive for Influenza B virus. Pt 2 underwent computed tomography (CT)-guided percutaneous transthoracic needle biopsy and the pathology report described focal fibrosis. In Table 2 are summarized details of severe pulmonary complications of the three cases. Due to the negative etiological report and the lack of response to broad-spectrum antibiotics high dose intravenous corticosteroid, methylprednisolone, was started. Only one pt needed endotracheal intubation and mechanical ventilation. We have seen clinical, gasometric and radiological improvement in few days in all pts.
Results: After recovery all pts were treated with no bortezomib-based therapy and two of them received autologous stem cell transplant without pulmonary complications.

Table 1.

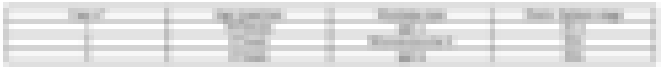

Table 2.

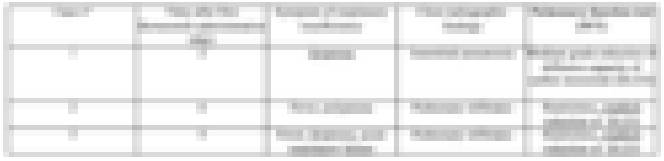

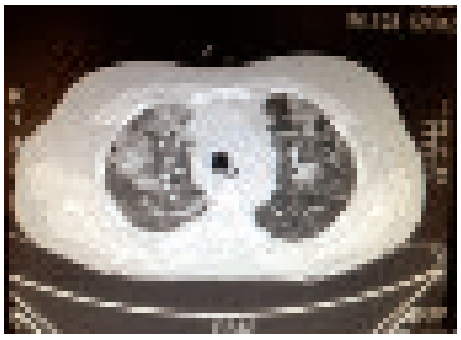

Figure 1.

Summary and Conclusions: This report underlines that bortezomib may cause serious lung injury as described in literature. PFT showed to be a useful diagnostic test before bortezomib-based treatment to identify patients at risk of respiratory failure and requiring second level investigations such as chest CT and pneumological evaluation.

PB1684

MANAGEMENT OF RELAPSED AND REFRACTORY MULTIPLE MYELOMA WITH BENDAMUSTINE

C Cerchione[1,*] E Madonna[1], A E Pareto[1], L Marano[1], N Pugliese[1], I Peluso[1], E Seneca[1], G Cerciello[1], S Avilia[1], S Basile[1], F Pane[1], L Catalano[1]
[1]Hematology, AOU "Federico II", Napoli, Italy

Background: Bendamustine is a bifunctional alkylating agent, with low toxicity, that produces both single- and double-strand breaks in DNA, and shows incomplete cross resistance with other alkylating drugs, proved to be effective either in relapsed or refractory and in new diagnosed MM as single agent or combined with steroid and has also additive/synergistic activity with bortezomib.
Aims: Here we evaluate the efficacy and tolerance of bendamustine in combination with bortezomib-dexamethasone in patients with relapsed and refractory multiple myeloma, whose prognosis is severe, so that there is a strong need for new options for the management of these patients. A retrospective analysis of patients with relapsed and refractory MM, who had received bendamustine as salvage therapy, has been performed.
Methods: 24 patients, 13 males, 11 females, with advanced multiple myeloma, treated with several lines of treatments, and refractory to all the lines previously performed, received a schedule Bendamustine-based. Median age at diagnosis was 63.2 years (range 39-82) while age at start of treatment was 66 years (range 48-83), and median number of prior lines of treatment was 6.3 (range 4-8). ISS was equally distributed, and cytogenetic characteristics were evaluable in 9 patients, only two of whom had cytogenetic abnormalities, and in particular one of them had del13q and in the other one was observed t(11;14). All the patients had previously been treated with schedule containing bortezomib and lenalidomide, while 90% of them had been treated with melphalan, 77% with cyclophosphamide and 34% with anthracyclines, and 30% had also received radiotherapy. 58% of patients had undergone at least to a single autologous stem cell transplantation. Last treatment before bendamustine was a bortezomib-based regimen in 39%, an IMIDs- based regimen in 49% (a combined bortezomib/IMIDs-based regimen in 27%), while 12% of patients had received other chemotherapies. All patients were relapsed and refractory to last therapies received.
Results: Only patients completing at least two two courses of Bendamustine were considered for analysis. A total of 87 cycles was administered (median 4.3, range 2-9). In 91% of patients bendamustine was variously associated to bortezomib (66%), or IMIDs (25%) and only in 8% it was combined only with dexametasone. In our schedule, Bendamustine was given, at a median dose of 90 mg/sqm (range total dose : 120-180 mg) on day +1 and +2 every 28 days. After a median follow-up of 6.1 months, median OS from diagnosis was 57.3 months, while median OS from start of Bendamustine was 6.7 months (range 2-19 months). 11/24 patients died for progressive disease. 2/24 patients died for other causes (one for cardiovascular disease and the other one had a gastric cancer). Grade 3 transfusion-dependent anemia occurred in 36% while in 53% grade 3 neutropenia occurred. We observed no severe extrahematologic toxicity, only grade 1 gastrointestinal side effect (nausea), treated by common antiemetic drugs. According to IMWG uniform response criteria, 15 out of 24 evaluable patients achieved a partial response after a median time of 2.4 months with an overall response rate of 62.5%. In particular, for 3 patients of this study, Bendamustine treatment was a bridge to second autologous stem cell transplantation, and for one patient for allogenic stem cell transplantation, after having achieved a PR.
Summary and Conclusions: In conclusion, Bendamustine has shown significant efficacy in a particularly severe setting of patients, relapsed and refractory to almost all available therapeutic resources, and in particular cases it could be considered as a bridge to a second autologous or to allogeneic BMT.

PB1685

EFFECTIVENESS OF HAEMODIALFILTRATION WITH HIGH-CUT-OFF MEMBRANE IN PATIENTS WITH MULTIPLE MYELOMA AND RENAL FAILURE, A SINGLE CENTER EXPERIENCE

A Jiménez[1,*] S Gómez[1], M Calbacho[1], MJ Blanchard[1], A Vallés[1], A Chinea[1], G Ruiz-Roso[2], F Liaño[2], FJ López[1]
[1]Haematology, [2]nephrology, Hospital Ramón y Cajal, Madrid, Madrid, Spain

Background: Acute kidney failure in multiple myeloma (MM) occurs in 12%>20% of patients and is a poor prognostic factor for patient survival. Recent studies have shown that dialysis with a High-Cut-Off membrane (HCO) removes free light chains (FLC) and is being an effective treatment for acute renal failure that could be a determining factor for the survival.We have retrospectively evaluated the effectiveness of HCO membrane in the recovery of renal function in addition to a standard anti myeloma treatment.
Aims: Effectiveness of haemodialfiltration with High-Cut-Off membrane in patients with multiple myeloma and renal failure.
Methods: From January 2010 to April 2013, 13 patients were diagnosed of MM with severe acute renal failure (ARF). Population: 8 female/5 male, median age: 67.7 years (40-83), Bence-Jones MM: 8, IgG:3, IgD: 1, IgA:1. Creatinine: 8.26 mg/dl (3.61-21.3), glomerular filtration rate, Cockcroft-Gault: 9.4 ccs/min (2.9-19.7). All patients were treated with bortezomib (1.3 mg/m2 days 1-4, 8-11) and dexamethasone (40 mg, days 1-4, 9-12) 2 patients received conventional haemodialysis (CH) and 11 with HCO membrane.
Results: Number of HCO haemodialysis sessions: 6 (1-12). Average Cr post treatment: 1.37 mg/dl. Renal response: CH: stable: 2. HCO: complete: 2, partial: 8, minor: 1. Dialysis Independence: Global: 12/13 (92.3%), HCO: 100%, CH: 50%. Time to renal response (days): minor: 17.5, partial: 59.3, complete: 210. MM response: sCR: 6, CR: 3, PR: 4. Number of chemotherapy cycles: 6 (4-8) The 3 patients with <65 years could receive an autologous hematopoietic stem cell transplant. After a median follow up of 27 months, relapse rate was: 4/13 (30.7%) and OS: 100%.
Summary and Conclusions: The combination of antimyeloma treatment plus HCO haemodialysis is a highly effective treatment for acute renal failure due to myeloma nephropathy, with a 100% rate of dialysis independence. In our series, only 2 patients remained with stable renal disease (1 with dialysis dependence), both of them treated with CH.

PB1686

I-FISH DETECTION OF THE MOST FREQUENT CHROMOSOMAL ABNORMALITIES IN SELECTIVE CD138+ PLASMA CELLS IN MULTIPLE MYELOMA

R Rothman[1,*] V Nadia[1], A Orr-Urtreger[1], T Svetlana[2]
[1]Genetic Institute, [2]Department of Hematology, Sourasky Medical Center, Tel Aviv, Israel

Background: Multiple Myeloma (MM), is characterized by the accumulation of Plasma Cells (PC) in the Bone Marrow (BM) and like other hematological malignancies has both normal and clonal neoplastic cells.

Aims: Cytogenetic studies in MM are hampered by the low proliferative capacity of PC. In order to detect the chromosomal abnormalities by Interphase Fluorescent *In situ* Hybridization analysis (I-FISH) it is important to perform the analysis on the PC.
Methods: Enrichment of PC by CD138 positive selection prior to I-FISH is one way to enhance diagnostic sensitivity. We used a panel of FISH probes to detect numerical and structural chromosomal aberrations (for chromosomes 1, 13, 14 & 17) by I-FISH analysis. The analysis was performed on whole BM samples (routine r-FISH) and on CD138 + BM cells separated with magnet beadsseparation for subsequent I-FISH analysis (ms-FISH) from the same 15 patients with MM.
Results: In this study the purity of the PC separation ranged between 51% to 91%. The ms-FISH is considered to be the reference standard method and detect all the chromosomal abnormalities tested (100% sensitivity). Comparing r-FISH with ms-FISH, we have demonstrated that all the patients had detectable chromosomal abnormalities after PC separation. In 8 out of 15 samples the percentage of PC was less than 10% and the percentage of chromosomal abnormalities in both r-and ms-FISH was under the cut off limit (10%) for FISH detection of chromosomes 1, 13 and 17. Interestingly, all the samples were positive for chromosome 14 (cut off limit: 1%). One sample with 10% PC, was also positive for the chromosome 13 deletion by ms-FISH. All the six samples with more than 10% of PC presented chromosomal abnormalities in both r-FISH and the ms-FISH, but the presence of these anomalies was higher and statistically significant after PC separation. We calculated that the ms-FISH detection was highly sensitive and may replace the r-FISH in confidence level of 90% for chromosome 1 and 17; 95% for chromosome 13 and 99% for chromosome 14 (wilcoxon signed-rank test).
Summary and Conclusions: In our experience the CD138+ magnetic separation was effective. The most frequent chromosomal abnormality in all the cases investigated was chromosome 14 (IGH) and can be used as a screening test. We thereby determine that r-FISH can be used only in the cases of high percentage of PC in the whole BM. Since, the majority of the MM cases had low number of PC in the BM aspirates we recommend to isolate the PC first, and then to perform the ms-FISH on the targeted cells.

PB1687

MYD88 MUTATIONS ARE CORRELATED WITH 6Q DELETION IN KOREAN PATIENTS WITH WALDENSTROM MACROGLOBULINEMIA

JA Kim[1,*] K Im[2], SN Park[2], J Kwon[2], Q Choi[1], SM Hwang[1, 3], N Sekiguchi[4], SS Yoon[5], SY Kim[1], DS Lee[1,2]
[1]Department of Laboratory Medicine, [2]Cancer Research Institute, Seoul National University College of Medicine, Seoul, [3]Department of Laboratory Medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of, [4]Hematology Division, National Hospital Organization Disaster Medical Center, Tokyo, Japan, [5]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic Of

Background: Waldenstrom Macroglobulinemia (WM) is a malignant lymphoplasmo-proliferative disorder with IgM monoclonal gammopathy. The genetic changes associated with WM are not fully elucidated. Recently, whole genome study revelaed MYD88 L265P mutation as the key mutation in WM.
Aims: The aim of this study is to find out MYD88 L265P mutation status of Korean WM patients.We also investigated cytogenetic aberrations using conventional G-banding and fluorescence *in situ* hybridization (FISH), and analyzed their correlation with MYD88 L265P mutation status.
Methods: A total of 22 patients diagnosed with WM according to consensus recommendations from the Second International Workshop on WM was enrolled. Conventional G-banding and interphase fluorescence *in situ* hybridication (FISH) targeting 6q21, *IGH*, *RB1*, *TP53*, 1p25/1q32, and CEP 9/CDKN2A were performed using bone marrow (BM) aspirates. Of 22 WM patients, 16 patients were subjected for MYD88 mutation study and *MYD88* mutation was detected by Sanger sequencing.
Results: Of 22 patients, 5/18 patients (28%) showed cytogenetic aberrations by G-banding study. The incidence of 6q21 deletion was 17% by conventional G-banding and 33% when analysed by FISH. By FISH, 9/21 patients (43%) showed cytogenetic aberrations; 6q deletion in 7/21 (33%) patients and *IGH* rearrangement in 4/21 (19%) patients. Two patients had both 6q deletion and *IGH* rearrangement, and 2 patients had only *IGH* rearrangement without 6q deletion. Of 16 patients, 11 (69%) patients presented L265P mutation of *MYD88* gene. MYD88 mutation significantly associated with presence of 6q deletions (*P* value 0.053). Among patients with 6q deletion, all the 5 patients for whom sequencing was possible, *MYD88* mutation was found. The MYD88 L265P mutation was also associated with high lymphocyte burden in BM biopsy. There was no significant differences in other clinical characteristics and laboratory findings including peripheral blood lymphocytosis, and overall survival according to *MYD88* mutation status.
Summary and Conclusions: We first report the high frequency of MYD88 L265P mutation in Korean WM patients. We observed significant association of MYD88 L265P mutation (on chromosome 3p22) and 6q deletion.

PB1688

BENDAMUSTINE-BASED-TREATMENT FOR HIGHLY TREATED PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA

AM Hernández-Sánchez[1,*] R García-Sánchez[1], A González - Fernández[1], M Rivas Luque[1], A Fernández Fernández[1], A I Rosell Mas[1], I Caparrós Miranda[1], A Campos Garrigues[1], MP Queipo de LLano[1], G Ramírez[1], A I Heiniger[1]
[1]Unidad de Gestión Clínica de Hematología Intercentros, Hospitales Regional y Virgen de la Victoria, Málaga, Spain

Background: Bendamustine is a nitrogen mustard that was developed as a bifunctional molecule with alkylator and antimetabolite properties. Compared with other frequently used alkylating agents, bendamustine induces higher rates of DNA double-strand breaks and is not cross-resistant with melphalan and several other cytotoxic drugs. Clinically, bendamustine has already been tested in patients with relapsed/refractory myeloma (MMRR). Based on these properties, we started using Bendamustine (combined or as single-agent), in patients with MMRR despite several previous treatment lines, in an attempt to control disease activity.
Aims: Our aim is to present a sample of 18 patients (from Nov´2009 to Oct´2013) with relapsed/refractory Multiple Myeloma (MMRR) treated at our institution with Bendamustine - based regimens. 11 women and 7 men, median age 58 years at the beginning of the treatment (range 43-79). The characteristics of the patients at the time of diagnosis were: ECOG ≥3 in 27,8%; types of MM: IgG 67%, IgA 11% and light chain of 22%; with state of ISS I in 39% of the instances, II in 16% and III in 45% of them. Bone lesions were presented in 70% of study population, those being >4 in 50% of the cases and plasmacytomas in 33,3%. Median previous lines received was 4 (with a 2-7 interval), including autologous-SCT in 4 patients (22%). 94% of the patients had received Bortezomib based regimen (VD 83% and VMP 44%) , all of them had received IMID's (Lenalidomide 94% and 22% Talidomide) and alkylants were administered in a 22% of patients. At the beginning of the treatment with Bendamustine 4 patients (22%) presented renal impairment (creatinine ≥ 2mg/dL) and 13 (72%) showed alterations in the free-light-chain ratio.
Methods: Response to treatment was assessed according to the IMWG criteria and the adverse events according to the National Cancer Institute´s Common Terminology Criteria for Adverse Event (3.0).
Results: Patients received a median of 3 cycles of Bendamustine (B) – based treatment (range 1-8) with a median dose of Bendamustine of 60mg/m2 (range 30-100) administered on days 1 and 2 of each cycle. Used treatment schedules were Bendamustine as single-agent in 3 patients, B+Prednisone in 9 patients, B+Dexametasone+Bortezomib in 5 patients, B+Lenalidomide in 1 patient. After a median of follow up of 6 month (range 2-13), the global response rate (≥ PartialResponse) according to the IMWG criteria was 33% (1 CR, 3 VGRP, 2 PR), with a 28% Stable Disease and 39% of PD. The average time until progression was 2.5 months (range 1-10). Grade 3-4 hematologic adverse events (AE) were observed as follows: anemia 28%, neutropenia in 28% and thrombocytopenia in a 33% of the patients. Non-hematologic grade 3-4 AE resulted in 22% patients with infection.
Summary and Conclusions: Multiple myeloma remains an incurable disease in most cases. In spite of the multiple lines previously received, Bendamustine is effective and well-tolerated in patients with MMRR. Based in our experience we would recommend early use of Bendamustine – based regiments (no later than third line or in combination with Bortezomib even earlier if there is evidence of renal impairment). More studies are required to establish and optimize its use.

PB1689

INTRAVENOUS SWITCHING OF BORTEZOMIB CAN OVERCOME RESISTANCE AFTER SUBCUTANEOUS ADMINSTRATION IN MULTIPLE MYELOMA PATIENTS

A Gozzetti[1,*] V Candi[1], G Papini[1], M Defina[1], L Schiattone[1], M Bocchia[1]
[1]Hematology, Siena, Italy

Background: Subcutaneous bortezomib (SC) is reported as noninferior in efficacy to intravenous bortezomib in multiple myeloma (MM) patients and is associated with a lower incidence of neuropathy. SC administration of bortezomib is comparable with the IV route, in terms of overall systemic availability and pharmacodynamic activity, similar toxicity profiles, and similar response rates. As expected, the time required for SC administration to be absorbed is longer than for the IV route and accordingly the mean plasma concentration values are significantly lower for SC administration, and the median time to reach the final plasma concentration is longer. Nevertheless, the 20S proteasome inhibition seems similar in both routes of administration, and the longer time required for SC formulation to be absorbed results in a less-pronounced initial spike in proteasome inhibition.
Aims: To test if MM patient resistant to the SC injection can have a disease response with the IV administration of bortezomib due to the higher peak values of plasma concentrations in the IV formulation.
Methods: Thirty patients (median age 69, range 56-82) consecutively

presented in a time period of one year (January 2013-January 2014) at a single center received bortezomib SC injections at MM relapse. Type of immunoglobulin was: 18 IgG (12 kappa ;6 lambda), 5 IgA (3 kappa; 2 Lambda), 5 BJ (3kappa, 2 lambda), 2 NS. ISS Stage was: I (n=16), II (n=7),III (n=7). Cytogenetics on bone marrow selected CD138 plasma cells was done. Patients had received a median of 3 previous lines of therapy (range 2-6). Six patients were bortezomib naive, while 24 had received bortezomib previously.
Results: VMP was administered in 5 patients, VCD in 16 , Vel-dex in 7, VTD in 1, PAD in 1. Patients received a median of 5 cycles (range 2-7). Overall response rate (ORR) was 76%. Responses were: 4 CR, 2 VGPR, 17 PR, 7 NR.We swicthed SC injections in the 7 NR patients. They received a median of 2 cycles of bortezomib and dexamethasone day 1,4,8,11(range 1-5). 3/7 patients showed a response (2PR, 1MR, 4 NR). In the responders response was seen after the first cycle. Responders received IV bortezomib until progression. A median of response of 3 months was seen. The 2 patients achieving PR were previously treated with 3 lines of therapy and 6 lines of therapy; they were bortezomib naive at the SC administration. Addition of a third drug (melphalan) did not recover response at disease progression. Data will be presented about response kinetics and duration.
Summary and Conclusions: IV administration of bortezomib in MM patients previously resistant to SC injections should be considered. It could be hypothesized that higher peaks of the drug in the IV administration can overcome resistance in few patients. Further studies are warranted to confirm these findings.

PB1690

INCIDENCE OF INFECTION ACCORDING TO INTRAVENOUS IMMUNOGLOBULIN (IVIG) USE IN AUTO-HCT RECIPIENTS WITH MULTIPLE MYELOMA
KH Yoo[1,*] S Park[1], MY Lee[1], DH Han[1], CW Jung[1], K Kim[1]
[1]Hematology and Oncolongy, Samsung Medical Center, Seoul, Korea, Republic Of

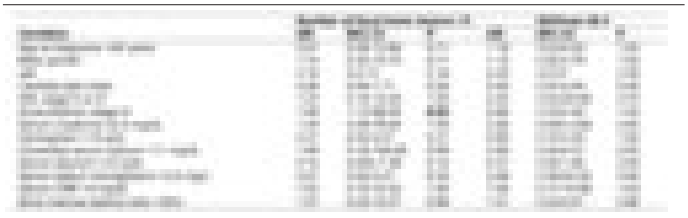
Background: According to the guidelines for preventing infectious complications among HCT recipients, administration of intravenous immunoglobulin (IVIG) is only indicated if the patients had severe hypogammaglobulinemia (ie, serum IgG level<400 mg/Dl). Although IVIG is not routinely recommended, many centers still use IVIG during post-HCT period.
Aims: In this study, we evaluated and compared the incidence of infection according to the post-HCT IVIG use in multiple myeloma (MM) patients with autologous HCT.
Methods: A total of 162 MM patients who received auto-HCT between Jan 2008 and Jun 2013 were retrospectively reviewed. Defining infectious events was based on the physicians' judgement at the time of recording a medical chart. Infectious events were counted from the date of discharge after auto-HCT to the first date of next treatment for the recurred/progressive disease, or to the last follow-up date for the patients without further treatment.
Results: The median age was 54.5 (23-67), and DSS at diagnosis was stage I in 23 patients (14.3%), II in 30 (18 6%), and III in 108 (67.1%). After auto-HCT, 53 of 162 patients (32.7%) experienced 103 infectious events. Upper respiratory tract infection was most common (n=31, 30.1%) and pneumonia (n=27, 26.2%) and herpes zoster (n=15, 14.6%) came next. Among the identifiable organisms causing respiratory tract infection, influenza virus (n=10) and pneumococcus (n=9) were predominated. Incidence of infection was not statistically different according to the IVIG use (34.8% in IVIG (-) *vs* 31.3% in IVIG (+), p=0.631). Incidence of infectious events requiring hospitalization and multiple infectious events showed no difference between the groups (p=0.147, p=0.156). Respiratory tract infection was occurred in 15 (22.7%) in no IVIG group and 16 (16.7%) in IVIG group (p=0.335). Although not statistically significant, patients receiving IVIG had a trend towards less lower respiratory tract infection (15.2% in IVIG (-) *vs* 6.3% in IVIG (+), p=0.062).
Summary and Conclusions: In auto-HCT recipients with MM, incidence of infectious events after transplantation was not different according to the prophylactic IVIG use. Potential benefit of IVIG for prevention of lower respiratory tract infection may be considered, which needs further evaluation.

PB1691

THE RELATION BETWEEN INITIAL PET FINDINGS AND CLINICAL PARAMETERS IN MULTIPLE MYELOMA PATIENTS
T Firatli Tuglular[1,*] F Pepedil Tanrikulu[1], T Toptas[1], A Karadeniz[2], A Eser[1], O Kara[1], I Kaygusuz Atagunduz[1]
[1]Hematology, [2]Internal Medicine, Marmara University Hospital, Istanbul, Turkey

Background: In a recent study, F-fluorodeoxuglucose (FDG) positron emission tomography (PET) in multiple myeloma (MM) patients was evaluated and a positive correlation with clinical parameters was reported. Moreover, it was found to be a predictor of outcome. However, the present data is still not enough for routine usage of FDG-PET in our daily practice beyond simply detecting the involvement of bone and extramedullary tissues.
Aims: We aimed to investigate the correlation between baseline FDG-PET findings and clinical parameters in our MM patients.
Methods: We conducted a retrospective review of our MM patients' files. As a total of 385 patients' data who were followed at our out-patient clinics from January 2005 to december 2013 were analysed. Among those, 48 patients who were chemotherapy naive were found to have baseline FDG-PET evaluation. We compared the initial clinical characteristics of these patients with their PET findings: the number of focal bone lesions (FLs) and the maximum standardized uptake value (SUVmax). Relationship between the above mentioned initial disease characteristics and FDG-PET parameters were analysed by chi-square test.
Results: A total of 48 patients (23 male) were included for analysis. The median age was 62 years (range 55-72). At diagnosis the median hemoglobin level was 10.5 g/dL (range 9.3-11.5) and 29.2% of patients had anemia. The proportion of patients with hypoalbuminemia, hypercalcemia and azothemia were 15%, 5% and 5% respectively. Median serum CRP was 4 mg/L (range:3-10.5) and 9% of patients had CRP more than 5 mg/L. Among patients with secretory disease (97.9%) IgA, IgG and light chain only disease were 8.3%, 62.5% and 27.1%. The median amount of bone marrow plasma cells were 40% (range 25-60) and 25% of patients had more than%30 plasma cells in the bone marrow. At presentation median serum beta-2 microglobulin was 3.5 mg/L (range: 2.5-5.0) and 20% of patients had international staging system (ISS) stage 3. The ratio of Durie-Salmon (DS) stage 3 disease was 43.8%. Regarding baseline FDG-PET findings, 41 (85.4%) patients had lesions on imaging. Of these FDG-PET positive patients, 17 (54.8%) had more than 3 FLs. The median SUVmax for these FLs was 6.5 (range: 4.9-10) and 6 patients had a SUVmax value greater than 6.5. Briefly, a positive relationship between DS stage 3 and number of FLs on PET was found. However, there was not any other statistically significant relationship considering others (Table 1).

Table 1. Relationship between the number of focal bone lesion, SUVmax value and baseline characteristics.



Summary and Conclusions: A statistically significant positive correlation was found between baseline FDG-PET findings and DS stage in MM patients. So, our findings partially support the evidence in the literature and it seems that imaging helps staging disease at the time of initial diagnosis. There is need for further studies.

PB1692

DOES IT MATTER THE TYPE OF MYELOMA? CLINICAL AND BIOCHEMICAL CHARACTERISTICS OF IGA AND IGD MYELOMA
V Vukovic[1,*] J Bila[1,2], J Jelicic[1], V Djurasinovic[1], A Sretenovic[1], B Andjelic[1], D Antic[1,2], M Todorovic[1,2], B Mihaljevic[1,2]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background: According to the type of M protein, patients (pts) with IgG multiple myeloma (MM) are the most common, representing ≈60% of cases. IgA and IgD myeloma occurs in 20% and 2%pts respectively.
Aims: The aim of study was to analyse clinical and biochemical features of pts with IgA and IgD myeloma in a view of the appropriate personalized treatment approach.
Methods: The study included 70 newly diagnosed MM pts with IgA (64pts, 30 male/34 female, mean age 58yrs, range 35-79) and IgD myeloma (10pts, 5 male/5 female, mean age 55yrs, range 31-78yrs). According to the clinical stage, distribution of IgA myeloma was: I 6pts (9,4%), II 24pts (37,5%); III 34pts (53,1%); and IgD: II 2pts (20%), III 8pts (80%). Regarding ISS score, within IgA myeloma predominate pts with ISS2 and ISS3 (30pts, 73,2%), while there was higher incidence of pts ISS1 (4pts, 66,7%) with IgD myeloma. Renal impairment existed in 20pts (27%; IgA MM: 17pts, 26,6%, and IgD MM: 3pts, 30%). Thalidomide based combinations were applied in the majority of pts (52pts, 70,2%). High-dose treatment and autologous stem cell transplantation were applied in 15pts (22,9%).
Results: Both of the groups were characterized with notable 24h proteinuria (IgA: mean value 1,26gr/l, SD=2,25, median 0,28gr/l, range 0,04- 8,70gr/l ; IgD: mean value 1,05gr/l, SD=1,57, median 0,22gr/l, range 0,06- 4,02gr/l), and significantly higher incidence of the LDH elevation above 500U/l in pts with IgA

myeloma (p <0,001). Similarly, there was higher incidence od LDH elevated above 500U/l in pts with IgD myeloma, but without statistical significance (R= 0,075, p= 0,669). Of notice, there was significantly higher incidence of extramedullary disease (p <0,008), and plasma cell leukemia (p <0,001) in pts with IgD myeloma. Treatment response (CR/VGPR/PR/MR) was achived in 57pts (77,1%; IgA MM: 49pts, 76,6%; IgD MM: 7pts, 70,0%) with median duration of 12m (range 8- 110m). Median overall survival (OS) for the whole group was 35m (range 1- 170m). There was no significant diference between pts with IgA and IgD myeloma in duration of TTP (median 10m *vs.* 20m; Log Rank =0,694, p =0,405), and OS (median 35 *vs.* 43m; Log Rank =0,048, p =0,826).
Summary and Conclusions: Clinical features that characterizes IgA and IgD myeloma are notable 24h proteinuria, significant LDH elevation, and occurrence of the extramedullary disease and plasma cell leukemia in patients with IgD myeloma which indicates the following aggressive course of disease, and necessity of the intensive first-line treatment.

PB1693

HAEMOSTATIC DISORDERS IN NEWLY DIAGNOSED MULTIPLE MYELOMA
E Urnova[1,*] L Mendeleeva[1], M Gracheva[1], O Pokrovskaya[1], S Vasiliev[1], E Gemdjian[1], I Tarandovskii[1], E Sinauridze[1], V Savchenko[1]
[1]Hematology Research Center, Russian Ministry of Health, Moscow, Russian Federation

Background: Multiple myeloma (MM) is associated with many hemostatic disorders, leading to thrombotic complications. The most frequently thrombosis is registered in patients with MM during the first year after diagnosis. Without prophylaxis thrombosis' rate can achieve 34-58%.
Aims: The aim of the study was to determine the frequency and characteristics of hemostatic disorders in patients with MM and to define the adequacy of anticoagulant and antiaggregant prophylaxis during induction therapy.
Methods: Between March 2012 and May 2013 25 patients (13 male and 12 female) at the age of 29-72 (median 54 years) with newly diagnosed multiple myeloma were included in a prospective study. Stage I was diagnosed in 2 patients, stage II in 9 patients, stage III in 13 patients according to Durie-Salmon, and in 9, 11 and 5 patients according to International Staging System respectively. Hemostasis investigation was performed with Activated Partial Thromboplastin Time (APTT), factor XIIa dependent time of fibrinolysis, D-dimer level. Integral methods of hemostasis investigation were used: thrombin generation assays (principle parameter was endogenous thrombin potential, ETP), thromboelastography and a new method of a spatial fibrin clot growth registration – thrombodynamics (TD). Induction therapy included courses PAD and VCD. All patients received heparin (500 ED/hour twenty-four-hour infusion) or acetylsalicylic acid (100 mg per day) as thromboprophylaxis. Statistical analysis was done with multiple linear regression method.
Results: Hypercoagulation was detected in 17 (68%) patients with at least one of the used methods. However APTT was normal in all patients. Five patients had a factor XIIa dependent time of fibrinolysis elongate. In 11 patients D-dimer levels were elevated. D-dimer concentration had a statistically significant correlation with ETP (Pearson correlation coefficient R: 0,65; p=0,01) and factor XIIa dependent time of fibrinolysis (Pearson correlation coefficient R: 0,63; p=0,01). Inverse relationship was established between paraprotein level and optical density of fibrin clot measured by TD (Pearson correlation coefficient R: 0,65; p=0,01). There was one episode of thrombosis in a patient 71 years old after he discontinued the use of acetylsalicylic acid on his own in the setting of prolonged immobilization.
Summary and Conclusions: Increased readiness for thrombogenesis was found in 68% of patients with newly diagnosed MM. Acetylsalicylic acid 100 mg per day or 500 ED/hour twenty-four-hour heparin infusion was found to be adequate thromboprophylaxis. Possible meaning of such risk factors as elderly age and prolonged immobilization was shown.

PB1694

VALIDITY OF STRINGENT COMPLETE RESPONSE IN ROUTINE MANAGEMENT OF MULTIPLE MYELOMA PATIENTS TREATED WITH THE NOVEL AGENTS
JL García De Veas Silva[1,*] P Menéndez Valladares[1], C Bermudo Guitarte[1], JA Martín Ruiz[1], R Duro Millán[2]
[1]Clinical Biochemistry, [2]Hematology, Hospital Universitario Virgen Macarena, Sevilla, Spain

Background: Normalization of serum free light chains (sFLC) ratio in patients with Multiple Myeloma (MM) achieving complete response (CR) may define a deeper degree of response after therapy than that defined by the CR criteria. The stringent CR (sCR) requires normalization of sFLC ratio and absence of clonal plasma cells in bone marrow in addition to the criteria for CR (Negative immunofixation of serum and urine, disappearance of any soft tissue plasmacytomas and <5% plasma cells in bone marrow).
Aims: The aim of this study is to evaluate the prognostic utility of sCR in patients newly diagnosed with MM treated with novel agents in the routine practice.
Methods: Twenty three patients with MM (10 IgG MM, 5 IgA MM, 2 IgD MM and 6 Bence Jones MM) achieving CR after therapy with Bortezomib/ Dexametasone were included in this study. Disease Free Survival (DFS or time after treatment where disease remains stable) was estimated by Kaplan-Meier method and compared by log-rank tests. Cox proportional hazard analysis was performed for multivariate analysis. Serum free light chains were measured by turbidimetry (Freelite) in a SPA PLUS analyzer (The Binding Site Group Ltd, Birmingham, UK) and immunofixation was performed in a HYDRASYS (Sebia, FR) analyzer.
Results: The median follow-up of the patients was 18 months (range 14-31 months). Eleven patients achieved sCR (48%; 7 IgG MM, 2 Kappa Light Chain MM and 2 Lambda Light Chain MM) and 12 patients (52%; 5 IgA MM, 3 IgG MM, 2 IgD MM and 2 Lambda Light Chain MM) achieved CR. During the period of study there were 8 relapses, six (2 IgA MM, 2 IgD MM, 1 IgG MM and 1 Lambda Light Chain MM) in patients achieving CR and two (1 IgG MM and 1 Kappa Light Chain MM) in patients achieving sCR. The median DFS for patients achieving CR was 18 months and not reached for those achieving sCR. Patients achieving CR had a DFS rate of 24% compared with 75% for sCR (p=0.022). Results showed that achieving a sCR was an independent prognostic factor for survival (HR = 6.57; 95% CI, 1.09-39.80; *vs* CR; p=0.039).
Summary and Conclusions: The presence of an altered sFLC ratio suggests the existence of a persistent clonal population that is secreting small amounts of monoclonal protein. Our results indicate that sCR represents a deeper response state compared with conventional CR which translates into a longer DFS. Despite the small cohort, analysis of sFLC ratio was able to identify a group of patients with more favorable prognosis and support its inclusion in the response criteria for MM patients treated with novel agents.

PB1695

A SEQUENTIAL AND NOT OVERLAPPED USE OF NEW DRUGS FOR INDUCTION THERAPY OF MULTIPLE MYELOMA: A PROPOSAL OF A COMBINED TREATMENT TO INCREASE THE COMPLETE REMISSION AND OVERALL SURVIVAL RATES
L Franceschini[1], M Postorino[1], L Giannì[1], M Rizzo[1], L Pupo[1], S Vaccarini[1], I Provenzano[1], A Zizzari[1], L Tonialini[1], D Nasso[1], G De Angelis[2], W Arcese[2], M Cantonetti[1,*]
[1]Oncohaematology, Azienda Ospedaliero Universitaria Tor Vergata, [2]Stem cells Transplant Unit, Azienda Ospedaliero Universitaria Tor Vergata-Rome Transplant Network, Roma, Italy

Background: Multiple Myeloma (MM) remains an incurable disease despite intensive therapy such as high-dose melphalan and autologous stem cell transplantation (ASCT). In multivariate analysis, we know that achieving a complete remission (CR) before ASCT is a significant independent variable for OS and TTP and maintenance therapy is an important option to protract PFS. Contemporary use of new drugs increases the overall response rate (ORR) and stringent complete remission (sCR) rate, but it's unclear the impact on PFS, TT retreatment, extra-bone disease incidence and 2nd line therapeutic strategies.
Aims: According this assertion, we planned a preliminary monocentric study to evaluate the results of a global intention to treat comprehensive of induction, transplantation, maintenance and further lines of treatment at relapse. It is based on a sequential therapy without the contemporary use of new class of drugs; it aims to obtain the same results of standard care, without the cumulative toxicity by overlapping use of new drugs, so to permit to reach again at least the VGPR at relapse,in good clinical condition for a possible second transplantation.
Methods: From September 06 to June 2011 we enrolled 24 pts (7 M, 17 F) with symptomatic and untreated MM; median age was 53 years (34 – 64); M-protein was measurable in 17 pts and 12 pts showed IgG type , 5 pts IgA; disease was classified as non secretory in 2 pts and micromolecular in 5 pts; ISS score was 1 in 15 pts, 2 in 5 pts and 3 in 4 pts . Patients underwent to VALD regimen (Vincristine 2 mg, Liposomal Adriamicine 40 mg/m2 on day 1 and Dexametasone 40 mg day 1-4) for 3 cycles (day 1 -21); 15-30 days after last VALD, pts started 3 courses bortezomib regimen (1.3 mg /m2 on day 1,4,8,11) and 15 days after last dose pts received Cyclophosphamide 4g/m2 and G-CSF for stem cell harvesting. After 1-2 months pts underwent to autologous stem cells transplantation with Melfalan 200 mg/ m2-based conditioning regimen. Finally, patients started maintenance therapy with Bortezomib 1.3 mg/m2 (day 1-21) for two years and Interferon α 1500000 UI/twice at week until progression.The refractory or relapsed pts received Lenalidomide based second-line therapy.
Results: the OS study shows 84% pts (20/24) alive, with a median follow up of 35 months (0-83 months); 17% (5/24 pts) died (2 for pneumonia and 3 for myeloma progression). ORR to first-line therapy was 79% (19/24 pts) , with sCR, VGPR, PR rate of 29,41,9% respectively; 21% (5/24 pts) had a stable disease and early underwent to the Lenalidomide-based second line therapy. 16% (4/24 pts) relapsed with a median of 24 months and underwent to the second-line therapy.The 2-years progression free-survival is 71% .50% of refractory and relapsed pts are alive and 60% of these achieved at least the

second VGPR. Toxicity was low and it mainly consisted of neutropenia (15%, WHO grade I-II) and mild peripheral neuropathy (20%, WHO grade I-II).1 pt showed an extra-bone disease at relapse (CNS).
Summary and Conclusions: Our study demonstrates how is possible to obtain analogous response in front of standard care in term of OR, PFS and ORR even without the overlapping the new drugs,moreover not yet officially allowed at the time of our experience. 1 pt (5%) showed an extrabone relapse, in contrast to 15-20% of cases in standard care;60% of the relapsed and refractory pts obtained again a new CR by short treatment with LenDex, with very limited toxicity, so to be able to program a second autologous or an allogeneic transplantation.

PB1696

PLEURAL EFFUSION AS CLINICAL FEATURE OF MYELOMA EXTRA-MEDULLARY INVOLVEMENT

A Pompa[1,*] S Mangiacavalli[1], F Cocito[1], L Pochintesta[1], V Ferretti[1], C Pascutto[1], A Corso[1]
[1]Hematology, IRCCS Fondazione Policlinico San Matteo, Pavia, Italy

Background: Emergence of extramedullary disease (ED) is a poor prognostic event in patients (pts) with multiple myeloma (MM). Extramedullary masses may either arise from bone (EM-B) or develop in extra-osseous organs (EM-S). Pleural involvement represents a very uncommon site of EM-S.
Aims: To describe the prevalence and outcome of MM pts developing pleural involvement among a cohort of 456 patients consecutively observed in our Centre between 2000-2010.
Methods: Following approval by our institutional Ethic Committee, we reviewed clinical and haematological data of 456 MM patients consecutively observed in our Department between 2000-2010 in order to identify pts with pleural extramedullary disease either at diagnosis or during follow-up.
Results: In our cohort, prevalence of EM-S was 14% (65 pts out of 456). Among these pts with EM-S, 16 (24.2%) developed pleural involvement. Pleural involvement was observed most frequently at relapse (10 of 16 patients, 87.5%). Two patients (12.5%) had pleural involvement at diagnosis. Pts characteristics at diagnosis were: male gender 62.5%, median age 58.6 years (range 37.1-65.5 years), myeloma type IgG/IgA/IgD/light chain respectively in 50%/18.8%/6.2%/25% (8,3,1 and 4 pts), prior MGUS in 33% (2 pts), ISS stage I-II and III respectively in 15.4 and 84.6%, extensive bone disease (>3 sites) 81%; median haemoglobin, creatinine, calcium, LDH and beta2microglobulin were respectively 11.2 g/dl, 0.87 mg/dl, 9.3 mg/dl, 339 mU/ml and 6310 mcg/l. At the time of first pleural involvement, all pts had B2M higher than normal (median value 7130 mcg/l, range 3030-43582); median hemoglobin, creatinine, calcium and LDH were respectively 10.4 g/dl, 1.1 mg/dl, 9.2 mg/dl and 273 mU/ml. Pleural involvement was the unique extramedullary site involved at diagnosis in both two pts. Pts with pleural involvement at diagnosis had extramedullary relapse located in different sites (1 pts at lung, 1 pts at costae). At relapse, pleural involvement was often associated with multiple extramedullary locations. In detail, 4 pts (28%) had single pleural involvement, 7 pts (50%) had two extramedullary sites involved, 3 pts (22%) at least three; concomitant paravertebral masses was detected in 50% (7 pts) and 31.3% (3 pts) had costal masses. Other concomitant extramedullary locations were plasma cell leukemia, lung and skin, (each in 2 pts) and lymph nodes, breast, mandible, muscles, testis, and oropharynx (each in 1 pts). In pts developing pleural localization during follow-up, 64% were treated with new drugs and 64% with autologous stem cell transplantation. Median lines of therapies number before pleural locations was 3 (range 1-9). Pts with pleural involvement at diagnosis had a significantly worse outcome with respect to pts with different EM-S (13 *vs* 40 months, p=0.049). Instead, OS of pts developing pleural localization during follow-up was similar to that observed in pts with other EM-S (1.8 *vs* 2.1 years , p=0.094).
Summary and Conclusions: Pleural involvement was a rare isolated myeloma presenting feature with a very dismal prognosis. At relapse, pleural involvement is often associated with other extramedullary localizations, especially paravertebral and paracostal masses; pts with pleural involvement at relapse had similar outcome to pts developing other EM-S.

PB1697

EPIDEMIOLOGICAL, CLINICAL, BIOLOGICAL AND IMAGING CHARACTERISTICS OF MULTIPLE MYELOMA OVER A PERIOD OF 13 YEARS

B Fatiha[1,2,*]M Hanan[2], AA Nacera[2], T Farida[2], A Naima[2], B Fateh[2], T Amina[2], A Sabrina[2], H RM[2]
[1]Hematology and Bone Marrow Transplant Department, Pierre and Marie Curie Center, , [2]Hematology and Bone Marrow Transplant, Pierre and Marie Curie Center, Algiers, Algeria

Background: Multiple myeloma (MM) or Kahler's disease is a malignant hematological disease due to a monoclonal tumoral proliferation of abnormal plasmocytes, located essentially in the bone marrow & producing a complete or no complete monoclonal immunoglobulin. The MM diagnosis is mostly easy by confronting the clinical, imaging, biological and cytologic criteria. In Algeria, the MM is the third most frequent malignant hematological disease with an incidence of 0.63/100.000
Aims: This retrospective study includes 495 patients diagnosed over a period of 13 years (from January 2000 to December 2012).
Methods: The diagnosis is based on: clinical findings, blood cell count, myelogram (a plasmocyte infiltration quantitatively ≥ 10%), trephine biopsy if normal myelogram, & immune-biochemical tests (protein electrophoresis & immune-electrophoresis or immune-fixation of serum proteins, creatininemia, calcemia & β_2 microglobulin). Full skeleton imaging (skull, cervical, dorsal & lumbar vertebrae, pelvis & chest) to screen for bone lesions. The tumoral mass & the prognosis are estimated using the Salmon & Durie staging & the International Scoring System (ISS) used since September 2005.
Results: 260 male and 235 female (sex-ratio : 1.1)). The average age was 60 years (29-89), 250 patients (50%) ≤ 60 years et 53 patients (11%) ≤ 40 years. Smoking was found in 70 (14%) pts, 05 pts have previously presented plasmocytoma , one patient followed-up for a monoclonal gammapathy, & one l patient had HIV disease . Familiar cancer history found in 40 pts (8%) . the most frequent appealing symptom was the pain in 298 pts (60%) , anemia form revealed MM in 75 cases (15%), a plasmocytar tumoral mass in 8 pts. The average delay to diagnosis was 4 months (0 – 48 months). The clinical exam objective an ECOG (Eastern Cooperative Oncology Group) > 2 in 231 pts (47%), 66 patients were painless (13%) & spine compression signs were present in 43 patients (9%). The average Hemoglobin was 9g/dl (≤ à 8g/dl in 231 patients), a calcemia > 120 mg/ l in 89pts (18%), serum creatinine > 20 mg/l in 141 pts (28%). The B2-migroglobulin dosing was performed in 211 patients (42%) including 94 patients (44%) having a B2-migroglobulin > 5.5mg/l. The monoclonal peak was found in 414 cases (84%): IgG in 244 pts (55%), IgA in 111 pts (25%) and IgD in 5 pts. Two patients presented however a biclonal peak & one presented an IgM peak. Seventy cases with light chain MM, 11 with non-secretory disease and 52 no determined . The light chain kappa in 270 pts (62%) and lambda in 165 pts (38%). The average peak level of monoclonal protein was 43 g/l (10-129), with a peak ≥ 50 g/l in 158 pts (38%) and ≥70g/l in 53pts (13%). The average medullary plasma cell was 30%, ≥ à 50% in 122 pts (25%) and less than 10% in 40 pts (9%), motivating the use of bone marrow biopsy in 39 pts. Diffuse bone lesions in imaging were present in 435 (88%), with fractures in 23 pts (5%) & a spine compression in 46pts (09%). The stage III of the Salmon-Durie staging system was reached by 470 pts (95%), stage II 12 pts and stage I :13 pts. The ISS was established in 211 pts (42%): I : 59 pts, II : 57 pts, III : 95pts.
Summary and Conclusions: We found in our department that the number of patients doubled in time: from 1994 to 2005 (12 years) = 216 pts (18 pts/year) and from 2000 to 2012(13 years) = 495 pts (38pts/year). Fifty percent were relatively young ≤ 60ans, and increase diagnosis delay ≥ à 4 months for 244 pts(50%) explain that almost of pts are at stage III

TREATMENT OF MULTIPLE MYELOMA IN PATIENTS ELIGIBLE FOR THE AUTOLOGOUS STEM CELL TRANSPLANTATION: MATTER OF CHOICE, RESPONSE AND EFFICACY

J Bila[1,*] J Jelicic[1], V Djurasinovic[1], D Antic[1], M Todorovic[1], D Vujic[2], D Sefer[1], N Kraguljac[1], M Bogunovic[1], B Andjelic[1], V Vukovic[1], A Sretenovic[1], M Gotic[1], I Elezovic[1], D Tomin[1], B Mihaljevic[1]
[1]Clinic of Hematology, Clinical Center of Serbia, University of Belgrade, [2]Institute "Dr Vukan Cupic", University of Belgrade, Belgrade, Serbia

Background: Flood of novel agents dramatically changed the course and prognosis of multiple myeloma (MM), previously considered as uncurable, devastating disease. Following drug developement, dilemma regarding the role of high-dose treatment (HDT) and autologous stem cell transplantation (ASCT) during first remission, was imposed.
Aims: The aim of study was to analyze efficacy of the HDT and ASCT during first remission, after different induction therapies, and to single out treatment factors of the impact on the overall survival (OS) of newly diagnosed MM patients (pts) eligible for the ASCT.
Methods: The analyzed group consisted of 93 newly diagnosed MM pts (44 male/ 49 female, mean age 55 yrs, range 36-65) eligible for the ASCT. IgG myeloma was diagnosed in 57pts (61,2%), IgA in 16pts (17,1%), IgD in 3pts (3,2%), light chains in 15pts (16,1%), and non-secretory in 2pts (2,2%). According to the clinical stage (CS, Durie-Salmon), patients were distributed as follows: II 23pts (24,7%); III 70pts (75,3%). Regarding ISS score, the group included: ISS1 29,4%; ISS2 30,3%; ISS3 40,3%. Renal impairment was present in 16pts (17,2%). According to the Hematopoietic Cell Transplantation Comorbidity Index (HCT-CI) distribution was as follows: 0-1 78pts (83,9%); ≥3 15pts (16,1%). Regarding applied treatment, patients were divided in three groups: CTD induction followed by HDT and ASCT (CTD+ASCT) in 31pts,

33,3%); VAD+ASCT in 27pts (29,0%); and CTD induction without HDT and ASCT in 35pts (37,7%). Conventional CTD chemotherapy without ASCT was applied in patients with HCT-CI ≥3.
Results: Patients treated with CTD+ASCT had significantly longer period of remission (median 24,3; range 10-42m, p<0,005) despite the lack of difference in the overall response (CR+VGPR+PR; χ^2 2,953, p= 0,079) between these three groups. Furthermore, patients treated with HDT+ASCT had significantly longer overall survival (OS) in comparison to the patients treated with standard CTD chemotherapy without ASCT (CTD+ASCT median OS 72,4m *vs.* VAD+ASCT median OS 48,2m *vs.* CTD median OS 35,8m, Log rank 7,813, p=0,02). In the model that included following factors: 1) Achievement of CR; 2) ASCT; 3) Remission duration ≥12m; and 3) treatment with thalidomide, only remission duration ≥12m was of significant impact on the overall survival (χ^2 10,841; p= 0,014).
Summary and Conclusions: Intensification of treatment with high-dose therapy and autologous stem cell transplantation strengthen with agents of novel mechanisms of action is of strong impact on the course of disease and overall survival in MM patients. Achievement of the long, sustainable remission ≥12m is of major significance for the overall survival of patients with multiple myeloma.

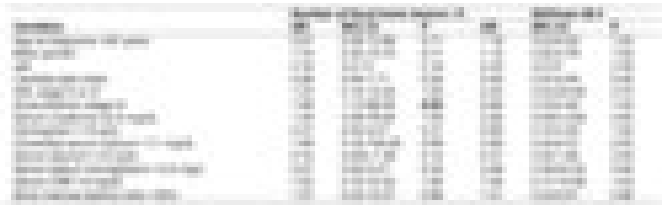
PB1699

EXTRAMEDULLARY INVOLVEMENT OF CENTRAL NERVOUS SYSTEM IN MULTIPLE MYELOMA: REPORT OF 4 CASES

S Rocco[1,*] S Palmieri[1], A Carbone[1], C Riccardi[1], O Finizio[1], C Copia[1], B Pocali[1], MC De Simone[1], P Angelillo[1], M Annunziata[1], F Ferrara[1]
[1]Hematology, AORN Cardarelli, Napoli, Naples, Italy

Background: Involvement of central nervous system (CNS) is a very rare event, described in about 1% of patients with no more than 200 cases reported in the literature. The involvement of CNS can occur as leptomeningeal myelomatosis and/or, less often, as intracranial masses. There are no predictory factors of such event, which is commonly associated with very poor prognosis. Median overall survival is of few months and no standard treatment is proposed.
Aims: to report 4 new cases of a very rare event
Methods: From 2010 until 2013, 268 newly diagnosed MM patients were observed in our Institution. None of our patients presented CNS localization at the time of diagnosis. On the other hand, during we observed 4 cases of CNS relapse during follow up.
Results: Main characteristic of these patients at diagnosis are summarized in Table 1.

Table 1.



Response to first line therapy was very good partial remission in patients n. 1, 3 and 4, while in patient n. 2 after first cycle second line therapy with intermediate doses of cyclophosphamide was needed to reach remission. Time from diagnosis to intracranial relapse was 24 months, 6 months, 18 months, and 11 months for patient 1 to 4, respectively. CNS localization was the first relapse for all patients except n. 1 who was at her third relapse. In all patients CNS involvement was the only manifestation of disease, none of them showing increase in monoclonal component or bone marrow plasmocytosis. Examination of cerebral spinal fluid was performeded in 3 patients (case n. 2, 3 and 4) because of ingravescent parestesias and paraparesis with pain. Examination was positive for the presence of monoclonal plasmacells, while MRI of spinal column and brain showed localization at the spinal column in case 3 and 4 and was completely negative in case n. 2. In patient n. 1 diagnosis of extramedullary myeloma was made after biopsy of one of 4 intracranial lesions mimicking meningioma detected by MRI. Symptoms were sudden letargia and confusion. Cerebral spinal fluid examination was negative. Treatment was intratecal methotrexate and aracytin twice a week in patient n. 2, 3 and 4. Patient n. 1 died one month after diagnosis due to progressive disease, and only a cycle with bortezomib and liposomial doxorubicine was done. Patient n. 2 died 1 month after diagnosis for pneumonia, without any other treatment. Patient n. 3, after intratecal therapy, underwent EDAP treatment for 2 cycles and then first ASCT. She is waiting for second ASCT and is alive after 10 months in complete remission. Patient n. 4, after 3 weeks intratecal treatment with negativization of cerebral spinal fluid, underwent systemic consolidation treatment with EDAP but died because of infection (Figure 1).

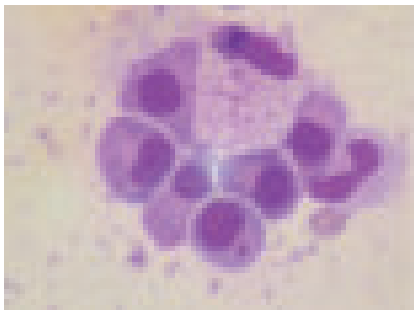


Figure 1.

Summary and Conclusions: As remarked above CNS involvement in multiple myeloma has a very poor prognosis. Some successful treatments are reported with new drugs.Our patients had all been previously exposed to bortezomib, and 2 of them to lenalidomide too, and relapse had occurred relatively quickly during the follow up. When eligible to therapy, we treated them with “old” drugs, and the only patient still alive at the time of writing underwent two courses of classical chemotherapy followed by ASCT.We propose that if alternative experimental treatment is not available, chemotherapy still can play a role in such cases.

PREDICTIVE FACTORS FOR SUCCESSFUL PERİPHERAL BLOOD STEM CELL MOBILIZATION IN PATIENTS WITH MULTIPLE MYELOMA: A SINGLE CENTER EXPERIENCE

A Gokmen[1,*] M Kurt Yüksel[1], E Soydan[1], D Ozbek[1], O Koktas[2], M Kurdal[2], O Arslan[3], O Ilhan[3], M Ozcan[3]
[1]Department of Hematolgy, [2]Ankara International Medicana Hospital, Ankara, Turkey, [3]Department of Hematolgy, Ankara University, Faculty of Medicine, Ankara , Turkey

Background: Autologous stem cell transplantation with high dose chemotherapy is considered the standard of care in patients with transplant eligible multiple myeloma patients . It is generally agreed that a minumum dose of 2.5 x 10 ^ 6 / kg CD 34 + cells is necessary for successful engraftment.
Aims: Our purpose of the study is to analyze predictive factors for successful peripheral blood stem cell collection in patients with multiple myeloma retrospectively.
Methods: 55 consecutive patients with multiple myeloma who proceeded to peripheral blood stem cell collection between March 2012 and February 2014 were analyzed retrospectively. There were 34 men and 21 women with a mean age of 58 (range 43-71) years. 14 patients (%25) had at least one prior autologous peripheral stem cell tranplantation history. 18 patients received recombinant human granulocyte-stimulating factor (G-CSF) alone. 4 patients who failed to mobilize with G-CSF alone were also received intermediate dose cyclophosphamide (4 gr/m²) with G-CSF. Total 41 patients were received cyclophosphamide plus G-CSF. At mobilization 17 patients (%30) were in complete response (CR), 7 patients (% 13) in very good partial response (VGPR), 20 patients (%36) in partial response (PR) and 11 (%20) patients in stabile (SD) or progesive disease(PD) . Mobilization failure was defined as the inability to collect 2.5 x 10 ^ 6 / kg CD 34 + cells following the collection.
Results: The rate of mobilization failure was%27 (15 of 55 patients). Mobilization failure was% 92 in patients with prior transplantation and% 5 in patients without transplantation (p<0.001). Mobilization failure rate was% 63 in patients with stabile disease or progresive disase prior to mobilization and%18 in patients with at least partial response (p: 0.028). Mobilization failure rate was%17 in patients with CR,% 14 in patients with VGPR,% 20 in PR but the difference was not significant (p:0.085) . Mean age was 61±6 in patients with mobilization failure *versus* 56±7 in patients who mobilized successfully (p: 0.034). 3 of 4 patients who failed to mobilize with G-CSF were mobilized successfully with cyclophosphamide plus G-CSF. 28 of 41 (%68) patients who received cyclophosphamide with G-CSF had febrile neutrophenic episode, and 14 (%34) patients had bacteremia during the febrile episode. Neither febrile episode nor bacteremia was associated with mobilization failure (p>0.05). 9 of 15 patients who failed to mobilized received plerixafor. 7 of 9 (%78) patients mobilized successfully with plerixafor. 1 patient died during mobilization with cyclophosphamide plus G-CSF due to pneumonia and respiratory failure.
Summary and Conclusions: The most significant predictors of mobilization

failure in patients with multiple myeloma was prior autologous stem cell transplantation. Achievement least PR before mobilization was an important predicting factor but CR and VGPR was not necessary for successful mobilization. Our data also indicate that plerixafor can rescue patients with mobilization failure especially patients with prior transplantation .

PB1702

CYBORD IS AN ACTIVE, WELL TOLERATED, COST-EFFECTIVE INDUCTION REGIMEN IN NEWLY DIAGNOSED MULTIPLE MYELOMA – A SINGLE CENTRE EXPERIENCE

J Krawczyk[1,*] S Khan[1], B Ahsan[1], S Eltom[1], K A Saeed[1], C Gibbons[1], K Maloney[1], T Meenaghan[1], G Walpole[2], M Abdelrahmen[1], A Hayat[1], A Hodgson[2], M Murray[1], ME O'Dwyer[1]
[1]Haematology, Galway University Hospital, Galway, [2]Haematology, Sligo Regional Hospital, Sligo, Ireland

Background: Background: Based on evidence from clinical trials there is a growing consensus that a three drug regimen involving at least one novel agent (proteasome inhibitor or immunomodulatory drug) should be used as initial induction in patients with newly diagnosed multiple myeloma (NDMM), usually for 3-4 cycles, prior to harvesting stem cells and proceeding to autologous stem cell transplantation (ASCT). Three drug regimens achieve deeper responses both before and after ASCT and this has been shown to translate into superior progression free survival (PFS). CR rates with the three drug regimens prior to ASCT are reported to be in the range of 20-30% with correspondingly high rates of very good partial response (VGPR) (50-60%). One such regimen is the combination of bortezomib with cyclophosphamide and dexamethasone (CyBorD). The published overall response rates (ORR) from phase II trials with CyBorD are approximately 90%, with at least 60% of patients achieving VGPR. At our center, CyBorD has been used as front line therapy since 2008.
Aims: In this report we analyse our experience using CyBorD regimen as initial therapy in transplant eligible patients.
Methods: Methods: We retrospectively analysed clinical and laboratory records for 31 NDMM patients treated with CyBorD at our institution between 2008 and 2013, all of whom subsequently proceeded to ASCT. The standard protocol consisted of bortezomib 1.3 mg/m^2 i.v. twice a week, cyclophosphamide orally at a dose of 300 mg/m^2 weekly, and dexamethasone orally of 40 mg daily given in 4 days long blocks weekly. Since November 2009 we have also used weekly CyBorD.
Results: Results: The median age was 57 years (range from 45 to 65), including 24 males and 7 females. According to ISS, 45% patients were classified as stage I, 5% stage II, and 50% as stage III. The ORR was 90% post cycle I and increased to 96% post cycle IV. At least VGPR was observed in 13% of patients after cycle 1 and 56% after cycle IV. Transplantation had improved the responses and 79% had at least VGPR post transplant *versus* 63% prior, and 24% patients achieved CR post ASCT in comparison to 16% prior ASCT (Figure 1). The therapy was well tolerated. Haematological adverse events were acceptable and no patient required significant dose reduction or experienced treatment delay due to haematological toxicity. Importantly, no patients developed ≥ grade 3 peripheral neuropathy and no patients required dose reduction or discontinuation of bortezomib due to neurological complications. Stem cell mobilisation was performed using a combination of cyclophosphamide 1.5g/m^2 and G-CSF. All patients mobilized successfully without requirement for plerixafor. The medium CD34+ yield after 2 collection days was 8.2 x10^6/kg (range 1.8 -19.4). The PFS at 2 years was 75% and 64% at three years of follow up. At 2 years post transplant, the patients achieving at least a VGPR had a longer median PFS in comparison to patients with PR (91% *vs* 76%, p=NS). The cost analysis has shown that on average, the drug only cost of 4 cycles of CyBorD was 18 000€. This compares to 38 000€ for 4 cycles of bortezomib, lenalidomide, dexamethasone (VRD).

Figure 1.

Summary and Conclusions: Conclusions: Our data confirm the safety and efficacy of the CyBorD protocol and its applicability to routine clinical practice outside of large academic myeloma centres. CyBorD is an active, well tolerated and cost effective option for patients with NDMM, which could be an ideal backbone for the incorporation of new modalities, such as monoclonal antibodies in induction therapy. A randomized comparison with other triple drug regimens are required to fully establish its place in the treatment of newly diagnosed multiple myeloma.

[1]Centre National de Greffe de Moelle Osseuse de Tunis, Tunis, Tunisia

Background: Renal failure is observed in 20% of multiple myeloma (MM) patients at diagnosis. Many of these patients are considered ineligible for autologous hematopoietic stem cell transplantation (auto-HSCT) because of a high-risk of treatment-related toxicity.
Aims: The goal of our study is to evaluate the feasibility and efficacy of auto-HSCT in patients with MM with renal failure at the time of transplant, to analyze the reversibility of renal failure and to determine the overall survival (OS) and progression-free survival (PFS) after auto- HSCT.
Methods: Between January 1993 and November 2012, 256 patients with MM underwent auto-HSCT at our institution. At the time of transplant, only seven patients have renal failure which is defined as serum creatinine≥ 177 µmol/l. All patients received induction therapy with Dexamethasone + Thalidomide (3 cycles). Peripheral blood stem cells (PBSC) were mobilized and collected following granulocyte colony-stimulating factor (G-CSF) alone (n=5) or Cyclophosphamide and G-CSF (n=2). Conditioning regimen before autologous consisted of Melphalan 100mg/m2 (n=6) or 140mg/m2 (n=1). Response criteria were used according IMSG.
Results: The median age was 52years (45- 55yrs). Sex-ratio was 2.5. Six patients had Durie and Salmon stage III. Monoclonal componement type was light-chain lambda in 3 cases, complete Ig in 4 cases. At the time of transplant, at least a partial response was achieved in 4/7 patients [CR (n=3); PR (n=1)] and 3 patients were in response failure. Median serum creatinine and cratinine clearance (CrCl) at the time of transplant were 249µmol/l (range; 186 - 349) and 31 ml/mn (range; 16 - 40) respectively. No patient was dialysis-dependent before transplant. The median number of CD34+ infused was 4.24x106/kg (range; 2.08-7,5). The median times to absolute neutrophil count (ANC ≥ 0.5x 109/l) and platelet recovery (≥20 109/l) were 11 days (range;11-15) and 12 days (range;12–15) respectively. The median inpatient stay was 19 days (range; 17-33). We did not observe a treatment-related mortality. Renal function recovery was observed in 3patients, and it's defined as an increase in CrCl by at least 25% compared to the baseline. The average time of renal function recovery was 5months (range; 1-6months). Median serum creatinine and CrCl after transplant were 145 µmol/l (range;103- 306) and 44 ml/mn (range; 17- 75) respectively. Median survival and PFS was 30 months and 14 months respectively. At the latest news and after a median follow-up of 24.5months (range; 6.5-102months), 2 patients were in CR, 4 patients were in progression with associated worsening of renal function in two of them, and 1 patient was not evaluable.
Summary and Conclusions: Auto HSCT is feasible in patients with MM and renal failure with acceptable toxicity and with a temporary significant improvement in renal function in approximately one-half of the transplanted patients.

PB1704

HEAVY/LIGHT CHAINS PAIRS (HLC) AS AN ALTERNATIVE METHOD FOR MONITORING AN IGA MULTIPLE MYELOMA PATIENT

JL García De Veas Silva[1,*] R Rios Tamayo[2], R Leyva Ferrer[2], P Garrido Collado[2], C Bermudo Guitarte[3], P Navarro Alvarez[2]
[1]Immunology, [2]Hematology, Hospital Universitario Virgen de las Nieves, Granada, [3]Clinical Biochemistry, Hospital Universitario Virgen Macarena, Sevilla, Spain

Background: The quantification of heavy/light chains pairs (HLC) by the new immunoassay Hevylite is based on the recognition of epitopes spanning the junction of the immunoglobulin´s heavy and light chains. This assay can identify separately the different light chain types of each immunoglobulin class: IgGK, IgGL, IgAK, IgAL, IgMK and IgMK. Of particular interest and novelty is the possibility to quantify separately both isotypes of the tumor related immunoglobulin. In this clinical case we show the utility of the quantification of HLC IgAK, IgAL and IgAK/IgAL ratio as a method to monitoring an IgAK Multiple Myeloma.
Aims: To present the utility of heavy/light chains pairs (HLC) in the monitoring of patients with Multiple Myeloma.
Methods: SPE were peformed on CAPILLARYS 2^{TM} (Sebia), the

monoclonal component were identified by IFE on HYDRASYS™ (Sebia), serum inmunoglobulins (IgA, IgG and IgM) were measured by nephelometry on BNII nephelometer (Dade Behring). Heavy/Light chains pairs and serum free light chains were measured by turbidimetry on a SPA PLUS Analyzer (The Binding Site).
Results: We present the rare case of 12 years old boy that was diagnosed of IgAK Multiple Myeloma ISS III stage [hypercalcemia (16.6 mg/dl), increased IgA (4449 mg/dl) and total proteins (12.6 g/dl), normocytic anemia (9.5 g/dl of hemoglobin), altered ratio of serum free light chains (free kappa=219 mg/dl, free lambda=1.01 mg/dl, ratio=216.83) and osteolytic bone lesions (punched-out lesions in skull and vertebral compression)]. At diagnosis (Day 0) the serum proteinogram (SPE) shows a well-defined monoclonal large peak in the gamma region (4.34 g/dl correspond to monoclonal component) and identified by immunofixation as IgA Kappa. The IgA HLC ratio (IgAK=66.604 g/l, IgAL=6.302 g/L, ratio=10.57) identified clonal disease IgAK at diagnosis too. The patient began treatment with Bortezomib, Cyclophosphamide and Dexamethasone and the monoclonal protein was monitorized by SPE, IFE and HLC. During the treatment, the monoclonal protein was decreasing with reduction of the peak in SPE and the HLC ratio remained altered confirming the presence of the monoclonal protein. The monoclonal component IgAK was decreasing due to the good response to the treatment. At day +58 (after 4th cycle of chemotherapy) there was a little peak in SPE (0.18 g/dl of monoclonal component), with positive IFE and altered ratio HLC (IgAK=3.566 g/l, IgAL=0.664 g/l, ratio=5.37). At day +68 the SPE was negative but the HLC ratio remained altered (IgAK=3.566 g/l, IgAL=0.664 g/l and ratio=5.37) confirming the existence of monoclonal protein that it was verified by IFE. At day +131 (end of 5th cycle of chemotherapy) the SPE, HLC and IFE were negative confirming the absence of monoclonal protein due to the good response to the treatment. At the end of the treatment (day +184) after six cycles of chemotherapy the patient achieved a status of complete remission with negative immunofixation, <5% of plasma cells in bone marrow and normal HLC pairs and ratio.
Summary and Conclusions: The monitorization of IgA MM requires the measures of SPEP, IFE and total IgA. The use of the HLC IgAK, IgAL and their ratio IgAK/IgAL presents itself as an alternative method with high sensitivity for monitoring these patients, particularly *in situ*ations where traditional techniques show limitations (*e.g.* low concentracions, interference of other serum proteins, strong polyclonal background). The high sensitivity of the determination of HLC allows typing monoclonal component providing equivalent information to the immunofixation, with the added value of reporting a quantitative value.

PB1705

COMPARATIVE EFFICACY OF SUBCUTANEOUS AND INTRAVENOUS ADMINISTRATION OF BORTEZOMIB IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

N Skvortsova[1,*] T Pospelova[1], I Kovynev[1], I Nechunaeva[1]
[1]Department of hematology and transfusiology, Novosibirsk State Medical University, Novosibirsk, Russian Federation

Background: Bortezomib is currently the basis of combined regimens as newly diagnosed and relapsing forms of multiple myeloma (MM). The main side effect of bortezomib therapy is the development of peripheral neuropathy (PN) , impairing the quality of life of patients. Results of a multicenter international study MMY- 3021 confirmed a significant reduction in the incidence of peripheral neuropathy by subcutaneous administration of bortezomib compared with intravenous in patients with previously untreated multiple myeloma. This opens new perspectives for the use of bortezomib-containing regimes in patients with high risk of PN and lack of peripheral venous access.
Aims: to compare the efficacy and tolerability of standard combination regimens MM with subcutaneous and intravenous administration of bortezomib in patients with newly diagnosed multiple myeloma.
Methods: 27 patients with MM analyzed. The average age of patients was 68 years. Bortezomib in 12 patients were injected subcutaneously (s.c) and at 15 - intravenously (i.v) as part of combination regimens of standard chemotherapy (PAD, CVD, VMP). The effect of the treatment was assessed using standardized international criteria EBMT. Toxicity assessment was performed using the criteria of the National Cancer Institute of the United States (the National Cancer Institute Common Toxicity Criteria - NCI CTC), version 3-0 (Cancer Terapy Evaluation Program, Depatment of Health and Human Services, December 2003).
Results: the overall response rate (ORR) after 4-6 courses of chemotherapy in patients with s.c and i.v introduction was 83% and 80%. CR + nCR was recorded in 25% and 26.7%, PR in 58% and 53.3%, respectively. PN was observed in 33% and 46% of patients on s.c and i.v introduction. Peripheral neuropathy 3rd degree awarded in 8% and 20% , respectively. It should be noted that in 58% of patients in the group of subcutaneous administration of bortezomib marked cutaneous manifestations (1-2 degrees) in the form of congestion in an injection formulation, which does not require modification of the dose were stoped and independently. Gastrointestinal toxicity, preferably 1-2 degrees registered in 26.7% and 40%, respectively. Manifestation of hematologic toxicity most frequent thrombocytopenia and anemia were noted in 25% *vs* 33,3% and 16,6% *vs* 33,3% , respectively. Intensity data of adverse events consistent with grade 1-2 toxicity scale , which did not require adjustment of therapy and modification dates of drug administration .
Summary and Conclusions: with equal effectiveness of subcutaneous administration of bortezomib in patients with newly diagnosed MM has a better tolerability compared with intravenous that helps to optimize therapy and improve the quality of life of patients with MM.

PB1706

BORTEZOMIB-CYCLOPHOSPHAMIDE-DEXAMETHASONE IS A GOOD INDUCTION TREATMENT FOR YOUNG PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

S Lakhwani[1,*] C Notario[2], C de Bonis[1], J Breña[2], JM Raya[1], A Sánchez-Quintana[1], P Ríos-Rull[2], M Trujillo-González[2], MT Hernández[1]
[1]Hematology, Hospital Universitario de Canarias, [2]Hematology, Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, Spain

Background: Based on evidence from clinical trials there is growing consensus that a three-drug regimen involving bortezomib, one steroid (dexamethasone or prednisone) and one immunomodulatory drug (thalidomide or lenalidomide) or an alkylating agent (melphalan or cyclophosphamide) should be used as induction treatment in young patient with newly diagnosed myeloma before autologous stem cell trasplantation (ASCT). One of these regimes is the combination of bortezomib, cyclophosphamide and dexamethasone (VCD). This scheme has been analyzed in several trials with very different results. Complete remission (CR) rate before ASCT ranges from 10% to 47%, with a very good partial response (VGPR) or better rate up to 61-65%. We have used this regimen in recent years as induction treatment in young patients with newly diagnosed myeloma.
Aims: The aim of this study is to analyze our experience in the response rate and tolerability to VCD, outside clinical trials, in young patients with multiple myeloma.
Methods: We retrospectively analyzed 22 young patients with symptomatic myeloma candidates for ASCT, who have received VCD as induction treatment between 2010 and 2013. Characteristics of the disease at diagnosis, as well as response and tolerability parameters were recorded.
Results: The mean age at diagnosis of these 22 patients was 56 years (range 42-65), with a predominance of males (69%). The distribution of myeloma type was as follows: 19 secretory myeloma (including two cases of Bence-Jones myeloma), 2 oligosecretory myeloma and 1 case of plasma cell leukemia. A significant proportion of poor-prognosis cases were included: 36% of patients had ISS stage 3, 27% had hypercalcemia at diagnosis, 23% had elevated LDH and 18% had poor prognosis cytogenetic [del 17p, t(4;14) or t(14;16)]. All the patients received 42-day courses of bortezomib 1,3 mg/m^2 (days 1, 4, 8 and 11 and 22, 25, 29 and 32); dexamethasone 40 mg (days 1-4 and days 22-25); and cyclophosphamide between 500 and 750 mg/m^2 (days 1 and 22). Number of courses ranged from 2 to 6 depending on the response. A CR was achieved in 8 patients (36%), including two patients with strict CR. The VGPR or better rate was 64% (14 patients) and a partial response or better rate of 86% (19 patients). Only three patients (14%) could be considered refractory to this treatment because of progressive disease or stable disease. From 19 patients who achieved at least PR, eleven have received an ASCT and have been subsequently evaluated, with a post-ASCT CR rate of 36%. Of the responders patients with measurable disease, main reduction of M component occurred within the first course and ranged from 40% to 95%. Concerning tolerability, VCD scheme is generally quite well tolerated. Nine patients (41%) required dose reduction of bortezomib, principally because of peripheral neuropathy but without stopping treatment. Two patients required dose reduction of cyclophosphamide because of myelotoxicity.
Summary and Conclusions: In our experience, VCD is a very good induction treatment with CR rates before ASCT similar to other three-drug induction regimes like VTD or VRD. This scheme is generally quite well tolerated. The main advantage of using VCD as induction treatment is that we can reserve immunomodulatory drugs (IMiDs), like thalidomide or lenalidomide, for subsequent relapses of the disease.

PB1707

OUTCOME OF MULTIPLE MYELOMA IN YOUNG PATIENTS UNDER 45 YEARS: ABOUT 41CAS.

M Hanan[1], B Fatiha[1,*] AA Nacera[1], T Farida[1], A Naima[1], B Fateh[1], T Amina[1], A Sabrina[1], H RM[1]
[1]Hematology and Bone Marrow Transplant, Pierre and Marie Curie Center, Algiers, Algeria

Background: Multiple myeloma (Kahler's disease) is a hematological malignancy due to tumor proliferation of monoclonal plasma cells in the bone

marrow, characterized by its clinical and biological polymorphism. The average age of onset of this malignancy is > 60 years. Multiple myeloma can also affect younger patients, 2.8% of cases are diagnosed under 40 years of age. Herein we present the characteristics and the outcome of 41patients (pts) aged under 45 years at diagnosis

Aims: a period of 12 years (2000-2011), between 444 patients (pts) with MM diagnosed 41 pts (9%) are under 45 years: 25 male and 16 female (sex ratio: 1.6). The median age was 41 years (32-44).Seventeen pts (4%) <40years old. Three pts had history of solitary plasmacytoma. The most commun sign is pain syndrome: 32 pts (78%), anemia syndrome: 6 cases (15%) and plasma cell mass: 2 pts.

Methods: Three pts had history of solitary plasmacytoma. The most commun sign is pain syndrome: 32 pts (78%), anemia syndrome: 6 cases (15%) and plasma cell mass: 2 pts. The median time to diagnosis was 3 months (0-48). ECOG 1-2: 20 pts (49%), the hematological parameters is characterized by a median Hb: 8g/dl (3-15), hyper calcemia ≥ 120 mg /l: 8 pts, serum creatinine ≥ 20 mg /l: 12 pts. Determination of β2 microglobulinemia is done in 13 pts (32%) with a rate ≥ 5.5 in 6 pts. The serum monoclonal peak was found in 32 cases (78%), the median peak: 40g /l (15-110) with a peak ≥ 50 g /l: 16 pts (50%), which is represented by an IgG: 21 pts (65%), IgA: 7 pts (22%), IgD: 1 pts, 09 cases of MM light chains, non-secreting: 2 pts and unspecified type in 1 pt. The median plasmacytosis in a marrow 35% (10-85). The PBJ is made in 37 pts (90%), positive in 19 pts (50%). Diffuse bone lesions are present in 37 pts (90%) , fractures in 2 pts and spinal cord compression in 7pts (17%). According to Salmon-Durie stage: III: 40 pts (97%) with 13 pts (32%) stage B, stage II: 1pt. International Staging System (ISS) used in 13pts (32%) I: 5pts, II: 2 pts, III: 6pts. The treatment used was: VAD (vincristine, adriamycin and dexamethasone) for 37 pts; TD (Thalidomide-Dexamethasone) for 3 pts and CTD (Cyclophosphamide-Thalidomide-Dexamethasone) for one pt. In December 2012, the median follow-up was 54 months(22-129).

Results: Nine pts are no evaluable because early death after 1-2 cycles. Thirty-two pts are evaluable, 28 pts received VAD (12 failures and 16 responses: 5 CR and 11 PR). Among patients in response, 12 pts were intensified with autologous stem cell transplantation after induction: 6 pts are alive in CR, 2 pts alive in PR and 4 pts died with a median survival of 49 months (19-129) and 4 pts without high dose chemotherapy and autologous stem cell cell transplantation died with a median survival of 5 months (4 -12). For the 12 treatment in failure : 2pts are alive (1 CR, 1 failure) and 10 pts died with a median survival of 10 months (3-66). Three pts received TD (1 CR, 2 PR) followed by autologous transplantation: 2pts are alive in CR (43.47 months), and one died (34 months). One patient treated with CTD grafted in CR is alive (22 months).

Summary and Conclusions: The prognosis of multiple myeloma patients remains poor, less than 5% of patients remain alive more than 12 years .The young's form disease is becoming more common with an aggressive clinical form and unfavorable evolution despite the introduction of new drugs.

Myeloproliferative neoplasms - Biology

PB1708

CALR-MUTATED OR TRIPLE-NEGATIVE (JAK-2 AND MPL) IN ESSENTIAL THROMBOCYTHEMIA AND PRIMARY MYELOFIBROSIS

B Ferrer Lores[1,*] J Martinez-López[2], R Ayala-Díaz[2]
[1]hematology, hospital clinico universitario de valencia, valencia, Spain, [2]hematology, Hospital 12 octubre, madrid, Saint Barthélemy

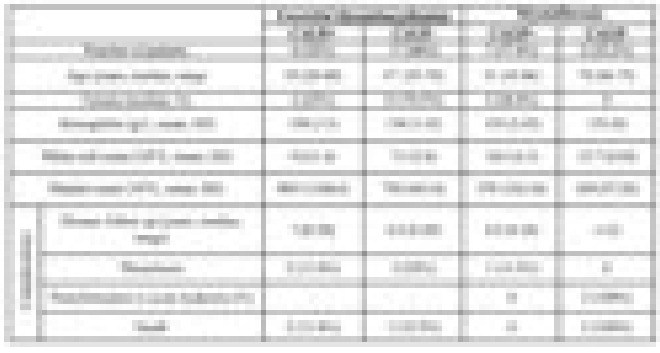
Background: Myeloproliferative neoplasms (MPN) are chronic myeloid cancers that manifest as expansion of one or more myeloid lineages, characterized by the overproduction of mature blood cells. The first insight into the molecular cause came when the somatic *JAK2 V617F* mutation was identified in the majority of patients with polycythemia vera (PV) and in a subset of patients with essential thrombocythemia (ET) and primary myelofibrosis (PMF). Subsequent studies identified *JAK2 exon 12* mutations in patients with PV and mutations in the gene encoding thrombopoietin receptor (*MPL*) in a subset of patients with ET and MF. Recent studies have identified additional novel mutations, in the gene encoding calreticulin (*CALR*) in patients with ET or PMF without *JAK2* or *MPL* mutations. The frequency described in these patients was 70-84%. For the moment, 36 different mutations (all deletions, insertions, or both) have been labelled. Understanding the molecular basis for ET and PMF in patients without *JAK2* mutations is the most relevant focus in the area of myeloproliferative neoplasms and efforts must be aligned in this direction.

Aims: The main purpose of the study is to identify *CALR* mutations and to analyse the impact in patients with ET and MF without *JAK2* or *MPL* mutations retrospectively and evaluate the influence of clinical and biological features.

Methods: All myeloproliferative neoplasms were classified in accordance with the 2008 World Health Organization criteria. The fragment analyses of *CALR* exon 9 mutations were sized on a 3100 xl Genetic Analyzer (Applied Biosystems), and results were analysed using the Gene Mapper software version 4.0 (Applied Biosystems). Samples for 3 different mutations were Sanger sequenced for confirmation and determination of the exact type of *CALR* mutation. Samples were screened by qPCR for the presence of *JAK2 V617F* and *MPL W515L/K* mutations.

Results: *CALR* exon 9 mutations were analysed in 36 patients with myeloproliferative neoplasms: 27 with ET and 9 with MF were diagnosed in our centre, in the period Jan-1985 to Dec-2013. *JAK2* mutated and *CALR* wild type was detected in 2 patients with TE and 1 MF. A relevant number of patients with mutation *CALR JAK2* and *MPL* negative was found in MF and patients with TE (77.8% and 32%, respectively). Most frequent mutations were type 1 (del 52bp) and type 2 (ins 5bp). In TE, type 1 represented the 62.5% and type 2 the 37.5%. In MF, type 1 was 57.14%, type 2 28.6% and a new deletion of 31bp was detected, sequenced and not described yet. Clinical data can be observed in Table 1, without being able to draw conclusions due to heterogeneity of groups.

Table 1.



Summary and Conclusions: A high frequency of mutations in patients with *CALR* + MF double negative (77.8%) was observed in the present study, with a value similar to the described in the literature, it was not the case for ET, accounting a lower frequency (32%). A higher platelet count in ET cases CALR + was also confirmed, however no clinical differences were observed. Even more, the importance in detecting new non-described indel must be remarked. Different clinical courses were described in these patients, a larger study in order to consolidate these results and detect possible new mutations seems necessary, since was more indolent than that in patients with the *JAK2 V617F* mutation.

Background: The pathogenesis of myeloid neoplasia is complex and involves genetic, epigenetic and molecular alterations. Excessive production of Reactive Oxygen Species (ROS) and/or a decrease in antioxidant pathways can lead to an imbalance state termed oxidative stress (OS), that contribute to cell damage, apoptosis and ineffective hematopoiesis. OS has been observed in several hematopoietic malignancies and some evidences suggest a role of OS in etiology and pathogenesis of hematological neoplasias, namely in Acute Myeloblastic Leukemis (AML), Chronic Myelomonocytic Leukemia (CMML), Myelodysplastic Syndromes (MDS) and Myeloproliferative Neoplasias (MPN), including those Philadelphia (Ph)-positive as Chronic Myelogenous Leukemia (CML). The genetic variability in oxidative stress related genes might contribute to the differences in individual susceptibility to oxidative damage since it can lead to increase in ROS production or to decrease in its elimination.
Aims: In this context, we investigated the influence of SOD1, SOD2, COX2, CAT and NADPH *oxidase p22 phox*polymorphisms, as a risk factor for myeloid neoplasia development.
Methods: This study enrolled 277 patients diagnosed with myeloid neoplasia (65 AML, 10 CMML, 101 MDS, 101 MPN) and 150 healthy controls. The genetic polymorphisms of SOD1 (A251G), SOD2 (Ala16Val), COX2 (G-765C), CAT (C-262T) and NADPH oxidase *p22 phox* (C242T) were assessed by RFLP-PCR. The strength of association between polymorphisms and disease risk was assessed by odds ratio (OR) with 95% confidence interval (CI95%).
Results: Our results show a lower *wild type* allelic frequency of SOD1 (90%), CAT (80%), OGG1 (18%) and NADPH *oxidase p22 phox* (67%) polymorphism and a higher variant allelic frequency of SOD2 (52%) and COX2 (79%) in myeloid neoplasia patients, compared to controls. In these patients the predominant genotype was AA (90%), CT (52%), GG (60%), CC (69%), CC (80%) and CC (48%), respectively for SOD1, SOD2, COX2, CAT, OGG1 and NADPH *oxidase p22 phox*. Besides that, individuals with COX2 and NADPH *oxidase p22 phox* CC genotype and with TT genotype of CAT have an increase risk for hematological neoplasia development about 2,54-fold (CI95% 1,05-6,28; p=0,038), 1,85-fold (CI95% 1,22-2,82; p=0,0005) and 2,03-fold (CI95% 1,10-3,74; p=0,0021), respectively. Besides that, individuals with NADPH *oxidase p22 phox* CC genotype have an increase risk about 1,81-fold for MPN development (CI95% 1,05-3,1; p=0,038), especially CML, where the risk is 2,36-fold (CI95% 1,04-5,40; p=0,032). Moreover, the TT genotype of CAT show and increased risk for AML, MDS and Ph^- MPN development of 11,53-fold (CI95% 1,53-87,2; p=0,004), 3,93-fold (CI95% 2,02-10,01; p=0,041) and 5,39-fold (CI95% 1,58-18,47; p=0,005), respectively.
Summary and Conclusions: These results show that genetic polymorphisms in oxidative-stress related genes might be related with myeloid malignancies development and may constitute novel genetic markers for MPN, MDS and AML susceptibility.
This work was supported by CIMAGO (Project 22/09).

PB1710

VORINOSTAT IMPAIRS VIABILITY, DIFFERENTIATION AND REDOX HOMEOSTASIS IN BCR-ABL-NEGATIVE MPN PATIENTS

BA Cardoso[1,2,*] H Belo[1,2], A Almeida[1,2]

[1]Unidade de Investigação em Patobiologia Molecular, Instituto Português de Oncologia, [2]CEDOC, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon, Portugal

Background: The classical BCR-ABL-negative myeloproliferative neoplasms (MPN) include polycythemia vera (PV), essential thrombocytosis (ET) and primary myelofibrosis (PMF). They are characterized by increased proliferation of hematopoietic precursors in the bone marrow resulting in an elevated number of terminally differentiated cells. Despite the recent description of JAK2 activating mutations and other mutations, these do not completely explain the pathophysiology and clinical heterogeneity of MPN. Epigenetic modifications, particularly histone acetylation, play pivotal roles in the pathogenesis of several hematological malignancies, and treatment of such disorders with histone deacetylase inhibitors results cell death and proliferation arrest. Importantly, epigenetic agents have proven to be quite effective in the clinical practice, by producing remissions and increasing the overall survival in several hematological disorders.
Aims: HDAC inhibition has been shown to reduce tumor burden in patients with MPN. In order to investigate the effects of HDAC inhibitors in MPN, we analyzed the impact of Vorinostat in the cellular biology of MPN cell lines and primary bone marrow samples.
Methods: MPN bone marrow samples were collected at diagnosis following informed consent and in course of routine clinical tests. Mononuclear cells from primary MPN samples were isolated by gradient separation and MPN derived cell lines and primary cells were incubated with Vorinostat. At different time points of culture, the cells were harvest, lyzed for RNA extraction and stained with different antibodies, Annexin-V/PI and DCF-DA to analyze cellular differentiation, apoptosis and Reactive Oxygen Species (ROS) respectively.
Results: Incubation of MPN cell lines with Vorinostat induced apoptosis in a time- and dose-dependent manner. Vorinostat induced the expression of genes associated with apoptosis and growth arrest and down-regulated the expression of genes associated with proliferation, growth arrest and also JAK-STAT signaling pathway target genes. Furthermore, incubation of primary MPN bone marrow samples with Vorinostat induced apoptosis, blocked differentiation and reduced ROS levels in a dose dependent manner. These effects were most marked in the monocytic lineage, a population which expresses the highest levels of ROS. Vorinostat also reduced the levels of GPA and CD61, markers of erythroid and megakaryocytic differentiation, respectively.
Summary and Conclusions: We have found that Vorinostat incubation impairs differentiation in MPN and also reduces cellular viability and ROS, possibly through the down-regulation of genes associated with cellular and proliferation, particularly the JAK-STAT target genes, and up-regulation of genes important for apoptosis and growth arrest. These results hold therapeutic promise as Vorinostat reduced differentiation markers associated with Polycythemia Vera and Essential Thrombocytosis. Furthermore, the discovery that Vorinostat is particularly noxious to the monocytic lineage is interesting since it has recently been shown in a mouse model that bone marrow monocytes are crucial for Polycythemia Vera pathogenesis. Our results point towards the potential of Vorinostat (and possibly other HDAC inhibitors) to treat MPN. This potential would require more clinical trials to confirm their clinical efficacy.

PB1711

MUTATIONS OF THE CALRETICULIN GENE IN MYELOPROLIFERATIVE NEOPLASMS IN JAPANESE PATIENTS

K Yoshinaga[1,*] N Mori[1], M Shiseki[1], H Kazama[1], M Ohwashi[1], M Ishii[1], J Tanaka[1]

[1]Hematology, Tokyo Women's Medical University, Tokyo, Japan

Background: Frequent somatic mutations of the *calreticulin* (*CALR*) gene in myeloproliferative neoplasms (MPN) patients were recently reported. These mutations were located in exon 9 and included several types of insertions or deletions, which cause a frameshift to the same alternative reading frame and generate an altered C-terminal peptide. Klampfl et al reported that the Ba/F3 cells expressing the 52-bp deletion showed cytokine independent cell growth and STAT5 auto-phosphorylation. Detecting specific mutations are useful for diagnostic tool, classification, and prognostic estimation. Elucidating the incidence of the mutations and clinical characterization in different race and country was important for establishing the disease classification system.
Aims: To determine the relevance of the somatic mutations in the *CALR* gene and its association with type of MPN in Japanese patients, we analyzed *JAK2* V617F, *MPL* W515L and the *CALR* gene mutations.
Methods: A total of 132 patients with MPN (68 essential thrombocytosis (ET), 42 polycythemia vera (PV), 7 primary myelofibrosis (PMF), and 15 other MPN) were analyzed (Table 1). Somatic mutations in the *CALR* gene were analyzed in MPN patients without *JAK2* V617F or *MPL* W515L mutations. Granulocytes were separated from peripheral blood after obtaining written informed consent. *JAK2* V617F and *MPL* W515L mutations were detected by allele-specific polymerase chain reaction (PCR) as previously reported (Yoshinaga K *et al.* 2008). Somatic mutations in the *CALR* gene were analyzed by bidirectional direct sequencing of purified PCR products covering the exon 9 of the *CALR* gene. The primer sequences were previously published (Nangalia J *et al.*, 2013). Current study was conducted within the guidelines and with the approval of the institutional ethical committee.
Results: *JAK2* V617F mutation was found in 33 of the 68 patients with ET and 40 of the 42 patients with PV. *MPL* W515L mutation was found in two of 22 patients with ET. *CALR* gene mutations were analyzed in 34 patients (30 patients with ET, 2 patients with PMF, one patient with AML from ET, and one patient with MF from ET). *CALR* gene mutations were found in 14 of the 30

patients with ET and one of the two patients with PMF. The identified *CARL* gene mutations were the followings; 52-bp deletion (p.L367fs*46) in 8 patients; 5-bp insertion (p.K385fs*47) in 6 patients; and 34-bp deletion in one patient (Table 1). We were unable to identify an apparent point mutation.

Table 1. Type of MPN and mutation status.

Summary and Conclusions: Sequencing analysis revealed that 46.7% of ET patients without *JAK2* V617F or *MPL* W515L mutations carried a somatic mutation of the *CALR* gene. This incidence of the *CALR* mutation may be slightly lower than those reported by Nanglia et al (71%) and Klampfl et al (67%). The mutations consisted of two common variants of 52-bp deletion and 5-bp- TTGTC insertion which accounted for 14 of 15 (93.3%) of the *CALR* mutations. This percentage is slightly higher than the previous reports. These discrepancies may reflect the differences between race or patient selection bias.

PB1712

JAK-2 V617F ALLELE BURDEN INCREASES OVER TIME IN HETEROZYGOUS PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA RECEIVING OR NOT TREATMENT WITH HYDROXYUREA

R Latagliata[1,*] F Stocchi[1], I Carmosino[1], A Di Francesco[1], F Vozella[1], A Romano[1], C Montagna[1], P Volpicelli[1], A Di Giulio[1], M Molica[1], G Pistilli[1], S Trasarti[1], A Salaroli[1], L Bizzoni[1], M Vignetti[1], M Mancini[1], M Breccia[1], A Tafuri[1], G Alimena[1]

[1]Cellular Biotechnologies and Hematology, University Sapienza, Rome, Italy

Background: JAK-2 V617F mutation is a cornerstone in the diagnosis of Essential Thrombocythemia (ET); however, it is still unclear if the JAK-2 V617F allele burden could be modified by the natural evolution of disease over time or by the cytoreductive treatment.
Aims: To evaluate allele burden variations over time in subjects receiving or not treatment with hydroxyurea (HU), 86 patients with ET and a 1st evidence of JAK-2 V617F mutation in a heterozygous state (allele burden<50%) were prospectively studied.
Methods: There were 30 males and 56 females, with a median age at diagnosis of 56.6 years [interquartile range (IR) 45.9 – 68.7]. Median time from diagnosis to 1st JAK-2 allele burden evaluation was 4.2 years (IR 0.5 – 9.6); in particular, 54 patients received 1st allele burden evaluation<6 years since diagnosis and 32 patients ≥ 6 years since diagnosis. Median interval between 1st and 2nd JAK-2 allele burden evaluation was 12.1 months (IR 11.1 – 14.1). As to treatment, 29 patients (33.7%) were not receiving any treatment while 57 patients (66.3%) were receiving HU when both JAK-2 allele burden analyses were done.
Results: JAK-2 V617F allele burden median values at 1st and 2nd analysis in the whole population were 17.2% (IR 6.1 – 32.7) and 22.3% (IR 8.9 – 35.3), respectively (p=0.003). In the 29 patients without treatment, 1st and 2nd analysis were 22.7% (IR 14.2 – 31.6) and 25.9% (IR 14.7 – 34.7) (p=0.013); in the 57 patients receiving HU, 1st and 2nd analysis were 15.2% (IR 4.2 – 34.5) and 20.0% (IR 6.8 – 36.3) (p=0.038). Patients with a shorter disease duration (< 6 years since diagnosis) showed a V617F allele burden increase from the 1st median value of 14.3% (IR 3.5 – 28.0) to the 2nd median value of 15.0% (IR 6.7 – 31.8) (p=0.028); patients with a longer previous disease duration (≥ 6 years since diagnosis) had an allele burden increase from the 1st median value of 29.0% (IR 10.4 – 35.4) to the 2nd median value of 31.0% (IR 17.9 – 40.0) (p=0.027). Moreover, 64/86 patients had a 3rd JAK-2 V617F allele burden evaluation after a median interval of 11.9 months (IR 11.2 – 13.4) from the 2nd sample: in these 64 patients, JAK-2 V617F allele burden median values at 1st, 2nd and 3rd analysis were 16.9% (IR 4.7 – 32.7), 21.6 (IR 10.1 – 36.4) and 28.2% (IR 11.6 – 41.7), respectively (p<0.001).
Summary and Conclusions: JAK-2 V617F allele burden seems to increase over the time in patients with ET; this increase seems to be significant during all disease course. In addition, HU does not seem to reduce the allele burden rise. However, a larger cohort of patients is warranted to confirm these data.

PB1713

THE FREQUENCY AND PROGNOSTIC OF EZH2 MUTATIONS IN PATIENTS WITH BCR-ABL-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

L Polushkina[1,*] I Martynkevich[1], E Petrova[1], L Martynenko[1], N Cybakova[1], M Petrova[1], E Shabanova[1], I Zotova[1], T Zamotina[1], M Fominykh[1], V Shuvaev[1], K Abdulkadyrov[1]

[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Recent studies have revealed a number of epigenetic alterations that contribute to myeloproliferative neoplasms (MPNs) pathogenesis and determine the clinical outcome. Mutations involving the *EZH2* gene which encodes the catalytic component of the histone methyltransferase have been described in MPN patients. These mutations are thought to result in loss of methyltransferase activity suggesting a potential role of tumor suppressor gene silencing as a mechanism in disease progression. According to the published data, mutations in *EZH2* are founded in 6% cases of primary myelofibrosis (PMF), 1% of polycythemia vera (PV) and 1-3% of essential thrombocythemia (ET) regardless of the presence of mutations in *JAK2* or *MPL*. *EZH2* mutations are thought to be of prognostic value in MPN's at the time of transformation to the blastic phase but data are inconsistent and require further verification.
Aims: The goal of our research was to determine the frequency of mutations in *EZH2* in two groups of patients with different chromosomal aberrations.
Methods: We have examined 48 patients with *BCR-ABL*-negative MPNs (24 pts with PV, 16 pts with ET and 8 pts with PMF). According to results of the cytogenetic studies 32/48 patients have a favorable karyotype, 4/48 have abnormalities with intermediate risk and 12/48 have chromosomal aberrations with unfavorable prognosis. Patients were divided into 2 groups. The first group included 20 patients with normal karyotype, and 16 patients with the isolated chromosomal aberrations del(13)(q22), del(20)(q12), -Y associated with favorable prognosis, and add(22)(q13), del(1)(p32), del(6)(q15), t(10;12)(q22;p13) that are referred to as an intermediate risk. The second group included 12 patients with complex abnormalities and the other chromosomal aberrations of unfavorable prognosis: +8, +7,-7, inv(7)(p11;q21). Mutations in 8, 10, 17, 18, 19 exons of *EZH2* were defined by sequence analysis.
Results: 2 mutations of *EZH2* gene have been found in 2 individuals with PMF (2/8) belonging to different groups of prognosis. Both mutations are located in the 19 exon. The Ile713Thr mutation was detected in the patient with a del(6)(q15) karyotype which is associated with an intermediate risk. This patient subsequently underwent transformation from PMF to myelodisplastic syndrome in 9 months after the disease onset. Another case of mutation harboring (Thr731Asp) was detected in a patient with PMF and poor prognosis karyotype (chromosome 7 monosomy). This patient had transformation PMF to acute myeloid leukemia and was died after 20 months.
Summary and Conclusions: Mutations in the *EZH2* gene could be preliminarily assessed as additional prognostic markers of unfavorable prognosis in patients with *BCR-ABL*-negative MPNs and with different chromosomal aberrations. Our results confirm its prognostic significance for PMF patients but further studies are needed to consider patients with other types of MPNs.

PB1714

TGF-B SIGNALING PATHWAY MOLECULAR REGULATION BY SMADS IN MYELOFIBROSIS PATIENTS

DPT Nunes[1,*] LT Lima[1], GW Gomes[1], CG Yassui[1], ML Chauffaille[2], MRR Silva[3], CC Ponce[3], FA Castro[4], EM Guerra-Shinohara[1]

[1]Departamento de Análises Clínicas e Toxicológicas, Faculdade de Ciências Farmacêuticas da Universidade de São Paulo, [2]Disciplina de Hematologia, Universidade de São Paulo, [3]Departamento de Patologia, Universidade Federal de São Paulo, São Paulo, [4]Análises Clínicas, Toxicológicas e Bromatológicas, Universidade de São Paulo, Ribeirão Preto, Brazil

Background: Myelofibrosis (MF) is a complex clonal hematopoietic stem cell malignancy classified as a myeloproliferative neoplasm. Besides the known TGF-β functions in MF fibrosis progression, detailed mechanism of TGF-β signaling in the pathophysiology of this disease remains unclear. Bone morphogenetic proteins (BMPs) are multifunctional growth factors, members of the TGF-β superfamily. Smads are a group of proteins critical for transmitting signals from TGF-β superfamily of the cell surface to the nucleus. They are classified as receptor-regulated (R-Smads: 1, 2, 3. 5 and 8/9), common-mediator (Co-Smad: Smad4), and antagonistic/ inhibitory (I-Smads: 6 and 7) Smads. As they regulate TGF-β signal transduction, they may have an important role in TGF-β modulation in MF process.
Aims: To investigate the molecular regulation of TGF-β signaling pathway by SMADs in MF patients, quantifying their mRNA expression and comparing it with controls.
Methods: Forty-two MF patients diagnosed according to the World Health

Organization criteria (2008) were selected from the Hematology Department of the Universidade Federal de São Paulo (UNIFESP) for this study. Twenty-three controls were also included and matched by age and gender with patients. Plasmatic TGF-β1 was measured by Luminex technology, and quantification of TGFB1 and SMADs 1 to 8 mRNA expressions was performed by real time qPCR, using Taqman assays. The statistical analyses were carried out with data of 42 MF patients when this group was analyzed separately. However, when the comparison was performed among MF group and matched controls, the number of subjects in each group was 23.
Results: TGF-β plasmatic concentrations of MF patients were similar to the matched controls (P> 0.05). Regarding to mRNA expression, SMAD6 was higher in MF patients in relation to controls (P=0.01), while SMAD7 was lower (P=0.01). When each group (MF or control) was analyzed separately, according to the median of TGFB1 mRNA (median of values in 42 MF patients = 0.138841; 23 controls = 0.08563) and classified as low and high expressions, it was observed that MF patients with high TGFB1 mRNA expression presented higher SMADs 1 to 7 mRNA expressions than those with low expression (p< 0.05). The controls with high TGFB1 mRNA expression had higher SMADs 2, 3, 5, 6 and 7 mRNA expressions than those with low expression (P< 0.005).
Summary and Conclusions: It seems that TGF-β molecular regulation by SMADs is different among MF patients and controls. Our findings suggest that MF patients have a lower negative feedback of TGF-β signaling by SMAD7 than controls. Furthermore, the fibrotic process involved in the disease may be modulated by SMAD6 overexpression, which inhibits BMPs signaling and its anti-fibrotic activity. (FAPESP 2012/12957-5).

PB1715

DETERMINING THE NUMBER OF CIRCULATING CD34+ CELLS FOR THE DIAGNOSIS OF MYELOPROLIFERATIVE NEOPLASMS IN DAILY PRACTICE
C Orvain[1,*] D Luque Paz[2], I Dobo[1], G Le Calvez[2], A Chauveau[2], F Boyer[1], JC Ianotto[2], M Zandecki[1], N Ifrah[1], V Ugo[2], F Genevieve[1]
[1]CHU d'Angers, Angers, [2]CHU de Brest, Brest, France

Background: A high number of circulating CD34+ cells has been advocated to distinguish primary myelofibrosis (PMF) from other Philadelphia-negative myeloproliferative neoplasms (MPN). However, this test is not included in the current WHO diagnosis criteria and literature remains sparse on the subject.
Aims: In this oligocentric study, we reevaluate the diagnostic interest of measuring circulating CD34+ cells for the diagnosis of MPNs in daily practice.
Methods: Between 2010 and 2012, the number of circulating CD34+ cells was determined in 26 healthy volunteers and 286 consecutive patients at diagnosis in whom the diagnosis of PMF was suspected (suggestive blood count, splenomegaly or investigation of a splanchnic thrombosis). The determination of circulating CD34+ cells was obtained through flow cytometry with a standardized simple platform technique (BD™ Stem Cell Enumeration Kit, BD Bioscience ; Stem-Kit™ CD34 HPC Enumeration kit, Beckman Coulter). Results for growth of progenitors on a collagen gel without and with growth factors (Stem Alpha ou StemCell Technologies) were available for 82 patients. Results were correlated with the entire clinical and biological data and the final diagnosis in regard to the 2008 WHO criteria for each patient.
Results: 31 patients were excluded from the analysis because they were diagnosed with acute leukemia, lymphoid neoplasm or thrombosis without MPN. The normal number of CD34+ determined in healthy volunteers is <5.4/µl (median number of 2.6/µl + 2 standard derivations of 1.32). The median number of CD34+ is significantly higher in MPNs than in healthy volunteers, but at levels somewhat different, in the following diseases (Mann et Whitney test): PMF (n=34 pts ; 51/µl [2.5–717]), essential thrombocytemia (ET) (n=93 pts ; 3.5/µl [1–32]), polycythemia vera (PV) (n=42 pts ; 4/µl [0.5–18]), chronic myeloid leukemia (CML) (n=10 pts ; 144/µl [3.4–1930]), chronic myelomonocytic leukemia (CMML) (n=8 pts ; 8.6/µl [1–899]) while the number of CD34+ was similar to healthy volunteers in patients with myelodysplatic syndrome (MDS) (n=11 pts ; 2.4/µl [0,5–378]) or with non-malignant transitory polyglobulia or thrombocytosis (n=43 pts ; 2.5/µl [0.5-18], n=12 pts ; 2.5µl [1-14], respectively). No correlation was found between the JAK2 V617F or MPL W515 molecular status and the number of CD34+ cells. The determination of the CALR molecular status in the 134 JAK2 V617F negative cases is underway. The ROC curve analysis shows that a number of CD34+ <10/µl excludes the diagnosis of PMF with a negative predictive value of 99.5% (ROC curve parameters: area under the curve: 0.93 [0.89-0.98] ; p<0.001 ; sensibility : 97%, specificity : 90%, positive predictive value : 60%). Endogenous growth in cell culture distinguishes MPNs (number of colonies: PV 10 [3-34], ET 9 [0-49] and PMF 8 [0-53]) from other diseases such as atypical cases of MDS (no growth) with a specificity of 92% and a positive predictive value of 96%.
Summary and Conclusions: Determining the number of circulating CD34+ cells is a fast, simple, and standardized test when a diagnosis of MPN is suspected: its excellent negative predictive value excludes the diagnosis of PMF when <10/µl. It is a tool of particular interest when a bone marrow biopsy is not informative or difficult to realize. Cell culture can differentiate PMF from other diseases with a high number of circulating CD34+ cells.

PB1716

HYPOXIC AND NON-HYPOXIC PROANGIOGENIC STIMULI IN MYELOPROLIFERATIVE NEOPLASMS
T Subotički[1], B Beleslin-Čokić[2,*] O Mitrović[1], M Diklić[3], D Marković[4], D Leković[5], D Šefer[5], M Gotić[5,6], V Čokić[3]
[1]Department for neuroendocrinology, Institute for Medical Research, University of Belgrade, [2]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, [3]Laboratory of experimental hematology, [4]Department for immunology, Institute for Medical Research, University of Belgrade, [5]Clinic of Hematology, Clinical Center of Serbia, [6]Medical Faculty, University of Belgrade, Belgrade, Serbia

Background: The role of nitric oxide (NO) has not been entirely clarified in tumor angiogenesis. NO may induce synthesis of vascular endothelial growth factor (VEGF) via PI3K/Akt/HIF1α pathway, while VEGF enhances NO production by endothelial NO synthase (eNOS). Additionally, hipoxia seems to induce NO production. In contrast, high NO concentration leads to HIF1α down-regulation, thus decreasing VEGF production.
Aims: A target of this study is to correlate the expression of key angiogenic molecules VEGF, eNOS and HIF-1α in myeloproliferative neoplasms (MPN): polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF) according to JAK2V617F mutation status.
Methods: The angiogenic factors VEGF, eNOS and HIF-1α mRNA levels are measured by real time PCR, while their protein expression is examined in granulocytes and CD34$^+$ hematopoietic progenitor cells of MPN using immunocytochemistry and Western blot. ELISA-based assay is used for the quantitative determination of eNOS concentrations in granulocytes of MPN.
Results: Using DNA sequencing, JAK2V617F mutation is detected in all PV and per 60% of both ET and PMF patients, out of total 198 MPN patients. eNOS mRNA levels are generally increased in granulocytes in comparison to CD34$^+$ hematopoietic progenitor cells of MPN patients. eNOS and HIF-1α mRNA levels are increased in MPNs *vs.* controls both in granulocytes and hematopoietic progenitors. Presence of JAK2V617F mutation exaggerated eNOS gene expression in hematopoietic progenitors, but not in granulocytes. JAK2V617F mutant allele burden increases HIF1α gene expression in hematopoietic progenitors of MPN patients and granulocytes of ET patients (3-5 fold). VEGF gene expression has the highest levels in hematopoietic progenitors of PMF patients, further on augmented by JAK2V617F allele burden. eNOS protein levels are increased in granulocytes of MPN patients, especially in ET heterozygous for JAK2V617F mutation. Analyses of protein expression of VEGF, eNOS and HIF1α in granulocytes show a significant increase in MPN patients in comparison to healthy controls. The activated HIF1α is significantly increased in nuclear fractions of PV and ET granulocytes (2 fold). In addition, there is a positive correlation between VEGF and eNOS as well as eNOS and HIF1α protein in MPN patients. Further on, the immunocytochemical analyses of granulocytes confirm that the percentage of VEGF- and eNOS-positive cells is generally increased in PV, ET and PMF JAK2 homozygous patients with a positive correlation among them. Moreover, in CD34$^+$ cells, VEGF- and HIF1α-positive cells are also increased in MPN patients with a positive correlation.
Summary and Conclusions: The presented triangle of angiogenic factors exhibit mostly elevated gene and protein expression in hematopoietic primitive and mature cells of MPN patients, confirming its importance in pathogenesis of disorders. The expression demonstrates tendency, but is not generally augmented by JAK2V617F mutation.

PB1717

JAK-STAT PATHWAY INHIBITOR DO NOT MODULATE DRUG TRANSPORTERS GENE EXPRESSIONS IN JAK2V617F POSITIVE CELL LINE
GW Gomes[1,*] LTD Lima[1], DPT Nunes[1], AC Rodrigues[2], FA de Castro[3], R Tognon-Ribeiro[4], EM Guerra-Shinohara[1]
[1]Departamento de Análises Clínicas e Toxicológicas, Faculdade de Ciências Farmacêuticas, Universidade de São Paulo, [2]Departamento de Farmacologia, Instituto de Ciências Biomédicas, Universidade de São Paulo, Sao Paulo, [3]Departamento de Análises Clínicas, Toxicológicas e Bromatológicas, Faculdade de Ciências Farmacêuticas de Ribeirão Preto, Universidade de São Paulo, Ribeirao Preto, [4]Departamento de Farmácia, Faculdade de Farmácia, Universidade Federal de Juiz de Fora/Campus Avançado, Governador Valadares, Brazil

Background: Discover of JAK2V617F mutation and the role of JAK-STAT pathway disregulation on myeloproliferative neoplasms (MPNs) pathogenesis lead to development of drugs targeted to inhibition of this pathway. The recent introduction of JAK-STAT pathway inhibitors in clinical practice represented a great advance in MPNs therapy. Little is known about the drug transporters expression effect on JAK inhibitors pharmacokinetics in MPN patients. The drug transporters play a role in drugs efflux (ABCB1 and ABCG2 molecules) or uptake (SLC22A1 and SLCO1A2 molecules) and could impact in patient response to therapy, causing variability of response and resistance to treatment.

Aims: To evaluate the effect of JAK inhibitors on ABCB1, ABCG2, SLC22A1 and SLCO1A2 mRNA expression in Caco-2, HepG2 and SET-2 cell lines.
Methods: Caco-2, HepG2 and SET-2 (JAK2V617F positive) cell lines were treated with 0 to 4 μM of *JAK Inhibitor I* (Merck/Calbiochem®, Darmstadt, Germany), a commercial ATP-competitive JAKs inhibitor, for 24 hours. After treatment, Caco-2 and HepG2 cells were submitted to viability and DNA fragmentation tests. JAK-STAT pathway inhibition was verified by STAT-5 phosphorylation inhibition (western blot) in SET-2 cells. The ABCB1, ABCG2, SLC22A1 and SLCO1A2 mRNA expressions were evaluated in Caco-2, HepG2 and SET-2 treated with *JAK Inhibitor I* by real time PCR, using Taqman® Gene Expression Assays (Applied Biosystems, Foster City/CA, USA).
Results: *JAK Inhibitor I* did not affect HepG2 cell line viability or DNA fragmentation when used in concentrations of 0 to 4 μM after 24h of cells treatment (P>0.05). In Caco-2 cells, the treatment with *JAK Inhibitor I* in a concentration of 2 μM and 4 μM by 24 hours leads to cell viability loss (P<0.001), although the DNA fragmentation were similar to control (P>0.05). The gene expression was analyzed in cell lines treated with *JAK Inhibitor I* in a concentration range of 0 to 1 μM. In SET-2, the treatment with 1 μM for 24 hours leads to JAK-STAT pathway inhibition. In HepG2, treatment with *JAK Inhibitor I* did not change ABCB1 and ABCG2 mRNA expression (P>0.05). Likewise, *ABCB1*, *ABCG2*, *SLC22A1* and *SLCO1A2* expressions were similar before and after *JAK Inhibitor I* treatment in Caco-2 and SET-2 cells lines (P>0.05).
Financing: FAPESP, process no. 2012/01081-1
Summary and Conclusions: Taken together, the data suggest that *JAK Inhibitor I* did not change the *ABCB1*, *ABCG2*, *SLC22A1* and *SLCO1A2 mRNA* expression in HepG2, Caco-2 and SET-2 cell lines. These findings indicate that JAK-STAT pathway inhibitors might not offer resistance potential by upregulation/downregulation of these drug transporters genes.

PB1718

GENETIC AND EPIGENETIC ABNORMALITIES IN MYELOPROLIFERATIVE NEOPLASMS
IS Kim[1,*] N Kim[1], HJ Shin[2], EY Lee[3]
[1]Department of laboratory medicine, Pusan National University Yangsan Hospital, Yangsan, [2]Hematology-Oncology, [3]Department of laboratory medicine, Pusan National University Hospital, Busan, Korea, Republic Of

Background: Recent studies have revealed a number of genetic and epigenetic alterations that likely contribute to disease pathogenesis and determine clinical outcome. In addition to the *JAK2 V617F* mutation, pathogenesis of myeloproliferative neoplasm (MPN) has evolved from a simple to a complex model, including a number of novel mutations. However, little is known about the frequencies and distribution patterns of genetic and epigenetic mutations in Korean population.
Aims: We investigated the frequencies and distributions of genetic and epigenetic mutations in Korean patients with MPN.
Methods: We investigated 75 patients with *BCL-ABL1* negative MPN. The *BCR-ABL1* rearrangement was assessed by reverse transcription polymerase chain reaction (RT-PCR). The *JAK2* V617F mutation was assessed by allele-specific PCR or direct DNA sequencing. We searched for mutational hot spots in *IDH1* (R132), *IDH2* (R140 and R172), *DNMT3A* (R882), *CBL* (exons 8 and 9), *EZH2* (exon 17~19), *WT1* (exons 7 and 9), *JAK2* exon 12, *MPL* (W515L), *ASXL1* (exon 13), *SH2B3* (exons 2, 7 and 8) and *SRSF2* (P95) using direct sequencing.
Results: In this study, *JAK2* V671F mutation was detected in 64% of *BCR-ABL1*-negative MPN. We found two *SH2B3* mutations in exon 8 which is recently reported mutational region in the Korean population study. Compared to the previous reports, the mutational hot spots in this study are not found except *SH2B3* (2.7%). However, we found 88% of *WT1* rs16754 and analyzed genotype-specific risks by comparing the genotype distribution. Especially, the individuals carrying mutant G alleles of *WT1* rs16754 found low prevalence of MPN for *WT1* rs16754 (Hazard ratio 0.103~0.648, p<0.05), therefore, G allele for *WT1* rs16754 might be risk reducing alleles for developing a MPN. There was no significant difference in overall survival between genotypes.
Summary and Conclusions: This study identified a very low prevalence of genetic and epigenetic mutations in the Korean patients with MPN except *SH2B3* .We observed a significant difference in allele and genotype frequencies of *WT1* rs16754 in an Asian population compared to a western population and wild allele G of *WT1* rs16754 might be a risk-reducing association for developing MPN in Korean population.

PB1719

OXIDATIVE STRESS IN MYELOPROLIFERATIVE NEOPLASMS
M Diklić[1,*] D Marković[2], D Djikić[3], S Milanović[4], S Mojsilović[2], G Jovčić[1], VP Čokić[1]
[1]Laboratory of experimental hematology, [2]Department for immunology, [3]Department for neuroendocrinology, Institute for Medical Research, University of Belgrade, [4]Department of biochemistry, Faculty of veterinary medicine, University of Belgrade, Belgrade, Serbia

Background: Oxidative stress is an invasive condition with increased reactive oxygen species, now recognized as an important characteristic of malignant disorders as well as their progression.
Aims: The aim of this study was to evaluate the role of oxidative stress induced genes and antioxidative enzymes in myeloproliferative neoplasms (MPN): polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF).
Methods: Using microarray analysis we studied oxidative stress induced gene expression in $CD34^+$ hematopoietic progenitors of MPN patients. An assay for superoxide dismutases (SOD) was based on the ability of SOD to inhibit the autoxidation of epinephrine at alkaline pH. The activity of glutathione reductase (GR) was based on the capacity of GR to catalyze the reduction of oxidized to reduced glutathione using NADPH as a substrate. Glutathione peroxidase activity was assayed following the oxidation of NADPH with t-butyl-hydroperoxide as a substrate. The antioxidative enzymes activities were determined in red blood cells lyzate.
Results: Oxidative stress induced FBJ murine osteosarcoma viral oncogene homolog (FOS) gene expression was highly elevated in ET (3.1 fold) and PV (3.7 fold) comparing to healthy controls. FOS gene expression was higher in JAK2V617F heterozygous PV patients (4.1 fold). Less prominent expression was observed for kelch-like ECH-associated protein 1 (KEAP1) gene in PV (1.6 fold) and PMF (1.8 fold). Regarding ET patients, heme oxygenase 1 (HMOX1) gene was preferentially expressed in JAK2V617F positive ET (2.4 fold), significantly higher than in healthy controls (p<0.05). Also, HMOX1 was significantly more expressed in JAK2V617F homozygous PV patients (2.5 fold), than in healthy controls (p<0.05). In contrary, v-maf musculoaponeurotic fibrosarcoma oncogene homolog F (MAFF) gene was significantly less expressed in JAK2 homozygous PV and PMF than in healthy controls (p<0.01). The levels of superoxide dismutase and glutathione peroxidase were the most abundant in PMF of MPN. The level of glutathione reductase was the highest in PV, not influenced by JAK2V617F mutant allele burden. However in PMF, the level of glutathione reductase was the most increased in JAK2 homozygous PMF and reduced in JAK2 negative patients, in opposite to glutathione peroxidase levels.
Summary and Conclusions: Presented oxidative stress induced gene expression demonstrated JAK2 dependence in MPN. The antioxidative enzymes activities were the most prominent in PMF. So, oxidative stress effects both at gene and enzyme levels revealed a variation specific for certain type of MPN.

PB1720

GENE EXPRESSION AND PROTEIN LEVELS OF MMPS, TIMPS AND SPARC AND THEIR RELATIONSHIP WITH PLASMA MARKERS OF ANGIOGENESIS IN MYELOFIBROSIS AND ESSENTIAL THROMBOCYTHEMIA PATIENTS
LT Lima[1,*] DPT Nunes[1], GW Gomes[1], ML Chauffaille[2], MRR Silva[3], CC Ponce[3], FA Castro[4], EM Guerra-Shinohara[1]
[1]Departmento de Análises Clínicas e Toxicológicas, Faculdade de Ciências Farmacêuticas, Universidade de Sao Paulo, [2]Disciplina de Hematologia, [3]Departamento de Patologia, Universidade Federal de São Paulo, Sao Paulo, [4]Departamento de Análises Clínicas Toxicológicas e Bromatológicas, Faculdade de Ciências Farmacêuticas de Ribeirão Preto, Universidade de Sao Paulo, Ribeirao Preto, Brazil

Background: Myelofibrosis (MF) and essential thrombocythemia (ET) are myeloproliferative neoplasms (MPNs) resulting from acquired hematopoietic stem cell mutations. The molecular mechanisms involved in MPNs pathogenesis are not completely elucidated. It is known that angiogenesis plays an important role in hematological neoplasias progression and prognosis. Matrix metalloproteinases (MMPs), tissue inhibitors of metalloproteinases (TIMPs) and secreted protein acidic and rich in cysteine (SPARC) are involved in tumor neoangiogenesis. In this context, evaluation of genes related with angiogenesis could be useful to better understand MPN pathobiology.
Aims: To investigate the mRNA and protein expressions of MMPs, TIMPs and SPARC and their relationship with plasma markers of angiogenesis (VEGFA and bFGF) in MF and ET patients.
Methods: Forty-three MPNs patients (MF=29 and ET=14) and 36 control were studied. The controls were matched with patients according age and gender. The MPN diagnosis was defined according World Health Organization criteria (2008). The MMP2, MMP9, TIMP1, TIMP2 and SPARC gene expression were evaluated in peripheral leukocytes and VEGFA and bFGF concentration were measured in plasma from MPN patients. mRNA gene expression and proteins levels were measured by real time PCR and Luminex technology, respectively.
Results: High MMP2, MMP9 and TIMP1 mRNA expression were observed just in MF patients compared to controls (P<0.05). High SPARC mRNA levels was detected in MF and ET patients when compared to controls (P<0.05). In MF group, SPARC mRNA expression was inversely associated with MMP9 expression (β=-0.436 ,R^2=0.3672 and P=0.002) and directly associated with TIMP1 and TIMP2 expression (β=0.625, R^2= 0.4984 and P<0.001; β=0.346, R^2=0.2510 and P=0.015). MF patients showed higher levels of VEGFA and bFGF then controls. Two models of multivariate linear regression were performed in MF

group. In model 1, it was observed that MMP9 levels were directly associated to dependent variable VEGFA levels (β=0.828, R^2=0.4556 and P=0.001). In model 2, MMP9 and TIMP1 levels were directly associated to dependent variable bFGF levels (β=0.866, R^2=0.4802 and P<0.001; β= 0.625, R^2=0.2641 and P=0.014, respectively). A third model of multivariate linear regression was performed with ET group and it was found that TIMP2 levels were directly associated to dependent variable bFGF levels (β=0.940, R^2=0.2641 and P=0.014). In controls, the independent variables MMPs, TIMPs and SPARC serum levels were not associated with each dependent variable (VEGFA or bFGF).
Summary and Conclusions: These preliminary results showed high SPARC mRNA expression in MF and ET. MMP9 and TIMP1 serum levels are associated with plasmatic VEGFA and bFGF in MF, whereas TIMP2 is associated with plasmatic bFGF in ET. These findings might be useful on understanding MF and ET pathobiology due to their role in angiogenesis. (FAPESP 2012/12957-5).

PB1721

WHOLE BLOOD PLATELET AGGREGATION IN PATIENTS WITH V617F JAK2 AND CALR MUTATIONS

A Gorbenko[1,*] M Stolyar[1,2], T Subbotina[1,2], I Olkhovskiy[1,3]
[1]Krasnoyarsk branch of Hematology Research Center Russian Ministry of Health, [2]Siberian Federal University,, [3]Krasnoyask Scientific Center of the Siberian Branch of the Russian Academy of Sciences, Krasnoyarsk, Russian Federation

Background: Platelet activity changes could cause the development of clinical symptoms of chronic myeloproliferative neoplasms (CMN). As we previously found, the mutation in the JAK2 gene leads to increase all parameters of whole blood aggregation (Olkhovskiy, Stolyar; 2013) and had weak or non significant correlation with platelet counts. In december 2013 two research groups independently demonstrated more than half of all cases of JAK2 negative, associated with a novel somatic mutations in the gene of CALR (Nangalia J. *et al.* and Klampfl T. *et al.*). CALR mutations associated with more marked thrombocytosis, but lower risk of thrombosis.
Aims: To measure platelet aggregation in whole blood in patients with V617F JAK2 and CALR mutations and evaluate the relationship between platelets number and aggregation in patients with CMN.
Methods: 120 patients: 51 women 55.6 (31-74) age and 69 men 55.5 (27-87) age with suspicion a CMN were examined. CALR gene deletion was determined by PCR and followed by electrophoresis. CALR insertion and mutations in JAK2 and MPL genes was detected by RT-PCR (IQ5, BioRad). Platelet aggregation in whole blood was measured in 67 healthy subjects and 91 patients with CMN by impedance method at Chronolog -700, with ADP inducer (5 μM).
Results: Total of 15 patients was found with a deletion in CALR gene and 5 with insertion in it. Including CALR mutation was found in 43% of all 42 patients without mutations V617F JAK2 and MPL but with thrombocytosis more than 500 000 per μl of blood. The parameters of platelet aggregation was increased in all patients with thrombocytosis and independent of the availability of mutations in JAK2 or CALR (Table 1). There is no correlation between aggregation and platelet counts both in general for the entire group of patients with CMN, and separately in subgroups with different mutations.

Table 1. Parameters impedance platelet aggregation (Me; Q25-Q75) in whole blood of healthy donors and patients with chronic myeloproliferative neoplasms (CMN) with thrombocytosis more than 500 000 per μl.

Summary and Conclusions: Increasing the platelet counts corresponds to the degree of increase of it aggregation in whole blood samples in patients with CMN. However, differences in the degree of thrombocytosis depend on JAK2 or CAL mutations to a greater extent than platelet aggregation. Functional activity of platelets in whole blood CMN rather determined by their quality than quantity.

PB1722

OXIDATIVE STATUS IN ESSENTIAL THROMBOCYTHEMIA

A Iurlo[1,*] R De Giuseppe[2], D Cattaneo[1], C Bucelli[1], N Orofino[1], P Bianchi[1], C De Vita[2], D Consonni[3], U Gianelli[4], F Bamonti[2], A Cortelezzi[1]
[1]Hematology Unit, [2]Department of Biomedical, Surgical and Dental Sciences, [3]Epidemiology Unit; Department of Preventive Medicine, [4]Hematopathology section, Division of Pathology, Department of Pathophysiology and Transplantation, IRCCS Ca' Granda – Maggiore Policlinico Hospital Foundation and University of Milan, Milan, Italy

Background: Oxidative stress (OS) is due to an excess of pro-oxidant species, like a Reactive Oxygen Species (ROS) and not counterbalanced by an adequate endogenous antioxidant molecules such as Reduced Glutathione (GSH). It has been demonstrated that it is involved in pathogenesis of atherothrombotic disease. Essential Thrombocythemia (ET), a BCR-ABL1-negative MPN, is characterised by increased platelet production and sustained thrombocytosis which can lead to thrombotic or hemorrhagic complications.
Aims: To investigate oxidative status in ET.
Methods: Thirty ET patients (13M/17F, age range 29-66 years) were recruited at our Hospital and compared to 26 healthy volunteers matched by age and gender (12M/14F, age range 28-69). All participants gave their informed consent. Serum ROS and whole blood GSH levels were measured by using a spectrophotometric method (dROMs test, Diacron International, Grosseto, Italy) and the HPLC method (Chromsystems Instruments & Chemicals, Munich, Germany) respectively. Reduced/oxidised glutathione ratio (GSH/GSSG) was also calculated. JAK2 mutational analysis was confirmed by direct sequencing (ABI PRISM 310 Genetic Analyzer, Applied Biosystems, Warrington, UK); for quantitative analysis of the allele burden of the JAK2 V617F mutation, we had to perform RQ-PCR using JAK2 MutaQuant™ (Ipsogen Inc., New Haven, CT). We compared levels of markers of OS between ET patients and healthy subjects using multiple linear regression models adjusted for gender, age (continuous), smoking (never, former, current), dyslipidemia (yes, no) and treatment with acetylsalicylc acid (yes, no).
Results: Oxidative stress results of our study group are reported in Table 1. No significant differences of oxidative status parameters were found between JAK2 positive and JAK2 negative groups.

Table 1. Results are expressed as mean (standard deviation).

*From multiple regression model.

Summary and Conclusions: Even if GSH levels were unusually augmented in ET, patients showed significantly increased levels of GSSG as well as a reduced GSH/GSSG ratio compared to the controls in place, therefore underlying that ET patients showed an altered oxidative status. Further studies are necessary to investigate if oxidative stress plays a role in ET thrombotic complications.

PB1723

8P11 MYELOPROLIFERATIVE SYNDROME: DIAGNOSTIC CHALLENGES AND PITFALLS

V Vukovic[1], D Antic[1,2,*] J Milosevic[3], R Kralovics[3,4], A Bogdanovic[1,2], M Dencic Fekete[1], M Perunicic Jovanovic[1], V Djurasinovic[1], J Jelicic[1], B Mihaljevic[1,2]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Faculty of medicine, University of Belgrade, Belgrade, Serbia, [3]CeMM Research Center for Molecular Medicine, Austrian Academy of Sciences, [4]Department of Internal Medicine I, Division of Hematology and Blood Coagulation, Medical University of Vienna, Vienna, Austria

Background: 8p11 myeloproliferative syndrome (EMS) is a very rare clinicopathological entity which is characterized by the appearance of a myeloproliferative neoplasm (MPN) in the bone marrow, peripheral lymphadenopathy, usually caused by a T or B lymphoblastic lymphoma/leukemia, a peripheral blood eosinophilia in the absence of basophilia, and a reciprocal translocation involving chromosome 8p11. Disruption of the fibroblast growth factor receptor 1 (*FGFR1*) gene at the 8p11-12 chromosomal locus, and creation of novel fusion genes and chimeric proteins result in constitutive activation of FGFR1 tyrosine kinase which, consequently, promotes activation of downstream signaling pathway resulting in oncogenesis.
Aims: We want to present a patient with a very rare disease such as EMS, and underline an importance of comprehensive diagnostics in patients presenting with eosinophilia in peripheral blood, lymphadenopathy and pattern of MPN in bone marrow biopsy specimens.
Methods: We analyzed medical records of patient with EMS.
Results: We described 22 year old male patient with unusual clinical presentation of EMS. Namely, initially he presented with prolonged epistaxis.

Complete blood count showed elevated hemoglobin (17,7g/dl), thrombocytopenia (98x10^9/l) and a leukocytosis (57x10^9/l). The white cell differential revealed an eosinophilia of 9%, with a leukoerythroblastic picture and a left shift (neutrophils 51%, bands 16%, metamyelocytes 3%, myelocytes 1%, promyelocytes 3%, lymphocytes 7%, monocytes 9%). Bone marrow aspirate and biopsy findings corresponded with the presence of a myeloproliferative neoplasm while cytogenetic analysis revealed t(8;13)(p11q12). After that ZMYM2-FGFR1 in-frame fusion was confirmed at the molecular level. Immediately after establishing diagnosis of MPN generalized lymphadenopathy was developed. Histopathologic examination of lymph node sample confirmed the diagnosis of a T cell lymphoblastic lymphoma without bone marrow involvement. Four cycles of Hyper CVAD chemotherapy was applied with effect of complete morphological and cytogenetic remission and resolution of lymphadenopathy. During the preparation for allogeneic (allo) stem cell transplant (SCT) from his HLA matched sister, 4 weeks after completion of chemotherapy, he developed a peripheral blood monocytosis and eosinophilia, along with a left shift, but without blasts. A bone marrow aspiration was performed confirming the recurrence of the myeloproliferative neoplasm. The repeat cytogenetic analysis on this marrow sample showed t(8;13) accompanied by complex numerical and structural aberrations. Because of generalized lymphadenopathy recurrence, lymph node biopsy was repeated with confirming previous diagnosis of T cell lymphoblastic lymphoma. The patient underwent an allo SCT and subsequently achieved a complete remission.

Summary and Conclusions: Patients with MPN and translocations involving chromosome 8 need to be carefully evaluated for EMS. However, having in mind very aggressive clinical course of EMS allogeneic SCT is the only potential curative option.

Myeloproliferative neoplasms - Clinical

THE MPN FATIGUE PROJECT STAGE 2: UNDERSTANDING THE ROLE OF COMORBID CONDITIONS AND FATIGUE-ALLEVIATING STRATEGIES IN MPN FATIGUE

R Scherber[1,*] Z Senyak[2], A Dueck[3], M Clark[4], M Goldstein[5], M Boxer[6], A McCallister[2], M Cotter[2], C Harrison[7], RA Mesa[8]

[1]Internal Medicine, Mayo Clinic, Scottsdale, [2]MPN Forum, Asheville, [3]Division of Biostatistics, Mayo Clinic, Scottsdale, [4]Division of Psychology, Mayo Clinic, Rochester, [5]Bio Med Psychiatry & Human Behavior, Brown University, Providence, [6]Arizona Oncology, Tuscon, United States, [7]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [8]Mayo Clinic, Scottsdale, United States

Background: The Philadelphia chromosome negative chronic myeloproliferative neoplasms (MPNs) are a group of diseases characterized by myeloid clonal lineage with hypersensitivity to or independence from cytokine regulation. These disorders include essential thrombocythemia (ET), polycythemia vera (PV), and myelofibrosis. Patients with these disorders suffer from a unique constellation of symptoms which includes severe, prevalent, and debilitating fatigue. Although the cause of this fatigue is not entirely clear, it is thought to arise from significant cytokine dysregulation and impaired hematopoiesis. Overall, it is a predominant cause of reduced quality of life and impaired functioning among MPN patients. Given the unique constellation of disease-related fatigue, this symptom has become known as MPN-Related fatigue (MRF). We have recently published the results of the initial phase I project initiated and hosted by *MPN Forum* evaluating fatigue-relieving strategies among MPN patients (Blood 2013;a1595). Among the 879 online respondents, patients most often employed exercise, diet, social interaction, nutrition, rest, and relaxation techniques to combat fatigue. Use of non-prescription energy-enhancing supplementation was common. Pharmacologic interventions included MPN-specific treatments, steroids, noradrenergic stimulants, prescription vitamin supplements, and erythropoietin analogues. Despite our previous efforts, little is known to date about the degree of relief from specific fatigue-alleviating strategies and the contribution of comorbid conditions to MRF.

Aims: The aim of this study is to evaluate the role of comorbidities and fatigue-alleviating strategies in MRF.

Methods: Our survey was developed using a compilation of validated questionnaires along with items developed by a team of investigators for specific use in this study. In total, a 70-item internet-based survey was developed and hosted by the Mayo Clinic Survey Research Center. The survey was promoted online via multiple MPN-related webpages including the *MPN Forum*, *MPN Net*, *MPN Research Foundation*, and *MPN Voice* during late February to March of 2014. Surveyed data included disease demographics such as splenomegaly, thrombosis, hemorrhage transfusions, medications, and phlebotomies. The MPN-SAF including the 10-item brief fatigue inventory was used to assess disease burden (Blood. 2011 Jul 14;118(2):401-8). Comorbid conditions were assessed, including hypothyroidism, anemias, sleep disturbances, obesity, and heart and lung disorders. Mental health was assessed using the POMS-short form (J Nerv Ment Dis. 1979;167(10):612-4), PHQ-2 (Ann Fam Med. 2010 . 8(4): 348–353) and MHI-5 (J Consult Clin Psychol. 1983. 51;730-742). Participant's attainable metabolic equivalents were also assessed as a measure of functional status. Fatigue was characterized using a set of questions to evaluate timing, frequency, duration, triggers, and impact on daily activities. Interventional strategies to cope with fatigue were complied based on responses from our previous study. Patients were queried as to whether they had utilized individual interventions and were asked to rate the success of each intervention on a 1 (not at all successful) to 5 (very successful) scale. All survey and study protocols were approved though the Mayo Clinic IRB prior to survey implementation. We anticipate a sample size of 850 participants.

Results: This trial began open online enrollment in late February 2014 and remains in the recruitment phase. Our updated preliminary data will be presented at the EHA 2014 meeting.

Summary and Conclusions: Overall patients with MPN experience an exclusive pattern of disabling fatigue. Further study of MRF will 1) help to better characterize this fatigue, 2) improve our knowledge on comorbid conditions that may be contributing to fatigue severity and prevalence, and 3) glean knowledge on non-pharmacologic interventions can be utilized to alleviate fatigue. We plan to use the results of this intervention to inform an interventional trial which pairs standard MPN therapies with integrational non-pharmacologic fatigue reduction techniques.

PB1726

ORAL IRON-CHELATION WITH DEFERASIROX IN PRIMARY MYELOFIBROSIS: A SINGLE CENTER EXPERIENCE.

E Elli[1,*] A Belotti[1], A Aroldi[1], M Parma[1], E Pogliani[1], P Pioltelli[1]
[1]Hematology Division, San Gerardo Hospital, MONZA, Italy

Background: Transfusion-induced iron overload is a frequent problem that clinicians have to face in the treatment of patients affected by myelodysplastic syndrome (MDS), resulting in multiple organ failures, with significant hepatic and cardiac involvement. Deferasirox (DSX) is the principal option currently available for chelation therapy, but the expertise in the management of iron overload in patients with primary myelofibrosis (MF) is limited.
Aims: We wanted to analyze our experience regarding iron-chelation therapy (ICT) with DSX in MF patients in order to evaluate safety, efficacy and hematological responses.
Methods: We identified in our MPN Ph- database, 154 patients affected by primary MF referred to our Division from 1990 to 2012: of them, 47 patients (30,5%) presented TD anemia at onset or during follow-up of disease; we analyzed our initial experience in 10 patients with MF treated with oral DSX from September 2010 to May 2013, starting from dose of 10 mg/kg/day, up to the maximum tolerated dose. Criteria for initiating ICT were an estimated life expectancy of at least 1 year and at least one of: ferritin level > 1000 microg/L, transfusion of > 20 RBC units, or organ dysfunction from iron overload, refractoriness and/or absence of concomitant therapy with stimulant erithropoietic agents.
Results: The median values of ferritin pre-treatment was 2280 microg/l and the median red blood cells (RBC) transfused was 2 units/month. The median dose tolerated of the DSX was 750 mg/day (10 mg/kg/day), with 3 transient interruption of treatment for grade 2 of drug-related adverse events (AEs), in particular 1 rash, 1 diarrhea and 1 transaminitis; 3 patients experienced a definitive discontinuation of the drug for grade 3 AEs (1 hepatitis, 2 renal failure). 2 patients interrupted DSX for leukemic evolution of disease. Overall, only 4/10 patients (40%) continued permanently the oral ICT. According to IWG criteria 2006, erythroid responses with DSX, comprising reductions in transfusion requirements or increases in hemoglobin levels, were observed in 4/10 patients (40%), with 2 patients (20%) who obtained transfusion independence. Median changes in serum ferritin levels were greater in hematologic responders (HR) compared with non-responders (NR) at any time from start of ICT, in particular already at 6 months, as showed in Figure 1. A trend of a better overall survival was present in HR respect to NR (90.7 *versus* 35 months, respectively), probably due to a longer time exposure to DSX (14.5 *versus* 6.5 months) and a lower incidence of AEs in HR. Moreover, the incidence of definitive discontinuation of ICT for AEs was higher in NR patients (66% *vs* 25%).

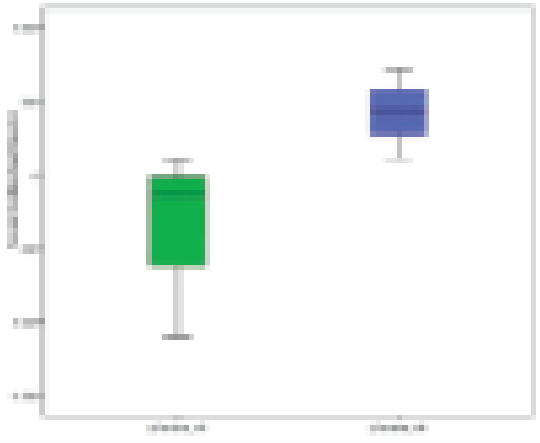

Figure 1.

Summary and Conclusions: Our preliminary data open new insights regarding the benefit of ICT not only in MDS, but also in MF patients with the possibility to obtain a partial or complete erythroid response, overall in 40% of patients. Moreover, there seems to be a potential positive impact of the ICT on survival in responding patients. However, the tolerability of the drug seems to be lower compared to MDS patients, both in terms of lower median tolerated dose (10 mg/kg/day) that for higher frequency of discontinuance for drug related AE (40%). The biological mechanism of action of DSX in this specific myeloproliferative setting, through an independent NF-κB inhibition and not based on the reactive oxygen species scavenging properties of the drug, could explain a direct action on the malignant clone during *in vivo* therapy, inducing a hematopoietic improvement, but further investigations are required.

PB1727

CALR MUTATIONS ARE RARE IN CHILDREN WITH ESSENTIAL THROMBOCYTHEMIA

E Peroni[1,*] ML Randi[1], G Geranio[2], I Bertozzi[1], C Micalizzi[3], U Ramenghi[4], F Tucci[5], L D Notarangelo[6], S Ladogana[7], G Menna[8], P Giordano[9], P Farruggia[10], G Russo[11], M Jankovich[1,2], G Basso[2], F Fabris[1,3], MC Putti[2]

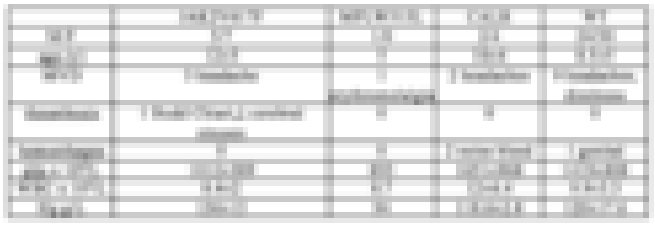
Background: Sporadic essential thrombocythemia (ET) is rare in children; they display rarely than adults a clonal pattern. *JAK2*V617F mutation occurs in 20-25% of cases and *MPL*W515L has been described only in 1 child. Therefore, diagnosis of ET in children is based on exclusion criteria in most cases. Somatic mutations in calreticuline gene (CALR) have been recently described in 80% of adult ET wild-type for *JAK2*V617F, thus reducing the rate of non-clonal cases in adults to 10-15%.
Aims: Research of CALR mutations in a large cohort of children with ET.
Methods: CALR mutations were searched in 72 children with a clinical diagnosis of ET, who were consecutively referred to our laboratory from 11 Italian Hematological Pediatric Centers. Platelet count >450x10^9/L was observed for at least 6 months; reactive thrombocytosis,familial patterns and BCR/ABL rearrangements were excluded in all cases. Bone marrow aspirates were performed in all cases; 40 cases had a histological picture consistent with ET. None of the children received any cytoreductive treatment before the study. The study was approved by the Ethic Committee of the Padua Hospital and informed consent was provided according to the Helsinki Declaration. *JAK2*V617F mutation was searched by quantitative real time-polymerase chain reaction assay. *MPL* mutations and CALR mutations were searched by direct sequencing.Comparison between means was made with ANOVA followed by Bonferroni post hoc test.
Results: 11 children (15.2%) harbour *JAK2*V617F and 1 (1.4%) *MPL*W515L mutations. Within the remaining 60 cases, 6 had one CALR abnormality (8.3% of total population & 10% of *JAK2/MPL* negative cases) and 54 (75%) were wild type (WT). In summary, 25% of patients had a clonal mutation as identified by current molecular studies: their clinical features are summarized in the Table 1.

Table 1.



No significant statistical differences were found among the different groups.

Summary and Conclusions: We present the first 6 cases of children with ET carrying a *CALR* mutations,albeit in a smaller proportion of cases than in adults. Other Authors did not found any mutations within 6 children with ET. In our large cohort of children,75% were WT for all known mutations: the proportion of clonal cases is smaller in children with clinical diagnosis of ET, than in adults. The absence of significant clinical or laboratory differences among the children with different molecular pattern confirms that ET in children is, at least in part, a different entity, may be not deserving the term myeloproliferative neoplasm. The children might suffer from an undefined thrombocytosis and their diagnostic process and follow-up need to be further established. In any case, the use of cytoreductive drugs in children with an increased platelet count has to be cautiously evaluated and deferred as much as possible.

PB1728

LEUKOCYTOSIS DURING DISEASE COURSE FOR PREDICTING THROMBOTIC/HEMORRHAGIC COMPLICATIONS IN PATIENTS WITH POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA

Y Lim[1,*] JO Lee[1], SH Kim[1], JW Kim[1], YJ Kim[1], KW Lee[1], JH Kim[1], JS Lee[1], SM Bang[1]
[1]Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of

Background: Recent clinical and preclinical findings suggest that leukocytosis seems to be related to thrombotic and hemorrhagic complications in polycythemia vera (PV) and essential thrombocythemia (ET).
Aims: The purpose of this study was to evaluate whether white blood cell (WBC) burden during the disease course affects the incidence of thrombotic or hemorrhagic events in PV and ET.
Methods: We have retrospectively analyzed PV and ET patients diagnosed and treated at Seoul National University Bundang Hospital between Jan. 2004 and Aug. 2012. To estimate the WBC burden per patient during the disease course, we calculated time-weighted averages of complete blood cell count (CBC) values of whole follow-up period per each patient. The calculated values were compared between groups with events and without events. Also the time-weighted average values of the 3 months period before the events were compared with those of the whole follow-up period in each individual patient with events.
Results: A total of 102 patients with PV (33 patients, 32.4%) and ET (69 patients, 67.6%) were analyzed. The median follow-up period was 54 months (range, 2-163). Median age at diagnosis was 64 years (range, 24-87); 52.9% were male. Thirty-five events (16 thrombotic, 19 hemorrhagic) occurred in 29 patients. The time-weighted averages of WBC were significantly higher in patients with events (12,015x10^3μL) compared to patients without any events (9,567x10^3μL)(*P*=0.003). There were no statistically significant differences in hemoglobin or platelet counts. The difference in time-weighted averages of WBCs between groups with or without events was more prominent in the subgroup of patients with ET (8,577x10^3μL *vs.* 11,674x10^3μL, *P*=0.007) than with PV, and with hemorrhage (9,567x10^3μL *vs.* 12,823x10^3μL, *P*=0.003) than with thrombosis. In the patients with events, the time-weighted average of WBCs in the 3 months period before the event (16,767x10^3μL) was significantly higher than that of the whole follow-up period (12,015x10^3μL)(*P*=0.002). The time-weighted average of platelets was also significantly higher in the 3 months period, but no significant difference in the average of Hb was observed.
Summary and Conclusions: WBC burden during the disease course seems to be related to higher occurrence of thrombotic and hemorrhagic events in PV and ET patients.

PB1729

BONE MANIFESTATIONS IN PATIENTS WITH MYELOFIBROSIS - A CROSS-SECTIONAL STUDY USING DXA AND HR-PQCT

S Farmer[1,*] H Frederiksen[1], AP Hermann[2], V Shanbhogue[2], S Hansen[2], C Stahlberg[3], H Vestergaard[1]
[1]Dept. of haematology, [2]Dept. of endocrinology, [3]Dept. of pathology, Odense University Hospital, Odense C, Denmark

Background: In patients with myelofibrosis, osteosclerotic changes appear in the bone tissue as the result of growing and thickening of the bone trabeculae. Despite this bone formation a recent nationwide population-based cohort study showed that patients with chronic myeloproliferative neoplasms (CMPN) in general have a higher rate and risk of hip fractures.
Aims: We conducted a cross-sectional study to evaluate bone structure MF patients using conventional DXA and HR-pQCT.
Methods: Patients who meet the diagnostic criteria of primary myelofibrosis or myelofibrosis secondary to another CMPN according to WHO 2010-criteria with *International Classification of Diseases,* 10th revision, from the department of haematology, Odense University Hospital, Denmark were included. Areal Bone mineral density was assessed by DXA (duel energy X-ray absorption), and 3D assessment of Bone geometry, volumetric BMD, and micro-architecture were measured using XtremeCT (High-resolution peripheral quantitative CT). Data are compared with healthy volunteers matched on age, sex, and height, in a 1:1 ratio. Blood samples were analyzes for markers of bone formation including PINP1 (procollagen type I N-terminal pro-peptide) and measurements of haemoglobin, leucocytes, thrombocytes, lactate dehydrogenase, potassium, sodium, creatinine, alkaline phosphatase, alanine transaminase, ionized calcium, thyroid-stimulating hormone, parathyroid-stimulating hormone (PTH) and 25-hydroxyvitamin (25(OH)D). Data are presented as mean-values including 95% confidence intervals (CI). Results from patients and controls are compared using t-test and the statistical significance level set at p<0.05. All diagnostic bone marrow biopsies (BMB) were reviewed by a hematopathologist, confirming diagnosis, grading of fibrosis and presence of osteosclerotic changes. p<0.05. Informed consent was obtained.
Results: 20 MF patients were included, mean age 69.8 (95% CI: 66.3-73.4). 11 patients had grade MF 1-2 and 9 patients had grade MF-3 fibrosis in their bone marrow biopsy, while osteosclerosis including focal ostesclerosis was observed in 12 patients. The patients had higher BMD in spine 1.10 (0.93-1.08) *vs.* 0.93 (0.87-1.00), but not of the hip 0.93 (0.85-1.02) *vs.* 0.90 (0.82-0.98). HR-pQCT showed consistently increased bone mass, particular trabecular volumetric BMD, trabecular BV/TV, and trabecular number, although statistical significance was not reached. Haemoglobin was below normal range (F: 11.6 (10.2-12.9) g/dL, ref: 11.8-15.3 g/dL; M: 10.8 (9.5-12.2) g/dL, ref: 13.4-16.9 g/dL) and lactate dehydrogenase is above normal range (374.11(269.89 - 478.34) U/L, ref: 155-255 U/L) as expected for a patient with myelofibrosis. 10 patients were below reference level of 25(OH)D, and respectively 7 patients had increased levels of PTH. Remaining biochemical measurements were within normal range. PINP was increased in patients (Figure 1).

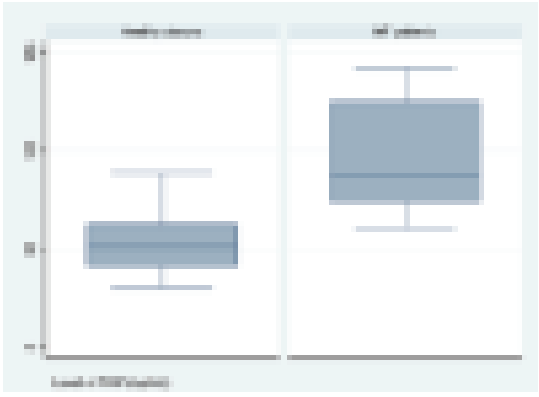


Figure 1.

Summary and Conclusions: This study demonstrated elevated level of PINP in MF patients indicating increased formation rate of collagen. Deficient level of 25(OH)D is common in the Nordic countries among the elder population. The DXA and HR-pQCT results indicate that these patients have increased trabecular bone mass, but did not reach statistical significance. Myelofibrosis is a rare disease and the number of patients included was small.

PB1730

RETROSPECTIVE ANALYSIS OF 260 PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA: IWG-MRT (IPSET MODEL; PASSAMONTI ET AL, BLOOD 2012) PROGNOSTIC SCORE IS A GOOD PREDICTOR OF SURVIVAL

G Benevolo[1,*] B Nicolino[1], E Beggiato[2], C Frairia[1], A Evangelista[3], F Pirillo[1], PM Manzini[4], L Riera[5], C Aguzzi[2], U Vitolo[1]
[1]SC Hematology, [2]SC Hematology-U , [3]Unit of Clinical Epidemiology and CPO Piemonte, [4]Struttura Complessa Banca del Sangue CPVE, [5]Anatomia Patologica Generale e Oncogenetica Molecolare-U, Città della Salute e della Scienza Hospital and University, Torino, Italy

Background: Life expectancy in Essential Thrombocythemia (ET) patients is generally considered similar to that of normal population of the same age, at least during the first decade from diagnosis. The main causes of death are thrombotic events and evolution into myelofibrotic phase or secondary myelodisplasia/acute leukemia. Recently, in a large study published by IWG-MRT (Passamonti et al, Blood 2012), authors developed a widely applicable prognostic model, delineating three different prognostic risk groups by age, leukocyte count and history of thrombosis (IPSET model).
Aims: In this study we tested the IPSET model in a retrospective cohort of 260 ET patients defined according to WHO criteria, diagnosed from 1974 to 2013 in a single Italian haematological centre (Turin).
Methods: We analysed 260 ET patients. According to the IPSET model, patients were divided into three groups: adverse points are assigned to age ≥60 years (2 points), leukocyte count ≥11 x109/l (1 point) and venous thrombosis (1 point). In this way patients were divided in low-risk(0 points), intermediate-risk (1 or 2 points) or high-risk (≥3 points) groups. We evaluated overall survival (OS) from diagnosis to death from any causes by Kaplan Meyer method; Hazard Ratio were estimated with Cox Models.
Results: Characteristics at diagnosis were as follows: median age was 59 years, 144 patients (55%) were female, cardiovascular risk factors and palpable splenomegaly were observed in 158 (61%) and 42 (16%) patients, respectively. Forty-one (16%) patients showed leukocytosis (≥11 x 109/L) whereas elevated HCT (≥45%) was present in 51 out of 125 evaluated patients (41%). Forty-seven (18%) patients had previous thrombotic events. As expected, approximately 119 patients (46%) resulted positive for JAK2 mutations (V617F). With a median follow-up of 73 months we observed 14 deaths (5.3%), 27 myelofibrotic transformations (10%) and 4 leukemic evolution (2%). The incidence of post diagnosis arterial and/or venous thrombosis were 8.8%, in the sub-group of 125 patients evaluated for HCT. The incidence was higher but not significantly (p=0.742) in patients with HTC>45 (9.8% *vs* 8.1%) than in patients with HTC<45%. OS at 6 years is 97.5% (95%CI: 93.5-99.1). The IPSET prognostic model displayed discrimination between high-risk (n= 95; 6-year survival 93.3%; *vs* low-risk HR 5.7; 95%CI: 0.9-34.7), intermediate-risk (n= 124; 6-year survival 96.0%;

vs low-risk HR 4.7; 95%CI: 1.3-17.6) and low-risk (n=91; 6-year survival 100%) groups. The C-statistic was 0.6814. (Figure 1).
Summary and Conclusions: In our retrospective cohort of ET patients, IWG-MRT (IPSET model) prognostic score was confirmed as a good predictor of survival. Elevated HCT seems to represent an additional thrombotic risk factor, besides in Polycythemia Vera, also in ET patients. This promising results need to be confirmed in larger prospective studies.

PB1731

SECOND MALIGNANT TUMORS ASSOCIATED WITH HEMATOLOGICAL MALIGNANCIES - FREQUENCY AND SIGNIFICANCE
B Marius Lucian[1,*] D Georgescu[1], O G Patrinoiu[1], M Popescu[1]
[1]Hematology, Clinical Hospital Colentina, Bucuresti, Romania

Background: Malignant diseases, regardless of the affected organs, have a common etiopathogenic background.
Aims: If malignancies involve a genetic susceptibility or if malignant diseases pathogenesis has common links or if a cancer therapy promotes the development of second malignancies, it is expected that the development of a second malignancy in patients with malignant disease to be more common as in the general population.
Methods: We've analyzed (retrospective and prospective) the frequency of the association of two different primary malignancies in patients with malignant hemopathies diagnosed in our clinic over the past five years. 486 patients have been reviewed: 261 (53.7%) females and 226 (46.3%) males. The average age was 59.9 years (patients between 18-98 years). Of these patients 301 (62%) had lymphoproliferative disorders whereas 185 (38%) had myeloproliferative disorders.
Results: A second malignancy has been identified in 68 patients: 32 males and 36 females, with an average age of 67.6 years. The overall frequency of the second neoplasm was 13.99%, with no significant difference between males and females (14.2% and 13.8% respectively). The frequencies of the second neoplasm in patients with lymphoproliferative disorders and myeloproliferative disorders were 13.82% and 15.13% respectively. We emphasize that in subjects with RAEB - 1 MDS and RAEB - 2 MDS, 17.5% had a history of neoplasms that required proapoptotic chemotherapy and radiation. The identified second primary malignancies associated with malignant hemopathies and their frequencies were: cutaneous cancers (melanoma, squamous-epidermoid carcinoma, basal cell carcinoma) - 30%, neoplasms of genital / breast area (carcinoma of prostate, carcinoma of the cervix , malignant ovarian tumors, breast carcinoma) – 27%, gastrointestinal carcinomas - 15%, neuroendocrine neoplasia – 7%, pancreas carcinoma – 7.5%, renal cell and bladder carcinoma 5%, connective tissue sarcomas - 4%, bronchogenic carcinoma – 3%, a second different hematological neoplasia - 1.5%.
Summary and Conclusions: A significant part (13.99%) of our patients with malignant hemopathies developed a second primary neoplasia. There was no significant difference between males and females regarding the frequency of the second neoplasm. Radiation / radiotherapy, chemotherapy and anti CD20 antibody therapy seem to be associated with the induction / unmasking of a second neoplasia. Regarding the genetic predisposition we note down that none of the eight patients (4 with CLL, 2 with NHML, and one with HD) diagnosed in our clinic with familial malignant hemopathies developed a second primary neoplasm. These data sustain the theory of the existence of a common ethiopathogeny of neoplastic afflictions.

PB1732

IMPACT OF MOLECULAR REMISSION ON CLINICAL OUTCOME AFTER ALLOGENEIC STEM CELL TRANSPLANTATION IN 14 PATIENTS WITH MYELOFIBROSIS
IC Casetti[1,*] C Cavalloni[1], E Rumi[2], D Pietra[2], E Sant'Antonio[1], M Bellini[1], C Milanesi[2], V Ferretti[2], E Boveri[3], C Pascutto[2], C Astori[2], F Ripamonti[2], M Della Porta[2], D Caldera[2], AA Colombo[2], P Bernasconi[2], E P Alessandrino[2], M Cazzola[1,2]
[1]Department of Molecular Medicine, University of Pavia, [2]Department of Hematology Oncology, [3]Anatomic Pathology Section, IRCCS Policlinico San Matteo, Pavia, Italy

Background: Myelofibrosis (MF) may occur as a primary disease (PMF) or as evolution of previous essential thrombocythemia (post-ET MF) or polycythemia vera (post-PV MF). Allogeneic hemopoietic stem cell transplantation (allo-SCT) is currently the only curative option for these patients, although associated with high rate of transplant-related mortality. Patients with primary or secondary MF may carry the *JAK2* V617F mutation, mutations in *CALR* gene or, more rarely, mutations within the *MPL* gene; few patients do not carry any mutation (triple-negative patients).
Aims: To evaluate the impact of mutational status (*JAK2*, *MPL*, *CALR*) and molecular remission on clinical outcome in patients with MF undergoing allo-SCT.
Methods: Diagnosis of PMF, post-ET MF and post-PV MF was made according to WHO 2008 criteria and International Working Group on Myelofibrosis Research and Treatment (IWG-MRT) criteria. Complete remission (CR) was defined according to the revised IWG-MRT and European Leukemia Net (ELN) response criteria. The absence of minimal residual disease was assessed by chimerism analysis (through microsatellites or FISH evaluation). Mutations of *JAK2*, *MPL* and *CALR* were assessed by allele specific qPCR, high resolution melting and Sanger sequencing, respectively.
Results: We analyzed 14 patients with MF (7 PMF, 4 post-ET MF, 3 post-PV MF) who received allo-SCT. In detail, 2 patients were *CALR* mutated, 9 patients were *JAK2* V617F mutated, 1 patient carried *MPL* W515A mutation, whereas 2 patients were triple-negative. The median age was 48.7 years (20.6-58.3). The median time from MF diagnosis to transplant was 53 months (range 8-118). The dynamic score (DIPSS) at time of allo-SCT was intermediate-1 in 2 patients, intermediate-2 in 10 patients and high in 2 patients. At the time of analysis 4 of 14 (28.5%) patients were dead. We did not find an impact of mutational status (*JAK2*, *MPL*, *CALR*) on overall survival (*P* 0.568) and achievement of CR (*P* 0.491), perhaps due to the low number of patients. The assessment of molecular remission after allo-SCT was feasible in 11 of 14 patients as one patient lacked a molecular marker (triple-negative) and two patients died early after allo-SCT for transplant related complications. Of the 11 evaluable patients, 9 patients achieved molecular remission: 7 were in CR according to the revised IWG-MRT and ELN criteria whereas 2 showed an incomplete blood counts recovery, perhaps due to the short time elapsed from allo-SCT. The remaining 2 patients who still carried the molecular marker after allo-SCT showed persistence of disease with a 100% pre-allo-SCT chimerism. Molecular response after allo-SCT was significantly correlated with the achievement of a clinical CR (*P* 0.028).
Summary and Conclusions: Driver founding mutations in myelofibrosis may be used to evaluate minimal residual disease after allo-SCT and their eradication appears to be predictive of clinical complete remission.

Abstract withdrawn

PB1734

SYMPTOMS TRIAL UPDATE: SYMPTOMS YIELDED IN MYELOFIBROSIS PATIENTS AFTER TRANSPLANT AS OBJECTIFIED BY THE MPN-SAF TSS
H Geyer[1,*] R Emanuel[1], A Dueck[1], H Alchaby[2], L Michaelis[3], N Kroger[4], S Giralt[5], V Guptas[6], U Popat[7], R Mesa[1], V Fauble[1]
[1]Mayo Clinic, Scottsdale, AZ, United States, [2]University Clinic, Hamburg, Germany, [3]Medical College of Wisconsin, Milwaukee, WI, United States, [4]University Cancer Center, Hamberg, Germany, [5]Memorial Sloan-Kettering Cancer Center, New York, NY, United States, [6]Princess Margaret Cancer Center, Toronto, Ontario, Canada, [7]MD Anderson, Houston, Texas, United States

Background: Patients with myelofibrosis (MF) including post-polycythemia vera (PV) and post-essential thrombocythemia (ET) MF, suffer from debilitating symptoms profiles, splenomegaly, cytopenias, reduced quality of life and shortened life expectancies. With standard medical therapy primarily focused on symptom management, allogeneic stem cell transplant (ASCT) remains the only available curative option for intermediate to high-risk disease. The

procedure, however, is associated with significant risks, symptomatology, financial burdens and impact on quality of life. To date, no study has investigated the MF symptom profile and its evolution in patients who undergo stem cell transplant.

Aims: This prospective clinical trial aims to asses the symptomatic burden in primary and post-PV/ET MF patients undergoing ASCT using the Myeloproliferative Neoplasm Symptom Assessment Form Total Symptom Score (MPN-SAF TSS), FACT-BMT, Global Impression of Change and financial assessment scoring tools prior to and post-allogeneic stem cell transplant.

Methods: This international study was approved by the Mayo Clinic Institutional Review Board and remains in active accrual. A total of 110 participants with PMF or post-ET/PV MF planning to undergo allogeneic ASCT will be prospectively enrolled. Patients will be randomized to the ASCT arm *vs.* the Standard Medical Therapy (SMT) arm based on matched or mismatched related/unrelated status. Patients undergoing ASCT will complete the MPN-SAF TSS, Global Impression of Change, FACT-BMT and financial questionnaire items pre-transplant (day 0) and post-transplant on days 30, 100 and 365. Patients randomized to SMT will complete the same packets at similar time points with day 0 representing completion of the first packet. Paired t-tests will be utilized to compare pre- and post-transplant results between MPN-SAF TSS and other scoring tools at each post-baseline time point. Global Impression of Change items will be used to assess responsiveness of the MPN-SAF TSS in each study. Descriptive and graphical techniques will include mean plots and stream plots from each continuous or ordinal scale/subscale item.

