Results: Data cutoff was Nov 6, 2017; 24 pts (Cohort A, n=6; Cohort B, n=9; Cohort C, n=9) were evaluable for safety and activity. Due to a partial clinical hold per the FDA, no Cohort C pt received atezo+len. The majority of pts were alive at data cutoff (median follow-up: 22 mo [Cohort A], 16 mo [Cohort B], 17 mo [Cohort C]). 4 (67%) pts in Cohort A, 3 (33%) in Cohort B and 1 (11%) in Cohort C were >65 y old. High-risk cytogenetic features were present in 4 (67%) pts in Cohort A and 1 (11%) pt each in Cohorts B and C; median (range) prior lines of therapy in Cohorts A, B and C were 2 (1-3), 3 (1-3) and 1 (1-2), respectively. All pts had ≥1 AE; 2 (33%) pts in Cohort A, 5 (56%) in Cohort B and 2 (22%) in Cohort C had Grade 3-4 AEs. Grade 3-4 SAEs occurred in 1 pt per cohort. No Grade 5 AEs were reported. 4 (44%) Cohort B pts and 1 (11%) Cohort C pt had AEs leading to atezo interruption; 4 (44%) Cohort B pts had len dose modification/interruption. No withdrawals from atezo or len due to AEs occurred. ORR was 11% in Cohort B (1 VGPR, atezo+len 15 mg). No Cohort A or C pt achieved ≥PR; 1 Cohort C pt had an MR. Median PFS (95% CI) was 4.9 mo (2.1, 4.9), 3.5 mo (2.9, 16.4) and 6.7 mo (2.8, NE) in Cohorts A, B and C, respectively. In Cohort A, an increase in activated CD8+ T cells (HLA-DR+Ki-67+), immune-activating (IFNγ/IL-2) and -suppressing (IL-6/IL-10) cytokines and PD-L1 MFI on CD8+ T cells was detected in blood by C1D15. Post-ASCT pts (Cohort C) had higher pre-tx IL-2 and an early rise in IL-10 (C2D1) in blood after atezo monotherapy *vs* R/R pts (Cohorts A, B). Addition of len (Cohort B) was associated with increased Tregs (CD4+CD25+CD127lo) in blood (C2D1) and bone marrow (C4D1) and a greater rise in circulating IL-6.
Summary and Conclusions: Atezo alone and with len in MM pts was safe and tolerable. Despite small pt numbers and limited time on study tx, no new safety signals were observed. No single-agent activity was seen with atezo in R/R pts, but results may differ post ASCT. Atezo+len had limited clinical activity regardless of len dose. Biomarker data suggest that atezo promotes T-cell activation as early as C1D14 in blood, but this is insufficient for optimal anti-tumor activity. Addition of len did not enhance immune stimulation or decrease tumor-promoting cytokines. Optimal combination partners for atezo in MM remain to be identified.

PF566

TIME TO PLATEAU AS A PREDICTOR OF SURVIVAL IN NEWLY DIAGNOSED MULTIPLE MYELOMA

P. Mellors[1,*], M. Binder[1], F. Buadi[1], M. Lacy[1], M. Gertz[1], A. Dispenzieri[1], S. Hayman[1], P. Kapoor[1], W. Gonsalves[1], Y. Hwa[1], A. Fonder[1], M. Hobbs[1], T. Kourelis[1], R. Warsame[1], S. Zeldenrust[1], J. Lust[1], N. Leung[1], R. Go[1], R. Kyle[1], V. Rajkumar[1], S. Kumar[1]

[1]Mayo Clinic, Rochester, United States

Background: Response rates in newly diagnosed multiple myeloma have improved dramatically with the introduction of highly effective novel therapies. However, survival in patients achieving optimal responses to initial treatment can vary significantly and new prognostic markers are required to improve risk stratification. Few studies have examined the relationship between the time required to achieve a best response plateau and survival outcomes in the era of novel agents.
Aims: The aim of this study was to characterize the relationship between time to best response plateau (T_{Plat}) and survival in newly diagnosed multiple myeloma treated with novel agents.
Methods: We investigated the relationship between T_{Plat} and survival in 1099 newly diagnosed patients treated with novel agents at our institution from December 2005 to December 2015. T_{Plat} was defined as time from initiation of first-line therapy to best response to first-line therapy. In order to avoid an immortal time bias, overall and progression free survival estimates were calculated from the time of best response to first-line therapy (landmark analysis). The log-rank test was used to compare survival outcomes in subgroups. Multivariable-adjusted proportional hazards regression was used to adjust for known prognostic factors including age, sex, best response to first-line therapy, first-line therapy (immunomodulator, proteasome inhibitor, upfront autologous hematopoietic stem cell transplantation), baseline paraprotein concentration, International Staging System stage, and the presence of cytogenetic high-risk abnormalities.
Results: Six hundred and forty of the 1099 patients (58%) were men. The

median age at diagnosis was 63 years (23 - 89). The five most common fist-line therapies were lenalidomide and dexamethasone (Rd; 37%), bortezomib, cyclophosphamide, and dexamethasone (VCD; 24%), bortezomib, lenalidomide and dexamethasone (VRd; 16%), bortezomib and dexamethasone (Vd; 7%), and ixazomib, cyclophosphamide and dexamethasone (ICd; 4%). The median T_{Plat} was 4.9 months (0.7 - 58.6) and plateau duration was 1.8 years (0.2 - 11.0). Patients who required >120 days to achieve a plateau had improved overall and progression free survival (p <0.001 for both comparisons). This effect was observed both in the patients who underwent autologous hematopoietic stem cell transplantation upfront and those who did not (p <0.001 for both comparisons). The estimates from the multivariable-adjusted regression models are shown in Table 1.

Table 1.

Effect estimates from multivariable-adjusted Cox regression models for the effect of time to plateau on overall and progression free survival.

Model	n	Parameter	HR (95% CI)	p-value
Overall survival landmark (time from best response to event)				
Unadjusted	1099	T_{Plat} > 120 days (vs. ≤ 120)	0.53 (0.43-0.66)	<0.001
Multivariable-adjusted 1	1099	T_{Plat} > 120 days (vs. ≤ 120)	0.59 (0.47-0.75)	<0.001
Multivariable-adjusted 2	1099	T_{Plat} > 120 days (vs. ≤ 120)	0.63 (0.49-0.79)	<0.001
Multivariable-adjusted 3	910	T_{Plat} > 120 days (vs. ≤ 120)	0.58 (0.45-0.76)	<0.001
Multivariable-adjusted 4	634	T_{Plat} > 120 days (vs. ≤ 120)	0.66 (0.48-0.89)	0.007
Progression free survival landmark (time from best response to event)				
Unadjusted	1099	T_{Plat} > 120 days (vs. ≤ 120)	0.62 (0.54-0.72)	<0.001
Multivariable-adjusted 1	1099	T_{Plat} > 120 days (vs. ≤ 120)	0.71 (0.61-0.83)	<0.001
Multivariable-adjusted 2	1099	T_{Plat} > 120 days (vs. ≤ 120)	0.73 (0.62-0.86)	<0.001
Multivariable-adjusted 3	910	T_{Plat} > 120 days (vs. ≤ 120)	0.73 (0.61-0.87)	<0.001
Multivariable-adjusted 4	634	T_{Plat} > 120 days (vs. ≤ 120)	0.76 (0.62-0.94)	0.011

The multivariable-adjusted models included the following baseline characteristics: Model 1 was adjusted for age, sex, and best response during first-line therapy. Model 2 was additionally adjusted for the type of first-line therapy (immunomodulator, proteasome inhibitor, upfront autologous hematopoietic stem cell transplantation). Model 3 was additionally adjusted for the paraprotein concentration (M spike). Model 4 was additionally adjusted for the International Staging System (ISS) stage and the presence of cytogenetic high-risk abnormalities.

Summary and Conclusions: Patients who responded more slowly to first-line therapy (T_{Plat} >120 days) experienced improved survival compared to those responding more rapidly. Patients with a prolonged T_{Plat} could represent an "ongoing responder" phenotype that portends a survival advantage independent of treatment modalities, depth of response, and established biomarkers. It is important to account for these biological differences as we design response adapted therapy approaches in multiple myeloma.

PF567

SAFETY AND EFFICACY OF POMALIDOMIDE+LOW-DOSE DEXAMETHASONE IMMEDIATELY FOLLOWING LENALIDOMIDE-BASED TREATMENT FAILURE IN PATIENTS WITH RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA

D.S. Siegel[1,*], G.J. Schiller[2], K. Song[3], R. Agajanian[4], K. Stockerl-Goldstein[5], H. Kaya[6], M. Sebag[7], C. Samaras[8], E. Malek[9], G. Talamo[10], C.S. Seet[11], J. Mouro[12], F. Zafar[12], W. Chung[12], S. Srinivasan[12], M. Qian[12], A. Agarwal[12], A. Thakurta[12], N. J. Bahlis[13]

[1]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, [2]David Geffen School of Medicine at UCLA, Los Angeles, United States, [3]Vancouver General Hospital, Vancouver, Canada, [4]The Oncology Institute of Hope and Innovation, Downey, [5]Washington University School of Medicine, St. Louis, [6]Cancer Care Northwest, Spokane, United States, [7]McGill University Health Centre, Montreal, Canada, [8]Cleveland Clinic, [9]University Hospitals Case Medical Center, Cleveland, [10]Penn State Hershey Cancer Institute, Hershey, [11]UCLA Medical Center, Los Angeles, [12]Celgene Corporation, Summit, United States, [13]University of Calgary, Calgary, Canada

Background: Pomalidomide (POM)+low-dose dexamethasone (LoDEX) is a standard of care for the treatment (Tx) of patients (pts) with relapsed and/or refractory multiple myeloma (RRMM). This regimen is being investigated in the MM-014 (NCT01946477) trial as a third-line Tx in pts with RRMM in whom last prior therapy with lenalidomide (LEN) failed (cohort A). As LEN becomes increasingly established in earlier lines of Tx, it is pertinent to demonstrate efficacy in pts who have exhausted the benefit of LEN as their last Tx.
Aims: To present safety and efficacy results of POM+LoDEX as a third-line Tx immediately after LEN in cohort A of the MM-014 trial, including a subset analysis of pts who were previously treated with proteasome inhibitors (PI) and/or bortezomib (BORT).
Methods: Eligibility criteria included age ≥18 y, documented MM, 2 prior Tx lines, and progressive disease (PD) after ≥2 cycles of second-line LEN-based therapy. Pts received 28-d cycles of POM 4 mg/d on d 1-21+LoDEX 40 mg/d (20 mg/d if >75 y) on d 1, 8, 15, and 22, with mandatory thromboprophylaxis. The primary endpoint was overall response rate (≥partial response per modified International Myeloma Working Group criteria). The clinical benefit rate was defined as the percentage of pts achieving complete response, very good partial response, partial response, or minimal response. Key secondary endpoints included progression-free survival (PFS), safety, and second primary malignancies (SPMs). All pts provided informed consent.
Results: A total of 56 pts were enrolled in cohort A. Median age was 68 y, with 62.5% of patients aged >65 y in the intention-to-treat (ITT) population (prior PI, 63.4% [n=41]; prior BORT, 64.1% [n=39]) and 57.1% overall (prior PI, 58.5%; prior BORT, 56.4%) were male. Most pts had an ECOG performance status of 0/1: 92.9%, 95.1%, and 94.9%, respectively. All pts were refractory or relapsed to their most recent LEN-containing regimen, and 91.1%, 92.7%, and 92.3% of pts were LEN refractory, respectively. A majority of patients had prior stem cell transplant: 64.3% overall, 63.4% with prior PI, and 61.5% with prior BORT. Cytogenetic data by FISH were available for 50 pts: 4 were positive for del(17p), 4 for t(4;14), and 2 for t(14;16). Median duration of prior LEN-containing Tx was 23.6 mos (range, 3.5-107.0 mos), and in 60.7% of pts, the most recent LEN dose was 25 mg/d. Median follow-up was 19.0 mos at the data cutoff (10/2/2017). Responses and PFS outcomes are reported in the Table 1. Of the 56 pts in the ITT population, 52 discontinued Tx, 31 (59.6%) due to PD, 7 withdrawal, 5 adverse events (AEs), 3 lack of efficacy, 2 death, and 3 other reasons. The most common grade 3/4 treatment-emergent AEs included anemia (25.0%), neutropenia (10.7%), fatigue (14.3%), and infections (25.0%, including pneumonia [14.3%]). Grade 3/4 pulmonary embolism was reported in 2 pts, and 1 pt had an SPM. Similar safety results were noted in pts with prior exposure to PI or BORT.

Table 1.

Outcome	Cohort A (n = 56)	Prior PI Exposure (n = 41)	Prior BORT Exposure (n = 39)
ORR, %	33.9	31.7	28.2
VGPR	12.5	9.8	7.7
CBR, %	44.6	41.5	38.5
PFS, median, months			
ITT (n = 56)	9.6	7.9	7.9
EE (n = 53)	13.8		

BORT, bortezomib; CBR, clinical benefit rate; EE, efficacy evaluable; ORR, overall response rate; PFS, progression-free survival; PI, proteasome inhibitor; VGPR, very good partial response.

Summary and Conclusions: POM+LoDEX is a safe and effective third-line Tx for pts with RRMM following second-line failure of LEN-based Tx, including pts with prior exposure to PI or BORT. All pts, including those with prior PI or BORT Tx, experienced lower rates of hematologic AEs and longer median PFS than what has been previously reported for other studies using POM+LoDEX in later lines of Tx.

PF568

PRE-TREATMENT CD38 EXPRESSION LEVELS IN MYELOMA CELLS AND CD38-POSITIVE REGULATORY T CELLS AFFECT THE RESPONSE OF RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS TO TREATMENT WITH DARATUMUMAB

A. Kitadate[1,*], H. Kobayashi[1], Y. Abe[1], K. Narita[1], M. Takeuchi[1], K. Matsue[1]

[1]Division of Hematology/Oncology, Department of Medicine, Kameda Medical Center, Kamogawa, Japan

Background: Daratumumab (DARA), a humanized antibody to CD38, is a promising agent for multiple myeloma treatment. DARA targets CD38-expressing myeloma cells and nonplasma cells that express CD38, including CD38-positive regulatory T-cells (Treg). Therefore, DARA has been shown to induce myeloma cell death through several mechanisms, including complement-dependent cytotoxicity (CDC), antibody-dependent cell-mediated cytotoxicity (ADCC), and immunomodulatory effects.
Aims: To investigate the mechanism of action of DARA, we analyzed baseline CD38 expression and lymphocyte subsets, including CD38-positive Treg cells, before and after DARA treatment.
Methods: We included 28 relapsed/refractory myeloma patients, who were treated with DARA at Kameda Medical Center. Patients who were followed up for more than one cycle of DARA were enrolled in the study. Peripheral blood and bone marrow samples were analyzed before and during therapy. Using flowcytometric analysis, we evaluated CD38 expression (MFI; mean

fluorescence intensity) and lymphocyte subsets (CD4/CD8 T cells, NK cells, and Treg cells). Treg cells were identified as a fraction of the CD4+CD25^{high}-CD127^{dim} population. We also examined CD55 and CD59 expression levels, which can be associated with CDC.

Results: The median age of the patients was 75 years (range: 53-91), and 14 of the patients were male. Twenty-two patients (79%) had received more than 3 prior therapies. Patients received a median of 4 prior lines of therapy (range, 2-11). Twenty-six patients (93%) were refractory to both proteasome inhibitors (PI) and immunomodulatory drugs (IMiDs). Eleven patients (39%) received a PI-based DARA-containing regimen, 14 patients (50%) received an IMiDs-based DARA-containing regimen, and three patients (11%) received other DARA-containing regimens. Seventeen patients (61%) had a partial response (PR) or better (responders), and 11 patients (39%) did not respond (non-responders). We confirmed that pretreatment levels of CD38 MFI were significantly higher in responders than in non-responders (p=0.001). There were no significant differences in the baseline expression levels of CD55 and CD59 in responders and non-responders. Before treatment, the absolute number of CD38-positive Treg cells was significantly higher in responders (median, 10.9/μl; range, 5.1-37.3/μl) than in non-responders (median, 4.8/ L; range, 1.1-12.8/μl, p=0.02), but absolute Treg cell numbers were not associated with DARA response. CD38-positive Treg cells were depleted in all treated patients, but total Treg cell numbers remained relatively stable after DARA treatment. In addition, we observed that absolute CD8-positve T-cell numbers significantly increased after DARA treatment (257.1±150.5 *vs* 379.6±193.6 / L, p=0.003). However, increased numbers of CD8-positive T-cells were not associated with clinical response. The numbers of CD4-positive T-cells significantly decreased after DARA treatment, while CD56-positive NK cells were immediately depleted in all treated patients.

Summary and Conclusions: Pretreatment levels of CD38 MFI could be a predictive marker for response to DARA treatment. Moreover, the frequency of CD38-positive Treg cells present before treatment also could serve as a response marker. These results suggest that depletion of CD38-positive Treg cells could contribute to some immunological mechanisms of DARA. This study provides evidence to support multiple mechanisms of action for DARA including ADCC and immunomodulatory effects.

PF569

UPDATED RESULTS OF A PHASE II STUDY WITH CARFILZOMIB, CYCLOPHOSPHAMIDE AND DEXAMETHASONE (CCD) FOR NEWLY DIAGNOSED TRANSPLANT INELIGIBLE MULTIPLE MYELOMA PATIENTS

A. Larocca[1,*], M.T. Petrucci[2], C. Conticello[2], L. De Paoli[2], M. D'Agostino[1], S. Spada[1], A. Bernardini[1], P. Musto[2], G. Benevolo[2], M. Offidani[2], A. Siniscalchi[2], P. Corradini[2], M. Cavo[2], M. Boccadoro[1], S. Bringhen[1]

[1]Myeloma Unit, Division of Hematology, University of Torino, A.O.U. Città della Salute e della Scienza di Torino, Torino, [2]Italian Multiple Myeloma Network, GIMEMA, Italy

Background: The standard treatment for newly diagnosed transplant-ineligible multiple myeloma (MM) patients includes the combination bortezomib-melphalan-prednisone (VMP) and lenalidomide-dexamethasone (Rd), which are associated with a median PFS of 21 and 26 months, respectively. Carfilzomib is a second-generation, irreversible proteasome inhibitor with significant activity in MM both at diagnosis and at relapse.

Aims: The combination carfilzomib-cyclophosphamide-dexamethasone (CCd) showed high complete response (CR) rates and a good safety profile in elderly newly diagnosed MM patients *(Bringhen S et al., Blood 2014).* Here we report an update after 5 years of follow-up.

Methods: Patients received oral cyclophosphamide (300 mg/m^2 day 1,8,15), oral dexamethasone (40 mg day 1,8,15,22) and iv carfilzomib administered over 30 minutes (20 mg/m^2 day 1,2, and 36 mg/m^2 day 8,9,15,16, cycle 1; 36 mg/m^2 day 1,2,8,9,15,16, cycles 2-9) for 9 28-day cycles, followed by maintenance with iv carfilzomib (36 mg/m^2 day 1,2,15,16) every 28 days until progression/intolerance.

Results: Fifty-eight patients were enrolled; median age was 71 years, 17 (29%) patients were older than 75 years, 23 (40%) had ISS stage III, 18 had unfavorable FISH profile [t(4;14) or t(14;16) or del17p] and 10 (17%) were frail, based on Charlson co-morbidity index, geriatric assessment scores ADL and IADL, and age. Fifty-five patients were evaluable for response. Median duration of induction treatment was 9 cycles. Overall, 94.5% of patients achieved at least PR, 69% at least VGPR, 51% nCR/CR, including 16% stringent-CR. Median time to PR was 1 month. After a median follow-up of 57 months, median PFS was 35.5 months and median OS was not reached; 3-year OS was 72% (Figure 1). The risk of progression or death was higher in patients with ISS stage III *vs* I (HR 2.54; 95%CI 0.98-6.58; p=0.054) and with high-risk chromosomal abnormalities (HR 2.41; 95%CI 1.16-5.00; p=0.02). Grade (G) 4 hematologic adverse events (AEs) included neutropenia (4 patients). G3 or higher non-hematologic AEs were infections (3 patients), cardiac (4 patients), constitutional (2 patients), renal (2 patients) and gastrointestinal complications (1 patient). Peripheral neuropathy was limited in severity to grade 1 or 2 (5 patients). Overall, CCd was well tolerated, 25% of patients required carfilzomib dose reduction and only 14% of patients required drug discontinuation during induction due to AEs. Among patients who completed induction, 43 patients could be evaluated for maintenance treatment. After a median duration of maintenance of 20 months, 100% of patients achieved a PR, 84% at least a VGPR, 60% a nCR/CR, including 21% stringent-CR. Median PFS from the start of maintenance was 33.4 months, median OS from start of maintenance was not reached and 3-year OS was 73%. The most frequent AE (all grades) during maintenance was fever (G1-2 in 10 patients, G3 1 patient), occurring during the evening following the Carfilzomib infusion and not associated with chills, rigors, dyspnea and/or creatinine increase. There was only 1 G3 neutropenia and 1 G2 pericardial effusion. Peripheral neuropathy remained limited (4 patients, only 1 G3).

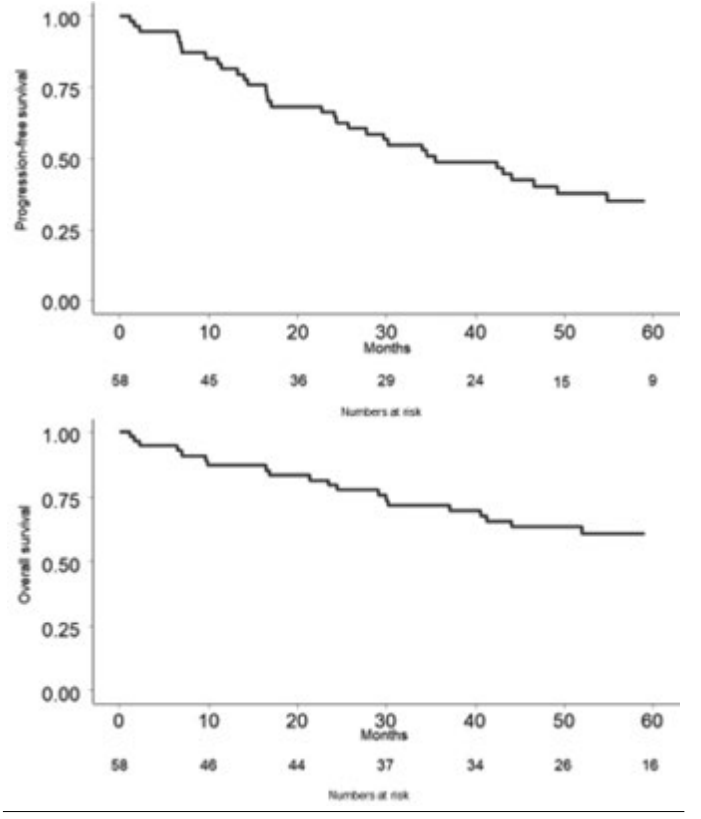

Figure 1.

Summary and Conclusions: CCd is highly active, showing rapid and deep responses that further improve during maintenance. Accordingly, PFS with CCd compares favorably with standard frontline regimens so far available in newly diagnosed MM patients. Maintenance with carfilzomib results into a significant increase in CR rate and a remarkably long PFS, with an acceptable toxicity profile.

PF570

DEVELOPMENT OF A PREDICTIVE MODEL OF MULTIPLE MYELOMA (MM) PATIENT OUTCOMES BASED ON TREATMENT (TX) SEQUENCING USING DATA FROM THE CONNECT® MM PATIENT REGISTRY

S. Jagannath[1,*], R.M. Rifkin[2], C. Gasparetto[3], K. Toomey[4], B.G. Durie[5], J.W. Hardin[6], H. Terebelo[7], L. Wagner[8], M. Narang[9], S. Srinivasan[10], A. YoussefAgha[10], A. Kitali[10], G. Larkins[10], A. Agarwal[10], R. Abonour[11]

[1]Mount Sinai Hospital, New York, NY, [2]US Oncology Research, Rocky Mountain Cancer Centers, Denver, CO, [3]Duke University Medical Center, Durham, NC, [4]Steeplechase Cancer Center, Somerville, NJ, [5]Cedars-Sinai Samuel Oschin Cancer Center, Los Angeles, CA, [6]University of South Carolina, Columbia, SC, [7]Providence Cancer Institute, Southfield, MI, [8]Wake Forest University School of Medicine, Winston-Salem, NC, [9]US Oncology Research, Maryland Oncology Hematology, Colum-

bia, MD, [10]Celgene Corporation, Summit, NJ, [11]Indiana University Simon Cancer Center, Indianapolis, IN, United States

Background: With the approvals of novel agents, the evolution of MM tx over the previous decade has considerably improved patient (pt) outcomes. (Rajkumar SV, 2016). The remitting-relapsing nature of MM and expanding tx options highlight the need to better understand tx sequencing and its impact on outcomes. Effectiveness and durations of response diminish with each successive line of therapy. In the US, pts with newly diagnosed MM (NDMM) are most often treated with lenalidomide (LEN), bortezomib (BORT), or the combination of an immunomodulatory agent and a proteasome inhibitor (PI). Recent randomized phase 3 trials exploring novel drug combinations at relapse may not reflect real-world outcomes, as they are limited by trial eligibility criteria. Connect® MM is a US, multicenter, prospective, observational cohort study designed to examine diagnostic and tx patterns, clinical outcomes and quality of life in pts with NDMM.
Aims: Using Connect MM, develop a novel model to test clinical outcomes in pts based on tx sequencing between agents throughout the MM disease course.
Methods: From 250 community and academic sites, adult pts ≤60 days from MM diagnosis were enrolled: Cohort 1 (n=1493) from Sept 2009 to Dec 2011, and Cohort 2 (n=1518) from Dec 2012 to Apr 2016. Tx transitions were analyzed at the time of disease progression as recorded by the treating physician. Pts were grouped (mutually exclusive) based on tx received before and after disease progression: 1) IMiD® agents (LEN- and POM-containing regimens), 2) PIs (BORT- and carfilzomib-containing regimens), 3) IMiD agent+PI, 4) Gap (pts off tx for ≥90 days), 5) Other (non-IMiD agent/PI regimens). Per common clinical practice, transitions could occur between any of the groups. Transitions were included for up to the 6th line of therapy and each pt could have >1 transition. Median and 3-y overall survival (OS) were estimated for each transition from the start of post-progression therapy until death or censoring using stratified covariate adjusted survival curves (Zhang 2007). Covariates included cohort, line at transition, duration of pre-transition therapy, age group, calcium, creatinine, hemoglobin, bone involvement, and transplant in first line.
Results: As of Feb 2017, a total of 1523 tx transitions at progression had occurred in 856 pts. Fewer tx transitions occurred with each successive line of therapy: 856 (line 1 to line 2); 385 (line 2 to line 3); 175 (line 3 to line 4); and lower numbers for subsequent lines. Frequencies of tx transitions between groups are shown in the Table 1. Median OS was longest for pts who transitioned from an IMiD agent to an IMiD agent+PI regimen (n=66 transitions; 61.9 mo; 3-yr OS: 71%) or from an IMiD agent+PI to another IMiD agent+PI regimen (n=41 transitions; 61.9 mo; 3-yr OS: 68%). Median PFS and OS were longest for front-line therapy, and decreased with each subsequent line of therapy.

Table 1.

		To Regimen, n (%) [Median OS, mo; 3-y OS rate]			
		PI	IMiD Agent	IMiD Agent + PI	Others/ Gap
From Regimen	PI (n = 514)	145 (28) [34.6; 0.48]	135 (26) [43.7; 0.6]	90 (18) [43.4; 0.61]	144 (28)
	IMiD Agent (n = 399)	198 (50) [37.1; 0.51]	67 (17) [41.5; 0.66]	66 (17) [61.9; 0.71]	68 (17)
	IMiD Agent + PI (n = 191)	57 (30) [35; 0.49]	34 (18) [NR; 0.53]	41 (21) [61.9; 0.68]	59 (31)
	Others/Gap (n = 419)	177 (42)	123 (29)	63 (15)	56 (13)
	Total (N = 1523)	577 (38)	359 (24)	260 (17)	327 (22)

Summary and Conclusions: Using the largely community-based Connect MM registry, we have developed a model which describes pt outcomes based on specific tx sequences. While not statistically tested, analyses showed that starting with an IMiD agent±PI regimen and then transitioning to an IMiD agent+PI after progression resulted in the best outcome for pts. Continued IMiD agent use at the time of progression may provide persistent immune modulation function, even in pts who have previously progressed on an IMiD agent-based regimen. This model may provide useful information on optimal tx sequencing and contribution of novel agents to clinical practice.

PF571

EXTERNAL VALIDATION OF THE MULTIPLE MYELOMA (MM) RISK-STRATIFICATION ALGORITHM IN A REAL-WORLD GREEK DATA SET

E. Terpos[1,*], M.A. Dimopoulos[1], E. Kastritis[1], M. Roussou[1], W. Bouwmeester[2], S. Kroep[2], L. DeCosta[3], M. Campioni[4], Z. Szabo[4], S. Gonzalez-Mcquire[4]

[1]Department of Clinical Therapeutics, National and Kapodistrian, University of Athens, School of Medicine, Athens, Greece, [2]Pharmerit International, Rotterdam, Netherlands, [3]Amgen Ltd, Uxbridge, United Kingdom, [4]Amgen (Europe) GmbH, Zug, Switzerland

Background: MM is heterogeneous, with varying drivers of progression, prognosis and response. There is a need for tools to help physicians evaluate MM prognosis at first relapse. A novel risk-stratification algorithm (RSA) was developed using real-world data from the Czech Registry of Monoclonal Gammopathies (RMG – Development Cohort (DC)) for patients with relapsed MM initiating second-line (2L) therapy. The RSA used 16 predictors from routine clinical practice to estimate risk scores: age; Eastern Cooperative Oncology Group performance status; extramedullary disease; new bone lesions; refractory status; severe toxicities at first line; time to next treatment; serum β-2 microglobulin and lactate dehydrogenase at diagnosis and at relapse; bone marrow plasma cell count, thrombocyte count, calcium and albumin at relapse; cytogenetic abnormalities at diagnosis. Scores were used to stratify patients into four risk groups (1 (lowest risk) – 4 (highest risk)), based on overall survival (OS) expectations. The RSA also provides a frailty and aggressiveness score to define drivers of risk.
Aims: External validation of the RSA is needed to ensure replicability of results in external data sets that can vary in terms of treatment patterns and demographics. This analysis aimed to assess validity of the RSA in a real-world data set in Greece.
Methods: To assess RSA validity, data from a single center registry between June 2000 to October 2017 were analyzed. All patients with MM initiating 2L treatment during this period were included. Data for one of the RSA predictors (new bone lesions at 1st relapse) were not available; bone lesion data were randomly assigned by applying the incidence of bone lesions observed in the DC. Missing values for other predictors were imputed five times using multiple imputation and the third imputation was selected for the base case analysis. A sensitivity analysis of five imputed data sets, pooled using Rubin's rules, and scenario analyses for the bone lesion data were performed.
Results: Data from 232 patients were analyzed. Patient characteristics showed differences from the DC which resulted in different distribution of risk groups in the two data sets. The median OS from initiation of 2L was 62.3 months. Median OS was not reached in group 1 and median OS in groups 2–4 was 74.9, 33.7 and 10.8 months, respectively. There was a clear discrimination of OS between the four risk groups; however, the confidence intervals (CIs) of the hazard ratios (HRs) overlapped (Figure 1). The frailty and aggressiveness scores across the four groups showed similar distribution to the DC, with a trend towards lower frailty-driven risk and similar aggressiveness-driven risk. The c-index was 0.77 (95% CI: 0.72–0.82); a value in the range 0.7–0.8 had been predetermined to identify accurate discriminative power. The R^2 value for the Greek data was 0.43.

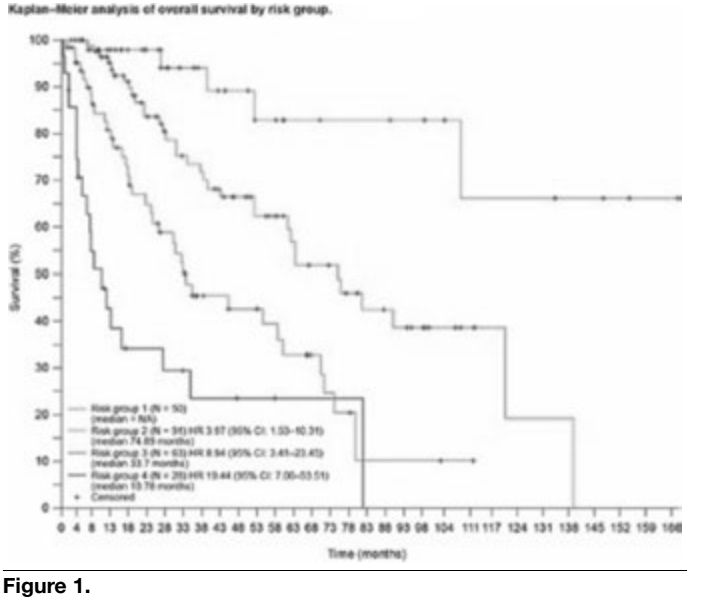

Figure 1.

Summary and Conclusions: The RSA was effective in quantifying risk and stratifying patients with relapsed MM, using long-term follow-up real-world data from a single center. The analysis is limited by a small sample size and the need for imputation of missing values, which can result in wider CIs than expected. Given the uncertainty in all analyses comparing risk groups, the HRs estimated by Rubin's rules gave results consistent with the base-case analysis. The RSA could be used as stratification criteria in clinical

trials for patients with relapsed MM. It may also help identify patient severity and drivers of risk to tailor management strategies, based on identifying both frailty and aggressiveness.

Background: Although the MPB regimen was established by the randomized phase III study comparing MPB with melphalan plus prednisolone (MP) (VISTA study) in patients (pts) with transplant-ineligible NDMM, the "intensive" MPB schedule was associated with a number of notable adverse events. Therefore, further refinement of the MPB regimen through a well-designed clinical trial was desired.
Aims: The objective of this randomized phase II study was to compare two less intensive modified MPB regimens for selecting a more optimal regimen in transplant-ineligible NDMM (UMIN000011180).
Methods: Pts with NDMM who were not candidates for stem cell transplantation because of age (65-79 years) or refusal (20-64 years) were eligible. Pts were randomly assigned 1:1 to Arm A (known as PETHEMA/GEM05 MPB) consisting of one cycle of subcutaneous (SC) or intravenous (IV) bortezomib at 1.3 mg/m² given twice-weekly plus 9 mg/m² of oral melphalan and 60 mg/m² of prednisolone on days 1–4 of a 6-week cycle, followed by 8 cycles of 4 weekly doses of bortezomib plus the same doses of MP of a 5-week cycle, or Arm B (further less intensive MPB) consisting of 9 cycles of SC or IV bortezomib at 1.3 mg/m² given in 3 weekly doses plus 7 mg/m² of melphalan and 60 mg/m² of oral prednisolone on days 1–4 of a 4-week cycle. The primary endpoint was the complete response rate (%CR). The planned sample size was 45 pts in each arm to achieve 85% probability for selecting the regimen with a higher%CR in one arm (30%) than in the other (20%) based on the Simon's selection design.
Results: Between July 2013 and April 2016, a total of 91 pts were randomized to Arm A (45 pts) and Arm B (46 pts), and their median (range) ages were 72 (65-79) and 72 (65-78) years. Efficacy analysis was performed for all 88 eligible pts. In both arms, only 1 pt each received bortezomib maintenance after 9 cycles of MPB. Median%planned and cumulative doses of bortezomib were 88% and 45.8 mg/m² in Arm A, and 100% and 35.1 mg/m² in Arm B. The%CR as a primary endpoint in Arms A and B was 18.6% (95% CI, 8.4-33.4) and 6.7% (95% CI, 1.4-18.3). The overall response rate was 79.1% (95% CI, 64.0-90.0) in Arm A and 73.3% (95% CI, 58.1-85.4) in Arm B. As of the data cut-off, the median follow-up of all pts was 26 months (range, 7-47). The 2-year and median progression-free survival (PFS) were 58.1% (95% CI, 41.1-71.7) and 2.5 years in Arm A, and 31.7% (17.8-46.6) and 1.4 years in Arm B, with a hazard ratio in Arm B to Arm A of 1.93 (95% CI, 1.09-3.42) (Figure 1). The 2-year overall survival was 90.2% (95% CI, 75.9-96.2) in Arm A and 92.2% (95% CI, 77.4-97.5) in Arm B. The most common grade 3/4 hematologic toxicities were leukocytopenia (73.3% *vs* 30.4%), neutropenia (64.4% *vs* 28.3%), and thrombocytopenia (35.6% *vs* 10.9%). Sensory peripheral neuropathy of grade 2/3/4 was observed in 24.4/2.2/0% in Arm A and 8.7/0/0% in Arm B, and all grades of diarrhea, nausea, fever and rash occurred frequently in Arm A. Only 1 treatment-related death due to pneumonitis was observed in Arm B.

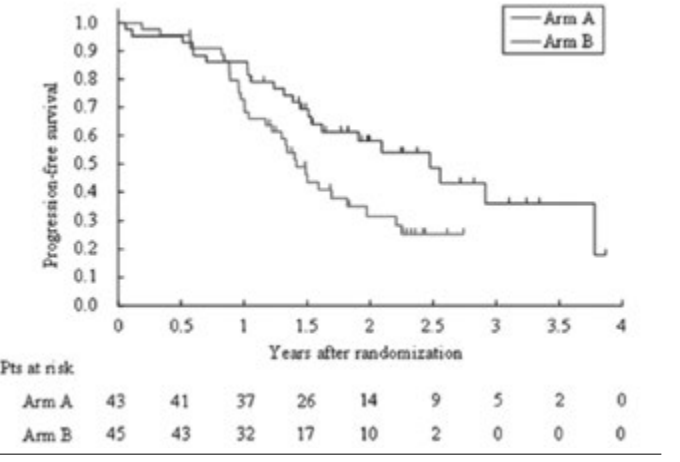

Figure 1.

Summary and Conclusions: Arm A had a higher%CR and superiorPFS with more frequent but manageable toxicities than those in Arm B. These results proposed that the intensive twice-weekly dosing in the first cycle and high cumulative dose of bortezomib were important in maximizing the efficacy of the modified MPB regimen.

PF573

REAL-WORLD TREATMENT PATTERNS AND PROGRESSION-FREE SURVIVAL (PFS) AMONG PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM) RECEIVING POMALIDOMIDE-BASED REGIMENS

R. Vij[1,*], C. Chen[2], C. Davis[2], H. Kim[3], H. Goldschmidt[4], B. Durie[5], D. Kuter[6]

[1]Washington University School of Medicine, St Louis, [2]Bristol-Myers Squibb, Princeton, [3]PAREXEL, Billerica, United States, [4]Heidelberg University Hospital, Heidelberg, Germany, [5]Cedars-Sinai Medical Center, Los Angeles, [6]Massachusetts General Hospital Cancer Center, Boston, United States

Background: Despite therapeutic advances such as novel immunomodulatory drugs (IMiDs), most patients (pts) with MM still relapse. The second-generation IMiD pomalidomide (pom), combined with dexamethasone (Pd), has shown efficacy in RRMM clinical trials, including in pts refractory to the standard-of-care IMiD lenalidomide and proteasome inhibitor (PI) bortezomib, as well as in pts with high-risk cytogenetics (Dimopoulos MA *et al. Leukemia* 2014). These data led to EU and US approval of Pd for pts with RRMM and ≥2 prior therapies (Tx), including lenalidomide and bortezomib (or other PI in the US), and with disease progression on their last prior Tx (or within 60 d of completion in the US). However, real-world data on Tx patterns and outcomes in pts who receive pom-based Tx are lacking.
Aims: To assess real-world Tx patterns and outcomes in pts with RRMM receiving Pd or a Pd triplet Tx.
Methods: PREAMBLE (NCT01838512) is an ongoing observational study exploring real-world Tx outcomes in MM. This analysis included pts ≥18 y of age, with RRMM and ≥1 prior Tx, whose first pom-based Tx was Pd or a Pd triplet received at any time during RRMM Tx. PFS was evaluated using Kaplan–Meier methods. Hazard ratios (HRs) were calculated using uni- and multivariate Cox regression; covariates for adjustment were selected using stepwise regression. 'Novel agents' included monoclonal antibodies and histone deacetylase inhibitors. Informed consent was obtained for all pts.
Results: At database lock (Nov 30, 2017), 240 pts were identified who started with Pd (Pd group; n=179, 75%) or a Pd triplet (Pd triplet group; n=61, 25%); median follow-up was 15 mo. Baseline characteristics were generally similar between the groups; however, pts in Europe were more

likely to receive Pd (66%) than Pd triplets (46%), whereas pts in North America were more likely to receive Pd triplets (54%) than Pd (34%). Overall median age at initiating pom was 67 y; at enrollment, 73% had refractory MM and 24% had stage III disease. Comorbidities were similar between groups. In the Pd group, median (range) number of prior Tx was 3 (1–14), and in the Pd triplet group, 2 (1–9); overall, 50% received ≥3 prior Tx. In prior Tx, pts in the Pd *vs* Pd triplet group were more likely to have received an IMiD (52% *vs* 28%; p=0.0011), whereas pts in the Pd triplet group were more likely to have received an IMiD+PI Tx (26% *vs* 7%; p<0.0001) or novel agent (15% *vs* 3%; p=0.0018). A greater proportion of pts finished Pd than Pd triplets (85% *vs* 66%; p=0.0011); median duration of Tx was similar between groups (3.8 *vs* 3.3 mo). In subsequent Tx, pts in the Pd triplet group were more likely to receive a novel agent than Pd-group pts (15% [6/40] *vs* 2% [2/131]); similar proportions in each group (Pd *vs* Pd triplet) received PIs (46% *vs* 45%), IMiDs (47% *vs* 33%), or IMiD+PIs (6% *vs* 8%). PFS was longer in pts who received a Pd triplet than pts who received Pd (Figure 1). In univariate PFS analysis, HR (Pd triplet over Pd) was 0.57 (95% CI 0.28, 1.19; p=0.134), but multivariate analysis revealed a significant PFS benefit for pts who received a Pd triplet *vs* Pd (HR: 0.46 [95% CI 0.21, 0.96]; p=0.041).

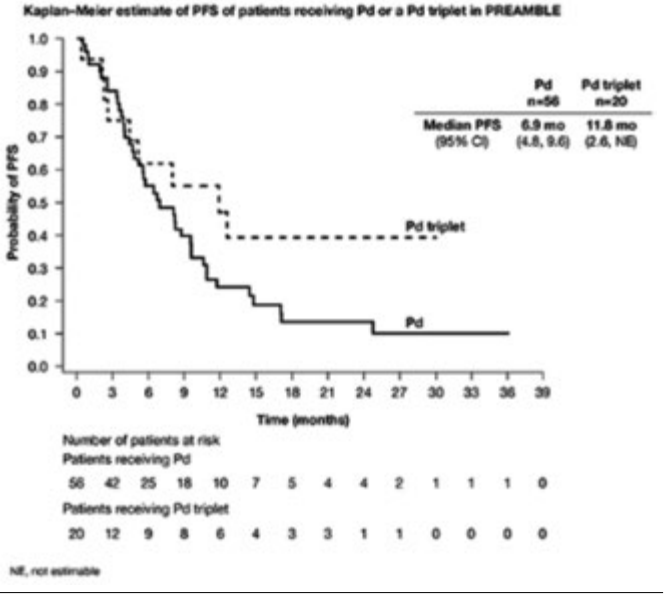

Figure 1.

Summary and Conclusions: 50% of pts who received Pd or a Pd triplet in PREAMBLE received ≥3 prior Tx. Real-world data in RRMM suggest Pd triplets may be linked to improved PFS *vs* Pd, and may represent an alternative Tx strategy. Ongoing additional analyses will evaluate outcomes from specific Pd triplet regimens.