Results: Since trial initiation (June, 2012), seven institutions have been enlisted to participate (Mayo Clinic, AZ USA; MD Anderson, Texas USA; University Medical Center, Hamburg Germany; Memorial Sloan Kettering, NY USA; Medical College of Wisconsin, Wisconsin USA; Princess Margaret Cancer Center, Toronto, Ontario Canada). A total of 9 patients have been enrolled with data available on 7 patients. Two patients have been randomized to HSCT and 5 patients have been randomized to SMT. Baseline patient demographic and clinical data is listed in Table 1. Additional patient information will be presented at the conference.

Summary and Conclusions: The symptomatic burden associated with allogeneic stem cell transplant in myeloproliferative neoplasm patients remains uninvestigated. The MPN-QOL Study Group aims to evaluate improvements in MPN symptoms and quality of life via the use of MPN-specific, validated survey instruments in this unique population. The study remains in active recruitment with updated results to be presented at the conference.

HYDROXYCARBAMIDE AS A RISK FACTOR FOR TRANSFORMATION TO ACUTE MYELOID LEUKEMIA IN ESSENTIAL THROMBOCYTHEMIA: SINGLE CENTER LONG TERM FOLLOW UP STUDY

M Popova-Simjanovska[1],* L Cevreska[1], S Trajkova[1], M Ivanovski[1], D Dukovski[1], A Stojanovik[1], G Amzai[1], L Hadji-Pecova[1], I Panovska-Stavridis[1]
[1]Hematology, University Clinic of hematology, skopje, Macedonia, The Former Yugoslav Republic Of

Background: Essential thrombocythemia (ET) is a classical myeloproliferative neoplasm characterized by sustained clonal thrombocythosis and bone marrow megakaryocytic hyperplasia with a prolonged clinical course and a near-normal life expectancy. Evolution to myelofibrosis is observed in 4%>8% of pts at 10 years, whereas leukemic transformation is rare but can increase with the use of certain cytoreductive drugs. Ideal treatment of ET is towards preventing vascular complications but without increasing the risk of transformation of the disease. Hydroxycarbamide (HU) is a well established effective first-line therapy. However there are controversial data regarding the possible leukemogenic effects of HU. Several new studies indicates dose dependent leukemogenic effect of HU, while other denied any association. In order to evaluate further those observation we analyzed in a retrospective study all patients diagnosed and followed in a period longer than 10 years at the University Clinic of Hematology-Skopje.

Aims: In order to evaluate further those observation we analyzed in a retrospective study all patients diagnosed and followed in a period longer than 10 years at the University Clinic of Hematology-Skopje.

Methods: Our study group consisted of f 164 pts diagnosed at the University Clinic of Hematology in Skopje, Macedonia, before 2006, was made according to the WHO diagnostic criteria for ET. We analyze their clinical characteristics at diagnosis, therapies received, and development of myelofibrosis or acute leukemia (MF/AL).

Results: Of 164 pts, 49 were men and 115 women (median age 55), all of them had a sustained platelet count of >450x10^9/L (median platelet count 1122x10^9/L).; JAK2V617F mutation was demonstrated in 105 pts (64%). Twelve patients presented with splenomegaly (7,3%); Fifteen patients (9,1%) presented with history of previous thrombotic events at the moment of diagnosis. Pts with low-risk disease received low dose Aspirin; 123 high-risk pts were treated with Hydroxyurea 2gr/per day, 10 pts were treated with Anagrelide and 12 with Interpheron alpha. During the follow up period, 22 pts (13,4%) experienced thrombotic and hemorrhagic complications. Progression to myelofibrosis occurred in 6 pts (4,8%) treated with Hydroxyurea after 9 yrs of diagnosis and only one HU treated patient experienced a leukemic transformation (0,9%), 10 yrs after diagnosis; among the group treated with anagrelide, one of the patient transformed to myelofibrosis.Statistical analysis did not show any association between clinical characteristics at diagnosis, or HU therapy, and development of MF/AML. In our study group 6,5% of the pts treated with Hydroxyurea, experienced disease transformation.

Summary and Conclusions: Result from our follow up study showed that Hydroxyurea is effective and safe therapy of choice for ET patients and does not increase leukaemogenicity or disease transformation risk . It is in our opinion that major role in disease transformation in ET patients have nontreatment-related factors. However, larger, prospective studies are needed to study this issue further.

PB1736

MUCOCUTANEOUS TOXICITY IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS TREATED WITH HYDROXYUREA: A RETROSPECTIVE MONOCENTER COHORT STUDY

A Ciminello[1],* E Rossi[1], T Za[1], S Betti[1], P Chiusolo[1], V De Stefano[1]
[1]Institute of Hematology, Catholic University, Roma, Italy

Background: Hydroxyurea (HU) is the mainstay treatment in high-risk patients with myeloproliferative neoplasms (MPN). Mucocutaneous (MC) toxicity HU-related was 4.8% and 8.3% in two retrospective studies on MPN patients, respectively (Antonioli E et al, Am J Hematol 2012; Latagliata R et al, Cancer 2012) and 11.1% in a prospective trial in patients with essential thrombocythemia (ET) (Harrison C et al, N Engl J Med 2005).

Aims: To assess the probability over time of MC toxicity HU-related in a retrospective monocenter cohort of MPN patients.

Methods: The cohort included 250 patients (males 105, 42%) with MPN (polycythemia vera [PV]=89, ET=153, myelofibrosis [MF]= 8) who started HU treatment from 1994 to 2014. Patients were followed by an unique medical team and 92% of them started HU from 2000. All cutaneous or oral lesions of clinical significance, *i.e.* requiring consultation with dermatologists and/or discontinuation of treatment, were recorded. The interval between the start of HU and discontinuation due to unacceptable MC toxicity (uncensored observations) or discontinuation due to other causes or the last visit to the center (censored observations) was analysed. Moreover, the total HU dose intake was calculated in patients having had MC toxicity.

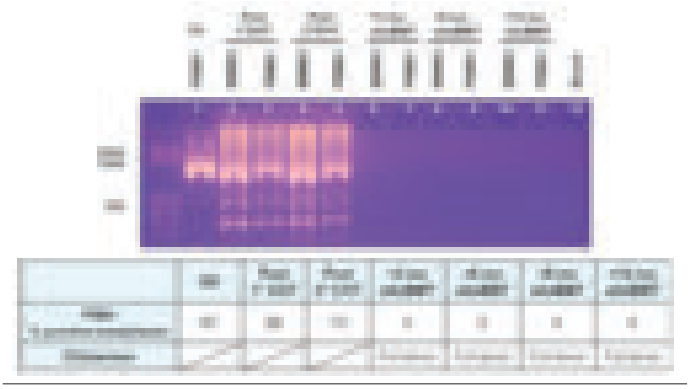
Results: The median time of exposure to HU was 37 months (range 1-217). Overall, 52 patients (20.8%) had MC toxicity (leg ulcers=21, oral aphtosis=12, keratosis=6, basalioma=6, dermatitis=4, squamous skin cancer=2, melanosis=1). In 15 of them (12 with aphtosis) toxicity was mild and allowed continuation of HU; 37 patients (14.8%) discontinued treatment. The median interval between start of HU and discontinuation for severe toxicity was 40 months (range 7-169). The cumulative probability of toxicity requiring discontinuation was 1.4% at 1 yr, 3.9% at 3 yrs, 18.7% at 5 yrs, and 30.5% at 10 yrs. Out of the 37 patients with severe

toxicity 17 were males (46%), 20 had PV (54%), 16 ET (43%), 1 MF (3%); 34 patients carried JAK2V617F (92%), at variance with those without MC complications (150/198, 76%, p=0.02). Among the 52 patients with MC toxicity the median total HU dose intake was 821 gr (range 209-4536) in those with leg ulcers, 852 gr (range 226-6166) in those with skin cancer, and 648 gr (range 69-12805) in those with other MC toxicity (p=0.5).
Summary and Conclusions: In this cohort the probability of MC HU-related toxicity was higher than previously reported and seems time-dependent and associated with JAK2V617F; interruption of treatment was required in 15% of the cohort.

PB1737

MOLECULAR MONITORING OF PCM1-JAK2 FUSION TRANSCRIPT IN A CASE OF ATYPICAL CHRONIC MYELOID LEUKEMIA WITH T(8;9)(P22;24)
E Masselli[1,2,*]L Prezioso[1], C Mecucci[3], G Sammarelli[1], S Bonomini[1], C Lambertini[1], L Craviotto[1], E Rossetti[1], C Caramatti[1], M Vitale[2], F Aversa[1]
[1]Hematology and BMT Unit, [2]Biological, Biotechnological and Translational Sciences, University of Parma, Parma, [3]Cytogenetic and Molecular Genetics, University of Perugia, Perugia, Italy

Background: Janus activated kinase 2 *(JAK2)* translocations have been described in hematologic malignancies involving both lymphoid and myeloid lineages. Better characterized translocation partners are *ETV6/TEL* on chromosome 12, *BCR* on chromosome 22 and the autoantigen Pericentriolar Material-1 *(PCM1)* on chromosome 8.
t(8;9) leading to *PCM1-JAK2* fusion are extremely rare and, to our best knowledge, less than 30 clinical cases have been reported so far in the literature. Although the clinical onset of these disorders is extremely heterogeneous, several patients present with a myelodysplastic/myeloproliferative neoplasm with a rapidly progressive disease and poor prognosis.
Aims: In this study we sought to assess the feasibility of a molecular monitoring of the *PCM1-JAK2* fusion transcript in a patient affected by atypical chronic myeloid leukemia (aCML) associated with t(8;9)(p22;p24)/*PCM1-JAK2* at time of diagnosis (Dx) and after: induction chemotherapy (1° CHT); consolidation chemotherapy (2° CHT); allogenic bone marrow transplant (alloBMT).
Molecular results are compared to the conventional monitoring tools for this peculiar disease such as FISH analysis and chimerism after alloBMT.
Methods: Break-apart FISH assays for *JAK2*/9p24, RP11-125K10 (5'*JAK2*) and RP11-39K24 (3'*JAK2*) and for *PCM1*/8p22, RP11-156K13 (5'*PCM1*) and RP11-484L21 (3'*PCM1*) was perfomed at time of diagnosis, after 1° and 2° CHT and at 3, 6, 9 and 12 months after alloBMT from a HLA-match sibling donor. Chimerism was assessed at same time points after transplant. Nested RT-PCR were performed using primers derived from *PCM1* Exon 25 and *JAK2* Exon 9 (as described by Reiter *et al. Cancer Res* 2005) on peripheral blood mononuclear cells (PBMC) and bone marrow mononuclear cells (BMMC) at time of diagnosis, after 1° and 2° CHT and at 3, 6 and 12 months after alloBMT.
Results: As shown in the Figure 1, the sole CHT wasn't able to reduce the number of metaphases carrying the t(8;9) and, consistently, nested RT-PCR documented persistence of the fusion transcript both in BMMC and PBMC (lane 2-5). Only the alloBMT was able to restore a normal karyotype and to clear the pathological transcript, both from PBMC and BMMC (lane 6-11). Molecular data correspond to chimerism results, revealing full donor chimerism at the time points indicated.



Fgure 1.

Summary and Conclusions: In this report we provide the first evidence that the detection of the fusion transcript by RT-PCR is a reliable tool to monitor the residual disease also in t(8;9)(p22;p24)/*PCM1-JAK2*-related disorders, similarly to what routinley used in the setting of *BCR-ABL* positive CML. Since we know that RT-PCR is very sensitive technique capable to predict an early disease relapse, our study suggests that this type of molecular monitoring may be extended also in this peculiar setting of hematologic neoplasms.

PB1738

ADHERENCE SUPPORT PROGRAM FOR PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA (ET) TREATED WITH ANAGRELIDE
G Ramirez[1,*] J Cárdenes[2], R Rejas[3], S Plaza[2], L García-Ortí[2], V Navas[2]
[1]Hematology Service, Hospital Virgen de la Victoria, Malaga, [2]Shire Pharmaceuticals Iberica S.L., [3]Camilo José Cela University, Madrid, Spain

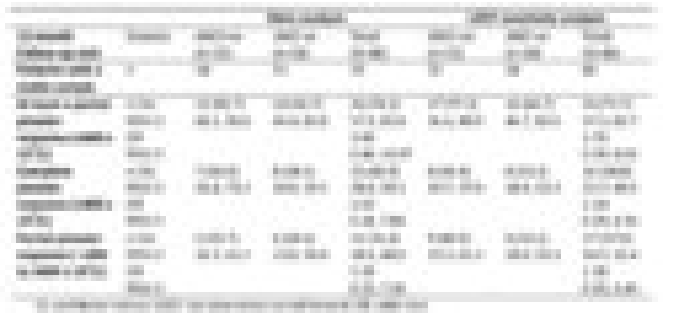
Background: Increasing patient medication adherence should be considered for chronic diseases such as ET, where treatment is prescribed to avoid thrombotic and hemorrhagic events. Patient support programs may substantially improve non-adherence by providing patients with information about pathology, treatment adherence, dose reminders, and cardiovascular risk factor management. One of the treatments used in ET is anagrelide.
Aims: To assess how an adherence patient support program (APSP) can improve treatment engagement and satisfaction in patients with ET treated with anagrelide and to evaluate APSP physicians' acceptance.
Methods: Canonical action research methodology was used (Principles of Canonical Action Research. Info System J 2004;14:65–86). A committee of experts (four hematologists, one cardiologist) designed the APSP. Trained nurses were responsible for keeping phone contact with patients and for providing educational materials. Patients were offered participation in the APSP according to their hematologists' criteria. 158 patients with ET from 149 sites gave written consent to enter this program. Two types of programs were offered: a) the basic program (BP) to help patients to learn more about their pathology and increase awareness of the need for treatment compliance, including the importance of taking prescribed doses, and b) the extended program to support patients in the management of cardiovascular risk factors (RFP). In order to assess and improve the implementation of the program, two surveys were performed among patients and doctors.
Results: In total, 190 patients were invited to enroll in the programs and 158 participated for 18 months: 138 patients in the BP and 20 in the RFP. Results from both programs show an adherence to treatment by 78% of patients in the first year. Overall, 130 patients participated in the survey, which showed an average satisfaction rating of 9 out of 10. 44% of the respondents thought that the program had helped them to better understand and treat their disease, and the majority of patients (85%) confirmed that it had been useful for them in some way. Physicians' survey outcomes from 106 hematologists showed that 15% frequently prescribed the APSP, 57% occasionally, and 8% never prescribed it. The main reasons for not using the program were: not having time, heavy workload, and forgetting about the program. The level of global satisfaction was rated 3.9 out of 5.
Summary and Conclusions: Adherence level achieved in the first year with the APSP was 78%. Most patients (85%) confirmed that it has been useful for them in some way. Overall satisfaction from patients and physicians was high. Other complementary interventions would probably be required to encourage greater participation in patient programs.

PB1739

AN OBSERVATIONAL, HYPOTHESIS-GENERATING, MULTICENTER STUDY INVESTIGATING THE IMPACT OF JAK2(V617F) MUTATIONS ON RESPONSE TO ANAGRELIDE IN ESSENTIAL THROMBOCYTHEMIA
AM Vannucchi[1,*] N Cascavilla[2], A Pancrazzi[1], P Wilde[3], J Smith[3], H Achenbach[4]
[1]University of Florence, Florence, [2]IRCCS – Ospedale Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, [3]Shire Pharmaceutical Development Ltd, Basingstoke, United Kingdom, [4]Shire GmbH, Eysins, Switzerland

Background: A *JAK2(V617F)* mutation is found in approximately 55% of patients with essential thrombocythemia (ET), and represents a key World Health Organization (WHO) diagnostic criterion.
Aims: To explore the impact of *JAK2(V617F)* mutation status on treatment response to anagrelide in patients with ET.
Methods: Patients with WHO-diagnosed ET, who were intolerant/refractory to their current cytoreductive therapy (CRT) and had started or were due to start anagrelide up to 7 days before study entry, were enrolled. Informed consent was obtained from all patients. Blood samples were collected to determine platelet response, hematologic values, and allele burden at baseline, 6, and 12 months. The primary objective was to compare the proportion of *JAK2*+ve patients vs *JAK2*-ve patients with ET who achieved at least a partial platelet response (≤600 x 10^9/L) after anagrelide therapy. Secondary objectives included comparing the proportion of patients in each group who achieved a complete platelet response (≤400 x 10^9/L), and evaluating the relationship between platelet response and allele burden in *JAK2*+ve patients. This study (NCT01352585), sponsored by Shire Pharmaceutical Development Ltd, was not statistically powered.

Table 1. Summary of patients with a platelet response at 12 months (full analysis set).



Results: Of the 47 patients enrolled, 46 were included in the full analysis set (*JAK2*+ve, n=22; *JAK2*-ve, n=24). Baseline characteristics were well balanced except for median time since ET diagnosis, which was greater in *JAK2*+ve patients than in *JAK2*-ve patients (8.2 *vs* 3.5 years, respectively). At 12 months, 35 patients (*JAK2*+ve n=14; *JAK2*-ve n=21) had a suitable platelet sample, of which 74.3% (n=26/35) achieved at least a partial response. The response rate was higher in *JAK2*+ve patients (85.7%, n=12) *vs JAK2*-ve patients (66.7%, n=14); odds ratio [OR] 3.00, 95% confidence interval [CI] 0.44, 33.97 (Table 1). A last observation carried forward sensitivity analysis was performed to account for the imbalance in patients with suitable samples between the groups due to a slightly higher withdrawal rate in the *JAK2*+ve group. The total response rate was 71.7% (n=33/46), with 77.3% (n=17/22) of *JAK2*+ve patients and 66.7% (n=16/24) of *JAK2*-ve patients achieving at least a partial response (OR 1.70, CI 0.39, 8.02). The median allele burden in the 12 patients who achieved at least partial platelet response at 12 months and had a suitable sample was 41.0% (17–47) in granulocyte DNA and 49.5% (31–58) in platelet RNA. There was no significant allele burden change over the 12 months. 31.9% of patients (n=15) experienced an adverse drug reaction (ADR), most commonly headache (12.8%, n=6). More *JAK2*-ve patients had an ADR than *JAK2*+ve patients (37.5%, n=9 *vs* 26.1%, n=6). No severe, serious, or fatal ADRs were reported.
Summary and Conclusions: The overall platelet response rate was high in both *JAK2*+ve and *JAK2*-ve patients with ET, but the odds of achieving at least a partial response were slightly higher if patients had a *JAK2(V617F)* mutation than if they did not. These results were not statistically significant and should be interpreted with caution due to the study size and imbalance in suitable samples. No clear relationship was found between allele burden and platelet response rate. Anagrelide was well tolerated and the safety profile was consistent with current literature. These data, presented on behalf of the EMIX investigators, are hypothesis generating and a controlled study would be required to further pursue any of these hypotheses.

PB1740

CLINICAL ASSESSMENT OF AQUAGENIC PRURITUS IN 70 PATIENTS WITH MYELOPROLIFERATIVE NEOPLASM

C Le Gall-Ianotto[1,*], E Brenaut[2], M Guillou[3], E Nowak[3], K Lacut[3], A Tempescul[4], V Ugo[5,6], L Misery[2], JC Ianotto[4]
[1]Laboratory of Neurosciences of Brest, Faculty of medecine, [2]Service dermatologie, CHU Brest - Hôpital Augustin Morvan, [3]CIC INSERM 0502, University hospital of Brest, [4]department of Hematology, CHU Brest - Hôpital Augustin Morvan, [5]INSERM U1078, [6]laboratory of Hematology, University hospital of Brest, Brest, France

Background: Aquagenic pruritus (AP) is an intense prickling and stinging sensation induced after contact with water. It is a frequent symptom of polycythemia vera (PV) and described by patients as one of the most troublesome aspect of their disease. Cytoreductive treatments can sometimes relief AP but classical symptomatic treatments are mostly inefficient. Pruritus has also been reported in other myeloproliferative neoplasms (MPN) such as essential thrombocythemia (ET) or myelofibrosis (MF) without specify if it was AP or not.
Aims: We conducted a prospective study on MPN patients who reported suffering from AP at the onset or later during the course of their MPN. The main objective of this study was to describe circumstances of occurrence, duration and characteristics of the pruritus, and the influence of received cytoreductive treatments. Secondary objective was to determine whether there is a single symptom whatever the MPN or if there is several types of AP depending on MPN.
Methods: This study was in the form of a questionnaire with 26 open and multiple choice questions. 70 MPN patients (44 PV, 14 ET or 12 MF, all JAK2V617F positive) were included.
Results: Our results revealed that AP occurred earlier prior to diagnosis in PV ($p<0.05$) and appeared to be more sensitive to any contact with water ($p<0.05$). A significant influence of the water temperature on pruritus was revealed only in PV and MF but not in ET. Furthermore, these patients experienced longer and more disabling crisis of AP with scratching till excoriation ($p<0.05$). In contrast, we didn't found any statistical difference between MPNs concerning the inducer of AP, the type of pruritus, the affected body areas, the intensity and the overall impact on quality of life. At the time of questionnaire, 42 of 70 patients (8 ET, 6 MF, 28 PV) still suffered from AP despite a complete hematological response (CHR) for 20 of these patients. Cytoreductive treatments appeared to be significantly more efficient to resolve AP in ET and MF.
Summary and Conclusions: In summary, this study shows that AP is not an exclusive symptom of PV and precisely describes some clinical differences between MPN subtypes that could help to better understand pruritus physiopathology and find appropriate therapies.

ANAGRELIDE AFTER FAILURE AFTER HYDROXYUREA TREATMENT IN ESSENTIAL THROMBOCYTHEMIA: EXPERIENCES OF A SINGLE HEMATOLOGICAL INSTITUTE

JL Ivanyi[1,*], É Marton [1], M Plander[1], T Szendrei[1]
[1]Dept Hematology, Univ Teach Hosp Markusovszky, Szombathely, Hungary

Background: Essential thrombocythemia(ET) is a chronic myeloproliferative neoplasm with risk of bleeding and thromboembolic complications during course of illness.Cytoreductive treatments, like non-selective hydroxyurea (HU) or interferon as first-line and specific,megakaryocyte-thrombocyte reductive anagrelide chosen as second-line therapy in cases of adverse,intolerable effects of HU can lower incidence of bleeding-thrombotic episodes in patienst(pts)with ET.
Aims: In this observational survey we investigated the effect of anagrelide in pts of ET with high risk,who were getting former HU and failed to have clinicopathological response (HU-resistant)or became HU-intolerant (adverse effects). Doses of HU and anagrelide were adjusted achieving clinicopathological response according to the criteria of European Leukemia NET, as well. Effect of anagrelide as monotherapy (first-line or second-line after HU)or in combination with hydroxyurea was followed during a teratment period in their pts with ET.
Methods: Between 2000 and 2013 in our hematological outpatient department 97 pts with ET were diagnosed (according to the updated WHO-ET classification)and treated primarily with HU(median weekly dose of 7500mg),anagrelide was given after intolerance and/or resistance to HU(median weekly dose of 7.5mg).Combination medication was used when response to monotherapy was insufficient.Bleeding and thrombotic events were also registered.Statistical analysis was made by the Windows Statistical package Software Program.
Results: From a total of 97 pts with ET (JAK2V617F mutation positive 55,negative 42 ones) HU as initial therapy was given to 86 pts, four were treated continuously with interferon and seven ones were getting only aspirin.Because of HU-intolerance (5pts) and -resistance (21 pts) second-line anagrelide was introduced as monotherapy in 16,combined again with HU in 10 pts, moreover 5 pts were getting as fisrt-line monotherapy(mostly younger ones),total of 31/97(31.9%). All pts of this latter group achieved complete remission(CR), from the second-line anagrelide monotherapy group CR and partial response in 16, and in the combined HU+anagrelide group nine pts responsed completely. During anagrelide medication maior bleeding and thrombotic events(myocardial infarction)in two pts were observed.Serious adverse events due to anagrelide were not detected.
Summary and Conclusions: Anagrelide as first- or second- line monotherapy or in partial response combined with hydroxyurea is a useful approach in treating patients of essential thrombocythemia.

PB1742

OUTCOMES FOR MYELOFIBROSIS PATIENTS WHO SWITCHED FROM FEDRATINIB TO RUXOLITINIB THERAPY

N Curto Garcia[1,*], T Somervaille[2], C Keohane[1], J Chadwick[2], A Mead[3], S Rhodes[4], M Drummond[4], J Ewing[5], D Radia[1], C Harrison[1]
[1]Haematology, Guy's and St.Thomas NHS Foundation Trust, London, [2]Haematology, The Christie NHS Foundation Trust, Manchester, [3]Haematology, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, [4]Haematology, Institute of Cancer Sciences, University of Glasgow, Glasgow, [5]Haematology, Heart of England NHS Foundation Trust, Birmingham, United Kingdom

Background: Fedratinib (FED), a JAK2-selective inhibitor, has recently been evaluated for treatment of myelofibrosis (MF) with demonstrated benefits of statistically significant reductions in splenomegaly and constitutional symptoms. Other studies suggest benefit of FED for patients who had previously been

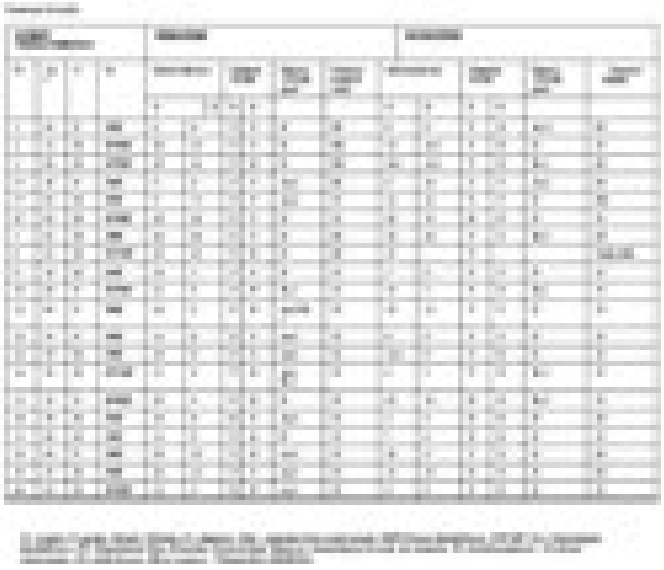
exposed to ruxolitinib (RUX) in the JAKARTA-2 study. However in 2013 development of FED was put on permanent clinical hold after reports of neurological adverse events (Wernicke's encephalopathy). As a result treatment for some patients with MF was switched from FED to RUX. Outcomes for such switches of therapy have not previously been reported.

Aims: We describe our experience in a cohort of these patients.

Methods: We recorded 20 MF patients who received treatment with FED in the JAKARTA trials whose treatment was switched to RUX therapy either following toxicity from FED (n =5), or after clinical hold of this drug (n = 15); 3 of these 20 patients had already switched from RUX to FED in the JAKARTA 2 trial. Responses are defined using IWG-MRT criteria and toxicity with CTCAE grading.

Results: See Table 1 below. Median age was 64 years, there were 13 male, 7 female, 12 PMF, 8 PPV-MF. At FED baseline, median spleen size by palpation was 17cm, and 18 had symptoms; at completion of FED median spleen size was 8cm, with a > 50% reduction in palpable spleen length achieved in 9, and resolution of symptoms in 8. After stopping FED splenomegaly and symptoms recurred or worsened in the majority of patients. No SAEs occurred on FED withdrawal. At initiation of RUX therapy median spleen size was 13cm and 15 patients reported symptoms; currently the median spleen size is 9cm, with > 50% reduction achieved in 6, and symptom resolution in 8. Responses with RUX following FED therapy were as good as those with FED and for symptom response were perhaps better. CI was achieved following FED in 13 patients for spleen and 4 for symptoms, and was generally maintained after RUX. One patient was transfusion dependent on FED and became transfusion independent on RUX, but later progressed to AML and died. Concerning patients (no. 4, 5, 6 in Table 1) who were switched to FED after previous RUX intolerance: re-exposure to RUX delivered a response similar to initial RUX therapy and intolerance has not yet recurred. Regarding hematological toxicity following switch to RUX there were 5 patients with thrombocytopenia – 3 CTCAE grade1, 2 grade3; of these 2 had experienced thrombocytopenia with FED (same grade). For anemia, on RUX there were 2 grade2 (1 experienced with FED); on FED there were 10 anemia-related toxicities (2 grade1, 2 grade2, 6 grade3). Thus far these patients have not experienced the same degree of anemia on RUX therapy although the duration of follow up is shorter.

Table 1.



Summary and Conclusions: Patients who switched JAK inhibitor therapy from FED to RUX experienced rebound of splenomegaly and symptoms after stopping FED. Symptom and spleen responses for MF patients after RUX were similar to those obtained with FED therapy. There was no unexpected toxicity, in this cohort of pre-treated patients. RUX therapy was possibly associated with less anemia, 9 patients experienced this with FED but not RUX, in contrast 3 patients experienced new onset thrombocytopenia on RUX. These data suggest that RUX following FED therapy is well tolerated and efficacious.

PB1743

JAK2 V617F ALLELE BURDEN LESS THAN 20% HAS NO INFLUENCE ON OUTCOME OF PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

M Domínguez Muñoz[1,*] I Montero Cuadrado[1], C Calderón Cabrera[1], R García Lozano[2], F Marquez-Malaver[1], J Perez-Simón[1]
[1]UGC Hematology and hemotherapy, [2]Immunology, Hospital Universitario Virgen del Rocío, Instituto de Biomedicina de Sevilla (IBIS)/CSIC/Universidad de Sevilla, Sevilla, Spain

Background: JAK2V617F mutation has been described in 40-60% of patients diagnosed with essential thrombocythemia (ET).

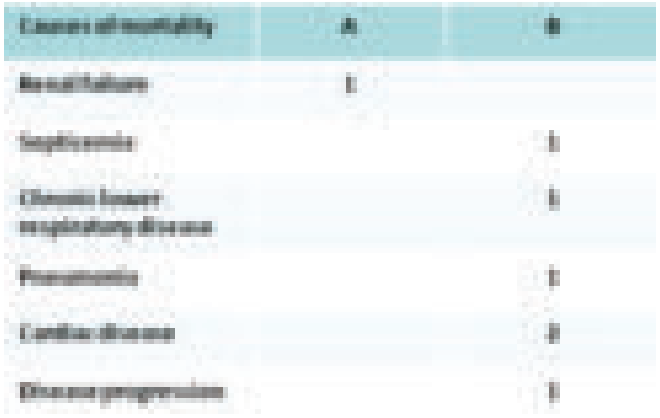
The role of this mutation and its allele burden in terms of thrombotic risk and clonal progression in this subgroup of patients is not well established. The early age of onset less than 40 years up to 15% of patients, makes it important to have tools to predict clinical behavior and new therapeutic approaches.

Aims: To analyze risk of thrombosis, risk of transformation to myelofibrosis (MF) and acute leukemia (AL) and survival in patients in patients diagnosed with ET and to correlate these parameters with mutational status and allele burden.

Methods: A total of 100 patients with ET were retrospectively analized from our center from 1996 to 2013. All patients received anti-platelet aggregation and/or cytoreductive treatment . JAK2 V617F mutation was detected by allele specific real-time quantitative in peripheral blood samples. Homozygous patients for the mutation occurred when the load allelic was > 50%, being the rest considered heterozygous.

Results: Median age at diagnosis was 63 years. A total of 73% presented JAK2 V617F mutation, 7% being homozygous. A lower overall survival was observed in mutated *versus* unmutated patients (88% *vs* 100%) without significant differences between both groups (p=0.07). Upon analyzing patients with JAK2 V617F mutation, displaying an allele burden above or below 20% the latter group had an overall survival similar to that observed for unmutated patients. Furthermore, unmutated and low allele burden patients (group A) were significantly younger as compared to those with ≥ 20% allele burden (group B) (59 *vs* 74 years, respectively; p=0.005), had a lower platelet (739x10e9 / L *vs* 896x10e9 / L p=0.024) and leukocyte counts (10.05x10e9 / L *vs* 11.82x109 / L p=0.010). Interestingly, patients in group A had a significantly better survival as compared to those in group B (98% *vs* 79% at 7 years, p=0.006). Nevertheless, no differences in terms of disease related mortality: progression to myelofibrosis (6.6% *vs* 13.9%, p=0.285);thrombotic events (8.2% *vs* 14.3%, p=0,489) was observed between groups A and B. None progressed to acute leukemia. Causes of mortality are shown in Table 1 and are related to age-related comorbidities in 1.58% *vs* 13.8% of patients from groups A and B, respectively.

Table 1.



Summary and Conclusions: Patients diagnosed with ET with unmutated JAK2 V617F or with a low allelic burden have a significantly better survival than those with a higher allelic burden. Nevertheless, according to the current study, these differences can not be attributed to disease related complications but to a different pattern of comorbidities among patients from both subgroups.

PB1744

COMBINATION THERAPY WITH RUXOLITINIB PLUS 5-AZACYTIDINE OR CONTINUOUS INFUSIONAL LOW DOSE CYTARABINE (LDAC) IS FEASIBLE IN PATIENTS WITH BLAST-PHASE MYELOPROLIFERATIVE NEOPLASMS (MPN)

A Mwirigi[1,*] S Galli[1], C Keohane[1], K Raj[1], N Shepherd[1], Y Francis[1], G Ong[2], D Radia[1], C Harrison[1], D McLornan[2]
[1]Haematology, GSTT, [2]Haematology, KCH, London, United Kingdom

Background: Leukaemic transformation of 'Philadelphia-negative MPN' or 'MPN/MDS overlap' syndromes occurs infrequently, but poses significant therapeutic challenges. Conventional AML treatment has limited efficacy and high toxicity, with poor outcome. Most patients are unsuitable for allogeneic stem cell transplant, the only definitive treatment. Estimated survival of blast phase (BP) is less than 6 months. Novel therapeutic approaches are required. Single agent Ruxolitinib displayed only modest anti-leukaemic activity in refractory/relapsed acute leukaemias.
Aims: We present three cases of BP-MPN treated with combination Ruxolitinib and 5-azacytidine or low dose cytarabine (LDAC) and demonstrate safety and efficacy in controlling disease progression and improving symptoms and quality of life.
Methods: Case 1: 71year old with *JAK2* V617F positive 'MPN/MDS', rapid progression to accelerated phase (16% blasts). Failed to respond to single agent 5-azacytidine or decitabine and developed BP. Ruxolitinib introduced, with marked improvement in symptoms, spleen size and transfusion requirements with stable disease (SD) for 4 months. LDAC then introduced as a single agent but failed. Ruxolitinib was re-introduced with infusional LDAC (3 weeks 20 mg/m2/day). After 17 weeks, has good leukaemic cytoreduction, complete resolution of splenomegaly and symptoms and has stable transfusion requirements. Case 2: 65 year old with PV. Ruxolitinib responder but progressed to post-PV MF 12 months later and then frank AML (37% blasts; complex karyotype). Standard dose 5-azacytidine was introduced and he continues on dual therapy. After 34 weeks, he remains asymptomatic, transfusion independent and has SD. Case 3: 69 year old with progressive *JAK2*V617F negative MF and worsening portal hypertension. 18 months after Ruxolitinib therapy progressed to BP. LDAC was ineffective. Switched to combination therapy with 5-azacytidine and Ruxolitinib, with marked objective improvements in portal hypertension, constitutional symptoms and reduced transfusion requirements. Stable blood counts sustained for 20 weeks, after which she succumbed to sudden overwhelming sepsis.
Results: These cases demonstrate the feasibility and tolerability of Ruxolitinib in combination with either LDAC or 5'aza in BP-MPN.
Summary and Conclusions: Conclusions are limited due to cohort size but these patients demonstrated good responses as regards attenuation of symptoms, splenomegaly and disease stability with minimal haematological toxicity. No adverse events occurred. A future UK trial is planned.
Conflict of interest: CHarrison declares research funding, speaker fees and consultancy for Novartis.

PB1745

USE OF ANAGRELIDE IN A COHORT OF PATIENTS FROM THE LAZIO REGION: COMPARISON WITH RECOMMENDATIONS FROM THE ITALIAN GUIDELINES

C Santoro[1,*] E Baldacci[1], I Carmosino[1], F Vozella[1], A Andriani[2], N Villivà[2], A Di Veroli[3], M Cedrone[4], B Anaclerico[4], R Porrini[5], E Montefusco[5], M Montanaro[6], A Spadea[7], L Scaramucci[8], F Spirito[9], A Rago[10], G Cimino[10], G Alimena[1], MG Mazzucconi[1]
[1]Cellular Biotechnology and Hematology, Hematology Sapienza University, [2]Ematologia, Ospedale Nuovo Regina Margherita, [3]Ematologia, Università Tor Vergata, [4]Ematologia, Ospedale San Giovanni, [5]Ematologia, Ospedale Sant'Andrea, Rome, [6]Ematologia, Ospedale Belcolle, Viterbo, [7]Ematologia, Ospedale Regina Elena - IFO, [8]Ematologia, Ospedale Sant'Eugenio, [9]Ematologia, Ospedale San Camillo, Rome, [10]UOC Ematologia 2(U), S. Maria Goretti Hospital-ICOT, Latina, Italy

Background: The aim of treatment of Essential Thrombocythemia (ET) is to prevent thrombotic/hemorrhagic complications, or leukemic transformation, due either to the natural history of the disease or possibly to the use of chemotherapeutic agents. The Italian guidelines for ET therapy were developed from an Expert Panel and an Advisory Committee, and published in 2004. Anagrelide (ANA) was recommended as 1st line therapy in patients with no child-bearing potential, either <40 years or ≥40<60 years but without a history of major thrombotic events.
Aims: To describe the use of ANA in a population of ET patients from the Lazio region and to evaluate the adherence between the Italian Guidelines recommendations on the use of this drug in the clinical practice.
Methods: Between 1981-2013, 153 ET patients (103F;50M) were treated with ANA for a median period of 4.6 years (0.1-23.2). Median age at diagnosis: 42.6 years (20.9-87.7); median age at the start of ANA: 46.3 years (22.7-87.8); median follow-up: 11.1 years (0.6-31.9).
Results: ANA was used as 1st line treatment in 52/153 patients (34%), as 2nd line treatment in 81/153 (53%) and as 3rd line therapy in 20/153 (13%). Responses (plts <600x10^9/L) were obtained in 125/153 patients (81.7%). While on ANA, 11 thrombotic (3 venous, 8 arterial) and 48 hemorrhagic events (8 major, 40 minor) were observed. One hundred and seven patients (76 F; 31 M) started ANA after the publication of the Italian guidelines: in 26/107 (24.3%) ANA was used as 1st line treatment, in 68/107 (63.5%) as 2nd line and in 13/107 (12.2%) as 3rd line therapy. In the table, age, platelet number at the start of therapy and previous thrombosis are described for patients undergoing ANA as 1st line medication.

Table 1.

In 81/107 (75.7%) patients treated with ANA as 2nd/3rd therapy line, 16 were <40 years and 29 between 40-60 years (45/81, 55.5%).
Summary and Conclusions: These data show that although ANA was indicated as 1st line treatment in patients <40 and ≥40<60 years with no thrombotic events, it has been more widely used as 2nd/3rd line therapy. In our series, when prescribed as 1st line, in 5/26 cases the recommendations were not followed: 3 patients were ≥40<60 years with previous thrombotic events and 2 patients were >60 years. We conclude that the use of ANA has not been very adherent to the Italian recommendations, but it depended more on the experience of the single center.

PB1746

PHILADELPHIA-NEGATIVE CHRONIC MYELOPROLIFERATIVE DISORDERS - ROLE OF INTERFERON ALPHA 2-A

K Raza[1,2,*] A Ni Chonfhaola[3], M McCloy[4], J Sergeant[4], P Murphy[1], P Thornton[1,2], J Quinn[2,3]
[1]Haematology, Beaunont Hospital, [2]Haematology, Connolly Hospital, [3]Beaunont Hospital, Dublin, [4]OLOL Drogheda, Drogheda, Ireland

Background: Role of interferon in MPD has been documented over 25 years. Peginterferon alfa-2a (Pegasys) is a covalent conjugate of IFN alfa produced by recombinant DNA technology in Escherichia coli with polyethylene glycol. Starting dose of IFN is usually 45 mcg sc once weekly as 2nd line or 1st line option (< 40 years). It is considered safe in pregnancy. The most Common side effects are anorexia, nausea, flu like symptoms and myelosupression. Rarely severe depression and suicidal behaviour has been documented with interferon treatment. It should be used withcaution in IHD.Pegylated interferon-α2 (peg-IFN) hasemerged as treatment option for patients with myeloproliferative disorders (MPD). In particular, it may be suitable for younger patients and those who are unable to tolerate standard agents. Furthermore, several recent studies have shown that peg-IFN is able to induce molecular remission with undetectable JAK2V617F in a subset of patients with essential thrombocythemia (ET) and polycythemia vera (PV).
Aims: We performed a retrospective review of 15 patients with MPDs who received treatment with peg-IFN with a focus on efficacy and tolerability.
Methods: Of 15 patients treated with peg-IFN, 11 were diagnosed with ET, 3 with PV and one patient had chronic neutrophilic leukaemia (CNL). JAK2V617F mutation was detected in 5 patients (PV 3, ET 2) with 8 patients being negative for this mutation. JAK2 mutation remains unknown in 2 patients who were diagnosed more than 10 years ago. 10 patients were younger than 60 years at the time of treatment.
Results: All patients with PV and 10 patients with ET had excellent response with either reduction in venesections or in platelet counts. In one patient therapy was discontinued due to worsening depressive symptoms. In all other patients IFN-α was well tolerated. The single patient with CNL had stable disease during treatment with no significant reduction in neutrophil count.
In one patient with essential thrombocythemia pregnancy was successfully contemplated with pegylated interferon alpha.
Summary and Conclusions: Peg-IFN is well tolerated and effective in patients with MPD. However, randomised studies and much longer term follow-up will be required to determine the overall tolerability of this agent and whether patients can enter durable molecular remissions.

PB1747

EFFICACY OF PEGYLATED INTERFERON IN ESSENTIAL THROMBOCYTHEMIA: A MONOCENTRIC EXPERIENCE

C Barate [1,*] G Fontanelli[1], E Ciabatti[1,2], A Azzara'[1], G Carulli[1], G Cervetti[1], R Fazzi[1], S Galimberti[1], M Petrini[1]
[1]Department of Clinical and Experimental Medicine, University of Pisa, U.O. Hematology, Pisa, [2]GenOMEC, University of Siena, Siena, Italy

Background: Essential Thrombocythemia (ET) is a clonal myeloproliferative chronic neoplasm: in Europe, its incidence is 0.38-0.6/100000 per year, with a prevalence in the old women subgroup. The molecular markers of disease are

represented by the JAK2V617F mutation, accounting about 50% of patients, by the less frequently detected MPLW515L7K mutation, and by the most recently identified calreticulin gene, that is mutated in about the half of the remaining cases. In young people affected by ET, the Interferon-alpha has showed good tolerance and efficacy, because of its antiapoptotic, anticytokine and anti-inflammatory effects. Recently, also the pegylated formulation showed a good toxicity profile and efficacy, with more than 60% complete responses (CR).
Aims: To assess the safety profile and efficacy of the pegylated interferon in the Essential Thrombocythemia
Methods: Twenty patients with ET received subcutaneous recombinant pegylated-interferon alpha2a (peg-IFN, PEG-INTRON®) at the Hematology Division of Pisa (Italy), from May 2004 to December 2013. The median age at diagnosis was 37 years (range 21-54 years), with an equal gender distribution. The drug was dispensed as off label use, after obtaining the informed written consent. The median weekly dose was 50 ug/week. All patients were also assessed at diagnosis for the JAK2V617F mutation.
Results: Five patients presented a thrombotic event at the time of diagnosis, and only one developed thrombosis during the peg-IFN treatment. Half of cases showed splenomegaly at the first visit; the median value of platelets was 917x 10^3/mmc (range 700-1800x10^3/mmc). With a median follow-up of 58 months, the CR rate was 88%, and in the majority of cases the response had been achieved during the first year of therapy. Early discontinuation of the drug was documented in 13.6% of patients, after a median of five months, due to primary intolerance (itch, skin atrophy in the side of injection, thyroid disfunction). Other four patients have stopped therapy (two female patients for procreation, another one for the hematology toxicity, and one for dysphoria), after a median of 2 years of treatment. A total of 31% of patients definitively discontinued the peg-IFN at the last observation. The efficacy of the peg-IFN is also sustained by the fact that all patients previously received the conventional IFN2b (INTRON A®) for almost one month; for all responders, at the start time of peg-IFN, the median value of platelets was still above the normal level. JAK2 V617V mutation was found at diagnosis in 72% of patients. Data were checked at least one year later during peg-IFN therapy in 12 patients. We observed a reduction in the mutated allele burden in 8/12 cases (66%), and the molecular remission was documented in another patient.
Summary and Conclusions: Recombinant IFN therapy has been shown to suppress megakaryopoiesis, induce cytogenetic remission and also reduce the JAK2V617F allele burden, sometimes completely. Efficacy has been demonstrated in myeloproliferative disease, but toxicities are still frequent and the adverse events often restrict the use of the drug, also in young patients. Changing it with peg-IFN, because of less toxicity, may be a valid alternative. In our patients, peg-IFN were well tolerated and allowed to reach good results in terms of hematological and molecular responses in the large majority. Finally, we observed a significant improvement in the quality of life, consequent to the less iatrogenic side effects and the reduction of the injection frequency for the pegylated formulation.

PB1748

LATE ONSET NON-SYNDROMIC JUVENILE MYELOMONOCYTIC LEUKEMIA WITH PTPN11 MUTATION

N Sarper[1,*] E Zengin[1], S A Gelen[1]
[1]Department of Pediatrics , Kocaeli University, Kocaeli, Turkey

Background: JMML is a rare hematological malignancy of early childhood. Somatic mutations in PTPN11 are the most frequent molecular lesions in patients with JMML.
Aims: Clinical and laboratory features of these patients are rarely reported. Here we report a non-syndromic JMML in a nine-year old patient.
Methods: A nine year-old girl referred to our hematology outpatient unit for mild thrombocytopenia and neutropenia. Initial physical examination was normal and there was no hepatosplenomegaly. After 11 months, she presented with malaise, fever and abdominal enlargement. Liver and spleen were 10 and 11 cm palpable below the costal margins respectively. Laboratory workup revealed anemia, leukocytosis and thrombocytopenia (Hb 9.6 g/dl, WBC 37,900/mm^3, ANC 21800/mm^3, monocyte 1895/ mm^3, PLT 29100/mm^3 and MCV 74 fl). Total bilirubine was 3.3 mg/dL, direct bilirubine 1 mg/dL, haptoglobin 8 mg/dL and HbF was 18%. Peripheral blood smear, showed basophylic stippling, cabot rings, polychromasia, anisocytosis and megaloblastic changes in red blood cells. There were large platelets, some lobulation defects in neutrophyl nuclei, and large basophylic granules in some lymphocytes. Nucleated cells showed 22% band, 22% lymphocyte, 21% neutrophyl, 9% normoblast, 9% erythroblast, 7% myeloblast, 5% monocyte, 1% metamyelocyte, 3% eosinophyl, 3% basophyl, and 1% promyelocyte. Repeated bone marrow smear showed hypercellularity, no megakaryocytes. Erythroid/myeloid ratio was 40/1. Almost all cells were erythroblast and normoblasts. Very few promyelocytes, lymphocytes and neutrophyls were seen. There was 85% celularity in marrow biopsy, megacaryocytes were normal in morphology and number. There was erythroid hyperplasia with increased glycophorin positive young cells. Granulocytic series were only seen in patchy areas and showed maturation and eosinophylic predominance. Monocytes were increased, erythroid/myeloid ratio was 2/1, 3/1 and there were no collagen fibers and hemosiderin. Cytogenetic analysis in 30 methaphases showed 46,XX [8]/46,XX,del (8q)[6]/45,XX,-8[16]. In FISH analysis 7.5% of interphase cells showed monosomy/deletion with 8q22 probe. After only one week, she had fever, tachypnea, tachycardia and edema in her legs. Hb was 7.2 g/dL, WBC 6360/mm^3, ANC1440/mm^3 and PLT 34,900/mm^3. Reticulocyte count was 49,000/mm^3. No chemotherapy was administered due to uncertainty in diagnosis. Piperasillin/tazobactam and supportive therapy with packed red cell and platelets and nasal oxygen were administered. She died with respiratory failure. Genetic study was completed after her death.
Results: DNA analysis performed from bone marrow sample, revealed a heterozygous mutation in the PTPN11 gene, exon 13 c.1508 G>T, aminoacid p.503 G>V. In her past medical history she was hospitalized when she was five-year-old due to multiple liver abcess and pulmonary empyema. *S aureus* was isolated from liver abcess and pleural effusion samples. No immunodeficiency could be defined by laboratory investigations.
Summary and Conclusions: Non-syndromic JMML with PTPN11 mutation can be seen in patients older than 5 years. A cytopenic phase may precede JMML. Leucocytosis may be transient and there may be erythroid predominance in the bone marrow. PTPN11 mutation may cause immune disregulation.
Acknowledgement: Thanks Prof.C.M.Niemeyer and EWOG-MDS for genetic study.

CYCLIC THROMBOCYTOSIS IN A PATIENT WITH PV RESOLVED BY RUXOLITINIB TREATMENT

DL Kämpfe[1,*] J Friemann[2], T Haverkamp[3], S Killburger[4], B Schulte[5], HL Pahl[6]
[1]Praxis für Hämatologie/Onkologie*Palliativmedizin Lüdenscheid, [2]Institut für Pathologie, Klinikum, Lüdenscheid, [3]Laboratoriumsmedizin, MVZ Dr. Eberhard & Partner, Dortmund, [4]Gemeinschaftspraxis Dr. med. Silke und Jürgen Killburger, Schalksmühle, [5]Institut für Hämatopathologie, Hamburg, [6]Sektion Molekulare Hämatologie, Klinik für Innere Medizin I, Universitätsklinikum Freiburg , Freiburg, Germany

Background: Cyclic thrombocytosis is a seldomly described and poorly understood phenomenon that occurs in conjunction with some congenital or acquired disorders.
Aims: We report two female patients with a long history of polycythemia vera (PV). A cyclic undulation of thrombocytes was observed in these patients following several years of treatment with hydroxyurea (HU).
Methods: Both patients belong to our single center register, with includes 191 MPN patients with 1163 patient-years of follow up treated in the medical practice Lüdenscheid. Of these, 138 patients were treated with HU, for which 558 years of follow-up are available.
Patient 1 is a 74 year old female, diagnosed with PV in 1987 at the age of 47. She was initially treated with two doses of ^{32}P in the year of her diagnosis. Following a wait and watch period, HU therapy was initiated in 1997 because of a global rise in blood cell counts. In 2013 clinical progression was noted, consisting of elevated LDH and progressive splenomegaly. A bone marrow biopsy revelaed fibrosis and ruxolitinib treatment was initiated in January 2014.
Patient 2 is a 70-year old female diagnosed with PV in 2006, at the age of 62. HU therapy was begun immediately upon diagnosis. Because of clinical progression, again manifested by elevated LDH, splenomegaly and progressive fibrosis in the bone marrow ruxolitinib treatment was started in the fall of 2013.
Results: Undulating platelet counts were noted in patient 1 in 2009, 22 years after diagnosis and in patient 2 in 2013, 7 years after diagnosis. The period of undulation was approximately 28 days in both patients, with thrombocyte counts ranging from 50 to 1350 x 10^9/l. Leukocyte counts varied concordantly but the undulation was less pronounced. No complications (thrombosis, bleeding) were observed. Both patients carry a $JAK2^{V617F}$ as well as a TET-2-mutation. Ruxolitinib promptly abolished platelet undulation and resolved the aquagenic pruritus in patient 2.
Summary and Conclusions: This is the first report of a resolution of undulating platelets following ruxolitinib treatment. Platelet undulation has previously been reported as a rare, often benign observation in some patients with PV, predominantly females. As HU treatment is common in PV and the co-occurrence of $JAK2^{V671F}$ and a TET2 mutation are far more frequent than undulating platelets, it is unlikely that either fact contribute to this poorly understood phenomenon, which appears amenable to treatment with ruxolitinib.

PB1750

IN PATIENTS WITH POLYCYTHEMIA VERA OLDER AGE IS THE PROGNOSTIC FACTOR AT HIGHEST IMPACT ON SURVIVAL

G Benevolo[1,*] B Nicolino[1], E Crisà[2], P Pregno[1], A Evangelista[3], F Pirillo[1], S D'Antico[4], A Pich[5], D Ferrero[2], U Vitolo[1]
[1]SC Hematology, [2]SC Hematology-U, [3]Unit of Clinical Epidemiology and CPO Piemonte, [4]Struttura Complessa Banca del Sangue CPVE, [5]Anatomia Patologica Generale e Oncogenetica Molecolare-U, Città della Salute e della Scienza Hospital and University, Torino, Italy

Background: Life expectancy of Polycythemia Vera (PV) patients is reduced compared with that of the general population mainly due to thrombotic events and evolution into myelofibrotic phase or secondary myelodisplasia/acute leukemia. Recently, in a large study published by IWG-MRT (Tefferi et al, Leukemia 2013) authors developed a widely applicable prognostic model, delineating three different prognostic risk groups by age, leukocyte count and venous thrombosis.
Aims: In this study we tested the IWG-MRT prognostic score in a retrospective group of 204 World Health Organization-defined PV patients, diagnosed from 1974 to 2013 by a single Italian haematological centre (Turin).
Methods: We analysed 204 PV patients. According to the IWG-MRT score, patients were divided into three groups: adverse points are assigned to age ≥67 years (5 points), age 57–66 years (2 points), leukocyte count ≥15 x109/l (1 point) and venous thrombosis (1 point). In this way patients were divided in low-risk (0 points), intermediate-risk (1 or 2 points) and high-risk (≥3 points) groups. We evaluated overall survival (OS) from diagnosis to death by the Kaplan Meyer method and Hazard Ratio were estimated with the Cox Models. The cumulative incidence of death due to PD was estimated by the method proposed by Gooley et al, accounting for competing events.
Results: Characteristics at diagnosis were as follows: median age was 65 years (31% were below age 57 years), 104 (51%) were male, constitutional symptoms and palpable splenomegaly were observed in 42 (21%) and 36 (18%) patients, respectively. Twenty-one (10%) patients showed leukocytosis (≥15 x 109/L) whereas thrombocytosis (≥450 x 109/L) was present in 77 (38%) patients. Fifty-three patients had prevoius thrombotic events (40 arterious and 13 venous). As expected, approximately 58% of the patients were positive for JAK2 mutations (V617F or exon12). At a median follow-up of 93 months we observed 27 (13%) deaths, 26 (13%) myelofibrotic transformations and 7 (3%) leukemic evolution. The incidence of post diagnosis thrombosis arterial *vs* venous and major hemorrage were 15%, 11% and 9% respectively The overall survival at 10 years was 85.3% (95%CI:77.6-90.5) and the cumulative incidence of death due to PD (leukemic transformation or evolution in myelofibrosis) adjusted for competitive risk event was 9.8% (95%IC: 4.5-15.0). The prognostic model displayed discrimination between high-risk (n= 91; 10-year survival 68.3%; *vs* low-risk HR 8.48; 95%CI: 1.94-37.16), intermediate-risk (n= 49; 10-year survival 94.7%; *vs* low-risk HR 3.23; 95%CI: 0.62-16.68) and low-risk (n=42; 10-year survival 100%) patient groups. The C-statistic was 0.751. Age was the prognostic factor at highest impact on OS (fig.1); when we consider the older age as a only prognostic factor the discrimination between risk group was similar to those defined by IWG-MRT. The C-statistic was 0.748.

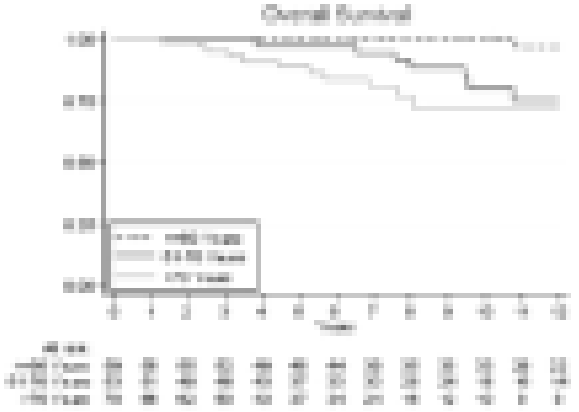

Figure 1.

Summary and Conclusions: In a retrospective cohort of PV patients, IWG-MRT prognostic score was confirmed as a good predictor of survival and prognosis. Older age was described with the prognostic factor at highest impact on OS.

PB1751

CLINICAL STUDY OF SRSF2 MUTATION IN CHINESE WITH CHRONIC MYELOMONOCYTIC LEUKEMIA

C Sun[1,*] S Zhang[2], X Yang[2], J Li[2]
[1]Department of Hematology, Wuxi People Hospital Affiliated of Nanjing Medical University, , Wuxi, [2]Department of Hematology, The First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, Nanjing, China

Background: Recently, spliceosome mutations have been identified in myeloid malignance. SRSF2, as one of components of the splicing machinery, has a high mutation frequency in chronic myelomonocytic leukemia (CMML) according to previous reports. However, little is known of it in Chinese people.
Aims: In our study, we enrolled 38 Chinese patients with CMML and analyzed the status of SRSF2 mutations and their clinical features.
Methods: 38 patients with CMML were recruited from department of hematology in Jiangsu province hospital and Wuxi people hospital bwtween 2012-01 and 2013-12. The diagnoses of all of them and acute myeloid leukemia(AML) transformation were according to the criteria of WHO 2008 classification. We analyze the state of SRSF2 and clinical features(age, sex, karyotype,peripheral blood count) by polymerase chain reaction (PCR) followed by direct sequencing.
Results: 8 of 38 patients(21%) existed SRSF2 mutations, including 4 P95R, 295H and 2P95L point mutations. No significantly statistical differences were observed with regard to their clinical characteristics such as sex, preipheral blood count and karyotype between mutant and wildtype group except age. 1 case with mutation had a early evolution to AML.
Summary and Conclusions: We conclude that SRSF2 mutation probably has a low frequency in Chinese patients with CMML and might be related to old age and unfavorable prognosis. It might be a potentially valuable diagnostic maker and therapeutic target in CMML.

PB1752

NOVEL QUANTITATIVE BEAD-BASED SUSPENSION ASSAY FOR DETECTION OF DNMT3A R882 MUTATIONS USING BNA(NC)-MODIFIED PROBES

V Shivarov[1,*] M Ivanova[2], E Naumova[2]
[1]National Hematology Hospital, [2]Medical University, Sofia, Bulgaria

Background: Somatic mutations in the human DNA methyl transferase 3A (*DNMT3A*) gene are found in a number of myeloid malignancies such as Philadelphia chromosome-negative myeloproliferative neoplasms (MPN), myelodysplastic syndromes (MDS). and acute myeloid leukemia (AML). They have been shown to confer worse prognosis in most of these entities. Notably, about 2/3 of these mutations are missense mutations in codon R882 of the gene. The identification of these mutations is gaining a wider recognition in the field of clinical hematology as part of the integrated molecular profiling of myeloid malignancies.
Aims: We aimed at the development and validation of a novel easily applicable in routine practice method for quantitation of the *DNMT3A* R882C/H/R/S mutant alleles using a bead-based suspension assay.
Results: We initially tested the performance of two sets of beads carrying specific hybridization probes. One set of the beads carried LNA-modified probes while the other set carried BNA(NC)-modified hybridization probes. Initial testing on plasmid constructs showed a better performance of the BNA(NC)-modified probes with an optimal hybridization temperature of 66°C. The method was further validated on the plasmid standards at different ratios between the wild type and mutant alleles and clinical samples from 120 patients with known or suspected myeloid malignancies. The method appeared to be quantitative and showed sensitivity of 2.5% for all mutant alleles, making it significantly superior to direct sequencing.
Summary and Conclusions: This is the first report on the detection of DNMT3A R882 mutations using bead-based suspension assay with LNA/BNA-modified probes. Our data showed that it could be successfully implemented in the diagnostic work-up for patients with myeloid malignancies, as it is rapid, easy and reliable in terms of specificity and sensitivity. Besides, coupling of the assay with techniques for mutations enrichment (*e.g.* COLD-PCR) or fluorescent signal enhancement can make it useful even for quantitative assessment of MRD.
Acknowledgements: This work is supported financially by Project ID_09_157 (Contract 5/16.12.2009) from the National Science Fund, Bulgaria. The authors are thankful to Dr. Nina Petkova and Dr. Evguenyi Hadjiev for providing the clinical samples.

DIABETES MELLITUS TYPE 2 AT DIAGNOSIS OF PRIMARY MYELOFIBROSIS AFFECTS THE PATIENT OVERALL SURVIVAL

G Sorriento[1,*] N Cenfra[1], A Andriani[2], M Cedrone[3], I Majolino[4], E Montefusco[5], M Breccia[1], R Latagliata[1], G Alimena[1], G Cimino[1,6]
[1]Department of Cellular Biotechnology and Hematology, University of Rome "Sapienza", [2]Department of Hematology, Nuovo Regina Margherita Hospital, [3]Department of Hematology, S.Giovanni Addolorata Hospital, [4]Department of Hematology, S. Camillo Hospital, [5]Department of Hematology, S. Andrea Hospital, Rome, [6]Hematology unit (2U) ICOT/S. Maria Goretti Hospital, AUSL, Latina, Italy

Background: Many evidences suggest that diabetes mellitus 2 (DM2) increases the risk and the mortality of several type of solid cancers. These findings are still debated in hematologic tumors, including Ph-negative myeloproliferative neoplasms (MPNs).

Aims: In the present study we aimed to evaluate whether DM2 affected the clinical outcome of 230 patients with primary myelofibrosis (PMF).
Methods: All the 230 PMF patients were diagnosed and followed in the Latium region (Italy) between 1981 and 2010. Diagnosis of PMF was made according to the criteria accepted at the time the patients were seen. Patients with a PMF following polycythemia vera or essential thrombocythemia were excluded. DM2 was defined as a fasting glucose level >126 mg/dL or a postprandial glucose level >200 mg/dL. Therapy for PMF was variable and reflected the disease individual characteristics and the therapeutic strategies adopted by single Institutions at the time of PMF diagnosis. During the patient follow-up we recorded the occurrence of thrombotic events and leukemic transformations (LT), defined as the appearance of 20% blast cells in peripheral blood and/or in bone marrow.
Results: At diagnosis of PMF, 44 of the 230 patients (19.1%) had DM2. Except for a platelet count that was significantly lower in the diabetic than in non-diabetic patients (333.53 x10^9/L *vs* 443.25 x10^9/L, P=.047), no other considered clinic-biologic features differed between the two studied groups. However, the 10 year overall survival rates and the median survival time in non–diabetic and diabetic patients were 37.1% *vs* 12.6%, and 101 (95% CI: 81-121) *vs* 52 (95% CI: 33-70) months, respectively (p=.0009). At the multivariate analysis DM2, older age, anemia and leukocytosis resulted the only independent prognostic factors affecting patient survival. Thrombosis and leukemia free survival rates were similar in either patient groups (Figure 1).

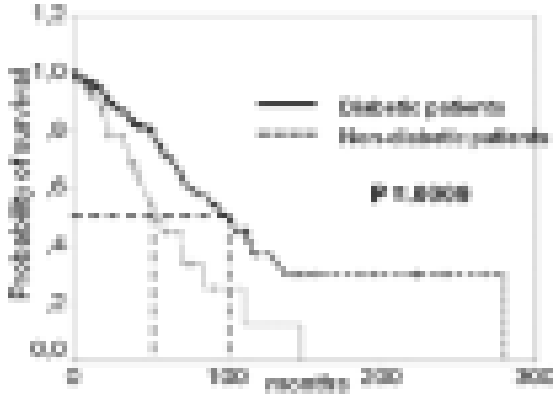

Figure 1. Probability of overall survival in PMF diabetic and non-diabetic patients.

Summary and Conclusions: The retrospective nature of our study did not allow to clarify whether DM2 would affect the probability of survival by acting on the progression of the disease or by promoting fatal events independently by PMF. However, our data still recommend to explore the possible pathogenic link between DM2, inflammation and Ph-MPNs and to be extremely careful to the diagnosis and the treatment of DM2, even increasing in this patient setting the use of metformina, an insulin sensitizers with proven anticancer activities.

BRENTUXIMAB VEDOTIN FOR RELAPSED OR REFRACTORY HODGKIN LYMPHOMA: EXPERIENCE IN TURKEY

B Ferhanoglu[1,*] A Salihoglu[2], T Elverdi[2], I Karadogan[3], E Ozdemir[4], G Erdem[5], N Karadurmus[6], G Akyol[7], L Kaynar[7], A Yegin[8], G Sucak[8], V Ozkocaman[9], P Topcuoglu[10], M Ozcan[10], E Birtas[11], H Goker[1,2], Z Baslar[2], S Paydas[1,3]
[1]Internal Medicine/Hematology, Koc University, [2]Internal Medicine/Hematology, Istanbul University Cerrahpasa Medical Faculty, Istanbul, [3]Internal Medicine/Hematology, Medstar Hospital, Antalya, [4]Stem Cell Transplantation Unit, Institute of Oncology, [5]Internal Medicine/Medical Oncology, 5-Gulhane Military Medical Academy, [6]Internal Medicine/Medical Oncology, Gulhane Military Medical Academy, Ankara, [7]Internal Medicine/Hematology, Kayseri Erciyes University, Kayseri, [8]Internal Medicine/Hematology, Gazi University, Ankara, [9]Internal Medicine/Hematology, Uludag University, Bursa, [10]Internal Medicine/Hematology, Ankara University Medical Faculty, Ankara, [11]Internal Medicine/Hematology, Kocaeli University Medical Faculty, Kocaeli, [12]Internal Medicine/Hematology, Hacettepe University Medical Faculty, Ankara, [13]Internal Medicine/Hematology, Cukurova University Medical Faculty, Adana, Turkey

Background: Current treatment modalities can cure up to 70-80% of patients with classical Hodgkin lymphoma (cHL) and 20-30% of patients require further treatment options. Brentuximab vedotin (BV) is an antibody-drug conjugate showing an impressive activity against relapsed/refractory cHL.
Aims: In this study we aimed to assess the efficacy and safety of BV and help determination of its best role and timing.
Methods: Eleven Turkish institutions participated in this multicenter, retrospective study. Eligible patients were required to be treated with at least two courses of BV without any limitations regarding performance status and organ function. The primary endpoint of the study was the objective response rate (ORR), secondary endpoints were safety, overall survival (OS) and progression free survival (PFS). Response was assessed by PET/CT or CT early during disease course after 2-5 cycles and after ≥ 6 cycles. Analysis of the data was carried out using STATA 11.1 SE software. All patients provided written informed consent.
Results: 58 patients treated from March 2011 to July 2013 were included. Demographics and baseline disease characteristics are summarized in Table 1. In total a median of 7 (range, 2-18) courses of BV were given as a single agent. Relative dose intensity was calculated as 81.56%. ORR of 63.5% with 26.5% complete remission (CR) was achieved at early assessment. Response assessment at ≥6 cycles showed an ORR of 32.4%. PFS at 12 months was 32.83% (95% CI, 19.74%>46.56%) and the median PFS was 7 months (95% CI, 4.81%>11.27%). Forty-four patients were alive at the time of data analysis. OS at 12 months was 70.58% (95% CI, 54.37%>81.94%) and the median OS has not been reached yet. Twelve patients had been treated with 3 or less previous chemotherapy regimens before BV and half of the patients achieved CR. CR rates in patients treated with >3 chemotherapy regimens before BV are significantly lower (p=0.016). Fourteen patients proceeded to transplantation (7 allogeneic, 5 haploidentical and 2 autologous transplantation) among whom 85% were alive. In general the treatment was well tolerated with dose reduction necessary in 5 patients (3 due to cytopenias, 1 peripheral neuropathy, 1 unknown). The most common (≥ 10%) adverse events were fatigue, nausea, neuropathy, neutropenia, vomiting, myalgia, alopecia and extremity pain. Two patients from different centers suffered from generalized tonic convulsions one of whom was on renal replacement therapy. Convulsions occurred after 5 and 2 cycles of BV treatment. Since drug induced neurotoxicity could not be excluded, BV was stopped in both patients.

Table 1. Patient demographics and disease characteristics.

Summary and Conclusions: In general treatment was well tolerated and toxicities were generally grade 1 and 2 in severity. As might be expected patients with less prior chemotherapy regimens had better CR rates compared with more heavily pretreated patients (p=0.016). Our study indicates that best responses to BV are observed early during the treatment course. Since best results are obtained with chemosensitive disease and minimal tumor burden both in autologous and allogeneic stem cell transplantation, transplantation should be considered earlier during BV treatment when best responses are achieved.

PB1755

AN ADDITIONAL POINT TO CONFIRM A REMISSION IN HODGKIN'S LYMPHOMA

V Misyurin[1,*] A Misyurin[1], A Lukina[2], D Marin [2], N Sharkunov [2], E Dubrovin [2], L Plastinina[2], S Kravchenko[2], A Baryshnikov[1]
[1]Federal State Budgetary Institution "N.N.Blokhin Russian Cancer Research Center" under the Russian Academy of Medical Sciences, [2]FSBI Hematological Research Center, Moscow, Russian Federation

Background: In recent years in the treatment of Hodgkin's lymphoma was achieved a considerable success. Nevertheless, in patients with large tumor mass in the onset of the disease, mediastinum involvement, a residual tissue after the end of therapy makes it necessary to clarify remission. We believe that determining an expression profile of cancer-testis genes (CTG) could help with it. These genes are expressed in germinal cells and tumor cells only.
Aims: To analyze CTG expression profile in biological samples of primary Hodgkin's lymphoma patients and compare this data with expression profile after an achieving of a complete remission (CR).
Methods: Peripheral blood (PB) and lymph nodes (LN) from 27 primary patients with Hodgkin's lymphoma were examined using RQ PCR to evaluate mRNA expression levels of CTG *GAGE1*, *NY-ESO-1*,*MAGEA1*, *PASD1*, *SCP-1*, *SEMG1*, *SPANXA1*,*SSX1* and *PRAME* in comparison with *ABL*expression level. The group of patients consisted of 12 men and 15 women. Median age was 36 y.o. Majority of patients had advanced stage of disease according Ann-Arbor classification, mediastinum involvement (20/27). All patients were treated according to the protocol BEACOPP-14. Also we examined a CTG expression profile in a PB of 7 patients after therapy. We PB samples of 15 healthy donors and 5 reactive lymph nodes were as a negative control.
Results: In PB of primary Hodgkin's lymphoma patients we observed an expression of *GAGE1* (2/27, 7%), *NY-ESO-1* (6/27, 22%), *PASD1* (2/27, 7%), *SEMG1* (12/27, 44%), *SPANXA1* (3/27, 11%), *SSX1* (6/27, 22%) and *PRAME* (4/27, 15%) in different levels. For example, median value for *GAGE1* was 1%; *NY-ESO-1* - 0,2%; *PASD1* - 0,3%; *SEMG1* - 11%; *SPANXA1* - 1,7%; *SSX1* - 0,1% and *PRAME* - 0,06%. We didn't observe an expression of *MAGEA1* and *SCP-1* in PB samples. We revealed an expression of *GAGE1* (2/27, 7%), *NY-ESO-1* (6/27, 22%), *MAGEA1* (2/27, 7%), *PASD1* (4/27, 15%), *SCP-1* (1/27, 4%), *SEMG1* (5/27, 27%), *SPANXA1* (4/27, 15%), *SSX1* (2/27, 7%) and *PRAME* (17/27, 63%) in a LN samples. Neither of analyzed CTG wasn't expressed in a PB of 7 patients after therapy has been finished.There wasn't any CTG expression in a control samples.
Summary and Conclusions: A CTG expression in a PB indicated that the tumor cells could circulate between healthy cells. A lack of these genes expression confirms the success of the therapy and can support a remission achievement.

PB1756

EVALUATION OF BONE MARROW INVOLVEMENT IN PATIENTS WITH LYMPHOMA: F-18 FDG PET/CT VERSUS BONE MARROW BIOPSY

F Aydin[1], O Salim[2], O K Yucel[2], D Ekinci[2], T Toptas[3], F Gungor[1], A Boz[1], A Yildiz[1], B Akkaya[4,*] L Undar[2]
[1]Nuclear Medicine, [2]Hematology Dept., Akdeniz University School of Medicine, Antalya, [3]Hematology Dept., Van Teaching Hospital, Van, [4]Pathology Dept., Akdeniz University School of Medicine, Antalya, Turkey

Background: The evaluation of bone marrow infiltration (BMI) is of crucial importance in the staging of lymphoma. Although bone marrow biopsy (BMB) is the reference method for the evaluation of BMI, it has limitations (e.g taken from a single field, invasiveness).
Aims: The aim of this study was to assess the performance of 2-deoxy-2-[18F]fluoro-D-glucose (18F-FDG) PET/CT against bone marrow biopsy (BMB) in the initial diagnosis of bone marrow infiltration (BMI) in patients with Hodgkin's Lymphoma (HL) and Non-Hodgkin's Lymphoma (NHL), retrospectively. Newly diagnosed 172 consecutive patients (50 female, 122 male; 64 HL, 108 NHL) who were referred to our department between July 2009 and December 2013 were included in this study. All patients were examined by whole-body 18F-FDG PET/CT scan for initial staging. Evaluation of BM with PET/CT scan was done visually and semi-quantitatively. The maximum standard uptake value (SUVmax) was used as quantitative parameters in the evaluation of PET/CT. PET/CT was considered positive for BMI in cases of uni-or multifocal bone marrow (18)F-FDG uptake that could not be explained by benign findings on the underlying CT image or history. A final diagnosis of BMI was considered if the BMB was positive.
Methods: Newly diagnosed 172 consecutive patients (50 female, 122 male; 64 HL, 108 NHL) who were referred to our department between July 2009 and December 2013 were included in this study. All patients were examined by whole-body 18F-FDG PET/CT scan for initial staging. Evaluation of BM with PET/CT scan was done visually and semi-quantitatively. The maximum standard uptake value (SUVmax) was used as quantitative parameters in the evaluation of PET/CT. PET/CT was considered positive for BMI in cases of uni-or multifocal bone marrow (18)F-FDG uptake that could not be explained by benign findings on the underlying CT image or history. A final diagnosis of BMI was considered if the BMB was positive.
Results: For all cases, in visual assessment for BMI with PET/CT, sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were 31%, 85%, 39% and 79%, respectively. In subgroup analysis sensitivity, specificity, PPV and NPV were; 80%, 78%, 24%, 98% in HL patients and 24%, 90%, 56%, 70% in NHL patients, respectively. In semi-quantitative evaluation, when the SUV max was set as 4 in HL, the sensitivity was 80% and the specificity was 68%. When the SUVmax was set as 3,2 in NHL the sensitivity was 65% and the specificity was 58%.
Summary and Conclusions: Currently, BMB is recommended for the detection of BMI in lymphoma. However PET/CT imaging is more valuable than BMB for the initial staging of the lymphoma. PET/CT detects more BM involvement in HL and NHL compared with BMB. Thus it can be also used as a complementary technique to determine the biopsy site for BMB.

PB1757

TAILORED THERAPY FOR ADVANCED-STAGE HODGKIN LYMPHOMA, GUIDED BY INTERIM 18FDG-PET, WITH BEACOPP-ESCALATED FOLLOWED BY ABVD REGIMEN DECREASES REFRACTORY DISEASE RATES

E Amutio[1,*] R A Del Orbe[1], I Amarika[1], E Landeta[1], M E Zamora[1], M Puente[1], AM Iglesias-Pérez[1], I Olazabal[1], M Dueñas[1], A Balerdi[1], L Elicegui[1], S Arambarri[1], JC García-Ruiz[1]
[1]Hematology, Hospital Universitario Cruces/BioCruces Health Research Institute., Barakaldo, Spain

Background: Hodgkin lymphoma has become a curable disease with the introduction of ABVD regimen (Doxorubicin, Bleomycin, Vinblastine and Dacarbazine), but some patients (pt) with advanced-stage Hodgkin Lymphoma (adv-HL) go through insufficient results: 15-20% of total behave as primary refractory, 20-30% undergo early and long-term relapses and 60-65% of freedom for treatment failure at 5 years. It means that 30%>40% of adv-HL pt treated with ABVD will experience treatment failure after first-line treatment, and will require salvage autologous stem-cell transplantation (ASCT) in most cases. The German Hodgkin Study Group developed a more intensive regimen for treatment of adv-HL consisting of Bleomycin, Etoposide, Doxorubicin, Cyclophosphamide, Vincristine, Procarbazine, and Prednisone (BEACOPP). An escalated dose variant, BEACOPP escalated (BEACOPP-esc) was studied in the HD9 trial, where it showed 86% of freedom for treatment failure at 10 years. However, BEACOPP-esc was more toxic than the other regimens.
Aims: Developing a tailored treatment BEACOPP-esc and ABVD-based guided by interim ^{18}FDG-PET (PET) in adv-HL, to try decreasing primary refractoriness to first-line treatment with least toxicity.
Methods: We defined adv-HL as stages IIB, III and IV, and International Prognosis Score (IPS) was used to stratify pt into intermediate risk (0-3) and high risk (4-7) of relapse. It was regarded classic treatment as ABVD regimen for 6-8 cycles followed by radiotherapy (RT) over bulky areas (especially mediastinal masses). Since July 2011, we changed therapy for adv-HL to that we named tailored regimen: BEACOPP-esc for two (IPS 0-3) or four cycles (IPS 4-7) followed by early response evaluation with interim PET. Patients with negative-PET, therapy was deescalated to ABVD for 4 cycles and RT was finally indicated over initial bulky areas or residual areas with positive-PET.
We analyzed retrospectively 33 consecutive adult pt with classic adv-HD treated since November 2008 until July 2013. Median age was 38 years [16-62]. Fourteen pt received the classic treatment (group 1) and 19 pt were treated with the tailored regimen (group 2). Pt older than 65 years were excluded because were uniformly treated with COPP (Cyclophosphamide, Vincristine, Procarbazine and Prednisone).
Results: After a median follow-up time of 24 months, we observed the results that are expressed in the Table 1. Twenty-one percent (3/14) of primary refractoriness and 21% of relapses was observed in Group 1, while only 1 refractory patient (1/19, 5%) was present in Group 2 with no relapses; there were not statistically significant differences because of the small number of patients in each group. Fifty-seven percent of relapsed/refractory pt were

underwent to ASCT, being successfully only in 50% of them. Acute toxicity was manageable, but the follow-up is not enough to describe deleterious late effects as secondary malignancies.

Table 1.

Summary and Conclusions: ABVD treatment is insufficient in terms of control of the disease in adv-HL, with a high rate of relapse and primary refractoriness, which only can be rescued with ASCT in half of cases. Initial treatment with BEACOPP-esc, guided by an early response evaluation with PET to deescalate therapy intensity to ABVD in responders allowed us reducing the rate of primary refractoriness to 5%, with no relapse. Based in our results, we propose this therapeutic strategy in pt with adv-HL.

PB1758

BONE MARROW INVOLVEMENT IN HODGKIN LYMPHOMA: CAN 18F-FDG PET/CT REPLACE TRADITIONAL BIOPSY?

S Lakhwani[1,*] D Cabello-García[2], C de Bonis[1], S Iraheta[1], A Martín[1], M Fernández-González[1], C Stoica[1], MT Hernández[1], L Hernández-Nieto[1], JM Raya[1]
[1]Hematology, Hospital Universitario de Canarias, [2]Nuclear Medicine, Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, Spain

Background: The bone marrow biopsy (BMB) in iliac crest, either unilateral or bilateral, is the standard method for detecting marrow involvement in Hodgkin lymphoma (HL). However, involvement use to be infrequent (5-14%) and mainly focal, reasons why some authors consider this procedure unprofitable. Moreover, ^{18}F-FDG (fluorodeoxyglucose-^{18}Fluor) is very rapidly absorbed by this type of lymphoma.
Aims: Our goal is to compare the BMB and ^{18}F-FDG PET/CT to detect marrow involvement in patients with HL, and to analyze the impact of this new technique in the staging and clinical management of the disease.
Methods: We retrospectively analyzed a total of 65 HL patients in which ^{18}F-FDG PET/CT and unilateral BMB was performed at initial staging or relapse. Clinical and biological parameters were recorded, together with the results of both procedures. We also analyzed those patients in whom the ^{18}F-FDG PET/CT caused a change in stage or a modification in treatment, when compared with the diagnostic combination of BMB plus CT.
Results: The 65 HL patients included 36 men and 29 women, mean age 37 years (range 13-76). Marrow involvement was detected by either of the two techniques in 23% (15/65) of patients: BMB was positive in 3/15 cases, while the ^{18}F-FDG PET/CT showed marrow disease in 15/15 cases. The 3 patients with positive BMB showed diffuse pattern of marrow involvement by ^{18}F-FDG PET/CT adding multifocal involvement in 2 of them. Of the 12 marrow-affected cases by ^{18}F-FDG PET/CT but negative by BMB, 6 had a multifocal pattern, 4 unifocal, one diffuse pattern without focal lesion, and one diffuse and multifocal. None of the cases with focal pattern had involvement in the iliac crest. In a case with unifocal rib lesion, directed biopsy confirmed marrow involvement. Forty of the 65 patients had a concomitant CT and in this group the ^{18}F-FDG PET/CT led to a change in staging in 15 cases (37%), always towards a more advanced stage. Finally, in 8 of these 15 patients, this change in disease stage was also associated to a change in the therapeutic approach, always towards a more aggressive treatment.
Summary and Conclusions: Although these data should be confirmed in larger series of patients, we have not found any diagnostic benefit of BMB over ^{18}F-FDG PET/CT in HL staging. Our results are consistent with those reported in the literature, showing all the series a greater sensitivity for 18F-FDG PET/CT in the diagnosis of bone marrow involvement, when compared with BMB. This increased sensitivity is probably related to the intense avidity of HL to ^{18}F-FDG of LH and to the higher frequency of patchy (instead of diffuse) marrow involvement. Directed biopsy to specific accumulation of ^{18}F-FDG may help to investigate the possibility of false positive cases.

PB1759

TREATMENTS AND CLINICAL BURDEN AMONG HODGKIN LYMPHOMA PATIENTS AT HIGH RISK OF RELAPSE AFTER AUTOLOGOUS STEM CELL TRANSPLANT: A LITERATURE REVIEW

V Bonthapally[1,*] R Ayyagari[2], H Yang[2], E Q Wu[2], O Shonukan[1]
[1]Millennium: The Takeda Oncology Company, Cambridge, MA, [2]Analysis Group Inc., Boston, MA, United States

Background: Hodgkin lymphoma (HL) patients with certain clinical characteristics such as refractory, relapsed, or progressive HL, extranodal involvement, or B symptoms are at high risk of relapse after receiving an autologous stem cell transplant (ASCT).
Aims: To conduct a literature review of the treatments and clinical outcomes among patients with HL at high risk of relapse after ASCT.
Methods: A literature review was conducted (search period: January, 1993 to December, 2013) to identify publications of randomized or observational studies that included HL patients who had received adjuvant therapy after ASCT and before relapse, and reported characteristics and outcomes in this subgroup of patients. Patient demographics, disease characteristics, prognostic factors, adjuvant therapies, and clinical outcomes were extracted from the full text of the identified studies.
Results: Of the 147 studies retrieved, 15 (9 prospective and 6 retrospective) studies met the inclusion criteria. The prognostic factors reported varied across studies. Most studies reported proportions of patients bearing a certain risk factor, but not overall proportions of high-risk patients. No studies included only high-risk patients. Reporting of key trial and patient characteristics was variable, with ranges as follows: sample size, n=13–245; patients' median age, 15–44 years;% male, 39%–69%; history of refractory HL, 15%–61%; relapsed/progressive HL, 13%–69%; extranodal involvement, 34%–54%; and B symptoms, 11%–85%. Adjuvant therapy use varied from 3% to 100%; the most common adjuvant therapies used included radiotherapy, tandem ASCT, and chemotherapy. No universal post-ASCT or pre-relapse standard of care was mentioned in the included studies. Clinical remission rates and survival were reported for overall study populations rather than for the high-risk population. Complete response rates after ASCT ranged from 71% to 92%, while 3-year survival ranged from 55% to 75%.
Summary and Conclusions: While factors prognostic for post-ASCT HL relapse are known, patients at high risk of relapse following ASCT are not a well-defined population in the literature. Although several studies suggest that patients with specific prognostic factors suffer from a higher clinical burden than those patients without the respective risk factors, no established guidelines exist for the treatment of such HL patients at high risk of relapse. Data on the efficacy of adjuvant treatments are sparse and come from subgroup analyses in a small set of non-randomized studies. Randomized studies in this population will be critical to establish effective adjuvant therapies and address this unmet need.

PB1760

SALVAGE TREATMENT WITH SINGLE-AGENT BENDAMUSTINE FOR RELAPSED/REFRACTORY HODGKIN LYMPHOMA: AN ITALIAN MONOCENTRIC EXPERIENCE

G Ricciuti[1,*] E Finolezzi[1], S Falorio[1], S Luciani[1], E Ranucci[1], F Angrilli[1]
[1]Department of Hematology, Civic Hospital Spirito Santo Pescara, Pescara, Italy

Background: The prognosis of patients (pts) with Hodgkin lymphoma (HL) who had multiple relapses or refractory disease remains poor. In transplant-ineligible pts and post-autologous stem cell transplantation (ASCT) recurrences, a standard treatment doesn't exist and allogeneic SCT can achieve a long-term disease free survival only in selected pts. However, some novel agents with promising single-agent activity, including bendamustine, has lately emerged.
Aims: To evaluate the safety and efficacy of bendamustine in advanced HL.
Methods: We retrospectively evaluate our experience on relapsed/refractory HL pts who received single-agent bendamustine at the dose of 120 mg/m2 every 21-28 days.
Results: From 2/2010 to 8/2013 10 pts affected by HL (8 with refractory disease and 2 in second relapse) received bendamustine at our Institution. Before starting bendamustine treatment, the clinical characteristics of pts were as follows: median age 39 years (range 22-70), 6 pts male and 4 female, median number of prior treatment lines 3 (range 2-3), including ASCT in 3 pts, and median time from initial diagnosis 29 months (range 11-103). The patients received a median of 4 courses of bendamustine (range 2-6). Treatment was well tolerated in all patients, without life-threatening or unexpected extra-haematological adverse events. Particularly, no cases of cutaneous adverse effects were recorded. Haematological toxicity was limited. Grade 3-4 thrombocytopenia occurred in 10% of cycles, grade 3-4 anaemia in 4% and

grade 3-4 granulocytopenia in 2%. The overall response rate was 50%, with 4 complete response (CR), 1 partial response, 1 stable disease and 4 progressive disease. Two of the 4 pts who achieved CR relapsed after 12 and 18 months, respectively. Today, after a median follow-up of 35 months for living pts, overall survival is 35% and median time to progression or relapse 6 months (range 2-24). Overall, 5 pts deceased for HL progression and 5 pts are still alive.
Summary and Conclusions: Our results confirm the safety and the efficacy of bendamustine in pts who had undergone multiple lines of treatment. With this in mind we look at some possible scenarios involving bendamustine. Firstly, because allogeneic SCT represents a chance of cure in a subset of relapsed/refractory pts, bendamustine may be considered a bridge to transplant. Furthermore, combination studies of bendamustine with other anticancer drugs or biological agents aimed to maximize the response rate and response duration are ongoing. In this regard, combination of brentuximab vedotin and bendamustine seems very promising. Currently, a phase I/II multicentre prospective study of bendamustine in combination with lenalidomide (LEBEN; ClinicalTrial.gov identifier NCT 01412307) is ongoing at our Institution. Finally, considering its favourable safety profile, single-agent bendamustine could be a valuable resource for frail patients who are not eligible to intensive salvage regimens for Hodgkin lymphoma.

PB1761

ABVD WITH OR WITHOUT RADIOTHERAPY IS SAFE AND EFFECTIVE FOR THE TREATMENT OF PATIENTS AFFECTED BY CLASSIC HODGKIN LYMPHOMA AGED 18 YEARS OR YOUNGER

G Ricciuti[1,*] S Falorio[1], E Finolezzi[1], A Sau[1], G La Barba[1], S Luciani[1], F Angrilli[1]
[1]Department of Hematology, Civic Hospital Spirito Santo Pescara, Pescara, Italy

Background: ABVD (doxorubicin, bleomycin, vinblastine and dacarbazine) with or without radiotherapy (RT) is the standard of care for the majority of adult patients affected by classical Hodgkin lymphoma (cHL). The treatment of pediatric cHL is based on the experience of adult treatment regimens. Since most pediatric patients with cHL are successfully treated and late toxicities vary according to the treatment modality, an important consideration in children and adolescents is the selection of the treatment regimen, particularly in reference to the anticipated late toxicities associated with anticancer therapy.
Aims: To evaluate safety and efficacy of ABVD alone or combined with RT in young patients affected by cHL.
Methods: We performed a retrospective analysis on cHL pts aged 18 years or younger, treated at our Institution with ABVD with or without RT as well as adults.
Results: From June 1991 to June 2013, 26 consecutive young pts affected by cHL were diagnosed and treated at our Institution. The clinical characteristics of pts at diagnosis were as follows: median age 16 years (range 6-18), 11 pts male and 15 female, clinical stage I-II 19 pts (73%) and III-IV 7 (27%), B symptoms 9 (35%), Bulky mass 9 (35%). Treatment strategy varied according to the extent of the disease: the pts with clinical stage I-II received ABVD plus involved field RT (IFRT) and the pts with stage III-IV received ABVD alone. According to the different periods of treatment, the number of cycles ABVD varied from 3 to 4 for initial stages, and from 6 to 8 for advanced stages. The dose of IFRT varied from 20 to 36 Gy. Overall response rate was 92%. In detail, 24 pts achieved complete remission (CR), while 2 pts failed to respond to ABVD. One of them died after 13 months for progressive disease, while the second one was rescued with IGEV salvage chemotherapy plus autologous PBSCT. After a median follow-up of 94 months (range 7-278) overall survival rate is 96% and freedom from treatment failure 92%. Among the 24 CR pts no relapses were recorded until now. With regard to the late toxicities, all 15 female pts present normal menses today, while 2 pts developed a mild hypothyroidism. Finally, there aren't serious cardiac and pulmonary complications so far.
Summary and Conclusions: Our results obtained in a small group of children and adolescents with cHL who received ABVD alone or in combination with IFRT seem very encouraging. The major concerns for children with HL treated with ABVD plus RT regard the risks of late toxicities, especially in the case of mediastinal RT. Modern pediatric treatment strategies have been focused on reducing late effects of therapy with the development of risk-adapted chemotherapy alone or response-adjusted combined-modality regimens. We think that the low burden of late effects that occurred in our experience may be in part due to the short follow-up of some pts. However, irrespective of this point of view, we believe that achieving CR is always the primary goal of a treatment regimen, because the prognosis of relapsed/refractory HL pts remains still poor. Therefore, outside of clinical trials, we think that ABVD alone or combined with modern RT, in agreement with clinical stages, may still constitute the standard of care for the majority of both pediatric and adult pts affected by cHL. In this context, the use of reduced volumes and doses of RT and the availability of liposomal doxorubicin could contribute to further reduce the risk of late toxicities.

PB1762

RESPONSE- ADAPTED THERAPY AFTER INITIAL TOW ESCALATED BEACOPP IN ADVANCED ADULT HODGKIN LYMPHOMA: TUNISIAN PROSPECTIVE TRIAL (MDH2008) RESULTS

R Ben Lakhal[1,*] Y Yahyaoui[1], K Kacem[1], R Mansouri[1], H Ben Neji[1], NEH Kraiem[2], L Aissaoui[1], M Zarrouk[1], Y Ben Abdennebi[1], R Jeddi[1], M Bechir[1], Z Bel Hadj Ali[1], H Ben Abid[1], B Meddeb[1]
[1]Clinical Hematology, [2]Radiology, Aziza Othmana Hospital, Tunis, Tunisia

Background: Advanced Hodgkin lymphoma (HL) still present many therapeutic problems of primary failure and relapses (20-30%) specially in developing countries. To improve the outcome of this unfavorable disease, Escalated(Esc) BEACOPP was used since 2008 to treat all advanced HL in Tunisia (Tunisian Prospective adult Hodgkin lymphoma trial: MDH2008 Group3).
Aims: We propose to report and analyze therapeutic results and prognostic factors in Tunisian advanced Hodgkin lymphoma patients(pts)
Methods: 85 newly advanced HL pts (Stage II with Bulky mediastinal disease, III and IV) were enrolled in group3 (Gr3) of the Tunisian prospective adult Hodgkin lymphoma trial (MDH2008) and treated in the clinical hematology department of Aziza Othmana hospital-Tunis from July 2008 to December2011. Pts were initially received two Esc BEACOPP followed by reevaluation with CT scans. When response≥75% was achieved, de-escalation of treatment to 6 ABVD was allowed to minimize long-term toxicity.Pts who failed to obtain this response received two other Esc BEACOPP with a second reevaluation:When response≥75% was achieved, pts received four Standard doses BEACOPP and Pts who failed to have this response received salvage therapy with autologous stem cell transplantation.
Results: Median age at diagnosis was 31 years. 22% of pts were classified as stage II with mediastinal Bulky and 45% as stage IV. International prognostic score≥3 was observed in 41% of pts. 77.5% of pts were in complete response after the first line therapy. At the univariate study, the mediastinal bulky (69% *vs* 93%, p:0.009) and response<75% to 2 Esc BEACOPP (70% *vs* 98%, p:0.002) were the adverse prognostic factors concerning response status at the end of therapy. 15% were refractory pts and the mediastinal bulky and response<75% to 2 Esc BEACOPP have consistently been demonstrated to be predictors of poor outcome. Three year event free survival (EFS), relapse free survival (RFS) and overall survival(OS) were respectively 68%, 87% and 86%. In multivariate study, the unfavorable prognostic factors emerging were mediastinal bulky for OS (82% *vs* 92%, p:0.05), lymphopenia <600/mm3 for EFS(20% *vs* 70%, p:0.000) and OS(40% *vs* 90%, p:0.000) and the response<75% to 2 Esc BEACOPP for EFS(57% *vs* 94, p:0.001). Acute hematologic toxicity was observed in about 71% of patients. Death related to acute toxicity was observed in 3 patients.
Summary and Conclusions: In our country, Esc BEACOPP improve the OS and the RFS but the EFS remains lower than in published studies . Bulky mediastinal disease and response <75% to 2 Esc BEACOPP have been demonstrated to be predictors of poor outcome, requiring treatment intensification.

PB1763

SECOND NEOPLASMS IN PATIENTS WITH HODGKIN LYMPHOMA

M Santos[1,*] R Guilherme[1], R Silva[1], M Gomes[1], E Magalhães[1], AI Espadana[1], L Rito[1], B Luz[1], S Almeida[1], E Cortesão[1], C Geraldes[1], JP Carda[1], L Ribeiro[1]
[1]CHUC-HUC, Coimbra, Portugal

Background: As the majority of patients with Hodgkin lymphoma (HL) are able to achieve long-term survival free of HL, late complications of treatment have emerged as a competing cause of death and morbidity. An important complication of the successful treatment strategies and the long-term survival is the occurrence of second malignant neoplasms.
Aims: Evaluate the occurrence of second neoplasms in long-term survivals after HL treatment.
Methods: It was analysed clinical datas of patients diagnosed with HL between January 1990 and December 2012.
Statistic analysis were performed with the SPSS (V20).
Results: We included 314 patients and have identified second neoplasms in sixteen of these patients (5,1%). There were 12 males (75%) and 4 females (25%). Ten patients received combined treatment with chemotherapy and radiotherapy and six patients were treated with chemotherapy alone. The median time to diagnosis of secondary neoplasms was 7,6 years (range, 0,74 to 23.34 years). Median age at diagnosis of second neoplasm was 41.5 years (32-71 years). The median follow-up time of the 314 patients was 5,49 years (range, 2 days – 21 years). Second neoplasms were: 3 non-hodgkin lymphoma, 3 acute myeloid leukemia, 2 bladder carcinoma, 2 gastric adenocarcinoma, 1 breast carcinoma, 1 Leydig cell testicular tumor, 1 cerebral sarcoma, 1 thyroid carcinoma, 1 neuroendocrine tumor, 1 chronic myelomonocytic leukemia, 1 prostatic adenocarcinoma and 1 pancreatic adenocarcinoma. Two patients developed 2 second neoplasms. Only two patients didn't receive treatment for the secondary malignancy. Eight patients are alive, 1 missed follow-up and seven patients died (3 with acute myeloid leukemia, 1 with chronic

myelomonocytic leukemia, 1 with resistant non-hodgkin lymphoma, 1 with gastric adenocarcinoma and 1 with pancreatic adenocarcinoma).
Summary and Conclusions: Patients treated with chemotherapy and/or radiotherapy for HL have an increased risk of developing acute myeloid leukemia, non-Hodgkin lymphoma and solid tumors, according to the literature. Long-term follow-up is mandatory for survivors of HL to early recognition of second neoplasms and initiation of adequate treatment for better results.

PB1764

HODGKIN LYMPHOMA IN THE WEST OF ALGERIA: PANORAMA OF EPIDEMIOLOGICAL AND CLINICAL FEATURES, INITIAL WORK-UP, SURVIVAL AND RISK FACTORS DISTRIBUTION

A Bekadja[1,*] T Alsuliman[1], H Touhami[2], F Mekkous-Touhami[3], Z Zouaoui[4], A Hadjeb[5], N Mesli[6], N Houti[7], N Mehalhal[8], A Bachiri[9], A Arabi[1], R Bouhass[1]
[1]Hematology and cell therapy, [2]CHU ORAN, [3]Hematology, University hospital Oran, Oran, [4]Hematology,CHU Bel Abbès, [5]Hematology, University Hospital, Sidi Bel Abbès, [6]Hematology, CHU Tlemcen, [7]Hematology, University hospital, Tlemcen, [8]Hematology, EPH , Mascara, [9]Hematology, HMRUO, Oran, Algeria

Background: In Algeria, the incidence of hematologic malignancies has been difficult to estimate for many years. Today, many hematological centers, including 14 university hospitals, have been developped in the entire north and have useful epidemiological data pertinent to Hodgkin'sLymphoma (HL).
Aims: The principal object of this study is to represent - in maximum accuracy- the real status of Hodgkin's lymphoma in west of Algeria, we think also it serves as an adequate indicator for the epidemiological characteristics of HL patients and as an overview of theses very patients treatment and survival in Algeria in general.
Methods: From January 2008 to December 2012 , 668 patients were included in this study, from the age of 15 to 88 years, and both genders. 8 hematology centers participated covering the west of Algeria. An including criteria which respects the representation of the socio-economic status distribution was adapted for this study. Also we included patients of most professions that present in reality with in the west Algerian community. All diagnostic procedures and treatment policies were unified between the involved center, the pilot center (Oran1) adapted a strict system for data collection, control and confirmation, this system included: standard follow-up and standard software that been installed in all other centers to serve as data collection and organization program which send full and unified tables to the study data manager to be reviewed and confirmed by control committee for the final processing. The therapeutic approach consisted of chemotherapy combined or not with radiotherapy according to clinical stage followed when appropriate with intensification protocol and autologous stem cell transplantation.
Results: Of our 668 patients: 53% were males, 47% females, global median age (36 years) and mean age (33 years). 65% of all patients had nodular sclerosis subtype, localized disease was presented in 22% of our study patients, while 78% presented advanced stages, rates of peripheral bulky disease, mediastinal bulky and non-bulky disease were 8%, 45% and 47% respectively. 9% of patients had bone marrow involved by HL, 18% of patients had imaging of affected spleen, while 9% had features of affected liver. 74% of patients had one or more of B symptoms, 68% of males and 74% of females were anemic, 28% of patients had leukocytosis. Cumulative Overall Survival (OS) was estimated in 352 evaluable patients: 59% (at 60 months) , 69% (at 48 months), while 79% of patients were alive after 5 years of follow-up. Cumulative OS male was 64% (at 48 months), and Cumulative OS female: 75% (48 months) P-value>0.05. For patients aged more or less than 45 years, cumulative OS were 43 and 49 months respectively for the means of OS (p=0.016). Of the 352 evaluable patients, 129 patients had reached CR and been qualified for DFS statistical analysis. Relapse rate was 16%, cumulative DFS was 69% (at 47 months), no statistically significant difference had been detected between males and females (p=0.811).
Summary and Conclusions: Differences in survival rates between this study and publications may be explained partially by the very high frequency of negative prognostic factors in our cohort like bulky and advanced disease, B-symptoms, and anemia positivity rates, lack of PET-CT and radiotherapy centers number may had also affected this rate, even though we found ourselves very interested in deepening further more in diagnosis, treatment and follow – up modalities standardization and development in west of Algeria in order to raise the level of health services offered to HL patients to meet eventually developed countries survival rates.

PB1765

EFFICACY AND TOXICITY OF BRENTUXIMAB VEDOTIN MONOTHERAPY IN RELAPSED OR REFRACTORY CD30+ CLASSICAL HODGKIN LYMPHOMA PATIENTS OUTSIDE CLINICAL TRIALS

P Minga[1,*] E Meli[1], C Rusconi[1], V R Zilioli[1], A Greco[1], M Zancanella[1], L Paris[1], E Morra[1]
[1]Hematology, H. Niguarda Ca' Granda, Milan, Italy

Background: Brentuximab Vedotin (BV) is a drug-conjugate antibody composed of an anti-CD30 antibody linked to a microtubule-disrupting agent monomethyl auristatin E (MMAE) with proven efficacy in various CD30 positive lymphoprolipherative disorders. In Italy BV is approved since October 2012 for the treatment of classical Hodgkin Lymphoma (cHL) patients (pts) relapsed after autologous stem cell transplantation (ASCT) or relapsed/refractory after at least two prior multiagent chemotherapy regimens if not eligible to ASCT.
Aims: We retrospectively collected safety and efficacy data of 9 consecutive CD30+ cHL pts treated in our institution with BV, with the purpose of confirming tolerability profile of this drug in the daily practice, outside clinical trials.
Methods: Nine pts with refractory and relapsed cHL received BV therapy at the standard dose of 1.8 mg/kg every 3 weeks by IV infusion. BV premedication consisted in acetaminophen 500 mg po and chlorphenamin 10 mg iv. No antimicrobial prophylaxis was scheduled. All patients had histologically confimed CD30+ disease. Toxicitiy was assessed according to National Cancer Institute Common Terminology Criteria for Adverse Events version 4.0. Response was defined according to the Revised Response Criteria for Malignant Lymphoma. In 8/9 pts BV therapy was started as bridge to allogeneic stem cell transplantation; in these pts BV was continued untill the best response was achieved. One pt refused allogeneic transplant and a full course of BV was planned, up to 16 cycles. BV was stopped in case of disease progression or unacceptable toxicity.
Results: Median age was 38 years (range: 22-46). Nodular sclerosis was the most frequent histological subtype (6/9 pts), while mixed cellularity and not otherwise specified accounted for 2 and 1 pts, respectively. Six pts were refractory to the previous treatment received, while 3 pts had relapsed disease. Median number of prior therapy regimens was 7 (range: 3-10). All pts had failed a prior ASCT and seven pts had received radiotherapy. Median number of BV cycles administered was 7 (range: 1-16). Response to BV was evaluated in all but one pts with FDG-PET after four cycles: 2/8 (25%) pts achieved a complete response (CR), 4/8 (50%) pts achieved a partial response (PR), while 2/8 (25%) pts had progressive disease. Between responding pts, one pt refused to proceed to allogeneic transplant; 2 pts proceeded to MUD allogeneic transplantation with reduced intensity conditioning, 1 pt proceeded to haploidentical allogeneic transplantation. BV therapy is ongoing in two responding pts, waiting for unrelated donor availability. As regard toxicity we registered: grade 3 reactivation of Varicella Zoster Virus followed by grade 2 pneumonia in one patient and grade 3 herpetic ocular infection in one patient. One case of grade 3 necrotic hemorrhagic acute pancreatitis occured in a 22 years old female, with no additional risk for pancreatitis, 10 days after the first BV administration. The event required admission to Intensive Care Unit and completely resolved without surgical intervention. This pt withdrew BV therapy definitely. Neither significat infusional reactions nor peripheral neuropathy occurence were recorded.mHematological toxicity consisted in grade 3 neutropenia in 5/9 pts, with no case of grade 3 and 4 anemia and thrombocytopenia.
Summary and Conclusions: BV confirmed to be effective as single agent therapy in heavily pretreated relapsed/refractory cHL pts and allowed the majority of pts to proceed to allogeneic transplantation. Acute pancreatitis is a threatening, potentially fatal and unpredictable adverse event that should be kept in mind in daily management of BV exposed pts. Viral reactivations in our serie were unexpectedly severe; this finding suggest the opportunity to better investigate the role of routinely antiviral prophylaxis in association with BV therapy.

PB1766

PREVENTION OF REACTIVATION OF CHRONIC HEPATITIS B IN PATIENTS WITH HODGKIN'S LYMPHOMA DURING CHEMOTHERAPY.

I Subortseva[1,*] S Lepkov[2], E Demina[3], S Kosura[2], U Ryabyhina[4], O Kolomeytcev[4], O Ettinger[5], G Storogakov[5]
[1]National Hematology Research Center, [2]General Medicine, Moscow Medical University, [3]Haematology, [4]Cancer Research Center, [5]Moscow Medical University, Moscow, Russian Federation

Background: In Russia, chronic hepatitis B (HBV) is a relatively frequent viral infection in patients with Hodgkin's lymphoma (HL). There is no consensus about the advisability prophylactic antiviral therapy during cytostatic therapy.
Aims: The aim of our study is the evaluation of the effectiveness of prophylactic antiviral therapy in patients with Hodgkin's lymphoma with markers of viral hepatitis B.
Methods: We analyzed the clinical data and results of therapy in 38 patients with, which were observed in the Russian Research Institute of Oncology from 2002 to 2012. Stages of HL were II in 21 cases, III-IV in 17 cases. B symptoms were in 17 patients. At diagnosis of LH increase the level enzymes was 21 patients: ALT ranged from 1.25 to 3 upper limit of norm in 21 cases; AST ranged from 1.5 to 2 upper limit of norm in 15 cases; GGTP ranged from 2 to 6 upper limit of norm in 11 patients, alkaline phosphatase was 2 upper limit of norm in 6 patients. HBV DNA was determined in 21 patients. Viral load was from $1.3x10^3$/ml to $6.5x10^7$/ml (median $1.4x10^4$/ml). HBsAg was revealed only in 17 patients. HL treatment was carried out in according to standards of treatment: 21 patients with II stage have received 6 cycles of ABVD, 17 patients with III-IV stages have received 6-8 cycles of BEACOPP. Additionally, high-dose

chemotherapy carried out in 6 patients due to inadequate effect of standard chemotherapy. All 38 patients were underwent antiviral therapy. Therapy with Lamivudine 100 mg/day was started 1-4 weeks before the chemotherapy and continued at the same dose during chemotherapy.
Results: Complete remission (CR) was achieved in 76% (16 of 21) of patients with II stage after ABVD and 59% of patients (10 of 17) with III-IV stages after BEACOPP. CR was achieved in patients after high-dose chemotherapy. The duration of therapy with Lamivudine was from 14 to 24 months. Therapy was effective. HBV DNA was identified only in 1 patient during the chemotherapy. Viral load was $1.5x10^4$. Enzyme levels did not increase. Relapse of HBV infection was in 11 patients (29%) after the end of Lamivudine preventive therapy.
Summary and Conclusions: Therapy with Lamivudine is effective and affordable for the prevention of HBV reactivation in patients with HL lymphoma receiving combination chemotherapy ABVD and BEACOPP. However, HBV infection recurrence rate was 29% after the end of therapy with Lamivudine. Nevertheless, we can conclude that at the time of chemotherapy LH should take preventive therapy with Lamivudine in patients with markers of HBV who previously untreated with antiviral therapy.

PB1767

THE PROGNOSTIC SIGNIFICANCE OF EXTRANODAL DISEASE IN HODGKIN'S LYMPHOMA

B Mohamed[1,*] H Asma[1], O Fouzia[1], Z Zahia[1]
[1]hematology, Hospital of Sidi Bel Abbes, Sidi Bel Abbés, Algeria

Background: Hodgkin's lymphoma (HL) is a highly curable disease. Usually confined to the lymph nodes, extranodal involvement can occur and has an independent prognosis value.
Aims: To analyze the presenting features and the prognostic significance of extranodal disease in HL.
Methods: We performed a retrospective single institution study of 155 HL cases; from January 1992 to December 2010.
The median age was 27 years (range, 15-80 years), Stages III-IV were present in 85 (54.8%) patients. Combined radio-chemotherapy was administered to 95 (61, 2%) patients and chemotherapy alone to 60 (38.8%).
We analyzed the prognostic relevance of extranodal involvements and their significance was tested according to response rate an overall survival (OS).
Results: Extranodal disease was documented in 52 patients (33.5%) and 49 (44%) had bulky disease. Extranodal sites included the liver in 21 (13.5%), bone marrow in 11 (7%), pleura in 5 (3%), pharynx in 5 (3%), bone in 10 (6%), lung in 4 (1, 7%) and eye in 1 (0, 6%). The 52 patients with extranodal disease had poor prognosis compared with the nodal group (5 year OS, 51% *versus* 77%; p<0.001). Compared with the nodal subset, the extranodal patients presented more frequently with advanced stage disease (92% *vs* 08%; p<0.0001), B symptoms (90% *vs* 10%; p=0.002), a significantly low serum albumin (63.4% *vs* 24%; p<0.001) and a higher ESR (77% *vs* 23% p=0.005). Complete remission rates in the extranodal and the nodal subsets of patients were 46% *vs* 81% (p<0.001), respectively.
Summary and Conclusions: In our study, extranodal disease in patients with HL is frequent, especially in advanced stages,and associated with a poor outcome. This subset of patients is eligible for more effective treatment .

PB1768

A CASE OF BLEOMYCIN TOXICITY AND IMATINIB

L Tay[1,*] M Browne[1], P Mudholkar[2]
[1]Haematology, [2]Respiratory, Coffs Harbour Hospital, NSW, Australia

Background: Pulmonary fibrosis secondary to bleomycin for treatment of Hodgkin lymphoma can be potentially fatal, and monitoring of lung function often varies between instituitions. Animal studies had showed tyrosine kinase eg Nilotinib was effective in reversal of bleomycin induced interstitial disease, but this drug or similar TKI is not approved for this indication. There is one case report of Imatinib use in interstial fibrosis published in the literature.
Aims: To report our experience of a case of patient with stage II, early unfavourable Hodgkin lymphoma who developed bleomycin induced pulmonary fibrosis with progession of this on steroid; but subsequent treatment with Imatinib (off-lable use) reveresed the fibrosis. Imatinib was effective in our patient where 300mg daily was used for a total of 6 months successfully.
Results: A 53 year old female, non-smoker, previously well was diagnosed of nodular sclerosing Hodgkin lymphoma. She presented with bilateral cervical lymphadenathy, further staging confirmed Arr Born stage II early unfavvourable disease and underwent 4 cycles of ABVD with routine pulmonary function tests during treatment. She presented with dysponoea and dry cough a week later, PE was excluded, and was initially treated for infection. Bronchoscopy was performed and did not show PCP. HRCT subsequently showed upper and lower lobe interstitial changes with ground glass opacities, consistent with bleomycin induced interstitial fibrosis. Initial LFT showed higher than normal diffusion capacity, DLCO 87% FEV1, RV and TLC all more than 100% of predicted; and at time of diagnosis DLCO was 38%; this decreased further to 18% (FEV1 1.14l 46% or predicted, FVC 1.4l 48% of predicted, TLC 4.93l 54% of predicted) after prednisone was started at 75mg daily for two weeks. At this point, patient required intubation in ICU for two weeks and Imatinib 300mg daily was commenced. She gradually improved in the next 6 months and was able to walk from 50m to 500m after 3 months of treatment. She completed 4 cycles of chemotherapy and achieved CR after two cycles on interim PET scan. Due to development of pneumonitis, IFRT was abandoned. Plot DLCO and lung function against time of treatment and progress will be provided.
Summary and Conclusions: Although this patient achieved complete remission, she suffered severe bleomycin pneumonitis, which progressed with initial steroid treatment; subsequent tyrosine kinase inhibitor, ie imatinib 300mg daily reversed fibrosis and lumg function and diffusion capacity. She was treated for a total of 6 months with tapeing off steroid during this time, near complete resolution of interstitial fibrosis on CT was achieved, and continued to improve after this. Prognosis with bleomycin toxicity can be dismal and with the novel treatment albeit off lable use, there is a potentially effective therapy to reverse interstial fibrosis with TKI such as imatinib.

PB1769

CARDIAC COMPLICATIONS OF SPECIFIC TREATMENT IN HODGKIN'S DISEASE

B Salah Eddine[1,*] T Faiza[1], K Fatma Zohra[1]
[1]Hematology, HCA, Algies, Algeria

Background: In recent decades, the survival of patients treated for Hodgkin's disease has improved considerably. Unfortunately, improving prognosis of the disease was accompanied by a Hodgkin long-term toxicity, such as high risk for cardiovascular complications. The supradiaphragmatic radiotherapy, next to its beneficial role recognized, may be responsible for potentially serious cardiac complications. This risk is increased in patients with conventional combination chemotherapy with anthracyclines.
Aims: We present our experience in the management of cardiac complications in Hodgkin's disease.
Methods: Over a period of 20 years from January 1988 to December 2012, 11 cases of 286 pts presented a cardiovascular complication following chemotherapy regimens with or without radiotherapy. We will describe the type of complication, their time of onset and evolution.
Results: This is 11 cases (3,84%) who presented a cardiovascular complication. 7 men and 4 women with an average age of 37 years [24-65years].2 patients stage II, 4 stage III, 5 stage IV.First-line chemotherapy: ABVD: 9 pts; MOPP: 1 pts, and radiotherapy combined: 5 pts (3 localized stages, 2 extended). Second-linechemotherapy and the third line (refractory disease) CNOP and DHAP: 1 pts, then BEACOP-ESHAP: 2 pts. 11 cases presented acardiovascular complication after a median time of 22 months with intervals [6 months to 56 months].In 2 cases: thrombosis of vessels of the neck, after stopping immediatly radiotherapy. In 8 cases: Cardiomyopathy, after a mediantime of 25 months [4 and 56 months]. Their evolution was unfavorable in 6 cases (54.5%) died in an array of congestive heart failure.1 case with CMD still alive, with a survival of 7 years and 1 case with CMD POS. These two latter cases were respectively treatedwith ABVD (x8) and MOPP (x3) + RT. In 1 case: Treated exclusively by ABVD (x6), presented a 12-month overhaul aortic valvesand received an aortic valve replacement. The latter is still alive, with a survival of 6 years.This is 3.84% or 11 patients who presented a cardiovascular complication. 7 men and 4 women with an average age of 37 {[24-65 years]. 2 patients stage II, 4 stage III, 5 stage IV. This is 11 cases (3.84%) who presented a cardiovascular complication. 7 men and 4 women with an average age of 37 years [24-65 years]. 2 First-line chemotherapy: ABVD: 9 pts; MOPP: 1 pts, and radiotherapy combined: 5 pts (3 localized stage).
Summary and Conclusions: In our series, 3.84% of cases presented with cardiac complications and are consistent with those described in the literature. In a Mexican study, cardiac complications represented 3.5%.
The treatment of Hodgkin's disease is one of the most successful medical hematology. However, progress remains to be made in the therapeutic escalation to limit these deadly complications and some with heavy for other serious functional impairment, psychological and social. Strategies for appropriate risk reduction should beings associated with specific treatment, such as treatment of hypertension, hypercholesterolemia, and not smoking.

ANALYSIS OF PATIENTS DIAGNOSED OF NODULAR LYMPHOCYTE-PREDOMINANT HODGKIN´S LYMPHOMA

A Pilar[1,*] R Fernandez[2], J Solano[1], E Alonso Nogues[1], Y Zanabilli[3], JM Alonso [4], AR Payer[1], JM Vicente[5], J Medina[3], F Taboada[6], M Vargas[7], C Alarcon[3], M Moran[3], A Gonzalez-Ordoñez[3], MA Palicio[7], S Ortiz[7], C Chamorro[8]

[1]Servicio de Hematología, Hospital Universitario Central de Asturias, Oviedo, [2]Servicio de Hematología, Hospital de Cabueñes, Gijon, [3]Servicio de Hematología, Hospital San Agustin, Aviles, [4]Servicio de Hematología, Hospital Valle del Nalon, Langreo, [5]Servicio de Hematología, Hospital de Mieres, Mieres, [6]Servicio de Hematología, Hospital Cangas de Narcea, Cangas de Narcea, [7]Servicio de Hematología, Hospital de Jarrio, Jarrio, [8]Servicio de Hematología, Hospital de Arriondas, Arriondas, Spain

Background: Lymphocyte-predominant Hodgkin Lymphoma (LPHL) is a rare entity with differences in pathology and clinical behaviour from classical Hodgkin lymphoma (cHL).
Aims: The objective of this study is to improve the knowledge of this infrequent disease, patient's characteristics and prognosis.
Methods: We retrospectively analysed all cases of Hodgkin lymphoma diagnosed in "Principado of Asturias" in a 10-year period (between 2002 and 2012). 259 patients were diagnosed with cHL, and we identified 21 cases of LPHL.
Results: Patients with LPHL had the following characteristics: median age 37 years (13-30) and 19 were males (90,5%). With regard to the stage, 15 pts (71.4%) presented with stage I/II disease, while N pts had stage III/IV disease. Only 9% of patients had B-symptoms and none had extranodal involvement or bulky mediastinal mass. 9 pts were treated with surgery and/or radiotherapy alone, while chemotherapy (ABVD) was administered to 12 (57,1%). Relapse occurred in 4 pts (19,1%); 2 patients of them with recurrence presented with histological transformation into aggressive lymphoma.
The median follow-up period was 76,27 months (range 8-130). The 10-year progression free survival (PFS) and 10-year overall survival (OS) were 69% and 100% for early stages, and 60% and 84% for advanced stages, respectively. A high level of beta-2 microglobulin was identified as a prognostic factor in our patients (RR 0,06; 0,005-0,68; p=0,020). In Table 1 we summarize the differences between LPHL and cHL. LPHL is an infrequent disease with a favourable prognosis. It's important a long follow-up and a repeat biopsy at the time of relapse in order to exclude histological transformation. The prognostic value of beta-2 microglobulin must be confirmed in larger series of patients.

Table 1.

Summary and Conclusions: LPHL is an infrequent disease with a favourable prognosis. It's important a long follow-up and a repeat biopsy at the time of relapse in order to exclude histological transformation. The prognostic value of beta-2 microglobulin must be confirmed in larger series of patients.

TREATMENT OF RELAPSE OF CHRONIC HEPATITIS B VIRUS IN PATIENTS WITH HODGKIN'S LYMPHOMA

S Lepkov[1,*], I Subortseva[2], E Demina[3], S Kosura[1], U Ryabyhina[4], O Kolomeytcev[4], O Ettinger[5], G Storogakov[5]
[1]General Medicine, Moscow Medical University, [2]National Hematology Research Center, [3]Haematology, [4]Cancer Research Center, [5]Moscow Medical University, Moscow, Russian Federation

Background: Treatment of HBV relapses in patients with Hodgkin's lymphoma (HL) is a not enough-studied problem. Preventive therapy with Lamivudine in patients with HL with viral hepatitis B was quite effective during chemotherapy LH, but was not effective in the treatment of relapses of HBV.
Aims: The aim of our work was to analyze the clinical presentation and treatment outcomes in patients with Hodgkin's lymphoma, evaluation of the effectiveness of antiviral therapy with recurrent hepatitis B in these patients.
Methods: We analyzed data from 38 patients with Hodgkin's lymphoma and markers of viral hepatitis B. Median HBV DNA was $1.4x10^4$/ml. All of these patients received polychemotherapy and prophylactic therapy with Lamivudine. Hepatitis B relapse developed in 11 patients. All these 11 patients had III and IV stages of HL. These patients had received from 6 to 8 cycles of chemotherapy BEACOPP. 3 patients had received high-dose chemotherapy due to inadequate effect BEACOPP. Relapse of chronic hepatitis B developed by 3-12 months (median 9.5 months) after preventive therapy with Lamivudine. At the time of relapse HBV infection HBV DNA level ranged from $1.5x10^4$/ml to $8.9x10^6$/ml (median $2.6x10^5$/ml), which was significantly higher than the HBV DNA level before start of antiviral therapy. At the relapse HBV ALT level ranged from 3 to 8 upper limit of norm in 11 patients, AST level ranged from 2.5 to 7 upper limit of norm in 7 patients, GGTP level ranged from 4 to 8 upper limit of norm in 5 patients. Therapy with Lamivudine 100 mg/day has been renewed for patients with relapse hepatitis B. Antiviral effect was not obtained at this group of patients. Therapy with Entekavir 1 mg/day was carried out in 6 patients, 3 patients have reached disappearance of HBV DNA and 3 patients had no effect. Therapy with Tenofovir 300 mg/day was appointed for 11 patients with resistant HBV. Level of HBV DNA ranged from $4.5x10^5$/ml to $1.9x10^8$/ml (median $3.9x10^6$/ml). ALT level ranged from 3 to 15 upper limit of norm in 10 patients, ACT level ranged from 2.5 to 9 upper limit of norm in 9 patients, GGTP level ranged from 4 to 7 upper limit of norm in 7 patients.
Results: Biochemical parameters were normalized after 3-6 months of therapy with Tenofovir (median 5 months).HBV DNA disappeared after 6-8 months (median 7.5 months) in all 11 patients. All patients received antiviral therapy during 6 - 8 months. Only 1 patient had relapse after discontinuation therapy with Tenofovir.
Summary and Conclusions: HBV relapses of HBV in patients with HL after chemotherapy developed only in patients with advanced stage HL. In the case of frequently relapsing hepatitis B, tenofovir therapy was effective after the discontinuation of preventive therapy with Lamivudine for relapse of HBV.

TUMOR ASSOCIATED MACROPHAGES AND FOXP3 LYMPHOCYTES CORRELATES WITH THE OUTCOME IN HODGKIN LYMPHOMA PATIENTS

B Andjelic[1,*] M Perunicic Jovanovic[2], L Jakovic[1], M Todorovic[1,3], D Antic[1,3], J Bila[1,3], A Sretenovic[1], V Djurasinovic[1], V Vukovic[1], J Jelicic[1], M Smiljanic[1], B Mihaljevic[1,3]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Department for Histopathology, Clinical Center of Serbia, [3]Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background: In the past decade the researches with the aim to identify powerful prognostic biomarkers for Hodgkin Lymphoma (HL) were very intensive. The structure of the tumor microenvironment and angiogenesis is found to have important role in tumor biology.
Aims: The aim of this study was to evaluate whether tumor associated macrophages (TAM), FOXP3 lymphocytes, microvessel density and the expression of vascular endothelial growth factor (VEGF) in tumor tissue could be important predictive factors for outcome of patients with HL, separately and combined with clinical and laboratory parameters.
Methods: The study included 84 newly diagnosed ABVD treated HL patients in the period 2000-2008. Immunohistochemical analysis using CD68, FOXP3, CD34 and VEGF monoclonal antibodies was performed on paraffin-embedded lymph node specimens. The examined clinical and laboratory parameters were presence of bulky disease, B symptoms, ESR≥50 mm/h, elevated LDH and high IPS score (3-7). By ROC curves were determined the most appropriate cut off values for number of TAM and FOXP3 lymphocytes, as well the microvessel density, which were used in subsequent survival and multivariate analysis.
Results: Five-year overall survival (OS) was 73,8% and 5-year event free survival (EFS) was 59,5%. In univariate analysis patients with high number of TAM, low number of FOXP3 lymphocytes and VEGF positivity had significantly shorter OS (p=0.017, p=0.003, p=0.046, respectively). Shorter EFS was found in patients with low number of FOXP3 lymphocytes (p=0.001) and VEGF positivity (p=0.026), while there was a trend toward worse EFS in patients with high number of TAM (p=0.068). Between clinical and laboratory parameters, patients with bulky disease, B symptoms, ESR≥50 mm/h and high IPS score had significantly shorter OS (p=0.006, p=0.022, p=0.013, p=0.024, respectively), while EFS was shorter in patients with ESR≥50 mm/h (p=0.026) and high IPS score (p=0.008). Multivariate analysis as the independent risk factors for poor OS identified high number of TAM and low number of FOXP3 lymphocytes in the group of biomarkers (p=0.034, p=0.006, respectively), while between clinical and laboratory parameters bulky disease (p=0.002) and high IPS (p=0.004) were identified. Low number of FOXP3 (p=0.002) and high IPS (p=0.011) were identified in analyzed groups as the independent factors for poor EFS. Afterwards, we performed survival analysis with aggregate scores of identified negative prognostic factors for OS for each patient (p=0.000). By merging groups with 0 or 1 and 3 or 4 negative prognostic factors (no difference in OS in intergroup analysis), we developed prognostic model for identifying patients at low (0-1 factors), intermediate (2 factors) and high risk (3-4 factors) for poor outcome (p=0.000). According to this model, in the examined group 28 (33.3%) patients had low, 24 (28.6%) intermediate and 32 (38.1%) high risk for poor outcome, with 5-year OS of 100%, 75% and 50%, respectively (Figure 1). This model retained its prognostic significance in multivariate analysis for OS (p=0.03; RR=3.271; 95% CI 1.516-7.057).

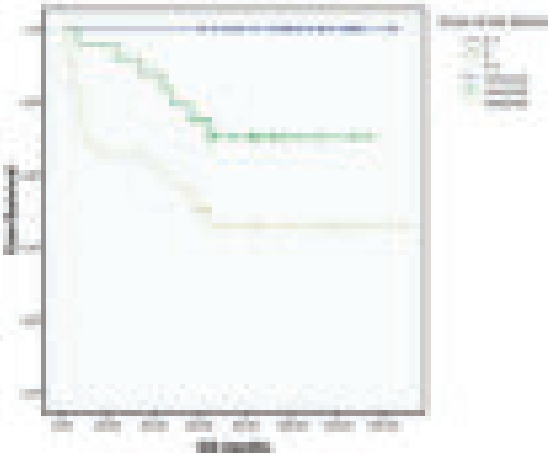

Figure 1.

Summary and Conclusions: Combining of TAM and FOXP3 lymphocytes with established clinical and laboratory prognostic factors could result in better risk stratification of patients with HL.

PB1773

THE PREDICTIVE ROLE OF MYELOID-DERIVED SUPPRESSOR CELLS (MDSC) IN LYMPHOMA PATIENTS

G De Tullio[1,*] F Merchionne[2], S Serrati[1], N Sgherza[1], P Petrillo[1], V De Fazio[1], C Minoia[1], G Loseto[1], A Rana[1], A Iacobazzi[1], P Iacopino[1], A Guarini[1]
[1]Department of Clinical and Experimental Oncology, Haematology Unit, Advanced Cell Therapy Center, National Cancer Research Centre , Istituto Tumori "Giovanni Paolo II", BARI, [2]Hematology and Bone Marrow Transplantation Unit, Antonio Perrino Hospital, Brindisi, Italy

Background: The immune suppression is one the most important mechanisms that contribute to tumor onset by impairing immune surveillance and by promoting tumor escape. Many aspects of lymphoma pathophysiology indicate that dysregulation of mutual interactions between the host immune system and lymphoid cells is involved in lymphoma pathogenesis through the suppression of T cell responses so that supporting escape and survival of lymphoma cells. Furthermore, the treatment outcome and survival were correlated with the presence of immune cells in the tumor microenvironment among which the myeloid-derived suppressor cells (MDSCs) have recently been demonstrated to have a significant ability to suppress innate and adaptive immune response, as resulting a crucial role in tumor progression as supported by their expansion during cancer and other pathological conditions, like inflammation, autoimmunity and infection. MDSCs represent a phenotypically and morphologically heterogeneous population of immature myeloid cells that promotes tumor growth and progression by supporting tumor tolerance as well as by non-immunological functions such as directly inducing tumor angiogenesis and metastasis formation. However, there are few data on their role in the clinical outcome of lymphoma patients as well as their correlation with relapse/progression of disease, especially in the case of Hodgkin's lymphoma patients whose no data are available.
Aims: The aim of this study was to assess the frequency of MDSCs in the Bone Marrow (BM) and Peripheral Blood (PB) of Lymphoma patients and healthy controls, in order to determine if they correlate with tumor burden and so to evaluate their role in clinical outcome and relapse/progression in Lymphoma patients (pts).
Methods: To detect MDSc as prognostic factors,BM and PB samples of 72 Lymphoma pts,with non-Hodgkin's Lymphomas(NHL) and classical Hodgkin Lymphoma(cHL),were collected at diagnosis and prospectively during the follow-up (1-6-12 months after chemo- or immuno-chemotherapy therapy) as well as at the relapse/progression. PB samples of 16 healthy donors were collected as controls. The MDSC population was defined by flow cytometric analysis as lineage: CD33+, HLA-DR$^{low/-}$, CD11b+ , discriminated for CD14+ and CD15+, by following direct antibody staining with: CD33+, CD11b+, CD15+, CD14+, HLA-DR$^{low/-}$. Data were acquired with Navios flow cytometer (Beckman Coulter) and analysed with Kaluza software (Beckman Coulter). All pts provided their informed consent in accordance with the Declaration of Helsinki.
Results: The percentage (mean±SE) of MDSCs in BM (3,770±0,0343) of Lymphoma pts was higher than in PB samples (2,836±0,0147) (p<0,0001) (Figure 1A). As demonstrated in previous studies the frequency of MDSCs in PB of lymphoma pts were increased as compared with healthy donors (p<0,0001) (Figure 1B). More interestingly their number seemed to be modulated both by disease and relapse/progression and correlated with histotypes. Specifically in cHL pts circulating MDSCs were significantly increased as compared with other histotypes (p=0.0003) (Figure 1C).

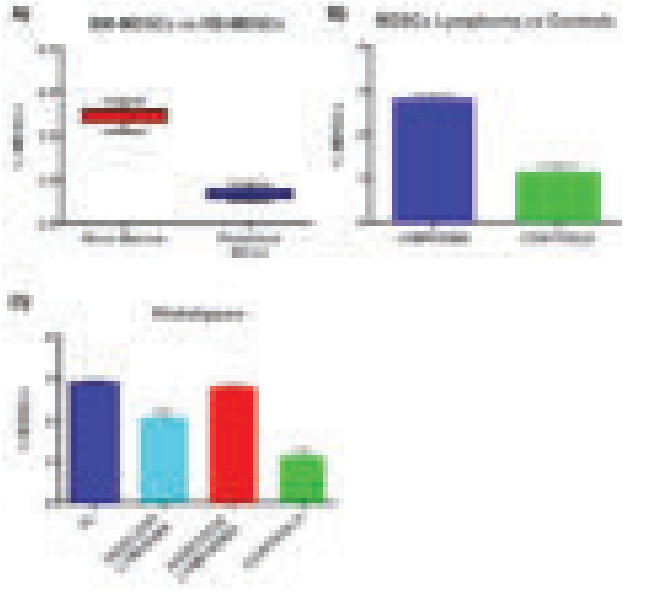

Figure 1.

Summary and Conclusions: Our study has demonstrated that the MDSCs could play an important role in both pathogenesis and progression of lymphomas as well as in treatment outcome. In addition, we demonstrated that circulating MDSCs were significantly increased in cHL as compared with NHL suggesting a characteristic immunosuppressive microenvironment in this histotype.

ARGINASE-1 IS AN IMMUNOSUPPRESSOR MEDIATOR INCREASED IN HODGKIN`S LYMPHOMA NEUTROPHILS ASSOCIATED TO POOR OUTCOME

A Romano[1,2,*]N L Parrinello[1], C Vetro[1], P La Cava[1], D Tibullo[1], C Giallongo[1], A Chiarenza[1], A Figuera[1], G Motta[1], G A Palumbo[1], U Consoli[3], F Di Raimondo[1]
[1]Department of Clinical and Molecular Biomedicine, Haematology Section, University of Catania, Catania, [2]Fondazione Veronesi, Roma, [3]Division of Hematology, ARNAS Garibaldi, Catania, Italy

Background: In Hodgkin Lymphoma (HL) elevated neutrophil (HL-N) count is a well recognized negative prognostic factor but its biological meaning is not elucidated. Our previous work showed that HL-N are dysfunctional and can suppress T-cell activation *in vitro*.
Arginase (Arg-1) in blood cells is mainly stored in N-granules and released as inflammation suppressor.
Aims: In order to investigate immunosuppressive properties of HL-N we evaluated arginase expression and activity in HL-N.
Methods: In N obtained from 15 HL patients we tested phagocytic activity by flow-cytometry, enzymatic activity of Arg-1 by colorimetric method, expression of Arg-1 in RT-PCR, and suppression of healthy T-lymphocytes activation in co-culture experiments. Amount of Arg+ cells was also evaluated in HL lymphonodes by IHC. We prospectively measured soluble Arg-1 (s-Arg-1) in 135 sera obtained from 60 patients with Hodgkin lymphoma, distinguished in a training set (N=25) and a validation set (N=35) and 21 healthy participants. In the training set, blood was taken at three fixed time-points prior, during, and after first-line therapy. Findings were compared with radiological assessment, including 2FDG-positron emission tomography scan after 2 cycle of chemotherapy (PET-2) and clinical variables.
Results: N-HL exhibited a reduced phagocytosis (93.2 ±1.9% *vs* 73.1±3.7, p=0.0008) and an increased arginase activity up to 15 times compared to healthy subjects matched for age and sex. We observed an increase of Arg-1 expression in HL-N up to 100 folds compared to healthy subjects matched for age and sex (p=0.001), independently from tumor load and other well-known prognostic factors, including sex, anemia, stage, bulky disease and IPS. In the lymphonodes, Arg-1 evaluated in immunohistochemistry showed a granular pattern distribution in lack of overlapping with CD68+ staining. s-Arg-1 was increased in HL patients compared to healthy subjects, reduced after therapy in responders and increased in relapsed patients (p<0.0001). s-Arg-1 was positively correlated to the amount of N and Arg-1 in N detected by RT-PCR. A cut-off level of 205 ng/mL for Arg-1 was chosen (equal to 2 times the 95thpercentile in controls and ROC value with sensitivity and specificity of at least 80%) to predict response status at 24 months. In the training set, 32% patients had high s-Arg-1, 24% had positive PET-2 and were addressed to an early salvage therapy accordingly to BEACOPP scheme. A level of 205 ng/mL s-Arg-1 resulted in 83% (95% C.I. 58-96) sensitivity and 81% (95% C.I. 42-96) specificity in predicting response status in the training set (area under curve, AUC, 0.81, p=0.02). In the validation set, baseline levels of s-Arg-1>205 ng/mL resulted in 83% (C.I. 95% 62-95) sensitivity and 87% (C.I. 95% 47-99) specificity in predicting response status. Patients with s-Arg-1 ≥ 205 ng/mL had shorter PFS than patients carrying Arg-1<205 ng/mL (despite both groups did not reach the median, because of the short follow-up, p=0.005).
Summary and Conclusions: Neutrophils in HL are dysfunctional for high amount of Arg-1. S-Arg-1 is a predictor of PFS even in the cohort of advanced-stage patients early addressed to salvage regimen in case of PET-2 positivity.

PB1775

PROGNOSTIC SIGNIFICANCE OF VASCULAR ENDOTHELIAL GROWTH FACTOR, OSTEOPONTIN AND MONOCYTE CHEMOTACTIC PROTEIN-1 IN DIFFUSE LARGE B-CELL LYMPHOMA TREATED WITH IMMUNO-CHEMOTHERAPY

T Juranović[1], A Načinović-Duletić[1,*] T Valković[1], E Fišić[2], S Štifter[3], K Lučin[3], I Seili-Bekafigo[4], D Petranović[1], I Host[1], N Jonjić[3]
[1]Department of Hematology, [2]Department of Laboratory diagnostic, Clinical Hospital Center Rijeka, [3]Department of Pathology, Medical School Rijeka, University of Rijeka, [4]Center for Cytology , Clinical Hospital Center Rijeka, Rijeka, Croatia

Background: Angiogenesis is gaining importance in hematological malignancies; it is regulated by a balance of various enhancing and inhibiting angiogenic factors. However, studies related to the prognostic value of angiogenic factors and aggressive Non-Hodgkin lymphomas are limited compared to solid tumors.
Aims: The aim of this study was to determine pretreatment serum level of vascular endothelial growth factor (VEGF), osteopontin (OPN) and macrophage chemotactic protein-1 (MCP-1), recognized to be involved in the angiogenesis. The expression was analyzed at the protein level in serum in patients with diffuse large B cell lymphoma (DLBCL) and investigated whether these biomarkers provide prognostic information.
Methods: We measured pretreatment serum levels of VEGF, OPN and MCP-1 by Enzyme-Linked Immunosorbent Assay (ELISA) in 76 patients newly diagnosed as diffuse large B-cell lymphoma and in 30 healthy controls. All patients were treated with rituximab-CHOP chemotherapy.
Results: The serum VEGF levels were found elevated in untreated DLBCL patients compared to controls: in patients ranged from 47.4 to 1512.6 pg/ml; median 423.4 pg/ml while VEGF levels of the healthy controls ranged from 41.8 to 289.4 pg/ml; median 192.6 pg/ml (P=0.002). There were significant differences in the serum OPN levels between DLBCL patients and controls (median 81.5 pg/ml *vs.* 29.5 pg/ml, P<0.001). Median serum levels of MCP-1 in patients with DLBCL was 1005 pg/ml and 790 pg/ml in control group (P=0.044). Serum VEGF levels were significantly higher in patients with an more advanced Ann Arbor stage (P=0.038), B symptoms (P=0.011), ECOG ≥2 (P=0.027), International Prognostic Index (IPI) ≥3 (P=0.018). Higher serum OPN levels were correlated with advanced Ann Arbor stage (P=0.006), B symptoms (P<0.001), ECOG ≥2 (P=0.027), IPI ≥3 (P<0.001), elevated serum LDH (P<0.001) and bone marrow infiltration (P=0.008). High MCP-1 was associated with Ann Arbor stage III-IV (P=0.009), IPI ≥3 (P=0.007) and bone marrow infiltration (P=0.016). Patients who achieved complete remission (CR) with therapy had a significantly lower value of VEGF (P=0.004) and OPN (P=0.007) in correlation to patients without CR achieved. The overall survival (OS) in patients with a serum level of VEGF lower than median VEGF was superior to those with VEGF higher than median (P=0.022). Furthermore, better OS was also noted in patients with OPN serum level lower than median (P<0.001). Serum MCP-1 levels did not predict outcome/response to therapy and survival. The univariate analysis for overall survival was identified to have prognostic significance: age, tumor grade, B symptoms, performace status, IPI, LDH, bone marrow infiltration, response to therapy, elevated OPN, VEGF and simultaneous elevation of 3 elevated biomarkers. Nevertheless, multivariate Cox proportional hazard regression analysis showed that no response to therapy (P<0.001), elevated LDH (P=0.006), elevated OPN (P=0.009) and VEGF (P=0.017) were considered independent prognostic factors for overall survival.
Summary and Conclusions: Our results showed that pretreatment serum level of VEGF and OPN are predictors of response to therapy and survival after immunochemotherapy and may help to further stratify DLBCL patients into risk groups.

PB1776

RITUXIMAB-INDUCED HYPOGAMMAGLOBULINEMIA AND SUPPORTIVE INTRAVENOUS IG (IVIG) TREATMENT IN PATIENTS WITH NON HODGKIN LYMPHOMA

A De Renzo[1], R Della Pepa[1], S Luponio[1], C Cerchione[1,*] G Beneduce[1], I Migliaccio[1], N Pugliese[1], C Cimmino[1], E Seneca[1], A E Pareto[1], O Vitagliano[1], L Simeone[1], F Pane[1], G Spadaro[2]
[1]Hematology, [2]Interdepartmental Center for basic and clinical Immunological Sciences, AOU "Federico II", Napoli, Italy

Background: Rituximab is a chimeric murine/human-engineered monoclonal antibody which can selectively deplete CD20-expressing B cells in peripheral blood and lymphoid tissues. It is demonstrated efficacy in patients with various lymphoid malignancies, including indolent and aggressive forms of B-cell non Hodgkin's lymphoma (NHL) and the favorable toxicity profile have led to its broad application in induction and maintenance regimens for B-cell malignancies, and, in particular, Non Hodgkin Lymphoma (NHL).
Aims: This retrospective single center analysis, aims to evaluate the incidence of Rituximab-related hypogammaglobulinemia (hypoIg).
Methods: In our institution, in patient affected by NHL in treatment with Rituximab-based regimens, we performed serial quantitative serum immunoglobulin (SIg) concentration at baseline, after chemotherapy, during and after Rituximab maintenance treatment. IgG, IgA and IgM deficit were respectively defined by level below 700 mg/dL, 70 mg/dL and 40 mg/dL. We considered patients as symptomatic if they developed at least two non-neutropenic infections in a 6-months observation period after or during Rituximab-based treatment.
Results: 88 patients with NHL and SIgG monitoring were retrospectively analyzed, 24% of them were relapsed or refractory after first courses of chemotherapy. The median age of patients was 61 years (range: 28-80 y).

From histological examinations, the patient were diagnosed as follicular lymphoma (FL) (n=53), small lymphocytic lymphoma (SLL) (n=9), marginal zone lymphoma (ML) (n=11), mantle cell lymphoma (MCL) (n=9), diffuse large B-cell lymphoma (DLBCL) (n=6). Patients received a median of 11 administrations of Rituximab (range: 6-27). The median follow-up of surviving patients was 3.6 years. Before treatment with Rituximab, 9/88 (10.2%) had low SIgG levels (6 FL, 1 MCL, 1 SLL, 1ML) and in 4/9 (44.4%), during R-maintenance treatment, IVIG administration was necessary. After R-based chemotherapy regimens, IgG deficiency was observed in 20/88 (22.7%), no one needed IVIG, despite 7/20 (35%) were symptomatic. After or during Rituximab-based maintenance treatment, in 22/88 (25%) IgG deficiency was observed after a median of 10 R administrations; the deficit was observed in 77% (17/22) within the fourth R maintenance administration and in no one after the sixth R administration. In this category, 12/22 (54.5%) were symptomatic and 4/22 (18.2%) required IVIG supportive treatment. In all 8 patients who needed IVIG treatment, at least two different Ig isotypes were deficient.

Summary and Conclusions: Rituximab treatment is associated with a high risk of hypoIg development. Moreover, the number of administrations is strictly related to the development of symptomatic hypoIg, and the risk of hypoIg increases in patients in Rituximab-based maintenance. The decision to introduce supportive treatment with IVIG in non-neutropenic patients was related to the number of infection episodes. HypoIg often is undiagnosed, in particular for the presence of confounding symptoms. Our study suggests that Ig levels monitoring and supportive IVIG treatment should be considered in this patients subset.

PB1777

RP6530, A DUAL PI3K DELTA/GAMMA INHIBITOR, DEMONSTRATES EFFICACY IN DLBCL CELLS IN VITRO

S Vakkalanka[1,*] S Nyayapathy[2], B Govindarajulu[2], S Viswanadha[2]
[1]Rhizen Pharmaceuticals SA, La Chaux-de-Fonds, Switzerland, [2]Incozen Therapeutics PVT. LTD, Hyderabad, India

Background: Diffuse Large B-Cell Lymphoma (DLBCL) is an aggressive, rapidly growing type of lymphoma that comprises of 30-40% of NHL cases. Chemotherapy remains the most widely used treatment for DLBCL thereby necessitating the need to develop targeted and safer drugs. Recent clinical trials have demonstrated a therapeutic potential for Ibrutinib, a small molecule BTK inhibitor in DLBCL, especially the ABC subtype. Given the expression pattern in DLBCL cells and overlapping pathway with BTK, treatment with a PI3K δ/γ may be a viable alternative to conventional chemotherapy. RP6530 is a novel, potent, and selective PI3K δ/γ inhibitor. RP6530 demonstrates high potency against PI3Kδ (IC_{50}=25 nM) and γ (IC_{50}=33 nM) enzymes with selectivity over α (>300-fold) and β (>100-fold) isoforms. Cellular potency has been confirmed in target-specific assays, namely anti-FcεR1-(EC_{50}=38 nM) or fMLP (EC_{50}=39 nM) induced CD63 expression in human whole blood basophils, LPS-induced CD19+ cell proliferation in human whole blood (EC_{50}=250 nM), and LPS-induced CD45R+ cell proliferation in mouse whole blood (EC_{50}=101 nM).

Aims: The objective of this study was to evaluate the effect of RP6530 in DLBCL cells.

Methods: RP6530 was tested for potency in viability, apoptosis, and Akt phosphorylation assays in the GCB and ABC subtype DLBCL cell lines, OCI-LY-1 and OCI-LY-10, respectively. Viability was assessed using the colorimetric MTT reagent after incubation of cells with RP6530 as a single agent or in combination with Ibrutinib for 72 h. Inhibition of pAKT was estimated by Western Blotting and bands were quantified using ImageJ after normalization with Actin. Apoptosis of OCI-LY-10 or OCI-LY-1 cells was determined by measuring Caspase-3 activity fluorimetrically. Primary cells from DLBCL patients were isolated, incubated with 4 μM RP6530, and analyzed for apoptosis or cytotoxicity by Annexin V/PI staining.

Results: RP6530 caused a dose-dependent inhibition in proliferation of OCI-LY-1 and OCI-LY-10 with half-maximal inhibitory values of 664 nM and 156 nM respectively Addition of 0.5 μM RP6530 caused a significant left-ward shift in the EC_{50} for ibrutinib (216 nM *vs.* 5 nM for OCI-LY-1 and 678 nM *vs.* 21 nM for OCI-LY-10). Reduction in cell viability was accompanied by corresponding inhibition of pAKT with EC_{50} of 6 & 70 nM in OCI-LY-1 and OCI-LY-10 cells, respectively. In addition, RP6530 increased apoptosis manifested by an elevation of caspase-3 activity in both cell lines. Treatment of patient-derived primary GCB-DLBCL cells with 4 μM RP6530 caused a 2-fold increase in total apoptosis as evident from Annexin V/PI staining.

Summary and Conclusions: RP6530 is a potent and selective dual PI3Kδ/γ inhibitor that inhibited growth of DLBCL cell lines with a concomitant reduction in the downstream biomarker, pAKT. Besides, RP6530 at clinically relevant concentrations potentiated the activity of ibrutinib by 30-40-fold. Additionally, the compound induced apoptosis in primary DLBCL cells. Findings provide a rationale for future clinical trials in DLBCL patients.

SOCIOECONOMIC AND ETHNIC VARIATIONS IN SURVIVAL OF PATIENTS WITH NON-HODGKIN'S LYMPHOMA IN USA

SK Mukkamalla[1,*] R Chakraborty[1], B Seligman[2]
[1]Internal Medicine, [2]Hematology/Oncology, Icahn School of Medicine at Mount Sinai/Queens Hospital Center, Jamaica, United States

Background: The incidence of Non-Hodgkin's Lymphoma (NHL) in the United States (US) has been increasing for the last several decades. However, US cancer mortality from NHL has seen a downtrend in the recent years. As per National Cancer Institute's (NCI) SEER factsheet the Annual percent change (APC) for NHL mortality from 1997-2009 was -3.01. This could be attributed to the cyclophosphamide, doxorubicin, vincristine, and prednisone (CHOP) combination regimen followed by addition of rituximab. Few studies have shown that socioeconomic status (SES) does influence diagnosis, treatment and survival of patients with NHL (Ewing et al, 2003; Bray et al, 2008; Rachet et al, 2008; Roswall et al, 2008, Wang et al, 2008; Kent et al, 2010). Several studies have been reported to demonstrate ethnic disparities in the past, however some of them looked into the elderly population alone while remaining failed to take into consideration other ethnicities (other than Hispanics, African Americans and Caucasians).

Aims: In our study we try to investigate socioeconomic and ethnic disparities in survival of NHL patients belonging to all age groups and all ethnicities.

Methods: A retrospective cohort of 22,419 NHL patients diagnosed from 2004 to 2005, belonging to all age groups and ethnicities, was identified from SEER database. The median follow up time was 4.5 years. Descriptive statistics (chi-square test) were used to analyze the differences in distribution of baseline characteristics by race. Cox proportional model was used to compare survival among different ethnic groups using PHREG procedure in SAS 9.2 (SAS Institute Inc., Cary, NC, USA).

Results: Of the cohort 85.2% were Caucasians, 8.32% African Americans and 6.48% from other ethnicities. The mean age of study population was 62.2±17.3 years. A large proportion of other ethnicities (non-black and non-white) were in the highest quartile of education (32.48%) and economic status (35.86%). Hazards ratio of all cause and NHL mortality increased significantly with age, stage, unemployment rate, smoking rate, language isolation rate and decreased with increase in household income ($p<0.05$). Married population was found to have better survival compared to single and divorced/widowed population ($p<0.0001$). After confounding for all other variables, including subtypes and stage at presentation, NHL mortality was found to be higher in African Americans (HR 1.055, 95% CI 1.003-1.109) and other ethnicities (HR 1.113, 95% CI 1.053-1.175) compared to Caucasians. There was no significant difference in NHL mortality between females and males ($p=0.13$).

Summary and Conclusions: In this study we tried to assess the ethnic and socioeconomic disparities in the survival of NHL patients belonging to all age groups and all ethnicities in US. Some important findings of our study were identification of age, stage of presentation, unemployment, smoking, language isolation and household income as significant influences on overall mortality of NHL patients. We found mortality to be significantly higher in African Americans and patients belonging to other ethnicities compared to Caucasians after controlling for demographic factors, socioeconomic factors and stage at presentation. However, there was no statistically significant difference in mortality between males and females. In conclusion, our study shows a strong correlation between social deprivation and decreased survival in NHL patients belonging to all age groups. Also, Caucasians seem to have higher survival compared to African Americans and other ethnicities. However additional studies, including all other possible prognostic variables, are required to substantiate this finding.

HEAT SHOCK PROTEIN 90 INHIBITOR NVP-AUY922 EXERTS POTENT ACTIVITY AGAINST ADULT T-CELL LEUKEMIA-LYMPHOMA CELLS

H Taniguchi[1,*] H Hasegawa[2], D Sasaki[2], S Mori[2], K Ando[1], Y Sawayama[1], D Imanishi[1], J Taguchi[1], Y Imaizumi[1], T Hata[1], K Tsukasaki[3], K Yanagihara[2], N Mori[4], Y Miyazaki[1]
[1]Department of Hematology, Atomic Bomb Disease and Hibakusha Medicine Unit, Atomic Bomb Disease Institute, Nagasaki University, [2]Department of Laboratory Medicine, Nagasaki University Hospital, Nagasaki, [3]Department of Hematology, National Cancer Center Hospital East, Kashiwa, [4]Department of Microbiology and Oncology, Graduate School of Medicine, University of the Ryukyus, Okinawa, Japan

Background: Adult T-cell leukemia-lymphoma (ATL), an aggressive neoplasm

etiologically associated with human T-lymphotropic virus type-I (HTLV-1), is chemo-resistant malignancy. Heat shock protein 90 (HSP90) is involved in folding and functions as a chaperone for multiple client proteins, many of which are important in tumorigenesis. In contrast to normal cells, tumor cells contain an abundance of catalytically active HSP90, which is found in multichaperone complexes. Therefore, HSP90 has emerged as a target of interest in cancer therapy. The HSP90 inhibitor 17-AAG, derived from geldanamycin, has shown potent antitumor activity against ATL. However, geldanamycin derivatives have several limitations, including poor solubility, formulation difficulties, and severe hepatotoxicity in clinical settings, which have prompted development of next generation synthetic HSP90 inhibitors including NVP-AUY922 (AUY922), an isoxazole-based nongeldanamycin HSP90 inhibitor that inhibits the ATPase activity of HSP90. AUY922 has shown nanomolar efficacy against a wide range of human cancer cells *in vitro* and also inhibits progression of a variety of tumors *in vivo*. Furthermore, in a phase I clinical trial of AUY922 in patients with advanced solid tumors, the agent exhibited acceptable tolerability.

Aims: We examined the effects of AUY922 on ATL cells *in vitro* and *in vivo* and explored a novel therapeutic target by investigating its molecular mechanisms.

Results: First, we analyzed the effects of AUY922 (kindly provided by Novartis) on proliferation of ATL-related cell lines [ATL-derived cell lines (KK1, SO4, LM-Y1, KOB and ST1) and HTLV-1-infected T-cell lines (MT2 and HuT102)]. Incubation with AUY922 at various concentrations (0–100 nM) for 72 hours inhibited cellular proliferation in a dose-dependent manner, as assessed by an MTS assay. The concentrations of AUY922 required to inhibit cellular proliferation of ATL-related cell lines by 50% (IC50) varied from 12.5 to 25.0 nM. Importantly, AUY922 was effective regardless of the presence of wild-type or mutant p53. We also assessed AUY922-induced inhibition of growth of peripheral blood mononuclear cells (PBMCs) obtained from both normal subjects and patients with ATL. Importantly, primary ATL cells were more susceptible to AUY922 than normal PBMCs. Also, when compared directly with 17-AAG, AUY922 was between 20- and 50-fold more active at inhibiting growth of ATL-related cell lines. FACS analysis revealed that AUY922 induced apoptotic cell death and/or G1 phase cell cycle arrest in ATL-related cell lines. To verify the molecular mechanisms, we also examined the expressions of several client proteins using Western blotting (WB) analysis. AUY922 treatment led to induction of HSP70, a surrogate marker for inhibition of HSP90 function, while it did not influence the protein level of HSP90 itself. AUY922 treatment also led to decreases in p-Akt, Akt, IKKα, IKKβ, IKKγ, Cdk4, Cdk6, Bcl-2 and survivin. In a xenograft model created with C.B-17/Icr-SCID mice, intraperitoneal administration of the vehicle or AUY922 was given after injection of HuT102 cells. In the control mice, bulky tumors grew within 4 weeks, whereas daily administrations of AUY922 significantly impaired tumor growth. To determine which molecules play important roles in AUY922-induced ATL-cell death, gene expression profiling was performed using DNA microarray analysis in 4 ATL-related cell lines (KK1, SO4, LM-Y1 and HuT102). Interestingly, decreases in 2 of the proviral integration site for Moloney murine leukemia virus (PIM) kinases, PIM-1 and -3, were commonly found in all cell lines we examined. PIM has multiple cellular functions related to cell survival, proliferation, differentiation, apoptosis and tumorigenesis. Its expression is also correlated with poor prognosis in most hematopoietic malignancies. However, its role in ATL remains unclear. Therefore, we examined the protein expression levels of PIM kinases using WB in 4 ATL-related cell lines (KK1, SO4, LM-Y1 and HuT102) treated by AUY922. Although the protein levels of PIM kinases varied in each of the ATL-related cell lines when untreated, the protein expression levels of PIM-1, -2, and -3 were decreased in all. To confirm the importance of PIM kinases in ATL cells, we evaluated the inhibitory effect of SGI-1776, a pan-PIM kinase inhibitor, on proliferation of ATL-related cell lines and primary ATL cells. SGI-1776 successfully inhibited the growth of primary ATL cells as well as ATL-related cell lines.

Summary and Conclusions: Our findings show that AUY922 may be potentially useful as a chemotherapeutic agent and PIM kinases may be a novel therapeutic target for treatment of ATL.

PB1781

APOPTOSIS INDUCING AGENTS IN CUTANEOUS T-CELL LYMPHOMA (CTCL) CELL LINES

V Bakou[1], E Papadavid[2], E Konsta[1], M Vikentiou[1], F Kontsioti[1], S Papageorgiou[1], ED Ioannidou[1], E Bazani[1], D Vasilatou[1], P Tsirigotis[1], C Antoniou[3], D Rigopoulos[2], G Dimitriadis[1], V Pappa[1,*]

[1]Second Department of Internal Medicine and Research Institute, [2]Second Department of Dermatology, Attikon University General Hospital, [3]First Department of Dermatology , Andreas Syggros Hospital, Athens, Greece

Background: Cutaneous T-cell lymphomas (CTCL) represent a heterogeneous group of non-Hodgkin lymphomas, derived from skin-homing mature T-cells. Mycosis fungoides (MF) and Sézary syndrome (SS) are the commonest types and together comprise 54% of all CTCL. MF evolves from patches to infiltrated plaques and eventually tumors. SS is a lymphoma-leukemia syndrome characterized by erythroderma and the presence of a malignant T-cell clone in the peripheral blood and the skin. Radiotherapy and classic anthracycline-based chemotherapy provide only short-lived remission; therefore current CTCL research efforts are focused on decoding the mechanisms of chemotherapy resistance and on identifying new pharmacological targets. Thus, several drugs have currently shown potentially significant activity either alone or in combination with conventional agents.

Aims: Few clinical studies have been conducted so far to test the most effective drug combinations. This study aims to investigate the apoptotic effects and the possible synergistic action of various, novel in CTCL treatment, drug combinations, using CTCL cell lines.

Methods: Three CTCL cell lines have been used: MyLa derived from a plaque biopsy of a patient with MF, SeAx and Hut-78 both derived from peripheral blood of patients with Sézary syndrome. All cells were cultured in RPMI 1640, supplemented with 10% FBS and 2 mM L-glutamine (37 ^{0}C,5% CO_2). Cells were treated with the following agents and their combinations for 72h: Bortezomib (10nmol/L), methotrexate (10μM) and interferon—a (100U/mL). Apoptosis and cell viability were determined by flow cytometry using the Annexin V/PI method.

Results: Hut-78 cells responded with enhanced apoptosis when treated with bortezomib and methotrexate, compared to untreated cells (control) (5.48 and 9.57 *vs* 1.32 respectively, p<0.001), while treatment with interferon-a had no significant effect on apoptosis. The methotrexate/interferon-a combination showed even higher apoptotic rates, compared to untreated cells (10.54 *vs* 1.32, p<0.001). Treatment with all three agents also significantly increased apoptosis compared to control (6.62 *vs* 1.32, p<0.001), but not at the same level as the methotrexate/interferon-a combination. Interestingly, all drug combinations led to great enhancement of late apoptosis, with the bortezomib/methotrexate/interferon-a combination presenting the most impressive effect, compared to control (67.44 *vs* 0.62, p<0.001). None of the above agents or their combinations seemed to affect early apoptosis in SeAx and MyLa cells. On the contrary, all drug combination treatments significantly increased late apoptosis in both cell lines, while the Bortezomib/methotrexate/interferon-a treatment presented the most impressive augmentation in late apoptosis rates for both cell lines (SeAx: 14.46 *vs* 0.38, p<0.001; MyLa: 76.19 *vs* 43, p<0.001).

Summary and Conclusions: Our data clearly demonstrate that CTCL cells respond to combination treatment better than to monotherapy, in terms of apoptosis' induction. We showed that methotrexate (which has a proven efficacy against CTCL), interferon-a and bortezomib have a synergistic action in CTCL, leading to enhanced sensitivity to apoptosis, in SS and MF cell lines. Although these results need to be further confirmed both *in vitro* and *in vivo*, they appear very encouraging for the integration of combination treatment in CTCL therapy.

PB1782

ANALYSES OF NUCLEAR ORPHAN RECEPTOR EXPRESSION AND CYTOTOXICITY FOLLOWING ANTI-CD 20 MONOCLONAL ANTIBODY TREATMENT IN AGGRESSIVE NON-HODGKIN'S LYMPHOMAS

K Wenzl[1,*] K Troppan[1], A Deutsch[1], P Neumeister[1]

[1]Haematology, Medical University of Graz, Graz, Austria

Background: Recently, we found a reduced *NR4A1* and *NR4A3* expression in aggressive B-cell lymphomas. The functional characterization of *NR4A1* in lymphoma cell lines demonstrated its pro-apoptotic effects. The standard therapy for aggressive B-cell lymphoma is a multiagent chemotherapy combined with anti-CD20 monoclonal antibody (mAb) Rituximab (Rtx). Recent studies demonstrated that monotherapy with Rtx exhibited cytotoxic activity *in vivo* and *in vitro*.

Aims: The aim was to investigate the effects of two anti-CD20 mAB (Rtx and GA101) on two CD20 positive cell lines (SuDHL4 and Raji) *in vitro* and their influence on *NR4A*s expression.

Methods: Therefore, we performed cytotoxicity assays combined with mRNA expression analysis of *NR4A1*, *NR4A2, NR4A3* and pro-apoptotic genes on two CD20 positive cell lines (SuDHL4 and Raji) treated with two anti-CD20 mAb (Rtx and GA101).

Results: Rtx treatment reduced cell viability significantly after 24h and caused a cell cycle arrest in SuDHL4 but not in Raji. In contrast, GA101 was able to reduce cell viability significantly after 3h of treatment in both cell lines. *NR4A* expression analyses demonstrated that anti-CD20 mAb treatment induces *NR4A1* and *NR4A3* expression in SuDHL4 after 3h. The highest induction of *NR4A1* (115 fold) and *NR4A3* (360 fold) expression was found in Rituximab treated SuDHL4 cells. Substantially lower, but still significant was the *NR4A1* (28 fold) and *NR4A3* (46 fold) up-regulation in GA101 treated SUDHL4 cells. By correlating the constitutive *NR4A1* and *NR4A3* expression of untreated cells with cytotoxic effects of Rtx and GA101, we observed a significant positive correlation between *NR4A1* expression and cytotoxic effects of Rtx (Spearman-Rho: 0.640 p=0.008) suggesting gene dosis of *NR4A1* might be critical for the cytotoxic effects of Rtx. Furthermore, treatment with Rtx resulted in a significant up-regulation of *BIM* (2 fold) and down-regulation of *TRAIL* (4 fold) after 3h and up-regulation of *BIK* (2 fold) after 24h in SuDHL4, whereas Raji showed only

an up-regulation of *BIK* (1.5 fold) after 24h of treatment. 12 h of GA101 treatment resulted in an up-regulation of *BIK* (2 fold) and *BAX* (2 fold) in SuDHL4 and an up-regulation of *PUMA* (1,5 fold) in Raji after 3h of treatment.
Summary and Conclusions: Our data demonstrate that Rituximab and GA101 differ in their cytotoxicity and induction of *NR4A1* and *NR4A3* expression in a cell line depending fashion. Hence, *NR4A1* and *NR4A3* might be important factors for mediating the cytotoxic effects of Rituximab and GA101 in diffuse large B-cell lymphomas.

WHOLE-EXOME SEQUENCING ANALYSIS OF DIFFUSE LARGE B-CELL LYMPHOMAS IN THE MEDIASTINUM OF FEMALE SIBLINGS

R Burkhard[1,*] I Keller[2,3], R Bruggmann[3], A Tzankov[4], S Dirnhofer[4], U Novak[1,5]
[1]Experimental Oncology/Haematology, Department of Clinical Research, [2]Department of Clinical Research, [3]Interfaculty Bioinformatics Unit, University of Bern, Bern, [4]Institute of Pathology, University Hospital Basel, Basel, [5]Department of Medical Oncology, Inselspital, Bern University Hospital, Bern, Switzerland

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common malignant lymphoma in adults, comprising ~40% of cases. By means of gene-expression profiling, the morphologically indistinguishable DLBCLs can be divided into three cell-of-origin subtypes characterized by distinct molecular and clinical features. Most lymphomas arise sporadically, yet familial clustering is known, but currently poorly understood at the molecular level.
We characterize a Swiss family with two female siblings affected by DLBCLs localized in the mediastinum with the age of onset being 25 and 30, respectively. While the younger sibling, presented with CD30+ DLBCL of the activated B-cell (ABC) type with PMBL-like compartmentalizing sclerosis, achieved complete remission, her older sibling died due to disease progression 11 months after being diagnosed with a primary mediastinal DLBCL (PMBL). Pathological analyses revealed different (*e.g.* BCL2 expression, positive in the PMBL, negative in the ABC-DLBCL), but also shared molecular features, *e.g.* gain of the *JAK2* locus by FISH. The similar clinical and molecular characteristics suggested a shared biological background.
Aims: To identify the possible genetic predisposition in this family.
Methods: We performed whole-exome sequencing on matched tumor and germline (extracted from peripheral blood) DNA from both siblings and the DNA from their unaffected brother and parents. The tumor DNA, isolated from laser-dissected formalin-fixed paraffin-embedded tissue, was highly degraded and required extensive adaptations of the standard library-preparation protocol, *e.g.* treatment with PreCR Repair mix from New England Biolabs. The exome was captured using the Illumina TrueSeq 62Mb exome enrichment kit, sequencing was performed on an Illumina HiSeq2000 to produce 100bp paired-end reads. After quality control (FastQC), the reads were aligned to the reference genome hg19 (bowtie-2). GATK Unified Genotyper was used to detect germline inherited and *de novo* variants, while somatic alterations were called by Strelka and SomaticSniper.
Results: On average, 16 and 56 gigabases were sequenced per tumor and healthy DNA, respectively. In all samples, ~95% of the sequenced reads mapped to the reference genome. Removal of duplicated reads resulted in an average exome coverage of 70 and 20 fold for each healthy and tumor DNA, respectively. In this analysis, we are focusing on *a)* rare (< 10% allele frequency according to the 1000 Genomes project) germline protein altering variants that are shared by the siblings and possibly implicated in lymphomagenesis, and *b)* somatic, lymphoma-specific alterations. This approach *e.g.* revealed 960 shared rare non-silent germline alterations, including 773 missense mutations and 187 indels, affecting 721 different genes. Of these, 951 variants were inherited, while the remaining variants were acquired *de novo*. To reduce the number of germline candidates, we will consider i) genes which have been linked to lymphoma or cancer, ii) mutations which are predicted to be deleterious and iii) genes which are mutated according the Knudson's two-hit theory. Further reduction will be achieved by integrating the results of the healthy brother. The proposed bioinformatics analysis is currently ongoing and candidates will be presented.
Summary and Conclusions: The identification of alterations possibly predisposing to familial DLBCL will contribute to the understanding of the genetic basis of this complex and heterogeneous tumor. In addition, analyzing the somatic landscape of both DLBCL might provide an explanation for the different diagnosis and outcome of the siblings.

PB1784

INVESTIGATION OF RHO-KINASE GEN AND PROTEIN EXPRESSIONS IN MANTLE CELL LYMPHOMA PATIENTS

D Yanardag Acik[1,*] M Yilmaz[1], I Sari[2], S Oztuzcu[2], Z A Sayiner[2], S Subari[2], AT Demiryurek[2]
[1]Hematology, [2]Gaziantep University, Gaziantep, Turkey

Background: Mantle cell lymphoma (MCL) is a rare but aggressive form of B-cell non-Hodgkin's lymphoma with a heterogeneous clinical presentation. In MCL, one allele of the cyclin D1 gene is translocated from its normal localization on chromosome 11 to chromosome 14. So, this disease is characterized by overexpression of cyclin D1. There is no proven curative therapy and no standard of care has been established for initial or subsequent lines of therapy. Rho-kinase (ROCK) is a serine-threonine protein kinase with multiple downstream effects. Two isoforms of ROCK protein, ROCK1 and ROCK2 have been characterized. ROCK is involved in the migration and proliferation of tumor cells. Increased expression of the ROCK proteins contributes to the metastatic behavior of some cancers. Furthermore, ROCK activation increases the expression of cyclin D1.
Aims: The aim of this study was to elucidate the role of ROCK gene and protein expressions in MCL.
Methods: This study was performed retrospectively. A total of 60 patients with MCL and 60 controls evaluated at the Hematology Department of Gaziantep University Hospital, Turkey between 2006-2012 years were recruited into this study. Controls were from the nonneoplastic tissue sections diagnosed as reactive lymphadenopathy at the Pathology Department. Hematoxylin and eosin stained slides in the entire archive was reevaluated and selected for immunohistochemistry and PCR. p53, p63, ROCK1 and ROCK2 stainings were scored according to staining ratio in tumor cells. Ki-67 was expressed as%. To confirm the expressions of ROCK in bladder tissue, mRNA was extracted; cDNA was produced and analyzed by a BioMark HD 96.96 dynamic array system (Fluidigm, South San Francisco, CA, USA). Data were analyzed using the $2^{-\Delta Ct}$ method, compared by using the Mann-Whitney U test.
Results: In immunohistochemical studies, there was significant increase in ROCK1 (P=0.0009) and ROCK2 expression in MCL patients when compared with control group (P<0.0001). ROCK2 expression was higher than ROCK1 in MCL patients (P<0.0001). There were significant positive correlations between age and ROCK1 (P=0.044). Expressions of p53 and Ki-67 were found to be stronger in patient group than control group. There was marked increase in *ROCK1* gene expression in patients group when compared to controls (P=0.0215). However, no significant change was observed in *ROCK2* gene expression (P=0.9194).
Summary and Conclusions: In conclusion, our data showed that *ROCK* gene expressions may contribute to the development of MCL. Our results may imply that up-regulation of ROCK may represent a prognostic factor in MCL. ROCK may be a potential target for MCL diagnosis and therapy.

PB1785

THE FOXO3A-P53 AXIS: FUNCTIONAL ANALYSIS IN MANTLE CELL LYMPHOMA

M Serra[1,*] A Obrador-Hevia[1], P Villalonga[1], S Fernandez de Mattos[1]
[1]IUNICS, Universitat de les Illes Balears, Palma, Spain

Background: Mantle cell lymphoma (MCL) is a rare subtype of B-cell non-Hodgkin lymphoma (NHL) that comprises around 6% of all NHL and presents a poor response to current therapeutic treatments. MCL is characterized by the t(11;14) chromosomal translocation, which results in aberrant expression of cyclin D1. This genetic event is present in virtually all cases of MCL, whereas additional genetic alterations that occur in subsets of MCL have been described. Most of these alterations appear to disturb the cell cycle machinery or interfere with the cellular response to DNA damage. FOXO transcription factors are relevant tumour suppressors that mediate the expression of genes involved in several biological processes, such as cell cycle arrest, DNA repair and apoptosis.FOXO3a is the predominant member of the FOXO subfamily in lymphoid tissues, plays an essential role in lymphomagenesis and is essential for proliferation of cells of the immune system. FOXOs are negatively regulated by the PI3K/Akt pathway; interestingly, members of the PI3K pathway such as *PI3KCA* or *Akt1* are over-expressed in MCL. Several nodes of interaction have been identified between FOXO3a and p53, a major tumor suppressor in humans and mice. Our group has reported the importance of FOXO3a in the biology of MCL cells, but little is known about the relevance of the FOXO3a-p53 axis in the context of MCL biology.
Aims: We have evaluated the role of FOXO3a-p53 interaction in a panel of MCL cell lines with different p53 status and its relevance in MCL biology.
Methods: We have analysed the response of MCL cells to chemical modulators of this pathway such as Nutlin-3a, Psammaplysene A and DNA damaging agents. Cell viability assays have been conducted in a panel of cell lines, and the expression levels of FOXO3a, p53 and its targets have been analysed by qRT-PCR and western blot. Inmunoprecipitation assays have been performed to demonstrate the interaction between p53 and FOXO3a.
Results: FOXO3a is activated in response to Nutlin-3a in MCL cells, and expression of FOXO/p53 target FOXM1 is decreased. Also, coimmunoprecipitation studies show evidence of FOXO3a-p53 binding in MCL cells. DNA damaging agents modulate FOXO3a activity, FOXM1 levels and FOXO3a-p53 binding.
Summary and Conclusions: Our results show the importance of the

interaction between FOXO3a and p53 in MCL biology and suggest that this signalling route can be considered as a potential therapeutic target in MCL.

PB1786

MICRORNA LEVELS IN HEPATITIS B OR C VIRUS-RELATED INDOLENT B CELL LYMPHOMAS

R Bruni[1], A Pulsoni[2,*] F De Angelis[2], GM D'Elia[2], G Annechini[2], P D'Urso[2], C Marcantonio[1], P Tataseo[3], E Spada[1], F Marcucci[4], P Bianco[5], U Villano[1], ME Tosti[4], AR Ciccaglione[1], A Mele[6]

[1]Department of Infectious, Parasitic and Immunomediated Diseases, Istituto Superiore di Sanità, Rome, Italy, [2]Department of Cellular Biotechnologies and Hematology, Sapienza University, Rome, Italy, rome, [3]Transfusional Medicine and Molecular Biology Laboratory, ASL Avezzano-Sulmona, Sulmona, [4]National Centre for Epidemiology, Surveillance and Health Promotion, Istituto Superiore di Sanità, Rome, Italy, [5]Department of Molecular Medicine, Sapienza University, Rome, Italy, rome, [6]Associazione Calabrese di Epatologia (ACE), Pellaro, Italy

Background: Epidemiological evidence links Hepatitis B Virus (HBV) and Hepatitis C Virus (HCV) to B-cell non-Hodgkin lymphoma (B-NHL). These B-NHLs, particularly those associated with HCV, may represent a distinct sub-group with peculiar molecular features, including peculiar expression of microRNAs (miRs).

Aims: Aim of the present study was to search for miRs whose level in indolent B-NHL tissues could be associated with HBV or HCV infection.

Methods: Fourteen Formalin Fixed Paraffin Embedded (FFPE) lymph node tissues from HBV+, HCV+ and HBV-/HCV- indolent B-NHL patients were analyzed for levels of 34 selected miRs by quantitative Real-Time PCR. Reactive Lymph Nodes (RLNs) from HBV-/HCV- patients were included as non-tumor control. Statistical analysis of output data included Pearson and Spearman correlation and Mann-Whitney test and were carried out by the STATA software.

Results: MiR-92a was decreased exclusively in HBV-/HCV- B-NHLs, while miR-30b was increased in HBV+ and HCV+ samples, though only the HCV+ achieved full statistical significance. Analysis of a small subset of B-NHLs belonging to the same histological subtype (Nodal Marginal Zone Lymphoma) highlighted three miRs associated with HCV infection (miR-223, miR-29a and miR-29b) and confirmed decreased level of miR-92a in HBV-/HCV- samples also when considering this restricted B-NHL group.

Summary and Conclusions: Although caution is needed due to the limited number of analyzed samples, overall the results suggest that differences at the miR expression level exist between indolent B-NHLs developed in patients with or without HBV or HCV infection. The identification of three further miRs associated with HCV by analyzing histologically homogeneous samples suggests that variations of miR levels possibly associated with HBV or HCV may be obscured by the tissue-specific variability of miR level associated with the different histological subtypes of B-NHL. Thus, the identification of further miRs will require, in addition to an increased sample size, the comparison of B-NHL tissues with the same histological classification.

SIMULTANEOUS HISTOLOGICAL AND MULTIPARAMETRIC FLOW CYTOMETRIC ANALYSIS OF TISSUES BIOPSY OF NON-HODGKIN LYMPHOMAS

R Di Gaetano[1,*] B Callegari[1], V Gasparetto[1], G Bortuzzo[2], A Scapinello[2], E Scarpa[1], G Tagariello[1]

[1]Haematology, [2]Pathology, Castelfranco Veneto Hospital, Castelfranco Veneto, Italy

Background: Our internal procedure for suspected lymphoma provides more than classical histology also the flow cytometric (FC) tissue analysis.

Aims: To compare the possibility of integrate diagnosis of histology and immunophenotyping in the case of lympho nodes speciments analized by both for the diagnosis of lymphoma

Methods: we reviewed biopsies diagnosed by the pathologist and concurrently analyzed by FC from 2003 to 2013. FC data were obtained by a multi-parametric analysis as altered scatter, co-expressions and different intensities of antigens and were used by the pathologist for the final diagnosis.

Results: on the total of 655 revised samples 416 were diagnosed as hematologic neoplasm and according to the WHO classification were: 291 (70%) B-NHL, 15 (4%) T cells-NHL, 100 (24%) Hodgkin lymphoma and 8 (2%) composite lymphomas (CL). Correlation between morphologic findings and FC was found in 264 cases of 291 NHL (91%). Furthermore, the immunophenotype characterized in the lymph node was tested by FC in other types of samples such as bone marrow, peripheral blood or biological fluids at the diagnosis and/or during the follow up. The role of FC was crucial in the T cell neoplasms diagnosis, where the evidence of an atypical pattern may suggest the need for further test and make the diagnosis easyer and quicker . In the case of CLs, the multi-parametric analysis by FC has been decisive in detecting easily the coexistence of clones related to different histotypes. Among the 27 cases (9% of total) "non-concordant" 4 follicular lymphoma, hystologically diagnosed, were included becouse they were previously defined by FC as polyclonal and so confirmed by Molecular Biology. Others 23 presented cytometric data conflicting - less frequent in the course of the years – mainly due to technical aspects such as the treatment of the tissues, the fluorochromes, the antibody combinations, etc. Also inadequate samples (non significant because too small or other technical problem , unnecessary fixation, necrotic tissue etc.) for analysis (31 on 655) decreases over time.

Summary and Conclusions: Our data show as immunophenotyping of solid tissues may be used to enhance the histopathologic evaluation of lymphomas and in particular in the cases of T cell or composite lymphomas, confirming the validity of the procedures to integrate different methods for diagnosis in routine. Our review confirms also that a procedure can evolve over time with continued collaboration, shares information and common renovation (from clinical evaluation to surgery, sampling, processing, analysis, etc.) to strengthen, to enhance and to take advantage of the integrated diagnostics.

PB1788

SENESCENT OR EXHAUSTED: INTRATUMORAL TIM-3+ T-CELLS IN DIFFUSE LARGE B-CELL LYMPHOMA

M Salamoon[1,2,*] B battah[3]

[1]hematology, [2]medical oncology, al Bairouni university hospital, [3]clinical pharmaceutics, faculty of pharmacy, damascus, Syrian Arab Republic

Background: Diffuse large B-cell Lymphoma (DLBCL) is the most common subtypes of non-Hodgkin Lymphoma (NHL). Tumor infiltration with T-cells plays an important role in cell mediated immunity with different impact on patients' outcome

Aims: To evaluate DLBCL microenvironment and the impact of T-cells exhaustion on response to chemotherapy

Methods: Fresh tissue was taken from newly diagnosed 20 patients with DLBCL and we measured CD28 expression on TIM-3+ T-cells. Several techniques were employed such as cell culture of the fresh tissue, flowcytometry and ELISA.

Results: CD28 expression was positive in 75% (median) of TIM-3+ cells indicating that TIM-3 expressing T-cells are not senescent. In the other hand, the remaining 25% (median) TIM-3+ not expressing CD28,further, cytokine production was restored by IL-2 in those cells indicating that they are exhausted T-cells. patients with either exhausted or senescent T-cells accompanied with slow response on Rituximab-CHOP regimen, however, there was a direct proportion between CD8 tumor infiltrating cell rate and response to the former regimen.

Summary and Conclusions: A giant step has been made on the treatment of NHL in the last decade, however, we are still handling challenging cases need a special attention and understanding of the biology and the status of tumor microenvironment before treatment.

PB1789

ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE ASPIRATION BIOPSY FOR DIAGNOSIS OF INTRAABDOMINAL LYMPHOMA WITHOUT ACCESSIBLE PERIPHERAL LYMPHADENOPATHY

K Fukumoto[1,*] S Nakaji[2], K Seike[1], M Fujisawa[1], Y Suehara[1], H Sugihara[1], Y Nishida[1], M Takeuchi[1], K Matsue[1]

[1]hematology/oncology, [2]gastroenterology, Kameda medical center, Kamogawa City, Chiba prefecture, Japan

Background: Endoscopic ultrasound-guided fine needle aspiration biopsy (EUS-FNAB) is considered the procedure of choice for the diagnosis and staging of intra-abdominal non-Hodgkin's lymphoma (NHL) without accessible peripheral lymphadenopathy. However, diagnosis and subclassification lymphoma by FNAB is often challenging due to variable cellularity and lack of architecture. Recent advances of ancillary techniques such as immunohistochemical staining, flowcytometry (FCM), fluorescence *in situ* hybridization (FISH) analysis and molecular analysis allowed classify lymphoma more precisely, although sufficient information can be obtained through this procedure remained undetermined.

Aims: The present study was performed to evaluate the yield of EUS-FNAB using a standard 19 or 22-gauge needle for diagnosis and subclassification of lymphoma, assessing the feasibility of immunohistological, FCM, molecular and cytogenetic assessments.

Methods: Between April 2008 and December 2013, 88 patients with malignant lymphoma who had an intra-abdominal mass without accessible peripheral lymphadenopathy underwent EUS-guided fine needle aspiration biopsy at our hospital. All patients received positron emission tomography/computed tomography and had 2-deoxy-2-(^{18}F)fluoro-D-glucose-avid lesions in abdomen

before examination. The aspirated materials were processed for flowcytometry (FCM), molecular analysis of immunoglobulin heavy (IgH) and T-cell receptor (TCR) gene rearrangement, cytogenetic analysis by conventional G banding, and FISH analysis, in addition to standard histopathological studies. Patients' baseline data, including age, sex, laboratory examinations, imaging studies, and final diagnosis of lymphoma, were collected and examined to determine the feasibility and sensitivity for diagnosis and subclassification of lymphoma.
Results: The mean of the diameter of mass was 37mm (9.7-149mm). Among the 88 patients, FCM analysis, standard cytogenetic analysis, and FISH were successfully performed in 77 (65%), 45 (51%), and 48 (55%) cases, respectively. FCM analysis showed immunoglobulin light chain restriction in 45 cases (79%) and were diagnosed as B-cell lymphoma. FCM could not determine the T-cell clonality. Molecular analyses for TCR and/or IgH receptor rearrangements were successful in 35 patients (40%), 31 rearranged in IgH and 4 rearranged in TCR, respectively. There were 32 cases with IgH/Bcl2 fusions by FISH analysis, 26 cases in follicular lymphoma (FL) and 6 cases in diffuse large B-cell lymphoma (DLBCL), respectively. IgH/Bcl6 fusion was seen in 2 case of DLBCL and IgH/C-myc fusion was seen in 1 case of Burkitt lymphoma (BL). Finally, our cohort included 82 B-cell lymphomas (93%) and 6 T-cell lymphomas (7%). Subclassification of lymphoma in accordance with WHO system included 40 cases of FL, 39 cases of DLBCL, one case of BL, 2 cases of lymphoblastic lymphoma, 5 cases of peripheral T cell lymphoma not specified, and one case of angioimmunoblastic lymphoma. Although all of the outpatients were hospitalized until the day after biopsy, there were no serious complications related to this procedure like bleeding, perforation, ileus, and infection.
Summary and Conclusions: EUS-FNAB using a standard 19 or 22-gauge needle is safe and feasible and has high diagnostic value for subclassification of intra-abdominal lymphoma without accessible peripheral lymphadenopathy. With the use of simultaneous immunophenotyping, molecular, and cytogenetic studies, lymphoma subclassification was possible in most of the cases.

PB1790

THE HISTONE DEACETYLASE INHIBITOR ROMIDEPSIN IN COMBINATION WITH LENALIDOMIDE ENHANCES CYTOTOXICITY VIA THE DOWN-REGULATION OF PI3K/AKT AND MAPK/ERK PATHWAYS IN T-CELL LYMPHOMA CELLS

S Sacchi[1,*] M Cosenza[1], M Civallero[1], S Pozzi[1], S Fiorcari[2], L Marcheselli[1]
[1]Department of Diagnostic, Clinical and Public Health Medicine, [2]Department of Medical and Surgical Sciences , University of Modena and Reggio Emilia, MODENA, Italy

Background: Histone deacetylase (HDAC) inhibitors are emerging as an exciting new therapeutic option for lymphoid malignancies. These drugs increase the acetylation status and modulate the activity of a wide range of non-histone proteins, and the effects on both histone and non-histone proteins may contribute to their anti-cancer activity. Romidepsin, a class I and II HDAC inhibitor has been approved by FDA for the treatment of cutaneous T-cell lymphoma (CTCL) and peripheral T-cell lymphoma (PTCL). Lenalidomide is an immunomodulatory agent highly effective for the treatment of a wide range of hematological malignancies, and a low toxicity profile.
Aims: Our goal is to evaluate if lenalidomide, in combination with romidepsin is able to enhance the apoptotic effect on T-cell lymphoma cell lines and to identify the molecular mechanisms involved.
Methods: Hut-78 (CTCL cell line) and Karpas-299 (anaplastic lymphoma cells) were treated with increasing concentrations of romidepsin (0,5 - 25 nM) and lenalidomide (1 - 100 μM) alone from 24 to 72 hours to identify the IC_{50} of each drug. The interaction between romidepsin (0,5 nM, 1 nM, 2,5 nM) and lenalidomide (2 μM, 4 μM, 10 μM) was evaluated using the Chou-Talalay method in order to determine if the combination had additive or synergistic effect. The cell cytotoxicity was assessed by MTT assay and apoptosis was studied by Annexin-V/propidium iodide (PI) and flow cytometry and confirmed by Western blot analysis for caspase activation. AKT/PI3K and MAPK/ERK signaling pathways were analyzed by Western blot.
Results: Treatment with romidepsin alone resulted in time- and dose-dependent increase in cytotoxicity in Hut-78 and Karpas-299 cell lines with an IC_{50} at 24-hour of 5.87 nM and 6.36 nM for Hut-78 and Karpas-299, respectively. Lenalidomide alone did not inhibit cells viability up to72 h of treatment in the two TCL cell lines, as we already observed in other cell lines. However, the combination of lenalidomide (10μM) with a low dose of romidepsin (2.5 nM) showed a strong synergistic interaction with combination index (CI) of 0.14 at 24 hours in Hut-78 cells, and an additive effect in Karpas-299 cells, (CI of 1.08). In Hut-78 cells sequential treatment with romidespin for 6 hours followed by washout and the next addition of lenalidomide for 24 hours enhanced the cytotoxic effect of romidepsin and confirm its irreversible effect. Noteworthy the combination did not trigger relevant decrease in the viability of normal peripheral blood mononuclear cells (PBMNCs). The apoptotic effect of the combination was confirmed by the activation of caspases -3, -9 -8 and PARP and was mediated by the increase of the pro-apoptotic protein Bim and by a decrease of the antiapoptotic proteins Bcl-xL and Mcl-1. No effect on the expression of Bcl-2 compared with each single treatment was observed. The effect of romidepsin with lenalidomide on cell cycle parameters is relatively modest. The combination of the drugs induced up-regulation of cell cycle protein p21and a slight decrease of cyclin E and cyclin D. These events were associated with the dephosphorylation of PI3K/Akt, MAPK/ERK pathways. Induction of histone acetylation (H3) and acetylated alpha-tubulin was confirmed.
Summary and Conclusions: Romidepsin with lenalidomide induced apoptosis in T cell lymphoma through signaling event involving the pro-survival pathways PI3K/AKT and MAPK/ERK. Further investigation is required to elucidate the molecular mechanisms of cell death induced by this combination in T cell lymphoma cell lines.

PB1791

PERTURBATIONS OF THE ENDOCANNABINOID SYSTEM IN MANTLE CELL LYMPHOMA; CORRELATIONS TO CLINICAL AND PATHOLOGICAL FEATURES

A Wasik[1,*] L Nygren[1], S Almestrand[1], F Zong[2], J Flygare[3], S Baumgartner Wennerholm[4], L Saft[5], P Andersson[6], E Kimby[4], B Christensson[1], B Sander[1]
[1]Dept. of Laboratory Medicine, Div. of Pathology, [2]Karolinska Institutet, Stockholm, Sweden, [3]Division of Clinical Chemistry, Department of Laboratory Medicine, [4]Division of Hematology, Department of Medicine,, Karolinska Institutet, [5]Clinical Pathology, Karolinska University Hospital Solna, [6]Department of Hematology, Stockholm South Hospital, Stockholm, Sweden

Background: The endocannabinoid system (ECS) has attracted attention as potential target for therapy in inflammatory disorders and cancer. A number of agents targeting various components of the ECS have been designed and tested in clinical trials. Mantle cell lymphoma (MCL) is an aggressive disease with usually poor survival and new therapeutic options are clearly needed.
Aims: The cannabinoid receptors have been reported to be upregulated in many types of cancers, including mantle cell lymphoma (MCL) and have been suggested to constitute novel therapeutic targets. The aim of this study was to analyze the expression pattern of the cannabinoid receptors and key enzymes for endocannabinoid metabolism in a well characterized MCL patient cohort and to correlate the findings to biological features.
Methods: Tumor tissue, n=107, were analyzed for the mRNA levels of cannabinoid receptors 1 and 2 (CNR1 and CNR2) and the two main enzymes regulating the endocannabinoid anandamide levels in tissue: NAPEPLD and FAAH (participating in synthesis and degradation, respectively). The expression was correlated to clinico-pathological data.
Results: NAPEPLD was overexpressed in MCL compared to non-malignant B cells, while in 88% of MCL cases FAAH expression was reduced. CNR1 was overexpressed in 98% and CNR2 in 100% of cases. Both low CNR1 and high FAAH levels correlate to lymphocytosis (p=0,016, and p=0,022, respectively) and to leukocytosis (p=0,0018 and p=0,047). Weak to moderate CNR1 levels were a feature of SOX11 negative MCL (p=0,006). Both high CNR2 and high FAAH levels correlated to anemia (p=0,0006 and p=0,038, respectively).
Summary and Conclusions: In MCL the relative expression of NAPEPLD and FAAH is perturbed in a way suggesting accumulation of anandamide. This finding, together with high expression of cannabinoid receptors, suggests enhanced anandamide signaling. The functional consequences of endocannabinoid system perturbations are not yet understood but we find the correlation to leukemic spread of the disease potentially clinically important.

PB1792

MANAGEMENT OF PRIMARY HEPATIC NON-HODGKIN'S LYMPHOMA AND CORRELATION WITH HCV INFECTION : EXCELLENT RESULTS WITH CONVENTIONAL CHEMOTHERAPY

A De Renzo[1], C Cerchione[1,*] F Perna[1], M Masarone[1], M Persico[2], R Della Pepa[1], C Cimmino[1], S Luponio[1], I Peluso[1], N Pugliese[1], E Seneca[1], C Mainolfi[3], I De Sio[4], G Ciancia[5], M Picardi[1], M Picardi[1], F Pane[1]
[1]Hematology, AOU "Federico II", [2]Hepatology, II University of Naples, [3]Nuclear Medicine - Radiology, AOU "Federico II", [4]Internal Medicine, II University of Naples, [5]Pathology, AOU "Federico II", Napoli, Italy

Background: Primary Hepatic (PHL) non-Hodgkin's Lymphoma is a rare entity, frequently associated with a poor prognosis. PHL was first described in 1965 by Ata *el al* and in 1986 Caccamo *et al* defined PHL as a localized lymphoma, limited to the liver without extrahepatic involvement. Small series of PHL have been reported, suggesting a non-fortuitous association with Hepatitis C Virus (HCV) infection. The prognosis is believed to be dismal, with early recurrence and short survival. To date, less than 150 cases have been published.
Aims: Eleven adult consecutive patients observed in our Division from 1990 to 2013 (median age : 58 years) fulfilled the diagnostic criteria for Primary Hepatic Lymphoma. Our series of patients were derived from 1083 patients with

non-Hodgkin's Lymphoma observed in our institution in the same period (*i.e.* with a prevalence of 1.0% for PHL).
Methods: We performed a study of the viral status and the result of cytotoxic treatment. The disease occurred in middle-aged patients (median age: 58 years). The main presenting complaint was right upper quadrant abdominal pain (4/11 patients). Tumor markers (-fetoprotein and CEA) were normal in 8 patients tested. Liver scans demonstrated either a solitary nodule or multiple lesions. Pathologic examination revealed diffuse large B cell lymphoma in seven patients, two cases of follicular lymphoma, one of small lymphocytic lymphoma and one case of T cell lymphoma. Eight patients (72%) were HCV-positive. Eight patients were treated with CHOP regimen (6 CHOP and 2 R-CHOP), two patients with R-FN, while a patient with a single focal lesion underwent to surgical treatment.
Results: The complete remission rate was 100% (11/11) after frontline therapy, and only one patient relapsed but underwent remission after additional chemotherapy courses; one of these patients, who had HCV-related cirrhosis, died because of hepato-renal syndrome, and another one died because of Acute Myeloid Leukemia.
Summary and Conclusions: Our study confirms the rarity of PHL. In our Division, the outcome of patients with PHL, who are treated with combination chemotherapy, seems excellent. The frequent association of PHL with HCV infection suggests a possible role of this virus in lymphomagenesis. HCV-infection does not appear to influence the outcome.

PB1793

CONSTITUTIVE ACTIVATION OF THE CANONICAL WNT PATHWAY IN AGGRESSIVE B CELL NON-HODGKIN'S LYMPHOMA
H Huang[1,*] Q Qu[1], F Chen[1], J Zhong[1]
[1]Renji Hospital, School of Medicine, Shanghai Jiaotong University, Shanghai, China

Background: B cell Non-Hodgkin's Lymphoma (B-NHL) represents a highly heterogeneous group of lymphoproliferative malignancies, its pathogenesis may involve in abnormalities of multiple signal transduction pathways. Canonical Wnt signaling pathway is a fundamental signaling pathway and plays an important role in normal cell growth and development. Abnormal activations of canonical Wnt signaling pathway have been found in a variety of solid tumors and hematological malignancies, including leukemia, which suggests that the canonical Wnt pathway may have a close relationship with pathogenesis of tumors. However, there is very little published information regarding potential Wnt pathway in lymphomas, especially in aggressive B-NHL
Aims: The present study was conducted using cell lines to preliminarily investigate whether canonical Wnt signaling pathway is abnormally activated in aggressive B-NHL, and to determine the emerging role of canonical Wnt signaling pathway in the process of tumorigenesis of aggressive B-NHL.
Methods: The 3 aggressive B-NHL cell lines, SUDHL-4, Raji and Namalwa were used, with normal human lymphocytes as the control. The localization of β-catenin was observed by immunocytochemical technique. The expression levels of β-catenin, glycogen synthase kinase-3β (GSK-3β) and its phosphorylated/inactive form (pGSK-3β), were detected by western blotting. The mRNA levels of canonical Wnt pathway relevant genes *CTNNB*1, low density lipoprotein receptor related protein 5(*LRP5*), *Wnt3A* and target gene *c-myc* were estimated by real-time fluorogenic quantitative PCR. After treatment of quercetin, a reported inhibitor of β-catenin, the mRNA and expression levels changes of *c-myc* were detected by real-time fluorogenic quantitative PCR and western blotting respectively. Moreover, biological characteristics including the proliferation, apoptosis and cell cycle changes after treatment of quercetin in cell lines were analyzed by CCK-8 assay and flow cytometry (FCM).
Results: The results revealed that there were different levels of β-catenin abnormal nuclear localization in 3 aggressive B-NHL cell lines compared to normal control. The total and the nuclear expressions of β-catenin proteins were also significantly up-regulated in all 3 B-NHL cell lines as compared with normal control. Different elevated levels of p-GSK3β protein expression were observed in 3 B-NHL cell lines; whereas there was no significant difference in the expression levels of GSK3β between the cell lines and the normal control. The mRNA levels of *CTNNB1, LRP5, Wnt3A* and *c-myc* gene were significantly higher in all 3 B-NHL cell lines than those in the normal control. Moreover, after treatment of quercetin, the mRNA levels and expression levels of *c-myc* were all down-regulated in B-NHL cell lines, the proliferative activity were significantly inhibited, and the majority of these cells were arrested in G2/M phase of the cell cycle, yet the apoptosis phenomenon was not observed.
Summary and Conclusions: Since β-catenin acts as the hallmark of the activation of canonical Wnt pathway, its up-regulated expression, together with other relevant molecular changes in canonical Wnt pathway, suggest that constitutional activation of canonical Wnt pathway may contribute to the pathogenesis of aggressive B-NHL.

PB1794

SYNERGISM BETWEEN ARSENIC TRIOXIDE AND MG132 ACHIEVED WITH LOW DOSES OF VALPROIC ACID AND VINCRISTINE
L I Kornblihtt[1,*] T Lombardo[2], V Cavalieri[3], E Alvarez[3], G A Blanco[2]
[1]Hematología, [2]Laboratorio de Immunotoxicologia (LaITO), IDEHU-CONICET, Hospital Clinicas, Universidad de Buenos Aires, Argentina, [3]Laboratorio de Inmunología Tumoral (LIT), IDEHU-CONICET, Facultad de Farmacia y Bioquímica, UBA, Buenos Aires, Argentina

Background: Arsenic trioxide (ATO) has low efficacy as a single cytotoxic drug in malignancies other than promielocytic leukaemia but may be combined with other drugs to achieve increased potency and reduced toxicity. The study of cytotoxic drugs interaction is an important aspect in the efficient design of targeted combined therapies. The method of combinatory index (CI) allows the qualification and quantification of drug interaction as synergic (CI<1), antagonistic (CI>1) or additive (CI=1) over the entire range of cytotoxic effects [0-100%]. ATO and MG132, a proteasome inhibitor that targets chemotrypsin-like activity as does Bortezomib, are antagonistic in Burkitt´s lymphoma cell line Raji.
Aims: We explored the possibility of changing the interaction between ATO and MG132 from antagonistic to synergic by adding subcytotoxic doses of two additional drugs: valproic acid (VPA) that targets histone deacetylase (HDAC), and vincristine (VCR) that disrupts the microtubule network. VPA upregulates BNIP3, a Bcl2 family member that is epigenetically silenced in various haematological malignancies and has a controversial role in autophagy and cell death.
Methods: The study was conducted in Raji cells exposed to a wide range of doses of ATO and MG132 for 24h or 72h with or without VPA and/or VCR. Cytotoxicity was assessed by flow cytometry, drug interaction was evaluated by the Chou-Talalay method, autophagy was evaluated by monodancyl-cadaverine (MDC) and UV-excited flow cytometry, mitochondria distribution was evaluated by mitotracker red and fluorescence microscopy and expression of BNIP3 was evaluated by fluorescence microscopy and RT-PCR
Results: Adding a subcytotoxic dose of 3mM VPA enhanced antagonism between ATO and MG132 (CI>1.91 against CI> 1.16 without VPA) and increased autophagy. The distribution of mitochondria was found clustered around the nuclei of Raji cells. The expression of BNIP3 as protein or mRNA was detected only in cells treated with 3mM VPA. Adding VCR at a subcytotoxic dose of 1μM blocked autophagy as compared to basal levels. In addition, the distribution of mitochondria was found elsewhere in the cytoplasm, apart from the nucleus. However, VCR did not revert antagonism between ATO and MG132 (CI>1.10), and in this case BNIP3 expression was undetectable. Adding VPA and VCR at subcytotoxic doses changed the interaction between ATO and MG132 from antagonism to synergism. (CI=0.7<1). In addition, autophagy was abrogated below basal levels, mitochondria distribution was found apart from the perinuclear area and towards cell edges and BNIP3 expression was upregulated at the protein and mRNA level.
Summary and Conclusions: We conclude that synergism between ATO and MG132 can be achieved by targeting simultaneously HDAC and the microtubule network by subcytotoxic doses of VPA and VCR. Burkitt´s lymphoma cell line sensitization was correlated to upregulation of BNIP3, inhibition of autophagy probably owing to blockage of fusion between autophagosomes and lysosomes, and altered intracellular distribution of mitochondria.

PB1795

FINE NEEDLE ASPIRATION AS A DIAGNOSTIC TECHNIQUE IN B-CELL NON-HODGKIN LYMPHOMA: THE USEFULNESS OF COMBINING CYTOMORPHOLOGY WITH FLOWCYTOMETRIC IMMUNOPHENOTYPING AND FISH ANALYSIS
H Donia[1,*] M Mikhail[1], N Farahat[1], A Sorour[1], A Elghandour[2]
[1]Clinical pathology, [2]Internal medicine, Faculty of medicine, Alexandria, Egypt

Background: The role of fine-needle aspiration biopsy (FNAB) in the primary diagnosis and subclassification of Non Hodgkin lymphoma (NHL) has been under intensive debate for a long time. The World Health Organization (WHO) classification of tumors of the hematopoietic and lymphoid tissues 2008 is based on their cytomorphologic, immunophenotypic, and genetic features. These criteria can be readily applied to cytologic specimens.
Aims: This study was designed to evaluate the value of lymph node FNA specimens in the diagnosis and subclassification of NHL according to WHO classification 2008 focusing primarily on B-NHL.
Methods: he current study was prospectively conducted on 129 patients with lymphadenopathy and a clinical suspicion of lymphoproliferative disorder. The sampling procedure was performed using fine needle sampling without aspiration.Cytomorphologic examination was performed on Leishman stained smears. Representative material for cytologic examination was available for only 120 cases (93.02%). One hundred-twenty two (94.57%) specimens collected on RPMI-1640 were submitted for flowcytometric immunophenotyping (FCI) using a battery of monoclonal antibodies specific for lymphoid antigens. I-FISH analysis was performed on 20 out of 48 cases diagnosed as B-NHL (by cytomorphology and FCI) for chromosomal rearrangements t(11;14)(q13;q32)

and/or t(14;18)(q32;q21). Slides for FISH were prepared from air-dried unstained FNA smears.
Results: Using a multiparametric algorithm including clinical data, cytomorphology, FCI, and FISH analysis , definitive final diagnosis was reached in 116/129 (90%) cases. The 116 cases with definitive diagnosis included: benign lymphadenopathy (45 cases) B-NHL (48 cases), T-NHL (7 cases), Hodgkin lymphoma (8 cases), and others (8 cases). Forty eight cases had a final diagnosis of B-NHL. Of these, 33 cases (33/48, 68.8%) could be subclassified according to WHO classification 2008 as follows: SLL (3 cases), CLL (5 cases), Richter's syndrome (2 cases), MCL (4 cases), low grade FL (1 case), LPL (2 cases), B-lymphoblastic lymphoma (1 case), B-lineage ALL (1 case), Burkitt lymphoma (3 cases), DLBCL (10 cases), and DLBCL/FL3 (1 case). The remaining 15 cases (31.2%) could not be classified and were reported as B-NHL-NOS. For the sake of validation studies of FNA as a diagnostic method, a gold standard was established to control FNA final diagnoses. This comprised histopathologic examination, FISH, clinical control (LDH and β_2-microglobulin, and imaging studies), and follow-up of the clinical course (for at least 6 months), or a combination of them. The estimated diagnostic sensitivity of FNA combined with ancillary studies in distinguishing between reactive and malignant lymphoid proliferations was 98.39%, with 100% specificity and 98.89% diagnostic accuracy. Sensitivity, specificity, and diagnostic accuracy of the FNA in B-NHL diagnosis were 98.04%, 100%, and 98.89% respectively.
Summary and Conclusions: Lymph node FNA offers a simple, safe, and minimally invasive procedure for obtaining a diagnostic material that allows a rapid accurate diagnosis and subclassification of B-NHL through the integration of cytomorphology, FCI, and FISH analysis.

PB1796

CYTOGENETIC CHARACTERISTICS OF SPLENIC MARGINAL ZONE LYMPHOMA

HL Julhakyan[1,*] TN Obukhova[1], VG Savchenko[1]
[1]Hematological Scientific Center, Moscow , Russian Federation

Background: Splenic marginal zone lymphoma (SMZL) is a well-recognized B-cell neoplasm which is characterized by splenomegaly, bone marrow involvement. The most frequent cytogenetic findings are involvement of chromosomes 1, 3, 7 and 8.
Aims: The aim of our study was to investigate the cytogenetic features of SMZL in Russian population.
Methods: In Hematological Scientific Center from January 2001 to December 2013 was observed 132 patients with SMZL.
Results: Standard cytogenetic study was conducted in 56 (65.1%) patients and in 30 (53.6%) patients were found various cytogenetic changes of the karyotype. Normal karyotype was detected in 14 (25%) patients. Mitoses were absent in 12 (21.4%) patients. Partial or full trisomy of chromosome 3 was detected in 5 (8.9%) patients, del7 chromosome - 7 (12.5%), trisomy of chromosome 12 - 3 (5.3%), trisomy of chromosome 18 - 4 (7%) cases and in 4 patients were found the combination of trisomy of chromosome 18 and 3. Translocation t(14;19)(q32;q13) was detected in three cases, in 2 patients were found translocation with rearrangement of immunoglobulin heavy chain gene, one - 17p inversion and translocation t(9;13)(p23;q21) in 1 patient.
Summary and Conclusions: Standard cytogenetic studies in SMZL weren't always revealing various cytogenetic changes of the karyotype. The main reason for failure is the lack of metaphases, due to the low proliferative activity of leukemic cells. A normal karyotype was determined in ¼ patients. Cytogenetic damage of chromosome 7 revealed del7 in 12.5% of cases, which is slightly less than those described in the literature. In patients with SMZL were found rare translocation: translocation t(14;19)(q32;q13) in 3 patients, translocation with BCL6 gene rearrangement in 2 patients. Past research has shown that t(14;19)(q32;q13)-positive SMZL was distinct variant and characterized by rapid progression after splenectomy, poor responses to chemotherapy and short survival. So t(14;19)(q32;q13) may be regarded as a poor prognostic factor.

PB1797

THE SPHINGOLIPIDS METABOLISM INDEXES AND RESPONSE TO CHEMOTHERAPY BY LYMPHOMAS

L Sahakyan[1,*] S Daghbashyan[2]
[1]Department of Science, [2]Director of Haematology center, Center of Haematology, Yerevan, Armenia

Background: The involvement of sphingolipids, and their metabolites, such as ceramides in cancerogenesis was demonstrated in solid tumors as well as in hematological malignancies. As is known, the appearance of multidrug resistant phenotype (MDR) - one of the major causes of failures in the treatment of malignant diseases. According to recent years' data, ceramide signaling plays an important role in tumor progression and development of chemoresistance.
Aims: The present study was to examine the modification of acid ceramidase (aCD) activity and ceramides level as an indicator of the drug resistance in patients by lymphoma.
Methods: The study included 123 patients with B-cell nonHodgkin's lymphoma (NHL), which were admitted to the Hematology Center of Armenia. After obtaining informed consent were evaluated clinical and hematological parameters of all patients. Patients' blood was taken before and after the treatment. For the normal control was used blood from 31 healthy donors of Hematology center. Ceramide has been determined using high performance liquid chromatography (HPLC). The aCDase activity determination was conducted according to the fluorogenic methods (Bedia C. *et al.*, 2010).
Results: According to obtained data two of 105 newly diagnosed and untreated NHL patients (1.9%) and seven of 18 previously treated patients and drug-resistant (38.9%) had detectable high levels of ceramides and twofold increased activity of aCD. Due to failure of therapy, 7 patients died in the treatment first trimesters, the remaining 2 patients 6 and 8 months ago. Development of MDR in NHL is in part driven by the inherent genetic heterogeneity and instability of the tumor cells. Our results suggest that ceramides level and ceramidase activity is a potential pharmacologic target for the NHL treatment. The inhibition of ceramides expression or ceramidase activity might represent a novel strategy to sensitize B-cell NHL patients to chemotherapy.
Summary and Conclusions: Sphingolipids metabolites can be considered promising therapeutic tools alone or in combination with other compounds, as well as valid targets in the attempt to lymphoma treatment and overcome drug resistance.

LOW TOXICITY IN BENDAMUSTINE PLUS RITUXIMAB. COMBINATION: RESULT OF A RETROSPECTIVE SINGLE CENTRE ANALYSIS

C Buquicchio[1,*] L ciuffreda[1], G De Santis[1], TM Santeramo[1], RM Miccolis[1], M Santoro[1], G Tarantini[1]
[1]Haematology Unit, Ospedale Dimiccoli, Barletta, Barletta, Italy

Background: Recent trials showed efficacy of bendamustine plus rituximab compared to gold standard therapy in Non Hodgkin's Lymphoma.
Aims: In our study the objective is to confirm also the less toxicity and consequentely the improved quality of life of this alkylating agent in frail patients.
Methods: : In our institution from 2011 to 2013 we treated with bendamustine 33 Non Hodgkin's Lymphoma(NHL) patients, performance status 1-3, (25 indolent, 8 aggressive) with age > 65 years (29 patients relapse/refractory) and while 4 first line patients<65 with severe dilatative cardiopathy. Of 33 patients (13 female and 20 male) the median age was 70 (range 52-88) and 14 (42%) patients were older than 75 years of age. Bendamustine was administered intravenous (minimum 70-maximum 90mg/m2/day) for 2 consecutive days in combination with rituximab 375mg/m2 for 1 day every 28-days cycle for a minimum of 4 courses to a maximum of 8, for a total of 156 courses. The patients comorbidities were:hepatopathy HCV/HBV correlated,hypertensive or ischemic or dilatative cardiopathy , chronic bronchitis, diabetes, chronic renal impairment without dialysis.We admistred routinely primary prophylactic granulocyte colony-stimulating factor support and antimicrobic therapy.
Results: At a median of 12 months' follow-up, 25 patients were evaluable for efficacy and safety. The overall response rate at that time was 90%, with 57% complete responses, 30% partial response, 12% stable disease and 3%early death (1 patients 77 yrs old, died in neutropenic fever after 2st cycle for staphylococcus haemoliticus sepsi) Adverse events were : in 31 patients (94%) prophylactic use of granulocyte colony-stimulating factor (G-CSF) reduced to grade 1neutropenia without infectious complications or therapy delayed or dose reductions applied, while cytopenias grade 4 occurred in 2 patients (6%)reverible with G-CSF and supported with red cell and platelet transfusions ;the fever infections that requiring IV antiobiotics were in 2 patients(6%)in particular 1 patients presented an E.Coli pneumonia and the other patient a staphylococcus haemoliticus sepsi;skin allergic toxicities as rash and pruritus in 3 patients (9%) of which in 2 reversible stopping concomitant cotrimoxazole and allopurinol (grade 1)and 1 patient urticaria (grade 2) treated with short and low doses steroid therapy, gastrointestinal toxicity as nausea, vomiting in 1 patients (3%) grade 2 corrected only with antiemetic medical treatment. In our updated analysis, no cases of myelodysplastic syndrome, secondary neoplasms or medically interaction with several drug taken by elderly patients,had been observed
Summary and Conclusions: The quality of life assessment questionnaire proposed to the patients showed willingly acceptance of this medical treatment without changing life personal routine. Frail NHL patients (elderly or severe co-morbidities) who would not be suitable to receive intensive chemotherapies and might be at increased risk of toxicities could benefit of bendamustine plus rituximab combination.

PB1800

DOES THE PATIENTS WITH FOLLICULAR LYMPHOMA IN LEUKEMIC PHASE HAVE WORST PROGNOSIS IN THE ERA OF IMMUNOCHEMOTHERAPY?

J Jelicic[1,*] M Todorovic[1], J Bila[1], V Djurasinovic[1], V Vukovic[1], A Sretenovic[1], B Andjelic[1], D Antic[1], B Mihaljevic[1]
[1]Clinical Center of Serbia, University of Belgrade, Clinic of Hematology, Belgrade, Serbia

Background: Follicular lymphoma (FL) is the most common indolent non-Hodgkin`s lymphoma and it is rarely presented with the FL cells in bloodstream. Introduction of the monoclonal antibody (rituximab) in the combination with conventional chemotherapy has made major improvement of the overall survival (OS).
Aims: The aim of the study was to analyze prognostic significance of the leukemic phase of FL at presentation in pts treated with immunochemotherapy.
Methods: The study included 162 newly diagnosed pts with FL (75 male/87 female, mean age 52yrs, range 20-74). According to the clinical stage 15 pts had I and II stage (9,3%), 135 pts had advanced III and IV stage (83,3%), while 12 pts (7,4%) had leukemic phase of FL. Regarding to FLIPI, low score was present in 26pts (16,1%), intermediate in 52pts (32,1%) and high in 84pts (51,8%). Low and intermediate FLIPI 2 score was present in 80pts (49,4%), and high score in 82pts (50,6%). In the first line therapy, 61pts (37,7%) received chemotherapy (CHOP/CVP), and 101pts (62,3%) received immunochemotherapy (R-CHOP/ R-CVP). In the group treated with chemotherapy (CH), 4pts had FL in leukemic phase, while in the group treated with immunochemotherapy (IHT) 8pts had FL in leukemic phase.
Results: Treatment response (CR, PR) in the group treated with CH was achieved in 88,5%pts, and 95% in the group treated with IHT. Pts treated with CH had significantly shorter OS in comparison to the pts treated with IHT (Log Rank 19,76, p <0.001). In the group of 4 pts in leukemic phase of FL treated with CH, 2pts died, while in the other group of 8pts, only 1pt with same characteristics died. According to the FLIPI score, there was no statistical difference in the OS (Log Rank 5,05; p=0,17) in all analyzed 162pts. However, there was high statistical difference in OS according to FLIPI 2 score (Log Rank 14,95, p <0,001) in analyzed group. In the group treated with IHT pts with low and intermediate FLIPI 2 had significantly longer OS in comparison to the pts with high FLIPI 2 score (Long Rank 12,8; p <0,001). According to the FLIPI 2 score, patients with FL in leukemic phase had similar OS to the pts with same values of FLIPI 2 score without leukemic presentation (Log Rank 0,05; p=0,83). We have tested a prognostic model for the pts treated with IHT which includes high FLIPI 2; presence of leukemic phase; number of infiltrated lymph nodes>4; ECOG performance status (ECOG PS); and elevated lactate dehidrogenase (LDH). In the proposed model which was statistically significant (χ^2 14,74; p= 0,012), FLIPI 2 index was of major impact on the OS, followed by ECOG PS (HR 7,89; 95% CI; 1,7-36,5).
Summary and Conclusions: Negative prognostic impact of the leukemic phase of follicular lymphoma is successfully overcome with current treatment recommendations of IHT. However high FLIPI2 score plus ECOG PS indicates special consideration in terms of individualized treatment approach followed by possible maintenance IHT.

SAFETY AND USE OF BENDAMUSTINE FROM THE BENDAMUSTINE EXPANDED ACCESS TRIAL IN CANADA (BEND-ACT)

CT Kouroukis[1,*] M Crump[2], D MacDonald[3], JF Larouche[4], D Stewart[5], J Johnston[6], S Sauvageau[7], É Beausoleil[7], LH Sehn[8]
[1]Dept. of Oncology, McMaster University, Juravinski Cancer Centre, Hamilton, [2]Princess Margaret Cancer Centre, Toronto, [3]Dept. of Hematology, Dalhousie University, Capital Health QEII Health Sciences Centre, Halifax, [4]CHU de Québec, Hôpital Enfant-Jésus, Québec, [5]University of Calgary, Tom Baker Cancer Centre, Calgary, [6]Cell Biology/Internal Medicine, University of Manitoba, Manitoba Institute of Cell BIology, Winnipeg, [7]Medical Dept., Lundbeck Canada Inc., Montréal, [8]Centre for Lymphoid Cancer, BC Cancer Agency, University of British Columbia, Vancouver, Canada

Background: Bendamustine is widely used in the treatment of indolent non-Hodgkin's lymphoma (iNHL) and chronic lymphocytic leukemia (CLL).
Aims: The purpose of the current study is to evaluate additional safety data of bendamustine in up to 100 patients with iNHL relapsing from a rituximab regimen or CLL.
Methods: An expanded access trial with the primary objective of safety was conducted at sixteen centres across Canada and enrolled patients from March 2012 to June 2013. Eligible patients were those at least 18 years old, able to provide informed consent with relapsed/refractory iNHL and were previously treated with a rituximab-containing regimen or had previously untreated CLL, ECOG performance status 0-2, and good organ function. Patients with iNHL received up to 8 cycles of bendamustine (120mg/m^2) on days 1 and 2 every 21 or 28 days; patients with CLL were given bendamustine 100 mg/m^2 on days 1 and 2 every 28 days for up to 6 cycles. Algorithms were followed for dose adjustments for toxicities. Patients were followed for up to 6 weeks after completion of treatment.
Results: Ninety patients started on treatment (74 iNHL; 16 CLL). The mean age was 64 y (range 40–90 y), 44% of the CLL patients were at least 70 years old. For iNHL patients, 77% were treated on a 28-day schedule, with a median of 6 cycles of treatment and 24.3% of patients received 8 cycles. Median time on treatment was 137 days (28–224 days). For CLL patients, the majority received at least 3 cycles and median time on treatment was 91 days (28–168 days). All patients reported at least one adverse event (AE). Grade 3 or 4 toxicities resulted in dose delays in 31.1% of patients with hematological toxicities being the most common reason (24.4.%). Withdrawal from treatment secondary to treatment emergent AEs occurred in 32.2% of patients. Withdrawals were mainly due to rash, hematological, gastrointestinal, respiratory and infectious reasons. Serious AEs were reported in 36.7% of patients and included fever (10%), gastrointestinal events (6.6%), febrile neutropenia (5.6%), pneumonia (5.5%), renal failure (3.3%), hypotension (2.2%), syncope (2.2%), and tumor lysis syndrome (2.2%). The cycle length did not result in any obvious difference in the rate of SAEs. Overall mortality was 4.4%. AEs associated with death included *Pneumocystis jiroveci* pneumonia, multi-organ failure (this was the only fatal AE deemed probably related to treatment), cardiac arrest, respiratory failure, and abdominal pain.

Summary and Conclusions: In this expanded access trial, hematological toxicities were the most frequent reason for dose delays and infections or fever were the most common reason for serious AEs. Overall, the toxicity and safety profile of single agent bendamustine is consistent with other published studies in a similar patient population.

PB1802

RETROSPECTIVE ANALYSIS OF PRIMARY CHEMOIMMUNOTHERAPY WITH BENDAMUSTINE IN COMBINATION WITH RITUXIMAB IN PATIENTS WITH INDOLENT AND MANTLE-CELL LYMPHOMAS

H Hagberg[1,*] K Högberg[2], B A Jensen[3], S Leppä[4], L Munksgaard[5], D Szatkowski[6]
[1]Department of Oncology, Akademiska Sjukhuset, Uppsala, [2]Mundipharma AB, Gothenburg, Sweden, [3]Department of Haematology, Odense University Hospital, Odense, Denmark, [4]Department of Oncology, Helsinki University Central Hospital Cancer Centre, Helsinki, Finland, [5]Department of Haematology, Roskilde Hospital, Roskilde, Denmark, [6]Department of Oncology, Haematology and Palliative Care, Førde Central Hospital, Førde, Norway

Background: Induction therapy for advanced indolent lymphoma (iNHL) and elderly mantle-cell lymphoma (MCL) patients consists of rituximab (R) in combination with chemotherapy; typically cyclophosphamide, doxorubicin, vincristine, and prednisone (CHOP). Bendamustine plus R (BR) has been shown to be effective in treating patients with relapsed or refractory disease. In a recent German study (Rummel *et al*. 2013)[1] for previously untreated patients with iNHLs, BR demonstrated increased progression-free survival (PFS) and was better tolerated than R-CHOP, thereby challenging R-CHOP's status as a standard first-line therapy.
Aims: This retrospective, Nordic multicenter study (BRiL study) aimed to evaluate the efficacy of BR as first-line chemotherapy in a population-based setting in patients with follicular lymphoma (FL), MCL and other iNHLs, determined via complete remission (CR) and overall response rate (ORR). PFS, overall survival and toxicity were also assessed.
Methods: Patients aged >18 years, with a histological diagnosis of iNHL (FL, MCL, splenic marginal zone lymphoma [SMZ], mucosa-associated lymphoma [MALT], plasmacytic lymphoma [PL, including Waldenström´s lymphoma], and low-grade lymphoma not specified [iNHL NOS]), who had received at least two cycles of BR (minimum dose of 70 mg/m^2) as first-line treatment were included. Previous R monotherapy and/or radiotherapy, and R maintenance following BR treatment, were allowed. Informed consent was obtained according to country regulations.

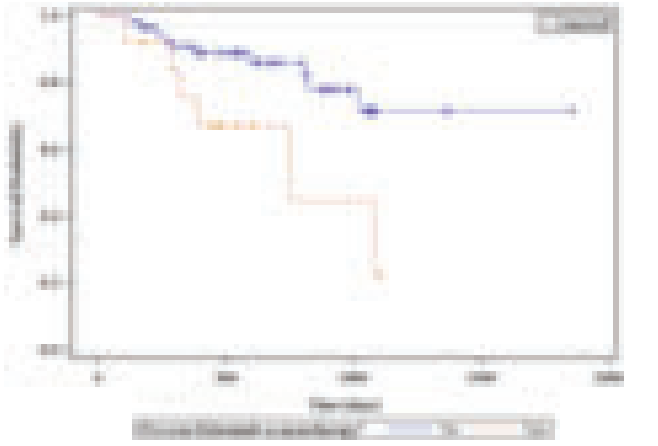

Figure 1. Kaplan-Meier plot showing PFS (days) in patients with FL. FL, follicular lymphoma; PFS, progression-free survival

Results: The study included 116 patients (n = FL, 71; MCL, 15; SMZ, 8; MALT, 9; PL, 6; iNHL NOS, 7); mean age 65.7 years (median, 67.0). Fifteen patients had previously received R monotherapy. After treatment with BR, CR was achieved in 56.9% of all patients, 57.7% of patients with FL, and 46.7% of patients with MCL. CR in patients who had previously received R monotherapy was lower than in those who had not (40.0% *vs.* 60.0% respectively). ORR was 85.3% for all patients, 87.3% of patients with FL, and 66.7% of patients with MCL. At the end of the study, 89% of patients were alive. Stem cells were harvested in four patients, all had >2x10^6/kg CD34 cells. R maintenance improved PFS. The incidence of adverse events was similar to previously reported trials with BR. Thirteen patients died but only two of the deaths were related to treatment: one patient died during treatment with BR due to sepsis, and one patient experienced progressive multifocal leukoencephalopathy and died during R-maintenance treatment. The remaining patients died due to progressive lymphoma (n=6), secondary malignancy (n=2), cardiac arrest (n=1), and other cause (n=2). During R maintenance another patient suffered from herpes encephalitis but survived. An update on side effects from R-maintenance treatment will be presented.
Summary and Conclusions: The results of this study confirm, at a population-based level, the efficacy and tolerability of BR as first-line chemoimmunotherapy for iNHL and MCL. The estimated 3-year PFS of 70% for patients with FL without previous R monotherapy (Figure 1) is similar to the comparable group in the German study.[1]
This study was funded by Mundipharma AB, Mundipharma Oy, Mundipharma AS, and Norpharma a/s. Writing assistance was provided by Watermeadow Medical, sponsored by Mundipharma International Limited.

RISK OF SECOND MULTIPLE MYELOMA AFTER NON-HODGKIN AND HODGKIN LYMPHOMA

N Pugliese[1,*] E Seneca[1], L Catalano[1], M Picardi[1], C Cimmino[1], C Cerchione[1], M Di Perna[1], F Pane[1], A De Renzo[1]
[1]Hematology, University of Naples Federico II, Naples, Italy

Background: Multiple Myeloma (MM), non Hodgkin (NHL) and Hodgkin (HL) Lymphoma are lymphoproliferative diseases (LD) arising from B-cells at several stages of differentiation. Although previous studies have reported an elevated risk of second malignancies following these disorders, few studies have investigated the development of two lymphoproliferative diseases in the same patient.
Aims: We assess long-term risk of MM emergence as a second malignancy in patients with NHL and HL.
Methods: From 2003 to 2013 a cohort of 419 NHL and 277 HL patients, at first diagnosis, were observed from a single center Institution and occurrence of MM was pointed out. Standardized Incidence Ratio (SIR) was calculated as the ratio of observed to expected number of incident MM.
Results: In total only two and one second MM occurred among NHL and HL patients, respectively. The cumulative risk of developing a MM following NHL and HL was respectively 0.43% (1/230) and 0.36 (1/277) among males and about 0.53% (1/189) and 0% (0/140) among females. SIR for male and female NHL patients was 0.83 (p=0.56) and 1.46 (p=0.79). Therefore, in HL group male and female SIR values were respectively, 0 (p=0.39) and 2 (p=0.61).
Among patients with secondary MM, one patient had a previous diagnosis of DLBCL (stage IIA) and was treated according to R-CHOP scheme for six cycles, the second patient was diagnosed with gastric MALT and was treated with four CHOP cycles and the last one was affected by classical HL (stage IIIA) and received six courses of ABVD-like treatment followed by involved field radiotherapy. All three patients obtained complete response after first line treatment for lymphoma and developed MM after the recognition of MGUS. One of them showed M-component since the time of LNH (DLBCL) diagnosis while the other two patients developed it during the follow-up. The average time from first lymphoproliferative diseases and MM diagnosis was 7.6 years (range 5-13), while the average time from MGUS and MM transformation was 3.3 years (range 2-5). Information for light-chain restriction of NHL and MM was available only for the patient with previous MALT diagnosis and the light-chain restriction was different in that case. Among these three patients who developed MM, one is on PR after only three course of liposomal doxorubicin, bortezomib and dexamethasone (PAD), one is on CR after thalidomide plus dexamethasone followed by autologous stem cell transplantation. For the last patient receiving only one administration of VTD (bortezomib, thalidomide and dexamethasone), it was not possible to evaluate response.
Summary and Conclusions: The occurrence of MM and lymphoproliferative diseases in the same patient is very rare. It is generally accepted that normal plasma cells are terminally differentiated, specialized cells arising from B-cells, and it is theoretically possible that the monotypic plasma cells are further differentiated or transformed neoplastic B-cells. But the two processes may arise independently from the same stem cell or from different B cells purely coincidentally. Although it would be rare, a possibility of independent of two infrequent malignancies in the same patient exists and seems to be more convincing theory.

PB1804

PROGNOSTIC SIGNIFICANCE OF BONE MARROW INVOLVEMENT PATTERN IN WALDENSTRÖM MACROGLOBULINEMIA: ANALYSIS OF A SERIES OF 46 PATIENTS

A Martín[1], JM Raya[1], S Lakhwani[1,*] H Álvarez-Argüelles[2], T Martín-Santos[1], R Díaz-Rodríguez[1], C de Bonis[1], S García-Hernández[2], MT Hernández[1], L Hernández-Nieto[1]

[1]Hematology, [2]Pathology, Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain

Background: WHO classification defines Waldenström macroglobulinemia (WM) as a lymphoplasmacytic lymphoma with bone marrow involvement and an IgM monoclonal gammopathy of any concentration. With a typically indolent course, factors associated with a worse prognosis include advanced age, cytopenias, functional status, elevated beta-2 microglobulin level and, for some authors, a diffuse pattern of bone marrow involvement.
Aims: Our aim was to analyze the clinical and biological features of patients with a WM diagnosis in our center, with special attention to the clinical and prognostic significance of bone marrow involvement pattern.
Methods: We studied 46 patients diagnosed between 1992 and 2012. Data collected at diagnosis were age, sex, hyperviscosity and B symptoms, organomegaly, lymphadenopathy, blood count, peripheral expression, beta-2 microglobulin, serum IgM, serum LDH, lymphoplasmacytic infiltration in bone marrow aspirate, tumor burden and predominant marrow pattern (interstitial, nodular or diffuse) in bone marrow trephine, and cytogenetics. We also collected treatment schemes and response, transformation to aggressive lymphoma, overall survival (OS), and mortality. Statistical analyzes were performed using SPSS and Statxact programs.
Results: Mean age was 71 years (range 41-92), male 72%. The presence at diagnosis of lymphadenopathy, splenomegaly, hepatomegaly and peripheral expression was 33%, 17%, 11% and 9%, respectively. Serum LDH and beta-2 microglobulin were found elevated in 11% and 26% of cases, respectively. The average values of tumor burden in bone marrow biopsy and lymphoplasmacytic infiltration in aspirate were 40% (range 10-95) and 37% (10-90). Only one case of transformation to aggressive lymphoma was observed. The predominant pattern was interstitial in 21 cases (46%), nodular 17 (37%) and diffuse 8 (17%). In 7 of 17 cases with a nodular pattern, paratrabecular aggregates were also present. A diffuse pattern was correlated with lower platelet counts (p=0.004) and lower values of hemoglobin (p=0.07), and the interstitial pattern was more frequent in younger patients (p=0.033). The median OS was 43.5 months (range 1-247). The type of marrow involvement pattern did not influence the OS and, specifically, the diffuse pattern was not associated with a worse prognosis. We observed a strong statistical correlation between older age and worse OS (p=0.006).
Summary and Conclusions: In our experience, in line with other authors, advanced age is a major adverse prognostic factor in WM. However, the pattern of bone marrow involvement does not influence the OS, and the diffuse pattern does not carry a worse prognosis when compared with other patterns.

PB1805

TEN YEAR SINGLE CENTRE EXPERIENCE IN TREATMENT OF 34 PATIENTS WITH OCULAR ADNEXAL NON HODGKIN LYMPHOMAS

M Smiljanic[1,*] R Milosevic[1], D Antic[1,2], B Andjelic[1], A Sretenovic[1], V Djurasinovic[1], J Jelicic[1], V Vukovic[1], J Bila[1,2], M Todorovic[1,2], B Mihaljevic[1,2]
[1]Clinic of Hematology Clinical Centre of Serbia, [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background: Ocular adnexal Non Hodgkin Lymphomas (NHL) consists 2% of all NHL and are in most cases (up to 68%) primary extranodal neoplasms. The most frequent histological subtype is extranodal marginal zone B cell lymphoma (MALT-Mucosa-Associated Lymphoid Tissue) or ocular adnexal MALT lymphoma (OAML), and all other subtypes, including diffuse large B-cell lymphoma (DLBCL, ~ 8%), are much less common. Only few cases of primary ocular adnexal T-cell lymphoma have been reported.
Aims: To investigate clinical parameters of patients (pts) with ocular adnexal NHLs, as well as to compare efficacy between different treatment modalities and to investigate disease and treatment outcome.
Methods: 34 pts with NHL eye involvement on presentation, diagnosed in the Clinic of Hematology, Clinical Centre of Serbia between January 2004 and January 2014, were enrolled. Clinical characteristics and the disease dissemination on presentation were researched. We compared various initial treatment modalities effectiveness, as well as treatment and disease outcome.
Results: In our group 27 pts (79.41%) were diagnosed with OAML, six (17.65%) with DLBCL, and one (2.94%) with extremely rare intraocular peripheral T-cell lymphoma (PTCL). The highest disease incidence rate was in the eight decade, with almost equal distribution among sexes (M/F ratio 1.12). Overall median age was 61.5 years (36-81), males 60 (36-79), females 63 (48-81). The median interval between onset of symptoms and diagnosis in the group of pts with OAML was 5.5 months (1-36) in comparison with median interval in the group of pts with DLBCL (2 months, 1-25). The most frequent sign on presentation was palpable tumor (23.53%). On presentation 19 pts (55.88%) had orbital involvement, conjuctival six (17.64%), lacrimal gland and eyelid three (8.82%) pts each, involvement of the iris two (5.88%) and uveal involvement one (2.94%) patient. Pts with OAML were predominantly (85%) staged as IE CS (Ann Arbor lymphoma staging system), as was a patient with PTCL. Most pts with DLBCL (66.67%) presented with disseminated disease. Chemotherapy (per oral Chloramucil) was the most common initial therapy for OAML pts (33.33%), followed by radiotherapy, surgery and combined approach (22.22% each). All pts with DLBCL received chemotherapy with monoclonal CD 20 antibody, Rituximab (R), and in most cases, intrathecal prophylaxis. The patient with intraocular PTCL received intensive chemotherapy as well. 5-year overall survival (5-y OS) for entire group was 89% and 5-y progression free survival (PFS) was 59%. In the group of pts with OAML, 5-y OS was 91% and 5-y PFS 50%**.** Median OS was 55 months (1-120). In the group of pts with DLBCL 5-y OS was 100%. Median OS was 46.5 months (1-60). Twelve pts (35.29%), all diagnosed with OAML, relapsed. Within this subgroup no significant difference in PFS, in terms of initial treatment option, was registered (p=0.8484, DF 4). Median PFS was 31 months (3-81). Two pts initially diagnosed with OAML have had subsequent transformation in DLBCL. No relapses were registered in the group of pts with DLBCL. Three pts died (two with OAML and one PTCL), of whom two deaths were related to NHL progression.
Summary and Conclusions: Within our group of 34 pts, all DLBCL pts achieved durable complete remissions with R-chemotherapy, whereas in the group of pts with indolent lymphoma (OAML), not treated with systemic chemotherapy, one third relapsed. Our results suggest superiority of initial chemotherapy use in treatment of patients with ocular adnexal NHLs.

EVALUATION OF BENDAMUSTINE-RITUXIMAB ROUTINE USE FOLLOWED BY RITUXIMAB MAINTENANCE THERAPY IN RELAPSED/REFRACTORY INDOLENT NHL: INTERMEDIATE RESULTS OF PROSPECTIVE OBSERVATIONAL PROGRAM BEN-RUS-004O

I Poddubnaya[1,*] L Babicheva[1], E Osmanov[2], G Tumyan[2], N Turina[3], M Vernyuk[3], O Pavlova[3], A Chervontceva[3], V Melnichenko[4], N Mochkin[4], K Kaplanov[5], E Volodicheva[6], E Kuznetcova[7], S Lebedenko[7], S Alexeev[8], V Moscov[9], E Mulberger[10], T Kaporskaya[11]
[1]Russian Academy for Postgraduate Medical Education, [2]N.N.Blokhin Russian Oncology Research Center, [3]P.A.Hertzen Moscow Oncology Research Institute, [4]N.I.Pirogov National Medical Surgical Center, Moscow, [5]Volgograd Regional Clinical Oncology Dispensary #1, Volgograd, [6]Regional Clinical Hospital of the Tula Region, Tula, [7]Regional Clinical Hospital of the Orenburg Region, Orenburg, [8]N.N.Petrov Institute of Oncology, St.Petersburg, [9]Krasnoyarsk Krai Clinical Hospital, Krasnoyarsk, [10]A.N.Kabanov Omsk City Clinical Hospital #1, Omsk, [11]Regional Clinical Hospital, Irkutsk, Russian Federation

Background: Combination bendamustine-rituximab (BR) has shown promising results with acceptable toxicity in patients with heavily pre-treated relapsed or refractory indolent B-cell non-Hodgkin lymphoma (iNHL).
Aims: To evaluate the efficacy and safety of bendamustine in combination with rituximab in patients with relapsed and refractory iNHL [clinicaltrial.gov, NCT02072967].
Methods: Starting from May 14, 2012 42 patients (pts) were enrolled at 25 study centres located in 19 Russian cities. Pts received bendamustine 90 mg/m^2 i/v on days 1 and 2 and rituximab – 375 mg/m^2 i/v on day 1 of each 28-day cycle. The 1st assessment of tumor response is performed after 3 BR cycles, in case of complete response (CR), partial response (PR) or stabilization disease (SD) treatment lasts up to 6-8 cycles followed by rituximab maintenance therapy.
Results: 36 pts were evaluated up to date (6 pts received less than 3 cycles of chemotherapy). Histological subtypes were: 23 patients – follicular lymphoma I-II cytological types (55%), 13 pts – small lymphocytic lymphoma (31%), 4 – marginal zone lymphoma (9%), 2 – Waldenstrom's disease (5%). Median age - 59 years (29 - 80) . The majority of pts had later-stage disease, stage III or IV – 34 (81%). 34 patients (48%) had B-symptoms, equal number - 15 (35%) cases of severe condition common scale ECOG (≥ 2) and large tumor masses. In pts with follicular lymphoma, FLIPI subgroups were: low risk (0-1 factor) assigned 6 (26%) patients, an intermediate risk (factor 2) - 9 (39%) pts, and high-risk group (factors 3-5) included 8 (35%) cases. All patients were heavily pre-treated: median of disease duration for all patients prior to study entry was 45 months (9-162). 17 (40%) pts had primary resistant lymphoma, 41% pts – 1st relapse , and 19% pts with two or more relapses of lymphoma. 38% pts had over three lines prior therapy. Thus, the group of patients included into this study is related to unfavourable prognosis. At median follow-up 8 months, in the group of indolent NHL overall response rate (ORR) was 80,5%, complete response (CR) was 28% (10 pts), unconfirmed complete response (CRu) was 5,5% (2 pts), partial response (PR) 38% (17 pts), stabile disease (SD) 5,5% (2pts), and disease progression (PD) 14% (5 pts). In the group of primary resistant lymphoma (17 pts) ORR was 70,5%, CR was 23,5% (4pts), PR – 47% (8 pts), SD – 6% (1 pt), PD – 23,5% (4pts). In the group of relapsed lymphoma (19 pts) ORR was 89,5%, CR

– 31,6% (6 pts), CRu – 10,5% (2 pts), PR – 47,4% (9 pts), SD – 5,25% (1 pt), and PD - 5,25% (1 pt). BR is more active in the group of relapsed lymphoma *versus* the group of primary refractory lymphoma (Table 1). Safety analysis was available for 36 pts. Overall, the combination BR was well-tolerate. The most common grade 2/3 adverse events were leucopenia (9%) and infections (9%).

Table 1. Efficacy outcomes.

Summary and Conclusions: Based on this intermediate results, BR combination is highly active and well tolerated in heavily pre-treated pts with relapsed lymphoma and in primary refractory pts.

Background: Hairy Cell Leukemia (HCL) constitutes 2-3% of all adult leukemias. This is characterized by infiltration of the bone marrow, liver, spleen and rarely lymph nodes by malignant B cells with hairy extension.
Aims: In this multicenter study, we aimed to present therapeutic outcomes and survival of 93 patients with HCL.
Methods: A retrospective analysis of clinical, laboratory and treatment results of 93 cases, who were diagnosed as having HCL in 13 centers in Turkey between October 1990 and July 2011 are presented in this report.
Results: Sixty-five of the patients were males and 28 were females, with a median age of 55. Splenomegaly was present in 92.6% of cases at diagnosis. At diagnosis, 57% of the patients had leukopenia, 17.2% leukocytosis, 77.4% anemia, 75.3% thrombocytopenia, 15.1% had cytopenia, 34.4% had bi-cytopenia, and 47.3% had pancytopenia. 63% of the patients showed a "dry tap" in bone marrow aspiration. Of the patients with an indication for treatment, 89.5% (77/86) were treated with cladribine as first-line treatment, while in 7% (6/86) of the patients splenectomy was preferred, and in 3.5% (3/86) interferon was preferred. Four patients died before being treated, and 3 could not be followed. Of the patients who were treated with cladribine, 80.5% (62/77) had a complete response (CR), 16.8% (13/77) had a partial response (PR); with a total response rate of 97.3%, 2 patients (2.6%) had died during treatment. Of the patients who were treated with a splenectomy, a CR was obtained in 66.7% (4/6), and a PR was obtained in 33.3% (2/6). No patients died in this group. A partial response (PR) was obtained in patients treated with IFN. The relapse rate was 16.9% (13/77) in patients treated with cladribine and in whom a CR or PR was obtained. In 66.7% (4/6) of the patients treated with a splenectomy and all of the patients treated with IFN, second line of treatment was given as a result of relapse. As second-line of treatment, in 95% (19/20) of the patients cladribine was used and rituximab was preferred in only one patient (5%). A CR was obtained in the patient treated with rituximab, while CR was obtained in 68.4% (13/19) of the patients treated with cladribine, while a PR was obtained in 31.5% (6/19) of them. A second relapse developed in 6 of these patients (6/19). In third - line of treatment, 3 of this 6 patients were given cladribine again (50%), while 2 were given rituximab (33.3%) and 1 was given (16.6%) deoxycoformycin. In third-line treatment, a CR was obtained in 66.6% (2/3) of the patients, PR was obtained in 33.3% (1/3), while CR was obtained in 100% (2/2) of the patients treated with rituximab. A PR was obtained in the patient treated with deoxyicoformicyn. The 28-month median OS was 91.7% in all patients followed-up in this study. In patients who were given cladribine as first-line treatment, OS was observed in 96% in a median 25 months of follow up. In the secondary cancer evaluation of these patients, one had a diagnosis of lung cancer before HCL was diagnosed, and an acute leukemia was diagnosed in one patient 3 months later HCL was diagnosed.
Summary and Conclusions: Cladribine treatment was confirmed as a safe and effective therapy in this study, where patients with HCL were followed up for a long time period, and demographic characteristics of patients with HCL are presented. Also, a long time period of follow up is important for evaluation of development of a secondary malignancy.

PRIMARY GASTOINTESTINAL NON-HODGKIN'S LYMPHOMA: RETROSPECTIVE EVALUATION OF 50 PATIENTS

S Berk[1,*] N Ozgur[2], FF Yalniz[1], T Elverdi[1], A Salihoglu[1], AE Eskazan[1], MC Ar[1], Z Baslar[1], T Soysal[1], B Ferhanoglu[3], N Tuzuner[4], Y Aydin[1], S Ongoren Aydin[1]
[1]Department of Internal Medicine, Division of Hematology, [2]Department of Internal Medicine, Istanbul University Cerrahpasa Faculty of Medicine, [3]Department of Internal Medicine, Division of Hematology, Koc University, School of Medicine, [4]Department of Pathology, Istanbul University Cerrahpasa Faculty of Medicine, Istanbul, Turkey

Background: Primary gastrointestinal non-Hodgkin's lymphoma (PGI-NHL) is a heterogeneous entity different from the nodal counterpart regarding definition, clinicopathological characteristics, histological subgroups, diagnosis, staging, prognosis and treatment.
Aims: The aim of this study is to define the epidemiologic and clinicopathological characteristics of and the prognostic factors related to PGI-NHL, and to evaluate treatment results combined with survival analysis retrospectively.
Methods: Clinical records of 50 patients presented in our center between 1985-2011, diagnosed with PGI-NHL according to the 'relaxed criteria' described by Lewin et al, and followed-up for at least 1 year, were reviewed retrospectively. Histopathologic classification was done according to WHO, 2008. Patients are staged according to the Lugano staging system. MIPI is used for the stratification of prognostic risk groups. Treatment modalities are heterogeneously chosen by the caring physician with regard to clinical characteristics, disease localization, histological subgroup and stage, according to current guidelines. Disease or therapy related toxicities were assessed according to National Cancer Institute-Common Terminology Criteria for Adverse Events (NCI-CTCAE) version 4.03.
Results: Twenty-four patients were male, and the median age was 56 years (22-80). The most common disease localization was the stomach (70%). Abdominal pain was the main symptom (64%). The most common histological subgroup was diffuse large B cell lymphoma (74%) followed by MALT lymphoma (16%). Localized disease was more common (66% *vs* 34%). Bulky disease had negative influence on PFS and DFS (p=0.021 and 0.026, respectively). Bone marrow and/or ≥2 extranodal involvement had adverse effect on OS, PFS and DFS rates (for bone marrow involvement p=0.007, 0.017 and 0.020, respectively; for ≥2 extranodal involvement p=0.001, 0.003 and 0.007, respectively). MIPI (0-1 *vs* ≥2) has been found to separate the study population into prognostically distinctive risk groups with different OS, PFS and DFS rates (p=0.009, 0.011 and 0.010, respectively). Multivariate analysis showed that MIPI was the strongest predictor of overall survival. Compared with single-modality conservative treatment (Campylobacter jejuni eradication, chemotherapy, autologous hematopoetic stem cell transplantation), combination with surgery resulted in better OS rates in intestinal lymphomas (p=0.031). Despite that, in gastric lymphomas surgery has largely been replaced by conservative treatment modalities which are comparable to combination treatments in terms of survival. Over a median follow-up of 31 months, 36 of the patients were alive, 7 were dead and the remaining seven were lost to follow-up. The most common etiology of death was disease progression (n:5). The projected 5-year overall, progression-free and disease-free survival rates were 82.2%, 69.3% and 65.8%, respectively, with gastric lymphomas having better survival rates than intestinal lymphomas.
Summary and Conclusions: Considering the challenging heterogeneity, a uniform definition, histologic classification and staging system is important for comparative interpretations. Although the number of patients with primary gastric lymphoma allowed for a detailed analysis, a larger study group is needed for intestinal lymphomas. This study shows that MIPI is an effective model in PGI-NHL patients enabling identification of patient groups with different prognoses. Clinicopathological characteristics and parameters which have a statistically significant or nearly significant effect on survival need to be evaluated in multidisciplinary, prospective, multicenter trials with a patient population of greater number treated with standardized regimens according to current guidelines.

USE OF BENDAMUSTINE AS FIRST LINE TREATMENT IN SELECTED POPULATION OF NON HODGKIN'S LYMPHOMA: TUSCANY REGION EXPERIENCE

L Rigacci[1,*] B Puccini[1], R Della Seta[2], E Capochiani[3], L Iovino[4], E Cencini[5], P Bernardeschi[6], S Kovalchuk[1], G Benelli[1], S Birtolo[7], M Petrini[4], A Fabbri[5], A Bosi[1]

[1]Haematology, AOU Careggi, Firenze, [2]Oncology, Ospedale Carrara, Carrara, [3]Oncology, Ospedale Livorno, Livorno, [4]Haematology, AOU S. Chiara, Pisa, [5]Haematology, AOU Senese, Siena, [6]Oncology, Ospedale Empoli, Empoli, [7]Oncology, Ospedale Pescia, Pescia, Italy

Background: Bendamustine was introduced in Italy from 2008 and in our region, starting from 2011 thanks to regional regulation, was possible to use Bendamustine in first line therapy as 'off-label' drug.
Aims: The aim of this study was to collect all consecutive patients treated in first line with Bendamustine in 7 Tuscany centers.
Results: From June 2011 to December 2012, 72 patients were prospectively included in the study. Diagnosis was: Lymphocytic in 25 patients (34%), Follicular in 18 (25%), Diffuse large B cell in 11 (15%), Mantle cell in 10 (14%), Lymphoplasmocytic in 5 (7%) and MALT in 3 (5%). Thirty-nine patients were treated with Bendamustine 90 mg/m2 for two days, 28 with 70 mg/m2 and 5 with 120 mg/m2. In 14 patients Bendamustine was used alone, in 56 in combination with Rituximab or other drug. The median age was 69 years (range 45-89), in DLBCL was 81 years and 78 years in MCL. Considering the advanced age of this population we applied the geriatric score assessment and 25% of patients were unfit or frail. The median number of cycles performed was 4 (range 2, 6). All patients but 2 were evaluable for response, 35 obtained a complete remission, 27 a partial remission with an overall response rate of 88%, stable disease in 2 patients and progressive disease in 6 patients. According to histotype to note that all but two indolent lymphoma obtained a response; in aggressive lymphomas 4/11 DLBCL and 5/9 MCL reached a complete remission but 4 DLBCL and 2 MCL experienced rapid progressive disease. Treatment was well tolerated, we observed: grade 3-4 neutropenia in 18 patients, no grade 3-4 anemia or thrombocytopenia, grade 3-4 infection in 3 patients. According to extrahematological toxicity no grade 3-4 were reported. Skin rush grade 1 was reported in in 5 patients. After a median follow-up of 14 months the overall survival was 83%; 10 patients died. Progression free survival, after a median observation period of 10 months, was 60%; sixty-two patients are alive, 31 in continuous complete remission, 3 relapsed and 28 with disease under control.
Summary and Conclusions: In conclusion in this 'real life' negatively selected population, the use of Bendamustine showed a very high response rate particularly in indolent lymphomas, promising results, also, are observed in aggressive disease.

PB1811

RAPID TRANSFORMATION OF FOLLICULAR LYMPHOMA, GRADE 1, ASSOCIATED WITH AN UNCOMMON C.796G>A PG266R MUTATION OF THE P53 GENE AND LOSS OF CD45 (LCA) EXPRESSION AT DIAGNOSIS

A Kwiecinska[1,*] M Ghaderi[1], I Xagoraris[1], A Matolcsy[2], L Saft[1], A Österborg[3], G Rassidakis[1]
[1]Pathology and Cytology, Karolinska University Hospital, Stockholm, Sweden, [2]First Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary, [3]Hematology, Karolinska University Hospital, Stockholm, Sweden

Background: Transformation of low-grade follicular lymphoma (FL) to aggressive diffuse large B-cell lymphoma (DLBCL) has been associated with acquiring new genetic events including p53 mutations during the disease course. In addition, the presence of p53 mutation at the time of diagnosis of follicular lymphoma may identify a high-risk group of patients with rapid disease progression and poorer survival (O'Shea *et al.*, Blood. 2008; 112:3126).
Aims: We report a case of rapid follicular lymphoma transformation associated with an uncommon p53 mutation, and loss of CD45 expression at diagnosis.
Methods: Histologic examination, immunohistochemistry, flow cytometry, molecular diagnostics including PCR for IgH and light chain gene rearrangements, and fluorescent *in situ* hybridization (FISH) for t(14;18) translocation were used as diagnostic methods for this case. p53 mutation analysis was performed for the exons 4-8 of the gene using PCR and automated direct sequencing techniques. Additional immunohistochemical studies were performed to assess p53 and c-myc protein levels.
Results: A 66-year old patient with a previous history of rheumatoid arthritis treated with rituximab and a TNF-alfa-blocking agent , presented with B-symptoms and a large tumor mass in abdomen with infiltration of the omentum. At presentation, LDH was 3,8 microkat/L and s-albumin 34 g/L. Bone marrow was negative. A diagnosis of stage III low grade follicular lymphoma was made with tumor cell proliferation <5%. The tumor cells were positive for t(14;18) assessed by FISH. The patient initially received rituximab (4x) without response and subsequently CHOP-21 x 6 with stable disease for 3 months. Because of clinical progression, the patient thereafter received bendamustin followed by local radiation therapy. Thirty five months after initial diagnosis, a new biopsy from abdomen confirmed transformation to DLBCL with high tumor cell proliferation (90%). In both, diagnostic low grade FL and DLBCL (transformed FL), a rare c.796G>A pG266R mutation of the p53 gene (exon 8) was detected, which is reported for first time in FL. This mutation is rarely detected in other lymphoma types accounting for <0.7% of all lymphomas (IARC database, R17). In addition, a silent mutation in exon 4 of the p53 gene was found in both samples. Moreover, aberrant loss of CD45 (LCA) in FL cells was seen in the diagnostic lymph node and DLBCL cells. By immunohistochemistry, overexpression of p53 protein (100% positive tumor cells) was detected in both samples. No change in the levels of c-myc protein was seen.
Summary and Conclusions: Our findings from this case report demonstrate for first time that mutations of the 266R codon of p53 gene may be involved in FL transformation. Therefore, this case along with previously reported data for the potential predictive value of p53 mutations in FL at diagnosis, support the use of immunohistochemical and molecular testing of p53 gene in all newly diagnosed low grade FL.

PB1812

TREATMENT OF HAIRY CELL LEUKAEMIA: LONG TERM FOLLOW UP AND TOXICITY

A Liyanage[1,*] V Ratnayake[1], K Saied[1], J Lindsay[1], M Capomir[1], C Pocock[1]
[1]Haematology, East Kent Hospitals , CANTERBURY, United Kingdom

Background: Hairy cell leukaemia (HCL) is Characterised by infiltration of the bone marrow, liver and spleen, by a malignant B-cell. First treatment choices were splenectomy and alpha-interferon with a Median survival of 4 years. The purine analogues, introduced in the 1980s, transformed this prognosis.
Aims: Aim of our study was to analyze the outcome of patients with active hairy-cell leukemia with different lines of therapy.
Methods: We retrospectively analysed 16 HCL patients followed in East Kent Hospitals between 1997 to 2013 (12 male, 4 female). Cases were identified by searching for "Cladrabine and Pentostatin" in the pharmacy data base.10/16 patients received Cladrabine (2-CdA) -SC infusion at a dose of 0.14 mg/kg/d over 5 consecutive days, 5/16 patients received Cladrabine -IV infusion at a dose of 0.1 mg/kg/d over 7 consecutive days and 1/16 patient received Pentostatin.
Results: At 6 months after treatment, complete response (CR) occurred in 14/16 patients (87.5) and partial response (PR) occurred in 2/16 patients (12.5%). Six patients (37.5%) have relapsed with a duration of response ranging 3-7 years. All six patients have been re-treated with 2-CdA (5/6) and Pentostatin (1/6) followed by Rituximab, and all achieved at least a partial remission. 3/6 relapsed and had recurrent disease and 1 patient has been refractory to vemurafenib. 75% of patients (12/16) suffered from Neutropenic sepsis requiring hospital admission.
Summary and Conclusions: With a median follow-up of more than 65 months, 13/16 patients (81.3%) continue to be in remission. Although only two deaths have occurred due to refractory disease, the relapse rate is high. Patients who relapse may be re-treated with 2-CdA, but subsequent remissions may be of shorter duration and alternative treatments are needed for patients with recurrent disease. Our data also showed that there is a markedly increased incidence of Neutropenic sepsis indicating that Cladrabine is not a gentle chemotherapy.

Aggressive Non-Hodgkin lymphoma - Clinical

PB1813

THE ROLE OF HIGH DOSE CHEMOTHERAPY FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANTATION AS FIRST LINE TREATMENT IN PATIENTS WITH AGGRESSIVE NON-HODGKIN LYMPHOMA: A SYSTEMATIC REVIEW AND META-ANALYSIS

D Dahan-Shriki[1], A Gafter-Gvili[1,2], L Vidal[1,2], P Raanani[1,2], O Shpilberg[2], R Gurion[1,2,*]
[1]Institute of Hematology, Rabin Medical Center, Petah Tikva, [2]Tel Aviv University, Tel Aviv, Israel

Background: Rituximab-cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) has been the mainstay of treatment in patients with aggressive non-Hodgkin lymphoma (NHL). Despite the improvement in survival rate with the addition of rituximab, there are still a significant proportion of patients who cannot be cured with conventional therapy. One of the strategies to improve survival rate is consolidation treatment with high dose chemotherapy (HDT) followed by autologous stem cell transplantation (ASCT), especially in young patients with high risk aggressive NHL. Randomized controlled trials that addressed this issue yielded conflicting results.
Aims: In order to examine the effect of HDT and ACST on overall survival, we performed a systematic review and meta-analysis.
Methods: Systematic review and meta-analysis of randomized controlled trials comparing HDT and ASCT after achievement of complete remission (CR) or partial remission (PR) to standard dose chemotherapy, with or without rituximab as first line treatment in patients with aggressive NHL. The Cochrane Library, MEDLINE, conference proceedings and references were searched until December 2013. The primary outcome was overall survival (OS). Secondary outcomes were relapse rate, overall response (ORR), CR and secondary malignancies. For dichotomous data, relative risk (RR) with 95% confidence intervals (CIs) were estimated and pooled and hazard ratios (HR) for time to event data were estimated and pooled. We used fixed effect model to pool results.
Results: Our search yielded 20 trials conducted between the years 1987 and 2011, including 4488 patients. In five trials rituximab was added to both arms. Median age of patients ranged between 31 to 51 years old. Seven trials included only patients with intermediate-high and high risk age-adjusted international prognostic index (aaIPI). Ten trials were judged to be at low risk for selection bias (allocation concealment and sequence generation).Data from 19 trials were available for analysis of OS. Treatment with HDT and ASCT did not improve OS as compared to standard dose chemotherapy, HR 1.09, 95% confidence interval (CI) 0.98-1.21, I^2 for heterogeneity 32%. Also, no survival benefit was shown in a sub- analysis of patients with intermediate-high and high aaIPI (HR 1.08 95% CI (0.95-1.24), I^2=66%, 10 trials). However, HDT and ASCT was associated with an increased rate of CR [RR 1.07 95% CI (1.02-1.11)], and a decreased rate of relapse, RR 0.58 95% CI (0.49-0.69). No statistically significant difference was observed regarding the incidence of secondary malignancies.
Summary and Conclusions: HDT and ASCT as first line treatment for aggressive NHL is not associated with increased OS, yet it improves CR rate and decreases relapse rate. The possibility to salvage relapsing patients with HDT and ASCT may contribute to the lack of effect of this treatment on OS when given as first line therapy.

PB1814

USEFULNESS OF 99M TC-TETROFOSMIN SCINTIGRAPHY IN THE FOLLOW UP IN PATIENTS WITH MALIGNANT LYMPHOMA IN THE ERA OF 18F-FDG PET-CT

D Vassileva[1,*] B Spassov[2], S Sergieva[3], M Garcheva[4], I Kostadinova[4]
[1]Nuclear Medicine, [2]Clinical hematology, NSBALHZ, [3]Cancer Center, [4]Nuclear Medicine, University Hospital Alexandrovska, Sofia, Bulgaria

Background: In patients with malignant lymphomas the precise staging and follow up is very important for treatment and prognosis of these patients. 99mTc-Tetrofosmin is currently used to study myocardial perfusion, but also has been reported to be localized in various types of malignant tumours, including lymphomas, giving their localization and proliferation activity. With previously used visualized techniques it has been extremely difficult to differentiate metabolically active tumour tissue from post-therapy fibrosis. Nowadays 18F-FDG PET-CT is a method of choice for these applications.
Aims: In this study, we aimed to evaluate the role of 99mTc-Tetrofosmin scintigraphy for therapy control of lymphoma patients in the era of 18F-FDG PET-CT.
Methods: We investigated 103 patients (56 men and 47 women) with Hodgkin's (HL) and non-Hodgkin's lymphoma (NHL), aged 19-73 years and treated with standard chemotherapy protocols. Planar and SPECT images were carried out 30 minutes and 3 hours after intravenous injection of 740 MBq 99m Tc-Tetrofosmin and analyzed qualitatively and quantitatively. The scintigraphic results were compared with the data of conventional methods (clinical examination, x-ray, CT). Additionally, patients underwent 18F-FDG PET-CT scan. Beta-2-microglobulin was measured by radioimmunoassay.
Results: 99mTc-Tetrofosmin scintigraphy was positive in 42 patients with HL and NHL before treatment. From 58 detected lesions 40 had lymph node involvement. Increased uptake of the radiotracer was demonstrated in mediastinal, neck, supraclavicular, axillar and inguinal lymph nodes. Extranodal localization was detected in 18 lesions. The tumour/background ratio ranged from 1.5 to 2.1. In six patients with false negative scintigraphy, CT investigation showed enlarged abdominal lymph nodes. True negative 99mTc-Tetrofosmin scan after chemotherapy was registered in 37 patients. Focal pathological tetrofosmin uptake was seen in ten patients and 21 lesions were identified. Fourteen lymph node lesions were detected in mediastinal, neck, supraclavicular, axillar and inguinal area. Seven lesions had extranodal localization – lungs and bones. False negative scintigraphy was found in 8 patients, whereas CT scan showed lesion with subdiaphragmatic localization. The presence of B-symptoms and elevated beta-2-microglobulin were found in these patients. The patients with inconclusive 99mTc-Tetrofosmin scan were referred to PET-CT. Additional 22 PET-CT positive nodal and extranodal subdiaphragmatic lesions were detected.
Summary and Conclusions: 99mTc-Tetrofosmin is a promising tracer in determining disease activity in supradiaphragmatic lesions. This method that has high sensitivity and low radiation burden, is appropriate in lymphoma patients especially with supradiaphragmatic localization of the lesions. In patients with small subdiaphragmatic lesions (<15 mm) and inconclusive 99mTc- Tetrofosmin scintigraphy, PET-CT is method of choice.

PB1815

BENDAMUSTINE PLUS RITUXIMAB FOR RELAPSED OR REFRACTORY DIFFUSE LARGE B CELL LYMPHOMA: A RETROSPECTIVE STUDY

F Merchionne[1,*] G Quintana[1], C Minoia[2], A Guarini[2], I Galise[3], G Quarta[1], G Loseto[2], A Melpignano[1]
[1]Hematology Unit , Ospedale Antonio Perrino , Brindisi, [2]Department of Medical and Experimental Oncology, Hematology Unit, IRCCS National Cancer Research Centre "Giovanni Paolo II", [3]Registro Tumori Puglia, IRCCS National Cancer Research Centre "Giovanni Paolo II", Bari, Italy

Background: After standard R-CHOP therapy, patients with relapsed or refractory diffuse large B cell lymphoma (DLBCL) are generally treated with aggressive salvage chemotherapy followed by high dose therapy with autologous stem-cell transplantation (ASCT). However, for patients who are not eligible for intensive chemotherapies and ASCT because of comorbidities and/or advanced age or relapse after heavy salvage regimens, treatment options are very limited and prognosis is poor. Based on the demonstration of efficacy and safety of bendamustine plus rituximab (BR) in patients with indolent and mantle cell non-Hodgkin lymphomas in terms of increased progression-free survival and fewer toxic effects than R-CHOP, additional studies are being carried out to assess the activity and safety of this combination in patients with DLBCL not eligible for intensive chemotherapy regimens.
Aims: To analyze a group of patients with relapsed or refractory DLBCL treated with combination BR between July 2010 and January 2014, and to evaluate overall response rate (ORR), progression-free survival (PFS) and treatment safety.
Methods: Of 22 patients registered, 19 (14 males and 5 females) are currently available for this analysis. Patients gave informed consent. The median age was 71 years (range 54-82); ECOG performance status was 1 (n=6, 27.2%), 2 (n=15, 68.1%) and 3 (n=1, 4.5%); R-IPI scores before starting therapy were good (n=13, 59%) and poor (n=9, 41%). The median number of prior chemotherapy regimens was 2 (range 1-5); lactate dehydrogenase was elevated in 12 patients (54.5%) and normal in 10 (45.4%). The Ann Arbor clinical stage at baseline was IV (n=8, 36.3%), III (n=8, 36.3%), and II (n=6, 27.2%). Rituximab was administered at the standard dose of 375 mg/m^2 and bendamustine at a dose between 70 and 120 mg/m^2 (mean 90 mg/m^2) on days 1 and 2 of each 28-day cycle for up to six cycles. Nine patients (41%) completed six cycles of treatment and the median number of cycles received per patient was 5 (range 1-6).
Results: ORR was 47.3% (complete response: n=7 patients, 36.8% and partial response: n=2 patients, 10.5%), with stable disease in 1 patient (5.2%) and progression disease in 9 patients (47.3%). At the median follow up of 6.4 months (range 1 to 37.4 months), the median PFS was 7 months (95% CI 4.4 - 26.6) for all patients. Four patients showed remission lasting longer than 24 months. Grade 3 / 4 toxicities observed were: lymphopenia (42.1%), neutropenia (36.8%), anemia (15.7%), and thrombocytopenia (10.5%). Infection by cytomegalovirus (CMV) was observed in two patients (10.5%). Common non-hematologic adverse events included nausea (31.5%), fever

(21%), fatigue (15.7%), cutaneous rash (5.2%), and diarrhoea (5.2%). One patient experienced transfusion-dependent anemia one year after the end of therapy, and a diagnosis of myelodysplastic syndrome refractory anemia type was made.
Summary and Conclusions: BR can be considered to have a role in the treatment of patients with relapsed/refractory DLBCL with limited therapeutic options, in that it can induce long-term remission in some patients with an acceptable toxicity profile. However, the high percentage of non-responding patients in this study suggests that larger trials are needed to assess the efficacy of this combination.
Disclosures: Off Label Use: bendamustine in salvage therapy in aggressive B-cell NHL.

ASSOCIATION OF POLYMORPHISM RS1625895 GENE TP53 WITH EFFECTIVENESS OF R-CHOP TREATMENT OF DLBCL
E Voropaeva[1,*] T Pospelova[2], M Voevoda[1], V Maximov[1], O Berezina[2]
[1]Scientific Research Institute of Therapy, The Russian Academy of Medical Science, [2]Novosibirsk State Medical University, Novosibirsk, Russian Federation

Background: In response to DNA damage the p53 protein functions to induce cell cycle arrest, DNA repair or apoptosis. Deficiency of p53 function is one of the adverse prognostic factors in NHL. In DLBCL incidence of *TP53* mutations and 17p deletion in the onset of the disease is rare. Peller *et al.* (1997) described rs1625895 gene TP53 associated with changes in apoptosis of leukocytes in patients with cancers.
Aims: The purpose of the present study was study association of rs1625895 with with effectiveness of R-CHOP treatment of DLBCL.
Methods: We studied the single nucleotide polymorphism rs1625895 in 106 unrelated patients with DLBCL treated by R-CHOP. Clinical response to treatment was assessed according to Cheson Criteria. Genotyping was carried out with use of PCR-RFLP. Overall survival (OS) and relapse-free survival (RFS) probabilities were estimated with the use of the Kaplan–Meier method and were compared between patients with a mutation and those without mutant alleles by means of the log-rank test. Multivariate analyses were conducted with the use of the Cox model with forward selection to identify independent prognostic variables influencing the OS and RFS.
Results: For rs1625895 genotype distribution in DLBCL patients was as follows: genotype G/G - 75,5%, G/A - 22.6% and A/A - 1.9%.
The response rate in subgroups of patients with rare allele and homozygous genotype G/G was 73.1% and 50.0%, respectively (p=0.0396). Odds ratio response to R-CHOP therapy in patients with genotype G/G, was 0.37 [95% CI: 0,15; 0,99, P <0,05]. In patients with DLBCL with genotype G/G rs1625895 5 - year OS was 42.5% *vs* 65.4% in patients with genotypes G/A and A/A (p =0.014). In the subgroup of patients with homozygous genotype G/G rs1625895 relapse-free survival was 36.3%. It was significantly lower (p=0.030) than in the subgroup of patients with genotypes G/A and A/A - 57.7%. In multivariate analysis by Cox regression method was shown that rs1625895, along with the index IPI, can serve as a predictor of the likelihood of achieving OS and DFS.
Summary and Conclusions: The present study showed that genotype G/G rs1625895 gene *TP53* is associated with a high probability of failure R-CHOP therapy of DLBCL patients. Future studies to confirm these data are required.

OUTCOMES AFTER 90YTTRIUM-IBRITUMOMAB TIUXETAN-BEAM IN DIFFUSE LARGE B-CELL LYMPHOMA: A META-ANALYSIS
S Auger[1,*] Y Duny[2], JP Daures[2], P Quittet[3]
[1]Internal médicine and hematology, ClinicBeausoleil, [2]Biostatistical and Epidemiology, INSERM Unit EA 2415, [3]Hematology, University hospital, Montpellier, France

Background: High-dose chemotherapy followed by autologous stem cell transplantation (ASCT) is a standard therapy in patients with relapsed/refractory diffuse large B-cell lymphoma (DLBCL) who are chemo-sensitive. The combination of carmustine, etoposide, cytarabine, and melphalan (BEAM) is commonly used as a conditioning regimen. The addition of yttrium-90 (^{90}Y)-ibritumomab tiuxetan (Zevalin®) to BEAM (Z-BEAM) is increasingly being used to improve outcomes and overcome refractory disease.
Aims: We conducted a literature review and meta-analysis in order to evaluate the clinical effects of Z-BEAM followed by ASCT in patients with DLBCL
Methods: A literature search was conducted for randomized controlled trials and observational studies of Z-BEAM as a conditioning regimen for ASCT in adult patients with DLBCL. Extracted data included baseline patient demographics, overall response (ORR), complete response (CR), overall survival (OS), progression-free survival (PFS), non-relapse mortality (NRM), median time to ANC and platelet engraftment, and rate of myelodysplastic syndrome. Mixed effects models were used to determine estimates.
Results: Twelve studies (N = 409) were included in the meta-analysis. The 2-year OS and PFS were 85.5% (n=409) and 67.7% (n=366), respectively. Outcomes were superior in patients with non-transformed lymphoma. Post-transplant, ORR and CR rates were 72.6% and 68.5%, respectively. The primary toxicity was neutropenia (49.9%). Two-year OS was significantly associated with pre-transplant ORR (p=0.002, tau square=0) and with pre-transplant CR rate (p=0.04, tau square=0.15). There was no significant association between PFS and pre-transplant response.
Summary and Conclusions: Z-BEAM is safe and effective as a conditioning regimen in relapsed/refractory DLBCL.

GOOD PROGNOSIS OF PATIENTS WITH PRIMARY INTRAOCULAR LYMPHOMA TREATED WITH SYSTEMIC HIGH DOSE METHOTREXATE AND INTRAVITREAL METHOTREXATE INJECTION: A STUDY OF 23 PATIENTS
WL Ma[1,*] YK Chen[2], HA Hou[2], JL Tang[2], W Tsay[2], CP Lin[3], HF Tien[2]
[1]Division of Hematology, Department of Internal Medicine, Department of Oncology, [2]Division of Hematology, Department of Internal Medicine, [3]Department of Ophthalmology, National Taiwan University Hospital, Taipei, Taiwan, Republic of China

Background: Primary intraocular lymphoma (PIOL) is a rare subtype of malignant non-Hodgkin's lymphoma which occurs either alone or in association with brain involvement. Diagnosis of PIOL can be challenging and the optimal treatment has yet to be defined.
Aims: This study is to assess the clinic-biologic features, diagnostic tools and treatment outcome in a cohort of patients with PIOL.
Methods: Retrospective case analysis of medical records and review of cytology of a consecutive series of 23 patients presenting with PIOL who were treated with systemic high dose methotrexate and intravitreal methotrexate injection at the National Taiwan University Hospital between Jan 2003 and Jul 2013 were investigated. Clinical data, including patient's age at the onset of disease, gender, medical history, clinical findings, laboratory investigations, mode of diagnosis, interval between the onset of symptoms and final diagnosis, type of therapy, disease course and duration of survival were obtained.
Results: Of 23 patients enrolled, 17 (73.9%) were female. The median age of onset of symptoms was 64.5 years with range from 36 to 76 years. All the patients were immune-competent and human immunodeficiency virus negative. The commonest symptoms reported by patients were blurred and/or floaters. The diagnosis of PIOL of these patients was based on the identification of abnormal lymphoid cells in vitreous fluid and 6 patients (26.1%) had bilateral eye involvement. The median time from the initial ocular presentation to diagnosis was 6 months (range 1.6–26.6 months). Eight patients had concurrent brain involvement at diagnosis, including three patients with parenchyma lesions. None had systemic involvement. Among 15 patients receiving flow cytometry examination, all patients were diagnosed as having B-cell lymphoma with monoclonality of light chain. All patients received both systemic chemotherapy with high-dose methotrexate (MTx, 8 gm/m^2 on day 1) and intravitreal injection with MTx as the induction regimen. Nineteen patients (79.2%) achieved first complete remission (CR1) with a median interval of three months. Among them, eight (42.1%) relapsed with a median remission duration of 7.8 months (range 2.8-21.4). Fortunately, seven (87.5%) patients achieved second CR after salvage chemotherapy with intravitreal MTx, systemic BOMES (BCNU 65 mg/m^2 on day 1 and day 2, oncovin 2 mg on day 1 and day 8, methotrexate 1.5 gm/m^2 on day 8, etoposide 50 mg/m^2 on days 1-5 and methylprednisolone 200 mg on days 1-7) or whole brain radiotherapy. The most common adverse effects of high-dose MTx were manageable and reversible, including hepatotoxicity (grade I, 9 patients; grade II, 6 and grade III, 6) and nephrotoxicity (grade I, 2 and grade II, 2). With a median follow-up duration of 81.8 months (range 4.4-117.3) the five-year overall survival (OS) rate was 64.7% and the median OS was not reached. A total of 5 patients died of lymphoma (21.7%). There was no survival difference between the patients with and without CNS involvement.
Summary and Conclusions: Diagnosis of PIOL requires both clinical suspicion and careful cytologic examination. The frontline treatment with high-dose MTx and intravitreal chemotherapy yielded a substantial remission rate and longer survival. It is proved to be an effective regimen with manageable side effects.

EFFICACY AND TOXICITY OF MOGAMULIZUMAB FOR RELAPLSED/ REFRACTORY ADULT T-CELL LEUKEMIA-LYMPHOMA: A RETEOSPECTIVE ANALYSIS IN SAGA PREFECTURE, JAPAN

K Kamachi[1,*] Y Kubota[1], H Ureshino[2], M Miyahara[2], M Yoshihara[1], H Kitamura[1], M Ide[1], T Shindo[1], T Ando[1], K Kojima[1], E Sueoka[3], S Kimuira[1]
[1]Department of Internal Medicine, Saga University, Saga, [2]Department of Internal Medicine, Karatsu Red Cross Hospital, Karatsu, [3]Department of Clinical Laboratory Medicine, Saga University, Saga, Japan

Background: Adult T-cell leukemia-lymphoma (ATL) is an aggressive peripheral T-cell neoplasm caused by human T-cell lymphotropic virus type I, and incurable by conventional chometherapy. CC chemokine receptor 4 (CCR4) is a chemokine receptor expressed on T-helper type 2 and regulatory T cells (Treg). CCR4 is also expressed on tumor cells from about 90% of patients with ATL. Mogamulizumab is a defucosylated humanized anti-CCR4 antibody that show potent antibody-dependent cell cytotoxicity (ADCC). In the phase II study, mogamulizumab has been shown to be effective and well tolerated against relapsed ATL patients. However, its efficacy and toxicity has not been evaluated in clinical practice.
Aims: We investigated and analyzed the efficacy and toxicity of 20 patients with relapsed/refractory ATL.
Methods: Relapsed or refractory ATL patients treated with mogamulizumab at Saga University Hospital and Karatsu Red Cross Hospital from April 2012 to December 2013, were evaluated. Overall survival (OS) was analyzed from the date of the first dose to death or to date of last follow-up.
Results: A total of 20 patients (13 male, 7 female) was evaluated. Median age was 70 years (range, 46-84). The disease subtypes at initial therapy included 17 acute, 2 lymphoma, 1 unfavorable chronic type ATL. The responses to prior therapy were 1 CR, 5 PR, 4 SD, and 10 PD. Mogamulizumab was intravenously administered once a week for 8 weeks at a dose of 1.0mg/kg, and 5 patients (25%) completed the schedule. Of the remaining 15 patients, 9 discontinued treatment because of disease progression, 1 because of skin rash, and 5 because of others. The median number of mogamulizumab infusion was 4 (range, 1-8). Eight of the 20 patients (40%) achieved objective response, including 4 with CR (20%) and 4 (20%) with PR. The response in the remaining12 patients was SD in 2 patients (10%) and PD in 10 patients (50%). Response rate for relapsed ATL and refractory ATL was 17% (1 in 6 patients), and 50% (7 in 14 patients), respectively. Responses according to disease site were 88% (of 17 patients, 12 CR and 3 PR) for peripheral blood, 38% (of 8 patients, 3 PR) for skin, and 27% (of 15 patients, 1 CR and 3 PR) for nodal lesions. Median OS were 5 months (range, 0.3-16.2). Adverse events at grades 3 to 4 were 8 lymphopenia (40%), 2 skin rash (10%), and 1 thrombocytopenia (5%).
Summary and Conclusions: In the present study, mogamulizumab showed efficacy similar to that shown in the phase II study for refractory ATL patients, however, the response rate for relapsed ATL patients was low. OS was also shorter than that of the phase II study. Further clinical investigations are required to examine whether concomitant use of this novel agent with other drugs with different mechanism of action would be more effective for ATLs. Though allogeneic hematopoietic cell transplantation (allo-HCT) is a promising treatment to achieve long-term survival for patients with relapsed or refractory ATL, mogamulizumab may be the good option for those who are ineligible for allo-HCT. In the congress, we will also discuss about the effect of mogamulizumab for graft-*versus*-host disease after allo-HCT.

IDENTIFYING LYMPHOMA ANTIGEN RECEPTOR SEQUENCES BY IMMUNE REPERTOIRE PROFILING

A Sherwood[1], H Robins[2,*]JR Fromm[3], HA Greisman[3], DE Sabath[3], R Emerson[1], M Rieder[1], BL Wood[3], D Wu[3]
[1]Adaptive Biotechnologies, [2]Fred Hutchinson Cancer Research Center, [3]University of Washington, Seattle, United States

Background: Neoplastic T and B cells rapidly expand, leading to T and B-cell receptor (TCR and BCR) repertoires dominated by one rearrangement. Techniques that use amplification of rearranged receptors from unselected populations of lymphocytes to identify malignancy, including high-throughput sequencing and the biomed primers, assume that neoplastic clones are present at conspicuously high frequency. However clones reacting to an antigen also expand. Differentiating high-frequency reactive clones from lymphomas is important for both diagnosing and monitoring lymphomas.
Aims: This project aims to use high-throughput sequencing of the antigen receptor repertoire to identify source-specific thresholds that differentiate high-frequency clones from neoplastic clones.
Methods: We developed a method that amplifies rearranged antigen receptor CDR3 sequences and uses high-throughput sequencing (HTS) to sequence tens of thousands of chains simultaneously. Because the technology utilizes gDNA the frequency of sequenced CDR3 chains is representative of the relative frequency of each CDR3 sequence in the sample population of lymphocytes. To demonstrate the potential of HTS of T and B-cell receptors to contribute to diagnosing and monitoring neoplasia in mature lymphomas; we amplify the TCR repertoire of 98 and the BCR repertoire of 60 index samples to identify high-frequency *TRB* or *IGH* rearrangements. Concurrently, we sequence the *TRB* and *IGH* repertoire in control blood, bone marrow, skin, and reactive lymph tissue from 7, 8, 6, and 14 samples respectively. Clones in the index samples are classified as neoplastic if occurring at a proportion greater than 7 standard deviations above the mean frequency of the most abundant rearranged *TRB* or *IGH* in matched control samples.
Results: Using control samples, we defined the expected frequency of highest-copy clones by source type (Table 1). Using our definition of neoplastic clone, Eighty-four percent of our 158 index samples have a tractable rearrangement.

Table 1. Average and standard deviation of highest copy TCR clones in control samples.

Summary and Conclusions: We find that for most disease diagnoses, high-throughput sequencing identifies a tractable clone and T-cell and B-cell receptor repertoire analysis may be useful for clinical laboratory evaluation of patients with T and B-cell neoplasms.

PB1823

NUMBER NEEDED TO TREAT AND COST UTILITY ANALYSIS OF GRANULOCYTE-COLONY STIMULATING FACTORS FOR PRIMARY PROPHYLAXIS OF CHEMOTHERAPY INDUCED FEBRILE NEUTROPENIA IN DLBCL PATIENTS IN THE NETHERLANDS

E Lugtenburg[1,*] MD Levin[2], L Somers[3]
[1]Hematology, Erasmus MC Cancer Institute, Rotterdam, [2]Hematology, Albert Schweitzer Hospital , Dordrecht, Netherlands, [3]OncoLogX, Antwerpen, Belgium

Background: Myelosuppression is a frequent side effect of (R)CHOP chemotherapy. Severe neutropenia can leave patients vulnerable to febrile neutropenia (FN), with associated in-hospital mortality rates in non-Hodgkin's Lymphoma (NHL) of up to 9.4%. Severe neutropenia and FN also have the potential to delay chemotherapy cycles and mandate dose reductions. Compromising the relative dose intensity of (R)CHOP-21 chemotherapy may result in poorer survival outcomes in diffuse large B-cell lymphoma (DLBCL). International guidelines by EORTC, ESMO, ASCO and NCCN recommend using granulocyte-colony stimulating factor (G-CSF) for primary prophylaxis (PP) to reduce the incidence of febrile neutropenia (FN) for patients at an overall FN risk of 20% or more. For adult patients with NHL treated with (R)CHOP-21 like chemotherapy, FN incidences between 17% and 50% have been reported, demonstrating the eligibility of this regimen for PP with G-CSF as indicated in international guidelines.
Aims: 1.To estimate the number needed to treat (NNT) to avoid an FN episode for different PP options in comparison to no prophylaxis in patients receiving 6 cycles of standard (R)CHOP-21 chemotherapy for DLBCL. 2. To assess the cost-utility in the Netherlands of PP with once-per-cycle pegfilgrastim compared to no prophylaxis, PP with daily filgrastim (11- or 6-days per cycle) and secondary prophylaxis (SP) with pegfilgrastim.
Methods: A decision-analytic model was constructed from the Dutch healthcare-payer perspective. Costs were obtained from official list prices (January 2014) or literature and included drugs (lowest list prices for each product), drug administration and FN-related hospitalization costs. G-CSF relative effectiveness inputs were based on a recent meta-analysis and previous NHL studies. Survival and utility variables were modeled from available data for NHL patients in the US SEER cancer registry and published literature. Univariate sensitivity analyses evaluated the robustness of the model for all input variables.
Results: PP with pegfilgrastim provides the most effective primary prophylaxis of FN with a NNT to avoid an FN episode of 4.7 (see Table 1). In the cost-utility analysis PP with pegfilgrastim was dominant (more effective and cost saving) compared to PP with 11-days filgrastim and cost-effective compared to no prophylaxis, PP with 6-days filgrastim and SP with pegfilgrastim. (see Table 2) The sensitivity analyses revealed that baseline

FN risk, G-CSF effectiveness in reducing FN and long term survival assumptions were the most sensitive parameters, and showed that the model was robust. Even when in a scenario analysis the price of daily G-CSF was reduced by up to 90%, PP with pegfilgrastim remained cost-effective compared to the daily G-CSF options.

Table 1. Number needed to treat to avoid an FN episode.

Table 2. Cost utility of PP pegfilgrastim in comparison to other strategies.

Summary and Conclusions: For DLBCL patients treated with (R)CHOP in the Netherlands, primary prophylaxis of FN with pegfilgrastim is a cost-effective use of healthcare resources.

PB1824

HIGH-DOSE METHOTREXATE, HIGH-DOSE CYTARABINE AND TEMOZOLOMIDE FOR THE TREATMENT OF PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA (PCNSL), SIX YEARS SURVIVAL IS REACHED

M Salamoon[1,2,*]M kenj[3]
[1]medical oncology, [2]hematology, al Bairouni university hospital, [3]cytogenetics, kenj labs, damascus, Syrian Arab Republic

Background: Treatment of primary central nervous system lymphoma (PCNSL) associates with low response rates and poor survival using conventional radio and chemotherapy. Due to its favorable toxicity profile, Temozolomide has emerged as a new option for treatment of PCNSL in young patients. In this study we report a series of (PCNSL) patients treated with an innovative regimen.
Aims: To evaluate a new intensive chemotherapy with Temozolomide, trying to assess response and progression free survival and overall survival taking into consideration the toxicity profile. The study was performed at Al Mowassa Charity hospital in Damascus (SYRIA).
Methods: 40 patients with histologically confirmed PCNSL median age 52 years (range 20-65) years were included. Biopsies were cultured and a Karyotyping was made in 32 patients. An induction chemotherapy was started Methotrexate 3 gr/m² over 12 hours on day1 , Cytarabine 3 gr/m² every 12 hours on day 1 and Temozolomide 150 mg/m² from day 2 through day 6 with a total of 6 cycles were given on a monthly basis.
Results: Among the 40 patients included in the study a complete response was observed in 34 patients (85%) and a partial response in the remaining 6 patients (15%). Disease progressed in 8 out of 40 patients (20%) while 32 patients are still living at five years making the overall survival reaching (80%). Grade II nephrotoxicity was observed in 2 patients while grade III and IV hematotoxicity was observed in 5 patients. The study was updated in January 2014 and we still have the same progression free survival but we lost a patient died from heart attack making the overall survival rate 77% at 6 years.
Summary and Conclusions: high-dose of both Ara-c and MTX combined with Temozolomide appears to be a good choice in the treatment of PCNSL, in the light of good response and overall survival rates

PB1825

PROGNOSTIC SIGNIFICANCE OF INTERIM POSITRON EMISSION TOMOGRAPHY SCAN IN PATIENTS WITH MATURE T-CELL AND NK-CELL LYMPHOMA

HY Yhim[1,*] NR Lee[1], EK Song[1], SY Jeon[1], CY Yim[1], YH Han[2], MH Sohn[2], B Lee[3], JA Kim[4], YH Park[5], WH Choi[5], HS Kim[6], JY Kwak[7]
[1]Department of Internal Medicine, [2]Department of Nuclear Medicine, Chonbuk National University Hospital, Jeonju, [3]Department of Internal Medicine, St. Vincent's Hospital, College of Medicine, Catholic University of Korea, [4]Department of Internal Medicine, St. VIncnet's Hospital, College of Medicine Catholic University of Korea, [5]Department of Radiology, St. Vincent's Hospital, College of Medicine Catholic University of Korea, Suwon, [6]Department of Nursing, Wonkwang University, Iksan, [7]Department of Internal Medicine, Chonbuk National Unviersity Hospital, Jeonju, Korea, Republic Of

Background: Interim positron emission tomography (PET) scan has been found to be effective in Hodgkin lymphoma (HL) and diffuse large B-cell lymphoma (DLBCL). The prognostic value of interim PET in mature T-cell and NK-cell lymphoma remains uncertain. Recently, the Deauville five-point scale (5-PS), which visually assess the uptake of lesions in comparison with background mediastinal and liver uptakes, has been validated in the large numbers of patients with HL and DLBCL. However, the prognostic impact of 5-PS on clinical outcomes has not been investigated in mature T-cell and NK-cell lymphoma.
Aims: The aim of this study was to determine the prognostic role of interim PET, assessed by Deauville 5-PS, in patients with mature T cell and NK cell lymphoma and treated with systemic chemotherapy.
Methods: We consecutively enrolled patients with newly diagnosed mature T-cell and NK-cell lymphoma, treated with CHOP/CHOP-like or non-anthracycline-based chemotherapy and had the baseline PET data with ³1 evaluable hypermetabolic lesion between 2006 and 2012 in two Korean institutions. Patients treated with upfront chemoradiotherapy before interim PET scan were excluded. Interim PET scan was performed after 3 cycles of chemotherapy, before 1 week of the next cycle. Interim PET response was visually assessed by 5-PS and four point or higher was regarded as positive. All PET assessment was performed by 2 nuclear medicine specialists at each institution, and the discrepancy of assessment was resolved by the agreement through discussion.
Results: A total of 35 patients was included in this analysis. The median age was 60 years (range, 31-79) and 26 (74%) were male. Histologic subtypes included were PTCL, not otherwise specified in 10 (29%), extranodal NK/T cell lymphoma in 8 (23%), angioimmunoblastic T cell lymphoma in 7 (20%), anaplastic large cell lymphoma, ALK negative in 4 (11%), and others in 6 (18%). 22 patients (63%) were presented as advanced stage disease and 9 (26%) had B symptoms. ECOG performance status was ≥ 2 in 7 (20%), serum LDH level was elevated in 16 (46%), and bone marrow was involved in 5 (14%). Thus, 14 patients (40%) were classified as high risk (≥ 2 factors) by the prognostic index for PTCL (PIT). 31 patients (89%) completed planned systemic chemotherapy±involved-field radiotherapy and 25 (71%) achieved complete response by systemic chemotherapy. 10 patients (29%) underwent consolidative autologous stem cell transplantation (ASCT). Using 5-PS, interim PET scan was visually scored as follows; 1 point in 10 patients (29%), 2 in 6 (17%), 3 in 8 (23%), 4 in 7 (20%), and 5 in 4 (11%). Among these, 11 patients (31%) had 4 point or above were considered positive for interim PET scan. With a median follow-up of 43.4 (range, 4.3-89.8) months, progression-free survival (PFS; median, 5.2 *vs* 38.0 months, respectively; *P*=0.001) and overall survival (median, 12.6 months *vs* not reached, respectively; *P*=0.004) was significantly worse in patients with positive interim PET than those with negative results. In multivariate analysis for PFS, high risk of PIT (HR, 3.67; 95% CI, 1.13-11.99) and positive interim PET (HR, 4.02; 95% CI, 1.32-12.23) were independently associated with faster disease progression.
Summary and Conclusions: This study represents that Deauville 5-PS is useful to predict early outcomes of patients with mature T-cell and NK-cell lymphoma. Patients with positive interim PET are associated with extremely poor early outcomes. Further studies regarding response-adapted stratification based on interim PET might be needed in mature T-cell and NK-cell lymphoma.

SIMILAR PROGNOSIS OF TRANSFORMED AND DE NOVO DIFFUSE LARGE B CELL LYMPHOMA TREATED WITH IMMUNOCHEMOTHERAPY

M Sorigue[1,*] O Garcia[2], MJ Baptista[3], G Tapia[4], JM Sancho[5], J L Mate[4], J Juncà[5], F Millà[5], E Feliu[5], JM Ribera[5], JT Navarro[5]
[1]Department of Hematology, ICO-Hospital Germans Trias i Pujol, [2]Department of Hematology, ICO-Hospital Germans Trias i Pujol, Josep Carreras Leukemia Research Institute, [3]Josep Carreras Leukemia Research Institute , [4]Department of Pathology, Hospital Germans Trias i Pujol, Universitat Autonoma de Barcelona, [5]Department of Hematology, ICO-Hospital Germans Trias i Pujol, Josep Carreras Leukemia Research Institute. Universitat Autónoma de Barcelona, Badalona, Spain

Background: Transformed diffuse large B cell lymphomas (TL) have historically been associated with an aggressive course and a poor prognosis. However, in the last decade some studies have shown an important improvement in their prognosis. Furthermore, diffuse large B cell lymphomas (DLBCL) are heterogeneous, with major groups defined by the cell of origin (COO). There are few studies aiming to characterize the COO in TL and its prognostic implications.
Aims: To compare the clinical and biological features (including the COO), as well as the prognosis between TL and DLBCL treated with rituximab and chemotherapy.
Methods: We revised the records of 163 patients with DLBCL with those from

31 with TL treated between 2003 and 2012 in our institution. The COO was established by the Hans' algorythm, which uses the imunohistochemical expression of CD10, BCL6 and MUM1 on tissue sections to classify DLBCL into germinal center B-cell like (GCB) and non-GCB. Only patients diagnosed by tissue biopsy were included. Patients not treated with immunochemotherapy, HIV positive, those whose biopsy specimen was unavailable for revision and those with specific subtypes of DLBCL such as primary cutaneous DLBCL, leg type and primary mediastinal DLBCL were excluded from the study.
Results: 29 patients with TL and 101 with DLBCL were included in the study. Of the 29 TL, 9 had a previous diagnosis of follicular lymphoma (FL), 6 of marginal zone lymphoma, 4 chronic lymphocytic leukemia (CLL) and 10 showed both DLBCL and FL in the same lymph node (composite lymphoma). There were no differences in the clinical or analytical parameters between TL and DLBCL. TL was diagnosed at advanced stages in 68% of cases while DLBCL was in 53% (p=0.198). Data on the COO was available for 23 TL and 76 DLBCL. All TL evolving from FL (7/7) and composite lymphomas (9/9) were GCB while all TL from marginal lymphoma (4/4) and CLL (3/3) were non-GCB. Overall, 16 out of 23 (70%) were GCB. 32 out of 76 (42%) DLBCL were CGB. TL were more frequently of GCB subtype than DLBCL (p=0.031) and CD10 was expressed more frequently in TL (p=0.002). TL and DLBCL were treated with RCHOP in 21 and 89 cases, respectively. Five TL cases received consolidation with autologous stem cell transplantation (SCT) in first remission and 2 were submitted to allogeneic SCT. No DLBCL patient received SCT in first remission. There were no differences between TL and DLBCL in the rate of complete remission with first line treatment (62% *vs.* 66%), nor in overall survival (OS, 63%, [95%CI 43%,83%] *vs.* 61% [95%CI 50%,72%]), or in progression-free survival (PFS, 61% [95%CI 42%,80%] *vs.* 60% [95%CI 49%,71%] respectively). Excluding the 7 patients with TL who received SCT, the OS and PFS in TL treated only with immunochemotherapy were 58% (95%CI 35%,81%) and 55% (95%CI 33%,77%), respectively, without differences with those observed in DLBCL patients. Analyzing only GCB lymphomas, there were no differences between TL and DLBCL in both OS (61% *vs.* 62%) and PFS (66% *vs.* 63%).
Summary and Conclusions: Patients with TL and DLBCL from this series had similar clinical and biological characteristics at diagnosis. GCB was more frequent in TL than in DLBCL. The prognosis of TL and DLBCL was similar in patients treated with immunochemotherapy.

TREATMENT WITH YTTRIUM-90 (90Y)-IBRITUMOMAB TIUXETAN (ZEVALIN®) IN DIFFUSE LARGE B-CELL LYMPHOMA: A META-ANALYSIS

S Auger[1,*] Y Duny[2], JP Daures[2], P Quittet[3]
[1]Internal médicine and hematology, ClinicBeausoleil, [2]Biostatistical and Epidemiology, INSERM Unit EA 2415, [3]Hematology, University hospital, Montpellier, France

Background: Diffuse large B-cell lymphoma (DLBCL) is the most frequently diagnosed non-Hodgkin's lymphoma (NHL). Current treatment paradigm in first line, is based on immunochemotherapy and, in case of relapse or refractory, on a salvage therapy with high-dose chemotherapy followed by autologous stem cell transplantation (ASCT). Yttrium-90 (^{90}Y)-ibritumomab tiuxetan, off label, offers a new therapeutic approach for DLBCL, both as first-line induction or consolidation and in relapsed or refractory disease. Data on this subject is increasingly being reported as well in consolidation as alone, in first line or after.
Aims: To assess efficacy and find the best place of Yttrium-90 (^{90}Y)-ibritumomab tiuxetan in DCLL, we conducted a literature review and meta-analysis of randomized clinical trials and observational studies on the effect of (^{90}Y)-ibritumomab tiuxetan treatment in this setting, except in ASCT.
Methods: The primary goal was to assess the effect of (^{90}Y)-ibritumomab tiuxetan on overall response rate (ORR) and complete response rate (CRR) then assess the 2-year overall survival (OS_{2y}) and 2-year progression-free survival rates (PFS_{2y})
Results: Sixteen studies were identified (399 patients) with DLBCL receiving (^{90}Y)-ibritumomab tiuxetan as consolidation or as treatment alone. The ORR and CRR were 74.8% (n=374) and 67.4% (n=365), respectively. Outcomes were superior when (^{90}Y)-ibritumomab tiuxetan is used in consolidation after immunochemotherapy induction at first line of treatment. OS_{2y} and PFS_{2y} were 87.5% and 82.8%, respectively. The primary toxicity was neutropenia (49.9%).
Summary and Conclusions: The use of (^{90}Y)-ibritumomab tiuxetan in patients with DLBCL is safe and effective.

Background: HBV infection is highly prevalent in Chinese patients (pts) with B-NHL, compared with the general population. Rituximab (R) and chemotherapy (chemo) have been associated with HBV reactivation, which may influence the continuation of therapy and can result in fatal liver dysfunction. Therefore, standardized management of HBV reactivation in pts receiving chemo is needed.
Aims: To describe the management status of B-NHL pts with HBV infections in real practice in China.
Methods: Pts with previously untreated DLBCL and FL who were eligible to receive R-chemo were enrolled in a multicenter, prospective, single-arm observational study in China. Data were collected and analyzed from medical records 120 d after the last R dose was administered. HBV infection management in pts was evaluated, including HBV infection and liver function screening before R-chemo, viral replication monitoring during and after R-chemo, antiviral prophylaxis use and HBV reactivation rates. HBsAg-positive (pos) pts had HBV reactivation if HBV DNA increased ≥ 1 log10 from baseline, if HBV DNA appeared (above the lower limit of detection) or if HBeAg appeared in HBeAg-negative (neg) pts. HBsAg-neg/HBcAb-pos pts had HBV reactivation if there was appearance of either HBsAg or HBV DNA (above the lower limit of detection). These analyses are preliminary.

Tablel 1. Antiviral treatment, HBV infection monitoring and HBV reactivation in R-chemo-treated DLBCL/FL pts.

Results: HBV screening data were available from 269/309 enrolled pts. At baseline (BL), 26 pts were HBsAg pos, 74 were HBsAg neg/HBcAb pos and 169 were double neg. HBV infection status was undefined for 40 pts. 20 HBsAg-pos, 7 HBsAg-neg/HBcAb-pos, 1 double-neg and 4 undefined pts had a history of hepatitis. HBV DNA levels were evaluated in 18/26 HBsAg-pos, 34/74 HBsAg-neg/HBcAb-pos, 33/169 double-neg and 7/40 undefined pts. 8/18 HBsAg-pos and 3/34 HBsAg-neg/HBcAb-pos pts were positive for HBV DNA. HBsAg-pos pts had a median log HBV level of 3.9 copies/mL (n=7). HBV DNA levels were below the level of quantification in 1 HBsAg-pos and 3 HBsAg-neg/HBcAb-pos pts who were HBV DNA pos. Levels of ALT, AST and total

bilirubin were tested in 99.0%, 98.7% and 98.4% of pts, respectively. Data on antiviral prophylaxis treatment, monitoring and HBV reactivation are in Table 1. Most pts who received antiviral prophylaxis were HBsAg pos-only 69% of HBsAg-pos pts were treated. By 120 d after the last R dose, some pts had already stopped prophylaxis. Not all pts were monitored for serologic markers, HBV DNA and liver function during induction therapy, and monitoring declined further after the last R-chemo dose. HBV reactivation occurred in 3 HBsAg-pos, 3 HBsAg-neg/HBcAb-pos and 1 double-neg pts. In contrast, investigators reported 1 case of HBV reactivation each in HBsAg-neg/HBcAb-pos, double-neg and undefined pts, based on clinical experience.

Summary and Conclusions: This study reports HBV load in previously untreated DLBCL/FL pts receiving R-chemo as first-line therapy in China. Most Chinese physicians acknowledge the importance of HBV screening before initiation of R-chemo. However, improvements in HBV infection monitoring and antiviral treatment duration are required. Even with monitoring, HBV reactivation is not defined consistently by physicians, which may lead to underreporting of reactivation as shown herein. By the time of analysis, some early reactivation had emerged, but late reactivation, especially after stopping antiviral treatment, should be monitored long term. Finally, standardized monitoring, follow-up strategies and education are needed for proper management of HBV infection in B-NHL pts receiving chemo.

PB1829

COMPARISON OF GEMCITABINE *VS.* NON-GEMCITABINE BASED SALVAGE CHEMOTHERAPY IN RELAPSED/REFRACTORY AGGRESSIVE LYMPHOMA

D Taylor[1,*] P Angelillo[1], C Ward[1], D Collins[1], R Salim[1], A Pettitt[1], A Arumainathan[1], N Kalakonda[1]

[1]Haematology, Royal Liverpool University Hospital, Liverpool, United Kingdom

Background: Despite advances in immuno-chemotherapy, outcomes in relapsed/refractory (R/R) lymphoma remain dismal. The treatment approach, in eligible patients, is intensive salvage chemotherapy followed by transplantation. The optimal salvage regime remains a matter of debate with wide institutional variations. (R)-DHAP (cytosine arabinoside, cisplatin, dexamethasone, ±Rituximab) remains the most commonly used regimen. Gemcitabine based regimens are, at least, non-inferior to (R)-DHAP and allow effective mobilization of haematopoietic stem cells even in heavily pre-treated patients. The combination of ifosfamide, gemcitabine and vinorelbine (IGEV) has a good profile of tolerability and efficacy in R/R Hodgkin' lymphoma (HL) and lends itself to use in an outpatient setting; but data for its use in non-Hodgkin' lymphoma (NHL) are lacking.

Aims: To assess feasibility, safety and efficacy of (R)-IGEV for the treatment of patients with R/R HL and NHL.

Methods: In a retrospective cohort study, we analysed the outcome of 46 consecutive patients treated for R/R lymphoma at our institution between January 2010 and October 2013. Patients received either IGEV or DHAP for HL and additional Rituximab for B-NHL. Primary outcomes were overall response rate (ORR); PFS (from first salvage to progression, relapse, or death from any cause); and overall survival (OS). OS and PFS were estimated using the Kaplan-Meier method and compared using the log-rank test. In addition, the likelihood of proceeding to transplantation, on an intent-to-treat basis, was assessed.

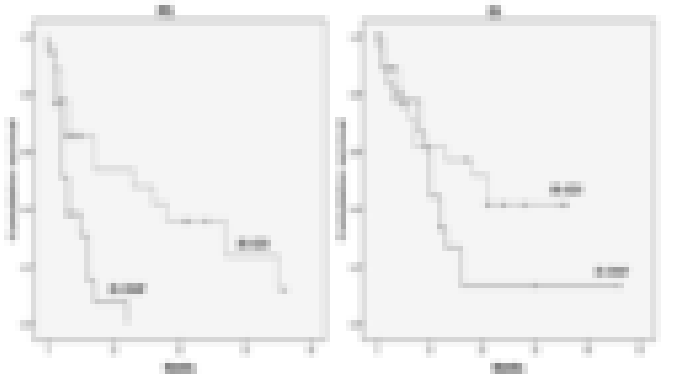

Figure 1.

Results: We analysed 46 consecutive patients treated at our institution for R/R HL and NHL between January 2011 and October 2013. Median age at salvage was 57 (19-78) yrs, 67% of the patients were male. At diagnosis, 86% of patients had stage III/IV disease, and 15 patients had a diagnosis of HL. In the (R)-IGEV group the ORR rate, after 2 courses, was 44% with a CR rate of 36% (as assessed by PET-CT). ORR and CR rates in the (R)-DHAP group were 27% and 25% respectively. After a median follow-up of 26 months, OS in the (R)-IGEV and (R)-DHAP groups was 21 months (95% CI, 10.1-31.8 months) and 10 months (95% CI, 8.6-11.4 months) (p=0.179) respectively. The percentage of patients that proceeded to transplantation was 50% in both groups. Median PFS in the (R)-IGEV and (R)-DHAP groups were 13 months (95% CI 1-24 months) and 3 months (95% CI 1.7-4.2 months) respectively (p=0.001). Principal grade 3/4 toxicities in both groups were cytopenias. Overall, the toxicity profile of the two regimens was comparable. Significantly, of a total 78 courses of IGEV, 53% were successfully administered in an outpatient setting. All courses of (R)-DHAP required in-patient stay.

Summary and Conclusions: In summary, (R)-IGEV represents a safe and effective outpatient salvage therapy for R/R lymphoma. In our cohort, patients in the (R)-IGEV group had a statistically superior PFS compared to patients in the (R)-DHAP group. Our data also suggest that subsequent transplantation rates are comparable in both groups. In addition, (R)-IGEV lends itself to administration in an outpatient setting thus avoiding potential delays because of inpatient bed availability, enhancing patient experience, and has health economic benefits.

PB1830

SIGNIFICANT SURVIVAL IMPROVEMENT OF THE ELDERLY PATIENTS AND WOMEN WITH LOW/INTERMEDIATE RISK MIPI MANTLE CELL LYMPHOMA OVER THE PERIOD OF 14 YEARS

P Vockova[1,*] P Klener[1], R Pytlik[1], K Benesova[1], J Stritesky[2], Z Velenska[2], R Jaksa[2], V Campr[3], M Petrova[1], M Trneny[1]

[1]First Internal Clinic – Clinic of Hematology, [2]General University Hospital in Prague, [3]University Hospital in Motol, Praha, Czech Republic

Background: Mantle cell lymphoma (MCL) is an aggressive type of B-cell non-Hodgkin lymphoma (NHL) with poor prognosis. In recent years the outcome of patients with MCL has been improved mainly by implementation of rituximab (R), high-dose araC (HDAC) into induction regimen, consolidation with autologous stem cell transplant (ASCT) and R maintenance.

Aims: A single center retrospective analysis of MCL patients treated since 1999 to 2012.

Methods: We retrospectively analyzed 185 consecutive patients with confirmed diagnosis of MCL treated at the Charles University General Hospital since 1999 to 2012. The whole cohort comprised 71% men and 29% women with median age of 66 years (both men and women). Most patients had advanced-stage disease (stage IV= 80% patients) and adverse prognosis according to the mantle-cell lymphoma prognostic index (MIPI): MIPI high (MIPI-H)= 48.1%, MIPI intermediate (MIPI-I)= 23.8% and MIPI low (MIPI-L)= 24.9%. Out of all 185 patients, 2 were not treated. Three most common types of induction therapy included R-CHOP (n=52), Nordic protocol (alternating 3 cycles of R-Maxi-CHOP and 3 cycles of R-HDAC, n=45) and R-COP (n=26). 45 patients received ASCT. Most patients (86.9%) had rituximab as part of induction.

Results: Overall response rate for all patients was 81.9% (CR/uCR= 57.9%, PR= 24%). Median progression-free survival (PFS) and overall survival (OS) was 2.84 years, and 6.27 years, respectively. The median follow-up was 4.4 years. The analysis revealed several interesting findings. First, patients (pts) diagnosed in 2006-2012 (2006+) *vs* 1999-2005 (1999+) had significantly better PFS (median 2.04 *vs* 3.38 years, p= 0.0222) and trend toward better OS (median 7.2 *vs.* 4.3 years, p= 0.11). Curiously, the age-stratified analysis revealed that only elderly patients (≥ 60 years) in 2006+ group had significantly improved PFS (median 2.74 *vs.* 1.63 years, p= 0.0086) and trend toward improved OS (median 4.2 *vs* 2.3 years, p=0.0625) compared to those in 1999+ group. The younger patients in 2006+ compared to 1999+ group had similar PFS (median 5.52 *vs.* 5.51 years, p= 0.884) and OS (median undefined in both subgroups, p= 0.784). The reason for the improved outcome of the elderly patients in recent years is probably a consequence of introduction of rituximab maintenance. In the elderly groups 1999+ and 2006+ two of 44 and 32 of 66 pts received rituximab maintenance, respectively. The elderly pts 2006+, who received rituximab maintenance (compared to those, who did not) had higher PFS (median 4.5 *vs* 2.23 years, p= 0.0055) and OS (median undefined *vs* 3.41 years, p= 0.0018). Second, MIPI discriminated well into 3 subgroups of patients only in the whole cohort. However, in the age-stratified analysis there remained only two relevant MIPI subgroups: MIPI-I merged with MIPI-H (in younger pts) or with MIPI-L (in elderly pts). Finally we observed trend toward better OS in the subcohorts of women with MIPI-L and MIPI-I compared to men (MIPI-L median undefined *vs* 8.48 years, p= 0.0692; MIPI-I median 10.51 *vs* 4.56 years, p= 0.0657). PFS was significantly prolonged in women with MIPI-I compared to men (median 8.31 *vs* 5.59 years, p= 0.539), but did not differ in women with MIPI-L (median 8.04 *vs.* 2.44 years, p= 0.0237).

Summary and Conclusions: On the large single center cohort of unselected MCL patients we demonstrated significant outcome improvement of elderly patients but not younger patients during the last 7 years. We found that MIPI discriminated only two prognostic subgroups when used in age-defined cohorts of patients. Finally, women with low and intermediate risk MIPI appeared to have better outcome compared to man.

CLINICAL IMPLICATIONS AND PROGNOSTIC SIGNIFICANCE OF POSITRON EMISSION TOMOGRAPHY (PET/CT) IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) AFTER R-CHOP CHEMOIMMUNOTHERAPY

T P Vassilakopoulos[1,*] A Kanellopoulos[1], S Papageorgiou[2], G A Pangalis[3], A Anastasopoulou[4], M Moschogianni[5], Z Galani[1], K Petevi[1], G Boutsikas[1], SI Kokkoris[6], M Dimou[7], L Papageorgiou[1], T Tzenou[7], G Gainaru[1], A Koutsi[1], E Pessach[7], V Telonis[1], S Sachanas[3], N Viniou[4], E Variami[4], MC Kyrtsonis[7], M N Dimopoulou[1], P Tsirigotis[2], E Plata[1], P Tsaftaridis[1], M Siakantaris[4], P Panayiotidis[7], J Meletis[1], H Ioannidou[2], V Pappa[2], M K Angelopoulou[1], K Konstantopoulos[1]

[1]Department of Haematology, Laikon General Hospital, [2]Second Propedeutic Departmant of Internal Medicine, Attikon Hospital, [3]Department of Haematology, Athens Medical Center, [4]First Department of Internal Medicine, Laikon General Hospital, [5]Athens Medical Center, [6]Transfusion Department, Attikon Hospital, [7]First Propedeutic Department of Internal Medicine, Laikon General Hospital, Athens, Greece

Background: About 30-40% of patients with DLBCL are primary refractory or relapse after first line treatment with the R-CHOP regimen. Among responders according to the IWC criteria, many patients still have post-treatment residual masses. Therefore, PET/CT is increasingly used for the identification of patients with active disease at the end of treatment, although relevant data are scarce in the literature.
Aims: The retrospective analysis of PET/CT findings in patients with DLBCL after conventional response to R-CHOP and the assessment of their impact on outcome in comparison to established prognostic factors.
Methods: From 2004 to 2013, 151 patients with DLBCL who achieved CR, CRu, or PR by conventional radiographic imaging (according to IWC) underwent posttreatment PET/CT. All patients had been treated with 4-8 cycles of R-CHOP or similar anthracycline-containing immunochemotherapy regimens. PET/CT was performed at the treating haematologist's discretion, but availability was also an issue, particularly during the earlier years of the study. The primary end-point of the analysis was progression free survival (PFS). PET/CT scans were interpreted according to the International Harmonization Project criteria.
Results: The main baseline patients' characteristics were: median age 61 (18-89), 65% male, 55% stage III/IV, 17% ECOG PS ≥2, 23% ≥2 E-sites, 53% abnormal LDH, IPI-L 42%,IPI-LI 21%,IPI-HI 24%, IPI-H 14%. Among the 151 patients, 117 (77%) became PET(-) (including 11 patients with indeterminate findings) and 34/151 (23%) remained PET(+). The 4-year PFS was 86% *vs* 40% for PET(-) and PET(+) patients respectively (p<0.0001). Among PET(-) patients, 107/117 remained in complete remission for a median follow-up of 25 months from the date of PET/CT. Among PET(-) patients, 10/117 relapsed. PS ≥2 was associated with inferior PFS in PET(-) patients (4-year PFS 89% *vs.* 69% for patients with PS 0-1 *vs.* 2-4; p=0.02). Marginally significant trends towards inferior PFS among PET(-) patients were also observed for males, multiple extranodal involvement and bone marrow involvement (0.10<p<0.15). Among 34 PET(+) patients, 16 progressed or relapsed for a 4-year PFS of 40%. Biopsy-proven false positive results and the use of consolidative irradiation (although limited) may have contributed to this promising figure (details to be presented at the meeting).
Summary and Conclusions: DLBCL patients who become PET(-) at the end of R-CHOP had a moderate risk of disease progression in the order of 15%. The risk increased with worsening PS at diagnosis, while the significance of several other adverse prognostic factors needs further investigation. DLBCL patients in PET(+) PR who respond to R-CHOP had 60% risk of relapse, but 40% of them remained disease-free despite the limited subsequent use of radiotherapy. Our findings could facilitate the design of follow-up and guide potential consolidative treatment in patients with DLBCL.

PB1832

AN ANALYSIS OF THE PHARMACOKINETICS AND TOXICITY OF HIGH-DOSE METHOTREXATE IN PATIENTS WITH HISTOLOGICALLY AGGRESSIVE NON-HODGKIN LYMPHOMA AT HIGH RISK OF CENTRAL NERVOUS SYSTEM DISEASE

S Ninkovic[1,*] C Y Cheah[1,2], M Tatarczuch[3], KL Burbury[1], H Quach[3], JF Seymour[1,2], SJ Harrison[1,2]

[1]Dept of Haematology, Peter MacCallum Cancer Centre, East Melbourne, [2]Sir Peter MacCallum Dept of Oncology, University of Melbourne, Parkville, [3]Dept of Haematology, St. Vincent's Hospital , Fitzroy, Australia

Background: CNS relapse in aggressive NHL is an infrequent yet devastating cause of treatment failure and patients (pts) at high risk [aaIPI >2 or multiple/specific extranodal sites of involvement (testis, breast, kidney, adrenal, BM, or epidural)] at our centres receive 2 courses of intravenous high-dose methotrexate (HD-MTX) as CNS parenchymal prophylaxis. HD-MTX can however result in significant toxicity leading to treatment delay so identification of predictors of toxicity is crucial.
Aims: The aim of this study was to examine HD-MTX pharmacokinetics, the incidence and predictors of delayed MTX clearance, hepatic and nephrotoxicity.
Methods: We conducted a retrospective analysis of pts receiving ≥1 cycle of HD-MTX for histologically aggressive NHL. Clinical and pharmacy databases were reviewed from 2004-2013 inclusive. Data collected included patient sex, age, diagnosis, MTX dose and number of cycles, rate of MTX infusion, peri-treatment radiological contrast exposure, baseline bicarbonate level as a measure of urine alkalinisation (mmol/L), nadir bicarbonate level during MTX exposure, peak serum and 24hr post-infusional MTX levels (μmol/L), time to clear MTX defined as level ≤0.05 (μmol/L) and hepatic and renal toxicity as defined by CTCAE v4.0.
Results: A total of 90 pts (54M, 36F) met the inclusion criteria with median age of 61.7yrs (19.8-82.6); 36 (40%) were >65yo (cut-off age for receiving MTX > 1g/m^2). A total of 161 cycles were delivered; 72 at 3g/m^2, 65 at 1g/m^2 and 24 at other doses (0.5, 1.5 or 2g/m^2). 71/90 (79%) pts received both planned cycles. 88% of 32 pts having 1g/m^2 in cycle 1 had 1g/m^2 in cycle 2, only 61% of 44 pts having 3g/m^2 had 3g/m^2 in cycle 2; 9% had a dose reduction, 30% did not have a second cycle. Most HD-MTX was given as a 24-hr infusion, only 4 pts had a 3hr infusion with 75% having significant toxicity or delayed clearance prohibiting cycle 2. The median peak MTX level (μmol/L) was 34.95 (5.18-125.95) in pts having 3g/m^2 (29/72 courses recorded) and 15.38 (1.21-22.19) in pts having 1g/m^2 (33/65 courses recorded), with median 24h post-infusion level of 0.37 (0.10-12.66) and 0.28 (0.03-3.51) respectively. The 24h MTX level correlates better with delayed clearance then end of infusion level does (R 0.77 *vs.* R 0.17). If 24h level >2.0, then 5/6 (83%) had delayed clearance; <2.0 then only 21/80 had delayed clearance, P=0.009. Median time to clear MTX was 57h (25h-137h) with median length of hospital stay of 98h (64h-385h). Delayed clearance, defined as MTX level >0.05 μmol/L at 72h, was observed in total of 39 cycles (24%). Grades 1-3 hepatotoxicity was observed in 26.7%, 10.6% and 6.8% of cycles respectively. Grades 1-4 nephrotoxicity was observed in 53.4%, 8.7%, 2.5% and 0.6% of cycles respectively. We analysed our postulated risk factors as predictors of delayed clearance or nephrotoxicity ≥G2 independently for cycles 1 and 2 because these are likely to represent different populations given most pts who have toxicity in cycle 1 usually don't have a second cycle. The only significant finding was an association between MTX 1g/m^2 in cycle 1 and delayed clearance but not nephrotoxicity. Overall, 74% (14/19) pts with nephrotoxicity ≥G2 had delayed clearance, but only 49% (14/39) pts with delayed clearance had nephrotoxicity ≥G2.
Summary and Conclusions: HD-MTX associated toxicity resulted in suboptimal delivery of CNS prophylaxis in 21% of our patients. A 24h level of >2.0 predicts for much greater risk of delayed clearance and could be a red flag for more aggressive intervention. Unlike previous reports of age as a predictor of toxicity, age-based dose adjustment diminishes this risk association. Patients having dose-adjusted MTX at 1g/m2 were more likely to have delayed MTX clearance but not nephrotoxicity. Other MTX doses, low serum bicarbonate as an indirect assessment of poor urine alkalinisation and rate of infusion were not associated with toxicity.

PB1833

COMPARISON BETWEEN CONTRAST-ENHANCED COMPUTERIZED TOMOGRAPHY (CECT) AND 18FLUORO-DEOXY-GLUCOSE POSITRON EMISSION TOMOGRAPHY (FDG-PET) FOR INITIAL AND END-OF-THERAPY STAGING OF T-CELL LYMPHOMA

C Rusconi[1,*] E Meli[1], V R Zilioli[1], A Greco[1], P Minga[1], L Paris[1], M Zancanella[1], C Popescu[2], C Rossetti[2], A Vanzulli[3], E Morra[1]

[1]Hematology, [2]Nuclear Medicine, [3]Radiology, Niguarda Hospital, Milano, Italy

Background: T-cell lymphoma are rare lymphoprolipherative disease, characterized by disappointing outcome. Even if T-cell lymphomas are usually considered as aggressive disease, very few data are available on the role of fluoro-deoxy-glucose positron emission tomography (FDG-PET) in T-cell non Hodgkin Lymphoma (NHL).
Aims: We retrospectively reviewed 96 FDG-PET scans performed since 2004 to 2014 in 38 T-cell NHL pts and we focused on 58 scans for which a simultaneous standard contrast-enhanced computerized tomography (CECT) was available for comparison, in order to evaluate the role of FDG-PET in optimizing this challenging disease management.
Methods: Patients' median age was 54 years (range: 25-77) and 21/38 pts (55%) were females. As regards histology, 19 pts (50%) had peripheral T-cell lymphoma not otherwise specified, 5 pts (13%) had angioimmunoblastic T-cell lymphoma, 13 pts (34%) had anaplastic T-cell lymphoma and 1 pt (3%) had nasal-type T-cell lymphoma. Baseline FDG-PET scans were 29, while 29 FDG-PET were performed for end-of-therapy disease reassessment.
Results: At baseline staging, PET and CECT pointed out the same disease sites of involvement in 7% (2/29) of cases. PET identified a higher number of disease sites compared to CECT in 66% (19/29) of the pts; on the contrary, in 24% (7/29) of cases PET showed a lower number of disease sites than CECT. In 1 pt (1/29, 3%) we observed a PET positivity, with CECT negativity after diagnostic lymphnode biopsy. Additional sites identified by PET were both nodal and extra-nodal: new nodal sites in 19 pts, spleen in 2 pts, bone in 3 pts, nasopharinynx, pancreas, muscle, bowel and testicle in 1 pt each. FDG-PET results led to change the an Ann Arbor stage in 44.8% (13/29) of cases, with an up-staging in 37.9% (11/29) of pts. At end-of-therapy restaging, 62% (18/29)

pts had a negative FDG-PET scan; CECT was concordant and consisting with complete response in 78% (14/18) of cases, while in the remaining 22% (4/18) of cases CECT showed a partial response with residual lesions. In the 11/29 (38%) final PET positive pts, CECT was concordant and pointed out a partial response in 7/11(64%) pts, while was negative in 4/11 (36%) cases. A survival analysis according to final PET result was not performed due to the low number of final PET positive pts. No statistically significant difference was found in PET behaviour between different histological subtypes.
Summary and Conclusions: In conclusion, in our hands FDG-PET allowed a more accurate baseline disease extension evaluation: it could identify additional sites, both nodal and extra-nodal, in two-thirds of pts. A change in clinical stage according to FDG-PET was observed in 44.8% of cases, with an upstaging in the majority of pts. A high level of concordance was observed between PET and CECT at restaging. Nevertheless, PET pointed out minimal residual disease in 22% of final CECT negative pts and complete remission in 36% of final CECT positive pts, allowing to optimize response evaluation in small but critical subgroups of pts.

PB1834

HIGH-DOSE CHEMOTHERAPY WITH AUTOLOGOUS STEM CELL TRANSPLANTATION IN FIRST LINE TREATMENT FOR HIGH-RISK DIFFUSE LARGE B CELL LYMPHOMA (DLBCL) IN THE RITUXIMAB ERA: AN INTENTION TO TREAT-ANALYSIS

MC Tisi[1,*] E Maiolo[1], F D'Alò[1], S Bellesi[1], F Sorà[1], P Chiusolo[1], L Laurenti[1], M Picardi[1], E Alma[1], LM Larocca[2], S Sica[1], S Hohaus[1]
[1]Institute of Hematology, [2]Institute of Pathological Anathomy, Catholic University, Rome, Italy

Background: The combination of Rituximab and CHOP (R-CHOP) is considered to be the standard treatment for patients (pts) with newly diagnosed diffuse large B-cell lymphoma (DLBCL). Treatment results are still unsatisfactory in a significant proportion of patients, particularly in those with a high-risk disease defined by the IPI score. The use of high-dose chemotherapy with autologous stem-cell transplantation (ASCT) is standard clinical practice for patients with relapsed/refractory DLBCL, while its significance as consolidation in first-line treatment remains unclear.
Aims: We analyzed safety and effectiveness of R-CHOP followed by salvage chemotherapy and ASCT for patients with young (<65 years) high-risk DLBCL, defined by an age-adjusted IPI score of 2/3, for whom from 2004 on our institutional guidelines recommended ASCT as consolidation. We analyzed prognostic factors in this group.
Methods: The treatment program consisted of 4 cycles R-CHOP-14 followed by 3 cycles of a DHAP-like salvage regimen, R-MICMA (Sorà et al, Cancer 2006; 106: 859), and consolidation with Busulfan-Melphalan supported with ASCT. We observed 76 consecutive patients (median age 50 years, range 15-64 years; 32 females and 44 males) diagnosed between May 2004 and January 2013 with DLBCL who had an age-adjusted IPI score of 2 or 3. Response was assessed according to Cheson criteria (Cheson et al, JCO 1999; 17:1244).
Results: Nine of 76 patients (12%) were not eligible for the treatment program that included ASCT. Reasons were important comorbidities in 6 pts (1 cardiac, 2 neurologic, 1 hepatic, 1 hematologic, 1 renal) and start of another treatment regimen (CODOX-M/IVAC in the suspicion of a Burkitt lymphoma) in 3 pts. Response after 4 cycles R-CHOP was CR/CRu in 40/67 pts (60%), PR in 21/67 pts (31%) and NR in 6/67 (9%). Sixty-one patients went on to salvage chemotherapy with R-MICMA, while 6 pts in CR/CRu continued R-CHOP, and 53 pts were transplanted. Reasons not to proceed to transplant were progressive disease (3 pts), infections (3 pts), mobilization failure (1 pt) and patient's decision (1 pt). The 3-year EFS and OS of the entire group of 76 patients were 67% (95% CI, 55-76) and 71% (95% CI, 59-80%), respectively. The 3-year EFS and OS of transplanted patients were 70% (95% CI, 55-80) and 76% (95% CI, 62-85). Factors associated with inferior EFS were age-adjusted IPI score (2 *vs.* 3, p=0.004) and disease status after 4 cycles R-CHOP (p=0.01) in univariate and multivariate analysis. These differences were also retained in the group of patients who received ASCT, with a three-years EFS of 78% in pts with an age-adjusted IPI score 2 *vs* 46% in pts with an age-adjusted IPI score 3 (p=0.003), suggesting that ASCT is insufficient for highest risk patients.
Summary and Conclusions: Our findings of an intention-to-treat, single centre experience indicate that 88% of patients with high-risk DLBCL and age <65 years are eligible for a treatment strategy that includes ASCT, and 70% will eventually receive ASCT as part of their first-line treatment. Consolidation with upfront ASCT for high-risk DLBCL is a feasible and promising therapy also in the Rituximab era, but there are still subsets of patients that continue to have a poor prognosis despite ASCT, and addition of new biologic drugs, as tyrosine kinase inhibitors, have to be tested to improve outcome in these patients.

PB1835

POST-TRANSPLANT MONOMORPHIC BURKITT'S LYMPHOMA: CLINICAL CHARACTERISTICS AND OUTCOME OF A MULTICENTER SERIES

S Bobillo Varela[1,*] P Abrisqueta[1], P Olivera[1], P Barba[1], A Salar[2], E Gonzalez Barca[3], JM Sancho[4], J Montoro[1], C Carpio[1], J Castellví[5], A López[1], F Bosch[1]
[1]Department of Hematology, Hospital Vall d´Hebron , [2]Department of Hematology, Hospital del Mar, Barcelona, [3]Department of Hematology, Institut Catalá d´Oncologia, L´Hospitalet de Llobregat, [4]Department of Hematology, Hospital Germans Trias y Pujol, Badalona, [5]Department of Pathology , Hospital Vall d´Hebron, Barcelona, Spain

Background: Post-transplant lymphoproliferative disorders (PTLD) are lymphoid neoplasms that develop after stem-cell or solid organ transplantation (SOT) associated with immunosuppressive therapy (IS) and Epstein-Barr virus (EBV) infection. Burkitt's monomorphic PTLD (BM-PTLD) is an uncommon and not properly described subtype of PTLD.
Aims: To gain insight into this rare lymphoma, the histological and clinical features of a series of adult diagnosed with BM-PTLD in four transplant centers were retrospectively reviewed.
Methods: All patients diagnosed with BM-PTLD between February 1996 and November 2013 were recorded and analyzed. Patients with PTLD negative for C-MYC breaks and/or diagnosed with unclassifiable lymphoma with intermediate features between DLBCL and BL were excluded.
Results: Ten patients with the diagnosis of BM-PTLD were included. Seven patients were female and the median age at diagnosis was 41 years (range, 25-52 yrs). All patients underwent SOT (7 kidney, 2 liver, and 1 lung). Median time of the diagnosis of PTLD from transplant was 94 months (range, 27-197 mos), and all patients were receiving IS, 7 with tacrolimus and three with cyclosporine. The PTLD was diagnosed in stage I-III in 4 patients and in stage IV in 6. Serum LDH was increased in 6/8 patients, and $\beta_2$microglobulin in 5/8. Immunohistochemistry analyses (n=8) revealed that all cases were CD20, CD10, and BCL-6 positive and negative for BCL-2. Ki67 expression was >95% in all cases. FISH showed the presence of the MYC translocation in all cases analyzed, while BCL2 and BCL6 translocations were excluded in all cases examined (5/5). *In situ* hybridation for EBV was positive in 3 of 5 cases. Six patients were treated with immunochemotherapy, 4 with R-CHOP along with CNS intrathecal prophylaxis and 2 with the Burkimab regimen (Ribera *et al.*, Cancer 2013;119 1660) that contains high-dose chemotherapy along with rituximab. One additional patient received 4 courses of rituximab with the withdrawal of IS. Finally, 3 patients diagnosed in the pre-rituximab era were treated with CHOP (n=2) and one with a combined regime (etoposide, cyclophosphamide, methotrexate, bleomycin, and vincristine). All patients that finished the initial treatment (n=8) obtained a complete remission (CR). Three patients died, two during the first course of treatment due to PTLD progression and a sepsis, and another one due to unrelated causes. Two patients that relapsed 12 and 9 months after R-CHOP and rituximab monotherapy, respectively, were salvaged with the Burkimab regimen achieving a second CR. After a median follow-up of 35 months (range 1 to 120), 7 patients remain in CR. The 3-year progression-free survival and overall survival was 55% and 80%, respectively, for the whole series, and of 63% and 100% for the 7 patients receiving rituximab-containing therapies.
Summary and Conclusions: In this retrospective series BM-PTLD appears as an infrequent and aggressive variety of PTLD usually diagnosed late in the evolution after transplant and in advanced stage of the disease. This lymphoid proliferation seems to have an excellent response to the immunochemotherapy combinations, including R-CHOP or to more intensive regimens like Burkimab. For those patients not candidate to intensive regimens, R-CHOP could be an excellent therapeutic alternative. A nation-wide collection of cases of BM-PTLD is now ongoing.