PF574

TIME TO FIRST ONSET OF TREATMENT-EMERGENT ADVERSE EVENTS (TEAES) OF INTEREST: A POST-HOC ANALYSIS FROM ASPIRE AND ENDEAVOR TRIALS

M.-V. Mateos[1,*], S. Knop[2], M. Delforge[3], L. DeCosta[4], F. Suzan[5], Z. Szabo[5], K. Wang[6], J. Mikhael[7]

[1]Hematology Service, University Hospital Salamanca, Salamanca, Spain, [2]Wuerzburg University Medical Center, Wuerzburg, Germany, [3]Department of Hematology, University Hospital (UZ) Leuven, Leuven, Belgium, [4]Global Biostatistical Science, Amgen Ltd., Uxbridge, United Kingdom, [5]Amgen (Europe) GmbH, Zug, Switzerland, [6]Global Safety, Amgen Inc., South San Fransisco, CA, [7]International Myeloma Foundation, North Hollywood, CA, United States

Background: In the ASPIRE and ENDEAVOR phase 3 trials, carfilzomib (K) in combination with lenalidomide and dexamethasone (KRd), or with dexamethasone alone (Kd), respectively, was investigated in patients with relapsed and/or refractory multiple myeloma (RRMM). An increased incidence of cardiac and vascular adverse events (AEs) was shown in K arms *versus* the comparator arms of these trials. Cardiac events typically occurred early (<5 cycles) in the course of K therapy. However, the underlying mechanism leading to AEs has not been established. Such exploration is complex due to multiple confounding factors such as the potential dose effect, disease burden, patient characteristics, co-medications, and comorbidity.

Aims: To describe time to first onset (TTFO) of TEAEs within each trial, beyond their incidences and severity reported earlier.

Methods: This post-hoc analysis describes the median TTFO of TEAEs of all grades or grade 3 or more (Gr3+) from the ASPIRE or ENDEAVOR trials. TTFO was calculated from start of treatment to the time when an AE first occurred. Repeated events occurring in a subject were excluded from this analysis. TTFO patterns were assessed within study; due to the differences in design and patient population, no cross-study comparison was performed.

Results: Results and cumulative incidence are presented in Figure 1 in the form of boxplots of TEAE Gr3+ grouped into 4 AE classes (hematological AEs, cardiac AEs, vascular AEs and non-hematological AEs). Median treatment duration in ENDEAVOR was 48 weeks for Kd and 27 weeks for bortezomib with dexamethasone (Vd) arm; in ASPIRE, it was 72 weeks for K in the KRd arm and 57 weeks for lenalidomide plus dexamethasone (Rd) arm. Hematological AEs Gr3+ occurred within 2-3.5 months (mos) in ASPIRE and within 1-2.5 mos in ENDEAVOR, and no differences in the median TTFO between arms of each trial were observed. Median TTFOs of cardiac AEs were earlier in KRd *vs* Rd subjects (cardiac failure [CF]: 4.5 mos for KRd, 9.3 mos for Rd; ischemic heart disease [IHD]: 4.9 mos for KRd, 9.1 mos for Rd). The reverse pattern was seen in ENDEAVOR, with longer median TTFOs and broader ranges among Kd *vs* Vd subjects (CF: 7.6 mos for Kd, 4.6 mos for Vd; IHD: 1.4 mos for Kd, 0.8 mos for Vd). KRd subjects had an earlier onset of vascular AEs *vs* Rd subjects, especially hypertension (HT: median TTFO of 7.3 mos in KRd *vs* 13.6 mos in Rd), whereas in ENDEAVOR, it was longer in Kd than Vd subjects (8.8 *vs* 3.0 mos), while no difference was observed for thrombo-embolic events. Median TTFOs of dyspnea were similar between treatment arms within each study. The median TTFO of acute renal failure (ARF) was longer for KRd subjects *vs* Rd (13.3 *vs* 7.6 mos, respectively), and the difference was even more pronounced in ENDEAVOR (Kd 7.2 *vs* Vd 1.6 mos). While the main limitation of this Gr3+ analysis was the small number of subjects (<10) for some TEAEs, TTFOs of all-grade TEAEs (not shown) generally showed a comparable pattern to that of Gr3+ TEAEs.

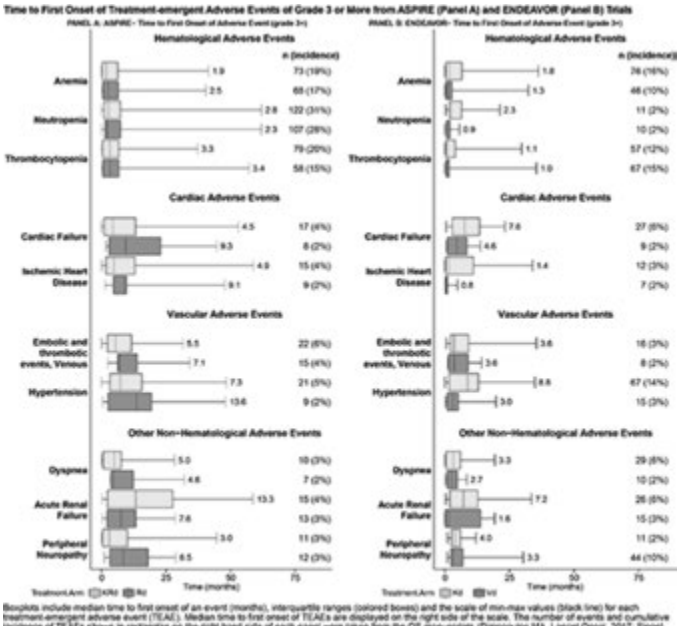

Figure 1.

Summary and Conclusions: CF and HT had a marked earlier onset in KRd *vs* Rd subjects and a later onset in Kd *vs* Vd subjects, although their incidence was higher in K *vs* comparator arms. The largest variations in TTFO patterns were seen for ARF that had a later appearance among K subjects. By contrast, hematological AEs were similar in all 4 arms. In this descriptive analysis, variations in TTFO of a TEAE between arms of a trial may suggest multiple mechanisms without any easily expected timing of toxicities (*e.g.*, cardiac events). The longer exposure to K *vs* Rd or Vd in these studies may also have accounted for TTFO variations.

PF575

SMOLDERING MYELOMA AFTER IMWG UPDATE: FACTORS PREDICTIVE OF EVOLUTION, ROLE OF ADVANCED IMAGING AND OF CLINICAL JUDGEMENT. A REAL-LIFE RETROSPECTIVE EXPERIENCE

L. Torti[1,*], A.M. Morelli[1], F. Bacci[2], P. Di Bartolomeo[1]

[1]Clinical Hematology, Department of Hematology, Transfusion Medicine and Biotechnology, "Spirito Santo" Civic Hospital, Pescara, [2]Section of Hematopathology, Department of Hematology and Oncological Sciences, S.Orsola Malpighi Hospital, Bologna, Italy

Background: Smoldering myeloma(SMM)is a heterogeneous clinical entity where a watch-and wait-approach has been standard of care up to now.Recently it has been demonstrated that a subset of high-risk cases can benefit of early-treatment.IMWG revised diagnostic-criteria adding markers as Myeloma-Defining-Events,allowing earlier intervention.We aimed to study diagnostic-workup and prognostic-factors predicting progression.We also focus on early-treatment.
Aims: We retrospectively reviewed data from 139 smoldering myeloma patients diagnosed from 1998 to 2016 in order to assess risk-profile and evolution in symptomatic-myeloma.Our aim was to define risk-factors and an effective followup-strategy.We also tried to understand when is right-time to start therapy comparing old-CRAB with new-MDE-events.
Methods: We evaluated 139 SMM-patients consecutively diagnosed at our centre in median-time of 18 years(median followup 13 years,range 2-19).
Results: We have found 62 low-risk SMM, 46 high-risk SMM and 31 ultra-high-risk-SMM in a retrospective single-center analysis.62 patients have evolved in myeloma requiring treatment and respectively:25/31 of the ultrahigh-risk-group progressed in a medium-time-span of 11months (range 6-39)(Figure 1AB), 23/46 of the high-risk-group ended in symptomatic myeloma with a medium time of 32 months(range 24-72)from diagnosis and only 10/62 of the low-risk-series after 94-median-months(range 39-140).In the low-risk evolved patients an important risk-factor for evolution was the amount of monoclonal-protein over time:most of patients evolved (8/10) have shown an evolving type SMM. In the high-risk-patients the most powerfull predictive-factors of progression were an unfavorable cytogenetic-picture (17 patients with a prevalence of amplification of 1q in 11 patients) (Figure 1C), focal lesions in MRI or PETCT (17 and 15 patients) and LDH-values (high in 13 patients).Among MDEs the most meaningful biomarker was FLCratio>100 (21/31 patients) followed by MRI-lesions (7/31 patients) and lastly by bone-marrow-plasma cell involvement greater than 60% (3/31 patients) (Figure 1AB). Between ultrahigh risk SMM 21 were diagnosed before 2014 IMWG update through a retrospective analysis and 10 after.Of the first group 18 patients have evolved in MM requiring therapy, median time of 11 months (Figure 1D).

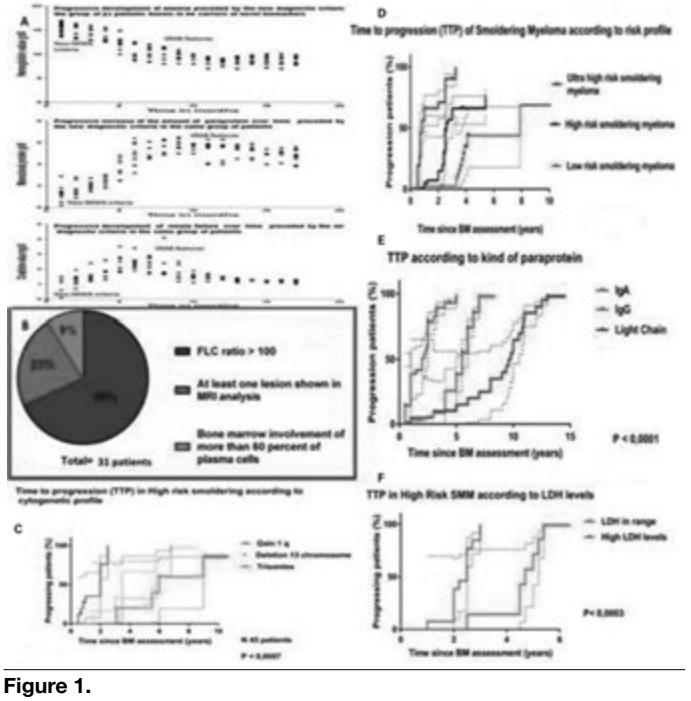

Figure 1.

Conversely in the second-group not all patients started therapy. In fact 3 young patients were not treated until now and continued a close-observation with a monthly-followup. They presented stable-monoclonal-protein and laboratory profile, excellent clinical condition.They presented only one slim-CRAB for at least 9 months(respectively plasma-cell-involvement>60% and in 2 patients FLCratio>100).Here earlier-treatment could not be beneficial but might instead results in greater toxicity.Other 7 presented deterioration of clinical-conditions with at least two-slimCRAB(respectively FLC ratio>100 and lesions on MRI)not preexisting.They showed an evolving-type-SMM.Biological-behavior in this subgroup was very aggressive and they started treatment.They are under therapy with a good-disease-control.Clinical-judgement must help physicians in making decisions.
Summary and Conclusions: Risk of SMM progression is not uniform and several-markers(cytogenetic,evolving type,lesions on advanced imaging,kind of paraprotein as described here (Figure 1E), LDH-levels (Figure 1F) are usefull in clinical-practice to predict evolution.Novel biomarkers will be available in the future to plan followup and to identify group benefiting of early-treatment.

PF576

SAFETY OUTCOMES IN PATIENTS (PTS) WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM) TREATED WITH LENALIDOMIDE FOR ≤24 MONTHS *VS* >24 MONTHS IN A EUROPEAN POST-APPROVAL SAFETY STUDY (EU PASS)

G. Semenzato[1,*], D. Kyriakou[2], P. Moreau[3], X. Leleu[4], I. Wolfgang Blau[5], A. Symeonidis[6], A. Bosi[7], E. Kueenburg[8], A. Di Micco[8], B. Rosettani[8], S. Peters[8], P. Bacon[8], B. Gamberi[9]

[1]Azienda Ospedaliera di Padova, Padova, Italy, [2]University Hospital of Larissa, Larissa, Greece, [3]CHU Nantes Hôtel Dieu, Nantes, [4]Hôpital La Miletrie, Poitiers, France, [5]Charité - Campus Benjamin Franklin, Berlin, Germany, [6]University of Patras Medical School, Rion of Patras, Greece, [7]AOU Careggi, Firenze, Italy, [8]Celgene International, Boudry, Switzerland, [9]Arcispedale S. Maria Nuova, Reggio Emilia, Italy

Background: EU PASS is a large, multicenter, observational study evaluating the safety and tolerability of lenalidomide (LEN)+dexamethasone (DEX) *vs* other agents in patients (pts) with RRMM in a real-world setting.
Aims: To compare the safety and tolerability of treatment (Tx) with LEN in pts treated for ≤24 mos *vs* pts treated for >24 mos.
Methods: EU PASS enrolled pts with RRMM who had received ≥1 prior therapy. Pts who initiated Tx with LEN+DEX were in the LEN cohort; pts who initiated a non–LEN-based Tx were in the background cohort. All pts provided informed consent. Off-label use of LEN was allowed. Adverse events (AEs) were graded per the National Cancer Institute Common Terminology Criteria for Adverse Events v3.0; treatment-emergent AEs (TEAEs) of special interest were analyzed using standardized Medical Dictionary for Regulatory Activities queries. Pts were followed up for ≤36 mos after Tx discontinuation to monitor for second primary malignancies (SPMs) per a July 2011 protocol amendment. From August 2008 to July 2014, 3630 pts were included in the safety population. A subgroup analysis was performed on the LEN cohort to compare the safety of LEN in pts treated for ≤24 mos *vs* pts treated for >24 mos.
Results: Of the 2151 pts receiving LEN, 1847 (85.9%) were treated for ≤24 mos and 304 (14.1%) for >24 mos. Demographics were balanced between the 2 groups. The median age was 70.0 yrs in the ≤24-mos group and 69.0 yrs in the >24-mos group; 53.0% and 56.6% of the pts were male. In both groups, ≈ one-quarter of pts were aged ≥76 yrs. The 2 groups had a similar median time from diagnosis to enrollment (≤24 mos: 2.8 yrs; >24 mos: 3.5 yrs). In both groups, >90% of pts experienced ≥1 TEAE; ≥1 grade 3/4 TEAE occurred in 57.2% and 61.5% of pts in the ≤24-mos and >24-mos groups, respectively. More pts discontinued due to a TEAE in the ≤24-mos group *vs* the >24-mos group (36.2% *vs* 22.4%, respectively). A lower percentage of pts had a dose reduction due to a TEAE (20.7% *vs* 44.1%) in the ≤24-mos *vs* the >24-mos group, respectively. Median times to first dose reduction (9.4 *vs* 34.9 wks) and first dose interruption (7.9 *vs* 20.4 wks) were shorter in the ≤24-mos group. The incidences of grade 3/4 neutropenia and venous thromboembolism (VTE) were lower and the incidence of grade 3/4 thrombocytopenia was higher in the ≤24-mos than in the >24-mos group. The incidences of other grade 3/4 TEAEs of special interest were similar between the 2 groups (Table 1). The rate of SPMs was lower in the ≤24-mos than in the >24-mos group (2.8% *vs* 9.5%, respectively). A lower frequency of solid tumor SPMs was observed in the ≤24-mos than in the >24-mos group (1.5% *vs* 3.0%, respectively). The 2 groups had a similar frequency of hematologic SPMs (0.6% *vs* 0.7%). However, the incidence rate per 100 person-years for SPMs was higher in the ≤24-mos than in the >24-mos group (4.61 *vs* 2.59, respectively).
Summary and Conclusions: There were no new safety signals with long-term (>24 mos) LEN Tx. Higher rates of grade 3/4 neutropenia and VTE

were observed in the pts with >24 mos of LEN Tx, whereas the rates of other grade 3/4 TEAEs of special interest did not increase notably. Pts in the >24-mos group maintained LEN Tx at starting-dose levels longer than did pts in the ≤24-mos group. The SPM incidence rate per 100 person-years did not increase with long-term LEN Tx. These results from a real-world setting show that long-term LEN Tx is generally safe and well-tolerated in pts with RRMM.

Table 1.

Grade 3/4 TEAEs of Special Interest by SMQ, n (%)	≤ 24 Months of LEN Treatment n = 1847	> 24 Months of LEN Treatment n = 304
Neutropenia	348 (18.8)	84 (27.6)
Acute and opportunistic infections	262 (14.2)	46 (15.1)
Thrombocytopenia	199 (10.8)	17 (5.6)
Renal failure	77 (4.2)	11 (3.6)
Venous thromboembolism	49 (2.7)	14 (4.6)
Neuropathy	24 (1.3)	6 (2.0)
Cardiac failure	22 (1.2)	6 (2.0)
Bleeding events	21 (1.1)	4 (1.3)
Cardiac arrhythmias	17 (0.9)	6 (2.0)
Rash	8 (0.4)	0 (0)
Hypothyroidism	1 (0.1)	0 (0)

LEN, lenalidomide; SMQ, standardized Medical Dictionary for Regulatory Activities query; TEAE, treatment-emergent adverse event.

CLINICAL CHARACTERISTICS AND OUTCOMES OF OLIGOSECRETORY AND NON-SECRETORY MULTIPLE MYELOMA

M. Migkou[1], Y. Cohen [2], E. Kastritis[1,*], M. Gavriatopoulou[1], E. Eleutherakis-Papaiakovou[1], E. Terpos[1], D. Fotiou[1], M. Roussou[1], D.C. Ziogas[1], E. Terpos[1], I. Avivi[2], M.A. Dimopoulos[1]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, Athens, Greece, [2]Department of Hematology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

Background: In multiple Myeloma (MM), clonal plasma cells secrete monoclonal immunoglobulins (MIg) which are identified and measured in the serum and/or urine. Typically, the amount of MIg is large enough to be followed serially with relative accuracy to allow disease evaluation. However, in a subset of patients, secreted MIg in serum and urine is low, below what is considered as "measurable" for precise serial evaluation (oligo-secretory MM). In addition, a small subset of patients has no detectable MIgs by conventional immunofixation in serum and urine (non-secretory MM).
Aims: Our aim was to evaluate the characteristics and outcomes of patients with oligo- and non-secretory myeloma, in a large dataset of patients diagnosed and treated with contemporary tools and regimens.
Methods: The study included 852 consecutive patients with complete baseline data on serum and urine PEP, diagnosed and treated in the Department of Clinical Therapeutics (Athens, Greece) and in the Hematology Department at Tel Aviv Medical center (TA, Israel). Oligosecretory disease was defined as both serum MIg<1 g/dL and urine MIg<200 mg/24h. Non-secretory disease was defined as negative immunofixation in both serum and urine.
Results: We identified 100 (11.7%) patients with oligo/non-secretory MM, including 20 (2.3%) with non-secretory MM. Compared to patients with secretory MM, patients with oligo/non-secretory MM were younger (p=0.03), less anemic (p<0.001), had less often renal dysfunction (p=0.05) and less extensive bone marrow infiltration (p=0.001). Bone disease was similar in frequency (p=0.22) and extent (p=0.13), but hypercalcemia was less common (p=0.002). Oligo/non-secretory patients were more often ISS-1 (55% *vs* 23%) than ISS-2 (16% *vs* 34%) or ISS-3 (29% *vs* 43%)(p<0.001). In patients with available FISH, high risk cytogenetics were slightly less common in oligo/non-secretory MM (16% *vs* 22%, p=0.26). Disposition in R-ISS stages -1, -2 and -3 was 31%, 53% & 16% *vs* 15%, 66% & 19% respectively (p=0.011). Patients with oligo/non-secretory MM, were treated more often with bortezomib (84% *vs* 60%) (p=0.001). Median follow up is 4 years and 4-year OS for patients with oligo-/non-secretory disease was 64% *vs* 58% for secretory MM (p=0.034). However, after adjusting for known prognostic factors in multivariate analysis, oligo/non-secretory MM was not associated with a different survival (p>0.3). Restricted analysis, focusing on patients with non-secretory disease, revealed that these patients were younger (p=0.02) and less anemic (p=0.008) compared to other MM patients, though the degree of marrow plasma cell infiltration was similar. Non secretory patients had more often an elevated LDH (p=0.052), however, they were more often ISS-1 (61% *vs* 25%) than ISS-2 (5% *vs* 33%) or ISS-3 (33% *vs* 42%) (p=0.002). Lytic bone disease (85% *vs* 75%, p=0.32) and hypercalcemia were similar (16% in both groups). Only 1 of 9 patients with non-secretory MM had high risk cytogenetics. FLCs were available in 17 patients with non-secretory MM: only 3 had normal FLC ratio; the others had abnormal FLC ratio and 9/14 had iFLC ≥100 mg/L. Patients with non-secretory myeloma had similar survival with the other patients (4-year OS: 53% *vs* 59%, p=0.68).
Summary and Conclusions: About 12% of MM patients present with oligo- or non-secretory disease at diagnosis and they have different characteristics but, in the era of the contemporary therapies, similar outcome to other MM patients. With the use of FLCs more than 60% of them patients with non-secretory disease can be followed for response and eligible for participation in clinical trials.

SERUM NEUTROPHIL GELATINASE-ASSOCIATED LIPOCALIN INDEPENDENTLY PREDICTS FOR RENAL RESPONSE IN MYELOMA PATIENTS WITH SEVERE RENAL IMPAIRMENT

E. Terpos[1], M. Roussou[1], I. Papassotiriou[2], M. Gavriatopoulou[1], E. Eleutherakis-Papaiakovou[1], A. Margeli[2], D. Fotiou[1], N. Kanellias[1], M. Migkou[1], G.-P. Papassotoriou[2], E. Kastritis[1,*], M.A. Dimopoulos[1]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, [2]Department of Clinical Biochemistry, "Aghia Sophia" Children's Hospital, Athens, Greece

Background: Severe renal impairment (RI) is a common complication of multiple myeloma (MM). Immediate anti-MM therapy can restore renal function in several patients, but we lack biomarkers that could predict renal outcomes. Neutrophil gelatinase-associated lipocalin (NGAL) is one of the earliest and most robust markers of acute kidney injury while serum Cystatin C (CysC) reflects renal function more accurately than creatinine and correlates with both tumor burden and renal function in MM.
Aims: To evaluate serum NGAL and CysC in MM patients with severe RI (eGFR<30 ml/min/1.73m^2, by CKD-EPI formula), including those on dialysis, as biomarkers for prediction of renal responses.
Methods: NGAL and CysC were measured in the same frozen serum sample collected before any therapy was given. Serum NGAL was measured using ELISA (BioPorto Diagnostics A/S, Gentofte, Denmark). CysC was measured using a latex particle-enhanced nephelometric immunoassay (Dade Behring-Siemens Healthcare Diagnostics, Liederbach, Germany). Patients on dialysis received dialysis with regular membranes. IMWG renal response criteria were used.
Results: The analysis included 82 newly diagnosed MM patients with severe RI treated and followed at the Department of Clinical Therapeutics (Athens, Greece). Median creatinine was 5 mg/dl (range 2-10), median eGFR was 11.3 ml/min/1.73 m^2 (1.3-29.8) and dialysis was required in 32 (39%) patients. The median age was 71 years, median involved FLC was 5225 mg/L, hypercalcemia was found in 24%, LDH ≥ULN in 41% and high-risk cytogenetics in 27% while 98% were ISS-3 and 56% were R-ISS-3. Treatment was bortezomib-based in all patients (in 23% VD and in 77% a triplet). Median NGAL levels were 191.5 ng/mL (range 20-550) and of CysC were 3.42 mg/L (1.1-7.8) and were strongly correlated (R^2=0.421, p<0.001); also both strongly correlated with eGFR (for CysC: R^2=0.43, p<0.001 and for NGAL: R^2=0.225, p<0.001) and both were higher in patients requiring dialysis *vs* those not in dialysis (median NGAL:308 *vs* 153 ng/mL, p<0.001, median CysC:4.99 *vs* 2.73 mg/L, p=0.001). Renal response (Rrenal) was achieved by 60% (including 50% major Rrenal) and 34% discontinued dialysis. Median time to Rrenal was 1 month and median time to dialysis independence was 2 months. Lower levels of NGAL (p=0.009) and CysC (p=0.014) were associated with higher probability of major Rrenal among patients with severe RI but not on dialysis, but baseline eGFR was not (p=0.346). None was associated with dialysis independence among those requiring dialysis. By ROC analysis, in patients with severe RI but not on dialysis, NGAL <130 ng/ml was strongly associated with major Rrenal (86% *vs* 24% at 3 months, p<0.001; Figure 1). Regarding CysC, levels <2.6 mg/L were associated with higher probability and shorter time to major Rrenal (p=0.012). Both NGAL and CysC had no predictive value for patients under dialysis. In multivariate analysis performed in patients not on dialysis, that included age, NGAL, CysC and eGFR, only NGAL<130 ng/ml was significantly associated with major Rrenal (HR 5, 95% CI 2-18, p=0.01).
Summary and Conclusions: Serum levels of NGAL were strong predictors of major Rrenal in MM patients with severe RI,not on dialysis. Serum NGAL could identify MM patients with severe RI who should be treated with more aggressive therapies, that could include high cut-off dialysis membranes and more effective and rapidly acting antimyeloma regimens.

Sammons Cancer Center, Dallas, TX, [11]University of Chicago Medical Center, Chicago, IL, United States, [12]Janssen Biologics, Leiden, Netherlands, [13]Janssen Research & Development, LLC, Raritan, NJ, [14]Tisch Cancer Institute, Mount Sinai School of Medicine, New York, NY, United States

Background: Lenalidomide-refractory patients have poor outcomes, highlighting an unmet medical need. In the phase 1b MMY1001 study (NCT01998971), D-Kd induced deep responses and was well tolerated in patients with relapsed MM.
Aims: We examined the safety and efficacy of D-Kd in lenalidomide-refractory patients.
Methods: In total, 85 carfilzomib-naïve patients with 1-3 prior lines of therapy were enrolled. Patients received carfilzomib (20 mg/m^2 on Cycle 1 Day 1 [C1D1] and 70 mg/m^2 on C1D8+) on Days 1, 8, and 15 of 28-day cycles and dexamethasone 40 mg QW. Daratumumab was given QW C1-C2, Q2W C3-C6, and Q4W thereafter; 10 patients received a standard first dose of daratumumab (16 mg/kg) on C1D1, and 75 patients received a split first dose of daratumumab (8 mg/kg on C1D1 and C1D2). Median infusion times during Week 1 were 7.08 hours (range: 6.5-8.9 h) for patients who received a standard first daratumumab dose and 4.25 hours (range: 3.9-10.6 h) and 4.17 hours (range: 3.9-8.6 h) for Day 1 and Day 2, respectively, among patients who received a split first daratumumab dose. Refractory MM was defined as progression during or within 60 days of completion of the last line of therapy.
Results: Among lenalidomide-refractory patients (n=51) in the MMY1001 D-Kd arm, median age was 66 years (range 38-85 years), and 92% had an Eastern Cooperative Oncology Group status ≤1. Patients had received a median of 2 (range 1-4) prior lines of therapy; 98% had received bortezomib, 18% had received pomalidomide, 43% were refractory to bortezomib, and 18% were refractory to pomalidomide. In total, 20 patients (39%) discontinued due to progressive disease (26%), adverse events (AEs; 6%), patient withdrawal (6%), or physician decision (2%). The most common hematologic grade 3/4 treatment-emergent AEs (TEAEs; ≥10%) were thrombocytopenia (37%), anemia (29%), neutropenia (28%), and lymphopenia (26%). Infusion-related reactions were observed in 37% of patients (43% for standard first daratumumab dose; 36% for split first daratumumab dose); none were grade 3/4. With 8.3 months of median follow up, median progression-free survival (PFS) was 14.1 months (95% CI 9.4-not estimable); the 12-month PFS rate was 69% (95% CI 49-82). Overall response rate (ORR) and minimal residual disease (MRD)-negative rates are summarized in the Table 1. Median time to MRD negativity (10^{-5}) was 5.1 months.

Table 1.

%	Lenalidomide refractory	All
ORR*	81	86
Stringent complete response	8	6
Complete response	4	14
Very good partial response	56	53
Partial response	13	14
MRD-negative rate		
10^{-4}	6	9
10^{-5}	2	5
10^{-6}	0	2

*Among response-evaluable patients who received >2 cycles or discontinued treatment.

Summary and Conclusions: The combination of daratumumab and weekly Kd was well tolerated and demonstrated promising efficacy in lenalidomide-refractory patients. Updated data will be presented.

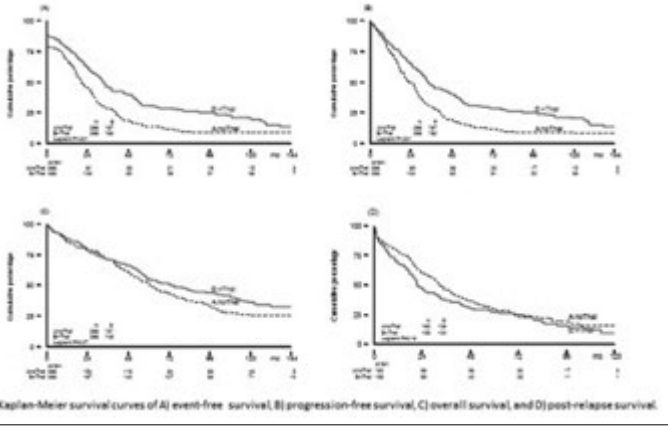
Background: The HOVON-50 phase 3 trial compared induction therapy with thalidomide+adriamycine+dexamethasone (TAD) followed by high-dose melphalan (HDM)/autologous stem cell transplantation (auto-SCT) and maintenance therapy with thalidomide until progression (arm A) to induction therapy with vincristine+adriamycine+dexamethasone (VAD) followed by HDM/auto-SCT and interferon-α until progression (arm B) in newly diagnosed multiple myeloma (MM) patients. In 2010 we showed that patients treated in the thalidomide arm had an improved response rate, as well as event-free survival (EFS) and progression-free survival (PFS), compared to the control arm. However, after a median follow-up of 52 months no benefit in terms of overall survival (OS) was observed. Long-term data are needed to determine the sustainability of the initially observed results, and to evaluate possible long-term side effects such as second primary malignancies (SPMs).
Aims: Final analysis with an extended follow-up of median 129 months to evaluate the impact of the first novel agent thalidomide on EFS,PFS, and OS, as well as SPMs in transplant-eligible MM patients.
Methods: A total of 556 MM patients were enrolled in the HOVON-50 trial. EFS was determined from the date of randomization until induction failure (less than PR), progression, or death, whichever came first.PFS was calculated from randomization until progression, relapse, or death, whichever came first. OS was measured from randomization until death from any cause. Cox regression analysis was used to evaluate the impact of treatment arm on survival when adjusted for baseline characteristics. For the current analysis, patients who received an allogeneic stem cell transplantation (allo-SCT; 94 patients) after HDM were censored for EFS,PFS, and OS at the date of allo-SCT. We will denote these three survival endpoints as EFSc,PFSc, and OSc.
Results: The best response achieved on protocol after long-term follow-up was slightly improved when compared to the initial analysis, and remained

significantly higher in the patients randomized to thalidomide (CR rate: 32% *versus* 24%; *P*=0.021). EFSc and PFSc remained significantly prolonged in the thalidomide arm, compared to the control arm (EFSc: hazard ratio (HR)=0.66, 95% confidence interval (CI): 0.54-0.81, *P*<0.0001; PFSc: HR=0.64, 95% CI: 0.52-0.79, *P*<0.0001). With long-term follow-up, we now also observed a superior OSc in the thalidomide arm, when adjusted for covariates in multivariate analysis (HR=0.79, 95% CI: 0.62-0.99, *P*=0.042). Elevated LDH was independently associated with impaired EFSc (HR=0.63, 95% CI: 0.48-0.84, *P*=0.001), PFSc (HR=0.62, 95% CI: 0.47-0.82, *P*<0.001), and OSc (HR=0.41, 95% CI: 0.29-0.58, *P*<0.001). Furthermore, female sex was associated with improved PFSc, while OSc was adversely affected by WHO performance status and ISS stage. Achievement of a CR, included as a time-dependent co-variate, was associated with a significantly enhanced EFSc, PFSc, and OSc. Survival after progression did not differ between both arms. Also the incidence of second primary malignancies (SPMs) was similar in both arms (4% at 5 years and 6-8% at 10 years after randomization) (Figure 1).



Kaplan-Meier survival curves of A) event-free survival, B) progression-free survival, C) overall survival, and D) post-relapse survival.

Figure 1.

Summary and Conclusions: With prolonged follow-up there is not only an EFSc and PFSc benefit for thalidomide before and after HDM/auto-SCT, but when adjusted for covariates, also an OSc benefit, without an increased risk of SPMs. Our data indicate, that thalidomide-based treatment is still a valid treatment option for transplant eligible MM patients in countries without access to proteasome inhibitors or next generation immunomodulatory drugs.

PF581

THE HORIZON STUDY: A PRELIMINARY REPORT ON EFFICACY AND SAFETY OF MELFLUFEN IN LATE STAGE RELAPSED-REFRACTORY MYELOMA (RRMM) PATIENTS REFRACTORY TO POMALIDOMIDE AND/OR DARATUMUMAB

Background: Melflufen is a next generation alkylator, belonging to the novel class of Peptidase Enhanced Cytotoxics (PEnCs) with a unique mechanism of action designed for efficient targeting of tumor cells. Melflufen provides a peptidase enhanced therapy with an alkylating payload, and triggers rapid, robust and irreversible DNA damage. The effect of melflufen is exerted through alkylation of DNA. The lipophilicity of melflufen leads to rapid and extensive distribution into cells where it is readily metabolized by intracellular peptidases (often over-expressed in malignant cells) into hydrophilic alkylating metabolites leading to 50-fold enrichment of these metabolites in MM cells. In addition, melflufen has potent anti-angiogenic properties.
This is a report on early efficacy of melflufen in RRMM patients that have been exposed to proteasome inhibitors (PIs) and immunomodulatory drugs (IMiDs) and are refractory to pomalidomide (pom) and/or daratumumab (dara). A completed Phase 1/2 study of melflufen+dexamethasone (dex) (O-12-M1, NCT01897714) has been previously reported.
Aims: To study the efficacy and safety of melflufen in combination with low dose dex in patients that are refractory to pom and/or dara (NCT02963493).
Methods: Melflufen 40 mg is given i.v. on Day 1 of each 28-day cycle, with dex 40 mg weekly (20 mg for ≥75yrs), in RRMM patients refractory to pom and/or dara with measurable disease and at least 2 prior lines of therapy including an IMiD and a PI. Response is investigator assessed at each cycle by IMWG criteria. The primary objective is overall response rate (ORR). Patients receive treatment until there is disease progression or unacceptable toxicity.
Results: As of 06 Feb 2018, 47 patients (16 ongoing) received a total of 126 doses (1-9 cycles) of melflufen. Median time since diagnosis was 6.6 years (1-16). Median number of prior therapies was 6 (3-12). 100% of patients received prior PIs and IMiDs with 81% refractory to a PI, 98% refractory to an IMiD and 79% refractory to both. 87% had received prior alkylators (incl. 77% prior ASCT) and 74% received prior monoclonal antibodies. 91% were refractory to pom, 66% to dara and 57% to both pom and dara. Of the 47 patients, treatment was ongoing in 16 (34%) and was discontinued in 31 (66%) due to PD (49%), AEs (9%) and other reasons (9%). Treatment-related G3/4 AEs were reported in 31 patients (66%); with those occurring in >10% of the patients included thrombocytopenia (53%), neutropenia (45%) and anemia (21%). Only 2 patients (4%) had a treatment-related G3/4 febrile neutropenia. No single non-hematologic AE occurred in more than 1 patient.
42 patients received ≥1 dose of melflufen and had at least 1 assessment of response and were included in the efficacy analysis. 2 patients (5%) achieved VGPR and 8 (19%) achieved PR for an ORR of 24%. 5 patients achieved MR for a CBR of 36%. 19 patients (45%) had maintained SD as their best response.
Summary and Conclusions: Despite the recent advances in therapy for MM the disease remains incurable. Late stage RRMM patients refractory to pom and/or dara have limited treatment options. Melflufen is well tolerated with few treatment discontinuations due to AEs and has encouraging results with an ORR of 24% and CBR 36% where most other conventional therapies have failed. Recruitment to this Phase 2 study and to the Phase 3 Ocean trial (NCT03151811) is ongoing.

PF582

PHASE I-B STUDY OF ISATUXIMAB+CARFILZOMIB IN RELAPSED AND REFRACTORY MULTIPLE MYELOMA (RRMM)

J. Richter[1], S. Wong[2], A. Chari[3], N. Shah[2], S. Jagannath[3], H.J. Cho[3], N. Biran[1], J. Wolf[2], S. Parekh[3], P. Munster[2], D. Madduri[3], F. Campana[4], T. Martin[2,*]

[1]Medicine, Hackensack University, Hackensack, [2]Medicine, UCSF, San Francisco, [3]Medicine, Mount Sinai Hospital, New York, [4]Oncology, Sanofi-Oncology, Boston, United States

Background: Isatuximab is an anti-CD38 mAb with potent anti-myeloma (MM) activity as monotherapy or in combination with lenalidomide (Len)+dexamethasone (d) in RRMM. Carfilzomib is a next generation proteasome inhibitor approved for use in RRMM as a single agent or in combination with d or Len+d. The hypothesis is that the combination of isatuximab (ISA) and carfilzomib (CFL) may demonstrate potent synergy for the treatment of RRMM.
Aims: The primary objective was to determine the maximum tolerated dose (MTD) of ISA+CFL in RRMM. Secondary objectives included assessment of safety, PK, immunogenicity, and efficacy (per IMWG response criteria (ORR)). (NCT-02332850)
Methods: Eligible patients (pts) had disease progression after 2 prior lines, an ECOG <3, and adequate organ function. Therapy included ISA IV every 2 weeks (Q2W), or weekly (QW) for 4 doses then Q2W together with CFL (20mg/m2 Day 1, 2=>27 mg/m2: Day 8, 9, 15, 16 Q28d and for all subsequent CFL doses). Dosing levels (DL) included: ISA 10 mg/kg Q2W, ISA 10 mg/kg QW x 4 then Q2W and ISA20 mg/kg QW x 4 then Q2W in a 3+3 dose escalation (DE) design. An expansion cohort (EC) of 18 pts was enrolled at ISA 10 mg/kg QW x 4 then Q2W (DL2).
Results: 15 pts have been treated in DE and 18 in the EC. The median age of the 33 pts was 61 (range 39-79) yrs, with a median # of prior lines of 3

(range 2-8). All pts were IMid and PI exposed: 26/29 Len refractory (Refr), 21/29 Bort Refr, 13/29 Pom Refr and 8/11 CFL Refr. Median follow-up is 7m (1 – 27m). 29 pts are evaluable for overall response (ORR). The ORR is 69% (1 sCR, 7 VGPR, 12 PR) and clinical benefit rate is 86% (5 MR). The median progression free survival has not been reached. Disposition: 15 patients have progressed (PD, with 4 deaths from PD), 1 pt withdrew after 27 cycles (for treatment holiday), and 17 remain on therapy. The median # of cycles given is 4 (range 1-27). No DLT or unexpected toxicity has been observed and no patients stopped therapy due to toxicity. The most frequent occurring treatment emergent adverse events (TEAEs-all grades, incidence ≥15%), were thrombocytopenia (66%), pain (back, chest wall, pelvis: 60%), upper respiratory infection (56%), diarrhea (40%), fatigue (40%), anemia (33%), cough (33%), elevated creatinine (30%), nausea (30%), neutropenia (27%), headache (27%), dyspnea (16.7%) and fever (16.7%). Serious AEs were infrequent (SAE=9 events: 4 fever, 3 URI, 1 sinus tachycardia, 1 hypotension) and overall <5% of AEs were Gr 3/4. Infusion reactions (IRs) were the most common ISA-related AEs. Seventeen IRs were reported in 16/32 pts (50%: Gr 1 (9)+Gr 2 (8)).

Summary and Conclusions: Combining ISA and CFL appears safe; with no unexpected toxicity and AEs consistent with the toxicity profile of the individual agents. Encouraging anti-MM activity was seen at all DLs in predominantly refractory patients with an ORR of 69% and CBR of 84%. Although an MTD was not reached at ISA doses of up to 20 mg/kg, the ISA dose of 10 mg/Kg QW x 4 then Q2W has been selected for combination studies. PK and PD studies support the use of ISA at 10 mg/kg when used in combination and 2 Phase III combination studies are underway in RRMM: IKEMA- ISA+CFL+d *versus* CFL+d (NCT03275285) and ICARIA- ISA+Pom +d *versus* Pom+d (NCT02990338).

PF583

IMPACT OF BASELINE RENAL FUNCTION ON EFFICACY AND SAFETY OF DARATUMUMAB PLUS BORTEZOMIB-MELPHALAN-PREDNISONE (VMP) IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS INELIGIBLE FOR TRANSPLANTATION (ALCYONE)

Background: In the phase 3 ALCYONE study, daratumumab (D) in combination with VMP (D-VMP) prolonged progression-free survival *versus* VMP alone, and exhibited favorable tolerability in patients with newly diagnosed multiple myeloma.

Aims: We conducted a subgroup analysis of the efficacy and safety of D-VMP *versus* VMP according to baseline creatinine clearance (CrCl; ≤60 mL/min [moderately impaired] and >60 mL/min).

Methods: Randomized patients were ineligible for high-dose chemotherapy with autologous stem cell transplantation and had baseline CrCl ≥40 mL/min. Up to nine 6-week VMP cycles (V 1.3 mg/m^2 subcutaneously on Days 1, 4, 8, 11, 22, 25, 29, 32 in Cycle 1 and Days 1, 8, 22, 29 in Cycles 2-9; M 9 mg/m^2 orally and P 60 mg/m^2 orally on Days 1-4 in Cycles 1-9) with or without D (16 mg/kg intravenously weekly for Cycle 1, every 3 weeks for Cycles 2-9, and every 4 weeks for Cycles 10+ [post VMP-treatment phase] until progression) were received. Minimal residual disease at 10^{-5}threshold was evaluated using clonoSEQ® (Adaptive Biotechnologies).

Results: Among 706 (350 D-VMP; 356 VMP) randomized patients, 295 (150 D-VMP; 145 VMP) patients had baseline CrCl ≤60 mL/min and 411 (200 D-VMP; 211 VMP) patients had baseline CrCl >60 mL/min. For D-VMP *vs* VMP, the median duration of study treatment was 15.3 months *vs* 12.0 months for the ≤60 mL/min subgroup and 14.5 months *vs* 12.0 months for >60 mL/min subgroup, respectively.

D-VMP prolonged progression-free survival *versus* VMP in ≤60 mL/min (median not reached [NR] *vs* 16.9 months; hazard ratio [HR] 0.36; 95% confidence interval [CI] 0.24-0.56) and >60 mL/min (median NR *vs* 18.3 months; HR 0.63; 95% CI 0.45-0.88) subgroups after median follow-up of 16.5 months. Overall response rate benefit was maintained for D-VMP *vs* VMP in the ≤60 mL/min (89% *vs* 73%; ≥complete response [CR]: 43% *vs* 24%) and >60 mL/min (92% *vs* 74%; ≥CR: 43% *vs* 25%) subgroups. Similar findings were observed with minimal residual disease-negative rates in the ≤60 mL/min (25% *vs* 8%; odds ratio [OR] 4.13; 95% CI 2.02-8.46) and >60 mL/min (20% *vs* 5%; OR 4.55; 95% CI 2.26-9.14) subgroups.

Safety findings for D-VMP *versus* VMP are summarized in the Table 1. In the ≤60 mL/min and >60 mL/min subgroups, infusion reactions were observed in 27% (Grade 3/4: 5%/0.7%) and 29% (Grade 3/4: 4%/0.5%), respectively.

Table 1.

	CrCl ≤60 mL/min		CrCl >60 mL/min	
Grade 3/4, %	D-VMP	V MP	D-VMP	V MP
Most common (≥10%) treatment-emergent adverse events				
Neutropenia	47	38	35	39
Thrombocytopenia	43	42	28	34
Anemia	21	29	12	13
Pneumonia	15	6	9	2
Peripheral sensory neuropathy	2	4	1	4

Summary and Conclusions: D in combination with VMP prolongs progression-free survival, induces deep responses, and demonstrates acceptable tolerability regardless of baseline renal function. NCT02195479.