PB1836

CLINICAL RELEVANCE OF SOME LYMPHANGIOGENIC AND INFLAMMATORY CYTOKINS IN DIFFUSE LARGE B-CELL LYMPHOMA

D Wolowiec[1,*] A Wosztyl[2], E Ziolkowska[3], E Robak[4], T Robak[3], A Korycka-Wolowiec[3]
[1]Department of Hematology, Wroclaw Medical University, Wroclaw, [2]Department of Hematology, Holycross Cancer Center, Kielce, [3]Department of Hematology, [4]Department of Dermatology, Medical University of Lodz, Lodz, Poland

Background: Pathological angio- and lymphangiogenesis, consisting in the new blood and lymphatic vessels development, within and around a malignant tumour, are differently regulated and bear different significance for neoplastic development, including DLBCL. VEGF-C,VEGF-D and VEGFR-3 are crucial for lymphangiogenesis, but the relationship between their plasma levels and clinical course of DLBCL is unknown. Similarly, there are no reports on the role of inflammatory cytokine IL-17B and its receptor IL-17BR in DLBCL.
Aims: The aim of our study was to assess the plasma levels of VEGF-C, VEGF-D, VEGFR-3, IL-17B and IL-17BR in DLBCL patients upon diagnosis in order to evaluate the predictive value of those cytokines as to the achievement of complete remission (CR) after standard R-CHOP treatment, and their prognostic value regarding the overall survival (OS).
Methods: The study was performed in 55 untreated DLBCL NOS type patients after their written consent (38 M, 17 F), aged 23-88 yrs (mean 65.4), and 30 healthy control individuals (9 M, 21 F), aged 39-88 yrs (mean 61.1). For each patient blood count, serum LDH activity, b-2microglobulin, albumin and CRP concentrations were determined. The clinical stage of the disease and the general

condition were determined according to the Ann Arbor classification, ECOG and the IPI system. The patients received 6-8 courses of the standard 21-R-CHOP regimen, and 24 of them (43,6%) achieved CR. The cytokines plasma concentrations were established by ELISA method. Results were processed statistically with the Mann-Whitney and the Wilcoxon tests, the Spearman rank correlation coefficient and the chi^2 test. The Kaplan-Meier survival curves were used for estimation of OS probability and compared with the log-rank test.
Results: Lymphangiogenic cytokines plasma levels did not significantly differ between patients and controls, except VEGFR-3 which was higher in patients than in controls (75.8±42.1 and 45.7±16.7ng/ml; respectively; p=0.0007). VEGFR-3 and VEGF-C values were significantly higher in patients with IPI (3-5) than with IPI<3 (63.5±40.6 and 83.5±41.8ng/ml for VEGFR-3; p=0.048, and 2309.0±1729.5 and 2895.6±1140.5pg/ml; p=0,02 for VEGF-C). VEGFR-3 was positively correlated with β-2microglobulin (R=0.37; p=0.01). VEGF-D was correlated positively with β-2microglobulin (R=0.35; p=0.02) and LDH (0.35; p=0.01) and negatively with serum albumin concentration (R=-0.44;p=0.001). The concentration of IL-17BR was significantly higher in patients than in controls (2,7±3,3 and 1,4±1,1pg/ml; respectively; p=0.03). There was a significant relationship between the concentrations of IL-17B and IL-17BR, and this relationship was stronger in the control group (R=0.89; p<0.0001) than in DLBCL patients (R=0.50; p=0.0001). We did not find a relationship between the plasma concentration of any cytokine and the achievement of CR. The OS probability curves did not significantly differ between the patients with concentrations of any evaluated cytokine above *versus* below the median value, but the Cox regression model showed negative prognostic impact of high VEGF-D concentration on OS (HR=1.005, 95% CI, p=0.008).
Summary and Conclusions: Relationship between plasma levels of lymphangiogenic cytokines and some markers of disease activity may reflect an influence of lymphangiogenesis on DLBCL progression. The negative impact of VEGF-D value on OS warrants further studies. Higher IL-17BR plasma concentration and its weaker correlation with IL-17B in patients than in healthy controls might indicate a deregulation of the IL-17BR expression in DLBCL

PB1837

COMPARISON OF PROGNOSTIC IMPACT OF ABSOLUTE LYMPHOCYTE COUNT (ALC), ABSOLUTE MONOCYTE COUNT (AMC), ALC/AMC PROGNOSTIC SCORE AND ALC/AMC RATIO IN PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA

O Markovic[1,2,*] L Popovic[3,4], D Stanisavljevic[5,6], D Marisavljevic[1,2], M Toodorovic[2,7]
[1]Hematology, Clinical Hospital Center "Bezanijska kosa" , [2]Mecial Faculty, University of Belgrade, Beograd, [3]Medical faculty, Novi Sad, Novi Sad, [4]Hematology, Institute of Oncology, Sremska Kamenica, [5]Mecial Faculty, University ofBelgrade, [6]Institute of statistics, [7]Hematology, Institute of Hematology, Beograd, Serbia

Background: The combination of absolute lymphocyte count (ALC) and absolute monocyte count (AMC) at diagnosis have prognostic relevance in patients with diffuse large B cell lymphoma (DLBCL).
Aims: Aims: The present study was designed to investigate prognostic significance of ALC and AMC and to determine whether ALC/AMC ratio or ALC/AMC prognostic score is better predictor of outcome in DLBCL.
Methods: We retrospectively analysed prognostic significance of ALC and AMC, ALC/AMC ratio and ALC/AMC prognostic score at diagnosis in 222 DLBCL patients treated with R-CHOP. ALC/AMC score was determined according to Wilcox's model. Namely, the patients were stratified into three risk groups: low risk (normal AMC and ALC), intermediate (high AMC or low ALC), and high risk (high AMC and low ALC).
Results: ROC analysis showed that optimal cut-off values of AMC and ALC/AMC ratio with the best sensitivity and specificity were 0.59x109/L and 2.8, respectively. Cut-off of ALC was determined according to the literature data (1x109/L). Median lymphocyte count was 1.4x109/L and the range was 0.2-13x109/L. Median of monocyte count was 0.5x109/L and the range was from 0.1 to 3.9x109/L. Median of ALC/AMC ratio was 2.8, and range was from 0.33 to 57. Distribution of patients according to ALC/AMC prognostic score was as follows: low risk 91(41.0%), intermediate risk 99(44.6%) and high risk 32(14.4%) patients.Low ALC, high AMC, low ALC/AMC ratio and high ALC/AMC prognostic score were in significant association with lower rate of therapy response and survival. In contrast, these parameters were not in significant correlation with relapse rate. The patients with low ALC, "high" AMC, low ALC/AMC ratio and high ALC/AMC prognostic score at diagnosis had significantly shorter EFS and OS. In multivariate analysis all tested parameters (ALC, AMC, ALC/AMC prognostic score and ratio) are independent risk factors along with "bulky" disease and IPI.
Summary and Conclusions: All tested parameters (ALC, AMC, ALC/AMC score and ratio) may be useful prognostic factors in DLBCL patients. ALC/AMC score has a slight advantage as it allows the classification of patients into three prognostic groups. Further studies are needed to determine which of these parameters has the highest predictive value.

PB1838

90Y-IBRITUMOMAB TIUXETAN CONSOLIDATION AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IMPROVES SURVIVAL OF INTERMEDIATE/HIGH-RISK DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS NOT RESPONDING ADEQUATELY TO FIRST

P Mondello[1,*] G Altavilla[1], E Derenzini[2], V Pitini[1], M Mian[3]
[1]Medical Oncology, Universitary Hospital "G. Martino", Messina, [2]Hematology, "L. and A. Seràgnoli", S. Orsola-Malpighi Hospital, Bologna, [3]Hematology, Hospital "S. Maurizio", Bolzano, Italy

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common lymphoma entity, accounting for approximately 25-30% of new cases of non-Hodgkin's lymphoma. Up to now the prognosis of high-risk patients, namely those with an elevated IPI, bulky disease, involvement of central nervous system or testes, is poor due to early relapses. Aggressive salvage treatments to improve their outcomes were unsatisfactory. Therefore a consolidation therapy after early salvage regimen with autologous stem cell trasplant (ASCT) could reduce the relapse rate and prolong survival.
Aims: This analysis was performed to evaluated whether the additional yttrium-90-ibritumumab tiuxetan (90Y-IT) after early salvage treatment is able to improve the outcome of high-risk DLBCL.
Methods: We retrospectively assessed 37 patients affected by intermediate-high risk DLBCL not in complete remission after 3 cycles od R-CHOP chemotherapy. All were addressed to early salvage treatment with ASCT and 20 eligible patients underwent additional 90Y-IT consolidation. Salvage treatment consisted of 3-4 courses of R-DHAP followed by stem cell mobilization with cyclophosphamide (3 g/m2) and triple ASCT with a high-dose of cytarabine conditioning regimen (3-4 g/m2 days 1-4).
Results: After completion of the salvage treatment, in the 90Y-IT group 45% achieved a complete remission (CR) and 55% a partial remission (PR) compared to 94% and 6% in the other group. After 90Y-IT consolidation all achieved a CR. Adverse events after 90Y-IT treatment consisted of moderate transient hematologic toxicity. During the 3-year median follow-up period, 50% in the 90Y-IT group relapsed, compared to 82.3% in the other cohort (p=0.002). Progression and disease free survival (Figure 1) were significantly longer in the 90Y-IT group. However, probably due to the relatively short follow-up period, no difference in overall survival (OS) was observed.

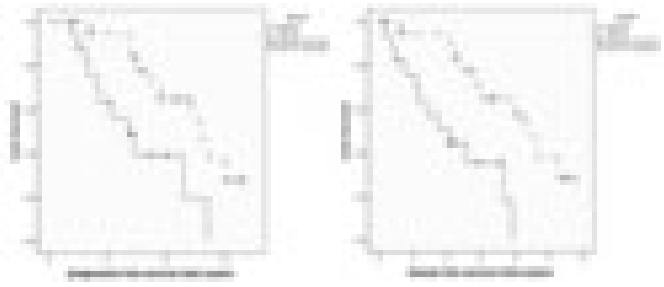

Figure 1.

Summary and Conclusions: 90Y-IT consolidation after early salvage chemotherapy improves treatment responses and reduces the percentage of relapses without significant additional toxicities. However, the follow-up time was not long enough to observe a difference in OS. Prospective confirmatory data is needed.

PB1839

MYC PROTEIN EXPRESSION IS THE POOR FACTOR IN DIFFUSE LARGE B CELL LYMPHOMA TREATED WITH RCHOP

J Ouyang[1,*] M Zhou[1], J Wang[1], J Xu[1], B Chen[1], XS Fan[2], HY Wu[2]
[1]Hematology, [2]pathology, the DrumTower Hospital of Nanjing University Medical School Nanjing China, Nanjing, China

Background: Diffuse large B-cell lymphoma (DLBCL) is a heterogeneous group of neoplasma. It is increasing important to search the predictive biomarkers which could identify cases who will fail to RCHOP.
Aims: This study aims to investigate the prognostic significance of the MYC protein expression in DLBCL patients treated with RCHOP.
Methods: A total of sixty patients with DLBCL from 2008 to 2013 were included. Formalin-fixed paraffin-embedded(FFPE) tumor samples were analyzed for MYC protein expression and divided into high or low MYC group. The MYC protein expression and the international prognostic variables were evaluated.
Results: The high MYC protein expression predicted a shorter 3-year estimated overall survival (OS) and progression-free survival (PFS) *versus* the

low MYC protein expression (57% *vs.* 96%, P<0.001 and 50% *vs.* 96%, P= 0.001, respectively). Multivariate analysis confirmed the prognostic significance of the MYC protein expression for both OS (HR, 11.862; 95% CI, 1.462-96.218; P= 0.021) and PFS(HR, 6.233; 95% CI, 1.292-30.071;P=0.023). MYC protein expression with IPI score distinguished patients into three risk groups with different 3-year OS rates ($X^2$23.079; P<0.001) and distinct 3-year PFS rates ($X^2$15.862; P<0.001).

Summary and Conclusions: the MYC protein expression is an important independent inferior prognostic factor for survival in patients with DLBCL treated with RCHOP. The combinative model with IPI score and MYC protein expression could stratify DLBCL patients into prognostically relevant subgroups more effectively than either the IPI or the MYC alone.

PB1840

PROGNOSTIC SIGNIFICANCE OF LYMPHOCYTE/MONOCYTE RATIO (LMR) AT DIAGNOSIS IN A COHORT OF PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA (DLBCL) TREATED WITH IMMUNOCHEMOTHERAPY: A SINGLE CENTRE EXPERIENCE.

E Doni[1,*] A Belotti[1], F Rossini[1], I Casaroli[1], S Bolis[1], S Pezzatti[1], S Bozzani[1], L Verga[1], P Perfetti[1], P Pioltelli[1], EM Pogliani[1]

[1]Hematology Unit, S. Gerardo Hospital, Monza, Italy

Background: Diffuse large B-cell lymphoma (DLBCL), the most common subtype of lymphoid neoplasm, is characterized as an aggressive lymphoma with heterogeneous clinical behaviors. A large number of studies have therefore focused on the search for surrogate biomarkers which are immunologically relevant and can serve as prognostic factors. Lymphopenia, a surrogate marker of immune suppression, was found to predict survival in DLBCL. Monocytes, which are considered immunologically relevant and are regarded as a surrogate marker of the tumor microenvironment, were also recently reported to be a prognostic factor in DLBCL. Although the introduction of rituximab combined with chemotherapy has greatly improved survival outcomes in DLBCL patients, there is limited available data about prognostic value of lymphocyte/monocyte ratio (LMR) in DLBCL patients (pts) in the rituximab era.

Aims: We investigated the prognostic role of LMR in terms of complete remission (CR) after first line treatment, overall survival (OS) and progression free survival (PFS) in a cohort of pts with DLBCL and treated with immunochemotherapy at our istitution.

Methods: We retrospectively analyzed data from a total of 133 DLBCL pts treated at our institution from January 2007 to July 2013. The median age of all pts at diagnosis was 64 years (range of 18–92 years). Pts were treated with immunochemotherapy with or without anthracycline (RCHOP or RCVP). We analyzed different LMR cut-off values and we found that the most discriminative LMR was 2.4; the absolute monocyte count (AMC) and absolute lymphocyte count (ALC) were derived from pre-treatment CBC counts. Survival curves according to Kaplan-Meyer method were employed to estimate PFS and OS. Log rank test was used to analyze differences. OS, PFS and relapse rate were defined by the standard criteria.

Results: The median follow-up time of the surviving pts was 24 months. 72 pts (54.1%) had localized disease (Ann Arbor stage I–II) and 61 extended disease (Ann Arbor stage III–IV); among them, 16 pts and 8 pts had extranodal localization, respectively. Based on the aaIPI score, 13 patients were in the aaIPI 0 group (9.7%), 50 pts in the aaIPI 1 group (37.6%), 48 pts in the aaIPI 2 group (36%) and 22 pts in the aaIPI 3 group (16.5%). An LMR value<2.4 was associated significantly with an advanced clinical stage (p=0.007), and a higher IPI score (p=0.004) and higher aaIPI (p=0.002). In the entire cohort, 90 pts obtained CR after first line treatment, while 43 pts did not obtain CR. CR rate (55% *vs* 61%) and 2 year-OS (85% *vs* 87%) were similar for pts with LMR<2.4 and for pts with LMR>2.4. Among 40 pts with an LMR>2.4 only one relapsed (6 months after CR), while 7/50 pts with LMR<2.4 relapsed after 4-22 months, with 2 year-PFS of 86% *vs* 96%, as shown in Figure 1 (p=0.07).

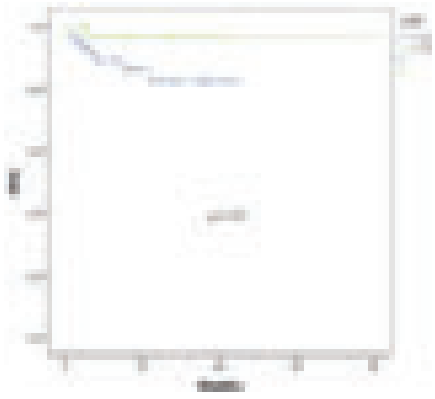

Figure 1.

Summary and Conclusions: Recent results have clearly shown that via CCL5, lymphoma B cells can recruit monocytes which in turn support the survival and proliferation of neoplastic B cells and suppress the proliferation of normal T cells. Our results confirm the hypotesis that the evaluation of LMR at diagnosis is a simple and robust tool to better define clinical response and long-term outcome of DLBCL patients receiving immunochemotherapy. Further study are needed to assess the role of LMR in DLBCL at diagnosis, supporting the idea that it could be incorporated into the IPI stratification.

PB1841

HIGH-DOSE METHOTREXATE CONSOLIDATION IN POOR-RISK DIFFUSE LARGE B-CELL LYMPHOMA IS ASSOCIATED WITH IMPROVED PROGRESSION FREE SURVIVAL

M Gilbertson[1], J Shortt[1,2], G Grigoriadis[1,2], S Patil[1,3], G Gregory[1], Z Wang[1], B Kumar[4], SS Opat[1,2,*]

[1]Haematology, Monash Health, [2]Faculty of Medicine, Nursing and Health Sciences, Monash University, Clayton, [3]Haematology, Alfred Health, Melbourne, [4]Anatomical Pathology, Monash Health, Clayton, Australia

Background: While the majority of patients with Diffuse large B-cell lymphoma (DLBCL) can expect to be cured with R-CHOP chemotherapy, the outcome for patients with poor risk disease is less certain with approximately 50% of patients eventually succumbing to their disease. Dose intense regimens have largely failed to improve outcomes, and are associated with increased toxicity. However certain regimens may have a role in younger poor risk patients.

The association of poor-risk disease with central nervous system (CNS) recurrence has led many centres to advocate the use of systemic high-dose methotrexate (HD-MTX) consolidation in poor-risk patients. Since 2007 our centre has been consolidating patients deemed to be at high-risk of CNS recurrence including those with IPI≥3, involvement of a high-risk site (testis, ovary, breast, kidney, extradural or skin) or those with two involved extra nodal sites and a raised lactate dehydrogenase with two cycles of intravenous methotrexate 3g/m^2 and rituximab 375mg/m^2 following the completion of R-CHOP. HD-MTX is only administered to patients in CR after completion of R-CHOP with adequate performance status.

Aims: In this study we examine the effect of HD-MTX on overall survival (OS) and Progression Free Survival (PFS) in patients with poor-risk DLBCL.

Methods: Patients were included in the study if they had DLBCL diagnosed according to WHO 2008 criteria, an R-IPI ≥ 3, received two or more cycles of R-CHOP-like chemotherapy, and had adequate clinical information that included baseline clinical characteristics, treatment regimens and clinical outcome. Patients were excluded if they were too frail to receive chemotherapy or failed to achieve a CR following R-CHOP therapy. A total of 92 patients met the entry criteria of which 17 received HD-MTX. Survival correlates were analysed by Cox regression using SPSS.

Results: While patients receiving HD-MTX were younger (median age 69 v. 74), the proportion over 60 years was similar in both groups; (HD-MTX 83% v. standard 85%). The proportions with advanced stage (100% v 85%) raised LDH (82% *vs.* 80%) and ECOG>2 (17% *vs.* 11%) were also similar, however the HD-MTX group had fewer patients with ECOG >1 (41% v. 60%). All patients received Rituximab containing chemotherapy regimens, with both groups receiving a median of six cycles (range 3-6).

The median follow up of surviving patients was 2.5 years. Patients who received HD-MTX had improved 5 year PFS: 65% *vs.* 34% (HR 0.50, p=0.048) and a trend to improved OS 73% v. 44% (HR 0.50, P =0.082) This was mainly attributable to a reduction in the five year systemic rela:pse rate: 17.6% *vs.* 38.7% (HR 0.46, P=0.063). No difference in the rate of CNS recurrence was evident however events in both groups were uncommon. The regimen was well tolerated with no severe toxicity (Figure 1).

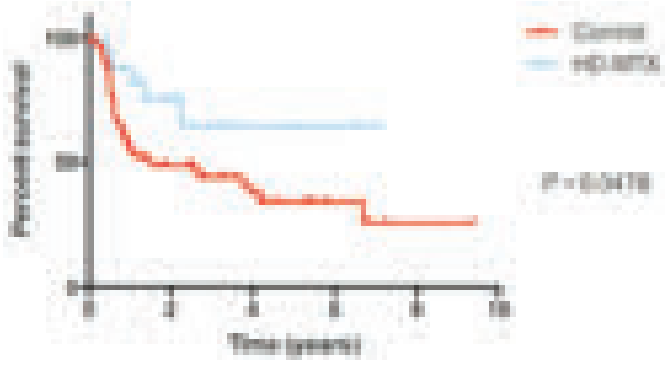

Figure 1. Progression free survival, IPI 3, 4, 5.

Summary and Conclusions: The use of HD-MTX is associated with improved PFS and a trend to improved OS when used as consolidation therapy in patients with poor-risk DLBCL, including the elderly. We speculate that the low rates of toxicity observed in our study may be due to sequential rather than concurrent administration of HD-MTX, and careful patient selection. Given the inherent limitations of this retrospective cohort study, further prospective studies are warranted to validate this approach in poor-risk patients with DLBCL.

PB1842

TRANSFORMED FOLLICULAR LYMPHOMA TREATMENT OUTCOME DURING THE RITUXIMAB ERA

E Elhassadi[1,*] R Flavin[2], P Browne[1], P Hayden[1], L Higgins[1], E Vanderberghe[1]
[1]Haematology Department , St. James's Hospital, Trinity College Dublin, [2]Histopathology Department , St. James's Department, Trinity College , Dublin, Ireland

Background: Follicular lymphoma transformation (tFL) to Diffuse Large B Cell lymphoma occurs in 16% to 60% of cases and is historically associated with a median survival of less than 2 years and there are no prospective studies specifically evaluating treatment approaches in patients with tFL and there is little published data on the outcome of tFL in the Rituximab era.
Aims: Retrospective study to evaluate treatment outcome of patients with tFL diagnosed between 2003 and 2012 after adapting specific treatment algorithm.
Methods: Patients diagnosed with tFL, between 2003 and 2012 identified from the institutional lymphoma database were included. Data collected included age, gender, stage and prior treatment, interval to tFL diagnosis, IPI score and tFL treatment. Only cases which fulfil the diagnostic criteria of DLBCL based on WHO criteria were evaluated.

Table 1. Patient clinical charateristics.

Male/Female	20/9	69/31%
Median Age/yrs	51	Range (27-72)
Denovo tFLvsKnown FL	15 *vs* 14	52% *vs* 48%
Stagel,II *vs* III,IV	6/23	20/80%
BM invol. NegvsPos	16/5	55/17%
Not available	8	
R-IPI 0-2 *vs* 3-4	25/4	86/14
B.Symptoms (+/-)	10/19	34.5/66.5%
Relapse Disease (+/-)	11/18	38/62%

Table 2. Consolidation treatment.

tFL	No	%
Rituximab Maintenance	8	27.5
Zevilan	3	10
Auto-SCT	8	27.5
AllO-SCT	8	27.5
Both-SCT	2	7

Figure 1. Our institutional transformed follicular lymphoma treatment algorithm.

Results: Over this period, 29 (7.25%) patients with biopsy proven tFL were identified from a total cohort of 400 patients with FL, 15 patients (51.7%) presented with de novo tFL and 14 (48.2%) had known FL with median time to transformation of 6.7 years. Twenty (65.5%) patients were male with a median age at transformation of 54 years (range 27-72) and 80% had stage III/IV disease at transformation. The median follow-up time from tFL diagnosis is 3.3 years. All patient received Rituximab - chemotherapy (R-CHOP or R-CHOP like), with 11 patients (38%) requiring second line therapy to attain remission. Consolidation therapy algorithm was adapted based on age, performance status and donor availability. 16 patients (55%) were transplant eligible, 8 patients (27.5%) received allogeneic SCT and 8 patients received autologous(A) SCT and 2 patients were allo-transplanted after relapsing post-ASCT . Thirteen (45%) patients were not SCT eligible and were consolidated with either Zevalin 3 (10%) or Rituximab maintenance 8 (27.5) patients. The median survival from transformation was 98 months with three deaths, (two from disease progression and one from transplant related mortality (Tables 1, 2 and Figure 1).
Summary and Conclusions: Compared to historical published data the median OS of 98 months in this small cohort of patients is encouraging and suggests that Rituximab therapy may have changed the natural history of tFL. Fourteen of 16 patients transplanted remain alive and disease free and these outcomes should be confirmed in a larger series.

PB1843

SECONDARY CNS INVOLVEMENT IN MALIGNANT LYMPHOMA: DATA FROM A PROSPECTIVE REGISTRY

A Menssen[1], F Strehlow[1], R Schroers[2], U Schlegel[3], M Schmidt-Hieber[4], P Reimer[5], F Griesinger [6], HG Höffkes [7], K Jordan[8], C Meyer zum Büschenfelde[9], J Mezger [10], S Kreher [1], L Fischer[1], A Korfel[1,*]
[1]Medizinische Klinik mit Schwerpunkt Hämatologie, Onkologie und Tumorimmunologie, Charité - Universitätsmedizin Berlin, Berlin, [2]Abteilung für Hämatologie und internistische Onkologie Knappschaftskrankenhaus, [3]Klinik für Neurologie, Knappschaftskrankenhaus, Ruhr Universität Bochum, Bochum, [4]Klinik für Hämatologie, Onkologie und Tumorimmunologie, Helios Klinikum Berlin-Buch, Berlin, [5]Klinik für Hämatologie, Internistische Onkologie und Stammzelltransplantation, Kliniken Essen-Süd, Essen, [6]Pius-Hospital Oldenburg , Klinik für Hämatologie und Onkologie, Oldenburg, [7]Abteilung für Medizinische Onkologie, Radiologie Hämatologie, Palliativmedizin, Klinikum Fulda, Fulda, [8]Abteilung für Hämatologie und Onkologie,, Universitätsklinikum Halle, Halle, [9]Abteilung für Hämatologie und internistische Onkologie, Asklepios Klinik Altona, Hamburg, [10]Abteilung für Hämatologie und Onkologie , St.Vincentius-Kliniken , Karlsruhe, Germany

Background: Secondary CNS involvement of malignant lymphoma (SCNSL) is extremely rare, and its optimal management is yet to be defined. In a prospective German registry we evaluated clinical characteristics, treatment and outcome of patients diagnosed with SCNSL since July 2011.
Aims: Collection of data on diagnosis making and treatment strategies in SCNSL in the clinical routine.
Methods: Patients with secondary CNS involvement of indolent or aggressive non-Hodgkin`s lymphoma (confirmed histologically or cytologically) with or without systemic involvement at time point of CNS involvement were eligible. Informed consent was obtained from all patients.
Results: Data of the first 69 patients (median age 60 years, range 26-80) were analysed. Eight (12%) patients had simultaneous CNS and systemic involvement at first diagnosis (cohort I), and 61 (88%) had CNS involvement at relapse (cohort II), 11 (16%) of whom simultaneously had active systemic disease. Histology at first diagnosis was aggressive B-cell lymphoma in 48 (70%) and mantle-cell and T-cell lymphoma in 2 patients (3%) each; 17 patients (25%) had indolent B-cell lymphoma. Primary therapy in cohort II was R-CHOP in 35 patients (51%), CHOP in 9 (13%), R-CHOP/CHOP combined with other systemic chemotherapy in 8 (12%) and other systemic chemotherapy in 7 (10%). CNS prophylaxis was given to 10 (14%) patients: intrathecal (i.th.) chemotherapy alone in 3, high-dose methotrexate (HDMTX) intravenously alone in 3, whole-brain radiotherapy in 1 and a combination of those in 3; 2 patients (3%) have not received any anti-lymphoma therapy. Median time from first diagnosis to CNS relapse (cohort II) was 16 months. CNS lymphoma localisation was brain parenchyma in 39 patients (57%), meninges in 18 (26%), spinal cord in 2 (3%) and combination of those in 10 (14%). Therapy for CNS involvement was systemic chemotherapy in 37 patients (54%), systemic + i.th. chemotherapy in 30 (43%) and i.th. chemotherapy alone in 2 (3%). Systemic therapy was HDMTX-based in 62 patients (90%) and high-dose cytarabine-based in 36 (52%); high-dose chemotherapy with autologous stem-cell transplantation was given to 23 patients (33%). Median follow-up time from inclusion in the registry was 17 months. In cohort I, 3 patients progressed/relapsed after 7.0-11.5 months and one died after 16 months following diagnosis of CNS involvement. Median progression-free survival (PFS) and overall survival (OS) from CNS involvement in cohort II was 6.7 months (95%CI 3.7-9.5) and 15.7 months (95%CI 7.0-24.3), respectively. Median PFS and OS of patients with parenchymal involvement were significantly longer (both not reached) as compared to patients with meningeal involvement with 5.5

(95%CI 2.9-8.0) and 8.2 (95%CI 5.2-11.1) months, respectively (P<0.001 for PFS and 0.007 for OS).
Summary and Conclusions: With modern and systemically more potent anti-lymphoma therapy the frequency of isolated CNS relapse seems higher than previously reported reflecting reduced ability to clear the CNS as compared to systemic disease. Despite frequent use of CNS-penetrating systemic chemotherapy outcome of patients with SCNSL, particularly with meningeal involvement, remains poor.

PB1844

SIGNIFICANT EFFECT OF RITUXIMAB MAINTENANCE IN FIRST LINE TREATMENT IN MANTLE CELL LYMPHOMA

S Vokurka[1],* A Jungova[1], V Vozobulova[1], M Schutzova[1], P Jindra[1], D Lysak[1], M Hrabetova[1]
[1]Haemato-Oncology, University Hospital in Pilsen, Plzen (Pilsen), Czech Republic

Background: Mantle cell lymphoma (MCL) is a relatively rare malignancy with unfavorable outcomes. Introduction of anti-CD20 rituximab maintenance (RM) treatment into therapeutic protocols should be beneficial.
Aims: To verify the importance of rituximab maintenance in MCL first line treatment.
Methods: Prospective single center observation of newly diagnosed MCL patients: n=57, median age 66 (47-82), 68% males, 84% Ann Arbor stage IV., prognostic MIPI index media 6 (2-10), 92% R-CHOP-like and 8% R-COP induction therapy protocol, 46% intensified with Autologous stem cells transplantation (SCT), 82% complete and 18% partial remissions prior to start of RM administration. Rituximab maintenance was administered as 375mg/m2 dose every 3 months for 2 years and the median number of administered doses was 7 (2-8), seven patients are still on treatment, eight patients discontinued the RM prematurely due to MCL relapse/progression, refusal of further treatment, or health insurance company obstacles. Progression free survival (PFS, time since diagnosis to relaps/progression) was analyzed separately in a group of patients with and without Autologous SCT and in respect to RM administration.
Results: In a group of non-intensified patients without Autologous SCT the probability of 2-years PFS and median PFS was 26% and 20 months if RM was not given (n=16) *versus* 86% and median PFS not yet reached at the median follow-up of 37 (14-65) months if RM (n=15) was administered (p=0,01). In Autologous SCT patients the probability of 2-years PFS and median PFS was 75% and 46 months if RM was not given (n=12) *versus* 95% and median PFS not yet reached at the median follow-up of 50 (22-82) months if RM (n=14) was administered (p=0,02). No statistically significant differences were observed when comparing age, gender, MCL stage, MIPI index, complete remission ratios prior to RM. RM administration was statistically significant predictor for prolonged PFS in the multivariable analysis (Figure 1).

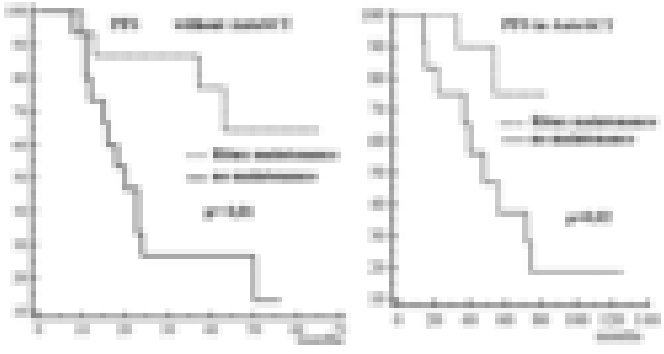

Figure 1.

Summary and Conclusions: Even though the numbers of our analyzed patients are small, we can observe that in newly diagnosed MCL patients responding to the initial induction therapy (R-CHOP-like, R-COP), the administration of RM significantly prolongs PFS in both Autologous SCT treated patients and in those non-intensified. The data are not mature enough to asses the overall survival.

PB1845

TREATMENT OF PERIPHERAL T-CELL LYMPHOMA WITH AN INTENSIVE PROTOCOL ACEP (ADRIAMYCIN,CYCLOPHOSFAMIDE,ETOPOSIDE AND PREDNISOLONE) AND IFOSFAMIDE SHOWING AN IMPORTANT OVERALL SURVIVAL AT 6 YEARS

M Salamoon[1,2,*] M kenj[3]
[1]medical oncology, [2]hematology, al Bairouni university hospital, [3]cytogenetics, kenj labs, damascus, Syrian Arab Republic

Background: Peripheral T-Cell Lymphoma (PTCL) is a group of lymphoid malignancies which has never been treated with any confidence as opposed to its counterpart B-Cell Lymphomas. Despite the studies, which were retrospective, the results in the majority of cases were disappointing, taking into consideration the aggressive clinical course of the disease, so survival did not exceed 2 years in median.
Aims: To assess the response, progression free survival and overall survival rates at 5 years using a new intensive combination chemotherapy
Methods: Enrolled patients were diagnosed with PTCL, confirmed by a referenced pathologist, treated with the new chemotherapy ACEP X 6 (Doxorubicine 75 mg/m² on day 1 + Cyclofosfamide 1200 mg/m² on day 1 + Etoposide 300 mg/m² on day 1 and Prednisolone 60 mg/m² from day 1 through day 5) and Ifosfamide X 4 (Ifosfamide 4 grams/m² on day 1) which were given after the completion of the first 6 cycles of ACEP . The study was performed at Al-Bairouni University Hospital and the study was approved by the Syrian Association of Clinical Oncology.
Results: 25 patients underwent the treatment. Most of them showed a complete response after the completion of the first six cycles (17/25) forming 68% of patients, while another 5 patients became complete responders after the completion of treatment. Consequently, 22 patients are still living after 5 years, with an overall survival rate of 88%, the study was updated in December 2013 and we still have 88% overall survival rate at 6 years.
Summary and Conclusions: (ACEP) and Ifosfamide appears to be a good choice in PTCLs, in light of the good response and overall survival rates, taking into account the acceptable toxicity profile. However, a larger sample is needed to make it acceptable new combination chemotherapy for PTCLs patients.

PB1846

A RISK OF DERMOPATHY AND OPOTUNISTIC INFECTION AFTER TREATMENT WITH ANTI-CCR4 ANTIBODIES FOR ADULT T-CELL LEUKEMIA

G Eguchi[1],* K Yamamoto[1], A Fukui[1], T Yamaguchi[1], Y Maeda[1]
[1]Hematology, National Hospital Organization Osaka Minami Medical Center, Kawachinagano, Japan

Background: Human T-cell leukemia virus type I (HTLV-I) is a human retrovirus that is an etiologic agent of adult T-cell leukemia/lymphoma (ATL/ATLL). The poor outcome of adult ATL is mainly because of an intrinsic resistance of the leukemic cells to conventional or high doses of chemotherapy and severe immunosuppression. The CC-chemokine receptor 4 (CCR4) is expressed in almost ATLL cells. Thus, anti-CCR4 antibodies can be used as a treatment strategy for ATLL. Mogamulizumab (MOG), which is a defucosylated anti-CCR4 monoclonal antibody, showed good results even in patients with recurrent ATLL in phase I or II studies. MOG has strong antibody-dependent cellular cytotoxicity (ADCC). The common adverse events in the phase II study were infusion reaction and skin rashes. In our study, MOG inhibited the growth of ATL cells and induced remission. CCR4 is expressed not only in ATL cells but also in non-ATL regulatory T cells (Treg). After treatment with MOG, the population of Treg decreased significantly, which boosted the antitumor activity. MOG treatment was associated with the risk of viral infection as an opportunistic infection and skin disturbance (dermopathy).
Aims: In the present study, we observe the effects of MOG as CCR4-specific ADCC against CCR4-positive ATL cells. However, CCR4 is not only on ATL cells but also on endogenous Treg. The decrease in the number of Treg after MOG monotherapy has been expected to boost the antitumor activity and to be involved in the development of immune disorders, including autoimmune diseases. On the other hand, we observed opportunistic viral infection including active CMV infection and skin disturbance associated with a rapid decrease in CD4+ T cells.
Methods: In the present study, we treated 14 patients with ATL who were resistant to chemotherapy using MOG monotherapy, and we observed CCR4-specific ADCC against CCR4-positive ATL cells. In this study, CMV infection was detected using C7- horseradish peroxidase (C7-HRP) methods.
Results: All patients showed CR with a marked decrease in the number of ATL cells. These results suggested that MOG was effective in chemotherapy-resistant ATL patients. ATL cells were not found in her peripheral blood, and no rearrangement of TCRab gene was observed, which indicated molecular CR. Skin disturbance (dermopathy) was found 9 cases of 14 ATL patients treated with MOG monotherapy. The skin rash spread throughout her body with bulla and skin biopsy was performed, and diagnosed as Stevens–Johnson syndrome (SJS) in 2 patients of them. Administration of steroid and intravenous immunoglobulin was performed, and SJS gradually improved. Further, In other patients, grade 2 and 3 dermopathy was found, and the patients was treated with glucocorticoid steroid. CMV infection was detected using C7-HRP methods. CMV infection was diagnosed in 5 patients of 14 MOG treated ATL patinets. One of the patients died because of severe CMV infection despite of adequate treatment.
Summary and Conclusions: Thus, physicians should be aware of CMV infection and development of immunocompromised condition after MOG monotherapy. Specific anti-CMV treatment for CMV reactivation should be recommended. Moreover, We have to find out the skin rash as soon as possible after treatment

with MOG and it should be recommended quick administeration with glucocorticoid. Futher study for the dermopathy should be considered.

PB1847

HOW TO TREAT B-CELL LYMPHOMA, UNCLASSIFIABLE, WITH FEATURES INTERMEDIATE BETWEEN DIFFUSE LARGE B-CELL LYMPHOMA AND BURKITT LYMPHOMA. SINGLE CENTRE EXPERIENCE

J Michalka[1,*] A Janikova[1], D Salek[1], Z Kral[1], J Mayer[1], M Moulis[2], L Kren[2]
[1]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno and Masaryk University, School of Medicine, Brno, [2]Department of Pathology, FN Brno, Brno, Czech Republic

Background: B-cell lymphoma, unclassifiable, with features intermediate between diffuse large B-cell lymphoma and Burkitt lymphoma (DLBCL/BL) is a separate entity in the WHO Classification of Tumours of Haematopoietic and Lymphoid Tissues 2008. It is nowadays a provisional category of a spectrum of features between two borderline lymphomas – difusse large B-cell lymphoma (DLBCL) and Burkitt lymphoma (BL). These lymphomas have morphological and genetic features of both DLBCL and BL, so they cannot be clearly included in either one of those two entities. DLBCL/BL generally has an agressive clinical course and no guidelines for treatment are available yet.
Aims: To compare efficacy of different treatment options.
Methods: Retrospectively we reviewed clinical data from our institution's register between years 2010-2013. Subsequently we analysed therapy outcome due to chosen regimens. The treatment strategy decision was made depending on patient's age, clinical stage of the disease and the IPI score. All of the histology samples were reviewed by experienced pathologists, in majority of the cases including FISH and genetic abnormalities diagnostic tests.
Results: Since January 2010 to December 2013 we registered 30 patients with newly diagnosed DLBCL/BL, constituting approximately 3.4% of all non-Hodgkin lymphomas (n=881). For comparison, in the same time period, we registered 301 cases of DLBCL (34%) and 16 cases of BL (1.8%). There were 14 men and 16 women, average age being 65 years (38-86y). One patient (86y) was treated by paliative radiotherapy only and died within 1 month due to lymphoma progression. 10/30 patients (33%), average age 53y (38-66y), clinical stage I-IV, average IPI score 3 (0-5), median LDH 5.27 µkat/l (2.79-107), were treated with intensive approach, when R-CHOP treatment was enhanced with 3-4 cycles R-CODOX-M with or without R-IVAC up to 5-7 chemotherapy cycles total. Two patients from this group died, one (53y) had confirmed concurrent BCL2-IGH and MYC rearrangement (double-hit lymphoma), was primarily chemoresistant, and died within 4 months from diagnosis due to lymphoma progression. The second one (60y) died due to treatment toxicity and concurrent illness (sepsis and ischemic cerebral stroke) immediately after treatment completion. The remaining 8 patients (80%) from a group of intensively treated are nowadays in complete remission lasting 3-31 months depending on the treatment completion date. 19/30 patients (63%), average age 71y (57-86y), clinical stage I-IV, average IPI score 3 (0-5), median LDH 4.99 µkat/l (2.5-40.14), got usual R-CHOP based chemotherapy, in 9 cases (47%) including 1-2 cycles of high dose methotrexate or high dose cytarabine finally. 3 patients (16%) from this group died during the treatment or within 6 months after treatment completion due to lymphoma progression. 3 patients (16%) from this group relapsed within one year and recieved another chemotherapy regimens. 13 patients (68%) from this group are in complete remission or the treatment is nowadays still ongoing. We haven't evaluated the disease free survival (DFS) and overall survival (OS) yet, because of short follow-up.
Summary and Conclusions: Despite short follow-up, our data suggest that R-CHOP based chemotherapy is less effective than it's combination with intensive regimens containing R-CODOX-M and R-IVAC. The most important factor that influenced the treatment strategy was patients' age. For setting the proper treatment guidelines bigger patients cohorts and a longer follow up of the survivals are required.

PB1848

POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDER AFTER KIDNEY TRANSPLANTATION

I Fiskvik[1,*] Ø Bentdal[2], H Holdaas[2], T Leivestad[2], T Grotmol[3], H Holte[1]
[1]Norwegian Radium Hospital, [2]Department of Transplant Medicine, Oslo University Hospital, [3]Norwegian Cancer Registry, Oslo, Norway

Background: Post-transplant lymphoproliferative disorder (PTLD) is a heterogeneous group of lymphoid lesions. Although rare, it is an important long-term complication in kidney transplant recipients.
Aims: To describe demographics and prognosis in a cohort of PTLD patients.
Methods: The Norwegian Nephrology Registry has a complete data set for renal recipients since 1969. The register was linked to the Norwegian Cancer Registry of Norway to identify cases of PTLD. Clinical data were retrieved from local hospitals. Demographic data, transplant history, outcomes and pathology were characterized using SPSS statistics.
Results: Fifty-five kidney transplant recipients with PTLD were identified, at a median of 7.1 years since transplantation. Mean age at time of lymphoma was 54.4 years, 80% were men, and median follow-up time for all patients was ten months, and six years for patients alive at last follow up. Sixty percent had a previous rejection, of whom 37% had been treated with ATG. Thirty-six percent of the lymphomas were nodal, 24% involved GI-tract, 18% CNS, and 21% other organs. Sixty-seven per cent were Diffuse Large B-Cell Lymphomas, 11% were polymorphic PTLD and 14% were others. Thirty-seven patients died with a five year overall survival of 34% (Figure 1).
Summary and Conclusions: Post-transplant lymphoma disorder affects kidney transplant recipients after several years with heterogenous clinical manifestations. PTLD is strongly associated with previous treatment for graft rejection. Early death was more common than what is seen in non-PTLD lymphomas, probably due to co-morbidity and increased infectious complication. Better supportive care and an individualized treatment approach seems important.

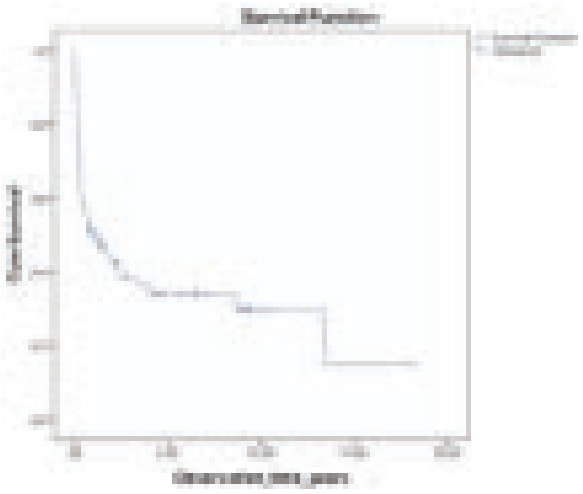

Figure 1.

PB1849

DEPO-ITV: A NEW SCENARIO WITH INTRATHECAL AND INTRAVENOUS DEXAMETASONE TO PREVENT CHEMICAL ARACHNOIDITIS RELATED WITH LIPOSOMAL CYTARABINE

A De La Fuente[1,*] M Olave[2], FJ Peñalver[3], M Estévez[1], L Arango Rial[4], P Martinez Barranco[3], L Villalón[3], S Solórzano[1], R Iglesias[1], C Montalván[1], R de Oña[1]
[1]Hematology, MD Anderson CC Madrid Spain, Madrid, [2]Hematology, H.C.U. Lozano Blesa, zaragoza, [3]Hematology, H. Fundacion Alcorcon, [4]Hematology, H.C.U. Lozano Blesa, Madrid, Spain

Background: Intrathecal Liposomal Cytarabine (LC) is FDA/EMA approved for Lymphomatous Meningitis (LM) treatment. Retrospective studies have evaluated LC in LM prophylaxis. Chemical arachnoiditis (headache, nausea, vomiting and high temperature) is the most common related adverse effect (25-40%). Steroids co-administration, intrathecal and/or systemic, is suggested to prevent this adverse event but there is no consensus about the best pattern of use.
Aims: The aim of this study is to evaluate the incidence of chemical arachnoiditis in patients with hematologic malignances and high risk of LM, treated with the new Depo-ITV (LC 50 mg IT + Dexametasone 4 mg IT + Dexametasone 20 mg iv, day 1) as LM prophylaxis.
Methods: We carried out a study on 3 different sites to analyze the toxic profile and the effectiveness of Depo-ITV. Inclusion criteria were as follows: patients≥ 18 at the time of treatment, confirmed diagnosis of hematologic malignance, treated with Depo-ITV as LM prophylaxis in the period 1st January 2010 to 1st January 2014. Exclusion criteria: previous lymphomatous or infectious meningitis, previous neurological toxicity related to systemic chemotherapy. Depo-ITV toxic profile was evaluated as *CTCAE v3.0 of NCI scale*. We also recorded demographic and clinical data, systemic treatment, systemic response, and LM incidence. This study has been approved by local ethics committees.
Results: One hundred twelve administrations of Depo-ITV in 54 pt, median per pt 2 (1-5), were analyzed during the above-mentioned period. Baseline characteristics median age 55 (20-79), M/F 32/22, histologic subtype; DLBCL 25 pt, Lymphoblastic Leukemia 13 pt, Follicular Lymphoma 4 pt, Myeloblastic Leukemia 4 pt, MCL 2 pt, Richter 2 pt, Burkitt 2 pt, T cell lymphoma 2 pt. HiDAC occurred in 1 case, high dose methotrexate in 4 cases and HiDAC plus high dose systemic methotrexate in 19 cases. Toxicity: There were 3 pt with grade 3 (no grade 4) AE, 4 (3.5%) cases out of 112 administrations, and the cases were

as follows: Case 1: 70 year old female diagnosed with DLBCL treated with 2 Depo-ITV administrations, after 1st administration grade 3 orthostatic headaches occurred, but the orthostatic characteristic the headache was also considered depo-ITV related. A second administration of Depo-ITV (no dose reduction) was performed without AE. Case 2: 41 year old male, Richter, headache grade 3 after 1st Depo-ITV admintration. Treatment was discontinued. Case 3: Lymphoblastic Leukemia, systemic HiDAC and 4 depo-ITV administrations. Headache grade 3 after 2nd and 4th administrations (no dose reduction after 2nd). Sings of intracranial hypertension occurred after 4th Depo-ITV. This toxicity was reversible. Systemic responses were as follows: CR 41, PR4, progression disease 7 and 2 non evaluated patients. With 10.4 (0.5-49) month median follow up, we report no cases of LM, 37 pt are alive and in CR, 13 pt are dead (10 p disease progression), 3 pt are currently in active treatment and 1 case is lost for follow up.
Summary and Conclusions: Depo-ITV reduces the incidence of post LC chemical arachnoiditis and is effective in preventing LM. The Depo-ITV pattern suggested here ensures chemical arachnoiditis prevention in contrast to the multiple day steroids patterns.

PB1850

HIGH-DOSE CYTARABINE AND MITOXANTRONE ±RITUXIMAB FOR COLLECTION OF PERIPHERAL BLOOD STEM CELLS IN HIGH-GRADE NON-HODGKINS´ LYMPHOMA. SINGLE CENTER EXPERIENCE WITH FILGRASTIM BIOSIMILARS.

I Skoumalová[1,*] Z Kapitáňová[1], R Urbanová[1], E Faber[1], Z Pikalová[1], T Papajík[1], K Indrák[1]
[1]Department of Hemato-Oncology, Faculty Hospital Olomouc, Olomouc, Czech Republic

Background: For the patients with aggressive non-Hodgkins´ lymphomas (NHL) chemotherapy – high-dose of cytarabine with mitoxantrone ±rituximab (R±HAM) is used for the standard collection of peripheral blood stem cells at our Department as a part of Sequential Protocol chemotherapy (2xPACEBO, IVAM, PACEBO, HAM ±rituximab).
Aims: We describe here the experience with the efficacy and safety together with the comparison of two filgrastim (G-CSF) biosimilars.
Methods: R±HAM was given as follows: rituximab 375 mg/m^2 on day 1; cytarabine 2g/m^2 in 4 doses on day 1 and 2; mitoxantrone 10 mg/m^2 in 2 doses on day 2 and 3. In patients with age over 60 the dose of cytarabine and mitoxantrone was reduced to 0.5 g/m^2 and 7 mg/m^2, respectively. Three different types of G-CSF at the same dosage (10μg/kg of body weight) were used to stimulate peripheral blood stem cells: Neupogen (39 patients), Zarzio (28 patients) and Tevagrastim (11 patients). Retrospective analysis was performed in cohort of 78 patients with NHL in the period January 2009 - September 2013. Median of age was 53 (22-64) years.
Efficacy of the type of G-CSF in terms of the leucopheresis number (collection days) and number of CD34+ cells per kg collected was the first goal of our study. The incidence of infections and other side-effects were recorded in addition. Kruskal-Wallis and Fisher exact tests were used for comparison.
Results: There were no differences among the groups of patients with respect to the gender, age, marrow involvement and previous treatment. There were no statistically significant differences in number of collection procedures among the groups (p=0.084); on average 1.69 procedures for Neupogen, 1.53 procedures for Zarzio and 1.81 procedures for Tevagrastim. Also there were no statistically significant differences in number of CD34+ cells per kg collected (p=0.497); on average 8.29x10^6 CD34+ cells per kg for Neupogen 8.51x10^6 CD34+ cells per kg for Zarzio and 6.66x10^6 CD34+ cells per kg for Tevagrastim. Patients hospitalized and central venous line inserted for the whole period of the priming (42 patients) have a significant higher risk of septicaemia (p=0.002). Patients who proceed to the transplantation engrafted in all cases.
Summary and Conclusions: R±HAM is well tolerated and highly efficient priming chemotherapy (average number of CD34+ cells collected was 7,82x10^6 per kg, 78 patients). Different types of G-CSF show no statistically significant differences in the stimulation efficacy. Prolonged hospitalization and central venous catheterization is associated with higher risk of septic complications. More patients should be analysed in order to further increase the validity of results.
Supported by the grants MSM-6198959205 and IGA UP LF-2013-004.

PB1851

ELEVATED BONE MARROW PROLYMPHOCYTES PREDICT SUPERIOR OUTCOME IN DIFFUSE LARGE B CELL LYMPHOMA

R Feng[1,*] X Wei[1], Y Wei[1], F Huang[1], M Xie[1], H Jing[1], X Hao[1], R Lin[1], X Xu[1], D Fang[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Elevated prolymphocytes with normal cytomorphology can be seen in bone marrow (BM) of patients with diffuse large B-cell lymphoma (DLBCL) from time to time. Whether elevated BM prolymphocytes, serving as a surrogate of host immunity, can predict prognosis of DLBCL patients remains unknown.
Aims: To explore whether elevated BM prolymphocytes serving as a surrogate of host immunity, could predict prognosis of DLBCL patients.
Methods: Two hundred and ten de novo DLBCL patients from 2001 to 2012 were retrospectively analyzed in the present study.
Results: Elevated BM prolymphocytes with normal cytomorphology (>1.5%) could be found in 18 DLBCL patients (8.6%). There was no significant difference in gender, age, B symptoms, performance status, LDH, stage and IPI score between patients with elevated BM prolymphocytes *versus* all the remaining cases (p>0.05). Patients with elevated BM prolymphocytes showed significantly superior OS and PFS compared with all the remaining patients (p=0.031 and p=0.043, respectively), especially in those high-risk patients (p=0.041and p=0.027, respectively). Of 40 patients with BM involvement (BMI), 20 had concordant BMI and 20 had discordant BMI. Concordant BMI had significantly shorter OS and PFS than uninvolved BM patients (p<0.001and p=0.005, respectively), whereas discordant BMI did not (p=0.390 and p=0.918, respectively). Multivariate analysis revealed elevated BM prolymphocytes remained a favorable factor for PFS (RR, 0.130; 95% CI, 0.018-0.950, p=0.044), but not for OS. However, concordant BMI was an unfavorable predictor for OS (RR, 2.474; 95% CI, 1.138-5.377, p=0.022, respectively), but not for PFS.
Summary and Conclusions: Elevated BM prolymphocytes at diagnosis may imply a good prognosis, allowing the identification of a superior outcome subgroup in high-risk DLBCL patients. Concordant BMI has a negative impact on survival in DLBCL patients.

PB1852

PROGNOSIS FACTORS IN ELDERLY PATIENTS WITH PRIMARY CNS LYMPHOMA TREATED WITH NONRADIATION, INTERMEDIATE-DOSE METHOTREXATE-CONTAINING REGIMEN

SY Lee[1], Y Okoshi[1], N Kurita[1], M Seki[1], Y Yokoyama[1], K Maie[1], Y Hasegawa[1], S Chiba[1,*]
[1]Department of hematology, University of Tsukuba , Tsukuba, Japan

Background: Nearly half of all patients with primary central nervous system lymphoma (PCNSL) are known to be aged over 60 years. However, clinical factors affecting treatment outcomes in elderly patients are understudied.
Aims: In this study,we intended to identify prognosis factors in elderly patients with PCNSL treated with nonradiation, intermediate-dose methotrexate (MTX)-containing regimen.
Methods: We analyzed 38 patients with PCNSL older than 60 years. All patients were treated with nonradiation, intermediate-dose MTX-containing protocol comprising an induction therapy and maintenance therapy between March 2005 and May 2013 at the University of Tsukuba Hospital. As an induction therapy, 1 g/m^2 intravenous (i.v.) MTX was given on days 1, 10, and 20; 40 mg/m^2 i.v. ranimustine, on day 1; 60 mg/m^2 oral procarbazine, from days 1 to 7; and i.v. or oral methylprednisolone, at a dose of 120 mg/m^2 every other day from days 1 to 20 and then at a dose of 60 mg/m^2 from days 21 to 45. Fifteen milligrams of MTX and 40 mg of cytarabine were injected intrathecally (i.t.) on days 1, 5, 10, and 15 with leucovorin rescue. As a maintenance chemotherapy, 1 g/m^2 i.v. MTX was given on day 1; 40 mg/ m^2 i.v ranimustine, on day 1; and 60 mg/m^2 oral procarbazine, from days 1 to 7; and 15 mg i.t. MTX and 40 mg i.t. cytarabine on day 1. Patients who achieved a complete remission or partial remission after 1 course of induction chemotherapy proceeded to further therapy with 5 courses of maintenance chemotherapy every 6 weeks. When progressive disease was documented, the protocol was stopped. Overall survival (OS) was calculated from the first date of the induction chemotherapy to the date of any cause of death. Progression free survival (PFS) was defined as the period from the first date of the induction chemotherapy to the first date of the documentation of disease progression or death as a result of PCNSL. The OS and PFS were estimated with the Kaplan-Meier method. Univariate analysis to see impact of clinical factors on OS or PFS was performed with the log-rank test. Independent predictive factors for OS were analyzed by Cox proportional hazards regression model.
Results: Twenty-four patients were able to finish the full protocol. Three-year OS and PFS rates were 56.2% [95% confidence interval (CI): 36.2%>76.2%] and 29.8% (95% CI: 9%>50.6%), respectively, with a median follow-up of 36.5 months. We found age > 75 years, Karnofsky performance score<70, altered mentation, and creatinine clearance (CrCl) > 90 ml min^{-1} were significant (p<0.05) factors associated with a worse survival by univariate analysis. The only parameter significantly associated with PFS was altered mentation with univariate analysis (p=0.024). Although patients with CrCl > 90 ml min^{-1} showed tendency toward worse PFS, it was statistically insignificant (p=0.118). Multivariate analysis revealed CrCl [p<0.05; hazard ratio (HR) = 3.39; 95% CI, 1.08–10.68] and altered mentation (p<0.05; HR = 6.27; 95%CI, 1.37–28.83) were independently significantly associated factors with OS. The most frequent adverse effect was myelosuppression, with grade 3 to 4 hematologic toxicities in 28 patients. Grade 3 to 4 hepatic toxicity was observed in 6 patients. Renal toxicity was documented in 13 patients, 5 of whom required dose reduction or modification of the protocol. No delayed neurotoxicities were observed.

Summary and Conclusions: More aggressive therapy may be introduced in selected patients with poor prognosis factors to improve outcomes.

PB1853

ROLE OF FDG-PET SCANS IN THE MANAGEMENT OF PEDIATRIC NON-HODGKIN'S LYMPHOMA. CCHE EXPERIENCE

H Abdelrahman[1,*] A Hamoda[1], M Sedky[2], E Moussa[3], I Attiya[1], A Youssef[4], T Raafat[4], W Omar[5], O Hassanein[6], A El Haddad[7]
[1]Pediatric Oncology, National Cancer Institute, [2]Pediatric Oncology, National Research Center, [3]Pediatric Oncology, Elmenufeya University, [4]Radiodiagnosis, [5]Nuclear Medicine, National Cancer Institute, [6]Clinical Reserch, Children Cancer Hospital Egypt, [7]National Cancer Institute, Cairo , Egypt

Background: Malignant lymphomas are the third most common malignancy among children and adolescents, with a propensity for widespread dissemination. 18-F-fluorodeoxyglucose (FDG)-positron emission tomography (PET) is a noninvasive, 3-dimensional imaging modality that has become widely used in the management of patients with malignant lymphomas. PET is the most important recent advance in noninvasive lymphoma assessment. Current applications of PET in lymphoma may be divided into pretreatment staging, restaging, therapy monitoring and post therapy surveillance. Evaluation of residual masses and the recommendation to document them histologically before intensifying treatment in cases of incomplete remission is one of the difficulties during patients' treatment. Usefulness of PET scanning to assess viability of a residual mass is under evaluation in childhood lymphoma with the hope that it might replace histologic documentation, but this evaluation is less advanced than in adult.
Aims: To evaluate the sensitivity, specificity and predictive values of PET scan during management of pediatric Non-Hodgkin's lymphoma. Correlation of PET results with conventional CT, the patients' clinical outcome, and its impact on the treating physician decision was done.
Methods: A retrospective study enrolled on pediatric patients with NHL at Children Cancer Hospital of Egypt (CCHE) during the period from July 2007 till end of June 2013 was done. Inclusion criteria included the diagnosis of mature B cell NHL, for whom PET - in addition to conventional CT scan- was done at any stage of the treatment. Blind revision of all PET and CT scans was specifically done for this study.
Results: For 115 pediatric NHL patients, 152 PET and 152 CT scan were done. Median age was 5.7 years (range 1-18 years). They were 85 males (74%) and 30 females (26%). One hundred twenty six scans (82.9%) were done for 100 Burkitt lymphoma patients, while 26 scan (17.1%) done for 15 DLBC. Nineteen examination (12.5%) were done before starting chemotherapy, 107 (70.3%) at time of evaluation while 26 (17.1%) during Follow up. For all patients, sensitivity was 91.6% for PET, while was 70.0% for conventional CT (p=0.02). Specificity was 84.1% for PET and 58.9% for CT (p< 0.001). PPV for PET was 50%, while was 22% for CT scan (p<0.001). NPV for PET was 98%, while was 92% for CT (p=0.01). In burkitt lymphoma; sensitivity of PET was 91.6%, while was 66.6% for CT (p=0.08). Specificity was 82.4% and 57.8% for PET and CT respectively (p=<0.001), while PPV and NPV were 35.4%, 14.2, 98.9%, 94.2% for PET and conventional CT (p= 0.0005) (p=0.05) respectively. In DLBCL patients; sensitivity was 85.7% and71.4% for PET and CT respectively (p value=0.31). Specificity was 89.4%, 57.8% for PET and CT (p =0.05). PPV and NPV were 75%, 38.4%, 94.4%, 84.6% for PET and CT (p =0.02) (p =0.18) respectively.
Summary and Conclusions: PET scan is significantly more sensitive than conventional CT in the management of aggressive mature B cell pediatric NHL.

PB1854

EFFICACY AND SAFETY OF DARBEPOETIN-ALFA IN POOR PROGNOSIS DIFFUSE LARGE B LYMPHOMA CELLS PATIENTS TREATED WHIT TWO-WEEKLY DA-EDOCH14

E Flores Ballester[1,*] J Garcia Suarez[1], M Callejas[1], E Magro Mazo[1], JJ Gil Fernandez[1], Y Martín[1], M Lopez Rubio[1], MA Calero[1], T Pascual[1], F Perera[1], M Cortti[1], C Casco[1], S Marcellini[1], L Juarez[1], I Gutierrez[1], C Burgaleta[1]
[1]Hospital Universitario Príncipe De Asturias, Alcala De Henares, Madrid, Spain

Background: Erythropoiesis-stimulating agents (ESAs) raised safety concerns about decreased overall survival (when used to maintain Hb>12 gr/dl) and increased venous thromboembolic (VTE) events in cancer patients. The impact of these agents has not been studied in aggressive lymphomas treated with dose-dense immunochemotherapy regimens, a strategy that triplicate the risk of anaemia and transfusion. (Leuk Lymphoma 2011;52:996).
Aims: The aim of the present study was to evaluate the efficacy and safety of darbepoetin alpha (DPA) in a prospective phase 2 study, single centre, of poor prognosis (aaIPI 2-3) diffuse large B-cell lymphoma (DLBCL) treated with the modern infusional regimen DA-EDOCH14-R. (Br J Haematol. 2013 Feb;160(4):510-4).
Methods: From 2008 to 2013, 26 patients (median age 56 years; range 18-70) newly diagnosed poor prognosis DLBCL were treated with 6 cycles of two-weekly DA-EDOCH14-R. These patients were treated with DPA s.c and blood transfusions according to usual clinical practice. Initial DPA dose: 150mcg/week. Increase dose DPA to 300 mcg/week if no response is seen in 6 weeks' time. We stopped DPA when response is seen, used to be 4 weeks after QT. We analyze these risk factors: HBP, DM, DL, smoke, CVC, steroids, cancer, obesity and age >60.
Results: We administered DPA at 25 patients (96%) for anaemia: 14(56%) Hb>11gr/dl, 10 (40%) Hb 9-11gr/dl and 1(4%) Hb<9. Median Hb when we initiated treatment of DPA: 11.4gr/dL. 18 patients (72%) started DPA within the first two months of treatment. Duration treatment median: 3 months. The dose was increased in 5 patients (20%). High incidence of DVP (24% patients) was distributed as follows: 2 VTE, 1 DVP left axillar, 1 DVP femoral popliteal, 1 mammary and jugular left vein, 1 DVP basilica left vein. No relationship was observed between VTE and high Hb level (median Hb: 10.1gr/dl (patients with VTE) *vs* 10gr/dl (patients without VTE), or with risk factors (median: 5(with TEV) *vs* 4(without TEV)). At a median follow up of 40.5 months, 3-year progression-free was estimated and overall survival was 85%.
Summary and Conclusions: Our data suggest that the use of DPA is associated with a low rate of transfusion, but a high incidence of VTE. ESAs don't seem to worse progression-free survival in patients treated with 14DA.EDOCH. ESAs recommendations should be followed in order to minimize thrombotic disease.

PB1855

A REVIEW OF HIGH GRADE NON-HODGKIN LYMPHOMA CARE IN A UNIVERSITY HOSPITAL GROUP IN IRELAND

MP Crowley[1,2,*] R Crotty[3], MR Cahill[1], CG Murphy[4], J O'Keeffe[4], BR Bird[4]
[1]Haematology, Cork University Hospital, [2]HRB Clinical Research Facility, [3]School of Medicine, University College Cork, [4]Medical Oncology, Bon Secours Hospital, Cork, Ireland

Background: High-grade non-Hodgkin lymphoma (NHL) is an aggressive malignancy that requires urgent, intensive management. It is estimated that 60% of patients are cured (Cancer Research UK) so rapid diagnosis and commencement of chemotherapy are crucial to ensure the best possible outcomes. Clinical practice guidelines are systematically developed statements designed to assist practitioners and patients in making decisions about appropriate healthcare for specific clinical circumstances. However, there remains a significant variation in the utility of recommended treatments in Lymphoma (Loberiza et al Leuk Lymphoma 2014).
Aims: In Ireland, data is lacking on how closely non-Hodgkin lymphoma management follows guidelines. This study is the first to address this issue.
Methods: The study was carried out in two university affiliated hospitals in Ireland. 125 consecutive high-grade non-Hodgkin lymphoma patients were identified from the National Cancer Registry of Ireland. Appropriate quality markers were chosen (Wennekes et al, J Clin Oncol 2011) and, in keeping with previous research, 90% adherence was set as the target. Data was obtained through a systematic retrospective chart analysis of paper and electronic records.
Results: Analysis focused on three areas – diagnosis and staging, treatment, and organization of care. Diagnosis and staging markers were generally well adhered to. 92% of patients were diagnosed with an appropriate biopsy, and 98% of patients had appropriate blood tests performed. However, adherence rates for treatment and organization of care markers were much lower. 85% of patients received a DA-CHOP-R or DA-EPOCH-R regimen, and 75% of patients received a histological diagnosis within the 21 day target period. Chemotherapy was commenced within 28 days of diagnosis in 83% of patients. Adherence rates for the recording of standardized information were particularly low. 54% of patients had an International Prognostic Index (IPI) score recorded. Use of the Cheson criteria to report treatment response was minimal.
Summary and Conclusions: These results are in keeping with previously published studies. Management guidelines are being met in 8 of 21 areas. Although guideline adherence rates are similar to international data, more needs to be done to achieve optimal standards of care. Follow-up investigations post-chemotherapy need to be carried out in a higher proportion of patients. Standardised information such as IPI and stage needs to be documented so that patients can be appropriately risk-stratified and treated according to the most up to date evidence. It is also important to document the severity of disease being treated in an institution. Given that some criteria are rarely applied, there is a question about their practicality in clinical practice.

PB1856

DIAGNOSIS AND CLINICAL OUTCOME OF 9 CASES OF NEUROLYMPHOMATOSIS; SINGLE INSTITUTIONAL EXPERIENCE OVER THE 7 YEARS

M Fujisawa[1,*] Y Suehara[1], K Seike[1], K Fukumoto[1], M Fukaya[1], H Sugihara[1], Y Nishida[1], M Takeuchi[1], K Matsue[1]
[1]Hematology/Oncology, Kameda Medical Center, Kamogawa city, Japan

Background: Neurolymphomatosis (NL) is an extremely rare neurologic manifestation of no-Hodgkin lymphoma (NHL) in which peripheral nerve infiltration of lymphoma cell is a dominant feature in both clinically and pathologically. We previously reported a high frequency of NL as a relapse disease of intravascular large B cell lymphoma (IVL), although NL could be presented as an initial disease as well as relapsed disease in other types of NHL. In addition, the clinical features and treatment outcomes of NL is largely unknown. However, recent enthusiastic use of PET/CT in lymphoma has facilitated the diagnosis of NL.
Aims: In this paper, we updated our experience on NL at our hospital over the period of January 2007 to February 2014.
Methods: We reviewed the clinical records at the Hematology/Oncology Department of Kameda Medical Center. The diagnosis of NL required the 1) clinical symptoms and neurological examination findings referable to the cranial or spinal nerves, and 2) histological confirmation of malignant lymphoma cells within the peripheral nerve, nerve root/plexus, or cranial nerve or 3) CT/MRI demonstration of nerve enhancement and/or enlargement of peripheral nerve(s) or nerve root that were also demonstrated by the accumulation of FDG by FDG-PET/CT. Patients with stomach limited mucosa associated lymphoid tissue (MALT) lymphoma and leukemic infiltration of peripheral nerve due to acute leukemias were excluded from the study.
Results: Over the past 7 years, there were 581 patients diagnosed as a NHL except for mucosa associated lymphoid tissue (MALT) lymphoma of stomach. Among them, we identified 9 cases (1.55%) diagnosed as having NL. The patients consisted of 2 men and 7 women with median age of 72 years (range; 63-83 years). NL occurred as a part of presenting disease in 2 patients and as a relapse disease in remaining 7. Four patients were presented NL as a relapse disease of intravascular large B-cell lymphoma (IVL), 3 patients were as a concomitant extranodal lymphoma (stomach, ileum, and uterus), and 2 were as a relapse disease of nodal DLBCL. IVL patients showed significantly higher frequency in the development of NL compare to non-IVL patients (4/14 *vs* 5/567, p=0.004). CD5 was positive in 8 cases. Diagnosis of NL was made by neurological findings, enlargement and enhancement of affected cranial or peripheral nerves by MRI, and FDG-uptake of affected nerve demonstrated by PET/CT in all of the patients. Autopsy also confirmed the lymphoma infiltration in one patient. Affected nerve included lumbosacral nerve (4 cases), peroneal nerve (1 case), cranial nerves (2 cases). Cerebrospinal fluid cytology was positive in 4 cases (44%). Six patients developed CNS involvement subsequently. Eight patients received high dose methotrexate (MTX) containing treatment in addition to systemic chemotherapy, and 4 patients additionally received but only 2 patients responded. Four patients additionally received involved nerve irradiation and all of them responded transciently. Five patients died due to NL with median of 5.1 months after NL development and 3 patients still receiving chemotherapy and irradiation.
Summary and Conclusions: NL is a challenging disease with respect to both diagnosis and treatment, but careful neurologic examination and contemporary imaging technique especially PET/CT often detect relevant neural involvement. Although most effective regimen remained undetermined, high dose MTX combined with systemic chemotherapy might benefit in a subset patients.

PB1857

THE SIGNIFICANCE AND OUTCOME OF THE FINDING OF PERSISTENT LOW GRADE UPTAKE ON FUNCTIONAL IMAGING USING 18F-FLUORODEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY (FDG-PET) IN LYMPHOMA PATIENTS

F Alwan[1,*] S Zemenides [2,3], D Hughes[1], K Cwynarski[1], A Martin[4], T Wagner[5], C Kyriakou[2], C McNamara[1]
[1]Department of Haematology, Royal Free Hospital, [2]Department of Haematology, Northwick Park Hospital, [3]National Institute of Health Research, [4]Department of Radiology, Northwick Park Hospital, [5]Department of Nuclear Medicine, Royal Free Hospital, London, United Kingdom

Background: Functional imaging using FDG-PET is increasingly used to assess the response to therapy of FDG-avid lymphomas. Clinicians generally refer to scans as either 'positive' or 'negative' however nuclear medicine physicians recognise a continuum of uptake, with persistent disease more likely at higher levels of activity. Importantly, the glucose analogue used in this technique is not specific for lymphoma. Recently published studies that used a program of biopsy or serial scanning and patient follow-up suggest poor positive predictive value of FDG-PET scans in some lymphoma subtypes.
Aims: We have analysed the clinical outcome of patients with initially FDG-avid lymphomas treated with curative intent who following completion of treatment had positive yet indeterminate findings at multi-disciplinary team (MDT) meetings in two London teaching hospitals. Our aim was to determine how patients with such findings are managed and to determine the clinical outcome for this cohort of patients.
Methods: We retrospectively reviewed all FDG-PET-CT end-of-treatment scan reports of patients with curable lymphoma subtypes over a seven year period. Cases were selected if the scan reported persistent low grade uptake of uncertain significance. The reports were not centrally reviewed. The patients' clinical course was interrogated for the presence of disease recurrence, results of subsequent FDG-PET scans, whether a biopsy of the area was performed as well as results of any ancillary investigations or review by other specialists.
Results: There were 42 patients (M:F 1.3:1) with a median age of 51 (range 20-76). The scans were performed at end of treatment and at varying time points thereafter. 23% of PET-CT performed were equivocal (80 scans from the 347 end of lymphoma treatment PET-CT scans performed at NPH). Histologies included Hodgkin lymphoma (15), diffuse large B-cell lymphoma (15), Burkitt lymphoma (5), and primary mediastinal B-cell lymphoma (2). After a median follow up of 21 months, 34 of 42 patients with persistent uptake at the end of treatment were alive and disease free. Five patients had died, only one from lymphoma. Seven patients had relapsed (five confirmed by biopsy) and all seven received salvage chemotherapy. Fifteen of 42 patients in this group underwent biopsy- five had confirmed disease. Other biopsy results included inflammatory or necrotic tissue, solid organ malignancy, tuberculosis and a mycetoma. Of the patients who did not undergo a biopsy, serial FDG-PET scanning (median 1 further scan, range 1-5) or additional studies such as MRI or high resolution CT-scanning suggested the following diagnoses: post-treatment inflammatory change (21 patients), thymic rebound (3) and pulmonary infection (3).
Summary and Conclusions: The finding of persistent low-grade uptake on end-of treatment FDG-PET is not an uncommon finding in our MDT meetings. In our series of patients, treated with curative intent, the majority of patients with positive but indeterminate findings did not have a clinical course consistent with persistent disease. The non-specific nature of FDG underlines the importance of careful review of patients with persistent low-grade uptake at the end of treatment, especially where decisions about further toxic therapies are made. We recommend a biopsy prior to further therapy wherever possible. For patients unable to undergo biopsy we suggest a team based approach that considers alternative causes coupled with follow-up scanning. Our study is limited by the fact that a range of lymphoma subtypes and different disease stages have been included.
**FA and SZ contributed equally to the work.*

FIRST-IN-MAN STUDY OF 4SC-202, A NOVEL ORAL HDAC INHIBITOR IN PATIENTS WITH ADVANCED HEMATOLOGICAL MALIGNANCIES; (TOPAS STUDY)

B von Tresckow[1,*] ME Goebeler[2], C Sayehli[2], S Gundermann[2], D Eichenauer[1], W Aulitzky[3], L Bacchus[3], S Igel[4], M Schwab[4], S Sasse[1], B Hauns[5], A Mais[5], B Hentsch[5], H Kohlhof[5], R Krauss[5], B Krauss[5], R Baumgartner[5], D Vitt[5], A Engert[1]
[1]University Hospital Cologne, Cologne, [2]University Hospital of Wuerzburg, Wuerzburg, [3]Robert Bosch Hospital, [4]Dr. Margarte Fischer-Bosch Institute of Clinical Pharmacology, Stuttgart, [5]4SC AG, Planegg-Martinsried, Germany

Background: 4SC-202 is a specific inhibitor of protein deacetylases HDAC1, 2 and 3 and lysine specific demethylase LSD1 (KDM1A). Enzymatic inhibition leads to transcriptional repression of Wnt and Hedgehog signaling. 4SC-202 provokes the inhibition of stemness-related properties of cancer cells and affects their viability.
Aims: Patients with advanced hematological malignancies including AML, ALL, CLL, MM, MDS or lymphoma were orally dosed either once daily (QD) or twice daily (BID) from days 1 to 14, or BID continuously, in a 21-day cycle. Dose escalation followed a 3+3 design. Study objectives include safety, tolerability and pharmacokinetics (PK), determination of MTD and DLT as well as optimization of dosing. Biomarker program includes measuring of HDAC inhibition, total lysine acetylation and gene expression profiling. Additionally, the anti-tumor effect of 4SC-202 was evaluated. Dose escalation part is completed and data allow for reliable evaluation. Further patients will be enrolled to establish the MTD at prior dose levels.
Results: 24 patients were treated at 7 dose levels of 25/50/100/200/400mg QD and 200mg BID (N=3, each), and 200mg BID continuous dosing (N=6). Treatment was very well tolerated by heavily pre-treated patients up to the highest dose group. Possibly drug-related AE were less frequent, *e.g.* low-grade GI complaints such as nausea. Higher-grade hematological toxicity *e.g.* leading to treatment changes was not observed. Elevation of liver enzymes was observed at 200mg BID during continuous dosing. Two objective responses (PR & CR, unconfirmed) were observed. 75% of patients went into follow-up treatment due to stable disease. Median time on treatment was 98 days with 3 patients treated > 400 days . Plasma exposure reached one digit µM concentrations over 24h. Modulation of Wnt pathway gene-signature was observed in blood samples, as well as HDAC inhibition and lysine acetylation.
Summary and Conclusions: 4SC-202 could be safely administered up to 200mg BID. Anti-cancer activity could be demonstrated by two patients achieving PR and CR, respectively, and long term stabilization of several patients. The mode of action of 4SC-202 is demonstrated by biomarker response.

PB1859

MANAGEMENT OF RELAPSED/REFRACTORY LYMPHOMA WITH BRENTUXIMAB VEDOTIN : OUR EXPERIENCE IN THE TREATMENT OF YOUNG PATIENTS

C Cerchione[1,*] C Cimmino[1], N Pugliese[1], E Seneca[1], R Della Pepa[1], S Luponio[1], C Mainolfi[2], F Pane[1], A De Renzo[1]
[1]Hematology, [2]Radiology, AOU "Federico II", Napoli, Italy

Background: Brentuximab vedotin is a CD30-directed antibody-drug conjugate (ADC), currently approved for treatment of relapsed Hodgkin lymphoma and relapsed anaplastic large-cell lymphoma after front-line chemotherapy.
Aims: In this work, we analyze a successful experience with brentuximab vedotin in the management of relapsed and refractory lymphoma.
Methods: Case 1 : N.A., 21 y.o. male patient, with diagnosis in November 2011 of Systemic anaplastic large-cell lymphoma (ALCL), Stage IIIB, non B non T, ALK-positive, CD30+. In November 2011 he underwent to frontline treatment CHOP/14 x 6 with CR. Then, he underwent to IEV protocol, but, after 2 courses, the patient referred to our Institution for abdominal pain : a PET/CT was performed documenting a relapse. So, he switched to DHAP, with an apparent improvement, but, one month after the first course there was a worsening of clinical conditions. Then, for progressive disease, there was a switch to Brentuximab treatment. After first course, the patient went to Emergency Medicine for respiratory problems, and, after the solution, we continued the protocol. The treatment was well tolerated, and, after 6 courses, the patient is in CR and he undergoes, in November 2013, to Allogenic BMT. Now, after 4 months, the patient has no signs of disease. Case 2 : T.A., 35 y.o. female patient, with diagnosis in February 2011 of classic nodular sclerosis Hodgkin's Lymphoma, Stage IIB, with mediastinal bulky disease. Frontline treatment was ABVD, 12 courses, with the result of a PR. After, Radiotherapy was started on mediastinal mass, remaining in SD. After 3 months, there were new localizations documented from PET/CT and IGEV protocol was started, total of 3 courses, after which she underwent to AutoBMT in September 2012. PET/CT performed in February 2013 documented a progressive disease : Brentuximab was started and even if after 3 courses the patient was in SD, after 6 courses there was a PR, which became CR after 12 courses. The treatment was well tolerated, and the only documented side effect was alopecia. Case 3 : G.R., a female 30 y.o., with diagnosis in April 2004 of classic nodular sclerosis Hodgkin's Lymphoma, Stage IIB, with splenic localization. Frontline treatment was VEBEP, 11 courses, with the result of a PR. Then, Radiotherapy was started but a relapse of disease was documented in May 2005. Then, programming a AutoBMT procedure, IGEV treatment was started, 3 courses and then she underwent to AutoBMT with a CR. In September 2006 PET/CT documented the second relapse : MOPP protocol was started (12 courses), until April 2007, when a PR was documented. In October 2007 a third relapse of disease was documented, treated with Gemcitabine, with a SD. The patient underwent to DHAP-R treatment, 4 courses, with the result of a PR. So, in October 2009, the patient started Rituximab maintenance, until July 2012, when it was interrupted for progression of disaese. In that moment the general condition were bad and the patient was not anymore able to walk. In that moment she switched to Brentuximab treatment and after 3 courses there was a nCR and after 6 courses she was in CR. The only side effect was a Grade 1 Neuropathy, which was documented only in the first three courses.
Results: Brentuximab Vedotin has been proved to be effective either in relapsed/refractory Hodgkin's and Non-Hodgkin's Lymphoma as single agent, at the dose of 1.8 mg/kg.
Summary and Conclusions: In our experience, Brentuximab Vedotin can be considered an effective option for advanced patients, relapsed and refractory to almost all available therapeutic resources, and moreover it could be considered as a bridge-treatment to AlloBMT.

STIMULATION OF TOLL-LIKE RECEPTOR 2 IN ALLOREACTIVE T CELLS PROVIDES RESISTANCE AGAINST CALCINEURIN INHIBITOR

WS Lee[1,*] YD Joo[2], SH Bae[3], SK Seo[4]
[1]Int. Medicine, Hemato-Oncology, Inje University Busan Paik Hospital, [2]Int. Medicine, Hemato-Oncology, Inje University Haewoondae Paik Hospital, Busan, [3]Int. Medicine, Hemato-Oncology, Daegu Catholic University Hospital, Daegu, [4]Department of Microbiology and Immunology, College of Medicine, Inje University, Busan, Korea, Republic Of

Background: Toll-like receptors (TLRs) play a fundamental role in innate immunity through their capacity to recognize pathogen-associated molecular patterns. Also, TLRs have been shown to play an important role in T cells as costimulatory receptors. However, the significance of TLR expression in allogeneic T cells remains unclear.
Aims: we investigated the role of TLR2 signal in allogeneic T cell responses and its function to resist against calcinurine inhibitors (CNIs).
Methods: Mixed lymphocyte reaction (MLR) cultures were set up with CFSE-labelled naïve Balb/c T-cell responder and B6 TLR2 KO splenic stimulator per well in the presence or absence of TLR2 agonist Pam_3CSK_4 (PAM). The MLR cultures were treated with various concentrations of CNIs (CsA and FK506) and determined the resistance through proliferation and cytokine levels. Purely isolated naïve T cells were stimulated with soluble anti-CD3 in the presence or absence of PAM and determined intracellular signaling pathway.
Results: Stimulation with TLR2 agonist promoted alloreactive T cell proliferation and survival. IL-2 and IFN-g production were also significantly increased by TLR2 ligation. In the condition of high dose CNI treatment, the activation of allogeneic T cells was prevented in either TLR2 stimulation or not. However, as the lower dose of CNI treatment, TLR2 stimulation led proliferation of allogeneic T cells but not without TLR2 stimulation. We found that TLR2 stimulation enhanced TCR-mediated IL-2 production through PI3K/AKT signaling which brought CNI-resistance.
Summary and Conclusions: Our results demonstrate that TLR2 stimulation directly enhances allogeneic T cell responses and provides the resistance against CNIs. Our study suggests that TLR2 signal might be responsible for meek efficacy of CNIs on GVHD prophylaxis.

PB1861

THE SPECIAL PHENOTYPIC CHARACTERISTICS OF IMMUNE RECONSTITUTION AFTER CORD BLOOD TRANSPLANTATION

J Wang[1,*] Z Sun[1], M Guan[1], H Liu[1], C Zheng[1], J Tong[1]
[1]Department of Hematology, Anhui Provincial Hospital, Hefei, China

Background: Cord blood transplantation (CBT) is being increasingly used for treatment of hematological malignancies because it's efficacy in the treatment of adult patients and showed many advantages. The immaturity of T cell contained in the graft and the T cell reconstruction is later than bone marrow transplantation (BMT) or peripheral blood stem cell transplantation (PBSCT), but the relapse rate after CBT to be comparable to that BMT or PBSCT from HLA matched sibling donors. Our clinical analysis revealed the outcome of CBT for high risk acute leukemia relapse after HLA-mismatched CBT was lower than that BMT or PBSCT, but the incidence of graft-*versus* host disease (GVHD) was similar. These clinical findings suggest that immunocompetent cells other than T cells may mediate the GVL effect after CBT. Natural killer (NK) cells play a major role in the development of GVL effect after an HLA-mismatched stem cell transplantation. The GVL effect by NK cells depends on the presence of cell recovery and this coincident with NK cells' characteristics of reconstruction. Because the recovery of NK cells promptly after CBT, so it is probably that NK cells may be more likely to contribute to the development of GVL effect.
Aims: Our purpose is to explore the characteristics of NK cells' reconstruction after CBT by detecting NK cells and their related functional phenotype on their subsets in this research.
Methods: Twenty-six CBT patients and eighteen BMT were studied in this research. We detected the expression of CD11b, CD27 and CD57 on $CD3^-CD16^+CD56^+$NK and their subset by multicolor flow cytometry at the different time after transplantation. Data were summarized as mean±SD. Student t test was used to determine whether there was a statistically significant difference between samples, with two-tailed P values less than 0.05 indicating a significant difference.
Results: 1) In general, the frequency of $CD3^-CD56^+CD16^+$NK cells in lymphocytes was below in CBT receptors compared with BMT, but the absolute number was below only on 1 , 6, 9 month. 2) The proportion of $CD3^-CD56^{bri}CD16^+$NK in CBT group was higher than that of BMT group. 3) The expression of CD11b on $CD3^-CD56^{dim}CD16^+$NK subset in CBT group was

higher than the BMT group only in the early 2 months, the expression of CD27 was higher than the BMT in 4 to 9 months, and the CD57 expression was lower than that of BMT group in 1 to 9 months. 4) The $CD3^-CD56^-CD16^+$NK in CBT group were higher than BMT group after 3 months, and the absolute number exceeds BMT group starting from the 2nd months. Compared with $CD3^-CD56^{dim}CD16^+$, $CD3^-CD56^-CD16^+$ was slightly lower in CD11b higher in CD27 and lower in CD57. The expression of CD11b and CD27 on $CD3^-CD56^-CD16^+$NK subset in CBT group had no significant difference with BMT group while the expression of CD57 was lower than BMT group in 2 to 9 months.

Summary and Conclusions: The frequency of $CD3^-CD56^+CD16^+$NK cells in lymphocytes was below in CBT recipients in the early stage after transplantation compared with BMT and there had no difference after two years, but the absolute number of $CD3^-CD56^+CD16^+$NK cells was not coincidence fully. The expression of CD11b on $CD3^-CD56^{dim}CD16^+$NK subset were higher in the early phase (<2M) after CBT suggest an increase in their strong ability of killing. The expression of CD27 or 57 on $CD3^-CD56^{dim}CD16^+$NK in CBT group showed they were secreting type and more immature in the early phase. This group of cells maybe have lower cytotoxicity but secrete plenty of cytokines. A marked increase in $CD3^-CD56^-CD16^+$NK cells in the peripheral blood was observed in the receptors after CBT. This NK subset showed more immature but was similar to $CD3^-CD56^{dim}CD16^+$NK cells in cytotoxicity or cytokine phenotype. Take together, our results suggest the special characteristics of NK cells in their unique subset and phenotype may contribute to enhance their GVL effect after CBT.

PB1862

COMPARATIVE ANALYSIS BETWEEN CORD BLOOD FROM MAIN BAG AND FROM ATTACHED SEGMENT AFTER THAWING: ATTACHED SEGMENT HAS HIGHER CD34+ CELLS AND CFU-GM THAN THE MAIN BAG AFTER THAWING

HR Lee[1,*] S Shin[2,3,4], JH Yoon[2,3,4], EY Roh[2,3,4], EY Song[2], KS Han[2], BJ Kim[5]
[1]Department of Laboratory Medicine, Gyeongsang National University Hospital, Jinju, [2]Department of Laboratory Medicine, Seoul National University College of Medicine, [3]Department of Laboratory Medicine, Boramae Hospital, [4]Seoul Metropolitan Government Public Cord Blood Bank (Allcord), [5]Department of Obstetrics and Gynecology, Boramae Hospital, Seoul, Korea, Republic Of

Background: A contiguous segment attached to the main bag of cryopreserved cord blood (CB) unit is used in release test for verifying HLA types, cell viability, and, possibly, hematopoietic potency before hematopoietic stem cell transplantation (HSCT), because CB of attached segment is considered to be representative of CB of main bag used in HSCT. However, little is known regarding the characteristics of contiguous segments in comparison with main bag of CB units, due to the difficulty in accessing a large number of cryopreserved CB units.

Aims: We evaluated whether CB from segment is representative of CB from main bag by comparing various CB parameters measured after thawing of a large number of cryopreserved CB units.

Methods: We used the 245 CB units rejected from the Seoul Metropolitan Government Public Cord Blood Bank inventory due to inappropriate test results after conventional processing. After thawing of the cryopreserved CB units, the numbers of total nucleated cells (TNC) and CD34+ cells, cell viability, apoptotic cells, colony-forming unit-granulocyte/macrophage (CFU-GM), and CFU-granulocyte/erythrocyte/macrophage/megakaryocyte (CFU-GEMM) were examined in both CB from main bag and CB from segment, respectively. We conducted the comparative and correlation analysis for identifying the statistically significant differences and correlation in the results between the CB from main bag and the CB from segment.

Results: The number of TNC in CB from main bags was significantly higher than that in CB from segments ($P<0.001$); in contrast, the number of CD34+ cells was significantly higher in CB from segments ($P<0.001$). In addition, the viability of TNC (determined by trypan blue and 7-AAD) and the viability of CD34+ cells (determined by 7-AAD) were also significantly higher in CB from segments ($P<0.001$, $P<0.001$, and $p=0.005$, respectively). While the proportion of apoptotic TNC was significantly higher in CB from segments ($P<0.001$), there was no significant difference in the proportion of apoptotic CD34+ cells ($p=0.105$). There was no significant difference in the number of CFU-GEMM between CB from main bags and segments ($p=0.990$); however, the numbers of both total CFUs and GM-CFUs were significantly higher in CB from segments ($p=0.017$ and $p=0.005$, respectively). All of the numbers of TNC, CD34+ cells, total CFU, CFU-GEMM, and CFU-GM in CB from segments showed significant correlations with the respective parameters in CB from main bags. While a significant correlation was observed between the viability of TNCs in the two parts of the CB units, no correlation was observed between the viability of CD34+ cells in the two parts of the CB units. There were significant correlations between the proportion of apoptotic TNC and CD34+ cells in the two parts of the CB units.

Summary and Conclusions: CB of segment has higher numbers of CD34+ cells and CFU-GM and lower number of TNC than CB of main bag, although the main bag and segment of cryopreserved CB units are highly correlated with each other. Therefore, it is concluded that CB from segment could serve as a source for quality evaluation of the cryopreserved CB units before HSCT. We expect that the results of our study are useful not only for interpreting the release tests of CB units but also for assisting the selection of high-quality CB units suitable for HSCT.

ANTIFUNGAL PROPHYLAXIS WITH FLUCONAZOLE IN HEMATOPOIETIC STEM CELL TRANSPLANTATION

AJ González[1,*] P Palomo[2], L Gutierrez[2], D Martínez[2], E Arija[2], C Martínez-Múgica[2], AP González[2], S González[2], C Rayón[2], C Vallejo[2]
[1]University Central Hospital of Asturias, Oviedo, Spain, [2]Hematopoietic Transplant Unit, University Central Hospital of Asturias, Oviedo, Spain

Background: Invasive fungal infection (IFI) is a potentially life-threatening complication of patients undergoing hematopoietic stem cell transplantation (HSCT). In several published papers fluconazole (FCN) proved to provide an excellent yeast-active prophylaxis in autologous and low-risk allogeneic HSCT recipients.
Aims: In order to decide if a systematic change to one of the new agents was necessary, we retrospectively analyzed the tolerability, safety and efficiency of primary prophylaxis with FCN in the last HSCT recipients in our center.
Methods: During the period January'08-November'13 we have performed 422 HSCT in 382 pts (217 male, 165 female) with a median age of 50 years (1-73). The patients' baseline diseases were: monoclonal gammapathy (41%), lymphoproliferative disorders (33%), acute myelogenous leukemia/ myelodysplastic syndrome (12%), acute lymphoblastic leukemia (6.5%), chronic myelogenous leukemia/myeloproliferative syndrome (1.5%), and others (6%). Distribution according to type of transplantation was: 278 auto-HSCT cases and 144 allo-HSCT (53% from unrelated donors and 47% from family donors,). A variety of conditionings were employed, 21.5% of which were RIC regimens. All patients with adequate liver function tests (defined as transaminases lower than three times the normal values) received FCN at 400 mg/day (or equivalent doses from children) from the beginning of the conditioning until day +30 (in the auto-HSCT setting) and until day+75 (in allo-HSCTs without prolonged neutropenia [> 2 weeks] or steroid therapy for graft *versus* host disease). The route of administration of FCN was oral or intravenous, depending on availability in each specific moment. In cases with history of proven or probable IFI, antifungal prophylaxis was started with a mould-active drug.
Results: 18 patients (4.2%) with a history of proven or probable IFI received secondary prophylaxis from the begging of the conditioning. In the rest of the cases (404; 95.8%) FCN was administered from the admission as scheduled. Of those, 334 (82.7%) tolerated FCN at 400 mg/day (or equivalent doses from children) during the scheduled period of time. Fifty-five cases (13.6%) presented with mild liver function tests alterations, which were easily overcome by reducing FCN dose to 200 mg/day and/or by discontinuing several doses of the drug. In only 15 cases (3.7%) FCN had to be definitively discontinued due to abnormal liver function tests (attributable or not to the azol), while antifungal prophylaxis was performed with an alternative drug. Peri-transplant mortality occurred in 14 cases (3.3%); causes of death included infections (60%), cardio-vascular complications (26%), and sinusoidal occlusive syndrome (1%), among others. No cases (0%) of invasive yeast infection occurred in our series.
Summary and Conclusions: Our study shows that administration of fluconazole at 400 mg/day (or equivalent doses from children) is a well tolerated, safe, and cost-effective approach for antifungal prophylaxis in autologous and low risk allogeneic and hematopoietic stem cell transplantation.

PB1864

DIFFUSE LARGE B-CELL LYMPHOMA WITH BONE MARROW INVOLVEMENT: RESULT'S OF HIGH-DOSE CHEMOTHERAPY WITH AUTOLOGOUS STEM CELLS TRANSPLANTATION

OA Gavrilina[1,*] NG Gabeeva[1], EE Zvonkov[1], VI Vorobyev[2], EG Gemdjian[2], SK Kravchenko[2], VG Savchenko[2]
[1]High-dose Chemotherapy of lymphomas, [2]National Research Center for Hematology, Moscow, Russian Federation

Background: Bone marrow involvement occurs in 10-20% of cases of diffuse large B-cell lymphoma (DLBCL). DLBCL with bone marrow involvement (DLBCL BM) is characterized by aggressive course and poor response to standard chemotherapy (CT). The worst results were obtained for the group of patients with concordant bone marrow involvement (CBM) 5-year overall survival (OS) rate of less than 10%. Application of the modified NHL-BFM-90 program in treatment of DLBCL BM patients (pts) didn't improve results. In the majority of cases we observed long-term persistence of the tumor clone in the bone marrow according to the study of B-cell clonality in complete regression of the rest of the tumor mass. Data of the efficacy of high-dose sequential chemotherapy (sHDT) with autologous stem cells transplantation (ASCT) to eradicate residual tumor in the bone marrow is limited and contradictory.
Aims: To evaluate the efficacy of the mNHL-BFM-90 program with sHDT and ASCT in the treatment for patients with DLBCL BM.
Methods: Since Feb 2005 18 untreated DLBCL BM pts (the median age was 44 yrs (23-58), the M/F ratio 2,6. IPI: IH 39%, H 61%; bone marrow involvement: concordant 44%, discordant 56%) were enrolled in the mNHL-BFM-90 with sHDT with/without ASCT treatment program. All the patients underwent 6-8 courses of polychemotherapy (PCT): 6 blocks of mNHL-BFM-90 chemotherapy program or 4 blocks of mNHL-BFM-90 chemotherapy program plus sHDT. sHDT was carried out, if complete remission (CR) wasn't achieved after 4 blocks. sHDT scheme included 1 DHAP course and 3 high-dose courses with the hematopoietic stem cells (HSC) mobilization and collection: cyclofosfamide 4 g/m^2 day 1, methotrexate 8 g/m^2 day 15 and vincristine 2 mg day 15, etoposide 500 mg/m^{2}q 12 hrs days 31–34. In cases of sufficient quantity of collected CD34+ cells (≥ 2x10^6/kg), the BEAM conditioning and the ASCT were applied. Due to unsufficient HSC collection, patients completed the therapy after the sHDT or one additional Dexa-BEAM course was carried out. The rates of overall survival (OS) and relapse free survival (RFS) were estimated by using the Kaplan-Meier method. Statistical analysis was done using JMP ver. 10.0 (SAS, Cary, NC).
Results: CR was achieved in all patients except one, who died after 3 PCT courses from infectious complications. Mortality associated with toxicity was 6%. In 7 cases of sufficient quantity of collected CD34+ cells, the BEAM conditioning and the ASCT were applied. The average amount of harvested HSC was 3,7x10^6/kg (range 2-7,2x10^6/kg). There were 2 pts in this group with relapse after 6 and 68 months of remission, with CBM both. Furthermore there was 1 course of Dexa-BEAM was applied in 4 of the 10 patients who did not have the sufficient amount of collected HSC after induction therapy (relapse occurred in 1 patient with DBM after 7 months of remission). In 6 of the 10 patients, where a sufficient number of CD 34 + cells was not collected , the therapy was accomplished after 6-8 courses PCT (recurrence in this group is not). At the median of 49 months (range 5–109) disease free survival was 88%±8%, and the overall survival was 79%±11% (Figure 1). In the group with concordant bone marrow involvement 6 out of 8 patients remission retained, meanwhile the observation time points were from 11 to 77 months.

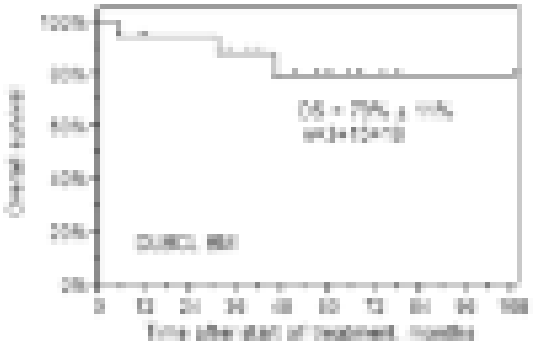

Figure 1. Time after start of treatment, months.

Summary and Conclusions: Bone marrow involvement in patients with DLBCL is an indication for high-dose chemotherapy. Long-term persistence of the tumor clone in the bone marrow necessitates prolonged treatment time. Application of high-dose PCT limited the mobilization and collection of HSC. sHDT with consolidation (ASCT or Dexa-BEAM course) is highly effective in achieving eradication of residual tumor in the bone marrow, after conducting an intensive induction program mNHL-BFM-90. Encouraging results of treatment obtained in the most unfavorable group of patients with DLBCL BM dictate continued research, increasing the number of patients and time of observation.

PB1865

BENDAMUSTINE IN THE TREATMENT OF HEAVILY PRETREATED PATIENTS WITH LYMPHOID MALIGNANCIES RELAPSING AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

A Shimoni[1,*] N Shem-tov[1], I Danylesko[1], A Avigdor[1], R Yerushalmi[1], A Nagler[1]
[1]Division of Hematology and Bone Marrow Transplantation, Chaim Sheba Medical Center, Tel-Hashomer, Israel

Background: Allogeneic stem cell transplantation (alloSCT) is potentially curative therapy in advanced lymphoid malignancies. Relapsed disease is the major cause of treatment failure. Treatment options are limited and prognosis is poor with short survival after relapse. Bendamustine is an effective therapy in various lymphoid malignancies, however, there is no data on the safety and expected outcomes in the treatment of relapsed disease after alloSCT.

Aims: To evaluate the feasibility, safety and outcome following bendamustine in the treatment of relapse of lymphoid malignancies after allogeneic SCT.
Methods: The outcomes of all patients (pts) relapsing after alloSCT and given bendamustine were analyzed retrospectively.
Results: Fourteen pts with lymphoid malignancies were given bendamustine for relapse after alloSCT. The median age at treatment was 52 years (21-69), 7 female, 7 male. Diagnoses included aggressive lymphoma (n=5), follicular lymphoma (n=1), CLL (n=1), mantle cell lymphoma (n=1), Hodgkin lymphoma (n=3), multiple myeloma (n=3). The donor was a matched sibling (n=8), matched unrelated (n=4), haploidentical (n=1) or cord blood (n=1). The conditioning regimen was reduced-intensity in all pts. At the time of alloSCT pts had a median of 3 lines of prior chemotherapy (2-6) including an autologous SCT in 11 pts. Pts relapsed in a median of 13 months (1-48) after SCT. Pts were given a median of 1 line of chemotherapy (0-4) and 5 pts were also given donor lymphocyte infusion (DLI) prior to bendamustine. In all, bendamustine was the median 7th line of therapy (range, 5th-10th). Eight pts had chronic GVHD before starting bendamustine. Bendamustine was started a median of 4 months after relapse (1-51). A median of 2 courses of therapy were given (1-6) at a dose of 50-100 mg/m^{2}x 2 per course either as a single agent (n=6) or combined with rituximab (n=4), bortesomib (n=2) or thalidomide (n=2). The overall response rate was 50%, CR (n=2), PR (n=5). Two of 3 pts converted from PR to CR with DLI given adjacent to response. The median duration of response in the 7 responders was 18 months (5-19). Only 2 of the responders subsequently progressed, 5 and 8 months after treatment, both did not achieve CR with bendamustine alone or following DLI. Responses were seen across all histologies including 3 of 5 pts with aggressive lymphoma, 1/1 in follicular lymphoma, 1/1 in CLL, 1/3 in Hodgkin lymphoma and 1/3 in myeloma. Treatment was relatively well tolerated. Four pts had ≥grade 3 neutropenia and 4 pts had ≥grade 3 thrombocytopenia. One pt died of sepsis and multiorgan failure during neutropenia after the first course. There was no significant effect on GVHD in most pts although one pt had worsening of chronic GVHD during treatment. With a median follow-up of 18 months (2-47), 7 pts are alive and 7 died, 4 of progressive disease, 1 of sepsis and 2 of late unrelated causes more than 1 year after stopping treatment while in CR. The median survival after bendamustine was 18 months and the 2 year overall survival (OS) was 37% (95%CI, 6-67). Median survival was 19 months and 6 months in pts responding and not responding to bendamustine, respectively (p=0.07).
Summary and Conclusions: Bendamustine is relatively well tolerated when given for relapse of lymphoid malignancies after alloSCT in a group of very heavily pre-treated pts. It is associated with a relatively high response rate of 50% and some of the responses are durable. Bendamustine treatment may serve as a bridge to immune therapy with DLI, and possibly may be synergistic with this treatment. These observations merit further study in larger prospective comparative studies.

PB1866

INCREASED PREVALENCE OF METABOLIC SYNDROME AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION

L Roziakova[1,*] M Mistrik[1], M Martisova[1], A Batorova[1], L Setteyova[2], B Mladosievicova[2]
[1]Department of Hematology and Transfusion Medicine, University Hospital, Bratislava, [2]Institute of Pathological Physiology, Comenius University, Bratislava, Slovakia

Background: Hematopoietic stem cell transplantation (HSCT) is widely used in the treatment of malignant and nonmalignant diseases. An increasing number of long-term survivors recover from their primary disease, but they are at risk of adverse late effects, including metabolic syndrome (MS), which seems to be common in long-term survivors of HSCT.
Aims: Our purpose was to determine the prevalence of metabolic syndrome, a clustering of risk factors associated with cardiovascular disease, among adult survivors with a history of allogeneic HSCT.
Methods: We analyzed our data on 74 patients with a median age at transplant of 35 years (12-63 years), who had been followed for a median of 5 years (range 2-23 years) after allogeneic HSCT. Metabolic syndrome was defined according to the National Cholesterol Education Program's Adult Treatment Panel III criteria by the presence of at least three of its five defining characteristics. Body mass index, waist circumference, arterial pressure, and triglycerides, HDL-cholesterol, and glucose levels were recorded at the time of study entry. The Framingham Heart Study's General Cardiovascular Disease (10-year risk) calculator for predicting the risk of cardiovascular disease was used.
Results: The prevalence of metabolic syndrome was 40,5% (95% CI, 27,3% - 57,8%) among HSCT recipients, a 2,02-fold (95% CI, 1,5–2,7, P <0.01) increase compared to the general Slovak population. Metabolic syndrome was more common in men (48,7% *vs* 30%), hormone replacement therapy in females may have influenced their cardiovascular risk. The most common MS features were abdominal obesity (96%), hypertriglyceridemia (70%), and a hypertension (76%). The prevalence of metabolic syndrome was 8,8% in the 20–29 years age group; 26,6% in the 30-39 years age group; 36,8% in the 40-49 years age group; 55,5% in the 50-59 years ager group and 88,8% in the 60-69 years age group. The 10-year cumulative incidence of MS was 32,5%. The most significant risk factor for MS was total body irradiation (P =0.03), positive family history (P=0,04) and age > 40 years at HSCT (P <0,01). Chronic graft-*versus*-host disease, corticosteroid therapy and smoking were not statistically significant. Three patients developed cardiovascular complications (coronary artery disease in 2 cases, myocardial infarction in 1 case). The median (95% confidence interval) 10-year general cardiovascular risk score for males was found to be 9,91% (7,82% - 21,3%) and 4,16% (2,73% - 7,28%) for females. Combination of four-five components were present in 41% of patients with metabolic syndrome.
Summary and Conclusions: We report a high prevalence of metabolic syndrome (40,5%) among adult allogeneic HSCT survivors compared to the general Slovak population. Male survivors of allogeneic HSCT have a long term persisting risk of cardiovascular events. We recommend prolonged follow-up for transplant recipients and appropriate treatment of cardiovascular risk factors such as diabetes, hypertension, and dyslipidemia for all HSCT recipients.

PB1867

POST-TRANSPLANT CYTOMEGALOVIRUS INFECTION IN HEMATOLOGICAL PATIENTS RECEIVING AUTOLOGOUS STEM CELL TRANSPLANTATION: IMPACT OF NOVEL THERAPIES

LM Juárez Salcedo[1,*] I Gutiérrez-Jomarrón[1], J García-Suarez[1], JJ Gil-Fernández[1], E Magro Mazo[1], S Marcellini Antonio[1], C Casco Amarilla[1], MJ Cortti Ferrari[1], Y Martín Guerrero[1], M Callejas Charavia[1], E Flores Ballester[1], I Arribas[2], M López-Rubio[1], MA Calero[1], T Pascual[1], C Burgaleta Alonso de Ozalla[1]
[1]Haematology Department, [2]Principe de Asturias University Hospital, Alcalá de Henares, Spain

Background: Routine monitoring of CMV in haematological patients (HP) undergoing autologous stem cell transplantation (ASCT) is not recommended because the low incidence of clinically relevant CMV infection in this setting. The recent use of novel agents such as Bortezomib and Rituximab in pre-transplant treatment of Multiple Myeloma (MM) and non-Hodgkin lymphoma (NHL) has led to a significantly increased incidence of viral infections. However, few studies have examined the relationship between CMV reactivation and development of complications after ASCT in the era of newer agents.
Aims: The aim of this study was to determine the incidence and clinical impact of post-engraftment CMV reactivations in HP after ASCT at a single institution.
Methods: From 2008 to 2014, 55 consecutive patients underwent ASCT were retrospectively analyzed: 27 MM (all of them received a pre-transplant bortezomib-based regimen), 23 NHL (13 received a pre-transplant Rituximab-based regimen), and 5 acute myeloid leukaemia (AML). The majority (91%) of patients were CMV-positive before ASCT. Routine DNAemia surveillance was performed weekly by PCR assay for at least the first 100 days after transplant. According to local policy, we started oral valganciclovir as pre-emptive therapy in all cases of CMV infection.
Results: Overall, 10 patients (18.2%) developed CMV infection at a median of 27.8 days (range 3 to 44) post-transplant. Patients with MM had a slightly higher CMV infection rate (6 cases; 22.2%) after ASCT than patients with NHL (4 cases; 17.4%) and AML (0%) (Table 1). All 6 patients with MM and CMV infection remained asymptomatic with moderate levels of DNAemia after pre-emptive therapy using oral valganciclovir. Interestingly, among the 4 patients with NHL and CMV infection, 2 patients (both of them had received pre-transplant Rituximab) developed graft failures. Both cases were rescue with hematopoietic growth factors and a second hematopoietic stem cell infusion, respectively.

Table 1. Patient characteristics and incidence of post-ASCT CMV infection.

Summary and Conclusions: 1) Overall, our CMV infection incidence was lower to that reported in the literature (50-60%); 2) but even so, MM patients treated with bortezomib-based regimens are at higher risk of CMV infection after ASCT as compared with other types of treatment (1%); 3) CMV-related graft failure can occur in the rituximab-treated patients; and 4) CMV surveillance strategy should be considered, especially in patients with pre-transplant Rituximab treatment.

PB1868

DEVELOPMENT AND APPLICATION OF A DOSE INDIVIDUALIZATION PLATFORM FOR INTRAVENOUS BUSULFAN IN GREEK HOSPITALS

E Neroutsos[1,*] A Spyridonidis[2], P Tsirigotis[3], A Dokoumetzidis[1], G Valsami[1]
[1]School of Pharmacy, University of Athens, Athens, [2]Medical School, University of Patras, Patras, [3]Department of Internal Medicine, Attikon General University Hospital, Athens, Greece

Background: Busulfan (BU) is widely used as an alternative to total body irradiation (TBI), in the preparative regimens before hematopoietic stem cell transplantation (HSCT). Since the introduction of the i.v. formulation, two dosing schemes have been developed the 0.8 mg/kg every 6 hours for 16 doses that was safer [4] than per os administration and the 3.2 mg/kg once daily for four consecutive days that was the safest. However, both i.v. and oral BU administration present a narrow therapeutic range (TR) and are associated with veno-occlusive disease (VNO) or graft failure. As a consequence they require dose individualization.
Aims: The aim of this study is to develop a BU dose individualization platform applied in two Bone Marrow Transplant Centers (BMTC) as a pilot. The ultimate plan is to form a nationwide network for BU individualization that will include five BMTCs in Greece and a central Pharmacokinetic Center (PKC). The platform consists of a Standard Operating Procedure (SOP) for collecting and handling blood samples at the Hospital site and, a low-cost validated HPLC-UV bio-analytical method for BU measurement and a procedure for dose modification for the PKC.
Methods: A new low-cost HPLC-UV bio-analytical method for BU quantification in small plasma volume was developed and validated. The method was applied to measure BU plasma levels in blood samples taken from 15 patients. Nine were administrated a 3 h i.v infusion of a once daily dose of 3.2 mg/kg of BU (BMCT, Rio General Hospital, University of Patras) and six were administrated a 2 h i.v infusion of a 0.8 mg/kg dose four times daily (BMCT, "ATTIKON" Hospital, University of Athens). Three blood samples were collected from each patient according to a SOP for blood sampling and handling at the hospital site developed within the framework of the proposed BU individualization platform. BU dose was individualized after BU plasma level quantification using AUC (Area under the Plasma Concentration-Time curve) as the PK parameter of choice as indicated by the manufacturer in the SPC of the BU marketed product Busilvex, assuming linear pharmacokinetics and applying the trapezoidal rule.
Results: The HPLC-UV bio-analytical procedure of Bu was developed for small plasma volume. The intra-day accuracy and precision ranged between 90.3-90.6% and 3.9-7.25% respectively, while the inter-day accuracy and precision ranged between 98.2-99.2%, and 1.9-4.0% respectively. The limit of quantification is 40.7±4.00% ng/mL. The SOP procedure describes in detail the blood sampling scheme, sample preparation, storage and the shipment from BMCT to PK center and was deemed necessary to ensure the smooth collaboration of the sites. Two out of the six patients who were administrated 0.8 mg/kg were found above the TR, while out of the nine who were administrated 3.2 mg/kg, 2 were found below the TR and one above the TR. Dose was corrected for all patients found outside the TR and BU plasma levels were measured again after dose correction. All individualized patients were measured within the TR after dose correction
Summary and Conclusions: A BU individualization procedure was developed and applied successfully in two BMTCs. The present study constitutes a pilot study for further application to all five Greek BMTCs one of which is for children. Thus a nationwide network for the individualization of BU will be formed. Further plans are to expand application to oral BU using a Bayesian method with population pharmacokinetic model.

PB1869

SECOND ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION DUE TO GRAFT FAILURE OR HAEMATOLOGICAL MALIGNANCY RELAPSE FOLLOWING THE FIRST STEM CELL TRANSPLANTATION

M López Parra[1,*] O López-Godino[1], M Cabrero[1], R Cabral[2], JM Bastida[1], E Pérez-López[1], AM Redondo[1], L Vázquez[3], FM Sánchez-Guijo[1], L López-Corral[1], C del Cañizo-Roldán[1], D Caballero[1]
[1]Hematology, Hospital Universitario De Salamanca, Salamanca, Spain, [2]Hematology, Hosital Santo Antonio, Oporto, Portugal, [3]Hematology, Hosital Santo Antonio, Salamanca, Spain

Background: Hematological malignancies relapsing after allogeneic hematopoietic stem cell transplant (HSCT) have a poor prognosis. A 2ndHSCT offers an opportunity for cure, but with a high rate of treatment failure and transplant related mortality (TRM). Graft failure is uncommon and can be overcome by additional HSCT, however lack of prospective studies makes difficult to establish basic principles.
Aims: The aim of this study is to analyse the outcome of these patients to identify factor predicting survival.
Methods: Between 1996 and 2013, 595 patients have received an allo-HSCT in our center. 32 of them underwent a 2nd allo-HSCT due to hematological disease relapse or graft failure. Statistical analysis was performed with SPSS v.20.
Results: Median age at 2nd HSCT was 39 years (range 14–65). Transplant was performed due to disease relapse in 28 cases (47% AML/MDS, 29%ALL, 3%MCL, 3%CLL, 3% NHL and 3%MM), and graft failure in 4 (3% ALL, 3% AML and 6% aplastic anaemia). Median time between 1st and 2ndHSCT was 13 months (1-72). In the group transplanted due to relapse, 92% patients received chemotherapy (alone or plus radiotherapy and/or donor lymphocytic infusion). Disease status includes complete remission (CR) in 41% of patients (22%: positive residual minimal disease –RMD-), active disease in 30% and with aplastic bone marrow in 26%. Overall, 65% patients had active disease at the 2ndHSCT (morphological evidence or positive RMD). Same donor was employed in 44% (72% sibling donor). Conditioning regimen was myeloablative in 37%. 97% received peripheral blood progenitor stem cells. Graf-*versus*-host disease prophylaxis in 2ndHSCT was cyclosporine alone (13%) or plus MMF (6%) or methotrexate (32%); or tacrolimus (plus rapamicine 16% or methotrexate 6% or MMF 3%). Incidence of acute and chronic graft-*versus*-host disease (aGVHD/cGVHD) was 59% (18% III-IV) and 47% (6% severe). 44% of cases had cytomegalovirus reactivation (CMV), 28% fungal infection (FI), 6% microangiopathy (TMA) and 13% veno-occlusive disease (VOD). With a median follow-up of 53 months (1-111), estimated overall survival (OS) and progression free survival (PFS) at 6 months, 1 year and 5-10 years was 52%, 32% and 21%, and 33%, 23% and 18%. All except 1 alive patients remain in CR. Estimated TRM is 20%, and TRM at day +100 is 6%. The main cause of death was progression disease (n=18). Factors significantly associated with a better OS were: graft failure as cause of 2ndHSCT (not reached *vs* 6 months; p=0.00), not active disease (23 *vs* 5 months; p=0.03), no development of FI (11 *vs* 4 months; p=0.00) or TAM (7*vs* 2 months; p=0.05), development of cGVHD (28 *vs* 7 months; p=0.043) and achieving CR as best response (8 *vs* <1month; p=0.00). No development of aGVHD in the 1stHSCT was the only factor associated with present cGVHD at the 2ndHSCT. A better PFS was associated with: not active disease (16 *vs* 4 months; p=0,015), no FI (6 *vs* 2 months; p=0.09) and achieve CR (5 *vs* <1 month; p=0.00). Considering only patients transplanted due to relapse, they had better OS and PFS when the interval higher than 1 year from 1st to 2nd HSCT (7 *vs* 2; and 5 *vs* <1 month p=0.00).
Summary and Conclusions: Patients with graft failure should be considered for a 2nd HSCT. In relapsing diseases, although TRM is acceptable, most of the patients will die due to disease. New agents improving quality of remission before transplant and perhaps maintenance after the transplant are needed.

PB1870

LIVER IRON CONCENTRATION AND STIFFNESS AND ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION OUTCOMES

V Pinto[1,*] M Balocco[1], L Bacigalupo[2], M Puntoni[1], C Di Grazia[3], A Dominietto[3], MT Van Lint[3], S Bregante[3], A Bacigalupo[3], GL Forni[1]
[1]Haematology, [2]Radiology, Ospedale Galliera, Genova, [3]Haematology, Ospedale San Martino, Genova, Italy

Background: Elevated ferritin levels were reported associated to adverse outcomes following hematopoietic cell transplantation (HCT). It is not clear if elevated ferritin level is cause of iron overload or infectious or inflammatory concomitant diseases.
Aims: To better clarify the role of iron overload in the outcome of the HSC we designed a study where we measured Liver Iron Concentration (LIC) and Liver Stiffness (LS) by non invasive methods, in patients underwent allogeneic HCT
Methods: We evaluated the LIC and LS in 52 patients who underwent an HCT, because of haematologic malignancies.The patients (pts) had a serum ferritin (SF) level > 500ng/ml or received transfusion therapy with more than 20 U of RBC. LIC was assessed by MRI-T2* or Magnetic Iron Detector (MID). LS was assessed by Fibroscan® and converted in Metavir hepatic fibrosis score. Patients were followed for 3 years after transplantation.
Results: Median age was 40 yrs (range:14-71), 1 pts resulted not iron overloaded (LIC <2.5 mg/g). Among patients with iron overload, median LIC was 7 mg/g (interquartile range, IQR: 4.8-11.0), 37 patients (73%) had mild LIC (2.5-12mg/g), 14 patients (27%) had severe LIC (>12mg/g). Metavir was assessed in 42 pts and score resulted F0 in 13 pts, F1 in 20 pts, F2 in 2 pts, F3 in 4 pts, F4 in 3 pts. Median ferritin level was 2209 ng/ml (IQR: 1159-4114). No statistical significant associations were found between the level of LIC and survival, probability of organ failure, acute or chronic GVHD. A positive statistical significant relationship between LS and the presence/degree of GVHD was found, both using the Metavir categorical score (p=0.002) and the liver stiffness continuous measurement (p=0.03); this association was confirmed in a multivariate logistic model, adjusting for age and sex. The levels of LIC, LS and ferritin were not correlated (pairwise Spearman's rho p≥0.3).
Summary and Conclusions: Level of Iron overload does not play a role in the outcome of HCT. Degree of Stiffness is associated with the presence and degree of GVHD

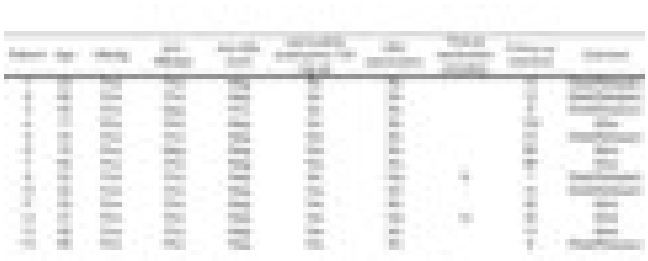
PB1871

A LONG-TERM FOLLOW-UP STUDY ON HEPATITIS B SURFACE ANTIGEN POSITIVE PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION

S Ongoren Aydin[1,*] FF Yalniz[1], T Elverdi[1], A Murt[2], A Salihoglu[1], E Eskazan[1], C Ar[1], Z Baslar[1], Y Aydin[1], T Soysal[1]
[1]Hematology, [2]Internal Medicine, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Hepatitis B virus (HBV) infection is one of the most common viral infections worldwide. Reactivation or exacerbation of HBV infection is a serious and potentially fatal complication of immunosuppression. Amongst hematology patients with past exposure to HBV, patients who have received high dose chemotherapy or immunosuppressive therapy can develop HBV reactivation during and after having applied the therapy. Various retrospective studies have identified that patients receiving hematopoietic stem cell transplantation are at a particularly high risk of reactivation.
Aims: The aim of this study is to evaluate the hepatic events and HBV reactivation among HBsAg positive patients undergoing stem cell transplantation.
Methods: Over a twenty year period time (1993-2013), total number of patients who received hematopoietic stem cell transplantation is 398, at Istanbul University Cerrahpasa Medical Faculty. Of those 398, 42 were allogenic and 356 were autologous. The median age at transplantation was 38 years (ranging between 15 and 65). Twenty out of 398 transplant recipients showed active Hepatitis B infection at baseline (HBsAg positivity). 6 out of 20 received allogenic and remaining 14 underwent autologous stem cell transplantation.
Results: The prevalance of HBsAg positivity was 5.02% of total number of our patient population which is 20. HBV reactivation was detected in 3 patients.
Among allogenic transplant recipients, 4 of them received lamivudine propylaxis during and after transplantation process. One patient had HBV reactivation, six months after the transplantation. This patient did not receive lamivudine and died soon due to the fulminant liver failure. 9 out of 14 HBsAg positive autologous transplant recipients, lamivudine propylaxis has been given. HBV reactivated in 2 of those receipients; at 6 and 12 months following the transplantation. One of them died one month later due to septic shock, other one is still alive even 36 months after transplantation. Remaining allogenic and autologous transplant recipients neither experienced major hepatic event nor HBV reactivation (Tables 1 and 2).

Tablel 1. Clinical details of hepatitis B surface antigene postive autologus transplant recipients.



Tablel 2. Clinical details of hepatitis B surface antigene postive allogenic transplant recipients.

Summary and Conclusions: The risk of fatal HBV liver disease among patients who are persistently HBsAg positive after transplantation is approximately 12% according to the literature. While transplantation is frequently avoided or delayed in candidates with abnormal serum aminotransferases, a finding of positive Hepatitis B surface antigen (HBsAg) alone is not considered a contraindication and does not confer an increased risk for VOD. Even in patients with very low levels of viral replication before transplantation and relatively normal liver function and histology, the impaired cellular immunity seen in the first 3 to 6 months after transplantation can result in HBV reactivation. Our retrospective analysis present an experience from a hepatitis prevalence high country. However, definitive conclusions cannot be drawn from these results beyond recommendations to monitor all hepatitis carrier status hematopoietic transplant recipients closely until full immune reconstitution has been established.

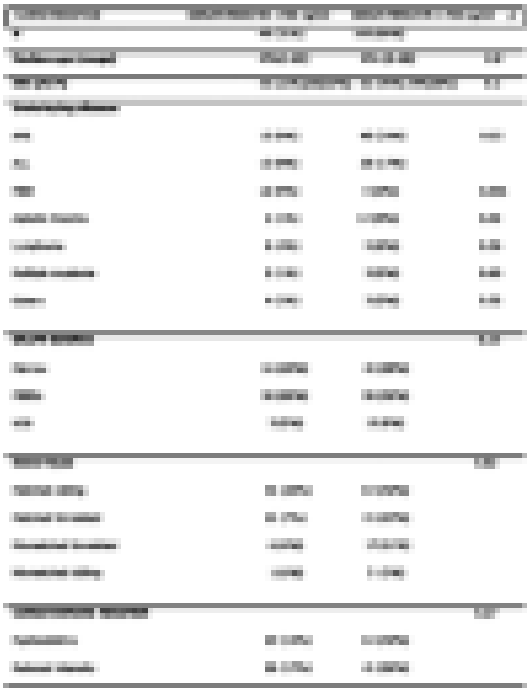
PB1872

IS USEFUL TO DETERMINE PRE-TRANSPLANT SERUM FERRITIN LEVELS IN HSCT?

E García-Torres[1,*] D Buenasmañanas[1], C Chic[1], MJ Llamas[1], C Martin[1], R Rojas[1]
[1]Hematology, Reina Sofía University Hospital, Córdoba, Spain

Background: Serum ferritin is an iron overload marker and an acute phase reactant. Several studies have reported associations between elevated ferritin levels and adverse outcomes following allogeneic Hematopoietic Stem Cell Transplantation (HSCT). It is unclear whether the association of elevated ferritin with adverse survival is primarily due to iron overload or to the presence of other infectious or inflamatory conditions in which ferritin might act as an indicator.
Aims: The aim of our study was to analyze retrospectively the pre-transplant serum ferritin levels in patients undergone allogeneic HSCT in our Hospital from 2005 to 2013. Patients were clasificated according to serum ferritin (< and >700 ng/ml) and they were compared to: overall survival, acute and chronic GVHD, infections (bacterial, fungal and cytomegalovirus), mucositis, interstitial pneumonitis, hepatic veno-oclussive disease, relapse, TRM-100 days and TRM-1 year.

Table 1. Patient demographics and transplant characteristics.



Methods: We have retrospectively analyzed the pre-transplant serum ferritin levels in 154 consecutive patients undergone allogeneic HSCT in our Hospital from January 2005 to October 2013. Patients were classified according to serum ferritin (< and >700 ng/ml) and we have analyzed: overall survival, acute and chronic GVHD, infections (bacterial, fungal and cytomegalovirus), mucositis, interstitial pneumonitis, hepatic veno-oclussive disease, relapse, TRM-100 days and TRM-1 year. Statistical analysis was performed using the SPSS 17.1 program.
Results: The baseline characteristics of these patients are shown in Table 1. In our series 154 patients were undergoing allogeneic HSCT (44% Reduced Intensity Conditioning regimen). The median follow up was 30 months (0-86), and the overall survival was 61±4% at 7 years (<700 ng/ml: 65±7% and >700 ng/ml 60±5%). TRM-100 days was 5% (4 patients in the >700 ng/ml group and 4 patients in the <700 ng/ml group. Mean pretransplant ferritin in the global series was 1114 ng/ml (range: 6-13080). Among patients with ferritin >700 ng/ml (105 patients) the mean ferritin was 1554 (704-13080) and <700 ng/ml (49 In patients with pre-HSCT ferritin levels >700 ng/ml we observed more incidence of infections (gram+ bacteremia: n=82 *vs* n=25 (p=0.001) and fungal infections: n=15 (10%) *Vs* n=0 (0%) (p=0.002). Serum ferritin levels >700 ng/ml were

associated with higher incidence of aGVHD N=33 *Vs* n=4 (p=0.001), mainly intestinal aGHVD grade 3-4 13% (n=20) *Vs* 1% (n=2), p=0.001 and higher incidence of chronic GVHD moderate-severe 16% (n=25) *Vs* 4% (n=6) (p=0.035). TRM-1 year was 8% (13 patients) and 4% (6 patients) in the > and<700 ng/ml group respectively. In the group with ferritin >700 ng/ml the TRM-1 year was due to infection (4.5%), GVHD (3%) and others (1.2%). In the group with ferritin <700 ng/ml the TRM-1 year was due to GVHD (2%), infection (1.2%), and others (0.6%). There were no differences in the 1-year probability of overall survival, higher TRM-1year, probability of relapse, Cytomegalovirus infection, mucositis, interstitial pneumonitis and hepatic veno-oclussive disease between goups with serum ferritin levels > or <700 ng/ml. In multivariate analyses, the serum ferritin did not impact risk of overall mortality (p=0.2).

Summary and Conclusions: The cut-off of serum ferritin > 700 ng/ml pre-HSCT is correlated with higher incidence of aGVHD grade III-IV, chronic GVHD moderate-severe and some types of infections, however we found no association between high ferritin levels and allogeneic HSCT outcomes. Future studies should use liver iron content to define iron overload instead of ferritin in this patients.

PB1873

DONOR'S CMV SEROPOSITIVITE, OLDER AGE, AND FEMALE GENDER FOR MALE PATIENT BUT NOT ABO GROUP NEGATIVELY INFLUENCED ON SURVIVAL OF ALLOGENEIC STEM CELL TRANSPLANT RECIPIENTS

AJ González[1,*] P Martínez[2], L Gutierrez[1], P Palomo[1], E Arija[1], D Martínez[1], AP González[1], S González[1], C Rayón[1], C Vallejo[1]
[1]Hematopoietic Transplant Unit, University Central Hospital of Asturias, [2]University of Oviedo, Oviedo, Spain

Background: Allogeneic hematopoietic stem cell transplant (allo-HSCT) is a potentially curative therapeutic approach for a number of malignant and non malignant disorders. When several comparably HLA-matched family or unrelated candidates are available, various criteria can be used to select a donor.

Aims: The aim of our study was to determine the influence of some of the donor characteristics (gender, age, CMV serologic status, ABO group) on the short and long term outcome of our patients undergoing allo-HSCT.

Methods: We retrospectively analyzed data from 212 patients who consecutively underwent allo-HSCT in our Unit. One hundred and twenty-nine patients were male (60.8%) and 83 female (39.2%). Median age of patients was 46 years old (range: 2-65). 62.3% of patients were CMV sero-positive and 37.7% were sero-negative. Baseline disease was: acute myelogenous leukemia/myelodysplastic syndrome (36.8%), lympho-proliferative disorder (18.4%), monoclonal gammapathy (16.5%), acute lymphoblastic leukemia (15.6%), aplastic anemia (5.7%), chronic myelogenous leukemia (4,2%), and others (2.8%). 64.2% of the allo-HSCTs were from a family donor and 35.8% from an unrelated donor. The SC source was PBSC in 50%, BM in 44.3%, and UCB in 5.7%. A variety of conditioning regimens were employed. Gender of donors was: 117 male (55.2%) and 95 female (44.8%). Median age of donors was 40 years old (range: 6-79). 47.6% of donors were CMV sero-positive and 52.4% were sero-negative. Patient-donor ABO group were major mismatched in 27.4%, minor mismatched in 15.6%, and matched in 57.0%. We investigated the impact of characteristics of the donor on transplant (HSCT-OS), day +100 (d+100-OS) and 1 year overall survival (1y-OS).

Results: CMV- patient/CMV+ donor, male patient/female donor, and older donor were adverse factors for the patients outcome, as shown in the attached Table 1. On the other hand, ABO group mismatched did not affect patients OS (major ABO incompatibility *vs* rest: HSCT-OS= 89.7% *vs* 90.9%; d+100-OS= 87.9% *vs* 84.4%, and 1 y-OS= 70.7% *vs* 63.0%; p=ns).

Table 1.

Summary and Conclusions: Our study shows that, when several comparably HLA-matched donors are available, the selection of CMV negative donors for CMV negative patients, male donors for male patients, and younger donors is an important decision for the patients' short and long term survival. Contrarily, the ABO incompatibility does not seem to be a major factor with regard to the patients outcome.

PB1874

T-LARGE GRANULAR LYMPHOCYTE PROLIFERATIONS IN PATIENTS WITH RITUXIMAB-RELATED LATE-ONSET NEUTROPENIA AFTER AUTOLOGOUS HEMATOPOIETIC CELL TRANSPLANTATION FOR LYMPHOMA: POSSIBLE PATHOGENETIC MECHANISMS

A Papalexandri[1,*] M Iskas[1], K Kotta[1], V Tachynopoulou[1], I Batsis[1], T Papadaki[2], K Stamatopoulos[3], I Sakellari[1], A Anagnostopoulos[1]
[1]Hematology Department and HCT Unit, G.Papanicolaou Hospital, Thessaloniki, [2]Hematopathology Department, Evangelismos Hospital, Athens, [3]Institute of Applied Biosciences, Center for Research and Technology Hellas, Thessaloniki, Greece

Background: Late-onset neutropenia (LON), an increasingly recognized adverse event of immunotherapy with the anti-CD20 monoclonal antibody Rituximab (R), is currently considered to be an immune-mediated process. Studies from our group have linked R-LON to the outgrowth of cytotoxic T-cell expansions, in particular with a phenotype of a T-large granular lymphocytes (LGL) *i.e.* $CD3^+CD8^+CD57^+$. R-LON develops frequently in patients with non-Hodgkin's lymphoma (NHL) after autologous hematopoietic cell transplantation (AHCT).

Aims: We report 7 patients with NHL presenting with R-LON after auto-HCT in a context of $CD3^+CD8^+CD57^+$ T-LGL lymphoproliferation and explore the possible implication of auto-immune myelosupression by Rituximab.

Methods: These patients concerned 4 males and 3 females, aged 36-58 years, suffering from mantle-cell lymphoma (n=4), follicular lymphoma (n=2) and diffuse large B-cell lymphoma (n=1) who received 5-10 cycles of Rituximab (median 7)±chemotherapy and underwent auto-HCT for either consolidation (n=4) or salvage for relapsed/refractory lymphoma (n=3).

Results: LON grade II-III (median ANC: $0.8x10^9$/l, 0.44-1.05) was observed at a median of 82 days (range, 34-370) after the last Rituximab administration. Two patients received Rituximab pre-HCT and R-LON was documented after engraftment; 5/7 patients developed neutropenia after maintenance with Rituximab for relapsed disease. Neutropenia developed at a median of 266 days (24-1112) after AHCT. R-LON persisted uncomplicated for median 185 days (42-560). Lymphocyte subpopulation analysis during neutropenia revealed (i) T4/T8 ratio<0.7, ii) increased (>1000/μl) T8 lymphocytes [5/7 patients, (mean: 1352/μl, median: 1177/μl)], (iii) increased (>20%) +CD3+CD8+CD57 lymhocytes. T-LGL hyperplasia was present before AHCT in two patients and persisted over 6 months after neutropenia resolution in 4/4 patients. In all patients, T-LGL proliferation was documented long after immune recovery (median 557 days, range: 189-1612). Bone marrow biopsy examination in 6/7 patients revealed: (i) small-to-moderate $CD20^-CD79a^-CD3^+CD45RO^+CD43^+$ (CD3>CD45RO) small lymphocytic infiltration in 3/6 patients; (ii) hypo- or hyperplasia with shift-to-the-left of the granulocytic series in 3/6 patients; and, (iii) pronounced hyperplasia of the erythroid and megakaryocytic series with prominent dyserythropoiesis and dysmegakaryopoiesis, respectively, including abnormal paratrabecular localization, suggestive of myelodysplasia (MDS), however, always with <2% CD34+ cells.

Summary and Conclusions: In conclusion, Rituximab administration in NHL patients undergoing AHCT can be accompanied by lymphocyte imbalances and T-LGL cytotoxic proliferations with variable impact on the hematopoietic marrow. In such cases, neutropenia probably represents the end of a spectrum of T-LGL-mediated autoimmune myelopathy. Further studies are required in order to explore possible implications for the recovery of T-cell compartment in R-LON after AHCT.

PB1875

MAJOR AND BIDIRECTIONAL ABO INCOMPATIBILITY POST ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: PURE RED CELL APLASIA AND TRANSPLANT OUTCOME

D Mallouri[1,*] I Sakellari[1], Z Bousiou[1], E Abela[1], C Apostolou[1], E Yannaki[1], I Batsis[1], C Smias[1], D Sotiropoulos[1], M Ganidou[2], G Bamihas[3], A Anagnostopoulos[1]
[1]Haematology department - BMT unit, [2]Blood Transfusion Service, [3]Nephrology department, George Papanicolaou Hospital, Thessaloniki, Greece

Background: Approximately 50% of allogeneic hematopoietic cell transplantations (alloHCT) are performed across the ABO system barrier and delayed red blood cells (RBC) engraftment and pure red cell aplasia (PRCA) complicates some, not all of the recipients (6-30%) with major and bidirectional ABO-incompatible transplants. The correlation with the transplant outcome concerning overall survival (OS), graft-*versus*-host disease (GVHD), treatment-related mortality (TRM) and relapse rate (RR) is still a subject of debate.

Aims: The aim of the study was to evaluate the incidence and outcome of delayed RBC engraftment and PRCA, correlation with possible risk factors and the transplant outcome of the pts.

Methods: We retrospectively analyzed the data of all consecutive patients (pts) who underwent an alloHCT during 2001-2011 from major and bidirectional ABO-incompatible donors.

Seventy four alloHCTs were performed in 72 pts suffering from myeloid (34), lymphoid (36) malignancies and aplastic anemia (2). The pts received grafts from major (57) and bidirectional (17) ABO incompatible donors, siblings in 45, not related (MUD) in 27 and double cord blood units in 2 pts, following a myeloablative (MA, 57) and non-myeloablative (NMA, 17) conditioning regimen.
Results: A total of 17 (22.9%) pts were diagnosed with either delayed RBC engraftment (4/17) or PRCA (13/17) with a median of 2 (0-13)% of erythroid precursors in bone marrow after a median time of 31 (20-95) days post alloHCT. The complication was not correlated with granulocyte (p=0.6) or platelet (p=0.1) engraftment delay, the type of donor (sibling *vs* MUD, p= 0.3) or the intensity of the conditioning regimen (MA *vs* NMA, p=0.5). All pts were initially treated with erythropoietin and 10 of them responded. The rest of them (7) were given additionally steroids but this was successful in only one pt. Finally, 6 pts with refractory PRCA were treated with plasmapheresis and all of them responded post 6 (5-11) sessions. None of them experienced a PRCA relapse until last follow-up. With a median follow-up of 33 (1-117) months, the transplant outcome was not found to be significantly different between the delayed red cell engraftment/PRCA pts group and the pts not experiencing red blood cell line delay reconstitution (control group). The primary disease RR was 23% for the PRCA pts group *vs.* 33% for the control group (p=0.4), OS was 64.3% *vs.* 40.4% (p=0.28) and TRM was 23.5% *vs.* 32.7% (p=0.18) respectively. Moreover, the incidence and severity of acute and chronic GVHD was not different in the two study groups (47.16% *vs.* 44.4%; p=0.85 and 70.6% *vs.* 72.7%; p= 0,545, respectively.
Summary and Conclusions: Conclusively in our study, delayed red cell engraftment and PRCA, accounted for 22.9% of ABO major and bidirectional incompatible alloHCT, was successfully treated with erythropoietin and plasmapheresis in refractory cases. It seems that occurrence is not related to the type of transplantation and is not affecting overall survival, TRM, RR or the incidence and severity of GVHD.

PB1876

OUTCOMES OF ESHAP (+/-RITUXIMAB) AS SALVAGE CHEMOTHERAPY FOR RELAPSED OR REFRACTORY NON-HODGKIN'S LYMPHOMA FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANTATION

M Alpoim[1],* M Badior[1], R Pinto[1], A Carneiro[1], F Príncipe[1], JE Guimarães[1]
[1]Hematology Department, Centro Hospitalar de São João, Porto, Portugal

Background: High dose chemotherapy followed by autologous stem cell transplantation (ASCT) is the gold standard treatment for patients with relapsed/refractory Non-Hodgkin's Lymphoma (NHL). Remission status at time of transplant is a significant prognostic factor because patients who do not achieve chemosensitivity after salvage therapy have a poor outcome after ASCT. An optimal salvage therapy should combine therapeutic activity without compromising stem cell mobilization potential and currently there is no proven standard for salvage chemotherapy regimen.
Aims: To analyse the outcomes of ESHAP (+/-Rituximab) as salvage chemotherapy for relapsed or refractory Non-Hodgkin's Lymphoma followed by autologous stem cell transplantation.
Methods: We have retrospectively analyzed the outcomes of 59 patients with relapsed/refractory NHL treated with ESHAP (Etoposide, methylprednisolone, cytarabine and cisplatin) as salvage chemotherapy with intent of receiving an ASCT, admitted to our department from 2002 to 2012.
Results: Median age was 54 (14-69) years. The majority (64.4%; n=38) of the patients had diffuse B cell lymphoma and 45 (84.9%) patients presented stage III-IV disease at time of diagnosis. Overall response rate (ORR) to ESHAP therapy was 72.9%, with 19 (32.2%) patients achieving complete remission (CR) and 24 (40.7%) partial remission (PR) before ASCT. Fifty-three patients (89.8%) have mobilized enough peripheral blood stem cells (PBPC's) for at least one ASCT. Median yield of CD34 collected was 3.12 x 10^6/Kg (0.7 – 15.9). Eight patients (13.6%) died during ESHAP therapy, 7 of progressive disease and one of cerebral haemorrhage. Thirty-four (57.6%) patients have received ESHAP plus Rituximab (R-ESHAP), while 11 (18.6%) did not received Rituximab at any time of the disease. Moreover, 6 patients (10.1%) who have not been exposed to Rituximab with first line chemotherapy received R-ESHAP and 14 (23.7%) patients who have received Rituximab upfront did ESHAP without Rituximab as salvage therapy. Overall response rate for R-ESHAP *vs.* ESHAP was 88.8% *vs.* 52%, respectively (p=.002). Median follow-up post ASCT was 30 months (1-120), the 3-year overall survival (OS) for the all cohort was 76.3% (+/-6.3%) and 3-year progression free survival was 63.3% (+/-7.2%). On univariate analysis, patients with chemosensitive response to ESHAP (+/-R) (3-year OS of chemosensitive *vs.* refractory disease was 86.3% *vs.* 25%, respectively, p<.0001) and patients who have received R-ESHAP (3-year OS R-ESHAP *vs.* ESHAP was 84.7% *vs.* 62.3%, respectively, p=.025) had superior overall survival. Age at transplant, type of NHL, stage at diagnosis and CR *vs.* PR to ESHAP (+/-R) did not had impact on OS.
Summary and Conclusions: Overall, ESHAP (+/-R) as salvage chemotherapy was well tolerated and had an adequate ORR without compromising PBPC's collection. Remission status at time of transplant had a significant impact on survival and it seems that the use of R-ESHAP as opposed to ESHAP increases the probability of having any form of response to salvage chemotherapy which subsequently increases the OS post autologous stem cell transplant.

PB1877

TREOSULFAN-FLUDARABINE-THIOTEPA COMBINATION AS PREPARATIVE REGIMEN FOR ALLOGENEIC HEMOPOIETIC STEM CELL TRANSPLANTATION IN HIGH RISK LYMPHOPROLIFERATIVE DISEASE PATIENTS

D Baronciani[1],* D Cristina[1], T Clara[1], SV Usai[1], F Pilo[1], D Derudas[1], F Culurgioni[1], D Pulisci[1], I Tandurella[1], E Angelucci[1]
[1]UO Ematologia e CTMO, Ospedale Oncologico "A. Businco", Cagliari, Italy

Background: Reduced-intensity conditioning regimens for allogeneic HSCT are accepted treatments for high risk patients non fitting criteria for an ablative approach. Many drugs have been tested to find less toxic but effective preparations. The association Treosulfan-Fludarabine demonstrated to be well tolerated and myeloablative but partially effective due to high relapse risk. To increase the anti-tumor activity we added Thiotepa to the Treosulfan-Fludarabine regimen in a subset of patients with advanced lymphoproliferative disease.
Aims: Primary objective was to evaluate regimen safety and feasibility, secondary objective was evaluation of OS, DFS, TRM and relapse rate.
Methods: Since November 2006 to February 2014, 28 consecutive patients (18 males,10 females) entered the study. Median age was 43 years (range 19-60). Underlying diseases were: NHL(15), HL (8) , Acute Biphenotypic Leukemia (1), Acute Ph+ Lymphoblastic Leukemia (1),CLL (2), Burkitt Lymphoma (1) . All but one patients were heavily pre-treated (19 had received previous autologous transplant). Four (4) had presented severe clinical problems in their medical history: 1 pulmonary Aspergillosis, 1 brain tumour, 1 HCV hepatitis , 1 renal failure with dialysis during the induction therapy. Only 1 patient was in 1st complete remission; 15 were in 2nd or subsequent CR, 2 in PR , and 10 in resistant or progressive disease .Mean HCT-CI was 1 according to the Seattle criteria. Conditioning consisted of Treosulfan 14 gr/m^2 for 3 days, Fludarabine 30 mg /m^2 for 5 days and Thiotepa 10 mg /Kg single day. CSA+short MTX were used as GVHD prophylaxis and anti-Lymphocyte globulins (Thymoglobulin® or ATG Fresenius®) were used in case of MUD transplants. Fifteen (15) patients received HSC from HLA identical siblings and 13 from match unrelated donors. Source of stem cells was bone marrow in 8 patients and peripheral blood stem cells in 20 patients.
Results: Twenty-six (26) patients (93%) regularly engrafted. In two patients engraftment was not evaluable because of early (before day 20) septic death. Five (5) patients experienced grade 3-4 GI toxicity (4 mucositis , 1 GI bleeding), 1 patient had grade 1 renal toxicity, 1 patient presented grade 4 CNS toxicity , 2 patients had grade 2 skin toxicity. Thirteen (13) patients presented grade 1-2 acute GvHD , 1 grade 4. CrGvHD occurred in 8/22 evaluable patients (extended in 1). Eighteen (18) patients are alive (64%), 17 in complete remission, with a median follow-up of 30 months (range 2-86 months). Ten (10) patients died (36%): 4 by recurrent disease and 6 by TRM.
Summary and Conclusions: This single Centre report, even if with the limited number of patients, underlines that the association Treosulfan-Fludarabine-Thiotepa can be safely used for allogeneic conditioning regimen in very heavily pre-treated patients with advanced lymphoproliferative disease. Engraftment is regular and sustained. Post-transplant toxicity is acceptable. The role of Thiotepa seems important in increasing the anti-tumour effect in this reduced toxicity regimen. Further prospective, randomized, larger studies are warranted.

PB1878

PRIOR MD-ARAC CHEMOTHERAPY AFFECTING PERIPHERAL BLOOD HEMATOPOIETIC STEM CELL MOBILIZATION IN AML

R Feng[1],* M Xie[1], X Wei[1], H Jing[1], M Dai[1], Y Zhang[1]
[1]Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, 510515,China, Guangzhou, China

Background: Prior chemotherapy had been reported to affect the efficiency of peripheral blood stem cell (PBSC) mobilization. As one of the major chemotherapeutic drugs for AML, the impact of cytarabine on mobilization remains unknown.Herein, weretrospectively ananlyzed AML patients performed PBSCs apheresis to explore the relation between prior medium-dose cytarabine(MD- AraC) chemotherapy and mobilization.
Aims: To explore the relation between prior MD-AraC chemotherapy and PBSC mobilization.
Methods: We retrospectively analyzed 90 patients with de novo AML, underwent mobilization inthe haematology department of Nanfang hospital from August 1999 and November 2012. Median age at mobilizaton was 38 years(range, 12-60 years). Before mobiliazation, all patients had received various chemotherapeutic regimens, including induction and consolidation or intensive chemotherapies. According to the course of MD-AraC chemotherapy,

patients were divided into group I, II,III. With a complete response, patients received the same mobilization regimen, EA (cytarabine 1.0g in IV, every 12 hours × 3 ~5days; etoposide 0.1~0.2g in IV, every 12 hours × 3~5 days) chemotherapy combined granulocyte-colony stimulating factor(G-CSF)5~10ug/kg/d. G-CSF starting after completion of chemotherapy 4 to 5 days when WBC down to the bottom until the end of thecollection. Apheresis was scheduled to start when the WBC count recovered ≥4.0 × 109/L or the CD34 cells ≥ 0.01% WBC of PB.After24~48h following high-dose conditioning regimens (mostly busulfan/cyclophosphamide) ,grafts were infused. The efficacy ofPBSC mobilization, hematopoietic reconstitution, survival rates were assessed for each AraC group.

Results: The median doses of CD34 cell in those three AraC groups were 4.7×106/Kg, 2.8×106/Kg, 2.2×106/Kg, respectively(P=0.006). In addition, patients collected ≥2.0×106/kg numbers of CD34 cells in groups I need the lowest leukapheresis, total bloodvolume processed, G-CSF total dose and days(P<0.05). A significantly greater proportion of good mobilization (≥2.0×106 CD34cells/kg with at most 3 leukapheresis procedures) in the group I (39/46, 84.8%) compared with the group II (13/22, 59.1%) and groupIII (10/19, 52.6%) ($\chi 2$=8.918, P=0.012). The sex, age, cytogenetic risk, the pior chemotherapy courses, the prior courses of the variouschemotherapeutic agent drugs except MD-AraC did not correlate with mobilization response. Multivariate analysis revealed thecourse of prior MD-AraC chemotherapy was an independent predictive factor for HSC mobilization[OR 0.627, 95% CI 0.421-0.935,P=0.022]. However, the MD-AraC chemotherapy has no effect on hematopoietic reconstitution and survival in AML patients treated with auto-HSCT(Figure1).

Figure 1. OS and RFS. A) Predicted 3-year OS was 72.3% for the group I, 82.9% for the group II, and 82.3% for the group III (P=0.803). B) Predicted 3-year RFS as 60.1% for the group I, 72.1% for the group II, and 64.8% for the group III (P=0.743).

Summary and Conclusions: Exposuring to the bone marrow toxic drugs is the major factor negatively effected mobilization, there mitoxantrone,fludarabine, lenalidomide, platinum, alkylating agent, carmustine, nucleoside analogue, melphalan were reported. As in previousstudies, prior exposure to MD-AraC also was an independent negative predictor for mobilization and without survival benefit. Theconventional chemotherapy not accurately presented a significant influence in the mobilization in AML. In preparation for Auto-HSCT, MD-AraC must be taken into account.

PB1879

AUTOLOGOUS STEM CELL TRANSPLANTATION UPFRONT IN THE TREATMENT OF PATIENTS WITH AGGRESSIVE B CELL LYMPHOMA: ANALYSIS OF PROGNOSTIC FACTOR FROM A SINGLE INSTITUTION IN JAPAN

A Nakaya[1,*] S Fujita[1], A Satake[1], M Hotta[1], H Yoshimura[1], K Ishii[1], T Ito[1], S Nomura[1]

[1]First Department of Internal Medicine, Division of Hematology and Oncology, Kansai Medical University, Osaka, Japan

Background: The efficacy of autologous stem cell transplantation (auto-SCT) during the first remission in patients with aggressive B cell lymphoma remains to be elucidated. A previous large study found that auto-SCT improved progression free survival (PFS) in aggressive non-Hodgkin's lymphoma patients, but not overall survival (OS). (P.J.Stiff et al, NEJM 2013). Then we need to identify patients who will gain the maximum benefit from auto-SCT in the upfront setting. Also, it is important to establish new prognostic factors to identify the eligible patients. We focused on Glasgow Prognostic Score (GPS) which has been proposed as a powerful prognostic tool for patients with various types of malignant tumors as well as hematologic malignancy. In this study, we evaluated the efficacy regarding auto-SCT for high risk aggressive B cell lymphoma and identified the prognostic factors including GPS for auto-SCT.

Aims: To evaluate significance of auto-SCT for high risk aggressive B cell lymphoma and identify its prognostic factors.

Methods: We retrospectively analyzed 39 patients with high risk aggressive B cell lymphoma who underwent auto-SCT between 2006 and 2012 in Kansai Medical University Hospital. High risk patients were defined as high-intermediate and high risk groups stratified by international prognostic index (IPI). 17 patients received auto-SCT as upfront and 22 patients did as second-line therapy. All patients were treated by rituximab as primary therapy and evaluated by PET-CT scan. The primary endpoints were 3y-OS and PFS.

Results: 3y-OS and 3y-PFS of all patients were 66.7% and 71.8%, respectively. 3y-OS and PFS in upfront group were 94.1% (p=*0.001*) and 88.1% (p=*0.09*). In second-line group, they were 45.5% (p=*0.001*) and 59.1% (p=*0.009*). In multivariate analysis, age (60y/o<) (HR 3.6, p=*0.047*), disease status at auto-SCT (HR 35.3 p=*0.006*), and GPS (HR 8.8, p=*0.047*) were significant predictors for worse 3y-OS and PFS, whereas bone marrow involvement, IPI, and number of prior chemotherapies were not.

Summary and Conclusions: Upfront auto-SCT for high risk aggressive B cell lymphoma appears to be beneficial. Age, disease status, and GPS can predict outcome for auto-SCT. It may be useful to identify the eligible patients using these prognostic factors in undergoing auto-SCT in Rituximab-era.

PB1880

IN SITU INJECTION OF CIK CELLS FOR EXTRAMEDULLARY RELAPSE OF LEUKEMIA AFTER TRANSPLANTATION: A CASE REPORT AND REVIEW OF THE LITERATURE

Q Li[1,*] X Zhu[1], Z Zhong[1], Y You[1], P Zou[1]

[1]Institute of Hematology, Union Hospital, Tongji medical college, Huazhong University of Science and Technology, wuhan, China

Background: Extramedullary leukemia relapse after allogeneic hematopoietic stem cell transplantation (HSCT) remains a formidable obstacle. Most of the patients suffered poor prognosis and eventually developed into bone marrow relapse. Current treatments including reducing and/or withdrawal of immunosuppressants, radiotherapy and chemotherapy did not permit any guarantee of promising effect.

Aims: We here report a patient with acute lymphoblastic leukemia (ALL) who had extramedullary relapse in manner of leukemia cutis 76 days after allogeneic HSCT.

Methods: We gave him chemotherapy with cytarabine 2.0 Q12h, d1-d3; idarubicin 10mg / day, d4-d5 from +85d to +89d. After chemotherapy the subcutaneous masses had transient narrowing but increased in two weeks after withdrawing chemotherapy (+103 d). The needle aspiration biopsy found immature leukemia cells. Then each mass had injection of cytarabine (20mg), but there was no significant improvement, subcutaneous masses still gradually increased. No leukemia cells was observed at 123 days in peripheral blood smears so peripheral blood mononuclear cells began to be collected for cytokine-induced killer cells (CIK) amplification *in vitro* after the informed consent was obtained. On day 137 after HSCT, we gave *in situ* subcutaneous injection into each mass with CIK cells (1ml, cell number was 1.56×10^5 / site).

Results: 4 days after CIK injection, the masses were flattening and gradually disappeared. During treatment the patient was well tolerated and did not re-appear the performance of extramedullary relapse afterward. This is the first case of giving adoptive cell therapy with CIK cells in the way of *in situ* injection.

Summary and Conclusions: Our case preliminarily demonstrates that *in situ* injection of CIK cells provides a new treatment option to therapy of extramedullary relapse after allogeneic HSCT and help to overcome the problem of inadequate targeting of extramedullary lesion during homing process of adoptive immune cells *in vivo*.

PB1881

A COMPARATIVE ANALYSIS OF EFFECTIVENESS OF TWO GRANULOCYTE COLONY-STIMULATING FACTORS (GCSF), AN ORIGINAL DRUG NEUPOGEN AND A BIOSIMILAR NIVESTIM, IN MOBILISATION OF PERIPHERAL BLOOD STEM CELLS

P Roncevic[1,*] B Dreta[1], A Ostojić[1], D Sertić[1], R Serventi Seiwerth[1], R Vrhovac[1], I Aurer[1], S Basic Kinda[1], A Boban[1], S Zupancic Salek[1], D Pulanic[1], N Durakovic[1], A Boban[1], I Radman[1], D Nemet[1]

[1]Dpt of hematology, University Hospital Center Zagreb, Zagreb, Croatia

Background: Original biological drug Neupogen (Amgen, Roche) was used for peripheral blood stem cells mobilisation in Clinical University Hospital Centre Zagreb until April 2012. When the drug stopped being available, biosimilar Nivestim (Hospira) was used for the same purpose.

Aims: We evaluated the effectiveness of two granulocyte colony-stimulating factors in mobilisation of peripheral blood stem cells in patients treated for hematological malignancies.

Methods: A retrospective analysis was performed in patients stratified

according to GCSF used for mobilisation (Neupogen *vs* Nivestim) and the hematological malignancy they were treated for (Acute myeloid leukemia, Multiple myeloma, non-Hodgkin`s lymphoma, Hodgkin`s lymphoma). 186 patients who were administered 10 mcg/kg of GCSF were analysed. The following parameters of stem cell mobilisation were surveyed: number of days GCSF was administered, total number of CD34 positive cells per kilogram collected, total number of colony forming units of the granulocyte macrophage order per kilogram collected. A matched pairs analysis was performed on a subset of patients treated for multiple myeloma. Mann-Whitney-U test was used for statistical analysis.

Results: When analysing the subset of patients treated for acute myeloid leukemia , the median number of days GCSF was administered before mobilisation was 11.5 for the Neupogen group, and 14 for the Nivestim group (p 0.892). Median value of CD34 positive cells collected was 7.6x10E6/kilogram for the Neupogen group and 7.0x10E6/kilogram for the Nivestim group (p 0.854). Median value of total number of colony forming units of the granulocyte macrophage order per kilogram collected (CFU-GM) was 58x10E4/kilogram for Neupogen group and 60x10E4/kilogram for Nivestim group (p 0.574). When analysing patient treated for multiple myeloma, we found that the median number of days GCSF was administered before mobilisation was 7 for the Neupogen group, and 8 for the Nivestim group (p 0.064). Median value of CD34 positive cells collected was 11.6x10E6/kilogram for the Neupogen group and 11.9x10E6/kilogram for the Nivestim group (p 0.459). Median value of total number of colony forming units of the granulocyte macrophage order per kilogram collected (CFU-GM) was 70x10E4/kilogram for Neupogen group and 74x10E4/kilogram for Nivestim group (p 0.574). When a matched pairs analysis was performed on this subset of patients no statistically significant difference was observed in the aforementioned categories. When analysing the subset of patients treated for non-Hodgkin's lymphoma, the median number of days GCSF was administered before mobilisation was 10 for both groups (p 0.750). Median value of total CD34 positive cells collected was 8.15x10E6/kilogram for the Neupogen group and 9.02x10E6/kilogram for the Nivestim group (p 0.728). When analysing the subset of patients treated for Hodgkin`s lymphoma, the median number of days GCSF was administered before mobilisation was 9 for both groups (p 0.755). Median value of CD34 positive cells collected was 10.9x10E6/kilogram for the Neupogen group and 13.37x10E6/kilogram for the Nivestim group (p 0.854). Median value of total number of colony forming units of the granulocyte macrophage order per kilogram collected (CFU-GM) was 58x10E4/kilogram for Neupogen group and 33x10E4/kilogram for Nivestim group (p 0.574).

Summary and Conclusions: Since no statistically significant difference was observed in the tested parameters we conclude that biosimilar Nivestim was not inferior when compared to the original biological drug Neupogen in peripheral blood stem cell mobilisation.

PB1882

STEM CELL MOBILIZATION IN ELDERLY MULTIPLE MYELOMA PATIENTS: SINGLE CENTER EXPERIENCE

SK Toprak[1],* G Cengiz Seval[1], E Ayyildiz[1], P Topcuoglu[1], O Arslan[1], M Ozcan[1], T Demirer[1], G Gurman[1], H Akan[1], M Beksac[1], N Konuk[1], O Ilhan[1]
[1]Department of Hematology, Ankara University School of Medicine, Ankara, Turkey

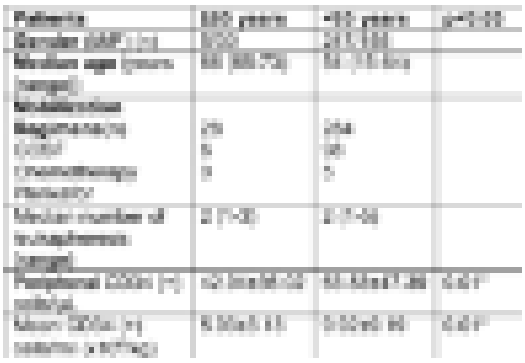
Background: Multiple myeloma (MM) has considerable impact in the older patient population. As the median age at diagnosis is 70 years for MM, more than half of newly diagnosed cases of these malignancies were made in patients' ≥60 years of age.

Aims: We retrospectively compared myeloma patients below the age of 65 with patients above 65 years of age, analyzing CD34 mobilization into peripheral blood and the number of leukapheresis needed to collect at least one single stem cell graft.

Methods: In our clinic; between 1993 and 2013, a total of 437 patients with MM who received autologous stem cell transplantation enrolled this study. Our thereshold for leukapheresis was 10 CD34 positive cells/μL whole blood. Only in patients achieving >10 CD34 positive cells/μL blood was a stem cell collection initiated. Thirty five of 437 patients were above 65 years of age (median age 66, range 65-73) and 402 patients were below the age of 65 (median age 54, range 15-64). Patients' characteristics are summarized in Table 1. Mobilization regimens for the younger patient population were cyclophosphamide based (n: 95), etoposide based (n: 3), G-CSF only (n: 284) and plerixafor+ G-CSF (n: 5). Mobilization in the older population was with cyclophosphamide based (n: 6) and G-CSF only (n: 28).

Results: There were no significant statistical differences in time from diagnosis to mobilization, number of prior therapies, disease status, and type and frequency of comorbidities between both patient groups. The number of CD34-positive circulating cells before scheduled leukapheresis was mean 62.11 cells/μL (median 48 cells/ μL, range 10-197; SEM±46.875) in all patients. The results are summarized in Table 1.

Table 1.



Summary and Conclusions: Our data support the observation that after a standard mobilization regimen with anti-myeloma chemotherapy and once-daily growth factor support, patients above 65 years of age show an impaired CD34 mobilization into peripheral blood compared to a younger population. This can be overcome by an increased number of leukaphereses.

PB1883

ASSOCIATION OF GRAFT-VERSUS-HOST-DISEASE SEVERITY WITH LEUKEMIA RELAPSE AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN CHILDREN

Y Kubota[1],* T Aoki[1], R Oyama[1], M Mori[1], Y Arakawa[1], M Hayashi[1], R Hanada[1], K Koh[1]
[1]Hematology & Oncology, Saitama Children's medical center, Saitama, Japan

Background: The graft-*versus*-leukemia (GVL) effect plays a major role in reducing the risk of relapse after allogeneic hematopoietic stem cell transplantation (HSCT). Because the GVL effect is extremely similar to that underlying graft-*versus*-host-disease (GVHD), severity of GVHD is believed to correlate with the GVL effect. GVHD may be associated with a reduced incidence of leukemic relapse; however, it is the leading cause of treatment deaths and increases treatment-related mortality.

Aims: The aim of this study was to investigate whether clinical outcomes of allogeneic HSCT in children are affected by GVHD severity.

Methods: We retrospectively analyzed 191 pediatric patients who received allogeneic HSCT at a single institution. All 191 patients received 217 allogeneic HSCTs from January 1, 1985, to March 31, 2013; these included 116 patients with acute lymphoblastic leukemia (ALL) and 75 patients with acute myeloid leukemia (AML) or myelodysplastic syndrome (MDS). Acute GVHD (aGVHD) was evaluated according to the International Bone Marrow Transplant Registry grading system and chronic GVHD (cGVHD) was categorized as either limited or extensive.

Results: In a comparison of grade 0-I *versus* grade II-IV aGVHD, overall survival (53.4% *vs.* 51.9%, p=0.958), leukemia-free survival (50.4% *vs.* 42.7%, p=0.586), cumulative incidence of relapse (41.2% *vs.* 42.6%, p=0.395), and treatment-related mortality (8.4% *vs.* 14.7%, p=0.856) did not significantly differ. For the absence *versus* the development of cGVHD, overall survival (52.5% *vs.* 56.5%, p=0.401), leukemia-free survival (47.3 *vs.* 51.6%. p=0.418), cumulative incidence of relapse (45.2% *vs.* 31.7%, p=0.137), and treatment-related mortality (7.5% *vs.* 16.7%, p=0.136) did not significantly differ. The group of patients who developed cGVHD had a tendency of lower cumulative incidence of relapse and higher treatment-related mortality than those who did not develop cGVHD. Compared with the entire cohort, patients with ALL or AML had similar survival probabilities.

Summary and Conclusions: The severity of aGVHD and cGVHD does not affect the clinical outcome of allogeneic HSCT in children. However, the clinical outcome of patients who develop cGVHD may improve as treatments for cGVHD advance and decrease treatment-related mortality.