PF584

UPDATE OF THE PHASE 2 STUDY OF CARFILZOMIB, THALIDOMIDE, AND LOW-DOSE DEXAMETHASONE AS INDUCTION/CONSOLIDATION IN NEWLY DIAGNOSED, TRANSPLANT ELIGIBLE PATIENTS WITH MULTIPLE MYELOMA, CARTHADEX TRIAL

R. Wester[1,*], B. van der Holt[1], E. Asselbergs[1], S. Zweegman[2], M.J. Kersten[3], E. Vellenga[4], M. van Marwijk Kooy[5], O. de Weerdt[6], M. Minnema[7], S. Lonergan[1], A. Palumbo[8], H. Lokhorst[2], A. Broijl[1], K. Iskander[9], P. Sonneveld[1]

[1]Hematology, Erasmus MC Cancer Institute, Rotterdam, [2]Hematology, VU University Medical Center, [3]Hematology, Academic Medical Center, Amsterdam, [4]Hematology, Univerisity Medical Center Groningen, Groningen, [5]Hematology, Isala Clinics, Zwolle, [6]Hematology, St. Antonius Hospital, Nieuwegein, [7]Hematology, UMC Utrecht Cancer Center, Utrecht, Netherlands, [8]Hematology, University of Turin, Torino, Italy, [9]Amgen, Thousand Oaks, United States

Background: This phase 2 dose escalation trial investigates the combination of Carfilzomib with Thalidomide and Dexamethasone (KTd) for induction and consolidation in transplant-eligible patients with newly diagnosed multiple myeloma (NDMM). We report the response, progression-free survival (PFS), overall survival (OS) and safety of 4 dose levels of Carfilzomib.

Aims: To investigate the efficacy of KTd for induction and consolidation therapy in NDMM.

Methods: Transplant-eligible patients aged between 18 and 65 years with NDMM were enrolled in this phase 2 trial. Patients were treated with 4 cycles of KTd. The dose of Carfilzomib in the first dose level was 20 mg/m^2 i.v. on days 1, 2 followed by 27 mg/m^2 on days 8, 9, 15, 16 of cycle 1 and on days 1, 2, 8, 9, 15 and 16 of cycles 2 to 4. Thalidomide dose was 200 mg orally on days 1-28 and Dexamethasone dose was 40 mg orally once per week. Carfilzomib was escalated to 20/36 mg/m^2, 20/45 mg/m^2, and 20/56 mg/m^2, in dose level 2,3 and 4 respectively. Induction was followed by stem cell harvest after Cyclophosphamide priming (2 to 4 mg/m^2) and G-CSF. Hereafter patients received high-dose Melphalan (200mg/m^2) and autologous stem cell transplantation followed by consolidation treatment with 4 cycles of KTd in the same schedule except a lower dose of Thalidomide (50mg). Primary endpoint was response after induction and overall, specifically complete response (CR) and very good partial response (VGPR). Secondary endpoints were PFS, OS and safety.

Results: Between September 16, 2010 and January 14, 2014, 111 patients

were enrolled with a median age of 58 years and a median follow-up of 73, 62, 55 and 49 months, in dose level 1-4 respectively. For all dose levels overall response rate was 94%. (s)CR rate after induction was 18%, ≥VGPR rate was 65%, and ≥PR rate was 93%. After HDM (s)CR rate increased to 31% and after consolidation to 63%. (s)CR and VGPR were higher after consolidation in dose levels 2-4 *versus* dose level 1, although not statistically significant (Fisher's exact p=0.17 and p=0.10, respectively). In all patients PFS at 48 months was 58% (95% CI, 48% to 67%). PFS per dose level was 59% (95% CI, 44% to 72%), 50% (95% CI, 27% to 69%), 65% (95% CI, 40% to 82%) and 55% (95% CI, 31% to 73%) in dose level 1,2, 3 and 4 respectively, and in dose levels 2-4 together PFS was 57% (95% CI 43% to 68%). PFS in dose level 1 *versus* dose level 2-4 was comparable (logrank p=0.89) (Figure 1A). In all patients OS at 48 months was 79% (95% CI, 70% to 85%). OS per dose level was 75% (95% CI, 61% to 85%), 75% (95% CI, 50% to 89%), 85% (95% CI, 61% to 95%) and 85% (95% CI, 60% to 95%) respectively. In dose levels 2-4 together OS was 82% (95% CI, 69% to 89%). OS in dose level 1 *versus* dose level 2-4 was comparable (logrank p=0.53) (Figure 1B). Safety analysis of all 111 patients showed grade 3/4 non-hematological toxicity mainly consisting of infections (11%), respiratory disorders (8%) and vascular disorders (9%). Cardiac adverse events were limited and included heart failure (n=3, 2 at 27 mg/m^2, 1 at 56mg/m^2), dyspnea (n=1 at 27mg/m^2) and chest pain (n=1 at 45mg/m^2).

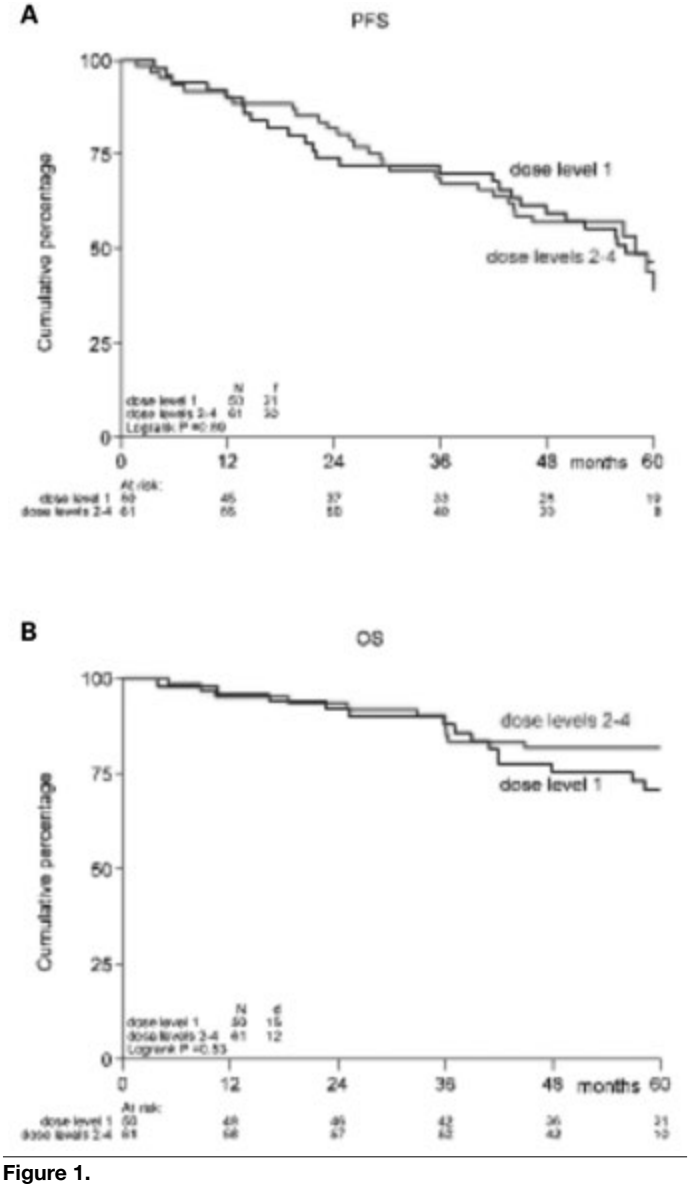

Figure 1.

Summary and Conclusions: KTd is an effective regimen with higher response rates in dose level 2-4 *versus* dose level 1. PFS and OS between dose level 1 and dose levels 2-4 were comparable. This study was registered at www.trialregister.nl as #NTR2422 and is supported by Amgen.

PF585

CLINICAL CHARACTERISTICS OF NEWLY DIAGNOSED PATIENTS WITH AL AMYLOIDOSIS WITH "NON-MEASURABLE" FREE LIGHT CHAINS: PROGNOSTIC IMPLICATIONS AND RESPONSE EVALUATION

M. Gavriatopoulou[1], M. Migkou[1], I. Dialoupi[1], E. Eleutherakis-Papaiakovou[1], D.C. Ziogas[1], N. Kanellias[1], D. Fotiou[1], E. Terpos[1], T. Bagratouni[1], A. Papathoma[2], M. Spyropoulou-Vlachou[2], M.A. Dimopoulos[1], E. Kastritis[1,*]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, [2]Immunology Unit, "Alexandra" Hospital, Athens, Greece

Background: Current criteria for the assessment of hematologic response in patients with AL amyloidosis are based on the measurement of the difference between the involved and uninvolved serum FLCs (dFLC). These criteria have been validated but require that dFLC should be ≥50 mg/L at baseline in order to assess hematologic responses. However, patients with dFLCs <50 mg/L are excluded from clinical trials as having "non-measurable" disease although the natural history of their disease may not differ from that of patients with "measurable dFLCs". Three different centres have published data indicating that patients with dFLC <50 mg/L may have a more favourable outcome, less cardiac involvement and more often renal involvement.
Aims: Our aim was to evaluate whether patients with light chain (AL) amyloidosis and "non-measurable" dFLCs (i.e with dFLC <50 mg/dL) have different clinical characteristics or outcome than patients with measurable dFLCs
Methods: The analysis included 244 patients with AL amyloidosis treated in a single centre (Department of Clinical Therapeutics, Athens, Greece). Organ involvement was defined according to the 2005 ISA criteria. Hematologic complete response (hemCR) was defined as a negative serum and urine immunofixation and a normal FLC ratio. Serum FLC concentration was measured using the FREELITE assay (The Binding Site, Birmingham, UK).
Results: Forty nine (20%) patients had dFLC <50 mg/L at the time of diagnosis and before initiation of any therapy. These patients had more often renal involvement (84% *vs* 64%, p=0.031), but had less often cardiac involvement (47% *vs* 72%, p=0.004), peripheral nerve (8% *vs* 25%, p=0.021) or soft tissue involvement (8% *vs* 23%, p=0.032). However, median eGFR was lower in patients with dFLC <50 mg/L (48 *vs* 77 ml/min/1.73 m2, p=0.005) and median BM infiltration was 10% *vs* 15% (p<0.001) while distribution per Mayo stage was 29% , 50% & 21% *vs* 17% , 49% & 34% for stage-1, -2, & -3 respectively (p=0.09). There was no difference in the treatments that were given (bortezomib based in 67% *vs* 59% respectively) or ASCT (8% *vs* 6%) (all p>0.5). The median OS was significantly longer for those with dFLC <50 mg/L (1-year OS: 82% *vs* 61%, 3-year OS: 82% *vs* 45%, 5-year OS: 70% *vs* 35%, p=0.001). In multivariate analysis for OS, dFLC<50 mg/L was associated with a 75% reduction in the risk of death (HR: 0.25, 95% CI 0.12-0.56, p=0.001) independently of cardiac involvement and Mayo stage. Regarding renal survival, we found no significant difference in rates of progression to dialysis for the two groups, with and without dFLC <50 mg/L. Among patients with dFLC <50 mgL but with dFLC ≥20 mg/L, the reduction of dFLC at 3 months landmark to <10 mg/L was associated with better OS (3 years OS 100% *vs* 80%).
Summary and Conclusions: About one fifth of newly diagnosed patients with AL amyloidosis have low level dFLC ("non-measurable" by current criteria) and this is associated with significantly better outcome, independently of other standard prognostic factors. This parameter should be included in the standard staging and risk assessment of patients with AL amyloidosis. Furthermore, patients with dFC <50 mg/L should be included in clinical trials as they benefit from reduction of their FLCs to <10 mg/L, and this criterion should be accounted for in the hematologic response criteria.

PF586

SELINEXOR COMBINED WITH POMALIDOMIDE AND LOW DOSE DEXAMETHASONE (SPD) IN A RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENT POPULATION

C. Chen[1,*], H. Sutherland[2], R. Kotb[3], M. Sebag[4], D. White[5], W. Bensinger[6], C. Gasparetto[7], R. LeBlanc[8], C. Venner[9], S. Lentzsch[10], G. Schiller[11], B. Lipe[12], A. Del Col[13], M. Kauffman[14], S. Shacham[14], J. Jeha[14], J.-R. Saint-Martin[14], J. Shah[14], N. Bahlis[15]

[1]Princess Margaret Cancer Center, Toronto, [2]Vancouver General Hospital, Vancouver, [3]Cancer Care Manitoba, Manitoba, [4]Royal Victoria Hospital, Montreal, [5]Dalhousie University and QEII Health Sciences Center, Halifax, Canada, [6]Swedish Cancer Center, Seattle, [7]Duke University Cancer Center, Durham, United States, [8]Hôpital Maisonneuve-Rosemont, Montreal, [9]Cross Cancer Institute, Edmonton, Canada, [10]Columbia University, New York, [11]UCLA Ronald Reagan Medical Center, Los Angeles, [12]University of Rochester Medical College, New York, United States, [13]Myeloma Canada, Laval,

Canada, [14]Karyopharm Therapeutics, Newton, United States, [15]Southern Alberta Cancer Research Institute, Calgary, Canada

Background: The nuclear export protein exportin 1 (XPO1) is overexpressed in a wide variety of cancers including multiple myeloma (MM). Selinexor is a first-in-class Selective Inhibitor of Nuclear Export (SINE) compound that binds and inactivates XPO1. Selinexor forces nuclear retention and reactivation of cell cycle regulators such as p53, IkB, and Rb. Pomalidomide/dexamethasone (Pd) is approved in relapsed/refractory MM (RRMM) with an overall response rate (ORR) of 30% and progression-free survival (PFS) rate of 3.6 months in patients (pts) having received a prior proteasome inhibitor (PI) and IMiD. Strategies to improve the ORR and PFS are needed. In murine MM models, the combination of selinexor with IMiDs shows synergistic anti-MM activity and good tolerability.
Aims: This Ph 1b/2 (NCT02343042), dose escalation study was designed to determine the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) for the safety, tolerability and efficacy of the combination of selinexor, pomalidomide, and low dose dex (SPd) in pts with RRMM.
Methods: Pts with RRMM who received ≥2 prior therapies including lenalidomide (len) and a PI were enrolled. Selinexor was evaluated in 2 different dosing schedules of once-weekly (QW, 60; 80 mg) or twice-weekly (BIW, 60; 80 mg), with pomalidomide (pom) 4 mg PO daily, and dexamethasone (dex) 20 mg BIW or 40 mg QW.
Results: As of Feb 27th 2018, 33 pts (16 male / 17 female) have been enrolled.The median age is 61 years, with a median of 4 (range, 2 – 9) prior treatment regimens. Thirty-one patients were IMiD refractory (20 len, 11 pom/len). Six dose limiting DLTs were observed: G3 fatigue (60 mg BIW, pom 4 mg), G3 febrile neutropenia (FN) (60 mg BIW, pom 3 mg), G3 FN and G4 neutropenia (ANC) (80 mg QW, pom 4), G3 thrombocytopenia (PLT) (80 mg QW, pom 3 mg) and 4 missed doses in Cycle 1 due to symptomatic hyponatremia (80 mg BIW, pom 4 mg). Enrollment on selinexor 80 mg QW, pom 3 mg is ongoing. Common treatment related Grade 1/2 adverse events (AEs) include: nausea (48%), fatigue (42%), anorexia (45%) and diarrhea (30%). Grade 3/4 AEs include: ANC (55%), PLT (30%), and anemia (27%). Twenty-seven pts were evaluable for response. Responses rates can be seen in Table 1. Median PFS is 11.6 months with a median follow up of 7.7 months.

Table 1. SPd – Response rates in evaluable patients.

Prior Therapy Status	N*	ORR	CBR
Pom Naïve & Len Refractory or Relapsed	19	12 (63%)	14 (74%)
Pom & Len Refractory	8	3 (38%)	5 (63%)

Overall Response Rate= VGPR + PR, Clinical Benefit Rate= VGPR + PR + MR (*Includes 1 unconfirmed PR and 1 unconfirmed MR)

Summary and Conclusions: Conclusions – Enrollment is ongoing to evaluating once weekly selinexor in combination with Pd. This all oral combination of selinexor, pom and dex (SPd) has significant clinical activity with an ORR 63% in pom naive pts with heavily pretreated MM compared to previously published data of 30% ORR. No unexpected adverse events were noted. Phase 1 dose escalation of the combination of SPd is ongoing to define the RP2D. SPd appears active and supports further clinical development in RRMM.

PF587

ABSENCE OF BONE DISEASE IS AN INDEPENDENT FAVORABLE PROGNOSTIC FACTOR OF OVERALL SURVIVAL IN SYMPTOMATIC MULTIPLE MYELOMA PATIENTS TREATED WITH NOVEL AGENTS

E. Katodritou[1,*], T. Triantafyllou[1], V. Palaska[1], N. Drougos[1], E. Verrou[1], K. Psianou[1], K. Loga[1], K. Kokoviadou[2], K. Keramidioti[1], N. Karampatzakis[1], E. Giannopoulou[1], V. Gastari[1], C. Chadjiaggelidou[1], D. Mallouri[3], G. Kaiafa[4], A. Kioumi[2], A. Anagnostopoulos[3], P. Konstantinidou[1], E. Terpos[5]

[1]Hematology, Theaganion Cancer Hospital, [2]Hematology, Papageorgiou General Hospital, [3]Hematology and Bone Marrow Transplantation Unit, George Papanikolaou General Hospital, [4]Hematology, AHEPA University Hospital, THESSALONIKI, [5]Clinical Therapeutics, National and Kapodistrian University, ATHENS, Greece

Background: Bone disease is a common clinical manifestation in Multiple Myeloma (MM). However, a remarkable number of patients are diagnosed with symptomatic MM without evidence of bone disease. The prognostic role of absence of bone disease has not been investigated.
Aims: We evaluated the clinical characteristics of patients presenting without bone lesions and we examined the possible prognostic significance of bone disease absence in symptomatic MM patients treated with novel agents.
Methods: We studied the medical records of patients with symptomatic MM defined by conventional criteria (*i.e.* anemia and/or hypercalcemia/and or renal insufficiency and/or lytic bone lesions) diagnosed and treated upfront with novel agent combinations. We compared those with symptomatic disease excluding bone lesions (group A) with those who had documented bone disease by conventional X-ray imaging (group B); computer tomography was performed per protocol, according to clinical indications. Patients characteristics between the 2 groups were compared with standard methods. Progression-free survival (PFS) and overall survival (OS) were plotted with the Kaplan Meier curve. Prognostic factors for OS were evaluated with cox regression; p<0.05 was considered as statistically significant.
Results: Three-hundred thirty-eight consecutive symptomatic MM patients were evaluated (M/F: 179/159, median age 67, range: 34-88, IgG: 184, IgA: 89, light-chain: 54, non-secretory: 11, ISS1: 101, ISS2: 105, ISS3: 132); 96/338 (28%) presented at diagnosis without bone disease. Patients characteristics such as median age, β2 microglobulin, lactate dehydrogenase (LDH), hemoglobin, platelets, albumin, creatinine, calcium, International staging system (ISS), revised-ISS (R-ISS), type of MM and high-risk cytogenetics were well balanced between groups. Patients with bone disease had more frequent worse performance status according to Eastern Cooperative Oncology Group (ECOG scale 3/4: 40% *vs* 22%, respectively; p=0.003). All patients were treated with novel agents in 1st line, and 20% underwent autologous transplantation. Type of first or second line treatment did not differ between the 2 groups; no difference in response rates or progression-free survival (PFS) after induction therapy was observed; PFS2 was marginally longer in patients without bone disease (49 months *vs* 36 months; p=0.058). After a median follow up of 71 months (95% CI: 61-80), the median OS for patients without bone disease was 65 months (95% CI: 46-84) *vs* 45 (95% CI: 37-53) for those with documented bone disease (log rank p<0.001); In the univariate analysis, ISS, R-ISS, high risk cytogenetics, estimated glomerular filtration rate (eGFR) <40ml/min/1.73m^2, LDH ≥300U/L and absence of bone lesions were predicted for OS (p<0.05 for all parameters); absence of bone lesions, and R-ISS were significant predictors for OS in the multivariate analysis (HzR: 0.64, p= 0.03, R-ISS1-3: HzR: 0.28, p<0.001,R-ISS2-3 HzR: 0.48, p=0.007, respectively) (Figure 1).

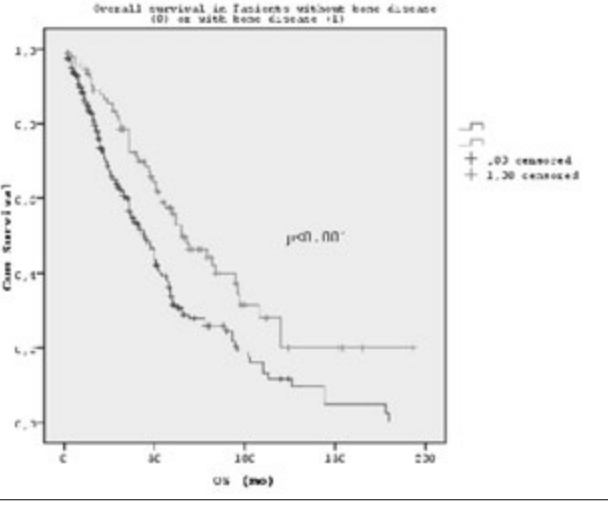

Figure 1.

Summary and Conclusions: Based on our analysis the absence of bone disease at diagnosis of symptomatic MM patients is one of the most powerful prognostic factors for OS, leading to a 36% reduction of death probability; of note, patients without bone disease exhibited marginally longer PFS2, suggesting that they may display a more sensitive first relapse. Further investigation is needed to confirm this finding, using modern imaging for the definition of bone disease in order to integrate this marker, in possible future prognostic models.

PF588

CORRELATION OF 11C-METHIONINE-PET AND FDG-PET IN MULTIPLE MYELOMA WITH MRD ASSESSMENT BY FLOWCYTOMETRY

M. Marcos[1,*], M.I. Morales[2], S. Villar[1], R. Figueroa[3], L.E. Tamariz[1], P. Rodríguez[1], A. Alfonso[1], R. Lecumberri[1], F. Prosper[1], C. Panizo[1], B. Paiva[4], M.J. García-Velloso[2], J. San Miguel[1]

[1]Hematology, [2]Nuclear Medicine, Clínica Universidad de Navarra, Pamplona, [3]Hema-

tology, Clínica Universidad de Navarra, Madrid, [4]Cytometry, Centro de Investigación médica aplicada Universidad de Navarra, Pamplona, Spain

Background: In 2016, the International Myeloma Working Group (IMWG) updated their criteria for response assessment in multiple myeloma (MM) and for the first time, 18FDG-PET/CT was included as a tool to define a imaging/metabolic complete response. However, standarization of 18FDG-PET/CT has not been yet achieved and both lack of specificity and sensitivity are important concerns. For this reason, other trazers such as 11C-methionine (MET) has recently emerged as a potentially more sensitive marker to evaluate tumor burden and disease activity in MM patients.
Aims: The purpose of this study is to evaluate the performance of 11C-MET-PET compared to 18FDG-PET. First, we have evaluated the correlation between both metabolic trazers (MET and FDG) and second, we will correlate the PET results with immunophenotypic response using multiparametric flow citometry (MFC) applying the EUROFLOW protocol (MRD 10^{-6}).
Methods: Between September 2016 and February 2018, both MET and FDG-PET were performed for staging or restaging in a total of 53 patients (61.8% male, range 11-78 years old): plasmacytoma (n=9), smoldering MM (SMM, n=3), and symptomatic MM (n=41). In 37 patients PET and MFC exams were simultaneously performed: 7 cases at diagnosis, 13 patients were in stringent complete response (sCR), 4 were in very good partial response (VGPR), two in partial response (PR), one with stable disease (SE) and 10 with progressive disease (PD). Nine out of 37 patients (23.4%) were MRD negative by using MFC. We compared frequency in dicothomous variables by Fisher exact test or Chi Squared depending on expected values.
Results: We found that MET-PET was more sensitive than FDG-PET: MET-PET was positive (detected focal lesions) in 38/52 subjects (73.1%), whereas FDG-PET/CT showed lesions in only 27 patients (51.9%; p<0.0001).
17 patients were studied at diagnosis or relapse (all with BM infiltration confirmed by MFC) and 20 cases were analyze after treatment for MRD assessment. At time of diagnosis/PD, we were able to detect focal lessions in all patients (sensitivity 100%) with PET-MET; however, FDG-PET negativity was observed in two over 20 (10%) patients. As above mentioned, at response evaluation, 20 patients were simultaneously studied for MRD by MFC and PET, upon correlating MET-PET and MFC, discordant results were found in 7/20 (35%, p=ns): MET-PET was positive with MRD negative in 4 (20%), the opposite (negative MET-PET and positive MRD) was observed in 3 patients (15%). The comparison between FDG-PET and MFC showed that 8/20 (40%, p=ns) patients had discordant results: FDG-PET positive and MRD negative occurred in only one case (5%) while 7 (35%) patients had FDG-PET negative and MRD positive.
Summary and Conclusions: This study demonstrates that MET has higher sensitivity in comparison to standard FDG to detect myelomatous disease both at diagnosis and at the time of MRD. Moreover, MET showed to be positive in 4/7 negative FDG cases that remained as MRD positive. Overall, these results confirm the complementarity and the value of high sensitive technologies to evaluate myeloma response. Further analysis will contribute to elucidate if MET has also a better predictive value as compared to FDG in the longterm follow-up.

PF589

TRANSLOCATION (14;16) POSITIVE MULTIPLE MYELOMA PATIENTS: CLINICAL FEATURES AND SURVIVAL OUTCOMES OF A HIGH-RISK POPULATION.

[1]Myeloma Unit, Division of Hematology, University of Torino, Torino, Italy, [2]Winship Cancer Institute/ Hematology and Medical Oncology, [3]Emory University, atlanta, United States, [4]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece, [5]Italian Multiple Myeloma Network, GIMEMA, Italy, [6]Department of Pathology, Emory University, Atlanta, , atlanta, United States

Background: Multiple myeloma (MM) is characterized by recurrent chromosomal abnormalities (CA); among those involving IgH genes, t(4;14), t(14;16) and t(14;20) have been associated with shorter survival. However, t(14;16) incidence is less than 5% in newly-diagnosed (NDMM) patients, so that the clinical features and outcomes of these patients have not been thoroughly described.
Aims: We retrospectively reviewed databases of patients treated in the context of Italian and EMN clinical trials (n=76), as well as patients treated at Winship Cancer Institute (WCI) at Emory University, USA (n=29), and the Department of Clinical Therapeutics, National and Kapodistrian University (NKU) of Athens, Greece (n=18).
Methods: Patients diagnosed between December 2006 and March 2017, carrying t(14;16) detected by FISH at diagnosis, were pooled. Baseline characteristics, response to 1st line treatment and survival outcomes were analysed.
Results: A total of 123 patients were evaluated. Median age at diagnosis was 66 years (range 38-87 years); 49% of patients presented with haemoglobin ≤10 g/dl and 11% with platelets ≤100 x10^9/L. Lactate dehydrogenase (LDH) levels above the upper limit of normal (ULN), hypercalcemia and creatinine values >2 mg/dl were observed in 19%, 17% and 13% of the patients, respectively and 43% of patients had ISS and R-ISS stage 3 disease.Eighty-two% of patients had at least 1 additional unfavourable CA, including del13q (71%), del17p (22%) and 1q gain (27%). Interestingly, concomitant t(4;14) or t(11;14) was observed in 11% and 4% of patients, respectively.Induction therapy consisted of an immunomodulatory drug, a proteasome inhibitor or a combination of both in 43%, 29% and 28% of patients, respectively. One fourth of the patients received consolidation with autologous transplantation in first remission (ASCT-1) and 43% of patients received maintenance therapy. Median progression-free survival (PFS) and overall survival (OS) for the entire cohort were 19 and 53 months, respectively (Figure 1). Among ASCT-eligible patients, those who received ASCT-1 had longer median PFS (31 *vs* 10 months; HR: 0.35, p=0.003) and OS (58 *vs* 34 months; HR 0.48, p=0.04) as compared to those who did not. Maintenance therapy significantly prolonged median PFS (36 *vs* 19 months, HR:0.56; p=0.03) as compared to no maintenance. The best response to 1st line treatment was ≥partial response (PR) in 83% of patients, with 26% of ≥complete remission (CR). Patients achieving ≥CR had prolonged PFS (HR:0.29, p<0.001) as compared to patients in PR/very-good PR. In the multivariate analysis, baseline hypercalcemia and beta-2-microglobulin >ULN were associated with significantly shorter PFS (HR: 2.3, p=0.02; HR: 2.7, p=0.001, respectively) and OS (HR: 5.4, p<0.001; HR: 1.9, p=0.02, respectively), while ASCT-1 (HR:0.3, p=0.001) and maintenance therapy (HR:0.43, p=0.07) confirmed their advantage in terms of PFS.

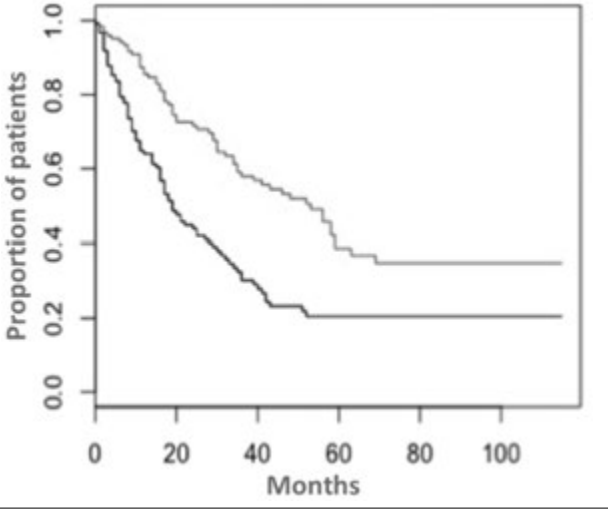

Figure 1.

Summary and Conclusions: In the largest cohort of t(14:16) patients described to date, t(14;16) characterizes a group of high-risk MM patients, presenting with frequent concurrent additional adverse CAs and advanced stage disease (R-ISS3), that result into a poor PFS and OS. Treatment intensification with ASCT in first remission and maintenance therapy prolonged survival of patients with t(14;16). Novel approaches and clinical trials are needed to improve outcomes of this high risk population.

PF590

THE SWEDISH MYELOMA REGISTRY: INCREASED SURVIVAL OVER TIME IN PATIENTS 66-80 YEARS OLD, DIAGNOSED 2008-2016

C.H. Blimark[1,*], A. Genell[2], B. Björkstrand[3], K. Carlson[4], K. Forsberg[5], G. Juliusson[6], B. Lauri[7], O. LInder[8], H. Nahi[3], R. Svensson[9], L. Veskovski[10], I. Turesson[11]

[1]Department of Hematology, Sahlgrenska University Hospital, Institution of Internal Medicine, Sahlgrenska Academy at University of Gothenburg,, [2]Regional Cancer Center

West, Western Sweden Health Care Region, Gothenburg, [3]Department of Hematology, Karolinska Institutet, Stockholm, [4]Department of Hematology, Uppsala University Hospital, Uppsala, [5]Department of Hematology, Umeå University Hospital, Umeå, [6]Hematology/Transplantation, Stem cell center, Skåne University Hospital, Lund, [7]Department of Internal medicine, Sunnerbyn sjukhus, Luleå, [8]Department of Hematology, Örebro University Hospital, Örebro, [9]Department of Hematology, Linköping University Hospital, Linköping, [10]Department of Hematology, Borås Hospital, Borås, [11]Department of Hematology, Skåne University Hospital, Malmö, Sweden

Background: The Swedish Myeloma Registry (SMR) is a prospective observational register documenting real-world management and outcomes in multiple myeloma (MM), smoldering multiple myeloma (SMM), solitary skeletal plasmacytoma (SSP), extramedullary plasmacytoma (EMP), and plasma-cell-leukemia (PCL) since 2008.
Aims: We present data with focus on treatment, response and survival.
Methods: Data were collected through report-sheets at diagnosis to all clinicians diagnosing any of the diagnoses in the register and, for MM, a year later after follow-up on initial treatment and complications.Using diagnostic data 2008-2016 and follow-up data on MM-patients diagnosed 2008-2015, we estimated baseline-characteristics and relative survival (RS). End of follow-up was at death or November 1, 2017, when data was extracted from the register.
Results: We present baseline-data on 6000 patients (coverage 98% compared to the mandatory Swedish Cancer Registry) and, at data from 1-year-follow-up on 4262 MM patients. The median age was 71 years (range 19-98), and 57% men and 43% women, twenty-four per cent were 80 years and above at diagnosis. In first line treatment, the use of high dose Melphalan and stem cell support (ASCT) was stable in the cohort 65 years and younger (ca 80%), and increasing in the patients 66-70 years (from 23 to 35%), the newer drugs bortezomib, thalidomide and lenaldomide were used in 85%, 76%, and 41% in the age cohorts <=65 years, 66-80 years, and 80+ years, respectively. In the study period 2008 to 2015, the use of the above drugs in 1st line treatment increased from 36% to 98% in the age cohort 65 years and younger, from 46% to 91% in patients 66-80 years, and from 21% to 64% in the cohort above 80 years. In the period 2008-2014, we could note a significant increase in response rates after 1st line treatment, from 60% 2008 to 76% VGPR or better in patients 65 years and younger, in the cohort 66-80 years and 80 and above, the figures were 35% 2008 to 60% 2014 and 24% 2008 to 40% 2014, respectively. (Data for 2015 too few to report). Survival: For MM, SMM, SSP and PCL the median RS (with 95% C.I) was 4.24 (4.06-4.46), 8.21 (6.77-9.08), 9.68 (8.70-NA) and 0.89 (0.65-1.68) years.The median RS for ESP was not reached/not available (NA) during the observed time. In the 3-year RS in all patients, there was a signficant survival benefit for patients diagnosed 2011 or later; 67.9%(95%CI 65.9-69.8) *vs* 63% (95%CI 60.8-64.9). This was most evident in the age-group 66-80 year, where in the periods of diagnosis <=2011 and >2011 the 3-year RS was 61.7 percent (95% C.I. 58.8-64.8 percent) and 70.7 percent (68.0-73.5 percent) (Figure 1).

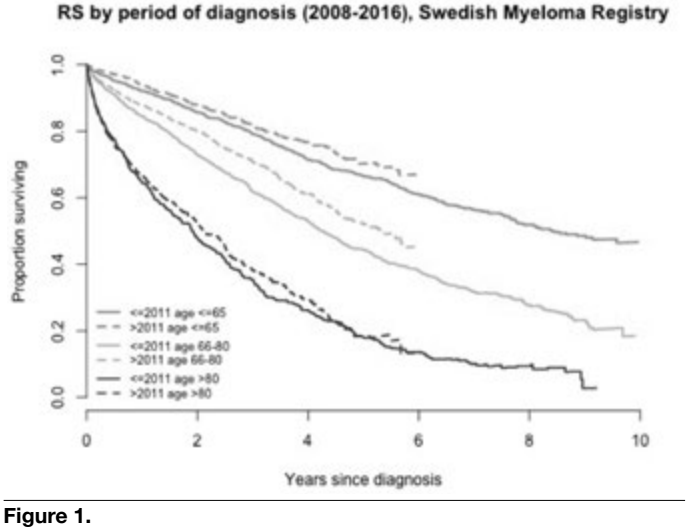

Figure 1.

Summary and Conclusions: In the Swedish Myeloma Registry, survival in MM, SMM and plasmocytomas are encouraging, and our data suggest an increased survival over time, especially in the age-group 66-80 years at diagnosis. We find an increased utilization of newer drugs and increasing response rates after 1st line treatment in the study period. There is still an need for improvement in the treatment of the very elderly. These results supports the need for population-based data as a valuable compliment to randomized clinical trials to monitor the real world outcome and survival in all patients with plasma cell disorders.

PF591

18F-FDG PET/CT AT DIAGNOSIS IS USEFUL FOR DETERMINING THE SURVIVAL OUTCOMES OF PATIENTS WITH MULTIPLE MYELOMA CLASSIFIED AS STAGE II WITH THE REVISED INTERNATIONAL STAGING SYSTEM

S.-H. Jung[1,*], S.-Y. Ahn[1], S.-S. Lee[1], D.-H. Yang[1], J.-S. Ahn[1], H.-J. Kim[1], J.-J. Lee[1]

[1]Chonnam National University Hwasun Hospital, Hwasun-Eup, Korea, Republic Of

Background: Although the Revised International Staging System (R-ISS) was validated in an analysis of an independent cohort of unselected patients with multiple myeloma (MM), stage II problematic increased and included a more heterogeneous population with various risk factors.
Aims: Therefore, we evaluated the prognostic role of 18F-FDG PET/CT at diagnosis in newly diagnosed patients with MM classified as stage II.
Methods: We retrospectively analyzed the records of 168 patients with newly diagnosed MM between February 2012 and March 2017 at Chonnam National University Hwasun Hospital.
Results: Using the R-ISS, 13.1% of patients were R-ISS I, 67.9% were R-ISS II, and 19.0% were R-ISS III. ISS was not prognostic for progression free survival (PFS) and overall survival (OS) when applied to the all patients, but the median PFS and OS were significantly different by the three stages of R-ISS. In total cohort, patients with more than 3 hypermetabolic focal lesion (FL) at baseline PET/CT showed significantly inferior PFS and OS than other patients (PFS, 31.0 months *vs* 16.7 months, P <0.001; OS, not reached *vs* 43.3 months, P=0.006). In addition, patients with extramedullary disease at baseline PET/CT had significantly inferior PFS and OS than those without extramedullary disease (PFS, 24.6 months *vs* 17.2 months, P <0.010; OS, P=0.006). In patients with R-ISS II, 54 patients (47.3%) had more than 3 hypermetabolic FL or extramedullary disease at baseline PET/CT, and the presence of hypermetabolic FLs (>3) or extramedullary disease was significantly associated with shorter PFS and OS (PFS, 31.0 months *vs* 16.4 months, P=0.001; OS, not reached *vs* 43.3 months, P=0.018). In multivariate analysis, the presence of >3 hypermetabolic FLs or extramedullary disease at baseline PET/CT was significantly associated with inferior PFS and OS in patients with R-ISS II (HR 2.439, 95%CI 1.402-4.243, P=0.002).
Summary and Conclusions: In conclusion, PET/CT at diagnosis may be useful for determining the survival outcomes of patients with R-ISS II.

PF592

HAEMATOLOGICAL DIAGNOSIS AND MANAGEMENT IN MONOCLONAL GAMMOPATHY OF RENAL SIGNIFICANCE: SINGLE CENTRE EXPERIENCE

E. Troy-Barnes[1,*], A. Kousios[1], R. Burrell[1], N. Duncan[1], T. Cook[2], H. Auner[3], C. Jakob[3], M. Bua[3], R. Charif[1], C. Roufosse[2], A. Chaidos[3]

[1]Renal Department, [2]Histopathology Department, [3]Department of Haematology, Imperial College Healthcare NHS Trust, London, United Kingdom

Background: Monoclonal Gammopathy of Renal Significance (MGRS) is a recently introduced term to describe kidney lesions caused by monoclonal immunoglobulins produced by B cell or plasma cell clonal disorders, which otherwise do not meet criteria of symptomatic lymphoma or myeloma and have no haematological indication for treatment. The size of the pathogenic clone is often small and occasionally it is undetectable in bone marrow biopsy. Haematological diagnosis could be challenging, but important for treatment decisions. Unlike symptomatic lymphoma and myeloma, treatment objective in MGRS is the preservation of kidney function.
Aims: We describe the spectrum of MGRS diagnoses made at the Hammersmith Hospital between April 2006 and September 2017.
Methods: We reviewed the records of all native kidney biopsies, haematological diagnosis and treatment in the above period.
Results: Out of 4,374 native kidney biopsies, monoclonal immunoglobulin associated lesions were identified in 163 cases (3.7%). After exclusion of symptomatic MM and lymphomas 60 biopsies (1.4%) were consistent with MGRS. The median age at diagnosis was 66 years (range 25-87 years). Renal histological diagnoses included: AIg amyloidosis (n=22, 37%), proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) (n=20, 33%), monoclonal immunoglobulin deposition disease

(MIDD) (n=10, 17%), light chain tubulopathy (n=1, 1.7%), type-1 cryoglobulinaemic glomerulonephritis (n=4, 6.7%), fibrillary glomerulopathy (n=2, 3.3%) and C3 glomerulonephritis (n=1, 1.7%). Mean eGFR at presentation was 54ml/min/1.73m². Thirty two patients presented (53%) presented with nephrotic range proteinuria (urine protein: creatinine ratio >300 mg/mmol) and of those 15 patients (47%) had eGFR>60ml/min/1.73m². Haematological diagnosis was possible in bone marrow histology in 49 patients. These included MGUS (n=32, 65%), smouldering myeloma (n=11, 22%), lymphoplasmacytic lymphoma / Waldenstrom's macroglobulinaemia (n=2, 4%), chronic lymphocytic leukaemia (n=2, 4%) and marginal zone lymphoma (n=1, 2%). Almost half of PGNMID cases (n=11) did not have a detectable clonal B cell or plasma cell clone in bone marrow biopsy. MGUS and smouldering myeloma cases were treated with chemotherapy indicated for myeloma. This included bortezomib-based protocols (VCD, VD), high-dose melphalan and autologous stem cell transplantation and cyclophosphamide with steroids with or without thalidomide. PGNMID treatment was heterogenous, including glomerulonephritis protocols (cyclophosphamide, steroids with or without Rituximab), myeloma regimens in confirmed plasma cell histology or monitoring only in cases with stage 1-2 CKD without significant proteinuria.

Summary and Conclusions: MGRS is an increasingly recognised clinical entity since its introduction by the International Kidney Myeloma Group (IKMG) in 2012. Haematological assessment of MGRS must exclude symptomatic myeloma or lymphoma and identify the pathogenic clone to direct specific therapy. Consensus diagnostic and treatment approaches are missing, at least for entities other than AIg amyloidosis. Case studies in our series suggest that rapid and deep haematological response offers the best renal outcome, an observation that follows the treatment paradigm of AIg amyloidosis.

PF593

IXAZOMIB, LENALIDOMIDE AND DEXAMETHASONE FOR RELAPSED AND REFRACTORY MULTIPLE MYELOMA – DATA FROM THE CZECH REGISTRY OF MONOCLONAL GAMMOPATHIES

Background: The combination of ixazomib, lenalidomide and dexamethasone (IRD) showed in the Tourmaline-MM1 trial an outstanding efficacy in relapsed and refractory multiple myeloma (RRMM).

Aims: The aim of our study was to evaluate the outcomes of IRD in a …real world" setting.

Methods: We analysed data of 118 patients with RRMM who started IRD treatment within a compassionate Named Patient Program between January 2016 and November 2017. The data were acquired from the Czech Registry of Monoclonal Gammopathies (RMG) and included eight hematological centres from the Czech Republic and Slovakia. Median age was 66,5 years (41-84) with M/F ratio 1,2:1 and standard representation of individual M-protein isotypes and ISS stage. Altogether 15,3% had extramedullary disease, 5,9% had elevated creatinine levels above 176umol/l. High-risk cytogenetics, including t(4;14), t(14;16) and del17 was found only in 13 patients, precluding valid statistical analysis. Most patients received IRD for their first relapse (58,5%), followed by second (23,7%) and third relapse (7,6%), some patients being treated in their fourth (5,9%), or higher relapse (4,2%). Most patients received prior bortezomib (94,1%), thalidomide (40,7%) with minor pre-treatment with lenalidomide (16,9%) or carfilzomib (5,9%). 74 patients (62,7%) underwent previous autologous stem cell transplantation (ASCT).

Results: The median follow up was 9,7 months. The therapeutic response was assessed according to IMWG criteria in 76 patients evaluable at the time of data collection. Complete response (CR) was in 11,8%, very good partial response (VGPR) in 15,8%, partial response (PR) in 40,8%, minimal response (MR) in 9,2%, stable disease in 14,5% and progressive disease (PD) in 7,9%. Overall response rate (ORR=PR and better) was 68,4% and Clinical benefit rate (CBR=MR and better) was 77,6%. Median time to response was 1,6 months.The median overall survival (OS) was not reached with 12 month OS 77,4% and 24 month OS 68,8%. Median progression free survival (PFS) was 23,1 months with 12 month PFS 60,3% and 24 month PFS 42%. Patients treated in the first relapse had significantly better PFS (median not reached) than in the second (23,1 months), third (8,7 months) or higher relapse (4,6 months). Patients with extramedullary plasmocytoma (N=18) had worse PFS (median 9,0 months) than the rest of the cohort. Most of the toxicities were grade ≤2. Grade ≥3 reached only neutropenia (37,7%), thrombocytopenia (24,5%), infection (18,9%), anemia (13,2%), other toxicities such as fatigue, neuropathy, exanthema, diarhea and VTE were all <5%.

Summary and Conclusions: We conclude that the fully oral IRD regimen belongs to the most effective novel drug combinations in relapsed or refractory multiple myeloma. It confirmed its efficacy in the "real world" setting. The treatment was safe and well tolerated even in elderly population. The introduction of IRD regimen lead to PFS prolongation to nearly 2 years and significant OS improvement. The patients with less pretreatment (*i.e.* in the first or second relapse) had significantly better outcomes than patients with more advanced disease.

With support of AZV 17-29343A.

PF594

ALLOGRAFT IN MULTIPLE MYELOMA: EXPERIENCE OF MULTIPLE MYELOMA GIMEMA LAZIO GROUP

F. Vozella[1,*], A. P. Iori[1], R. Cerretti[2], A. Severino[3], P. Chiusolo[4], A. Piciocchi[5], S. Grammatico[1], L. Cesini[1], E. Mariggiò[1], F. Fazio[1], L. Cudillo[2], L. Franceschini[2], T. Za[4], S. Sica[4], M.T. Petrucci[1], V. De Stefano[4], L. De Rosa[3], W. Arcese[2], R. Foà[1]

[1]Hematology, Sapienza University of Rome, [2]Hematology, Tor Vergata University of Rome, [3]Hematology, San Camillo Hospital, [4]Hematology, Cattolica del Sacro Cuore University of Rome, [5]Hematology, Gimema Data Center, Rome, Italy

Background: In the era of new drugs prognosis of patients (pts) with multiple myeloma (MM) has significantly improved. New or old drugs, followed by single or tandem autologous stem cell transplant, is the standard of care for pts with newly diagnosed MM. In the last three years MM received the most drug approvals for any one malignancy, both in the United States as well as in Europe. Nevertheless, MM is still considered to be an incurable disease and current therapies can only slow disease progression, prolong survival, and minimize symptoms. In fact, the majority of pts with MM will relapse or become refractory and the remission duration in relapsed MM decreases with each regimen.

Aims: If the role of autologous stem cell transplantation in MM has been confirmed by many trials, allogeneic hematopoietic cell transplantation (HCT) is less commonly used due to high treatment related mortality (TRM) and worsening of the quality of life. As a result of this issues, it is still unclear how to best utilize this potent and effective treatment modality. We report the experience of Multiple Myeloma GIMEMA Lazio Group in 70 pts with newly diagnosed (38) or relapsed/refractory (32) MM who underwent HCT between February 1985 and February 2017.

Methods: The median age was 45.7 years (range, 32.1 - 67.1), 43 men and 27 women. Median age at HCT was 48.6 years (range, 32.6 - 65.8), median time from diagnosis to HCT was 16.8 months (range, 3 - 130.6). As induction treatment 43/70 pts received old drugs, *i.e.* vincristine, doxorubicin and dexamethasone (VAD; n=33) or melphalan and prednisone (MP; n=10), while 27/70 pts were treated with novel agents, *i.e.* velcade-based (n=13) or IMiD-based regimens (n=14). Among newly diagnosed MM, HCT was performed as frontline therapy in 24/38 pts and in a tandem autologous/allogeneic in 14/38 pts. No differences in terms of OS and PFS were found between HCT "frontline *vs* relapse", p=0.72 and p=0.34 respectively, neither between induction treatment with "old *vs* new drugs", p=0.72 and p=0.15 respectively. After induction, 9 pts (13%) achieved complete response (CR), 8 pts (11.3%) achieved a very good partial response (VGPR), 41 pts (58.6%) achieved partial response (PR), 1 patient (1.4%) maintained a stable disease (SD) and 11 pts (15.7%) performed HCT in progression disease (PD).

Results: Overall, 65 pts (93%) achieved a response (CR; n=32, VGPR; n=2, PR; n=31), 2 pts (2.8%) showed PD during or immediately after HCT, 3 pts (4.2%) died for TRM. More in detail a CR was observed in 7/9 pts who underwent HCT in CR, 4/8 in VGPR, 17/41 in PR and 4/11 in PD. Among 65 pts who obtained a response, 35 pts (54%) presented a disease recurrence

in 48% and 54% at 5 and 10 years, respectively. TRM was 14% and 18% at 5 and 10 years, respectively. Acute and chronic GVHD occurred in 37 and 36 pts respectively. Overall survival (OS) and progression-free survival (PFS) at 10 years was 43.1% (range, 32.3 - 57.4) and 25.1% (range, 16.5 - 38.2) respectively (Figure 1).

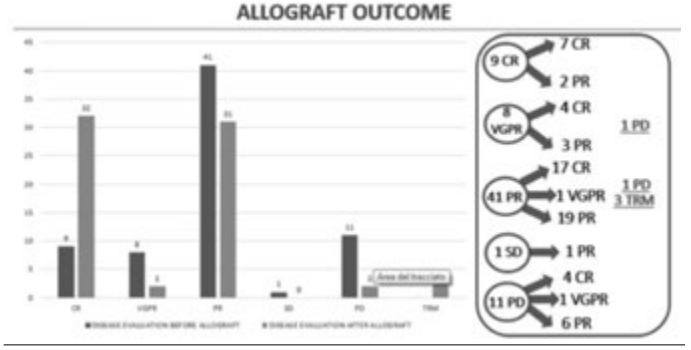

Figure 1.

Summary and Conclusions: Autologous stem cell transplant remains the standard of care for young MM pts but it's not curative. Our retrospective analysis presents some methodological limitations but it shows that the role of HCT is not clear. Physicians should evaluate its combination in prospective trials for young high-risk or relapsed/refractory pts (not beyond the first relapse), in a tandem autologous/allogeneic transplant, with an induction and a possible maintenance based on new drugs.

PF595

CAN STANDARDISATION BE ACHIEVED? ASSESSMENT OF PLASMA CELL MYELOMA MINIMAL RESIDUAL DISEASE TESTING BY FLOW CYTOMETRY: AN INTERNATIONAL INTER-LABORATORY STUDY

Francisco Xavier Hospital, Lisbon, Portugal

Background: Minimal Residual Disease (MRD) testing has been established as a common primary endpoint in Plasma Cell Myeloma (PCM) clinical trials, and is increasingly being used to manage patients with the disease. Much effort has gone into standardising MRD testing by flow cytometry (FC) on PCM patients.
Aims: To assess the implementation of consensus guidelines for technical and reporting aspects of MRD testing by FC in PCM patients in an inter-laboratory study.
Methods: Ten laboratories, adhering to consensus guidelines, were included in this study: 4x US, 1x Spain, 1x Switzerland, 1x Portugal, 1x India, 1x UK and 1x New Zealand. A dilution series of 4 samples were sent to each laboratory. Samples contained stabilised bone marrow cells from a PCM patient mixed with a stabilised peripheral blood stem cell harvest to mimic a PCM patient after induction chemotherapy/stem cell transplant. Samples were manufactured to contain 0% malignant plasma cells (PC) (Sample A), and then approximately 0.1% (Sample B), 0.01% (Sample C), 0.001% (Sample D), 0.0001% (Sample E).
Results: Eight laboratories returned results. All, detected malignant PCs at levels of 0.1%, 0.01% and 0.001% malignant PCs. 6/8 laboratories detected malignant PCs at a level of 0.0001%. 1/8 laboratories erroneously detected a malignant PC population in sample A (0% level). Quantitative data returned by laboratories showed good consensus for detecting malignant PCs at levels of 0.1% (Coefficient of Variation (CV)=28%) and 0.01% (41%) but with greater variation at the levels of 0.001% (CV=153.7%) and 0.0001% (CV=233.1%). Of the laboratories that detected a malignant PC population in all 4 relevant samples (n=6), all showed good assay linearity (R2=0.9986-1.0000; slope value 0.7843-1.3830); however, examples of post analytical (calculation error) and systematic error were identified.Additionally, the median results calculated for laboratories using the Beckman Coulter Navios flow cytometer (n=3) were consistently 1.6 fold higher than laboratories using the Becton Dickinson FacsCanto for samples B-D with a statistically significant difference for sample B (P=0.0336) and sample C (P=0.0398) identified. Only 2 participants using the Beckman Coulter Navios quantified the sample E so we were unable to calculate statistics for this sample. Analysis of marker staining classification (Absent, Weak, Moderate, Strong) was shown to be unreliable with no consensus identified (Figure 1).

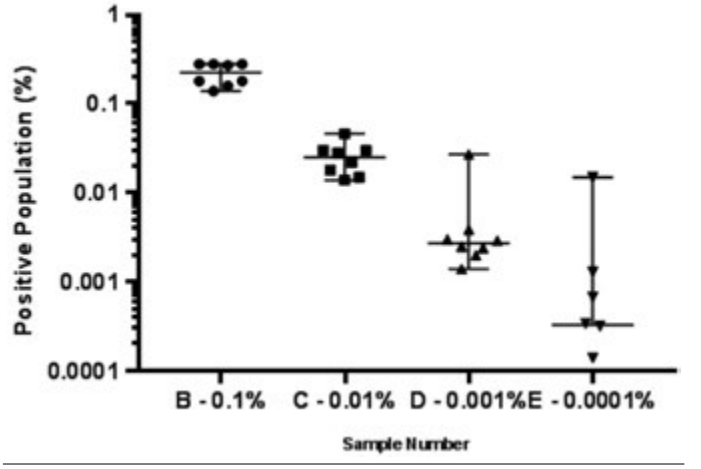

Figure 1.

Summary and Conclusions: In this study, we found that laboratories could reliably detect MRD in PCM patients using FC down to the levels required by current clinical trials (0.01%). Importantly, we have shown that even at levels of 0.001% malignant PCs, well standardised FC assays can attain good consensus important in future clinical trials, thus providing reassurance that PCM MRD testing by flow cytometry is fit-for-purpose when performed in line with international guidelines. Furthermore, we have shown that of the cohort 6/8 laboratories detected a malignant PC population at 0.0001% in line with the theoretical limit of detection of molecular methods of MRD detection. Participant assays showed good linearity down to 0.0001%, allowing the possibility of predicting survival based on log reduction in malignant PC populations in future clinical trials. The consistently different results seen when comparing laboratories using the Beckman Coulter Navios and the Becton Dickinson FacsCanto flow cytometers must be considered when assessing results from clinical trials.

Background: Upregulation of both the vascular endothelial growth factor

(VEGF) and hepatocyte growth factor (HGF) pathways are implicated in tumor survival, growth, angiogenesis, and loss of response to therapy and linked to poor prognosis in relapsed-and-refractory multiple myeloma (RRMM). MP0250 is a first-in-class, tri-specific multi-DARPin® drug candidate neutralizing VEGF-A and HGF as well as binding to human serum albumin to increase plasma half-life. MP0250 shows activity in multiple preclinical tumor models including a MM model in which it enhances the effects of bortezomib in terms of M protein production and bone lysis.
Aims: To determine the safety, tolerability, and efficacy of MP0250 in combination with bortezomib and dexamethasone (dex) and the recommended dose for further development in MM.
Methods: This trial (NCT03136653) is recruiting adults ≥18 years of age with RRMM who have progressed after at least two prior treatment regimens including bortezomib and an immunomodulatory drug (IMiD). A dose-escalation phase (part 1) consisting of two cohorts will define a safe dose of the combination of bortezomib+dex and MP0250 followed by a dose expansion phase. Up to 40 patients will be enrolled. Patients will receive treatment until there is documented disease progression or unacceptable toxicity. The primary endpoint is efficacy in terms of overall response rate (ORR) per International Myeloma Working Group (IMWG) criteria. Secondary endpoints include safety, immunogenicity, progression free survival (PFS) and duration of response (DOR). Exploratory endpoints include Pharmacokinetics and potential biomarkers. The safety analysis set (SAF) is defined as patients who have received at least 1 dose of combination of MP0250 plus bortezomib+dex.
Results: As of 19 February 2018, 8 patients have been treated with 8 mg/kg MP0250 in cohort 1 and were included in the SAF, with the last patient enrolled on 02 January 2018. Median time from initial diagnosis to first dose of MP0250 was 4.8 years (range, 1-10). Median number of prior therapies was 3 (range, 2-5). All 8 patients had been exposed to IMiDs and proteasome inhibitors (PI) and 37.5% were considered PI refractory. The most frequent drug-related grade ≥3 AEs included thrombocytopenia in 3 pts (37.5%) and hypertension in 2 pts (25%). Grade 3 proteinuria and transient grade 3 liver enzyme elevation was seen in 1 patient each (12.5%). One dose-limiting toxicity has been reported in cohort 1 (grade 3 hypertension). There were no infusion-related reactions. All patients treated at the 8 mg/kg dose were evaluable for response assessment. At last follow-up, 5 (62.5%) patients had achieved a partial response. Pharmacokinetic data obtained from the first 3 patients are in agreement with results obtained in the phase 1 study with MP0250.
Summary and Conclusions: Early data from patients treated in cohort 1 with MP0250 plus bortezomib+dex show an acceptable safety profile and promising activity in RRMM patients. Enrollment is ongoing and updated data from cohorts 1 (8 mg/kg) and 2 (12 mg/kg) will be presented.

PF597

STATIN USE IMPROVES MYELOMA-SPECIFIC SURVIVAL AND IS SAFE TO USE IN LYMPHOMA: A POPULATION-BASED STUDY OF 20,464 PATIENTS WITH LYMPHOID MALIGNANCIES DIAGNOSED IN SWEDEN 2007-2013

E. Brånvall[1,*], S. Eloranta[1], S. Ekberg[1], B.M. Birmann[2], K.E. Smedby[3]

[1]Department of Medicine, Solna, Unit for Clinical Epidemiology, Karolinska Institutet, Stockholm, Sweden, [2]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's hospital and Harvard Medical School, Boston, United States, [3]Department of Medicine, Unit for Clinical Epidemiology, Karolinska Institutet, Stockholm, Sweden

Background: Reduced cancer-specific mortality with statin use has been described among patients with several cancer forms, as well as in a few studies of lymphoid neoplasms including multiple myeloma (MM). Statins inhibit cholesterol- and isoprenoid biosynthesis, and *in vitro* data suggest several downstream effect mechanisms inhibiting cancer cell signaling and growth. There is also *in vitro* evidence of inhibited MIP-1a expression in MM, suggesting a potential protective role in MM progression. In lymphoma however, *in vitro* data suggest statins might inhibit rituximab binding to CD20, and concern has been raised that statins could impair rituximab treatment efficacy.
Aims: We aimed to assess if statin use around the time of diagnosis and initial treatment of a lymphoid neoplasm alters lymphoma/MM-specific survival overall or in subtypes.
Methods: Using the Swedish population-based national health care registers: the Cancer Register, Cause-of-Death Register, Prescribed Drug Register, LISA database, and the National Lymphoma Quality Register, we identified all incident diagnoses of major lymphoid neoplasms (non-Hodgkin lymphoma (NHL) subtypes including chronic lymphocytic leukemia (CLL) and MM) from January 1st 2007 until Dec 31st 2013. Persons with any dispensing of statins during a 6-month period before or after diagnosis were considered statin users before or after diagnosis respectively. We used Cox regression models with time-lagged statin exposure in order to avoid reverse causation. Models were adjusted for age at diagnosis, sex, year of diagnosis, education level, and concomitant medication with anticoagulants, diuretics, beta-blockers, ACE inhibitors, calcium blockers and anti-diabetics to capture comorbidity. NHL models were also adjusted for International Prognostic Index score and active lymphoma treatment (yes/no). Follicular lymphoma was divided in treated *versus* not treated patients, in order to assess effect modification in rituximab-treated patients. Statin dose intensity was classified according to the American College of Cardiology/American Heart Association statin guidelines into high, moderate and low intensity therapy where simvastatin, pravastatin, fluvastatin, atorvastatin and rosuvastatin were classified based on average mg/day dispensed during the 6-month period before diagnosis.
Results: There were 20,464 patients with incident lymphoid neoplasms: 12,865 with NHL, 3,279 with CLL and 4,323 with MM. Overall, 20% used statins at the time of diagnosis. Simvastatin accounted for 83% of the statin dispensings; 68% used moderate-intensity and only 4% used high-intensity statin therapy. Pre-diagnosis statin use was not associated with altered lymphoma-specific death among patients with NHL (HR: 0.95 (95% CI: 0.85-1.07)), major NHL subtypes, or CLL. Among patients with MM, statin use was associated with a statistically significant reduced MM-specific mortality (HR 0.81 (95% CI: 0.70-0.95)) (Figure 1). Results were similar for statin use after diagnosis (MM HR 0.73 (95% CI: 0.60-0.89)). There was no evidence of an association between statin dose-intensity and lymphoma/MM-specific death.

Figure 1.

Summary and Conclusions: In this large population-based cohort of lymphoid neoplasm patients, statins were safe to use during lymphoma treatment and were associated with an improved disease-specific survival in MM. Additional analyses of statin use and dose-intensity throughout follow-up and lymphoma/MM-specific outcomes are in progress and will be reported at a later stage.

PF598

A PROSPECTIVE ANALYSIS ON THE FREQUENCY AND PREDICTIVE VALUE OF MINIMAL RESIDUAL DISEASE ASSESSMENT BY FLOW CYTOMETRY AND PET-CT IMAGING AMONG MYELOMA PATIENTS ON/OFF MAINTENANCE

M. Beksac[1,*], G. Cengiz Seval[2], U. Sahin[3], M. Merter[4], S. Ipek[1], E. Ozkan[5], K. Dalva[2]

[1]Hematology, [2]Ankara University School of Medicine, [3]Yildirim Beyazit University Yenimahalle Education and Research Hospital, [4]Firat University School of Medicine, [5]Nuclear medicine, Ankara University School of Medicine, Ankara, Turkey

Background: The IMWG uniform response criteria have been revised to include assessment of marrow and extra-marrow minimal residual disease (MRD) by functional imaging and multi-color flow cytometry (MFC) and/or molecular methods (Kumar et al Lancet 2016).
Aims: The aim of this study was to evaluate MRD by PET CT imaging and MFC among patients who stopped treatment following achievement of immunological complete remission (CR) and completion of induction or first relapse.

Methods: In this ongoing study 62 patients in CR-1 (n:47),CR-2(n:2) or VGPR (n:13) as defined by IMWG criteria and not on any anti-myeloma treatment excluding bisphosphonates (n:2 Denosumab) or Lenalidomide (n:10), Bortezomib (n:2) and Panobinostat-Bortezomib-Dexamethasone (n:1) maintenance were enrolled (Table 1). Bone marrow EDTA anti-coagulated samples have been collected between Nov 2016- February 2018. Patients had immunological evaluation every three months; Flow-MRD and PET CT evaluation at CR staging repeated if found positive. Except for 3 patients, all have received autologous stem cell transplants (ASCT). MRD assessment by MFC using these antibodies CD27PC7, $CD56^{PC5}$, $CD19^{ECD}$, $CD38^{A750}$, $CD138^{APC}$, $CD45^{KO}$, $CD38^{FITC}$, $CD81^{PE}$, $CD117^{PC7}$ Rabbit Immunogloblin Fraction (DAKO X0903) Polyclonal Rabbit Anti-Human Kappa Chains /FITC, Rabbit F(ab')2 (DAKO F0434)and Anti-Human Lambda Chains /PE, Rabbit F(ab')2 (DAKO R0437) analyzed by the Beckman Coulter Cytometer. Flow MRD negativity was accepted as levels clonal plasma cells below the threshold of 10^{-6} Progression Free Survival (PFS) analysis was calculated using the SPSS (IBM SPSS Statistics 21; IBM Corp., Chicago, IL) statistical tool kit.
Results: Among all patients MRD was found to be negative in 34/62 of the cases. Fifteen of these cases were either in the early postASCT/maintenance period or on maintenance with IMID/PI /Denosumab. Except for two, all patients who had stopped treatment in CR due to toxicity or re-imbursement reasons were found to be MRD positive. PET-CT was able to detect residual disease in four cases with a Flow MRD negative result. A strong correlation between Flow and PET results (p=0.01). FCM analysis was repeated with 6 months intervals among 12 patients. MRD positivity was associated with biochemical (4/62) and clinical (4/62) progression within a median follow-up of six months. No progression could be documented within the FCM and PET (-) MRD group. Three-years PFS analysis revealed simultaneous either FCM/PET MRD (+) (n=2) to exert a delay in progression compared to MRD (+) with both methods (n=2) (89.5%±7.1% *vs* 75.0%±21.7%; p:0.88) (Figure 1).

Table 1.

General characteristics of patients	
Age (median, range)	61 (37-80)
Gender, male/female (n)	37 / 25
Chain type, IgA/IgG/light chain (n)	12 / 39 / 11
ISS I/II/III (n)	16/ 32 / 14
FISH, negative/high risk/others/unknown (n)	19 / 10 / 2 / 11
ASCT +/- (n)	52 / 10
Last treatment before MRD, Bortezomib-based/IMiDs/ASCT/others (n)	8 / 18 / 7 / 15
Time from CR to MRD assessment (median, range)	23,5 (4,5-121,7)
Maintenance treatment +/- (n)	15 / 47
Post MRD follow-up period, months (median, range)	6.1 (1-20)

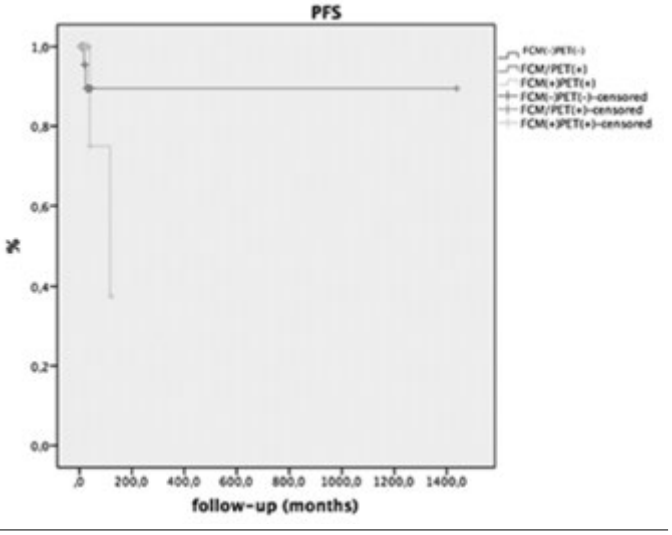

Figure 1.

Summary and Conclusions: In this ongoing prospective study among patients who are on/off treatment, MFC was able to detect MRD in the majority of patients at levels 10^{-6}. With additional patients and follow-up we will be able to observe the impact of Flow-MRD on progression kinetics more accurately.

PF599

EARLY RELAPSE IS A POWERFUL INDEPENDENT NEGATIVE PREDICTOR FOR OVERALL SURVIVAL IN MULTIPLE MYELOMA PATIENTS TREATED WITH NOVEL AGENTS

E. Katodritou[1,*], V. Palaska[1], T. Triantafyllou[1], K. Kokoviadou[2], E. Verrou[1], N. Drougos[1], K. Loga[1], K. Psianou[1], A. Adamoudi[1], E. Fytopoulou[1], E. Giannopoulou[1], N. Karampatzakis[1], I. Batsis[3], K. Keramidioti[1], S. Georgiadou[1], M. Varthaliti[1], V. Gastari[1], C. Chadjiaggelidou[1], G. Kaiafa[4], A. Kioumi[2], I. Sakellari[3], A. Anagnostopoulos[3], P. Konstantinidou[1], E. Terpos[5]

[1]Hematology, Theaganion Cancer Hospital, [2]Hematology, Papageorgiou Genaral Hospital, [3]Hematology and Bone Marrow Transplantation, Papanikolaou General Hospital, [4]Hematology, Ahepa University Hospital, Thessaloniki, [5]Department of Clinical Theraputics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

Background: Novel agents have improved outcomes of Multiple Myeloma (MM) patients yet some patients display early relapse (ER), defined as relapse occurred within 12 months from starting initial therapy.
Aims: The aim of the study was to examine the clinical characteristics related to ER, the impact of ER on survival and possible factors predicting ER, in patients treated upfront with novel agents.
Methods: We reviewed the medical files of patients with symptomatic MM treated with novel agents; eligible for analysis were considered patients who achieved at least partial response (PR) after initial therapy and lived for >12 months. Patients with ER were compared with those who either progressed or continued to response beyond 12 months. Patients characteristics between the 2 groups were compared with standard methods. Progression-free survival (PFS) and overall survival (OS) were plotted with the Kaplan Meier curve. Prognostic factors for ER and OS were evaluated with binary logistic and cox regression analysis, respectively; p<0.05 was considered as statistically significant.
Results: Two hundred and fifty-six consecutive symptomatic MM patients were evaluated (M/F: 129/127, median age 66, range: 37-88, IgG: 138, IgA: 68, light-chain: 41, non-secretory: 9, ISS1: 81, ISS2: 79, ISS3: 96); ER occurred in 22/256 patients (8%). Median age at diagnosis did not differ between the 2 groups; ER patients had more frequently lower platelets, higher β2 microglobulin (β2M), higher bone marrow plasma cell (BMPC) infiltration and advanced ISS stage, compared to others (p<0.05); The number of patients with high risk cytogenetics did not differ between groups (p>0.05); 45% of patients received upfront IMiD-based therapies and 55% bortezomib-based therapies. There was no significant difference in treatments applied in each group either initially or at first relapse; 60/256 (23%) patients underwent autologous stem cell transplantation after induction; patients with ER displayed less frequent complete response (CR) compared to others (18% *vs* 47%; p=0.01). The median time to progression for ER patients was 7 months (95% CI: 5-8.7 months) *vs* 35 months (95% CI: 30-39 months) for the remaining patients (p<0.001); PFS2 was significantly shorter in patients with ER compared with the rest (49 months *vs* 19 months; p<0.001). After a median follow up of 76 months (95% CI: 69-82), the median OS for patients with ER was 25 months (95% CI: 12-37) *vs* 57 months (95% CI: 51-63) for those who continued to respond beyond 12 months (p<0.001); ER and high-risk cytogenetics were the most powerful negative predictors of OS in the multivariate cox regression analysis (p<0.001; HzR: 3.7 and p=0.009; HzR: 1.9). In the univariate logistic regression analysis, platelets <100.000/ L, hemoglobin <10g/dL, β2M>5.5mg/dL and bone marrow (BMPC) plasma cells >50%, were independent predictors for ER (p<0.05); platelets <100.000/ L and BMPC >50% were significant predictors for ER in the multivariate logistic regression analysis (OR: 4.9, p= 0.01 and 3.6, p=0.03, respectively).
Summary and Conclusions: Our data demonstrate that despite the use of novel agents, ER remains a clinical issue and correlates significantly with parameters related to high tumor burden. Platelets <100.000/ L and BMPC>50% were independent predictors for ER; ER led to significantly shorter PFS2 and a 4-fold increase of the probability of death, suggesting that patients displaying ER should be treated with an aggressive therapeutic approach in the early lines of myeloma therapy.

PF600

SENSIVITY AND CLINICAL VALUE OF POSITRON EMISSION TOMOGRAPHY/COMPUTED TOMOGRAPHY AND WHOLE BODY MAGNETIC RESONANCE IMAGING TO ASSESS BONE DISEASE IN NEWLY DIAGNOSED MULTIPLE MYELOMA

E. Fernandez-Poveda[1,*], V. Cabanas-Perianes[1], M.-J. Moreno-Belmonte[1], M. Blanquer-Blanquer[1], F. Guzman-Aroca[1], B. Torregrosa-Sala[1],

D. Abellán-Rivero[1], A. Lopez-Sanchez[1], M. Berenguer-Piqueras[1], F. Labbadia[1], R. Perez-Lopez[1], J.-J. Cerezo-Manchado[1], M. Moya-Arnao[1], A. Martinez-Marin[1], B. Navarro-Almenzar[1], J.-M. Moraleda-Jimenez[1]

[1]Hospital Clinico Uiniversitario Virgen de la Arrixaca, Murcia, Spain

Background: Bone disease extension in symptomatic multiple myeloma has prognostic implications. However, new image methods are necessary to establish the diagnosis according to the updated International Myeloma Working Group criteria (IMWG).
Aims: Our aim was to compare the sensitivities of whole body magnetic resonance imaging (WB-MRI) and 18-fluoro-deoxyglucose positron emission tomography/computered tomography (PET/CT) for the detection of skeletal lesions, and to determine if additional lesions detected by MRI are of clinical relevance.
Second aim was to detect differences in the assessment of extramedullary disease and bone fractures.
Methods: MRI and PET/CT were performed in the initial work-up to 54 patients diagnosed with symptomatic multiple myeloma at our institution between 2013 and 2017. Any focal lesion seen on PET-CT ≥5 mm in size or >1 focal lesion in WB-MRI ≥5 mm was considered a myeloma defining event (MDE) according the IMWG. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of PET-CT to detect MDE, extramedullary disease and fractures at diagnosis were assessed. PET-CT was compared to WB-MRI using Cohen`s quadratic-weighted Kappa.
Results: Baseline characteristics of the 54 patients are shown in Table 1.
PET-CT showed a very low PPV (59.4%) and moderate NPV (81.8%) to detect MDE compared to WB-MRI with a low concordance rate (Kappa 0.39, p=0.003). However, PET-TC findings matched those of WB-MRI in the evaluation of extramedullary disease at diagnosis with a Kappa score =1 (p<0.001). Our data showed a high PPV (100%) and low NPV (72,5%) of PET-TC to detect fractures, with high level of disagreement between the two techniques (Kappa score 0.23, p=0.009).

Table 1.

Baseline Characteristics					
Gender	n	%	Durie-Salmon	n	%
Female	29	53,7	IA	11	20,4
Male	25	46,3	IB	2	3,7
			IIA	15	27,8
Age			IIB	0	0
mean (range)	63,9 (39-81)		IIIA	21	38,9
median	64,5		IIIB	5	9,3
MM	n	%	ISS	n	%
IgG K	17	31,5	I	27	50
IgG L	13	24,1	II	16	29,6
IgA K	7	13	III	11	20,4
IgA L	4	7,4	R-ISS	n	%
BJ K	5	9,3	I	26	48,1
BJ L	4	7,4	II	24	44,4
Others	4	7,4	III	4	7,5
ECOG	n	%	High-risk genetic*	n	%
0	10	18,5	Positive	4	7,5
1	24	44,4	Negative	50	92,5
2	17	31,5			
3	3	5,6	* t (4;14), t (14;16), P53 deletion		

ISS: International staging system
R-ISS: Revised international staging system

Summary and Conclusions: Our data indicate that WB-MRI is a better technique than PET-TC to detect myeloma defining events. Although extramedullary disease is equally assessed by both techniques, PET-TC is less useful in the diagnosis of bone fractures. Overall WB-MRI seems to be more useful than PET-TC in newly diagnosed myeloma multiple patients.

Myeloproliferative neoplasms – Biology & Translational Research

ANTI-SLAMF7 ANTIBODY SUPPRESSES FIBROCYTE DIFFERENTIATION AS A POTENT THERAPEUTIC AGENT FOR MYELOFIBROSIS

T. Maekawa[1,*], Y. Osawa[1], T. Izumi[1], S. Nagao[1], K. Takano[1], Y. Okada[1], N. Tachi[1], M. Teramoto[1], T. Kawamura[1], T. Horiuchi[1], R. Saga[1], S. Kato[1], T. Yamamura[1], J. Watanabe[1], A. Kobayashi[1], S. Kobayashi[1], K. Sato[1], M. Hashimoto[2], S. Suzu[2], F. Kimura[1]

[1]Division of Hematology, Department of Internal Medicine, National Defense Medical College, Tokorozawa, [2]Center for AIDS Research, Kumamoto University, Kumamoto, Japan

Background: Myelofibrosis (MF) occurrence can be attributed to various pathogenic mechanisms, such as elevated circulating cytokine levels, cellular interactions and genetic mutations. A recent study showed that the neoplastic clone of fibrocytes, spindle-shaped fibroblast-like blood cells derived from monocyte lineage, was essential in primary MF pathogenesis and that serum amyloid P (PRM-151), which suppressed fibrocyte differentiation, markedly improved survival and MF in a murine xenograft model. Using a romiplostim (Rom)-induced murine MF model, we demonstrated that fibrocyte differentiation could be directly induced by myeloproliferative leukaemia protein (MPL; TPO receptor) activation and lead to progression of MF. Fibrocytes are now one of the possible therapeutic targets for MF. We previously demonstrated using DNA microarray analysis that in comparison with macrophages, human fibrocytes expressed SLAMF7. Elotuzumab (Elo) is an anti-SLAMF7 antibody recently used for treating relapsed/refractory multiple myeloma, with encouraging results and promising safety. Here, we try to elucidate the efficacy of Elo as a therapeutic agent for MF.
Aims: This study aimed to investigate the effects of Elo against human fibrocyte differentiation promoting MF *in vitro* and *in vivo*.
Methods: We compared the SLAMF7 expression in monocytes of the peripheral blood between patients with MF and healthy donors. We cultured human peripheral blood mononuclear cells (PBMCs) with or without Elo *in vitro* to evaluate whether Elo suppressed fibrocyte differentiation and calculated the spindle-shaped cells ratio. Then, we cultured human PBMCs by combining Elo and natural killer (NK) cells, Rom, ruxolitinib or IFNα2 to evaluate their interactions. To evaluate the efficiency of Elo for a Rom-induced murine MF model, we transplanted human peripheral blood or cord blood stem cells into NOG mice with 2.5-Gy radiation, and administered 1 mg/kg Rom once a week after 8-12 weeks of transplantation. Humanised NOG mice were sacrificed 1 to 2 weeks after Rom administration, and MF grade of bone marrow and spleen weight were examined.
Results: In comparison to healthy donors, the SLAMF7 expression in monocytes of the peripheral blood was significantly increased in patients with MF. While Elo independently inhibited fibrocyte differentiation from human PBMCs, NK cells augmented the inhibitory effect. Fifty and 100 g/mL of Elo showed comparable inhibitory effect for fibrocyte differentiation *in vitro*. Elo represented the inhibitory effect even after Rom administration, and addition of ruxolitinib diminished the inhibitory effect of Elo on fibrocyte differentiation. IFNα2 demonstrated the severe cytotoxic effect. In humanised NOG mice, Elo administration suppressed MF development. Amelioration of splenomegaly and anaemia was also observed in mice treated with Elo and Rom than Rom alone.
Summary and Conclusions: The SLAMF7 expression was elevated in monocytes of patients with MF. Anti-SLAMF7 antibody Elo administration significantly suppressed fibrocyte differentiation *in vitro*, and ameliorated MF *in vivo*. Elo could be a potential therapeutic agent for MF, and this effect of Elo may be partly dependent on the JAK–STAT pathway.

PF602

HETEROZYGOUS CONSTITUTIVE CALR DEL52 KNOCK-IN MICE SHOW A TRANSPLANTABLE ET-PHENOTYPE WHILE THE HOMOZYGOUS STATE IS LETHAL DUE TO A HEART DEFECT

T. Balligand[1,*], J.-P. Defour[1], Y. Achouri[2], G. Gaudray[1], S.N. Constantinescu[1]

[1]Ludwig Cancer Research / de Duve Institute, [2]de Duve Institute, Woluwe Saint-Lambert, Belgium

Background: Frame-shifting mutations (-1/+2) of the human calreticulin (*CALR)* gene are responsible for 25-30% of cases of essential thombocythemia (ET) and primary myelofibrosis. The mutant CALR proteins are now known

to activate the thrombopoietin receptor and therefore induce cytokine-independent hyper-proliferation of megakaryocyte progenitors (Chachoua *et al.*; Marty *et al.*; Elf *et al.*; Araki *et al.*). We have already shown that CRISPR-Cas9 engineered homologous mutations in the murine *Calr* gene are able to induce an identical oncogenic effect *in vitro* in a mouse-derived cell-line at an endogenous level of expression and that murine CALR mutants induce persistent JAK2 signaling in the presence of TpoR (Balligand *et al.*).
Aims: We aimed to generate a mouse model of myeloproliferative neoplasms (MPNs) that would be physio-pathologically relevant to the development process of the disease.
Methods: We microinjected CRISPR/Cas9 constructs for introducing del52 *Calr* along with a small oligoDNA as repair template into fertilized B6D2 mouse zygotes. Allele burden analysis was carried out by PCR amplification of the exon 9 of the *Calr* gene before analysis using a GeneScan machine.
Results: We observe that our *Calr* del52/WT mice develop an ET-phenotype characterized by a 1.5-fold increase of platelet levels in peripheral blood as soon as 11 weeks of age, compared to *Calr* WT/WT littermates. Total white blood cell levels showed a 2-fold increase starting at 52 weeks of age. Total red blood cell levels were unchanged across the two groups. Anatomohistopathology shows a significant 1.4-fold increase in megakaryocyte size and a significant 1.5-fold increase in megakaryocyte numbers in the bone marrow. No hematopoiesis was evident in the spleen with the absence of splenomegaly. Transplantation of different ratios of *Calr* del52/WT and *Calr* WT/WT bone marrow in lethally irradiated wild-type B6D2 mice reproduces a significant 1.5-fold increase in platelet level that starts at 14 weeks post-transplantation (Figure 1A). No differences in WBC or RBC levels were observed until 60 weeks of age. We monitored the allele burden for the *Calr* del52 mutation and observed an increasing trend in the mice reconstituted with 80% or with 50% of *Calr* del52/WT bone marrow that became statistically significant starting at 150 days post transplantation, effectively showing that the *Calr* del52/WT hematopoietic population is achieving dominance over the *Calr* WT/WT population (Figure 1B). Finally, we could not obtain any *Calr* del52/del52 pups by crossing our mice, showing that the homozygous state of the mutation is lethal during embryogenesis. We show that *Calr* del52/del52 embryos have heart development defects characterized by a thinning of the ventricular walls much like what has been described with the *Calr* knock-out model of Michalak (*J Cell Biol. 1999 Mar 08;144(5):857-68*). This brings evidence that the loss of the C-terminus of the protein, which has an important calcium-buffering role, is sufficient to reproduce the heart development defects observed with loss of the full protein.

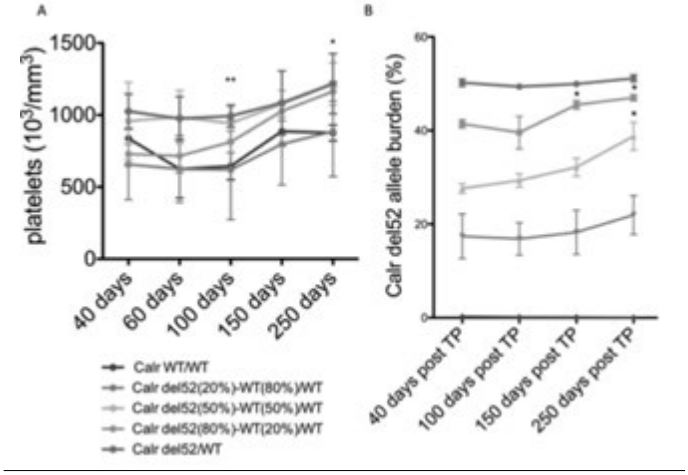

Figure 1.

Summary and Conclusions: We report successful creation of a mouse model of the type-1 mutated *Calr* induced MPNs, that shows an ET-phenotype that is transplantable with evidence of a slow expanding dominance over co-transplanted wild-type bone marrow. We also show that total loss of the C-terminus of the calreticulin protein is sufficient to disrupt critical calcium signaling that is important for heart embryogenesis by reproducing the phenotype observed in the total absence of the calreticulin protein.

PF603

PHARMACOLOGIC TARGETING OF NEOPLASTIC STEM CELLS IN HUMAN MAST CELL LEUKEMIA

Background: Leukemic stem cells (LSC) are increasingly recognized as new promising targets of potentially curative therapies in various forms of leukemia. Systemic mastocytosis (SM) is a rare hematopoietic neoplasm characterized by an abnormal expansion of mast cells (MCs) in the bone marrow (BM) and other organs. Whereas patients with indolent SM (ISM) have a normal life-expectancy, patients with advanced forms of SM have a grave prognosis. MC leukemia (MCL), the rare leukemic variant of advanced SM, is defined by a rapid expansion of immature MCs in various hematopoietic organs and a poor prognosis with short survival times. The role of LSC in the development and progression of aggressive SM (ASM) and MCL is poorly understood.
Aims: We have recently been able to show that the putative MCL LSC reside within a $CD34^+$ fraction of the neoplastic clone. The aims of the present study were to characterize the cell surface phenotype, frequencies, and functional properties of LSC in patients with advanced SM and MCL and to explore the effects of various targeted drugs on growth and survival of these cells.
Methods: LSC were purified from BM mononuclear cells by flow sorting and injected intravenously in NOD-SCID-IL-$2Rg^{-/-}$mice exhibiting human membrane-bound SCF (NSG_{SCF}). Engraftment was assessed by analysing the murine BM for the presence (percentage) of human $CD117^+$ cells. Phenotyping studies were performed on whole BM after erythrocyte lysis. Effects of targeted drugs on survival of LSC were assessed by multi-color flow cytometry and Annexin-V and DAPI staining.
Results: We found that the NSG_{SCF}-engrafting leukemia-initiating LSC in MCL reside in a $CD34^+/CD38^-$ fraction of the clone, similarly to LSC in CML and normal hematopoietic stem cells. As assessed by cell-dilution experiments, 0.0003-0.0045% of all $CD45^+$ cells and as little as 500 $CD34^+$ cells were found to induce robust MCL-like engraftment in NSG_{SCF} mice. Phenotypic assessment of LSCs from patients with MCL and ASM by flow cytometry and gene chip analysis revealed a distinct phenotype. Compared to $CD34^+/CD38^-$hematopoietic stem cells from the BM of healthy donors, MCL LSCs expressed higher levels of CD30 (Ki-1) but lower levels of CD117 (KIT). In 3/10 MCL patients (30%) and 1/11 ASM patients (9%) MCL LSC expressed elevated levels of IL-1RAP and in 1/12 MCL patients (8%) and 3/16 ASM patients (19%) LSC expressed elevated levels of CD52 (CAMPATH-1). Furthermore, CD371 (CLL-1) and CD33 (Siglec-3) were overexpressed on $CD34^+/CD38^+$ progenitor cells in MCL compared to healthy BM. Application of the KIT-targeting drug midostaurin or the CD33-targeting drug gemtuzumab-ozogamicin (GO) as single agent was not able to induce apoptosis in primary MCL LSC. However, a combination of these two agents produced a synergistic apoptosis-inducing effect on LSC. Moreover, pre-incubation with GO or a combination of GO and Midostaurin were found to inhibit the engraftment of MCL LSC in NSG_{SCF} mice. Finally, we were able to demonstrate that treatment of MCL or ASM patients with midostaurin is able to reduce the numbers (percentage) of $CD34^+/CD38^-$cells in the BM of these patients, although LSC were never completely eliminated.
Summary and Conclusions: Together, we have characterized the phenotype of MCL LSC and identified clinically relevant molecular targets in these cells. Since targeted drugs are indeed able to counteract growth of MCL LCS, our studies may have clinical implications and may help develop curative treatment approaches in this fatal leukemia.