PB1884

THE ASSESMENT OF THE STEM CELL MOBILIZATION IN LYMPHOMA PATIENTS: A SINGLE CENTER EXPERIENCE

AK Güneş[1], G Özet[1],* S Dagdas[1], F Ceran[1], M Aylı[2], M Falay[1], N Zengin[3]
[1]Hematology, Ankara Numune Training and Research Hospital, [2]Hematology, Ufuk Universiy Hematology Department, [3]Oncology, Ankara Numune Training and Research Hospital, Ankara, Turkey

Background: High-dose chemotherapy in conjunction with auto-SCT is widely recognized as the preferred modality of treatment for patients with relapsed or refractory Hodgkin disease or non-Hodgkin lymphoma at the time of chemo-

sensitive first relapse. Successful transplant requires the infusion of a sufficient number of hematopoietic stem cells. Previous studies in patients with lymphoma varying definitions of 'mobilization failure', show that 10-25% of patients fail to mobilize a sufficient number of HSC.

Aims: The purpose of this retrospective analysis is to identify the factors causing the mobilization failure with lymphoid malignancies.

Methods: A total of 90 patients with HL or NHL, referred for the Autologous SCT to the Bone Marrow Transplantation Unit in Ankara Numune Training and Research Hospital between 2004-2013, evaluated in this retrospective study.Mobilization failure were defined as patients failed to collect at least 2x106 CD34 cells/kg of body weight in ≤4 leukapheresis procedure.

Results:

Through the first line mobilization regimen, 70 of 90 patients (78%) have been successfully mobilized except for 20 (22%) patients. The mean age of the successfully mobilized patients is 36.4 whereas the mean age in unsuccessful ones 43.6 (p=0.023). 15 of 20 patients with mobilization failure have the diagnosis of NHL and 5 of 20, HL (p=0.008, OR= 4.24). 10 of 20 patients (50%) have bone marrow involvement at the time of the diagnosis (p=0.044 OR = 2.68).No relationship has been found among the mobilization failure and gender (p=0.24), disease stage (p=0.39), B symptoms(p=0,18) splenic involvement (p=0.47) disease status at the time of the mobilization (p=0.74), the number of the chemo regimens (p=0.121), the mean number of total chemo cycles (p=0.895) and Rituximab Therapy for NHL group (p=0.18). Among the salvage regimen, no relationship has been detected between the mobilization failure and the salvage regime used. When the patients have been evaluated according to their mobilization regimens: Cyclophosphamide+Etoposide+G-CSF with 100% success (p=0.018), Cyclophosphamide+G-CSF with 72.2% success (p=0.301), G-CSF with 70% success (p=0.369), ICE+G-CSF with 66.7% success (p=0.454), DHAP+G-CSF with 100% success (p=0.331). The mean CD 34 yield in Cyclophosphamide+Etoposide+G-CSF group is 5,38 x 106 cells/kg while in G-CSF group the mean is 3,68 106 cells/kg , in Cyclophosphamide +G-CSF group the mean is 3,88x106 cells/kg. (p=0,001 and p=0,004). In multivariate analysis, the older age (p=0,029), bone marrow involvement at diagnosis (p=0,047), the number of prior chemo regimens (p=0,044) play a role in mobilization failure (Table 1).

Table 1.

Age		38(16-63)
Gender (Male/Female)	Male 55 (61%)	n=90
	Female 35 (39%)	
Diagnosis	Non-Hodgkin Lymphoma	44 (47%)
	Hodgkin Lymphoma	46 (53%)
Bulky disease		7 (7,8%)
Splenic involvement		12(14.4%)
Bone marrow involvement		29 (32.3%)
Radiotherapy		33 (36%)
B symptoms		76 (84%)
Rituximab for NHL		22 (50%)

Summary and Conclusions: Diagnosis of NHL, older age, bone marrow involvement at the time of diagnosis, the number of prior chemo regimens, and the used mobilization regimen are the factors affecting the mobilization in our group. Randomized and controlled multi-center prospected studies are to describe the definite risk factors for the mobilization failure in lymphoma patients. In this context, "the high risk group" suggesting the use of newer agents like plerixafor and the use of etoposide addition to the cyclophosphamide in the first line is available.

PB1885

TRANSFORMING GROWTH FACTOR BETA GENE POLYMORPHISM AS A RISK FACTOR FOR THE DEVELOPMEMT OF GVHD AFTER STEM CELL TRANSPLANTATION FROM AN IDENTICAL SIBLING

A Kamel[1,*] GT Ebid[1], A Gamil[1], R Abd El-Fattah[2], HK Mahmoud[2]
[1]Clinical Pathology, [2]Medical Oncology, NCI, Cairo University, Cairo, Egypt

Background: Stem cell transplantation (SCT) is a standard therapeutic modality for many benign and malignant hematological disorders. Graft *versus* host disease (GVHD) is among its serious complications. The role of some cytokine gene polymorphisms has been documented. Few studies are available about the role of TGFβ and the impact of polymorphisms at codon 10 or codon 25 on the development of aGVHD and cGVHD with controversial results.

Aims: We wanted to evaluate the impact of both codon 10 and codon 25 TGFβ polymorphisms on the development of acute and chronic GVHD as well as infectious complications.

Methods: The work was performed according to Helsinki declaration, the protocol was approved by the IRB of the NCI, Cairo University and an informed consent was obtained from all subjects. The study cohort included 97 patient/donor pairs and 8 more patients (total 105 patients) who received SCT from an identical sibling at Nasser Institute, MOH, Egypt in the period from December 2010 –February 2013. We determined the genotype of TGFβ, by SSP typing using Cytokine Genotyping Tray REF CYTGEN (one Lambda, Inc, 21001 Kittridge st., Canoga Park, CA 91303 USA) classifying cases as high, intermediate and low producers. Patients were followed up for at least one year; development of GVHD and infectious complications was recorded.

Results: Of the 107 cases, 29 developed acute GVHD, 7 developed chronic GVHD on top and another 12 developed de-novo chronic GVHD. The genotypes with the corresponding phenotype are presented in Table 1. TGFβ was of the low producer genotype in 27/29 (93.1%) patients who developed acute and in 18/19 (94.7%) patients who developed chronic GVHD. The corresponding figure for those who did not develop GVHD was 55/64 (85.9%). Among donors of patients who developed GVHD, low producer genotype was encountered in 27/28 (96.4%) for acute and 16/17 (94.6%) for chronic GVHD; the corresponding figure for donors of patients with no GVHD was 51/57 (89.5%). Pulmonary infectious complications developed in 14 patients, 13 (92.9%) of which were low producers as compared to 80/91 (87.9%) in patients with no infectious complications. Though the differences did not achieve statistical significance, a clear trend of association of low TGFβ producer genotype with GVHD and pulmonary infection is evident. Lack of statistical significance may be partly attributed to the predominance of the low producer genotype among our population presented in both patients and donors which might be an ethnic characteristic.

Table 1. TGFB1 Genotypes and corresponding phenotypes in patient and donors in relation to graft *vs.* host disease after allogeneic stem cell transplantation.

Summary and Conclusions: TGFβ of high or intermediate producing genotypes are uncommon in patient/donor pairs but has a trend to be protective from GVHD and pulmonary infections in patients receiving allogeneic stem cell transplantation; yet statistical significance was not achieved.

PB1886

STANDARDIZATION OF MOBILIZATION PROTOCOL IS ASSOCIATED WITH SUCCESSFUL COLLECTION OF PERIPHERAL BLOOD STEM CELLS FOR AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH ONCOHEMATOLOGICAL DISEASES

AA Kuzjaeva[1,*] SV Gritsaev[1], IM Zapreeva[1], ZV Chubukina[2], NA Potichonova[3], KM Abdulkadyrov[1]
[1]Hematological clinic, [2]Immunologic laboratory, [3]Clinico-diagnostic laboratory, Russian Institute of Hematology and Blood Transfusion, St.Petersburg, Russian Federation

Background: Autologous stem cell transplantation (AutoSCT) is a very important stage of oncohematological patients' therapy as there is the possibility to treat the patients with myeloablative regimen to reduce the volume of minimal residual disease and to improve relapse-free or overall survival.

The main condition of successful AutoSCT is harvesting of $2x10^6$/kg CD34+ cells or more. There are different methods to increase the quantity of CD34+ cell in autotransplant and we supposed that one of them is to standardize regimen of mobilization regimen.

Aims: The aim of the study was to compare the characteristics of autotransplants in different periods when different mobilization regimens were used.

Methods: Retrospective analyses of autotransplants which were harvesting during 1995-2011 and 2012-2013 periods have been done. During 1995-2011 period (Group 1) next mobilization regimens were used: filgrastim alone in dose 10 mkg/kg s.c. 1-5 days or cyclophosphomide (Cph) 1-5.0 g/m^2 in combination with filgrastim or lenograstim 5 mkg/kg s.c. beginning from day 3 after mobilization regimen. During 2012-2013 period (Group 2) the scheme of mobilization regimen was unique for all patients: Cph 3.0 g/m^2 plus G-CSF: filgrastim (10%), lenograstim (85%) or pegfilgrastim (5%). Injections of G-CSF were started on day 5 after mobilization regimen. The everyday dose of G-CSF was 10 mkg/kg. The treatment was begun after the signing of the informed consent. The level of CD34+ cells in peripheral blood more than 10/mL was chosen to start aphaeresis.

Results: In Group 1 there were 105 patients with Me age 45 y. (16-65). The patients were diagnosed with multiple myeloma (MM) (45%), acute myeloid

leukemia (AML) (19%), non-Hodgkin lymphoma (NHL) (16%), acute lymphoid leukemia (10%) and Hodgkin disease (HD) (8%). Me number of aphaeresis was 2 (1-3). Me number of collected CD34+ cells was $2.8x10^6$/kg (0.05-12.2). Poor mobilization with the number of CD34+ cells less than $2x10^6$/kg was verified in 37/105 (36%) patients. In Group 2 there were 21 patients with Me age 48 y. (24-67). The patients were diagnosed with MM (71%), AML (14%), NHL (10%), and HD (5%). Me number of aphaeresis was the same like in Group 1. Me number of collected CD34+ cells was $6.7x10^6$/kg (0.2-29.4). It was significantly higher than in Group 1; p=*0.010*. Poor mobilization was diagnosed in 4/21 patients (19%) and it was significantly lower than in Group 1; p=*0.000*. It is necessary to point that there was no increased rate of organ toxicity and no any case with disease progression in Group 2.
Summary and Conclusions: We conclude that standardization of mobilization regimen with increased dose of Cph and G-CSF is accompanied with improved results of autotransplant collection in oncohematological patients irrespective of diagnosis. This strategy is not more toxic than previously used regimens. Nevertheless there were some patients with poor stem cells collection who are the potential candidates to treat with plerixafor during mobilization regimen.

PB1887

PERIPHERAL BLOOD CELL MOBILIZATION AND COLLECTION PROCEDURES IN PLERIXAFOR ERA: A MONOCENTRIC RETROSPECTIVE EXPERIENCE

V Bozzoli[1,*] AR Messa[1], P Forese[1], M Dargenio[1], G Loglisci[1], D Canaris[2], A Soda[1], R Matera[1], L Conte[1], P Mazzotta[1], N Di Renzo[1]
[1]Hematology, [2]SIMT, Ospedale Vito Fazzi, Lecce, Italy

Background: High dose chemotherapy followed by autologous peripheral blood stem cell transplantation (PBSCT) represents a potentially curative treatment in hematological malignancies. Granulocyte colony stimulating factor (G-CSF), alone or in combination with chemotherapy are usually used to mobilize stem cells in peripheral blood which are then collected through one or more apheresis procedures. A suboptimal collection has been associated to delayed or engrafment failure, as well as to a reduced PFS and OS and increased transplant related toxicity. Unfortunately a considerable proportion of patients, ranging from 11% to 40%, is unable to collect this target and is therefore considered ''poor mobilizer''.
Aims: By this retrospective analysis we wanted to report our monocentric experience in the process of stem cells mobilization and collection, during the era of novel reversible inhibitor of CXCR4, Plerixafor.
Methods: We retrospectively analyzed 66 patients: 2 Hodgkin Lymphoma (HL), 25 non-Hodgkin Lymphoma (NHL), 27 Multiple Myeloma (MM), and 12 Acute Myeloid Leukemia (AML), who underwent a mobilization procedure at our institution from January 2011 to January 2014. Our group was constituted by 43 males and 23 females, whit a median age of 56 years (range 18-75).
Results: In the triennium of analysis we performed 73 mobilization procedures (6 second attempt) and 61 autologous PBSCT (n=24 MM, n=21 lymphomas, n=8 AML) including 8 second procedures. Median time from diagnosis to mobilization was 8.3 months in MM, 12.5 in lymphoma, 2.6 in AML. The mean number of prior lines of therapy was 1 for MM patients, 2 for NHL, 2 for HL and 1 for AL. 14 patients (n=8 MM and n=6 NHL) received radiotherapy prior to mobilization. At mobilization, 37% (n=10) MM patients were in Complete Remission (CR), 18.5% (n=5) achieved Very Good Partial Remission (VGPR) and 44.5% (n=12) was in Partial Remission (PR). In Lymphoma (HL and NHL) group, 26% (n=7) were in CR, 67% (N=18) in PR and 7% (n=2) in PD. All AML patients (n=12) achieved morphologic CR before stem cells collection. In line with published data, we report 22% mobilization failure (n=16, 10 in first and 6 in second attempt). The group failing first mobilization, was constituted by 7 females and 3 males, 1 MM, 5 NHL and 4 AML, the median age was 52 (range 32-70). The median number of previous therapy was significantly higher in patients failing than in patients succeeding first mobilization, both in MM (6 *vs* 1.27) (p=*0.0003*) and in Lymphoma (2.4 *vs* 1.8) (p=*0.005*). Of the seven patients who underwent a second mobilization procedure, 86% failed. Thirty (16 MM, 14 NHL) of the 54 MM and lymphoma patients, received plerixafor at any time of their mobilization history, and in 90% (n=27) of cases, a dynamic approach based on the CD34 monitoring, guided us in plerixafor use "on demand". The median number of plerixafor injection was 1.6 (range 1-3). The median interval from mobilization to collection was respectively 11 days for MM and 15 days for Lymphoma patients mobilized without and 13 days for MM and 14 days for Lymphoma mobilized with plerixafor. Considering CD34+ cells/µl baseline count at the expected day of collection and after plerixafor injection, we found a 5.7 and 4.1 fold increment, respectively in MM and lymphoma patients. The median CD34+ x 10^6/kg harvest was 4.16 in MM and 3.7 in lymphoma patients receiving the new mobilizing agent and 5.3 for MM and 11.67 for lymphoma patients group who did not receive plerixafor *(p<0.001)*. Seven patients (n=3 MM, n=4 Lymphoma) mobilized without chemotherapy, 3 in first and 4 in second attempt. The median CD34+ x 10^6/kg yield of this group was 0.64 (range 0.39-1). Considering the number of apheresis, we reported a significant difference in Lymphoma patients mobilized with and without plerixafor (1.2 *vs* 1.8) *(p=0.001)*, but not for MM patients (1.68 *vs* 1.7) *(p=0.08)*.
Summary and Conclusions: This retrospective analysis underlines the importance of a dynamic approach in plerixafor use, to change the course of a "poor mobilizer" first mobilization procedure into a chance to go through an high-dose treatment.

PB1888

ALLOGENEIC UNRELATED DONOR HAEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) IN HAEMOGLOBINOPATHIES – A PAEDIATRIC BONE MARROW TRANSPLANTATION UNIT EXPERIENCE

E Goussetis[1], A Paisiou[1], CM Vadikolia[1,*] I Peristeri[1], V Kitra[1], G Vessalas[1], G Augerinou[1], K Zisaki[1], E Petrakou[1], M Theodosaki[1], S Graphakos[1]
[1]ELPIDA Bone Marrow Transplant Unit, Aghia Sophia children's Hospital, Athens, Greece

Background: Supportive and preventive therapeutic interventions, such as regular transfusions and chelation treatment, remain the standard of care for patients with congenital haemoglobinopathies. Allogeneic bone marrow transplantation is the only approach available with curative intent. More than 90% of transplanted patients with matched sibling donors demonstrate reconstitution of normal haemopoiesis, with a success rate of nearly 100% when the transplantation is performed in a young age. The implementation of conditioning regimens that eliminate the risk of rejection, as well as the refinement of histocompatibility testing have allowed the performing of non related HSCT. In literature however, the use of unrelated donors (VUD) has been complicated by poor engraftment, excessive regimen related toxicity and graft *versus* host disease (GVHD).
Aims: The principal objective of this study is to present our results in survival and the complications associated with allogeneic VUD HSCT in children with haemoglobinopathies. Correspondingly, to assess and examine the risks against the potential long term gain of HSCT.
Methods: From January 2004 until February 2014, 13 haemoglobinopathy patients (8 male), with a median age of 3.4 years (range 1.2-14.8 years) were transplanted from unrelated donors in our unit. 9 patients had β-Thalassaemia while 4 of the patients suffered from Sickle Cell Disease (SCD). 9 out of 13 patients were given a fully matched graft while the rest 4 patients had 1 HLA antigen mismatched donors. 11 patients had bone marrow and 2 patients had peripheral blood as the source of HSCs. 4 grafts were manipulated accordingly in order to not exceed more than $5x10^7$/kg $CD3^+$ cells. The conditioning protocols used were Busulfan based with the addition of a combination of Cyclophosphamide, Fludarabine and ATG. GvHD prophylaxis consisted of Cyclosporin A and Methotrexate. The median numbers of $CD34^+$ and $CD3^+$ cells were $7x10^6$/kg and $4{,}25x10^7$/kg respectively.
Results: Engraftment was achieved in 11/13 patients. Autologous back up HSCs were given to the remainder 2 patients, with autologous haematopoietic recovery. Neutrophil and platelet engraftment occurred at a median of 19 (range 14-28 days) and 22 days (range 18-30 days) respectively. Subsequent donor lymphocyte infusions (DLI) were administered in 2 patients with mixed chimerism and restored engraftment in one of them, whereas the second one experienced an eventual late graft rejection. Acute GvHD (stage II-IV) was recorded in 7 patients, in one of whom post the administration of DLI. Chronic GvHD has been evident in 2 patients. With a median follow up of 58,3 months (range 1.1-111.0), all patients are alive and well with 10 of them having an entirely normal haemopoiesis with complete chimerism, nonetheless one of them developed an episode of autoimmune haemolytic anaemia later in the post transplant period and was successfully managed accordingly. 3 out of the 13 patients remain transfusion dependent.
Summary and Conclusions: Even though there is an overall survival of 100%, VUD allogeneic HSCT in children with haemoglobinopathies, is likely to be related with an increased risk of complications. Evaluation in larger patient cohorts, is necessary to further assess the long term benefits against the risks and perhaps to attain some insight into the mechanism of graft failure. As the development of GvHD and older age at transplant appear to be important impairing factors, providing there is a 10/10 HLA allele matched donor available, HSCT should be performed after thoughtful contemplation of the individual parameters and risk factors, also taking into account the survival expectancy conferred by conservative therapy.

PB1889

ALLOGENEIC TRANSPLANT OUTCOMES IN MPN BLAST PHASE

K Gowin[1,*] C Cherington[1], J Slack[2], R Tibes[3], L Sproat[2], R Mesa[3]
[1]Hematology and Medical Oncology, [2]Bone Marrow Transplant, [3]Hematology, Mayo Clinic Arizona, Scottsdale, United States

Background: The Philadelphia (Ph) negative myeloproliferative neoplasms (MPNs) including polycythemia vera (PV), essential thrombocythemia (ET), and

primary myelofibrosis (PMF) are clonal disorders of the hematopoietic system associated with an approximate 5%>10% risk of leukemic transformation. Allogeneic stem cell transplant is the only potentially curative therapy.
Aims: We retrospectively reviewed 10 consecutive patients with MPN blast phase that underwent allogeneic stem cell transplant (ASCT) and report our centers experience.
Methods: Consecutive patients were identified at Mayo Clinic Arizona who underwent ASCT between 2006-2013. All patients had a previous diagnosis of a Ph negative MPN (ET, PV, PMF) and underwent leukemic transformation to MPN blast phase. Both myeloablative and reduced intensity conditioning regimens were employed, all transplants were performed utilizing peripheral blood stem cells, and outcomes were retrospectively analyzed.
Results: MPN Blast Phase Presentation and Management: 10 patients with post-PV/ET fibrosis or PMF MPN blast phase were identified. Prior MPNS were PV in 5/10 (50%), ET in 3/10 (30%), and PMF in 2/10 (20%). Jak V617F mutation occurred in 70%. Cytogenetic analysis revealed poor risk karyotype (3 complex, 1 del (7)) in 4/10 (40%) and intermediate risk (3 normal, 2 trisomy 8, 1 t(16;21)) in 6/10 (60%). Median performance status was EGOG 1. Induction chemotherapy included Ara-C, daunorubicin, and etoposide (ADE) in 5/10 (50%) and cytarabine and daunorubicin (7+3) in 5/10 (50%) patients. High dose cytarabine (HiDAC) consolidation was utilized in 3/10 (30%). Salvage mitoxantrone based chemotherapy was employed in 30%. A CR was obtained in 7/10 (70%) of patients however, 2 patients (20%) had <5% residual marrow blasts and 1 patient (10%) had >5% marrow blasts. Allogeneic Stem Cell Transplant: At time of transplant, the median age was 61 years. Conditioning regimens used were myeloablative fludarabine+busulfan in 2 patients, and reduced intensity in 8 patients, including 5 patients who received fludarabine/BCNU/Melphalan and 3 patients who received fludarabine+busulfan. Donors were matched related donor (MRD) in 50% and 10/10 matched unrelated donor (MUD) in 50% peripheral blood stem cells. GVHD prophylaxis regimens included ATG in 7/10 (70%), and tacrolimus was utilized in all regimens with either the addition of mycophenolate (60%) or methotrexate (40%). Grade 3-4 GVHD (GI) developed in 1 patient. Chronic GVHD was seen in 4 patients (2 skin, 1 GI, and 1 skin and GI). Long Term Outcomes: At median followup of 44 months, 5 patients (50%) are alive in CR, 4 patients (40%) have expired, and 1 patient was lost to follow up. The median survival after transplant was 31 months. Transplant related mortality occurred in one patient. Causes of death included relapsed disease in two, and one patient with gram-negative sepsis two years after transplant. Of those with persistent disease after induction chemotherapy (3/10), two expired of relapsed disease, occurring at 8 and 2 months post transplant.
Summary and Conclusions: Historically, the median survival for MPN blast phase is approximately 6 months or less. Allogeneic stem cell transplant may offer improved survival for MPN blast phase patients who are candidates for this intervention. Adequate leukemic clearance prior to ASCT is associated with improved outcomes. Conversely, those with poor risk karyotype have worse outcomes. More studies are needed to evaluate long-term survival as well as optimal induction and conditioning regimens in this patient population.

PB1890

ALTERATION OF HEPATITIS B SEROSTATUS AMONG ALLOGENEIC BLOOD STEM CELL TRANSPLANT RECIPIENTS AT INHA UNIVERSITY HOSPITAL

CS Kim[1,*] MH Lee[1], HG Yi[1], JH Lim[1], YH Park[1], HJ Chang[2], I Kim[3]
[1]Department of Hematology/Oncology, Inha University Hospital, Incheon, [2]Department of Hematology/Oncology, Kyunghee University Hospital at Kangdong, [3]Department of Hematology/Oncology, Seoul National University Hospital, Seoul, Korea, Republic Of

Background: Chronic hepatis B is prevalent in many countries in Asia. Reactivation of hepatitis B in recipients or infection of hepatitis B from donors has been reported in the setting of allogeneic blood stem cell transplant (alloBSCT) to be uncommon although worrisome.
Aims: We have investigated the alteration of hepatitis B serostatus in 72 recipients of alloBSCT performed at Inha University Hospital, to estimate the true prevalence of hepatitis B serostatus change during the process of alloBSCT in South Korea, where hepatitis B virus (HBV) infection is still endemic.
Methods: Medical records of a total of 113 pairs of recipients and donors for alloBSCT were reviewed from which data regarding hepatitis B serology were retrieved. Hepatitis B surface antigen (HBsAg)/antibody (HBsAb) assay was done by chemiluminescence immunoassay, using the Architect i2000 system (Abbott Laboratories, Abbott Park, IL).
Results: Post transplant serology of the recipient was unavailable in 41 cases (death, omission of the test, or lost to follow up) and data of 72 pairs were available. There were no HBV carriers among donors; 23 were seronegative and 48 had antibody against HBV. There were six HBV carriers among recipients; 20 were seronegative and 46 seropositive for HBV antibody. Two HBV carriers among recipients showed seroconversion with loss of HBsAg and gain of HBsAb, one from seronegative donor and the other from HBsAb positive donor. One HBV carrier lost HBsAg without seroconversion after receiving alloBSCT from seropositive donor. Three HBV carrier remained persistent carrier after receiving alloBSCT from two seropositive and one seonegative donors. Twelve seronegative recipient gained HBsAb, 8 from HBsAb positive donors and 4 from seronegative donors. Seven seropositive patients lost HBsAb, 3 recipients from HBsAb positive donors and 4 from HBsAb negative donors. Reverse seroconversion occurred in one patient who was transplanted from HBsAb positive donor.
Summary and Conclusions: Twenty three of 72 allogeneic blood stem cell transplant recipients (32%) showed alteration in their serostatus against HBV. Adoptive seroconversion was noted in 2 of 6 HBV carriers (33%). Seroreversion occurred in one of 46 seropositive recipients (2%). For further refined study, prospective study design and serial quantitative titration of HBsAb are needed.

PB1891

MAINTENANCE THERAPY AND EVENT-FREE SURVIVAL OF PATIENTS WITH MULTIPLE MYELOMA IN POSTTRANSPLANT PERIOD.

LV Steljmashenko [1,*] SV Voloshin[1], AA Kuzajeva[1], AV Schmidt[1], SV Gritsaev[1], S Bessmeljtsev[1], K Abdulkadyrov[1]
[1]Hematological Clinic , Russian Institute of Hematology and Blood Transfusion, St.Petersburg, Russian Federation

Background: Autologous stem cell transplantation (AutoSCT) is the important stage of treatment of patients with multiple myeloma (MM) younger than 65 y. The role of maintenance therapy (MT) is controversial and there are some publications that MT is the method to improve event-free survival (EFS) of MM patients who were treated with AutoSCT.
Aims: The aim of the study was to evaluate the possibility of MT to improve RFS of MM patients after AutoSCT.
Methods: The data of 48 patients with MM were analyzed retrospectively. The data from 1995 till 2012 was collected. There were 23 men and 25 women. Median age of patients was 49 y. (25-64). According to the Durie-Salmon scale distribution of patients was next: 17 patients with II stage and 31 patients with III stage. According to immunochemistry variant distribution of patients was next: 27 patients with IgG, 9 patients with IgA, 10 patients with BJ and 2 patients with nonsecreted MM. The number of treatment lines before AutoSCT was 1-3. Complete response was diagnosed in 17 patients and partial response in 31 patients. Tandem AutoSCT was done in 27 patients and interval between transplantation was 4-9 months. 22 patients were treated with MT: 16 patients with CR and 6 patients with CR. Patients were treated with immunomodulators or proteosome inhibitors. To evaluate the effectiveness of MT criteria of EBMT were used. Relapse, progression, serious adverse events of death of patients were considered as events.
Results: Relapse and progression were diagnosed in 25 patients (52,1%). Relapse were diagnosed in 14 patients after tandem AutoSCT and in 11 patients after single AutoSCT. EFS in these groups of patients were 23 and 24 months respectively. 8 patients died according to MM progression or chemoresistance. The reason of death of 2 patient was not related to MM.
In the group of patients with CR who were treated with MT EFS was 31.6 months. In the group of patients with CR who was not treated with MT EFS was 8.3 months; p=*0.000*. The difference in EFS between groups of patients with PR was not significant.
Summary and Conclusions: We conclude that MT after AutioSCT is effective method to improve the time to relapse or to progression in MM patients.

PB1892

UNRELATED CORD BLOOD TRANSPLANTATION FOR PATIENTS WITH SEVERE ACQUIRED APLASTIC ANEMIA□RESULT OF A SINGLE CENTER

Y Lu[1,*] X Zhang[1], X Liu[1], X Qin[1]
[1]The third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: In recent years, umbilical cord blood transplantation(CBT) has become a promising treatment for patients with hematologic diseases with its advantages of rapid availability and lower rate of graft *versus* host disease despite broader HLA disparity.
Aims: The aim of this work is to analyse the outcome of patients with SAA underwent unrelated CBT.
Methods: Nine patients were included in this study and median age was 23 years(range 13-34 years). The patients received a conditioning regimen composed of cyclophosphamide (total dose 75mg/kg), rabbit antithymocyte globulin (ATG, total dose 15 mg/kg).Cyclosporin and mycophenolate mofetil were used as GVHD prophylaxis. For Cord blood, total nucleated cells (TNCs) had to exceed 3×10^7/kg and HLA(A,B,DR-B1) at least four of six loci matched. Patients had monthly chimerism check in the first three months after CBT by analysis of STR polymorphisms then repeated according to the patients' condition.

Results: All cases received one cord unit transfusion and HLA loci 5/6 matched for six, 4/6 matched for three.The median TNCs of cord units was 3.9×10^7cells/kg(range 3.1-6.4) and the $CD34^+$ cells was 2.5×10^5cells/kg (range 0.8-5.36).One case wasn't evaluated because of early death on day 14 due to intracranial hemorrhage. All of the remaining eight patients acquired autologous myeloid recovery and the median time to neutrophil count of 0.5×10^9/L was 37 days (range 14-45 days). The median time to 20×10^9/L platelets was 79 days (range31-120days). Only 1 case had engraftment with complete donor chimerism on day 30 and the time for neutrophil cell>0.5×10^9/L and platelet>20×10^9/L was respectively day 14 and day 31 after CBT. But this patient's chimerism became mixed of donor and recipient two months after CBT and turned back to recipient three months after CBT with neutrophil cell and platelet transiently decreased leastly to 0.9×10^9/L and 35×10^9/L,then increased gradually to normality.
Summary and Conclusions: Althoug with low engraftment, CBT for SAA using CTX and ATG-based conditioning may quicken autologous recovery and improve survival with low risk of transplant-related mortality.

PB1893

THE ROLE OF AUTOLOGOUS HAEMATOPOIETIC CELL TRANSPLANTATION IN SYSTEMIC SCLEROSIS: REGRESSION OF DERMAL FIBROSIS AND STABILIZATION OF VISCERAL DISEASE

I Sakellari[1,*] D Mallouri[1], I Batsis[1], C Smias[1], P Kaloyannidis[1], E Yannaki[1], A Ilias[2], P Argyropoulou-Pataka[3], M Katsounaros[4], A Fassas[1], A Anagnostopoulos[1]
[1]Haematology department - BMT unit, [2]Gastrenterology department, [3]Pneumonology department, [4]Internal medicine department, George Papanicolaou Hospital, Thessaloniki, Greece

Background: Autologous haematopoietic cell transplantation (AHCT) is considered a treatment option for selected patients (pts) with severe progressive systemic sclerosis (SS) and may induce regression of dermal fibrosis, sustained improvement functional status, stabilization of visceral involvement and lower mortality due to disease progression.
Aims: The aim of the study was to evaluate the outcome of the pts who underwent AHCT for severe and progressive SS in our centre.
Methods: We retrospectively analyzed the outcome of 8 pts (6 women, 2 men), 35(30-48) years old, who underwent AHCT for SS in our unit. The pts were transplanted for severe progressive disease post 3(2-7) lines of immunosuppressive treatment, including cyclophosphamide (Cy) pulses in 7/8 pts [total dose 6(2.5-12) g] and at a median (Δm) time of 4(2-13) years post disease diagnosis. The Δm modified Rodnan skin score was 32(2-49) out of 51. All pts presented joint, lung and gastrointestinal involvement. Peripheral hematopoietic stem cells were mobilized with Cy 4g/m2 and GCSF without major complications. The conditioning regimen used was Cy 200 mg/kg plus ATG 7.5 mg/kg and pts received 6(3.9-8.65) x 10^6/kg CD34+ cells.
Results: Engraftment was prompt and sustained in all pts, at a Δm of 10(7-14) days for neutrophils, 9(5-13) for platelets and 7/8 pts were discharged on day +14(13-38). A female pt with severe and rapidly progressive disease, post 7 lines of immunosuppressive treatment, died on day +87 from sepsis and multiorgan failure. In the rest of the pts the complications observed were: pneumothorax during central line catheter placement (1), neutropenic fever (6), mild pulmonary infection (1), BK polyoma virus hemorrhagic cystitis (1), herpes zoster (1), CMV (2) and EBV (4) reactivation. Modified Rodnan skin score was improved post-transplant and was 15(2-41) at +3 months (m) and significantly lower 7(2-18) post 32 (14-87) m in 5/7 pts who could proceed to our unit for further follow-up. With a Δm follow-up 20 (4-87) m, all pts referred improvement or complete remission of dysphagia symptoms and significant improvement of performance status. Respiratory evaluation revealed stable FEV1 and DLCO in 3, improved in 2, asymptomatic mild progression in 1 and clinically symptomatic progression (15m post-transplant) in another pt. Until now 5/7 pts are off further treatment. One female pt was diagnosed with sarcoidosis at +27m and is under corticosteroid treatment.
Summary and Conclusions: With the limitations of a retrospective study and the small number of pts, AHCT seems to be a valuable treatment in selected pts with SS offering them a better quality of life.

PB1894

WASHING OF HEMATOPOIETIC PROGENITORS FOR DMSO REMOVAL BEFORE TRANSPLANT. COMPARISON OF TWO SOLUTIONS

C Cava[1,*] M Blanquer Blanquer[1], A Sánchez Salinas[1], V Cabañas[1], J Monserrat[1], F Labbadia[1], JM Moraleda[1]
[1]Hospital Clínico Universitario Virgen de la Arrixaca. IMIB. Universidad de Murcia, El Palmar, Spain

Background: Cryopreservation with liquid nitrogen is necessary in the autologous hematopoietic stem cells transplant. Cryoprotectant agents are needed to preserve the viability of the cells during freezing. DMSO is the most commonly used cryoprotectant agent. However, DMSO is known to produce toxicity in the patients during the infusion of the thawed product. To avoid this toxicity, our group tested the efficacy of washing the cells using a closed automated system (Sepax) and normal saline with 2.5% albumin (NSA) (Sanchez-Salinas et al, 2012). An excellent CD34+ cells recovery and cell viability after washing was demonstrated, as well as absence of infusion-related events and no negative impact on engraftment dynamics. We also collaborated in the validation of a simpler washing solution without human derived products consisting in Voluven 6% (Saccardi *et al.* ASH 2012), obtaining good results.
Aims: To compare the efficacy of NSA and Voluven as washing solutions in terms of total nucleated cells (TNC) and CD34+ cells recovery, as well as cell viability.
Methods: 102 transplant procedures matched for age, sex, weight, and diagnosis, performed between December 2009 and September 2013 were selected. NSA was used in 51 procedures and Voluven in the remaining 51. T-Student test for paired data was used to study if each of the solutions was able to adequately recover the TNC and CD34+ cells and keep their viability. T-Student test for independent data was used to inquire if there was any difference between both solutions.
Results: The 290 washing procedures (142 with NSA and 148 with Voluven) needed to perform the 102 transplant procedures were analyzed. Confirming our previous studies, there were no significant differences in CD34+ cells numbers or cell viability before and after thawing using either NSA 1 (p 0,237 and p 0,306, respectively) or Voluven (p 0,760 and p 0,799, respectively). However, a significant number of CNT were lost with both solutions. When comparing both solutions, there were no significant differences in CD34+ cells recovery + (p 0,454) or cell viability (p 0,608). NSA presented an increased CNT loss (mean -0,809+/-1,303) than Voluven (mean: -0,588+/-0,535) with marginal significance (p 0,059).
Summary and Conclusions: Both NSA and Voluven are equally effective for washing cryopreserved hematopoietic stem cells with Sepax.

PB1895

THE INFLUENCE OF HAPLOTYPE HLA-A3/A11 IN EVOLUTION AFTER HSCT

D Bratu[1,2,*]I Constantinescu[2,3], A Moise[2,3], Z Varady[1], A Tanase[1]
[1]Haematology, Clinical Institute Fundeni, [2]Medical Universty Carol Davila, [3]Immunogenetics, Clinical Institute Fundeni, Bucharest, Romania

Background: It is known that some patients haplotypes are ligands for inhibitories and activatories donors KIR allele in HSCT.The same haplotype can be protective again postHSCT complication,like ligand or not.
Aims: Haplotype HLA-A3/A11 is described in literature like ,,good,, haplotype.In this study,we try to demonstrate the influence of this haplotype at patients with acute leukemia after HSCT.
Methods: Eighteen pairs patients-donors are evaluated :patients with acute leukemia,lymphoblastic and non-lymphoblastic and their genoidentics donors.Fifteen patients have HLA-A3/A11 haplotype.Following the impact of inhibitory KIR3DL2 and activatory KIR2DS4 on survival and complication development,we proved the protective efect of HLA-A3/A11 haplotype.The source of HSCT was PBSC.The method used was PCR-SSP (Innotrain DIAGNOSTIK GMBH,Dynal BIOTECH PEL-FREEZE)The complications like graft *versus* host disease acute and chronic,relapse,TMA and the recovery with leucocytes and thrombocytes are followed
Results: HLA-A3/A11 haplotype is protective for both types of leukemia,the patients survival is much better(56 month ,comparative with 10 month)with statistical significance(sig<0,05).Is protective against relapse,TMA ,cGVHD and leucocytes recovery,with statistical significance.Like ligand for KIR2DS4 improve survival.Like ligand for KIR3DL2,also improve survival,so,,missing ligand,, theory in this case is not confirmed.
Summary and Conclusions: Like ligand or not,HLA-A3/A11 improve survival and protect against most complication at patients with acute leukemia and related donors with 100% allele match.

PB1896

HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR LANGERHANS CELL HISTIOCYTOSIS

N Karadaş[1,*] S Aksoylar[1], S Kansoy[1], M Kantar[1], N Çetingül[1], ZÖ Siviş[1], AB Akıncı[1]
[1]Pediatric Hematology Oncology, Ege University School of Medicine, izmir, Turkey

Background: Langerhans cell histiocytosis (LCH) is a reactive clonal proliferation of dendritic cells(1-3) that comprises a wide range of clinical presentations, from localized disease (single system disease) with excellent outcome to disseminated disease involving 2 or more organ or systems (multisystem disease, MS,LCH). Treatment has varied from conservative to intensive combination chemotherapy. When the systems involved are ''risk organs'' and/or the patient is younger than 2 years at diagnosis, MS-LCH has

been considered particularly devastating, and as carrying a potentially fatal prognosis. LCH treatment is not standardized, and based on anecdote. A strategy for the management of this disease needs to be developed. More intensive treatments than the standard prednisolone and vinblastine regimens are required, and the addition of methotrexate , etoposide or the cytarabine based regimens have been explored. Despite the treatment intensification, the mortality rate is approximately 40%. Refractory patients and those with multiple reactivations present a challenge. Cladribine, Cladribine – cytarabine arabinoside combination and clofarabine can be used as salvage therapy.
Aims: We report 3 patients with refractory Langerhans Cell Histiocytosis who were treated with hematopoetic stem cell transplantation.
Results: See Tables 1 and 2.

Table 1. Patients characteristics.

Table 2. Details of hematopoietic stem cell transplantation and outcome.

Summary and Conclusions: We report three resistant langerhans cell hystiocytosis which respond well to hematopoetic stem cell transplantation.

PB1897

SUCCESSFUL MOBILIZATION WITH PLERIXAFOR PLUS GRANULOCYTE COLONY-STIMULATING FACTOR IN PEDIATRIC PATIENTS
CR Hong[1,*] JY Choi[1], JW Lee[1], HY Ju[1], HJ Kang[1], H Kim[1], KD Park[1], HY Shin[1], HS Ahn[1]
[1]Department of Pediatrics, Cancer Research Institute, Seoul National University College of Medicine, Seoul, Republic of Korea, Seoul, Korea, Republic Of

Background: Collection of sufficient hematopoietic stem cells is required for autologous hematopoietic stem-cell transplantation (ASCT) after high-dose chemotherapy.
Aims: This study evaluated the clinical efficacy and tolerability of plerixafor, a CXCR4 receptor antagonist, in pediatric patients.
Methods: We retrospectively reviewed 13 patients (7 males, 6 females) who received plerixafor plus granulocyte colony-stimulating factor (G-CSF) for hematopoietic stem cell mobilization at Seoul National University Children's Hospital.
Results: We used plerixafor plus G-CSF in patients who previously failed peripheral blood stem cell mobilization by chemotherapy and G-CSF. All patients received G-CSF (10 μg/kg) for 4 days, without prior chemotherapy. Then plerixafor (240 ug/kg) and G-CSF (10 ug/kg) were administered subcutaneously, at 10 and 2 hours before each apheresis. All 13 patients were mobilized successfully, and the median number of CD34+ cells were 9.54 (range 3.17-28.97) x 10^6/kg after 1 to 3 cycles of apheresis without serious complications. Twelve ASCTs were performed and 1 patient is planning to have ASCT. Ten patients achieved neutrophil engraftment at median 12 days (10-13 days) after ASCT. Platelet engraftment was achieved at median 18 days (14-231 days) in 9 patients and 1 patient who is now at 22nd day of ASCT is waiting for the platelet engraftment. Two patients showed treatment-related mortality before engraftment.
Summary and Conclusions: Our study suggests that the mobilization with plerixafor and G-CSF could improve the success rate of peripheral stem cell mobilization in pediatric patients.

PB1898

AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN ELDERLY PATIENTS WITH PLASMA CELL MYELOMA OR LYMPHOMA
HA Ozkan[1,*] UG Ozer[1], D Cekdemir[1], Z Gulbas[1]
[1]Hematology, Anadolu Medical Center Hospital, Bone Marrow Transplantation Center, Istanbul, Turkey

Background: The feasibility and efficacy of high-dose chemotherapy followed by autologous hematopoietic stem cell transplantation (auto-SCT) in elderly patients with plasma cell myeloma (PCM) or lymphoma are discussed.
Methods: A total of 392 patients have undergone auto-SCT between July 2010 and January 2014. Of these, 29 (7.4%) were elderly with a median age of 67 years (range 65-73 years). Most of the patients (72%) had PCM. The majority (79%) had received at least 2 (range 1-4) prior regimens of chemotherapy. Twenty-three (79%) patients had active or residual disease at the time of transplantation and 4 (13,8%) patients had received at least one cycle of melphalan or fludarabine or lenalidomide treatment. The median time from diagnosis to transplantation was 10 months (range; 5-135).
Results: Mobilization: 34 mobilizations were performed for 29 patients. In 3 patients, chemomobilization was repeated with another agent because of mobilization failure. Of 34 mobilizations, 21 were done with high-dose (HD) cyclophosphamide + G-CSF, 7 with HD etoposide +CSF, 4 with ICE + G-CSF and 2 with DHAP + G-CSF. Seventy-six percent of patients were able to have successful CD34+ cell collection (>2 x 10^6 /kg CD34+ cells) within a median 3 apheresis (range; 1-8) days. Median total peripheral CD34+ cell count was 9.2 cells/μl (range; 1.2-209). Median total CD34+ cells/kg collected was 8 x 10^6 (range; 0.14-31.3). Twenty (58.8%) of the mobilizations required at least one RBC transfusion and 5 (14.7%) required at least one platelet transfusion. Febrile neutropenia occurred in 7 (20.6%) mobilization. Transplantation: Source of stem cells was the peripheral blood in all patients. A high dose sequential chemotherapy regimen named as BEAM was employed as a conditioning regimen for lymphoma patients and high dose melphalan for PCM patients before auto-SCT. Median total infused stem cells was 5.4 x 10^6 cells/kg (range; 3.2-21.3). Time to neutrophil engraftment was 10 (9-13) days and time to platelet engraftment was 11 (9-17) days. Incidence of bacterial infection was 12.1%. No viral infection was demonstrated. A median admission day at hospital was 21 (13-36) days. Ten patients (34.5%) have shown relapsed or residual disease within a median follow-up 4 (1-33) months. Four PCM patients were undergone second auto-SCT. Of these one died due to intracranial hemorrhage in the first 100 day (1/29, first 100 day mortality 3.4%).Overall survival at one year was 77.5%. Non-relapse mortality at one year was 11.7% (2/17).
Summary and Conclusions: The current study seems to provide evidence for the efficacy of auto-SCT in elderly PCM and lymphoma patients. A prospective study of auto-SCT in elderly patients using strict eligibility criteria is required to evaluate the prolongation of survival in the era of novel agents.

PB1899

AUTOLOGOUS HAEMATOPOIETIC STEM CELL TRANSPLANTATION (AHSCT) CAN BE A SUCCESSFUL THERAPY FOR PATIENTS WITH ADVANCED FOLLICULAR LYMPHOMA
A Kopinska[1,*] M Krawczyk-Kulis[1], G Helbig[1], I Grygoruk-Wisniowska[1], S Kyrcz-Krzemien[1]
[1]Dpt of haematology and Bone Marrow Transplantation, Katowice, Poland

Background: Follicular lymphoma (FL) is one of the most frequent non-Hodgkin lymphoma (NHL) with a recurrent disease course. Standard induction treatment includes an anti-CD20 monoclonal antibody combined with chemotherapy. High dose chemotherapy (HDT) followed by autologous haematopoietic stem cell transplantation (AHSCT) is a method of choice for the pts who haven't achieved complete remission (CR) after the first line of treatment or achieved CR after at least the second line of treatment. However high-dose therapy followed by autologous stem cell transplantation (ASCT) is becoming more widely used, especially as a remission consolidation in patients (pts) with advanced disease or as second-line therapy, leading to improved progression-free survival (PFS) rates.
Aims: We here present the treatment's results of 54 pts with FL who underwent AHSCT between March 1993 and April 2013 in our Department.
Methods: There were 28 males and 26 females, with a median age of 45 (range 19-69 yrs). Ann Arbor staging at the diagnosis was as follows: II-9%(n=5), III-35%(n=19), IV-56%(n=30); 52%(n=28) of pts manifested B-symptoms. 83% of pts had FLIPI1 (International Prognostic Index for Follicular Lymphoma) 2(n=26), 3(n=24) or 4 (n=1). The induction treatment consisted of R-CHOP (rituximab, cyclophosphamide, vincristine, adriamycin, prednisone) in 21 pts, CHOP in 15 pts, R-CVP (rituximab, cyclophosphamide, vincristine, prednisone) in 10 pts ,CVP in 4 pts and other schema in 4 cases. Complete remission was achieved in 29 pts (53%), and a partial response in 25 pts (47%).Conditioning regimens preceding AHSCT consisted of CBV (karmustine, cyclophosphamide, etoposide) in 44 cases, BEAM (karmustine, etoposide,

arabinoside cytosine, melphalan) in 4 and Z-BEAM (zevalin, +BEAM) in 6 pts. A median number of transplanted CD34+ cells was 6,5 (1.7 - 27x10^6/kg).
Results: All pts successfully engrafted. Hematopoietic recovery was as following: WBC count > 1,0x10^9/L after median of 14 days (range 8-21 days), ANC> 0,5x10^9/L after median of 14 days (range 8-21 days) and platelet count >50x10^9/L after median of 14 days (range 10-21 days). The major complications after AHSCT were rare and included: bacterial infections of the respiratory tract (n=15), viral infections (n=10), oral mucositis (n=9).
Eight year disease free survival (DSF) was estimated to be 29% with a 9 year overall survival (OS) of 44%.
Summary and Conclusions: HDT followed by AHSCT seems to be a effective and safe procedure for FL pts with high risk at the diagnosis.

PB1900

STUDY OF FEW CYTOKINES GENES POLYMORPHISM AND EVOLUTION AFTER HSCT

D Bratu[1,2,*] I Constantinescu[2,3], A Moise[2,3], Z Varady[1], A Tanase[1]
[1]Haematology, Clinical Institute Fundeni, [2]Medical University Carol Davila, [3]Immunogenetics, Clinical Institute Fundeni, Bucharest, Romania

Background: Introduction:Cytokines gene polymorphism is part of transplant immunology with strong implication in evolution and development of early and late complication.This remain an open and acute problem for study and discussion.
Aims: We studied a lot of eighteen pairs ,patients with acute leukemia, lymphoblastic and non-lymphoblastic, and their donors ,for polymorphism genes of few cytokines.
Methods: Methods:All related donors and recipients had 100% HLA alleles match.The source of HSCT was PBSC. The following cytokines are observed:IL-1a pos 889,IL-1RA pos mspa 11100,gIFN pos 874,TGFβ1 codon 10,TNFa pos 308,IL-6 pos 174,IL-10 pos 1082,IL-10 pos 592.The method used was PCR-SSP (Dynal Genotyping SSP Kit)The complications like graft *versus* host disease acute and chronic, relapse,TMA and the recovery with leucocytes and thrombocytes are followed.
Results: Results:IL-1a pos 889 ,absence of CC/TC ,TNF-a pos 308 GA/GA,absence of GG/GG,IL-10 pos 1082 AA/AA are favorable for early recovery with thrombocytes(<17 days) with statistical significance.gIFN pos 874,absence of AT/AT are protective against TMA.IL-10 pos 592 AA/CA are also favorable for thrombocytes recovery.No influence,with statistical significance ,was established in our study.
Summary and Conclusions: Conclusions:A study like this,a small number of pairs,genoidentical,with PBSC like HSCT source,prouve us that some alleleles can influence the complication like TMA, and early thrombocytes recovery .

PLATELET DERIVED GROWTH-BB INHIBITS PROLIFERATION OF HUMAN BONE MARROW DERIVED MULTIPOTENT MESENCHYMAL STEM CELLS IN PRESENCE OF FETAL CALF SERUM AND RAPIDLY SUPPRESSES PDGF-RB EXPRESSION

F Aerts Kaya[1,*] G Guney[1], G Aydin[1], R Donmez[1], B Kuskonmaz[2], D Uckan[1,2]
[1]Center for Stem Cell Research and Development, Hacettepe University, [2]Pediatric Hematology Bone Marrow Transplantation Unit, Hacettepe University Ihsan Dogramaci Children's Hospital, Ankara, Turkey

Background: Platelet Derived Growth Factor (PDGF)-BB is a growth factor largely synthesized by platelets, although it is produced by other cells as well. It is a potent mitogen for cells of mesenchymal origin and a major source of growth activity in serum. We have previously found that local PDGF-BB levels in the human bone marrow (BM) endosteal region are twofold lower ($p<0.05$) in comparison to the vascular region. In contrast, the PDGF-Receptor b (PDGFRb or CD140b) was significantly higher expressed by Mesenchymal Stem Cells (MSCs) derived from endosteal than from vascular BM samples.
Aims: Here, we wanted to explore the interactions between PDGF and its receptor in order to unravel their role in the BM hematopoietic microenvironment.
Methods: Granulocyte-Colony Stimulating Factor (G-CSF) treated (n=8) and unstimulated (n=15) healthy donor BM samples obtained from endosteal (superficial) and vascular (central) bone marrow punctures were used to isolate MSCs. MSCs were maintained in complete medium (CM), consisting of 60% DMEM-LG/40% MCDB201, supplemented with 10% heat-inactivated FBS, 1% penicillin/ streptomycin and 2 mM L-Glutamin. MSCs were cultured up to passage 3 (P3) and when confluent MSC/P3 supernatants were collected, filtered 0.45 µm and stored at -20ºC until use. PDGF levels in supernatants from endosteal and vascular region derived MSCs were determined using the PDGF-BB human ELISA kit (Abcam, ab100624). Proliferation indices were assessed using the XCelligence Real Time Cell Analysis system (Roche, Turkey) and FACS analysis was performed for expression of CD140b (PDGFRb) using a FACSARIA (Becton Dickinson, Turkey).
Results: PDGF-BB levels in supernatants of unstimulated healthy donor MSC/P3 derived from the endosteal region (8,79±1,96 pg/mL) were found to be significantly higher ($p=0.01$) than in supernatants from vascular region MSC/P3 (5,25±2,41 pg/mL). G-CSF treatment of donors resulted in a significant increase ($p<0.001$) in PDGF-BB levels by MSC/P3, indicating a lasting effect of G-CSF treatment on bone marrow stromal cells. Stimulation of MSCs with doses of PDGF-BB ranging from 5-20 ng/mL in CM, resulted in a reciprocal effect, with increasing doses of PDGF-BB resulting in increased suppression of proliferation. Incubation with doses of PDGF exceeding 5 ng/mL resulted in irreversible suppression of proliferation. In contrast, doses of 5 ng/mL resulted in delayed proliferation, but after initial suppression, proliferation at day 10 was comparible to cultures maintained in CM only. In comparison to expression levels of CD140b by MSCs maintained in CM only (83.9%), incubation of MSCs in presence of 5 ng/mL PDGF-BB for 24 or 48 hours resulted in a rapid and reproducible initial decrease of CD140b expression to 31.3% at 24 hrs with some recovery of expression of CD140b to 44,6% at 48 hrs. In contrast, doses of PDGF in excess of 5 ng/mL resulted in permanent suppression of the PDGF receptor.
Summary and Conclusions: PDGF-Receptor expression by MSCs was rapidly adjusted in response to exogenously delivered PDGF-BB. Prolonged exposure to high doses (>5 ng/mL) of PDGF-BB resulted in irreversible suppression of PDGFR expression and MSC proliferation. Exposure to moderate doses of PDGF-BB (5 ng/mL) resulted in temporary suppression of PDGFR expression, followed by recovery, resulting in delayed, but overall not decreased proliferation of MSCs. Based on these results, we hypothesize that the low expression of PDGFR by MSCs from the vascular region is caused by locally produced high levels of endogenous PDGF-BB, whereas the increased expression of PDGFR by MSCs from the endosteal region is the result of relatively low levels of PDGF in the endosteal BM microenvironment.

ASYMMETRIC ANEUPLOIDY IN ADULT MESENCHYMAL STROMAL CELLS AND IN BONE MARROW WITH HEMATOLOGIC MALIGNANCIES DETECTED BY FLUORESCENCE IN SITU HYBRIDIZATION: SUGGESTIONS FOR NORMAL REFERENCE VALUES FOR ST

SY Kim[1,*] JA Kim[1], K Im[2], SN Park[2], J Kwon[2], JA Kim[1], Q Choi[1], SM Hwang[3], DS Lee[1]
[1]Department of Laboratory Medicine, [2]Cancer Research Institute, Seoul National University College of Medicine, [3]Department of Laboratory Medicine, Seoul National University Bungdang Hospital, Seoul, Korea, Republic Of

Background: *In vitro* culture of stem cells confers clonal heterogeneity with

emergence of cytogenetic aberrations. G-banding assay, most widely used for cytogenetic study, is not sufficient for detection of minor clones and sensitivity of molecular methods is too low. We investigated the frequency of cytogenetic aberrations of mesenchymal stromal cells (MSCs) by G-banding implemented with fluorescence *in situ* hybridization (FISH) and suggest the reference values for aneuploidy in MSCs.
Aims: The aims of this study were to use *in situ* karyotyping and FISH techniques to detect chromosomal abnormalities and aneuploidy in primary MSCs, to determine the most effective method to screen MSCs for medical use and to determine the criteria for the selection of safe MSCs, and to to comparison of the pattern of aneuploidy in stem cells with those of aneuploidy found in bone marrow cells from patients with hematologic malignancies, to have a guidance for assessing the significance of aneuploidy clones.
Methods: Cytogenetic analysis was done on 103 consecutive cultures from 68 kinds of MSCs. We compared the aneuploidy patterns of MSCs with those of 259 patients with hematologic malignancies and 22 patients with benign hematologic diseases.
Results: Interphase FISH showed variable proportions of aneuploid clones (1% to 20%) in 68 kinds of MSCs. The patterns of aneuploidy were asymmetric, and aneuploidy of chromosome 16, 17, 18, and X was most frequent. Clones with polysomy was significantly higher than those with monosomy ($P<0.001$). The cut-off value of maximum polysomy rates (upper 95-percentile value) was 13.0%. By G-banding, 5 among 61 MCSs presented clonal chromosomal aberration. The structural abnormalities frequently involved chromosome 7. When compared the aneuploidy patterns of hematologic diseases, patients with various hematologic malignancies presented heterogeneous and asymmetric patterns of aneuploidies in different chromosomes, while patients without malignant cells showed tetraploidy clones with symmetric pattern.
Summary and Conclusions: We suggest the cut-off value for aneuploidy as 13%, and FISH for aneuploidy of chromosome 16, 17, 18, and X would be informative to evaluate the genetic stability of MSCs. Though it is uncertain whether aneuploid clones might mean the senescent cell population or actually transforming cells, more attention should be paid for the safety of MSCs, and G-banding combined with FISH should be performed.

CLEC12A: A NEW AML STEM CELL-ASSOCIATED ANTIGEN
V Guadagnuolo[1,*] E Imbrogno[1], A Ghelli Luserna di Rorà[1], A Padella[1], G Simonetti[1], E Ottaviani[1], C Papayannidis[1], I Iacobucci[1], A Ferrari[1], M Perricone[1], R Valentina[1], C Venturi[1], G Martinelli[1]
[1]Institute of Hematology "L. e A. Seràgnoli", Bologna, Italy, bologna, Italy

Background: Acute myeloid leukemias (AML), a heterogeneous and complex group of diseases, is a clonal malignant disorder derived from a small number of leukemic stem cells (LSCs), which are sustained by self-renewing and responsible for the propagation of leukemic blasts (LBs). Monoclonal antibodies have emerged as effective targeted therapies for the treatment of human malignancies and their mechanisms of action are able to deliver the therapeutic effects with minimal toxicity.
Aims: The challenge is the identification of cell surface antigens which could be preferentially expressed on AML LSC compared with normal hematopoietics stem cells and that could be helpful to target therapies.
Methods: On 16 AML patients (pts) at diagnosis (peripheral blood of 12 pts and bone marrow of 4 pts) myeloblast leukemic cells were identified using a FACSCanto flow cytometer (Becton Dickinson), based on low expression of CD45 and low side scatter (SSC) properties (CD45 low/SSC low). On these subpopulation we used an antibody panel against cell surface antigens, for the detection of immature markers and potential leukemia-associated antigens: CD34, CD38, CD90, CLEC12A (C-type lectin domain family 12 member A), CD44, CD99, TIM-3 (T cell immunoglobulin mucin-3), CD32, CD133, CD74, CD47, CD58, CD25, CD22, CD96.
Results: The proportion of LBs was positively correlated with CD45 low/SSC low (median 51,8%). This gated population of LBs were positive for CD34 (median 44,65%), CD38 (median 18,75%), CD90 (median 0,90%), CLEC12A (median 93,7%), CD44 (median 99,9%), CD99 (median 96,6%), TIM-3 (median 84,4%), CD32 (median 14%), CD123 (29,15%), CD133 (median (8,95%), CD58 (median 97,5%), CD47 (median 99,9%), CD74 (median 3,2%), CD25 (median 0,6%), CD96 (median 87%), CD22 (median 0,55%).
Summary and Conclusions: The expression of CD34 and CD38 antigens is heterogeneous in LBs. In particular we found that the 50% of patients were $CD34^+$ and 50% were $CD38^+$. CLEC12A, CD44, CD99, TIM-3, CD58, CD47 and CD96 were highly expresses in LCSs. CD90, CD32, CD123, CD133,CD74, CD25 and CD22 were low. Interestingly we identified that the expression of CLEC12A distinguished two different populations: the $CLEC12A^{high}$ cells correlated with the blast cells $CD45^{low}/SSC^{low}$; on the other hand, $CLEC12A^{low}$ cells could be compared with $CD45^{high}/SSC^{high}$ population, representing normal hematopoietic cells. In conclusion, this marker is a good candidate to target therapies against leukemic stem cells. However further studies with an higher number of patients must be carried out to confirm that CLEC12A is an appropriate antigen for a new monoclonal antibody-based therapy.

PB1904

POTENTIAL HEMATOTOXICITY OF NEW DRUG CANDIDATES MEASURED IN HEMATOPOIETIC PROGENITORS IN BONE MARROW SAMPLES
D Primo[1], A Espinosa[1], E Arroyo[1], V Garcia-Navas[1], J Sanchez-Fenoy[1], M Jimenez[1], E Martin Clavero[2], ML Paciello[2], J Gorrochategui[1], A Robles[1], M Gaspar[1], A Jimenez-Velasco[3], J Ballesteros[1,*] P Hernandez-Campo[1], J Martinez-Lopez[2]
[1]Vivia Biotech, [2]Hematology, Hospital Doce de Octubre, Madrid, [3]Hematology, Hospital Carlos Haya, Malaga, Spain

Background: Hematotoxicity, the result of Bone Marrow (BM) failure, contributes significantly to morbidity and mortality by inducing severe infections and bleedings. Recently, knowledge of the specific genetic markers responsible for hematological malignancies and their associated signaling pathways has generated many new targets that promise to increase drug efficacy while reducing side effects such as hematotoxicity. However lesser hematotoxicity of drug candidates is not investigated until expensive preclinical studies in dogs. There is a need to estimate human hematotoxicity in early drug development.
Aims: To measure depletion analysis of different subsets of CD34+ progenitors in human healthy bone marrow samples that could reflect the degree of drug's induced hematotoxicity, using our flow cytometry-based automated Exvitech© platform.
Methods: 10 Normal Bone Marrow (NBM) samples at diagnosis from lymphoma patients prior to any therapeutic intervention with confirmed absence of BM infiltration by flow cytometry were included. For a first approach, we have selected two known and related nucleoside cytotoxic drugs (Cytarabine and Clofarabine). The whole sample was plated into 96-well assay plates containing 8 concentrations of each drug and incubated for 48-hours. A multiple staining (CD45v450/Anexin-FITC/CD117-PE/CD34PerCP/CD38-APC/CD19APCya7) was capable to identify and distinguish the most immature population ($CD34^+/CD45^{dim}/CD38^+$ or $CD38^-$), B-precursors ($CD34^+/CD45^{dim}/CD19^+$) from the more mature B-($CD45^+$/ $CD19^+/SSC^{lo}$), or T-($CD45^+$/ $CD19^-/SSC^{lo}$) lymphocytes. Drug response was evaluated as a depletion survival index of each cell population relative to the average of 6 control wells in each plate.
Results: As expected, both drugs induce hematotoxicity in most of the studied person's samples, but not all. Using the same drug concentration for each drug for all the patient samples, results reflect that Cytarabine has similar activity than Clofarabine in terms of efficacy (Emax: 28% *vs* 27%) but with 33-fold less potency (EC_{50}: 7μM *vs* 0.21μM) in the immature population. This reflects a lower hematological toxicity which is consistent with clinical practice. Interestingly, for both drugs there is a large range of interpatient variability inside this population in terms of efficacy (Cytarabine, range Emax: 2%>76% and Clofarabine, range Emax: 12%>42%) and potency (Cytarabine, range EC_{50}: 3μM-14μM and Clofarabine, range EC_{50}: 0.01μM-2μM) suggesting that in a subsets of vulnerable patients, drug doses could be tailored. Interestingly, the figure shows a person's sample where Clofarabine eliminates all precursors, while Cytarabine eliminates only 20% of the progenitors and would thus not be expected to cause hematotoxicity. Figure 1 show these drug's effects on progenitor subtypes CD34+, myeloid and totipotential; their dose responses are similar as expected given their non-selective mechanisms of action.

Figure 1.

Summary and Conclusions: These preliminary results show that Vivia Exvitech© platform is able to measure hematopoietic progenitors depletion in addition to other cell populations for novel drugs or before patient´s treatment that could contribute to a more selective drug development or a better clinical management of patients. Because increasing number of novel drugs with different mechanism of action are coming to the clinic, Vivia Exvitech© platform represent an attractive method to screen potential effects in any of the interested cell subsets, including the more immature ones that are associated with hematologic BM complications.

HYDROXYCARBAMIDE DEMONSTRATES NITRIC OXIDE SYNTHASE DEPENDENCE IN PROLIFERATION AND APOPTOSIS
T Subotički[1], O Mitrović[1], M Diklić[2], M Mićić[1], S Mojsilović[2], S Vignjević[1], M Budeč[1], G Jovčić[2], V Čokić[2,*]

[1]Department for neuroendocrinology, [2]Laboratory of experimental hematology, Institute for Medical Research, University of Belgrade, Belgrade, Serbia

Background: It has been reported that nitric oxide (NO) inhibition of erythroleukemic cell growth is due to inhibitory interaction with ribonucleotide reductase, similarly to the cytostatic hydroxycarbamide effect.
Aims: The study has been performed to investigate hydroxycarbamide dependence of NO in proliferation and apoptosis of K562 erythroleukemic cells.
Methods: The globin gene expression was examined by real-time PCR in human erythroid progenitor cultures, while quantity of bone marrow burst forming unit-erythroid (BFU-E) and colony-forming unit-erythroid (CFU-E) was determined by colony assays in mice. K562 cell cycle analysis was achieved by flow cytometry with propidium iodide, while proliferation and apoptosis were evaluated by immunocytochemistry using Ki67 antibody and apoptotic index.
Results: To examine the erythroid phenotype during NO treatment, we showed the NO stimulation of γ/β ratio (1.7 fold) in erythroid progenitors, while *in vivo* NO synthase (NOS) inhibition by L-NAME significantly increased the number of BFU-E and CFU-E colonies in mouse model. Moreover, hydroxycarbamide and NO donors demonstrated permanent *versus* temporary inhibition of erythroid cell growth during their differentiation. Treatment of K562 erythroleukemic cells with NO donors (CysNO, DEANO or DETANO) and hydroxycarbamide resulted in a similar dose-dependent and steady inhibition of cell growth up to 40%. Cell cycle analysis revealed that prolonged treatment with NO donors resulted in a higher proportion (58-62%) of cells in G_0/G_1 phase, similarly to hydroxycarbamide (65%). DETANO and hydroxycarbamide also decreased the percentage of K562 cells in G_2/M phase. L-NAME reversed hydroxycarbamide effects, increasing percentage of K562 cells in G_0/G_1 (1.6 fold) and G_2/M (2 fold) phases and reducing a cell cycle arrest in S phase (1.6 fold). More profound inhibition of K562 cell proliferation, up to 50%, was observed with 50 μM hydroxycarbamide after 24 hours. NO donors significantly increased apoptosis both after 24 and 48 hours, whereas hydroxycarbamide preferentially augmented apoptosis after 48 hours of incubation in K562 cells. Hydroxycarbamide stimulation of apoptosis was 33% reduced by L-NAME both after 24 and 48 hours.
Summary and Conclusions: Hydroxycarbamide and NO donors share a long term stimulation of apoptosis and a short term inhibition of proliferation, inducing cell cycle arrest in the G_0/G_1 phase. Obtained results indicate that the effects of hydroxycarbamide on proliferation and apoptosis of erythroleukemic cells are NOS dependent.

PB1906

CYTOGENETIC CHARACTERIZATION OF BONE MARROW MESENCHYMAL AND HEMATOPOIETIC STEM CELLS FROM PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND FROM HEALTHY CONTROLS

E Kouvidi[1,*] A Batsali[1], A Stratigi[1], S Mastrodimou[1], E Mavroudi[1], H Papadaki[1]
[1]Department of Hematology, School of Medicine, University of Crete, Iraklion, Crete, Greece

Background: Mesenchymal Stem Cells (MSCs) are functional cellular components of the Bone Marrow (BM) microenvironment and their immunomodulatory and hematopoiesis support functions make them an ideal candidate for clinical application. Myelodysplastic Syndromes (MDS) are acquired clonal BM disorders characterized by ineffective hematopoiesis and high risk of evolving into leukemia. The role of BM MSCs in the pathogenesis of MDS remains elusive.
Aims: To confirm our previous results regarding the cytogenetic characteristics of BM MSCs in comparison to Hematopoietic Stem Cells (HCs) from MDS patients and healthy controls by expanding our sample pool and to examine the genetic stability of BM MSCs during passages (P).
Methods: Conventional cytogenetic analysis using GTG-banding was performed on BM cultured HCs and MSCs at P2 in 29 MDS patients and in 25 healthy controls, at P6 in 18 MDS patients and 10 healthy controls and at P10 in 10 MDS patients and 6 healthy controls. Whenever possible, 15 – 20 metaphases were analyzed. When needed, molecular cytogenetic analysis (Fluorescence *in situ* Hybridization - FISH) was performed.
Results: Conventional cytogenetic analysis of BM HCs revealed clonal abnormalities in 9/29 MDS patients (del(5q) n=4, del(5q) and an additional del(7q) subclone n=1, trisomy 8 n=2, loss of Y n=1, trisomy 11 n=1). The chromosomal analysis of the corresponding MSCs showed chromosomal abnormalities in 4/29 MDS patients (trisomy 7 n=1, del(12q) n=1, trisomy 5 n=1, 51,XY,+4,+5,+5,+7,+12 n=1) at P2, in 3/18 MDS patients (trisomy 5 n=2, trisomy 7 n=1) at P6 and in 1/10 MDS patients (trisomy 5 and an additional trisomy 5 and 7 subclone) at P10. Conventional cytogenetic analysis of BM HCs from all healthy controls showed normal karyotype. However, chromosomal analysis of the respective MSCs revealed chromosomal abnormalities in 2/25 healthy controls (trisomy 5) at P2 and in 1/10 healthy controls (trisomy 5) at P6. Using FISH technique, the presence of all abnormalities was verified, 2 more MDS patients and 2 more healthy controls were identified with trisomies 5 and 7.
Summary and Conclusions: The present results indicate that the cytogenetic abnormalities found in BM MSC cultures from MDS patients are different from those found in the corresponding BM HCs at diagnosis and accordingly they do not belong to the abnormal clone. It must be noted that most of the reported aberrations in BM MSCs are non – characteristic of MDS and have also been identified in MDS cases with normal HC karyotype and in MSCs derived from normal controls, implying that they could be attributed to the *in vitro* cell expansion process. MSCs cultures from both MDS patients and healthy controls displayed chromosomal stability during passages, however, they may develop irrelevant chromosomal aberrations with unknown pathophysiologic significance. Larger future studies are needed to examine the chromosomal stability of BM MSCs during passages, since it is of great interest their therapeutic potential in hematologic malignancies.
This work was supported by the European Commission FP7 programme 'Translational Potential' (TransPOT; EC contract number 285948)

PB1907

CHARACTERIZATION OF MICROPARTICLES FROM HEALTHY AND MALIGNANT BLOOD CELLS BY FLOW CYTOMETRY

E Crompot[1,*] M Van Damme[1], H Duvillier[2], K Pieters[1], M Vermeesch[3], D Perez-Morga[3], N Meuleman[2], D Bron[2], P Mineur[4], L Lagneaux[1], B Stamatopoulos[1]
[1]Laboratory of Clinical Cell Therapy, [2]Hematology, Jules Bordet Institute, ULB, Bruxelles, [3]The Center for Microscopy and Molecular Imaging (CMMI), Gosselies, [4]Onco-Hematology, Grand Hopital de Charleroi, Gilly, Belgium

Background: Recently, microparticles (MPs) have been described as a new way of intercellular communication. MPs are plasma membrane fragments with sizes ranging from 0.1 to 1μm, containing products of the original cell, such as microRNA, mRNA and proteins that can be delivered to other cells. However, little is known about their phenotypic characterization.
Aims: Here, we would like to investigate the phenotypic characterization of healthy and malignant blood cell-derived MPs by flow cytometry.
Methods: We analyzed blood-derived MPs from platelets, erythrocytes, B-cells, T-cells, NK-cells, monocytes and chronic lymphocytic leukemia (CLL) B-cells. Cells were purified by positive magnetic-separation and cultured during 48h. Cells and MPs (obtained after ultracentrifugation at 20000g) were phenotypically characterized by the following monoclonal antibodies; CD19,20,184,45 for B-cells, CD3,8,5,27 for T-cells, CD16,56 for NK-cells, CD14,11c for monocytes, CD235a for erythrocytes and CD41,61 for platelets. All analyses were performed on a Navios cytometer, calibrated by Megamix Beads PLUS (Biocytex). Isolated MPs were stained with Annexin-V-FITC and gated between 300nm and 900nm. Then latex bead technique for easy detection of MPs (increasing element's size and antigen's detection) was also performed.
Results: For all samples, MPs defined as positive event for Annexin-V and included in gate of 300-900 nm of size were detected. MPs production was confirmed by scanning electron microscopy (SEM) and transmission electron microscopy (TEM). In principle, MPs are characterized by antigen expression from mother cells. Our results showed that characteristic antigens of platelets (CD41 and CD61) and of erythrocytes (CD235a) were found on MPs. However, for other cell type-derived MPs, we were not able to detect any antigen present on the original cells (T, B, NK, monocytes or CLL-cells) while these antigens were clearly expressed on the cells. Using latex bead technique, we confirmed detection of CD41, CD61 on platelet-derived MPs and CD235a on erythrocyte-derived MPs. However, for all other antigens, results found turned out to be false positives, proved by the use of other type of negative controls (same labeling on MPs from different origins).
Summary and Conclusions: We observed that mother cell antigens were not always detected on corresponding MPs by direct flow cytometry or latex bead flow cytometry. Our results demonstrated that the characterization of the MPs is a difficult field requiring the use of several negative controls.

PB1908

SUCCESSFUL TREATMENT OF ADULT LANGERHANS CELL HISTIOCYTOSIS. A CASE REPORT

P Klonizakis[1,*] E Vlachaki[1], D Sakellari[2], M Arico[3], I Onoufriadis[1], N Sousos[1], P Boura[1]
[1]2nd Department of Internal Medicine, Hippokration General Hospital, [2]Dental School , Aristotle University of Thessaloniki, Thessaloniki, Greece, [3]Department Pediatric Hematology Oncology, Istituto Toscano Tumori, Florence, Italy

Background: Langerhans Cell Histiocytosis (LCH) is a very rare and heterogenous disease that may affect various organs of the body. There is no standard first line therapy for LCH in adults, in contrast with the established therapeutic protocols in children. Therapy may be urgent, especially if vital organs are involved or if specific sites are affected, such as the facial bones that are associated with intracranial tumor extension.

Aims: To present the diagnostic difficulties and the selection of treatment during the eight-years clinical course of a young adult with LCH.
Methods: A 26 yrs-old male patient presented in 2009 at a periodontologist with tooth ache, gum tenderness and aggressive periodontitis not responding to treatment with antibiotics during the last three years. He had a history of cigarette smoking during the last ten years and suffered from a persistent cough during the last year. The diagnosis of LCH was based on a superior maxilla bone biopsy, which revealed characteristic morphological and immunological findings of histiocytosis from Langerhans cells (Cd1a+). The patient was referenced to our hematology clinic for further assessment. Screening tests revealed a simultaneous involvement of the zygomatic bones and the lungs according to a bone scan and a chest High Resolution Computerized Scan (HR CT), respectively. Therapy was based on the protocol of the first international study for adult LCH (LCH-A1). Initial treatment comprised Prednisone (60 mg/day), as a 4-week course (tapering over a period of 2 weeks), and vinblastine (8 mg/week) until day 36. The patient responded to initial treatment and continued with maintenance treatment with 6-mercaptopurine (50 mg/day), prednisone (60 mg, day 1-5, every 3 weeks) and vinblastine (8 mg day 1, every 3 weeks), administered for 12 months.
Results: The treatment with vinblastin and steroid was very well tolerated with no relevant toxicity. At the end of therapy, in 2010, there was no evidence of residual disease at the maxilla and zygomatic bones, and there was a clear improvement of the lesions in the lungs, according to HR-CT. Unfortunately, the patient restarted smoking and, six months later, HR-CT documented disease progression in the lungs. Then the patient stopped smoking but refused initiation of any therapy. In 2011, six months after cigarette smoke withdrawal, a new HR-CT showed no new lesions and even a slight improvement compared to the previous evaluation. On the contrary, both clinical and imaging findings from the facial bones were significant worse. We decided to retreat him with the same chemotherapy protocol. The patient tolerated the complete twelve-month therapy without any complications and significant improvement of the initial bone lesions was documented. Two years later he is still in follow-up, in a very good condition (Figure 1).

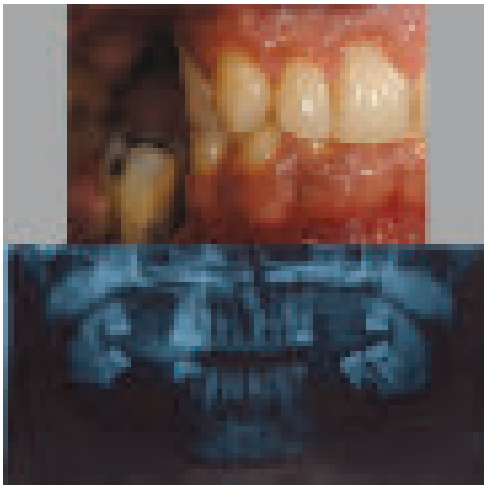

Figure 1.

Summary and Conclusions: Multidisciplinary approach is instrumental in diagnosis and treatment of LCH. Although the trial LCH-A1 had to be stopped due to insufficient accrual, treatment with vinblastin and steroid (even when repeated for a second full 12-month course) turned out to be safe and effective in this patient. The relationship with cigarette smoking in patients with pulmonary disease is well known and its role as a triggering agent is confirmed also in this case.

PB1909

IMPACT OF VITAMINS B12, B6 AND FOLATE SUPPLEMENTATION ON THE HOMOCYSTEINE METABOLISM OF AN ELDERLY COMMUNITY OF SHARPEVILLE, SOUTH AFRICA

C Grobler[1,*] W Oldewage-Theron[2]
[1]Health Sciences, [2]CSL, Vaal university of Technology, Vanderbijlpark, South Africa

Background: In a vulnerable low income group, like the elderly in the day-care centre, with a confirmed high risk of cardiovascular disease an acute intervention is needed in order to improve their health profile. The effect of vitamin B12, B6 and folate supplementation on the inflammatory response, thrombotic risk, lipid profile, hypertension, risk for metabolic syndrome and the homocysteine metabolism in an elderly, black South African population has never been reported.
Aims: The aim of this interventional study was to assess the effect of vitamins B12, B6 and folate supplementation at 200% RDA for six months on the homocysteine metabolism of an elderly semi-urbanised black South African community.
Methods: A homogenous group of respondents were included into the study. All subjects were equivalent in age (>60 years), race (black), unemployed / pensioner (socio-demographic) and 60 years and older attending a day care centre in Sharpeville, situated in the Vaal region, Gauteng, SA. Informed consent for inclusion in this study was given by the participants. The distinctiveness of this study was the evaluation the red cell parameters, serum homocysteine levels in correlation with the increased nutritional intake of vitamin B6, B12 and Folate.
Results: A very high incidence (66.36%) of hyperhomocysteinaemia is present in the sample. The mean serum homocysteine level in group A decreased statistical significantly (25.30±8.00 µmol/l to 18.76±12.00 µmol/l), whereas the mean homocysteine level in group B increased (12.04±3.40 µmol/l to 13.64±6.00 µmol/l). Serum vitamin B12 and folate levels in both groups fell within the normal reference range. Although a slight but statistical significant decrease of these two parameters occurs after intervention in both groups, the mean levels were still within the normal reference range. Very low vitamin B6 levels were observed in both groups and improved statistical significantly after the intervention. In group A the serum vitamin B6 increased from 1.35±0.69 µg/ml (baseline) to 5.03±0.69 µg/ml (follow-up), in group B the serum vitamin B6 increased from 1.40±0.80 µg/ml (baseline) to 5.72±6.15 µg/ml (follow-up). The prevalence of macrocytosis decreased significantly. In group A the respondents with macrocystosis decreased from 31% (baseline) to 7% (follow-up) and in group B the percentage decreased from 23% to 5%.
Summary and Conclusions: It is concluded that a vitamins B12, B6 and folate supplementation at 200% RDA for six months had a homocysteine lowering effect in hyperhomocysteinaemic individuals but not for normohomocystaemic individuals. The supplementation was beneficial to all the individuals (independently of their homocysteine status) vitamin B6 serum levels and on their haemopoeiesis (decrease macrocytosis).

PB1910

CYTOGENETIC HETEROGENEITY AND DYNAMIC CHANGES DURING CANCEROUS TRANSFORMATION OF MESENCHYMAL STEM CELLS

JA Kim[1,*] JS Kwon[2], Q Choi[1], KO Im[2], SN Park[2], SY Kim[1], SM Hwang[1,3], YM Oh[4], SD Lee[4], DS Lee[1,2]
[1]Department of Laboratory Medicine, [2]Cancer Research Institute, Seoul National University College of Medicine, Seoul, [3]Department of Laboratory Medicine, Seoul National University Bundang Hospital, Seongnam, [4]Department of Pulmonary and Critical Care Medicine, Asthma Center and Clinical Research Center for Chronic Obstructive Airway Diseases, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: G-banding analysis is widely used to detect the cytogenetic aberrations of mesenchymal stem cells (MSCs). However, G-banding reflects the chromosomal status of metaphase cells only, which compose less than 0.01% of the tested cells.
Aims: The aim of this study is to investigate whether the minority cells within a population have a minimal impact on the biology of population and are ultimately suppressed during passaging. Using interphase FISH combined with G-banding analysis, we tracked the quantitative changes of the cells with chromosomal aberrations during passaging.
Methods: In MSCs that acquire cytogenetic aberrations during cell culture, we tracked the quantitative changes of each clone in a population of heterogeneous clones during passaging, using G-banding and fluorescent *in situ* hybridization (FISH). Using FISH, we counted the number of chromosomes using enumeration probes (chromosome 7 and 9) and we also used locus specific probes and bacterial artificial chromosome probes to confirm structural anomalies. In each passage, telomere length was measured using interphase FISH.
Results: . In adipose MSCs and umbilical cord MSCs, 4 types and 2 types of chromosomal aberrations, respectively, appeared during passaging. Abnormal clones could be detected earlier using interphase FISH than when using G-banding analysis. Through all passages, the quantitative G-banding results were inconsistent with those of the interphase FISH analysis. Telomere length gradually decreased until a cytogenetic aberration appeared and then increased again.
Summary and Conclusions: The cytogenetic profile of late passage cells was similar to that of transformed cancer cells; however, G-banding did not detect abnormal clones in earlier passages. We observed that MSCs with only 1 aberrant cell, which does not fit into definition of clone, become predominant at late passages. FISH revealed hidden aberrations in stem cells that had normal karyotypes by G-banding analysis. It is critical to test chromosomal aberrations by both G-banding and FISH to ensure the safety of human stem cells that are manufactured *in vitro* for clinical application.

COMPARATIVE ANALYSIS OF INTRACELLULAR NEUROTRPHIC FACTORS IN MONONUCLEAR CELLS OF CORD BLOOD AND G-CSF MOBILIZED PERIPHERAL BLOOD

YH Lee[1,*] K Hwang[2], H Koh[2], HR Kang[3], KA Hwang[3], JY Seo[3], HY Im[4], JH Moon[1]
[1]Department of Pediatrics, Hanyang University Medical Center, [2]Department of Translational Medicine, Hanyang University Graduate School of Biomedical Engineering and Science, [3]Blood and Marrow Transplantation Center, [4]Medical Science Institute, Hanyang University Medical Center, Seoul, Korea, Republic Of

Background: Among a series of stem cell sources used to repair neurological diseases, intravenous administration of autologous cord blood (CB) has been used to try to counteract neurological injuries and impairments. We suggest that mobilized peripheral blood mononuclear cells (mPBMC) could potentially be used for treating neurological impairments, because stem cells from CB and mPBMC are comparable in long-term culture-initiating cells. While previous studies have investigated the cytokines and/or neurotrophic factors of mesenchymal stem cells derived from CB or mPBMC, to our knowledge there have been no comparative studies between mononuclear cells of CB and mobilized peripheral blood.
Aims: To investigate a possible use for cell therapy in the field of neurological disorders using mPBMCs as well as CB, we compared the expression of inflammatory cytokines and neurotrophic factors in PBMCs and mPBMCs from children with cerebral palsy (CP) to those from healthy adult donors and to CB donated from healthy newborns.
Methods: We evaluated the intracellular expression of neurotrophic factors and inflammatory cytokines in PBMCs and mPBMCs from 14 CP children and 14 healthy adult volunteer donors as well as CB mononuclear cells (CB-MNCs) donated from healthy newborns. Both PBMC collected prior to G-CSF administration and apheresed mPBMC were cryopreserved. We performed flow cytometric analysis with intracellular staining for various cytokines after thawing PBMCs and mPBMCs as well as CBs.
Results: In cells from CP children, the expression of IL-6 was significantly increased in mPBMC as compared to PBMC, and IL-3 was significantly decreased in mPBMC as compared to PBMC. In healthy adults, the expression of both IL-1β and IL-6 were significantly increased in mPBMC as compared to PBMC. The expression of BDNF in mPBMC from CP children was significantly higher than in CB or mPBMC from healthy adults. The expression of G-CSF in mPBMC from CP children was comparable to that in CB but significantly higher than in mPBMC from healthy adults. Lower expression of IL-1β, IL-3, and IL-6 and higher expression of IL-8 and IL-9 was observed from CB and mPBMCs from CP children rather than in healthy adults. Lower expression of IL-1β, and higher expression of IL-8 was observed from mPBMCs from CP children rather than in healthy adults.
Summary and Conclusions: The altered expression of neurotrophic factors and anti-inflammatory cytokines in mPBMC in CP children and CB from healthy children could provide a new potential source for cellular therapy for individuals with neurologic diseases.

Gene therapy, cellular immunotherapy and vaccination

THE SECOND EPISODE OF ADOPTIVE IMMUNOTHERAPY WHEN REPEATED RELAPSE OF ACUTE MYELOID LEUKEMIA (AML) AFTER ALLOGENEIC BONE MARROW TRANSPLANTATION (ALLO-BMT)

R Bogdanov[1,*] L Mendeleeva[1], I Galtseva[1], L Kuzmina[1], E Parovichnikova[1], V Savchenko[1]
[1]Bone marrow transplantation, Research center of Hematology, Moscow, Russian Federation

Background: Chemotherapy followed by donor lymphocyte infusions (DLI) allow to achieve remission in the majority of patients with relapse AML after allo-BMT. Even so, repeated relapse of leukemia is the main cause of failure in adoptive immunotherapy.
Aims: The study the effectiveness of re-use adoptive immunotherapy in the second relapse after a first episode of adoptive immunotherapy. The T-cells for immunotherapy were obtained from a bone marrow donor.
Methods: 6 patients with AML aged 23-58 years (median 31), were diagnosed with a second relapse after allogeneic BMT from HLA-matched sibling donor. Median time after first successful treatment relapse following allo-BMT scheme chemotherapy + DLI (±IL-2) to the second relapse of AML was equal to 7 months (2-30 months). DLI the second relapse after chemotherapy was performed in the aplasia period (n=3) or in remission after chemotherapy (n=3). Total amount of the $CD3^+$cells varied from 1 to 41x10^7$CD3^+$cells/kg (median 28x10^7$CD3^+$cells/kg). After every DLI performed intravenous IL-2 in a dose of 6 MUE. Interval between transfusion was 1-4 weeks. Each patient performed 1-4 (median 2) DLI. Chimerism was monitored by PCR analysis (VTTR and STR) and by FISH – analysis for centromers of X and Y - chromosomes.
Results: In 5 patients achieved remission with full donor chimerism, which last from 4 to 127 months (median 6 months). In two cases, the duration of remission after a repeat episodes adoptive immunotherapy, including chemotherapy and DLI has exceeded a previous remission duration. 3 patients alive in remission with full donor chimerism.
Summary and Conclusions: DLI after chemotherapy for AML patients with repeated relapse after adoptive immunotherapy may be achieved long-term remission with restoration of full donor chimerism. In 83% of AML remission with recovery of 100% donor chimerism, which lasts from 4 to 127 months (median 6 months) after successful treatment with a second relapse after allo-BMT.

PB1913

EXPANSION OF NK CELLS FROM PERIPHERAL BLOOD MONONUCLEAR CELLS USING GMP-COMPLIANT SUBSTANCES WITHOUT FEEDER CELLS FOR ADAPTIVE NK CELL THERAPY

J Tanaka[1,*] K Mitsuhashi[1], YH Wang[1], H Shimura[1], S Kodama[1], M Ishiyama[1], H Kazama[1], Y Imai[1], K Yoshinaga[1], M Shiseki[1], N Mori[1]
[1]Hematology, Tokyo Women's Medical University , Tokyo, Japan

Background: NK cell receptor (NKR)-expressing cells have cytolytic activity against leukemic cells, and solid tumor cells escape from T cell recognition because of the low expression level of HLA class I molecules in both allogenic and autologous settings. This characteristic nature of NK cell recognition of target cells in contrast with T cells provides a strategy to overcome tolerance in the tumor-bearing host. Furthermore, donor alloreactive NK cell which was induced by killer cell immunoglobulin-like receptor (KIR) ligand incompatibility between donor and recipient HLA class I in graft-*versus*-host (GVH) direction can attack leukemic cells and host antigen-presenting cells (APC), resulting in the enhancement of graft-*versus*-leukemia (GVL) effect and the suppression of graft-*versus*-host disease (GVHD) at the same time. Therefore, adoptive transfer of NK cells is a potential immunotherapy to induce an anti-leukemia/tumor effect. However, expansion of NK cells from peripheral blood mononuclear cells (PBMC) without feeder cells is not easy for adaptive NK cell therapy.
Aims: In this study, we tried to expand NK cells from PBMC with antileukemic activity using good manufacturing practice (GMP)-compliant substances without feeder cells. We used tacrolimus to inhibit T cell proliferation and dalteparin to support NK cell proliferation during NK cell expansion using IL-2, IL-15 and OKT3 *in vitro*.
Methods: PBMC ($1x10^6$/mL) were cultured with IL-15 (10 ng/mL)(PeproTech Inc., Rocky Hill, NJ, USA), IL-2 (5 ng/mL) (R & D Systems, Minneapolis, MN, USA) and anti-CD3 mAb (OKT3, 10-1,000 ng/mL, Janssen Pharmaceutical Company, Tokyo, Japan) with tacrolimus (0.02-0.1 ng/mL, Fujisawa, Osaka, Japan) and dalteparin sodium (Fragmin, 5-10 U/ml, Pfizer Japan, Tokyo, Japan) in culture medium SCGM (CeeGenix, Freiburg, Germany) which was produced under GMP with 5% human AB serum without feeder cells. Cell cultures were split approximately one-second to one-fourth after 3-4 days of culture, and fresh medium, cytokines and reagents were added.

Results: After 3-weeks culture of PBMC (1x10^6/mL) with IL-15, IL-2, anti-CD3 mAb, dalteparin sodium and tacrolimus without feeder cells, CD56$^+$CD3$^-$ NK cells had increased by more than 3,000 fold with about 80% purity (before *vs* after culture, CD56$^+$CD3$^-$; 6.6±3.7 *vs* 83.2±7.6, CD56$^+$CD3$^+$; 0.9±1.0 *vs* 9.5±5.3, CD56$^-$CD3$^+$; 54.6±17.1 *vs* 3.3±2.0,%, n=7). Finally, we could obtain about 80x10^6 NK cells from 1x10^6 unmanipulated PBMC under GMP conditioned medium with 5% human AB serum without feeder cells (before *vs* after culture, CD56$^+$CD3$^-$ NK cells; 0.025±0.012 *vs* 80.6±25.7 x10^6, n=7). These expanded NK cells expressed stimulatory NK cell receptor NKG2D and intracellular cytotoxic molecule granzyme (before *vs* after culture, NKG2D$^+$CD56$^+$; 0.9±0.8 *vs* 76.1±9.0, CD56$^+$Granzyme$^+$; 1.3±2.3 *vs* 72.9±17.7,%, n=7). Also, the expanded CD16$^+$CD56$^+$ NK cells expressed inhibitory NK receptors, but significantly higher levels of stimulatory NK cell receptors including NKG2D and NKp44 than the levels of these receptors on CD16$^+$CD56$^+$ NK cells in resting PBMC before culture measured by mean fluorescence intensity (MFI) were noted. The cytolytic activities of expanded NK cells were tested against ^{51}Cr-labeled K562 human leukemic cell lines using standard 4-hour ^{51}Cr release assays. The expanded NK cells had a high level of cytolytic activity against the K562 leukemic cell line with specific lysis of more than 50% under the condition of an effector: target ratio (E:T ratio) of 10:1.
Summary and Conclusions: In this study, we could obtain more than 80 x10^6 NK cells from 1x10^6 unmanipulated PBMC using IL-2, IL-15 and OKT3 with tacrolimus and dalteparin sodium without feeder cells (more than 3,000 fold increase). Thus, autologous or alloreactive KIR-mismatched NK cells from PBMC might be able to expand for adoptive NK cell immunotherapy to induce an anti-leukemia/tumor effect for patients with malignant diseases.

PB1914

EXTRACORPOREAL PHOTOPHERESIS (ECP) AS SECOND LINE TREATMENT FOR REFRACTORY GRAFT VERSUS HOST DISEASE (GVHD): PRELIMINARY SINGLE CENTRE EXPERIENCE

B Aguado[1,*] C Fernández-Arandojo[1], M González-Pardo[1], E Acuña[1], S Guijarro[1], I Vicuña[1], A Alegre[1]
[1]HEMATOLOGY, HOSPITAL UNIVERSITARIO DE LA PRINCESA, MADRID, Spain

Background: Steroid-refractory GVHD is a common cause of morbidity and mortality and remains a challenging therapeutic problem after allogeneic hematopoietic stem cell transplantation (HSCT). There is currently no standard of care for this complication. ECP is an immunomodulatory therapy which has been used in the treatment of acute and chronic GVHD. We present our experience of ECP as second line treatment option for GVHD post-HSCT.
Aims: The aim of this analysis was to evaluate the clinical effect of ECP, its impact on intensity of immunosuppressive therapy, safety and tolerance of the procedure.
Methods: Since May 2012 we have performed 140 ECP procedures with the Therakos Cellex® device that is an integrated "on line" system. 8 patients are evaluable with median age 56y (47-65) and weight 52.5kg (38-71) presented with acute (2 patients) or chronic (6 patients) therapy-dependent/refractory GVHD. Allogeneic HSCT was myeloablative in 7 cases and reduced intensity conditioning in one case. Five patients were diagnosed of acute myeloid leukemia, two myelodisplastic syndromes and one acute lymphoblastic leukemia. The transplant was from an unrelated donor in 4 cases and 4 from a sibling donor, all of them HLA matched. All patients but one (with exclusive skin presentation) had multiorgan involvement, all suffered from skin changes in combination with liver, lung, oral or ocular disease. As first line treatment they all received esteroids plus cyclosporine or mycophenolate mofetil. Median ECP per patient was 15 (4-35). ECP procedures were performed for two consecutive days, in initial phase weekly (in those with aGVHD), or every two weeks (cGVHD) and then monthly according to clinical response. Median of ECP treatment duration was 4 months (1-26). Response was evaluated by clinical assessment and reduction in immunosuppression.
Results: In the cGVHD group response was complete in 3/6 (50%), partial in 3/6 (50%), ECP led to ≥ 50% improvement in symptoms and signs of cGVHD and significant reduction or even withdrawal of esteroids was observed. The first response was seen in skin and mucosal symptoms. Therapy of aGVHD led to complete remission in 1 patient, who finally died because of pneumonia, and no response was seen in other. The tolerance to the procedure was excellent and the unique complications seen were related with two central venous catheter infections.
Summary and Conclusions: In our preliminary experience, the ECP is associated with excellent tolerance, significant response rates and successful reduction of steroids in patients with cGVHD. More experience is required to assess response on aGVHD patients.

HB BURGOS [ALPHA1 CD64(E13)(ASP→ASN)]: A NEW HEMOGLOBIN VARIANT

F De La Fuente Gonzalo[1,*] MJ Torrejon[2], D Velasco[3], LA Mayor[4], J M Nieto[1], F A Gonzalez[1], A Villegas[1], J Diaz-Mediavilla[1], P Ropero[1]
[1]Hematology, [2]Analisis Clinicos, Hospital Clínico San Carlos, [3]Hematology, Laboratorio BR Salud, Madrid, [4]Hematology, Hospital Reina Sofía, Tudela, Spain

Background: The HbA1c test by HPLC is a useful tool for the follow-up of diabetes mellitus patients. Some structural hemoglobin (Hb) variants caused by abnormalities in the genes encoding the globin chains are known to cause analytical interference in glycated Hb measurements.
Aims: In this study, it has been characterized a new Hb variant in four patients during their regular glicosylated Hb control.
Methods: Four patients with abnormal Hb elution peak during a routine check of glycated Hb were referred to our section. Glycated Hb analysis was performed using cation-exchange HPLC (Tosoh G8). HbA2 and F quantification and the separation of abnormal Hb were performed by ion-exchange HPLC (VARIANT™). The abnormal Hb also was separated by capillary electrophoresis (Sebia). The study of the globin chains was performed by reverse phase HPLC. Hematological data were obtained on a haematology analyzer (Coulter LH750). Genomic DNA from peripheral blood (Biorobot EZ1) was used for the molecular study. The most frequent mutations were ruled out by a-*globin StripAssay* (ViennaLab). The molecular characterization was performed by specific sequencing in an ABI PRISM 3100 Genetic Analyzer using the ABI PRISM BigDye Terminator V1.1 Cycle Reaction Kit (Applied BioSystems).
Results: A new structural variant of hemoglobin (Hb Burgos) clinically silent was detected by cation-exchange HPLC with a retention time of 1.02 (Figure 1) during the routine HbA1c test of four diabetes mellitus patients. An abnormal Hb was observed both by capillary electrophoresis (Hb A, Hb X and Hb A2) and by ion-exchange HPLC (Figure 1). A 17% of the Hb X was eluted by ion-exchange HPLC. The study of the globin chains by reversed-phase HPLC showed only two normal peaks (a and b) (Figure 1). Selective a1 gene sequencing showed a mutation GAC>AAC at codon 64. This produces a change of aspartic acid (Asp) by asparagine (Asn) identified as Hb Burgos [a1 64(E13)Asp>Asn]. This mutation was found in heterozygous state in 3 patients and in homozygous state in the last one.

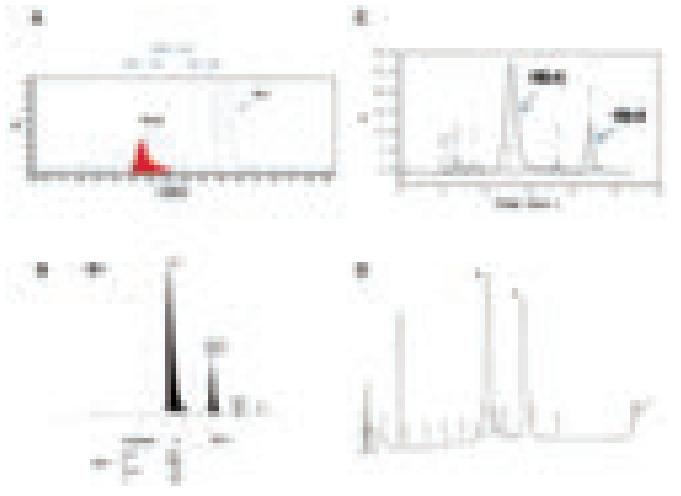

Figure 1.

Summary and Conclusions: The residue 64 is located on the outer surface of the molecule that is easily separated by capillary electrophoresis and HPLC. However, the change of Asp to Asn does not result in a functional change in the Hb that behaves as a silent hemoglobinopathy because it is precisely a change in the molecular surface. On the other hand, the percentage of Hb Burgos found by ion-exchange HPLC (13-17%) is somewhat lower than expected, which could be explained by the lower rate of a1 *versus* a2 gene expression. Besides, it has been found a homozygous case of Hb Burgos, where it has been found 34.3% of this variant by ion exchange HPLC. This finding corroborates the decreased expression of α1 *versus* α2 gene. This hemoglobinopathy and other structural Hb variants can be detected during the measurement of HbA1c and glycated Hb values may be altered. These cases, though rare, require examine the chromatograms thoroughly, for potential

interferences. Some pathological Hbs that interfere with the measurement of glycated Hb such as Hb G-Coushatta, Hb Queens and Hb Bologna-St.Orsola underestimate or overestimate the HbA1c levels which in some cases can be solved using a program with a longer elution time in the chromatography. However, since there are more than 1000 different Hb variants, many of which are rare, it is need to be aware when it comes to measuring HbA1c.

PB1916

VITAMIN B12 LEVELS IN SENIOR CITIZENS REMAIN STABLE AS THEY GET OLDER

D W Meier[1,*] U Nydegger[1], B Sakem[2], C Risch[3], M Risch[4], L Risch[3]
[1]Haematology, [2]Microbiology, [3]Clinical Chemistry, labormedizinisches zentrum Dr. Risch, Liebefeld bei Bern, [4]Clinical Chemistry, Kantonsspital Graubünden, Chur, Switzerland

Background: The evolution of the vitamin B12 backup in senior citizens is ill defined but decrease in levels is anticipated from reduced haematinic provision and/or impaired intestinal uptake.
Aims: To recruit healthy senior citizens (722 f, 557 m) passing a severe selection process to exclude relevant comorbidities and to analyze in their fasting serum samples for Vitamin B12 and surrogate markers methylmalonic acid (MMA), holotranscobalamin (HoloTC) and homocysteine confirming/denying vitamin B12 deficiency.
Methods: Abbott Architect analyzer and SCIEX automatic platforms were used in our routine laboratory flow-charts. HoloTC was measured using an Axsym platform. The Mentzer index computes MCV related to RBC count.
Results: See Table 1.

Table 1.

	60-69 yrs	70-79 yrs	>80 yrs	P values*
MCV (fl)	89	90	91	<0.001
B12 (pmol/L)	239	230	237	0.09
HoloTc (pmol/L)	53	56	54	0.38
MMA nmol/L	196	215	234	<0.001
Glomerular FR (ml/min/1.73m2)	110	98	82	<0.001
Homocysteine (µmol/L)	12	14	16	P<001
Mentzer index	19	19	20	<0.001

Summary and Conclusions: Whereas the vitamin B12 levels remain steady over the age range, we see a significant increment of median MMA levels which go along with increments of homocysteine, a homologue of cysteine known to accumulate in vitamin B12 deficiency sometimes used as a biomarker to predict cardiovascular risk events. Whereas it is possible that the MMA levels rose because of GFR reduction or because of vitamin B12 deficiency remains to be determined.

PB1917

RED CELL INDICES FOR BETA THALASSEMIA TRAIT SCREENING

S Ayari[1], N Ajmi[1], B Hammami[1], S Omar[2,*]M Feki[1], N Kaabachi[1]
[1]Laboratory of Biochemistry, Hospital Rabta, [2]Laboratory of Biology, Institut of Neurology, Tunis, Tunisia

Background: Isolated microcytosis and microcytic anemia due to β thalassemia trait are often wrongly diagnosed as iron deficiency anemia. Red cell indices such as red blood cells (RBC), Hemoglobin (Hb), middle cell volume (MCV), middle concentration of Hb (MCH) and Mentzer index (MI) may help for suspecting β thalassemia trait.
Aims: This study aimed to establish cut off values of these indices for the screening of β thalassemia according to Hb level.
Methods: From July 2001 to December 2012 the laboratory has received 2284 request for Hb exploration. Each patient beneficed of blood cell count, Hb electrophoresis at alkaline pH and dosage of HbA2 by ion exchange chromatography. The diagnosis of β thalassemia trait was based on a rate of Hb A2 ≥ 4% and the family study. Receiver operative characteristic curves were constructed to establish cut off values.
Results: A total of 835 subjects were considered carrying β thalassemia trait, among whose 697 (83.5%) have microcytic anemia. In patients with anemia (7< Hb<12 g/dl), RBC≥ 4.6 10^6/mm^3, MCV≤ 68 fl, MCH≤ 21 pg or MI≤ 14 allow to suspect β thalassemia trait with a sensitivity varying from 0.96 and 0.98. In patients without anemia (Hb≥ 12 g/dl), RBC≥ 5.2 10^6/mm^3, MCV≤ 71 fl, MCH≤ 23 pg or MI≤ 14 allow to suspect the β thalassemia trait with a sensitivity of 100%.
Summary and Conclusions: Red cell indices are very helpful for suspecting β thalassemia trait. The choice of optimal cut off values should take into account Hb concentration. Determination of HbA2 level remains necessary to confirm β thalassemia trait.

PB1918

BONE MARROW IRON ASSESSMENT AND FAT QUANTIFICATION BY MRI-R2* IN PATIENTS WITH IRON OVERLOAD

R Grosse[1,*] B Schoennagel[2], R Fischer[1], J Yamamura[2], P Nielsen[1]
[1]Pediatric Hematology, [2]Radiology, University Hospital Hamburg Eppendorf, Hamburg, Germany

Background: Patients with iron overload suffer from different organ damage due to increased iron concentration. Liver failure, heart failure and loss of endocrine function are well known complications in iron overloaded patients. Iron overload in the bone marrow may play an additional role in these patients and is until now not well examined.
Aims: To perform MRI-R2* measurements in the vertebral bone marrow using water-fat chemical shift relaxometry for estimation of iron and fat content in comparison to hepatic and splenic iron concentrations in patients with red cell aplasia and hereditary hemochromatosis (HHC).
Methods: Patients with iron overload (n=112, mean age: 32 y, *e.g.* transfusion dependent thalassemia major (TM), Diamond-Blackfan anemia (DBA) and HHC) and 14 control subjects underwent MRI for determination of the transverse relaxation rate R2* assessed from ROI based signal intensities of one transversal slice (10mm) through the liver, spleen, and mid-vertebral bone marrow. Breathhold water-fat relaxometry (12 echo times, TE=1.3–26ms, FA=20°, bandwidth=1955Hz/px) was performed to determine apparent fat contents (aFC) and bone marrow R2*. Additionally, serum ferritin values and other hematological parameters were assessed.
Results: Relative to controls (n=14, R2* = $95s^{-1}$) and HHC (n=10, R2* = $95s^{-1}$), median bone marrow R2* rates were significantly increased in patients with TM (n=65, R2* = $398s^{-1}$, $p<10^{-4}$) or DBA (n=12, R2* = $252s^{-1}$, p=0.005). R2* of the bone marrow significantly correlated with serum ferritin (r_S=0.52, $p<10^{-4}$), splenic R2* (r_S=0.43, $p<10^{-4}$), cardiac R2* (r_S=0.43, $p<10^{-4}$), and hepatic R2* (r_S=0.37, $p<10^{-4}$). No significant correlation of aFC with marrow R2* could be obtained. However, these latter findings are currently spoiled by the ambiguity of fat or water dominance at 50%.
Summary and Conclusions: Determination of R2* rates for estimating iron overload can simultaneously be assessed in the liver, spleen and vertebral bone marrow. Water-fat chemical shift relaxometry allows precise determination of bone marrow R2* rates and estimation of the apparent fat content, which may add additional information to these patients. Patients with transfusion related iron overload have significant higher bone marrow iron content than patients with iron overloaded due to hereditary hemochromatosis.
Clinical Relevance: Water-fat chemical shift relaxometry has the potential for accurate determination of bone marrow R2* rates and allows monitoring of iron trafficking especially in patients with red cell aplasia under different transfusion and chelation treatment regimens

PB1919

TARTRATE-RESISTANT ACID PHOSPHATASE TYPE 5B AS A MARKER OF OSTEOCLAST ACTIVITY IN CHILDREN AND ADOLESCENTS WITH SICKLE CELL DISEASE: RELATION TO BONE DISEASE

G Mokhtar[1,*] A Tantawy[1], A Adly[1], A Shoeib[1], E Ismail[2], S Mekkeya[1]
[1]Pediatrics Department, [2]Clinical Pathology Department, Faculty of Medicine,Ain Shams University, Cairo, Egypt

Background: Bone involvement is a frequent cause of acute morbidity in sickle cell disease (SCD). It ranges from acute manifestations, such as painful vaso-occlusive crisis or osteomyelitis, to more chronic and debilitating complications, such as osteonecrosis, osteoporosis and osteopenia, impaired growth and chronic infections. Iron overload was reported to be associated with a lower bone mass index. However, current information is inconclusive for a possible correlation between bone mineral density (BMD) and iron stores. Tartrate-resistant acid phosphatase (TRACP) type 5 is an enzyme that is produced by bone-resorbing osteoclasts, inflammatory macrophages and dendritic cells. TRACP 5b is the bone resorption marker which is produced specifically by activated osteoclasts. Normal bone metabolism requires TRACP 5b expression. Adults with SCD have increased osteoclast activity and high TRACP 5b levels due to a potential role of inflammation rather than increased iron stores.
Aims: To assess BMD in young patients with SCD and asymptomatic sickle cell trait (SCT) siblings, determine levels of TRACP 5b and assess its possible relation with markers of hemolysis , iron overload and bone complications.
Methods: Thirty children and adolescents with SCD and 8 asymptomatic siblings with SCT were compared with 32 age- and sex-matched healthy controls. Patients were studied stressing on anthropometric measures, transfusion history, hydroxyurea therapy, hematological profile, serum ferritin, serum calcium and alkaline phosphatase (ALP). TRACP 5b was measured by

enzyme linked immunosorbent assay (ELISA). Assessment of BMD was performed for whole body and lumbar spine using dual energy X-ray absorptiometry (DEXA) technique.
Results: Among SCD patients, 66.7% received hydroxyurea and 60% were on chelation therapy. Bone fractures and avascular necrosis were found in 13.3% and 10% of SCD patients, respectively, and none in SCT .BMD was decreased in SCD patients as defined by Z score (mean -2.11±1.74) compared with SCT (mean- 0.79 ±1.1) and controls (mean -0.85±0.88); p=0.005, while no significant difference was found between the latter 2 groups. SCD patients had higher incidence of low bone density (40.7%) and osteoporosis (7.4%) than SCT group (12.5% and 0.0%, respectively) and controls (4.8% and and 0.0%, respectively); p=0.03. SCD patients with abnormal DEXA scan had higher age (13.30 years±2.82 *versus* 9.26±3.6 years), serum ferritin (3427.82±2401.6 *versus* 1738.79±2008.8 μg/L) and ALP (251.30±127.51 *versus* 149.16±58.2 IU/L) compared with SCD with normal BMD. Abnormal BMD was associated with higher incidence of splenectomy (36.4% *versus* 0.0%; p=0.005) and endocrine abnormalities (45.5% *versus* 5.3%; p=0.008). Serum TRACP 5b was significantly higher in SCD patients (4.10±2.72 U/L) than SCT (2.50±1.39 U/L) and controls (1.89±0.81 U/L) while levels were consistent between traits and controls. Hydroxyurea-treated patients as well as those on chelation therapy had lower TRACP 5b levels than untreated patients although levels did not reach a significant level. TRACP 5b was positively correlated to lactate dehydrogenase (LDH) (r=0.363, p=0.045) while no relation with other variables including serum ferritin, ALP,and BMD. BMD was positively correlated with body mass index (BMI) (r=0.624, p<0.001) while negatively correlated with platelet count (r=-0.686, p<0.001) and ALP (r=-0.402, p<0.001). There was positive correlation between whole body and lumbar spine BMD (r=0.919, p<0.001).
Summary and Conclusions: Ostopenia and osteoporosis frequently occur in SCD patients as reflected by decreased BMD and high ALP and TRACP 5b levels. The lack of correlation between abnormal DEXA scan and high TRACP 5b levels suggests that bone disease in SCD is multifactorial . Hemolysis and iron overload may be contributing factors in the occurrence of these complications .However longitudinal studies with large number of patients could identify the interaction between different factors contributing to decreased bone density in SCD.

PB1920

THE RED BLOOD CELLS' (WT-BETA+GAMMA)/ALPHA RNA RATIOS CORRELATES STRONGLY WITH THE BETA-THALASSEMIA MAJOR OR BETA-THALASSEMIA INTERMEDIA TYPES IN PATIENTS HOMOZYGOUS FOR THE IVS-II-1 MUTATION

M Banan[1,*] A Azarkeivan[2], H Najmabadi[1]
[1]Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, [2]Pediatric Hematology Oncology, Blood Transfusion Research Center; High Institute for Research and Education in Transfusion Medicine, Tehran, Iran

Background: Previously, we had studied the association of 5 genetic markers [beta-globin mutations (beta^{o},beta^{+},beta^{++}), co-inheritance of alpha-thalassemia (alpha-thal), and single nucleotide polymorphisms (SNPs) in the XmnI, BCL11A, and HBS1L-MYB loci] with the beta-thalassemia major (beta-TM) and intermedia (beta-TI) types in a cohort of 306 Iranian patients. Using multivariate regression analysis, a strong correlation was observed between beta^{++} mutations, the XmnI T allele, and the BCL11A rs4671393 (A) allele with beta-TI [Banan et al (2013) Hemoglobin 37(5), 413]. A scoring system based on odds ratios (OR) was used to facilitate the beta-thal type prediction (beta^{++} mutations=2 points, XmnI T allele=1 point, BCL11A rs4671393 (A) allele=1 point). Using this system, patients with a low score of (0, 1) were predominantly beta-TM whereas those having a high score (≥3) were beta-TI. Prediction, however, was especially difficult in the IVS-II-1 homozygous patients, largely composed of those having a score=2.
Aims: We hypothesized that variations in wildtype (Wt)-beta/alpha and gamma/alpha levels may account for differences in the disease severity of these patients. To gain insight, we determined the (Wt beta+gamma)/alpha RNA ratios in the RBCs of a subset of these patients (n=16 beta-TM, 15 beta-TI) as well as in healthy adults (n=4).
Methods: After acquiring informed consent, approximately 5 ml of fresh blood was obtained from patients in EDTA-containing tubes. RNA was extracted from red blood cells (RBC) as previously described [Kabanova et al (2009) Int J Med Sci 6(4), 156], and its quality assessed by gel electrophoresis. The RNA was DNase I treated and subjected to reverse transcription. For PCR of the full-length beta-globin cDNA, primers spanning exons 1 and 3 were used. Real-time PCR of the alpha-, beta-, and gamma-globin RNA were performed by using previously described primer sets (Smith *et al.* (2000) Blood 95 (3), 863.) and SYBR-green on an ABI 7500 system.
Results: PAGE and sequencing analyses of the full-length beta-globin cDNA suggested the presence of a number of alternatively spliced products in the IVS-II-1 homozygous patients. The predominant RNA products, however, consisted of an exon 1-3 RNA and the Wt exon 1-2-3 RNA. These results suggested that primers spanning exons 2 and 3 could be used to quantify the Wt beta-globin by qRT-PCR. Real-time PCR experiments showed variation in the beta/alpha and gamma/alpha RNA ratios among patients (from 0 up to7). Furthermore, in many cases the beta-TM patients had high (rather than low) levels of gamma/alpha transcript levels. Nevertheless, the (Wt beta+gamma)/alpha RNA ratios seemed to be a good predictor of the beta-TM/beta-TI type [control= 1.57±0.57; beta-TI= 2.12±0.67; beta-TM= 5.5±0.94.] Using a 2-tailed t-test to compare beta-TM and beta-TI, P <0.01.
Summary and Conclusions: The (Wt beta+gamma)/alpha RNA ratios seems to be a good predictor of the beta-TM/beta-TI types in the IVS-II-1 / IVS-II-1 patients. Furthermore, our results suggest that unidentified factors influencing beta-globin splicing (resulting in Wt beta-globin RNA production) and gamma-globin expression (other than the known HbF QTLs) may affect the beta-TM/beta-TI types in these patients.

PB1921

NON-TRANSFUSION DEPENDENT COMPOUND HETEROZYGOTES FOR THALASSAEMIC MUTATIONS. REPORT OVER A 15 YEAR- PERIOD IN NORTHERN GREECE

S Theodoridou[1,*] D Giannakopoulou[1], A Markantonatou[1], A Teli[1], M Economou[1], D Adamidou[1], E Boutou[2], B Delaki[2], A Balassopoulou[2], V Aletra[1], O Karakasidou[1], T Karafoulidou[1], E Voskaridou[2]
[1]Haematology, Hippokration Hospital of Thessaloniki, Thessaloniki, [2]Thalassaemia Centre, Laikon Hospital , Athens, Greece

Background: Greece is a Mediterranean country with a high frequency of haemoglobinopathies. The β-Thalassaemias constitute an heterogeneous group of disorders with a reduction of β-chain synthesis. The interaction of classic β-Thalassaemia mutations with mild β-globin gene mutations or several Haemoglobinopathies results in the clinical phenotype of Thalassaemia Intermediate. Since 1974 a nation wide program for Thalassaemia prevention has been implemented. Through population screening program that is performed, natives and immigrants are screened and counselled free of charge.
Aims: We report the non-transfusion dependent compound heterozygotes for thalassaemia detected over a 15 year period (1999-2013) in Northern Greece through the population screening program.
Methods: The carrier identification was carried out by a standard scheme, which included, CBC and red cell indices using the Coulter ONYX, a Cation Exchange HPLC variant system (Bio-Rad, Variant β-Thalassaemia Short Program), to determine HbA, HbA2 and HbF levels and the different abnormal structural haemoglobins, electrophoretic techniques both at alkaline pH on cellulose acetate and at acid pH on citrate agar, sickling test and tests for HbH inclusion bodies. Haemoglobin A2 was also quantified by column micro chromatography and serum ferritin levels were measured by micro Elisa technique. Biosynthesis of the α- and β- globin chains and DNA techniques are also performed on selected cases.
Results: From the total 35.797 subjects who underwent screening during this period we identified 34 cases of compound heterozygotes for thalassaemic mutations with mild phenotype, non-transfusion dependent. Nine cases of compound heterozygotes for severe β-thalassaemia mutations and the "silent" -101C-T mutation, 4 cases of common severe thalassaemia mutations and the +1480 C-G silent β-gene, 4 cases of beta thalassaemia and delta beta thalassaemia with mild phenotype, 11 cases of beta thalassaemia and triple α. They all had minimal bone changes and satisfactory growth.We also detected two cases of compound heterozygotes for beta thalassaemia/D-Punjab, 2 cases for β-thalassaemia/ O Arab, one case for α-thalassaemia/Hb E and one case of E-Saskatoon- β-thalassaemia. They all were non transfusion dependent except three cases of women than were transfused during their pregnancy. The two of them were compound heterozygotes of common severe thalassaemia mutations and the +1480 C-G silent β-gene and one carried the IVSI-1 and triple α. Pertaining to their ethnic background, they all were of Greek origin except one coming from Albania and one of Pomakic origin (β-thalassaemia/ O Arab).
Summary and Conclusions: The identification of such combinations is important in the genetic counseling of couples at risk, in a country such as ours where the high frequency of thalassaemia and haemoglobinopathies has a major impact on public health.

PB1922

PREGNANCY IN BETA-THALASSEMIA INTERMEDIA: A 20-YEAR EXPERIENCE OF A GREEK THALASSEMIA CENTER

E Voskaridou[1,*] A Balassopoulou[1], E Boutou[1], V Komninaka[1], D Christoulas[2], M Dimopoulou[1], EE Delaki[1], D Loukopoulos[3], E Terpos[4]
[1]Thalassaemia Center, 'Laiko' University General Hospital of Athens, [2]Department of Hematology, 251 General AirForce Hospital, [3]Hematology Research Laboratory, Biomedical Research Foundation, Academy of Athens,

[4]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

Background: Thalassemia is the most commonly inherited disease worldwide. Thalassemia intermedia (TI) represents a phenotype ranging from thalassamia major (TM) to thalassemia minor. Progress in the management of patients TI enabled increasing rates of pregnancies among TI women worldwide. Nevertheless, information regarding TI pregnancy management and outcome is quite limited in the literature.

Aims: The aim of this study was to report our experience regarding the maternal and fetal outcome of TI patients.

Methods: Approximately 250 patients with TM and 275 with TI are treated and followed up regularly in our center. We prospectively collected data for all pregnancies during the last 20 years. Therefore we analyzed our data recorded from 60 pregnancies in 34 women over this period of time.

Results: Thirty four patients achieved full-term pregnancies (mean maternal age±SD: 27.4±6.5 years) within 37±3 gestation weeks. Their mean hemoglobin value was 8.33±1.22 g/dl; 26.5% of patients were not transfused at all or they had been transfused only once during gestation. Caesarean section was performed in 29/44 (65.9%) of natural pregnancies and in 4/5 of IVF (80%) pregnancies. Six patients had more than two normal deliveries. There was one extra-uterine pregnancy while there were no stillborn births. There were eleven abortions (18.3%) including 6 spontaneous (10%) and 5 (8.3%) for medical reasons. The spontaneous abortions (5/11) were related to high HbF levels. Nineteen newborns (38.8%), which weighed 2-3 kg, required hospitalization to an intensive neonatal care unit for 1-3 weeks. Ten (29.4%) women required none or few transfusions (two units or less) during the first or the second pregnancy while they were transfused during the second or third pregnancy. Eighteen (52.9%) women were transfused up to 36 units during gestation. A 28 year old woman with beta/delta-beta thalassemia (FSC6/$\delta\beta^{Sic}$), no prior need for transfusions, normal spleen size and almost 100% HbF in Hb electrophoresis presented with decreasing Hb levels and platelet counts and progressive splenomegaly during the 6th month of her first pregnancy. The patient was regularly transfused until delivery because of hypersplenism and severe haemolytic anaemia. Due to worsening anemia and thrombocytopenia splenectomy was performed one month after delivery with full resolution of cytopenias. In another case, two consecutive pregnancies of a single patient were complicated by two episodes of spastic paraparesis due to compression of the spinal cord by extramedullary paravertebral masses. The woman developed asymmetrical weakness in her lower extremities, hypoesthesia, paresthesias, hyperreflexia, and bilateral Babinsky responses during the 6th month of pregnancy. A spinal MRI investigation revealed extensive bilateral paravertebral masses spanning from T2 to T9 together with corrosion of the vertebral bodies. The patient was successfully treated by hypertransfusion and local irradiation.

Summary and Conclusions: Although several complications can occur during a pregnancy in TI women, the careful and frequent monitoring by Special Units and multidisciplinary management by both haematologists and obstetricians can lead to successful deliveries.

PB1923

SAFETY AND EFFICACY OF COMBINATION OF DEFERIPRONE AND DEFERASIROX IN PATIENTS WITH THALASSEMIA MAJOR

S Kakkar[1,*] PC Sobti[2], PK Jhinger[3]
[1]Pediatrics, Hemato-Oncology Unit, Dayanand Medical College, Ludhiana, [2]Pediatrics, Hemato-Oncology Unit, Christian Medical College, Ludhiana, [3]Pediatrics, Government Medical College, Chandigarh, India

Background: Combination of two oral iron chelators, deferiprone (DFP) and deferasirox (DFX) looks promising as these target separate iron pools and do not require parenteral administration.

Aims: To study safety and efficacy of combination of deferiprone & deferasirox in thalassemia patients

Methods: Forty consenting patients (5-18 yrs) were randomized to 3 groups. Group 1 (n=10) and Group 2 (n=10) received DFP (75-100 mg/dl) and DFX (30-40 mg/kg/d) respectively. Group 3 (n=20) received both drugs administered sequentially every alternate week. Cardiac and liver MRI were done at beginning and end of the study. Serum ferritin was done every 3 monthly. CBC, liver enzymes and renal function tests were performed monthly.

Results: Mean cardiac MRI T2* at the beginning of the study were 28.67±4.56, 29.97± 4.01, 29.75±4.66 ms in group I, II, III respectively. Cardiac MRI T2* at the end of the study was slightly better in group I as compared to group III although was not statistical significant (p=0.07). Mean values for liver MRI T2* were 6.19±1.97ms, 5.89±0.70ms & 5.62±0.99 ms in group I, II and III respectively. Liver MRI T2* was not significantly different before and after the study. Serum ferritin reduced significantly in group I and II but not in group III. Group receiving combination therapy did not show any untoward side effects as compared to single drug regimen.

Summary and Conclusions: Combination therapy is safe but not more effective as either drug alone.

PB1924

COMPARATIVE ASSESSMENT OF LIVER IRON CONCENTRATION IN PATIENTS WITH THALASSEMIA BY MRI AND FERRISCAN

E Voskaridou[1,*] M Douskou[2], D Christoulas[3], V Komninaka[1], M Aliberti[2], E Terpos[4]
[1]Thalassemia Center, Laikon General Hospital, [2]Bioiatriki Medical Center, [3]Department of Hematology, 251 General AirForce Hospital, [4]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

Background: Iron overload is a significant problem in hemoglobinopathies. Iron accumulation affects mainly the endocrine glands, the liver and the heart leading to life-threatening complications. Therefore accurate monitoring of total body iron is clinically needed in thalassemia. Magnetic resonance imaging (MRI) gradient echo (T2*), the reciprocal of T2* (known as R2*) and spin echo (T2) techniques have been developed to quantify tissue iron in the liver and the heart. More recently St. Pierre *et al* (Blood 2005;105:855-61) described an accurate method of determining hepatic iron concentration (HIC) using R2 (where R2=1/T2) signal decay rates with a high correlation found between R2 values and biopsy results, commercially available as FerriScan.

Aims: The aim of this study is the comparative assessment of liver iron concentration in patients with thalassemia by MRI and by the more recent technique FerriScan.

Methods: We prospectively studied 15 patients (7M/8F, median age 45 years, range 40-61 years) with thalassemia major who are followed-up in our Center. All patients had MR examinations of the liver that were performed on a General Electric 1.5T Signa HDxt scanner (GE Healthcare, Milwaukee, USA). The pulse sequence used to estimate the T2* relaxation time of the examined tissues is a multi-echo fast gradient echo which has the ability to acquire 3 to 16 echoes in a breath hold time of 12 to 18 sec. The post processing of the data is performed with use of relevant software on a GE Advantage Windows 4.6 workstation according to the relevant literature. On the same day serum ferritin was also measured while hepatic iron concentration (HIC) was obtained using FerriScan. More specifically, images were transmitted to the FerriScan Analysis Centre in DICOM format according to the FerriScan protocol. Images were analyzed off-site, as previously described by St Pierre et al, and average HIC results were returned electronically to our center.

Results: Liver T2* and R2* values were (mean±SD) 7.82±6.38 mgr/gr and 303±257 Hz, respectively. HIC values as determined by FerriScan were 132±135 mmol/kg, while ferritin levels were 700±652 ng/ml. There was a strong correlation between R2* and FerriScan values (r=0.937, p<0.0001). Both R2* and FerriScan values strongly correlated with ferritin levels (r=0.709, p=0.004 and r=0.720, p=0.004 respectively).

Summary and Conclusions: We were able to demonstrate a very strong positive correlation between R2* values and FerriScan determined HIC. This could potentially lead to more timely patient results and cost savings.

PB1925

CORRELATION BETWEEN CLINICAL FEATURES AND HEMATOLOGICAL-COAGULATIVE PARAMETERS IN PEDIATRIC CARRIERS OF SICKLE CELL DISEASE

F Menzato[1,*] R Colombatti[1], E De Bon[2], A Bertomoro[2], A Casonato[2], MT Sartori[2], A Steffan[3], G Basso[1], L Sainati[1]
[1]Clinic of Pediatric Hematology-Oncology, Department of Child and Maternal Health, [2]Clinic of Internal Medicine, Department of Cardiothoracical Sciences, Azienda Ospedaliera-Università di Padova, Padova, [3]Department of Diagnostic Laboratory and Cellular Therapy, Centro di Riferimento Oncologico, Aviano, Italy

Background: Sickle Cell Disease (SCD) is the most frequent structural hemoglobinopathy in the world.Sickle Cell Trait (HbSA) affects 300 million people worldwide and is considered as a benign state. However, several cases of heterozygous adult patients with the clinical manifestations of the SCD subjects were recently described, including: hematuria, renal papillary necrosis, ipostenuria, splenic infarcts, sudden death with rhabdomyolysis related to intense physical activity, acute chest syndrome (ACS) and painful vaso-occlusive crisis (VOC). In addition, an increased incidence of renal medullary carcinoma in HbSA patients has been reported.

Aims: 1) To describe a pediatric population with HbSA from a clinical, hematological and coagulative point of view. 2) To compare clinical and laboratory characteristics of HbSA children with those of SCD children (HbSS, HbSβ^0, HbSC) and healthy controls. 3) To possibly identify a subgroup of HbSA children who present clinical features of the affected SCD patients.

Methods: At our Center HbSA patients receive clinical evaluation and blood test once a year. Hematological and coagulation parameters were determined during the once a year blood test. Demographic, clinical and laboratory data of HbSA children were retrospectively collected from the Sickle Cell Database in use at our center and compared to those of the SCD children followed at our Center and of a group of healthy controls recruited at the coagulation Clinic.

Results: 41/88 consecutive HbSA children (mean age: 6,85; range: 1-15) were

enrolled from January 1st 2012 to July 31st 2013. 20 M and 21 F. 88% were Africans, 9,5% European. Hematological and coagulative parameters of SCD and HbSA patients are shown in Table 1 and Table 2 respectively. HbSA children had an hematological profile similar to the ones of HbSC patients (affected by a milder form of SCD), with mild anemia and similar levels of HbS, leucocytes and platelets (Tab 1). HbSA children had lower levels of endothelial activation and thrombin generation markers than patients affected by the most severe form of SCD (HbSS and HbSβ^0), but also completely different from those of the healthy controls. HbSA patients presented also similarities with HbSC patients from a coagulative point of view (Tab 2). 13/41 HbSA children presented manifestations characteristic of SCD: 3/41 ACS and 10/41 VOC; the events were managed at home (9/41) or by hospitalization (4/41). Children with history of ACS or VOC (Group 1), presented higher levels of Hemoglobin (12,47±0,81 gr/dl *vs* 11,41±1,05; p=0,01), MCV (79,28±4,13 fL *vs* 73,84±7,82; p=0,01) and P-selectin (37,24±12,30 ng/dl *vs* 23,39±10,92; p=0,04) than patients without these clinical events (Group 2).

Table 1.

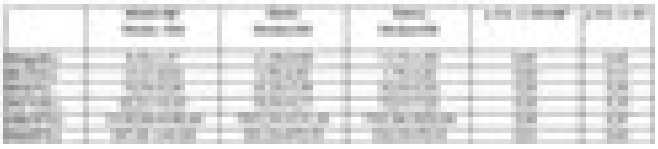

Table 2.

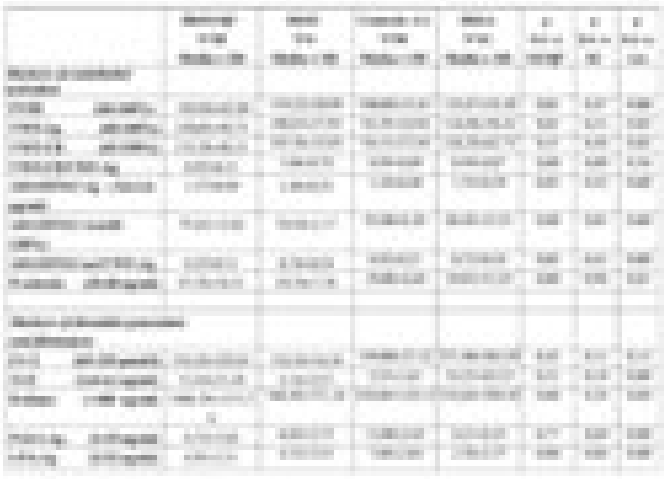

Summary and Conclusions: HbSA patients presented a typical hematological and coagulative profile, that is significantly different from healthy controls and similar to HbSC children, characterized by a mild activation of the coagulation cascade, but without severe anemia, leukocytosis and thrombocytosis typical of SCD. A subgroup of HbSA patients had also clinical manifestations characteristic of SCD at an early age. Those with clinical events presented higher levels of Hb, MCV and P-selectin, that could be explained by increased viscosity, hemolysis or endothelial activation, respectively. Therefore there is a subgroup of pediatric HbSA patients, that maybe needs a more intensive follow-up.

PB1926

STUDY OF THE EFFECTS OF DIFFERENT TYPES OF IRON CHELATION THERAPY ON N-TERMINAL PRO BRAIN NATRIURETIC HORMONE [NT-PRO-BNP] SERA LEVELS AND ECHOCARDIOGRAPHIC TISSUE DOPPLER ABNORMALITIES IN PATIENTS WI

U El Safy[1,*] L Sherief [1], E Rifky[1], M Fathy[1], AS Ali[2], NX Khalifa [3], N Kamal[4]
[1]Pediatric Hematology and Oncology, [2]Pediatric cardiology, [3]Clinical pathology, zagazig university, Zagazig, [4]Pediatric Departments, cairo University, Cairo, Egypt

Background: The prognostic predictive value of NT-pro BNP in patients with thalassemia major as a model disease with isolated diastolic dysfunction has been assessed where there were a direct relationship between the diastolic indices on echo Doppler and the serum level of NT-pro BNP.
Aims: This study was designed to study the effects of different types of chelation therapy on the LV systolic and diastolic functions using Tissue Doppler (TD) echocardiography and serum level of N-terminal pro brain natriuretic hormone (NT- pro BNP) in patients with β-TM.
Methods: The study was conducted on patients with β-TM (n = 80, age 15.7±8.9 years) and an age-matched controls (n =20, age 15.9±8.9 years). Patients with β-TM were classified into four groups according to regimen of iron chelation therapy. Group 1 was on desferoxamine, Group 2 on Deferiprone therapy, Group 3 on Deferasirox and Group 4 on combined regimen of desferoxamine and Deferiprone. Each group included 20 patients with β-TM. In all participants, TD echocardiography was performed and blood samples were withdrawn for measuring the serum level of NT-pro BNP, ferritin, and alanine transaminase.
Results: The mean serum NT pro-BNP in β-TM was significantly higher compared with controls (*P*< 0.05).There was significant decrease of the mean serum NT pro-BNP in combined iron chelation therapy than other groups of mono chelation therapy, while no significant difference among three groups of mono iron chelation therapy. The tissue doppler systolic wave (Sm) velocity and the early diastolic wave (Em) were significantly lower in β-TM group compared to controls. The tricuspid valve velocity was significantly higher in β-TM patients compared with controls .The tissue Doppler systolic wave (Sm) velocity and the early diastolic wave (Em) were significantly lower in three groups of mono chelation than combined iron chelation therapy.
Summary and Conclusions: We conclude that pro-BNP can be used as a sensitive cardiac biomarker in monitoring of cardiac dysfunction In B-TM, which is positively correlated with the early diastolic dysfunction (E/Em ratio). Group 4 had significant lower in pro-BNP and higher systolic wave (Sm) velocity and the early diastolic wave (Em) than those groups

PB1927

CLINICAL AND RADIOLOGICAL ASSESSMENT OF DEFERIPRONE RELATED KNEE ARTHROPATHY IN EGYPTIAN CHILDREN AND ADOLESCENTS WITH B-THALASSEMIA MAJOR

G Mokhtar[1,*] A Tantawy[1], W Tantawy[2], N Nassar[3], A Abdelmaksoud[1], H Sakr[2], M Shams[1]
[1]Pediatrics Department, [2]Diagnostic Radiology Department, [3]Physical Medicine,Rehabilitation, and Rheumatology Department, Faculty of Medicine,Ain Shams University, Cairo, Egypt

Background: The most common clinical problem associated with Deferiprone therapy is arthropathy that mainly involves the knees. The cause of deferiprone-related arthropathy is not known. It has been hypothesized that the arthropathy is due to a toxic effect of deferiprone mediated by free radicals.
Aims: To assess knee arthropathy and its possible risk factors, both clinically and radiologically in patients with β- thalassemia major receiving Deferiprone monotherapy.
Methods: A longitudinal prospective study conducted on 80 patients with β-thalassemia major aged 8-18 years following up at in the Pediatric Hematology Unit, Ain Shams University Hospitals in the period from 2010 to 2013. It included 40 patients on deferiprone monotherapy and 40 patients on subcutaneous deferoxamine monotherapy .The chelation duration ranged from 1 to 8 years (mean 2.9±1.6 years).All patients were subjected to full history and examination mainly involving joint symptomatology and examination. Laboratory investigations included complete hemogram, serum ferritin, liver functions, viral hepatitis markers (B, C) and echocardiography. Knee joint assessment was done using modified hemophilia joint health score (JHS: total score of zero means normal and 40 means maximum affection), bilateral knee joints X-ray and ultrasound with particular comment on epiphyseal irregularities, synovial thickness and articular effusion. Knee MRI was done for patients in the deferiprone group with abnormal ultrasound findings.
Results: There was no significant difference between both groups as regards age, sex, transfusion index, , BMI, Tanner staging, hepatitis B and hepatitis C infection, pre transfusion hemoglobin, liver functions, serum ferritin and ejection fraction in ECHO .There was significant difference between both groups regarding *duration* of chelation therapy (p=0.000,longer duration for desferal), *compliance* (p=0.001,less compliance among desferal group) and *height* (p=0.002,desferal patients were shorter). Among the deferiprone group, 25 patients (62.5%) had knee symptoms compared to 17 (42.5%) symptomatic patients in deferoxamine group (p=0.309). Fourteen of the deferiprone asymptomatic patients (93.3%) had evidence of knee joint affection by JHS. Seven patients (17.5%) had symptoms of other joints' arthropathy. In deferiprone group ,knee symptoms were more prevalent with longer *duration of* therapy (p=0.049), *knee joint effusion in ultrasound* (p= 0.047) and *higher platelet* count (p=0.021), while in the deferoxamine group it was related to poor *compliance* (p= 0.009) and higher serum *ferritin* levels (p= 0.00). In the deferiprone group, the JHS ranged from 0-33 with 39 (97.5%) affected patients. JHS was positively correlated to *age*, *weight* ,*height , BMI*, *Tanner* staging and *platelet* count (p<0.01), and negatively correlated to

transfusion index (p=0.00) with no significant correlation to ultrasound or MRI findings. JHS was higher among *splenectomized* patients in both groups (p<0.01). There was no significant difference between both studied groups regarding JHS, premature epiphyseal fusion and ultrasound findings (p>0.05). US was 100% sensitive and 81.3% specific in detecting knee joint synovial thickening with 82.4% sensitivity and 100% specificity in detecting knee joint effusion.

Summary and Conclusions: Deferiprone induced knee arthropathy in patients with β thalassemia major could be asymptomatic. It increases with increased age, weight, height, BMI, platelet count, duration of treatment and lower transfusion index as well as among splenectomized patients. Ultrasound is good, sensitive, and specific for evaluation of knee arthropathy.

PB1928

ABSOLUTE RETICULOCYTES COUNT/IMMATURE RETICULOCYTE FRACTION RATIO, A NEW APPROACH IN THE SCREENING OF HEREDITARY SPHEROCYTOSIS

G Ferreira[1,*] R Barreira[1], P Ferreira[1], JR Pinheiro[1], AT Simões[1], AC Oliveira[1], R Salvado[1], JC Almeida[1], L Ribeiro[1]
[1]Hematologia, Centro Hospitalar Universitario Coimbra, Coimbra, Portugal

Background: Hereditary spherocytosis (HS), the most common type of hemolytic anemia, is characterized by an increased fragility of the erythrocytes membrane due to the weakening of the vertical interactions connecting the cytoskeleton and the lipid bilayer. Main clinical signs are jaundice, enlarged spleen and anemia with reticulocytosis. With the last generation of full blood counters it is possibly to obtain the number of reticulocytes (RET#) and the immature reticulocytes fraction (IRF), and it has been observed that HS patients have increased RET# but not increased IRF. However, we have to be aware that IRF has different meanings in the different analyzers, and we need to have the reference value for each analyzer. Hereditary spherocytosis (HS), the most common type of hemolytic anemia, is characterized by an increased fragility of the erythrocytes membrane due to the weakening of the vertical interactions connecting the cytoskeleton and the lipid bilayer. Main clinical signs are jaundice, enlarged spleen and anemia with reticulocytosis. With the last generation of full blood counters it is possibly to obtain the number of reticulocytes (RET#) and the immature reticulocytes fraction (IRF), and it has been observed that HS patients have increased RET# but not increased IRF. However, we have to be aware that IRF has different meanings in the different analyzers, and we need to have the reference value for each analyzer.
Aims: With the objective of looking for HS screening tools based on hematological parameters, we analyzed the reticulocytes counts and the immature reticulocytes fraction available on our routine analyzer ABX HORIBA Pentra DX 120.
Methods: ABX HORIBA Pentra analysers employ Thiazole Orange technology to reticulocyte count (RET#) and via "RET channel" differentiate 4 sub-populations: RETL Low fluorescence, low RNA content; RETM Medium fluorescence, variable RNA content; RETH High fluorescence, high RNA content and IMM Immature reticulocytes/erythroblastic (NRBC) population (DNA). Immature Reticulocyte Fraction (IRF) = (RETH#+RETM#+IMM#)/RET#. Peripheral blood samples (n=150) processed on EDTAK3 in analyzer Pentra DX 120, levels of RET# and IRF determined in a cohort of 25 confirmed HS and in 125 samples divided in 5 groups: Autoimmune hemolytic anemia (AIHA) = 15; iron deficiency anemia (IDA) = 30; Intermedia Beta Thalassemia (IBThal) =8; Cord blood samples (CB) = 30; healthy subjects (control) =42 and then compared with the HS group. Statistical analysis of RET#, IRF, RETH#, RETM#, IMM#. ROC curve analysis for the sensitivity, specificity indices using GraphPad Prism 5.
Results: See Table 1.

Table 1.

Median x10^9/L	Control	AIHA	IDA	HS	IBthal	CB
RET#	48.5	220	50	299	215	187
RETH#	1.7	1.2	2.1	0.7	11.2	7.5
RETM#	7.5	10.1	8.3	5.8	22.6	20.4
IMM#	0.03	0.01	0.03	0.04	0.79	0.1

Summary and Conclusions: HS presented high RET# count (median=299) and IRF (median=12.8). RET#/IRF cut-off was >10 with excellent sensitivity (100%) and specificity (91%). The increased IMM in the IBThal group is due to high number NRBC. Despite increased IMM the RET# in the cord blood are unexpected near normal. This simple methodology can be used to screen HS using the HORIBA ABX PENTRA Hematological instruments. However, the diagnostic of HS still has to be confirmed by more specific and accurate tests such as, eosin-5'-maleimide (EMA) binding test and cryohemolysis.

PB1929

GROWTH HORMONE – INSULIN-LIKE GROWTH FACTOR-I AXIS AND BONE MINERAL DENSITY IN ADULTS WITH THALASSEMIA MAJOR

M Yassin[1,*] A T soliman[2], V Desanctis[3]
[1]Hematology /BMT, National Centre for Cancer Care and Research Hamad Medical Corporation, [2]pediatric, Hamad medical corporation, Doha, Qatar, [3]pediatric, Quissana, Ferrara, Italy

Background: Bone disease and short stature are frequent clinical features of patients with beta-thalassaemia major. Dysfunction of the GH-IGF-1 axis has been described in many thalassemics children and adolescents with short stature and reduced growth velocity
Aims: to investigate GH secretion in adult thalassemic patients in relation to their bone mineral density (BMD) and serum ferritin concentrations
Methods: We performed clonidine stimulation test in 30 thalassemic patients (18 males, 12 females) with a mean age of 31.5± 7.2 years. The cut-off level for GH response was set at 7ug/l, according to the literature. Serum ferritin, IGF-I, liver enzymes, alkaline phosphatase (ALP) and type 1 Collagen Carboxy Telopeptide (CCT1) were also determined
Results: We diagnosed GH deficiency (GHD) in 12 patients (40%) and IGF-I defi ciency (IGF-I SDS <-2) was diagnosed in 20 patients (67%). Adult patients with TM had signifi cantly decreased IGF-I concentrations and bone mineral density (BMD) at the femur neck and lumbar spine compared to normal controls. Thalassemic patients with GHD and IGF-I deficiency had significantly lower BMD T score at the lumbar spine compared to patients with normal GH and IGF-I levels
Summary and Conclusions: GH status should be tested in adult thalassemic patients especially those with short stature and/or decreased BMD. Clonidine test appears to be effective and safe in adults with TM. If the diagnosis of adult GHD is established, GH treatment may be considered for possible improvement of bone mineral density and heart function in patients with TM.

PB1930

HYDROXYUREA IN THE MANAGEMENT OF PEDIATRIC B-THALASSEMIA INTERMEDIA: EIGHT YEARS' FOLLOW-UP IN EGYPT

A El Beshlawy[1,*] M El-Ghamrawy[1], M Abou EL-Ela[1], F Said[2], S Adolf[3], AR Ahmed Abdel-Razek[1], R Ismail Magdy[1], A Abdel-Salam[1]
[1]Pediatric Hematology, [2]Clincal Pathology , Cairo University, [3]Pediatric Department, National Research Center, Cairo, Egypt

Background: One of the promising approaches for pharmacotherapy of β-thalassemia Intermedia (TI) is fetal hemoglobin (HbF) synthesis stimulating agents**.** Hydroxyurea (HU) has been shown to increase fetal hemoglobin (HbF) in TI patients. Its effects in increasing total hemoglobin (Hb) have been inconsistent. Studies of long term HU therapy in pediatric TI patiants are rather uncommon.
Aims: This study aimed to evaluate the overall response to HU therapy among Egyptian TI patients with variable clinical severity. The impact of genetic background and other disease variables on the likelihood of response were also studied.
Methods: An observational retrospective study, included 100 β-TI patients; 82 were children (mean age 9.9±4.1 years, range 2-18 years) and 18 adults (mean age 24.8±4.6 years). All patients were treated with hydroxyurea (mean dose 20.0±4.2 mg/kg/day, range 10-29 mg/kg/day) over a follow-up period of 4 to 96 months (mean 35.4±19.2 months). Minimum set of recorded clinical and laboratory data included baseline, at end of first year of therapy and/or last results at the time of the study. Clinical data included age, duration of disease, splenic size, frequency of transfusion, side effects and compliance to treatment. Laboratory studies included total hemoglobin, fetal hemoglobin percent by HPLC, serum ferritin levels by ELISA, liver and kidney functions. Molecular characterization was performed for 42 patients.
Assessment of Response: Major responders transfusion-independence and/or increase in their hemoglobin level by more than 2g/dl; minor responders: having a reduction in transfusion frequency by 50% or more and/or showing increase hemoglobin level by 1-2g/dl**.**
Results: Responders constituted 79/100 (79%); 64/82 (78%) children and 15/18 (83.3%) adult patients. Major and minor responders were 33% and 46% respectively. A significant decrease in transfusion frequency and increase in hemoglobin level. Response was evident in 25/79 (32%) of responders at 1-3 months with a peak reached at 12 months. Study of HbF and serum ferritin in 45 of responders revealed significant changes. *Transfusion dependency:* after one month of HU therapy, 11/25 (44%) transfusion dependent patients received no further blood, 12/25 (48%) needed less frequent transfusions. *Splenic Status:* Nineteen patients were splenectomized before starting HU**.** Decreased splenic size was found in 30/81 (37%) while increased in 6/81 (7.4%). *Molecular Characterization:* Molecular study of 42 patients showed that I*VS* 1.6 T>C was the most prevalent genotype among responders (n=28/36). *Pediatric vs. Adult response:* Both pediatric and adult groups were comparable regarding response

rate and parameters of response. *Predictors of Response:* Bivariate analysis carried out to identify predictors of response to HU in TI patients failed to show significant predictors. *Adverse effects:* Two patients developed single episode of neutropenia resolved upon temporary interruption of HU. One patient had increased liver enzymes improved spontaneously when decreasing HU. All pediatric patients showed good compliance to HU therapy (Table 1).

Table 1. Clinical and laboratory data of HU responders (n=79).

Summary and Conclusions: Hydroxyurea is a good therapeutic modality in management of pediatric TI patients as in adalts. It can minimize or stop transfusion needs with concomitant iron overload and blood-born viral transmission especially in developing countries like Egypt. Compliance to HU was good with minimal manageable side effects.

PB1931

EFFICACY OF DEFERASIROX IN CARDIAC IRON OVERLOAD OF B-THALASSEMIA MAJOR PATIENTS AFTER FIVE YEARS OF TREATMENT

A Agapidou[1,*] E Vlachaki [1], G Spanos[1], E Vetsiou[1], P Boura[1]
[1]Thalassemia Unit, Ippokrateio Hospital, Thessaloniki, Greece

Background: B-thalassemia major patients suffer from iron overload due to regular red blood cell transfusions. The efficacy of Deferasirox (DFS), as a chelation agent, in reducing or preventing cardiac iron burden was retrospectively investigated in 26 patients with β-thalassemia major after five years of therapy.
Aims: Efficacy of Deferasirox in cardiac iron overload of β-thalassemia major patients.
Methods: All regularly transfused patients had MRI T2* evaluation of their cardiac iron load before starting Deferasirox and after a period of at least 5 years. Cardiac iron burden was categorized into 3 groups: A) increased load when T2*<8 ms, B) intermediate iron load when T2*=8-20ms, C) low /no iron load when T2*>20ms.Ferritin levels and left ventricular ejection fraction (LVEF) were also monitored.LVEF>60% was considered normal and was evaluated along with the MRI. Deferasirox was administered in starting dose of 30mgr/kgr/day and never increased more than 40mgr/kgr/day.
Results: Among 26 patients 17 were women (mean age 32, 8 years old) and 9 were men (mean age 33, 7 years old).Before starting deferasirox(DFS), 24 patients had MRI T2*cardiac iron>20msec, 2 had MRI T2*8-20ms and no one had MRI T2*<8ms.Mean serum ferritin levels were 1583, 73 ng/m L before DFS and 1668, 15 ng/ m L after 5 years of therapy. MRI T2* cardiac iron load before DFS was 32 ms and after was 37,5ms. LVEF was 66,2% before treatment with DFS and 64,8 after DFS therapy.Ferritin levels in patients with intermediate iron load was 3139,5 ng/m L before DFS and 1938 ng/m L after. MRI T2* in this group was 15,5ms before and 26,0ms after. No serious adverse events were seen.
Summary and Conclusions: Deferasirox is considered an effective chelating agent used as monotherapy even in patients with intermediate cardiac iron load.

PB1932

DEFERASIROX AND RENAL FUNCTION IN THALASSEMIC PATIENTS:A TEN YEAR EXPERIENCE OF A SINGLE CENTER

M Economou[1,*] A Teli[1], N Printza[1], A Papagianni[1], E Papadopoulou[1], F Papachristou[1]
[1]Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Data regarding renal function in thalassemic patients was limited until recently. Renal involvement is now beginning to be recognized in this patient group and is related to multiple factors, such as chronic hypoxia, iron overolad and / or chelation nephrotoxicity - especially in the context of new chelator use.
Aims: The aim of the present study was to retrospectively evaluate the presence of renal dysfunction in young, transfusion dependent thalassemic patients receiving chelation with deferasirox (Exjade®) during a ten year period.
Methods: The study included 47 patients receiving deferasirox during the 10 year period assessed. Deferasirox was given orally at a dose of 20 – 30 mg/kg/day. Information reported concerned sex, age at initiation of deferasirox, duration of deferasirox treatment, values of creatinine and estimated glomerular filtration rate (eGFR – Schwartz formula) at the time of chelation initiation and at the end of follow-up. In addition, the presence of hypercalciuria during the last year of deferasirox treatment was examined (defined as urine calcium of > 4mg/kg/day) and the urine calcium/creatinine rate during the same period was measured (normal values $U_{Ca}/U_{Cr} \leq 0.21$). Moreover, yearly ultrasound renal evaluations were assessed for the given 10 year period.
Results: Mean age at deferasirox initiation was 8.2±4.6 years (range 2 – 19.5 years) and mean duration of treatment 44.9±33.1 months (range 2.5 – 115 months). With regards to glomerular filtration paramenters, a statistically significant elevation of creatinine value was noted between start of drug and end of follow-up (0.52±0.11 και 0.65±0.16 mg/dl, respectively, $p<0.05$). In addition, mean eGFR presented a statistically significant decrease (136±20 ml/min/1.73m^2 and 125.9±21.9 ml/min/1.73m^2, respectively, $p=0.005$). Hypercalciuria was detected in 23/47 (48.9%) patients, of which 8/23 were put on hydrochlorothiazide treatment after conservative measures failed to improve urine calcium status. In 5/23 patients drug discontinuation we decided because of renal function deterioration, with subsequent laboratory parameter normalization. Kidney stone formation was detected on ultrasound evaluation of 2 patients while on deferasirox treatment, none presenting with parathyroid dysfunction.
Summary and Conclusions: This single center ten-year experience of deferasirox use shows that the drug can be safely administered to young thalassemic patients, given that close renal monitoring is performed. Relative renal abnormalities can be easily managed with conservative measures in the majority of patients, while discontinuation of the drug reverses abnormal laboratory parameters.

PB1933

DEFERASIROX AND OTOXICITY: A SINGLE CENTER 10 YEAR EXPERIENCE

A Teli[1], V Gourtsa[1], A Papastergiopoulos[1], M Athanassiou[1], M Economou[1,*]
[1]Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: The incidence of audiologic impairment in thalassemic patients has been well described and has mainly been associated to desferrioxamine chelation treatment. Although ototoxicity is a possible side effect of the newest chelator, deferasirox, literature has focused on other toxicities of the drug -*i.e.* nephrotoxicity.
Aims: To evaluate the effect of deferasirox on hearing function in young patients with transfusion dependent beta-thalassemia
Methods: Thalassemic patients receiving deferasirox chelation treatment during the period June 2003-June 2012 were retrospectively evaluated. Inclusion criteria were deferasirox treatment for at least 2 years and audiologic evaluation using pure tone audiometry prior to drug initiation and yearly during treatment. Data recorded consisted of sex, age at initiation, duration of treatment and audiometry results. In addition, mean hemoglobin and mean ferritin values were recorded, as well as deferrasirox dose at initiation, at time points of abnormal results and at the end of follow-up
Results: Out of 30 patients receiving deferasirox during the study period, 18 full-filled inclusion criteria. Mean age at initiation was 8.7 years (4.5-14years), mean treatment period 71.4 months (33-117 months), mean initial dose 21.44 mg/kg/day and mean initial ferritin 1417 ng/ml. One patient presented at the beginning of treatment with mild bilateral sensorineural hearing loss, but recovered 3 months later and remained impairment free until the end of follow up. Out of 18 patients 4 (22.2%) presented new findings related to sensorineural hearing loss during the study period. In 3 out of 4 cases intervention with dose reduction or drug discontinuation resulted in full recovery, while in one case improvement but not full recovery was noted after dosing intervention.
Summary and Conclusions: The study indicates the need for close audiologic monitoring in thalassemic patients receiving deferasirox so that early changes may be recognized and treatment may be judiciously adjusted in order to prevent or reverse hearing impairment

PB1934

SAFETY AND EFFICACY OF DEFERASIROX IN MANAGEMENT OF TRANSFUSION RELATED IRON OVERLOAD IN SICKLE CELL PATIENTS; SINGLE CENTER EXPERIENCE

A Tarawah[1,*] Z M AlHawsawi[1]
[1]Pediatrics Hematology, King Abdullah Medical City, Madinah, Saudi Arabia

Background: Regular blood transfusion for patients with sickle cell disease (SCD) is a major supportive and preventive measure. Eleven percent of SCD patients will develop stroke by the age of 20 years. Chronic Regular blood transfusion therapy significantly reduces the risk of primary and secondary stroke in pediatric patients with SCD. However risk of iron overload is increased, which has been associated with morbidity and mortality in SCD patients. Iron chelation for SCD patients once liver iron concentration increases to 7 mg Fe/g dry weight, if serum ferritin more than1000 ng/l, or if patients have received cumulative transfusions of at least 20 top-up transfusions. Deferasirox is a once-daily, oral iron chelator that has shown effectiveness in reducing iron burden in SCD patients with acceptable safety profile.
Aims: Prospective single arm at a single center study, to assess Safety and efficacy of Deferasirox in management of transfusion related iron overload in Sickle cell patients. Report of One and two years results
Methods: SCD patients on regular blood transfusion, 2-15 years old and Serum ferritin levels >1000 ng/mL or received > 10 top up blood transfusion were included. Safety has monitored by Complete blood count, blood chemistry, liver enzymes, renal function parameters and urine examination for proteinurea was estimated at study entry and subsequently every 3 months. Efficacy has monitored through measurement of Serum ferritin level every 3 months. Hepatic and cardiac iron load was measured by magnetic resonance imaging (MRI) T2*, R2 and R2*.
Results: Twenty three SCD patients have enrolled in this study. Eighteen patients have continued study. Mean age was 9.8±5 years, 11 males and 7 females. Deferasirox dose range from 10 to 40 mg/kg/day (mean 25±6.5). Baseline mean serum ferritin level was 1451±594 and median was 1219 ng/mL (1006 -3950). At the end of the first year of Deferasirox treatment, serum ferritin levels had reduced in 14 patients and increased in 4 patients. Mean serum ferritin level was 1180±868 ng/mL, and median was 870 ng/mL (241 - 2978). Median serum ferritin reduction from baseline to the end of the first year was 707 ng/mL (78-1279), with a median reduction rate of 40%. Eight patients have completed the second year of Deferasirox, where serum ferritin levels had reduced in all 8 patients. By the end of the second year mean serum ferritin level was 660±670 ng/mL, and median was 313 ng/mL (145 - 2039). Median serum ferritin reduction from the end of the first year to the end of the second year was 615 ng/mL (96-2061), with a median reduction rate of 26%. While the median serum ferritin reduction from the baseline to the end of the second year was 1219 ng/mL (341-2160).with a median reduction rate of 93%. MRI T2*, R2 and R2* to assess liver and heart iron load has been planned to be done at baseline and every year after. The first 10 patients (56%) have shown normal results at baseline. Median cardiac MRI T2* was 35 ms (31-40) and median liver MRI R2* was 5 ms (4.5-8). This result lead panel to re-assess this tool benefit in the study where panel has decided to eliminate MRI tool from efficacy assessment. Normal MRI T2*, R2 and R2* results has been reported before. One patient had > 5 folds increase in liver enzymes, which has returned to normal after Deferasirox discontinuation. One patient had 43% increases in serum creatinine level at one occasion. Adverse reactions happened in 6 patients, vomiting in 2 patients, abdominal pain in 2 patients, and painful crisis in 2 patients. Tested trace elements have not been affected (Figure 1).

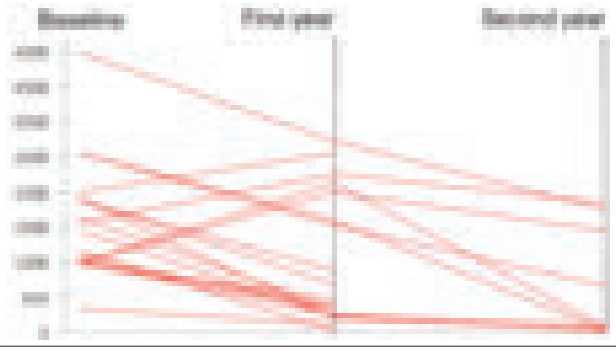

Figure 1.

Summary and Conclusions: Safety and efficacy of Deferasirox in SCD patients has investigated in 18 patients. Serum ferritin levels had reduced by 40% and 93% by end of first and second year respectively. No major adverse effects has reported. Deferasirox was safe and effective in management of transfusion related iron overload in sickle cell patients.

PB1935

ADULT-ONSET DIAMOND-BLACKFAN ANEMIA (DBA) WITH A *DE NOVO* NOVEL MUTATION IN THE EXON 5 OF RPL11

E Flores Ballester[1,*] JJ Gil-Fernandez[1], M Callejas [1], J Garcia-Suárez[1], E Magro[1], Y Martin[1], M Lopez-Rubio[1], M Calero[1], T Pascual[1], F Perera[1], M Cortti[1], C Casco[1], I Gutierrez[1], LM Juarez[1], S Marcellini[1], C Burgaleta[1]
[1]Hospital Universitario Príncipe De Asturias, Alcala De Henares, Madrid, Spain

Background: DBA is a rare disease characterized primarily by normochromic macrocytic anemia and reticulocytopenia. Classical DBA affects about7/1000000 live births and presents during the first year of life. Recent advances in identifying the genotype that underlies DBA have shown involvement of genes encoding both large and small ribosomal subunit proteins. However, as mutated genes have been discovered in DBA, non-classical cases with less distinct phenotypes are being described in adults as well as in children
Results: Case Report. 35-year-old male patient, with congenital hypoplasia of the thumb of the right hand and syndactyly between first and second fingers of the left hand, attended the emergency department complaining of progressive fatigue and headache for the past 15 days. A normocytic normochromic reticulocytopenic anaemia was disclosed (Hb7.2, MCV92.9, reticulocyte13x109/L).Iron, ferritin, transferrin saturation, B12vitamin and folic acid were normal. Was excluded thalassemia. Renal, liver function, direct and indirect antiglobulin tests, autoimmune studies, biochemical parameters of hemolysis, HIV, HBV, HCV, syphilis and EBV, B-19 Parvovirus, PNH clone, CT-body scan, ecocardiogram were normal or negative. Inmunophenotypic study of peripheral blood was negative for clonally B and T cells. BM aspiration showed moderate hypoplasia of the erythroid lineage without any signs of dysplasia. Perls' reaction in the BM smear was negative. Skeleton plain radiographs showed fusion of the phalanges of the finger with the thumb metacarpal in the left hand and absence of the first finger in the right hand. Fanconi Anaemia was excluded. A molecular study for DBA genes was performed and a heterozygous mutation C489_490delGCinsT in exon 5 of the RPL11 gene was detected. This mutation produces a variation in the composition of the last 16 a.a residues of the normal protein. This is previously NON-described mutation for DBA development. Molecular studies of the RPL11 gene were done in both parents and her sister and disclosed normal results. Our patient also exhibited other variations of the RPS19 (IVS4+14G>A) and RPS26 (5'UTR-22C>G) genes, that were considered as polymorphism and not pathological variations. According to the diagnostic criteria, our patient should be classified as sporadic non-classical form of DBA. The patient was initially treated with prednisone, folic acid and vitamin B12. He needed regular red-blood cells transfusions and iron chelation with deferasirox was started. We decided start cyclosporine to reduce the number of transfusions and reduce steroids effects. Also was added Danazol. With this combination, we observed a progressive erythroid response and transfusions were avoided. A Familiar HLA typing was performed and his only sister was found to be HLA genetically identical. Molecular studies of the RPL11 gene was performed on both parents and his only sister and was all normal. Until now the possibility of performing an allogeneic hematopoietic stem cell transplantion has been postponed.
Summary and Conclusions: We described a real clinical case of DBA in adulthood. Our case illustrates that late onset is not incompatible with the diagnosis of DBA. In the last 20 years, different mutations and deletions have been discovered and being associated with a development of DBA. Our patient has a previously undescribed mutation in exon 5 of RPL11. It was a de novo mutation. The RPL11 gene mutations have previously been associated with congenital bone malformations as those presented at the birth in our patient.

PB1936

GLUTATHIONE S-TRANSFERASE GENE POLYMORPHISMS (GSTM1, GSTT1 AND GSTP1) IN EGYPTIAN PEDIATRIC PATIENTS WITH SICKLE CELL DISEASE

H F Shiba[1], MK El-Ghamrawy[2,*] IAEM Shaheen[1], RAEG Ali[1], SM Mousa[1]
[1]Clinical Pathology, [2]Pediatrics, Faculty of Medicine, Cairo University, Cairo, Egypt

Background: Sickle cell disease (SCD) complications are associated with oxidative stress. Glutathione S-Transferases (GSTs) are a group of enzymes that protect against oxidative stress.
Aims: To evaluate the prevalence of GSTM1, GSTT1 and GSTP1 gene polymorphisms among homozygous sickle cell anemia (HbSS) patients and to investigate the possible association between the presence of those polymorphisms and SCD severity and complications.
Methods: This cross-sectional study included 50 Egyptian pediatric steady-state homozygous sickle cell patients (HbSS) aged 3-18 years. Fifty age and sex matched children free from hemoglobinopathies were included as a control group. All subjects were recruited only after informed consents were freely obtained from their guardians. Genotyping the polymorphisms in GSTT1 and GSTM1 genes was performed using multiplex PCR method. The GSTP1 ILe105Val polymorphism was determined using PCR-RFLP.
Results: No statistically significant difference was detected between patients and controls regarding prevalence of GSTM1, GSTT1 and GSTP1 genotypes

(p=0.153, 0.469 and 0.110 respectively). The GSTM1 null genotype was the most prevalent genotype among controls and sickle cell patients (68% and 52% respectively), followed by the mutant GSTP1 genotype (46% and 44% respectively) and the GSTT1 null genotype (18% and 26% respectively). GSTM1 null genotype was significantly associated with increased risk of severe VOC (Odds ratio=1.52, 95% Confidence Interval= 0.42-5.56, p=0.005). We found no significant association between GSTs genotypes and frequency of sickle cell-related pain, transfusion frequency, disease severity or hydroxyurea treatment.

Summary and Conclusions: GSTM1 gene polymorphism may be associated with risk of severe VOC among Egyptian SCD patients.

PB1937

IDENTIFICATION OF A NOVEL MUTATION IN THE B-GLOBIN GENE 3' UNTRANSLATED REGION [HBB: C.*+118 A>G] IN SPAIN

P Ropero[1,*] A Herrera[2], F de la Fuente-Gonzalo[1], J M Nieto[1], A Villegas[1], J Díaz-Mediavilla[1], FA González[1]
[1]Hematology, Hospital Clínico San Carlos, Madrid, [2]Hematology, Hospital Virgen del Rocío, Sevilla, Spain

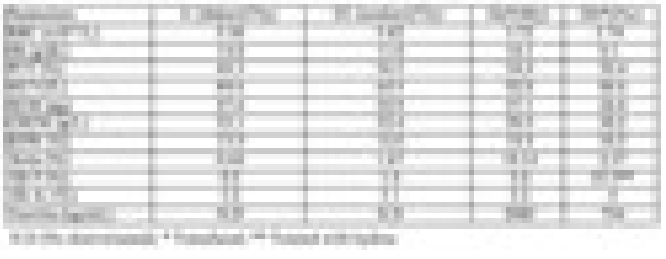
Background: The 3' UTR region is well known to be associated with mRNA stability because of its associations with 3' end processing, polyadenylation and mRNA capping. The 3' end processing of the pre β-mRNA involves some proteins bound to the 3' UTR, known as PTB, hnRNP, PAP and CstF. The αCP and nucleolin areas are also associated with the 3' UTR and involved in β-globin gene mRNA stability. Mutations located in this area cause a β-thalassemia phenotype compatible with β^+-thalassemia.

Aims: We describe one novel mutation located in the 3' UTR of the β globin gene and attempt to elucidate the resulting phenotype.

Methods: Two brothers, the first a 49-years-old male and the second a 41-years-old male. Both, were diagnosed with β-thalassemia intermedia at 2 years old. The oldest at the following year underwent a splenectomy. Both receive monthly erythrocyte transfusions. They are undergoing chelation therapy. Their parents have also been studied. The hematological data were obtained with an automated cell counter. The Hb A_2 and Hb F levels were measured by HPLC-VARIANT™. Hemoglobin was studied by capillary zone electrophoresis and cation exchange HPLC. The isolation of genomic DNA was made with an automatic method. Most frequent α globin mutations were screened with a commercial Alpha-Globin StripAssay kit. The β globin gene from promoter regions to the 3' UTR was automatic sequenced. All studies were made with the prior informed consent of the family.

Results: Both brothers were compound heterozygous for HBB:c.*+118 A>G and HBB:c.118C>T mutations according to DNA sequencing. Their mother was a carrier of HBB:c.118C>T mutation, the father was a carrier in the 3' UTR of the HBB:c.*+118 A>G mutation. The mother had mild anemia, clinically asymptomatic. Her hematological data correlated with the β-thalassemia trait. The father did not have hematological parameters associated with the β-thalassemia, and his blood smear revealed normocytosis and normochromia of the red blood cells (Table 1).

Table 1.



Summary and Conclusions: The adenine at position +1592 or +118 bases downstream of the termination codon is highly conserved among primates and placental mammals, as it is located between the poly(A) Signal (PAS) and the poly(A) Cleavage (PAC) site. Given its location, it is likely that this mutation would interfere with mRNA maturation; however, the clinical data of the heterozygous carrier show virtually no significant alterations in MCV or MHC, which were at the lower limit of normality. Therefore, we suggest that the impact on CstF recognition of the mRNA sequence would be minimal and not significantly alter polyadenylation. Therefore, the mRNA is likely stable enough that β-globin chain synthesis is not substantially affected. However, based on the observed β-thalassemia intermedia phenotypes, the accompanying mutation in compound heterozygous patients and the blood indices of the carriers, we believe that this novel β globin gene 3' UTR mutation is a silent mutation.

PB1938

NEUTROPHIL GELATINASE-ASSOCIATED LIPOCALIN (NGAL) LEVEL IN BETA THALASSEMIA PATIENTS

MA Hesham[1,*] UR Elsafy[2], MR Besher[1], MM Fathy[1], GS Gerges[1]
[1]Pediatric, Zagazig University-Faculty of Medicine, [2]Pediatric, Zagazig University - Faculty of Medicine, Zagazig, Egypt

Background: Oxidative status has been reported in beta-thalassemia patients due to iron overload as iron plays a critical role in the formation of Reactive Oxygen Species. Neutrophil Gelatinase-Associated Lipocalin (NGAL) is known for its capacity to bind siderophores, transporting them inside the cells to activate cytoplasmic iron-dependent pathways, thus protecting the same cell from oxidative stress. It has also been found to have a role in kidney development and tubular regeneration after injury.

Aims: To evaluate serum levels of neutrophil gelatinase-associated lipocalin(NGAL) in beta-thalassemia patients in order to determine its possible relationships with iron status and iron chelation therapy and its value as indicators of renal function.

Methods: A prospective case control study was conducted on thirty thalassemic patients (14males and 16 females) aged 5-15 years during their regular follow-up visits and twenty age- and sex-matched healthy children as a control group at the Outpatient Clinic of Hematology Unit of Pediatric Department and Clinical Pathology Department at Zagazig University Hospitals - Sharkia, Egypt in the period from January 2012 to January 2013.
Thalassemic patients were randomized into three groups according to the type of iron chelation therapy .All patients and control were subjected to full medical history , thorough clinical examination and laboratory investigations in the form of complete blood picture, serum Iron and ferritin levels , renal functions and creatinin clearance and plasma concentrations of Neutrophil Gelatinase-Associated Lipocalin (NGAL) protein (ng/ml) by ELISA method.

Results: Our results showed that 63.3% of our patients were on Desferal, 26.7% on Kelfer and 10% on Exjade . The serum level of of NGAL was highly significant elevated among cases compared with controls. There were highly significant positive correlations between urea , creatinine , ferritin and duration of chelation and serum level of NGAL while there was non-significant relationships between types of iron chelators and serum NGAL level.

Summary and Conclusions:
the potential use of serum NGAL measurements among beta-thalassemic patients may be of great potential, but the findings made in the present study are only preliminary. Therefore, no clinical application can be contemplated without, for instance, specifically evaluating the effect of chronic inflammation on circulating NGAL levels, and making an effective cost-to-benefits analysis since rapid NGAL measurement incurs considerable economic costs.

PB1939

TIME TO LOOK AT COMBINATION CHELATION. EFFICACY AND SAFETY OF DIFFERENT IRON CHELATION COMBINATIONS IN TRANSFUSION DEPENDENT ANEMIAS

V Berdoukas[1,*] M Puliyel[1], S Carson[2], J Wood[3], T Hofstra[4], A Nord[4], T Coates[5]
[1]Hematology/oncology and bone and marrow transplantation, [2]Hematology/oncology and bone and marrow tranplantation, CHLA, Keck School of Medicine, USC, [3]Cardiology, CHLA, KSM, USC, [4]Hematology/Oncology and Bone and Marrow Transplantation, CHLA,KSM,USC, [5]Hematology/Oncology and Bone and Marrow Transplantation , CHLA,Keck School of Medicine, USC, Los Angeles, United States

Background: Routine MRI screening of hepatic and extrahepatic iron stores allows us to tailor the use of all three iron chelators according to specific organ loading. In most cases this is usually monotherapy with one of the three available medications, deferoxamine (DFO), deferiprone(DFP) or deferasirox (DFX). The decision on which chelator to offer is based on the severity and pattern of iron loading in the different organs, the amount of iron they are receiving through transfusions, adverse effects associated with the use of any of the compounds and patient preference. In cases where there was combined hepatic and extrahepatic loading, we have prescribed combination therapy with the oral agents DFP and DFX (N=14), DFP and parenteral DFO (N=2), as well as DFO and DFX (N=1).

Aims: The aim of this analysis was to determine the efficacy and safety of the chelation regimes used

Methods: We received IRB approval for retrospective review and anonymous publication. Data were acquired from 17 patients. Five with Sickle Cell Anaemia, 1 with pyruvate kinase deficiency , 1 with HbE thalassaemia and 10 with thalassaemia major. The age range was 9 to 36 years. Time of combined therapy ranged from 9 to 96 months. All patients were reviewed according to intention to treat. The numbers in each subgroup of combination of chelators were too small for statistical evaluation of each subset according to medications prescribed and compliance. We therefore report a single case, the outcomes in good compliers who had cardiac iron at the start of combination and simple

statistics on 7 patients who were good compliers on combination. Of those seven who did not have excess cardiac iron, the 5 were offered combined therapy because of excess hepatic and pancreatic iron

Results: One patient with SS was prescribed deferiprone and deferasirox with almost zero compliance and over a 20 month period his liver iron concentration(LIC) deteriorated from 29-34 mg/g dry weight (gdw), pancreatic iron from R2*90-450 herz and ferritin from 5050 to 18,500. Cardiac T2*changed from 31.6 to 20.5ms, indicating a downward trend. In two of the good compliers with combination DFO + DFP, cardiac T2* improved from 4.8ms to 5.4 in 12 months with left ventricular ejection fraction (LVEF) improving from 50.8 to 60.4% and 4.4 to 22.4 in 58 months with LVEF from 46.1% to 56.7% and one with DFX + DFP, T2* improved from 8.6 to 21.4 in 18 months with stable LVEF. In 6 compliers with excess hepatic and pancreatic iron the change in LIC per month (/m) was 0.6± 0.45 gdw (p=0.015), pancreatic R2* change/m was 24.0 ±18.6 hz(p=0.003) and ferritin reduced by 82.3±56.3 per month (p<0.001) It is clear that all three combinations are effective in reducing the iron content in areas of concern when patients adhere to the regimen. Every patient with better than 50% adherence significantly improved target organ iron burdens. Even in the patients with poor adherence (results not shown), there may be some cardiac protection as evidenced by the maintenance, and in some cases, improvement in LVEF. The adverse events associated with the combination therapy were no different from those with the use of each agent as monotherapy and there were no new previously unreported toxicities. The most common were gastric upset with both DFP and DFX and some very mild neutropenia in one patient on DFP. There were no elevations in creatinine or increased proteinuria in any patients on DFX.

Summary and Conclusions: The tailoring of mono and combination chelation therapies according to MRI assessment of hepatic and extrahepatic stores offers the ability to bring all patients to normal iron levels, prevent morbidities, and even potentially reverse existing functional deficits. Clearly, adherence remains the dominant challenge in effective chelation. It would be valuable for a registry to collect data on all patients on such combinations in order to confirm the efficacy and safety.

PB1940

EVALUATION OF CHILDREN WITH THALASSEMIA MAJOR WITH DEPRESSION SCALE AND SELF-CONCEPT TEST.

G Aydogan[1,*] SS Oral[1], A Akcay[1], D Tugcu[1], F Akici[1], Z Salcioglu[1], H Sen[1], M Gundogdu[1], G Keskindemirci[1], N Ayaz[1]
[1]Pediatric Hematology, Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey

Background: Beta Thalassemias are a group of inherited blood disorders caused by reduced or absent synthesis of the beta chains of hemoglobin, resulting in variable phenotypes ranging from severe anemia to clinically asymptomatic individuals. Individuals with beta thalassemia major usually present within the first two years of life with severe anemia, poor growth and skeletal abnormalities during infancy. Affected children will require regular lifelong blood transfusions. Thalassemic patients are vulnarable to emotional problems. Unfortunately, there are few psychological studies referred on the literature.

Aims: The study aimed to determine the prevalence of depression and low self concept in patients with thalassemia major and compare them with healty children.

Methods: The study was done with 40 voluntary children with thalassemia major having regular blood transfusions and iron chelation treatment and 20 healthy children between the ages of 9-16 years. Psychological data, including depressive disorder and low self concept were assessed by Child Depression Scale and Piers-Harris Self Concept Scale. Demographic data included age, sex, mothers and fathers educational levels, school achievement, serum ferritin levels,prevalence of transfusion, iron chelation treatment. Statistical analysis was performed by chi-square test, using the SPSS software.

Results: The prevalance of depressive disorder in thalassemic patients were more then control group: 27.5%, 10% respectively. However self concept scales in the study group were lower then the control group, but there was no statistically significant difference.

Summary and Conclusions: Beta thalassemia major, a chronic, genetically determined hematological disorder causes emotional and behavioral problems. This study indicated that the prevalance of depressive disorder and low self scales were more common in thalassemia major patients.

PB1941

VITAMIN E AND SELENIUM IN EGYPTIAN THALASSEMIA AND SICKLE CELL DISEASE PATIENTS: ARE THEY DEFICIENT?

M Hamdy[1,*] D Mosallam[1], W Rabie[2], A Gamal[1], A Abdelsalam[1]
[1]Pediatric Hematology, [2]Clinical Pathology, Cairo University, Cairo, Egypt

Background: Increased oxidative damage is well known in hemoglobinopathies due to increased resting oxygen consumption and circulating pro-oxidative free hemoglobin. It is important to know whether the level of antioxidants differ in beta thalassemia and sickle cell anemia or contribute to differences in the severity of oxidative damage in these two diseases.

Aims: To study the levels of vitamin E and selenium as antioxidants in transfusion dependant Egyptian beta thalassemia major (TM) and sickle cell disease (SCD) patients and whether these variables differ among these two diseases or correlate with iron overload status or transfusion requirements.

Methods: A case-control study conducted at the hematology clinic of the children hospital, Cairo University, Egypt. The study group consisted of 30 thalassemia patients (mean age 12.9±3.2), 30 SCD patient (mean age 11.8±2.9) and 30 healthy controls. After obtaining a written informed consent, blood samples were withdrawn for measuring vitamin E, selenium and Lipid profile (cholestrol, HDL, LDL, triglyceride (TG)) in addition to serum ferritin, AST, ALT, CRP, retix and LDH.

Results: β-Thalassemia group showed significantly higher mean transfusion frequency when compared to SCD group (p=0.005). LDH was nearly five times larger than normal values and C-reactive protein (CRP) was also almost 3-fold larger in SCD patients and SCD patients showed statistically significantly higher values of LDH and CRP when compared to TM group (p<0.05). Thirteen percent TM patients exhibited abnormal values of AST and ALT exceeding 2 folds *versus* none of SCD group. All TM and SCD cases had below normal Selenium level *versus* 11 (36.7%) of the control group, and mean Selenium level was comparable between Thalassemia and SCD groups (p>0.05) and both groups showed significantly lower levels when compared to the control group (p<0.05). Similarly, all TM and SCD cases had below normal vitamin E level *vs.* none of the control group, and mean vitamin E level was comparable between TM and SCD cases (p>0.05) and both groups had significantly lower levels when compared to the control group (p<0.05). Total cholesterol, LDL-cholesterol, as well as TG were comparable in patients with TM and SCD (p>0.05) and all were significantly lower than relevant controls (p<0.05). However, there was no significant differences between mean HDL- cholesterol levels in the three groups (p>0.05). Among TM group; serum ferritin and selenium levels didn't correlate with any of the tested variables including other antioxidants. Levels of vitamin E were proportionally correlated with ALT values *(r* = 0.4; p=0.049) and AST *(r* = 4; p=0.039), however, no other clear correlation was found between vitamin E and other variables. Transfusion rate correlated positively with CRP (r=0.341, p=0.065), AST correlated inversely with TG (r=-0.389, p=0.034) and Retics correlated negatively with Hb (r=-0368, p=0.046) and positively with ALT (r=0.424, p=0.020). Among SCD cases, serum ferritin, selenium and vitamin E levels didn't correlate with any of the tested variables.

Summary and Conclusions: These results demonstrate that Children with TM and SCD have increased oxidative stress and depleted antioxidants relative to healthy controls. However, levels of these antioxidants did not correlate with indices of iron overload, hemolysis, or inflammation in chronically transfused TM and SCD patients

PB1942

ASSOCIATION BETWEEN DUFFY ANTIGEN EXPRESSION AND DISEASE SEVERITY IN SICKLE CELL DISEASE PATIENTS

H Farawela[1,*] H Helmi[1], M EL-Ghamrawy[2], M Farhan[1], R Soliman[1]
[1]Clinical Pathology Hematology, [2]Pediatrics, Cairo University, Cairo, Egypt

Background: Sickle cell anemia (SCA) is associated with a pro-inflammatory state, characterized by an elevated baseline leukocyte count & inflammatory cytokines. White blood cell adheres to vascular endothelium with subsequent endothelial injury and repeated ischemia-reperfusion injury contributes to disease pathogenesis. Identification of genetic polymorphisms that may modulate disease severity in SCD has become an active area of research.
The Duffy blood group system, Fy*A and Fy*B, are codominant alleles, located on chromosome 1. Four phenotypes are present on the RBCs: Fy(a+b–), Fy(a+b+), Fy(a–b+), and Fy(a–b–). The positive Duffy blood group antigen thwarts the activation of white blood cells and hinders the dissemination of chemokines from blood into organs reducing the inflammatory process.

Aims: This paper investigates the effect of the RBCs Duffy antigen expression and its genetic polymorphisms on modulating Sickle cell disease severity as well as its complications.

Methods: Cross-sectional study included 100 patients with SCD. Patients were divided into complicated and non complicated SCD individuals. Complications were determined according to scoring system (0-5) based on the presence or absence of each of the following: 1) pulmonary dysfunction; 2) avascular necrosis of the hip or shoulder; 3) central nervous system (CNS) abnormality; 4) kidney dysfunction,; and 5) history of leg ulcers. For each item, one point was assigned if present. The expression of the Duffy phenotype was detected by indirect anti-globulin test using both: tube and gel methods. The Duffy genotype was determined with PCR-Restriction Fragment Length Polymorphism (RFLP) assay.

Results: In regards to Duffy genotype in SCD patients, the frequency of FY positive genotype was 56% and FY negative genotype was 44%.Total leucocytic

count was strongly associated with the Duffy genotype. Duffy-positive patients had significantly higher WBCs, than those detected in Duffy-negative patients (p=0.002).Comparison between each measure of disease severity (pulmonary dysfunction, avascular necrosis, CNS dysfunction, kidney dysfunction and leg ulcers) in Duffy positive and negative patients in our study revealed no statistical significant difference.
Summary and Conclusions: Our study suggests that RBC DARC expression increases the plasmatic levels of white blood cells in SCA patients and that Duffy genotype at the GATA site may not be a potential biomarker for early end-organ damage in SCD and no association was detected between RBC DARC quantitative phenotype and the occurrence of the studied SCA complications.

RELATIONSHIP BETWEEN BCL11A SEQUENCE VARIATIONS AND RESPONSE TO HYDROXYUREA THERAPY IN IRANIAN BETA-THALASSEMIA INTERMEDIA PATIENTS

M Karimi[1,*] T Zarei[1], S Haghpanah[1], A Ebrahimi[2], M Moghadam[1], N Rezaei[1], R Moghtaderi Nasab[3], Z Fereydooni[3], N Hemat Shirazi[3], M Ejraie[3], M Mirzaie[3]
[1]Hematology Research Center, Shiraz University of Medical Sciences,, Shiraz, [2]Shahid Beheshti University of Medical Sciences, Tehran, [3]Islamic Azad University, Arsanjan Branch, Arsanjan, Iran

Background: Increased HbF levels can ameliorate the disease severity in β-globin gene disorders such as β-thalassemia intermedia (β-TI).Hydroxyurea (HU) is a chemotherapeutic agent that have been known as a fetal hemoglobin (HbF) induction agent that can alleviate the symptoms in β-TI patients. The HbF level is influenced by many loci inside or outside the β-globin gene cluster. BCL11A gene on chromosome 2p16 is one of the three major loci that may play a role in the regulation of HbF levels.
Aims: The aim of this study was to assay the possible relationship of HU responder and BCL11A gene sequence variations in Iranian patients affected with β-TI.
Methods: In this cross sectional study 102 β-TI patients who were taking HU with a dose of 8□15 mg per kg body weight per day for a period of about 6 months to 13 years were randomly selected between February 2012 and October 2013 in southern Iran. Based on the need to blood transfusion and hemoglobin level, our patients were divided into two groups: good responder and poor responder. Response to HU treatment was defined based on decrease or cessation of the need to blood transfusion as well as evaluation of Hb level.
Results: We compared demographic and clinical variables between good and poor responders. There were no statistically significant association between hematological data and also age with response to HU (P>0.05).None of the evaluated SNPs were not significantly associated with response to HU(P>0.05).
Summary and Conclusions: In this study none of the evaluated SNPs showed significant association with response to HU, but further larger studies as well as evaluation of other genes are suggested.

REPORT OF 15 YEARS OF GENETIC COUNSELLING FOR HAEMOGLOBINOPATHIES IN NORTHERN GREECE

S Theodoridou[1,*] A Markantonatou[1], D Giannakopoulou[1], P Nicolaos[1,2], D Adamidou[1], V Delaki[1], E Boutou[3], A Balasopoulou[3], T Theodoridis[2], L Zepiridis[2], T Daglis[2], O Karakasidou[1], V Aletra[1], E Voskaridou[3]
[1]Haematology, Hippokration Hospital of Thessaloniki, [2]Obstetrics Gynecology, Aristotelion University, Thessaloniki, [3]Haematology, Thalassemia Center, Athens, Greece

Background: Genetic counselling is defined as a communication process which deals with the human problems associated with the occurrence, or risk of occurrence, of a genetic disorder in a family. Greece is a country with an 8% carriers of thalassaemia and 1-1,5% carriers of Sickle cell trait. Since 1974 a population screening program is performed for Thalassaemia and Sickle cell disease prevention. Through this program, natives and immigrants are screened and counselled free of charge and the genetic counselling is mainly focused in the prevention of thalassaemia and sickle cell syndromes. We find the couples at risk for giving birth to a thalassaemic offspring and convey to the individuals information about risks, the consequences of the testing procedure and the potential choice of continuing or discontinuing the pregnancy. We also try to facilitate the decision making although the personal values and beliefs vary.
Aims: We report our experience of the genetic counselling of couples at risk for Haemoglobinopathies over a 15 year period (1999-2013).
Methods: The carrier identification is carried out by a standard scheme, which included, CBC and red cell indices using the Coulter ONYX, a Cation Exchange HPLC variant system (Bio-Rad, Variant β-Thalassaemia Short Program), to determine HbA, HbA2 and HbF levels and the different abnormal structural haemoglobins, electrophoretic techniques both at alkaline pH on cellulose acetate and at acid pH on citrate agar, sickling test and tests for HbH inclusion bodies. Haemoglobin A2 is also quantified by column micro chromatography and serum ferritin levels are measured by micro Elisa technique. Biosynthesis of the- α and β- globin chαins and DNA techniques are also performed on selected cases.
Results: From the total 35.797 subjects who underwent screening during this period we found 3883 couples that came for screening and counselling. The pregnancies at risk for the birth of a child suffering from thalassaemia or sickle cell disease, involved 315 couples, out of the 360 that both partners carried abnormal genes. Few had a positive family history, while the rest were identified through preconception and prenatal carrier screening at our Thalassaemia Prevention Unit. Prenatal diagnosis was mainly carried out by chorionic villous sampling (CVS) at 11-12 weeks of gestation, and in few cases by amniotic fluid sampling, collected at 16-18 weeks. Very few late comers were tested by foetal blood sampling at 20-24 weeks of gestation. During the same period, prenatal diagnosis was not carried out in 45 pregnancies, because it was not indicated as the combination phenotype is clinically very mild. Gene interactions in these cases were as follows:α thalassaemia with β-thalassaemia, α thalassaemia with δβ-thalassaemia, silent β-thalassaemia with β-thalassaemia, α thalassaemia with sickle cell trait, α thalassaemia with α thalassaemia, Hb Agrinio with β-thalassaemia, Hb E with Hb E, HbE-Saskatoon / HbS , HbE-Saskatoon/β-thal, HbO-Arab/HbO-Arab, HbD-Punjab/α-thal, HbD-Punjab/β-thalassaemia.
Summary and Conclusions: As is the case for all genetic diseases, counselling of parents with the potential danger of bearing a sick child requires extreme sensitivity, in relation to psychosocial and ethical issues.

PB1945

SAFETY AND EFFICACY OF INTERFERON AND RIBAVARIN THERAPY IN HCV POSITIVE THALASSEMIC PATIENTS

S Kakkar[1,*] P C Sobti[2], A Markan[3]
[1]Pediatrics, hemato-oncology unit, Dayanand Medical College, Ludhiana, [2]Pediatrics, hemato-oncology unit, Christian medical college, [3]pediatrics, Dayanand Medical College, Ludhiana, Ludhiana, India

Background: Liver disease in thalassemia is secondary to transfusional iron overload and viral hepatitis (hepatitis B and C). Universal immunization against HBV has markedly reduced the incidence of hepatitis B, hence hepatitis C remains the main risk factor for development of liver fibrosis and hepatocellular carcinoma. Treatment of chronic hepatitis C has been controversial due to increased transfusion requirement secondary to ribavirin induced hemolysis resulting in increased iron overload.
Aims: To determine safety and efficacy of interferon and ribavirin combination therapy in thalassemia patients with chronic Hepatitis C (genotype 3).
Methods: Fourteen thalassemia major patients with chronic hepatitis C (genotype 3) who gave informed consent for the treatment and were negative for HBsAg and HIV were included in the study. Patients were treated with Pegylated interferon α 2a and ribavirin for 24 weeks. Monitoring of treatment efficacy was based on HCV RNA measurements done at 4, 12, 24 and 48 weeks. CBC, liver and thyroid functions were assessed regularly during the treatment. Transient elastography was done at baseline and 1 year later to assess the liver fibrosis.
Results: The mean age of the patients was 15.14 (7-28) years. Ten (71.4%) were male and 4(28.6%) were female. Twelve (85%) patients achieved rapid virological response. All patients achieved complete early and end of treatment response. SVR was attained in 7/13 (53.8%) patients. Response rate in patients being treated for the first time was 60% (3/5) as compared to 50% (4/8) in non responders. Flu like symptoms is the most common adverse effect seen. Two patients required growth factor support for neutropenia. Eight (57%) out of 14 patients developed thrombocytopenia (platelet count<1, 00,000/mm3). Transfusion requirement increased by 35% during the treatment.
Summary and Conclusions: The efficacy of interferon and ribavirin combination in achieving SVR in thalassemia patients with chronic hepatitis C (genotype 3) is lower than that in general population.

PB1946

RED BLOOD CELLS ANTIOXIDANT SYSTEM COMPENSATES OXIDATIVE EFFECT OF HYPOXIA DURING CHRONIC INFLAMMATORY LUNG DISEASES

G Tkachov[1], N Koretskaya[2,*]
[1]Russian cardiological scientific-industrial complex, [2]University / Research institute MSMSU named after A.I.Evdokimov, Moscow, Russian Federation

Background: Red blood cells (RBCs) disorders (sickle-cell anemia, thalassemia) increase oxidative damage as result of release heme and iron from hemoglobin. Nevertheless, RBCs oxidative stress is not the main reason

of chronic hemolytic complaints at patients with these diseases because RBCs have tolerance of oxidative damage. This extensive antioxidant system prevents of formation of reactive oxygen species (ROS), scavenges ROS, and repairs of oxidized molecules. A partial defect in any of these processes can harm RBCs, but is without chronic hemolytic complaints too (van Zwieten R et al, 2013). Persons with hereditary RBCs disorders can get chronic inflammatory lung diseases (these pathologies have high morbidity). Chronic obstructive pulmonary disease (COPD) and bronchial asthma (BA) could be additional causes of peroxidation. For example, chronic inflammatory lung diseases lead to a hypoxia as a result of bronchial obstruction. Hypoxia is a condition to macrophage activation and ROS production. During exacerbations of chronic diseases inflammation is accompanied by growth amount of neutrophils and degranulation. Probably patients with RBCs pathologies need in more intensive medical care in the case of great role of RBCs in prevention of blood oxidant-antioxidant imbalance during COPD or BA .

Aims: to determine whether RBCs can compensate oxidative effect during chronic inflammatory lung diseases.

Methods: Informed agreement was received from all subjects. All subjects (mean age 45±15) were without RBCs disorders and with/without lung pathology. Patients received standard therapy in City clinical hospital No. 70 of Department of Healthcare of Moscow. There were 20 COPD,12 BA and 12 community-acquired pneumonia (CAP) patients on study. Control group include 10 health subjects. There were two times to blood assay – the 1 day (exacerbation) and 10 day at a hospital. Blood samples were collected in 4 ml tubes, 60 USP Units of Lithium Heparin. We study blood superoxide dismutase (SOD), glutathione peroxidase (GPX) and catalase activity in COPD and BA in comparison with CAP (acute inflammation) and Control. Blood processing (cells washing with isotonic saline solution) means that main source of antioxidant enzymes is RBCs. SOD activity was measured with using RANSOD kit, Randox. GPX activity was measured with using Paglia DE and Valentine WN method, 1967 (RANSEL kit, Randox) . Catalase activity was measured with spectrophotometric detection of the breakdown of hydrogen peroxide (Beers J, Sizer IW, 1952). We determined thiobarbituric acid reactive substances (TBARS) level in plasma to estimate oxidative stress by thiobarbituric acid test (Uchiyama M, Mihara M, 1978). Statistical analysis was applied using Statistica 6.0 and GraphPad Prism5. Data are expressed as the mean +/− standard deviation (SD). * - P value <0.05 was accepted as significant in comparison with Control.

Results: According our data in patients with lung diseases antioxidant enzyme activity changes similarly (results in Figure 1). Despite low activity of GPX (1 day Kruskal-Wallis test p=0.017) we can't say about oxidative damage in all groups. High plasma TBARS concentration shows enhanced oxidative stress during acute lung inflammation (1 day CAP group in comparison with Control, Mann-Whitney's criterion p=0.015). However there was no increasing of this parameter during exacerbation of COPD or BA. PlasmaTBARS concentrations in COPD (1 day p=0.51) and BA (1 day p=0.78) didn't differ from normal values. Therefore blood antioxidant system can prevent of oxidant-antioxidant imbalance in the case of chronic inflammation.

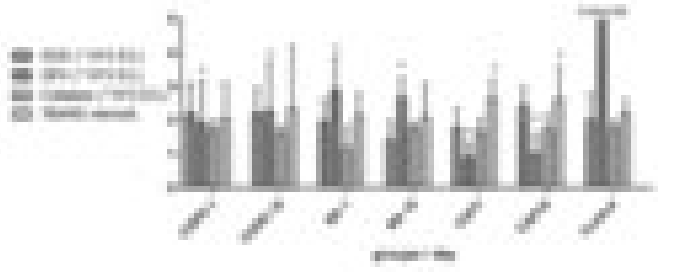

Figure 1. Antioxidant enzymes activity and TBARS concentration.

Summary and Conclusions: The results testify to blood antioxidant system compensates oxidative damage during COPD and BA. Therefore hereditary RBCs disorders can influence an oxidant-antioxidant balance and outcome of chronic inflammation. So the further proteomics investigations in RBCs antioxidant defense can help to improve quality of life.

PB1947

IRON DEFICIENCY IS NOT ASSOCIATED WITH INCREASED BLOOD CADMIUM IN INFANTS

S Park[1,*] Y Kim[1,2], S Kim[3], K Yoo[4], J Park[5]
[1]Pediatrics, [2]Occupational and Environmental Medicine, Ulsan University Hospital, Ulsan, [3]Pediatrics, Inha University Hospital, Incheon, [4]Pediatrics, Korea hemophilia foundation, Seoul, [5] Occupational and Environmental Medicine, Ulsan University Hospital, Ulsan, Korea, Republic Of

Background: Because iron is absorbed via mechanisms similar to those of other divalent metal ions, including cadmium, manganese, and lead, a dietary deficiency in iron can lead to excess absorption of cadmium, a widespread toxicant with detrimental effects on health. Indeed, iron deficiency has been found to predispose animals to cadmium toxicity by increasing gastrointestinal cadmium absorption. Several studies have suggested an association between iron status and blood cadmium concentration in adults, especially pre-menopausal women, whereas few studies have been conducted in children.

Aims: We assessed whether blood cadmium concentrations are higher in iron-deficient than in control infants, and whether treatment of the former with iron supplements affects cadmium concentrations.

Methods: Thirty one infants with iron deficiency, ranging in age from 6 months to 2 years, were selected from infants being treated at an ambulatory pediatric hematology clinic at Ulsan University Hospital, Ulsan, South Korea. Thirty-six healthy, age- and sex-matched control subjects, with serum ferritin concentrations higher than 15 µg/L, were selected from among the infants visiting a general pediatric clinic in the same hospital. Subjects were excluded if they were delivered preterm or at low birth weight; had a history of any disease, or had concurrent acute or chronic infection or inflammation; or if their parents had a history of occupational exposure to cadmium. All 31 iron-deficient infants were treated with ferric hydroxide-polymaltose complex (6 mg/kg Fe^{3+}/day) for 1-6 months. Blood cadmium concentrations were determined in all control subjects and in all iron-deficient subjects prior to iron supplementation. Blood cadmium concentrations were assessed again in 19 iron-deficient infants after their ferritin concentrations returned to the normal range; the other 12 iron-deficient infants were lost to follow up.

Results: Age and gender distribution were similar in the iron-deficient and control groups, as were their GM blood cadmium concentration. However, hemoglobin concentrations, hematocrit levels, and serum ferritin levels differed significantly in the two groups. Mean duration of breast feeding was longer in iron-deficient than in control infants. All the iron-deficient infants were treated with an iron supplement, and 19 were tested again for blood cadmium concentrations after their ferritin concentrations reached the normal range. The GM blood cadmium concentration in these 19 infants was not significantly altered by ferric hydroxide treatment, while their hemoglobin, ferritin, and Fe/TIBC (%) levels were significantly higher after than before treatment (Table 1).

Table 1. Laboratory features of iron-deficient infants before and after iron therapy.

Group characteristics	Before iron therapy (n=19)	After iron therapy (n=19)	*P* value
Cadmium (µg/L)	0.58 (0.06-1.40)	0.47 (0.06-1.38)	0.529
Hemoglobin (g/dL)	10.49±1.75	12.38±0.85	0.001
Hematocrit (%)	32.77±3.80	36.87±2.24	0.002
Ferritin (µg/L)	7.03±3.16	20.83±7.0,4	<0.001

Summary and Conclusions: These findings indicate that iron deficiency does not increase blood cadmium concentrations in infants, in contrast with the effects of iron deficiency on manganese and lead concentrations.

PB1948

CLINICAL AND BIOCHEMICAL ASPECTS OF ANEMIA IN CANCER PATIENTS

S Park[1,*] MJ Kim[2], JY Lee[2], KH Yoo[2], SH Lim[2], CW Jung[2], JH Jang[2]
[1]Internal medicine, [2]Samsung Medical Center , Seoul, Korea, Republic Of

Background: Although anemia further weakens the cancer patients and is also associated with poorer outcome, it can be easily ignored in practice. Actually, multifactorial pathogenesis is involved in anemia of cancer patients and defining the causes of anemia is not always simple.

Aims: In this study, we looked at cancer anemia from two perspectives including clinical and biochemical aspects.

Methods: There are two separate data sets for the analysis. First data for analyzing clinical aspects of anemia is collected from the 345 patients who were treated in Samsung Medical Center for the 4 major cancers in Korea (gastric, colorectal, lung cancer and hepatocellular carcinoma) between Jan 2012 and Apr 2012. Second data for biochemical aspects of anemia is from the patients having storage serum samples. Twenty-nine stored frozen serum samples from 4 types of cancer (gastric cancer, biliary tract cancer, lung cancer, and lymphoma) were used to analyze ferritin, soluble transferring receptor (sTfR), CRP, and hepcidin. Anemia at diagnosis was defined by hemoglobin (Hb) of 11g/dL or below. During treatment, Hb ≤11g/dL and a drop of Hb 2g/dL or more is also defined as anemia for patients whose baseline Hb level was over 11g/dL.

Results: Of the total 345 patients, there were 152 lung cancer (44.1%), 101 gastric cancer (29.3%), 69 colorectal cancer (20.0%), and 23 hepatocellular carcinoma (6.7%) patients. Forty nine patients (14.2%) had anemia at their initial diagnosis of cancer, and 129 patients (37.4%) experienced anemia during 1st line anti-cancer treatment. Among these 129 patients, 34 patients (26.4%) were

treated for their anemia, almost by RBC transfusion. For analyzing biochemical aspects of cancer anemia, we included patients with serum samples, which included 11 gastric cancer (37.9%), 6 biliary tract cancer (20.7%), 8 lung cancer (27.6%) and 4 lymphoma patients (13.8%). When comparing to the reference value from general population, cancer patients tended to show higher ferritin, sTfR and CRP level and lower hepcidin level. Among the cancer patients, anemic patients showed significantly higher level of sTfR compared to non-anemic patients (p=0.011). Although not statistically significant, the level of ferritin, CRP, and hepcidin was more elevated in anemic patients.

Summary and Conclusions: This study shows that cancer patients are being insufficiently paid attention for their anemia. Consistent increase of three inflammatory markers (ferritin, hepcidin, and CRP) in anemic patients with cancer implies that cancer anemia seems to be closely related to inflammatory process (ACD). Of note, however, we can also identify that iron deficiency and/or iron restricted erythropoiesis also contributes considerably to pathogenesis of anemia in cancer patients.

PB1949

CLINICAL SIGNIFICANCE OF THE NEW BECKMAN-COULTER PARAMETERS IN THE DIFFERENTIAL DIAGNOSIS OF ANEMIA

M Karagulle[1,*] D Goren Sahın[1], N Andiç[1], H Uskudar Teke[1], E Gunduz[1], OM Akay[1]
[1]Hematology, Eskisehir osmangazi Univercity, eskisehir, Turkey

Background: The differential diagnosis of anemia is based some biochemical indicators of iron metabolism. These are parameters of erythrocytes, ferritin, transferin saturation, transferin, serum iron and total iron binding capacity. These parameters are useful parameters to determine iron status, but they may not provide conclusive criteria for determining iron deficiency because of their high variability and low sensitivity.

Aims: In recent years, some studies reported that these convantional parameters is weak or relatively, so the researchers recommended that more sensitive tests (RSf, LHD, MAF, Transferrin/ Log Ferritin) are used in the differential diagnosis of anemia. In our study, we aimed to evaluate the these parameteres in the differential diagnosis of anemia.

Methods: The study was conducted at Eskişehir Osmangazi University, Faculty of Medicine, Department of Hematology. After obtaining the approval of the Ethics Committee and informed consent, 136 patients with iron deficiency anemia(IDA) (serum hemoglobin <12 gr/dl, TSAT <20% and serum ferritin <20 ng/ml), 50 patients with anemia of chronic disease (ACD) (serum hemoglobin <12gr/dl, TSAT >20% and serum ferritin >50ng/ml), 34 patients with beta thalassemia , 56 patients with anemia of chronic kidney disease (CKD) and 166 patients with healthy controls were included the study. These parameters are calculated with the following formulation, RSf= √(MRV X MCV), MAF={(Hgb X MCV)/100}, LHD= 100 X $\sqrt{1-\{1/(1 + e^{1.8\ (30-MCHC)})\}}$, Transferrin/Log Ferritin.

Results: Present measurements showed that RSf and MAF levels were lower in patient with iron deficiency anemia and beta thalassemia compared to patients with anemia of chronic disease and anemia of CKD. LHD and Transferrin / Logaritmic ferritin were markedly higher in patients with IDA when compared to patients with ACD and CKD. A statistically significant difference was seen in each group with RSf, MAF, LHD and T/LF. RSf and MAF showed a significant positive correlation with hematocryte, MCV, MCH, MCHC, serum ıron, transferrin saturation and serum ferritin level. But these parameters showed negative correlation with transferrin and total iron binding capacity. As well as, LHD and T/LF showed a significant negative correlation with hematocryte, MCV, MCH, MCHC, serum ıron, transferrin saturation and serum ferritin level. But these parameters showed positive correlation with transferrin and total iron binding capacity.

Summary and Conclusions: In recent years, some studies reported that these convantional parameters is weak or relatively. For example,Serum ferritin is acute phase reactant and it levels are increased in acute/chronic inflammation. Serum iron level is decreased in infection, inflammation and malignancy but it increased for used iron supplement, ineffective erythrophoesis and liver diseases. Transferrin saturation fluctuates due to the diurnal variation . Parameters used in routine differential diagnosis of anemia , as well as the current need for more sensitive and robust indicators available. In our study, we showed that these parameter that can be confidentially used in the differential diagnosis of anemia.

PB1950

DECREASED LIPID PROFILE IN PATIENTS WITH SICKLE CELL ANEMIA IS NOT A GOOD PROGNOSTIC MARKER

WE Ibrahim[1], I Ragab[1,*] NR Mohamed[2], SA Mohamed[1]
[1]Pediatrics, [2]Clinical Pathology, Ain Shams University, Cairo, Egypt

Background: Children with sickle cell disease (SCD), even in steady-state, have differences in several biomarkers as compared to healthy age-matched children. Those differences are related to numerous mechanisms associated with infection, inflammation and vaso-occlusion in the disease. Concerning Lipids, it was observed that changes in lipid profile in SCD patients were associated with hemolysis, inflammation and renal metabolism.

Aims: to evaluate the lipid profile in SCD and sickle thalassemia patients in correlation to various complications encountered in those patients.

Methods: A case- control study was performed in the Pediatric Hematology Clinic, Ain Shams University hospital in the period from October 2011 to June 2012.It included 25 patients with SCD and sickle thalassemia in steady state, and 25 age and sex- matched healthy controls.Patients were subjected to medical history taking and revision of hospital records for history of blood transfusion, number of hospital admissions and their causes, transfusion index, number of vaso-occlusive episodes, number of strokes details of hydroxyurea theapy, packed RBCs transfusion and chelation therapy. Full clinical examination was done and laboratory investigations including CBC, lipid profile and serum ferritin.

Results: We found a significant lower median HDL 35.6 (29.25-43.25) mg/dl (P= 0.015), median LDL 70 (54.25-81.25)mg/dl (P=0.037), mean cholesterol levels 127.96±32.45 mg/dl (P= 0.038) in sickle cell patients compared to control group where median HDL 44 (39.5-51) mg/dl, median LDL 81 (66.75-97.25)mg/dl, mean cholesterol levels 146.64±29.5 mg/dl, with no significant difference concerning triglycerides. Triglycerides levels were significantly lower in patient with sickle cell disease 112 (80.5- 126.5)mg/dl compared to patients with sickle thalassemia disease 69 (52-94) mg/dl (P=0.020).In patients group, a positive correlation was observed between triglycerides with HbF (r= 0.550, P= 0.005), ALT (r= 0.467, P= 0.019) and LDH (R= 0.410, P=0.047), while a negative correlation with pre-transfusion hemoglobin (r= -0.527, P= 0.025) was found. A negative correlation was found in patient with sickle cell disease between total cholesterol and Hb S level (r= -0.829, P= 0.042) and a positive one between total cholesterol and mean ferritin level (r= 0.431,P=0.032). A significant positive correlation was found between LDL and WBCs (r= 0.492, P=0.012) and direct bilirubin level (r= 0.494,P= 0.012). A positive correlation was noticed between HDL with total number of hospital admission due to vaso-occlusive crises and infections (r= 0.520,P=0.011) and dose of hydroxyurea (r= 0.845,P= 0.034).By classifying the patient group according to HDL level (>,<40 mg/dl) we found significant increase in hospital admission with increasing HDL level 6.5 (3.5-18.75) (P= 0.037).

Summary and Conclusions: Significant decrease in cholesterol, HDL and LDL levels was found in patients with sickle cell disease and sickle thalassemia, HDL level was associated with increasing hospital admissions, and triglycerides level was associated with increased hemolytic markers. Increasing HDL level is not a good prognostic factor in patients with SCD as in normal population.

PB1951

HFE MUTATIONS C282Y AND H63D IN IRANIAN POPULATION WITH TYPE 2 DIABETES

A Zare Bidoki[1,*] N Golchin[2, 3], HB Shahbazian[4], H Shahbazian[4], J Mohammadi-Asl[4]
[1]Molecular Immunology Research Center, Tehran University of Medical Sciences, Tehran, [2]Cancer Research Center, Ahvaz Jundishapur University of Medical Sciences, [3]Noor Genetics Laboratory, [4]Diabetes Research Center, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran

Background: HFE gene, which is also responsible for Hereditary Hemochromatosis (HH), is involved in iron metabolism. It has revealed that there is a link between type 2 diabetes (T2D) and HH so that 20 to 50% of patients with HH also develop T2D.

Aims: Regarding the relationship between type 2 diabetes and hereditary chromatists, we conducted a genetic analysis on two previously reported mutations C282Y and H63D related to the *HFE* gene in our population.

Methods: Altogether, 145 patients with type 2 diabetes and 145 healthy controls were examined. A Genotyping assay performed using electrophoresis of the DNA digestion products from MboI and RsaI for H63D and C282Y, respectively.

Results: Results showed a significant difference between case and controls regarding C282Y (P value=0) and H63D genotypes (P value=0.013). We also found a relationship between both mutations and nephropathy. Moreover, the difference between C282Y genotypes of patients with retinopathy and healthy controls were statistically significant (P value=0.020) while there was no association between H63D and retinopathy. In addition, observed differences of both mutations were significant when nephropathic patients compared to the controls. No relationship detected between blood parameters and typed mutations.

Summary and Conclusions: Our study showed a significant association between H63D and C282Y mutations and the risk of type 2 diabetes in Iranian population

PB1952

IMPACT OF GENOTYPE ON ENDOCRINAL COMPLICATIONS IN BETA THALASSEMIA MAJOR PATIENTS

T Hassan[1,*] A Al-Akhras[1], H Abdelrahman[1], M Mourad[2], M Zakaria[1]
[1]Pediatrics, [2]Clinical Pathology, Zagazig University, Zagazig, Egypt

Background: β-thalassaemias are a group of recessively inherited hemoglobin disorders characterized by reduced synthesis of β-globin chains. Some mutations cause a complete absence of β-globin chain synthesis termed β0 thalassemia, while others may allow some β-globin production and are termed β+ or β++thalassemia. The homozygous state results in severe anemia, which needs regular blood transfusion. The combination of transfusion and chelation therapy has dramatically extended the life expectancy of thalassemic patients who can now survive into their fourth and fifth decades of life .On the other hand, frequent blood transfusion in turn can lead to iron overload which may result in several endocrinal complications.
Aims: We aimed to investigate the impact of genotype on the development of endocrinal complications in β thalassemia major patients.
Methods: A cross sectional study was conducted on 100 thalassemia major patients (54 males, 46 females) aged over 10 years, who were registered in and followed up at pediatric hematology unit of Zagazig university hospital. Data abstraction form was designed to capture the appropriate information from the individual medical records including full clinical, laboratory, transfusion and chelation data. Genotype and hematologic phenotype of patients were also identified.
Results: The mean age of our patients was 14.2±1.37 years. Patients with β0β0 hematologic phenotype showed earlier age of start transfusion and chelation as well as more frequent transfusions compared to those with β0β+ and β+β+ hematologic phenotypes. Also, Patients with β0β0 hematologic phenotype had significantly higher prevalence of growth retardations, hypogonadism, hypothyroidism and hypoparathyrodism compared to those with β0β+ and β+β+ hematologic phenotypes ($p<0.001$, $p<0.001$, $p<0.001$, $p=0.037$ respectively). Patients with homozygous IVS-1 mutation had significantly higher prevalence of growth retardations, hypogonadism, hypothyroidism and hypoparathyrodism, while patients with homozygous IVS-1-110 mutation and homozygous IVS-1-6 mutation had significantly lower prevalence of growth retardations, hypogonadism ,hypothyroidism and hypoparathyrodism ($p=0,039$, $p=0.013$, $p=0.006$, $p=0.008$ respectively). Patients with homozygous IVS-11-745/VS-11-745 mutation had significantly higher prevalence of diabetes ($p=0.001$).
Summary and Conclusions: Endocrinal complications were common in β thalaasemia major patients with a clear association between hematological phenotype, genotype and clinical disease severity.A significant relationship was also observed between serum ferritin levels and the presence of endocrine complications, emphasizing the important role of iron overload in the development of these complications.

PB1953

IRON OVERLOAD IN ACUTE LEUKEMIA LONG SURVIVORS

R Sartori[1,*] E Scarpa[1], C Tassinari[1], P Radossi[1], N Maschio[1], L Candiotto[1], G Tagariello[1]
[1]Haematology, Castelfranco Veneto Hospital, Castelfranco Veneto, Italy

Background: Iron overload, primarily related to RBC transfusions, is a relatively common complication in patients receiving induction/consolidation chemotherapy for acute leukemia.
Aims: The rate and amount of tissue iron accumulation are the two most important factors that determine the risk of iron-related organ toxicity. Estimation of liver iron concentration (LIC) by liver biopsy or imaging is recommended after regular transfusion to determine the need for iron-chelation therapy. Although serum ferritin and transferrin saturation is not as reliable as LIC for estimating body iron stores, the risk of cardiac disease and early death is increased in patients with serum ferritin of more of 2500 ng/ml while clinically significant iron overload is uncommon in patients with serum ferritin level less than 1000 ng/dl.
Methods: In our institution we studied, approximately 2 years after the last transfusion, the iron status of 32 evaluable adult acute myeloid and lymphoid leukemia (AL) survivors who were treated between 2005 and 2009 with intensive chemotherapy and in 3 cases with first remission allogeneic bone marrow transplantation. 26 patients showed high ferritin levels.
Results: Their mean (+/-SD) age was 47 +/- 16 years (range, 35 - 67 years). The ratio men to woman was 1.45 (16 man and 11 woman).They received an average of 28 RBC units each (range, 18 - 45), the median serum ferritin level for all patients was 1870 ng/ml (normal range 30- 365 ng/ml) and transferrin saturation was 47% (normal range 15% - 45%).
Summary and Conclusions: We suggest that iron build-up is present also some years after chemiotherapy and transfusional treatment. Transferrin saturation values confirm the suspicion of iron overload, as for patients with hemochromatosis. During a median 33 months (range between 13 and 47 months) of follow-up no patients expressed cardiac diseases (documented with ECG), transaminases elevation or increased rate of infections. During this period of observation we are enable to suggest for patients an iron-depleting therapy with phlebotomy or iron chelators because remain a number of unanswered questions about the short and the long term fibrosis impact of iron overload in adult leukemia survivors. Furthermore is not clear if performing this kind of therapy during or after transfusion treatment. Our observation could be compared with collaborative multi-institutional long term studies to better understanding the contributions of iron overload on late effects of leukemia treatments.

EMPIRICAL ANTIBIOTIC THERAPY IN FEBRILE NEUTROPENIA OF ACUTE LEUKEMIA: EPIDEMIOLOGIC ORIENTED-STRATEGY IN A SINGLE DIVISION IN THE ERA OF MULTIDRUG RESISTANCE BACTERIA

L Marbello[1,*] A Nosari[1], V Mancini[1], M Mazzucchelli[1], M Zancanella[1], E Zucchetti[1], E Ravano[1], E Meli[1], E Roncoroni[1], C S Vismara[2], E Morra[1]
[1]Hematology, [2]Microbiology, A.O. Ospedale Niguarda, Milan, Italy

Background: In acute leukemia and high risk myelodisplastic syndrome treated with chemotherapy febrile neutropenia needs prompt treatment with antibiotic therapy. A delay in starting optimal empirical therapy can lead to septic shock and death in a few hours. An anti-pseudomonal beta-lactam combined with an aminoglycoside can be an adequate therapy. Recently a Cochrane review concerning a beta lactam-aminoglycoside combination *versus* beta lactam monotherapy in sepsis has been published. All-cause mortality rate was similar but risk of nephrotoxicity was more frequent in combination therapy. Guidelines for febrile neutropenia in high risk patients recommend monotherapy with anti-pseudomonal cephalosporins, piperacillin/tazobactam or carbapenem (ECIL 2011).
Aims: Aim of this study was to verify the applicability of published recommendations in our Division in presence of resistant bacteria.
Methods: Since June 2013 we have conducted an overseeing of carbapenemase-producing Klebsiella Pneumoniae species because of their emergence in our Hospital. All inpatients had a rectal swab searching for carbapenemase-producing Enterobacteriacee when they were admitted to the ward. Our empirical first-line therapy in febrile neutropenia was ceftazidime, in association with amikacin in presence of hemodynamic instability. We reviewed all febrile neutropenia episodes (absolute neutrophil count<500 x 10 9/L or expected to decreased<500 x 10 9/L during the next 48 hours) in 44 patients affected by acute leukemia or high risk myelodisplastic syndrome treated with aggressive chemotherapy in our Division from 1.1.2013 to 31.1.2014. All patients had prophylaxis with levofloxacin.
Results: There were 78 episodes of febrile neutropenia. Blood culture results were positive in 35 (45%) episodes. In 19 (54%) episodes sepsis was due to Gram-positive bacteria. In 16 (46%) episodes sepsis was due to Gram-negative bacteria. In 44% (7/16) of Gram-negative episodes, the isolated bacteria (4 Escherichia Coli, 3 Enterobacter Cloacae, 1 Klebsiella Pneumoniae) showed resistance to ceftazidime but sensitivity to amikacin.. All the isolated Gram-negative bacteria resistant to ceftazidime and sensitive to amikacin were sensitive to carbapenem. Only in 3/7 patients surveillance swab cultures confirmed the same bacterium as blood cultures (Escherichia Coli). One patient in monotherapy had a septic shock and died. In the surveillance of carbapenemase-producing Enterobacteriacee conducted in the Division we found 7 patients colonized by carbapenemasi-producing Klebsiella Pneumoniae but no bacteremia.
Summary and Conclusions: The increasing development of carbapenemase-producing Enterobacteriacee in our Hospital discourages the use of carbapenem as empirical first line therapy except in patients with surveillance cultures positive for ESBL. Choise of empirical antibiotic therapy for febrile neutropenia of leukemic patients should consider not only the epidemiologic data of the Division but also the epidemiologic data of the Hospital. In our epidemiological contest antibiotic monotherapy could be inadequate. Risk of nephrotoxicity due to the combination of a beta lactam with an aminoglycoside could be reduced by rapid de-escalation of aminoglycoside if possible.

PB1955

EPIDEMIOLOGY AND CLINICAL CHARACTERISTICS OF BACTEREMIA IN ACUTE MYELOID LEUKEMIA (AML): EXPERIENCE IN A TERTIARY REFERRAL CENTRE IN PORTUGAL

M Koehler[1,*] J Parreira[1], A Nunes[1]
[1]Hematologia, IPO Lisboa, Lisboa, Portugal

Background: Antibiotic (atb) resistance has become a major public health concern. Atb efficacy is vital for the management of AML patients (pts) because they are at high risk for infection. Local surveillance of atb resistance, atb consumption, and patient outcomes is essential for defining the best empirical approach for infection treatment and also to minimize the selection of resistant pathogens. Bloodstream cultures are a very useful model for surveillance of atb resistance and its clinical impact.
Aims: The incidence and pathogenesis of bacteremia episodes (BE) in AML pts were analyzed, as well as the atb resistance profile (ARP) of the pathogens. We also analyzed pts' characteristics, clinical outcomes and the end-point of BE.
Methods: We conducted a retrospective analysis of all BE in AML pts treated in our Institution between Jan 2011 and Dec 2013. Our pts are usually treated in an open medical ward (2-4 pts each), with filtered air.
Results: A total of 107 episodes of bacteremia occurred in 65 patients. Seventy one percent (n=76) of the pathogens responsible for BE in our institution were gram negative (GN), 26% (n=28) gram positive (GP) and only 3% (n=3) were fungal. We observed a high fluoroquinolone (FQ) resistance among our isolates (52%), even in pts without FQ prophylaxis, which was done in 20% of our pts. Additionally, an important 3rd generation cephalosporins resistance among GN (27%) was noted, as well as the prevalence of ESBL producers (21%). Piperacillin-tazobactam (Pip-taz) resistance was 24% (n=18) among the GN, but there were much lower rates of Amikacin resistance: 8% (n=6). Concerning GP, 32% (n=11) were *Enterococcus* species, with the rest being mostly *non-aureus Staphylococcus.* We documented only 2 BE associated with methicillin-sensitive *S. aureus*. Four out of eleven of the *Enterococcus* species were VRE. The frequency of multidrug resistant organisms (MDRO) was 29% (n=32), but in 66% of the cases this occurred in the setting of prior very recent broad-spectrum atb, with only 5 of this 32 isolates not having prior atb. Surprisingly, the majority of BE (48.6%) were recorded after post-remission therapy, 25.2% in the context of relapsed/refractory (R/R) hematologic disease and only 15.8% after induction therapy, indicating that, for this type of infection in AML pts, an important contributor factor might be a cumulative risk associated with the typical nosocomial infections. Sixty percent of BE were associated with indwelling venous devices, and 81.3% have occurred in the context of severe neutropenia. Almost 35% progressed to sepsis or septic shock. The overall mortality rate was 15,3%, with 8 out of 9 pts dying in the setting of R/R disease. There was a cumulative incidence of 13 BE per thousand days of hospitalization, with 15% of admissions for AML registering BE. The average length of stay (ALS) in AML pts with BE was 25,29 days, significantly higher than the overall ALS in AML pts - 14,01 days ($p<0.001$). It is also interesting to note a remarkable decrease in the ALS in AML pts with BE between 2011 and 2013 (32,46 days in 2011, 24,24 in 2012 and 20,67 in 2013), which may reflect an improvement in our care.
Summary and Conclusions: BE due to GN organisms are the dominant type of bacteremia in our AML pts, with an increasing epidemiological burden of severe infections by MDRO. It is crucial for the management of such infections, not only the choice of prophylaxis – whereas our resistance pattern to FQ makes us question its value – but also the initial atb therapy. Among our ARP, Pip-taz resistance is of major importance since this is our first line atb for neutropenic fever. Despite this, the low resistance to amikacin is reassuring because we use it in association with Pip-taz when there are signs of clinical severity.

PB1956

EPIDEMIOLOGY AND ANALYSIS OF ANTIFUNGAL PRESCRIPTIONS IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES: A SINGLECENTER REAL LIFE EXPERIENCE

HD Kiper Unal[1,*] N Soyer[1], F Vural[1], F Sahin[1], M Tobu[1], A Donmez[1], M Tombuloglu[1], B Arda[2], G Saydam[1]
[1]hematology, [2]infectious diseases, ege university medical faculty, izmir, Turkey

Background: Invasive fungal infection (IFI) causes morbidity and mortality among patients with hematological malignancies who receive cytotoxic chemotherapy or hematopoietic stem cell transplantation (HSCT).
Aims: Invasive fungal infections generally constitute a major clinical and therapeutic challenge associated with high morbidity and mortality rates in the course of cytotoxic treatment of hematological malignancies. In this retrospective study we aimed to check out our IFI rates and antifungal treatment modalities.
Methods: We retrospectively evaluated the diagnoses, antifungal prescriptions, and incidence and treatment outcomes of proven andprobable IFI in our center between October 2012 and December 2013 following the recent European Organization for Research andTreatment of Cancer/Mycosis Study Group (EORTC/MSG) consensus criteria.
Results: We evaluated 511 patients with hematological malignancies. Systemic antifungal agents were used 126 (24.6%) of 511 patients. Seventy five (59.5%) of the 126 patients received prophylaxis. IFIs were diagnosed in 37 (29.3%) patients (9 proven, 28 probable) of all, including 9 patients who underwent HSCT. Thirty nine patients had received mold-active prophylaxis, consisting in 35 with posaconazole and 4 with voriconazole. Thirty six patients received no mold-active prophylaxis with fluconazole. Liposomal amphotericin B (n=69) was the most common single-agent therapies. In 56 (44.4%) of all patients, first antifungal agent was changed another (Table 1). Seven (18.9%) of 37 patients with proven (3 patients) and probable (4 patients) IFI were died in one month. 28 patients of all were diagnosed with probable pulmonary IFI as determined by computed tomography scan and positive galactomannan assay. Serum galactomannan antigen was detected in 40 (31.7%) patients of all; 9 (7.1%) had positive cultures (5 Aspergillus sp, 2 Candida sp and 2 Mucor sp), and 55 (43.6%), abnormal computed tomography scans. One patient who received posaconazole prophylaxis was diagnosed proven IFI and 7 patients were diagnosed probable IFI. Also 2 patients received fluconazole prophylaxis were diagnosed proven IFI and 7 patients were diagnosed probable IFI. Four

patients who received voriconazole prophylaxis were diagnosed probable IFI (2) and possible IFI (2).

Table 1. First and second line antifungal agents and reasons for change.

Summary and Conclusions: First of all, results indicated that our probable and proven IFI incidences are significantly higher than literature (29.3% *vs* 2-8%) although one- month mortality still remains similar (18.9% *vs* 13%). This crucial inference prompted us to determine the underlying potentials of actual engrossing consequence. Mainly it may be related with diagnostic explication differences and local clinical conditions. Retrospectively we noticed that High-Resolution Computed Tomography (HRCT) findings were usually non-specific however prepossession of radiologist might lead to interpret the diagnosis on the side of IFI. Furthermore with a slight probability, our galactomannan assays occasionally might be conflicting due to technical problems or patient-related conditions like wide-spread use of penicillin-based antibiotherapy. High incidence of proven IFI may be related to managing diagnostic invasive procedures properly and successful mycological culture practice. Environmental and host-related factors may also be effective. Clinical awareness, competent assessment of risk factors, appropriate prophylactic implementation, determining right antifungal choice, time of treatment initiation and length of therapy are the critical steps in the administration of this clinical process. Improved strategies are required to reduce the frequency of IFI and to increase the proven IFI.

PB1957

LOW RELIABILITY OF GALACTOMANNAN ANTIGEN ASSAYS IN ROUTINE CLINICAL CARE – CLINICAL TRIAL RESULTS ARE NOT EASILY REPRODUCED

M Pereira[1,*] G Marques[2], N Silva[2], R Tenreiro[1], E Cortesão[1], A Espadana[1], C Geraldes[1], L Ribeiro[1], G Ribeiro[2]
[1]Clinical Hematology Department, [2]Clinical Pathology Department, Coimbra University Hospital Centre, Coimbra, Portugal

Background: The diagnosis of invasive fungal infections (IFI) in neutropenic and non-neutropenic hematologic patients remains a challenge, with many patients treated empirically within the context of suspected, probable or presumptive diagnoses. For IFI by Aspergillus spp., the serum galactomannan antigen assay (GalAg) – detecting a cell wall molecule - has been proposed as a biomarker to orient preemptive antifungal therapy, with favorable results in clinical trials, more so when used in conjunction with other diagnostic tests. Nevertheless, its efficacy in everyday clinical practice differs markedly across centers and its routine use is debated, with starchy foods and Penicillum-derived antibiotics inducing false-positive results.
Aims: We aim to evaluate the results of GalAg testing outside clinical trials, in routine clinical practice, to clarify its utility and reliability, and thus its ability to orient antifungal use.
Methods: We reviewed all GalAg detections performed on hematology patients in our center between 1-1-2012 (when the test was started in our Lab) and 31-12-2013. According to our local practice, culture was considered the gold standard for the diagnosis of IFI – cultures were considered relevant for the interpretation of GalAg results if performed up to four days before or after GalAg testing; GalAg results without a relevant culture within the time-frame thus defined were excluded. According to the manufacturer's specifications, positive tests were subjected to confirmatory testing.
Results: We obtained 953 GalAg determinations with relevant cultures over the two-year study period; in 4.8% of these cases, a positive culture for fungus was observed. Considering Negative GalAg results, cultures were positive for fungi in 3.6% of cases. Considering Positive GalAg results, 56.2% of cultures were negative, 22.9% were negative for fungi but positive for bacteria, and 22.9% were positive for fungi, although all were positive for Candida spp. and none for Aspergillus spp. Although three cases observed during the time-frame were positive for Aspergillus spp. (niger and flavus), all three were negative for GalAg; two (A. flavus) were being treated with antifungals, while the third (A. niger) was not; no other cause for false-negativity could be identified in the latter. Considering bacteria-positive GalAg-positive results, only 22% of patients were being treated with antibiotics known to originate false-positive results in GalAg determinations; in the remaining 78% of patients, no known causes for false-positivity were identified (although the patients' diet could not be thoroughly reviewed).
Summary and Conclusions: In our series of non-selected, retrospective patients treated outside clinical trials, results obtained with GalAg assays were markedly inferior to the published results that led to its approval. We found that GalAg was unable to detect any of our confirmed Aspergillus infections. While in 2/3 cases, a source of false-negative results was suspected (treatment with antifungals), in 1/3 cases no cause was identified. Over half of GalAg-positive cases had negative cultures; on the other hand, while almost a quarter of GalAg positive-cases tested positive for fungi, all corresponded to Candida spp., which should not cross-react with the GalAg assay. A quarter of cases were positive for bacteria, but a cause for false-positivity could only be identified in a quarter of those. We suggest that GalAg testing remains an unreliable tool, with low reproducibility, associating with very disparate results across centers. Local dietary traditions (in particular the use of starchy foods) could account for the wide variation in false-positive rates and, therefore, the decision to use GalAg testing to orient empirical-vs-preemptive antifungal treatment should be established locally. It remains an ancillary test, unable to replace established diagnostic tests.

PB1958

OUTPATIENT EXPERIENCE WITH BIOSIMILAR FILGRASTIM IN PATIENTS WITH LYMPHOID NEOPLASMS: LESSONS FROM ROUTINARY USE

A Broccoli[1,*] V Stefoni[1], C Pellegrini[1], E Derenzini[1], L Gandolfi[1], F Quirini[1], B Casadei[1], R Maglie[1], L Argnani[1], PL Zinzani[1]
[1]Hematology, Institute of Hematology "L e A Seràgnoli" - University of Bologna, Bologna, Italy

Background: Filgrastim derived biosimilars are now extensively used in routine clinical practice and together with their originators they are recommended for the prophylaxis of febrile neutropenia (FN) in cancer patients undergoing chemotherapy.
Aims: A monocentric observational study to investigate the efficacy and safety of biosimilar filgrastim in patients with lymphoid neoplasms at various stages of their disease treated with different non-myeloablative chemotherapy regimens on an outpatient basis.
Methods: Data from 141 patients affected by chronic lymphoproliferative disorders and treated with a non-myeloablative chemotherapy regimen from January 2012 to December 2013 were obtained from our institutional database. Median age was 56 (range: 15-86) years. Diffuse large B-cell lymphoma (47 patients), Hodgkin's disease (29 patients) and follicular lymphoma (16 patients) were the prevalent subtypes; among the remaining, there were 12 indolent non-follicular lymphomas, 11 mantle-cell lymphomas, 7 T-cell lymphomas and 2 Burkitt's lymphomas; 9 patients had hairy cell leukemia, 7 chronic lymphocytic leukemia, and 1 had Langerhans' cell histiocytosis. A total of 148 chemotherapy lines were administered (7 patients received two lines): 123 were delivered first-line. The most represented chemotherapies were: CHOP/COMP (38 cases), ABVD (25), fludarabine-containing regimens (22), third-generation CHOP-like regimens (MACOP-B/VNCOP-B, 20), cladribine (8) and ifosfamide-containing regimens (IEV, 14). Other regimens were: bendamustine, ibritumomab, lenalidomide, high-dose cyclophosphamide or cytarabine. Filgrastim biosimilar was applied to prevent or treat FN in accordance with the European Society of Medical Oncology guidelines.
Results: Overall, 1,806 vials were used, at an average of 12.9 vials per patient. The number of vials/patient for each regimen is detailed in the Table 1. Biosimilar filgrastim was used for the prophylaxis of FN in 143 cases; in 5 cases (3.4%) it was used for the therapy of FN. All chemotherapy-induced cytopenias were managed on an outpatient basis; hospitalization rate was 5.4%, due to intensive treatment for FN. No treatment was interrupted because of persistent neutropenia or unrecovered myelotoxicity. Neutropenia was always transient and FN easily manageable with biosimilar filgrastim and intravenous antibiotics. No septic shock nor infection-related deaths were documented. Adverse events were infrequent and mainly consisting of bone pain (4%), fever (1.3%) and tachycardia (0.7%). Drug administration was interrupted in only 1 case due to an adverse event.

Table 1.

Regimen	Patients treated	Vials used	Vials/patient (range)
CHOP/COMP	38	436	11.5(3-18)
ABVD	25	442	17.7 (3-40)
Fludarabine-Mitoxantrone	15	184	12.3 (3-18)
VNCOP-B	14	160	11.4 (2-21)
IEV	14	83	5.9 (4-10)
Cladribine	8	150	18.8 (8-42)
Fludarabine-Cyclophosphamide	7	52	7.4 (3-13)
MACOP-B	6	54	9.0 (2-20)

Summary and Conclusions: Biosimilar filgrastim is easy and safe to use on an outpatient basis, with no clinically relevant adverse events reported and without any significant difference from its originator. It shows efficacy in both the prevention of FN among several chemotherapy regimens and its treatment.

PB1959

FIRST EXPERIENCE WITH THE THERAKOSTM CELLEX® PHOTOPHERESIS SYSTEM

B Árpád[1], E Toth[2], ,*J Baan[2], J Somogyi[2], B Bognar[2], A Fodor[2], A Barta[1], P Remenyi[1], M Reti[2], T Masszi[2]
[1]BMT Unit, [2]ESZSZK, Budapest, Hungary

Background: At our department, the TherakosTM Cellex® photopheresis system (CLX) has partially replaced the Therakos Uvar XTS (XTS) system for extracorporeal photochemotherapy (ECP) since 25 September, 2013. The Cellex technology incorporates several innovative developments, providing higher level of safety and patient-focused care for the patients (pts).
Aims: We present our first 4 months experience with TherakosTM Cellex® photopheresis system and the opinion of our pts.
Methods: 103 ECP treatments in 25 pts were performed by CLX during the first 4 months period. Data of these CLX treatments were compared with data of 150 XTS procedures performed in the same 25 pts.Patient's characteristics: there were 18 males and 7 females. The median age was 41 years (range:20-67) and the median weight was 66 kg (range:36-100). Indication of ECP was graft *versus* host disease:18 pts, cutan T cell lymphoma:4 pts and graft rejection after solid organ transplantation:3 pts (lung:2, heart:1). Procedures characteristics: selection of technique for pts was random, however, there was a slight tendency to use CLX for pts being in poorer condition and having worse venous access. CLX group: the apheresis volume was fixed at 1500 ml as determined by the system. One arm procedure was used in 26% of cases. Peripheral veins were used in 94% of procedures. XTS group: XT125 bowl was used for all cases. Six treatment cycles were performed for pts with body weight > 50 kg and 5 treatment cycles for patients with body weight<50 kg. Peripheral veins were used as venous access in 95% of procedures. One of our nurses conducted a telephone survey of pts. Two questions were asked: 1: Did they experience any difference between CLX and XTS? 2: Which machine would be preferable for them?
Results: Set up and priming are much faster in CLX than XTS giving more time to nurses to care the patient. Buffy coat: volume was significantly less in CLX than XTS (median 163 ml *vs.* 263 ml, p=1,17E-72) needing significantly less Uvadex (median 2,8 ml *vs.* 4,5 ml, p=2,4E-74) for CLX treatments. Photoactivation time: was significantly shorter in CLX than XTS (median 21 min, *vs.* 27 min, p=2E-07), which provides sparing of UVA lamp hours. Procedure time: was significantly less in CLX than XTS (median 95 min, *vs.* 166 min, p=8E-29). This was also shorter in one arm procedures (median:151 min *vs.* 166 min, p=0,2), however this was not statistically different. Platelet loss: post-apheresis decrease of platelet count was significantly less in CLX than XTS (median:-12%, *vs.*-20%, p=2,5E-07). Success of treatments: All CLX treatments were finished successfuly. There were 2 early treatment abortions due to venous access problem in XTS group. Side effects: The venous access issue was the most frequent problem. CLX was less sensitive for this. One female pt had mild vasovagal reactions in 2 CLXs and 1 XTS treatments. There were no other clinically relevant side effects in either group. Patients' survey: 21/25 pts were interwieved successfuly. 18/21 pts market CLX to be preferable, all of them indicated the higher speed to be the major advantage. 2/21 pts responded that there is no difference and there was only 1 pt who liked more the old XTS. 4/25 pts did not participate in the survey 2 of them due to death.
Summary and Conclusions: Our data prove that the innovation of TherakosTM Cellex® system was very successful providing faster and safer machine for ECP. Our opinion well coincided with the pts' very positive attitude.

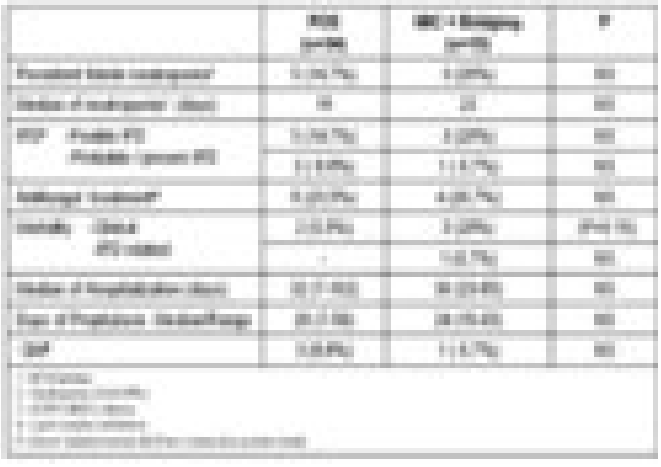
PB1960

EFECTIVENESS OF ANTIFUNGAL PROPHYLAXIS WITH NEW AGENTS COMBINED WITH A DIAGNOSTIC-DRIVEN ANTIFUNGAL THERAPY STRATEGY IN HIGH-RISK NEUTROPENIC PATIENTS. A SINGLE-CENTER PROSPECTIVE STUDY

S Marcellini Antonio[1],* J García Suárez[1], JJ Gil Fernández[1], I Arribas[2], I Gutiérrez[1], LM Juárez[1], C Casco[1], MJ Cortti[1], M López[1], M Callejas[1], T Pascual[1], Y Martín[1], E Magro[1], M A Calero[1], F Perera[1], E Flores[1], C Burgaleta[1]
[1]Haematology, [2]Príncipe de Asturias University Hospital,, Madrid, Spain

Background: Invasive fungal diseases (IFDs) are a leading cause of morbi-mortality in haematological patients undergoing intensive chemotherapy. Previous studies have shown that primary antifungal prophylaxis (PAP) with new agents reduces the incidence of proven/probable IFD to less than 3%. Despite this efficacy, 30-60% of these patients receive a subsequent empirical antifungal therapy (EAT), a strategy associated with unnecessary costs.
Aims: To compare the efficacy of PAP with posaconazole (POS) and micafungin (MIC) in a real-life setting of high-risk neutropenic patients.
Methods: Between January 2012-January 2014, all patients receiving intensive chemotherapy and a mold-active PAP for at least 7days were included in the study patients were hospitalized in rooms with HEPA filtration and positive pressure. Our PAP policy was as follows: oral POS (200mg/tid) was our standard PAP, but it was replaced by iv MIC (50mg/day) in patients with ALL receiving vincristine and MIC was also used as bridging in patients with severe mucositis and/or significantly elevated liver function tests (POS-MIC). A surveillance-driven strategy was applied (galactomannan twice-weekly all the period of neutropenia). High-resolution CT scans were performed when an IFD was clinically suspected. Antifungal therapy (liposomal amphotericin B) was administered only when a diagnosis of IFD was made according to 2008 EORTC/MSG definitions. EAT was reserved to patients with persisting febrile neutropenia, a negative intensive diagnostic work-up and worsening clinical condition. Endpoints were incidence of IFD, EAT, persistent febrile neutropenia, as well as IFD-free and overall survival.
Results: 49 episodes were included; median age of 54 years (range 32-83); disease distribution was as follows: 30 AML induction, 12 AML consolidation/Intensification, 4 ALL induction and 2 Burkitt's L. and 1 AA; 34 of 49 (69%) received POS for a median time of 26 days and 15 of 49 (31%) received MIC (9 MIC and 6 POS-MIC for a median time of 24 days). The main Patient's clinical characteristics and outcomes are summarized in Table 1. No significant differences were observed in the incidence of proven/probable IFD (POS 8.8% *vs* MIC 6.7%), possible IFD (POS 14.7% *vs* MIC 20%), antifungal therapy (POS 23.5% *vs* MIC 26.7%) and IFD-associated mortality. No patient received EAT as a result of our diagnostic-driven antifungal therapy strategy. There was no grade III/IV CTCAE toxicity related to PAP.

Table 1. Treatment success by type of prophylaxis.



Summary and Conclusions: Both prophylactic regimens are feasible, safe and effective. The use of an overall strategy combining both an intensive diagnostic approach (to reduce the underdiagnosis of IFD) and a diagnostic-driven antifungal therapy may reduce the requirement for EAT, and saving additional costs.

Background: Several studies have demonstrated that a prompt addition of a systemic antifungal therapy in AML (Acute Myeloid Leukemia) patients suffering Invasive Fungal Disease (IFD) improves clinical outcome, anyway there are not clear tests able to distinguish patients that will benefit an empiric antifungal treatment and patients that will not.
Aims: We investigated the possible diagnostic role of pan-fungal DNA PCR for the early detection of IFD in patients receiving antifungal prophylaxis.
Methods: 28 patients with AML have been analyzed: 15 patients underwent a prophylaxis with posaconazole 200 mg tid per os and 13 patients a prophylaxis with amphotericin-B 10 mg bid per aerosols and Nystatin 600,000 IU orally tid.

The serological monitoring was performed twice a week through the beta-D-glucan (BG) (Fungitell) and the antigen galactomannan (GM) (Platelia ™ Aspergillus EIA) detection. Chest CT was performed in presence of fever lasting more than 72 hours. Invasive Fungal Disease (IFD) was diagnosed according to the EORTC criteria. The empirical antibiotic and antifungal therapy were administered according to ISDA guidelines. The fungal DNA was evaluated on whole blood after lysis of the white blood cells according to[1] two times a week and was interpreted as positive if revealed in two consecutive detections. The qualitative data were analyzed using the chi-square test.

Results: Eight patients (32% of the total) had fever unresponsive to antibiotic therapy, 4 of which had positive fungal DNA. 5 patients received antifungal prophylaxis with posaconazole, 1 of these responded to antifungal treatment (voriconazole) and had a positive fungal DNA. 3 patients received prophylaxis with amphotericin-B per aerosols and Nystatin, two of which were sensitive to antifungal treatment (1 treated with voriconazole and caspofungin in combination and the other with liposomal amphotericin-B), both with positive fungal DNA , 1 patient with high-risk AML resistant to induction therapy with positive BG and fungal DNA did not respond to the combination of caspofungin and liposomal amphotericin –B. Except for the latter patient, no other patients refractory to antifungal therapy had positive fungal DNA. No differences emerged with regard to the rate of fever resistant to antibiotics between the 2 groups (p=0.68). Overall, fungal DNA positivity conferred a greater likelihood of responding to the antifungal therapy compared to negative (p=0.03) (Table 1).

Table.1

Data analyzed	Response to antifungal	No response to antifungal	Total
DNA pos	3	1	4
DNA neg	0	4	4
Total	3	5	8

Chi-square test: p=0,03

Summary and Conclusions: The performance of DNA-PCR assay will be of great help in the early detection of patients with antibiotic resistant fever with a great probability to respond to antifungal empiric therapy.

MONITORING THE INTRODUCTION OF MICAFUNGIN IN THE DEPARTMENT OF HAEMATO-ONCOLOGY AT BARTS HEALTH NHS TRUST

F Nannini[1,*] N Desai[1], S Guler[1], S G Agrawal[1,2]
[1]Pathology Group, Blizard Institute, Queen Mary University of London, [2]Haemato-oncology, Barts Health NHS Trust, London, United Kingdom

Background: In acute lymphoblastic leukaemia (ALL), azoles are contraindicated for prophylaxis of invasive fungal disease (IFD) because of the vinca-alkaloids in ALL regimens. We changed our guidelines to include Micafungin as a prophylactic alternative to AmBisome in first induction therapy of ALL.

Aims: This audit aims at monitoring the introduction of Micafungin, including adherence to the guidelines and its use for other indications.

Methods: Data was collected from Jan to Dec 2013. The selection criteria included patients with ALL and patients receiving Micafungin in the Haemato-Oncology Unit. 40 patients were identified; some with multiple admissions (*i.e.* separate episodes of IFD risk, such as cyclical intensive chemotherapy). We evaluated prophylactic drug use and, for each episode of treatment of suspected IFD, chest CT or Galactomannan (GM) results.

Results: 48 episodes from 40 patients were included. Mean age was 45 yrs, range: 21-67; 18 were female and 22 were males. The primary diagnosis was ALL (n=24, 60%), AML (7, 18%) and other (9, 22%: 2 HD, 3 lymphoma, 1 CLL, 1 CML, 1 MDS and 1 myeloma). In 10 episodes of ALL induction therapy, the antifungal prophylaxis was: Micafungin (n=1) AmBisome (2), Fluconazole (6) and no prophylaxis (1). No patient had their prophylaxis changed. In the other 38 episodes, prophylaxis was: Fluconazole (23) Micafungin (3), AmBisome (2), Posaconazole (2) and no prophylaxis (8). Suspected IFD was treated in 19 episodes: Micafungin (n=8), Ambisome (10) and Caspofungin (1). In 3 cases, AmBisome was changed to Micafungin (1 - due to liver abnormaities, 2 – not stated); and 1 from Caspofungin to Micafungin, as per guidelines. Fungal diagnostics: in 4/19 (21%) episodes of treatment, no CT/GM testing was performed. In the remaining 15, 4 patients started treatment prior to CT/GM testing. Overall, in 15/19 cases, the clinical suspicion of IFD was not supported by CT, GM or cultures. In 22/48 (46%) episodes, no antifungal treatment was given, of these, 11 cases a CT chest/GM test were performed with no evidence of IFD. 8 patients (20%) died, 5 in ICU. 6/8 had CT chest/GM testing - with only one positive CT scan for IFD. Despite the lack of evidence, 7/8 patients were treated for suspected IFD: Micafungin (n=6), AmBisome (1). There was missing/incomplete drug information in 7 episodes of the total 48 (15%).

Summary and Conclusions: There was a lack of adherence to the guidelines for ALL IFD prophylaxis in 1st induction therapy. 90% of Micafungin use was outside of the guideline indication, which can be explained by removal of Caspofungin from the formulary to avoid having two echinocandins in our Unit. Fungal investigations were largely performed appropriately, with only 4 antifungal treatments starting before CT/GM testing. However, in 15/19 episodes of treatment, there was no CT/GM evidence of an IFD. Following re-training of the clinical teams on the antifungal guidelines, better adherence for ALL prophylaxis is expected and this is being re-audited. Nevertheless, the data shows that the clinical decision to treat for suspected IFD often occurs with negative CT/GM results. Perhaps a way forward to implement a diagnostic-driven approach is to have a small, dedicated team responsible for all fungal management, *i.e.*, the concept of antifungal stewardship.

Maria della Misericordia, Perugia, [10]Clinica Pediatrica, Università degli Studi "A. Moro", Bari, [11]Clinica Pediatrica, Università degli Studi di Udine, Udine, [12]Unità di Cardiologia Pediatrica, Seconda Università di Napoli- Ospedale Monaldi, [13]UOSD Microcitemia, AORN "A. Cardarelli", Naples, Italy

Background: Asplenia is a condition due to spleen absence or dysfunction, which leads to high risk of infections and thrombotic events with significant chance of mortality and morbidity. A number of national and international recommended interventions in asplenic or hyposplenic patients has been published but adherence to recommendations was shown to be poor in several studies. The cost to the health system of asplenia- related complications can be significant, and systematic approaches to prevention were demonstrated to be cost-effective. In Europe very little experience exists in comprehensive national program for management of asplenia. Particularly, in Italy no common policy of patient care has yet been developed, and management of asplenia is mainly case or locally directed.

Aims: Our aim was to investigate the feasibility of a systematic national integrated program for the management of asplenia in Italy and to create a national working group focused on asplenic patients.

Methods: Centers of the Italian Association of Pediatric Hematology Oncology (AIEOP) and the Italian Society of Thalassemia and Hemoglobinopathies (SITE) were invited to participate in the Italian Network on Asplenia. The coordinating centre sent a registration form to all doctors who formally agreed to the proposal.

Results: Twenty-seven pediatric care centers and two adult care centers formally agreed to the project during a recruitment period of six months. During the following four-month period, twelve centers sent back the completed forms containing data about reason and duration of asplenia, type of surgery and post-surgery complications for splenectomized patients, long term infectious and thrombotic complications, antibiotic and vaccine prophylaxis and causes of death. At the last update, the database included data from 318 patients. Meetings of involved parties were held to discuss key points in the management of asplenic patients and to develop a consensus on recommendations for patient care.

Summary and Conclusions: This is the first systematic approach to the management of asplenia in Italy and the most recent study in Europe, as previous reports are long-standing. This preliminary analysis shows that a comprehensive national project is feasible in Italy. Recruiting patients through representatives of national scientific societies is an effective way to involve the main national centers where the majority of asplenic patients are followed up. A call for participation in the Italian Network on Asplenia will be addressed to other national scientific societies involved in the asplenic patient care, such as the Italian Society of Hematology, Oncology, Surgery, Cardiology, Pediatric Cardiology, ect. The disparity of participation between pediatric and adult care centers suggests a deeper awareness of risks due to asplenia among

pediatricians and the need for more active involvement of doctors treating asplenic adults. Till now the main concern for asplenic patients has been the high risk of overwhelming infections, but there is a growing body of knowledge on thrombotic risk in asplenic patients. The novelty of this project consists in collecting data regarding this issue, which has been neglected so far. Finally, this project has the potential for implementing research and public health purposes in this target population at a national level.

BACTEREMIA AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION – RESULTS OF A 13 YEARS SINGLE CENTRE STUDY

AM Balan[1,2,*]A Oprisoni[1,2], C Jinca[1,2], A Isac[2], A Pascalau[2], L Balint-Gib[2], O Ciocarlie[1,2], M Serban[2], S Arghirescu[1,2]
[1]Paediatrics, Victor Babes University of Medicine and Pharmacy , [2]Bone Marrow Transplantation, Louis Turcanu Emergency Hospital for Children, Timisoara, Romania

Background: Successful management of bacterial infections after hematopoietic stem cell transplantation (HSCT) is mandatory for improving outcome of transplant recipients. One of the most frequent bacterial pathogens' isolation site in neutropenic HSCT patients is bloodstream, therefore the spectrum of microbial strains isolated, as well as their antibiotic susceptibility has major implications on both prophylactic and empirical antibiotherapy choices.
Aims: To evaluate the incidence, outcome and pattern of bacteremias after HSCT with emphasis on the identified pathogens and their *in vitro* susceptibility to antibiotic agents.
Methods: In a 13 years retrospective study we have included 287 consecutive patients, both children (n=83) and adults (n=204) admitted between 2001-2013 for HSCT (autologous-232, allogeneic-55). Anti-infective prophylactic measures included: nursing in laminar air-flow or HEPA-filtered sterile rooms, sterile diet, gut decontamination with quinolones and weekly immunoglobulin substitution. In addition, all the patients received a short course of amoxicillin/clavulanic acid and metronidazole. Bloodstream cultures were drawn from a central venous line in all patients with febrile neutropenia before initiation of empirical antibiotic therapy. Susceptibility and resistance of isolated microbial strains were evaluated using either disk-diffusion method or an automated blood culture system.
Results: Cumulative incidence of bacteremia was 14% (auto-13%, allo-20%), overall being registered 55 episodes of bacteremia (auto-38, allo-17) in 41 patients (auto-30, allo-11). The median time from the day of stem cell graft infusion to the day of bacteremia was 126 days (1-2610 days), with more than 90% of episodes occurring in the first 100 days after HSCT. In both autologous and allogeneic transplant setting, gram-negative pathogens were more frequently isolated than gram-positive ones (73% *vs.* 27%). Gram-negative strains included: *Escherichia coli* (auto-39%, allo-47%), *Pseudomonas aeruginosa* (auto-11%, allo-12%), *Klebsiella pneumoniae* (auto-16%, allo-0%, p=0,04) and *Enterobacter spp*. (auto-11%, allo-6%). Coagulase-negative staphylococci represented 73% from the gram-positive bacteria, followed by *Staphylococcus aureus* (13%). Over 80% of identified gram-negative strains were resistant to quinolones, while 33% of *Klebsiella pneumoniae* and 17% of *Escherichia coli* produced extended-spectrum beta-lactamases. Methicillin-resistance was found in 70% of *Staphylococcus spp* isolates. Multi-drug resistant gram-negative strains represented 30% of the gram-negative isolated rods; all the gram-negative pathogens retained their susceptibility to colistin. Crude mortality in patients with bacteremia after HSCT was 51% (auto-40%, allo-82%, p<0,01) with a mortality attributable to bacteremia of 22% (auto-23%, allo-18%), related only to gram-negative pathogens: *Pseudomonas aeruginosa*-44%, *Escherichia coli*-33%, *Klebsiella pneumoniae*-11%, *Enterobacter spp*.-11%.
Summary and Conclusions: Although, recent published studies describe a shift to predominance of gram-positive strains responsible for severe infections after HSCT, in our study, both the incidence and direct mortality of pathogens isolated in blood cultures of HSCT recipients were dominated by gram-negative life-threatening multi-drug resistant gram-negative rods.

PB1965

DEVELOPMENT OF EARLY INFECTIONS DURING AZACITIDINE THERAPY FOR HIGH-RISK MYELODYSPLASTIC SYNDROMES.

V Dueñas[1], D Rodriguez[1], E Pardavila[1], M Arguello[1], S Rodriguez[1], N Lorenzana[1], E Luño[1], T Bernal[1,*]
[1]Hematology, Hospital Universitario Central de Asturias, Oviedo, Spain

Background: The incidence and risk factors for infection during azacitidine treatment are only partially known. Specifically, risk factors for infection during the first cycles of treatment, when haematological improvement has not been achieved yet, and the impact of comorbidities have not been addressed.
Aims: To analyse factors associated to early infection in a cohort of myelodysplastic syndromes (MDS) patients treated with azacitidine as front-line treatment.
Methods: Patients with a diagnosis of high-risk MDS and those with an intermediate-low risk IPSS and absolute platelet count (plt) <30 x10^9/L or absolute neutrophil count (ANC)<0.5 x10^9/L receiving azacitidine as front-line treatment were studied. Only the first 4 courses of azacitidine treatment were analysed for the purpose of the study. Univariate comparisons between cycles with and without infection were done using a Chi-square or a T-test as appropriate. A propensity score to match patients according to their probability of receiving prophylaxis was calculated. Variables with a significant difference were included in a logistic regression model, and odds ratios (OR) with their 95% confidence interval were computed.
Results: From 15th September 2007 to 1th December 2013, fifty patients received azacitidine and 188 episodes of treatment were recorded. Median age at the beginning of treatment was 69 years (range 25-88). According to IPSS score, 75% of patients were classified as high risk and 25% as intermediate risk. Sorror comorbidity score was low in 36%, intermediate in 26% and high in 38% of the patients. Azacitidine was administered during 7 consecutive days in 78% of the patients, 18% received a 5-0-2 scheme and 4% received 5 days of treatment for each cycle. Regarding prophylaxis, no antimicrobial agent was administered in 55% of the cycles; a single antimicrobial agent (either antibacterial or antifungal) was administered in 14% and a combined antibacterial plus antimicrobial regimen in 31% of the cycles. There were significant differences in age, blast number and ANC among patients receiving prophylaxis or not. ANC, platelets and haemoglobin (hb) at the beginning of each cycle were 0.8 x10^9/L (range 0.05-11.14), 95 x10^9/L (range 11-885) and 94 g/L (range 55-142). During the first 4 cycles, 30 infectious episodes occurred and 8% of the patients died as a result of infection. Seventy percent of the infectious episodes occurred in the first 2 cycles of azacitidine. In univariate analysis, a high comorbidity index, alternative schemes of administration of azacitidine other than 7 consecutive days and the number of packed red blood cells and platelets concentrates transfused were associated with infection. A multivariate analysis was done including those variables with significant differences in the univariate analysis and the computed propensity score. Predicitive factors for infection in this model were: a high comorbidity score {p=0.008, OR 2.41 (CI 1.28-4.84)} and ANC below 0.5 x10^9/L {p= 0.056, OR 5.13, (CI 0.91-27.89)}. Combined antifungal and antibacterial prophylaxis showed a trend towards a decreased risk of infection {p= 0.06, OR 0.07 (0.003-1.24)}.
Summary and Conclusions: Comorbidity index is the most important factor in predicting infection during azacitidine treatment for high-risk MDS. The impact of neutropenia and antimicrobial prophylaxis must be studied in larger population.

PB1966

COMPREHENSIVE PULMONARY REHABILITATION IN PATIENTS WITH PULMONARY CHRONIC GRAFT VERSUS HOST DISEASE

I Song[1,*] SJ Jee[2], HW Ryu[1], YS Choi[1], HJ Lee[1], HJ Yun[1], S Kim[1], DY Jo[1]
[1]Department of Internal Medicine, [2]Departement of Rehabilitation Medicine, Chungnam National University Hospital, Daejeon, Korea, Republic Of

Background: Pulmonary chronic graft *versus* host disease (cGVHD) is a serious late complication of allogeneic hematopoietic stem cell transplantation (HSCT), which hampers quality of life and increases mortality of survivors. Medical treatments have limited efficacy at improving pulmonary function.
Aims: We investigated the therapeutic effects of comprehensive pulmonary rehabilitation (CPR) in patients with deteriorated lung function due to pulmonary cGVHD .
Methods: We retrospectively analyzed the medical records of patients who had pulmonary cGVHD and participated in the CPR program, which consisted of aerobic exercise, inspiratory muscle strengthening, accessory respiratory muscle strengthening and mechanically assisted coughing. The subjects were planned to undergo maximal cardiopulmonary exercise test and a body composition test with bioelectrical impedance analysis at baseline and 3 months. Exercise testing parameters, skeletal muscle mass of lower extremities and body mass index (BMI) were analyzed.
Results: Nine patients were assessed (two males, seven females; median age 40 (range 24–64) years). Donor lymphocyte infusion was performed in two patients. All patients had skin, mucosal and visceral manifestations, in addition to pulmonary cGVHD. When starting CPR, the median FEV1 was 25% (range 18% – 51%). Eight patients received concomitant corticosteroid and three received imatinib. At a median follow-up of 11 (range 2–16) months, the patients had participated in the CPR program for a median of 40.5 (range 10–148) days. Eight patients (88.9%) had completed more than 20 sessions of the CPR program. The rehabilitation programs were readily tolerable and had no adverse effects. The median change in the maximum oxygen consumption (VO_{2max}) was 28.5% (range –31.8% to 60.1%) and the muscle mass of the lower extremities changed by 3.0% (range –0.2% to 24.1%). All four patients who had an increased muscle mass in the lower extremities had an increase in VO_{2max}. There were no marked changes in BMI.

Summary and Conclusions: Our comprehensive pulmonary rehabilitation program for patients with pulmonary cGVHD with limited lung function was feasible and improved the exercise capacity in a population of patients.

PB1967

GRANULOCYTE-MACROPHAGE COLONY STIMULATING FACTOR AND GRANULOCYTE COLONY STIMULATING FACTOR AUTO-ANTIBODIES IN CHRONIC HEPATITIS -C VIRUS INFECTED PATIENTS WITH NEUTROPENIA

MAS Abdelhamid[1,*] AE Saad Abdelhamid[2,2], NA Nemr[3], EA Abdelfattah[4]
[1]Community Medicine, [2]Clinical Pathology, [3]Internal Medicine, Faculty of Medicine, Suez Canal University, Ismailia, [4]Health Insurance Hospital, Suez, Egypt

Background: .HCV infection is frequently associated with hematological disorders such as anemia, leucopenia and thrombocytopenia. Neutropenia is common during combination antiviral therapy for chronic hepatitis C. Haematopoietic growth factors are generally well tolerated and they may be useful for managing hematological side effects of anti-HCV therapy.G-CSF and GM-CSF are mainly responsible for the proliferation of granulocytes and macrophages.There is increasing evidence that spontaneous anticytokine autoantibodies are associated with chronic infections and autoimmune diseases.
Aims: Assessment of auto-antibodies against Granulocyte Macrophage Colony Stimulating factor (GM-CSF) and Granulocyte Colony Stimulating factor (G-CSF) in chronic HCV infected neutropenic patients.
Methods: Patients: (87) chronic HCV infected patients were included, the study group included (50) neutropenic (ANC<2.5 cmm) chronic HCV infected patients, while the control group included(37) chronic hepatitis C virus inrected patients without neutropenia. The following investigations were carried out: Complete blood count (CBC), biochemical assessment: Liver function tests, 3)Serological assessment: -Serum HCV antibody using anti HCV enzyme immunoassay 4-Detection of HCV –RNA by RT-PCR 5-Detreminaiton of serum (G-CSF) and (GM-CSF) level by using ELISA Kit 6-Assesment of anti (G-CSF) &(GM-CSF) by using ELISA technique.
Results: The mean value of serum (G-CSF) In neutropenic group (90.23±62.06 µg/mL) was significantly higher than the same for non neutropenic group (5.49±4.90 µg/mL) P value<0.001. The mean value of serum (GM-CSF) In neutropenic group(77.29±71.40µg/mL) was significantly higher than the same for non neutropenic group (0.80±0.65µg/mL) P value<0.001. Anti-G-CSF antibody was positive only in 5 patients (10%)of neutropenic group and negative (not detected) in non neutropenic group. Anti-GM-CSF antibody was positive only in 3 patients (8.3%)of neutropenic group; niether of both autoantibodies was detected in the in non neutropenic group.
Summary and Conclusions: · The higher level of serum G-CSF and GM-CSF in neutropenic group suggest intactness of G-CSF and GM-CSF physiologic feedback mechanism; in conjunction with the low level of anti-G-CSF and anti-GM-CSF suggest that the etiological factors for neutropenia in HCV infected patients could be confined to the committed hematopoietic stem cells and the early myloid proginators which should be targeted in future studie.

PB1968

THE EPIDEMIOLOGY AND PROGNOSTIC FACTORS OF FUNGEMIA IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

H Jing[1], X Wei[1], M Xie[1], R Feng[1,*]
[1]Department of Hematology, Nanfang Hospital,Southern Medical University, Guangzhou, China

Background: Despite the growing antifungal armamentarium, fungemia remains an extremely poor prognosis in hematological patients and clinicians still face many challenges in diagnosing and treating fungal septicemia.
Aims: The objective of the current retrospective study was to investigate the epidemiology of fungemia and its prognostic factors in patients with hematologic malignancies.
Methods: We retrospectively analyzed patients with hematologic malignancy and positive cultures for fungi at the Nanfang Hospital in China (2003-2012). The medical and electronic records of patients were reviewed for demographic data and clinical information, including clinical presentations, the infecting fungi species, treatment and outcome.
Results: Forty-seven patients were identified based on blood cultures in our study, and other causes of death except fungemia-related cause were excluded. Acute myeloid leukaemia was the most common underlying disease in hematological patients with fungemia (61.7%). The majority of patients (91.5%) received chemotherapy and 32(68.1%) patients belonged to nosocomial infections. 42(89.4%) patients existed severely agranulocytosis, and the median time of agranulocytosis duration was 9 days (range, 4-40 days). 43(91.5%) patients were complicated by infections of other sites, and respiratory infections most frequently presented in 33/43 patients (78.6%). Non-albicans Candida strains (83%) was the predominant species found in our survey, and Candida tropicalis (57.1%) was confirmed the importance of this species as cause of fungemia. Outcomes were divided into success and death and the mortality rates was 25.5% (n=12). By multivariate logistic regression analysis, the duration of agranulocytosis, presence of shock, and the initiation time of antifungal therapy were the independent risk factors for death.
Summary and Conclusions: In order to prevent the prevalence of fungemia in hematological patients, a prophylactic strategy against fungemia in high risk patients should be considered. In those patients who had developed fungemia, providing timely and appropriate antifungal therapy, promoting recovery of agranulocytosis and preventing the shock will improve the prognosis of the patients.

PB1969

INCIDENCE AND OUTCOME OF SEPTIC SHOCK IN PEDIATRIC CANCER PATIENTS (CCHE EXPERIENCE)

A Hamoda[1,*]
[1]Pediatric Oncology, National Cancer nstitute, ELMANIAL, Egypt

Background: Sepsis is the leading cause of death in cancer patients and may lead to Systemic Inflammatory Response Syndrome (SIRS). Severe sepsis, left unmanaged, may lead to the inevitable septic shock. Septic shock is severe sepsis with persistent hypotension despite adequate fluid resuscitation in the presence of a known infection.
Aims: To Identify incidence and cause of septic shock among pediatric cancer patients receiving chemotherapy and to survey the outcome of septic shock among pediatric oncology intensive care unit (PICU).
Methods: A study done on 92 patients below age of 18 years having cancer, receiving chemotherapy and admitted to CCHE PICU by septic shock and started inotropes in the period from October 2010 till March 2012.
Results: Total number of patients are 92.Their age ranged from 9 months to 18 years with a mean of 7.3±4.8 years. The included patients were 41 males (44.6%) and 51 females (55.4%). Blood cultures and sensitivity were performed during the infectious episodes:31/92 cultures (33.7%) showed Gram +ve organisms, 52/ 92 cultures (56.5%) showed Gram –ve organisms , 2 cultures showed Candida and another 2 showed mixed gram positive and Candida ,while 5/92 cultures (5.4%) showed no growth. Outcome of the studied patients was recovery of 54/92 (58.7%) &and death of 38/92(41.3%). Heart failure is the most common complication (27.2%) followed by renal failure (14.1%), typhilities(6.5%),and pancreatitis(5.4%).
Summary and Conclusions: Gram negative organisms are the most common cause of septic shock in pediatric cancer patients with the highest mortality rate. Heart failure was the most common complication associated with septic shock in pediatric cancer patients.

PB1970

VANCOMYCIN RESISTANT ENTEROCOCCI COLONIZATION AND INFECTION IN PEDIATRIC PATIENTS WITH CANCER

SM Farid[1], I Ragab[1,*] S Girgis[2], WI Sarhan[1]
[1]Pediatrics, [2]Microbiology, Ain Shams University, Cairo, Egypt

Background: Vancomycin-resistant enterococci (VRE) may cause a serious hospital-acquired infection.
Aims: The study aimed to assess the VRE intestinal colonization status in children with cancer, the associated risk factors and resistance profile.
Methods: A cross-sectional study was performed in Ain Shams University, Pediatric Hospital, Hematology-Oncology Section. It included 50 children with cancer divided into two groups. Outpatient group including 25 patients with no symptoms and signs suggestive of infection and with neutrophil count more than 500/uL and 25 inpatients admitted for febrile neutropenia compared to 25 healthy age and sex matched control group. Data collection for the type of cancer, febrile episode during the previous 6 months, antimicrobial use, and bacteriologic studies . Colonization and infection studies were performed. For inpatient group stool culture , rectal swab and blood culture were done on admission, after 72 hours and one week post-admission and the concomitant neutrophil count. Outpatient group and control group were studied for rectal swab and stool culture. The analysis of samples included culture, isolation, identification and detection of susceptibility of isolates to antibiotics.
Results: No age or sex difference was found between studied groups. 38 patients had hematopoietic malignancies and 12 had solid tumors. Eleven inpatients(44%) had associated GIT symptoms and thirteen (52%) had respiratory symptoms. One week post admission only 3 (12%) were still had GIT symptoms and 5(20%) were still having respiratory symptoms. The median duration of admission was 15 days (9-60). 20% of blood culture showed VRE isolates. VRE were detected in one inpatient on admission, compared to 5 patients after one week (p=0.01). There was no significant difference in age ,sex, duration of neutropenia and duration of admission between infected inpatient and non infected inpatients (p>0.05), infected inpatients had significant

lower neutrophil count compared to non infected ones (p<0.001). They had significant higher usage of vancomycin ,flagyl and imipinem compared to non-infected ones (p<0.05). Stool culture were negative in 72% of inpatients after one week compared to 100% on admission, with detected enterococci in 4% 72 hours post admission, compared to 28% one week post admission . 18(72%) patients had negative rectal swab one week post admission, compared to 21(84%) on admission results. Stool culture showed in one (4%) inpatient 72 hours post admission, compared to 7(28%) one week post admission. 8(32%) inpatients had enterococcal colonization ,3(37.5%) of them were resistant to vancomycin. In control group, enterococci were detected in 2(8.0) and none of them were resistant to vancomycin. There was no significant difference in sensitivity pattern of stool culture and rectal swab to vancomycin between outpatients and control group.(p>0.05) .The frequency of sensitivity of detected enterococci to different antimicrobial in inpatient group was as follow; ciprofloxacin (28.5%), gentamycin (85.7%), azithromycin (28.5%), pipercillin/tazobactam (14.3%), ampicillin(42.8%), levofloxacin (28.5%), erythromycin (14.3%) . While sensitivity pattern in outpatient group was gentamycin (66%), azithromycin (33.3%), pipercillin/tazobactam (33.3%), levofloxacin (33.3%), erythromycin (0%).

Summary and Conclusions: children with Cancer are at high risk for VRE colonization and infections. Neutropenia, excess use of vancomycin long hospital stay are important risk factor; Newer less toxic antimicrobials and with broader spectrum could be an alternative to vancomycin

PB1971

CMV REACTIVATION IN MULTIPLE MYELOMA TREATED WITH BORTEZOMIB-BASED REGIMENS

VS Sampath[1,*] A Tso Ching Yee[1], LK Lee[1], SZ Fong[1], YC Lim[1], K Ponnudurai[1], J Rajendran[1], KH Ong[1]
[1]Haematology, Tan Tock Seng Hospital, Singapore, Singapore

Background: Bortezomib therapy in multiple myeloma increases the risk of reactivation with herpes simplex and herpes zoster viruses and acyclovir prophylaxis is recommended to prevent reactivation. Recent data from the Rome Transplant Network suggest that multiple myeloma patients treated with bortezomib-based regimens are at higher risk of developing a symptomatic CMV reactivation after autologous stem cell transplantation. There is little or no data regarding CMV reactivation after bortezomib therapy in the initial treatment of myeloma.

Aims: To describe two patients with multiple myeloma who developed CMV reactivation after bortezomib therapy prior to autologous stem cell transplantation.

Methods: Patient 1: A 59 year old gentleman presented with loss of weight, cough and lump on the right side of the chest wall for 2 weeks. Laboratory evaluation revealed renal failure, hypercalcemia, anemia, lytic bone lesions, IgA lambda paraproteinemia, plasmacytoma and malignant pleural effusion. Bone marrow examination confirmed the diagnosis of multiple myeloma. He was treated with VCD (Bortezomib, Cyclophosphamide and Dexamethasone). During the second cycle of treatment he developed melena. Endoscopy showed an oesophageal ulcer, prepyloric erosions and duodenal ulcer. Biopsy was not performed because of concern that it may worsen bleeding. In view of oesophageal ulcers, blood was tested for CMV PCR which was positive at 480 copies/ml and peaked at 2700 copies/ml. He was treated with valganciclovir following which CMV PCR became negative. Acyclovir prophylaxis was reinstituted and there was no further reactivation. Paraprotein has disappeared after five cycles of VCD and autologous stem cell transplant is being planned. Patient 2: A 62 year old lady presented with chest and right shoulder pain for 2 weeks. Evaluation revealed osteolytic lesions and multiple rib fractures. Further evaluation revealed anemia, hypercalcemia and destructive vertebral lesions. MRI of the spine revealed cord compression.Bone marrow examination confirmed the diagnosis of multiple myeloma.She was treated with urgent radiotherapy to the spine and VCD. During the second cycle she developed odynophagia which was treated with empirical fluconazole. Upper GI endoscopy showed acute oesophagitis with ulceration and both biopsy and the blood was positive for CMV PCR. She was treated with Valganciclovir and there was complete resolution of the ulcers and CMV PCR became negative. Acyclovir prophylaxis was reinstituted and there was no further reactivation.She achieved stringent CR after five cycles of VCD, had an autograft and remains in stringent CR with no further CMV reactivation.

Results: We have described two cases of CMV reactivation with bortezomib treatment for multiple myeloma. Low level CMV reactivation may be common after Bortezomib but there are no data on its incidence. Patient 1 had low level CMV reactivation and treatment was given because of the presence of oesophageal ulcer although there was no proof the ulcer was due to CMV.Patient 2 had definite evidence of CMV oesophagitis.The reasons for no recurrence of CMV reactivation are not clear but may be due to recovery of immune function as there was excellent response to treatment in both patients.

Summary and Conclusions: CMV reactivation can occur with bortezomib therapy prior to autograft. Most of the reactivations are likely to be low-level without any clinical significance. However, if patients have clinical features suggestive of CMV disease(like oesophagitis, hepatitis or retinitis), reactivation has to strongly considered. Patients with multiple myeloma treated with bortezomib should be prospectively monitored for CMV reactivation in future studies. This will help us determine the incidence of CMV reactivation and CMV disease in this patient population.It will also help us determine whether CMV monitoring and preemptive treatment is needed in patients receiving bortezomib based regimens.

PB1972

VISCERAL LEISHMANIASIS MIMICKING LYMPHOPROLIFERATIVE DISORDERS

A Paolini[1,*] G Bonacorsi[1], P Zaldini[1], M Morselli[1], L Potenza[1], G Leonardi[1], V Coluccio[1], M Maccaferri[1], S Bigliardi[1], V Fantuzzi[1], L Faglioni[1], E Colaci[1], F Soci[1], V Nasillo[1], A Messerotti[1], A Cuoghi[1], P Bresciani[1], R Marasca[1], F Narni[1], W Gennari[2], F Rumpianesi[2], E Franceschini[3], M Codeluppi[3], C Mussini[3], G Guaraldi[1], M Luppi[1], F Forghieri[1]
[1]Department of Medical and Surgical Sciences, University of Modena and Reggio Emilia, [2]Department of Diagnostic and Laboratory Services and Legal Medicine, Azienda ospedaliero-universitaria Policlinico, [3]Department of Surgery, Medicine, Dentistry and Morphological Sciences, University of Modena and Reggio Emilia, Modena, Italy

Background: Visceral leishmaniasis (kala azar) usually occurs with fever, splenomegaly and blood exams abnormalities, such as cytopenias and hypergammaglobulinemia. Early infection typically presents with skin lesions, such as nodules or plaques.

Aims: To investigate Leishmania spp infection in patients observed with symptoms suggesting either new onset or relapsed aggressive lymphoproliferative disorders.

Methods: We report on 6 either immunocompetent or immunocompromised patients, admitted between September 2012 and January 2014, because of either cytopenias or fever or splenomegaly with or without adenopathies. All of them underwent bone marrow (BM) aspirate and/or trephine biopsy for morphologic and flow cytometry examinations, together with molecular analyses for either lymphocyte clonality or Leishmania spp detection by nested polymerase chain reaction (nPCR).

Results: All 6 patients (1 female and 5 males, aged 45 to 84 years) were living in the neighborhood of Modena and Bologna (Italy). One of them had a previous diagnosis of B-chronic lymphocytic leukemia (CLL), while the woman was HIV-seropositive. At least one cytopenia, usually leukopenia with mild to severe neutropenia and thrombocytopenia, was documented in all patients, while fever occurred in 5 cases. Three of them showed splenomegaly and adenopathies. One case presented with acute liver failure. Only the patient in follow-up for CLL had severe polyclonal hypergammaglobulinemia. BM smear cytological evaluation on May-Grünwald-Giemsa staining documented the presence of Leishmania amastigotes, either into macrophage cytoplasms or dispersed, in 3 out of 6 cases. In the remaining samples, in which parasites were not microscopically visible, features suggesting increased inflammatory response, such as macrophages activation and plasmocytosis, were described. Moreover, in one case a definite hemophagocytic syndrome was demonstrated. nPCR for Leishmania spp, carried out on BM samples, was positive in all cases, allowing a diagnosis of visceral leishmaniasis also in 3 patients in which Leishmania amastigotes were not found by microscopic observation. Targeted therapy with liposomal B amphotericine (3 mg/Kg/daily for 5 days) was started, immediately after diagnosis, namely the same day of BM aspirate when Leishmania amastigotes were microscopically observed, or within one week when parasite molecular detection was needed. Hematologic recovery and clinical improvement were seen in all patients by one month (Figure 1).

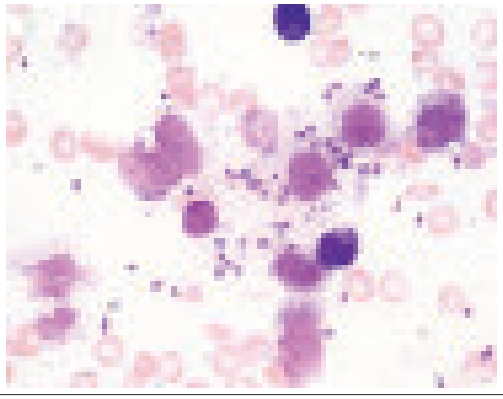

Figure 1.

Summary and Conclusions: Our small series suggests the importance to consider Leishmania spp protozoal infection in the differential diagnosis in patients presenting with at least one of the following symptoms: fever, one or more cytopenias, non homogeneous splenomegaly and/or lymph node enlargement. Specific features of our cases, diagnosed with visceral leishmaniasis, clinically mimicking aggressive lymphoproliferative disorders, in a non-endemic area, relies on the heterogeneous clinical manifestations, with disseminated infection in the absence of skin involvement and usually without hypergammaglobulinemia. Besides thorough clinical history, physical examination and imaging, diagnostic workup should also include BM examination in these cases. Of note, we would like to remark the relevance of collecting BM aspirate samples not only for morphologic examination, but also for molecular analysis, which is currently the highest sensitive diagnostic method for leishmaniasis. Prompt start of specific therapy against Leishmania is essential to obtain resolution of symptoms and parasitic eradication.

PB1973

PRE-TREATMENT BLOOD INFLAMMATORY MARKERS WITHIN NORMAL RANGE: AN INDICATOR OF LOWER PROBABILITY OF SYSTEMIC INFECTION DURING INDUCTION CHEMOTHERPAY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA?

J Hong[1,*] HS Woo[1], YS Kim[1], I Park[1], HK Ahn[1], SJ Sym[1], J Park[1], JY Ahn[2], EK Cho[1], DB Shin[1], JH Lee[1]
[1]Department of Internal Medicine, [2]Department of Laboratory Medicine, Gachon University School of Medicine, Incheon, Korea, Republic Of

Background: For patients with acute myeloid leukemia (AML), systemic infection is a frequent and serious problem during dose-intensive chemotherapy. Blood inflammatory markers, such as C-reactive protein (CRP) and ferritin, are known to have a predictive value for the incidence of systemic infection in patients who underwent hematopoietic cell transplantation (Hong et al, Biol Blood Marrow Transplant 2013;19:994).
Aims: This study aimed at evaluating the role of CRP and ferritin in predicting the incidence of systemic infection and infectious treatment-related mortality (TRM) among adult patients with newly diagnosed AML who were treated with current standard induction chemotherapy.
Methods: Patients were included if they were: 1) age > 20 years, 2) diagnosed as AML according to 2008 WHO criteria, and 3) treated with induction chemotherapy within 5 days after diagnosis. Patients with APL or with a HIV infection, were excluded. Induction chemotherapy consists of continuous infusion of cytarabine 100 mg/m^2 /d for D1~7 with idarubicin 12 mg/m^2/d (or daunorubicin 90 mg/m^2/d) i.v. for D1~3. Identical prophylactic measures including prophylactic antibiotics/antifungals, use of G-CSF, use of isolation room with a low bacterial diet, were provided. Systemic infection was defined as an infection in which the pathogen is distributed throughout the human body rather than in localized areas, with systemic inflammatory response syndrome. Informed consent was waived by the institutional review board, considering no actual intervention for the patients.
Results: A total of 110 patients (median age 54.5 years, range 20-80) were included. Pre-treatment CRP was measured in all patients and baseline serum ferritin was acquired from 79/110 patients (71.8%). Thirty nine events of systemic infection were reported in 38 patients (38.5%). Twenty two patients experienced infectious TRM (21/110 = 19.1%). Elevation of serum CRP (p=0.032) and ferritin (p=0.002) were related to the incidence of systemic infection. Elevation of CRP was also related to infectious TRM (p=0.029), whereas elevation of ferritin was not (p=0.119). Elevation of CRP and ferritin were not related to age<or ≥ 60 years (p=0.259 for CRP and p=0.696 for ferritin, respectively). However They showed a borderline relationship with a performance status<or ≥ 2 (p=0.087 and p=0.065, respectively). In multivariate analysis, serum ferritin was an independent risk factor affecting the incidence of systemic infection (p=0.026), although CRP failed to reach statistical significance (p=0.161) despite a trend with the odds ratio of 3.31 (Table 1). Both pre-treatment CRP and ferritin level showed correlation with WBC count. However, elevation of WBC itself was not related to systemic infection or infectious TRM. More frequent incidence of systemic infection was observed in patients with elevated levels of the inflammatory markers, whether they had higher (≥10x10^3/μL) or lower (<10x10^3/μL) WBC counts. These finding implies that, although elevation of CRP or ferritin above their conventionally appointed normal range is predictive of systemic infection, higher blood level of inflammatory markers does not indicate a greater probability of systemic infection and it is possibly affected by the expansion of leukemic myeloblasts.
Summary and Conclusions: Pre-treatment CRP and ferritin within normal range showed an association with decreased probability of systemic infection in patients with AML who underwent induction chemotherapy. These cheap and easily testable blood markers could be useful in selection of a subgroup with a lower probability of systemic infection in those patients.

Table 1.

PB1974

CMV PROPHYLAXIS WITH GANCICLOVIR, FOSCARNET AND VALGANCICLOVIR IS HIGHLY EFFECTIVE IN PREVENTING CMV INFECTIONS AFTER IN VITRO CD3-DEPLETED HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION

SW Lee[1,*] JK Suh[1], ES Choi[1], KN Koh[1], S Jang[2], HJ Im[1], JJ Seo[1]
[1]Department of Pediatrics, University of Ulsan College of Medicine, Asan Medical Center Children's Hospital, [2]Department of Laboratory Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic Of

Background: Haploidentical hematopoietic stem cell transplantation (HHCT) has become a possible alternative treatment for patients with malignant or non-malignant diseases who lack an HLA-matched related or unrelated donor. Compared to transplantation from other sources, HHCT is limited by delayed immune recovery and subsequent infections. Cytomegalovirus (CMV) is the most prevalent infectious agent and one of the major causes of death after transplantation.
Aims: We compared the incidence of CMV reactivation and disease between before and after CMV prophylaxis to evaluate the efficacy of the prophylaxis in HHCT.
Methods: Between July 2008 and January 2013, 28 children and adolescents underwent a total of 35 HHCTs using *in vitro* CD3-depleted peripheral blood stem cells at AMCCH. In July 2011, we initiated CMV prophylaxis with ganciclovir (5mg/kg twice per day) prior to HHCT, and forcarnet (60mg/kg/day) from the time of infusion and up until engraftment. After engraftment, valganciclovir (25mg/kg/day) was administered until 100 days post-transplantation and until the recovery of CD4$^+$ cell numbers >100/μL. Therefore, among 28 patients, 15 received CMV prophylaxis per protocol, but 13 did not.
Results: CMV reactivation occurred in 15 of the 28 patients at a median of 47 days after their first HHCT, leading to a cumulative incidence (CI) of 53.6%. Four patients developed CMV diseases (retinitis in two, pneumonia in one, and encephalitis in one), and two patients died of CMV disease (pneumonia and encephalitis in one each). After July 2011, at which point CMV prophylaxis was initiated, only 5 out of the 15 patients experienced transient reactivation and none developed CMV disease. The CI of CMV reactivation was lower in patients who received prophylaxis than that of those who did not (33.3% *vs* 76.9%, *P*=0.014). In addition, the CI of CMV disease was significantly lower in prophylaxis group (0.0% *vs* 30.8%, *P*=0.033).
Summary and Conclusions: The CMV prophylaxis with ganciclovir, foscarnet and valganciclovir is highly effective in decreasing the incidence of CMV disease as well as its reactivation in HHCT. Given the delayed immune reconstitution in certain type of transplantation, CMV prophylaxis with anti-viral drugs is recommended in transplantation using T-cell depleted graft or umbilical cord blood.

PB1975

IMAGING OF PULMONARY INFECTIOUS COMPLICATIONS IN HEMATOLOGICAL MALIGNANCIES

C Federica[1,*] S Armenio[2], F Angela[1], S Lidia[3], I Francesca[1], P Raffaele[3], B Daniela[1], C Nicola[3], G Roberto[1]
[1]Institute of Radiology, Second University of Naples, Napoli, [2]Department of Radiology, [3]Hematology and Hematopoietic Transplantation, A.O.R.N. San G. Moscati, Avellino, Italy

Background: Pulmonary complications frequently occurred in immunocompromised hosts, and specifically in patients treated for hematologic malignancies or undergoing hematopoietic cell transplantation. Infections are the most common (75%) and are associated with high morbidity and mortality. These infections occur despite routine prophylaxis for common pathogenic organisms and empiric therapy of febrile episodes during the early neutropenic period. High-Resolution Computed Tomography (HRCT) scans have high

degree of sensitivity (>85%), high negative predictive value (>85%) in detecting pneumonia with gain of 5 days compared with chest radiography.
Aims: The aims of this study were to examine characteristics and frequencies of high-resolution computed tomography (HRCT) patterns found in case of infectious pulmonary complications in patients with hematological malignancies and to examine the correlation between the etiological agent and a specific HRCT pattern.
Methods: 133 patients with hematological malignancies, **t**hat had pulmonary abnormalities on HRCT of the lungs images after treatment with chemotherapy or hematopoietic cell transplantation, were enrolled and retrospectively evalueted. Chi-square test was performed for the statistical analysis.
Results: Seventy-seven (58%) of the 133 patients, that showed parenchymal abnormalities on HRCT, had single patterns and 56 (42%) had mixed patterns. Fifty patients (38%) of 133 were positive at microbiological analysis. There were 27 cases (54%) of bacterial pneumonia, 7 (14%) of fungal pneumonia, 2 (4%) of viral pneumonia and 14 (28%) of mixed pneumonia. The statistical analysis showed a statistically significant association between the following HRCT patterns and the etiology: centrilobular micronodules and fungal pneumonias (p <0.01); mixed pattern solid nodules, consolidations and air-crescent sign and fungal pneumonias (p <0.05); nodules with halo and mixed pneumonia (p <0.05).
Summary and Conclusions: Centrilobular nodules (with or without tree-in-bud) and mixed pattern solid nodules, consolidations and air-crescent sign are suggestive of fungal pneumonias; halo sign pattern is suggestive of mixed pneumonia. Other high-resolution CT patterns are not helpful in distinguishing among the various types of infection seen in neutropenic – immunocompromised patients.

PB1976

FEBUXOSTAT FOR MANAGEMENT OF INTERMEDIATE RISK OF TUMOR LYSIS SYNDROME WITH HEMATOLOGICAL MALIGNANCIES.
M Takai[1,*] T Yamauchi[1], M Ookura[1], Y Matsuda[1], K Tai[1], S Ikegaya[1], S Kishi[1], A Yoshida[1], Y Urasaki[1], T Ueda[1]
[1]Hematology and Oncology, University of Fukui, Fukui, Japan

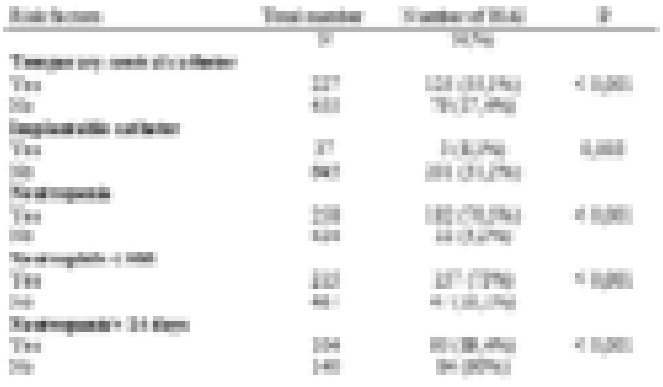
Background: Tumor lysis syndrome (TLS) is a rare but life-threatening oncological emergency, and controlling the serum uric acid level (S-UA) is crucial. In the guidelines, a xanthine oxidase inhibitor, allopurinol, is employed in the management of an intermediate risk of TLS. However, patients at risk of TLS are occasionally complicated with renal failure, which may increase the risk of adverse reactions to allopurinol. Febuxostat (FEB), a new non-purine xanthine oxidase inhibitor is a more selective and potent inhibitor of xanthine oxidase than allopurinol and applicalble to patients with renal insufficiency. Because the use of a potent UA-lowering agent rasburicaseis limited due to its immunogenicity and cost, FEB should be the choice for TLS.
Aims: In this single institute, short-term, and pilot prospective study, the efficacy of FEB in patients with an intermediate risk of TLS was evaluated.
Methods: A total of 10 patients who presented to our insutitute between April and December in 2012 were enrolled. All patients were evaluated with an intermediate risk of TLS using the 2008 guidelines of Coiffier, *et al.* FEB was administrated orally for 7 days at 60 mg for patients with eGFR ≥ 90 ml/min/1.73 m^2 and 40 mg for patients with eGFR between 30 and 90 ml/min/1.73 m^2. Induction chemotherapy was started within 48 h after the first administration of FEB. The primary endpoint was the reduction of S-UA to ≤ 7.5 mg/dl by day 5. As the secondary endpoints, the renal function, pharmacokinetics of FEB, and resultant increase in the metabolites xanthine and hypoxanthine by FEB were measured.
Results: The median age was 67 (range: 52 - 79), with 4 males and 6 females. They were all diagnosed with hematological malignancies including leukemia and lymphoma. Three patients received 60 mg of febuxostat, while 7 patients received 40 mg. The median S-UA at the baseline was 8.0 mg/dl (range: 3.2 – 10.6), and the median S-UA on the 5th day was 3.3 mg/dl (range: 1.1 – 5.8) (P<0.0001). All patients achieved S-UA levels≤7.5 mg/dl. Overall, S-UA levels differed among the patients but decreased over time despite chemotherapy-induced tumor lysis, thereby supporting the efficacy of febuxostat. The median S-Cr levels decreased from 0.86 mg/dl (range: 0.7 – 1.38) to 0.72 mg/dl (range: 0.57 – 1.35) (P<0.0003). The median eGFR value increased from 56.4 ml/min (range: 37.8 – 111.9) to 66.7 ml/min (range: 49.2 – 126.5) (p=0.038). Febuxostat and allopurinol are both xanthine oxidase inhibitors that inhibit the conversion of hypoxanthine to xanthine and inhibit the conversion of xanthine to UA. While S-UA decreased over time, serum hypoxanthine and xanthine concentrations increased on day 1 (5.6, 3.1 µg/ml, respectively) and persisted at these levels through day 4. Urinary UA concentration decreased over time, a trend which might correspond with changes in S-UA. The mean urinary hypoxanthine and xanthine concentrations increased on day 1 (94.3 µg/ml and 191.8 µg/ml, respectively) and decreased on day 7.Serum FEB concentrations at 2 h after administration were 767.9 ng/ml for the 40-mg dose and 770.6 ng/ml for the 60-mg dose (no significant difference). The trough levels achieved steady state at day 4, with values of 30.4 ng/ml (mean) for the 40 mg dose of febuxostat and 27.1 ng/ml (mean) for the 60 mg dose of febuxostat. Day 7 values were 42.5 ng/ml (mean) (p=0.20) for the 40 mg dose of febuxostat and 28 ng/ml (mean) (p=0.90) for the 60 mg of febuxostat, suggesting no drug accumulation during the treatment period. No patients exhibited TLS progression. No grade 3, 4 adverse reactions related to FEB were reported.
Summary and Conclusions: FEB successfully controlled S-UA without major adverse reactions together with improvement of renal function during chemotherapy for intermediate-risk TLS. The determination of oxypurines suggested the clinical efficacy of FEB to inhibit xanthine oxidase in the recruited patients. The present results strongly suggest that FEB is an excellent alternative to allopurinol for the management of TLS.

PB1977

APPLYING THE CONCEPT OF HEALTHCARE ASSOCIATED INFECTIONS IN HEMATOLOGY AND ONCOLOGY PEDIATRIC UNIT OF CASABLANCA
S Fares[1,*] M Lamchahab[1], Z Serhier[2], K Zerouali[3], S Benchekroun[1], A Quessar[1]
[1]hematology and oncology pediatric unit, hopital 20 Aout, [2]informatique médicale, [3]bacteriologie-microbiologie, CHU Ibn Rochd, Casablanca, Morocco

Background: Infections in neutropenic patients are a cause of morbidity and mortality. They represent in onco-hematology (9-12%) compared to not cancerous patients (6-7%). The incidence of nosocomial infections (NI) is about 20%. Unlike NI, data of healthcare associated infections (HAI), are less available. The rigging of a register for HAI monitoring in the Pediatric Hematology and Oncology Unit of Casablanca allow a better knowledge of care practices and develop a prevention strategyermettra une meilleure connaissance des pratiques de soins et l'élaboration d'une stratégie de lutte conte les IAS.
Aims: Objectives of this study were to determine the incidence rate of HAI, and define risk factors, and ecological and bacterial profile, and evolution of these patients.
Methods: Prospectively, study was conducted over a period of eleven months, between February and December 2012. Were included all patients older than 18 years, admitted to hospital in the adult and transplant sectors. An operating sheet was developed according to WHO criteria. Data analysis was performed by Epi Info software. HAI rate was calculated per 1000 patients days.
Results: 682 admissions were recorded in 338 patients, median age was at 38 years old, and sex ration M/F=1.5. Incidence rate of HAI was 38.4% against 30% for NI. Incidence density of HAI per 1000 patients days was 31.6% against 24.6 for NI. HAI were microbiologically documented in 41% with bacteremia in 25% of all HAI cases. Pneumonia was noted in 32.8% and Infection was of unknown origin in 22.5%. Gram negative bacteria were isolated in 35% and Gram positive bacteria in 50%, and fungal in 15%. Median duration of hospitalization in infected patients was at 22 days [2- 70] (p<0.001), and death by infection was at 6% (Table 1).

Table 1. Risk factors in the group of infected patients.



Summary and Conclusions: Results of systematic monitoring of HAI in onco-hematology constituted a fundamental step to release the constraints of implementation of the register. They also helped to identify risk factors and ecological profile for development of a prevention strategy.

PB1978

PEGFILGRASTIM VERSUS FILGRASTIM IN THE MANAGEMENT OF POST-CHEMOTHERAPY NEUTROPENIA IN RELAPSED AND REFRACTORY MULTIPLE MYELOMA
C Cerchione[1,*] S Basile[1], V Russo[1], E Seneca[1], F Pane[1], L Catalano[1]
[1]Hematology, AOU "Federico II", Napoli, Italy

Background: Patients receiving cancer chemotherapy are at increased risk of neutropenia, leading to increased risk of infections and delay in subsequent chemotherapy treatments. Recombinant granulocyte colony stimulating factors (G-CSFs) have been developed to stimulate proliferation and differentiation of neutrophils in patients receiving chemotherapy. Pegfilgrastim is a pegylated long-acting recombinant form of G-CSF that extends the half-life and allows for once-per-cycle dosing, requiring less frequent dosing than nonpegylated G-CSF. Multiple Myeloma (MM) in advanced phases of disease may be managed by regimens combining agents not frequently employed in early phases of treatment (*e.g.* Anthracyclines, Alkylating agents, etc), but myelotoxicity is the main expected side effect. In this context, G-CSFs are often necessary to counteract the risks of febrile neutropenia: their use is bound to frequent evaluation of neutrophil counts that may not be easy for patients in home-care. Avoiding severe neutropenia by prophylactic pegfilgrastim seems particularly useful in these cases.
Aims: The objective of this study was to compare the efficacy and safety of pegfilgrastim in patients affected by Multiple Myeloma in advanced phase of disease. In order to determine whether a single subcutaneous injection of pegfilgrastim is as effective as daily injections of standard filgrastim, in terms of haematological toxicity, febrile neutropenic episodes, antibiotic usage and hospedalization duration.
Methods: We have enrolled in our study 29 patients (16 male and 13 female) with a median age of 64.7 years (range 39-82) affected by multiple myeloma, all relapsed and refractory to a median of 6.3 lines of therapy (range 4-8), all previously exposed to Bortezomib, Lenalidomide, Melphalan and all relapsed after auBMT, treated with different chemotherapy regimens combining Bortezomib, Lenalidomide, Bendamustine, Melphalan, Doxorubicine.
Results: Since first course, received in our out-patient department, patients performed blood counts twice weekly and received, from day +8 to day +19 (considering "day + 1" the day in which the chemotherapy protocol starts), prophylactic oral chinolonic antibiotics and anti-fungal drugs. During neutropenia after first cycle of chemotherapy, Filgrastim (5 µgr/kg/day for 3 days) was given if neutrophils count was <1500 x 10^9 cells/L. Median number of filgrastim administrations was 4.7 (r. 3-6); nadir neutropenia was registered after a median of 11.3 days (r. 8-14); median of nadir neutrophil count was 1.16 x 10^9 cells/L (range 0.4 – 1.8 x 10^9 cells/L), with maximum duration of 13 days. From the second course of chemotherapy, all patients switched to prophylactic therapy with pegfilgrastim (6 mg), injected subcutaneously with a single administration on day +3 independently from the neutrophil count at that time. Primary endpoint of this study was the duration of neutropenia (neutrophil count<1.5 x 10^9 cells/L), comparing pegfilgrastim and filgrastim. During pegfilgrastim, neutropenia was never longer than 8 days, with a consequent reduction of neutropenia-related infections. Median nadir neutrophil count, evaluated for every patients for at least three courses of therapy (r. 3-6) registered at day +11, was 1.628 (range 0.93-2.25 x 10^9 cells/L); only four patients (13.7%) needed, one week after pegfilgrastim administration, a supplement of 3 administrations of filgrastim. During pegfilgrastim prophylaxis, neutropenia was shorter than during Filgrastim treatment. Besides the mono-administration, pegfilgrastim was well tolerated in all patients: main side effects in our patients were mild fever and bone pain, (5/29 patients,17%)
Summary and Conclusions: In conclusions, in patients affected by MM exposed to myelosuppressive agents in advanced phases of myeloma disease, pegfilgrastim seems to reduce the incidence of neutropenia and may increase the possibility to maintain the scheduled time of treatment.

RELEVANCE OF PARALLEL USE OF GALACTOMANANN AND BETAGLUCAN ASSAY IN THE DIAGNOSIS AND FOLLOW UP OF FUNGAL INFECTION

JM Bergua Burgues[1], R Siguenza[1,*] C Pazos[2], H Fernandez-Leyva[1], F Ibañez[1], J Prieto[1], ML Martín-Mateos[1], I Casas[1], H Bañas[1], C Cabrera[1], F Carnicero[1], N Bermejo-Vega[1]
[1]Hematologia, [2]Microbiology, Hospital San Pedro de Alcántara. Caceres, Caceres, Spain

Background: Simultaneous detection of D-beta glucan, galactomannan and TAC are rarely performed jointly. We explore preventive strategy of fungal infection using these indirect markers of fungal infection in haematological patients
Aims: Retrospective analysis of positive determinations of galactomanann or betaglucan assays in patients with haematological diseases. We also compared with TAC images and calculate specificity of galactomann and betagulcan assays. Comparison between both test and TAC, survival after treatment, change of treatment after positivity of beta-D-betaglucan or galactomanan were analyzed.
Methods: Design and surveillance of patients at risk: All patients receiving AML treatment, ALL induction treatment, Bone marrow transplantation patients and patients with inmunosupressive drugs, such cyclosporine, anti-lymphocyte serum, or allentuzumab were monitoring in a preventive strategy every Monday and Thursday until neutropenia recovery or immunosuppressive therapy period. Patients: 48 patients admitted in Haematology from March 2010 to March 2013 were positive to beta-D-glucan or galactomanan assays. The median age was 65,7 year (16-91,69). The diagnosis of the patients were acute myeloid/lymphoid leukaemia: 21 (43%); multiple myeloma:9(18%), non and Hodgkin's lymphoma:10(20%), CLL/T-prolymphocytic leukaemia 5(10%); aplastic anaemia 2(4%) and haemolytic uremic syndrome 1(2%). The type of treatment was: Inmunosupression: 8 (16%), palliative: 4(8%) and chemotherapy 37(75%). The infection site reported were: Adenitis 1(2%), nail 1(2%), lung: 46 (94%), and lung+brain: 1(2%). Previous prophylaxis was performed in 29 patients(fluconazole 13(26%), itraconazole 14(28%) and posaconazole 2(4%)). Thirtynine (79%) of the patients were in respiratory insufficiency; median baseline oxygen saturation was 88(40-100). The median title of galactomanan was 0.8 ng/ml(0,5-7,6), and the median title of beta-D-glucan 291 pg/ml(7-781). The number of patients who were positive to galactoman: 43(89%) and beta-glucan positive in 43(89%). The number of positive determinations of galactomanan and betaglucan after treatment were 2,5 and 3 respectively. TAC images were: pneumonia 14(36%), cavity pneumonia: 9(23%), pleural effusion: 8(21%), nodular infiltrates: 6(15%), brain abscess+ lung cavity: 1(2,6), pulmonary embolism: 1(2,6%) and no images: 2 (5). Halo sign was detected in 12 (30%).
Results: Results: The first antifungal treatment was: Voriconazole in 35 (70%), Caspofungin in 10(20%), Fluconazole 2(4), Posaconazoles 1(2%), Ambisome 1(2%). Seven patients change of antifungal agents, 6 to Voriconazole and 1 to Ambisome; 11 patients were treated with combination therapy (7 with caspofungine+ voriconazole, 4 with ambisome+Voriconazole). Only 27 patients (62%) recover neutrophils>0.5x10^9/L. The results of treatment were death in 19 patients and curation of the lesions in 28 (58%). The median survival of the patients was 12,6 months (1,4 –non reached). The median survival time of the patients who recovered neutrophils was 22,2 months *vs* 4,4 months who did not (p<0,0001).Following EORTC criteria of invasive fungal infection: Proven 5 (6%), Probable: 40(83%) and false positive: 3 (6%). Specificity of galactomanan probe is 98% and betaglucan 96.5%. In 8 patients results of betaglucan and galactomanan were discrepant. T. ROC area unde the curve: 0.81. In one case, brain abscess and lung cavity, was detected after positivity to galactomanan .No fever, respiratory or neurological signs were detected before and was a surprise in TAC images.
Summary and Conclusions: A strategy of preventive treatment with antifungals (voriconazole) could be worthy using galactomanan and beta-D-glucan assays.

PB1980

EPIDEMIOLOGY OF VISCERAL MYCOSIS IN AUTOPSY CASES OF LEUKEMIA AND MDS IN JAPAN

T Togano[1,*] Y Suzuki[2], M Higashihara[1], H Kume[3]
[1]Hematology, Kitasato university school of medicine, Sagamihara, [2]Blood transfusion and Transplantation immunology, Fukushima medical university, Fukushima, [3]Pathology, Kitasato university school of medicine, Sagamihara, Japan

Background: There are many reports described an increase of invasive fungal infections. Moreover, patients are higher risk in case with leukemia and MDS. Although the risk should be considered in the present clinical settings, there are no detailed reports on visceral mycoses in autopsy cases in the survey at the national level.
Aims: It is important for us to clarify the recent trends concerning the frequency of mycoses in autopsy cases. We epidemiologically analyzed the data reported in the "Annual of pathological autopsy cases in japan".
Methods: The data on visceral mycoses reported in the "Annual of pathological autopsy cases in japan" were analyzed epidemiologically at intervals of four years in 2011 after 1989 and in 2011.
Results: The frequency rates of visceral mycoses decreased rapidly 1989(4.5%) and 1994(3.2%), but increased again (4.0-5.0%). The predominant causative agents were *Candida* and *Aspergillus.* Although the rate of candidosis showed a gradual decrease, the rate of aspergillosis exceeded that of candidosis in 1994. The rates of them still showed an increase. In addition, *Mucorales* increased gradually in recent years. In cases of leukemia and MDS, the rate of mycoses were higher (15-30%) in comparison with all of cases (4-5%). in each year. The rate of causative agents were *Aspergillus*(42%), *Candida*(14%), *Mucorales*(10%), and complicated infection cases(12%) in 2011. Interestingly, the rate of complicated infection cases increased gradually in recent years. The combination of causative agents in cases of complicated infection were *Asperugillus* and *Mucorales*(5.10%), and *Asperugillus* and *Candida*(4.08%) in 2011.
Summary and Conclusions: We epidemiologically analyzed the data reported in the "Annual of pathological autopsy cases in japan". We showed the data of visceral mycoses in Autopsy cases of leukemia and MDS in japan. The results of our study suggest that clinicians should increasingly focus on visceral mycoses.

PB1981

RATE OF FUNGAL INFECTIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA DURING INDUCTION TREATMENT PERFORMING TWO PROPHYLACTIC STRATEGIES: PRELIMINARY RESULTS

C Vetro[1,*] L Trovato[2], V Calafiore[1], G Giulietti[3], A Romano[1], D Berritta[1], M Parisi[1], E Mauro[1], S Oliveri[2], F Di Raimondo[1]
[1]Department of clinical and molecular biomedicine, Division of Haematology, [2]Department of Bio-Medical Science , University of Catania, Laboratory Analysis Unit, [3]Department of Diagnostic and Interventional Radiology, Azienda Ospedaliera 'Policlinico-Vittorio Emanuele', Catania, Italy

Background: The prophylactic approach, consisting in a prophylactic treatment of at risk patients, has been gaining more and more diffusion. Recently the SEIFEM group has demonstrated that posaconazole-based prophylaxis can significantly reduce the incidence of fungal infection *to court*. Indeed this kind of prophylaxis has gained an "A" level of evidence, especially in naive patients and patients undergoing to allogeneic bone marrow transplantation. However, no studies have compared the effectiveness of Posaconazole *versus* topical therapy.
Aims: The aim of this study was to determine the differences in Invasive Fungal Disease (IFD) incidence and outcome between two prophylactic regimens, *i.e.* Posaconazole *vs* Aerosolized amphotericin plus nistatin.
Methods: We analyzed 28 patients with AML undergoing induction treatment: 15 received prophylaxis with posaconazole 200 mg tid per os. and 13 prophylaxis with amphotericin-B 10 mg bid per aerosols; Nystatin 600,000 IU orally tid. The serological monitoring was conducted twice a week through the demonstration of beta-D-glucan (BG) (Fungitell) and the antigen galactomannan (GM) (Platelia ™ Aspergillus EIA). The Chest CT was performed in presence of fever lasting more than 72 hours. Invasive Fungal Disease (IFD) was diagnosed according to the EORTC criteria. The empirical antibiotic and antifungal therapy were administered according to ISDA guidelines. The qualitative data were analyzed using the chi-square test and chi -square for trends tests.
Results: No differences in terms of age, sex, Charlson comorbidity index according to subtype of AML, risk category, refractory to induction therapy and promyelocytic morphology were recorded between the two groups. BG resulted positive in 17.5% of patients (5/28), all of them underwent prophylaxis with amphotericin-B per aerosols and oral Nystatin (p=0.013 , relative risk 2.87 , 95% CI 1.64 to 5.03). Of these, only two patients out of 13 (15%) have reached, due to the presence of infiltrates on chest CT fitting the EORTC criteria, the clinical evidence of an IFD. No cases of IFD emerged in the group who received posaconazole prophylaxis. Stratifying patients according to Maertens *et al.* 2012 (1), it was evident that patients who received posaconazole prophylaxis were more likely to remain in the group "A" and "B", while patients who received amphotericin-B per aerosols and oral Nystatin were more likely to be within the groups "C" and "D" (p=0.01) (Table 1).

Table 1.

	Aerosolized amphotericin plus nistatin	Posaconazole
A	4	9
B	1	4
CI	1	0
CII	3	2
CIII	2	0
CIV	0	0
D	2	0

Chi Square Test for Trend: p=0,01

Summary and Conclusions: Considering the new criteria for patient stratification, prophylaxis with posaconazole determines a lower probability to develop an IFD in respect to amphotericin-B per aerosols and oral Nystatin.

PB1982

UP-REGULATION OF NKG2A IS INVOLVED IN NK CELL CYTOTOXICITY IMPAIRMENT IN B-THALASSEMIA MAJOR PATIENTS WITH LONG TERM BLOOD TRANSFUSION

Y Lu[1,*] S Liao[1], W Liu[1], Y Zou[1], X Liu[1]
[1]the third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: Allogeneic blood transfusion can induce immunosuppression in recipients and natural killer (NK) cells play important role in this effect. Killer activated receptors (KARs) and killer inhibitory receptors (KIRs) are expressed on NK cells .Whether NK cells exert function or keep silence depends on which receptors(KARs or KIRs) and their following pathway take advantage.
Aims: The aim of this work is to explore possible mechanisms involved in NK cell cytotoxicity impairment in β-thalassemia major patients with long term blood transfusion.
Methods: 20 β-thalassemia major patients, 20 β-thalassemia minor patients and 20 healthy volunteers were included in this study and median ages were respectively 9,10 and 9 years. The cytotoxicity (CD107a expression), KARs□ NKP30,NKP46, NKG2D□and KIRs (NKG2A,CD158a) on peripheral NK cells were detected by multicolor flow cytometry. IFN-γ production by NK cells was detected by intracellular cytokine staining. Statistical analysis was performed by T test. P<0.05 is considered significantly different.
Results: Compared with β-thalassemia minor patients or healthy volunteers, CD107a were lower in β-thalassemia major patients(P< 0.05). Expression of NKG2A in β-thalassemia major was remarkably up-regulated(P< 0.05), but there was no significant difference in expression of NKP30, NKP46, NKG2D, CD158a and IFN-γ(P>0.05).
Summary and Conclusions: Up-regulation of NKG2A may related to NK cell cytotoxicity impairment in β-thalassemia major patients with long term blood transfusion .

PB1983

SEARCH FOR EXTENDED PHENOTYPE-MATCHED BLOOD UNITS TO TRANSFUSE ALLOIMMUNIZED PATIENTS – IMPLICATIONS FOR THE BLOOD BANK

V Bakaloudi[1], V Constantinou[1], E Ntinopoulou[1], A Konstantinidou [1], F Girtovitis[1], M Pape[1], P Chalkia[1], D Pantelidou[1], M Chatzikyrkou[1], S Bountola[1], A Tzioura[1], H Hassapopoulou-Matamis[1,*]
[1]Blood Center, Ahepa Hospital, Thessaloniki, Greece

Background: Red cell antigen alloimmunized patients, especially sickle cell or thalassemia intermedia patients, need to be transfused with respect to their red blood cell (RBC) extended RBC phenotype, including mainly the Rhesus (DCE), Kell, Duffy, MNSs and Kidd systems.
Aims: The aim of our study was to register the reagents consumed and the labor needed to satisfy the need for transfusion of alloimmunized patients with respect to their extended phenotype and subsequently estimate the cost and identify possible alleviating strategies.
Methods: During a five month period (January through May 2013) our center was asked to supply 45 patients with extended phenotype RBC compatible units. We used the gel test technique (BIORAD's monoclonal antisera gel cards, or neutral gel cards with the addition of specific antisera), to screen blood units of the same ABO, Rhesus, and Kell phenotype for antigens of the Duffy, MNSs and Kidd systems, as well as Lewis, P, Lutheran, if needed. The RBC phenotype of each unit screened, was registered in the donor's card who was then added to our electronic registry. In all cases where the combination of antigens in the patient produced a rare phenotype, instead of screening random blood units, we used our rare donor registry, to call blood donors with the phenotype needed.
Results: A total of 1086 RBC units were screened for 1-6 red cell antigens each. 2090 red cell antigen phenotyping tests were performed in total, with a cost of 2.6-3.5 euros per test (without counting the cost of the labor man-hours). A frustrating fact is that not all patients are transfused with the units found proper for them, because the clinicians postpone the transfusion or their condition gets ameliorated by other means. The most illustrative example was a patient with acute myeloid leukemia who received 28 out of 165 RBC units found proper (of the phenotype needed). For each of the other 44 patients the number of transfused extended phenotype compatible units was 0-3. So, many screened phenotyped units are finally given to non-alloimmunized patients.
Summary and Conclusions: Screening random units to identify a specific extended phenotype for alloimmunized patients is a non cost-effective approach. For non-urgent cases, the best solution is to call donors with the phenotype needed. Keeping an updated registry of phenotyped donors, is of great help especially when RBC units with rare phenotypes are needed. Blood Centers –like ours- that routinely have to perform extended RBC phenotyping, should create electronic registries and share them with others.

PB1984

HUMAN PLATELETS STORED AT MINUS 196°C RETAIN NORMAL CALCIUM-SIGNALLING AND ACTIVATION IN RESPONSE TO STRONG AGONISTS

S Rochat[1], B Gerber[2], U Schanz[2], G Stussi[3], L Alberio[1,*]
[1]Haematology, University Hospital Inselspital, Bern, [2]Haematology, University Hospital Zurich, Zurich, [3]Haematology, Oncology Institute of Southern Switzerland, Bellinzona, Switzerland

Background: Human platelet concentrates (hPC) can be stored at 20 – 24°C for 5 days. This limiting storage time might be extended to several years by cryopreservation in liquid nitrogen.
Aims: The aim of the present work was to evaluate intracellular calcium-signaling and surface activation end-points of cryopreserved platelets.
Methods: Four hPC were frozen by computer-controlled rate freezing in 10% DMSO with human albumin, stored at minus 196°C for 4-6 weeks, thawed in a water-bath at 37°C and analysed by flow-cytometry as published (Daskalakis *et al.* Cytometry B. 2014).
Results: We observe two populations of cryopreserved and thawed platelets. One population (median ca. 40%) expresses negatively charged phospholipids, has a decreased surface density of glycoprotein (GP) Ib, and cannot be activated. The other platelet population (median ca. 60%) has surface densities of GP Ib, IIb, and IIIa similar to control fresh platelets, does not bind annexin-V (detecting the expression of negatively charged phospholipids) nor PAC-1 (recognizing an activation-induced epitope of the fibrinogen-receptor), is able to mobilize intracellular calcium in response to strong agonists, such as convulxin (a specific agonist of the collagen receptor GPVI) or thrombin, and behaves as fresh control platelets for secretion of alpha- and dense-granules, activation of the fibrinogen-receptor, and development of procoagulant activity.
Summary and Conclusions: We show that cryopreservation and thawing of human platelets results in a fraction of platelets (about 60%) maintaining normal calcium mobilisation, granule-secretion, activation of the fibrinogen-receptor, and development of procoagulant activity in response to strong platelet agonists. According to these findings cryopreserved platelets presumably could have normal haemostatic effects *in vivo*.

PB1985

CONSENT FOR BLOOD TRANSFUSION IN MAJOR ELECTIVE VASCULAR SURGERY IN THE UK - CURRENT REGIONAL PRACTICE

M Thomas[1,*] P Wong[2], E Kothmann[3]
[1]Department of General & Vascular Surgery, University Hospital North Durham, Durham, [2]Department of Vascular Surgery, [3]Department of Anaesthetics, James Cook University Hospital, Middlesbrough, United Kingdom

Background: Providing patients receive the "right blood, to the right patient at the right time", risks of transfusion are low, but potentially fatal. Major vascular surgical procedures have a high incidence of transfusion requirements. The UK Advisory Committee on the Safety of Blood, Tissues and Organs (SaBTO) has produced guidelines on the standards for seeking consent for blood transfusion. We sought to audit our practice against these standards.
Aims: To audit the current practice on consent for blood transfusion, amongst vascular surgeons and anaesthetists in one region of the UK.
Methods: All Consultant Vascular Surgeons, Consultant Vascular Anaesthetists and higher vascular surgical trainees in one geographical region of the UK were invited by email to complete an on-line questionnaire. Data was analysed using Microsoft Excel software.
Results: 38 responses were received (9 consultant surgeons, 18 consultant anaesthetists, 11 surgical trainees). 63% were not aware of the SaBTO guidelines; awareness was lowest amongst surgical trainees. Only 53% stated they "always" take consent for transfusion. 86% of those taking consent documented this somewhere in the clinical notes, but patient information leaflets were rarely provided. Retrospective notification that a patient has received a transfusion was given only "sometimes" by 55%, or "never" by 21%.
Summary and Conclusions: Awareness of SaBTo guidelines was low in our region. Areas identified for change in our practice following this audit include: provision of patient information leaflets to be part of pre-operative assessment; consent for transfusion to be documented on the surgical consent form; patients receiving transfusion during surgery are to be retrospectively informed and provided with patient information leaflet. This will be documented in the clinical notes.

PB1986

ANTI-JKA AUTO-ANTIBODY CAUSING HEMOLYSIS IN A PATIENT WITH IMMUNE THROMBOCYTOPENIA: AN INTERESTING CASE REPORT

V Bakaloudi[1], V Constantinou[1], C Vadikolia[1], E Ntinopoulou[1], M Pape[1], F Girtovitis[1], A Konstantinidou[1], M Chatzikyrkou[1], H Hassapopoulou Matamis[1,*]
[1]Blood Center, Ahepa Hospital, Thessaloniki, Greece

Background: Bibliography about anti-jka auto-antibodies is not rich. Rare reports exist about anti-jka auto-antibodies that caused significant hemolysis. Most patients involved, had either an autoimmune disease (ulcerative colitis, lupus erythematosus, autoimmune thrombocytopenia) or drug intake (chlorpropamide, methyldopa etc).
Aims: We report an interesting case of a patient with autoimmune thrombocytopenia who presented hemolysis caused by anti-jka autoantibodies.
Methods: The patient was a 63 year old male with a history of immune thrombocytopenia diagnosed 15 years ago, drug-resistant tuberculosis and mild anemia (Hb 11.7 g/dl, Ht 34% at steady state). The patient had not been transfused within the last 9 years.
Results: In May 2013, he presented deteriorating anemia which was attributed to both hemolysis (LDH increase to 652 IU/dl and unconjugated bilirubin 3,2 gr/dl) and gastric blood loss (melena). Cross-matched blood units were found incompatible. The direct antiglobulin test (DAT) was positive (3+) with polyspecific antiserum, weakly positive with monospecific anti-IgG (+ weak), and strongly positive with anti-C3d (4+). The DAT was negative with anti-IgA, anti-IgM and anti-C3c monospecific antisera. The indirect antiglobulin test (IAT) was positive. For identification of the antibody in the serum, we used a commercial panel (BIORAD's) of eleven cells. Elution of the antibodies coating the red cells was performed with the acid elution technique and commercial reagents (DiaCidel's Elu-Kit). The IAT was positive with the gel test LISS-Coombs technique at 37 º C (low ionic strength saline as enhancing agent, incubation at 37º C) and clearly indicated anti-jka specificity. The same antibody specificity was identified in the eluate. The results were negative with the 11 enzyme-treated cells of the panel. The patient's red blood cells were positive for both the jka and the jkb antigen of the Kidd system. All jka-negative red blood cell units were found compatible with the patient's serum. All the above indicate that the patient had autoantibodies showing anti-jka specificity. The patient was transfused with 2 compatible units of jka-negative red cell concentrates and was administered high dose corticosteroid treatment with satisfactory response (the Hb level stabilized and LDH normalized). Two months later all tests were repeated and gave the same results, but additionally the panel of enzyme-treated cells gave positive results indicating anti-jka, too.
Summary and Conclusions: Anti-jka autoantibodies were formed in a patient with immune thrombocytopenia and drug-resistant tuberculosis. The antibodies activated complement and caused moderate hemolysis. Strange enough, at the time of the initial identification, the antibodies did not give a positive reaction with enzyme-treated panel cells, which happened upon control, later on. The DAT and IAT were still positive two months later while the hemoglobin was stable and the patient was transfusion-independent. In this case it is unclear whether the autoantibody formation was related solely to the autoimmune disorder or to a drug received for the tuberculosis.

PB1987

WHICH PATIENTS CAN BENEFIT FROM PREOPERATIVE AUTOLOGOUS BLOOD DONATION?

IM Parra Salinas[1,*] JJ Mateos-Mazón[2], A Uresandi Iruin[2], JA García-Erce[3], E Landeta Callejo[2], I Amarika Ibarrondo[2]
[1]Hematology, Miguel Servet Universitary Hospital, Zaragoza, [2]Baracaldo Universitary Hospital, Baracaldo, [3]San Jorge Hospital, Huesca, Spain

Background: Preoperative autologous blood donation (PABD) brings benefits for recipient, transfusion services and hospitals. Advantages of PABD are reduction of infectious disease transmission, decrease of alloimmunization, transfusion-asociated reactions, post-operative thrombotic events and other immunologic efects such as transfusion-related-immuno-modulation (TRIM), transfusion-asociated acute lung injury (TRALI), graft-*versus*-host disease, transfusion refractoriness, among others. Other benefits of PABD are blood availability for patients with unusual blood group or immunohematologic problems, diminution in global blood reserves, hospital costs, length of in-hospital stay and even in judicial complaint. Nevertheless, alternatives of allogenic blood transfusion are not innocuos and they not always accomplish cost-effective criterion
Aims: In accordance with the abovementioned it is neccesary to evaluate programs of PABD and proceed to create correction and/or improvement strategies to apply more effective protocols having into account patient´s, surgery and even surgeon characteristics.
Methods: We retrospectively revised PABD experience (2007-2012) of the Tranfusion Service at Baracaldo Universitary Hospital. We defined *effectiveness* as the percentage of patients who exclusively received autologous blood transfusion with respect to the total patients transfused, and *Yield* as the ratio between transfused units/removed units in patients included in the program. The PABD program at this center consists on the extraction of one unit per week, beginning 30 to 35 days before the surgery and finalizing at least one week before it. We prescribe oral iron since the first appointment and until two months after surgery.
Results: 193 patients (71♀ and 122♂) were sent to PABD consultation. Global effectiveness was 74,2%. Twenty three (11,9%) patients were excluded from

PABD, eleven of them required allogenic transfusion. Despite there are no important differences in global transfusion rates among included and excluded cases (50,6% *vs.* 47,8%), these latest patients were transfused with minor values of hemoglobin (7,8 g/dL *vs.* 8,9 g/dL, *p <0,001)*. 86 (50,5%) patients from the 170 patients included at PABD, required transfusion and 14 (8,2%) of them needed allogenic blood. Global yield was 44%. Patients who showed statistically greatest yield were: 50 years old or younger (p=*0,048*), hemoglobin values at pre-anesthetic evaluation between 14.4 -15.6 g/dL (p=*0,005*) and maxillofacial surgery (p=*0,043*). There is a direct negative correlation between hemoglobin values at pre-anesthetic evaluation and yield in patients of knee surgery (*Spearman Rho: -0,478,* p=*0,002*), woman (*Spearman Rho: -0,362,* p=*0,004*) or older than 50 years old (*Spearman Rho: -0,232,* p=*0,025*). Overtransfusion risk were observed in patients included at PABD program, men (38,2% *vs* 11,9% in women, p=*0,004)*, younger than 50 years old (39,5% *vs* 16,7% in older than 50 yeras old, p=*0,012)* or maxillofacial surgery. The total quantity of removed units during the period reviewed were 338 units, and we observed adverse effects related with extraction in 6 patients, none of these events were severe and the most frecuent was hypotension (*n*=4).

Summary and Conclusions: PABD program at this center is a secure alternative of allogenic blood transfusion in most of patients without increasing postoperative morbi-mortality. Likewise, it is a usefull strategy in specific cases.

PB1988

TRANSFUSION INDICATION PREDICTIVE SCORE [TIPS]: A PROPOSED RISK STRATIFICATION SCORE FOR PERIOPERATIVE RED BLOOD CELL TRANSFUSION IN CARDIAC SURGERY

AZ Al-Riyami[1,*] M Al-Khabori[1], M Mukaddirov[2], H Al-Sabti[2]
[1]Hematology, [2]Surgery, Sultan Qaboos University hospital, Muscat, Oman

Background: Allogeneic packed red blood cell (PRBC) transfusion is known to be associated with increased morbidity and mortality in cardiac surgery. A number of scores have been developed to predict the risk of perioperative blood transfusions.

Aims: This study was performed to derive a score to predict the risk in our patients.

Methods: Clinical, surgical and laboratory details of all patients underwent cardiac surgery at the Sultan Qaboos University Hospital (SQUH) over five years were reviewed. We used univariable and multivariable logistic regression to develop the score, the Hosmer-Lemeshow test for calibration, the receiver operator curve for discrimination, and the bootstrap procedure for internal validation of the derived score.

Results: The studied sample included 413 patients with mean age of 58±12 (16-87) years. Seventy-four percent of patients underwent coronary artery bypass, 20% value surgery and 6% had other procedures. The following were found to be statistically significant transfusion predictors (score given): cerebrovascular disease (4), use of aspirin or clopidogril within seven days of surgery (3), non elective surgery (2), hematocrit (Hct)<35% (2), underlying Glucose-6-phosphate dehydrogenase (G6PD) deficiency (2), use of cardiopulmonary bypass (CPB) (2), age > 60 years (1), diabetes mellitus (1) and male gender (-2). We classified the observations into three groups: group 1 including observations with total score of <2, group 2 including observations with total score of 2-5 and group 3 including observations with total score of >5. The calculated probabilities of receiving transfusion were 42%, 63% and 91% for groups 1, 2 and 3 respectively.

Summary and Conclusions: We derived a simple score that can be utilized to assess the need of blood transfusion in patients undergoing cardiac surgery. We are the first to report G6PD deficiency and history of cerebrovascular disease as predictors. We recommend prospective external validation of the proposed score on a larger cohort of patients.

PB1989

FACTORS AFFECTING POST-TRANSFUSION PLATELET INCREMENTS AND REFRACTORINESS IN CHILDREN WITH HEMATOLOGIC AND ONCOLOGICAL DISEASES

WE Ibrahim[1], I Ragab[1,*] HM Afifi[2], SK Sallam[1]
[1]Pediatrics, [2]clinical pathology, Ain Shams University, Cairo, Egypt

Background: Children with aplastic anemia and cancer receive frequent platelets transfusion but most of them became refractory to transfusion during their treatment course

Aims: to study the frequency of platelet refractoriness among the hematologic and oncologic patients in an Egyptian University center, to identify the determinants of platelet refractoriness including the immune causes by evaluating the antiplatelets antibodies and the non-immune causes.

Methods: A cross sectional study was performed including 60 children with onco-hematologic diseases necessitating platelets transfusions and admitted at Ain-Shams university pediatrics hospital ,hematology-oncology unit . They were divided into 2 groups; thrombocytopenia secondary to aplastic anemia and secondary to childhood cancer. Revision of hospital records for diagnosis and its date, history of platelet transfusion , bleeding, its site and severity, number of platelets transfusions prior to testing, drugs used with emphasis on amphotericin B/vancomycin/ ciprofloxacin. Laboratory investigations including complete blood picture prior to platelet transfusion, 1 hour post transfusion, and 18-24 hours after transfusion with calculation of platelets increments and corrected count increment .Poor response to platelets transfusion was considered if CCI is less than 5000. Screening for antiplatelet antibodies was done by platelets immunofluorescence test using flowcytometry.