[1]CRIMM - Hematology, Careggi Hospital, [2]CRIMM - Hematology, [3]Hematology, University of Florence, Florence, [4]Bioinformatics, Prato Hospital, Prato, [5]Hematology, Catholic University, Rome, [6]Hematology, Pavia University, Pavia, [7]Hematology, Bergamo Hospital, Bergamo, [8]Hematology, Tor Vergata University, Rome, [9]Hematology, Brescia Hospital, Brescia, Italy

Background: The mechanisms of evolution of myeloproliferative neoplasms

(MPN) into secondary acute myeloid leukemia (sAML) are not fully understood. Molecular studies described heterogeneous leukemogenesis patterns depending on persistence or loss of the MPN driver mutation in the predominant clone. Mutations of *de novo* AML are typically absent in sAML, conversely enriched in TP53 mutations; in 20-30% of sAML, preexisting MPN-related driver mutations are lost at evolution. Data on phenotypic features of sAML are scarce.
Aims: We studied a large set of sAML by a systematic phenotypic study aimed at highlighting distinct features and potentially getting insight into leukemogenesis.
Methods: Inclusion required sAML diagnosis according to WHO and availability of a pre-defined minimum set of phenotypic data. Flow cytometry FCS files were sent to coordinating center (Florence) for central analysis. Major cell compartments were identified by FSC/SSC, reactivity for CD45/CD34 and lineage-specific antigens; a total of 34 parameters were expressed as mean intensity and percentage of positivity. FSC/SSC and antigen intensity were normalized to internal T lymphocytes and negative controls. A cohort of 114 *de novo* AML cases observed in Florence was analyzed in parallel.
Results: From 2007 to 2017, 103 sAML pts were enrolled, including 32 (31.1%) with sAML after PMF, 69 (67.0%) after PV/ET and 2 after unclassifiable MPN. Median age at evolution was 66y (43-90 y); time from MPN diagnosis to sAML was 10.4y (0.3-27.1y). As per driver mutation status at sAML, 58 had *JAK2*V617F, 19 *CALR* mutation, 4 *MPL* mutation; 12 patients were triple-negative, including 6 who converted to *JAK2*-wt sAML; data were not available in 10 cases. The median distribution of compartments was: blasts 24.7%, granulocytic cells 22.9%, monocytic 14.6%, erythroid 5.5%, eosinophil 0.5%, basophil 1.2% and dendritic cells 2.6%. The comparison between *JAK2+* and *CALR+* subsets highlighted a higher involvement of monocytic lineage in the former (28.5% *vs* 3.1%; p=0.010) without other meaningful difference in phenotypic parameters. In the comparison between *de novo* and sAML, several parameters were found to differ significantly, either for blasts and maturing cells. Blasts from sAML displayed higher CD34 expression (96% *vs* 64%; p<0.0001), as expected from different incidence in NPM1+ cases (0.9% *vs* 26.3%), correlating with reduced CD34 positivity. Granulocytic cells were more represented in sAML (22.9% *vs* 15.0%; p=0.0031), consistent with the underlying MPN. Noteworthy, dendritic cells were relatively expanded in sAML (2.6% *vs* 0.51%; p<0.0001) and represented the predominant population within leukemic clone in 12 (11.7%) sAML cases *vs* 3 (2.6%; p=0.0135) in *de novo*. By hierarchical clustering analysis of 44 sAML cases where extensive genetic data were available we observed a strong tendency for sAML to segregate from *de novo* AML (Figure 1; p<0.0001). This allowed also the identification of smaller clusters sharing genotypic abnormalities beyond driver mutations (*i.e.* TP53); their backward analysis highlighted a recurrent phenotypic signature with multiple cell populations identified by APS tool (Figure 1).

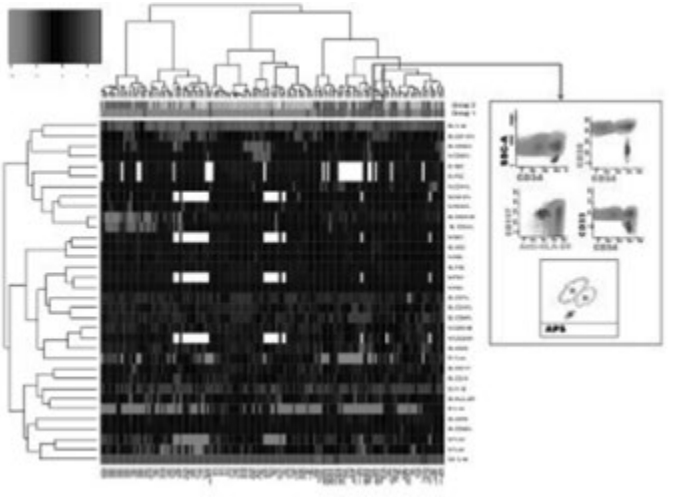

Figure 1.

Summary and Conclusions: A systematic analysis of phenotypic profile of sAML revealed common features distinct from *de novo* AML, largely independent from MPN driver mutation status, involving both immature and maturing cell compartments. Some findings (*i.e.* dendritic cell expansion, enrichment for genotypes in unique phenotypic clusters) deserve further studies and might be relevant for understanding mechanisms of clonal progression and leukemogenesis.

PF605

POTENT ACTIVITY OF AZACITIDINE ON LEUKEMIA-INITIATING CELLS IN A XENOGRAFT MODEL OF JUVENILE MYELOMONOCYTIC LEUKEMIA

M. Erlacher[1,*], C.F. Krombholz[1], S. Sushree[1], K. Aumann[2], C. Niemeyer[1], C. Flotho[1]

[1]Division of Pediatric Hematology and Oncology, [2]Institute of Pathology, University Medical Center Freiburg, Freiburg, Germany

Background: Juvenile myelomonocytic leukemia (JMML) is an aggressive myeloproliferative neoplasm of early childhood, often with fatal outcome. Hematopoietic stem cell transplantation is required in most cases. The driving force of JMML is deregulated activation of the RAS signaling pathway. In addition, epigenetic modifications are disease drivers and affect clinical picture and prognosis. In line with this, the clinical efficacy of the DNA-demethylating agent azacitidine was demonstrated in a retrospective case series, which led to an ongoing trial for prospective evaluation of azacitidine in children with JMML (ClinicalTrials.gov NCT02447666).
Aims: We used our previously developed xenotransplantation model to gain further insight into the antileukemic activity of azacitidine in JMML.
Methods: Newborn Rag2-/-gc-/- mice were sublethally irradiated and transplanted with 1x10^6 primary JMML cells. Upon stable xenologous engraftment, mice were treated with azacitidine (3mg/kg/day i.p.), cytarabine (20mg/kg/day i.p.) or saline. Recipient mice received 2 or more treatment cycles (*i.e.* 5 days treatment+9 days of recovery) and were then analyzed in detail by flow cytometry and histopathology. Human leukemic cells were extracted from bone marrow and subjected to methylome analysis (Infinium 450K arrays). Reactivation of endogenous retroviral elements was analyzed by qRT-PCR.
Results: Xenotransplantation of primary JMML cells reproduced a characteristic JMML phenotype with chronic disease course. Epigenomes were highly comparable between patient samples and human cells isolated from recipient mice 8 weeks after transplantation. After two treatment cycles, both azacitidine and cytarabine strongly reduced JMML infiltration in all organs analyzed. However, only azacitidine but not cytarabine depleted early CD34+ stem and progenitor cells within the human leukemia population. Accordingly, human cells isolated from azacitidine-treated mice did not initiate leukemia in secondary recipients while leukemia cells isolated from cytarabine or mock-treated animals were serially transplantable. When recipient mice treated with two cycles of azacitidine or cytarabine, were analyzed 9 weeks after cessation of treatment, partial recovery of leukemia was observed in all mice but the suppressive effect was more sustained in the azacitidine group. The strong anti-leukemic effects of azacitidine *in vivo* were accompanied by dramatic global DNA demethylation with a complete loss of fully methylated CpG sites. As a result, the profiles of azacitidine-treated JMML cells resembled more healthy human CD34+ cells than mock-treated JMML. In addition, azacitidine led to reexpression of endogenous retroviral sequences. Cytarabine neither induced epigenetic changes nor reactivated endogenous retroviral elements in JMML cells.
Summary and Conclusions: Both cytarabine and azacitidine repress JMML in xenograft mice. However, only azacitidine but not cytarabine efficiently targets leukemia-initiating cells and abrogates their retransplantation capacity. Cellular effects of azacitidine include dramatic global DNA demethylation and reactivation of endogenous retroviral sequences.
In sum, azacitidine-mediated reversal of aberrant DNA methylation patterns present in JMML results in efficient suppression of leukemia growth in xenograft mice. Most importantly, azacitidine depletes CD34+ leukemic stem cells *in vivo* and abrogates their retransplantation capacity.

PF606

PATIENT-DERIVED INDUCED PLURIPOTENT STEM CELLS REVEALED CALCIUM/CALMODULIN DEPENDENT PROTEIN KINASE 2 AS A POTENTIAL THERAPEUTIC TARGET OF MYELOFIBROSIS

M. Miyauchi[1,*], K. Taoka[1], Y. Masamoto[1], S. Yamazaki[1], S. Arai[1], M. Kurokawa[1]

[1]Department of Hematology and Oncology, The University of Tokyo, Graduate School of Medicine, Tokyo, Japan

Background: Myelofibrosis (MF) is a myeloproliferative neoplasm characterized by megakaryocytic atypia, fibrosis in bone marrow, and extramedullary hematopoiesis. Although mutational analyses reveal that about 90% of patients with primary MF harbor JAK2, CALR or MPL mutation that constitutively activates JAK-STAT pathway, the outcome of JAK2 inhibitor treatment for MF patients still remains to be improved. However,

only a limited number of humanized disease-models are currently available to develop a novel therapeutic strategy for MF. We have previously reported that induced pluripotent stem cells (iPSCs) established from MF patients (MF-iPSCs) by using retroviral vectors recapitulated the disease phenotype (Hosoi *et al.* 2014), indicating that MF-iPSCs are one of the useful humanized disease-models of MF.
Aims: The aim of the present study is to identify novel therapeutic targets of MF.
Methods: We have established iPSCs from three independent MF patients harboring a JAK2 V617F, CALR type 1, or CALR type 2 mutations by using integration-free episomal vectors and confirmed that established MF-iPSCs harbored the identical mutations to parental cells. After hematopoietic differentiation, we obtained hematopoietic progenitor cells (HPCs) immunophenotypically defined as CD34+/CD43+ cells for further analyses.
Results: Viability assays revealed that JAK2 inhibitors (Ruxolitinib and HSP90) impaired cell survival of MF-HPCs compared to normal-HPCs, suggesting that MF-HPCs also reproduce drug-sensitivity. To investigate therapeutic targets of MF, we optimized culture condition of HPCs to perform compound screening. By the use of small chemical library containing 192 compounds and two MF-iPSCs harboring a JAK2 or CALR mutation, we identified KN93, calcium/calmodulin dependent protein kinase (CAMK) 2 inhibitor, as a compound which inhibited the viability of MF-HPCs from all three patients in dose-dependent manner, compared to normal-HPCs. For validation, we used Trifluoperazine (TFP), another CAMK inhibitor and TFP had similar inhibitory effects on MF-HPCs, indicating that CAMK2 is a candidate of therapeutic target for MF. To address the efficacy of CAMK2 inhibition in other models mimicking MF, we used Ba/F3 mouse cell line ectopically expressing MPL W515L mutant (Ba/F3_MPLmu; IC50 of ruxolitinib=112 nM), along with ruxolitinib-resistant Ba/F3_MPLmu (Ba/F3_MPLmu_R; IC50 of ruxolitinib=642 nM) cells established through one-month exposure to ruxolitinib. KN93 and TFP decreased cell growth, induced apoptosis, and suppressed the phosphorylation of Stat5, a major signaling event in MF, in both Ba/F3_MPLmu_R and Ba/F3_MPLmu cells. Moreover, combination of CAMK2 inhibitors and ruxolitinib induced apoptosis and inhibited the phosphorylation of Stat5 more efficiently than single agent, suggesting that CAMK2 inhibitors and ruxolitinib exhibited a cooperative effect against MF cells. To address the effectiveness of CAMK2 inhibition in primary samples, we used CD34+ cells isolated from peripheral blood mononuclear cells of MF patients. Although either KN93 or ruxolitinib inhibited the colony forming capacity of primary MF cells with similar efficiency, combination of KN93 with ruxolitinib showed cooperative inhibition. Taken together, these findings indicate that CAMK2 would be a therapeutic target of MF patients.
Summary and Conclusions: In conclusion, we established MF-iPSCs form three independent patients harboring a JAK2 V617F, CALR type 1, or CALR type 2 mutations. Compound screening assay of MF-HPCs with small chemical library identified CAMK2 as a potential therapeutic target of MF.

PF607

MUTATIONAL MECHANISMS OF EZH2 INACTIVATION IN MYELOID NEOPLASMS

A. Chase[1,*], J. Score[1], F. Lin[1], C. Bryant[2], K. Waghorn[1], A. Villasante[3], T. Ernst[4], N. Cross[1]

[1]University of Southampton, Salisbury, [2]University of Southampton, Southampton, United Kingdom, [3]Department of Biomedical Engineering, Columbia University, New York, United States, [4]Universitätsklinikum Jena, Jena, Germany

Background: The polycomb repressive complex 2 (PRC2) component EZH2 catalyses the trimethylation of histone H3 lysine 27 (H3K27), a mark associated with transcriptional repression. Inactivating EZH2 mutations are seen in myeloid malignancies and we have previously shown that missense mutations within the catalytic SET domain and neighbouring CXC domain can result in loss of catalytic activity (See Table 1, mutations 17, 18, 19). The significance of missense mutations outside of these regions however is unclear. The majority of missense mutations outside of the SET/CXC domains fall within domains DI and DII suggesting that they affect function.
Aims: To determine the functional consequences of non-SET/CXC domain missense mutations.
Methods: (1) The PRC2 complex was isolated by immunoprecipitation from Sf9 insect cells transfected with EED, SUZ12 and wild type (WT) or mutant FLAG-EZH2. PRC2 histone methylation activity was assessed in an *in vitro* reaction with histones as substrate and S-adenosyl methionine as a methyl donor. (2) A murine Ezh2-null induced pluripotent stem (iPS) cell line, EZH2 Δ/Δ clone 10 (Villasante *et al.*, Cell Cycle 2011;10:1488-98) was transiently transfected with WT or mutant EZH2. H3K27 methylation was then measured by immunostaining with anti-H3K27me3 followed by flow cytometry. (3) Splicing was assessed by PCR on cDNA extracted from patient leukocytes using primers in flanking exons. Exon 8 mutations were further assessed using the pSliceExpress minigene system with transfection into HEK293 and HeLa cells.
Results: The *in vitro* methylation assay on isolated PRC2 and histones demonstrated non-SET/CXC domain mutations (See Table 1, mutations 4, 6, 8) retained H3K27 trimethylation activity. Since in the cellular context PRC2 interacts with accessory proteins which may differentially interact with WT and mutant EZH2 to affect function, we developed an EZH2-null iPS cell-based assay. As expected, transfection of WT EZH2 into the EZH2-null iPS cell line resulted in gain of H3K27 methylation whilst transfection of EZH2 with catalytically inactive SET domain mutations (muts. 18, 19) showed no change. Transfection with domain DI and DII mutations showed differential effects with all DI mutations showing complete or partial loss of methylation activity (muts. 1-5) whilst the majority of DII mutations retained full activity (muts. 8-12, 14). Using RT-PCR we then examined the effect of missense mutations on splicing. Single mutations in exons 5, 6, 7 and 14 (muts. 1, 6, 7, 16) had no effect on splicing whilst 4/4 exon 8 mutations, encoding most of DII, resulted in complete skipping of exon 8 or partial loss of exon 8 due to use of a cryptic splice site (muts. 10, 11, 12, 14). Aberrant splicing was confirmed using a minigene assay for all four exon 8 mutations plus a further three exon 8 mutations for which cDNA was not available (muts. 8, 9, 13).

Table 1.

EZH2 mutation details and assay results.

Mutation No.	Variant (NM_004456)	Exon	Domain	In-vitro histone methylation assay	Cell-based methylation assay	Splicing

17	c.1728C>G p(C576W)	15	CXC	Inactive[1]	ND	ND
18	c.2068C>T p.(R690C)	18	SET	Inactive[1]	Inactive	ND
19	c.2191T>G p.(Y731D)	19	SET	Inactive[1]	Inactive	ND

(1) Data published in Ernst et al, Nat. Genet. 2010, 42(8):722-6.

Summary and Conclusions: The majority of EZH2 missense mutations outside of the SET/CXC domains lie within domains DI and DII. A combination of histone methylation and splicing assays has shown these to have differential functional mechanisms. DI mutations affect catalytic activity of the PRC2 complex in a cellular context whilst the majority of DII mutations fall within exon 8 and affect splicing. The pathogenic consequences of DI and DII missense mutations is therefore consistent with our current understanding of EZH2 as a tumour suppressor gene in myeloid malignancy

PF608

MUTANT CALRETICULINS ASSOCIATED WITH MYELOPROLIFERATIVE NEOPLASM RETAIN *IN-VITRO* CHAPERONE ACTIVITY

A. Roy[1,*], D. Colau[1], C. Pecquet[1], E. Leroy[1], I. Chachoua[1], E. Fertig[2], S.N. Constantinescu[1]

[1]Signal Transduction Unit, Ludwig Institute for Cancer Research, Universite catholique de Louvain, Brussels, Belgium, [2]Laboratorul de Patologie Ultrastructurala, Institutul National Victor Babes, Bucharest, Romania

Background: Around 15% of myeloproliferative neoplasms have recently been linked to calreticulin (CALR) mutations. The mutant CALRs induce aberrant, persistent JAK2 dependent-thrombopoietin receptor (TpoR)/MPL

signaling and autonomous proliferation of Ba/F3 TpoR cells. The dependence on TpoR and JAK2 explains the clinical observation of thrombocytosis and the megakaryocyte hyperplasia in the bone marrow. However, the mutant CALRs may have other biological consequences that are yet to be unraveled. CALR is an endoplasmic reticulum (ER) resident molecular chaperone that helps in polypeptide folding through lectin-dependent and peptide-dependent mechanisms. Literature also indicates that mutations in CALR can affect its chaperone activity. We examined HLA Class I surface expression in UT7-TpoR cells expressing mutant CALRs (CALR del52 and CALR ins5) and found decreased cell-surface levels when compared to UT7-TpoR-CALR WT cells. We asked whether this is the result of impaired chaperone activity by the mutant CALRs.
Aims: In this study, we analyzed the *in-vitro* chaperone activity of the two CALR mutants – type I (CALR del52) and type II (CALR ins5).
Methods: Recombinant CALR WT, CALR del52 and Malate Dehydrogenase as well as purified IgY and pre-formed HLA-A2 complex were used to study the *in-vitro* chaperone activity of CALR. Ba/F3 cells expressing either CALR WT, CALR del52 or CALR ins5 was used for immunoprecipitation assays. Immunofluorescence staining of the ER followed by confocal microscopic observation was used to determine the morphology of ER.
Results: We performed an *in-vitro* chaperone activity assay using recombinant CALR WT and CALR del52 with purified HLA-A2 complex. In this assay, CALR del52 was observed to be as efficient a chaperone as CALR WT. Moreover, we used two other substrates- Malate Dehydrogenase and IgY to differentiate between peptide-dependent and lectin-dependent chaperone activity. Again, no significant difference was observed between CALR WT and CALR del52 when they were used with their substrates at 1:1 stoichiometry. Significantly, CALR del52 itself showed slightly reduced *in vitro* thermal stability when compared to CALR WT. CALR in living cells forms complexes with other ER resident chaperones. Using immunoprecipitation, we observed the presence of CALR del52 and CALR ins5 in complexes containing calnexin, BiP and PDIA3. Finally, expression of the mutant CALRs did not induce ER stress and gross ER morphology remained unchanged.
Summary and Conclusions: Our results indicate that CALR del52 and CALR ins5 retain when equivalent protein levels are used their chaperone activity. CALR mutants exit the ER due in part due to the lack of the KDEL signal. Of interest, we established that the mutant CALRs exhibit reduced cellular expression when compared to CALR WT. Thus, although mutant CALRs retains chaperone activity, the end result is a decreased absolute level of chaperone activity. We suggest that patient cells may have insufficient CALR chaperone activity in the ER, due to lower total cellular CALR expression and not to due to an impaired chaperone activity, although masking of the N-terminus by yet to be identified proteins cannot be completely ruled in the case of mutated CALRs. Further investigations are underway to understand how this affects myeloproliferation and potential immunogenicity of the new C-terminal tail.

PF609

SDF1 ALPHA-INDUCED CHEMOTAXIS OF JAK2-V617F POSITIVE CELLS IS DEPENDENT ON BRUTON'S TYROSINE KINASE AND PHOSPHOLIPASE C GAMMA 1

S.C. Nimmagadda[1,*], S. Frey[1], P. Müller[1], D. Wolleschak[1], B. Edelmann[1], T. Fischer[1]

[1]Department for Hematology and Oncology, University Clinic of Magdeburg, Magdeburg, Germany

Background: Myeloproliferative neoplasms (MPNs) including polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF) are clonal myeloid disorders and are often accompanied by JAK2-V617F mutation. The most common symptoms of MPN patients are leukocytosis, increased risk of thrombosis, splenomegaly and an inflammatory response syndrome.
Aims: Aberrantly active p65 regulates Burton's tyrosine kinase (BTK) expression in multiple myeloma and in acute myeloid leukemia cells. p65 transcriptionally regulates expression of CXCL10 in JAK2-V617F cells. These observations led us to investigate if JAK2-V617F kinase induces BTK expression (via activated p65) and activation and further characterize its physiological relevance.
Methods: 32D myeloid and BaF3 lymphoid progenitor cells expressing EPO-R and JAK2-WT or JAK2-V617F (32D and BaF3 JAK2-WT/ -V617F) and primary granulocytes isolated from JAK2-V617F positive MPN patients or healthy donors (HD) were used. Cells were treated with inhibitors against, JAK1/2 (ruxolitinib), BTK (ibrutinib) and PLC 1 (U17322) or PLC 1 shRNAs and analyzed by immunoblotting, promoter, chemotaxis, and RhoA GTPase assays.
Results: BTK and p65 are constitutively active in 32D and BaF3 JAK2-V617F cells compared to JAK2-WT cells. Of note, BTK was overexpressed in 32D JAK2-V617F cells. The observations, p65 activation, and BTK overexpression led us to hypothesize a role for activated p65 in BTK expression and perform luciferase-based BTK promoter assays. 32D JAK2-V617F cells indeed demonstrated elevated luciferase activity in comparison to JAK2-WT (control) cells. Confirming a role for JAK2-V617F dependent p65 activity on BTK promoter, ruxolitinib treatment negatively affected BTK promoter activity and protein expression. Ibrutinib treatment further demonstrated that BTK lies upstream of PLC 1. Growing evidence supports a role for BTK and chemokine SDF1α in cell migration. We, therefore, used SDF1α as a chemoattractant and performed chemotaxis assays. Basal migration of 32D JAK2-V617F cells was significantly higher as compared to control cells. SDF1α further enhanced migration of 32D JAK2-V617F cells, indicating a collaboration between JAK2-V617F signaling and SDF1α induced chemotaxis. Inhibitors targeting JAK1/2 (ruxolitinib), BTK (ibrutinib), and PLC (U17322) suppressed SDF1α-induced chemotaxis in both 32D and BaF3 JAK2-V617F cells. Knockdown of PLC 1, the downstream target of the JAK2 V617F-BTK signaling confirmed chemotaxis data using inhibitors. Interestingly, granulocytes isolated from MPN patients in comparison to HD demonstrated increased basal migration. SDF1α treatment further enhanced migration in MPN granulocytes. Clinically achievable concentrations of ibrutinib (0.5 μM) significantly reduced SDF1α-stimulated migration in MPN granulocytes. Since SDF1α and BTK family kinases are important in the regulation of Rho GTPases, we evaluated RhoA GTPase activity. Ibrutinib treatment negatively affected basal and SDF1α induced RhoA GTPase activity, indicating RhoA GTPase as one of the downstream targets of the JAK2-BTK signaling axis.
Summary and Conclusions: Here, we describe the molecular basis for JAK2-V617F-induced abnormal and SDF1α-induced cell migration via BTK, PLC 1, and RhoA GTPase. The data provide a rationale to further investigate the contribution of these molecules in abnormal cell motility of JAK2-V617F myeloid progenitors from bone marrow to peripheral blood and to extramedullary organs. Future studies are warranted to further understand molecular mechanisms and clinical potential of these targets.

PF610

HDAC INHIBITION BY VALPROIC ACID DECREASES JAK2V617F LEVELS IN MYELOPROLIFERATIVE NEOPLASMS VIA UP-REGULATION OF MIR-101, *IN VIVO* AND *IN VITRO*

E. De Marinis[1,*], N. Cenfra[2], D. Liberati[3], M. C. Scerpa[1], F. Pagano[1], A. Quattrocchi[1], S. Tomassini[2], M. Gentile[1], A. Ceccherelli[1], A. Cicalini[1], F. Fantasia[1], G. Cimino[2], C. Nervi[1]

Background: Epigenetic-modifying drugs, such as the histone-deacetylase inhibitors (HDACi) are active in myeloproliferative neoplasms (MPN) patients bearing JAK2V617F mutation. However, the long term-tolerability and toxicity of these agents are important concerns. Valproic acid (VPA) is a safe and widely used neurologic agent that acts as a potent HDACi. VPA targets normal and neoplastic hematopoietic stem cells, but its activity in MPNs remains to be determined.
Aims: The present study aims to investigate the efficacy of VPA in MPNs and the molecular mechanisms driving its effect in MPN patients carrying JAK2V617F mutation, *in vitro* and *in vivo*.
Methods: Peripheral blood (PB) buffy coat specimens were collected from healthy donors or patients with MPN. Furthermore, a JAK2V617F+ Essential Thrombocythemia (ET) patient was treated *per os* with 1500mg VPA/die and blood samples were collected periodically. Primary cells, myeloid JAK2WT K562 cells, and JAK2V617F+ HEL, SET2 and UKE1 cells were employed and tested by: i) Trypan blue exclusion, annexinV and propidium iodide staining for cell growth and apoptosis analysis; ii) Western blot and qRT-PCR (Applied Biosystem 7000) to evaluate proteins and mRNA levels; ChIP assay to investigate gene promoters status. Clonogenic assays from peripheral blood mononuclear cells were performed using MethoCult™ (Stem Cell Technologies); Colony genotyping for JAK2 performed by qPCR.
Results: Clinical response, without toxicity, and a significant reduction of JAK2V617F mutant allele burden have been observed over the time of treatment with VPA (>80 months) in a patient with a diagnosis of JAK2V617F+ ET, intolerant to hydroxyurea, who received VPA *per os* for a bipolar disorder. Furthermore, VPA treatment significantly suppressed JAK2V617F+ MPN patients derived BFU-E colonies growth, with a major effect on mutat-

ed clones. VPA treatment also arrested cell growth and induced apoptosis in myeloid cell lines carrying JAK2V617F but not in JAK2WT cells. In JAK2V617F+ cells, VPA inhibited phospho-STAT5 levels and decreased the expression levels of JAK2 and chromatin remodeling proteins EZH2 and DNMT3a. Strikingly, either JAK2, EZH2 or DNMT3a are miR-101 post-transcriptional targets. We found that miR-101 and its precursors pri-miR-101-1 and pri-miR-101-2 expression levels increased time-dependently upon VPA treatment in the ET JAK2V617F+ patient undergoing treatment with VPA and in JAK2V617F-mutated cells. Indeed, in JAK2V617F+ cells, VPA promoted the recruitment of RNA polymerase II and H3K4me3 enrichment at primiR-101-2 promoter, thus increasing its transcriptional activity and miR-101 production. In turn, miR-101 induces the post-transcriptional silencing of JAK2, thus affecting the JAK2/STAT signaling pathway, and of chromatin modifiers EZH2 and DNMT3A.

Summary and Conclusions: Overall, our results relate the changes induced by VPA on chromatin accessibility of pri-miR-101 promoters and modulation of miR-101 activity with its clinical efficacy and molecular response of a JAK2V617F+ ET patient and JAK2V617F+ primary myeloid cells and cell lines. miRNAs can be involved in HDACi mechanisms acting as additional molecular determinants for epigenetic regulation, re-establishing the correct pattern of gene expression. These mechanisms may contribute to the VPA efficacy in JAK2V617F+ MPNs.

Myeloproliferative neoplasms – Clinical

PF611

RESULTS FROM 48-WEEK FOLLOW-UP OF THE EXPAND STUDY: A PHASE 1B, OPEN-LABEL, DOSE-FINDING STUDY OF RUXOLITINIB IN PATIENTS WITH MYELOFIBROSIS AND LOW PLATELET COUNTS (50-99 × 10^9/L) AT BASELINE

A.M. Vannucchi[1,*], P. te Boekhorst[2], C.N. Harrison[3], G. He[4], M. Caramella[5], D. Niederwieser[6], F. Boyer-Perrard[7], M. Duan[8], N. Francillard[9], B. Molloy[10], M. Wroclawska[10], H. Gisslinger[11]

[1]Center for Research and Innovation of Myeloproliferative Neoplasms, Azienda Ospedaliero-Universitaria Careggi, University of Florence, Florence, Italy, [2]Erasmus MC/Centrumlocatie, Rotterdam, Netherlands, [3]Guy's and St Thomas' NHS Foundation Trust, Guy's Hospital, London, United Kingdom, [4]No.1 Hospital of Nanjing Med., Nanjing, Jiangsu, China, [5]ASST Grande Osp Metropolitano, Milano, Italy, [6]University of Leipzig, Leipzig, Germany, [7]Centre Hospitalier Universitaire d'Angers, Angers, France, [8]Peking Union Medical College Hospital, Beijing, China, [9]Novartis Pharma S.A.S, Rueil Malmaison, France, [10]Novartis AG, Basel, Switzerland, [11]Department of Medicine I, Division of Hematology and Hemostaseology, Medical University of Vienna, Vienna, Austria

Background: Ruxolitinib (RUX, JAK inhibitor) was approved by FDA and EMA for patients (pts) with myelofibrosis (MF) with baseline (BL) platelet (PLT) counts ≥50 × 10^9/L. However, the recommended starting dose of RUX in pts with BL PLT counts 50 to <100 × 10^9/L is 5 mg twice daily (bid), followed by a dose titration. The purpose of the EXPAND study was to gather further information on pts with BL PLT counts ≥50 × 10^9/L and <100 × 10^9/L. The results from the dose-escalation (DE) phase of the EXPAND study established 10 mg bid as the maximum safe starting dose (MSSD) for both cohorts of pts with PLT counts of 75 to 99 × 10^9/L and 50 to 74 × 10^9/L (Vannucchi. *Blood.* 2015;126:2817). Here, we report the results from 48-week (wk) follow-up of the EXPAND study.

Aims: To evaluate 10 mg bid as a safe starting dose of RUX in MF pts with low PLT counts.

Methods: EXPAND (NCT01317875) is an open-label, phase 1b, dose-finding study in MF pts with BL PLT counts of 50 to 99 × 10^9/L. The study consists of 2 phases: DE and safety expansion (SE). In the DE phase, pts were assigned to stratum 1 (S1 [N=27; 75-99 × 10^9/L]) or stratum 2 (S2 [N=19; 50-74 × 10^9/L]) based on their BL PLT counts with the primary objective of determining the MSSD (incidence rate of dose-limiting toxicity [DLT]). The key secondary objectives included safety (adverse events [AEs]) and efficacy (spleen response [SR]: proportion of pts achieving ≥50% of reduction in palpable spleen length); the key exploratory objectives included PROs (change in TSS [modified MFSAFv2.0 diary]). After determination of the MSSD, additional pts were enrolled in the SE phase.

Results: Overall, 69 pts were enrolled (S1=44; S2=25; age ≥65 years=62%, male=48%, primary MF=74%, high-risk MF=41%, JAK2 mutation positive=80%). Median exposure to RUX was 51.43 wks in S1 and 67.43 wks in S2. At wk 48, 14 pts in S1 and 3 pts in S2 were still receiving RUX treatment (Tx). At data cutoff, primary reasons for end of Tx were AEs (S1=11 pts; S2=7 pts), Tx duration completed (S1=7 pts; S2=6 pts), physician decision (S1=4 pts; S2=3 pts), disease progression (S1=4 pts; S2=1 pt), and deaths (S1=0; S2=3 pts). Reported AEs were consistent with known safety profile of RUX (Table 1).

Table 1.

AEs (All Grades, in ≥20% of pts in Either Stratum [Regardless of Study Drug Relationship])

Preferred Term	Stratum 1 (N=44)		Stratum 2 (N=25)	
	All Grades	Grade 3 or 4	All Grades	Grade 3 or 4
Thrombocytopenia	28 (63.6)	22 (50.0)	19 (76.0)	19 (76.0)
Anemia	23 (52.3)	14 (31.8)	12 (48.0)	6 (24.0)
Diarrhea	13 (29.5)	2 (4.5)	8 (32.0)	0
Pyrexia	9 (20.5)	0	7 (28.0)	2 (8.0)
Asthenia	8 (18.2)	3 (6.8)	7 (28.0)	2 (8.0)
Cough	4 (9.1)	0	10 (40.0)	0
Abdominal pain	8 (18.2)	0	5 (20.0)	0
Headache	6 (13.6)	0	6 (24.0)	0
Back pain	6 (13.6)	1 (2.3)	5 (20.0)	1 (4.0)
Epistaxis	10 (22.7)	1 (2.3)	1 (4.0)	0
Nasopharyngitis	5 (11.4)	0	6 (24.0)	0
Nausea	5 (11.4)	0	5 (20.0)	0
Edema peripheral	5 (11.4)	3 (6.8)	5 (20.0)	0
Pain in extremity	4 (9.1)	0	6 (24.0)	0
Hypocalcemia	3 (6.8)	0	6 (24.0)	0
Hypertension	2 (4.5)	2 (4.5)	5 (20.0)	0

Grade (G) 3 or 4 AEs were reported in 57/69 pts. AEs (regardless of study drug relationship) led to Tx discontinuation in 13 pts in S1 and 10 pts in S2.

Overall, 44/69 pts had AEs that required dose adjustment/Tx interruption (most common reason: thrombocytopenia [S1=16; S2=17]). Thrombocytopenia (G4) was the only DLT (related to study drug) reported in both strata at 10 mg bid (S1=1 pt; S2=2 pts). A G4 worsening from BL in PLTs was seen in 4/44 pts in S1 and 8/25 pts in S2. Reasons for on-Tx death included AML (1), cardiac arrest (1), unknown (1; not suspected to be related to study drug) in S1 and complications after GI ulcer (1), multiple organ failure (1) in S2. At wk 48, 7/22 pts in S1 and 5/14 pts in S2 achieved SR; while majority of pts achieved SR at any time point in both strata (S1=22/43 pts; S2=17/25 pts [Figure 1]). Improvement in TSS was observed at MSSD in both strata (mean change from BL at wk 24: S1 [N=20], −7.7; S2 [N=18], −3.9).

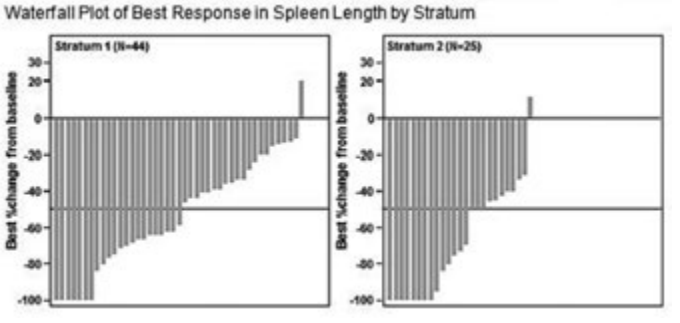

Figure 1.

Summary and Conclusions: In pts with low PLT counts, starting dose of 10 mg bid was safe, generally well tolerated, and consistent with known safety profile of RUX, with only 3 reported cases of DLTs. RUX Tx also provided spleen reduction and TSS benefit in majority of pts. Study results confirmed that 10-mg bid dose is suitable for use in low-PLT population of pts with MF.

PF612

AVAPRITINIB (BLU-285), A SELECTIVE KIT INHIBITOR, IS ASSOCIATED WITH HIGH RESPONSE RATE AND TOLERABLE SAFETY PROFILE IN ADVANCED SYSTEMIC MASTOCYTOSIS (ADVSM): RESULTS OF A PHASE 1 STUDY

[1]Department of Internal Medicine and the Huntsman Cancer Institute (HCI), University of Utah, Salt Lake City, [2]Division of Hematology, Stanford Cancer Institute/Stanford University School of Medicine, Stanford, [3]Medical Oncology, University of Colorado Denver, Aurora, United States, [4]Hematology, Guys and St Thomas NHS Foundation, London, [5]Hematology, Beatson Cancer Centre, Glasgow, United Kingdom, [6]Hematology and Oncology, University of Michigan, Ann Arbor, [7]Medicine/Abramson Cancer Center, University of Pennsylvania, Philadelphia, [8]Leukemia, Division of Cancer Medicine, University of Texas MD Anderson Cancer Center, Houston, [9]Blueprint Medicines, Cambridge, [10]Hematology/Oncology, Dana-Faber Cancer Institute, Harvard Medical School, Boston, United States

Background: AdvSM is a life-threatening disease of neoplastic mast cells (MCs) associated with bone marrow (BM) involvement and organ damage. Approximately 90-95% of patients (pts) exhibit the *KIT* D816V mutation, which results in ligand-independent proliferation and increased survival of MCs. Avapritinib (AVA) is a potent and selective tyrosine kinase inhibitor with subnanomolar activity against KIT D816V.
Aims: This 2-part Phase 1 study was designed to determine the recommended Phase 2 dose (RP2D) of AVA in pts with AdvSM (Part 1) and to assess preliminary efficacy (Part 2).
Methods: Part 1 used a standard 3+3 dose escalation design, with enrichment of cohorts after higher dose levels were cleared for safety. Adult pts with AdvSM (aggressive SM [ASM], SM with an associated hematologic neoplasm [SM-AHN] or mast cell leukemia [MCL]), or other myeloid neoplasm were eligible. Part 2 will enroll approx 35 pts with AdvSM treated at the RP2D. In both study parts, there were no restrictions on prior therapies and pts were required to have a "C-finding" of organ damage based on World Health Organization (WHO) criteria but not on modified (m) International Working Group Myeloproliferative Neoplasms Research and European Competence Network on Mastocytosis (IWG-MRT-ECNM) response criteria. AVA was administered orally once daily, continuously, in 28-day cycles (C), starting at 30 mg. Efficacy assessments, including BM biopsy and liver and spleen imaging for volume assessment, were performed on day 1 of C3, C7, C11, C18 and then every 6 mo; serum tryptase and *KIT* D816V mutant allele fraction (MAF) and other myeloid gene mutations were assessed at central laboratories. Response was assessed using local BM results by m-IWG-MRT-ECNM response criteria with confirmation of response 12 wks after initial response.
Results: With a data cutoff of 04/10/17, a total of 32 pts were treated in Part 1 (17 ASM, 9 SM-AHN, 3 MCL, 2 smoldering SM [SSM], 1 other) at doses between 30 mg and 400 mg daily. *KIT* D816V was present in 88% of pts; 69% had prior SM treatment (4 with midostaurin). Median baseline BM MCs was 25% (range, 5-95%) and serum tryptase was 170 ng/mL (range, 41-1414). No maximum tolerated dose was reached; the RP2D was 300 mg daily. The most common adverse events (AEs) were periorbital edema (59%), fatigue (41%), peripheral edema (34%), and nausea, anemia, and thrombocytopenia (28% each). Only 1 Grade 3 or 4 AE was reported in ≥1 pt (neutropenia, 13%). Dose was reduced in 41% of pts; 2 pts discontinued, none due to AE. Among all 32 pts, normalization (complete response) or ≥50% reduction from baseline (partial response), respectively, was observed for BM MCs (15/26, 58%; 6/26, 23%), tryptase (15/25, 60%; 10/25, 40%), and splenomegaly (6/11, 55%: 4/11, 36%). *KIT* D816V MAF decreased by ≥50% in 19/26 (73%). Improvement in cutaneous mastocytosis was observed in 13/15 pts (87%). 18 pts had an evaluable C-finding at baseline per m-IWG-MRT-ECNM criteria (35% splenomegaly, 28% cytopenias, 19% abnormal liver function, 13% weight loss and/or ascites, 6% hypoalbuminemia); best overall response rates (ORR), confirmed and unconfirmed, are shown in the Table 1. Responses were observed at all dose levels. Median duration of treatment is 9 mo. Part 2 of the study has started with 17 pts treated as of 31/01/18.

Table 1.

Best response n (%)	ASM (n=7)	SM-AHN (n=8)	MCL (n=3)	Overall (n=72)
Overall response rate (Complete response + partial response + clinical improvement)	6 (86)	5 (63)	2 (67)	13 (72)
Complete response	2 (29)	0	0	2 (11)
Partial response	3 (43)	4 (50)	1 (33)	8 (44)
Clinical improvement	1 (14)	1 (13)	1 (33)	3 (17)
Stable disease	1 (14)	3 (38)	1 (33)	5 (28)

Summary and Conclusions: Avapritinib has a tolerable safety profile and is highly active in all subtypes of AdvSM, with an ORR of 72% by m-IWG-MRT-ECNM criteria and improvement in all measures of MC burden in pts with AdvSM and SSM. These data support further evaluation of avapritinib across the spectrum of SM.

Seràgnoli", Sant'Orsola-Malpighi University Hospital, Bologna, [25]Division of Hematology, Città della Salute e della Scienza Hospital, Torino, Italy

Background: Ruxolitinib (RUX) is a JAK1/2 inhibitor able to control myelofibrosis (MF)-related splenomegaly, with around 60-80% of patients (pts) achieving a reduction in spleen length by at least 25%. The achievement of a single spleen response was not found to correlate with survival in previous analysis. Also, no data are available on the dynamics of spleen response over time and on the impact of RUX-response feature on outcome.
Aims: To report the dynamics of spleen response on outcome of 284 evaluable MF pts treated with RUX according to prescribing information.
Methods: A clinical database was created in 23 European Hematology Centres including retrospective data of 462 MF pts treated with RUX from Jan 2011 to July 2017. 284 pts (61.5%) received at least 4 evaluations of spleen length by palpation for a period of at least 12 months and were included in the analysis. Spleen response was defined as reduction of spleen length ³25% by palpation. Overall Survival (OS) was calculated from the start of RUX. Progression-free survival included progression to acute leukemia (AL) and death, whichever came first. Event-free survival (EFS) included also RUX discontinuation for any cause.
Results: A total of 284 (52.1% primary, 47.9% post Polycythemia Vera/Essential Thrombocythemia) MF-patients were analyzed. After a median follow-up of 25.8 months from RUX-start, 48 deaths, 18 progressions to AL, and 85 RUX discontinuation were recorded. Overall, 195 pts (68.7%) achieved a spleen response at 6 months. By landmark analysis at 6 months, OS of pts in spleen response at 6 months was comparable to non-responders at that time-point, after adjustment for DIPSS risk (p=0.12), while spleen responders had significantly better PFS and EFS (p=0.02, p=0.005 respectively) (Figure 1a,b,c). Pts were classified into three groups of response: a) pts with stable response (SR) at all evaluations; b) pts with fluctuating results (FR); c) pts with no response (NR). Compared to pts with FR/NR, pts with stable response were less frequently at high DIPSS risk (OR 0.36, 95% CI 0.14-0.94, p=0.04), carried less frequently a large (>10 cm) splenomegaly (OR 0.20, 95% CI 0.09-0.45, p<0.001), and started RUX more frequently <2 yrs from MF diagnosis (OR 0.47, 95% CI 0.26-0.83, p=0.01). Among the three groups of response, we observed 172 (60.6%) SR, 50 (17.6%) FR, and 62 (21.8%) NR. Using a Cox model adjusted for DIPSS category, OS and PFS were significantly worse for pts with NR compared to pts with SR/FR (p=0.04 and p=0.05) (Figure 1d,e). 3y-EFS according to different group of response was 73.2%, 58.3% and 45.2% for SR, FR and NR, respectively (p=0.004) (Figure 1f).

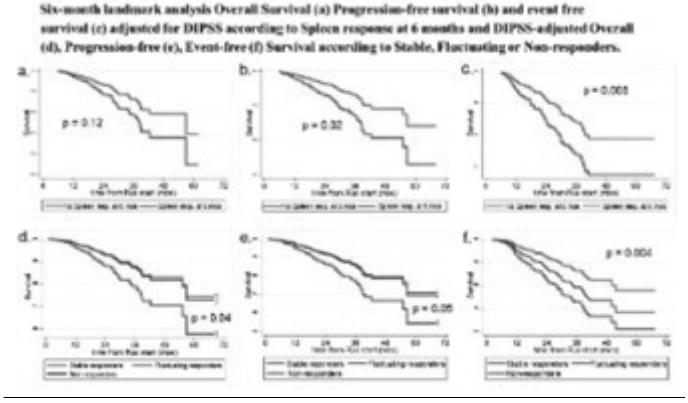

Figure 1.

Summary and Conclusions: This large study failed to detect a direct correlation between spleen response at a specific time-point (6-month) and OS. Additionally, the absence of a spleen response for a period ≥12 months significantly correlated with worse OS and PFS. Noteworthy, achieving a FR correlated with lower EFS, mainly due to a higher rate of drug discontinuation, but did not hamper OS and PFS compared to stable responders. Overall, the study shows that around 40% of pts did not achieve a stable response to RUX, and points out that the dynamics of response, more than a single evaluation of response, correlates with OS.