Results: Oncology group were 26 children with mean age ±SD 7.67±4.59 years , 14 females (53.8%) and 12 males (46.2%) and aplastic group were 32 children with mean age 10.03±4.65 years, 13 females (40.6%) and 19 males (59.4%).52.9% of the oncohematological patients have CCI <5000 .There was no significant difference between patients with CCI above and below 5000 as regard gender, diagnosis, type of platelet transfused, blood group, age , frequency of transfusion, frequency of fever or use of concurrent use of ciprofloxacin or amphotericin use .CCI was lower in patients using vancomycin (P=0.029) and with different blood groups (P=0.012).We had a mean platelets increment of 27.04 and 22.77 in the one and 18-24 hours in the oncology group and 13.28 and 9.07 x 10 ^{9}/L in the aplastic group (P=. Aplastic group had higher frequency of transfusion (P=0.010)and longer duration since diagnosis (P=0.013) and lower use of single donor platelets(P<0.001).No significant correlation found between Ab% and CCI at 1h post transfusion and at 18-24 hours post transfusion in oncology & aplastic patients. The best cut off point for antibody levels between positive and negative patients was found > 11.3 with a sensitivity of 96.55% and specificity of 100%.

Summary and Conclusions: Conclusion : we had a frequency of poor platelets response to transfusion of 52%. using non-leuco-reduced platelets products. Platelets antibodies were not correlated with platelets increments. Patients with aplastic anemia had a higher levels of antibodies compared to children with cancer probably due to higher use of random platelets preparation and higher frequency of previous transfusions. CCI was lower in children using vancomycin.

PB1990

OUTCOMES OF THERAPEUTIC LEUKAPHERESIS FOR HYPERLEUKOCYTOSIS IN ACUTE MYELOID LEUKEMIA VERSUS OTHER HEMATOLOGIC NEOPLASMS

IM Parra Salinas[1,*] VP Gonzalez Rodriguez[1], JA García-Erce[2], P Delgado Beltrán[1]
[1]Hematology, Miguel Servet Universitary Hospital, Zaragoza, [2]Hematology, San Jorge Hospital, Huesca, Spain

Background: Hyperleukocytosis is arbitrarily defined as a leukocyte count greater than 100 x 109/L, and typically appears in some hematological neoplasms. Hyperleukocytosis implies a higher morbimortality related to the possible development of leukostasis, tumor lysis syndrome and/or disseminated intravascular coagulation. The number of leukocytes necessary for leukostasis changes with each pathology, owing to, among other factors, different morphological, molecular and plasticity characteristics of the blast cell, as well as the capacity of the endothelial cell to release cytokines. Leukoreduction is a measure to prevent adverse events and death owing to hyperleukocytosis, since it influences cell differentiation in the bone marrow by increasing the proportion of blast cells in S-phase, a fact that translates into increased efficiency of certain antineoplastic agents. Although some scientific societies support leucocytapheresis (LCP) implementation in specific cases, there is insufficient evidence about its use in the early treatment of leukemia with hyperleukocytosis. In addition, the efficiency of LCP remains controversial. The invasive and risky nature of this technique, the need for experienced staff and, in some cases, central venous access, as well as the additional costs and limited scientific evidence proving its effectiveness in global long-term survival are reasons why some centers prefer more conventional treatment in asymptomatic and pediatric patients.

Aims: To analyze the safety and effectiveness of therapeutic LCP as a leukoreduction strategy and its influence on early mortality in our case series, adjusted to the independent mortality risk factors described in the literature. And to compare results obtained between patients with Acute Myeloid Leukemia (AML) *versus* other hematologic neoplasms.

Methods: We did a retrospective review of LCP procedures carried out over nine years (June 2003 to June 2012) for the treatment of hyperleukocytosis at the Hematology and Hemotherapy service of Miguel Servet Universitary Hospital. Data was obtained from patient clinical histories and electronic medical records (Intranet, Modulab, Netbank, Izasa®). Registration during each LCP session in the transfusion unit was performed in a prospective way, to ensure there was no loss of data. At our center, we considered starting LCP

with a leukocyte count greater than 100 x 109/L, or at presentation of leukostasis symptoms. Demographic, clinical, analytical and technical variables were reviewed. Tumor lysis syndrome was defined according to the following criteria: hyperkalemia, hyperuricemia, hyperphosphatemia, hypocalcemia and uremia13. Early mortality was defined as death within the first 14 days after diagnosis.
Results: Thirteen patients underwent a total of 27 leukocytapheresis procedures. After an average of 2 sessions, a statistically significant drop in the initial leukocyte counts was observed ($p<0.01$), as well as a relevant drop (>50%) in lactate dehydrogenase levels. The only analytical value in the global series statistically related to early mortality in univariate analysis was initial creatinine levels greater than 1.2 mg/dL ($p=0.012$, OR=2.5). Patients with acute myeloid leukemia had worse outcomes within 6 months of having finished leukocytapheresis sessions, and in terms of mean global survival and mean time of mortality. However, global mortality rates were similar in patients with and without AML.
Summary and Conclusions: Despite the limited and only slightly homogeneous casuistry of our case series, we can conclude that leukocytapheresis is a safe and effective therapeutic measure for leukoreduction in hematological pathologies of any lineage, primarily in patients without acute myeloid leukemia.

PB1991

THE EFFECTIVENESS OF PLATELETS TRANSFUSIONS AND OXIDATIVE STRESS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA DURING INDUCTION CHEMOTHERAPY

B Davaasambuu[1,*] SV Gritsaev[2], LP Ribakova[3], LR ALeksanyan[3], SI Kapustin[3], AV Koloskov[1], AV Chechetkin[2]
[1]Transfusiology clinic, North-Western State Medical University named after Mechnikov I.I., [2]Hematology clinic, [3]Biochemistry laboratory, Russian Institute of Hematology, St-Petersburg, Russian Federation

Background: The effectiveness of platelets transfusions is dependent on immune and nonimmune factors. Nonimmune factors are fever, sepsis, splenomegaly, disseminated intravascular coagulation (DIC), venoocclusive disease, graft *versus* host disease and others. Development of many nonimmune factors are associated with reactive oxygen species (ROS) formation and disturbance of antioxidant status. So one may suppose relationship between ROS formation and/or antioxidant status imbalance and effectiveness of platelets transfusion.
Aims: The aim was to study the interface of platelets transfusion effectiveness with ROS formation and antioxidant enzymes' activity in patients with acute myeloid leukemia (AML) during induction chemotherapy (ICT) scheme "7+3".
Methods: Data of 15 patients with de novo AML with median age 42 years (31-63) were analyzed. AML was diagnosed according to WHO 2008 criteria. ICT scheme included Ara-C 100 mg/m^2 IV every 12 h 1-7 days and idarubicine 12 mg/m^2 IV 1-3 days. Conditions to start platelets transfusions were platelets level less than $10x10^9$/l or hemorrhagic syndrome irrespective of platelets level or DIC. The effectiveness of platelets transfusions were evaluated by corrected count increment 24 hours (CCI_{24h}). Level of malondialdehyde (MDA) in serum was used to characterize the ROS formation. Antioxidant status was evaluated by activity of antioxidant enzymes like superoxide dismutase (SOD), catalase (CAT) and ceruloplasmine (CP). Collection of peripheral blood (PB) samples was done before and after ICT, during the lowest parameters of PB and after restoration of hematopoiesis. The treatment was begun and PB samples were collected after the signing of the informed consent.
Results: Complete remission was diagnosed in 10 patients (66.6%). Median number of platelets transfusions was 8 doses. Two groups of patients were formed): with effectiveness of ≥50% platelets transfusions (8 patients) and with effectiveness of <50% platelets transfusions (7 patients). In group of patients with effectiveness of ≥50% platelets transfusions gradual decreasing of enzymes with maximal low levels during bone marrow aplasia was found. In a subsequent there was the increasing of enzymes level with maximal activity of SOD. This dynamics of antioxidant enzymes activity was accompanied by absence of MDA level changing significantly. In group of patients with effectiveness of <50% platelets transfusions gradual decreasing of SOD level was found after ICT and in a subsequent period its level remained reduced. Opposite situation was found for 2 other enzymes: there was the trend to increasing level of CP and CAT in most of CP. This dynamics was accompanied by increased level of MDA which did not decrease to initial level after restoration of hematopoiesis although there was some kind of trend.
Summary and Conclusions: Dynamic changes of MDA level and activity of antioxidant enzymes was found in AML patients during ICT. The changes of separate enzymes activity were different in patients with different effectiveness of platelet transfusions. The relationship is unknown. It is possible to suppose that MDA level's excess continuing during all ICT period may contribute to development of such serious complications as infection or damage of vessel endothelium with subsequent formation of consumption syndrome and ineffectiveness of platelets transfusions.

PB1992

SEARCH ROR EVENTUAL BACTERIAL CONTAMINATION OF BLOOD COMPONENTS PRESENTING VISIBLE HEMOLYSIS OR IMPLICATED IN ADVERSE TRANSFUSION REACTIONS

M Pape[1], V Bakaloudi[1], E Chrysoulidou[1], E Ntinopoulou[1], A Konstantinidou[1], F Girtovitis[1], M Xatzikyrkou[1], P Chalkia[1], D Pantelidou[1], V Konstantinou[1], A Tzioura[1], O Perperidou[1], A Vafiadou[1], B Gina[1], E Protonotariou[2], O Vasilaki[2], L Skoura[2], H Hassapopoulou-Matamis[1,*]
[1]Blood Center, [2]Laboratory Department, Ahepa Hospital, Thessaloniki, Greece

Background: The risk of bacterial contamination of blood products still exists despite efforts to conform with all rules of hygiene and safety at each step of the collection and preparation of blood components. Possible mechanisms include: donor bacteremia at the time of donation or contamination during the collection procedure (use of a contaminated bag, poor skin decontamination, entry of air) contamination during the blood processing procedure or during storage. Transfusion of blood components heavily contaminated will result in sepsis and occasionally death, especially in immunocompromised recipients. Contaminated platelets are more commonly associated with adverse reactions than packed red cells, because the storage temperature of platelet units (20-24°C) favors bacterial growth.
Aims: Since issue of relatively fresh blood and the administration of antibiotics to several transfused patients for their underlying disease, might prevent the appearance of fully blown symptoms of bacteremia, we decided to screen for possible bacterial contamination every unit of packed red cells or platelets implicated in a febrile transfusion reaction –both hemolytic and non-hemolytic- and every unit of packed RBCs with visible hemolysis.
Methods: During one year (2013), the Microbiology Department performed bacterial culture of samples from a) 39 units of packed RBCs presenting visible hemolysis (4 collected and processed in our Center and 35 in other Blood Banks) and b) 3 units of platelets and 24 units of packed RBCs, implicated in transfusion reactions characterized by chills, rigor, fever, with or without vomiting, diarrhea etc. Leukocyte depletion had been carried out with post storage and bedside filters in 7 and 6 units respectively. The samples were inoculated into appropriate nutritious materials (Blood Brain Heart Infusion agar, MacConkey agar, Chocolate agar, Sabouraud dextrose agar, Phenylethyl alcohol agar) that allow fast bacteria growth and incubated for 5 days under aerobic and anaerobic conditions. Enrichment broth techniques were also used in order to exclude false negative results.
Results: Of the 66 blood samples cultured, none grew positive.
Summary and Conclusions: Our reassuring results probably reflect the efficacy of: detailed interview and questioning of donors to identify symptoms that might indicate any underlying infectious process; not accepting donors during digestion to avoid transient intestinal bacteremia; meticulous skin disinfection and diversion of the first 30 ml of donated blood; optimal blood component processing and storage. The febrile reaction in the case of non-leukodepleted units (11/24) could be attributed to anti-leukocyte antibodies. The techniques used for bacterial culture were sensitive enough for all microorganisms except for *Y. entercolitica*. However, the absence of severe clinical picture and the excellent outcome is not in favor of such contamination.

THERAPEUTICAL LIPID APHERISIS IN CHILDREN:A SINGLE CENTER EXPERIENCE

Z Salcioglu[1,*] D Tugcu[1], A Akcay[1], S Dal[1], H Sayilan Sen[1], G Keskindemirci[1], G Aydogan[1], F Akici[1], M Gokce[1], N Aktay Ayaz[1]
[1]Pediatric Hematology and Oncology Clinic, Istanbul Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey

Background: Familial hypercholestrolemia (FH) is a genetic disorder which is characterized by high cholesterol levels, spesically very high levels of low density lipoproteins (LDL). Most of FH patients generally resistant drug teratment and diet. Untreated pediatric patients with homozygous familial hypercholesterolemia usually have myocardial infarctions, heart failure, or death by the teenage years. For the last 30 years or so, LDL apheresis has been used and progressively become a mainstay in the management of FH.
Aims: Therapeutical Lipid Apherisis (TLA) decrease LDL and cholesterol. This procedure aim to prevention high risk cardiovasculer disease. We evaluated our TLA procedures retrospectively.
Methods: 180 TLA procedures have succesfully applied 6 FH patients in our center between August 2012 - February 2014. Left ventricular function and valvular status was checked every apheresis therapy. Central veneous cathaters used to intravenous acces for all patients. We used DALI (Direct absorbpsion of Lipoproteins, Fresenius) and Liposorber D-System (Kaneka) for TLA. Blood samples were taken directly before and after each therapy. Blood count, electrolytes, albumin, total cholesterol, LDL, high density lipoprotein (HDL), triglycerides and fibrinogen were measured. Adverse events were documented weekly.

Results: Four of the cases were boys and two were girls. The age range was between 10-15 years (median age 12.5). LDL pre-treatment value was 222 - 900 (mean 444 mg/dl) and the post-treatment value was 64-685 (mean 192 mg/dl). This corresponded to a%57 acute reduction of LDL. Cholesterol pre-treatment value was 267-1014 (mean 514 mg/dl), and the post-treatment value was 88-830 (mean 240 mg/dl). This corresponded to a%53 acute reduction of cholesterol. The resulting data showed a significant decrease in the amount of trigliserid (22%), HDL (24%), albumin (12%), fibrinogen (20%), hemoglobin (9%), platelet (8%) and leukocyte (0.2%).
Summary and Conclusions: Low-density lipoprotein apheresis effectively lowers LDL cholesterol in the short term, but there is little published information on the long-term safety and efficacy of this treatment in children.

KNOWLEDGE,ATTITUDE AND PRACTICE OF BLOOD CONSERVATION STRATEGIES AMONG CLINICIANS IN TWO TERTIARY HOSPITALS IN NIGERIA

S John-Olabode[1,*] A Akinbami[2], M Odesanya[3], O Dada[4]
[1]Haematology, Ben Carson School Of Medicine, Babcock Unversity, Ogun, [2]Haematology, Lagos State University College of Medicine, [3]Oak Hospitals, [4]Medicine, Lagos State University College of Medicine, Lagos, Nigeria

Background: Millions of lives are saved each year through blood transfusions, yet the quality and safety of blood transfusion is still a concern particularly in the developing countries. The need for sophisticated blood processing, storage and cross-matching, coupled with increasing public concerns about the safety of blood products, have fuelled the need for blood conservation strategies to minimize transfusion
Aims: To assess the extent of available knowledge, as well as the attitudes and the utilization of blood conservation strategies amongst medical doctors, who are the implementers of blood transfusion and conservation in clinical practice.
Methods: A cross-sectional study was conducted among doctors in public and private tertiary hospitals. A pre-tested, self-administered questionnaire was devised to collect data. Data was entered and analyzed descriptively and qualitatively.
Results: A total of 104 doctors participated in the study consisting of 57 males (54.80%) and 47 females (45.29%). Almost all participants had transfused blood in their practice and all participants were aware that blood transfusions have complications. Majority 80 (76.9%) had heard about blood conservation techniques, about 51 (49%) had used any of the strategies.
If available, 93 (89.4%) would use any of the strategies, only 1 (1%) would not.
Summary and Conclusions: This study has revealed the need for an effective transfusion committee in our hospitals that will actively educate and increase the drive for utilization of blood conservation methods amongst doctors, so as to increase its practice. More studies will also be required to assess the effectiveness of blood conservation strategies in our environment, with the aim of developing more effective and efficient ways of blood conservation.

PB1995

RED CELL ANTIBODIES IN PATIENTS WITH HEMOGLOBINOPATHIES. REPORT OF A CENTRE

E Kapsali[1,*] E Zervou[2], C Tsaousi[3], C Memmos[1], E Briasoulis[1]
[1]Hematology, [2]Blood Bank, [3]Laboratory of Hematology, University Hospital Ioannina, Ioannina, Greece

Background: Delayed hemolytic reactions and incompatibility problems are sometimes encounterd in blood banks. Such problems arise mainly in heavily transfused patients.
Aims: Patients with hemoglobinopathies (thalassemia major and intermedia, sickle cell syndromes) need regular transfusions. This study is to determine the incidence of red cell alloantibodies and autoantibodies in this group of patients in our centre as well as clinical significance of these antibodies.
Methods: This is a retrospective study of the last decade (2003-2013) that includes data from the blood bank and hematology department involved in the care of patients with hemoglobinopathies. Eighty five (85) patients with thalassemia major and intermedia and 33 patients with sickle cell syndromes are in a regular follow up and transfusion program. Leukodepleted Packed red cell units are transfused. All units are checked for ABO and Rh (D) antigens. Prior to every transfusion sera of the patients are tested for the presence of alloantibodies by indirect antiglobulin test (IAT) and after a positive result antibody identification is performed by a RBC panel Direct antiglobulin test (DAT) is performed every 12 months and in any case of incompatibility. DAT is performed with Dianed ID-Gel and IT with ID –Gel and Capture R assays.
Results: Eighty five patients with thalassemia major and intermedia are in a regular follow-up. Thirty eight (44.7%) of them had positive DAT and IAT tests during the previous ten years. This group includes 17 females age (26-60) and 21 males age (19_66)Most of them had splenectomy dyring their childhood (24/38). DAT was positive in 33 patients (86.8%). IgG was the predominant antibody .Reactivity was 1+-3+, but only two patients had 3+. IAT was positive in 20 patients (52.6%) with specific antibodies identified in 17 patients (anti Fyb,anti-S, anti-Kell, anti-D, anti-e, anti-Kell, anti-kpa, , anti-Cw, anti- Fya, anti-Jka, anti- Leb, anti-Lea, anti-C) Cross matching was impossible in 4 cases and prednisone was given .Three of these patients had more than two antibodies.In the group of sickle cell syndromes patients (5F, 5M) 10 patients (10/33, 30%) had IAT positive test and only one had also DAT positive. Antibodies that were identified include the following : anti-Kell, anti-kpa, anti- Jka, anti-e, anti-Jkb, anti-E,anti- A1, anti-Cw, anti-Fya, anti-D, anti-C. One of these patients had delayed transfusion hemolysis, received prednisone and fully compatible blood transfusions and finally had splenectomy.
Summary and Conclusions: Patients with hemoglobinopathies are in need for regular transfusion. This important therapeutic approach makes them vulnerable in developing auto and alloantibodies against red cell .Pathogenesis of antibodies formation is not fully understood, it seems that patients with sickle cell syndromes who are not regularly transfused are prone for developing alloantibodies more frequently compared to thalassemia patients who acquire autoantibodies and alloantibodies as well.Although most of the times these antibodies have no clinical significance, regular testing with DAT and IAT as well as extended red cell cross matching in some cases is essential for preventing delayed hemolytic reactions and difficulty in identifying compatible red cell units.

PB1996

ACTIVITY OF OXIDATIVE STRESS DURING EFFECTIVE IRON CHELATION THERAPY

SV Gritsaev[1,*] L P Ribakova[2], II Zotova[1], II Kostroma[1], SI Kapustin[2], KM Abdulkadyrov[1]
[1]Hematological clinic, [2]Biochemical laboratory, Russian Institute of Hematology and Blood Transfusion, St.Petersburg, Russian Federation

Background: The toxic effect of posttransfusional iron overload on cardiac and liver tissue is the result of damage caused by reactive oxygen species (ROS). ROS are the consequence of nontransferrin bound iron formation. Previously different positive effects of therapy with deferasirox (DFX) were demonstrated including decreased serum ferritin (SF) level. On the other hand it was recommended to take care with the DFX dose after decreasing SF level till ≤1.000 ng/L. But it is really unclear whether it is necessary to modify the dose of DFX if the SF level reached the specified borderline.
Aims: The aim of the study was to determine the activity of oxidative stress during iron chelation therapy (ICT) with DFX by measurement the concentration of malondialdehyde (MDA) and activity of such antioxidant enzymes like ceruloplasmin (CP) and katalase.
Methods: The data of 8 patients who were treated with DFX during at least 1 year was collected and analyzed retrospectively. The diagnoses were like myelodysplastic syndromes (5 patients), mixed myeloid neoplasm (1 patients), aplastic anemia (1 patient) and pure red cell aplasia (1 patient).
Levels of SF, MDA, and antioxidant enzymes were determined before ICT and then every 3 months after the beginning of treatment with DFX.
Results: The median age of patients was 62 years (33-71). Indications to start ICT were at least 2 of the next conditions: regular RBC transfusions, number of RBC transfused >20 units, SF level >1.000 µg/L and/or transferring saturation >80%. The pretreatment SF level was 3733±1761 µg /L (1037 – 7353). The initial dose of DFX was 10-20 mg/kg/day according to the intensity of RBC transfusion and the aim of ICT. The dose of DFX was reduced temporary in 2 patients because of gastrointestinal toxicities of grade 2-3. Daily dose of DFX did not exceed 20 mg/kg/day. After 12 months of ICT the SF level was decreased on 1544±1063 µg /L (from +182 to -5013); p=*0.026*. In 2 patients the SF was decreased to the level <1.000 µg/L and in 1 patient SF level was not changed after 12 months of ICT. In spite of the biochemical effects of DFX all patients continued to be transfusion dependent. At the same time the concentration of MDA was not changed significantly even in patients with decreased SF level <1.000 µg /L. After 1 year of ICT the activity of CP was decreased from 0,83±0,3 till 0,69±0,1 g/L and activity of catalase was increased from 2,9±1,7 till 4,1±1,5 U/ml but the differences were not significant.
Summary and Conclusions: Treatment with DFX may decline posttransfusional SF level after 12 months of ICT effectively. The remaining high concentration of MDA is a marker of persistent oxidative stress as a consequence of continuing RBC transfusion dependence. So we conclude that ICT with DFX has to be continued all the period when patients transfused with RBC even if SF level is decreased successfully.

PB1997

TRANSFUSION ASSOCIATED GRAFT VERSUS HOST DISEASE IN AN IMMUNOCOMPROMISED PATIENT AFTER AUTOLOGUS HAEMATOPOIETIC STEM CELL TRANSPLANTATION - A CASE REPORT

A Zivanovic-Ivic[1,*] D Stamatovic[1], O Tarabar[1], B Balint[2], L Atanaskovic[1], O Radic-Tasic[3], Z Tatomirovic[3], L Tukic[1]

[1]Military medical academy, Clinic of haematology, [2]Military medical academy, Institut of transfuziology, [3]Military medical academy, Institut of pathology, Belgrade, Serbia

Background: Transfusion-associated graft-vs-host-disease (TA-GVHD) is rare but usually fatal complication of transfused cellular blood components. The incidence of TA-GVHD is uncertain. The three primary risk factors for developing TA-GVHD are: degree of recipient immunodeficiency, number of viable T lymphocytes transfused and genetic diversity in HLA expression between donor and recipient. Diagnosis of TA-GVHD may be difficult at a time due to rarity in occurrence and overlapping clinical features with infections and drug reactions. TA-GVHD present with fever, rasch, abdominal pain and diarrhoea 2-30 days after transfusion. Laboratory data revealed pancytopenia and liver disfunction. Mortality rate is >90%. Death occurs on average 51 days following the transfusion.
Aims: We describe a fatal case of TA-GVHD that occurred after transfusion of blood in an immunocompromised patient who has conducted autologous stem cell transplantation.
Methods: Case report: In a 49 year old men patient (Pt), diagnosis of Myeloma Multiplex was established in 2008. Pt received six cycles of chemotherapy (VAD) prior to autologus SCT. The maintenance therapy was applied after transplantation.One year after the transplantation relapse occured and secondary SCT had been done in pt (in decembar 2009.). In his medical history was partial resection of the sigmoid with coloprotectomiam and J Pouch for familial polopoze sixteen years ago. Posttransplanted autologous hematopoietic reconstitution was done timely. Two weeks after transfusion he presented with fever, nausea,vomiting and diarrhea with normal biochemistry. Infection were excluded. Histopathologic analysis of biopsy Pouch confirmed Pouchitis chronica. But twenty-three days after transfusion on physical examination noted skin rash and patechie all over the body. The raches were diffuse confluent erythematous maculopapular rash over trunk and extremities, which blanches on pressure.His respiratory, cardiovascular and central nervous system examination was normal. Laboratory data revealed pancytopenia (Hb: 8,5g/dL, WBC counts: $2,3x10^9$/L; platelat count $75x10^9$/L). Biochemistry parametar revalead high value SGPT (196 U/L), SGOT (455U/L), LDH (421U/L), serum alkaline phosphatase (276U/L), creatinine (232umol/L). X-ray chest and ultrasonography of abdomen were normal. Histology of bone marow was normal. Histology of skin confirmed TA-GVHD.
Results: He was treated with supportive care therapy with broad spectrum antibiotics and antifungal agents as appropriate. After the evidence TA-GVHD was treated with pulse steroids, then the triple immunosuppressive therapy (Cyclosporin A, Mycophenolate mofetil,steroids). During treatment leads to the development of infection (blood culture grew Staphilococcus aureus). The effect of treatment is reflected in the loss of fever, diarrhea and skin rash with recovery of renal function, of liver function and of blood count parameters. Six months after transfusion leads to deterioration of general condition and development of severe infectious syndromes, pancytopenia, heart and liver failure. Blood culture grew Pseudomonas aeriginosa. Demonstrated reactivation of cytomegalovirus infection. The therapy is turned off CsA, continued implementation Mycophenolate mofetil and again implementation steroids. Eight months after transfusion leads to worsening TA-GVHD and death.
Summary and Conclusions: As in our case, fever, nausea,vomiting and diarrhea, skin rash and patechie all over the body, renal and liver dysfunction were suggestive, but the diagnosis was confirmed at skin biopsy. He is treated with triple immunosuppressive therapy (Cyclosporin A, Mycophenolate mofetil,steroids) complicated with severe infectious syndromes.The reason for pt death is TA-GVHD, but he lived four times longer that the average. Due to its rarity, TA-GVHD requires further investigation in order to define uniform approach and develop treatment and transfusion guidelines.

PB1998

ABO-INCOMPATIBLE IN ALLOGENIC BONE MARROW TRANSPLANTATION

B De Rueda[1],* M Tercero-Mora[1], J Gimeno[1], JA Gracia-Pina[1], V Gonzalez[1], P Delgado[1]
[1]Hematology Department, Miguel Servet University Hospital, Zaragoza, Spain

Background: Practically, the totality of patientes undergoing hematopoietic stem cell transplantation (HSCT) need transfusion support at some point along its evolution. In the HSCT in which there is no existing identity between donor and recipient in the ABO system, it can occur that the recipient presents antibodies which react to the donor's antigens (major incompatibility) , or that the donor presents antibodies against recipient's antigens (minor incompatibility) . If both situations occur simultaneously , it is called mixed incompatibility. The barrier group does not affect the future of TPH , but it can cause more or less severe hemolytic reactions during the recovery period.
It is important to correctly choose the blood group component to transfuse until a stable chimera is achieved, with a complete group change and a negative Direct Coombs Test. In case of major incompatibility, the transfused homoderivatives should be those compatible with the recipient's group. On the contrary, in the case of a minor incompatibility, the transfused homoderivatives should be compatible with the donor's group. In case of mixed incompatibility, will have to transfuse red blood cells group O. The type of immunohaematological complication will depend on the degree of incompatibility . Major incompatibility: delayed or immediate hemolysis, delayed red cell production, pure red cell aplasia . In those patients with minor or mixed incompatibility, we differentiate immediate or delayed hemolysis.
Aims: We collected all ABO-incompatible allogeneic transplants performed at our center in the last 2 years
Methods: It has been analyzed the degree of incompatibility, hemolytic complications and the type and quantity of reed blood cells transfused within 4 weeks after the infusion of progenitors.
Results: A total of 25 allogeneic HLA-identical sibling transplants (17 men / 8 women), 20 of them with myeloablative conditioning and 5 with a reduced-intensity conditioning, were performed. According to pathology: 10 patients with acute myeloid leukemia , 3 with acute lymphoblastic leukemia , 1 with acute leukemia of ambiguous lineage , 3 with myelodysplastic syndrome, 1 with myelofibrosis, 1 with chronic myeloid leukemia, 2 with non-Hodgkin's lymphoma, 1 Hodgkin lymphoma , 2 with bone-marrow aplasia and 1 for multiple myeloma. 5 patients presented ABO incompatibility: 3 with minor incompatibility, 1 with mayor incompatibility and 1 displayed mixed incompatibility. In none of these cases, hemolisys parameters were observed.
The average of red blood cells transfused were 5.2 units (2↔10): 2 in major incompatibility, 6 in minor incompatibility and 1 in mixed incompatibility. The average recovery time for the red series was 31.4 days (12↔74): 14 days in major incompatibility, 27.7 in minor incompatibility and 74 days in the patient with mixed incompatibility.
Summary and Conclusions: The average recovery time of the red series in our cases was 31.4 day , in comparison to those patients who had no ABO incompatibility which was of 21 days approximately.
The patient with mixed incompatibility, there was not an increase of the transfusional requeriments, in spite of a more long time of recovery of the red series.

PB1999

THE INFLUENCE OF ANTI HUMAN LEUKOCYTES ANTIBODIES I AND II CLASS ON PLATELETS TRANSFUSIONS EFFECTIVENESS IN PATIENTS WITH ONCOHEMATOLOGICAL DISORDERS

B Davaasambuu[1],* SV Gritsaev[2], TV Glazanova[3], LN Bubnova[3], AV Chechetkin[2]
[1]Transfusiology clinic, North-Western State Medical University named after Mechnikov I.I., [2]Hematological clinic, [3]Immunological laboratory, Russian Institute of Hematology and Transfusiology, St-Petersburg, Russian Federation

Background: It is supposed that development of human anti-platelet (anti-HPA) and anti-leukocyte (anti-HLA I and II class antibodies – HLA I and HLA II Ab) is the main mechanism of ineffectiveness of platelet transfusions in patients with oncohematological diseases. There are different methods to prevent Ab production including blood products filtration or irradiation. It has been shown that chemotherapy (CT) by itself may inhibit immune system activity and reduce Ab production significantly. However the immune mechanism may lead to the absence of expected increment of platelet number in peripheral blood after transfusions.
Aims: The aim of the study was to evaluate the concentration of HLA I/II Ab during the course of intensive CT, and thus to determine the role of immune mechanisms in development of platelet transfusions ineffectiveness.
Methods: We have analyzed data of 37 patients including 24 with acute myeloid leukemia (AML) and 17 with multiple myeloma (MM). AML patients were treated with induction scheme "7+3" (7 patients) or consolidation CT including high dose Ara-C (17 patients). All MM patients were treated with melphalan 200 mg/m^2 as a conditioning regimen before autologous stem cell transplantation. Corrected count increment 24 hours (CCI_{24h}) was used to determine the effectiveness of platelet transfusions. Solid phase ELISA method (GEN-PROBE: LIFECODES QuickScreen and LIFECODES B-Screen) was used to determine HLA Ab persistence in peripheral blood.
Results: Median age of patients with AML and MM was 42 yrs (23-60 yrs) and 52 yrs (34-65 yrs), respectively. HLA I and/or II class Ab were detected in 34.6% of patients before intensive CT (of them 83.3% – female). Additionally, there were 5 (13.5%) and 3 (8.1%) patients in whom we determined HLA I and HLA II Ab during dynamic monitoring, respectively. The concentration of HLA I and HLA II Ab decreased in 7 (53.8%) and 9 (75.0%) patients, increased in 4 (30.8%) and 3 (25.0%) patients, and was without any changes in 2 (15.4%) and 0 patients, respectively. Different scenarios of platelet concentration have been found. All patients (AML+MM) were distributed in 2 groups according to effectiveness of platelet transfusions. HLA I and HLA II Ab were determined in 1 (3.8%) and 5 (20.8%) patients with ≥50% platelet transfusions effectiveness, and in 12 (92.3%) and 8 (61.5%) patients with <50% platelet transfusions effectiveness. The inverse relationship between effectiveness of platelet

transfusion and presence of HLA I and HLA II Ab was found: *r=-0.881;* p=*0.000* and *r=-0.336;* p=*0.042,* accordingly.
Summary and Conclusions: In spite of the fact that HLA-A I and II class Ab are rare events in patients with oncohematological diseases, our data show that immune mechanisms participate in the development of platelet transfusions ineffectiveness during CT. At the same time, decrease of HLA Ab concentration even during the short period of dynamic monitoring allowed us to suppose that intensive CT may reduce the immune system activity by lowering Ab production and thus, at some degree, prevent the rate of platelet transfusions ineffectiveness. But as there is high incidence of platelet transfusions ineffectiveness, we may conclude that non-immune mechanisms play a principal role.

Non-malignant hematopoietic disorders

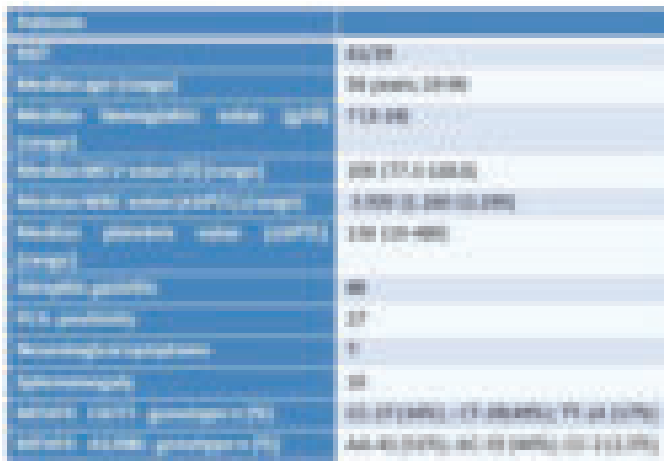
VITAMIN B12 DEFICIENCY: CORRELATION BETWEEN MTHFR POLYMORPHISMS AND CLINICAL AND LABORATORY FINDINGS

S Giammarco[1,*] P Chiusolo[1], L Laurenti[1], F D'Alò[1], G Leone[1], S Sica[1]
[1]Hematology, Università Cattolica del Sacro Cuore, Rome, Italy

Background: Vitamin B_{12} deficiency is a common condition, particularly among the elderly. The classical manifestations include megaloblastic anemia, due to ineffective erythropoiesis, and neurological complication such as peripheral neuropathy, depression, cognitive disturbances and dementia, due to demyelination of the cervical and thoracic dorsal and lateral columns of the spinal cord. Most common causes are pernicious anemia, gastrectomy, ileal resection, atrophic gastritis, long-term vegetarian or vegan dietary. The interaction between folate and B_{12} is responsible for the megaloblastic anemia seen in both vitamin deficiency. Folate metabolism plays an essential role in DNA synthesis and methylation processes. Methylfolate trap hypothesis is based on the assumption that 5-methyltetrahydrofolate (5-MTHF) cannot be transformed back to its precursor 5,10-methylenetetrahydrofolate (5,10-MTHF), because the reaction catalyzed by MTHFR is irreversible. In cobalamin deficiency, methionine synthase is inactive, causing accumulation of 5-MTHF. So trapped 5-MTHF flows out of the cells, leading a progressive cellular loss of plyglutamated folates. The C677T and A1298C MTHFR gene polymorphisms are associated with a decreased enzyme activity. So homozygous genotype may protect patients with reduced methionine synthase activity from defective DNA synthesis because folate metabolism tends to be shifted to thymidylate synthesis.
Aims: Our aim is to examine cobalamin-deficient patients with reduced MTHFR activity, according to the polymorphisms mentioned, in order to evaluate their predisposition to develop anemia, neurological symptom and atrophic gastritis.
Methods: We studied 80 Caucasian patients with a diagnosis of megaloblastic anemia consecutively admitted to our Hematology Division from 2006 to December 2013. All patients were tested for C677T and A1298C SNPS by polymerase chain reaction. By univariate analysis we correlate hemoglobin, MCV, white blood count (WBC), neutrophil count, platelets count, folate and B12 levels, neurological symptoms and presence of atrophic gastritis and positivity of parietal cells antibody (PCA) at diagnosis with the distribution of C677T and A1298C genotypes (Table 1). Statistical analysis was performed using Fisher's exact test and x^2 test.
Results: We found a correlation statistically significant between patients carrying MTHFR C677T homozygous genotype and lower hemoglobin value (P= 0.022), higher MCV value (P=0.05), lower WBC (P=0.03) and lower platelet count (P=0.05). Forty of the 80 patients had a diagnosis of atrophic gastritis documented by istological examination; twentyseven patients were positive for PCA. We found a significant association between patients carrying MTHFR C677T homozygous genotype and patients with a diagnosis of atrophic gastritis and the absence of antiparietal cell anytibodies (P=0.03). MTHFR A1298C polymorphism showed no correlation with all the variables previously analyzed. Moreover the analysis of plasma levels of folate and vitamin B12 showed the presence of low folate levels in patients with gastric biopsy negative (p=0.02) and antibody negative (P= 0.04).

Table 1.



Summary and Conclusions: On the basis of results it can be assumed that MTHFR C677T polymorphism, which shunt folate towards thymidylate

synthesis and away from methionine synthesis, do not protect against macrocytic anemia and it is associated with a lower WBC and a lower platelet count. Moreover we can speculate that impaired MTHFR function could increase susceptibility to atrophic gastritis in cobalamin deficient-patient with PCA negativity.

PB2001

DELTA BETA THALASSEMIA PATIENTS WITH HOMOZYGOUS XMN-1 POLYMORPHISM THAT ARE CHARACTERIZED BY A MILDER PHENOTYPE

S Ashraf[1,*]
[1]Haematology, Sultan Qaboos University, Muscat, Oman

Background: Thalassemia intermedia is an inherited group of disorders with clinical presentations varying between the thalassemia carrier state and thalassemia major phenotype. This variability depends on the heterogeneous molecular mechanism of the disease. db-Thalassemia is a heterogeneous disorder characterized by elevated levels of Hb F in adult life. It is a rare disorder in Pakistan. The homozygous variety Gg (Ag db)^o are rare , present with a wide range of clinical phenotypes, and belong to the group of thalassemia intermedia.
Aims: We determined clinical, haematological and genetic features of Inv/Del G_g ($A_g$db)^o
Methods: Blood samples were first screened for common beta chain mutation found in Pakistani population and then screened for Inv/Del G_g ($A_g$db)^o db, Xmn-1 polymorphism and alpha chains deletions.
Results: We determined clinical, haematological and genetic features of Inv/Del G_g ($A_g$db)^o db in 100 thalassemia intermedia patients, six of which had Inv/Del G_g ($A_g$db)^o mutations, all were homozygous (+/+) for Xmn-1 polymorphism. Among pathological features, high levels of hemoglobin F, late clinical presentation, hepatosplenomegaly, variable transfusion dependence and an absence of alpha chain deletions were observed. This study explains strong link between the Xmn-1 Gg-polymorphism and the Asian-Indian Inv/Del.
Summary and Conclusions: These findings explain the determined capacity of patients to produce fetal hemoglobin in delta beta-thalassemia. These patients lack alpha chain deletions and may potentiate the qualification of factors favouring HbF production as a prominent source of the thalassemia intermedia phenotype.

PB2002

CHALLENGES IN THE MANAGEMENT OF CHRONIC REFRACTORY AUTOIMMUNE CYTOPENIAS IN CHILDREN: SINGLE CENTRE EXPERIENCE

F Fioredda[1,*] M Scalzone[1], J Svhan[1], M Calvillo[1], E Palmisani[1], L Banov[1], M Miano[1], C Micalizzi[1], K Perri[1], C Dufour[1]
[1]Giannina Gaslini Children's Hospital, Genoa, Italy

Background: Autoimmune cytopenias are a group of heterogeneous primary or secondary conditions (mainly Autoimmune Lymphoproliferative Syndrome, ALPS) characterized by immune-mediated destruction of one or more hematopoietic cell lineages. Steroids and intravenous immunoglobulin (IVIgG) alone or in combination represent the drugs of choice. Refractoriness, lack of compliance and risk of early and late side effects may be reasons to change strategy and use other treatment. Immunosuppressors like mycophenolate mofetil (MMF) and sirolimus seem particularly efficacious and safe therapeutic alternatives.
Aims: To evaluate long term efficacy of immunosuppressive agents in chronic refractory autoimmune cytopenias
Methods: Medical records of patients treated at the Unit of Hematology from 1989 to January 2014 have been revised. For the scope of this study definitive and probable ALPS were stated according to the 2009 revised criteria and ALPS related diagnosis was defined if at least one absolute or primary additional criteria was present. Primary autoimmune cytopenia was considered if none of the ALPS criteria was present. Chronicity and refractoriness were defined by disease duration (> 6 months) and by lack of remission or dependence on steroids and/or IVIgG. Alternative therapies used when failure or dependence on first line option occurred were: cyclosporine A, azathioprine, rituximab,methotrexate, 6-mercaptopurine, cyclophosphamide, fludarabine, MMF, sirolimus and splenectomy. The choice of treatment sequence was done according to availability of drugs in the past and more recently according to an institutional protocol, designed according to the current literature. Chi-square test was applied to assess significance in populations'comparison.
Results: A total of 58 patients were considered eligible for the study. 36 (62%) were females and median age at diagnosis was 5,3 years (0.1-15.3y) while median age at last follow up was 13,5 years (1.7-48.5y). Within the whole group, 11/58 subjects (19%) were diagnosed with definitive and probable ALPS, 25/58 (43%) subjects were defined as ALPS related syndrome, while the remaining 22/58 (38%) were classified as primary autoimmune cytopenia. Thrombocytopenia was documented, both isolated or combined with other cell lineage cytopenia, in the majority of subjects (81%). In the whole group, only 4/58 (7%) patients didn't receive any therapy. Among 54/58 (93%) who needed treatment, steroids and immunoglobulin alone or in combination were able to control cytopenia in 16/54(30%); in 38/54 patients (70%) other immunosuppressive regimens were necessary. Nineteen out of 38 patients receiving more than one line therapy (50%) showed complete or partial response to MMF, 13/38 (34%) to sirolimus, 1/38 (3%) to cyclosporine; in 5/38 of cases (13%) the response was not defined because contemporary treatment or the follow up is too short. Treatment failure or transient response was observed using other immunosuppressive agents, monoclonal antibodies and chemotherapies. In one case even splenectomy alone was not able to reach stable remission. Response to immunosuppressive treatment according to subtype of disease is shown in the following Table 1. The efficacy of MMF in ALPS compared to ALPS related and primary autoimmune cytopenia showed a statistical significance (P=0.002, chi square test). MMF and sirolimus have been well tolerated by the patients except transient abdominal pain, nausea, headache and dermatitis in 15% of patients assuming MMF.

Table 1. Response to immunosuppressive treatment according to diagnostic subtype.

Summary and Conclusions: In our experience more than 2/3 of the cohort required more than one line of therapy. MMF and sirolimus allowed to obtain partial or complete, and sustained remission in 82% of patients refractory to other treatment or dependent to corticosteroids. Moreover in patients affected with ALPS, MMF controlled cytopenia in almost all cases. Use of MMF and sirolimus may be considered in primary and secondary autoimmune cytopenia, mainly in resistant diseases thus sparing corticosteroids, cytotoxic chemotherapies and monoclonal antibodies burdened by known side effects.

PB2003

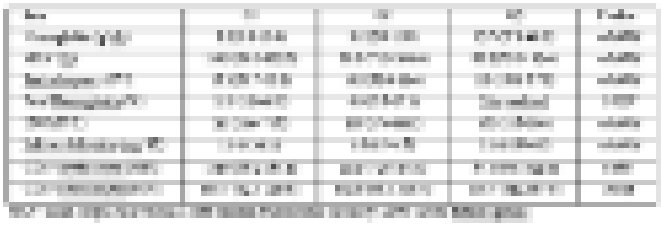
HYDROXYUREA AND CD47 EXPRESSION IN RED BLOOD CELLS IN ADULTS WITH SICKLE CELL DISEASE

G Mecabo[1,*] M Yamamoto[1], EYS Kimura[1], FP Guirao[1], SS Matsuda[1], MS Figueiredo[1]
[1]Hematology and Blood Transfusion Division, Escola Paulista de Medicina, Universidade Federal de São Paulo, Sao Paulo, Brazil

Background: Senescent or abnormal erythrocytes are removed by a particular apoptotic phenomenon called eryptosis. Sickle cell disease (SCD) is known as presenting excessive eryptosis. CD47, a membrane antigen, is an important self-recognition marker and its reduced expression is a trigger to red blood cells (RBCs) phagocytosis. In addition, RBCs are known by their abnormal adhesion to endothelial cells and CD47 has been identified among the molecules involved in these interactions. Hydroxyurea (HU) is the only approved drug for treatment of SCD, since HU improves laboratorial and clinical manifestations, such as hemoglobin level, fetal hemoglobin, and frequency of vaso-occlusive crisis. However, the overall mechanisms involved in the HU action are not fully elucidated. Early studies have shown that HU may increase the expression of membrane proteins, including CD47.
Aims: Due to the increasing interest on the role of CD47 in SCD, we aimed to analyze the expression of CD47 in sickle RBCs and its relationship with HU treatment.
Methods: Fourty patients [70% female, median age 30 years old (range: 18-70y)] in steady state SCD followed at Anemia-Out-Patient Clinic from Escola Paulista de Medicina/UNIFESP were studied. Of those, 20 were in use of maximum tolerated doses (MTD) of HU for more than six months (G1) and 20 without HU (G2). As controls, 10 healthy individuals (G3) were also included. Ethical Committee approved this study, and all patients and control individuals gave their informed consent. RBCs from patients and controls were stained using the Monoclonal Antibodies CD47-FITC (clone B6H12, BD Bioscience) and CD71-PE (clone YDJ1.22, Beckman Coulter®), according to the manufacturer instructions. Data acquisition (100.000 events) and analysis were done using FACS Calibur flow cytometer and CellQuest software (Becton Dickinson, San Jose, CA). Expression of CD47 was evaluated on total RBCs (SSCxFSC) and on reticulocytes (CD71 positive cells) and the results expressed in median fluorescence intensity (MFI). Data were analyzed by non-parametric tests, with α=5%.
Results: The laboratorial data showing the positive effect of HU are presented in Table 1. CD47 expression in patients reticulocytes was higher than in controls

(p=0.043). No difference was seen between G1 and G2 (p=0.291). On total RBCs no difference on CD47 expression among the three groups was observed (p=0.188) (Table 1).

Table 1. Laboratorial data (median, range) of the three groups analyzed: G1) patients in use of HU; G2) patients without HU and G3) normal individuals.



Summary and Conclusions: There are few studies regarding the CD47 expression in SCD, all of them in children. Those studies showed an overexpression of CD47 in erythrocytes and reticulocytes of patients undergoing HU treatment, suggesting that HU acts modulating the adhesion receptor expression. We observed high expression of CD47 in patients' reticulocytes probably due to the high number of immature RBCs. Similar to previous studies, our patients in use of HU presented higher CD47 expression than patients without HU, but without significance. It is important to point out that we studied only adult patients.

Supported by FAPESP (11/17349-0) and CAPES/SUS.

TEN YEARS OF EXPERIENCE WITH MIGLUSTAT IN TREATMENT OF TYPE 1 GAUCHER DISEASE: THE SPANISH ZAGAL PROJECT

P Giraldo[1,2,3,*]M Andrade[1,2,4], P Alfonso[2,3,5], P Irun[3,6], L Atucha[7], A Acedo[8], V Diaz-Morant[9], A Barez[10], M Fernandez-Galan[11], R Franco[1,2], V Giner[1,3], I Loyola[1,4], E Luño[1,5], J de la Serna[1,6], L Villalon[1,7], O Salamero[1,8], M Pocovi[6]
[1]Hematology, [2]Traslational Research Unit, Miguel Servet University Hospital, [3]CIBERER, ISCIII, [4]Researcher Rio Hortega, [5]Traslational Research Unit, IACS, [6]Biochemistry, Molecular and Celular Biology, University, Zaragoza, [7]Hematology, Hospital Basurto, Bilbao, [8]Hematology, Hospital General , Valencia, [9]Internal Medicine, Hospital de Malaga, Malaga, [10]Hematology, Hospital Ntr Sra de Sonsoles, Avila, [11]Hematology, Hospital Virgen del Puerto, Plasencia, [12]Hematology, Hospital Punta Europa, Cadiz, [13]Internal Medicine, Hospital Virgen de los Lirios, Alcoy, [14]Hematology, Hospital Montecelo, Pontevedra, [15]Hematology, Hospital general de Asturias, Oviedo, [16]Hematology, Hospital doce de Octubre, [17]Hematology, Hospital Alcorcon, Madrid, [18]Hematology, Hospital Val dHebron, Barcelona, Spain

Background: The most common clinical variant of Gaucher disease is type 1, which is characterized by anemia, thrombocytopenia, hepatosplenomegaly and
skeletal manifestations. Real-world clinical experience with the substrate reduction therapy (SRT), miglustat (Zavesca®; Actelion Pharmaceuticals), in type1, Gaucher disease (GD1) has developed in Spain since2, 004.

Aims: To report updated follow-up data from a prospective, open-label investigational study that evaluated miglustat in terms of efficacy and safety in naïve GD1 patients and as maintenance in GD1 previously stabilized with enzymatic replacement therapy (ERT)

Methods: The ZAGAL study as a prospective observational study that was initiated in 2004 to establish a set of recommendations for the collection of efficacy, safety and quality of life data in a structured longitudinal manner, and to coordinate the use of miglustat for the treatment of GD1 in real-life settings. Guidelines for miglustat therapy in GD1 were devised by the Spanish Foundation for the Study and Therapy of Gaucher Disease (FEETEG) in order to optimize and standardize miglustat use. All patients received 100 mg miglustat t.i.d. with dietary recommendations to exclude carbohydrates during the first weeks of starting therapy.

Results: We have included in treatment of 53 patients with GD1 who were attending routine clinic visits; 15 naive patients and a further 38 patients who had been switched from previous enzyme replacement therapy (ERT). Long-term changes in organ size, blood counts, disease biomarkers, bone marrow infiltration, bone mineral density (BMD), and overall clinical status were analyzed. Safety and tolerability were also evaluated. Assessments were performed every 6 or 12 months. Approximately 69.8% of patients achieved and maintained therapeutic goals. The plasma biomarkers, chitotriosidase activity and CCL-18/PARC concentration, showed a trend toward progressive increases but did not show a good correlation with clinical activity. Bone marrow infiltration was reduced, as evidenced by a statistically significant decrease in S-MRI scores. Improvements in BMD were also observed after long-term monotherapy with miglustat. In safety and tolerability assessments, 47.1% of patients showed gastrointestinal disturbances and 30% discontinued miglustat therapy for this reason. Nevertheless, gastrointestinal adverse effects were reversible, and symptoms could be improved with a controlled diet, a disaccharidase supplement, and probiotic foods.

Summary and Conclusions: After ten years on follow-up miglustat shown as effective therapy as in naïve with mild or moderate GD1 Spanish patients as in a long-term maintenance therapy in patients previously stabilized with ERT

PB2005

EVALUATION OF ALPHA THALASSEMIA IN CASES WITH HYPOCHROMIC MICROCYTIC ANEMIA: ISTANBUL EXPERIENCE

Z Karakas[1,*] BS Koc[1], S Temurhan[2], T Elgun[2], S Karaman[1], O Devecioglu[1], C Timur[3], Y Yıldırmak[4], T Celkan[5], F Aydın[2]
[1]Pediatric Hematology/Oncology, [2]Medical Biyology, Istanbul University, Istanbul Medical Faculty, Istanbul, TURKEY, [3]Pediatric Hematology, Medeniyet University, Goztepe Research and Training Hospital, [4]Pediatric Hematology, Sisli Etfal Research and Training Hospital, [5]Pediatric Hematology/Oncology, Cerrahpasa Medical Faculty, İstanbul, Turkey

Background: Hypochromic microcytic anemia is a common condition in clinical practice and alpha-thalassemia has to be considered as a differential diagnosis. Alpha thalassemia is not rare in Turkey, carrier frequencies a represented as 2.9-4.1%. Alpha-thalassemia syndromes are caused by defects on one or more of the four α-globin genes. The α-globin gen mutations could be either more commonly deletional or non-deletional. The clinical course is correlated with number of affected genes. Single gen defect causes silent carrier status, while four gen defects cause Hb-Barts and hidrops fetalis.

Aims: The aims of this study were to determine the frequency of alpha-gene mutations in subjects with unexplained hypochromic microcytic anemias and to evaluate genotype-phenotype correlation.

Methods: In this study, 180 children (109 male, 71 female) with hypochromic microcytic anemia not responding to iron therapy were eligible. They were tested for alpha thalassemia after evaluated with Hb electrophoresis for beta thalassemia. Two ml venous blood sample was drawn from each patient into the EDTA tubes for DNA isolation. *in vitro* amplification was made with PCR multiplex method using Biotin marked primers belonging to alpha globin encoding gene zones. Products of the amplification process were investigated for mutations of the alpha globulin genes using the Vienna Lab α-Globlin StripAssay TM commercial kit that includes 21 alpha thalassemia mutations.

Results: Thirteen different mutations were determined in 75 (41.6%) of the 180 patients. The most common mutation was 3.7 single gene deletion (n:34 patients, 45.3%). Others were 20,5 kb double gen deletion (n:12, 16%), MED double gen deletion (n:11, 14.6%), α2 IVS1 (n:8, 10.6%), α2 cd142 Hb Koya Dora (n:6, 8%), α2 poly-A1(Saudi type) (n:5, 6.7%), and α1 cd 14 (n:2, 3%), respectively. Hb Adana, Hb Ikaria, 4.2 single gen deletion, α2 poly-A2 (Turkish type) and FIL mutation were found in 1.3% (n:1) of the patients. Seven patients (9.3%) had alpha thalassemia triplication. Some deletions (-SEA, -THAI) and some mutations (α2 cd19, α2 init cd, α2 cd59, α2 cd125, Hb Paksé and Hb Constant Spring) weren't determined in our patients. The clinical forms were mild hypochromic anemia (silent carrier, n:26,%34.6), moderate hypochromic anemia (alpha thalassemia trait (n:30, 40%), alpha thalassemia triplication, n:5, 6.7%) and non-transfusion dependent thalassemia (NTDT) (Hb H (n:12, 16%) and triplication with Beta thalassemia trait (n:2, 2.6%). The mean Hb values were 11.1 g/dl, 10.8 g/dl and 9.5 g/dl among silent carriers, alpha thalassemia traits and patients with Hb H disease, respectively.

Summary and Conclusions: Triplication causes thalassemia intermedia phenotype when it was together with beta thalassemia trait. The most common clinical form of alpha thalassemia is alpha thalassemia trait among patients with hypochromic microcytic anemia. Alpha thalassemia should be considered in the differential diagnosis of hypochromic microcytic anemia especially in cases without iron deficiency and β-thalassemia carrier state. We were able to diagnose 41.6% of unexplained cases of hypochromic microcytic anemia as a-thalassemia carriers. Alpha thalassemia genetic testing appears cost-effective in an otherwise unexplained, longstanding hypochromic microcytic anemia in Turkey similar to Mediterranean and the Middle East countries.

PB2006

BONE INVOLVEMENT IN SPLENECTOMIZED AND NON-SPLENECTOMIZED PATIENTS WITH TYPE I GAUCHER DISEASE

K Lukina[1], E Sysoeva[1,*] G Yatsyk [2], V Mamonov[3], A Maksimov[2], S Kulikov[4], E Lukina[1]
[1]Department of Orphan Diseases, [2]Department of Radiology, [3]Department of Orthopedics, [4]Department of Biostatistics, Hematology Research Center of Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Gaucher disease is caused by a deficiency in the lysosomal enzyme glucocerebrosidase which leads to accumulation of glucocerebroside in the body, predominantly in the liver, spleen, and bone marrow. Skeletal involvement occurs in 70% to 100% of patients with Gaucher disease and includes a diverse array of symptomatic and radiological findings. Skeletal manifestations do not consistently correlate with the severity of systemic manifestations and contribute much of the morbidity and disability associated with Gaucher disease. Before the era of enzyme replacement therapy splenectomy has been the only treatment option. At present, when effective treatment is available, senvsitive assessment and monitoring of skeletal involvement are critical to timely intervention before permanent disability is incurred.
Aims: The aim of this study was to assess bone involvement in treatment-naïve adult patients with type I Gaucher disease and compare the severity of bone involvement in splenectomized and non-splenectomized Gaucher patients.
Methods: The group included 100 treatment-naïve adult patients with Gaucher disease type I aged from 16 to 79 years (median age 30 years): 36 males and 64 females. Splenectomy was performed in 39 patients in the past when it had been the only treatment option. Standard radiographs and MRI of femurs, hip and knee joints were used to assess the bone involvement. The following criteria were used to characterize bone involvement: bone marrow infiltration with Gaucher cells; osteonecroses in diaphysis and/or metaphyses of femurs; avascular necroses of femoral heads; pathological fractures. Statistical analysis included descriptive statistics, frequency analysis and analysis of variance. All statistical analyses were performed with the SAS software. Statistical significance was defined as a p value <0,05.
Results: Four degrees of bone involvement were established: 1. Mild bone involvement – 14% of patients: bone marrow infiltration with Gaucher cell; 2. Moderate bone involvement – 58% of patients: bone marrow infiltration with Gaucher cells; osteonecroses in diaphysis and/or metaphyses of femure; 3. Severe bone involvement – 25% of patients: bone marrow infiltration with Gaucher cells; osteonecroses in diaphysis and/or metaphyses of femurs; avascular necroses of 1 or both femoral heads; 4. Extremely severe bone involvement – 3% of patients: bone marrow infiltration with Gaucher cells; osteonecroses in diaphysis and/or metaphyses of femurs; avascular necroses of femoral heads; > 2 pathological fractures. Statistical analysis showed that splenectomy was a strong risk factor for severe bone involvement (p<0,0001, OR=6,97 (CI 95% 2,64-18,45). The age when splenectomy had been performed was revealed to contribute: the mean age of splenectomy in patients with severe and extremely severe bone involvement was 11,6 years whereas in patients with mild and moderate bone involvement the mean age of splenectomy was 19,6 years (p=0,03).
Summary and Conclusions: The simple and convenient system for the assessment of bone involvement in Gaucher patients was developed. Splenectomy, especially performed in the early age, is a risk factor for severe bone involvement in patients with Gaucher disease. Hence splenectomy in Gaucher patients might be performed only in urgent cases (*e.g.*, traumatic rupture of the spleen).

PB2007

CORRELATION BETWEEN CEREBRAL AND CARDIO-PULMONARY VASCULOPATHY IN CHILDREN WITH SICKLE CELL DISEASE

V Munaretto[1,*] R Colombatti[1], M Pierobon[1], P Rampazzo[1], G Meneghetti[1], R Manara[1], N Maschietto[1], M Ermani[1], L Sainati[1], G Basso[1]
[1]University of Padua, Padova, Italy

Background: Sickle Cell Disease (SCD) is a systemic disease with heterogenic clinical manifestations. Vasculopathy leads to progressive organ damage in SCD, mainly in brain and lungs. Cerebrovascular disease is evident since childhood while cardio-pulmonary complications manifest in adulthood. Relationship between cerebral and cardiopulmonary organ damage is not clear. In literature there are only few studies and results are contrasting.
Aims: (1) To evaluate prevalence of cerebral and cardio-pulmonary vasculopathy through instrumental examinations in children with SCD; (2) To explore correlation between cerebral and cardio-pulmonary vasculopathy.
Methods: Data were retrospective and systematically collected. We included children with SCD with neurosonology, neuroimaging and echocardiography examinations performed in a maximum 6 month interval. We applied the Stroke Prevention Trials (STOP) criteria to detect altered cerebral velocity by Transcranial Doppler and Transcranial Doppler Imaging (TCD and TCDi); Magnetic Resonance Imaging (MRI) is classified abnormal if there is at least one lesion measuring at least 3 mm visible in at least 2 planes of T2-weighted images. To evaluated vascular lesions at Magnetic Resonance Angiography (MRA) we used a modified Houkin score[4]: when score is > 1, MRA is considered abnormal. To evaluate echocardiography we considerate TRV ≥ 2.5 m/s as threshold for suspect of pulmonary hypertension and functional parameters measured by Tissue Doppler Imaging (TDI).
Results: 38 children (F 18, M 20), mean age 8.67±3.8 years, were included. 95% were Africans. Cerebral Vasculopathy: TCD/TCDi were conditional or abnormal respectively in 16% and 21%. Ischemic silent infarcts on MRI were observed in 42% (bilateral 95%). Intracranial stenosis were detected on MRA in 68% (bilateral 73%). 34% had abnormalities at MRI and MRA, suggesting both small and large vessel vasculopathy. Cardio-pulmonary vasculopathy: The left ventricle, whose mean end-diastolic and end-systolic diameters were increased, showed signs of early diastolic dysfunction in 33%, TRV ≥ 2.5 m/sec in 24%. Statistical analysis showed: (1) correlation between blood velocity at TCDi and stenosis at MRA. (2) linear correlation between volume lesion at MRI and grade of stenosis at MRA in patients with abnormalities at MRI and MRA. (3) correlation between some echocardiographic parameters and cerebral velocity at TCD.
Summary and Conclusions: The systematic assessment of cerebral and cardio-pulmonary vasculopathy shows high prevalence of organ damage since young age. The limited correlation between cerebral and cardio-pulmonary organ damage could be explained by the different ages of onset of vasculopathy in the two vascular beds and needs further prospective evaluation.

PB2008

EVALUATION OF BONE DISEASE BY IMAGING TECHNIQUES AND THEIR CORRELATION WITH PROINFLAMMATORY CYTOKINE PROFILE AND GENETIC VARIABILITY RELATED TO BONE REMODELING IN TYPE 1 GAUCHER DISEASE

J Gervas[1,2], M Andrade[3,4,5,*], M Roca[6], P Alfonso[1,4,7], P Irun[2,7], J Cebolla[2], M Pocovi[2], P Giraldo[3,4,7]
[1]Traslational Research Unit, IACS, [2]Biochemistry, Molecular and Celular Biology, University, [3]Hematology, [4]Traslational Research Unit, Miguel Servet University Hospital, [5]Researcher Rio Hortega, IACS, [6]Radiology, CIBERER, [7]CIBERER, ISCIII, Zaragoza, Spain

Background: Bone disease and bone complications are a major cause of morbidity in type 1 Gaucher disease (GD1), and more than 80% of patients have some type of bone involvement (bone infarcts, osteonecrosis, osteoporosis, spine collapse). The bones in GD may be affected by one of several mechanisms, infiltration by Gaucher cells, secretion of cytokines by these cells which enhance the osteoclastic activity that leads to bone resorption. In addition there are genetic component related to bone remodeling, which may explain 70% of bone mass variability. The combination of bone marrow MRI, bone plain X-ray and the measure of bone density permit to assess the extension and complications of bone disease in GD.
Aims: To evaluate the relation to bone disease indicators and proinflammatory cytokine profiles and some of the relevant polymorphisms related with osteoporosis in GD1.
Methods: Data from 93 adult GD1 patients from the Spanish GD Registry, diagnosed between 1995-2008 and follow-up during at least 5 years, stratified by age and gender, were analysed. Bone marrow changes were evaluated by a semi-quantitative score [S-MRI], bone density was evaluated using calcaneal ultrasound CUBA CLINICAL BONE DENSITOMETER. Analytical study were performed in frozen stored DNA and plasma quantifieation of 9 cytokines (IL4, IL6, IL7, IL10, IL13, MIP1α, MIP1β, TNFα). In addition, the genotype, clinical characteristics, surrogate biomarkers profile were collected. Data were analyzed using Kolmogorov-Smirnov analysis, t-test or Mann-Whitney-U-test, one-Way ANOVA or Kruskall-Wallis test and correlations using the Spearman test.
Results: 43 males (46.2%) mean age: 34.7 years (18-70) and 50 females (53.8%) mean age: 39.3 years (18-68). Concerning S-MRI score the patients were classified as normal 20.4%, mild infiltration12.9%, moderate 29.0% and severe with complications 30.1%. Related to BMD 15.1% had osteoporosis, 17.2% osteopenia and 21.5% normal density. Significant differences were observed among *VDR* TaqI genotypes of normal and bone affected patients (p=0.031) and in MIP-1α concentration between affected and non-affected patients (p=0.016) but with overlap. *VDR* gene codifies vitamin D receptor. Significant positive correlations were found in non-BD group between IL10/IL13/IL4/IL6/IL7; MIP1α/MIP1β/IL6/IL7/TNFα and in bone affected group between IL10/IL4/IL7/TNFα and IL6/IL13
Summary and Conclusions: According our study the splenectomised patients have more severe indicators of bone disease. The VDR TaqI genotype and MIP-1α concentration have a predictive value in GD bone involvement.

PB2009

EARLY DIAGNOSIS OF BONE MARROW NECROSIS (BMN): CORRELATION BETWEEN MRI AND HISTO-PATHOLOGIC FINDINGS

G Elyamany[1,2,*]H Kassem[3,4], O Alsuhaibani[2], Y Elborai[5,6], K Fadalla[7], H Yousif[7], A Al-Abulaaly[2]
[1]Department of Hematology and Blood Bank, Theodor Bilharz Research Institute, Cairo, Egypt, [2]Dept. of Pathology and Laboratory Medicine, [3]Radiology Department, Prince Sultan Military Medical City (PSMMC), Riyadh, Saudi Arabia, [4]Radiology Department, Benha University Hospital, Benha, Egypt, [5]Pediatric Hem/Onc and Stem Cell Transplant, Prince Sultan Military

Medical City (PSMMC), Riyadh, Saudi Arabia, [6]Pediatric Hem/Onc and Stem Cell Transplant, National Cancer Institute (NCI), Cairo University, Cairo, Egypt, [7]Dept. of Adult Hematology/Oncology, Prince Sultan Military Medical City (PSMMC), Riyadh, Saudi Arabia

Background: Bone marrow necrosis (BMN) is defined as necrosis of myeloid tissue and medullary stroma of the hematopoietic bone marrow (BM) and frequently manifests with bone pain, fever, and peripheral cytopenia. MRI is being used increasingly in evaluation of disease of the bone marrow because it is a noninvasive method of imaging large portions of the marrow in a short time. The underlying diseases of BMN are diverse, with the most common being hematological malignancies, followed by non-malignant causes such as sickle cell disease, infections, drugs, and others.
Aims: The purpose of this study is to correlate between the MRI and histo-pathologic findings in BMN, assess the MRI features that distinguish BMN from similar conditions such as avascular necrosis (AVN) and to illustrate the role of MRI in early diagnosis of BMN in cases where hidden hematological malignancy is suspected.
Methods: We retrospectively reviewed the clinical, laboratory and MRI findings of eight (8) cases of histo-pathologically proven Bone marrow necrosis (BMN). The diagnosis was based on the results of BM aspirate and trephine biopsy. MRI was done using a 1.5-T unit (Signa, GE Healthcare). Sagittal T1-,T2-, STIR sequences of the whole spine were performed in all cases. Gadolinium was injected in 6 cases. The histologic findings in each case were reviewed by two consultant hematopathologist and the MR images were reviewed by two consultant radiologists. Informed consent was obtained from patients.
Results: In our study, 4 patients had hematological malignancies with proliferative features (2 cases of acute leukaemia and 2 cases of lymphoma), 2 patients were post-chemotherapy and two patients were known sickle cell disease. In all cases, MRI of the spine showed extensive, diffuse, geographic pattern of signal abnormality consisting of a central area of variable signal intensity surrounded by a distinct peripheral enhancing rim which was serpiginous in 6 cases. Bones other than the spine like iliac bones, sternum and sacrum were involved in 5 patients. Early extraosseous intraspinal anterior epidural extension of disease was present in 4 cases. Marked compression on the spinal cord and cauda equine was detected in 3 patients. Bone marrow aspirate showed blurred, faint cellular outlines (necrotic cells) that appeared as a mixture of smeared cells, bare degenerating nuclei, and cell debris with increased amounts of amorphous pink background material. The BM biopsy revealed that hematopoietic tissue replaced by amorphous eosinophilic material and the trabecular bone had been preserved (Figure 1).

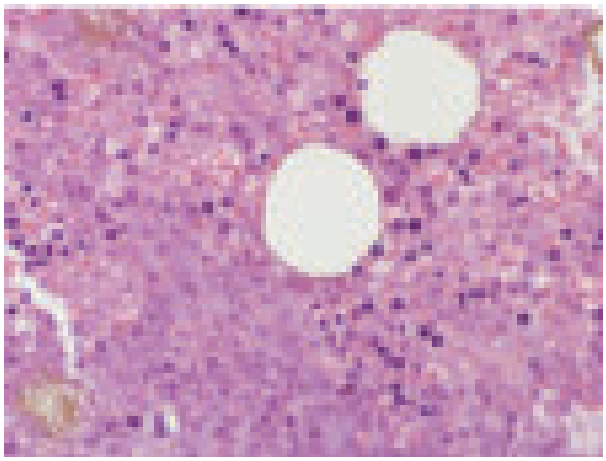

Figure 1. High power of bone marrow trephine biopsy showing areas of necrosis. Note the necrotic cells appearing as eosinophilic cell ghosts.

Summary and Conclusions: Early diagnosis of BMN and its possible underlying hidden malignancy can prevent clinical deterioration and death. MRI plays an increasingly important role in the evaluation of bone marrow disease. Unlike most of the marrow disorders, which often have nonspecific findings, BMN which is a rare clinico-pathologic entity has a distinctive MRI appearance. The lesions in BMN can be differentiated from those of AVN on MRI on the basis of the site, extensive distribution, and natural history of the lesions.

PB2010

AUTOIMMUNE HEMOLYTIC ANEMIA: DESCRIPTIVE STUDY OF 91 CASES

A Bechir[1,*] A Jihed[2], R Haifa[1], BS Nesrine[1], R Amel[2], A Amira[3], BY Yosra[1], L Chedia[2], B Fethi[3], K Abderrahim[1]

[1]Hematology, Farhat Hached Hospital, [2]Internal Medecine, Sahloul, [3]Internal Medecine, Farhat Hached Hospital, Sousse, Tunisia

Background: Autoimmune hemolytic anemia (AIHA) is caused by autoantibody-induced hemolysis (the premature destruction of circulating red blood cells); usually idiopathic, it is also associated with infection, lymphoproliferative disorders, autoimmune diseases, and some drugs.
Aims: Study the epidemiological, clinical, biological, etiological and therapeutic aspects of AIHA.
Methods: This is a retrospective and analytic study about 91 cases of autoimmune hemolytic anemia (AIHA) observed in the hematology and the two internal medicine departments of Sousse, over a period of 14 years. In this work, we have tried to describe the clinical aspects of these AIHA and evaluate the contribution of different diagnosis exploration and therapeutic means used.
Results: There were 33 men and 58 women (sex ratio = 0.56) with a mean age of 51 years [14 – 87]. Regarding the medical history, 19 patients were hypertensive, of whom 8 were receiving Methyldopa, 9 patients were diabetic, 7 had thyroid dysfunction and 18 had a history of autoimmune disease. The circumstances of discovery were an anemic syndrome in 68 of patients, mainly due to paleness and asthenia found in 68 and 60 patient respectively. Physical examination revealed icterus in 42 cases, splenomegaly in 41 cases, hepatomegaly in 8 cases, lymph node in 16 cases and fever in 21 cases. Concerning biology, regenerative anemia was normocytic in 43 cases and macrocytic in 48 cases, thrombocytopenia below 100000/mm3 was observed in 13 patients. There were also biological signs of hemolysis : hyperbilirubinemia in 58 patients, high LDH rate in 60 patients. Direct Coombs test was positive for IgG in 50cases, C 3 in 10cases, Ig G + C 3 in 21cases, IgA in 1 case, IgG+C 3+IgM in 3 cases and cold agglutinins search returned positive in 6cases. There was Evans syndrome in 13 patients. AIHA was idiopathic in 39 cases including 3 cases of pregnancy. In the other cases, it was secondary : lymphoproliferative desorders in 16 cases, autoimmune disorders in 26 cases, 8 cases were secondary to Methyldopa, 1 case was associated with a myelodysplastic syndrome and 1case of CMV infection. The therapeutic consisted of transfusion in 37 cases and all patients underwent a corticosteroid treatment in addition to folic acid therapy in 65 cases and etiological treatment in the non idiopathic cases. We were thus able get a complete remission in 55 cases. In severe cases of chronicity or relapse, immunosuppressive therapy was prescribed in 14 patients, anti-CD20 monoclonalantibody were prescribed in 4 patients and splenectomy was performed in 3 patients.
Summary and Conclusions: Glucocorticoids and/or intravenous immunoglobulins are the mainstay of the treatment in the majority of patients with warm AIHA. When these treatments fail, patients often require cytotoxic drugs or splenectomy. The current research in many other autoimmune diseases that can sometimes be associated with AIHA should still allow a better understanding of the mechanisms involved in the occurrence of these diseases and to refine treatments whose essential aim is to improve the effectiveness of both new and already available treatments (including rituximab) in order to limit the use of corticosteroids.

PB2011

EVANS SYNDROME MANAGEMENT: A MONOCENTRIC RETROSPECTIVE STUDY OF 11 CASES

C Gourguechon[1,*] B Royer[1], JP Marolleau[1]
[1]Clinical Hematology , University Center Hospital, Amiens, France

Background: Evans syndrome (ES) is a rare auto-immune cytopenia disease, characterised by positive direct Coombs auto-immune haemolytic anemia (AHAI) and immune thrombocytopenia (ITP). Lacking of prospective clinical trials, actual Evans Syndrome management is based on empirical data and indirect clues from ITP and AHAI treatment-guidelines. Glucocorticoids and immunoglobulins are usualy the first-line treatments. The efficacy of second-line therapies, as Thrombopoietin-receptor agonist (TPO-ar), splenectomy or rituximab, is not actually well known.
Aims: Describe clinical characteristics, response to treatment and outcome of adult patients with ES.
Methods: Medical records and biologic data of patients with autoimmune cytopenia diagnosis or both anemia and thrombocytopenia in first diagnosis were reviewed for inclusion criteria assessment.
Results: Eleven of the 308 eligible patients fulfilled the inclusion criteria, including 6 women and 5 men. The mean age at diagnosis was 53.8 - +/- 23 years for autoimmune cytopenia and 54.6 + / - 24.1 for Evans syndrome. ITP preceded the onset of AHAI in 6 (54.5%) patients whereas cytopenia occurred simultaneously in 3 cases. A need for transfusion was observed in 4 cases and ITP related bleeding symptoms in 54.5% of patients, with nor life threatening haemorrhage. ES was considered as “primary” in 3 cases and “associated” in others cases (72.7%). Aetiologies were Systemic Lupus Erythematosus (=1), Primary Antiphospholipids Syndrome with venous and arterial thrombosis (=1), Coeliac disease (=1) Chronic Lymphocytic Leukemia (=1), angioimmunoblastic T-cell Lymphoma (=1), IgG1 subclass primary immunodefiency (=1) and 2

patients with undetermined disease (1 atypic lymphoproliferative disorder and 1 lung fibrosis with non granulomatous mediastinal lymphadenopathies). Concerning the management, all patients received oral or intravenous glucocorticoids as first-line treatment and achieved complete response (CR) in 9 cases or and partial response (PR) in 1. Simultaneously intravenous immunoglobulins were used in 5 cases. Second-line treatment was necessary for 5 patients: four patients underwent splenectomy, with relapse in 3 cases and 4 patients were treated with rituximab with constant CR but relapse in 3 cases after a mean follow-up of 15 months for both treatmenst. Others second-line treatments included azathioprine (=3), hydroxychloroquine (=1) and vinka-alcaloids (=1). One patient with CLL benefited from alemtuzumab. Finally one patient was treated with TPO-ar for a severe corticoresistant ITP, relapsing after splenectomy and rituximab, firstly with romiplostim and secondly with eltrombopag, he maintains CR under eltrombopag, allowing oral glucocorticoids withdrawal. Mean follow-up was 5.2 years +/- 5.8. At end of follow-up, 80% of patients were in prolonged response included 6 in CR, 2 in PR. Three patients remain in CR off treatment. Four patients had died during follow-up, at mean age of 72 years +/- 15.8, from underlying lymphoid malignancies.

Summary and Conclusions: ES is rare chronic autoimmune disorder, with recurrent relapses and currently refractory to glucocorticoids. Splenectomy and rituximab seem to be effective as second-line therapies, but with frequent relapse. TPO-ar may be effective for refractory ES-related.

PB2012

INFLUENCE OF THE PROTEIN KINASES INHIBITOR MALEIMIDE DERIVATIVE ON BLOOD CELLS PARAMETERS OF RATS WITH 1,2-DIMETHYLHYDRAZINE-INDUCED COLON CARCINOGENESIS

I Byelinska[1,*] O Lynchak[1], T Rybalchenko[1], V Rybalchenko[1]
[1]Taras Shevchenko National University of Kyiv, Kyiv, Ukraine

Background: Maleimide derivative (MI-1, 1-(4-Cl-benzyl)-3-Cl-4-(CF_3-phenylamino)-1H-pyrrole-2,5-dione synthesized in Taras Shevchenko National University of Kyiv, Ukraine) is a competitive inhibitor of PDK1, VEGF-R1,2,3, Src(h), Syk(h) and other protein kinases. MI-1 inhibits the proliferation of the tumor cells (HCT-116, SW-620 – Colon Cancer and others).

Aims: Histological studies revealed MI-1 decreases the number of colon tumours in rat with 1,2-dimethylhydrazine(DMH)-induced colon carcinogenesis. The aim of the study was evaluation of MI-1 effects in these rat on blood cells parameters.

Methods: The Wistar male rats were divided into 8 groups (8-15 rats per group): I, V (control) – was treated 0.1 ml saline subcutaneous once a week for 20 weeks and/or 0.1 ml sunflower oil *per os* daily for 20 and 26 weeks; II, VI – 20 mg/kg DMH dissolved in 0.1 ml saline subcutaneous once a week for 20 weeks; III, VII – 20 mg/kg DMH for 20 weeks and MI-1 *per os* daily at the dose of 0.027 mg/kg dissolved in 0.1 ml of the sunflower oil for 20 and 26 weeks; IV, VIII – 20 mg/kg DMH for 20 weeks and 2,7 mg/kg MI-1 for 20 and 26 weeks, respectively. The dose of 0.027 mg/kg corresponds to a concentration that caused 50% inhibition of tumor cells proliferation *in vitro*, and the dose of 2.7 mg/kg – 90%. The data were statistically processed using Kruskal-Wallis and Mann-Whitney U-test using SPSS 16.0 for Windows.

Results: Administration of MI-1 at the dose 2.7 mg/kg for 20 weeks to rat with DMH-induced carcinogenesis decreases in the number of reticulocytes (median (25;75 percentile) *0,19 (0,15;0,21);* p=0,006), and trend to increases in MCH (*18,02 (17,44;19,03)* p=0,074) and MCHC (*309,42 (292,38;318,27);* p=0,036) in erythrocytes *vs.* DMH group *(0,28 (0,24;0,39); 17,50 (17,00;17,96)*; *288,10 (284,71;303,73),* respectively). These parameters in group 2,7 mg/kg MI-1+DMH do not differ from the control group *(0,17 (0,15;0,19); 18,31 (17,95;18,45); 310,78 (306,25;316,18),* respectively*)* at the same time in DMH group reticulocytes is increased (p=0,0001), MCH (p=0.002) and MCHC (p=0.007) are decreased. At 26 weeks of DMH-induced carcinogenesis in DMH group hemoglobin concentration (*135,04 (127,16;138,33)* and erythrocytes count (*7,54 (7,46;7,69)*) trend to decrease (p=0,014 and p=0,048) *vs.* control group (*141,02 (135,14;144,32)**;** 7,89 (7,49;8,01),* respectively) and do not differ in 2,7 mg/kg MI-1+DMH group (*141,01 (132,85;146,21); 7,69 (7,46;7,82),* respectively). Administration of MI-1 at the dose 2.7 mg/kg for 26 weeks to rat with DMH-induced carcinogenesis decreases in the number of monocytes *(1,40 (0,95;2,50)* and platelets (*646,32 (575,23;700,50)*) that do not differ from the control group (1,23 (0,94;1,68); *629,34 (590,19;711,48),* respectively) at the same time are increased in DMH group (*1,97 (1,52;2,58)* p=0.008; (*783,90 (687,64;922,27),* p=0.006, respectively).

Summary and Conclusions: MI-1 prevents anemia in rat with DMH-induced colon carcinogenesis, as evidenced by a decrease in the number of reticulocytes and restore mean corpuscular hemoglobin and mean corpuscular hemoglobin concentration in erythrocytes. MI-1 normalizes the number of monocytes and platelets in the blood after 26 weeks of DMH-induced carcinogenesis, reduces the involvement of these cells in the tumors progression. Reduction of the monocytosis and thrombocytosis may be mediated by: 1) decrease in the number and size of tumors and, consequently, the influence of their cytokines on hematopoietic tissue; 2) maleimide oppression of proliferation and differentiation of hematopoietic progenitor cells through inhibiting of VEGFR-kinase and of non-receptor PDK1-, Src- and Syk-kinases, that are involved in hematopoiesis and carcinogenesis.

PB2013

UNUSUAL ASSOCIATION OF CD8+ T-CELL LYMPHOCYTOSIS WITH INVASIVE THYMOMA

HJ Her[1,*] JW Chung[1], HJ Lee[2], SL Chae[1]
[1]Laboratory medicine , [2]Internal Medicine, Dongguk university Isan Hospital, Gouang-si, Korea, Republic Of

Background: T-cell lymphocytosis in association with invasive thymoma is a rare finding. In the majority of previous cases, the lymphocytosis consisted of a mixed population of T cells expressing CD4, CD8, or neither marker and showed a negative result for T-cell receptor (TCR) gene rearrangement.

Aims: We report an unusual case of a patient with a previous history of invasive thymoma and myasthenia gravis who was subsequently found to have pure red cell anemia as well as peripheral blood and bone marrow CD8+ T-cell lymphocytosis.

Results: A 38-year-old woman presented to the emergency department with abdominal pain. She had received a diagnosis of invasive thymoma and myasthenia gravis 9 years prior. The thymoma was treated surgically and followed by chemotherapy and radiation therapy until 1 year prior. A computed tomography scan of the abdomen and chest showed multiple thymoma metastasis involving the lung, pleura, pericardium, liver, both ovaries, and peritoneal seeding. The patient's CBC showed the following: white blood cell count, 44,400/μL (58.9% neutrophils, 34.9% lymphocytes); hemoglobin, 9.5 g/dL; and platelet count, 170,000/μL. Progressive anemia (6.5 g/dL) and persistent lymphocytosis (7,700–31,000/μL) were noted over 3 months. Analysis of a peripheral blood smear showed an increased number of small lymphocytes with dense chromatin, no nucleoli, and scanty agranular cytoplasm. Flow cytometry of the peripheral blood revealed that 78.4% of lymphocytes were T cells with CD3+ and CD8+. The ratio of CD4+/CD8+ cells was 0.13. A bone marrow study was performed, which showed hypocellular marrow with erythroid aplasia and diffuse interstitial infiltration of small lymphocytes. Immunophenotyping by flow cytometry showed proliferation of T cells with expression of CD2, CD3, CD5, CD7, and CD8. The result of TCR gene rearrangement was negative.

Summary and Conclusions: In most reported cases of T-cell lymphocytosis associated with thymoma, lymphocytes consisted of a mixed mature population of T cells, and patients showed only peripheral blood lymphocytosis with absence of extensive bone marrow lymphocytosis. Chronic peripheral T-cell lymphocytosis with bone marrow lymphocytosis generally reflects the proliferation of a neoplastic T-cell clone. The differential diagnosis between reactive lymphocytosis and lymphoma/leukemia is of chief importance in patients with thymoma. Flow cytometric studies and TCR gene rearrangement analysis can establish the monoclonality or polyclonality of lymphocytes and thereby provide the appropriate diagnosis. Our case was diagnosed as T-cell lymphocytosis associated with thymoma, which was confirmed by a combination of lymphocyte morphology, immunophenotyping, and TCR gene rearrangement.

PB2014

ANALYSIS OF CHIMERISM BY QUANTITATIVE REAL-TIME PCR IN PATIENTS RECEIVING ALLOGENEIC STEM CELL TRANSPLANTATION FOR NON MALIGNANT DISEASES

A Contento-Gonzalo[1,*] K Hurst[1], AI Rodriguez-Jimenez[1], A Pascual-Martinez[1], A Jimenez-Velazco[1], AI Heiniger-Mazo[1]
[1]Hematology, Malaga Regional Hospital, Malaga, Spain

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is a procedure to reestablish hematopoietic function in patients whose bone marrow or immune system is damaged or defective, constituting a therapeutic option not only in hematological malignancies but also in non-neoplastic diseases. Chimerism monitoring has become an important tool for assessment and follow up in these patients. New techniques for analysis of hematopoietic chimerism by quantitative real-time PCR (qrt-PCR) amplification of null alleles or insertion/deletion polymorphisms (indels), can detect up to 0.01% of host cells in the post- HSCT period.

Aims: To evaluate the sensitivity of the technique and the relationship between hematopoietic chimerism and the evolution of non-malignant diseases in the post- HSCT period

Methods: We studied 8 patients diagnosed with nonmalignant disorders (1 familial hemophagocytic lymphohistiocytosis, 2 severe aplastic anemias, 1 osteopetrosis, 1 adrenoleukodystrophy, 1 Chediak-Higashi syndrome and 2 immunodeficiencies) diagnosed between January 2007 and 2012 at our center. The median age at diagnosis was 3.1 years (r, 1-9 years) . Matched unrelated donors were used in 7 (87%) cases and 100% (8) were HLA identical. 7 patients

(88%) were infused with bone marrow (BM) and 1 (2%) with cord blood . The conditioning regimens used were 3 busulfan-cyclophosphamide (BUCY), 4 fludarabine-melphalan + antithymocyte globulin (ATG) and 1 fludarabine + cyclophosphamide + Alemtuzumab . Chimerism was determined in DNA extracted from whole peripheral blood samples on days +21, +60, +90, +120, +150 and +180 post- HSCT, by quantitative real-time PCR (qrt-PCR) amplification of insertion/deletion polymorphisms. Qualitative variables were analyzed using chi -square and non-parametric tests were used for quantitative variables.

Results: The median time to neutrophil recovery was 15 days (r, 11-29 days) and platelet recovery, 25 days (r, 15-44 days). 25% (2) developed acute GVHD grade II -IV. No patients developed chronic GVHD. Primary graft failure was observed in 1 patient (12%) and 12% (1) presented secondary graft failure. The median recipient chimerism in patients with acute GVHD was 3.5% at day +21, 1.15% and 1.35 at days +60 and +90, while those without GVHD presented 23%, 18% and 16% on days +21, +60 and +90, respectively. Recipient chimerism was significantly associated with implant failure and subsequent recurrence of underlying disease, showing lower levels of chimerism in those who maintained the graft *versus* those that did not. Mortality was 37% (3) 2 of infectious cause and 1 GVHD.

Summary and Conclusions: New qrt-PCR techniques have proven to be a valuable diagnostic tool for monitoring residual host hematopoiesis in hematological malignancies, however there are no studies that validate its usefulness in non-malignant diseases. In our experience we find that this technique could be used for monitoring these patients with adequate sensitivity to predict implant failure and relapse. However we believe multicenter analysis with larger series are necessary to validate theses results.

Platelets disorders

PB2015

A COLLECTIVE DESCRIPTIVE STUDY OF MANAGEMENT OF IMMUNE THROMBOCYTOPENIC PURPURA (ITP) IN THREE HOSPITALS

D Gunawardena[1,*] N Senadheera[1,2], IS Wijesiriwardena[1], SS Lorensu Hewage[1]

[1]Heamatology, University of Sri Jayawardenapura, Colombo, [2]Heamatology, General hospital,Ratnapura, Ratnapura, Sri Lanka

Background: Adult idiopathic thrombocytopenic purpura (ITP) is an autoimmune disorder caused by antiplatelet autoantibodies that cause platelet destruction by the reticuloendothelial system. The disease has been well-documented in Sri Lanka and the rest of the south East Asia. Since the disease itself gives rise to minimum morbidity and mortality, we often find that the patient suffers from complications of overtreatment rather than the disease itself. Therefore it is vital to have an understanding of "when to treat the patient" which is mostly decided on an individualized patient basis. Countries where expensive treatments such as rituximab and thrombopoietine receptor agonists are not a freely available option, management has to be optimized at an "individual basis". We studied 72 patients with chronic ITP followed up over a minimum period of 2yr to 8yr in three tertiary care hospitals in Sri Lanka. We looked at the age groups and gender, modes of presentation and time taken for response to initial therapy and the current options of therapy with their side effects. Our study evaluates the relationship between the severity of the thrombocytopenia and the incidence of bleeding and thereby to come to a consensus on the best approach to management options.

Aims: To study the characteristics of immune thrombocytopenic purpura(ITP), response and side effects of standard therapy, other possible options of management in three centers in Sri Lanka.

Methods: Retrospective data was collected from 72 patients with diagnosed ITP and followed up for a minimum of 2 years from January 2007, at three tertiary care hospitals in Sri Lanka. Department of Haematology, University of Sri Jayawardenapura. General Hospital, Ratnapura. General Hospital, Gampaha.

Results: The platelet count was below $10x10^9$/l in 40(55%) at presentation.Skin bleeding was the commonest presentation and seen in 37(51%). In 17(23.6%)it was an incidental finding. Out of the total 72 patients, 69 were considered for treatment either due to the degree of thrombocytopaenia (< $30x10^9$/l) or the presence of significant bleeding manifestations. All of them were treated with steroids initially and 67(97%) achieved a platelet count of more than 50 x 10^9/l during the first course.But only 12(17%) patients managed to retain this response and achieve a remission. Out of the patients who relapsed, 6 underwent splenectomy which led to a remission in 3(50%). In the 54(78%) who did not achieve remission, medical second line therapies were not effective. Out of the 69 patients who were treated only 15 (22%) went in to complete remission. Out of the patients who were considered for treatment, 11(16%) had platelets counts less than $30x10^9$/l but were asymptomatic and were managed by a 'watch and wait' policy. Only 1 (9%) of them had bleeding episodes.

Summary and Conclusions: Our study revealed that majority of patients was middle aged females with muco cutaneous bleeding. Most of the study subjects continued to have low counts througout the disease and remained corticosteroid dependent which caused significant long term side effects due to treatment. ITP has a very tumultuous clinical course and assessing each patient and tailoring the management on an individual basis is important. In this study16% of patients with a platelet count below 30 x 10^9/l were safely managed without treatment.

PB2016

PLATELET KINETIC EARLY NORMALIZATION IS A STRONG PREDICTOR OF SUBSTAINED RESPONSE AFTER DISCONTINUATION OF TREATMENT WITH ROMIPLOSTIM IN IMMUNE THROMBOCYTOPENIC PATIENTS.4 YEARS FOLLOW-UP

F Iuliano[1,*] A Perricelli[1], E Iuliano[2], A Pomillo[1], G Cervo[1], F Corea[3], S Fortino[1], D Leone[1], F Barbano[4]

[1]Internal Medicine, U.O di Onco-Ematologia S.O. "N.Giannettasio" ASP1 Cosenza, Rossano (CS), [2]Internal Medicine, Magna Grecia University S.Venuta Campus, Catanzaro, [3]Tor Vergata University , Rome, [4]Nuclear Medicine, Casa Sollievo della Sofferenza, S.Giovanni Rotondo, Italy

Background: Background: (TPO)-receptor agonists (romiplostim and eltrombopag) are new therapeutic modalities in the treatment of ITP. Romiplostim treatment was associated with a number of benefits compared with the standard of care in non splenectomized ITP patients: higher platelet response rate, lower rates of treatment failure and splenectomy, fewer bleeding events, and fewer blood transfusions. As reported in different case series only 15% of patients achieve a durable response after treatment discontinuation

Furthermore, there are no criteria to identify patients potentially cured and that could stop therapy. For all these reasons we have carried out a study of platelet kinetics in all patients treated with TPO- receptor agonists and we have identified a subset who achieved a normal platelet kinetics and that is no longer relapsed 4 years after discontinuation of the drug.

Aims: To validate the study of platelet kinetics as a predictor of response to therapy with romiplostim and if the its early normalization can identify a subset of patients who may discontinue the drug .

Methods: A total of 18 adult patients, female (63%),median (range) age 55 (31 – 78) years, median (range) baseline platelet count 19 (3 – 32) x 109/L.,median of 4 (1 – 7) prior ITP therapies, received romiplostim administered once weekly sc, with dose adjustments to maintain platelet counts in the target range of 50–150x109/L. The median time since ITP diagnosis was 6,8 years (range, 0.6–12.8 years) and 10% had undergone a splenectomy. Patients received romiplostim for a median of 98 weeks (range, 18–104); taking the average weekly dose of all patients, the median was 4 mcg/kg. Home administration was started by 16% of patients (3/18) but 2/3 patients discontinued home administration and resumed weekly outpatient injection. All patients achieved a platelet count 50x10^9/L.

Results: Results: 3 out of 18 experienced thrombocytosis and rebound thrombocytopenia. A PKS with (111)In oxine-labeled autologous platelets was performed in all patients failing steroid treatment, before romiplostim was started. A gamma function was used for the calculation of platelet mean life span (MLS) that was greatly reduced in 100% of patients.3 patients, who had achieved early a stable platelet count 150x109/L. despite the discontinuation of romiplostim maintain normal platelet count after 48 months of follow-up. Stricking a second PKS six months after starting the treatment showed in these subset, a normal platelet half-life with normal uptake on the spleen and liver.

Summary and Conclusions: In our opinion early PKS normalization is a strong predictor of sustained responses after discontinuing romiplostim without additional therapy and may easily detect patients cured by the drug.

PB2017

THROMBOEMBOLISM RISK IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA (ITP)

MH Hu[1,2,*]YC Liu[2,3]
[1]Division of Haematology and Oncology, Department of Medicine, Cardinal Tien Hospital, New Taipei City, [2]Division of Haematology and Oncology, Department of Medicine, Taiepi Veteran General Hospital, Taipei City, [3]Department of Medicine, Taipei City Hospital, Taipei, Taiwan, Republic of China

Background: Patients with immune thrombocytopenia (ITP) may be at increased risk of thromboembolism because of the abnormal platelet function.

Aims: This study aimed to characterize risk of thromboembolic events in ITP patients.

Methods: We retrospectively evaluated 239 patients (107 men, 132 women; median age: 61 years) diagnosed between January 1997 and August 2011. Every patient received steroid treatment according to the platelet count and the extent of bleeding. Logistic regression analysis was used to identify risk factors associated with the development of thromboembolic event after ITP diagnosis.

Results: Sixty-four (26.7%) patients had operation after ITP diagnosis. Among those who had operation, most of them were treatment-responsive (complete response 63.7%, response 18.9%) and had manageable postoperative blood loss (<250ml) (89.1%). Ten patients (4.2%) developed a thromboembolic event after diagnosis. Multivariate analysis revealed that operation (HR 9.998, 95% CI 1.999~50.004, p=0.005) and higher platelet count (>30.0 ×10^9/l) at diagnosis (HR 4.636, 95%CI 1.157~18.574, p=0.03) were independent risk factor for thromboembolism (Table 1).

Table 1. Demographic and clinical characteristics of patients with immune thrombocytopenia.

Summary and Conclusions: ITP patients who had operation have increased risk of thromboembolism, although clinical bleeding was minimal and manageable. Patient who had higher platelet count (>30.0 ×10^9/l) at diagnosis also have increased risk of having thromboembolic event.

PB2018

THROMBOPOIETIN RECEPTOR AGONISTS (TPO-RA) IN REFRACTORY IMMUNE THROMBOCYTOPENIC PURPURA (ITP): ABSENCE OF CROSS-RESISTANCE BETWEEN ELTROMBOPAG AND ROMIPLOSTIM IN TWO PATIENTS.

L Scaramucci[1,*] A Tendas[1], P Niscola[1], D Piccioni[1], A Perrotti[2], M Giovannini[1], P de Fabritiis[1]
[1]Hematology, Sant'Eugenio Hospital, [2]Hematology, San'Eugenio Hospital, Rome, Italy

Background: The recent availability in clinical practice of thrombopoietin (TPO) receptor agonists (TPO-RA), such as eltrombopag and romiplostim, which are effective in increasing the platelet count by stimulating TPO receptor on progenitors of megakaryocytic and inducing their proliferation and maturation with relatively low toxicity, has lead to important advances in the therapeutic management of ITP.

Aims: The potential absence of cross-resistance between the two drugs, likely due to their different mechanisms of action, is illustrated by the following description of two cases, recently observed by us, with therapeutic response symmetrically opposite to these thrombomimetic drugs, having these two patients failed previous treatment with one or the other agents.

Results: The first case regarded a 54-year old female (Patient A, Figure 1) with an ITP which was refractory to steroids and intravenous immunoglobulins (IVIG); the patient was also unresponsive to romiplostim, which dosage was appropriately escalated and maintained at the maximum weekly dose of 10 mcg/kg for about 4 weeks. So that, eltrombopag (50 mg/day) was started (Figure 1). A prompt platelet response (platelet count: 41 × 10^9/L) was observed 1 week after the start of treatment (Figure 1). A complete response was achieved after other 4 weeks of treatment, being the patient on 50 mg/day of eltrombopag without any adverse events. However, at that time, after four additional weeks of eltombopag, the platelet count exceeded 350 × 10^9/L. Therefore, eltrombopag was withdrawn. Since then, 19 months after treatment discontinuation (Figure 1), her platelet count was maintained between 189 and 367 × 10^9/L; the last platelet count performed in February 2014 was of 312 × 10^9/L. The second case (Patient B, Figure 1) was a 73 years old woman with a 5-years history of steroid-refractory ITP and occasional IVIG requirement. She refused splenectomy so that eltombopag was started at the dose of 25 mg/day and then escalated to 50 mg/day and finally 75 mg/day; the last dose was maintained for 4 weeks without any benefit (Figure 1). Therefore, she was started on gradually increasing subcutaneously doses (from 1, 3, 7 to 10 mcg/kg/week) of romiplostim for a total of eight weeks, achieving platelet counts higher than 20 and 80 x 10^9/L after 4 and 8 weeks respectively. To date, about 29 months after the first dose (Figure 1), a normal platelet count is maintained by romiplostim without any side effects.

Figure 1.

Summary and Conclusions: In conclusion, we suggest that further confirmation of a distinct pattern of response and the absence of cross-resistance between these two thrombomimetic drugs should be explored by prospective studies by directly comparing the two TPO-RAs.

PB2019

EFFICACY AND SAFETY OF ROMIPLOSTIM FOR TREATMENT OF INMUNE THROMBOCITOPENIA (ITP): EXPERIENCE OF A SINGLE CENTER

C Stoica[1], S Lakhwani[1,*] JM Raya[1], M Fernández-González[1], B Soria[1], P Pecos[1], MJ Rodríguez-Salazar[1], MT Hernández[1]
[1]Hematology, Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain

Background: ITP is an autoimmune disease characterized by increased platelet destruction and suboptimal platelet production. Thrombopoietin receptor agonists (TRA) romiplostim and eltrombopag have changed in the last years the treatment of ITP. Both can increase platelet production without acting on the immune system, and they are approved for treatment of chronic ITP in adults.
Aims: To describe the efficacy and safety of romiplostim use for ITP in our center.
Methods: We retrospectively analyzed a total of 20 adult patients at our institution, who were treated with romiplostim for ITP. Clinical and biological parameters were recorded as well as treatment response and tolerability.
Results: Our series comprises 9 men and 11 women with a mean age of 59 years (range 19-85). All the patients received steroids as the first line treatment. After that, 65% received rituximab, 65% received anti-D immunoglobulin and in only 25% splenectomy was performed before starting romiplostim. None of them had been previously treated with eltrombopag. The mean number of previous lines before romiplostim was 2.7 (range 1-4), and only 3 patients (15%) received romiplostim as second line. Romiplostim was effective, increasing platelet count over 50.000/mm^3, in 75% (15/20 cases) of our adult ITP patients. However, only six of these patients (30%) are still on treatment. For the remaining 9 patients in whom romiplostim was successful, the evolution was as follows: four patients achieved a resolution of ITP and they are currently without treatment; two patients stopped the treatment after 4 and 43 months, because of poor adherence; finally, three patients died while they were on treatment with normal platelet count. The average dose among patients in which romiplostim was effective was 2.9 µg/kg/week. In five patients (25%) romiplostim was not effective, and the maximum dose they received ranged from 5 to 10 µg/kg/week before stopping the treatment. Two of these patients died while they were on treatment without response. Change of TRA from romiplostim to eltrombopag took place in 5 patients due to three circumstances: lack of efficacy (2 cases), platelet count fluctuations (1 case), and poor adherence (2 cases). In this setting, eltrombopag was effective in 4 of these 5 cases (80%). We have analyzed if age, duration of the disease, number of previous lines of therapy, the previous use of rituximab or anti-D immunoglobulin, or previous splenectomy, may be associated with efficacy of romiplostim. We found statistically significant association only with the number of prior lines, with a higher probability of efficacy in patients with fewer prior lines (p=0.033). In terms of drug tolerability, our results were: no adverse effect in 12 patients (60%); a mild adverse event (grade <2) which did not require decrease or suspension of any dose, mostly headache, joint and muscle pain, in 5 cases (25%); an adverse event grade 3 (headache) requiring dose reduction was observed in two patients (10%); finally, only one patient (5%) presented a severe adverse event, grade 4 (deep venous thrombosis and pulmonary embolism) which required temporary suspension of the treatment. Five deaths occurred on treatment, but none of them seems to be related to romiplostim; three of them (60%) had an infectious etiology, in which previous immunosuppressive treatments may have played some role.
Summary and Conclusions: In our series, romiplostim was effective in 75% of ITP adult patients, including ITP resolution in 20% of cases. The number of prior lines of therapy seems to be related to the efficacy of treatment, achieving a better response those patients with fewer prior lines. In our experience, tolerability to romiplostin is quite good and only a dose reduction or a temporary suspension of the drug is occasionally required.

PB2020

RITUXIMAB IN HAEMATOLOGICAL AUTOIMMUNE DISEASES: A SINGLE CENTRE EXPERIENCE

MP Simula[1,*] E Usala[1], A Emanuele[1]
[1]Ematologia e CTMO Ospedale Oncologico Cagliari, Cagliari, Italy

Background: Rituximab is a anti-CD20 monoclonal antibody broadly used in the treatment of lymphomas CD20+ that have shown efficacy also in the treatment of autoimmune disorders.
Aims: We report the outcome results of 21 consecutive adult patients (14 females and 7 males) with autoimmune diseases treated with Rituximab in our Hematology Department. Sixteen of them had primary immune thrombocytemia (pITP), 1 ITP secondary to HCV infection, 1 cyclic ITP, 2 suffered from autoimmune hemolytic anemia (AHA), 1 from Evans syndrome (ES). All the patients received Rituximab after failure of at least one previous line of therapy (always including also steroids) or after relapse. Tirthteen had a standard dose (SD) of Rituximab (375 mg/m^2 weekly for four administrations) and 8 low dose (LD) (100 mg flat dose weekly for four administrations); all patients but 2 completed the planned 4 doses of drug: 1 of these, a pITP patient, had 3 administrations and the other (the ES patient) had only 2 doses because of sudden hearing loss considered probably related to the drug.
During the therapy with monoclonal antibody all of our patients continued low doses steroids that stopped when the response occurred.The median age at infusion of Rituximab was 55 years (range 26-80 y).The median time between diagnosis and Rituximab therapy was 43 months (range 1-345).
Results: The overall response was 61.9% (13/21: 11 females (78%) and 2 males (28%)), particularly 9 out of 16 pITP patients had a complete response (CR) (56%), the HCV associated ITP had a partial response (PR) (100%), the 2 AHA had a CR as the Evans syndrome patient (100%). Only 2 of the responders relapsed (15%), they had both pITP (relapse rate: 22%) and their recurrence of disease occurred after 6 months in one case and 71 months in the other. Tirthteen patients were less than 60 years old (62%) and 8 more than 60 y (38%) at the time of anti-CD20 immunotherapy; in the first age group 6 responded (46%), in the older one 7 (87%) (p 0.058). Considering only pITP: 4 (25%) received Rituximab in the first year of disease, 12 (75%) after 1 y and between those 9 (56%) after 5 y; the responses were 75%, 37%, 44% respectively (p 0.38). The median time to response was 1.4 months (range: 5 days-8 months) and its median duration 17.6 months (1-70). Nine of 11 patients still in response had a follow up (FU) shorter than 2 y (81%), 2 (19%) had a longer FU time. Considering the dose, 7 of the recipients of SD responded (54%) , so did 6 of those had LD (75%). P(0.058). Considering sex of responders 11 were females and 2 males (p 0.026). The side effects were 4, reported in 3 patients: we observed a grade 1 neutropenia, a grade 1 abnormal liver function test , 1 reversible hearing loss and 1 relapse of a sarcoma.
Summary and Conclusions: Our experience confirms that Rituximab is an effective and safe therapy option in the management of autoimmune diseases and, although the small number of people analyzed could represent a limitation, does show better response in females but there was not significant differences according the age, the dose of the drug and the duration of the disease.

PB2021

A SURVEY OF THE ETIOLOGY OF IMMUNE THROMBOCYTOPENIA (ITP)

N Haq[1], S Darwish[1], V Arias[1], J Stein[2], E Shabbir[1], J Bussel[1,*]
[1]Department of Pediatrics, Division of Hematology, Weill Cornell Medical College-New York Presbyterian Hospital, New York, [2]Biostatistics Unit, The Feinstein Institute for Medical Research North Shore- LIJ Health System, Manhasset, United States

Background: Immune Thrombocytopenia Purpura (ITP) is an autoimmune disorder characterized by accelerated platelet destruction and suboptimal platelet production. Patients with ITP have variable disease progression and response to treatment indicating that ITP has a heterogeneous etiology. Factors contributing to this heterogeneity are not well understood.
Aims: To determine patterns relating socioeconomic, environmental and lifestyle factors associated with treatment response in ITP patients.
Methods: A self-reported prospective questionnaire-based study was created based on literature searches and 45 ITP patient interviews. The survey was reviewed by Platelet Disorder Support Association (PDSA) members and hematologists, revised and then administered to ITP patients at Weill Cornell Medical College-New York Presbyterian Hospital. The survey comprising of 83 multi-step questions relating to socioeconomic, environmental and other patient characterization factors was given to 110 patients or the patients' parents if the patient was <18 years old. 95 subjects were analyzed for the treatment responses (15 did not receive treatment) and all 110 subjects for overall patient characteristics. Associations between responses to rituximab and thrombopoietic (TPO) agents (Eltrombopag and/or Romiplostim), and potential factors influencing ITP were assessed using chi-square and fisher's exact test. All analyses were performed using SAS version 9.3 (Cary, NC).
Results: Patients were between 1 - 89 years old (median age: 37 years). Of 110 patients, 19 had ITP for<6 months, 80 had ITP for > 6 months and 11 did not specify duration. Rituximab treatment outcomes: 63 subjects received Rituximab, of which 21 had complete response (CR), 10 partial response (PR), and 32 no response (NR). Factors significantly associated with poor response to Rituximab included: more stress prior to diagnosis, specifically having a relative pass away (p=0.001 for CR/PR *vs.* NR and p=0.007 for CR *vs.* NR); easy bruising/increased petechiae (p=0.027 for CR *vs.* NR) and exercise infrequency prior to diagnosis (p=0.025 for CR *vs.* NR). TPO agent treatment outcomes: 56 subjects received TPO agents, of which 45 had CR, 8 PR, and 3 NR. Factors significantly associated with poor response to TPO agents included subjects experiencing fatigue prior to diagnosis (P=0.02 for CR *vs.* PR *vs.* NR); frequent drinking of cranberry juice prior to diagnosis (p=0.005 for CR *vs.* PR *vs.* NR) and having diabetes (P=0.007 for CR *vs.* PR *vs.* NR).
Summary and Conclusions: Preliminary analysis in this pilot study indicates potential associations between unexpected epidemiologic factors and treatment response. Subjects who did not experience stress from a relative passing away,

exercised more prior to the diagnosis of ITP, and who did not have easy bruising/increased petechiae responded better to rituximab treatment. Subjects who did not experience fatigue, did not frequently drink cranberry juice prior to the diagnosis of ITP, and those who did not have diabetes appeared to respond better to TPO agents. Surprisingly, these results did not identify environmental, chemical or toxic exposures to be related to response to treatment (outcome from). IVIG and steroid responses were too historical to be analyzable and too few patients had had a splenectomy. Based on the initial analysis, an updated, simplified version of the questionnaire will be used in a larger study to identify sub-groups of patients in whom onset of ITP and other characteristics can be related to outcomes including but not limited to treatment response.

PB2022

PREDICTORS OF PLATELETS COUNT IN PEDIATRIC PATIENTS WITH CONGENITAL CYANOTIC HEART DISEASE

R Matter[1], I Ragab[1,*] A M Roshdi[2], A G Ahmed[1]
[1]Pediatrics, [2]cardiology, Ain Shams University, Cairo, Egypt

Background: Congenital heart defects are the commonest non-infectious causes of mortality in newborns in the western world. Erythrocytosis, thrombocytopenia, platelet function defects, coagulation factors deficiencies are the main hematologic disorders described in cyanotic congenital heart disease.
Aims: to assess the immature platelets fraction in pediatric patients with congenital heart disease and thrombocytopenia compared to non thrombocytopenic , detecting the risk factors that may predispose patients with congenital heart disease to low platelet count
Methods: The study included 60 pediatric patients with congenital cyanotic heart diseases attending at pre-catheter visit at Ain-Shams University-cardiology department between October 2012 and July 2013.Patients were subjected to history taking including data for age , gender , type of congenital cyanotic heart disease, age of onset of cyanosis , cyanotic episodes and their frequencies , drugs and family history. Physical examination included anthropometric measures, oxygen saturation by pulse-oximetry and vital signs. Laboratory investigation included *complete blood count (CBC)* using Coulter Counter GEN-S (Coulter Corporation, USA), *C-reactive protein (CRP)* by latex agglutination test using spectrum kits latex (Fortress, England), reticulated platelet count as a marker of platelet production using Sysmex XE-2100 (Sysmex, Japan), *Prothrombin Time* (*PT*, Pro Time) test, *Partial thromboplastin time* (*PTT*) and D-dimer for patients with thrombocytopenia.
Results: Our patients had a median age of 18.5 months and interquartile range of 51 months 30, (65.2%) males and 16 (34.8%) females. Nine patients had transposition of great arteries, 30 patients had tetralogy of Fallot, 6 patients had double outlet right ventricle and one of them had single ventricle. There was no significant difference between patients with thrombocytopenia and patients with normal platelet count as regard demographic data or clinical presentation, type of congenital cyanotic heart disease or C-reactive protein status. Immature platelets fraction (IPF) was higher in patients with thrombocytopenia 14.15±5.2 compared to non-thrombocytopenic 6.68± 3.39(P=0.003), and PT was longer (17.08±3.37, 13.99±1.41 sec, P= 0.01 respectively) with no difference in PTT between both groups (P=0.272). A significant positive correlation was found between platelets count with D-Dimer and a significant negative correlation with PT and IPF. A significant positive correlation was also found between IPF and hemoglobin, RBC count , Hematocrit, PT and reticulocytic count, and a significant negative correlation between IPF and MCHC, D Dimer, platelets count, reticulocyte hemoglobin content and platelets large fraction. Patients with different types of CCHD had no significant difference as regard platelets count. There was significant higher RDW and D Dimer in patients with TOF. There was significant higher mean platelet volume and PT in patients with CRP positive compared to those with CRP negative.
Summary and Conclusions: thrombocytopenia was detected in 13% of the screened pediatric patients with congenital cyanotic heart disease. Immature platelets fraction as a marker for platelets production; together with D-dimer were elevated in patients with thrombocytopenia suggesting peripheral platelets destruction as an underlying mechanism for thrombocytopenia. RBC count ,hemoglobin level, hematocrit and reticulocyte hemoglobin content as a marker for iron deficiency were not significant determinants for platelet count.

PB2023

THROMBOTIC THROMBOCYTOPENIC PURPURA AND SJOGREN SYNDROME, A RARE ASSOCIATION

R Mendes Silva[1,*] M Santos[1], R Guilherme[1], E Cortesao[1], L Rito[1], ML Ribeiro[1]
[1]Hematology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Thrombotic thrombocytopenic purpura (TTP) is a rare and serious disease that is potencially lethal without prompt recognition and treatment. The classic pentad of symptoms consists of microangiopathic hemolytic anemia, thrombocytopenia, renal impairment, central nervous system involvement and fever. However, virtually any system may be affected. Sjögren's syndrome (SS) is a common autoimmune disease with exocrine gland damage, with special salivary and lacrimal envolvement. TTP is frequently associated with connective tissue diseases (1-6% in general population), but association with Sjogren syndrome (SS) is rare. The etiology remains unclear in about 37% of the cases of TTP and can be associated with autoimmune diseases in 13% of the cases. The association of SS and PTT is a rare condition, with high death rate, only 14 cases reported to date, at our knowledge. Measuring of ADAMTS13 activity is helpful for a correct diagnosis of PTT which has a specific treatment, differentiating it from another thrombotic microangiopathies.
Aims: Report of two cases of TTP in context of a SS, with different clinical outcomes.
Methods: Review of clinical data about two patient admitted in 2013 in our unit with diagnosis of TTP associated with SS. Abnormal levels of ADAMTS13 activity were considered under 40% and abnormal titer of ADAMTS13 antibody above 15 U/l, according to our lab.
Results: Case 1: A 40 year old healthy woman presented to the emergency service (ES) with subit aphasia, hemiparesia and confusion. Images studies were normal. Laboratory data showed Hb 10,1 g/dL, platelets 6 G/L, schystocyte on blood smear, LDH 709 U/l and indirect bilirrubin 1,4 mg/dL. Creatinine and hemodinamic status were normal. Patient started immediately plasma ex-change (PEX), after collecting blood samples for study of an eventual TTP. Extreme low activity (0%) of ADAMTS13 and high level of anti-ADAMTS13 confirmed the diagnosis of acquired TTP. Patient was furtherly studied and autoimmune panel showed strong positivity for anti-SSA60 and anti-SSB what was suggestive of SS, besides lacking classic symptoms of this autoimmune disease. After 6 sessions of daily PEX and corticotherapy, patient was in complete response (>48h of platelets > 150 G/L and no symptoms) and remains stable. Case 2: A 59 year old woman, with know history of SS and already under corticotherapy (5mg prednisolone daily) presented to the ES with epistaxis, gingivorrhagia and mild abdominal pain. Blood analytics showed Hb 12,1 g/dL, platelets 6 G/L, creatinine 1,49 mg/dL (acute renal insufficiency), LDH 1683 U/L, and indirect bilirrubin of 3,2 mg/dL. No schizocytes reported at presentation. Corticotherapy was intensified, but clinical situation deteriorated with appearance of paresthesia and general muscle weakness. Blood smear showed schizocytes and the possible diagnosis of TTP was assumed, with beggining of PEX. Patient became hemodynamic unstable, with neurologic aggravation and elevation of cardiac enzymes. The situation had a quick and inexorable evolution to death. Low levels of ADAMTS13 activity (0%) and very high antibody titer (>99 U/L) confirmed the diagnosis of acquired PTT.
Summary and Conclusions: Either TTP or SS are rare entities. Association of both is far rarer. The combination of SS and TTP has particular high death rate, so high suspicion is essential to quick start of therapy.

PB2024

THE ROLE OF THROMBOPOIETIN RECEPTOR AGONISTS (TPO-R) IN THE TREATMENT OF CHRONIC IMMUNE THROMBOCYTOPENIA OF ADULT-THE EXPERIENCE OF FUNDENI CLINIC OF HEMATOLOGY

I Ursuleac[1,*] AC Colita[1], M Vasilica[1], RA Stoia[1], D Coriu[1]
[1]Hematology, Fundeni Clinical Institute, Bucharest, Romania

Background: TPO-R agonists represent an available therapeutical option for those patients with chronic immune thrombocytopenia (ITP) refractory or with contraindication for splenectomy. The two agents are : Eltrombopag(Revolade) with oral ,daily administration and Romiplostim(N'Plate), with subcutaneously, weekly administration. Clinical trials showed their efficacy in order to maintain a safe number of platelets ~50000/mmc ,prevent fatal bleeding and offer to the patients a good quality of life with few adverse reactions.
Aims: To evaluate indications for TPO-R treatment of patients diagnosed with ITP and clinical evolution after the treatment.
Methods: a clinical epidemiological retrospective study of 33 patients with ITP, treated with TPO-R agonists in Fundeni Clinic of Hematology between 2011-2013.
Results: therapeutical indications were – third line therapy (failure after splenectomy and corticosteroids):6 patients; bridging through splenectomy -11 patients; second line therapy- 13 patients(4 patients with hepatitis C and B active infection, who undergone concomitant antiviral therapy, maintaining normal level of platelets).The age was variable, between 21-68 years old. 27 patients received Eltrombopag and 9 patients Romiplostim. 2 patients received both Eltrombopag and Romiplostim. 29 patients responded with platelets above 50000/mmc,9 of them had a sustained response,maintained after stopped medication :4 after Romiplostim therapy and 5 after Revolade treatment . 2 patients were lost from evidence. During treatment were reported as adverse reactions headache, artralgias and one female patient had a transient episode of hepatocytolysis and cholestasis, but without clinical evidence.
Summary and Conclusions: the TPO-R agonists are a good option for the treatment of ITP refractory patients , for splenectomy bridging or for those with antiHCV/HVB therapy. The terapy is safe, with minimum adverse events. Because of the financial reasons the period of the treatment is limited.

PB2025

NOVEL MUTATIONS IN THE GPIIB GENE IN TURKİSH CHILDREN WITH GLANZMANN THROMBASTHENIA

H Tokgoz[1,*] U Caliskan[2], N Akar[3]
[1]Pediatric hematology department, [2]Necmettin Erbakan University Meram Medical Faculty, Konya, [3]Ankara University medical faculty, Ankarak, Turkey

Background: Glanzmann thrombasthenia (GT) is an inherited disorder of platelet aggregation, characterized by qualitative and quantitative defect on platelet αIIb-β3 integrin (GpIIb/IIIa), resulting in lifelong bleeding tendency due to defective platelet plug formation.
Aims: In this study, we examined 20 patients with Glanzmann thrombasthenia for clinical findings and molecular genetic analysis to determine whether there was any mutation in the GPIIb gene, and a correlation between clinical phenotype and genotype. This is the first genetic study conducted in Turkey about GT.
Methods: There were twelve females and eight males with a median age of 15.25 years. The most common bleeding type was epistaxis (85%). Life threatening bleedings were seen in five patients.
Results: Seven (35%) patients showed various mutations (five novel and two previously described mutations) in the GPIIb gene. Novel mutations including 9079 T>A (p. S416G), 9092 G>T (p. V420L) and 9179 T>A (p. P448T) were located in exon 13. The others including 4466 G>T (p.G159V) and 11453A>G (p.T646A) were located in exon 4 and exon 19, respectively. Previously described mutations including 4420 T>G (p.V147G) and 9607 T>G were located in exon 4 and exon 13, respectively. No correlation was found between clinical phenotype and genotype.
Summary and Conclusions: In conclusion, our findings showed that exon 13 was an important region for platelet aggregation; therefore, we suggest that 13 patients without diagnosis of mutation may have mutations in β3 integrin gene. Furthermore, molecular genetic analysis should be performed in these patients.

PB2026

THROMBOPOIETIN LEVEL IN HCV EGYPTIAN PATIENTS

N El- Husseiny[1,*] HM fahmy[1]
[1]Clinical Haematology Unit, Kaser Al Aini, Giza, Egypt

Background: Thrombocytopenia is a common finding in patients with chronic hepatitis. A variety of pathogenic mechanisms are reported to be implicated in thrombocytopenia related to chronic HCV infection.
Aims: The aim of the present study is to evaluate the role of thrombopoitin (TPO) in pathogenesis of thrombocytopenia in HCV infected patients and to demonstrate if there is a correlation between TPO level and viral load, degree of inflammation and degree of fibrosis.
Methods: This study was carried out on a group of 30 HCV infected patients recruited from Kasr El-Eini hospital. Liver function tests, polymerase chain reaction (PCR) for HCV, complete blood counts, serum TPO levels and abdominal ultrasonography were done to all case. Patients were classified according to their viral load into 3 groups *Group I* (6 cases) with low viral load *Group II* (14 cases) with moderate viral load and *Group III* (10 cases) with high viral load.
Results: showed that platelets count and serum TPO are significantly higher in patients with mild viremia compared with groups with moderate or high viremia . No statistically significant differences were found between group II and III. Liver biopsies were done for 17 patients. It was found that the platelets count is significantly higher in patients with mild inflammation (*Group A)* when compared with patients with moderate inflammation (*Group B)*. Again TPO was found to be significantly higher in *Group A* when compared with *Group B.* When those patients were classified according to degree of fibrosis, the platelet count showed significant relationship with degree of fibrosis being higher in patients with less fibrosis. A positive correlation between platelets counts and serum TPO was found.
Summary and Conclusions: several contributing factors may lead to HCV related thrombocytopenia , of which TPO level which is affected by viral load , grade of inflammation , stage of fibrosis ,being the higher viral load and the more inflammation and fibrosis ,the lower level of TPO and accordingly the lower platelets counts.

PB2027

BONE MARROW EXAMINATION IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA: IS THERE ANYTHING DIFFERENT IN OLDER PATIENTS?

E Gunduz[1,*] B Kara Kivanc[2], M Karagulle[1], D Arik[3], S İsiksoy[3], C Bal[4], OM Akay[1]
[1]Hematology, [2]Internal Medicine, [3]Pathology, [4]Biostatistics, Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey
Background: Immune thrombocytopenia (ITP) is a disorder characterized by immune-mediated accelerated platelet destruction and supressed platelet production. In the bone marrow examinations of patients with ITP, some investigators found megakaryocyte numbers to be increased while others have found them to be normal. Similarly,abnormal megakaryocyte morphology including diminished granularity and decreased nuclear ploidy among other findings were observed by some investigators but not by others. Although recent guidelines recommend against bone marrow examinations in typical ITP patients the recent introduction of thrombopoietin receptor agonists as an effective treatment for ITP has refocused attention on abnormalities of bone marrow megakaryocytes.
Aims: In this sudy, we retrospectively analysed the bone marrow aspiration, flow cytometry-CD45 sidescatter (SSC) and biopsy results of our patients with ITP by dividing them into two groups according to age (<60 years and ≥60 years) and tried to determine the differences between two groups.
Methods: Ninety eight newly diagnosed ITP patients who were admitted between 2010-2013 and who had available bone marrow aspiration, CD45 SSC and biopsy results are included in the study. ITP was diagnosed according to American Society of Hematology criteria with a platelet count below $100x10^9$/L and no cytopenias except iron deficiency anemia. Since all patients with thrombocytopenia (<$100x10^9$/L) undergo bone marrow biopsy regardless of age in our clinical practice, patients are divided into two groups: <60 years old (group 1) and ≥60 years old (group 2). All bone marrow aspirates and biopsies were performed using the same techniqueand the same method of slide preparation. CD45 SSC results were recorded as percentages of normoblasts, granulocytes, lymphoctes, monocytes and myeloid/erythroid ratio. Bone marrow biopsies were evaluated by experienced pathologist. Length of the specimen, cellularity, presence of dysplasia or fibrosis with number, morphology and distributionof megakaryocytes were recorded. Informed consent was obtained from patients.
Results: In group 1 there were 49 patients. Mean age was 41.31±12.77 years, 31 (63.3%) female and 18 (36.7%) male. In group 2 there were 49 patients. Mean age was 70.78±7.88 years, 26 (53.1%) female and 23 (46.9%) male. All blood and bone marrow samples were obtained before starting therapy for ITP. Unfortunately, megakaryocyte numbers on bone marrow aspirates were not recorded in most patients so we could not comment on this point. However, flow cytometry results and bone marrow findings were not different between two groups.
Summary and Conclusions: In conclusion, we could find no difference between bone marrow examinations of young (<60 years) and older (≥60 years) patients with ITP and our study supports that biopsy should not be recommended in typical ITP patients as already mentioned in guidelines.

PB2028

IMMUNE THROMBOCYTOPENIA IN THE ELDERLY: CLINICAL COURSE AND TREATMENT

C Ionita[1,*] I Ionita[1], L Cheveresan[1], M Ionita[1], D Calamar[1], D Oros[1], I Hortensia[1]
1Hematology, University of Medicine and Pharmacy "Victor Babes" Timisoara, Timisoara, Romania

Background: Immune thrombocytopenia (ITP), which is often diagnosed in the elderly, is a hematologic disorder characterized by thrombocytopenia induced by autoimmune mechanism.
Aims: In this study, we evaluated the clinical features, the risk of bleeding and the response to various treatment options in elderly ITP patients (age≥60 yr) at our center from 1980 to 2012.
Methods: A retrospective study for 210 ITP patients was performed in Department of Hematology, County Hospital, Timisoara, Romania. Patients demographics, medical history, current treatments and side effects, were abstracted from the patient's medical charts for the 12 months prior to their most recent visit.
Results: The median age was 65 years with 61% women and 39% men. The median platelet count was 22×109/L (range 1-75×10^9/L) at diagnosis. Median time from the diagnosis of ITP to the start of the observational period was 23 months. Prior to the observational period, 28% of patients had been splenectomized and the most reported treatment was corticosteroids. During the observational period, 65% of all patients were treated. The most frequent reasons given for treatment were platelet count (58%), followed by bleeding symptoms (49%). Corticosteroids represented 63% of treatments, followed by IVIg (20%), azathioprine (8%) and rituximab (3%). Splenectomies (4% of patients) and platelet transfusions (38% of patients) were performed during the observational period. For monitoring the platelet levels, 70% of patients visited their hematologist 1 to 6 times during the observation. Main reasons for a visit were a low platelet count (42% of visits) and bleeding (34% of visits).
In the evaluable 15 patients who died during follow up, eight deaths were considered. To be directly attributable to hemorrhage induced by thrombocytopenia.
Summary and Conclusions: There are more females in the ITP patients over 60 years of age. The risk of bleeding is quite high in elderly ITP patients, but life-threatening bleeding events rarely occur. This study provides the results of treatment practices in our country.

PB2029

CHANGES IN PLATELET AGGREGATION DURING PREGNANCY AND IMMEDIATE POSTNATAL PERIOD

B Hussein[1,*] J Davies[1], K Gomez[1], R Kadir[1]
[1]Haemophilia Centre and Thrombosis Unit, Royal Free Campus, University College London, London, United Kingdom

Background: Platelet dysfunction is implicated in uteroplacental disorders. During the early stages of gestation platelets have important roles in the process of placentation. Platelet function contributes to enhanced haemostasis at delivery. However, there is limited data on the changes of platelet function during normal pregnancy. Understanding physiological changes of platelet aggregation during different stages of pregnancy is helpful for better understanding of pathophysiology of abnormal placentation.
Aims: To assess platelet aggregation during three trimesters of pregnancy and immediate postnatal period in normal healthy women compared to control non-pregnant group.
Methods: Cross-sectional cohort study including a total of 46 women: 10 participants for each trimester, 10 postnatal cases and 6 control non-pregnant women. Case selection was based on specific inclusion criteria. 30mL of venous blood was obtained from each participant following consent. Light transmission aggregometry was performed with Dual channel Payton 600B aggregometer using six platelet aggregating agonist (epinephrine, adenosine triphosphate, collagen, ristocetin, arachidonic acid and U46619).
Results: Platelet aggregation in response to ADP and epinephrine was decreased in 4/10 and 3/10 women in the first trimester, respectively. A significant difference (p=0.0075) was detected in percentage aggregation at 3 minutes induced by epinephrine 2 μM in the first trimester group compared to non-pregnant controls (47% *vs* 82%). In addition, mean aggregation at 3 minutes induced by epinephrine 3μM was reduced in the first trimester (48% *vs* 82%) (p=0.0042). 6/10 and 4/10 women in the third trimester had abnormal aggregatory response to ADP 2 μM and ADP 3 μM respectively. A significant difference (p=0.0005) was detected in percentage aggregation at 3 minutes with ADP 2 μM in the third trimester compared to non-pregnant controls (45% *vs* 81%). One woman had abnormal aggregation response in the third trimester including prolonged lag time and reduced maximal aggregation with collagen, and reduced maximum aggregation with ristocetin 1.5 mg/ml, arachidonic acid and U46619.
Summary and Conclusions: Pregnancy is associated with reduced platelet reactivity in response to epinephrine during early pregnancy and an abnormal aggregation response to ADP in the third trimester. These changes may have important role in the process of placentation in early pregnancy as well as haemostasis at delivery.

PB2030

THE ANTIOXIDANT TREATMENT IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA

AM Gaman[1,2,*] MA Gaman[3]
[1]Hematology, Filantropia City Hospital, [2]Pathophysiology, University of Medicine and Pharmacy of Craiova, Craiova, [3]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background: Oxidative stress (OS) plays a role in the pathophysiology of immune thrombocytopenia (ITP). Several studies revealed increased reactive oxygen species (ROS) levels and a decreased antioxidant capacity in ITP, suggesting a possible antioxidant mechanism of therapy in chronic ITP.
Aims: To evaluate the response of treatment in patients with ITP, with and without antioxidants.
Methods: We studied 24 patients with chronic immune thrombocytopenia hospitalised in the Clinic of Hematology from Craiova (Romania) between 2011 and 2013, with high levels of reactive oxygen species (FORT test) and low antioxidant capacity (FORD test). The patients were distributed in two groups: 12 patients (group A) received only corticosteroids as first line therapy and 12 patients (group B) received corticosteroids and antioxidant supplementation (informed consent obtained).
Results: In group A, seven patients responded to corticosteroids and the non-responders were treated, as second line therapy, with Vinca alkaloid regimens (one), laparoscopic splenectomy (two) or thrombopoietin receptor agonists (two). In group B, eleven patients responded to corticosteroids plus antioxidant supplementation; at one there was necessary a second line therapy (thrombopoietin receptor agonist). Follow-up at one year revealed that all eleven patients who received antioxidant supplementation and had a healthy diet were in clinical complete remission, whereas only seven patients from group A were in clinical remission.
Summary and Conclusions: In our small groups of patients, the antioxidant supplementation had a beneficial role in the response to therapy and the evolution of patients with ITP.

PB2031

DEMOGRAPHICAL AND CLINICAL CHARACTERISTICS OF ELDERLY PATIENTS WITH IDIOPATHIC THROMBOCYTOPENIC PURPURA: A RETROSPECTIVE MULTICENTER STUDY

I Nizam[1,*] H Terzi[2], S Korkmaz[2], M Keklik[3], I Kuku[1], E Kaya[1], M Sencan[2], M Cetin[3], L Kaynar[3], O Ilhan[4]
[1]Hematology, Inonu University, Malatya, [2]Hematology, Sivas University, Sivas, [3]Hematology, Erciyes University, Kayseri, [4]Hematology, Ankara University, Ibni Sina Hospital, Ankara, Turkey

Background: Idiopathic thrombocytopenic purpura (ITP) is a chronic, immune-mediated disease characterized by a temporary or sustained decrease in platelet counts. ITP is associated with various clinical consequences which may be serious, especially for the elderly, when it's not properly treated.
Aims: We aimed to present our experience about 50 elderly patients with ITP from 4 different centers.
Methods: Data from 4 centers in Anatolia were collected and analyzed in order to put forward the demographical and clinical characteristics of elderly patients with ITP over the age of 65.
Results: Total of 50 patients who were above the age of 65 at the time of ITP diagnosis were evaluated retrospectively. Sixty-two percent of the patients were female. The mean age was 71,5±6 (SD) years. Among the comorbidities, hypertension was the most common disease with a percentage of 24%, followed by coronary artery disease and diabetes mellitus, both with a rate of 8% and chronic obstructive pulmonary disease with a rate of 3%. Ninety-two percent of the patients had no organomegaly, while 4% had mild hepatomegaly and 2% had mild splenomegaly and 2% had mild hepatosplenomegaly. Mean followup duration was 31,6 ±25 (SD) months. At the time of evaluation, 94% of the patients were alive, 6% were deceased, and reasons of death were not related to ITP. Mean hemoglobin value was 13,13±1,9(SD) gr/dl. Female patients had statistically significant lower hemoglobin levels, compared to male patients. Mean platelet count was 12.760±10.000(SD)/μl . There was no significant difference between two genders in terms of platelet count. As first line therapy, 86% of the patients were given methylprednisolone, 8% were given dexamethasone and 6% were followed up without therapy. Mean remission duration after first line therapy was 27,9±22,8(SD) months. As second line therapy, 45% of the patients were given methylprednisolone, 35% were given dexamethasone, 10% were performed splenectomy and 10% were treated with other modalities. Ninety percent of the patients responded well to the second line therapy. Mean remission duration after second line therapy was 12,9±8,5(SD) months. Twelve percent of the patients needed third line therapy, where 50% of these were given eltrombopag, 33% had splenectomy and 17% were given rituximab. All patients responded well to the third line therapy. Mean remission duration after third line therapy was 17,9±18,9(SD) months.
Summary and Conclusions: Female and male patients had similar platelet counts, where female patients tend to have lower hemoglobin levels. Female patients had longer remission durations at first line therapy, compared to the male patients and the difference was statistically significant. Studies with larger patient groups should be performed in order to see if there's a difference between genders in terms of response to therapy.

PB2032

HERMANSKY-PUDLACK SYNDROME DURING PREGNANCY: A SYSTEMATIC REVIEW

B Hussein[1,*] A Chaqmaqchi[2], K Gomez[1], R Kadir[1]
[1]Haemophilia Centre and Thrombosis Unit, Royal Free Hospital , London, United Kingdom, [2]Haematology Department, Nanakali Hospital For Blood Disorders and Cancer, Erbil, Iraq

Background: Hermansky-Pudlak Syndrome (HPS) is an autosomal recessive disorder, it is characterised by oculocutaneous albinism, bleeding diathesis and decreased visual acuity. HPS can also cause pulmonary fibrosis, inflammatory bowel disease and renal diseases. The prevalence of HPS is 1 in 500000 – 1000000 and in Puerto Rico is 1 in 1800 with carrier rated 1 in 21.
Aims: To see how does Hermansky-Pudlack syndrome affect the pregnancy, labour/delivery and postpartum period.
Methods: Review of literature of HPS during pregnancy wa performed for the period of 1970 to 2010 which is revealed 7 articles including 11 pregnancies in 8 women (4 were from Puerto Rico).
Results: The commonest bleeding symptoms in these women were menorrhagia, easy bruising and nose bleeding. There was no reported ante partum haemorrhage. Haemostatic coverage for labour and delivery was given in 7 pregnancies, platelet transfusion in 2 and DDAVP in 5 pregnancies. Mode of delivery was emergency caesarean section in 3 pregnancies (all for obstetric indications) and remaining had vaginal delivery. Regional analgesia used in one woman without haemostatic cover and no complications. Postpartum haemorrhage reported in 6 pregnancies (including one who had DDAVP as

prophylactic measure during delivery), 2 required blood and platelet transfusion, 2 received blood alone and one only platelet transfusion. Pregnancy outcome was 10 alive babies without any complications.
Summary and Conclusions: This review revealed a high risk of PPH in women with HPS. Close collaboration between obstetric and haemophilia team is essential to reduce this risk.

Bleeding disorders (congenital and acquired)

PB2033

CIRCUMCISION IN CHILDREN WITH CONGENITAL FACTOR DEFICIENCY
Z Salcioglu[1,*] H Sayilan Sen[1], D Tugcu[1], A Akcay[1], G Keskindemirci[1], G Aydogan[1], F Akici[1], M Gokce[1], N Aktay Ayaz[1], U Guvenc[2], Z Mahmud[2]
[1]Pediatric Hematology and Oncology Clinic, [2]Pediatric Surgery Clinic, Istanbul Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey

Background: Circumcision is the most frequently performed surgical prosedure for religious reasons in Turkey.
Aims: Examination of hemostasis tests carefully before circumcision leads to the recognition of patients with bleeding diathesis. We evaluated 158 records of patients diagnosed as congenital factor deficiency (CFD), underwent circumcision in our clinic between 1990-2014, retrospectively.
Methods: Information of patients were retrieved from patient records and from the records contained in the data-processing environment introduced in 2005. Circumcisions performed with an open method, with dorsal slit technique. Fibrin glue was not used during circumcision procedures. All of the factor preparations were administered as bolus via the peripheral vein. No catheters were used.
Results: Of the patients, 84 (53.2%) had Hemophilia A, 45 (28.5%) FVII deficiency, 11 (6.9%) Hemophilia B, 4 (2.5%) vWF deficiency, while 4 (2.5%), 3 (1.9%), 3 (1.9%), 2 (1.3%), 2 (1.3%) had fibrinogen, FV, FXI, FX, FXIII deficiencies retrospectively. Age of patients ranged from 2 to 24 years (mean 14.4 years). Thirty-four asymptomatic patients were diagnosed before circumcision (21.5%). In 35 patients circumcision were applied without any replacement therapy (22.2%). We used FVIII in 80 patients, FIX in 11 patients, vWF+FVIII in 4 patients, fresh frozen plasma in 13 patients, rFVIIa in 10 patients, PCC in 2 patients and fibrinogen in 3 patients during surgical interventions. Replacement therapy was achieved with single dose in 36 patients for circumcision (29.3%). Also in 87 patients 2-10 doses replacement therapy was needed (70.7%). In 35 patients antifibrinolytic agents were used also (28.5%). Bleeding during and after surgical procedures were observed in nine patients (5.6%). Transfusion was needed in two patients (1.3%). Thrombotic events were not observed. Antibody occurrence was not detected in these patients. No delay in surgical wound healing was noted.
Summary and Conclusions: Children with CFD can be safely circumcised in a center with experience In our study, we evaluated preparation before circumcision factor replacement prior to surgery and postoperative processes in patients.

PB2034

ACQUIRED HEMOPHILIA A WITH IMMUNE THROMBOCYTOPENIA IN ADOLESCENT PATIENT
HS Kim[1,*] SL Jin[1], SM Hahn[1], JW Han[1], CJ Lyu[1]
[1]Department of Pediatric Hematology and Oncology, Yonsei University Health System, Seoul, Korea, Republic Of

Background: Acquired hemophilia A (AHA) is rare autoimmune disorder caused by autoantibodies against coagulation factor VII (FVIII) in the nonhemophilic population. The age distribution of autoantibodies typically biphasic with small peak between 20 and 30 years (mainly postpartum inhibitors) and a major peak in patients aged 70 to 80 years. The incidence of AHA in children is very rare. Indeed, the incidence in children under 16 years has been estimated to be 0.045 per million/year compared with 14.7 per million/year in the elderly over 85 years. Also, immune thrombocytopenia is an acquired immune-mediated disorder caused by increased destruction of platelets opsonized by anti-platelet autoantibodies.
Aims: We experienced a case of AHA with thrombocytopenia caused by autoantibody in 18 years old boy.
Methods: He without any previous bleeding history presented easy bruise on lower extremities and he had diagnosed AHA. A initial activated partial thromboplastin time (APTT) was 136 seconds, the level of FVIII was 0.6% and FVIII inhibitor was 13.1 Bethesda Units (BU). Moreover, platelet counts were low (34,000/uL), and we proved platelet-associated autoantibody. Other autoimmune diseases were ruled out. He was instantly treated with oral prednisolone (1mg/kg/d) and added to oral cyclophosphamide (2mg/kg/d) one week later due to elevation of FVIII inhibitor (14.7 BU).
Results: About seven weeks later after treatment, FVIII inhibitor was disappeared and APTT was normalized, we started to tapering off the medication. During treatment of inhibitor eradication, platelet counts were also increased and normalized.
Summary and Conclusions: We report our experience as first successful antibody eradication for FVIII inhibitor and platelet-associated autoantibody simultaneously in adolescent AHA patient.

PB2035

RADIOISOTOPE SYNOVECTOMY IN PATIENTS WITH HAEMOPFILIA: SINGLE CENTER EXPERIENCE

T Patiroglu[1,*] E Unal[1], M Ozdemir[1], F Mutlu[1], M Kula[2], M Karakukcu[1], S Doganay[3]
[1]Department of Pediatric Hematology, [2]Department of Nuclear Medicine, [3]Department of Pediatric Radiology, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Haemophilic arthropathy represents the most common clinical manifestation of haemophilia, related to recurrent haemarthoses and chronic synovitis. Haemophilic arthropathy is radiologically characterized by destructed articulation, bone deformities, complete closure of intra-articular spaces. Surgical synovectomies are not cost-effective procedures whereas radioisotope synovectomy (RS) is both less invasive and inexpensive procedures. It is accepted that RS is the gold-standart therapy before surgical synovectomy
Aims: We aimed to investigate the efficacy and complications of RS in the patients with haemophilia.
Methods: Twenty five RS were performed in 12 patients with haemophilia A and B, age ranging 6-21 mean (11 years) at the time of RS,for last five years. We preferred to use Yttrium ^{90} (Y^{90}) for knees and ankles, and Erbium ^{169} (Er^{169}) for elbows. Radioisotopes such as Y^{90} and Er^{169} were injected intra-articularly for treating target joints and chronical synovitis.
Results: We have evaluated our experience for knees (n:12), for ankles (n:9) and for elbows (n:4) in total 25 RS procedures for 12 patients. After RS joint bleedings were decreased for all patients. Radioisotop injections were three times repeated in right ankle of one patient. We have observed local hematoma after RS in three patients. For elbows, RS with Er 169 seems to be safe treatment method.
Summary and Conclusions: We had observed that RS was a safe and efficient therapeutic strategy.
Key Words: Haemophilia A and B, Haemophilic arthropathy, radioisotope synovectomy.

PB2036

LUPUS ANTICOAGULANT HYPOPROTHROMBINEMIA SYNDROME WITH SEVERE BLEEDING IN A 4-YEAR-OLD CHILD

H Lahlou[1,*] I Beukinga[1], O Pradier[1]
[1]Laboratory of hematology, Hopital Erasme, Université libre de Bruxelles, Brussels, Belgium

Background: Lupus anticoagulant is an acquired inhibitor which is commonly associated with thromboembolic manifestations. But in some rare cases, the antibody has affinity to prothrombin and patients have hemorrhagic tendency; sometimes they may present with severe bleedings, depending on their factor II level. The association of acquired factor II deficiency and lupus anticoagulant is recognized as "Lupus Anticoagulant Hypoprothrombinemia Syndrome" (LAHS).
Aims: We report a case of a 4-year-old boy with severe bleeding due to LAHS, with spontaneous recovery.
Results: A 4-year-old boy was admitted in pediatric emergency for macroscopic hematuria. He had no other symptom. Physical examination was normal. Initial laboratory evaluation consisted of a urine examination that confirmed hematuria (32833 red cells/µL and 75 leucocytes/µL, without infection) and blood tests revealed a decreased PT (40%) and a prolonged APTT (69.9 sec (24.0 – 35.0 sec)). Platelet count was normal (279 G/L). The measure of clotting factors showed an isolated factor II deficiency (20%). Lupus anticoagulant was positive. C-reactive protein was 10 mg/L (<10 mg/L). An abdominal echography was performed to exclude other hemorrhagic sites and showed signs of gastro-intestinal infection. The patient was diagnosed with LAHS related to gastro-intestinal infection. Two days after his admission, hematuria disappeared. Ten weeks later, a control blood evaluation showed that all parameters became normal. We performed a specific research of antiprothrombin antibodies (INOVA Quantalite) what demonstrated increased rates of IgG and IgM antiphosphatidylserine antiprothrombin (Table 1).

Table 1.

	Patient	Normal values
antiphosphatidyl serine IgG	50,78 U/ml	<11 U/ml
antiphosphatidyl serine IgM	17,49 U/ml	<25 U/ml
antiphosphatidyl serine IgA	2,82 U/ml	<20 U/ml
antiphosphatidylserine/prothrombine IgG	>150 U/ml	30 U/ml
antiphosphatidylserine/prothrombine IgM	>150 U/ml	<30 U/ml

Summary and Conclusions: LAHS was first described in 1960. In 2011, the 74 cases reported between 1960 and 2011 had been reviewed (Mazodier K, Arnaud L, Mathian A *et al.* Lupus Anticoagulant Hypoprothrombinemia Syndrome, report of 8 Cases and Review of the Literature. Medicine 2012; 91: 251-260). LAHS mostly affects young women. But sometimes it occurs in children. It is mainly related to autoimmune diseases, in particular systemic lupus erythematosus, or to acute viral infection. However, few cases of drug-induced LAHS or lymphoma-associated are reported. Clinical features and the severity of bleeding are correlated to the factor II level. According to the review of the 74 cases reported in the literature, some patients were asymptomatic, but 89% of them had hemorrhagic manifestations with severe bleedings in 51%. Macroscopic hematuria was present in 15% of patients. In children, it is generally a transient situation which does not need any treatment, and clinical and biological features usually normalize in few days except when the LAHS is revealing an autoimmune disease or when there are severe complications in relation to the bleedings.

PB2037

DIRECT APTT RATIO (PLATELINLS / ACTINFS) PERMITS TO QUICKLY AND RELIABLY DETECT BLEEDING RELATED FACTOR DEFICIENCY WHEN ISOLATED PROLONGATION OF APTT IS FOUND IN PEDIATRIC PRE-OPERATIVE SC

R Li[1,*] C Swaelens[1], F Vandermijnsbrugge[1], B Cantinieaux[1]
[1]Laboratory of Haematology, Institut Jules Bordet et CHU Saint Pierre, ULB, Brussels, Belgium

Background: Isolated prolongation of activated partial thromboplastin time (aPTT) found during paediatric pre-operative screening could be due to coagulation factor deficiency or more frequently to nonspecific inhibitor like lupus anticoagulant (LA).
Aims: The aim of our study is to evaluate the clinical values of an additional aPTT with ActinFS and/or a mixing aPTT study to identify the bleeding related factor deficiency (BRFD) like Factor VIII, Factor IX or Factor XI deficiency.
Methods: During 4 years, an aPTT with ActinFS and a mixing aPTT were added for 308 paediatric patients in which an isolated prolongation of aPTT with PlatelinLS was found among 9048 pre-operative screening. A direct aPTT ratio between PlatelinLS and ActinFS was calculated. For 156 patients (50.6%), this prolonged aPTT was confirmed in a second sample. Measurements of bleeding related factors (FVIII, FIX and FXI), Factor XII and the LA research were performed respectively in 141,131 and 88 samples.
Results: We found 17 BRFD, 26 FXII deficiency and 64 positive LA. A prolonged ActinFS had a significant association with BRFD ($P<0.0001$) while a corrected mixing study had not. The direct aPTT ratio had a significant association not only with BRFD ($P<0.0001$) but also with positive LA ($P<0.05$). In applying a cut-off value of this ratio as <1,29, the sensitivity and specificity for BRFD were 82% and 76% respectively, while they were 59% and 93% using ActinFS alone. Normal ActinFS was found in 7 mild BRFD cases with factors levels superior to 30%, five of 7 had a direct ratio <1,29.
Summary and Conclusions: The direct aPTT ratio between PlatelinLS and ActinFS without mixing study permits to identify quickly and reliably a BRFD for an isolated prolongation of aPTT found in paediatric pre-operative screening.

PB2038

SINGLE CENTER REGISTRY OF RARE BLEEDING DISORDERS FROM TURKEY

T Patiroglu[1,*] M Ozdemir[1], M Karakukcu[1], E Unal[1]
[1]Department of Pediatric Hematology, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Deficiencies of coagulation factors (except factor VIII and factor IX) are generally much rarer than the hemophilias.
Aims: The purpose of this poster presentation is to review the disorders in terms of clinical manifestations and complications from hemorrhage.
Methods: Records at Erciyes University Medical School, department of pediatric hematology, were reviewed from 1998 to 2012 and 31 patients with rare bleeding disorders (RBD) were evaluated. The data were collected based on age at diagnosis, familiy history of disease, bleeding sites, treatment strategies and complications of disease.
Results: Ten patients had afibrinogenemia (plasma fibrinogen level<100 mg/dl), five had factor V deficiency, three had factor VII deficiency, five had factor X deficiency, three had factor XI deficiency, and the last five had factor XIII deficiency, respectively. The mean age of the patients was 6.41 years (ranging from 3 months to 13 years) at diagnosis. Twenty two out of 31 patients were male, and nine were female. Out of 31 patients, three with afibrinogenemia, two with factor V deficiency, two with factor X deficiency, and four with factor XIII deficiency coming from two diferrent families were siblings. Among all RBDs, the most common sites of bleeding were skin and mucus membranes. Furthermore, 11 patients had intracranial hemorrhage (ICH), one patient had

gastrointestinal hemorrhage, one patient had hematuria. Six patients with afibrinogenemia and three patients with factor XIII deficiency had ICH. Four patients diagnosed preoperatively and three patients postoperatively after circumcision and tonsillectomy as RBD. The patients were administered fresh frozen plasma, cryoprecipitate and fibrinogen concentrates. All patients survived, but four of them with ICH had sequelae such as decrease in intellectual capacity and motor deficit.
Summary and Conclusions: This registry provides a comprehensive information and could be an important resource for hematologists.
Key Words: Rare bleeding disorders, registry.

PB2039

STUDY OF THROMBIN GENERATION IN PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA
RG Mihaila[1,*] A Olteanu[2], D Lienerth[2], A Catana[2], O Flucus[2], C Bus[2], RC Cipaian[1]
[1]Faculty of Medicine, Lucian Blaga University of Sibiu, [2]Emergency County Clinical Hospital Sibiu, Sibiu, Romania

Background: Although thrombocytopenic, patients with primary immune thrombocytopenia rarely have severe bleeding episodes, mainly because their blood platelets are hyperfunctional.
Aims: We aimed to study if the level of thrombin generation is another factor that may explain the rarity of bleeding in patients with primary immune thrombocytopenia.
Methods: We made a pilot study on a group of 10 patients with primary immune thrombocytopenia found in the records of the Hematology Service of Emergency County Clinical Hospital Sibiu, who presented consecutively to clinical and biological control in January 2014. We retained age, peak of thrombin generation (obtained wiht alpha Ceveron device), the platelet count, blood hemoglobin level, the hematocrit, white blood cells number, international normalised ratio (INR), and the activated partial thromboplastin time. The peak of thrombin generation of these patients was compared with that of a control group - 10 voluntarily subjects without any known disease. The results were analyzed with arithmetic mean, standard deviation, Student's t test, and Pearson test, and they have allowed conclusions that we hope to have implications for clinical practice.
Results: The mean age of surveyed patients was 59.11+/-15.14 years. The average peak of thrombin generation in patients with ITP was 166.57+/48.88, and in the witnesses - 123.29+/-20.64; the difference is statistically significant ($p < 0.05$). The thrombin generation peak in patients with ITP was inversely correlated with age (r=-0.316), platelet count (r=-0.672), hemoglobin (r=-0.756), hematocrit (r=-0.433) and INR (r=-0.294); it did not correlate with the number of leukocytes and activated partial thromboplastin time.
Summary and Conclusions: Patients with ITP have an average peak of thrombin generation significantly higher than that of witnesses. The lower the age of patients with ITP, the higher the peak of thrombin generation. The higher the peak of thrombin generation in patients with ITP, the smaller the hemoglobin, hematocrit and INR values. The smaller the platelet count in patients with ITP, the higher the peak of thrombin generation - another reason for them to present bleeding rarely.

PB2040

HAEMORRHAGIC SYNDROME DUE TO PRIMARY HYPERFIBRINOLYSIS AS THE FIRST CLINICAL SIGN OF PROSTATE CANCER
Z Cvetkovic[1,*] A Kulic[2], B Cvetkovic[3], V Libek[2]
[1]Department of hematology, [2]Blood bank department, [3]Department of urology, Clinical Hospital Center Zemun, Belgrade, Serbia

Background: Hematologic disorders are commonly seen in patients with prostate cancer (PCa). The most frequently observed disorder in PCa patients is acute or chronic disseminated intravascular coagulation (DIC). The incidence of DIC complication in PCa rages from 13% to 30%, and can be presented as catastrophic bleeding or various thrombotic events. In contrast, bleeding symptoms in the setting of primary hyperfibrinolysis in this malignancy are seen in only 0.40% to 1.65% patients, usually provoked by surgical procedures. It is supposed that metastatic PCa cells produce high levels of urokinase type plasminogen activator. Laboratory diagnosis of hyperfibrinolysis is based on the increase of biomarkers like D-Dimer; fibrinogen split products, plasminogen, and euglobulin lysis test (ELT). But, these tests are not specific for primary hyperfibrinolysis and they are also elevated in other pathological condition.
Aims: We reported the diagnosis and treatment of a rare case of haemorrhagic syndrome caused by primary hyperfibrinolysis, which was the first clinical symptom of metastatic prostate cancer.
Methods: The patient's blood was collected in vacuum tubes containing 3.2% sodium citrate and lithium heparin.Thrombelastometry analysis was performed with the Rotem® analyzer. Routine coagulation test was performed with IL ELITE PRO®and ACL 300® analyzer.
Results: A 64-year-old male was admitted to our hospital with large haematomas: in the right pectoral and axillary area, size 20x7 cm, right hemiabdomen size, 30x30 cm and left lumbal area, size 25x5 cm. Hematomas developed two days before hospitalization. Patient denied neither subjective symptoms nor any medication. Performed labory analises showed mild normocytic anaemia of chronic disease (Hb 108g/L, MCV 90fL, RBC $3.72x10^{12}$/L, Hct 0.331, Plt $419x10^{9}$/L, WBC $9.5x10^{9}$/L, Neutrophils 60%; serum iron 12,9µmol/L, ferritin 7820µ/L), highly elevated alkaline phosphatase (1390U/L), lactate dehydrogenase (1740U/L) and prostate specificic antigen (above 150ng/mL). Viral test vere negative (HBs Ag, anti HCV and anti HIV). Initial coagulation testing: protrombin time and activated partial thromboplastin time were within the normal range (14.4s and 31.9s, respectively), as well as anti-thrombin III (86.6%), while fibrinogen level was very low (1.068 g/l) and D-Dimer assay result was 1122 ng/mL. Results obtained by rotation thrombelastometry have pointed on primary fibrinolysis. First line treatment for patient was combined administration of tranexamic acid (3x500 mg intravenous) and transfusion of ten units of cryoprecipitate (400 ml). Next day, fibrinolytic function measurements by rotation thrombelastometry were within the normal ranges. APTEM test wasn't registered pathological fibrinolysis. Fibrinogen level was normalized within two days (2.4 g/l). There were no newly developed hematomas. Transrectal biopsy of prostate was successfully performed without any haemorrhagic complications, revealing prostate adenocarcinoma-G3, Gleason score 9. Further examination confirmed the laboratory findings of metastatic bone disease. Afterwards, the patient was referred to the oncologist for further treatment with androgen deprivation therapy together with oral tranexamic acid.
Summary and Conclusions: This case represent primary hiperfibrinolysis with bleeding diathesis as the first clinical sign of previousy undiagnosed metastatic PCa. Rotation thrombelastometry in this severe complication helps to achieve prompt and proper diagnosis.The management of hyperfibrinolysis was done within a short period of time thanks to adequate diagnostic procedure.

INTRACRANIAL HEMORRHAGE IN HEMOPHILIA PATIENTS
K Lee[1,*]
[1]Pediatrics, Kyungpook National University School Of Medicine, Daegu, Korea, Republic Of

Background: Intracranial hemorrhage (ICH) in hemophilia patients is the most common cause of death in Korea. Early suspicion and prompt treatment of ICH is a very important for saving their life and minimizing neurologic sequelae.
Aims: We investigate the prognosis of the hemophilia patients with ICH who registered in Daegu & Kyungpook area.
Methods: We evaluated the clinical courses, laboratory findings, brain image, effect of treatment and prognosis of ICH. Nine of 161 patients registered in our Department of Pediatrics suffered 16 episodes of ICH for 10 years.
Results: All were male hemophilia A patients (severe; 5, moderate; 3 and mild; 1) with median age of 48 months at diagnosis of ICH. Two patients who had inhibitor became negative and one patient who had found inhibitor on annual routine follow-up has had inhibitor until now. The median time interval from first symptom to hospital visit was 7 hours. Chief complaints were vomiting in 6 patients, headache in 4, seizure in 3 and mental change in 1. All patients except one were initially given factor VIII concentrate, 50 units/kg and then continuous infusion, 2-3 units/kg/hour. One patient who had factor VIII inhibitor was given factor IX concentrates, 100 units/kg with activated prothrombin complex (FEIBA), 75 units/kg at every 12 hours. All except one with hematoma in cerebellar vermis and the third ventricle are alive without any neurologic sequela
Summary and Conclusions: It is desirable to have early treatment, prophylaxis, regular follow-up and patient education about abnormal symptoms to reduce the complications of them.

PB2042

ACQUIRED HEMOPHILIA IN ELDERLY PATIENTS WITH NON HODGKIN'S LYMPHOMA
C Cerchione[1,*] S Luponio[1], R Della Pepa[1], I Migliaccio[1], G Beneduce[1], N Pugliese[1], E Seneca[1], E Cimino[2], A Coppola[2], AM Cerbone[2], A Tufano[2], M Notarangelo[1], I Peluso[1], G Di Minno[2], F Pane[1], A De Renzo[1]
[1]Hematology, [2]Reference Centre for coagulation disorders, AOU "Federico II", Napoli, Italy

Background: Acquired hemophilia is a rare disorder characterized by autoantibodies against circulating coagulation factors. Patients often have not history of bleeding disorder and present spontaneous hemorrhage, an isolated prolonged aPTT and PT and antibodies against coagulation factors. It has an incidence of 0,2-1 cases/million/year. This condition may be associated in 50% of cases with autoimmune disease, solid tumor, lymphoproliferative disorders and pregnancy.

Aims: In this work, we describe our experience with three cases of indolent NHL with isolated prolonged aPTT and PT.
Methods: Case 1 : A 72 year-old man referred to our Institution because of recurrent epistaxis and abnormalities of coagulation tests PT INR 2.5, aPTT ratio 2.73. No history of bleeding disorders, recent surgery or new drug intake were reported. Spleen enlargement, with a large focal lesion, and pancytopenia (Leukocytes 2800/μL; Haemoglobin 9 g/dL; Platelets 82,000/μL) were observed. Moreover, it was present a reduction of Factor VIII, Factor II, Factor V, Factor VII, Factor IX, Factor X and Factor XI activity (FVIII:C 16%; FII: 44%; FV:8%; FVII: 11%; FIX: 10%; FX:30%; FXI:27%) and positivity of antibodies against coagulation factors. Lymphoid infiltrates were observed in bone marrow examination. Moreover, increased PET/CT splenic uptake and in a supraclavear lymphonode was observed. FNAB in the supraclavear lymphonode, performed after an injection of 60 μg/Kg recombinant Factor VIIa enabled the NHL CD5-CD22+lambda+ diagnosis. The patient underwent to six administrations of chemotherapy with CEOP and achieved complete remission with coagulation parameters and factor activity normalization. Then, during followup, 11 months after the end of frontline treatment, the patient came to our Department for the onset of abdominal bleeding and relapse of the lymphoproliferative disease. After surgical treatment, the patient underwent to R-FN chemotheapy treatment (6 courses), with complete remission of disease. After the end of treatment, he underwent to Rituximab-based maintenance treatment with persistence of normality of coagulation and factor activity parameters. Case 2 : A 62 year-old woman came to our observation for lymphoadenopathy, hepatoplenomegaly, anemia and lymphocitosis. She didn't present any personal or familial history of bleeding disorders and didn't take any drug. Laboratory tests showed: PT INR 3.26, aPTT ratio 4.92; there was also a reduction of factor VIII activity, Factor II activity, Factor VII activity, Factor IX activity, Factor activity X and Factor activity XI (FVIII:C: 2.3%; FII: 32%; FVII: 47%; FIX: 1%; FX:43%; FXI:1%) and appearance of antibodies against many coagulation factors. PET/CT revealed increased uptake at axillary and inguinal lymphonodes and spleen. Bone marrow analysis showed a lymphoid infiltrate and enabled the diagnosis of NHL CD5-CD22+lambda+. The patient underwent to six courses of R-Fludarabine, and after the second administration it was observed a PT and aPTT normalization. Case 3 : A 80 year-old man came to our observation because of pancytopenia and abnormalitites of coagulation tests: PT INR 2.28, aPTT ratio 3.2. No story of previous bleeding disorders. The activity of various coagulation factors was reduced : FII 54% FV 68% FX 60%. PET/CT documented splenomegaly with increased splenic uptake. Bone marrow examination enabled the NHL CD20+CD19+CD5-CD22+CD23-lambda+ diagnosis. The patient underwent to R-Chlorambucil courses, after which a normalization of PT and PTT was observed.
Results: All patients of this study underwent to Rituximab-based maintenance treatment to prevent the emergence of lymphoproliferative clone.
Summary and Conclusions: The onset of an acquired coagulation disorder can be an useful diagnostic and progonostic marker of immunological impairment due to an underlying lymphoprolipherative disease. In particular, maintenance treatment may actively control the neoplastic clone reducing the risk of bleeding.

Thrombosis and vascular biology

PB2043

PULMONARY EMBOLISM – RETROSPECTIVE STUDY OF A PORTUGUESE ONCOLOGY CENTER

P Silva[1,*] M Rosales[2], MJ Milheiro[2], L Lopes dos Santos[2]
[1]OncoHematology, [2]ImunoHemotherapy, Instituto Portugues de Oncologia Francisco Gentil, E.P.E. - Porto, Porto, Portugal

Background: The association between cancer and venous thromboembolism (VTE) is well-established, and about 20% of oncologic patients will develop it. Pulmonary embolism (PE) is an important cause of morbidity and mortality in this group of patients.
Aims: Characterization of patients with the diagnose of PE in a Portuguese Oncology Center.
Methods: Retrospective study of all episodes (n=234) of PE referenced to Clinical Board Administration in the last five years (from January/2009 to December/2013). Demographics, past medical history, risk stratification of PE (Caprini and Khorana) and probability of mortality at 30 days (PESI - Pulmonary Embolism Severity Index) were analyzed.
Results: A median age of 63 years (15-87 years) was encountered, with a female prevalence (58.5%). The most prevalent malignancies was colorectal cancer (20.9%), followed by lung (18.4%) and breast cancer (18.4%). Metastatic disease was found in 60.3%. The following risk factors for PE were identified: chemotherapy (62.8%); central venous catheter (31.6%); recent surgery (8.5%); hormonal therapy (6.4%); and at least one cardiovascular risk factor (54.7%). Of note, 3 patients (1.3%) had a previous diagnose of VTE, and were under anticoagulation therapy. In patients treated with chemotherapy, Khorana's risk scoring was: 37.1% low risk, 51.5% intermediate risk and 11.4% high risk. According to Caprini's risk stratification all hospitalized patients had a moderate to high risk of developing PE. Most of the cases were reported in ambulatory patients (80.3%), only one (0,4%) patient was under anticoagulation prophylaxis. Most hospitalized patients (80.4%) were receiving prophylaxis. More than a half of the PE (59.8%) were apparently asymptomatic and were diagnosed by radiological assessment for unrelated reasons. The association between deep venous thrombosis and PE was found in 12.8%. The probability of mortality at 30 days, based on the PESI's scale was 2.6% in class I, 6.6% in class II, 34.2% in class III, 31.6% in class IV and 25.0% in class V. There was an overall 30-day mortality of 13.2%. All patients were treated with low molecular weight heparin and oral anticoagulants were initiated approximately three months after.
Summary and Conclusions: In our study, PE was more frequently diagnosed in advanced stages of the disease, in patients undergoing chemotherapy treatment and with central venous catheter. The authors emphasize that most cases of PE were asymptomatic and occur mainly in ambulatory patients. This findings highlight the need to sensitize health´s professionals to recognize and assess the risk for PE in oncologic patients and further prevent it.

PB2044

HEMORHEOLOGIC DISTURBANCES IS VTE RISK FACTOR IN CHILDREN WITH ALL

I Kolesnikova[1,*] E Roitman[1], J Roumiantseva[1], S Roumiantsev[1]
[1]FSCC of Pediatric Hematology Oncology and Immunology, Moscow, Russian Federation

Background: Acute lymphoblastic leukaemia (ALL) is the commonest childhood malignancy with high risk of venous thromboembolism (VTE).
Aims: The aim was to investigate blood rheology properties in children with ALL during first remission and with not symptomatic organs failures.
Methods: The study's population was 48 children (age<16y.o.). Six patients had VTE during follow-up despite standard anti-VTE prevention. Whole blood viscosimetry, plasma viscosimetry, erythrocytes aggregability and deformability, B-type natriuretic peptide (BNP) level and plasma ions concentrations were assayed.
Results: All patients had normal plasma viscosity and unimpaired erythrocyte deformability. Whole blood viscosity was increased by shear rates 5-300 s-1 and mainly by shear rates 5-75 s-1. We found erythrocytes hyperaggregability in all patients. Elevated BNP level was found in 16 patients, and from them six VTE had been developed. These patients had the combination "most increased whole blood viscosity - erythrocytes hyperaggregability" but they had not symptomatic heart failure.
Summary and Conclusions: Totally increased blood viscosity with erythrocytes aggregability are factors leading to thrombosis. The slightly decrease of blood flow rate might be assumed when BNP-level have been raised. Both signs elevates the risk of VTE. Despite antithrombotic prevention directed to hypocoagulation the revealed hemorheologic disturbances could

be as a trigger to start of VTE in children with ALL. The obtained results suggest that the study should be continued.

PB2045

IMPACT OF DABIGATRAN ON PLATELET AGGREGATION, SECONDARY HAEMOSTASIS AND FIBRINOLYSIS, COMPARED TO ACENOCOUMAROL

E Kyriakou[1,*] I Ikonomidis[2], D Stylos[1], S Bonovas[3], I Papadakis[2], S Kokoris[1], D Kalantzis[1], P Douramani[1], A Chimarioti[1], A Tsantes[1]
[1]Laboratory of Haematology & Blood Bank Unit, [2]Second Cardiology Department, "Attiko" University Hospital, School of Medicine, University of Athens, Athens, Greece, [3]Department of Pharmacology, , School of Medicine, University of Athens, Athens, Greece, Athens, Greece

Background: Dabigatran etexilate (DE) is an oral direct thrombin inhibitor. Thrombin, which is inactivated by DE, has a central role in the whole haemostatic process by affecting all of its phases. It activates platelets; amplifies the haemostatic response by activating factors V, VIII and XI; converts fibrinogen to fibrin; stabilizes the fibrin clot through activation of FXIII; and further affects fibrinolysis by regulating an important factor in the clot stabilization, the thrombin activatable fibrinolysis inhibitor. Despite the crucial role of thrombin in almost all phases of coagulation, no research on the impact of DE on platelet function and fibrinolysis has been conducted, while there is disagreement about optimal methods to monitor its anticoagulant effect in certain clinical settings.
Aims: Our aim was to compare the impact of dabigatran and acenocoumarol on primary and secondary haemostasis and fibrinolysis, and to identify laboratory assays that can be used to assess the anticoagulant activity of DE.
Methods: We recruited 20 patients with non valvular atrial fibrillation (NV-AF) treated with DE (110 mg per os bid) and 20 patients on acenocoumarol, matched on age and sex, from Cardiology Department in a tertiary hospital in Athens, Greece. Exclusion criteria were the following: platelet count<100×109/l, active thrombosis or bleeding, simultaneous anticoagulant and antiplatelet therapy, INR out of the defined limits, renal, hepatic, thyroid dysfunction, malignancy and infectious disease. Conventional coagulation tests, endogenous thrombin potential (ETP), thromboelastometry (ROTEM), epinephrine-induced light transmission aggregometry (LTA), and hemoclot thrombin inhibitors (HTI) were performed. Non-parametric tests (the Fisher's exact test and the two-sample Wilcoxon rank-sum [Mann-Whitney] test) were used for the statistical evaluations. Correlations were assessed by the Spearman rank correlation coefficient and the respective p-value.
Results: The two groups were similar in terms of descriptive characteristics, comorbidities, haematological and biochemical parameters. ROTEM® analysis showed a greater impact of DE on procoagulant activity than acenocoumarol, but only the difference in clotting time reached statistical significance (p=0.004). The lysis index at 60 min was significantly lower in patients receiving dabigatran (p=0.011) indicating an increased fibrinolytic activity. In epinephrine-induced LTA, patients on dabigatran showed decreased aggregation compared to those on acenocoumarol, marginally insignificant (p=0.068). Regarding the correlation of dabigatran levels, as assessed by the HTI assay, with the haemostatic parameters, it is noteworthy the statistically significant associations between them and almost all parameters of ETP assay. Specifically, positive correlations between dabigatran levels and lag time (p=0.001) and time to peak (p=0.018) were detected, while area under the curve (AUC, p<0.001) and peak height (C max, p<0.001) were inversely correlated with HTI values.
Summary and Conclusions: Compared to acenocoumarol, dabigatran seems to affect more fibrinolysis, while a clear impact on platelet aggregation was not determined. Taking into consideration that a small sample size has been studied, this hypothesis deserves further research, since it could be of clinical relevance in certain clinical settings. On the other hand, ETP use in dabigatran monitoring seems to be helpful.

PB2046

PREVALENCE OF COMBINATION OF TRIPLE ALLELIC MUTATIONS ASSOCIATED WITH THROMBOPHILIA IN PATIENTS WITH VENOUS THROMBOEMBOLISM

S Betti[1,*] E Rossi[1], T Za[1], A Ciminello[1], V De Stefano[1]
[1]Institute of Hematology, Catholic University, Roma, Italy

Background: Triple thrombophilic abnormalities have been rarely reported and most patients carried polymorphisms nowadays not included in the recommended laboratory investigation for thrombophilia, such as those in the MTHFR gene.
Aims: To assess the prevalence of triple allelic mutations associated with thrombophilia in patients with venous thromboembolism (VTE).
Methods: We selected from a cohort of 2,199 individuals with VTE who were referred to our Thrombosis Center those with triple thrombophilic abnormalities (*i.e.* deficiency of antithrombin [AT], protein C [PC], protein S [PS], factor V Leiden [FVL], prothrombin [PT] 20210A) and/or triple allelic mutations (*i.e.* triple heterozygosity [Het], homozygosity [Hom] plus Het).
Results: We identified 10 patients (M/F 5/5) (0,45%) (Table 1). Four patients had triple Het, and the remaining carried a combination of Hom and single Het. No patient in the cohort carried double Hom neither Hom for deficiency of natural anticoagulants, nor triple deficiency of natural anticoagulants. Het for deficiency of natural anticoagulants was present in 5 patients (AT=2, PC=1, PS=1, PC+PS=1), associated with FVL or PT20210A (Table). Four patients had triple abnormalities (various combinations of AT,PC,PS deficiency, and FVL or PT20210A) (0.18%), and 6 had double abnormalities (AT deficiency and Hom for FVL in one case, FVL and PT20210A in the remaining ones).
The first VTE was deep vein thrombosis (DVT) of one leg in 9 cases, in 2 of them with pulmonary embolism (PE), and superficial vein thrombosis (SVT) in 1 case. The median age of first VTE was 27 years (range 2-73), in 8 cases <45 years. The first event was provoked in all cases. Two of them had an additional thrombophilic acquired abnormality (hyperhomocysteinemia and lupus anticoagulant, respectively). Four patients had recurrent VTE events. Eight patients received lifelong treatment with vitamin K antagonists (VKA).

Table 1.

Summary and Conclusions: In patients with VTE triple allelic mutations associated with thrombophilia are uncommon but not exceedingly rare (0.45%), and diagnosis of a single thrombophilia abnormality should not discourage from an exhaustive laboratory investigation.
Abnormality can be a combination of Hom and Het or a combination of triple Het. The clinical onset occurs in young age in the large majority of cases. Surprisingly, such conditions seem not associated with unprovoked events, and recurrence occur in a minority of subjects.

PB2047

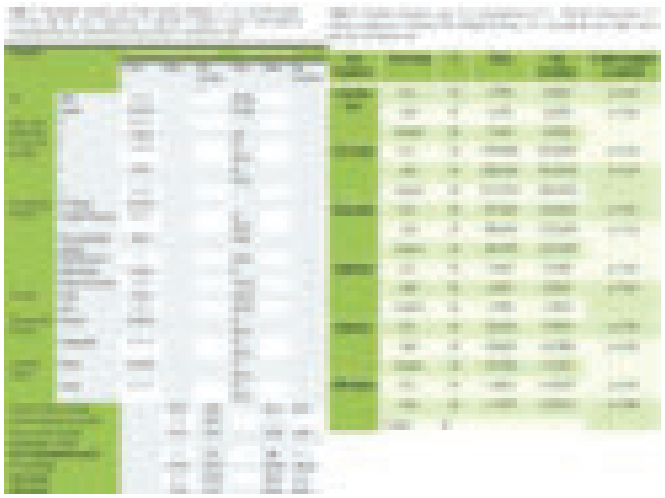
MICROPARTICLE (MPS) RATIO IS HIGHLY CORRELATED WITH ALL PARAMETERS OF THROMBIN GERENATION ASSAY (TGA) PARAMETERS IN MULTIPLE MYELOMA AND CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

Y Bilen[1,*] F Erdem[1], M Gundogdu[1], N Bilen[2], R Yildirim[1]
[1]Hematology, [2]Internal Medicine, Atatürk University Medical Faculty, Erzurum, Turkey

Background: Microparticles (MPs) are small membrane derivatives that generally released from either live cells or apoptosed cells. MPs have been studied with various types of diseases and has been shown that presence of MPs is accompanies with increased risk of thrombe embolic (TE) events.
Aims: In this study we aimed to detect presence of MPs , analyse Thrombin Generation Assay (TGA) parameters to improve understanding of pathophysiology in a patient population that includes Multiple Myeloma (MM) and Chronic Lymphocytic Leukemia (CLL) patients whose had a high risk for TE events compare to normal population.
Methods: We include 40 MM and 30 CLL patients who diagnosed and followed in Hematology Department and outpatient clinic of Atatürk University Medicine Faculty between January 2010 and July 2013. 26 Healthy individual also included to the study as control group. At the begining of the study samples for TGA and MPs tests were taken from the patients and control group after informed consents were given. Patients were followed prospectively during the study. Chemotherapy responses, disease related informations and demographic data were recorded. At the end of the study TGA and MPs test results were investigated statistically with collected data.
Results: In this study, patients' mean follow-up period was found 22.6 months for the MM, 38.8 months for CLL. The patient characteristics were given in

Table 1. At the end of the study; 13 TE events and 10 mortality observed in MM patients. 10 Thromboembolic events and 3 mortality was observed in CLL patients. Calculated MPs ratio of patients with CLL and MM were 1.46±1.03, 1.16±0.52, respectively (According to calculated reference value 0.99±0.29 of control group). During the study, The incidence of thromboembolic events during the study in patient group (CLL and PCM patients) was detected that statistically significantly has positive correlation with the stage of the disease (p=0.01), presence of co-morbid disease (p<0.001), mortality (p=0.002),age (p=0.011), Lag-time in TGA test (p=0.048). We also detected that the incidence of thromboembolic events has a statistically significant negative correlation with ETP and Peak time in TGA test (p=0.021 and 0.046 in orderly),quality of the therapy response (p=0.008). Decrease in ETP and peak values were statistically significantly accompanied by an increased incidence of thromboembolic morbidity. We also detected that all parameters of TGA test (Lag time, ETP, TtPeak, Peak value) were statistically significantly correlated with MPs ratio both in CLL (p<0.001, p=0.006, p<0.001, p=0.002 in orderly) and MM (p<0.001, p=0.006, p<0.001, p=0.002 in orderly)patient groups.TGA test parametersof CLL, MM and control groups were given in Table 2.

Table 1 and Table 2.



Summary and Conclusions: As a result, we detected that CLL and MM patients found significantly high incidence for TE. Stage of the disease, co-morbid diseases, age, chemotherapy response and some TGA test parameters were statistically significantly correlated with TE evente. We also detected that MPs ratio was statistically significanlty correlated with all parameters of TGA test. This close relationship of MPs with TGAin CLL and MM patient can be interpreted as a clue for increased acquired thrombophilia due to presence of MPs in these patient groups. TE events are significant morbidity and mortality cause for hematological malignancies and other cancers. We speculated that TGA and MPs evaluation to obtain an idea for Tissue Factor activity can be a valuable parameter for the determination of the high-risk patients to administer prophylaxis. Further multicentered prospective large scaled studies were required to support such an idea.

PB2048

CALIBRATED AUTOMATED THROMBOGRAM ALLOWS INDIVIDUALIZED APPROACH TO ANTITHROMBOTIC TREATMENT AND PROPHYLACTICS IN THROMBOPHILIA PATIENTS.

V Shmeleva[1,*] A Polyakova[1], O Matvienko[1], Y Namestnikov[1], O Golovina[1], V Kobilyanskaya[1], T Morozova[1], S Kapustin[1], L Papayan[1]
[1]laboratory of blood coagulation, Russian Research Institute Of Haematology and Transfusion, St-Petersburg, Russian Federation

Background: Proper thrombosis prophylaxis without increasing risk of hemorrhages is of great importance, so optimal duration of prolonged anticoagulant use is still of interest for thrombophilia patients, particularly those with lupus anticoagulant (LAC), factor V Leiden (FVL) and prothrombin G20210A mutations. The Calibrated Automated Thrombogram (CAT) is now considered to better correlate with patients phenotype compared to traditional coagulation tests and has wide clinical utility, including evaluation of prothrombotic risks .
Aims: Aim of our study was to assess the use of CAT in identifying patients who need prolong antithrombotic regimens.
Methods: Calibrated Automated Thrombogram (CAT) was done according to Hemker *et al.* with fluorogenic assay, at 5 pM TF and 4 µM phospholipids in platelet poor plasma (PPP) with PPP plasma+/-TM reagent (Thrombinoscope BV, Maastricht, The Netherlands). Thrombin generation curves were calculated using the Thrombinoscope software (Thrombinoscope BV, The Netherlands). Our selected group of 38 patients (M/F 15/23, mean age 38,0±9,0 yrs) with venous thromboembolism (VTE) manifestation under the age of 45 years involved 14 heterozygous for FVL, 4 LAC and 3 prothrombin G20210A mutation carriers respectively. Investigation was performed at least 6 months after the thrombotic episode. STATISTICA 6.1 was used.
Results: Endogenous thrombin potential (ETP) and peak thrombin (PT) were markedly reduced in the presence of TM. Normal ranges of inhibition were calculated in 28 age and sex matched controls. The percentage of inhibition below 21% for ETP and/or 14% for PT (*i.e.* activated protein C resistance - APRC) were found in 8 (57%) of patients with FVL and 4 (100%) patients with LAC. Importantly abnormal inhibition of PT was found to be more sensitive in determining of APCR, as it was in all these patients and abnormal inhibition of ETP only in 50% cases with FVL and 75% with LAC. Both in the absence and in the presence of TM significant correlation with LAC was found for lag time (R =0,45; p<0,05), ETP and PT (R =-0,45 and R =-0,44, respectively, p<0,05). One patient with prothrombin G20210A mutation and increased factor VIII activity also demonstrated APCR. Importantly not all patients with increased FVIII activity (>200%) demonstrated APCR, it was found in 50% of cases (3 from 6).). As for the parameters derived from the thrombin generation curves (lag time, ETP, PT, time to peak) both in presence and absence of TM, no one showed correlation with factor VIII activity.
Summary and Conclusions: APCR (both inherited and acquired) is associated with high risk of VTE and its recurrence. As FVL is the main cause of APCR, little attention is paid to the fact that not all the carriers of this mutation demonstrate APCR, at the same time acquired APCR is enough common. According to our data APCR could be effectively detected by CAT performed with PPP plasma+/- TM reagent. It is possible to find APCR and LAC even when patients are on vitamin K antagonists (VKA) treatment. We suggest important to use CAT before making decision on VKA discontinuation. Patients demonstrating APCR, would benefit from extended VKA treatment. Whether FVL patients without APCR phenotype do not need further prolongation of antithrombotic prophylactics remains to be established. Our data support the position that CAT allows individualized approach to antithrombotic treatment and prophylactics.

PB2049

DIFFERING COAGULATION PROFILES IN PATIENTS WITH MYELOMA AND MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE.

MP Crowley[1,2,*]S Quinn[1], E Coleman[3], J A Eustace[2], O M Gilligan[1], S I O'Shea[1]
[1]Haematology, Cork University Hospital, [2]HRB Clinical Research Facility, University College Cork, [3]Cork University Hospital, Cork, Ireland

Background: Armand Trousseau first noticed the link between cancer and thrombosis almost 150 years ago. The link between myeloma and thrombosis was first noted in the 1970s. It came to prominence with the advent of thalidomide and related agents which further increased this risk. The mechanism has not been well established so it has been difficult to measure an individual patients' risk. Monoclonal gammopathy of undetermined significance (MGUS) has also been associated with an increased risk of VTE, but to a lesser extent. Thromboelastography is a technique that measures the visicoelastic properties of whole blood under low shear stress. Trelinski et al recently demonstrated that patients with myeloma display changes in ROTEM tests at the time of diagnosis that may indicate a prothrombotic state. There is little data with regard to changes in thromboelastographic profiles in patients with myeloma or MGUS.
Aims: To investigate the differing coagulation profiles of patients of patients with myeloma, MGUS and normal controls by means of conventional coagulation tests and thromboelastography.
Methods: Having obtained informed consent, fresh whole blood was taken by direct venepuncture into tubes containing citrate 0.105M from patients with myeloma (prior to treatment), MGUS and normal age and sex-matched controls. It was stored at room temperature for 30 minutes prior to analysis. 500µl of whole blood was activated with 12.5µl of Kaolin and thromboelastography was performed by the same technician on 340µl of activated blood in combination with 20µl of calcium chloride using a TEG 5000 Thrombelastograph®analyzer according to the manufacturer's protocol. The remainder of the investigations were performed in the hospital laboratory. Statistical analysis was performed using the unpaired t-test for normally distributed variables and a Mann-Whitney U test for non-normally distributed variables. A *p*-value of <0.05 was considered statistically significant.
Results: Eight patients were recruited in each of the three groups. None of the patients were hospitalised. The mean age in each group was similar. Patients with myeloma had a significantly lower mean haemoglobin level than patients with MGUS or normal controls (10.7 *vs* 13.9 *vs* 14.9g/dl, p<0.001). Pateints with myeloma had a significantly more prolonged mean prothrombin time (PT) than normal controls (11.4 *vs* 10.6sec, p=0.024) but not patients with MGUS

(p=0.126). Patients with myeloma had significantly higher median D-Dimer levels than normal controls (0.98 *vs* 0.17mcg/ml, p=0.024), as did patients with MGUS (0.45 *vs* 0.17mcg/ml, p=0.015). Patients with myeloma had a significantly higher mean factor VIII level than normal controls (243.4 *vs* 131.6%, p=0.016) and there was a non-significant trend towards patients with MGUS having higher factor VIII levels than normal controls (208.75 *vs* 131.6%, p=0.084). There was no significant difference in TEG parameters (r time, k time, alpha angle, maximum amplitude) between the three groups.

Summary and Conclusions: In keeping with previous studies, patients with myeloma have prolonged PT times, elevated D-dimer levels and factor VIII levels when compared with normal controls. Moreover, patients with MGUS showed a trend towards hypercoagulability. No differences were seen in the thromboelastographic profiles of the three groups.

WILMS TUMOUR AND VENO-OCCLUSIVE DISEASE. THE ROLE OF MICROPARTICLES AND PAI-1

A Piccin[1,*] MT Sartori[2], M Van Schilfgaarde[3], G Bisogno[4], L Marcheselli[5], I Pusceddu[1], S Cesaro[6]

[1]Haematology Dept, San Maurizio Regional Hospital, Bolzano, [2]Dept of Internal Medicine, University of Medicine, Padua, Italy, [3]Onze Lieve Vrouwe Gasthuis OLVG, University of Amsterdam, Amsterdam, Netherlands, [4]Paediatric Onco-Haematology Dept, University of Medicine, Padua, [5]4Dept of Diagnostic, Clinical and Public Health Medicine, University of Modena and Reggio Emilia, Modena, [6]Paediatric Onco-Haematology Dept, University of Medicine, Verona, Italy

Background: Venous occlusive disease (VOD) of the liver has been reported to be associated with haematopoietic stem cells transplant. This condition has been associated with high mortality rate of up to 90% as multiorgane failure may occur [McDonald *et al.* 1993]. Several markers of thrombosis have been suggested to be involved in the VOD pathogenesis. However, this condition continues to have a poor prognosis and to be poorly understood. Recently an increment of plasminogen activator inibitor (PAI-1) has been identified as a possibile valid marker of VOD. Patients with solid tumours may also develop VOD. Interestingly, patients with Wilms Tumor (TW) develop VOD following chemotherapy treatment without any HSCT. Microparticles have been reported in several prothrombotic conditions [Piccin et al 2007], however studies on their association with PAI-1 are lacking. We report on VOD cases within a paediatric cohort of children affected by TW treated with chemotherapy.

Aims: The aim of this study was to investigate new biological marker involved with VOD.

Methods: Twelve consecutive patients (F=7; M=5) with a diagnosis of TW were treated with a combination of chemotherapy regimen based on vincristin, actinomicine-D and doxorubicine. Only five patients developed VOD after a median of 4 weeks from diagnosis (range 1-14 weeks). In all cases, poor platelets plasma was stored at -80C°. Three consecutive sampling at intervals of 3 weeks, were carried out during hospitalisation on each case. Standard coagulative parameters were studied (PT, PTT, Fibrinogen, D-Dimer). Microparticle studies were carried out using flow cytometry. PAI-1 antigen (PAI-1:Ag) was measured by ELISA (Tint-Elize PAI-1, Hyphen BioMed - Neuville-sur-Oise, France), while PAI-1 activity (PAI-1:act) was measured using chromogenic assay (TriniLIZE PAI-1 Activity, Trinity Biotech - Jamestown, NY, USA).

Results: The analysis of consecutive measurements over time revealed a statistically significant negative correlation for PT (-0.264; p<0.001) and for Fibrinogen (-0.023; p< 0.008). MP, PAI-1:Ag and PAI-1:act showed a positive trend over time, however statistical significance was not reached. A linear regression study showed an inverse relationship of PAI-1: Ag and MP coeff (Mp= -0.005, P= 0.521). Interestingly, a polynomial relationship between PAI-1:act and MP was seen [PAI-1:act = cost+ $(MP/1000)^{-2}$ + $(MP/1000)^{2}$; coeff MP^{-2}:23.0; p=0.002; MP^{2} :11.9; p=0.006; Model , p=0.006] (Figures 1 and 2).

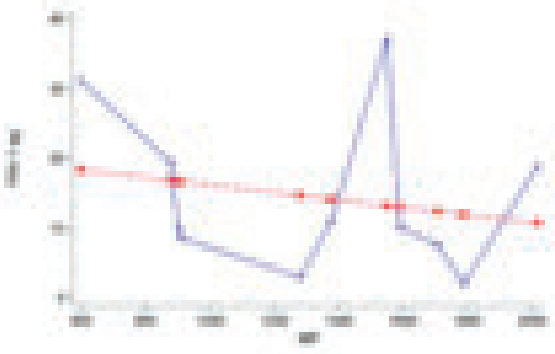

Figure 1. Inverse relationship of PAI-1: Ag and MP coeff (Mp=-0.005, P= 0.521.

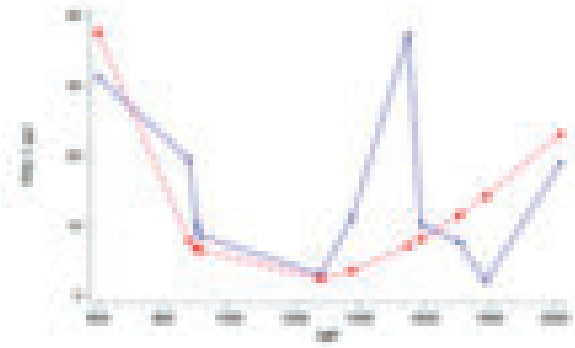

Figure 2. Polynomial relationship between PAI-1:act and MP was seen [PAI-1:act = cost+ $(MP/1000)^{-2}$ + $(MP/1000)^{2}$; coeff MP^{-2}:23.0; p=0.002; MP^{2} :11.9; p=0.006; Model , p=0.006.

Summary and Conclusions: In conclusion, this preliminary data shows that following chemotherapy for TW based on vincristin, actinomicine-D and doxorubicine, some coagulative changes are present and persist over time. Moreover, we demonstrated a polynomial relationship between PAI-1:act and MP in patients with WT after chemotherapy. Although our numbers are small, we believe that prospective studies on MP and PAI-1 may help to shed light on VOD pathophysiology.

PB2051

VENOUS THROMBOEMBOLISM: EPIDEMIOLOGICAL DATES AND RISK FACTORS IN OVER AGE 55

N Cruz Cruz[1,*] L Torres [1], I Balda[1], MK Torres[1], M Moreno[1], T Molero[1]

[1]Servicio hematología, Hospital universitario Gran Canaria doctor Negrin, Las Palmas de Gran Canaria, Spain

Background: The venous thromboembolism (VTE) occurs in one-two of every thousand individuals per year and rises exponentially with age after 60. Certainly, around a third of patients with sintomatic VTE manifets pulmonary embolism (PE), whereas two-thirds manifest deep vein thormbosis (DVT) alone. Overall, 25% to 50% the patients with first-time VTE have an idiopatic condition, without a readily identifiable risk factor. Although use of oral contraceptives (OAC) have been associated with VTE in women, published data suggest no consistent differences in the incidence of VTE among men and women.

Aims: *This study aims to analyze* the etiopathogenic data patients that have VTE at age below 55 and check whether there were gender differences in relation to the location of the thrombotic event and the presence or absence of risk factors.

Methods: The analysis was performed on 300 consecutive patients (150 men and 150 women) with VTE at age below 55, seen in Doctor Negrin Hospital de GC from August 2007 to October 2013. Data were obtained from the software (Sintromac web 3.4) and a local base. Data were collected regarding a thrombotic event location, risk factors and results of the thrombophilia.

Results: In this observational study, the results was: 1. The mean age of presentation of the first thrombotic event was 38 years. 2. The location of the thrombotic event: DVT of the lower limbs (DVT LL) was seen in 215 patients (71.6%) of which 37 (17.2%) were embolized in lung; 28 patients showed pulmonary embolism (PE) without evidence of DVT so the overal prevalence of PE was 22,3%. We saw 24 (8%) DVT in upper limbs (DVT UL), 10 (3,3%) cerebral venous sinus thrombosis (CVST) and 15 (5%) abdominal thrombosis (AT). 3. No triggers of thrombosis were found in 182 patients at the prevalence of primary VTE was 60.6%. Among secondary VTE, major trigger of thrombosis were surgery, trauma and immobilization; in 6 patients the thrombotic event was paraneoplastic. A third of women taking oral contraceptives, half of which, presented a trigger usually associated with trauma/immobilization. 4. We found 54 cases to congenital thrombophilia (22.6%) of the 238 patients studied; one hundred and three patients (33%) were obese (BMI>30) and 59 (19%) presented two or more cardiovascular risk factors.

Summary and Conclusions: Results from the present study indicate that there are any differences among sexes except the higher frequency of LLL DVT in women and more CVST in women too, while the abdominal thrombosis is more common in men.

PB2052

VENOUS THROMBOEMBOLISM (VTE) IN PATIENTS WITH PANCREATIC CANCER

KH Kim[1,*] SY Yoon[1], J Yoon[2], HJ Kim[3], SH Kim[2], HJ Kim[2], SC Lee[3], SB Bae[3], CK Kim[2], N Lee[1], SK Park[2], JH Won[1], DS Hong[2], HS Park[1]

[1]Soonchunhyang University Hospital, Seoul, [2]Soonchunhyang University Hospital, Bucheon, [3]Soonchunhyang University Hospital, Cheonan, Korea, Republic Of

Background: Venous thromboembolism (VTE) is a critical complication of malignant disease. Pancreatic cancer is one of the cancers most commonly associated VTE. In general, the VTE incidence rate of Asians is lower than that of Caucasians. In 2007, a Korean study reported that only four cases of VTE (5.3%) occurred in Seventy five patients with advanced pancreatic adenocarcinoma.
Aims: We evaluated VTE incidence in pancreatic cancer and characteristics of pancreatic cancer patients with VTE.
Methods: We retrospectively reviewed the medical records of patients with histopathologically proven pancreatic cancer from January 2006 to December 2012 at Soonchunhyang university hospital. We detected VTE through CT (chest CT, pulmonary embolism CT) and low extremity ultrasoundgraphy.
Results: Five hundred and fourteen patients with pancreatic adenocarcinoma were enrolled. (M: F, 300:214, localized: locally advanced: metastatic=31:230:253, mean age: 66.7 years). Ninety six of 514 patients (18.6%, symptomatic: aymptomatic=38:58, PE: DVT: PE+DVT: visceral thrombosis=20:19:19:38) were diagnosed as VTE. At the time of DVT diagnosis, cancer status of 50 patients cancer was progression, and that of 15 was stable. Thirty one patients were diagnosed with the pancreatic cancer and VTE, at the same time. They all had metastatic lesions. Fifty VTE patients were treated with antithrombotic therapy. Ninety three of 96 patients died, and three of them have probability that cause of death was VTE. The others died of pancreatic cancer progression. From pancreatic cancer diagnosis to VTE diagnosis, the period is 1.7month. (95%CI 1.1-2.3 month). Median overall survival (OS) was not significantly different between pancreatic cancer with VTE or without VTE. OS was significantly longer VTE patients after pancreatic cancer diagnosis than VTE patients with pancreatic cancer at the same time (10.73m *vs.* 1.7, p=0.00).
Summary and Conclusions: The incidence of VTE (18.6%) in Soonchunhyang university hospital with pancreatic cancer was not lower than that in western groups.

PB2053

PLATELET INDICES IN PATIENTS WITH ACUTE MYOCARDIAL INFARCTION

P Tsiatsiou[1,*] D Lazaridou[1], G Goulas[1], L Skoura[1], A Nikolaidou[1]
[1]Clinical Microbiology, AHEPA University Hospital, Thessaloniki, Greece

Background: The involvement of platelets in the pathophysiology of coronary artery disease has long been recognized and well defined. Large platelets, which can easily be identified during routine hematological analysis, are associated with increased platelet activation and thrombosis, because they produce more prothrombotic factors and aggregate more easily. Mean platelet volume (MPV) reflects to the platelet size and the rate of platelet production in bone marrow, and it may be used as an indicator of platelet activation. PDW indicates the platelet distribution width and p-LCR indicates the percentage of platelets larger than 12 fL.
Aims: The aim of this study is to determine the possible impact of platelet indices, such as mean platelet volume (MPV), platelet distribution width (PDW) and platelet large cell ratio (P-LCR) on the incidence of acute myocardial infarction.
Methods: Over a period of nine months, from 12/05/2013 to 12/02/2014, platelet indices MPV, PDW and p-LCR of 77 patients with acute myocardial infarction were identified. Also, 77 patients without acute myocardial infarction were included in this study as a control group. The two groups were similar in regard to sex (66 males - 12 females) and age (29 - 93 years avg = 63 years). The blood samples were drawn and analyzed on the first morning after admission. Platelet indices were measured by SYSMEX XE-5000. A series of statistical analysis (descriptive statistics, compare means and correlations) have been used to demonstrate the relationship between patient with acute myocardial infarction and MPV, p-LCR, PDW indicators. The significance level was defined as $p<0.05$. All statistical analysis was performed using SPSS 20 and Mc Excel 2010.
Results: All PVI [mean platelet volume (MPV), platelet distribution width (PDW), and platelet large cell ratio (p□LCR)] were significantly raised in patients with AMI (mean MPV, 11.09 (SD, 1.02) fL, mean PDW, 13.95 (SD, 2.28) fL, mean p□LCR, 33.06% (SD, 8.32%) compared with those from the control group (mean MPV, 10.72 (SD, 0.99) fL, mean PDW, 12.93 (SD, 2.25) fL, mean p□LCR, 30.73% (SD, 8.09%). T test analysis was used in order to examine the statistical significance between patients with acute myocardial infarction and the indicators. All the findings revealed 0.000 ($p<0.05$) significance and a positive correlation between these indicators and acute myocardial infarction MPV ($r=0.15$, $p<0.05$), PDW ($r=0.004$, $p<0.05$), p-LCR ($r=0.021$, $p<0.05$).
Summary and Conclusions: This study has shown an elevation of MPV, PDW and p-LCR in patients with acute myocardial infarction and a statistically significant correlation between the platelet indices and AMI. Elevated values of the platelet indices suggest that the presence of large platelets, possibly juveniles, which are more active than the smaller ones, play a major role in coronary thrombus formation. Platelet indices are potentially useful biomarkers of platelet activity because they are easily accessible and widely used laboratory tests, as a part of a routine complete blood count. Further research is required in order to define the prognostic role of platelet indices in the pathogenesis of acute myocardial infarction.

PB2054

CEREBRAL VENOUS THROMBOSIS IN THE SETTING OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) AND APLASTIC ANEMIA (AA): A CASE REPORT

V Coccini[1], M Carpenedo[2,*]E M Pogliani[2]
[1]Hematology, Ospedale S Geraro di Monza, [2]Hematology, Ospedale S. Gerardo di Monza, Monza, Italy

Background: The most frequent and feared complication of paroxysmal nocturnal hemoglobinuria (PNH) is thrombosis. Because the mortality rate of cerebrovascular events in PNH patients remains high, prompt diagnosis and urgent intervention is required. The propagation of thrombosis and the occurrence of further thrombosis appears to be prevented by eculizumab.
Aims: Development of any thrombosis in a patient with PNH is now considered one of the primary indicators to commence eculizumab therapy, and this should be done without delay.
Results: We report a case of a 68-years old woman who was diagnosed with aplastic anemia (AA) in 2009 and was treated with rabbit anti-thymocyte globulin and cyclosporine A (CsA) with a good response for four years. In June 2013, for worsening of laboratory data, we performed bone marrow biopsy that showed a cellularity of 40% with a normal maturation of the three series. FC analysis revealed two discrete populations of cells one of which showed levels of CD55 and CD59 antigen expression compatible with the diagnosis of PNH (granulocyte 93,6%, monocyte 93,4%, red cell 8,6%). The eculizumab beginning was delayed for the difficulty to source tetravalent meningococcal vaccination. She was admitted to our hospital one month later for development of seizures. Laboratory data showed worsening of renal function (creatinine 1,6 mg/dl), marked elevation of LDH (1127 U/L) with haptoglobin consumption. An MRI scan documented thrombosis of a left parasagittal cortical vein. She was treated with therapeutic dose of low molecular heparin and then oral anticoagulation when platelet count was steadily above 50000/mm^3. She started seizures prophylaxis, that was continued until now. After meningococcal vaccination, she promptly started eculizumab. The MRI of 3 months later showed a good response to the treatment with a reduction of extension of thrombosis. Thrombophilia evaluation was negative. In September 2013 there was progressive worsening of laboratory data: hemoglobin 7,4 g/dl, white cell count 1570/mm^3, platelet count 55000/mm^3, despite normal markers of hemolysis. Bone marrow cellularity was decreased (20%), with a certain degree of dyserythropoiesis and megacaryocite with slight dysplastic changes. We started steroid and then oral CsA, suspended a month later for renal toxicity. Indeed we started Danazol, in association with manteinance dose of eculizumab, with a discrete response particularly on platelet count (Figure 1).

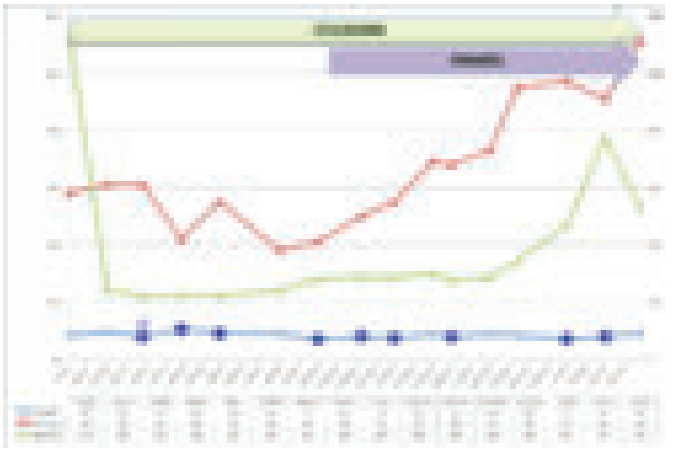

Figure 1.

Summary and Conclusions: Despite the availability of eculizumab, the management of paroxysmal nocturnal hemoglobinuria (PNH) remains complicated because of disease heterogeneity and close association with BM failure syndromes. The thrombophilia of PNH also appears to be ameliorated

by eculizumab, but the drug has no effect on the BM failure component of the disease. If BM failure dominates the clinical picture, treatment should focus on the underlying BM failure syndrome. A better understanding of the pathobiology that underlies the thrombophilia of PNH is needed, and this case report demonstrate the complex relationship between PNH and BM failure syndromes that determine clonal selection and clonal expansion and may ultimately lead to therapy that targets the disease at the level of the hematopoietic stem cell. In conclusion, thrombosis has been well-recognized as the leading cause of death in PNH and the impact of eculizumab on thrombosis largely explain the improved survival seen with eculizumab therapy.

PB2055

EVALUATION OF RISK FACTORS FOR DEVELOPMENT OF POST THROMBOTIC SYNDROME IN PATIENTS WITH DEEP VEIN THROMBOSIS

S K Atri[1], M Mahapatra[1],* S Sharma[2], P Mishra[1], T Seth[1], R Saxena[1]
[1]Hematology, [2]Radiology, AIIMS, New Delhi, New Delhi, India

Background: The post-thrombotic syndrome (PTS) is an important, under-appreciated, chronic consequence of deep vein thrombosis (DVT). It is characterized by symptoms as chronic, persistent pain, heaviness, swelling, cramps and itching in the affected limb. Various risk factors are attributed to the development of PTS. There is a paucity of data from India.
Aims: To evaluate the incidence and risk factors for development of PTS in Indian DVT patients.
Methods: All the DVT patients at least 6 months after the diagnosis, attending the thrombosis clinic in the department of hematology at AIIMS, New Delhi from April 2012 to December 2013 were analyzed. A total of 102 patients were screened for the signs and symptoms of PTS. The severity of PTS was graded according to Villalta Scale and all the patients with PTS were looked for various risk factors. Patients with oral anti-coagulants were regularly monitored with INR. D-dimer assay (semi-quantitative) and Doppler ultrasound were carried out at the time of enrollment and at 3, 6 months interval.
Results: Median age of study patients (male: female: 82:20) was 35 years (range 17 - 68 years). Duration of symptoms of DVT at the time of diagnosis was varied from 2 to 180 days with median of 14 days. Body Mass Index of patients was from 13 to 33 Kg/m^2 (median: 24 Kg/m^2). Ninety eight patients had proximal and rest four had distal DVT. Most common site of DVT was left lower limb (63 patients). Median duration of resolution of symptoms of DVT was 18 months (range: 5 – 60 months). Fifty six patients (55%) had signs and symptoms of PTS and out of these, 15 patients had mild, 18 patients had moderate and 23 patients had severe PTS. Heaviness (62.5%) and pain (56%) in lower limb were the most common symptoms experienced by PTS patients. Venous ulcer (41%) was present in all patients with severe PTS. In univariate analysis development of PTS was strongly associated with male sex (p=*0.002*), proximal DVT (p=*0.001*), lesser achievement of therapeutic INR (less than 50% of total visits) (p=*0.048*), prolonged symptoms duration of DVT at the time of diagnosis (p=*0.001*) and prolonged symptoms resolution of DVT (p=*0.001*). In multivariate analysis, male sex (odds ratio 0.067, 95% CI 0.004-1.286, p=0.001), proximal DVT (odds ratio 1.234, 95% CI 1.026-2.625,p=0.03), prolonged symptoms duration of DVT at the time of diagnosis (odds ratio 1.029, 95% CI 1.009-1.033, p=0.004) and prolonged symptoms resolution of DVT (odds ratio 1.289, 95% CI 1.150-1.427, p=0.001) showed strong correlation. However, achievement therapeutic INR has lost its significant correlation (odds ratio 0.081, 95% CI 0.001-4.601, p=0.223). D-Dimer remained elevated in all patients having chronic DVT and moderate and severe PTS but only in few cases of mild PTS and had high statistical significance (p=*0.001*).
Summary and Conclusions: Post thrombotic syndrome was seen 55% of DVT patients. The development of PTS was strongly associated with male sex, proximal DVT, prolonged symptoms duration of DVT and prolonged symptoms resolution of DVT. D-dimer showed useful screening test and showed strong correlation with DVT and PTS.

PB2056

ACUTE EFFECT OF SILDENAFIL ON FIBRINOGEN LEVELS IN ERECTILE DYSFUNCTION PATIENTS

Z Pallantza[1],* N Ioakeimidis[2], M Kozanitou[1], A Vlachopoulou[1], E Andronopoulou[1], G Malios[1], I Daruis[1], C Vlachopoulos[2], C Stefanadis[2], Z Pallantza[1]
[1]Haematology, [2]1st Cardiology Unit, Hipoocratio General Hospital, Athens, Greece

Background: Acute effect of sildenafil on fibrinogen levels in erectile dysfunction patients.
Aims: Aim of this study is to investigate the acute effect of sildenafil on fibrinogen levels in men with erectile dysfunction.
Methods: 20 erectile dysfunction patients without known history of cardiovascular disease participated in the study. The study comprised a randomized double-blind, crossover trial with sildenafil or placebo administration. The study was carried out on two separate arms: one with sildenafil, 100 mg and one with placebo. Thereafter, following a 1-week washout period, patients were switched to treatment period with the other drug. Fibrinogen levels were measured by immunonephelometry. The measurements of inflammatory markers were made by researchers unaware of the study hypothesis.
Results: There were no differences in baseline fibrinogen levels between sildenafil and placebo sessions. Response is defined as net Drug 1 effect minus Drug 2 effect at each time point. P value on the graph refers to repeated-measures analysis of variance significance between Drug 1 and Drug 2 session throughout the study (drug interaction). Acute administration of sildenafil produced a significant reduction of fibrinogen (P<0.05, maximal absolute response of −45mg/dl at 4 hours).
Summary and Conclusions: The present study shows for the first time that sildenafil has an acute favourable effect on fibrinogen levels in patients with erectile dysfunction. This finding may have important implications in erectile dysfunction patients who are considered to be at increased cardiovascular risk.

PB2057

INCIDENCE OF VENOUS THROMBOEMBOLISM (VTE) IN ACUTE MYELOID LEUKEMIA (AML): RISK ASSESSMENT BY PADUA PREDICTION SCORE (PPS)

G Catania[1],* R Santi[1], F Salvi[1], F Zallio[1], B Anna[1], MT Corsetti[1], L Contino[1]
[1]Ospedale San Antonio e Biagio e Cesare Arrigo, Alessandria, Italy

Background: The hematological malignancies are associated with a high risk of venous thromboembolism (VTE). Low molecular weight heparin (LMWH) is usually recommended for VTE prevention in cancer patients. However, no experience has been reported in patients with acute myeloid leukemia (AML), usually at risk of bleeding because thrombocytopenia. The Padua Prediction Score (PPS) is a simple model of assessment to identify the thrombotic risk in hospitalized patients.
Aims: To evaluate the risk of VTE in patients with acute myeloid leukemia (AML) undergone conventional chemotherapy by the PPS.
Methods: We performed a retrospective analysis of patients with acute myeloid leukemia (excluded promyelocytic leukemia and patients undergone to allogenic transplantation) between January 2007 and May 2013. All patients had a central venous catheter and received at least two cycles of conventional chemotherapy. None of the patients received thromboembolic prophylaxis. We assessed VTE risk during the hospitalization and 90 days the end of treatment after.
Results: 43 patients were considered. The median age was 55 years (range 32-74) and 26 (60%) were male. Eleven patients were at high risk and thirty-two were at low risk. We observed 4 venous thromboembolic events (9.2%); three in low risk and one in high-risk patients (table2) Moreover three patients had thrombosis with platelets counts less than 100x10^{9} /L.
Summary and Conclusions: In our study, PPS is not useful to identify patients affected by AML at high risk for VTE. Nevertheless in those patients VTE risk Is quite similar to solid tumor. In prospective it could be useful to evaluate a modified PPS where patients affected by AML are identified at high risk (3 points). Of course these preliminary data have to be on larger number of patients.

PB2058

HOW WE SHOULD TREAT THE PATIENTS WITH CRYPTOGENIC ISCHEMIC STROKE OR TRANSIENT ISCHEMIC ATTACKS AND ANTIPHOSPHOLIPID SYNDROME?

N Bermejo[1],* C Martín Aguilera [1], H Bañas[1], MJ Arcos[1], F Ibañez[1], R Salgado[1], I Casas[1], F Carnicero[1], J Bergua[1]
[1]Hematology, Hospital San Pedro de Alcántara, Cáceres, Spain

Background: As a result of retrospective and observational studies it was thought that stroke associated with antiphospholipid syndrome (APS) carried a high risk of recurrence, so anticoagulation with vitamin K antagonists (VKA) should be considered, but there is no strong evidence that it is more effective than aspirin. Guidelines issued in 2011 by the American Heart Association and American Stroke Association recommended antiplatelet therapy for patients with cryptogenic ischemic stroke or transient ischemic attacks (TIA) and who test positive for antiphospholipid antibodies (aPL). In contrast, VKA are recommended for patients with ischemic stroke who meet all the criteria for APS. But how we should treat the patients with cryptogenic ischemic stroke or TIA who meet all the criteria for APS?
Aims: Analyze recurrence of stroke and risk factors for recurrence of a serie of patients with cryptogenic ischemic stroke or TIA as the first thrombotic manifestation of APS, who received low-dose aspirin as prophylactic treatment during five years of follow-up.

Methods: Small retrospective study following six consecutive patients (1 man and 5 women, range of age between 35 and 68 years) with APS treated with aspirin 100 mg daily for a median of 2 years (mean 3.9 years) after cryptogenic ischemic stroke (n:4) or TIA (n:2). Analysis included laboratory and clinical criteria of APS, together with established cardiovascular risk factors, inherited thrombophilias, malignancy, immobilization and surgery.
Results: There were no significant differences in the frequency or titers of different antiphospholipid antibodies, cardiovascular or thrombophilic risk factors, with the exception of the age. Only two young patients (<50 years) had a recurrent TIA (after 1 TIA and 1 cryptogenic ischemic stroke, respectively).
Summary and Conclusions: Our results suggest that young patients (<50 years) with cryptogenic ischaemic stroke or TIA and APS may be at high risk of recurrence and low-dose aspirin doesn't appear effective for preventing recurrent stroke in these patients.

PB2059

THE ROLE OF THROMBOELASTOGRAPHY IN EVALUATING THE EVOLVING HYPERCOAGULABILITY IN PATIENTS WITH MYELOMA ON TREATMENT: A PILOT STUDY

MP Crowley[1,2,*]S Quinn[1], E Coleman[3], JA Eustace[2], OM Gilligan[1], SI O'Shea[1]
[1]Haematology, Cork University Hospital, [2]HRB Clinical Research Facility, University College Cork, [3]Cork University Hospital, Cork, Ireland

Background: Patients with myeloma have an increased risk of venous thromboembolism (VTE). Increased rates of VTE, above the baseline, have been noted in patients on specific myeloma treatment regimens. This is likely due to enhanced expression of tissue factor, increased cellular adhesion molecules, Von Willebrand Factor and thrombin generation and a decreased capacity of endothelial cells to activate protein C. Immunomodulatory agents, in combination with steroids or anthracyclines, lead to the highest rates of VTE, especially in the absence of thromboprophylaxis. Thromboelastography assesses the viscoelastic properties of whole blood under low shear stress. Its main advantage over routine tests of haemostasis is the global assessment of the different components of clot formation such as coagulation factors and platelets. It has mainly been used in the operative setting, to assess bleeding patients. However, it has also been used to assess hypercoagulability in the obstetric and surgical oncology setting. A recent study (Trelinski et al 2014) demonstrated that patients with myeloma display changes in ROTEM tests at the time of diagnosis that may indicate a prothrombotic state.
Aims: To investigate whether thromboelastography was a useful tool in evaluating the evolving hypercoagulability state in patients with myeloma.
Methods: Patient s with newly diagnosed/relapsed myeloma who met criteria for treatment were recruited. Fresh whole blood was taken by direct venepuncture into tubes containing citrate 0.105M at diagnosis and prior to cycle 2 of treatment. Samples were stored at room temperature for 30 minutes prior to analysis. 500µl of whole blood was activated with 12.5µl of Kaolin and thromboelastography was performed by the same technician on 340µl of activated blood in combination with 20µl of calcium chloride using a TEG 5000 Thrombelastograph®analyzer according to the manufacturer's protocol. The remainder of the tests were performed in the accredited hospital laboratory. Patients were excluded if they had a history of VTE or were on an anticoagulant.
Results: 8 patients were recruited. The mean (SD) age at recruitment was 72.8 (11.1) years. 5/8 had IgG myeloma and 6/8 were women. Table 1 shows the laboratory values at baseline and after one cycle of chemotherapy. A paired samples t-test was performed to see if there were any differences between the groups. Both the FVIII level and the VWF:RiCoF were significantly different between the groups. Among the thromboelastography indices that were looked at, only the alpha angle was significantly different between the groups. While the maximum amplitude appeared higher in the chemotherapy group, this was not significant.
Summary and Conclusions: Similar to previous studies, there was a significant increase In FVIII and VWF after chemotherapy. The α- angle was also significantly elevated in the chemotherapy group suggesting that thromboelastography may have a role to play in assessing the coagulation status in patients with myeloma as an increased α-angle has been shown to be associated with hypercoagulability. Thromboelastography has the advantage of being a relatively quick and inexpensive means of assessing a patient's coagulation status when compared with testing for other markers of hypercoagulability such as FVIII and VWF. The main drawback is that it is heavily dependent on platelets so if a patient is thrombocytopenic secondary to their disease, it may not accurately assess their coagulation status. This is only a small pilot study and so it would need to be replicated on a larger scale to validate it.

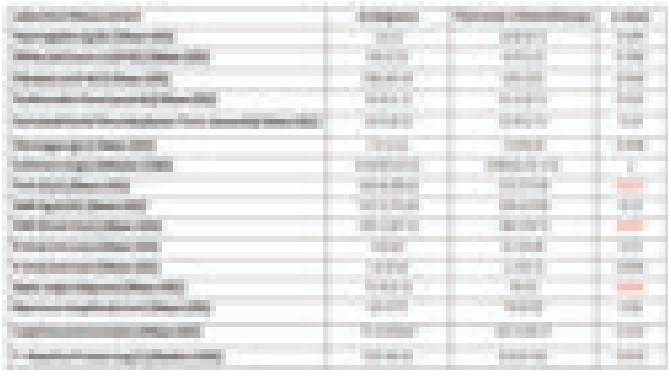

Table 1. Laboratory measurements at diagnosis and following one cycle of chemotherapy.

Quality of life, palliative care, ethics and health economics

PB2060

A CROSS SECTIONAL STUDY OF FACTORS EFFECTING BETA THALASSEMIA AMONG MULTI ETHNIC GROUPS IN PAKISTAN

H Yasmeen[1,*] S Hasnain[1,2]
[1]Department of Microbiology and Molecular Genetics, University of the Punjab, Lahore, [2]The Women University Multan, Multan, Pakistan

Background: Among hemoglobinopathies, thalassemia is constantly upturning the burden on economy of multicultural and multi-ethnic country like Pakistan. This autosomal recessive genetic disorder is caused by either reduced production or complete absence of beta-globin chains following production of immature erythroblasts due to dyserythropoiesis. Severe anemia, general fatigue, repeated or frequent blood transfusion following post transfusion hepatitis intensifies the severity of disease.
Aims: Present multicenter study undertaken in five cities of Pakistan aims to investigate the prevalence of beta thalassemia in different caste/ethnic groups using suitable approach.
Methods: Data for present study was collected from a period of 2011 to 2013. After consent, 450 patients of beta thalassemia excluding patients of any other blood disease were interviewed for different epidemiological parameters including their gender, age, transfusion history, family and personal history. Sero-negative blood samples were further preceded for RBC indices, quantification of hemoglobin including variant hemoglobin testing and other blood chemistry tests.
Results: Out of 450 patient samples 340 were seronegative. Beta thalassemia major (>95%) was most common followed by thalassemia intermedia (<5%) and very few structural variants (<1%) *e.g.* HbS and HbH. It was observed that in our population, females (55.29%) are more affected with beta thalassemia than males (48.82%). When compared to the normal age span, it was observed that only 2.64% of the patients crossed the second decade of their life. Early onset disease (before 6 months) was more common (24%) than the late onset *e.g.* above 24 months (10%). The high ratio of consanguinity (>80%) showed that it was in common practice among affected families. Further work on beta globin genotyping of these subjects is under progress.
Summary and Conclusions: Short life span and high number of HCV/ HbBAg status depicts that in a country like Pakistan, insufficient facilities, poor management and compromised socioeconomic status are deteriorating the disease status. More multicenter study covering cities from different regions of country are needed in developing preventive measurements at regional and national level.

PB2061

SAVING MONEY AND COMFORT BY GAINING CYTOSINE ARABINOSIDE MICROGRAMS

N Pugliese[1,*] M De Nisco[2], V Martinelli[1], S Pedatella[3], L Catalano[1], M Manfra[4], N Marra[5], G Beneduce[1], A Bolognese[6], F Pane[1]
[1]Hematology, [2]Dipartimento di Scienze Chimiche, University of Naples Federico II, Naples, [3]Dipartimento Farmaco-Chimico, Università di Messina, Facoltà di Farmacia, Dip, Messin, [4]Dipartimento di Scienze Chimiche, Università della Basilicata, Potenza, [5]Onco-Hematology, A.O.R.N. Santobono Pausillipon Napoli, Naples, [6]Dipartimento di Scienze Chimiche, Università di Messina, Facoltà di Farmacia, Dip, Messin, Italy

Background: Cytarabine (4-Amino-1-(β-D-arabinofuranosyl)-2(1H)-pyrimidinone, Ara-C) a deoxycytidine analogue, is one of the most active drugs in the treatment of acute leukemias and is widely applied at a variety of other hematological malignancies. Although chemical and physical in-use stability of commercial Ara-C has been recommended for 48 hours at room temperature after dilution, from a microbiological point of view (data from drug informative sheet of Aracytin, available in Italy), the product should be used immediately. The cancer drugs preparation and dispensing in designated centralized chemotherapy (CHT) preparation pharmacy units (CPU) has been extensively studied to improve its quality and minimize personnel exposure to these drugs. We know relative little about the possibility to optimize and economize the use of CHT agents in CPU.
Aims: Here we explore the chemical and microbiological stability of a commercial Ara-C sample (Aracytin) in its pharmaceutical form after its reconstitution and storage at 4°C, in order to save drug.
Methods: Commercial Ara-C has been investigated under the common conditions of the clinical use to be degradable in water as in physiological solution. Ara-C samples reconstituted according to the commercial reported instructions and stored at 4°C, in controlled and validated aseptic conditions, were analyzed by high-field nuclear magnetic resonance spectroscopy (NMR). The results obtained were compared with those derived from identical samples bubbled with air at 4 °C, and 25 °C, at different time and concentrations, respectively. Microbiological assay, applying the cylinder-plate method, was performed. After an initial entry through the vial closure with a sterile syringe with needle, aliquots of reconstituted and unused solution were withdrawn after multiple aseptic entries trough the cap at 1 to 5 days and were assayed against solutions of reference standard.
Results: All the samples remained chemical unchanged for one month. Low temperature and scarce contact with air decrease the degradation process. We demonstrate the absence of any microbiological contamination, respecting the described aseptic condition, for at least 5 days.
Summary and Conclusions: We demonstrate chemical and microbiological stability of Ara-C solutions for at least 30 and 5 days respectively, allowing the use of the same vial for a prolonged time. It seems to be cheap and particularly useful for CPU and hospital, in order to economize without losing in efficacy and safety. We can also auspicate the use of the same vial, after a specific training about aseptic and sterile procedures to collect multiple doses, for outpatients who receive subcutaneously daily administration of low doses of Ara-C for more than a week. It could avoid to discard a great amount of drug and allow the outpatient to self administrate drug without daily return to the Hospital only for a simple and short-term injection. The opportunity to save Ara-C micrograms could positively impact both on health economic and patients quality of life.

PB2062

ASSESSMENT OF GERIATRIC SYNDROMES AND FUNCTIONAL STATUS IN ELDERLY HEMATOLOGIC CANCER PATIENTS IN TURKEY

K Silay[1,*] S Akinci[2], T Guney[2], E Ozturk[3], M Canbaz[3], A Yalcin[4], I Dilek[5]
[1]Geriatrics, Yildirim Beyazit University, [2]Hematology, Ataturk Research and Training Hospital, [3]Family Medicine, Yildirim Beyazit University, [4]Geriatrics, Ataturk Research and Training Hospital, [5]Hematology, Yildirim Beyazit University, Ankara, Turkey

Background: Management of elderly patients with cancer is complex and requires a multidisciplinary approach. Utilizing Geriatric Screening tools for the identification of vulnerable older patients with hematologic cancer is needed.Geriatrics is an emerging and newly developed specialty in Turkey. This study is one of the first studies analyzing geriatric hematology cancer population by using geriatric assessment tools in Turkey.
Aims: The goal of this study was to characterize an elderly population with hematologic malignancies presented to hematology outpatient clinic and determine the prevalence of comorbidities, polypharmacy, functional dependencies and geriatric syndromes.
Methods: 48 patients with hematologic malignancies, age 51 years and older were assessed at hematology outpatient clinic over 3 months period. Numerous standard geriatric screening tests (ADL, IADL, MNA, Mini Cog and MMSE, TUG (timed up and go test), GDS (geriatrics depression scale) were administered to assess mood, functional status , nutritional and cognitive status. Demographic and medical data were obtained from patients' medical records.
Results: The mean age of the patients was 67.1 years (standard deviation, 10.6 years). There were 19 female (39.6%) and 29 male (60.4%). About 20.8% and 29.2% had limitations on one or more ADL and IADL domains respectively. Geriatric syndromes detected by geriatrician included cognitive impairment (minimal cognitive impairment (4.2%) and dementia (20.8%), depression (35.4%), risk of malnutrition (25%), and polypharmacy (54.2%).Out of 48 patients 83.3% had comorbidity score equals to 5 and more. TUG test as an indicator for fall risk found positive at 9 patients (18.8%).There were no statistically significant correlation between comorbidity and ADL , IADL scores. 18 patients were unaware of severity of their diagnosis but no correlation was found between awareness and mood.
Summary and Conclusions: In this descriptive study, many older hematologic cancer patients were found to have geriatric syndromes The study demonstrates that comprehensive geriatrics assessment provides insights into understanding the needs of elderly patients with hematologic cancer. Geriatrics is an emerging and newly developed specialty in Turkey. This study is one of the first studies analyzing geriatric hematology cancer population by using geriatric scales in Turkey. It revealed that numerous geriatric syndromes may be underdiagnosed in a regular visit. Larger and longer term well controlled clinical studies evaluating geriatric hematology cancer populations are needed in the future.

PB2063

THE BURDEN OF HEALTHCARE COST AMONG RELAPSED DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) PATIENTS: (A SEER MEDICARE DATASET EXAMINATION)

C Flowers[1], B Chastek[2], L Becker[2], D Mahmoud[3], ,*E Dulac[3]
[1]Emory University, Atlanta, [2]Optum, Eden Prairie, [3]Celgene Corporation, Summit, United States

Background: DLBCL is the most common form of Non-Hodgkin Lymphoma in the US accounting for ~33% of newly diagnosed pts. For newly diagnosed pts treatment with rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) is the standard of care (Coiffier, NEJM 2002). While roughly 50% of first-line pts are cured with R-CHOP, older pts who relapse have a poorer prognosis and are often treated with a variety of therapies, but the downstream costs of this care are not well known.
Aims: This study examined initial and downstream health care costs among adult DLBCL pts who received additional lines of therapy (LOT) following R-CHOP.
Methods: Pts diagnosed with DLBCL and treated with R-CHOP first line between 2001 and 2009 were identified from the linked Surveillance, Epidemiology, and End Results (SEER) US Medicare database using ICD-O codes 9680-9689. Pts with at least two lines of therapy, neither of which were censored, were included in the study. The start of chemotherapy was considered the start of first line of therapy, and the regimen included all medications received in the first 36 days following therapy initiation. TheLOT ended with either the addition of a new chemotherapeutic agent or discontinuation of all agents. Second- and third-line therapy (LOT2 and LOT3) were identified using a similar algorithm. Receipt of stem cell transplant was not included when identifying LOT1 or LOT2. All health care costs from inpatient, outpatient, physician services, and medications were calculated during LOT1, during LOT2, and following LOT2. Mean monthly costs during LOT1 and LOT2 were calculated by dividing mean costs by length of LOT. Sensitivity analysis was conducted examining costs during LOT1 among pts with a non-censored LOT1.
Results: Among 6,617 pts diagnosed with DLBCL, 3,257 had a complete (non-censored) LOT1 of R-CHOP, and of those 352 had a complete LOT2. Mean age was 73 years, 47% were female, 86% were Caucasian. At diagnosis, 39% of pts had stage I/II, 53% had stage III/IV, and 7% no stage information. Mean (median) length of LOT1 was 113 days (104 days) with mean cost of $59,617 (median $37,539). Sensitivity analysis demonstrated that first-line costs (Mean: $62,055, Median: $37,168) were similar for pts with a first line of R-CHOP irrespective whether they subsequently received a 2nd line treatment or not. LOT2 started an average of 418 days after LOT1 (median 200 days; interquartile range 21 - 595 days) and lasted 56 days (median 43 days) with a mean total cost of $41,947 (median $23,276). LOT2 most commonly involved treatments with cyclophosphamide (55%), etoposide (43%), and vincristine (42%), but a number of different treatment strategies were used. For both LOT1 and LOT2, costs were comprised largely of outpatient services (60%), physician visits (33%), inpatient stays (6%), and pharmacy (0.5%,). Average monthly costs for LOT1 and LOT2 were $15,828 and $22,472, respectively. Median follow-up after LOT2 was 518 days (mean 753); initiation of a LOT3 was observed among 77 pts. Mean cost after LOT2 was $125,029 (median: $90,670).
Summary and Conclusions: Older DLBCL pts failing to respond adequately to first-line R-CHOP therapy incur substantial aggregate costs across their treatment history. Importantly, calculated average monthly costs were higher during a second line of therapy (*vs.* a first line) – representing almost a 42% increase in monthly costs when incur a first relapse.

PB2064

FEASIBILITY AND LONG TERM OUTCOME OF PERCUTANEOUS VERTEBROPLASTY IN ELDERLY MULTIPLE MYELOMA PATIENTS

P Tosi[1,*] M Sintini[2], AL Molinari[1], M Imola[1], AM Mianulli[1], S Tomassetti[1], V Polli[1]
[1]Oncology and Hematology, Hematology Unit Infermi Hospital Rimini Italy, [2]Clinical Pathology and Radiology, Neuroradiology Unit Infermi Hospital, Rimini, Italy

Background: Vertebral fractures occur in over 70% multiple myeloma (MM) patients and can cause pain, disability and poor quality of life. This is particularly relevant for elderly patients, as pain and disability may add to other comorbidities. Vertebral fractures occur in over 70% multiple myeloma (MM) patients and can cause pain, disability and poor quality of life. This is particularly relevant for elderly patients, as pain and disability may add to other comorbidities.
Aims: The present study aimed at evaluating retrospectively the medium and long-term effects of percutaneous vertebroplasty when performed in elderly MM patients, in order to assess whether the procedure can result into subjective clinical improvement or lead to side effects not expected in younger patients populations.
Methods: Forty patients (24M/16F, median age 72 years, range 68-87 years) with newly diagnosed (n= 26) or relapsed-refractory (n = 14) MM and painful vertebral lesions underwent vertebroplasty prior to proceed to induction or salvage therapy. Eighty-four procedures were performed at D2-L5 levels, 26 patients were treated at ≥ 2 levels. The visual analog ten points scale (VAS) was used to evaluate pain prior to and upon completion of the procedure, on day +1 and monthly thereafter, till three months after the conclusion of the transplantation program. Pain response to vertebroplasty, irrespective of pretreatment values, was graded as follows: complete response VAS = 0; optimal response VAS = 1; good response VAS = 2-3, no response VAS ≥4
Results: Twenty-six patients (65%) obtained a complete or optimal pain control; this was not related to disease status, as at least optimal pain response was achieved in 69% newly diagnosed patients as compared to 57% relapsed-refractory ones. No difference in achievement of a complete/optimal pain response was observed in patients aged ≥ 75 yrs (70%) as compared to those<75 yrs (63%). Response to antimyeloma therapy, however, predicts for an optimal and more durable pain control, as patients achieving a very-good partial response or better had a significantly higher probability of pain control (p=0.04). No significant side effects were registered.
Summary and Conclusions: In conclusion, percutaneous vertebroplasty is useful in elderly MM patients with painful vertebral fractures as it allows a rapid and long-lasting pain control; the combination with an effective antimyeloma therapy may warrant better results

PB2065

AUTONOMIC DYSFUNCTION IS AUGMENTED DURING THERAPY, BUT CAN BE IMPROVED BY PHYSICAL EXERCISE IN PATIENTS WITH HEMATOLOGICAL MALIGNANCY. RESULTS OF A PILOT TRIAL.

A Janikova[1,*] I Hrncirikova[2], L Dovrtelova[2], M Zvonar[3], M Hrouzek[2], T Vodicka[3], P Seman[2], Z Svobodova[4], A Mala[4], Z Racil[1], D Zackova[1], M Praskova[1], J Mayer[1]
[1]Hematology and Oncology, University Hospital Brno, [2]Department of Health Support , [3]Department of Kinesiology , [4]University Sports Centre , Faculty of Sports Studies University Brno, Brno, Czech Republic

Background: Autonomic dysfunction is common in patients with cancer and may have considerable negative effects on quality of life and mortality. Vagal nerve activity, indexed by heart rate variability (HRV), could have a role of prognosticator in cancer. Exercise enhances cardiac autonomic regulation of cancer patients. Because of the association of higher HRV-parameters and prolonged survival in cancer patients, improvement in autonomic control may be important goal of exercise.
Aims: Therefore, the aim of this prospective longitudinal study was to assess parameters of physical fitness and HRV in patients with hematological malignancy before, during chemotherapy and after supervised physical training.
Methods: Patients with hematological malignancies treated with systemic anticancer therapy were enrolled. HRV, physical fitness and muscle strength were measured in three time-points: before start o systemic therapy (15pts), after end of treatment (56pts with response) and after 12-week exercise program (30pts). HRV was tested by vagal activity (VA), sympatovagal balance (SVB) and global score (GS), physical fitness was measured with cycle ergometer (pVO_2max), muscle strength with hand grip test. Exercise training consisted of spinning (about 45-60%), resistance exercise (15-25%), remaining activities included balance exercise and stretching. Lesson duration was 50-90 minutes with intensity between 60-75% HRmax with frequency of three times per week.
Results: Totally 64 patients were included in this prospective study (43 NonHodgkin´s lymphoma, 14 Hodgkin lymphomas and 7 leukemias). Median age was 54 (19-77) years, and 36/64 pts were women. At baseline (before chemotherapy), physical fitness (pVO_2 max) was normal and HRV was only mildly reduced compared to common population. After treatment significant decrease in pVO_2max (p0.065) and in HRV were observed (SVB; p0.018). Exercise training lead to improvement of the global fitness measured by pVO_2max (p.0.0029), and influenced also HRV (VA p0.086; CS p 0.098); in 7 pair-matched patient subset HRV was significantly changed in all parameters (VA p.0.045, SVB p.0.01, CS p.0.01).
Summary and Conclusions: Exercise training is feasible and able to improve significantly physical fitness of patients with hematological malignancy. Training is also related to improvement in autonomic dysfunction and could potentially contribute to better survival. Further investigation is needed in this area.

PB2066

PROPHYLAXIS WITH LAMIVUDINE FOR THE PREVENTION OF REACTIVATION IN OCCULT HEPATITIS B (OBI) IN NHL : A COST-EFFECTIVE ANALYSIS

C Cerchione[1,*] M Masarone[2], M Persico[2], G Signoriello[3], F Perna[1], C Cimmino[1], N Pugliese[1], E Seneca[1], I Peluso[1], M Notarangelo[1], F Pane[1], A De Renzo[1]
[1]Hematology, AOU "Federico II", [2]Hepatology, [3]Department of Statistical Sciences, Second University, Napoli, Italy

Background: Occult HBV infection (OBI) is defined by the persistence of HBV in the liver without serum HBsAg and HBV-DNA. It represents a life threatening event during immunosuppressive chemotherapies. An OBI occurs in approximately 18% of HBcAb+ patients. International guidelines suggest surveillance for HBV markers in immunosuppressed patients, in particular

monoclonal antibodies. In our study, the prevalence of OBI reactivation in Non-Hodgkin Lymphoma (NHL), in 498 NHL patients in our centre of Southern Italy, was 10.42% in HBcAb+ HBsAb- patients. In this work, we want to perform a cost-effectiveness analysis regarding the use of Lamivudine for the prevention of reactivation in OBI in patients with Non-Hodgkin Lymphoma undergoing chemotherapy with or without Rituximab. In fact, considering guidelines and literature, universal prophylaxis should have been applied to all HBcAb positive HBsAg negative patient. A cost-benefit issue arises : is it more cost-effective to treat all the HBcAb positive HBsAg negative patients with Lamivudine to prevent the OBI reactivation occurrence in a small quote of them, or may it be more effective a "wait and see" protocol?

Aims: Our idea was to perform a cost-effectiveness analysis, comparing the costs of prophylaxis of an eventual HBV reactivation and the "monitoring" approach that was used in our patient based on the international guidelines.

Methods: We calculated the cost of prophylaxis with Lamivudine in a time interval of twelve months, which encompasses the time of a standard Rituximab-containing chemotherapeutic protocol and a minimum time of follow-up. It has to be noticed that, very often, NHL patients need more than one chemotherapy cycle to obtain NHL remission, and, sometimes, if they do not obtain a complete remission, undergo to long-term "maintenance" treatments with Rituximab. These patients (HBcAb positive) are at high risk of HBV reactivations, due to long times of immunosuppression.

Results: Nevertheless, even if our calculations underestimated the costs of prophylaxis, the "monitoring approach" resulted cost-effective. Moreover, even though in our series no serious events in terms of morbidity and/or mortality occurred, in other literature reports a monitoring approach did not guarantee patients survival. These detrimental results could be ascribed to the delayed start of Lamivudine treatment if the monitoring is not adequately strict (less than one evaluation/month). Also, it has been reported that performing only the transaminase monitoring should not be acceptable to prevent severe reactivations. Our monitoring approach resulted efficacious probably because of the monthly ALT assay was strictly observed (Table 1).

Table 1.

Summary and Conclusions: We report an advantage in the "monitoring" approach that was used in our patient in respect to universal prophylaxis. Due to the retrospective nature of our study, we cannot draw any firm conclusion on which should be the best approach for patients with isolated HBcAb positivity who should undergo chemotherapeutic regimens (universal prophylaxis *vs* monthly ALT monitoring). A randomized controlled trial might be needed to properly address this issue.

PB2067

THE SOUTHERN TRANSYLVANIA PATIENTS' OPINION ON THE RELATIONSHIP BETWEEN THROMBOPHILIA AND QUALITY OF LIFE

RG Mihaila[1,*] IM Cobirje[2], I Dragomir[2], C Catana[2], L Vecerzan[2], RC Cipaian[1]
[1]Faculty of Medicine, Lucian Blaga University of Sibiu, [2]Emergency County Clinical Hospital, Sibiu, Romania

Background: Thrombophilia is a public health problem which is increasingly being studied and whose complications are increasingly recognized in practice.

Aims: We aimed to study the opinion of hospitalized patients on the relationship between thrombophilia and quality of life.

Methods: A transversal study was performed on a sample of 246 consecutive hospitalized patients in medical departments of Emergency County Clinical Hospital Sibiu in January 2014 who responded to a questionnaire on the relationship between thrombophilia and quality of life. The results were analyzed and they have allowed conclusions that we hope to have implications for clinical practice.

Results: The mean age of surveyed patients was 53,32+/-15,35 years. Distribution by gender: women 56,10%, men 43,90%. Less than half of respondents (45.53%) have heard of thrombophilia, but we explained them that it is a hypercoagulable state that predisposes to thrombosis. The appearance of a lower limb deep venous thrombosis can be life threatening in the opinion of 60.16% of patients. Most patients (89.43%) would agree to about 10 days of injectable anticoagulant therapy if they had deep venous thrombosis, but only 62.68% of respondents would accept long-term therapy with acenocoumarol, under periodic control of INR (weekly in the first month, then monthly). Most people believe that the health ministry should include analyzes that allow diagnosis of thrombophilia in basic health services package in order to be free. The majority (86.18%) believe that loss of vision in one eye caused by central retinal vein thrombosis (one of the thrombophilia complications) reduces quality of life. A similar proportion of respondents (87.8%) believe that stroke increases maintenance costs related to thrombophilic patient. The vast majority of surveyed patients (91.06%) believe that a paralyzed and bedridden retired in Romania does not have sufficient income to support himself. Over 60% of those surveyed believe that a woman who is going to remain pregnant should be subject for thrombophilia screening because it can cause abortion. Fewer than half of them (47,97%) believe that the anticoagulant treatment carried out throughout all their life due to a thrombophilia complication reduces the quality of life of the patient. The majority (77.24%) advocates for popularizing thrombophilia. They opt for talks with your GP (58,78%) and media (20,94%) and less for letters addressed to the patients (12,16%), messages sent over the internet (5,41%), conferences, or facebook (by 1.35%). The majority (86.18%) agree that it is cheaper to prevent thrombophilia complications through early diagnosis and information than to treat them (after they have occurred).

Summary and Conclusions: Patients hospitalized in Southern Transylvania want to be informed about thrombophilia especially by their family doctor. Their complications reduce the quality of life, which is why it is desirable that they are prevented. They believe that to resolve the problems raised by thrombophilia the state should get involved financially.

PB2068

ASSESSMENT OF QUALITY OF LIFE IN THALASSEMIA PATIENTS IN A DEVELOPING COUNTRY

S Kakkar[1,*] PC Sobti[2], P Dewan[3]
[1]Pediatrics, hemato-oncology unit, Dayanand Medical College, Ludhiana, [2]Pediatrics, hemato-oncology unit, Christian medical college, [3]Dayanand Medical College, Ludhiana, India

Background: Thalassemia major is an inherited disorder requiring life- long blood transfusion and chelation therapy. It is also associated with various complications arising out of iron overload and transfusion transmitted infections. With increasing lifespan of these patients due to advances in the medical management, quality of life has become an important parameter reflecting the efficacy of health care system.

Aims: To assess the quality of life of thalassemia patients attending thalassemia day care centre in a tertiary care hospital in India.

Methods: 60 thalassemia patients between 10-18 years of age regularly attending Thalassemia Day Care Centre were included in the study. Quality of life was assessed by using WHOQOL-BREF scoring. The QOL was assessed on four parameters. The QOL was assessed on four parameters. Independent variables evaluated included clinical and sociodemographic characteristics.

Results: The mean overall score was found to be 119.37 with scores in physical, psychological, social and environmental domains being 135.7, 101.6, 59.23 and 134.89 respectively. Higher socioeconomic status was related to higher scores. Presence of co-morbidities like TTI'S & endocrinopathy was associated with lower overall score.

Summary and Conclusions: Adolescent thalassemics in our unit have reasonable quality of life. An association is found between co-morbidities and quality of life.

PB2069

EVALUATION OF MENTAL HEALTH AND PHYSICAL PAIN AMONG PATIENTS WITH BETA-THALASSEMIA MAJOR IN NORTH GREECE.

E Vlachaki[1], N Neokleous[2,*]D Paspali [3], E Vetsiou[1], E Onoufriadis[1], N Sousos[1], P Boura[1]
[1]Thalassemia Unit, 2nd Department of Internal Medicine , Aristotle University, Ippokration Hospital, Thessaloniki, Greece, [2]Hematology Department, General Hospital of Limassol, Limassol, Cyprus, [3]Psychiatric Clinic, Ippokration Hospital, Thessaloniki, Greece

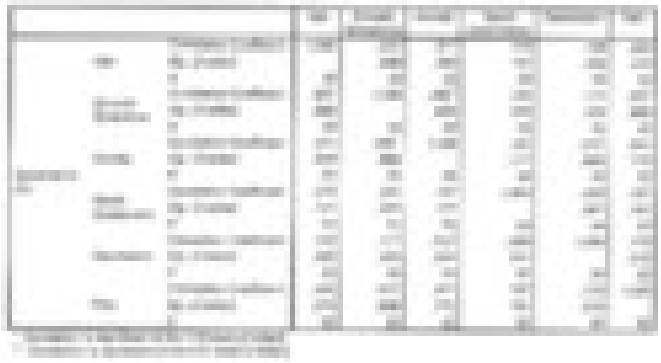
Background: Beta-thalassemia major (β-TM) is a chronic, genetic blood disorder. Patients are considered to be vulnerable to emotional and behaviour problems.

Aims: The aim of this study was to assess mental health and the somatic pain of patients with homozygous β-TM who are transfused systematically in our unit.

Methods: In this survey, 54 adults patients aged 37,5+/-18,5 years were studied. The female patients were 59,3%. The general health questionnaire by David Goldberg (GHQ-28) was used as mental health assessment model aiming to detect mental disorders. The model of Binary was used as scoring method of GHQ-28. Overall rating below 5 indicates no psychiatric problem,

while total score over or equal to 5 indicates the likelihood of diagnosis with any psychiatric disorder. The GHQ-28 allows separate evaluation of four subscales which are "somatic symptoms", "anxiety", social dysfunction" and "depression disorder". The Visual Analogue Scale of Pain (VAS) was used as model for pain evaluation. Data was analyzed with software SPSS 17.0 and Microsoft Office Excel 2010. The significance level was set at p=0.05.
Results: One out of four examined patients was presented with GHQ-28 score above or equal to 5 as having an increased chance to be diagnosed with any psychiatric disorder. Concerning the pain, the majority of the studied patients assessed at scores between 1 and 3 meaning that they are feeling mild pain. There is no statistical significant correlation between age and GHQ-28 score. There is a statistical significant correlation between age and somatic symptoms (p=0,026), anxiety and somatic symptoms (0,004) as well as anxiety and depression (p=0,022) (Table 1).

Table 1. Correlation between the examined parameters.



Summary and Conclusions: Thalassemic patients tend to be diagnosed with psychiatric disorders and it seems that they do not feel severe pain. More quantitive and comprehensive studies has to be conducted in order to estimate specific effective factors in psycho-social health.

PB2070

ECOG ROLE IN THE ASSESSMENT OF THE FUNCTIONAL STATUS OF ELDERLY PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

H Jelena[1,*] N Stanisavljevic[1], D Marisavljevic[1,2], O Markovic[1], R Zivkovic[1]
[1]Hematology, Medical Center Bezanijska Kosa, [2]University of Belgrade, Medical faculty, Belgrade, Serbia

Background: Cancer is the leading cause of death in elderly patients aged 60 to 79 years. ECOG performance score is a common tool in everyday practice but an older cancer population requires more specific tools to access their condition as Comprenhensive Geriatric Assesment (CGA).
Aims: The aim was to assess whether ECOG score correlate with CGA assessment.
Methods: The 32 patients older than 65 years (with different ECOG score) diagnosed with hematologic malignancies hospitalized in Medical Center "Bezanijska kosa" underwent uniform CGA assessment including Activities of Daily Living (ADL), Instrumental Activities of Daily Living (IADL), Mini Mental Status Examt (MMSE), Geriatric Depression Scale (GDS) and Mini Nutritional Assessment (MNA).
Results: Median age of 32 pts was 75 years (min 65, max 86). Eighteen (56%) patients were ECOG≤1, and 14 (34%) ECOG ≥2. According to CGA results, ADL dependence was found in 8 (25%) pts, IADL in 11 (34,4%) pts, minimal cognitive impairment was present in 8 (18.8%) pts; dementia in 13 (40.6%) pts; 11 (34,4%) pts were at risk of depression; 15 (46.8%) pts were at risk of malnutrition. ECOG correlated (Pearson coefficient) with ADL, IADL, MMSE, GDS and MNA with statistically significant difference with ADL (p=0.001), IADL (p=0.001), MMSE (p=0.038) and MNA (p=0.029).
Summary and Conclusions: A high proportion of elderly patients with hematological malignancy and poor ECOG score presents with abnormalities on a baseline CGA. ECOG correlate with CGA components and could be used in estimation of ADL, IADL, MMSE and MNA.

PB2071

ANALYSIS OF QUALITY-OF-LIFE AFTER RED BLOOD CELL TRANSFUSIONS IN HEMATOLOGICAL MALIGNANCIES PATIENTS WITH ANAEMIA

N Romanenko[1,*] I Kostroma[1], D Bulgan[1], S Gritsaev[1], I Karmatskaya[1], K Abdulkadyrov[1]
[1]Clinical Hematology, Russian Research Institute of Hematology and Transfusiology, FMBA of Russia, Saint-Petersburg, Russian Federation

Background: Anaemia frequently decreases survival rate and overall Quality-of- life (QoL) in patients with hematological malignancies (HM). Red blood cell (RBC) transfusions can quickly correct severe symptoms of anaemia, increase hemoglobin (Hb) and improve QoL.
Aims: To study QoL in HM patients with anaemia before and after RBC transfusions.
Methods: HM patients (n=69) with anaemia: myelodysplastic syndrome (n=12), acute myeloid leukemia (n=10), primary myelofybrosis (n=8), chronic myeloid leukemia BC (n=3), multiple myeloma (n=17), non-Hodgkin's lymphoma (n=5), chronic lymphocytic leukemia stadium C (n=12) and acute lymphoblastic leukemia (n=2). The median age of patients was 64.0 years (range 21-82). Initial Hb concentration was <8.0 g/dl and target Hb > 8.0-9.9 g/dl. QoL was assessed with the Functional Assessment of Cancer Therapy-Anemia questionnaire scale General (FACT-G) and Anaemia (FACT-An). Patients filled up the special forms of questionnaire before and after RBC transfusion.
Results: Mean baseline Hb concentration in our patients was 4.0-8.9 g/dl (Me=68 g/dl). During the hospitalization period were transfused 1-9 (mean 3.4±2.1) RBC Units. Hb concentration increased from baseline to 7.9-9.9 g/dl (Me=98; p<0.01). The Hb increasing was 0.88±0.54 g/dl per Unit. The most patients registered reducing symptoms of amaemia. After RBC transfusion in the most subscales of FACT-An we observed improving. In FACT-G in measuring domains of "Physical well-being" were ascertained of improving from 12.9±5.3 to 11.0±5.7 points (p<0.001), "Social/ family well-being" - from 13.4±4.4 to 13.6±4.3 (p=0.6), "Emotional well-being" - from 9.2±4.8 to 8.0±4.8 (p<0.05), and "Functional well-being" - from 9.6±4.7 to 11.0±4.5 (p<0.02). In FACT-An Anemia subscale we observed improve from 35.9±11.2 to 29.8±11.5 points (p=0.001). In detail study of Anemia subscale we found out statistically significant (p<0.05) improve at the next items: 1-6, 10-13 and 15 of the FACT-An questionnaire. 1) I feel fatigued; 2) I feel weak all over; 3) I feel listless ("washed out"); 4) I feel tired; 5) I have trouble starting things because I am tired; 6) I have trouble finishing things because I am tired; 7) I have energy; 8) I have trouble walking; 9) I am able to my usual activities; 10) I need sleep during the day; 11) I feel lightheaded; 12) I get headaches; 13) I have been short of breath; 14) I have pain in my chest 15) I am too tired to eat; 16) I am interested in sex; 17) I am motivated to do my usual activities; 18) I need help doing my usual activities; 19) I am frustrated by being too tired to do the things I want to do; 20) I have to limit my social activity because I am tired.
Summary and Conclusions: In this study was showed that RBC transfusions effective improve QoL in hematological malignancies patients with anaemia.

PB2072

ANALYSIS OF SOME ASPECTS OF QUALITY OF LIFE IN PATIENTS WITH ACUTE LEUKEMIA IN REPUBLIC OF ARMENIA

Y Hakobyan[1,*] K Hakobyan[1]
[1]Clinical department, Center of Haematology, Yerevan, Armenia

Background: Since hematological cases can be treated and prolongation of life is achieved, many different spirituals and psychological concerns must be addressed to maintain smooth functioning and optimize quality of life (QoL).
Aims: Analysis of some aspects of quality of life in patients with acute leukemia in Republic of Armenia
Methods: This research study has been designed the first time to place into hematological practice in Armenia a modified QoL questionnaire and find out correlations between efficiency of treatment of AL and QoL.
QoL questionnaire include common and disease related specific problems: over 50 questions about psychological and functional conditions of the patients their relationship with others, self-esteem issues, etc. The questionnaires were first filled out within the 7 days after admittance and after two weeks.
Results: The study of questionnaires revealed that weakness impaired the patients' QoL in 80% (n=64), the bone pain – in 85% (n= 68), fever- in 75% (n=60), dyspepsia – in 60% (n=48), followed by the decreased ability to work – in 60% (n=48) and lower personal relations – in 62.5% (n=50) of cases. Patients with high-risk and AML have shown the poorer indicators of QoL then the patients with low-risk and ALL. Acknowledgment and understanding by the patients, that many of side effects and spiritual feelings are impermanent and predictable, may create sense of confidence. On the other hand, fear, anxiety and aloofness would complicate extensively the course of clinical management and expected outcomes in each single case. Our research data indicates that patients in general trust and are confident in their healthcare practitioners (physicians and nurses). The first step towards dealing with the routine chemotherapy treatment is communication. The second step is QoL information: perception that many of depressive feelings are predictable and not fatal, and many of side effects are impermanent, may become meaningful. Low personal relations, depression and anxiety, financial burden problems play negative and significantly impair patients' QoL.

Summary and Conclusions: The modified QoL questionnaire for the patients with AL is one of the well-validated instruments to place into everyday practice to obtain reliable scores and meaningful data on QoL and it should become an integral part in AL treatment decision-making.

PB2073

DEVELOPMENT OF PROGRESS TEST BASED ON EHA CURRICULUM AND EHA CV PASSPORT, USED FOR YEARLY EVALUATION OF HEMATOLOGY RESIDENCY IN SWEDEN

J Ungerstedt[1,*] A Eriksson[2], E Ölander[3], J Theander[4], M Liljeholm[5], C Isaksson[6], G Birgegård[2,7]
[1]Department of Medicine, Karolinska Institute, Stockholm, [2]Department of Medical Sciences, Uppsala University, Uppsala, [3]Department of Medicine, Sundsvall Hospital, Sundsvall, [4]Hematology, Department of Medicine, Lund, [5]Department of Hematology, [6]Hematology, Department of Hematology, Umeå, [7]Hematology, Institute for Medical Sciences, Uppsala, Sweden

Background: In Sweden, after 5.5 years of medical school and 1.5 years of general internship, you can pursue a residency in internal medicine and hematology, which takes an additional 6.5-7 years. This can take place at a University clinic, as well as at non-University hospitals.
Aims: The Swedish Hematology Association appointed a Work Unit (WU) of resident hematologists lead by two senior colleagues with a vast teaching experience, to develop a yearly progress test for evaluation of hematology residents in Sweden. The framework for the progress test was the EHA curriculum and EHA CV Passport, which divides the Hematology Specialty into eight large parts, with subunits to systematically cover the whole of Hematology.
Methods: Individuals or groups of Swedish experts in each field, *e.g.* the National Diagnostic Groups, were asked to produce a number of multiple choice (MCQ) questions. The questions were read, revised and sorted by the appointed WU, after which 75 MCQ questions were selected for the first progress test. These questions covered the eight major fields of the EHA CV Passport: benign clinical hematology (n=8), myeloid malignancies (n=11), lymphoid and plasma cell disorders (n=18), stem cell transplantation and special therapy (n=9), laboratory diagnosis (n=11), thrombosis and hemostasis (n=8), transfusion medicine (n=4 as this is a separate specialist education in Sweden, not sorting under Hematology), and general skills (n=5). The WU has prepared, revised and sorted questions for another three progression testes. The test was available via our homepage www.sfhem.se for one week in November 2013, whereafter the test was removed and the answers posted. Instructions were to complete the test within 2 hours, and when answers were available, sit down and discuss with the clinical mentor. Two months after the progress test, we sent out a questionnaire about the contents and success rate.
Results: Among 90 listed resident physicians in the Swedish Hematology Association registry, 48 work at university hospitals and 42 at non-university hospitals. Ten residents responded that they did not take the test, and until now 36/80 questionnaires have been completed. Correct answers varied from 36-60 points of the maximum 75 points. Years of active work in hematology varied from 1.5-5.5 years, where higher scores of correct progress test answers were associated with longer clinical experience. Comments from residents were that the test was well received, the questions adequate to assess skills, and that it will help point out weaknesses to work on. Furthermore, residents expressed eagerness to take the test again next year to see improvement.
Summary and Conclusions: There is a need for continuous evaluation of acquired skills during residency, and a progress test that reflects the EHA CV Passport may be good for yearly progress evaluation. Thus, we will continue this work with a forthcoming test in November 2014.

Maria della Misericordia di Udine, Udine, Italy, [11]Centre Hospitalier Universitaire de Toulouse, Toulouse Cedex 09, France, [12]University of Alberta Hospital, Edmonton, Canada, [13]Hospital Central de Asturias, Oviedo, Spain, [14]Universitätsklinikum Leipzig, Leipzig, Germany, [15]Azienda Ospedaliero-Universitaria di Bologna - Policlinico S.Orsola-Malpighi, Bologna, Italy, [16]Dana Farber Cancer Institute, Boston, [17]Celgene Corporation, Summit, United States, [18]Universitätsklinikum Ulm, Ulm, Germany

Background: Older patients (pts) with AML have poor prognoses. Previous studies with a range of chemotherapy drugs or best supportive care (BSC) only have consistently shown median overall survival (OS) of 2-8 months (Oran 2012; Kantarjian 2012). Azacitidine (AZA) prolonged OS *vs* conventional care regimens (CCR) in older AML pts with low bone marrow (BM) blast percentage (20-30%) (Fenaux 2010).
Aims: To compare effects of AZA *vs* CCR on OS, response, and safety in a large cohort of older pts with newly diagnosed AML in an international phase 3 study.
Methods: This multicenter, randomized, open-label study (ClinicalTrials.gov NCT01074047) included pts aged ≥65 years (yrs) with newly diagnosed *de novo* or secondary AML (>30% BM blasts), ineligible for allogeneic stem cell transplant. Pts were to have ECOG PS 0-2; WBC ≤15x10^9/L; and intermediate- or poor-risk cytogenetics. Before randomization, pts were preselected to receive 1 of 3 CCRs per investigator choice of best treatment (Tx): intensive chemotherapy (IC; standard 7+3 regimen), low-dose Ara-C (LDAC; 20 mg SC BID x10d/28d cycle), or BSC only. Pts were then randomized to AZA (75 mg/m^2/d SC x7d/28d cycle) or CCR, and received their preselected Tx. The primary endpoint was OS. Additionally, a prespecified sensitivity analysis for OS censored pts at start of subsequent AML Tx. OS was estimated by Kaplan Meier methods and compared by log-rank test. Also measured were 1-yr survival and hematologic response per IWG AML criteria (Cheson 2003). Grade 3-4 hematologic adverse events (AEs) were assessed per CTCAE v4.0.
Results: In all, 488 pts (median age 75 yrs, 59% male) were randomized to AZA (n=241) or CCR (n=247 [BSC n=45, LDAC n=158, and IC n=44]). Baseline demographic and disease characteristics were similar between groups. In the AZA and CCR arms, 20% and 15%, respectively, had AML secondary to MDS, 35% and 34% poor-risk cytogenetics, median blast counts 70% and 74%, and 77% of both groups had ECOG PS 0-1. Median (range) Tx cycles were 6 (1-28) with AZA, 4 (1-25) with LDAC, 2 (1-3) with IC, and median exposure 65 days (6-535) with BSC. Median OS (95%CI) in the AZA arm was 10.4 (8.0-12.7) months (mos) *vs.* 6.5 (5.0-8.6) mos with CCR (unstratified HR=0.84 [95%CI 0.69, 1.02], p=0.0829; stratified HR=0.85 [95%CI 0.69, 1.03], p=0.1009) (Figure 1). The sensitivity analysis showed a significant AZA benefit: median OS was 12.1 (9.2–14.2) mos *vs* 6.9 (5.1–9.6) for CCR (stratified HR=0.76 [95%CI 0.60, 0.96], p=0.019) (Figure 2). One-yr survival was 47% with AZA *vs* 34% with CCR, for a significant difference of 12.3% (95%CI: 3.5%, 21.0%). Responses of CR and CRi, respectively, were seen in 20% and 8% of AZA pts and 22% and 3% of CCR pts. Grade 3-4 anemia, neutropenia, febrile neutropenia, and thrombocytopenia rates, respectively, were 16%, 26%, 28%, and 24% with AZA; 5%, 5%, 28%, 5% with BSC; 23%, 25%, 30%, 28% with LDAC; and 14%, 33%, 31%, 21% with IC. There was no difference in 30- or 60-day mortality between Tx groups.
Summary and Conclusions: Median OS with AZA was 10.4 mos, a 3.8 mos (58%) increase over CCR and 1-yr survival with AZA was 47%, a 36% increase *vs* CCR. These findings represent the largest OS and 1-yr survival benefits seen with a low-intensity therapy in elderly AML (Kantarjian 2012; Burnett 2007, 2013). Rates of grade 3-4 hematologic AEs were higher with AZA than BSC,

and similar to LDAC and IC, and consistent with previous experience. These data show that AZA is an effective and safe therapy for newly diagnosed elderly AML pts.

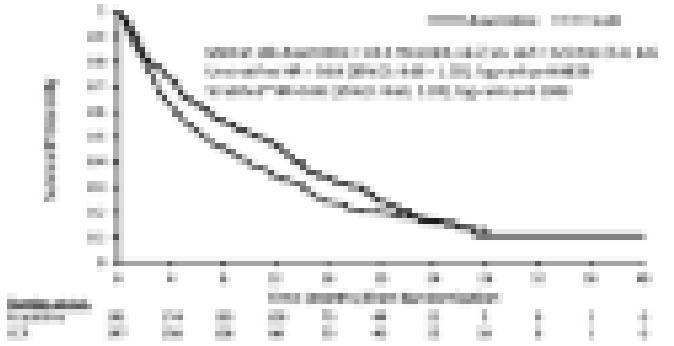

Figure 1. Overall survival: AZA *vs.* CCR (ITT population).

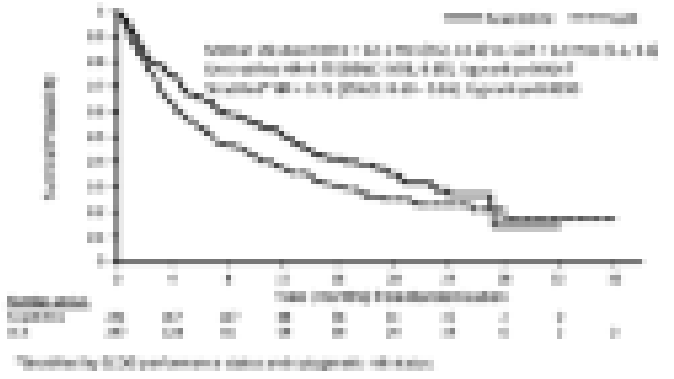

Fgure 2. Overall survival sensitivity analysis (Censored for subsequent AML therapy): AZA *vs.* CCR (ITT population).

LB2434

A PHASE I STUDY OF AG-221, A FIRST IN CLASS, POTENT INHIBITOR OF THE IDH2-MUTANT PROTEIN, IN PATIENTS WITH IDH2 MUTANT POSITIVE ADVANCED HEMATOLOGIC MALIGNANCIES

S Agresta[1], EM Stein[2], MS Tallman[3], RL Levine[3], H Yua[1], K Yen[1], B Fan[1], IW Flinn[4], AT Fathi[5], RM Stone[6], DJ DeAngelo[6], S DeBotton[7,*], DA Pollyea[8]
[1]Clinical Development, Agios, Cambridge, [2]Clinical Development, [3]Leukemia Service, Memorial Sloan-Kettering Cancer Center, Weill Cornell Medical College, New York, [4]Sarah Cannon Research Institute, Sarah Cannon, Nashville, [5]Massachusetts General Hospital Cancer Center, Massachusetts General, [6]Harvard Medical School, Harvard, Boston, United States, [7]Institut Gustave Roussy, Institut Gustave Roussy, Villejuif, France, [8]University of Colorado Cancer Center, University of Colorado Cancer Center, Aurora, United States

New Information: AACR in 4/2014. The clinical data from this phase I study will be updated with new safety and clinical efficacy data for the EHA presentation. (Total N of at least 31 patients). Data on the first 22 patients enrolled was presented at AACR.

Background: Cancer metabolism represents an emerging field of novel drug discovery. Somatic point mutations in the metabolic enzymes isocitrate dehydrogenase 1/2 (IDH1/2) confer a novel gain-of-function in cancer cells resulting in accumulation and secretion of the onco-metabolite, R-2-hydroxyglutarate (2-HG). High levels of 2-HG have been shown to inhibit a-KG dependent dioxygenases including histone and DNA demethylases, regulating the epigenetic state of cells resulting in altered cellular differentiation. IDH2 mutations have been identified in a spectrum of solid tumors and hematologic malignancies. This first clinical study explores the safety and clinical activity of AG-221 in advanced hematologic malignancies, the first mutant IDH inhibitor in clinical trials. AG-221 is an oral, potent, reversible, and selective inhibitor of mutated IDH2 protein. In a primary human AML xenograft model, AG-221 treatment reduced 2-HG levels and demonstrated a survival benefit. Data from the ongoing dose escalation, phase 1 study of AG-221 in patients with advanced IDH2 mutant positive hematologic malignancies are reported here.

Aims: This first in man phase I study of oral AG-221 is designed to evaluate the safety, pharmacokinetics (PK), pharmacodynamics (PD) including 2-HG levels, and clinical activity. AG-221 is administered orally once (QD) or twice per day (BID) in continuous 28-day cycles. Sequential cohorts of patients are enrolled at higher dose levels, followed by planned expansion cohorts. Eligible patients include those with relapsed or refractory AML, myelodysplastic syndromes (MDS) and elderly untreated AML that harbor an IDH2 mutation. Blood and bone marrow is collected at multiple times for determination of the PK/PD effects of AG-221. Bone marrow examination for response are performed on Days 15, 29, 57, and every 56 days (2 cycles) thereafter.

Results: The study was activated in September 2013. As of the March 20th, 2014, 22 patients have been enrolled; 21 with AML and 1 with MDS. All patients were IDH2–mutant positive. AG-221 doses administered included 30 mg BID (n=7), 50 mg BID (n=5), 75 mg BID (n=5), and 100 mg QD (n=5). Two patients were added to the 30 mg BID cohort to replace PK un-evaluable patients. Sixteen of 22 patients remain on study drug treatment. Therapy has been well tolerated with no dose-limiting toxicities. The maximum tolerated dose has not been reached. Possible drug-related severe adverse events occurred in two patients: grade 2 hyperleukocytosis and grade 3 confusion. There were four deaths due to sepsis within 30 days of study drug termination, three on cohort 1 and one on cohort 4. Preliminary analysis of PK at 30 and 50 mg demonstrated excellent oral AG-221 exposure. Mean plasma half-life is greater than 40 hours. Evaluation of PD demonstrated sustained reduction in 2-HG plasma levels of up to 100% following AG-221 dosing in cohorts 1 and 2. Efficacy evaluation at the time of the data cutoff from patients enrolled in cohorts 1 and 2 are shown below in Table 1. Ten AML patients were treated: (N=5 at 30 mg BID, N=5 at 50 mg BID), 5 men and 5 women, with a median age (range) of 62.5 years (53-74). Eight patients had an R140Q mutation, two had a R172K mutation. Median number of prior regimens was 2 (1-4). One patient relapsed after an allogeneic bone marrow transplant. Six of 10 patients have had investigator assessed objective responses (International Working Group Criteria): 3 complete responses (CR), 2 complete responses with incomplete platelets recovery (CRp), 1 partial response (PR). Three were not evaluable for efficacy (NE). Marked differentiation of myeloblasts into mature forms, consistent with preclinical models, was associated with responses. All responding patients demonstrated neutrophil recovery. Only one patient experienced disease progression. One patient with a CR was removed from study to undergo allogeneic BMT. Five of the 6 responding patients remain on AG-221.

As of April 15th, 31 patients have been enrolled into the study into existing and new dose cohorts. Dose escalation continues and updated safety, efficacy, PK/PD, and molecular data will be presented.

Table 1. Summary of efficacy from cohorts 1 and 2.

Summary and Conclusions: AG-221, a novel, oral, potent IDH2 mutant inhibitor is well tolerated and as predicted by preclinical models, triggers the terminal differentiation of leukemic blast cells that ultimately leads to objective responses including complete remissions. These data provide early validation of mutant IDH2 as a therapeutic target in cancer.

LB2435

ORDER MATTERS: MUTATION ORDER INFLUENCES TUMOUR EVOLUTION AND STEM CELL POTENCY BY ALTERING TRANSCRIPTIONAL CONSEQUENCES OF THE SECOND MUTATION

D Kent[1,2,*], CA Ortmann[1,3], Y Silber[1], J Nangalia[1,3], J Baxter[3], CE Massie[1], E Papaemmanuil[4], S Menon[5], B Bellosillo[6], C Besses[7], K Doehner[8], GS Vassiliou[3,4], PJ Campbell[3,9], AR Green[1,2,3]
[1]Haematology, [2]Stem Cell Institute, University of Cambridge, [3]Haematology, Addenbrooke's Hospital, Cambridge, [4]Wellcome Trust Sanger Institute, Hinxton, [5]Cancer Research UK Cambridge Research Institute, Cambridge, United Kingdom, [6]Pathology, [7]Haematology, Hospital del Mar, Barcelona, Spain, [8]Department of Internal Medicine III, University of Ulm, Ulm, Germany, [9]Wellcome Trust Sanger Institute, Cambridge, United Kingdom

Background: Cancers result from accumulation of somatic mutations and their properties are thought to reflect the sum of these mutations. However, virtually nothing is known about the cellular and molecular consequences of altering the order of mutation acquisition.

Aims: To determine whether the order of mutation acquisition impacts tumour evolution and/or stem cell and progenitor cell biology in myeloproliferative neo-

plasm patients who carry both JAK2V617F and a TET2-inactivating mutation in the same clone.
Methods: We genotyped >7000 colonies from 24 patients with myeloproliferative neoplasms (MPNs) who harbored mutations in both *JAK2* and *TET2*. Stem and progenitor cells were isolated to study the impact of mutation order on mature and immature hematopoietic cells. Gene expression profiling was performed to determine whether mutation order impacted the transcriptional alterations caused by the second mutation.
Results: *JAK2* and *TET2* mutations each occurred first in 12/24 patients, with *TET2*-first and *JAK2*-first patients observed in all 3 MPN subtypes. Age of presentation, acquisition of JAK2V617F homozygosity and the balance of immature progenitors within a tumor were all influenced by the order in which *TET2* and *JAK2* mutations were acquired. In studies of single hematopoietic stem and progenitor cells (HSPCs), mutation order influenced the proliferative response to JAK2V617F and the generation of functional progenitors. The capacity of double-mutant HSPCs to generate colony-forming cells was markedly different in TET2-first compared to JAK2-first patients; and the HSPC compartment was dominated by *TET2* single-mutant cells in TET2-first patients but by JAK2/TET2 double-mutant cells in JAK2-first patients. Transcriptional profiling on individual colonies with different genotypes from 7 patients (4 TET2-first, 3 JAK2-first) was performed, thereby allowing direct comparison of genetically distinct cells within a patient, thus controlling for differences in age, sex, treatment, germline genetic background and other confounding variables. Mutation of *JAK2* or *TET2* was associated with altered patterns of gene expression that were strikingly dependent on the antecedent genotype (*e.g.*, most genes up-regulated or down-regulated when JAK2V617F was acquired on a TET2-wild-type background were not altered when JAK2V617F was acquired on a TET2-mutant background). Analysis of altered gene sets revealed up-regulation of translational machinery when JAK2V617F was acquired on a WT background and downregulation of cell cycle progression genes when JAK2V617F was acquired on a TET2-mutant background. Since JAK2 plays a key role in normal erythroid differentiation and TET2 modulates the epigenetic landscape, we investigated whether prior mutation of *TET2* influences the transcriptional response to JAK2V617F. We compared genes up-regulated when JAK2V617F was acquired by TET2-wildtype cells with those down-regulated when JAK2V617F was acquired by TET2-mutant cells. This approach identified 10 genes discordantly regulated by JAK2V617F depending on the *TET2* genotype. Remarkably, six of these have been implicated in DNA replication (MCM2, MCM4, MCM5) or regulation of mitosis (AURKB, FHOD1, TK1). These data demonstrate that acquisition of a prior *TET2* mutation dramatically alters the transcriptional consequences of JAK2V617F in a cell-intrinsic manner.
Summary and Conclusions: The order in which *JAK2* and *TET2* mutations are acquired influences clinical presentation, stem/progenitor cell biology and clonal evolution in MPN patients. In addition to providing a paradigm for other malignancies, these results have clinical implications for MPN patients including the prediction that mutation order will influence therapeutic efficacy.

RUXOLITINIB PROVES SUPERIOR TO BEST AVAILABLE THERAPY IN A PROSPECTIVE, RANDOMIZED, PHASE 3 STUDY (RESPONSE) IN PATIENTS WITH POLYCYTHEMIA VERA RESISTANT TO OR INTOLERANT OF HYDROXYUREA

AM Vannucchi[1,*], JJ Kiladjian[2], M Griesshammer[3], T Masszi[4], S Durrant[5], F Passamonti[6], CN Harrison[7], F Pane[8], P Zachee[9], R Mesa[10], S He[11], MM Jones[11], W Garrett[11], J Li[12], N Francillard[13], D Habr[12], S Verstovsek[14]
[1]University of Florence, Florence, Italy, [2]Hôpital Saint-Louis et Université Paris Diderot, Paris, France, [3]Johannes Wesling Clinic, Minden, Germany, [4]St. István and St. László Hospital, Budapest, Hungary, [5]Royal Brisbane & Women's Hospital, Brisbane, Australia, [6]Ospedale di Circolo e Fondazione Macchi, Varese, Italy, [7]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [8]University of Naples Federico II, Naples, Italy, [9]ZNA Stuivenberg, Antwerp, Belgium, [10]Mayo Clinic Cancer Center, Scottsdale, [11]Incyte Corporation, Wilmington, [12]Novartis Pharmaceuticals Corporation, East Hanover, [13]Novartis Pharma S.A.S., Rueil-Malmaison, [14]The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Polycythemia vera (PV) is a myeloproliferative neoplasm characterized by erythrocytosis, burdensome symptoms, and an increased risk of vascular events. A key goal of therapy is to maintain hematocrit (HCT) control. Hydroxyurea (HU) is often used as a first-line cytoreductive treatment; however, not all patients (pts) achieve HCT control or tolerate therapy with HU.
Aims: RESPONSE is an open-label phase 3 study to evaluate the efficacy and safety of ruxolitinib (RUX), a JAK1/JAK2 inhibitor, compared with best available therapy (BAT) in PV pts resistant to or intolerant of HU.
Methods: HU-resistant/intolerant pts with splenomegaly (≥ 450 cm^3 by MRI) who required phlebotomy (PBT) for inadequate HCT control were randomized 1:1 to RUX 10 mg bid or BAT. The primary endpoint was the proportion of pts who achieved both HCT control without PBT from wk 8 to 32 (with no more than 1 PBT postrandomization and prior to wk 8) and a ≥ 35% reduction in spleen volume (SV) from baseline (BL) by MRI at wk 32. The key secondary endpoints included proportion of pts who maintained primary response at wk 48 and proportion of pts who achieved complete hematologic response (CHR) at wk 32. Other endpoints included duration of primary response, symptom improvement, and safety. The MPN-SAF diary was used to assess 14 disease-related symptoms on a scale of 0 (absent) to 10 (worst imaginable). In addition, symptom clusters related to the following were evaluated: cytokines, hyperviscosity, and splenomegaly. BAT-treated pts could cross over to RUX from wk 32. Primary analysis occurred when all pts reached wk 48 or discontinued.
Results: 110 and 112 pts were randomized to RUX and BAT, respectively. The median time since PV diagnosis was 8.2 and 9.3 y; 35% and 29% of pts had a history of thrombosis; and 31% and 42% had ≥ 3 PBTs within 24 wk of screening, respectively. The respective median BL SV in RUX and BAT pts was 1195 cm^3 and 1322 cm^3. The median duration of exposure to RUX and BAT was 81 and 34 wk, respectively: 17 (15%) of RUX and 108 (96%) of BAT pts discontinued randomized treatment (96/108 pts [89%] crossed over to RUX), of which 3.6% and 1.8% were due to adverse events (AEs). The primary endpoint was achieved in 21% of RUX *vs* 1% of BAT pts ($P < .0001$); 91% of RUX pts achieved durable response at wk 48. Overall, 77% of RUX pts met at least 1 component of the primary endpoint: 60% of RUX and 20% of BAT pts achieved HCT control without PBT from wk 8 to 32; 38% of RUX and 1% of BAT pts achieved ≥ 35% SV reduction at wk 32 (Figure 1A). CHR was achieved in 24% and 9% of RUX and BAT pts, respectively ($P = .003$). At wk 32, 49% *vs* 5% had ≥ 50% improvement in MPN-SAF 14-item total symptom diary score; a greater percentage of pts in the RUX arm also achieved ≥ 50% improvement in each symptom cluster (Figure 1B). AEs in the RUX and BAT groups during the first 32 wk of randomized treatment were evaluated. Grade 3/4 anemia or thrombocytopenia occurred in 1.8% and 5.5% of RUX pts, respectively, *vs* 0% and 3.6% of BAT pts. The most common grade 3/4 nonhematologic AEs that occurred in > 2 pts in either treatment group (RUX *vs* BAT) were dyspnea (2.7% *vs* 0%), pruritus (0.9% *vs* 3.6%), and fatigue (0% *vs* 2.7%); all of these events were grade 3. Thromboembolic events occurred in 1 RUX and 6 BAT pts.

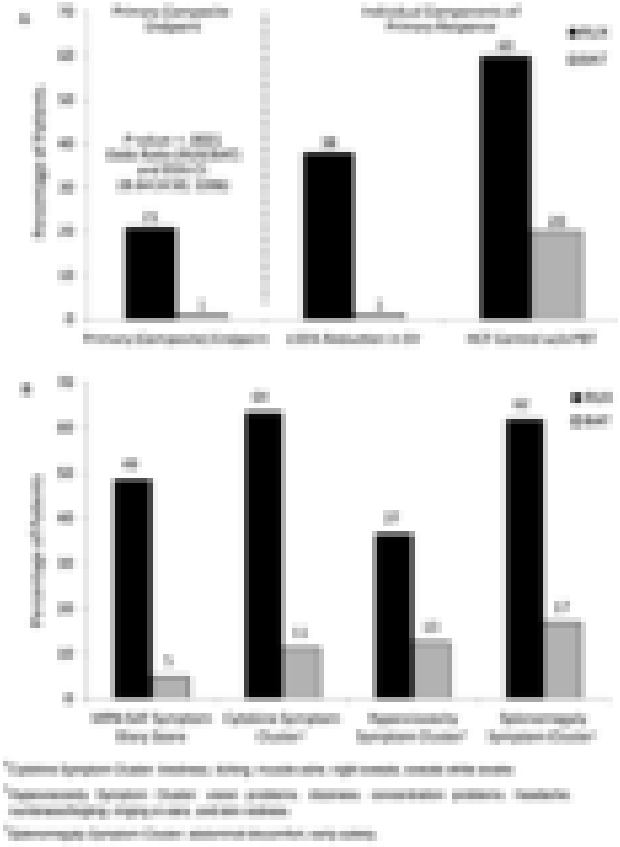

Figure 1. Percentage of patients achieving (A) the primary endpoint and components of the primary endpoint and (B) ≥50% improvement in MPN-SAF symptom scores.

Summary and Conclusions: This is the first phase 3 study of a JAK inhibitor demonstrating that in pts with PV resistant to or intolerant of HU, RUX treatment is well tolerated and effective in controlling HCT without PBT, decreasing SV, and improving PV-related symptoms.

Background: Initiation of prophylactic factor VIII (FVIII) therapy at a young age is recommended for the treatment of severe haemophilia A to prevent bleeding and consequent joint disease. Current therapy requires frequent infusions of FVIII. Previous reports indicate that FVIII half-life is shorter in children than in adults, which could necessitate even more frequent dosing. Long-acting FVIII products may allow for prophylaxis with less frequent infusions. In a Phase 3 study of recombinant FVIII Fc fusion protein (rFVIIIFc) in adolescents and adults, rFVIIIFc demonstrated an increased half-life relative to rFVIII, and prophylactic rFVIIIFc infused once to twice a week yielded low annualized bleeding rates (ABR). Kids A-LONG was the first phase 3 study of a long-acting FVIII in previously-treated paediatric subjects.
Aims: The objective of Kids A-LONG was to evaluate the safety, efficacy, and pharmacokinetics (PK) of rFVIIIFc in previously-treated subjects less than 12 years of age with severe haemophilia A.
Methods: Kids A-LONG was a global, multi-centre, open-label, phase 3 study that enrolled male subjects <12 years old, with severe haemophilia A (<1 IU/dL FVIII activity), ≥50 prior exposure days (ED) to FVIII, and no history of FVIII inhibitors. All subjects were initially to be treated with twice-weekly prophylactic infusions of rFVIIIFc (25 IU/kg day 1, 50 IU/kg day 4). Dosing frequency could be increased (to as often as once every 2 days) and dose could be increased (to ≤80 IU/kg) as needed by the investigator. A subset of subjects (<6 yrs, n=25; 6 to <12 yrs, n = 35) underwent sequential PK evaluations with their prior FVIII therapy (50 IU/kg) followed by rFVIIIFc (50 IU/kg). The primary endpoint was development of inhibitors (neutralizing antibodies). Key efficacy endpoints were ABR and number of infusions required to control a bleed.
Results: 71 subjects from 23 centres (36 were <6 years of age [range, 1 – 5 yrs] and 35 were 6 to <12 years of age [range, 6 – 11 yrs]) were enrolled. Eighty-nine percent of subjects received a pre-study FVIII prophylaxis regimen, the majority (74.6%) of which required 3 or more infusions/week. The median time on study was 26 weeks, and 61 subjects had ≥50 EDs to study drug; 94.4% of subjects completed the study. No subject developed inhibitors to rFVIIIFc. Overall, the pattern of adverse events reported on rFVIIIFc treatment was typical of the population studied. No serious adverse events were assessed to be related to the product by the investigator. The arithmetic mean (95% CI) terminal half-life in subjects <6 years and 6 to <12 years was 12.67 hrs (11.23, 14.11) and 14.88 hrs (11.98, 17.77), respectively, based on the one-stage aPTT assay. The relative increase in half-life over prior FVIII therapy was consistent with the 1.5-fold increase in half-life seen in the A-LONG study of adults and adolescents. Median (IQR) ABR overall was 1.96 (0.00, 3.96) and for spontaneous bleeds was 0.00 (0.00, 0.00). Median average weekly dose and dosing interval were 88.1 IU/kg and 3.5 days, respectively. 93.0% of all bleeding episodes were controlled with 1-2 infusions (median dose per bleeding episode: 54.9 IU/kg).
Summary and Conclusions: In this study, rFVIIIFc prophylaxis was well-tolerated, resulted in low bleeding rates, and was efficacious for treating bleeding episodes. The increase in half-life compared to current FVIII and the safety profile were generally consistent with that observed in the Phase 3 study in adults and adolescents. rFVIIIFc offers the potential of prolonged dosing intervals and fewer infusions for paediatric patients with severe haemophilia A.

MULTIPLEX GENOME EDITING OF TCRALPHA/CD52 GENES AS A PLATFORM FOR "OFF THE SHELF" ADOPTIVE T-CELL IMMUNOTHERAPIES

L Poirot[1], B Philip[2], R Galetto[1,*], C Schiffer-Mannioui[1], S Derniame[1], G Weng-Kit Cheung[2], A Gouble[1], S Arnould[1], J Smith[1], M Pule[2], AM Scharenberg[1]

Background: Adoptive immunotherapy using autologous T-cells endowed with chimeric antigen receptors (CARs) has emerged as a powerful approach to treating cancer. However, a limitation of this approach is that CAR T-cells must be generated on a bespoke basis.
Aims: To permit adoptive T cell therapy using allogeneic T cells, we have developed a platform for the large scale production of "off-the-shelf" CAR T-cells from unrelated 3rd party donor T-cells.
Results: We applied Transcription Activator-Like Effector Nucleases (TALEN) gene editing technology to overcome the key barriers to the adoptive transfer of 3rd party CAR T-cells. We eliminated the potential for T-cells bearing alloreactive TCR's to mediate GvHD by disrupting the TCRalpha constant (TRAC) gene, and we exploited the requirement for preparative lymphodepletion for engraftment of allogeneic CAR T-cells through disruption of the CD52 gene. Simultaneous editing of the TRAC and CD52 genes results in TCR/CD52-deficient T-cells that may follow alemtuzumab-mediated lymphodepletion/immunosuppression.
Summary and Conclusions: We provide proof of concept for the general applicability of this approach by manufacturing a TCR/CD52-deficient universal CD19 CAR T-cell (UCART19), and demonstrating that this product does not mediate alloreactivity. In addition, it can be selectively engrafted in the presence of alemtuzumab, while maintaining potent anti tumoral activity equivalent to standard CD19 CAR T-cells in an orthotopic CD19+ lymphoma mouse model. Our approach is being developed as a platform for large scale manufacturing of allogeneic, off-the-shelf, non alloreactive CD19 specific T Cells that offer the possibility to cure, in both salvage and consolidation therapy, high risk CD19+ B-cells leukemias.

THE PD1/PD-L1 AXIS PROTECTS NORMAL KERATINOCYTES FROM CAR T-CELL ATTACK: RATIONALE FOR THE SKIN SAFETY OF CD44V6-TARGETED T CELLS

M Casucci[1,*], B Nicolis di Robilant[1], L Falcone[1], B Camisa[1], M Norelli[1], B Gentner[1], P Genovese[1], M Ponzoni[1], A Saudemont[2], C Bordignon[1], L Naldini[1], F Ciceri[1], G Dotti[3], C Bonini[1], A Bondanza[1]
[1]San Raffaele Scientific Institute, Milano, Italy, [2]Anthony Nolan Research Institute, London, United Kingdom, [3]Baylor College of Medicine, Houston (TX), United States

Background: Off-tumor expression of the target antigen raises justified safety concerns about newly designed chimeric antigen receptors (CARs). We have recently developed a CAR targeting the tumor-promoting antigen CD44v6 and demonstrated potent antitumor effects against acute myeloid leukemia (AML) and multiple myeloma (MM) both *in vitro* and *in vivo* (Casucci et al, *Blood* 2013). Despite promising activity against epithelial tumors, the administration of the CD44v6-specific mAb used for deriving our CAR (bivatuzumab) showed reversible myelosuppression and severe skin toxicity when conjugated with the potent cytotoxic drug mertansine. Preclinically evaluating the potential off-tumor toxicities of CD44v6-targeted T cells is therefore crucial before they can be safely translated to the clinic.
Aims: To profile the off-tumor expression of CD44v6 and to verify the susceptibility of expressing cells to CAR-T cell killing.
Results: Quantitative RT-PCR analysis on a wide panel of cDNA from normal tissues revealed restricted CD44v6 expression on flat stratified epithelia, like the skin, albeit at considerably lower levels compared with primary leukemic blasts. We therefore addressed the issue of normal keratinocyte recognition in co-culture experiments. Strikingly, at the E:T ratios allowing the potent antitumor effects of CD44v6-targeted T cells, keratinocytes were not killed and there was no cytokine production. Differently from leukemic blasts, keratinocytes expressed significant lower levels of adhesion molecules (ICAM-1, LFA-3 and B7.2), but higher levels of the checkpoint molecule PD-L1. Blocking experiments with mAbs indicated that lower ICAM-1 expression is involved in keratinocyte resistance to direct CAR T-cell killing, while higher PD-L1 expression restrains secondary expansion of CAR T cells. Interestingly, comparative CFSE-dilution experiments revealed that normal keratinocytes are as immunosuppressive as mesenchymal stromal cells and that, similarly to them, can be licensed by interferon-gamma for even higher immunosuppressive activity. Of the different cells of the hematopoietic system analyzed, only circulating CD14+ monocytes expressed CD44v6 and were killed by CD44v6-targeted T cells. Moreover, by immunohistochemistry, we found no CD44v6 expression on bone-marrow monocytes, lymph-node macrophages, brain microglia, liver Kuppfer cells and dermal macrophages, suggesting a low risk for by-stander toxicity against these tissues. Accordingly with lack of CD44v6 expression on normal hematopoietic stem cells (HSCs) and progenitors, CD44v6-targeted T cells did not interfere with their clonogenic potential *in vitro* and, in co-culture experiments with whole bone marrow from MM patients, were able to selectively eliminate tumor cells, while sparing HSCs and progenitors. Finally, we tested the potential hematological toxicities of CD44v6-targeted T cells in NSG mice transgenic for human IL-3, SCF and GM-CSF (NSG-3GS). NSG-3GS mice transplanted with human CD34-selected cord blood cells showed enhanced myeloid reconstitution compared to NSG mice, including CD44v6+ monocytes. The infusion of CD44v6-targeted T cells in reconstituted NSG-3G mice resulted in the selective elimination of monocytes, but in the preservation of the HSC pool. For enabling rapid and conditional ablation of CD44v6-targeted T cells, we

have finally co-expressed the CD44v6 CAR with TK or the inducible caspase-9 and validated the suicide gene approach in hyper-acute xenogeneic GVHD surrogating maximal toxicity.
Summary and Conclusions: Our results suggest that the PD1/PD-L1 axis is involved in the protection of normal tissues from CAR T-cell attack and that, differently from immunotoxins, therapeutic doses of suicidal CD44v6-targeted T cells might associate with acceptable and/or reversible toxicities.

Background: The advent of tyrosine kinase inhibitors (TKI) has substantially improved survival of chronic myeloid leukemia (CML) with a high percentage of patients reaching deep molecular responses (MR; Hehlmann JCO 2014). There is a reasonable expectancy not only to further improve survival but to cure the disease. An important step to cure CML is to increase the rate of patients in durable deep MR (MR4 or deeper) after withdrawal of TKI. In several studies, it have been shown that in a substantial proportion of patients with deep MR, treatment can be safely and successfully stopped (Mahon 2010, Ross 2013).
Aims: The EURO-SKI study (European stop TKI study) was set up to define prognostic markers to increase the rate of patients in durable deep MR after stopping TKI. Further aims are the evaluation of harmonized methods of molecular monitoring, assessment of quality of life, and calculation of saved treatment costs per country.
Methods: Adult CML patients in chronic phase CML on TKI treatment in confirmed MR for at least one year (>4 log reduction on TKI therapy for >12 months confirmed by three consecutive PCR results) and under TKI treatment for at least 3 years were eligible. Final MR4 confirmation had to be performed in a standardized laboratory (n=6) according to the definition by Cross *et al.* (Leukemia 2012). Primary endpoint is the assessment of the duration of deep MR (defined by loss of MMR) after stopping TKI. Patients with previous or planned allogeneic stem cell transplantation or after a prior TKI failure were excluded. According to protocol, an interim analysis was planned after 200 patients with eligible molecular results at month 6 were available to test the null hypothesis that relapse-free survival at 6 months is less or equal 40%.
Results: From June 2012 to July 2013, 254 patients in chronic phase from 8 countries were registered. 54 were excluded (consent withdrawal n=1, protocol violation n=1, not eligible n=34, restart of TKI without relapse n=4, atypical or unknown transcript n=6, missing data n=8). Of the eligible 200 patients, 41.5% were female. Median age at diagnosis was 53.3 years (range 13.8 to 85.5). In assessable patients with spleen size recording 8.7%, 18.2 % and 0% were high-risk according to EUTOS, Sokal and EURO-Score, respectively. 103 patients were pretreated prior to TKI therapy, mostly with hydroxyurea and/or interferon. First-line TKI was imatinib in 97%, dasatinib in 1.5% and nilotinib in 1.5% of the patients. Twenty-four patients switched to second-line TKI due to intolerance, 16 to dasatinib, 2 to imatinib, and 6 to nilotinib. Time from diagnosis of CML to first day of stopping TKI varied from 34.4 months to 232.9 months, median time was 95.4 months. Median duration of TKI treatment was 94.8 months (range 34.2 to 150.6 months) and median duration of MR4 before stopping TKI was 65.1 months (range 11.1 to 140.7 months). For all patients MR4 could be confirmed through a MR4-standardized laboratory. Nineteen patients with detectable transcripts were in MR 4 (9.5%), 37 patients in MR4.5 (18.5%) and 18 in MR5 (9.0 %), respectively. 123 patients had undetectable transcripts, of them 49 patients were in MR4 (24.5%), 48 in MR4.5 (24%) and 25 in MR5 (12.5%); exact classification of 3 patients with confirmed MR4 is pending.
A pre-planned interim hypothesis testing was performed. Since 123 of the 200 patients (61.5%, 95% confidence interval: [54.4%; 68.3%]) remained without relapse the first 6 months, the null hypothesis could be discarded ($p < 0.0001$).
Summary and Conclusions: As compared to the "A-STIM" study (Rousselot *et al.* JCO 2014) this first European Leukemianet stop trial in CML confirms that loss of MMR can be used as a criterion for restarting therapy. In addition, it improves the chance to stay in treatment-free remission in the setting of standardized molecular testing. The EURO-SKI trial will further elucidate prognostic factors which allow a better selection of patients to improve the rate of durable deep MR after withdrawal of TKI.

TREATMENT OF IRON DEFICIENCY ANAEMIA OF LATE PREGNANCY WITH A SINGLE INTRAVENOUS IRON POLYMALTOSE OR FERRIC CARBOXYMALTOSE *VERSUS* ORAL IRON SULPHATE: A PROSPECTIVE RANDOMIZED CONTROLLED STUDY (TIDAL)

A Khalafallah[1,2,*], A Chuang[3], C Kwok[3], C Yan[4], A Hyppa[5], R Mathew[4], A Dennis[3], D Seaton[6], T Brain[6], T Pavlov[3]
[1]Menzies Research Institute, University of Tasmania, Hobart, [2]Haematology, [3]Obstetrics and Gynaecology, LAUNCESTON GENERAL HOSPITAL , [4]School of Medicine, University of Tasmania, Launceston, Australia, [5]School of Medicine, University of Saarland, Homburg, Germany, [6]Pathology, LAUNCESTON GENERAL HOSPITAL , Launceston, Australia

Background: Conferring the World Health Organisation (WHO) statistics, iron deficiency (ID) is the most common nutritional deficiency disorder in the world, affecting at least two billion people, with pregnant women at particularly high risk. ID affects more women than any other health disorder in the world, constituting a public health crisis in many developing countries. Recent studies in the developed world showed that ID is present in up to 20% of pregnant women (PMID: 20546462). Therefore, it is important to diagnose ID during pregnancy and hence to offer the appropriate management avoiding the significant side effects of ID.
Aims: We conducted a comparative, prospective, open labelled randomized-controlled trial to compare the efficacy, safety, tolerability and compliance of standard daily oral iron sulfate 325 mg (elemental iron 105 mg) *versus*1g of intravenous iron polymaltose or carboxymaltose.
Methods: We recruited 205 pregnant women between September 2013 and April 2014 with iron deficiency at our tertiary referral Hospital. Median age was 28 years (range, 18-47) with a median and mean gestational age of 27 weeks. Median baseline serum ferritin level was 9 mcg/L (mean, 10 mcg/L) with serum transferrin saturation below 20%.
Results: Hb and iron stores after 4 weeks of treatment showed that the intravenous iron group was superior to the oral iron arm as measured by the increase in Hb level (mean of 9.5 g⁄L *vs.* 3.2 g⁄L; P < 0.02); the increase in mean serum ferritin level was 196 mcg⁄L in the IV iron group *vs.* 62 mcg⁄L in the oral iron arm; (P < 0.001). The percentage of pregnant women with ferritin levels below 30 mcg⁄L was 14% in the IV iron group *vs.* 42% in the oral iron group after 4 weeks of treatment (P < 0.01). There was no significant difference noticed in patients who received iron carboxymaltose *versus* polymaltose in terms of Hb increment. However, ferric carboxymaltose showed greater ferritin increments from baseline with a mean ferritin increase after 4 weeks of treatment to 198 mcg/L in the ferric carboxymaltose arm *versus* a mean of 119 mcg/L in the iron polymaltose arm. Furthermore, a single dose of intravenous iron carboxymaltose was better tolerated than iron polymaltose in terms of delayed side effects after treatment with bone aches and nausea, however without significant side effects in both groups.
Summary and Conclusions: Our data indicate that intravenous iron carboxymaltose application during pregnancy is safe and leads to improved efficacy and improvement of iron stores compared to oral iron in pregnancy-related ID. Integration of iron studies as a screening tool in addition to regular full blood count in the routine antenatal visit allows early diagnosis and management of ID in pregnanacy.

LB2442

UNIQUE DEPENDENCE OF MALIGNANT, BUT NOT NORMAL HEMATOPOIESIS, ON CD44V6-MEDIATED SURVIVAL SIGNALS WITHIN THE BONE MARROW

B Nicolis Di Robilant[1,2,*], M Casucci[1], M Norelli[1,2], L Falcone[1], B Camisa[3], B Gentner[4], L Naldini[4], F Ciceri[5], C Bordignon[6], C Bonini[3], A Bondanza[1,2,5]
[1]Leukemia Immunotherapy Group, San Raffaele Scientific Institute, [2]Vita-Salute San Raffaele University , [3]Experimental Hematology Unit, [4]Gene Transfer Technologies Unit, Division of Regenerative Medicine, Stem Cell and Gene Therapy, [5]Hematology and Bone Marrow Transplantation Unit, Department of Oncohematology, San Raffaele Scientific Institute, [6]MolMed SpA, Milan, Italy

New Information: A preliminary report presented at ASH 2013. This abstract includes comprehensive and conclusive results, including HSCs silencing, *in vivo* proliferation and cell death of CD44v6-silenced tumor cells and primary AML and MM susceptibility to CD44v6 mAb.
Background: Targeting the unique interactions within the tumor microenvironment is an exciting new frontier in cancer therapy. Tumors of hematopoietic origin are addicted to specific survival signals provided within the bone marrow (BM). Unfortunately, the majority of these signals are shared with normal hematopoietic stem cells (HSCs), rendering their therapeutic targeting a challenging task. Monoclonal antibodies (mAbs) to the hyaluronate receptor CD44 inhibit leukemia initiation in immunocompromised mice and are currently investigated in humans. In principle, targeting the tumor-restricted CD44 isoform variant 6 (CD44v6) would have clear advantages over targeting the ubiquitously expressed standard molecule (CD44s). However, before proceding, it is needed to validate CD44v6 as a clinically relevant tumor antigen.
Aims: To demonstrate a non-redundant role for CD44v6 in hematopoietic tumor-cell biology and to preclinically estimate the safety and the therapeutic efficacy of targeted strategies.
Results: By RT-qPCR and FACS analysis on a wide range of hematopoietic tumor cell lines and primary cells, we established CD44v6 over-expression in a relevant fraction of acute myeloid leukemia (AML) samples (15/25, 60%) and in the majority of multiple myeloma (MM) patients (13/15, 80%). We previously showed that CD44v6 silencing by means of a shRNA completely inhibited primary AML and MM cell lines engraftment in NSG mice (P<0.01, Casucci *et al.,* 2013). Conversely, CD44v6-silenced HSCs engrafted and efficiently repopulated both myeloid and lymphoid compartments in NSG mice triple transgenic for human c-Kit ligand, GM-CSF and IL-3 (NSG-3GS). NSG-3GS mice drive human CD34+ toward a higher reconstitution of the myeloid compartment, allowing the study of CD44v6+ monocytes. These results suggest that CD44v6 has a non-redundant role in tumor biology. To assess its specific functions in tumor growth, we interfered with CD44v6 by either a mAb or by shRNA and observed no inhibition in tumor-cell homing to the BM. In line with these findings, CD44v6-silenced cells lost their *in vivo* tumorigenicity even when directly injected in the BM (P<0.05). Interestingly, this phenomenon is not associated with a reduced *in vivo* proliferation, but with a dramatic increase in spontaneous apoptosis, especially in the BM (P<0.05). Hypothesizing that CD44v6-silenced tumor cells had lost responsiveness to specific microenvironmental signals mediating survival, we set-up a co-culture system with BM-derived mesenchymal stromal cells (MSCs). MSCs, or their supernatants, protected AML and MM cells from spontaneous (P<0.01) and drug-induced apoptosis (P<0.01). Although present, known CD44v6 co-factors such as VEGF and HGF, were not involved in the phenomenon, as demonstrated by inhibition experiments with bevacizumab and crizotinib, respectively. Contrariwise, protection from apoptosis by MSCs associated with significant CD44v6 up-regulation (P<0.01) and with tumor cell-autonomous production of the CD44v6 ligand osteopontin, suggesting an autocrine loop. Preventing CD44v6 up-regulation by shRNA interference restored AML and MM cell lines sensitivity to apoptosis without affecting their ability to adhere to MSCs. Consistently, interference with CD44v6 by a mAb derived from VFF-18 clone, enhanced AML and MM primary cells susceptibility to drug-induced cell death (P<0.01 and P<0.05).
Summary and Conclusions: CD44v6 expression by hematopoietic tumors, but not by normal HSCs, is required for sensing survival signals within the BM microenvironment. Targeting CD44v6 in combination with chemotherapy is therefore a promising therapeutic approach for AML and MM.

Background: Hepatitis C virus (HCV) has been found to be associated with B-cell non-Hodgkin's lymphomas, mostly marginal zone B-cell lymphomas (MZL) and diffuse large B cell lymphoma (DLBCL). Deregulation of signaling pathways involved in normal marginal zone development (NOTCH pathway, NF-κB, and B-cell receptor signaling) has been demonstrated in splenic MZL (SMZL).
Aims: To assess deregulation of NOTCH, NF-κB and B-cell receptor signaling in HCV-related DLBCL in comparison with HCV- DLBCL cases, the relationship of molecular lesion with clinical and histological features and the impact of signaling deregulation on the outcome of HCV-related DLBCL.
Methods: We studied mutations of NOTCH, NF-κB and B-cell receptor signaling in 46 pts with HCV-related DLBCL and in 64 pts with HCV- DLBCL.
Results: All cases were HCV-RNA positive. Extranodal disease was present in 29 pts and 17 pts had splenic involvement (primary splenic in 15 pts). In 12/46 (26%) cases a minor area of the diagnostic biopsy was composed of small to medium sized monocytoid B-cells, suggesting a progression from a MZL that was not previously recognized. Overall, the NOTCH pathway was recurrently

mutated in 26% (12/46) of HCV+ DLBCL: *NOTCH2* was mutated in 9/46 (19.6%), *NOTCH1* in 2/46 (4.4%), and SPEN in 1/46 (2.2%). *NOTCH2* mutations were represented in all instances by truncating events and clustered within a hotspot region in exon 34, including a recurrent p.R2400* nonsense mutation in 4 cases. *NOTCH1* was affected by a recurrent two-bp deletion (p.P2515fs*4) that truncates the PEST domain, similarly to *NOTCH2* lesions. The prevalence and type of NF-kB pathway mutations overlapped with the ones of DLBCL of non-GC phenotype arising in the HCV- pts. Among NF-kB genes, *TNFAIP3* was mutated in 5 (26.3%) (all of non-GC origin), *MYD88* was mutated in 1 patient (5.3%) while *IKBKB*, *BIRC3* and *TRAF3* were wild type in all cases. Differently from DLBCL of the HCV- population, in HCV+ DLBCL the BCR pathway (*CARD11*, *CD79A* and *CD79B*) was never affected by genetic lesions. Among pathologic features, NOTCH pathway mutations were enriched in cases harbouring a small to medium cells component, histologically resembling MZL, coexisted with the large cell component proper of DLBCL (6/12, 50% in cases with low-grade component *vs* 6/34, 17.7% in cases without low grade component; p=0.05). *NOTCH2* and *NOTCH1* mutations were investigated in a cohort of 64 HCV- DLBCL. *NOTCH2* was rarely mutated in 1/64 (1.6%) in HCV- DLBCL (comparison with HCV-positive cases resulted statistically significant, p = 0.002) while *NOTCH1* was never affected (0/64). After a median F-UP of 3.7 yrs for entire series, 5-yr OS was 53% (95% CI: 37%>67%). In univariate analysis, a worse OS resulted associated with age > 60 yrs (p=0.02), mutation of *NOTCH2* (p=0.03), NOTCH pathway disruption (p=0.008) and mutation of *NOTCH1* or *NOTCH2* (p=0.03). 5-yr OS was 29% (95% CI: 5%>59%) for pts carrying *NOTCH1* or *NOTCH2* mutation and 60% (95%CI: 41%>75%) for pts without these mutations. 5-y OS was 22% (95% CI: 1%>59%) for pts carrying *NOTCH2* mutation and 60% (95%CI: 41%>74%) for pts without *NOTCH2* mutation. 5-yr OS was 27% (95% CI: 5%>56%) for pts carrying NOTCH pathway mutation and 62% (95%CI: 42%>77%) for pts without these mutations. In multivariate analysis, NOTCH pathway disruption retained its prognostic effect also adjusting for IPI score (HR=7.7; 95%CI: 1.3-47.3; p=0.028), while IPI score was not statistically significant. When adjusting also for age (as continuous variable), NOTCH pathway was still significant (HR=9.0, 95%CI: 1.3-60.1; p=0.024) as well as age (HR=1.1; 95%CI: 1.0-1.2; p=0.043) (Figure 1).

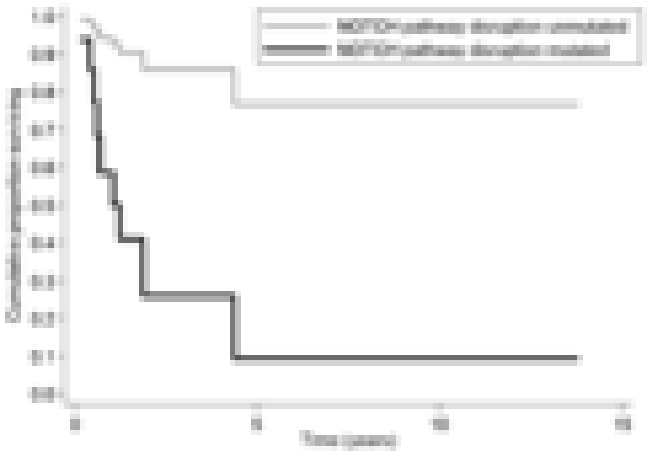

Figure 1.

Summary and Conclusions: In conclusion, a subset of patients with HCV-positive DLBCL displays a molecular signature of splenic MZL and has a worse clinical outcome.

ACCELERATION OF BCR-ABL+ LEUKEMIA INDUCED BY DELETION OF JAK2

E Grundschober[1,*], A Hoelbl-Kovacic[1], N Bhagwat[2], R Levine[2], V Sexl[1]
[1]University of Veterinary Medicine, Vienna, Austria, [2]Memorial Sloan Kettering Cancer Center, New York , United States

Background: The role of Jak2 in leukemia and lymphoma formation is beyond doubt. As a consequence several clinical studies on Jak2 inhibitors are still ongoing. Hematopoietic side effects observed upon treatment with Jak2 inhibitors indicated a crucial requirement for JAK2 in normal hematopoiesis.
Aims: To investigate the role of Jak2 in hematopoietic stem cells and for slowly evolving Bcr-Abl ^{p210} driven chronic myeloid leukemia we used *Jak2$^{f/f}$Mx1Cre* mice. Bone marrow derived from *Jak2$^{+/+}$* and *Jak2$^{f/f}$Mx1Cre^{+}* mice was transduced with a retrovirus encoding Bcr-Abl^{p210} and transplanted into non-irradiated NSG recipient mice. Jak2´s role for the hematopoietic stem cell compartment was investigated by performing serial as well as competitive transplants. To analyse whether differences in homing contribute to the inability of *Jak2* HSCs to repopulate we also performed competitive transplant experiments where we mixed *Jak2$^{+/+}$* Ly5.1 and *Jak2$^{f/f}$Mx1Cre^{+}* Ly5.2 BM cells in a 1:1 ratio and reconstituted lethally irradiated Ly5.1 recipient animals. Deletion of Jak2 was initiated after transplantation.
Results: BM transplantation experiments of non-irradiated NSG mice were performed using 1x10^6 Bcr-Abl^{p210} transduced BM cells. Under these conditions, disease evolves slowly and the absence of *Jak2* accelerated disease development with increased white blood cell counts (WBCs) and severe splenomegaly. Disease acceleration was attributed to the fact that Bcr-Abl transformed leukemic stem cells have overcome the necessity for Jak2-dependent signalling whereas non transformed HSCs depend on the presence of Jak2. In line, *Jak2* deletion was associated with a drastic reduction of HSCs (hematopoietic stem cells) and HSCs fail to repopulate lethally irradiated recipients upon Jak2 deletion in serial transplant settings. In a competitive transplant a detailed analysis over a period of 17 weeks revealed a pronounced and continuous decrease of *Jak2* Ly5.2^{+} cells in the peripheral blood, whereas numbers of *Jak2$^{+/+}$* Ly5.2^{+} cells remained constant. The drop in *Jak2* Ly5.2^{+} cells was pronounced for B220^{+} cells and even more prominent for CD11b^{+}Gr1^{+} cells, which were no longer detectable after 7 weeks. After 17 weeks almost complete absence of hematopoietic stem cells and progenitors in *Jak2* recipients was confirmed.
Summary and Conclusions: Jak2 is critical for HSC maintenance, survival and function. This dependence does not extend to Bcr-Abl^{p210} transformed leukemic stem cells. Thus, in the absence of Jak2 Bcr-Abl^{+} leukemic stem cells outcompete regular HSCs and accelerate Bcr-Abl^{+} leukemia.

KINETICS OF ORGAN RESPONSE AND SURVIVAL FOLLOWING NORMALIZATION OF THE SERUM FREE LIGHT CHAIN RATIO IN AL AMYLOIDOSIS

GP Kaufman[1,*], A Dispenzieri[1], MA Gertz[1], MQ Lacy[1], FK Buadi[1], SR Hayman[1], N Leung[1], D Dingli[1], JA Lust[1], Y Lin[1], P Kapoor[1], RS Go[1], SR Zeldenrust[1], RA Kyle[1], SV Rajkumar[1], SK Kumar[1]
[1]Mayo Clinic, Rochester, United States

Background: Despite successful treatment of the clonal plasma cell implicated in its pathogenesis, patients (pts) with AL amyloidosis (AL) have significant morbidity related to amyloid mediated organ dysfunction. While normalization of the serum free light chain measurements (normal ratio of involved and uninvolved free light chains (nFLCr)) is the goal of therapies and centerpiece of hematologic response criteria, achieving meaningful organ response (OR) remains the ultimate goal of treatment. Expectations for OR following successful therapy leading to nFLCr in AL remain poorly described.
Aims: To evaluate the clinical implications of the kinetics of OR following successful nFLCr in AL.
Methods: Pts with confirmed AL, treated and followed at Mayo Clinic Rochester, who obtained nFLCr were retrospectively studied for evidence of OR. Demographic and clinical information including hematologic and organ related labs were obtained from medical records. Organ involvement and response criteria were defined by established standards. The research was performed with IRB approval. Survival curves were constructed per Kaplan-Meier estimates and compared using the log-rank test. Landmark analysis comparing groups of organ responders and non-responders was performed at one-year from initiation of therapy and from nFLCr. Cox-proportional hazard analysis was performed to assess variables influencing both time to OR and overall survival (OS). Effect likelihood ratio tests, hazard rates and 95% confidence intervals were calculated. Statistical analysis was performed using JMP v.10.
Results: Three-hundred-thirteen pts with AL obtaining nFLCr after therapy initiation formed the study cohort. Median follow up from diagnosis was 46.7 months (4.2-180.0). Renal, heart, liver and nervous system involvement were seen in 75%, 54%, 14%, and 12% of pts respectively. Primary treatments included auto-BMT (54%), melphalan-dexamethasone (28%), and proteasome inhibitor inclusive regimens (13%). Median time to nFLCr from start of therapy was 3.8 months (interquartile range 3.2-7.7). Seventy-two percent of pts obtaining nFLCr achieved OR in at least one organ. The median time to first OR from initiation of therapy was 6.7 months (interquartile range 3.4-12.2) and was 0.4 months (interquartile range [-1.2]-[+7.9]) from documented nFLCr. Median OS for the entire cohort was not reached, while it was 58.5 months for those who failed to obtain any OR. Landmark analysis of pts surviving at least 12 months from the start of treatment and nFLCr, showed superior OS in early organ responders (log-rank test p=0.038 and p=0.009 respectively) Figure 1. Having high levels of the involved FLC (iFLC) at diagnosis was predictive of having an OR following nFLCr (HR 1.45 (1.09-1.92) p=0.012). Other factors predicting OR include the presence of monosomy 13 on plasma cell FISH panel (HR 1.46 (1.01-2.08) p =0.044). In pts with renal involvement, having a lambda iFLC was predictive of not obtaining an OR despite nFLCr (HR 0.61 (0.44-0.86) p=0.005).

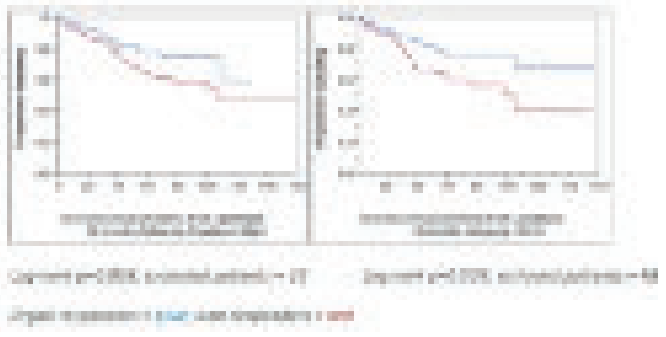

Figure 1. Landmarked survival curves comparing overall survival between organ responders and non-responders at landmarked time.

Summary and Conclusions: AL pts obtaining early OR following nFLCr have superior OS compared to those who obtain nFLCr but do not have early OR. High iFLC at diagnosis and monosomy 13 predict early OR. Interestingly, for pts with renal amyloid involvement, the presence of iFLC lambda predicts against obtaining renal response despite achieving nFLCr. These results provide new and significant clinical insight for the prognostication and management of successfully treated AL.

IRON-INDUCED EPIGENETIC ABNORMALITY OF MOUSE BONE MARROW THROUGH ABERRANT ACTIVATION OF ACONITASE AND ISOCITRATE DEHYDROGENASE WITHOUT GENE MUTATION: ANALYSIS BY HIGH THROUGHPUT SEQUENCER AND GC-MS.

M Yamamoto[1,*], H Tanaka[2], Y Toki[1], M Hatayama[1], S Ito[1], J Inamura[1], M Shindo[1], K Sasaki[2], K Ikuta[1], T Ohtake[1], M Fujiya[1], Y Torimoto[3], Y Kohgo[1]
[1]Division of Gastroenterology & Hematology/Oncology, [2]Department of Gastrointestinal Immunology and Regenerative Medicine, Asahikawa Medical University, [3]Oncology Center, Asahikawa Medical University Hospital, Asahikawa, Japan

Background: Iron overload in MDS contribute to a poor prognosis of the patients due to organ insufficiency and/or conversion to acute leukemia, both of which could be improved by iron chelation therapy. Iron is utilized in many biological processes such as oxygen transfer, energy metabolism and gene expression; we therefore hypothesized that iron overload itself may induce epigenetic change by systemic alterations of cellular metabolism, which may affect the production of 2-hydroxyglutarate (2HG), the crucial metabolite of isocitrate dehydrogenase (IDH) gene-mutated leukemia.
Aims: In order to clarify the role of iron on this issue, we evaluated the whole changes of gene expressions relating energy and glucose metabolism in the iron-overloaded mouse bone marrow cells using RNA sequencing and digital PCR analysis.
Methods: For iron overload model mice, iron dextran (10 mg/head/day) was intraperitoneally injected into C57Bl/6 mice for 5 days. After injection of iron dextran, deferoxamine (DFO) was also administered into the some mice. The mice were sacrificed, and peripheral blood and bone marrow cells were taken. RNA samples were then extracted from the bone marrow cells, and comprehensive gene expression analysis was performed using the high throughput sequencer Ion Proton (Life Technologies). The gene expression levels were further validated by the digital PCR system QuantStudio 3D (Life Technologies). Intracellular levels of 2-HG were enumerated by GC-MS analysis and DNA methylation levels were analyzed by ELISA.
Results: From the RNA sequencing and digital PCR analysis, the increased expression of metabolic enzymes, which are involved in glycogenolysis (Agl, Pgm1) and glucose metabolism (Aco1, Idh1) were observed in the bone marrow cells of iron overloaded mice. Furthermore, by GC-MS and ELISA, the levels of 2-HG and DNA methylation were also increased in these mice. These observations were canceled by DFO treatment (Figure 1).
Summary and Conclusions: As ACO1 is an iron-dependent enzyme, which converts citrate into isocitrate, and supplies isocitrate to IDH1/2, which converts isocitrate into a-ketoglutarate in the TCA cycle. We hypothesized that aberrant activation of the ACO1-IDH pathway by iron overload might induce 2-HG production and further cause DNA methylation even in the absence of IDH mutation. These whole RNA sequence analyses clearly indicate that the up-regulation of the ACO1-IDH pathway caused by iron overload trigger the production of 2-HG and finally induce DNA methylation that may develop leukemia even in the absence of IDH mutation.

RESPONSE TO LISINOPRIL IN PATIENTS WITH SICKLE CELL ANEMIA AND PROTEINURIA

A Aleem[1,*], MI AlSharif[1], A Al-Sultan[2], K Alsaleh[1], A Alsuwaida[3], F Algahtani[1], A Almomen[1]
[1]Medicine, Hematology/Oncology, [2]Pediatrics, Hematology/Oncology, [3]Medicine, Nephrology, King Khalid University Hospital, King Saud University, Riyadh, Saudi Arabia

Background: Patients with Sickle cell anemia (SCA) are surviving longer and this has led to more chronic complications of SCA. Kidney is particularly susceptible to sickling of red cells and hypoxic damage because of the hypertonic and acidic environment of renal medulla. Proteinuria is an early manifestation of sickle cell related renal disease and considered to be a risk factor for developing renal impairment in future. Previous small studies have shown the benefit of ACE-inhibitors but this role remains to be defined.
Aims: The aim of this study was to assess the role of lisinopril, an angiotensin-converting enzyme inhibitor, in reducing proteinuria in patients with sickle cell anemia.
Methods: Patients older than 15 years with known sickle cell disease (HbSS or HbS-β^0) participated in the study. Patients with renal impairment and sickle cell trait were excluded. Twenty four hour urine collection was carried out to quantify proteinuria and urine collection was done in steady state without an acute illness during the last 2 weeks. All patients gave informed consent and the study was approved by the institutional review board.
Results: A total of 35 patients were recruited with a mean age of 28.5 ± 6.98 (range 20-47, 54% males). The mean Hb was 9.26 g/dl, mean HbF 11.2%, mean LDH 369 IU/ml, and mean serum creatinine 44 µmol/l. Median Pre-treatment 24 hour urine-protein was 0.3006 grams while median 24 hour urine-protein post-treatment was 0.150 grams (p=0.01). After a median follow-up of 38 months, 24 hour urine-protein decreased in 27 (77%) patients and normalized in 18 (52%) patients. Protein increased in 2 (6%) patients and remained stable (no change) in 6 (17%) patients. There was no significant difference in the pre and post systolic and diastolic blood pressures. Average dose of lisinopril was 5 mg. Nineteen patients are still on lisinopril. The reason(s) to stop lisinopril include: normalization of protein (9), non-compliance (3), side effects (2), and pregnancy (1). Adverse events include cough (5), dizziness (1), and diarrhea (1). None of the patients in the study developed deterioration of renal function.
Summary and Conclusions: Lisinopril is effective in reducing proteinuria in

patients with SCA without significant drop in the blood pressure. Only few patients developed adverse events which were mild & tolerable. It is unclear for how long to continue lisinopril and whether it can be stopped in patients who normalize urine protein. Larger studies with longer follow-up are needed to address these questions.

ICARS: ENGINEERED SAFETY FOR T CELL IMMUNOTHERAPY

V Fedorov[1,*], M Themeli[1], M Sadelain[1]
[1]Memorial Sloan Kettering Cancer Center, New York, United States

Background: Despite being potentially curative, T cell immunotherapies have been hampered by toxic side effects in clinical use. "On-target but off-tumor" fatalities have occurred in immunotherapy trials due to toxic cross-reactivity with heart, lung, and brain tissues. Similarly, donor lymphocyte infusion in allogeneic bone marrow transplantation can lead to lethal acute or chronic graft-*versus*-host disease. Available approaches to limit T cell-mediated toxicities are inadequate and abrogate the beneficial effects of the therapies.
Aims: Using novel synthetic receptors, we sought to engineer dynamic cell intrinsic control to allow T cells to regulate their own functions and limit unwanted toxicities. Thus, trying to educate T cells on what to kill and what not to kill.
Methods: We engineered human T cells to express inhibitory chimeric antigen receptors (iCARs), which combined unique surface antigen recognition and intracellular inhibitory signaling based on CTLA-4, PD-1, LAG-3, 2B4, or BTLA immune-inhibitory receptors.
Results: Using iCARs in human T cells, we were able to control cytokine secretion, cytotoxicity, and proliferation driven either by endogenous T cell receptors or by clinically relevant chimeric antigen receptors. *In vivo,* iCARs could restrict tumor target T cells to eliminate on-target tumor cells but not off-target cells expressing the iCAR antigen. Additionally, iCAR-expressing T cells protected human cells expressing the iCAR antigen despite potent TCR-mediated allogenicity, in a novel *in vivo* induced pluripotent stem cell allogeneic response model. We have defined that iCARs function through reversible stoichiometric signaling allowing for sequential antigen encounters and potent function.
Summary and Conclusions: iCARs provide novel *engineered safety* to prevent toxicities in autologous and allogeneic T cell therapies, while preserving therapeutic efficacy through dynamic self-regulation.

LB2450

EFFECT OF FTY720 ON THE SET-PP2A COMPLEX IN ACUTE MYELOID LEUKEMIA. SET BINDING DRUGS HAVE ANTAGONISTIC ACTIVITY

R Pippa[1,*], A Dominguez[1], DJ Christensen[2], I Moreno-Miralles[1], M Blanco-Prieto[3], O Bachs[4], K Ye[5], MP Vitek[2], MD Odero[6]
[1]CIMA, Center of Applied Medicine Research, Pamplona, Spain, [2]Oncotide, Durham, United States, [3]Pharmacy and Pharmaceutical Technology, University of Navarra, Pamplona, [4]Cell Biology, Immunology and Neurosciences, University of Barcelona, Barcelona, Spain, [5]Pathology & Laboratory Medicine, Emory University School of Medicine, Atlanta, United States, [6]Biochemistry and Genetics, University of Navarra, Pamplona, Spain

Background: PP2A is a phosphatase that functions as a tumor suppressor in several cancers. Our group showed that PP2A inactivation is a recurrent event in acute myeloid leukemia (AML), and that overexpression of SET, an endogenous inhibitor of PP2A, is a poor prognostic factor in this disease. Furthermore, restoration of tumor-suppressor activity by PP2A-activating drugs has anti-leukemic effects in AML cells. Interestingly, the anticancer activity of several PP2A activating drugs, such as FTY720 and OP449, depends on interaction/sequestration of SET.
Aims: Our aim was to clarify the domains involved in SET and PP2A catalytic subunit (PP2Ac) binding in AML and to elucidate the molecular mechanisms of PP2A activation by FTY720, in order to establish the basis of new PP2A activating drugs in AML.
Results: Immunoprecipitation of PP2Ac in untreated cells confirmed that SET interacts with PP2Ac, though treatment with FTY720 effectively disrupted this association. Next, we treated HL-60 cells with biotin-labeled FTY720, and immunoprecipitated the complexes formed in cell lysates with streptavidin-labeled dynabeads. We detected endogenous SET, but not PP2Ac, indicating that FTY720 is interacting with SET and activates PP2A in AML by preventing the PP2Ac/SET complex formation, in agreement with the recent observations obtained in lung cancer and in chronic myeloid leukemia cells (CML). We next analyzed the effect of FTY720 on the SET/PP2Ac complex by affinity chromatography analysis. Our results indicate that FTY720 binds SET within the last 100 amino acids of the C-terminal fragment of SET (from 177 to 277), in agreement with Saddoughi *et al.* (2013). This interaction produces a destabilization of the inhibitory SET/PP2Ac complex, with a consequent re-activation of PP2A activity and a reduction of cell viability. Additionally, we found that SET is predominantly cytoplasmic; however, after treatment with FTY720 there was a marked increase of nuclear localized SET, together with an intensification of PP2Ac into the cytoplasm. Our group and others have demonstrated that both FTY720 and OP449 can inhibit cell growth and re-activates PP2A activity in CML and AML cells. FTY720 is a relatively nontoxic drug currently used in patients with relapsing multiple sclerosis (MS). However, the dose used as an anticancer drug is much higher than the dose given to MS patients. Therefore, we evaluated the effect of combining FTY720 with OP449 to establish whether OP449 could help to reduce the dose of FTY720. Our results showed that FTY720 and OP449 have antagonistic effects, suggesting the need for testing new combinations of OP449 with second generation FTY720-derivatives for the treatment of AML.
Summary and Conclusions: SET forms an inhibitory complex with PP2Ac in AML, impairing the activity of PP2A, and the whole structure of SET is involved in the binding. We confirm that FTY720 reduces the inhibition of PP2A by SET, and shed light on the mode of action of this drug. Furthermore, we demonstrate for the first time that FTY720 induces an accumulation of SET into the nucleus, allowing PP2A to recover its activity in the cytoplasmic compartment. Finally, we show that FTY720 and OP449 have antagonistic effects, encouraging the hypothesis of an alternative combination of OP449 with derivatives of FTY720 could be a better strategy for SET inactivation in AML.

PRETREATMENT D-2-HYDROXYGLUTARATE SERUM LEVELS PREDICT OUTCOME IN IDH1-MUTATED ACUTE MYELOID LEUKEMIA

C E Heilig[1,*], J Balss[2], T Bochtler[1], JG Okun[3], M Saadati[4], A Benner[4], G Ehninger[5], M Schaich[5], AD Ho[1], C Thiede[5], A von Deimling[2], A Krämer[1]
[1]Department of Internal Medicine V, [2]Department of Neuropathology, [3]Department of Pediatrics, University of Heidelberg, [4]Department of Biostatistics, German Cancer Research Center (DKFZ), Heidelberg, [5]Department of Internal Medicine I, University of Dresden, Dresden, Germany

Background: Mutations in isocitrate dehydrogenases (IDH) 1 and 2 frequently occur in acute myeloid leukemia (AML) and result in the production of the oncometabolite D-2-hydroxyglutarate (D2HG), which is elevated in the serum of most patients with IDH-mutated (IDHmut) AML. Measurement of serum D2HG has been shown to be useful in identifying patients with IDH mutations, and can serve as a marker of tumor burden and response to treatment. Interestingly, D2HG has been shown to have leukemogenic properties *in vitro*, independent of mutated IDH. Whereas the impact of IDH mutations on outcomes has been investigated in large studies, the relevance of pretreatment serum D2HG levels is a matter still open to debate.
Aims: This studied investigated the impact of pretreatment D2HG serum levels on outcomes in the to date largest cohort of uniformly treated patients with IDHmut AML.
Methods: Pretreatment D2HG serum levels were measured in 86 IDHmut and 70 IDHwt AML patients enrolled in the prospective, randomized, multicenter AML2003 trial of the German Study Alliance Leukemia (SAL). D2HG was measured using gas chromatography/mass spectrometry (GC/MS) as well as a fluorometric assay (Balss et al, Acta Neuropathol. 2012 Dec;124(6):883-91).
Results: Measurement of D2HG with GC/MS and the fluorometric assay in 93 samples showed a strong correlation between the two methods (R=0.83). Further analyses were carried out using the fluorometric method. Median D2HG serum levels were significantly higher in patients with IDHmut than IDHwt AML (41.6 µmol/l (range 1.9 - 595 µmol/l) and 5.0 µmol/l (range 0.1 - 13.7 µmol/l), respectively, p<0.0001). D2HG correlated with leukocyte count, serum LDH and bone marrow blast percentage (R=0.67, R=0.5, R=0.39, respectively). In a multivariate Cox regression model, D2HG had a negative impact on event-free survival (EFS; HR 1.33; p=0.04), but not overall-survival (OS; HR 1.1; p=0.47), independently of the established risk factors age, ELN risk group, WBC, and LDH. A subgroup analysis showed that this impact on EFS solely resulted from a striking effect of D2HG levels on EFS in patients with mutations in IDH1 (HR 2.42; p=0.0029) , with no effect in patients with mutations in IDH2 (HR 1.0; p=0.99).
Summary and Conclusions: Recent studies investigating D2HG in AML have been performed with only small numbers of uniformly treated patients, or measured total 2HG instead of the actual oncometabolite D2HG. Our study comprises the to date largest number of uniformly treated patients with IDHmut AML. Pretreatment D2HG serum levels negatively impacted on EFS in IDH1mut AML, independent of established risk factors, and did so as a continuous variable, thus consistent with the concept of a dose-dependent effect of the metabolite. The effect on OS was not statistically significant, likely due to the frequent use of allogeneic SCT in the AML2003 trial, which could have rescued the negative effect of D2HG. No significant impact of D2HG on outcome was found in patients with IDH2mut AML. This variable effect of D2HG levels, apparently dependent on the isoenzyme mutated, *i.e.* IDH1 *versus* IDH2, or possibly the localization of the D2HG-producing mutant isoenzyme warrants further investigation.