PF614

DEVELOPMENT OF A PROGNOSTICALLY RELEVANT 'CACHEXIA INDEX' IN PRIMARY MYELOFIBROSIS USING SERUM ALBUMIN AND CHOLESTEROL LEVELS

M. Nicolosi[1,*], D. Penna[1], M. Mudireddy[1], N. Szuber[1], T. Lasho[1], C. Hanson[1], R. Ketterling[1], N. Gangat[1], A. Pardanani[1], A. Tefferi[1]

[1]Hematology, Mayo Clinic, Rochester, United States

Background: "constitutional symptoms" is a consistent risk variable in current prognostic models in primary myelofibrosis (PMF), including the international prognostic scoring system (IPSS), dynamic IPSS (DIPSS), DIPSS-plus and the recently unveiled mutation-enhanced IPSS (MIPSS70 and MIPSS70-plus) (*JCO. 2018;36:310*). The individual components of "constitutional symptoms" are poorly standardized, subjectively influenced and their accuracy is difficult to ascertain. Constituional symptoms in PMF reflect the hypercatabolic/cachectic state of the disease and are thus amenable to more objective quantification using laboratory biomarkers of cachexia.
Aims: To develop a new 'cachexia index' for PMF.
Methods: Patient histories were retrospectively reviewed and serum albumin or cholesterol levels were collected at time of diagnosis or first referral to our instituion. Receiver operating characteristic (ROC) plots were employed in order to determine serum cholesterol and albumin levels that were prognostically most discriminative.

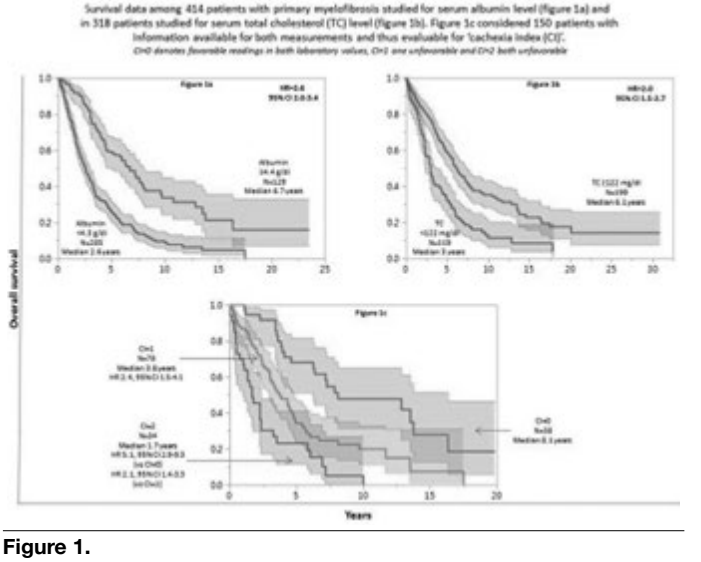

Figure 1.

Results: Among 1,109 consecutive patients with PMF reviewed, serum albumin level was recorded in 484 patients and total cholesterol (TC) in 374; 179 patients had information on both. Patients with serum albumin level of <4.3 g/dl were older and universally displayed prognostically adverse clinical features; by contrast, differences in cytogenetic or mutation profiles were not apparent. Patients with serum TC of <122 mg/dl were also more likely to display adverse features but, in addition, displayed male preponderance and significant clustering with the presence of *JAK2* and *ASXL1* mutations. In age-adjusted univariate analysis, lower levels of serum albumin (p<0.001), TC (p<0.001), high-density lipoprotein (HDL) (p<0.001) and low-density lipoprotein (LDL) (p<0.001) cholesterol, but not triglycerides (p=0.6), were associated with shortened survival; only the first two retained their significance on multivariable analysis. Subsequent ROC analysis resulted in TC level of 122 mg/dl and serum albumin level of 4.3 g/dl as the most optimal cutoff values for survival prediction. Serum albumin level of <4.3 g/dl and TC level of <122 mg/dl both remained significant during multivariable analysis that included DIPSS,

DIPSS-plus or the revised cytogenetic risk stratification; their respective HRs (95% CI) were 1.8 (1.2-2.8) and 1.8 (1.2-2.8) with DIPSS, 1.7 (1.1-2.6) and 1.7 (1.1-2.5) with DIPSS-plus and 2.8 (1.8-4.4) and 2.2 (1.4-3.4) with cytogenetic risk. Additional multivariable analysis that included the individual components of DIPSS/DIPSS-plus resulted in complete loss of significance for constitutional symptoms and circulating blasts ≥1%. The two laboratory parameters were consequently used to develop three-tiered "cachexia index (CI)": a score of "0" (CI-0), "1" (CI-1) or "2" (CI-2) was assigned depending on the absence or presence of one or two unfavorable readings, respectively. The PMF CI eclipsed "constitutional symptoms" in its prediction of inferior survival; HRs (95% CI) were 4.9 (2.7-9.1) for CI-2, 2.4 (1.5-4.1) for CI-1 and 1.2 (0.7-1.8) for constitutional symptoms. PMF CI was also prognostically independent of DIPSS, DIPSS-plus and the revised cytogenetic risk stratification (Figure 1).

Summary and Conclusions: We have developed an operational 'cachexia index' for PMF using two simple and widely available laboratory tests: serum albumin and cholesterol levels. The PMF cachexia index overtook the prognostic contribution of 'constitutional symptoms' and remained significant in the context of all contemporary prognostic models.

PF615

PATIENTS WITH LOW JAK2 ALLELE BURDEN HAVE A HIGH RATE OF CO-OCCURRENT CALR MUTATIONS BEARING AN EFFECT ON DISEASE PHENOTYPE IN ESSENTIAL THROMBOCYTHEMIA AND PRIMARY MYELOFIBROSIS.

B. Mora[1,*], M. Maffioli[1], D. Barraco[1], M. Merli[1], D. Caramazza[1], L. Elli[2], R. Accetta[2], A. Bussini[2], F. Pallotti[23], S. Uccella[4], R. Casalone[2], T. Giorgino[5], F. Passamonti[13]

[1]Hematology, Department of Specialist Medicine, Ospedale di Circolo, ASST Sette Laghi, Varese, Italy, [2]Cytogenetics and Medical Genetics Laboratory, ASST Sette Laghi, Varese, Italy, Varese, [3]Department of Medicine and Surgery, University of Insubria, Varese, Italy, [4]Department of Medicine and Surgery, Unit of Pathology, University of Insubria, Varese, Italy, [5]Biophysics Institute, National Research Council of Italy, Milano, Italy

Background: Co-occurrence of driver mutations (*JAK2*, *CALR*, *MPL*) in myeloproliferative neoplasms has been described in 10-15% of patients with low (<5%) *JAK2*V617F allelic burden (*JAK2* AB). Information on the biologic correlates of co-existing driver mutations and differences with "single mutated" cases is scant.

Aims: The primary objective of this study is to assess the frequency of "double mutated" cases in our Institutional dataset of essential thrombocythemia (ET) and primary myelofibrosis (PMF) with low *JAK2* AB. In addition, clinical relevance of co-existing mutations is investigated.

Methods: Diagnosis of ET and PMF was performed from 2004 to January 2018, reviewed according to the last WHO criteria. Informed consent was obtained from all patients. *JAK2* AB was evaluated with allele specific quantitative PCR (sensitivity threshold: 0.001%); *CALR* mutation screening was performed with fragment length analysis, followed by Sanger sequencing in case of positive results. *MPL* mutations were detected by Sanger sequencing. Differences between covariates were evaluated with Wilcoxon rank-sum and Fisher's exact tests.

Results: Within our cohort of 463 molecularly annotated patients (313 ET and 150 PMF), *JAK2*V617F mutated cases were 206 (65.8%) and 102 (68%), respectively. *JAK2* AB was available in 237 cases (160 ET and 77 PMF). We categorized patients into three groups on the basis of the *JAK2* AB: low (<5%), intermediate (5-10%) and high (>10%). Then, we searched for *CALR* and *MPL* mutations (Table 1).

Table 1.

JAK2 AB, % (n. pts)	*CALR* mutational status, n. pts			*MPL* mutational status, n. pts			Double mutated, n. pts
	Mutated	Wild type	Not done	Mutated	Wild type	Not done	
Low, <5% (25)	7	17	1	1	15	9	8
Intermediate, 5-10% (24)	0	24	0	0	0	24	0
High, >10% (188)	0	70	118	0	12	176	0

In the group of 25 low (<5%) *JAK2* AB mutated cases, 7 patients showed *CALR* mutation (4 ET and 3 PMF) and one PMF case resulted *MPL* mutated. We then evaluated all patients with intermediate (5-10%) *JAK2* AB for *CALR*, without finding any mutated case. Finally, a random sample of patients with high (>10%) *JAK2* AB was screened for *CALR* and *MPL*, finding no co-occurence. Hence, we found an imbalance in *CALR-JAK2* co-mutations in the low *JAK2* AB group respect to other *JAK2* AB groups (~ 30% *vs* 0%, *P* <.0001). Within the set of low *JAK2* AB, *CALR-JAK2* co-mutated *versus* single-mutated cases showed significantly higher hemoglobin level (median value, 14.8 *vs* 12.5 g/dL; *P*=0.01), and platelet count (median value, 956 *vs* 531 x 10^9/L; *P*=0.002) at diagnosis. The effect on hemoglobin was mostly evident in PMF (Figure 1a), while that on platelets was independent from diagnosis (Figure 1b). No differences were found as for leukocyte count, blast count, spleen size, symptoms and age at diagnosis; neither imbalance was evident in vascular events and second malignancies (pre, at, and post diagnosis), and survival.

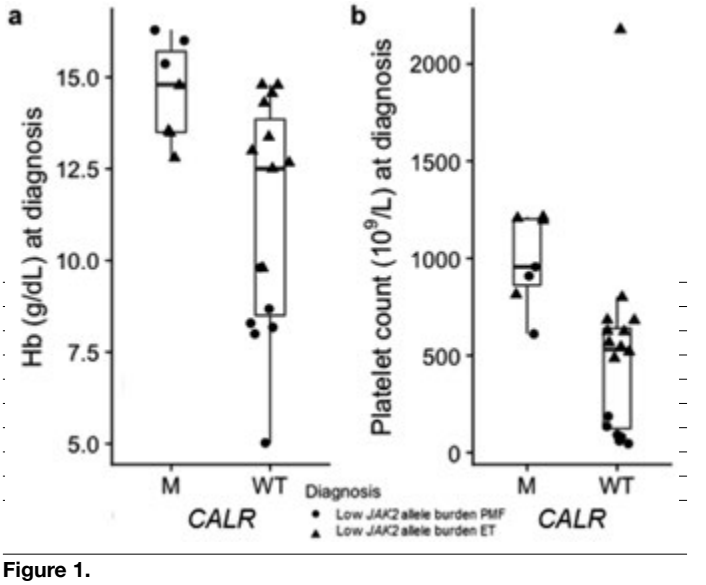

Figure 1.

Summary and Conclusions: In our dataset of 237 *JAK2* mutated ET and PMF patients, ~ 30% of low (<5%) *JAK2* AB mutated patients also harbor other driver mutations. These patients have a more myeloproliferative phenotype respect to single mutated ones (higher values of hemoglobin and platelets). Our data supports the relevance of investigating *CALR* mutational status in low *JAK2* allele burden ET and PMF patients.

PF616

PREDICTORS OF RESPONSE TO RUXOLITINIB (RUX) IN PATIENTS (PTS) WITH MYELOFIBROSIS (MF) IN THE PHASE 3B EXPANDED-ACCESS JUMP STUDY

V. Gupta[1,*], M. Griesshammer [2], B. Martino[3], L. Foltz[4], R. Tavares[5], H.K. Al-Ali[6], P. Giraldo[7], P. Guglielmelli[8], E. Lomaia[9], C. Bouard[10], J. Perez Ronco[10], R. Tiwari[11], P. Raanani[12]

[1]Princess Margaret Cancer Centre, Toronto, Ontario, Canada, [2]Johannes Wesling Clinic, Minden, Germany, [3]Azienda Ospedaliera Bianchi-Melacrino'-Morelli, Reggio Calabria, Italy, [4]St. Paul's Hospital, University of British Columbia, Vancouver, British Columbia, Canada, [5]Universidade Federal de Goiania, Goiania, Brazil, [6]University Hospital of Halle, Halle (Saale), Germany, [7]Miguel Servet University Hospital and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Zaragoza, Spain, [8]CRIMM, Center for Research and Innovation of Myeloproliferative Neoplasms, AOU Careggi, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy, [9]Almazov National Medical Research Centre, St. Petersburg, Russian Federation, [10]Novartis Pharma AG, Basel, Switzerland, [11]Novartis Healthcare Pvt. Ltd., Hyderabad, India, [12]Davidoff Cancer Center, Rabin Medical Center, Petah Tikva, Israel

Background: RUX is a potent JAK1/JAK2 inhibitor that leads to reductions in splenomegaly and symptoms and improved overall survival in pts with MF. Although most pts with MF benefit from RUX treatment, response to RUX may vary among pts. JUMP is the largest phase 3b, expanded-access trial in MF in countries with no access to RUX outside a clinical trial. Analysis of this large, prospective, multinational database may allow for the identification of clinical factors associated with a response to RUX.

Aims: To analyze the impact of baseline pt characteristics and dose on spleen and symptom response in pts with MF in the JUMP study.

Methods: Pts were treated for up to 24 months after the last pt's first visit (23 December 2014) unless discontinuation criteria were met. Eligible pts had IPSS intermediate (Int)-2– or high-risk MF, with or without splenomegaly, or Int-1–risk MF with a palpable spleen (≥5 cm). Starting doses were based on baseline platelet (PLT) count (5 mg bid [≥50 to

<100×10⁹/L], 15 mg bid [100-200×10⁹/L], or 20 mg bid [>200×10⁹/L]) and could be titrated during treatment. Spleen response was evaluated according to IWG-MRT criteria. Symptom responses were evaluated using the FACT-Lymphoma total score (FACT-Lym TS) and FACIT-Fatigue scales.
Results: Data were collected from 2233 pts treated at 279 clinical sites across 26 countries. Overall, 54.5% of pts were male and 59.4% had primary MF. Median baseline characteristics were age, 67 y (range, 18-89 y; ≥65 y, 59.7%); spleen length, 12 cm; time since diagnosis, 25.8 mo; hemoglobin (Hb), 106 g/L (<100 g/L, 38.3%); and PLT count, 254×10⁹/L (<100×10⁹/L, 6.2%). Mean FACT-Lym TS and FACIT-Fatigue scores were 113.9 and 32.7, respectively. Median RUX exposure was 12.4 mo. Improvements in splenomegaly and symptoms were seen in all pt subgroups. Overall, 34.3% of evaluable pts (672/1960) achieved a spleen response by IWG-MRT criteria at wk 24. In univariate analysis, baseline factors associated with lower spleen response were IPSS Int-2/high risk, Hb <10 g/dL, PLT count <100×10⁹/L, time since MF diagnosis >2 y, prior treatment, and blasts ≥1%. Two factors remained significant by multivariate analysis: IPSS Int-2/high risk and prior treatment. Additionally, spleen response was correlated with a higher RUX dose, with pts treated with ≥10 mg bid in the first 12 wk having better response rates (39.7% *vs* 25.3%, adjusted OR, 0.58 [95% CI, 0.37-0.91]). Among evaluable pts, 53.7% (753/1403) achieved a symptom response on the FACT-Lym TS scale; 49.1% (709/1443) achieved a response on the FACIT-Fatigue scale. In univariate analysis, only a RUX dose titrated to <10 mg bid during the first 12 wk of therapy negatively correlated with symptom response (FACT-Lym TS, 44.7% *vs* 54.9%; OR, 0.66 [95% CI, 0.50-0.89]; FACIT-Fatigue, 42.0% *vs* 50.3%; OR, 0.72 [95% CI, 0.54-0.95]). No associations were seen by multivariate analysis (Figure 1).

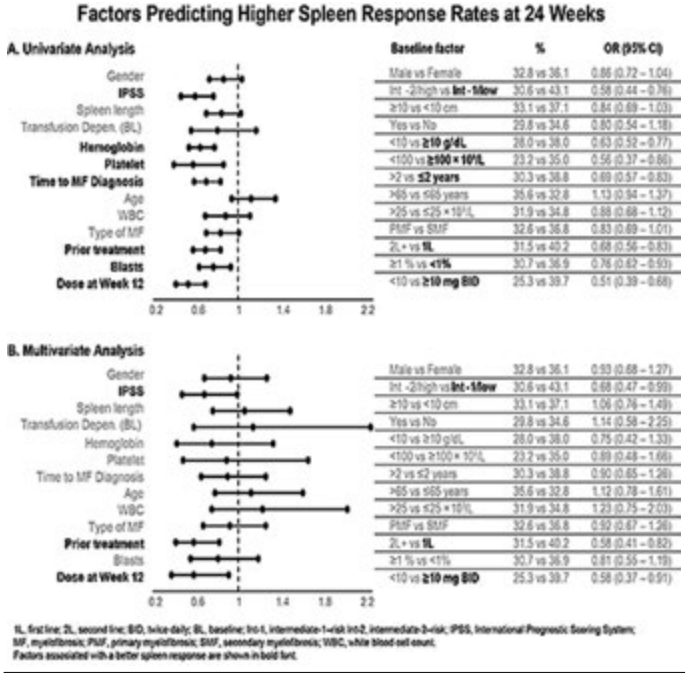

Figure 1.

Summary and Conclusions: This study used factors available in routine clinical practice to identify pts likely to have a better response to RUX. Less-advanced disease, dose ≥10 mg bid, and RUX as first-line therapy were the independent factors associated with higher spleen response rates. No predictive factors were identified for symptom response. These findings suggest that treating pts with RUX earlier in the disease course and at higher doses may lead to greater splenic responses.

PF617

HIGH RISK OF RECURRENT VENOUS THROMBOEMBOLISM IN BCR-ABL-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS AFTER TERMINATION OF ANTICOAGULATION

K. Wille[1,*], P. Sadjadian[1], T. Becker[1], K. Vera[1], A. Horstmann[1], M. Griesshammer[1]

[1]Universitiy Clinic for Hematology, Oncology, Hemostaseology and Palliative Care, Johannes Wesling Medical Center Minden, Minden, Germany

Background: Venous thromboembolism (VTE) is a major burden in patients with *BCR-ABL*-negative myeloproliferative neoplasms (MPN). In addition to cytoreductive treatment anticoagulation is mandatory, but optimal duration of anticoagulation is a matter of debate.
Aims: In this analysis we included 526 MPN patients seen in our center since 2006.
Methods: A VTE associated to MPN was defined as a venous thrombosis at any site, which occurred at least 5 years before MPN diagnosis or thereafter.
Results: In total, 82 of 526 MPN patients (15.6%) had a MPN associated VTE. Median age at first VTE was 52.5 years (range 23-81). During follow up time of 3781 years 110 VTE events (VTEs) have occurred with an event rate of 2.9% per patient/year. 44.5% (49 of 110) of all VTEs appeared before or at MPN diagnosis and 51.8% (57 of 110) occurred at "unusual" sites like splanchnic or cerebral veins. MPN patients with VTEs were significantly more frequent *JAK2* positive (p<0.001) or were diagnosed as polycythemia vera (p=0.004). MPN patients without VTEs had a higher rate of *CALR* positivity (p=0.022). Total follow up time after first VTE was 382 years with 27 VTEs accounting for a recurrence rate of 7.1% per patient/year. In 43 of 75 MPN patients with VTEs (57.3%), prophylactic anticoagulation was terminated after a median time of 12 months (range 1-204) and 19 patients (44.2%) had a VTE recurrence after a median of 13 months (range 4-168). In contrast, only three of 32 patients with ongoing anticoagulation had a VTE recurrence (p=0.001).
Summary and Conclusions: Thus, termination of prophylactic anticoagulation was associated with a significant higher risk of VTE recurrence. Our data suggest that in MPN patients with VTEs a prolonged duration of anticoagulation may be beneficial.

PF618

RESULTS FROM ONGOING PHASE 1/2 TRIAL OF SL-401 IN PATIENTS WITH INTERMEDIATE OR HIGH RISK RELAPSED/REFRACTORY MYELOFIBROSIS

N. Pemmaraju[1,*], V. Gupta[2], G. Schiller[3], S. Lee[4], A. Yacoub[5], H. Ali[6], M. Talpaz[7], M. Sardone[8], H. Wysowskyj[8], S. Shemesh[8], J. Chen[8], C. Brooks[8], T. Goswami[8], V. Dunn[8], A. Pardanani[9], A. Tefferi[9], S. Verstovsek[1], J. Khoury[1], M. Patnaik[9]

[1]The University of Texas MD Anderson Cancer Center, Houston, United States, [2]Princess Margaret Cancer Centre, Toronto, Canada, [3]UCLA, Los Angeles, [4]Weill Cornell Medical Center, New York, [5]Kansas University Cancer Center, Westwood, [6]City of Hope, Duarte, [7]University of Michigan Health System, Ann Arbor, [8]Stemline Therapeutics, New York, [9]Mayo Clinic, Rochester, United States

Background: Myelofibrosis (MF) patients that have failed or are intolerant to JAK inhibitors (JAKi) have no standard treatment options. SL-401 is a novel targeted therapy directed to the interleukin-3 receptor-α (CD123), a target expressed on a variety of malignancies, including certain myeloproliferative neoplasms (MPNs) such as MF. CD123 is also expressed on plasmacytoid dendritic cells (pDCs), which can reside in the tumor microenvironment and may play a role in promoting growth of MPN and other malignancies. Accordingly, a therapy directed at CD123-expressing malignant cells and/or neighboring pDCs may offer a novel therapeutic approach. SL-401 demonstrates high levels of clinical activity against blastic plasmacytoid dendritic cell neoplasm (BPDCN), a CD123+ malignancy derived from pDCs, and is being evaluated in Phase 1/2 trials of other cancers.
Aims: Primary objectives include assessment of safety, determining optimal dose/regimen, and evaluating efficacy outcomes.
Methods: This multicenter, 2-stage Phase 1/2 trial is enrolling MF patients that were relapsed, refractory, or unable to tolerate JAKi. In the Stage 1 dose escalation cohort (completed), SL-401 was dosed as a daily IV infusion at 7, 9, and 12 mcg/kg/day, on days 1-3 every 21 days (cycle 1-4), every 28 days (cycles 5-7), and every 42 days (cycles 8+). In Stage 2 (ongoing), the optimal dose determined in Stage 1 (12 mcg/kg) is being employed.
Results: As of 2/1/18, 14 patients (pts) with MF were treated with SL-401 (n=6 as 2nd-line; n=8 as 3rd-line, and beyond; with JAKi being the most commonly administered prior therapy). Median age 69 yrs (range 55-81); 71% female. DIPPS Plus risk group was intermediate-1 in 7% (1/14), intermediate-2 in 57% (8/14), and high in 36% (5/14) of pts. Median platelet count 56K/uL (range 19-232). 79% (11/14) of pts had baseline platelets <100K/uL, of which 4 pts (29%) had platelets <50K/uL. 79% (11/14) of pts had baseline splenomegaly defined as 5 cm below costal margin (BCM) by physical exam. Most common treatment-related adverse events (TRAEs), all grades, were thrombocytopenia, hypoalbuminemia and dizziness (all 29%). Most common ≥grade 3 TRAEs were anemia (21%) and thrombocytopenia (14%). Capillary leak syndrome

reported in 1 pt (7%; grade 3). 55% (6/11) of pts with baseline splenomegaly had spleen reductions 25% (range 29-100%), including 3 pts (27%) with spleen reductions 35%, by physical exam: baseline to best response of 5 to 0 cm (100%), 19 to 10 cm (47%), 35 to 19 cm (46%), 30 to 20 cm (33%), 17 to 12 cm (29%), and 14 to 10 cm (29%) BCM. 5 spleen reductions occurred in pts with platelets <100K/uL, including 1 pt with a platelet count <50K/uL (100% spleen reduction [5 to 0 cm]). 75% (9/12) of evaluable pts experienced reductions in total symptom score (TSS) (range: 25%>100%), of which 4 pts (33%) had ≥50% TSS reduction. Median overall survival has not been reached (median follow-up 6.5 mos; range 0.1-20.6+ mos).

Summary and Conclusions: Single agent SL-401 was well-tolerated and demonstrated spleen reductions and symptom improvement in relapsed/refractory MF pts, including in some pts with thrombocytopenia. Given CD123 expression on certain myeloid neoplastic cells and tumor microenvironmental pDCs, SL-401 may offer a novel targeted approach in MF. Enrollment continues, and updated safety and efficacy data will be presented. Registration-directed designs are being evaluated. Clinical trial information: NCT02268253.

PF619

MUTATIONAL LANDSCAPE AND ITS IMPACT ON OUTCOMES IN ACCELERATED AND BLAST PHASE OF MYELOPROLIFERATIVE NEOPLASMS

C. Mcnamara[1,*], T. Panzarella[2], J. Kennedy [1], A. Arruda[1], J. Claudio[1], J. Ho[1], G. Daher-Reyes[1], R. Al Blooshi[1], N. Siddiq[1], R. Devlin[1], T. Stockley[3], M. Sukhai[3], N. Kanwar[3], H. Tsui[4], S. Chan[1], D. Maze[1], A. Schimmer[1], A. Schuh[1], H. Sibai[1], K. Yee[1], M. Minden[1], S. Kamel-Reid[3], V. Gupta[1]

[1]Department of Medical Oncology and Hematology, [2]Department of Biostatistics, [3]Advanced Molecular Diagnostics Laboratory, Princess Margaret Cancer Centre, [4]Department of Pathology, Toronto General Hospital, Toronto, Canada

Background: There is a paucity of data regarding the impact of mutations on outcomes in accelerated phase (AP) and blast phase (BP) of myeloproliferative neoplasms (MPN). Moreover, it is unknown whether mutational status affects survival as seen in chronic phase.

Aims: To comprehensively describe the mutational spectrum of patients with AP/BP of MPN and correlate molecular profile with baseline clinical features and outcomes.

Methods: All patients with Philadelphia negative MPN in AP/ BP and assessed at Princess Margaret Cancer Centre between January 1998 and April 2017 were identified by cross referencing the MPN and leukemia databases. Targeted sequencing with a 54 myeloid gene panel was performed. The primary endpoint was overall survival defined from the time of transformation to AP/ BP until death or last follow-up. Overall survival endpoints were estimated using the Kaplan-Meier method and log rank test. For univariate and multivariable analyses, overall survival endpoints were fit using the Cox proportional hazards model.

Results: All patients with MPN in AP/BP and with an available molecular sample (n=122; AP=14; BP=108) were included in the study. Treatment consisted of intensive therapy (induction chemotherapy and/or transplant) (n=44), less intensive (azacitidine/ low dose cytarabine/ clinical trial) (n=27) or best supportive care (BSC) (n=51). *JAK2V617F* was the most common mutation occurring in 55% of subjects, *CALR* in 13% and *MPL* in 6%. Thirty-two (26%) patients were triple negative at the time of AP/BP. Frequently mutated genes included: *ASXL1* (30%), *TET2* (25%), *SRSF2* (22%), *RUNX1* (21%) and *TP53* (17%). Mutations in 1, 2, 3 and ≥4 genes were seen in 18 (15%), 16 (13%), 30 (25%) and 56 (46%) patients respectively. *SETBP1* mutation was enriched in triple negative patients (25% *vs* 3%, p=0.002). Apart from LDH, there was no significant difference in the baseline clinical and laboratory variables and overall survival (OS) between *JAK2/ CALR/ MPL* mutated and triple negative patients in AP/ BP. Median OS for the entire cohort was 5.8 months. The 2 year OS was 18%, 15% and 9% for the intensive, less intensive and BSC groups respectively. *TP53* was the only individual mutation to correlate with shorter OS (HR 1.91, 95% CI: 1.02-3.56, *p*=0.04; Figure 1). Number of mutations was also significant with ≥4 mutations associated with worse survival (HR 5.51 95% CI: 2.50-12.15 p<0.0001). Other factors significant on the univariate and multi-variable analysis and associated with shorter OS included: lower albumin level, increased percentage of blasts in peripheral blood and ≥3 cytogenetic abnormalities.

Summary and Conclusions: *TP53* mutation and ≥4 mutations predict shorter survival in patient with AP/BP of MPN. Mutational profile along with cytogenetics can help in selecting patients who may benefit most from curative approach. This is an area of unmet clinical need and alternative treatment strategies are urgently needed.

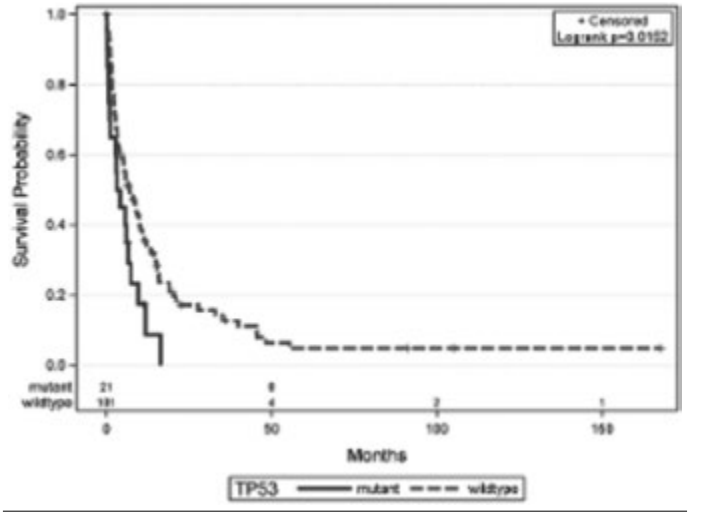

Figure 1.

PF620

SAFETY AND EFFICACY OF COMBINATION THERAPY OF INTERFERON ALPHA-2 AND RUXOLITINIB IN POLYCYTHEMIA VERA AND LOW-/INTERMEDIATE-1-RISK MYELOFIBROSIS – A ONE YEAR FOLLOW-UP UPDATE OF A PHASE II STUDY

S.U. Mikkelsen[1,2,*], L. Kjær[1], M.E. Bjørn[1], T.A. Knudsen[1], A.L. Sørensen[1], V. Skov[1], C.B.L. Andersen[1], O.W. Bjerrum[2], N. Brochmann[1], D. El Fassi[3,4], T.A. Kruse[5], T.S. Larsen[6], H.T. Mourits-Andersen[7], C.H. Nielsen[4], N. Pallisgaard[8], M. Thomassen[5], H.C. Hasselbalch[1]

[1]Department of Hematology, Zealand University Hospital, Roskilde, [2]Department of Hematology, Rigshospitalet, [3]Department of Hematology, Herlev University Hospital, [4]Institute for Inflammation Research, Rigshospitalet, Copenhagen, [5]Department of Clinical Genetics, [6]Department of Hematology, Odense University Hospital, Odense, [7]Department of Hematology, South-West Jutlandic Hospital, Esbjerg, [8]Department of Pathology, Zealand University Hospital, Roskilde, Denmark

Background: Interferon-α2 (IFNα2) reduces elevated blood cell counts and splenomegaly in pts with myeloproliferative neoplasms (MPN), and has demonstrated the potential to restore polyclonal hematopoiesis. In a subset of pts, long-term treatment with IFNα2 may induce 'minimal residual disease' defined by normal blood cell counts, normal bone marrow morphology, and low clonal allelic burden (<1%). Its use is limited by inflammation-mediated toxicity, leading to treatment discontinuation in 20-30% of pts. Ruxolitinib (Rux), a potent anti-inflammatory agent, has shown benefit in pts with myelofibrosis (MF) and polycythemia vera (PV) in regard to reducing splenomegaly and symptoms. However, in the majority of pts Rux does not markedly reduce the mutant allelic burden. Combination therapy (CT) with these two agents may be more efficacious than monotherapy with either, potentially improving tolerability of IFNα2 as well.

Aims: To investigate the safety and efficacy of CT with IFNα2 and Rux in MPN pts.

Methods: The COMBI study (#EudraCT2013-003295-12) is a prospective, open-label, single-arm, multicenter phase II study of CT with pegylated IFNα2 (PEG-IFNα2) and Rux in MPN pts (off-label use). Initial therapy was PEG-IFNα2a 45 g or PEG-IFNα2b 35 g once weekly SC and Rux 20 mg BID PO. Planned treatment duration is 24 months. Enrollment is completed, and we report the results from 12 months of follow-up in the 50 enrolled pts. Of these, 32 pts had PV, and 18 pts had low-/intermediate-1-risk MF (primary MF, n=13; post-PV MF, n=4; post-essential thrombocythemia, n=1). The majority of the pts (n=47) were resistant and/or intolerant to IFNα2 monotherapy. Objectives included remission (ELN and IWG-MRT 2013 revised criteria encompassing histologic, hematologic, and clinical responses), toxicity, complete hematologic response (CHR), and molecular response. All pts provided written informed consent.

Results: Partial remission (PR) and sustained CHR were achieved in 9% and 44% of PV pts, respectively. In MF pts, complete or partial remission was achieved in 39%, and sustained CHR in 58%. The median *JAK2*V617F allelic burden declined significantly from 47% (range, 1.8-97%) to 23.5% (range, 0.73-89%; *P*<.0001) in PV pts, and from 45% (range, 0.1-97%) to 18% (range, 0.08-95%; *P*<.0001) in MF pts. Hematologic toxicity was the most common adverse event (AE) and was managed by dose reduction. The most common non-hematologic AEs were arthralgia and/or myalgia (n=40, in 24

pts), symptoms related to PEG-IFNα2 injection (flu-like symptoms, injection site reactions; n=36, in 24 pts), and gastrointestinal symptoms (nausea, abdominal pain, dyspepsia, diarrhea; n=31, in 27 pts). Thirty-seven serious adverse events (SAEs) were recorded in 23 pts. Four SAEs; angina pectoris, herpes zoster (n=2), and anemia/thrombocytopenia, were considered causally related to study therapy. One thromboembolic event (ischemic stroke) was recorded in a PMF pt. The discontinuation rate was 20% (Table 1).

Table 1.

Summary and Conclusions: We conclude that CT with IFNα2 and Rux is feasible and efficacious in pts with low-/intermediate-1-risk MF and, to a lesser extent, in pts with PV including in pts who were unresponsive or intolerant to IFNα2 monotherapy. A high number of SAEs was reported which in many cases reflected short hospitalizations (<24 hrs) elicited by signs of infection. These preliminary results encourage phase III studies as well as a study with CT in newly diagnosed MPN pts.

PF621

BONE MARROW MORPHOLOGY IN PATIENTS WITH POLYCYTHEMIA VERA RESISTANT TO FIRST AND SECOND LINE THERAPIES

H.M. Kvasnicka[1,*], G.L. Frank[1], M. Lemp[1], F. Lang[2], J. Thiele[3]

[1]Senckenberg Institute of Pathology, [2]Department of Medicine, Hematology/Oncology, University of Frankfurt, Frankfurt, [3]Institute of Pathology, University of Cologne, Cologne, Germany

Background: Resistance to first and/or second line therapies in polycythemia vera (PV) is frequently associated with an aggressive disease course and incresed risk of progression to Post-PV myelofibrosis (PPMF). In this regard, treatment failure to Hydroxyurea (HU) as the most frequently used cytoreductive agent is seen in about 15–20% of patients (pts).
Aims: This study was conducted to gain insight into the morphological and clinical heterogeneity of inadequately controlled PV, in particular after standard long-term HU therapy.
Methods: More than 500 consecutively collected cases with PV were screened in this observational study. Only pts with available bone marrow (BM) trephine biopsies at this disease stage were selected. PPMF was defined according to the WHO 2016 criteria and HU resistance was assessed according to ELN. BM trephines were evaluated for grade of BM fibrosis, cellularity, amount of CD34+ progenitors and morphology of megakaryocytes including the occurrence of myelodysplastic features associated with disease progression. Hematological and clinical data were collected at corresponding time points. The total cumulative HU dosage, the average dosage per years, as well as the highest used dosage to control disease were calculated.
Results: 61 cases (32 males, 29 females, median age 66 years) were analyzed. Median time after diagnosis was 8.3 years (range 2.7 – 20 years), median treatment time with first-line cytoreductive agents (HU in 89.3%) was 6 years (range 1 – 13 years years). Only 60.7% (37/61) of cases presented at this time point with a BM fibrosis grade ≥2, *i.e.* PPMF. 9 cases (14.8%) revealed a BM fibrosis grade of 1, whereas an uncontrolled myeloproliferation defined by increased platelet and/or leukocyte counts was found in 15 cases (24.6%). In 5 patients (8.2%) a blast phase was diagnosed at the time of treatment failure which was not associated with progressive fibrosis. Cases with grade 1 fibrosis or uncontrolled myelo-proliferation had higher hemoglobin levels, lower leukocytes count, and higher platelet counts at time of treatment failure as compared to the PPMF group. Classical PPMF more often was presenting with relevant cytopenia and erythrocyte transfusion dependency. MDS-like progression characterized by highly atypical megakaryocytes was observed in 15 pts (24.6%). There was no difference in the amount of CD34+ progenitors between classical PPMF and cases presenting with either grade 1 fibrosis or uncontrolled myeloproliferation. Pts presenting with MDS-like BM features (Figure 1) received a significantly higher total HU dosage (median 4,500 *vs* 721 gram, p=0.018) and showed a longer median treatment time with HU (8 *vs* 4 years), whereas the average annual dosage showed no significant difference.

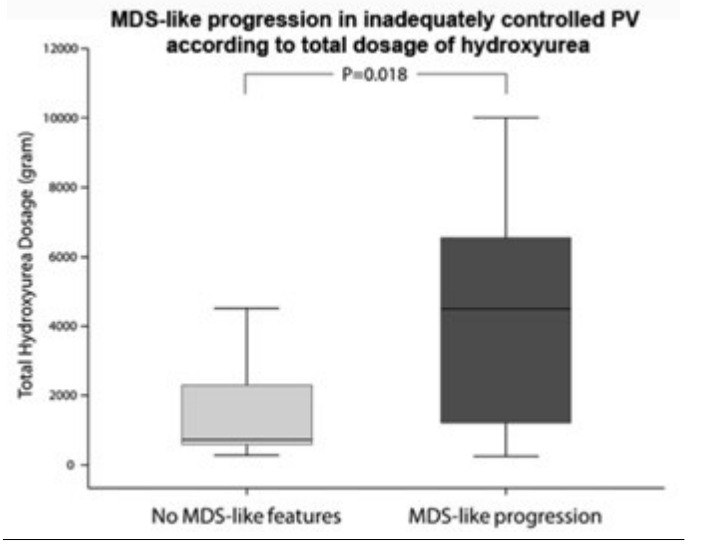

Figure 1.

Summary and Conclusions: Progression of inadequately controlled PV represents a biological spectrum and is not restricted by degree of BM fibrosis as in classical WHO defined PPMF, but can also be defined by resistance to cytoreductive agents like HU. In clinical practice it is important to recognize that high dosages of HU and long treatment duration are more often seen in the important subgroup presenting with MDS-like features.

PF622

WHO 2016 CLASSIFICATION IN 80 CHILDREN AND ADOLESCENTS WITH CHRONIC MYELOPROLIFERATIVE NEOPLASMS

M. Santopietro[1,*], G. Palumbo[1], M.L. Moleti[1], L. Cardarelli[1], L. Rizzo[1], F. Malaspina[1], C. Presicce[1], S.M. Orlando[2], R. Foà[1], F. Giona[1]

[1]Hematology, Department of Cellular Biotechnologies and Hematology, Sapienza University of Rome-Azienda Policlinico Umberto I, [2]Gimema Foundation, Rome, Italy

Background: The first classification of chronic myeloproliferative neoplasms (MPNs) was proposed in 1951 by Dameshek and since then it has been modified several times. The last classification of *BCR-ABL1*-negative MPNs, defined in 2016 by the World Health Organization (WHO), considers morphologic bone marrow (BM) features and driver mutations ($JAK2^{V617F}$, JAK2 exon 12, CALR and MPL) as major criteria. Thus, the WHO 2016 criteria better define MPNs as polycythemia vera (PV), essential thrombocythemia (ET), prefibrotic/early primary myelofibrosis (PMF) (pre-PMF) and overt PMF, making the identification of masked PV (mPV) and "true" JAK2-mutated ET easier. Our experience has suggested that MPNs in children and adolescents are characterized by subtypes that differ from those found in adults and require specific diagnostic criteria.
Aims: The present study was carried out in order to (a) retrospectively review the diagnosis of MPNs in patients aged <20 years based on the WHO 2016 classification and adapted in accordance with our experience in this category of patients, and (b) analyze their clinical and biologic features according to both the initial diagnosis criteria and the adapted WHO 2016 criteria.
Methods: Out of 93 patients aged <20 years with a diagnosis of MPNs carried out from 1980 to 2015, 80 (median age: 14.6 years) with bone marrow (BM) evaluation and available molecular analysis ($JAK2^{V617F}$, JAK2 exon 12, CALR, MPL, EPO-R and HIF) were considered. These patients were divided into different subgroups according to the criteria of their initial diagnosis (PVSG 1975, 1986, 1996, WHO 2001 and 2008): ET, PV, PMF. The subgroups were then retrospectively revised according to the WHO 2016 criteria into: ET, mPV, PV, pre-PMF, overt PMF. Patients with *HIF* mutations and/or criteria of familial erythrocytosis were defined as FE. Patients with MPL^{S505A} mutation were diagnosed as hereditary thrombocytosis (HT).
Results: As shown in Figure 1, of the 56 patients with an initial diagnosis of

ET, 16 (28.5%) had HT due to a *MPL*^{S505A} mutation, 3 (5.4%) were classified, according to the WHO 2016 classification, as mPV and 2 (3.6%) as PMF. Two out of 8 patients, with an initial diagnosis of PV, had FE due to a HIF2α mutation. Considering the adapted WHO 2016 classification, JAK2^{V617F} mutation was found in 28.5% and 44% of ET and PV patients, respectively. CALR mutations and *MPL*$^{W515\_P518>KT}$ were found in 26% and 2.7% of ET patients. Of 23 HT patients, 87% showed *MPL*^{S505A} and 13% *MPL*^{V501A}. Considering both the classification at initial diagnosis and the adapted WHO 2016 criteria, hemoglobin and hematocrit values were significantly higher in FE and slightly lower in PV patients (p<0.0001) and platelet counts were higher in ET and slightly lower in HT patients (p <0.0001) compared to other subgroups. Regarding the other features at diagnosis, leukocyte counts were significantly higher in PMF and ET patients (p= 0.0032), and the presence of medullary fibrosis (≥2 WHO grading) became significant in PMF patients (p= 0.0052), only according to the adapted WHO classification.

Diagnosis at the onset of the disease	N. of patients (%)	WHO 2016 classification (adapted)						
		PV	mPV	FE	ET	HT	pre-PMF	Overt PMF
PV	8 (10%)	6 (75%)	-	2 (25%)	-	-	-	-
FE	8 (10%)	-	-	8 (100%)	-	-	-	-
ET	56 (70%)	-	3 (5.4%)	-	35 (62.5%)	16 (28.5%)	1 (1.8%)	1 (1.8%)
HT	7 (8.75%)	-	-	-	-	7	-	-
PMF	1 (1.25%)	-	-	-	-	-	1	-
N. of patients (%)	80	6 (7.5%)	3 (3.75%)	10 (12.5%)	35 (43.75%)	23 (28.75%)	2 (2.5%)	1 (1.25%)

Figure 1.

Summary and Conclusions: The WHO 2016 criteria are able to identify mPV, pre-PMF and overt PMF in children and adolescents with MPNs also. On the whole, 43%, 56% and 75% of ET, PV and PMF, respectively, did not show gene driver mutations. Hereditary forms can be observed in a significant proportion (41%) of young patients with MPNs. Taken together, our observations suggest that molecular analysis to identify inherited molecular defects must be performed in children and adolescents with MPNs.

PF623

SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN PATIENTS (PTS) WITH DIPSS LOW-RISK MYELOFIBROSIS (MF) IN THE PHASE 3B EXPANDED-ACCESS JUMP STUDY

P. Guglielmelli[1,*], P. Raanani[2], R. Tavares[3], L. Foltz[4], B. Martino[5], E. Lomaia[6], M. Griesshammer[7], H.K. Al-Ali[8], V. Gupta[9], C. Bouard[10], J. Perez Ronco[10], R. Tiwari[11], P. Giraldo[12]

[1]CRIMM, Center for Research and Innovation of Myeloproliferative Neoplasms, AOU Careggi, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy, [2]Davidoff Cancer Center, Rabin Medical Center, Petah Tikva, Israel, [3]Universidade Federal de Goiania, Goiania, Brazil, [4]St. Paul's Hospital, University of British Columbia, Vancouver, British Columbia, Canada, [5]Azienda Ospedaliera Bianchi-Melacrino'-Morelli, Reggio Calabria, Italy, [6]Almazov National Medical Research Centre, St. Petersburg, Russian Federation, [7]Johannes Wesling Clinic, Minden, [8]University Hospital of Halle, Halle (Saale), Germany, [9]Princess Margaret Cancer Centre, Toronto, Ontario, Canada, [10]Novartis Pharma AG, Basel, Switzerland, [11]Novartis Healthcare Pvt. Ltd., Hyderabad, India, [12]Miguel Servet University Hospital and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Zaragoza, Spain

Background: RUX, a potent JAK1/JAK2 inhibitor, led to reductions in splenomegaly and symptoms and improved overall survival in pts with intermediate (Int)-2– and high-risk MF according to the International Prognostic Scoring System (IPSS) in the phase 3 COMFORT studies. Similar findings were observed in pts with Int-1–risk MF in the JUMP study, the largest phase 3b, expanded-access trial with RUX in countries with no access to RUX outside a clinical trial. However, data on RUX in pts with low-risk disease are limited.
Aims: To assess the safety and efficacy of RUX in a cohort of pts with Dynamic IPSS (DIPSS) low-risk MF in the JUMP study.
Methods: DIPSS scores were determined using pt characteristics at baseline, and pts with low-risk MF were included. Starting doses were based on baseline platelet (PLT) count (5 mg bid [≥50 to <100×10^9/L], 15 mg bid [100-200×10^9/L], or 20 mg bid [>200×10^9/L]) and could be titrated during treatment. The primary endpoint was RUX safety and tolerability. Changes in palpable spleen length and symptom scores were also assessed.
Results: Based on available data, 60 pts (primary MF, 53%) were determined to have DIPSS low-risk disease; 63% were male. Median baseline characteristics were age, 56.5 y (range, 29-65 y); time since diagnosis, 40.8 mo; hemoglobin, 124.5 g/L; and PLT count, 263.5×10^9/L. Mean spleen length was 13.4 cm (SD, 7.37 cm). Most pts had completed treatment per protocol (68.3%). Reasons for treatment discontinuation included adverse events (AEs; 13.3%), physician decision (5.0%), disease progression (3.3%), and death (1.7%). Overall, 63.3% of pts had dose modifications (AEs, 51.7%); 26.7% had temporary interruptions (AEs, 23.3%). Median exposure was 25.8 mo. The mean average daily dose was 30.4 mg (SD, 10.97 mg). The most common hematologic grade 3/4 AEs were anemia (20.0%) and thrombocytopenia (6.7%); 1 pt discontinued due to anemia (grade 1/2). AEs (all-grade, grade 3/4) in >10% of pts included pyrexia (18.3%, 0%), diarrhea (16.7%, 1.7%), headache (15.0%, 0%), asthenia (13.3%, 5.0%), fatigue (13.3%, 0%), cough (13.3%, 0%), and increased weight (11.7%, 0%). Infections in >2 pts were influenza (10.0%), nasopharyngitis (8.3%), respiratory tract infection (5.0%), and herpes zoster (5.0%). At wk 24, 67.4% of pts (31/46) had a ≥50% reduction from baseline in spleen length, and 10.9% (5/46) had 25%>50% reductions; rates were similar at wk 48 (61.0% [25/41] and 17.1% [7/41]). Best response in spleen length by wk 72 is shown (Figure 1). Most pts (82.1%) achieved a ≥50% reduction at any time. Median time to a ≥50% reduction in spleen length was 8.0 wk (range, 3.1-60.3 wk), and the estimated probability of maintaining a response was 0.92 (95% CI, 0.78-0.97) at 72 wk. Pts also experienced significant improvements in symptoms. From wk 4 to 48, 17.3%>21.4% and 36.5%>42.6% of pts achieved a clinically meaningful response on the FACT-Lymphoma total score and FACIT-Fatigue, respectively.

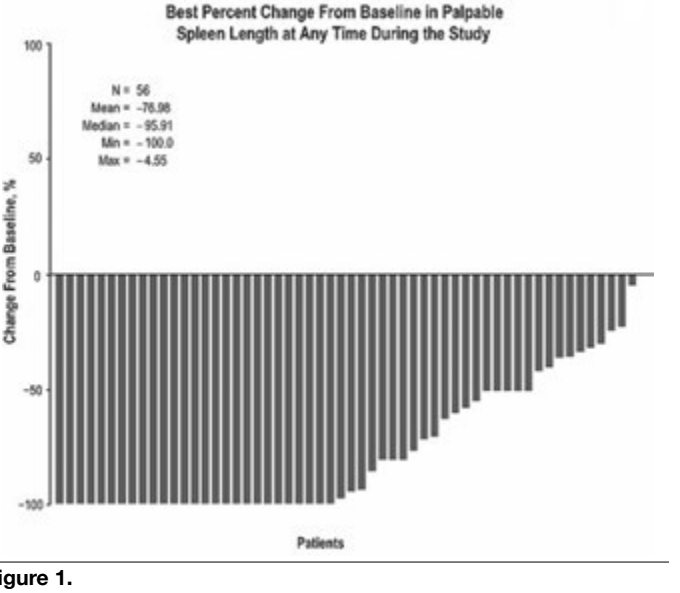

Figure 1.

Summary and Conclusions: RUX demonstrated a safety and AE profile consistent with previous reports. Interestingly, rates of hematologic AEs and discontinuations due to AEs were lower than in the overall JUMP population, despite longer exposure to RUX (25.8 *vs* 12.4 mo). Additionally, low-risk pts achieved slightly greater spleen size reductions, with 92% of pts maintaining a response for >1 y. Symptom improvement was also consistent with that seen in pts with higher-risk disease. These findings suggest that earlier RUX treatment may lead to greater benefits in pts with MF.

PF624

PRIMARY THERAPY AND SURVIVAL IN PRIMARY MYELOFIBROSIS: A NATIONWIDE POPULATION-BASED ANALYSIS AMONG 1,445 PATIENTS DIAGNOSED IN THE NETHERLANDS BETWEEN 2001 AND 2015

S. Slot[1], O. Visser[2], M. Schaap[3], J. Janssen[4], P. te Boekhorst[5], S. Zweegman[1], A. Dinmohamed[5,6,7,*]

[1]Hematology, VU University Medical Center, Amsterdam, [2]Registration, Netherlands

Comprehensive Cancer Organisation (IKNL), Utrecht, [3]Hematology, Radboud University Medical Center Nijmegen, Nijmegen, [4]Hematology, VU University Medical Center, Utrecht, [5]Hematology, Erasmus MC Cancer Institute, Rotterdam, [6]Research, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [7]Public Health, Erasmus University Medical Center, Rotterdam, Netherlands

Background: Primary myelofibrosis (pMF) is a chronic myeloproliferative neoplasm that is incurable in the vast majority of patients. It remains largely unclear how current management strategies impacted outcome of pMF patients at the population level.
Aims: The aim of this nationwide, population-study was to assess trends in primary therapy and survival among pMF patients diagnosed during a 15-year period in the Netherlands.
Methods: We selected all 1,445 pMF patients diagnosed between 2001-2015 (median age 70 years; range 20-95 years; 63% males) from the nationwide Netherlands Cancer Registry (NCR) with survival follow-up through December 31, 2016. Patients were categorized into 2 periods (2001-2007 and 2008-2015) and 3 age groups (≤60, 61-70, and >70). Data on therapy—chemotherapy (CTx), non-CTx therapies (eg, immunomodulatory drugs [IMiDs] and ruxolitinib), and allogeneic stem cell transplantation (alloSCT)—initiated within 9 months since diagnosis were available in the NCR. Data on the International Prognostic Scoring System (IPSS) and the exact therapeutic regimens were available for the period 2014-2015. Relative survival (RS) was calculated as a measure of disease-specific survival. $P<0.05$ indicates statistical significance.
Results: Slightly more patients received non-CTx therapies over time—albeit that increase was modest, namely from 2% to 8% ($P=0.028$), 4% to 12% ($P=0.007$), and 3% to 9% ($P=0.001$) across all 3 age groups (Figure 1). There were no statistically significant changes over time in the application of CTx and alloSCT across the 3 age groups (Figure 1). Of note, the age range of alloSCT recipients was 32-68 years.Data of 256 patients diagnosed during 2014-2015 showed that 136 (53%) patients received no anti-neoplastic therapy, of whom 24/43 (56%), 47/82 (57%), 33/65 (51%), and 17/42 (40%) had low, int-1, int-2, and high risk IPSS, respectively. In 24/256 (9%) patients, the IPSS was unknown. The distribution across the 4 IPSS groups among the 120 (47%) treated patients were 19 (16%), 35 (29%), 32 (27%), and 25 (21%), respectively. All 59 CTx recipients received hydroxyurea (HU), except one who received melfalan. HU was applied in 14/19 (74%), 20/35 (57%), 14/32 (44%) and 5/25 (20%) patients across the 4 IPSS groups, respectively. Most of the 49 non-CTx recipients received ruxolitinib (70%), followed by IMiDs (14%), interferon-α (12%), and momelotinib (4%). Ruxolitinib was applied in 5/19 (26%), 7/35 (20%), 11/32 (34%), and 8/25 (32%) patients across the 4 IPSS groups, respectively. Ten of 12 alloSCT recipients had high risk IPSS. Five-year RS (95% confidence intervals) did not improve over time across 3 age groups and was 76% (67%>83%), 49% (39%>58%), and 31% (24%>39%) in 2001-2007, as compared with 80% (72%>86%), 53% (46%>60%), and 39% (33%>46%) in 2008-2015, respectively ($P>0.05$ for all comparisons; Figure 1). There was a hint that RS reached a plateau after 6 years since diagnosis for patients age ≤60 in 2008-2015.

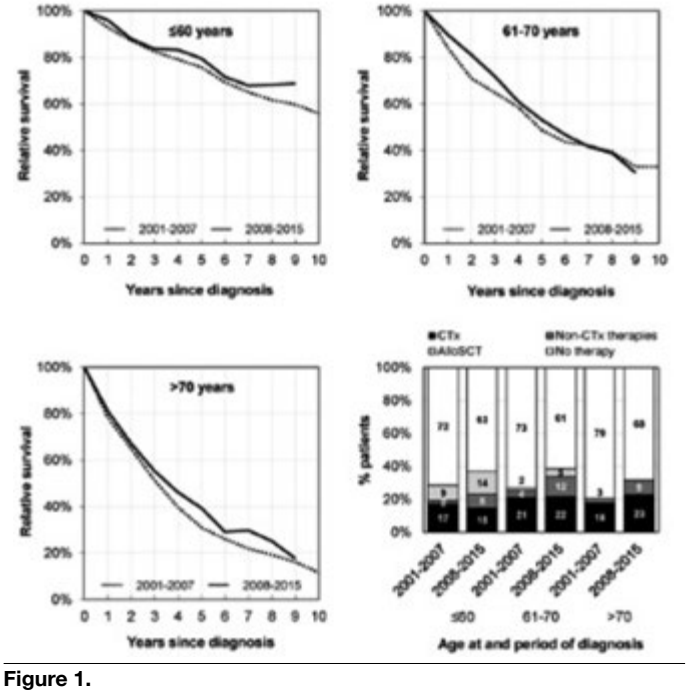

Figure 1.

Summary and Conclusions: We show that pMF patients have excess mortality—as compared to the general population—which did not significantly decline over time, irrespective of age. This might suggest that current treatment practices are inadequate to improve outcome for most patients. Future population-based research is needed to assess the impact of improved management (eg, broader application of reduced-intensity conditioning alloSCT among younger, transplant-eligible patients) and novel agents (eg, wider use of ruxolitinib that was approved for routine use in the Netherlands since 2014) on the outcome of pMF patients managed in daily practice.

PF625

RUXOLITINIB COMPARED WITH BEST AVAILABLE THERAPY FOR POLYCYTHAEMIA VERA PATIENTS RESISTANT OR INTOLERANT TO HYDROXYCARBAMIDE IN MAJIC - AN INVESTIGATOR-LED RANDOMISED TRIAL

Background: Polycythaemia vera (PV) is a myeloproliferative neoplasm driven by *JAK2* mutation & is associated with thrombotic/haemorrhagic events, systemic symptoms & disease transformation. Hydroxycarbamide (HC) is the standard first-line treatment for high-risk PV; however, symptom control is poor & »25% of patients become HC resistant/intolerant (RES/INT). Ruxolitinib (RUX) a JAK1/2 inhibitor has significant clinical benefits in myelofibrosis (MF) & in selected HC RES/INT PV patients. The role of RUX for many patients with HC RES/INT PV encountered in routine clinical practice remains unclear.
Aims: To evaluate efficacy of RUX compared to Best Available Therapy (BAT) treatment in a "real-world" setting of PV patients who met modified European LeukaemiaNet (ELN) criteria for HC RES/INT.
Methods: We conducted a randomised, phase II, trial of RUX *vs* BAT for patients with HC RES/INT PV. Primary outcome was achievement of complete haematological response, CR within 1 year (according to ELN guidelines); secondary outcomes included partial haematological response, safety, thrombosis, haemorrhage, transformation (all adjudicated by central review), as well as symptom & quality of life assessment. Patients were recruited over 48 months (2012-2016) & randomised to receive 5-10mg bd of RUX (determined by baseline platelet count) or BAT, with stratification by gender & planned follow-up of 5 years without crossover within the trial. Patients eligible for modified intention to treat (mITT) analysis were those who commenced study treatment & had at least one response assessment. Patient reported outcomes were assessed using EQ5D, MDASI & MPN Symptom Assessment Form (MPN10).
Results: Overall 190 patients were recruited, 182 (107 male) were eligible for mITT analysis, 93 (51%) & 89 (49%) in RUX & BAT arms respectively, mean age 64.6yrs & HC RES/INT (55.4%/44.5%). Baseline characteristics at randomisation were balanced. The primary outcome was achieved in 46 (49.5%) of the patients in the RUX arm *vs* 24 (27.0%) in the BAT arm (p= 0.0009). Partial response occurred in 44 (47.3%) & 59 (66.3%) of those treated with RUX & BAT respectively. Median dose of RUX received was 10mg bd & median follow-up was 2.6 years. Both speed of attaining response (Figure 1A) & duration of overall response (Figure 1B) were also significantly superior for RUX treated patients. Mean MPN-10 TSS, itching, fatigue, night sweats, early satiety, weight loss, bone pain, inactivity, & concertation during the first 12 months were all significantly lower for RUX *vs* BAT (all p<0.05). In RUX treated patients, 12 thrombotic events were experienced by 10 patients & 9 haemorrhagic events by 9 patients; for BAT, 12 thrombotic events occurred in 10 patients & 9 haemorrhagic events in 8 patients. There was no difference in overall survival but a trend to

improved transformation-free survival with RUX was observed (Figure 1C). No new pattern of safety events was noted: grade 3 anaemia occurred in 6.5% of RUX patients *vs* 1.1% in the BAT arm, grade 4 thrombocytopenia in 1.1% of RUX *vs* 0% of BAT patients respectively, & grade 3/4 infections occurred in 8.6%/2.2% of RUX arm *vs* 2.2%/3.4% in BAT arm.

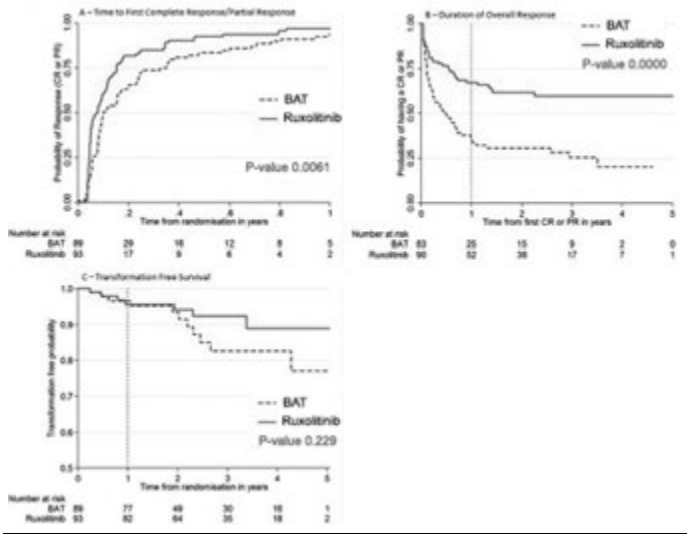

Figure 1.

Summary and Conclusions: Clinically & statistically significant improvement in complete haematological responses within 1 year occurred in RUX compared to BAT treated patients. Responses were more rapidly achieved & were more durable with RUX than BAT & associated with improved symptoms. Our data show RUX is superior to BAT in a "real world" setting of HC RES/INT PV & for the first time that RUX may improve TFS.

PF626

RESULTS FROM ONGOING PHASE 1/2 TRIAL OF SL-401 IN PATIENTS WITH RELAPSED/REFRACTORY CMML

M. Patnaik[1,*], H. Ali[2], V. Gupta[3], G. Schiller[4], S. Lee[5], A. Yacoub[6], M. Talpaz[7], M. Sardone[8], H. Wysowskyj[8], S. Shemesh[8], J. Chen[8], C. Brooks[8], T. Goswami[8], A. Pardanani[1], A. Tefferi[1], S. Verstovsek[9], J. Khoury[9], N. Pemmaraju[9]

[1]Mayo Clinic, Rochester, [2]City of Hope, Duarte, United States, [3]Princess Margaret Cancer Centre, Toronto, Canada, [4]UCLA, Los Angeles, [5]Weill Cornell Medical Center, New York, [6]Kansas University Cancer Center, Westwood, [7]University of Michigan Health System, Ann Arbor, [8]Stemline Therapeutics, New York, [9]The University of Texas MD Anderson Cancer Center, Houston, United States

Background: The outcomes for chronic myelomonocytic leukemia (CMML) patients are poor, with overall response rates (ORR) of ~16% for hypomethylating agents (HMA) in first-line registration studies, and median overall survival (OS) of ~4-7 months in the relapsed/refractory setting. SL-401 is a novel targeted therapy directed to the interleukin-3 receptor-α (CD123), a target expressed on a variety of malignancies, including certain myeloproliferative neoplasms (MPNs) such as CMML. CD123 is also expressed on plasmacytoid dendritic cells (pDCs), which can reside in the tumor microenvironment and may play a role in promoting growth of MPN and other malignancies. Accordingly, a therapy directed at CD123-expressing malignant cells and/or their neighboring pDCs may offer a novel therapeutic approach. SL-401 has demonstrated high levels of clinical activity against blastic plasmacytoid dendritic cell neoplasm (BPDCN), a CD123+ malignancy derived from pDCs, and is also being evaluated in Phase 1/2 trials of other cancers.
Aims: Primary objectives include assessment of safety, determining optimal dose/regimen, and evaluating efficacy outcomes in patients with relapsed/refractory CMML.
Methods: This multicenter, single-arm 2-stage Phase 1/2 trial is enrolling patients with MPN including relapsed/refractory CMML. In the Stage 1 dose escalation cohort (completed), SL-401 was dosed as a daily IV infusion at 7, 9, and 12 mcg/kg/day, on days 1-3 every 21 days (cycle 1-4), every 28 days (cycles 5-7), and every 42 days (cycles 8+). In Stage 2 (ongoing), the dose determined to be optimal in Stage 1 (12 mcg/kg) is being employed.
Results: As of 2/27/18, 14 CMML patients (CMML-1 [n=8]; CMML-2 [n=6]) received SL-401. 12 patients were second-line and 2 patients were third-line, with HMAs being the most commonly administered prior therapy. Median age was 70 years (range 42-80); 71% patients were male. Of the 13 patients with cytogenetic risk categories available, 5 patients (38%) were high risk, 5 patients (38%) were intermediate risk, 2 patients (15%) were low risk, and 1 patient (8%) was other. At baseline, median bone marrow (BM) blasts were 8% (range 0-18%); 57% of patients had splenomegaly (range: 2 to 20 cm palpable below costal margin (BCM) by physical exam). Most common treatment-related adverse events (TRAEs), all grades, were hypoalbuminemia and vomiting (36%), thrombocytopenia, fatigue, edema and nausea (each 29%). Most common ≥grade 3 TRAEs were thrombocytopenia (29%) and hypotension (14%). Capillary leak syndrome was reported in 3 patients (21%; all grade 2). 71% (5/7) of patients with baseline splenomegaly had 50% reduction in spleen size by physical exam: baseline 5, 4, 2, and 2 cm all reduced to 0 cm (100%) BCM; baseline 20 cm reduced to 10 cm (50%) BCM. 17% (2/12) of evaluable patients had BM complete response (BMCR), including 1 CR (15 months on treatment) and 1 BMCR (4+ months on treatment, ongoing).
Summary and Conclusions: Single agent SL-401 was well-tolerated and demonstrated 71% (5/7) rate of spleen reductions and a 17% (2/12) rate of BMCR (1 CR and 1 BMCR) in relapsed/refractory CMML, an area of unmet medical need. Given CD123 expression on certain myeloid neoplastic cells and pDCs in the tumor microenvironment, SL-401 may offer a novel targeted approach for CMML patients. Enrollment continues, and updated safety and efficacy data will be presented. Registrational designs are being evaluated. Clinical trial information: NCT02268253.

PF627

DABRAFENIB IN PEDIATRIC PATIENTS WITH BRAF V600–POSITIVE LANGERHANS CELL HISTIOCYTOSIS

J.A. Whitlock[1], A. Broniscer[2], S.R. Ambati[3], J.R. Hansford[4], T.R. Hummel[5], S. Leary[6], L.V. Marshall[7], V. Shen[8], M.W. Russo[9], K. Dasgupta[10], L. Tseng[9], B. Mookerjee[9], D. Hargrave[11,*]

[1]University of Toronto, The Hospital for Sick Children, Toronto, Canada, [2]St. Jude Children's Research Hospital, Memphis, [3]Memorial Sloan Kettering Cancer Center, New York, United States, [4]The Royal Children's Hospital, Murdoch Children's Research Institute, University of Melbourne, Melbourne, Australia, [5]Cancer and Blood Diseases Institute, Cincinnati Children's Hospital Medical Center, Cincinnati, [6]Cancer and Blood Disorders Center, Seattle Children's Hospital, Seattle, United States, [7]The Royal Marsden Hospital and The Institute of Cancer Research, Sutton, United Kingdom, [8]Children's Hospital of Orange County, Orange, [9]Novartis Pharmaceuticals Corporation, East Hanover, United States, [10]Novartis Healthcare Pvt. Ltd., Hyderabad, India, [11]Great Ormond Street Hospital for Children, London, United Kingdom

Background: Langerhans cell histiocytosis (LCH) is a rare tumor disorder associated with varied clinical manifestations and morbidities. LCH often occurs early in life, and there are limited effective therapies. *BRAF* V600 alterations (which constitutively activate the MAPK pathway) are oncogenic in many tumor types and are present in ≈ 57% of patients with LCH.
Aims: Here we report the safety and preliminary efficacy of the BRAF inhibitor dabrafenib in a phase I/IIa multicohort study in pediatric patients with *BRAF* V600–positive LCH (NCT01677741; BRF116013).
Methods: Patients aged 1 to <18 years with *BRAF* V600–positive LCH and refractory, recurrent, or progressive disease following ≥1 standard therapy were treated with dabrafenib (2 equal daily doses) in the dose-escalation (ESC) cohort (3.75 or 4.5 mg/kg/day) or in the disease-expansion (EXP) cohort at the recommended doses of 5.25 mg/kg/day (patients aged <12 y) and 4.5 mg/kg/day (patients aged ≥12 y). Primary objectives were safety and tolerability, and secondary objectives included tumor response, disease activity, and pharmacokinetics. Tumor response was reported by investigator assessment using Histiocyte Society criteria (HSC), and disease activity was measured using the Donadieu total scoring system (DTS).
Results: At the data cutoff for this interim analysis (September 12, 2017), 13 patients (enrolled from October 2013 to September 2016) had been treated with dabrafenib across the ESC (n=2) and EXP (n=11) cohorts. Median age was 3 years (range, 1-11 years), and prior therapies included chemotherapy (n=13), biologics, hormonal therapy, and immunotherapy (n=1 each). Overall, median duration of dabrafenib exposure was 92 weeks (range, 31-206 weeks), and 9 of 13 patients (69%) had treatment ongoing at data cutoff. The most frequent treatment-related adverse events were vomiting (46%), blood creatinine increase, dry skin, and melanocytic nevus (each 31%). One patient experienced treatment-related serious adverse events (headache, pyrexia, somnolence, and vomiting) that resolved without sequelae following dose interruption. No on-treatment deaths occurred. The overall response rate was 77% (10 of 13 patients; 5 patients with complete resolution [38%] and 5 with regression [38%]). Nine patients were continuing in response at

data cutoff (duration of response: range, 145 to 1236 days [both ongoing] with a minimum follow-up of ≈ 1 year). Three patients (23%) had stable disease. Twelve of 13 patients were on treatment and progression free at 12 months. One patient discontinued treatment at 31 weeks due to an adverse event (grade 2 creatinine increase), as required by protocol, while in complete remission. At screening, 8 patients (62%) had a DTS ≥1. Following treatment with dabrafenib, all but one patient (score unchanged) achieved a reduction in DTS, with 6 of 8 scores (75%) declining to 0.

Summary and Conclusions: Dabrafenib demonstrated a manageable safety profile in pediatric patients with *BRAF* V600–positive LCH. Observed responses and improvements in disease activity with dabrafenib in the majority of patients merit further investigation in this patient population.

PF628

COMPARISON OF RUXOLITINIB AND REAL-WORLD BEST AVAILABLE THERAPY IN TERMS OF OVERALL SURVIVAL AND THROMBOSIS IN PATIENTS WITH POLYCYTHEMIA VERA WHO ARE RESISTANT OR INTOLERANT TO HYDROXYUREA

A. Alvarez-Larran[1,*], S. Verstovsek[2], M. Pérez-Encinas[3], J.-J. Kiladjian[4], F. Ferrer-Marín[5], A.M. Vannucchi[6], J. Martínez López[7], C. Besses[8], C. Cameron[9], A. Situ[9], A. Charter[10], J.C. Hernández-Boluda[11]

Blasco Ibáñez 17, 46010, Valencia, Spain

Background: Ruxolitinib is a Janus kinase (JAK) 1 and 2 inhibitor approved for the treatment of patients with hydroxyurea-resistant/intolerant polycythemia vera (PV). In randomized controlled trials, ruxolitinib proved superior to best available therapy (BAT) in achieving hematocrit control without phlebotomy and reducing symptoms. However, comparison of overall survival (OS) and rate of thrombosis has been complicated due to a high degree of patient crossover from BAT to ruxolitinib in these trials.

Aims: To compare OS and thrombosis for ruxolitinib *versus* real-world BAT in patients with hydroxyurea (HU) resistant/intolerant PV.

Methods: Propensity score matching (PSM) was conducted using individual patient data (IPD) for patients treated in the ruxolitinib arm from the Phase III RESPONSE trial, and IPD for real-world patients treated with BAT from the Grupo Español de Enfermedades Mieloproliferativas Crónicas Filadelfia Negativas (GEMFIN) registry. The distribution of therapies for patients in the matched real-world BAT group were as follows: hydroxyurea (44%), busulfan (10%), radioactive phosphorus (2%), interferon (6%), anagrelide (12%), other therapy (11%) or no cytoreductive therapy (26%) (Some patients in the real-world BAT group were treated with multiple therapies). Eligible patients had resistance or intolerance to HU according to the modified European Leukemia Net criteria (Barosi G, *et al.* Br J Haematol 2010). Covariates selected for calculating propensity scores (PS) included age, sex, history of thrombosis at time of resistance/intolerance, cytopenia at the lowest HU dose and *JAK2* mutational status. PSM was performed using caliper matching with a caliper width of 20% of the standard deviation of the logit-transformed PS, using sampling without replacement. Hazard ratios (HRs) were estimated from Cox proportional hazards models.

Results: Prior to performing PSM, there were statistically significant differences between ruxolitinib (n=110) and real-world BAT (n=191) in terms of age, sex, and cytopenia at the lowest HU dose or JAK2 mutational status. Before PSM, patients treated with ruxolitinib had significantly longer OS (HR=0.27 [0.12–0.62]) and a lower risk of thrombosis (HR=0.18 [0.05–0.61]) than patients treated with real-world BAT. The matched ruxolitinib and BAT cohorts formed after PSM (n=89 and 92 in each cohort for OS and thrombosis, respectively) were balanced for all covariates included in calculating PS. After PSM, ruxolitinib maintained a significantly prolonged OS (HR=0.28 [0.11–0.72]) and a lower risk of thrombosis (HR=0.21 [0.06–0.76]) compared with real-world BAT (Figure 1).

Summary and Conclusions: PSM analysis showed that patients resistant/intolerant to HU and treated with ruxolitinib in the RESPONSE trial had a significantly reduced risk of thrombosis and mortality compared to those with matched characteristics receiving BAT in the GEMFIN registry. Future studies are needed to validate these findings, and also assess comparative efficacy for other outcomes such as AML/MF/MDS. However, our study further supports the use of ruxolitinib in patients with resistance/intolerance to HU.

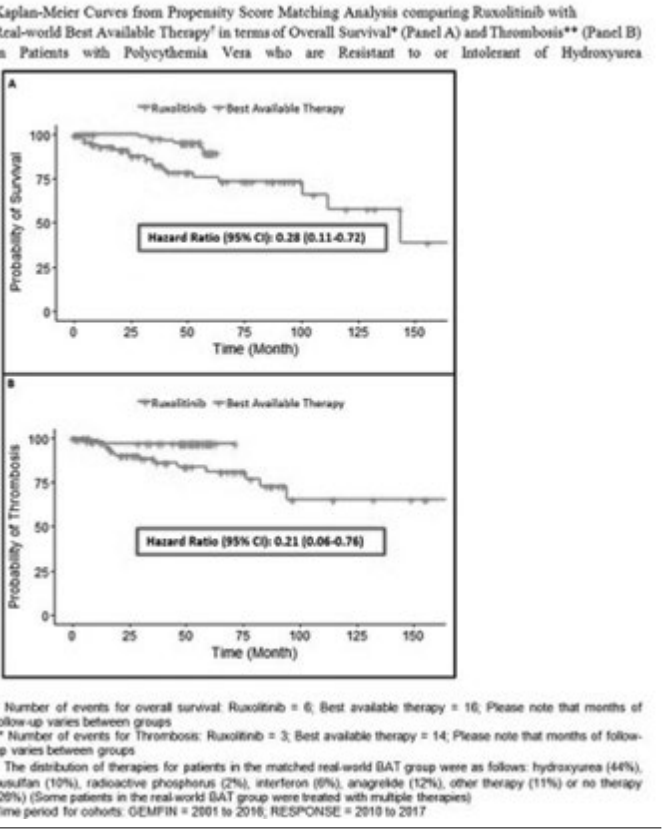

Figure 1.

PF629

RELATIONSHIP BETWEEN MPN PAIN AND EMOTIONAL HEALTH: AN ANALYSIS BY THE MPN QUALITY OF LIFE INTERNATIONAL STUDY GROUP

H. Geyer[1], R. Scherber[2,*], J. Palmer[1], A. Dueck[1], M. Girardo[1], L. Padrnos[1], R. Mesa[3]

[1]Mayo Clinic, Phoenix, [2]OHSU, Portland, [3]University of San Antonio, San Antonio, Texas, United States

Background: Debilitating pain is a frequent complaint in myeloproliferative neoplasms (MPNs). It is well recognized that close relationships exist between pain and expressions of emotional health including cognitive performance, social engagement and physical function. Uncontrolled pain has furthermore been associated with the development of depression and anxiety. The degree to which severe pain relates to the emotional health of MPN patients remains underexplored.

Aims: We aimed to analyze the relationship between MPN pain (bone pain or abdominal pain) and neurocognitive complaints, along with other MPN symptoms, demographic features and patient functionality.

Methods: Data was collected among an international cohort of MPN patients including MF, ET and PV. Subjects completed the EORTC-QLQC30, Brief Fatigue Inventory (BFI) and Myeloproliferative Neoplasm Symptom Assessment Form (MPN-SAF). Pain was assessed using the MPN-SAF quantitative questions related to 'bone pain' and 'abdominal pain' on a 0 (all reported symptoms absent) to 100 (all reported symptoms worst-imaginable) scale. Patients with mean pain scores of 4 and above were considered 'Severe Pain' whereas those under that value were considered 'Limited Pain'. Chi-square tests were used for categorical variables and two sample t-test were used for continuous variables.

Results: ***Demographics.*** A total of 2321 subjects with MPNs (ET 874, PV 953, MF 486) were prospectively enrolled and administered the MPN-SAF, BFI and EORTC QLQ-C30. Patient demographics including median age (61) and gender (M 46.8%) were within expected range. In comparison to Limited Pain patients, all Severe Pain patients demonstrated significant reductions in

mean EORTC QLQC30 scores for functional domains (Figure 1, all p<0.0001). They were also more likely to describe feeling irritable (32.5% *vs* 11.4%, p<0.0001) and depressed (33.2% *vs* 10.4%, p<0.0001; TSS 4.3 *vs* 1.8, p<0.0001) and have compromised relations with other people (TSS 3.9 *vs* 1.6, p<0.0001). Severe Pain patients also described difficulty with concentration (TSS 4.6 *vs* 1.8, p<0.0001), sleeping (TSS 4.9 *vs* 2.3, p<0.0001) and unintentional weight loss (2.3 *vs* 0.9, p<0.0001) while demonstrating marked reductions in overall quality of life (TSS 4.0 *vs* 6.0, p<0.0001).

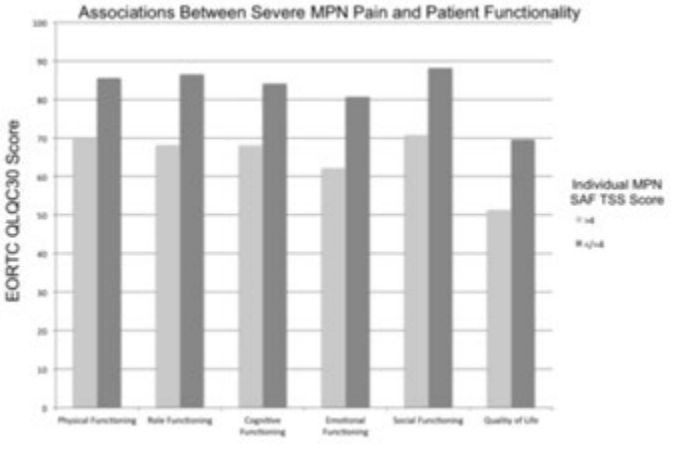

Figure 1.

Summary and Conclusions: The presence of severe abdominal or bone pain in MPN patients is significantly associated with compromised emotional health. Previous studies have demonstrated that MPN disease burden does not necessarily correlate with symptom severity, suggesting that Severe Pain patients may experience significant mental health afflictions even with low-risk disease. Appropriate measures for screening and management of MPN pain should be further investigated.

PF630

ANALYSIS OF IPSET-THROMBOSIS *VS* R-IPSET-THROMBOSIS IN A POPULATION OF 776 ESSENTIAL THROMBOCYTHEMIA PATIENTS - A MULTICENTER RETROSPECTIVE STUDY

M. Sobas[1,*], I. Andrasiak[2], K. Lewandowski[3], M. Narkun[3], J. Czyż[4], L. Szukalski[4], P. Nierychlewska[4], A. Czyż[1], A. Gołos[5], A. Masternak[6], A. Abuin Blanco[7], M. Perez Encinas[7], M.T. Gomez Casares[8], M.S. Noya Pereira[9], J. Marczyk[1], K. Roczek[1], T. Wróbel[1]

[1]Hematology, Medical University, [2]WroMedica Research Center, Wrocław, [3]University of Medical Science, Poznań, [4]University Hospital, Bydgoszcz, [5]Institute of Hematology, Warsaw, [6]Szpital Wojewódzki, Opole, Poland, [7]University Hospital, Santiago de Compostela, [8]Hospital Universitario Dr. Negrin, Gran Canaria, [9]Hospital Complejo Hospitalario Universitario, A Coruna, Spain

Background: The main morbidity of essential thrombocythemia (ET) are thrombotic complications. Classical risk score includes age>60 yrs and history of thrombosis separates patients into high and low-risk groups. Recently, JAK2 mutation and cardiovascular (CV) risk factors were additionally included in a 3-tiered (Low, Intermediate and High) International Prognostic Score of Thrombosis (IPSET-thrombosis). New revised IPSET-thrombosis (R-IPSET-thrombosis), based on thrombosis history, age>60 yrs and JAK2+, separates patients in four group: very low (no factors), low (JAK2+), intermediate (age>60 yrs) and high (history of thrombosis or age>60 yrs plus JAK2+).
Aims: To compare IPSET-thrombosis and R-IPSET-thrombosis in a population of 776 ET patients
Methods: We performed a retrospective, multicenter (5 Polish and 3 Spanish) study. Diagnosis was made according to WHO 2016 criteria. Clinical and analytical data were collected. Patients were assessed according to the IPSET-thrombosis and R-IPSET-thrombosis. Thrombosis free survival (TFS) was calculated from diagnosis and analyzed for each risk score.
Results: Out of 776 patients, 500 were female (64%), 392 were older >60 yrs (50.5%) and 451/770 (57%) presented CV factors at diagnosis. Mutation JAK2 was present in 65% of ET patients, and mutation CALR was present in 72% of ET JAK2- patients. Thrombosis before diagnosis occured in 13,5% and after diagnosis in 9%. Distribution of risk groups according to IPSET-thrombosis and R-IPSET-thrombosis is presented in a Table 1. The median follow-up period was 58 months (range 3-354). The potential prognostic factors: age >60 yrs, CV factors, platelet and white blood cell (WBC) count, JAK2 and CALR mutation, antiagregation/anticoagulation treatment were evaluated for TFS in univariate analysis. The following factors were found to be significant: CALR mutational status, age >60 yrs, the presence of CV factors, and high platelet count. In multivariate analysis, TFS was significantly impacted only by CALR mutational status (HR 0.39; p=0.06) and age >60 yrs (HR 1.2; p=0.035). Interestingly, we observed a significant association between JAK2+ and thrombosis incidence before diagnosis (25.3% *vs* 12.9%; p<0.001), however we did not find such association after diagnosis. According to IPSET-thrombosis, a 15 years – TFS for low *vs* intermediate *vs* high risk group was 91% (95%; CI 84-98) *vs* 87% (95%; CI 80-94) *vs* 72% (95%; CI 63-81), respectively (p=0.008). There were no significant differences in a TFS for a different risk groups assessed according to R-IPSET-thrombosis.

Table 1.

	R-IPSET-thrombosis				
IPSET-thrombosis	Very Low	Low	Intermediate	High	Total
Low	146	0	33	0	179
Intermediate	0	115	82	3	200
High	0	84	1	312	397
Total	146	199	116	315	776

Summary and Conclusions: Our results confirm that CALR mutation status and age influence TFS. However, we are not able to confirm the superiority of R-IPSET-thrombosis *vs* IPSET-thrombosis. We think that it could be related to the relatively short follow-up period and the possible influence of antiagregation/anticoagulation treatment in JAK2+ patients, who developed thrombotic complications before diagnosis and received anticoagulation/antiagregation treatment thereafter.

PF631

SKEWED RATIO BETWEEN TYPE 1 AND TYPE 2 CALR MUTATIONS IN ESSENTIAL THROMBOCYTOSIS PATIENTS WITH CONCOMITANT JAK2 V617F MUTATION

A. Aggerholm[1,*], L. Mors Haunstrup[1], M. Tang Severinsen[2], L. Hyldahl Ebbesen[1]

[1]Hematology, Aarhus University Hospital, Aarhus C, [2]Hematology, Aalborg University Hospital, Aalborg, Denmark

Background: Most patients with essential thrombocytosis (ET) and primary myelofibrosis (PMF) can be molecularly characterized by mutations in either Janus kinase 2 (JAK2, 60-65%), Calreticulin (CALR, 20-25%) or thrombopoitin receptor (MPL, 5%) and mutations in these genes are overall believed to be mutually exclusive. Several studies have analyzed the clinical and hematological features of ET and PMF patients according to mutational status. Younger age, high platelet counts but low risk of thrombosis has been associated with CALR mutated ET and PMF compared to JAK2 mutated cases. Numerous different indel mutations in exon 9 of CALR have been found with Type 1 (52 bp deletion) and Type 2 (5 bp insertion) as the most common variants. Recent reports indicate that Type 1 mutations are associated with PMF or ET with an increased risk of myelofibrotic transformation, while Type 2 mutations are associated with ET, low risk of thrombosis and indolent clinical course. Even though, overall believed to be mutually exclusive recent reports have shown concomitant mutations of JAK2 V617F and CALR in some MPN patients.
Aims: To ensure adequate molecular characterization for aiding clinicians providing more precise diagnoses and prognostication in patients with PMF and ET, we addressed the issue of double mutants in our patients. We retrospectively analysed for CALR mutation in all MPN patients initially analysed for JAK2 V617F between January 2012 and April 30th 2015 for whom allele frequencies of the JAK2 mutation was between 0.01% and 5%. 136 patients were positive for JAK2 V617F with allele frequencies in this range. In addition, 46 patients with JAK2 V617F allele frequencies between 6% and 10% were analysed.
Methods: The JAK2 V617F analysis was performed with allele specific qPCR with sensitivity at 0.01% and CALR exon 9 mutations were analysed by fragment length analysis with sensitivity at 2%.
Results: We identified 15 patients with concomitant CALR mutation within the group of MPN patients with JAK2 V617F allele frequencies below 5%, while none of 46 patients with JAK2 V617F allele frequencies above 5% had a CALR mutation. Ten patients were diagnosed with ET, three with PMF and two patients were MPN-unclassifiable. We identified five Type 1 and ten Type 2 CALR mutations with allele frequencies in the range 9 - 44%. Median age of all patients was 70 y (40 – 76) and all except two

patients with PMF had thrombocytosis. Median age of patients with ET was 69.5 y (40 – 75) and median thrombocyte count was 1195 (715 – 1755). None of the ET patients progressed to myelofibrosis (median follow-up 89 m, 40-204). In the ET group 3 patients were positive for CALR mutation Type 1 and seven were positive for Type 2. Two of 3 ET patients with Type 1 mutation experienced thrombosis two years prior to diagnosis (DVT and non-stemi, respectively), while only one patient with Type 2 mutation had thrombosis (DVT, 2 y post diagnosis).

Summary and Conclusions: Screening of 136 patients with low allele frequencies of JAK2 V617F (<6%) revealed 15 patients with a concomitant CALR mutation. In our cohort of MPN patients, the ET diagnosis was overrepresented among patients with concomitant JAK2 V617F and CALR mutation. We observed more patients with CALR Type 2 mutation than Type 1, which is contrary to previous reports. Our data indicate an association between double mutation in JAK2 V617F and CALR, an ET diagnosis, older age and indolent disease. These data stress the importance of extended molecular analyses in MPN patients with low JAK2 V617F allele frequencies.

Papanicolaou Hospital, Thessaloniki, Greece, [13]Hematopathology Department, University of Athens, School of Medicine, Athens, Greece, [14]Division of Haematology, Department of Translational Medicine, University of Eastern Piedmont, Novara, Italy

Background: Clonal B cell lymphocytosis of marginal zone origin (CBL-MZ) is used to characterize cases with isolated clonal B lymphoproliferation and immunophenotypic features suggestive of MZ derivation.

Aims: To further investigate this diagnostic conundrum so as to reach to definitive conclusions regarding its precise nature, diagnostic criteria and management.

Methods: In extension of our previous publication of the largest cohort of CBL-MZ thus far described, (Group A; n=102), here we update outcome data for Group A, describe an additional series of CBL-MZ cases (Group B), consolidated through a multi-institutional collaboration within the International Splenic Lymphoma Study Group, and compare Groups A and B. Cases included in the study were selected according to the following criteria: clonal lymphocytosis regardless of clonal size; Matutes score ≤2; absence of lymphadenopathy, organomegaly or concurrent cytopenias; and, absence of any diagnostic hallmark of a well-defined lymphoma.

Results: Overall, 58 novel cases (males/females: 33/25) were included in the study with a median age at diagnosis of 73 years and a median lymphocyte count of 6.3x10^9/l (range: 1.5-36 x10^9/l); 15/46 (32.6%) cases with available data exhibited paraproteinemia. Histopathological examination of the bone marrow biopsy (BMB) was performed in 27/58 cases. The BM infiltration ranged from 7-70%; in most cases, BMB examination disclosed mixed patterns of neoplastic lymphocytic infiltration from mostly small and medium-sized B cells. Some lymphocytes exhibited villi but this was not a consistent finding. Of 15 cases tested, 3 (20%) were found positive for the *MYD88*^{L265P} mutation and were all positive for paraproteinemia (IgM). Karyotype data was available in 34 cases; 15/34 (44%) had an abnormal karyotype and in 4 (11.7%) the karyotype was complex. Deletion 7q32 was observed in 2 patients and trisomy12/dup(12q) and i(17q) in 3 patients. Regarding immunogenetics, the IGHV4-34 and IGHV3-23 genes predominated (3/26, 11.5% each) whereas the IGHV1-2 gene was utilized by a single case; 4/26 rearrangements (15.4%) carried IGHV genes with no somatic hypermutations (SHM), while the remainder (22/26, 84.6%) exhibited some impact of SHM. With a median follow-up of 4 years, only 3 cases exhibited clinical or histopathologic evidence of a known lymphoma: a single case developed diffuse large B cell lymphoma of the skin and 2 cases developed splenomegaly and thus, can be considered as splenic MZ lymphoma or SMZL/leukemia unclassifiable (SMZL/SLLU). Turning to Group A, with a median follow-up of 6 years, a total of 22/102 (21.5%) cases evolved: 16 developed splenomegaly (most of them requiring splenectomy or treatment), likely representing SMZL/SLLU, and 1 each were diagnosed with nodal MZ lymphoma, gastric MALT lymphoma, lymphoplasmacytic lymphoma, DLCBL of the skin, nodal DLBCL and follicular lymphoma grade 1 (clonal relationship was confirmed in the gastric MALT lymphoma case). Groups A *vs* Group B differed significantly only regarding clinical evolution (p=0.02)

that was lower in Group B, likely due to the fact that 16/58 Group B cases were newly diagnosed with a follow-up of less than 2 years.
Summary and Conclusions: Overall, our present findings highlight a rather consistent biological profile for CBL-MZ, while also offering further supportive evidence for its overall indolent clinical nature. Admittedly, open questions remain especially regarding the heterogeneity in clinical outcome and can only be addressed within large collaborative groups and multidisciplinary approaches.

PF633

BUILDING PRECLINICAL MOUSE MODELS FOR MANTLE CELL LYMPHOMA

T. Pieters[1,*], S. T'Sas [1], F. Matthijssens[1], J. Morscio [1], L. Reunes[1], B. Lintermans[1], J. Van Dorpe[2], G. Berx[3], J. Haigh[4], S. Goossens[1], P. Van Vlierberghe[1]

[1]Department for Pediatrics, Center for Medical Genetics, Ghent University, [2]Department of Pathology, Ghent University and Ghent University Hospital, Ghent, [3]Department for Biomedical Molecular Biology, Ghent University, Zwijnaarde, Belgium, [4]Australian Centre for Blood Diseases, Department of Clinical Haematology, Monash University and Alfred Health Alfred Centre, Melbourne, Australia

Background: Mantle cell lymphoma (MCL) is a highly aggressive subtype of B-cell lymphoma that is characterized by a poor response to current treatment regimens. Most MCLs carry a prototypical translocation, t(11;14), which juxtaposes the *CCND1* gene towards the immunoglobulin heavy chain *(IGH)* locus, resulting in cyclin D1 overexpression. Strikingly, MCL has not been recapitulated in transgenic mouse models of Ccnd1 overexpression alone. Notably, a subset of MCL patients are cyclin D1 negative but instead overexpress cyclin D2 (encoded by *CCND2*) as a consequence of recurrent genomic rearrangements involving the *CCND2* locus. These *CCND2* rearrangements were acknowledged in the revised 2016 WHO classification of lymphoid neoplasms and hints towards a putative role for Cyclin D2 in the etiology of MCL.
Aims: We wanted to evaluate if cyclin D2 could act as a bona fide oncogene in the pathogenesis of MCL. Furthermore, we aimed to model MCL in mice and use them as a preclinical tool to identify novel therapeutic options for MCL patients.
Methods: To identify the role of Cyclin D2 in the formation of MCL *in vivo*, we developed a conditional R26-driven Ccnd2 overexpression mouse model. For this, we used a targeting vector that contained a floxed stop cassette followed by the *Ccnd2* gene and a EGFP/luciferase reporter, which was subsequently targeted in mESCs using recombinase-mediated cassette exchange (RMCE, Figure 1A).

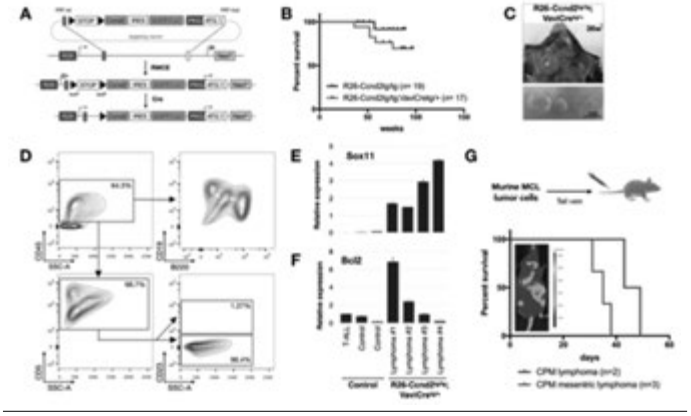

Figure 1.

Results: We found that hematopoietic-specific Ccnd2 activation (using VaviCre) is sufficient to drive MCL formation in mice. Moreover, we could show that this murine model recapitulates several clinical features of MCL patients, including CD19+, CD5+, CD23- immunophenotype, clonal tumor expansion, lack of somatic hypermutation, high expression of Sox11 and Bcl-2, and infiltration in spleen, liver and GI tract (Figure 1B-F). Detailed molecular analysis of these murine MCLs using shallow sequencing and whole exome sequencing revealed genetic aberrations similar to these found in MCL patients, including a somatic deletion of Crfl2. Furthermore, these murine MLC tumors were transplantable and homed to sites within the lymphatic system, but unfortunately did not show aggressive growth *in vivo*. Finally, we tested putative synergism between Ccnd2 overexpression and other cooperating genetic lesions that occur in human MCL, such as loss of p53. To this end, we generated mice with B-cell specific Cyclin D2 overexpression and p53 deletion. These mice also formed MCL-like tumors and developed "full blown" MCL within weeks upon their transplantation into immunocompromised mice (Figure 1G). Importantly, the transplanted tumor cells are luciferase-positive and are therefore suitable for *in vivo* drug testing using bioluminescence. As proof-of-principle, we tested the efficacy of known MCL drugs, such as Ibrutinib and Venetoclax, alone or in combination in our model system.
Summary and Conclusions: In conclusion, we generated novel cyclin-D2-driven MCL mouse models that can be used for preclinical drug screening and will hopefully lead to a better outcome for MCL patients.

Background: Recent studies revealed number of genomic aberrations associated with transformation of follicular lymphoma (FL) to diffuse large B-cell lymphoma (DLBCL) including frequent aberrations activating MYC. However, the precise molecular mechanisms underlying this process are largely unclear.
Aims: We aim to understand the role of miRNAs in the process of high-grade transformation of FL (tFL).
Methods: We performed a global miRNA expression analysis in 16 paired primary samples from FL patients before and after transformation to DLBCL. The gene expression/IHC studies were performed on samples from an additional 10 paired FL-tFL and 85 FL.
Results: *miR-150* was uniformly down-modulated (~3.5-fold) in all examined tFL (n=26, 13 paired samples). We showed that elevated levels of MYC protein are responsible for repressing *miR-150* in tFL, and rare MYC-positive FL had significantly lower *miR-150* expression compared to MYC-negative FL cases. Additionally, samples of CLL with MYC aberration had lower *miR-150* levels. We have shown that silencing of MYC leads to up-regulation of miR-150 in B cells, and MYC over-expression leads to repression of *miR-150*. This was not dependent on LIN28A/B proteins, which are induced by MYC and impair the *miR-150* maturation in myeloid cells. The LIN28A/B protein was absent in all examined B cell lines and primary samples. Our data from chromatin-IP for MYC show that MYC regulates *miR-150* expression directly by binding in the region upstream of *MIR150* transcription start site. Interestingly, low-level *miR-150* expression predicted a substantially shorter overall survival (OS) in FL in a univariate and multivariate analyses (median 9.1 yrs *vs* not reached; P=0.008; HR 3.5 [CI: 1.3-9.2]). *miR-150* was also significantly lower in patients with early death or relapse within 2 years from diagnosis, which suggests that measuring *miR-150* levels could be useful for identifying the ~20% of FL patients with the most aggressive course (Casulo *et al.*, 2015). We showed that low *miR-150* levels in FL and tFL lead to upregulation of its target FOXP1, which is a positive regulator of B cell activation and BCR signalling. The high-level FOXP1 expression associated with high Ki67 proliferation index and shorter OS in FL (median 33 months *vs* not reached; P=0.03; HR 5.0 [CI: 1.1-22.6]. However, *miR-150* likely regulates also other targets that influence cell cycle alone or together with FOXP1.
Summary and Conclusions: We have shown for the first time that miRNAs are involved in FL transformation. *miR-150* is transcriptionally repressed by MYC in transformed FL and aggressive FL, and this leads to higher

FOXP1 levels. The low levels of *miR-150* and high levels of its target, FOXP1, are associated with shorter OS and early relapse in FL, and this suggest that *miR-150* could serve as a promising biomarker.

THE AXL TYROSINE KINASE INHIBITOR, BGB324, INDUCES CELL DEATH IN MANTLE CELL LYMPHOMA

P. Gelebart[1,*], J. Han[2], I. Karlsen[2], M. Eriksen Gjerstad[2], L. Helgeland[3], F. Baran-Marszak[4], B. Papp[4], E. Mc Cormack[2]

[1]Clinical Science, [2]University of Bergen, Bergen, Norway, [3]Pathology, University of Bergen, Bergen, Norway, [4]INSERM U978, Université Paris 13, Bobigny, France

Background: Mantle cell lymphoma (MCL) is an aggressive B-cell non-Hodgkin lymphoma with poor overall survival.Thus, there is an urgent need to develop and identify new therapeutic target for MCL.
Aims: In this study, we report that the tyrosine kinase receptor AXL is consistently expressed in MCL. MCL cells express the AXL isoform 1 and 2 as well as the more recently describe isoform 3. In the view of previously describe oncogenic function of AXL in several solid and hematopoietic cancer, we hypothesized that AXL may be involved in the deregulation of cell signaling observed in MCL.
Methods: MCL cell lines or patient cells were treated with BGB324 or vehicle for a period of 2 days. Analysis of cell proliferation was assessed by trypan blue exclusion and MTA assays. Cell cycle was investigated by a flow cytometry and apoptosis induction was monitored by caspase activation. For the *in vivo* study, NSG mice were injected with Jeko-1 luciferase MCL cells and treated with vehicle (N=8) or BGB324 (N=8). Tumor development was monitored by an imaging approach (IVIS).
Results: We first demonstrated the expression of AXL at the mRNA and protein level in six MCL cell lines as well as in 7 patient samples examined using reverse transcription polymerase chain reaction and western blot approaches. To confirm the transcript identity, we cloned and sequenced the different AXL isoforms. We also found that AXL was constitutively activated in MCL cells using different phopho-AXL antibodies. Importantly, pharmacologic inhibition of AXL activity, with BGB324, resulted in a decrease in cell proliferation, cell cycle arrest and cell apoptosis of MCL cell lines and patient cells *in vitro*. Moreover, treatment of MCL cells lines with BGB324 led to a significant decrease in cyclin D1, b-catenin expression as well as a decrease in AKT and NF-kB activity. *In vitro*, the inhibition of BTK, by ibrutinib, and AXL show synergetic effect in induction of MCL cell apoptosis. *In vivo*, in a xenograft mouse model of MCL, treatment with BGB324 suppresses the growth of MCL cells with a higher efficacy than ibrutinib.
Summary and Conclusions: Taken together these data seem to support the concept that AXL contributes to the pathogenesis of MCL and that BGB324, an AXL inhibitor already engage in clinical trial, may hold promises for treating MCL as a single agent or in combinatory treatment with BTK inhibitor.

PF636

MODELLING MYD88 P.L265P DRIVEN LYMPHOMA

G. Knittel[1,*], T. Rehkämper[1], R. Flümann[1], P. Nieper[1], F. Beleggia[1], C. Fritz[1], A. Da Palma-Gueirrero[1], P. Pfeiffer[1], A. Klatt[1], L. Frenzel[1], R. Büttner[1], C. Reinhardt[1]

[1]University Hospital of Cologne, Köln, Germany

Background: The adaptor protein MYD88 is critical to relay activation of Toll-like receptor signaling to NF-kB activation. MYD88 mutations, particularly the p.L265P mutation, have been described in numerous distinct B cell malignancies, indluding diffuse large B cell lymphoma (DLBCL). 29% of activated B cell (ABC)-type DLBCL, which is characterized by constitutive activation of the NF-kB pathway, carry the p.L265P mutation. In addition, ABC-DLBCL frequently displays focal copy number gains affecting BCL2.
Aims: Here, we aimed to investigate the role of the Myd88p.L265P point mutation in lymphomagenesis by generating mouse models harbouring this recurrent mutation and to use these models for therapy development.
Methods: We generated a novel mouse model (termed Myd88c-p.L252P), in which Cre-mediated recombination, specifically in B cells, leads to the conditional expression of Myd88p.L252P (the orthologous position of the human MYD88p.L265P mutation) from the endogenous locus. More precisely, the endogenous exons 2 to 6 of Myd88 (which consists of 6 exons) were flanked by loxP-sites. Downstream of the last exon, a second set of exons 2 to 6 was inserted, harboring the point mutation p.L252P. Cre-mediated recombination leads to the excision of the endogenous exons 2 to 6 and expression of the inserted, mutated set of exons. This system very closely mimicks the situation observed in the clinic, as it allows for the heterozygous expression of Myd88p.L252P from the endogenous locus.
Additionally, we generated a BCL2-overexpression allele, which mimicks recurrent chromosomal amplifications of the BCL2 locus in DLBCL.
Results: BCL2 overexpression and MYD88 p.L265P strongly cooperate in generating a hyper-reactive state of the B cell compartment in double-mutant animals. This hyper-reactive state is characterized both by the loss of self-tolerance and an increased response to stimulation by foreign antigen. Double-mutant animals ultimately develop clonal lesions mainly in the mesenterial area, presumably out of the enhanced pool of activated B cells. These lesions histologically resemble DLBCL with plasmacytic features. Cells isolated from these tumors can be cultivated *ex vivo* and are transplantable, hence provide a useful tool for the investigation of new treatment strategies.
Summary and Conclusions: In summary, we generated a mouse model that enables Cre-mediated expression of Myd88p.L252P from the endogenous locus. Specifically in combination with BCL-2 overexpression, B cell-specific expression of Myd88p.L252P results in the development of an aggressive lymphoma with plasmoblastic features, most reminiscent of ABC-type DLBCL. These tumors are sensitive to BCL-2 inhibition by ABT-199.

CD3 BISPECIFIC ANTIBODY SCREEN IDENTIFIES CD20 AS THE MOST EFFICIENT TARGET FOR ELIMINATION OF B CELL MALIGNANCIES; PRE-CLINICAL EVALUATION OF DUOBODY-CD3XCD20

P. Engelberts[1,2,*], I. Hiemsta[1], J. Meesters[1], B. De Jong[1], T. Salcedo[1], S. Verploegen[1], E. van den Brink[1], D. Schuurhuis[1], S. Horbach[1], A. Labrijn[1], P. Parren[2], J. Schuurman[1], E. Breij[1]

[1]Genmab, Genmab, Utrecht, [2]Hematology and blood Transfusion, Leiden University Medical Center, Leiden, Netherlands

Background: The field of immuno-oncology is evolving rapidly through the addition of CD3 bispecific antibody (BsAb) molecules to its arsenal. While such T-cell retargeting bsAb have shown clinical activity in lymphoid malignancies, it is not known which B cell targets are optimally targeted using CD3 BsAb.
Aims: (i) To screen B cell targets suitable for CD3 BsAb targeting, using Genmab's proprietary bispecific antibody platform, (ii) preclinical development of a highly potent CD3 BsAb to target B cell malignancies in the clinic.
Methods: To identify the most potent B cell-targeting CD3 BsAb, an *in vitro* functional screen was performed with a panel of CD3 bispecific antibody molecules containing tumor-targeting Fab-arms recognizing the medium-to-highly expressed B-cell surface antigens CD19, CD20, CD22, CD24, CD37, CD70, CD79b, CD138 and HLA-DR. Target binding capacity *in vitro* was assessed using flow cytometry and the cytotoxic potential towards B cell lymphoma cell lines was tested using chrome-release assays. *In vitro* T cell activation (determined by the upregulation of CD69, CD25, PD-1) and T cell-mediated cytotoxicity (measured as the reduction in number of remaining tumor cells) of the most potent CD3-BsAb, a CD3xCD20 BsAb designated DuoBody-CD3xCD20, were measured by flow cytometry. Anti-tumor activity *in vivo* was measured using cell line-derived xenografts in humanized mouse models. Finally, the capacity of DuoBody-CD3xCD20 to induce depletion of normal B cells from peripheral blood and lymphoid structures after intravenous or subcutaneous administration in cynomolgus monkeys was assessed as part of the non-clinical safety studies.
Results: Functional screening of a panel of B cell-targeting CD3 BsAbs *in vitro* identified multiple targets that could be used to induce T-cell mediated cytotoxicity towards malignant B cells. No correlation between target expression and BsAb-induced T cell-mediated cytotoxicity could be found. CD20-targeting BsAbs were among the most efficient CD3 BsAbs. Specifically, one of the CD3xCD20 BsAbs showed extraordinary potency and outperformed the other CD20-targeting BsAb as well as CD3 BsAbs against all other B cell targets tested. This BsAb, designated DuoBody-CD3xCD20, was shown *in vitro* to only activate T cells in the presence of B cells and to

induce potent T-cell-mediated cytotoxicity of B cell lymphoma cell lines with EC_{50} values in the low picomolar range. DuoBody-CD3xCD20-dependent T cell-activation and T cell-mediated cytotoxicity resulted in tumor growth inhibition in xenograft models *in vivo*, both in prophylactic and therapeutic settings. Non-clinical safety studies with DuoBody-CD3xCD20 in cynomolgus monkeys showed potent, long-lasting B cell depletion from both peripheral blood and lymphoid organs. Comparison of intravenous and subcutaneous administration demonstrated lower peak cytokine levels after subcutaneous antibody administration, while bioavailability and the capacity to deplete B cells were comparable to the intravenous route.
Summary and Conclusions: DuoBody-CD3xCD20 was identified as the most potent B cell-targeting CD3 BsAb in a panel of BsAbs targeting 9 different B cell targets. In non-clinical safety studies, DuoBody-CD3xCD20 showed efficient depletion of B cells and an acceptable safety profile. The clinical safety of DuoBody-CD3xCD20 (GEN3013) in patients with B cell malignancies will be assessed in a first-in-human study.

PF638

TG-1701 A NOVEL, ORALLY AVAILABLE, AND COVALENTLY-BOUND BTK INHIBITOR

E. Normant[1,*], L. Gorelik[2], R. Shmeis[1], H. Le[1], R. Nisch[1], H.P. Miskin[1], P. Sportelli[1], M.S. Weiss[1]

[1]TG Therapeutics, Inc., [2]Fortress Biotech, New York, NY, United States

Background: Targeting Bruton's tyrosine kinase (BTK), an essential component of the BCR signaling pathway, has been demonstrated to be an effective treatment option for B-cell lymphomas and autoimmune diseases. However, new BTK inhibitors are needed to allow for better safety and efficacy as a single agent and in combination with other agents.
Aims: Herein we present TG-1701, a novel, orally available and covalently-bound BTK inhibitor that exhibits unique pharmacologic properties compared to prior BTK inhibitors.
Methods: TG-1701 was evaluated and compared to ibrutinib and/or acalabrutinib in numerous enzyme based, cell-based, and animal models
Results: TG-1701 and ibrutinib have comparable IC50s against BTK (3 nM and 1 nM respectively). TG-1701 exhibits superior selectivity to BTK compared to ibrutinib in *in vitro* whole kinome screening (DiscoverX, San Diego, CA) (Table 1).

Table 1.

IC50 (nM)	BTK	HER2	ITK	HER4	CSK	EGFR
TG-1701	3	> 3000	> 3000	147	347	270
ibrutinib	1	36	62	4	57	2

In addition, TG-1701 is 61-fold less active on EGFR compared to BTK with a Kd of 270 nM and 4.4 nM respectively. Ibrutinib, however, is only 6.7-fold less active on EGFR compared to BTK with a Kd of 2 nM and 0.3 nM respectively. TG-1701 inhibited the growth of the follicular lymphoma DOHH-2, mantle cell lymphoma Mino and DLBCL SU-DHL-6 cell lines with GI50% of 369, 449 and 313 nM respectively. TG-1701 inhibited IgM-activated BCR pathway in DOHH-2 cells, in particular the phosphorylation of BTK, PLCy2 and ERK1/2. In a cell-based assay, TG-1701 blocked IgM-dependent CD69 expression, adhesion of JEKO cells to VCAM-1, and CXCL12-dependent migration. A fluorescent BTK-occupancy assay was developed and validated *in vivo*, in the spleen of mice, where BTK was found to be completely occupied after administration of a single dose of TG-1701 at 12.5 mg/kg. *In vivo*, the anti-tumor efficacy of TG-1701 was assessed in several lymphoma xenograft models, *e.g.* SU-DHL-6, Mino, and OCI-Ly10 ABC-DLBCL, where TG-1701 showed potent anti-tumor activity equivalent to or greater than ibrutinib and similar to the recently approved BTK inhibitor, acalabrutinib. In addition, the pharmacodynamic profile of TG-1701 allows for a once a day dosing.
Summary and Conclusions: TG-1701 is a novel and highly-selective, irreversible BTK inhibitor with potent *in vitro* and *in vivo* activity. TG-1701 is currently being tested in a phase 1 dose escalation study.

PF639

DASATINIB ENHANCES ANTHRACYCLIN-BASED CHEMOTHERAPY IN PRE-CLINICAL MODELS OF T-CELL LYMPHOMA

C. Carniti[1,*], M. Magni[1], G. Biancon[1], P. Quaranta[1], P. Corradini[12]

[1]Medical Oncology and Hematology Department, Fondazione IRCCS Istituto Nazionale Tumori, [2]Department of Oncology and Hemato-oncology, Università degli Studi di Milano, Milano, Italy

Background: Although new treatment approaches for T-cell lymphomas (TCLs) have been studied over the past several years, anthracycline-based chemotherapy programs, cyclophosphamide, doxorubicin, vincristine, and prednisone (CHOP) or CHOEP (CHOP+Etoposide), remain the only form of effective chemotherapy for patients with newly diagnosed T-cell lymphomas. We previously reported that stem cell transplantation (SCT) is a curative option for T-cell Lymphoma patients but 25-30% of patients do not become transplant eligible due to primary refractory or early progressive disease and have very poor prognosis and few therapeutic options.
Aims: In this study, we investigated the mechanisms associated with different responses to CHOEP in preclinical models of T-cell lymphomas. Results of these analyses prompted us to investigate whether dasatinib (DA), a pan-tyrosine kinase inhibitor, could enhance response to CHOEP in T-cell lymphoma experimental models.
Methods: Six different T-cell lymphoma and leukemia cell lines (Jurkat, HD-MAR-2, Karpas 299, Sup-T1, HH and OCI-Ly12) representative of TCL heterogeneity, were incubated with escalating doses of CHOEP. Gene expression profiling (GEP) and western blotting (WB) analysis were performed to assess effects of treatments. Escalating doses of DA were used in order to calculate the concentration of drug able to inhibit 50% of proliferation (IC_{50}) for every cell line. Suboptimal concentrations (IC_{20}) of CHOEP and DA were used to assess the efficacy of the combination. Analysis of cell viability, cell cycle distribution, apoptosis and mitochondrial depolarization were performed using flow cytometry. ANOVA one-way test was adopted to establish if drug combinations significantly reduced proliferation. The *in vivo* effect of the combination was tested in xenograft models and tumor growth assessed.
Results: CHOEP treatment induced concentration and time-dependent growth inhibition in all cell lines, with the most sensitive cells being HH and the least sensitive being HD-MAR-2 (5 fold more resistant). To gain insights into the molecular mechanisms of action of CHOEP, GEP analysis was conducted. CHOEP treatment induced a marked upregulation of genes encoding for Src family kinases (SFKs). WB analysis confirmed that SFKs are activated upon CHOEP treatment thus suggesting the rationale for combining a tyrosine kinase inhibitor to potentiate CHOEP activity. Accordingly, the addition of DA to CHOEP significantly inhibited cell proliferation in SUP-T1, Jurkat, HD-MAR-2, OCI-Ly12 and HH cells (mean inhibition: CHOEP 20,56%±4 range 14% - 26%; DA 19%±2%, range 14% - 28%; DA-CHOEP 45%±8% range 32% - 56%; mean±SD, $p \leq 0.001$) but not in Karpas 299 cell line (CHOEP 22%±3%; DA 26%±2%; DA-CHOEP 35%±2%, mean±SD, p:ns). The antiproliferative effect of the DA-CHOEP combination was related to a significant increase in cell death, associated with severe mitochondrial depolarization. In xenograft models obtained by the subcutaneous inoculation of SUP-T1 and OCI-Ly12 cell lines in NOD/SCID mice, the DA-CHOEP combination strongly reduced tumor weights when compared to DA and CHOEP used alone (DA-CHOEP tumor growth inhibition, TGI= 98%; DA TGI=38.9%; CHOEP TGI=77.4% for SUP-T1 cell line and DA-CHOEP TGI: 74.5%; DA TGI 27.5%; CHOEP TGI: 11.5% for OCI-Ly12 cell line).
Summary and Conclusions: This study provides the first preclinical evidence supporting that dasatinib could potentiate CHOEP efficacy in TCLs irrespective of histologies and of CHOEP sensitivity *per se*.

PF640

ELEVATED SERUM IL-8, IL-10, IL-22, AND MCP-1 ARE ASSOCIATED WITH INFERIOR CLINICAL OUTCOMES IN PATIENTS WITH PERIPHERAL T-CELL LYMPHOMA

J. H. Yi[1,*], W.S. Kim[2], S.J. Kim[2]

[1]Hematology-Oncology, Chung-Ang university Hospital, [2]Hematology-Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of

Background: Cytokines are one of the major non-cellular component of tumor microenvironment, and they act as messengers between malignant cells and the cellular component of tumor microenvironment.
Aims: While the role of cytokines in Hodgkin's lymphomas or B-cell lymphomas has been widely investigated, little is known about in case of PTCL. We evaluated how the pre-treatment serum level of various cytokines impact on clinical outcomes in patients with PTCL.
Methods: Patients out of our prospective cohort studies (NCT#00822731, NCT#01877109) who had PTCL and whose serum samples were collected for measurement of cytokines before receiving any kinds of treatments were included in the analysis. We measured the levels of eotaxin, GROα, IFN-

α&γ, IL-1α,1β,1RA,2,4,5,6,7,8,9,10,12p70,13,15,17α,18,21,22,23,27, and 31, IP-10, MCP-1, MIP-1α&β, RANTES, SDF1α, TNFα&β in triplicate with the Procarta cytokine profiling kit (Panomics, CA, USA). The endpoints were OS and CR rate.

Results: A total of 137 patients were included, and the median age was 57 years (17 - 85 years). The histologic subtypes were as follows: PTCL-NOS(N=55, 40%), AITL(N=44, 32%), ALCL(N=30, 22%), others(N=8). In the whole cohort, with the median overall survival being 63.7 months, we found that expression of IL-22, serum level of IL-10 above 3.8 pg/mL, serum level of MCP-1 above 300 pg/mL, and serum level of IL-8 above 40 pg/mL negatively affect clinical outcomes in terms of complete response rate and the overall survival. Compared to other subtypes, patients with AITL were more likely to have higher level of IL-10 (p=.003), IL-22 (p=.013) and MCP-1 (p=.042), reflecting the inflammatory milieu of the disease. Buth the impact on clinical outcomes were greater in ALCL patients as most of the OS differences were produced in these patients. In patients with PTCL-NOS, increased IFN-γ (>1.0 pg/mL) and expression of IL-13 was associated with adverse outcomes (Figure 1).

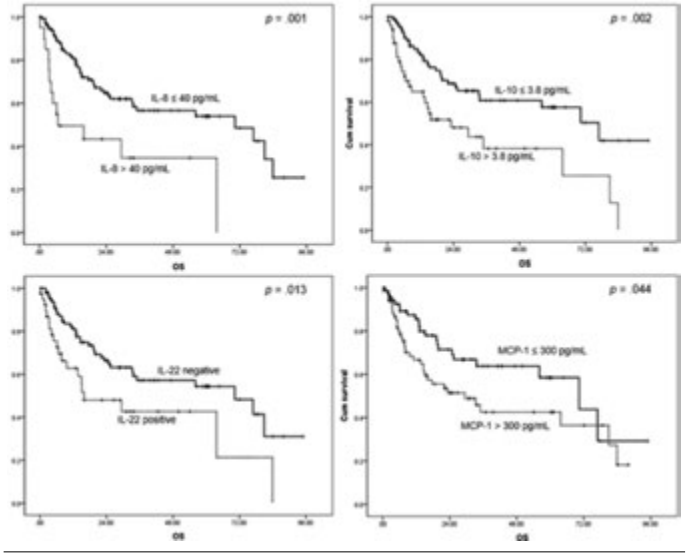

Figure 1.

Summary and Conclusions: The current study demonstrated that several cytokines related to JAK pathway (IL-10, 22) or tumor microenvironment (MCP-1, IL-8) have prognostic relevance, which is an important finding in understanding the pathogenesis of PTCL and suggesting the future direction of treatment.

PF641

BIOMARKER ANALYSES OF PATIENTS WITH RELAPSED DIFFUSE LARGE B-CELL LYMPHOMA, FOLLICULAR LYMPHOMA, OR RICHTER'S TRANSFORMATION TREATED WITH IBRUTINIB+ NIVOLUMAB IN THE PHASE 1/2A LYM1002 STUDY

Background: Ibrutinib (ibru) is a first-in-class, oral, covalent Bruton's tyrosine kinase inhibitor approved in various B-cell non-Hodgkin's lymphomas (NHL). Preclinical research suggested synergistic antitumor activity due to T-cell activation and Th1 polarization when ibru was combined with programmed cell death protein-1 (PD-1) pathway inhibitors. A phase 1/2a study (LYM1002, EudraCT 2014-005191-28) evaluating ibru/nivolumab (nivo) combination demonstrated acceptable safety and efficacy comparable to single-agent ibru in multiple B-cell malignancies; clinical response in Richter's transformation (Richter's) exceeded expectation (overall response rate [ORR] 30.0% for follicular lymphoma [FL], 35.6% for diffuse large B-cell lymphoma [DLBCL], and 60.0% for Richter's) (Younes, *et al. Blood.* 2017;130:833).

Aims: To identify predictive and mechanistic biomarkers correlated with response to ibru+nivo combination in patients (pts) with DLBCL, FL, or Richter's.

Methods: LYM1002 was an open-label, single-arm study in which NHL pts received intravenous nivo (3 mg/kg) on a 14-day cycle with ibru 560 mg once daily. Responders were defined as pts who achieved complete response (CR) or partial response (PR) except blood lymphocyte count control. PD-L1 levels were measured by immunohistochemistry (IHC) staining with Dako 28-8 antibody and gene expression profiling (GEP) using AffyMetrix HG-U133+2 arrays in baseline tumor biopsy tissue. PD-L1 elevation was defined as ≥5% tumor cells (IHC) or expression above the median (GEP). Proportions of 22 distinct immune cell types were evaluated by GEP.

Results: 39 pts with DLBCL, 35 with FL, and 20 with Richter's were evaluable for biomarkers. DLBCL pts with elevated PD-L1 by IHC had a trend toward increased ORR (62.5% *vs* 18.8%, *p*=0.06), as well as significantly increased CR (37.5% *vs* 0; *p*=0.03). There was also a trend toward improved progression-free survival in DLBCL pts (n=23), as well as in germinal center B-cell (GCB)-DLBCL subtype (n=13) pts with elevated PD-L1 compared with those without elevation (Figure 1). This trend was not noted in FL pts; only 3 FL pts were positive for PD-L1 by IHC and only 1 had elevated PD-L1. In Richter's, 12/16 evaluable pts responded, but only 3/15 pts with IHC data had elevated PD-L1 levels; all 3 achieved PR. For immune cell analysis, GEP data were available in 14 responders (7 each for DLBCL and FL) and 22 nonresponders (12 for DLBCL, 10 for FL). Regarding the levels of 22 distinct immune cell types in responders *versus* nonresponders, results were generally more consistent between all DLBCL and the GCB subtype, but were substantially different between DLBCL and FL. Increased numbers of cytotoxic CD8 T cells, M1 macrophages, and resting dendritic cells were significantly associated with response in DLBCL but not FL; however, in FL, increased γ-δ-T cells were associated with response.

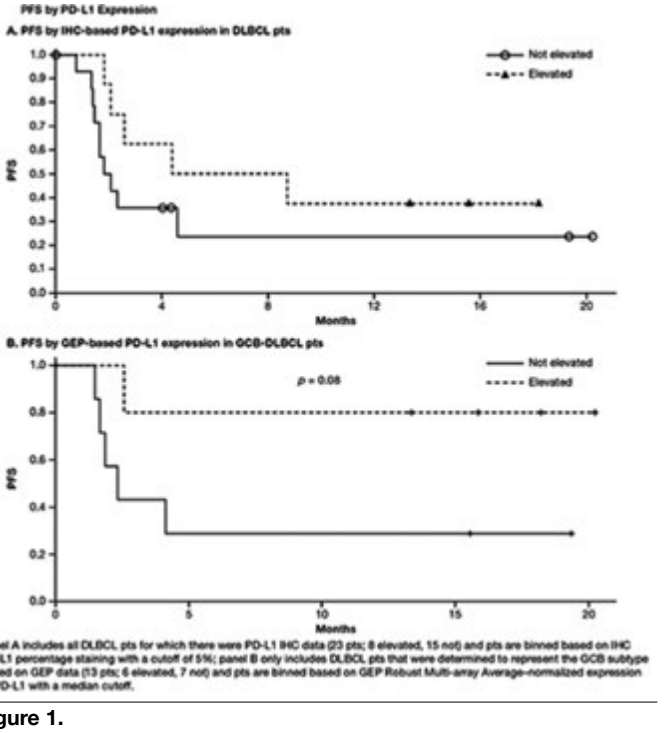

Figure 1.

Summary and Conclusions: In this study, DLBCL pts with elevated PD-L1 expression showed a trend toward better response and survival with ibru+nivo treatment, although pt number was small and significance was reached only for CR. PD-L1 elevation was low in FL and Richter's, although the few pts with elevated PD-L1 in Richter's had a response. Histology-dependent variations in tumor infiltrating immune cells at baseline suggest that differences in microenvironment are critical to the differential ibru+nivo response in DLBCL and FL. Our findings may support the identification of

pts who benefit most from ibru+nivo and suggest development of novel combination therapies to enhance ibru clinical activity.

PF642

SYSTEMS BIOLOGY ANALYSIS OF RESPONSIVENESS OF NON-HODGKIN LYMPHOMA B-CELL LINES TO CD37 TARGETING RADIOIMMUNOTHERAPY

K.B. Melhus[1], E. Gaudio[2], L. Cascione[2], A.H. Repetto-Llamazares[1], J. Dahle[1], S. Patzke[1,3,*], F. Bertoni[2]

[1]Research & Development, Nordic Nanovector ASA, Oslo, Norway, [2]Institute of Oncology Research, Università della Svizzera italiana, Bellinzona, Switzerland, [3]Radiation Biology, Institute for Cancer Research, OUH Norwegian Radium Hospital, Oslo, Norway

Background: CD37 is an internalizing transmembrane glycoprotein widely expressed on mature B-cells and B-cell malignancies. The next generation anti-CD37 radioimmunoconjugate (RIC) ^{177}Lu-lilotomab satetraxetan (Betalutin®), containing the beta-emitting radionuclide lutetium-177, is currently being tested as one time injection therapy in a clinical phase 2b trial for follicular lymphoma (FL) and phase 1 trial for diffuse large B-cell lymphoma (DLBCL).
Aims: The present work is the first to explore intrinsic genetic factors and expression features that correlate with the responsiveness of well characterized B-cell lymphoma cell lines to treatment with ^{177}Lu-lilotomab satetraxetan.
Methods: Fifty five biologically well characterized human lymphoma cell lines (including 7 activated B-cell-like (ABC) and 20 germinal center-like (GCB) DLBCL cell lines) were treated for 18 hours with increasing doses of ^{177}Lu-lilotomab satetraxetan (from 0 to 20 µg/ml; 600 MBq/mg), washed, and seeded on micro-well plates. Cell viability was assessed by flow cytometry directly after treatment and dose-response profiles were determined six days post seeding using a CyQuant direct cell proliferation kit. Cell lines were grouped by dose-response-curve profiles and IC50 values into subgroups with different sensitivity to ^{177}Lu-lilotomab satetraxetan. Correlation analysis of sensitivity subgroups to genetic aberrations and baseline gene/protein expression was performed using appropriate statistical tools as previously described (PMID: 29066507).
Results: Hierarchical clustering analysis of dose-response curves of inhibition of proliferation identified five major groups.The most sensitive cell lines showed >80% growth inhibition at <1 µg/ml of ^{177}Lu-lilotomab satetraxetan (mostly DLBCLs) and most resistant cell lines showed <50% growth inhibition even at 20 µg/ml ^{177}Lu-lilotomab satetraxetan (mostly cutaneous T cell lymphoma). Sensitivity was not directly correlated to CD37 mRNA expression. The median IC50 of ABC-DLBCLs was 1.2 µg/ml, with only U2932 and RIVA being treatment resistant cell lines. The median IC50 of GCB-DLBCLs was 5.2 µg/ml, showing bi-modal distribution in groups of 10 cell lines below and above the median IC50. Treatment resistance in GCB-DLBCLs was not inversely correlated to CD37 mRNA or protein expression and neither correlated to aggressiveness associated mutations in *TP53*, or translocation/amplification of *MYC* or *BCL2* loci. Differential gene expression analysis between response groups of GCB-DLBCL cell lines identified 80 modulated genes, 40 of them (50%) with elevated base-line expression in sensitive cell lines and 40 (50%) of them with elevated base-line expression in resistance cell lines. Gene set enrichment analysis revealed increased expression of cytoskeleton and metabolism regulatory genes in treatment sensitive and increased expression of inflammation and survival regulatory genes in treatment resistant GCB-DLBCL cell lines. Further bioinformatic analysis including cell lines of other indications as well as additional genome wide copy number variation, methylation, RNA sequencing and miRNA datasets is currently ongoing.
Summary and Conclusions: ^{177}Lu-lilotomab satetraxetan shows promising activity against not only GCB-DLBCL cell lines, but also several ABC-DLBCL cell lines. Resistance/sensitivity is not predicted by genetic hallmarks of lymphoma aggressiveness. Initiated correlation analysis of global genetic/transcriptomic/proteomic markers will prove valuable for identification of clinically relevant biomarker(s) and putative co-targetable conveyors of treatment resistance.

PF643

CBL-MZ IS NOT A SINGLE BIOLOGICAL ENTITY: EVIDENCE FROM GENOMIC ANALYSIS AND PROLONGED CLINICAL FOLLOW UP

J. Strefford[1,*], H. Parker[1], N. McIver Brown[2], Z. Davis[2], M. Rose-Zerilli[1], A. Xochelli[3], J. Gibson[4], M. Parry[1], R. Walewska[2], D. Oscier[2]

[1]Cancer Sciences Unit, Faculty of Medicine, University of Southampton, Southampton, [2]Department of Molecular Pathology, Royal Bournemouth Hospital, Bournemouth, United Kingdom, [3]Institute of Applied Biosciences, Centre for Research and Technology Hellas, Thessaloniki, Greece, [4]Biological Sciences, Faculty of Natural and Environmental Sciences, Southampton, United Kingdom

Background: The term clonal B cell lymphocytosis of marginal zone origin (CBL-MZ) has recently been suggested for asymptomatic individuals whose routine blood count shows a persistent modest lymphocytosis. However, it remains unclear if CBLMZ is the precursor to one or several well defined WHO entities and what factors predict for disease progression.
Aims: To address this, we performed a genomic analysis of a well-characterized CBL-MZ cohort with long follow-up.
Methods: 37 patients (M/F ratio 1.2:1, median age at presentation was 73.2 years [range 47.8 – 95.5 years]) who fulfilled the diagnostic criteria for CBL-MZ and in whom clinical, morphological, immunophenotypic, immunogenetic and cytogenetic data was available, were followed up for a median of 9.6 years (range 2.5-22.4 years). All cases were screened for the presence of somatic mutations in KLF2, NOTCH2, CCND3, BCOR, MAP2K1, BRAF V600E, MYD88, TNFAIP3 and TP53 using a bespoke Haloplex Target Enrichment system (Agilent Technologies). DNA from
buccal cells [n=22] was used to confirm the somatic origin of variants identified in these genes.
Results: 9/37 (23.6%) cases showed evidence of progressive disease with a median time to progression of 69 months. Five cases evolved to splenic marginal zone, two to splenic lymphoma/leukemia unclassifiable and one each to lymphoplasmacytic lymphoma, and MALT lymphoma. Fifteen genomic mutations, involving all candidate genes screened apart from BCOR and BRAF V600E, were identified in 12 cases. The most frequent mutations involved MYD88, CCND3 and TP53 in five, three and three cases respectively, but the pattern and incidence of mutations differed from that reported in any well-defined WHO disorder. While neither cytogenetic nor immunogenetic data correlated with the natural history of CBL-MZ, 5/9 patients with progressive disease had one or more mutations
compared to 6/28 with stable disease (p=0.03).
Summary and Conclusions: Our clinical outcome data indicate that CBL-MZ usually pursues a stable course but the higher rate of progression in the current study compared to previous studies probably reflects the longer follow-up and reinforces the need for long term clinical management. CBLMZ can evolve into several well-defined WHO disorders especially those of MZ origin. The genomic data is consistent with this observation as although the genomic abnormalities in CBL-MZ overlap with those found in any of the well-defined entities to which it could evolve, the incidence of mutations is lower and does not mirror any specific disease. In summary, both the clinical outcome and genomic data indicate that CBL-MZ is not a single biological entity.

PF644

HETEROGENEOUS MUTATIONS AT RHOA EXON 2 REVEALED BY TARGETED SEQUENCING OF CELL FREE DNA AND PERIPHERAL BLOOD MONONUCLEAR CELL DNA IN PERIPHERAL T-CELL LYMPHOMA

B. Ottolini[1], N. Nawaz[1], S. Mamand[1], R.L. Allchin[1], P. Fields[2], R. Dillon[3], M.J. Ahearne[1], S.D. Wagner[1,*]

[1]Leicester Cancer Research Centre, University of Leicester, Leicester, [2]Department of Haematology, Guys and St. Thomas' NHS Trust, [3]Department of Medical and Molecular Genetics, King's College London, London, United Kingdom

Background: Angioimmunoblastic T-cell lymphoma (AITL) and ~20% of peripheral T-cell lymphoma-not otherwise specified (PTCL-NOS) are likely to be derived from normal follicular helper T-cells. These Tfh lymphoma cases share genetic abnormalities including a point mutations leading to RHOA^{G17V}. The new genetics has potential to provide biomarkers for diagnosis and to guide treatment but this approach is limited because adequate tissue biopsies can be difficult to obtain.
Aims: To determine the usefulness of cell free DNA (cfDNA) or peripheral blood mononuclear cell (PBMNC) DNA to detect the mutational burden associated with peripheral T-cell lymphoma.
Methods: Whole exome sequencing (WES) and targeted sequencing (using a 60 amplicon panel of 12 genes and covering 12 kb) were carried out on lymph node tissue, cell free DNA and PBMNC DNA. Validation was by droplet digital PCR (ddPCR).
Results: WES of PBMNC DNA from two patients with PTCL showed a novel point mutation leading to RHOA^{F25L} (patient 1, 32% (59/124 reads) and patient 2, 26% (43/121 reads)) without other detectable RHOA mutations. Targeted sequencing (mean read depth 3554x) of cfDNA and PBMNC DNA in 16 patients with AITL and PTCL-NOS demonstrated mutations in

TET2, DNMT3A, IDH2, STAT3, JAK2 and P53 as previously reported in PTCL. Focusing on RHOA exon 2 we found four recurrent point mutations. These included G17V (median variant allele frequency (VAF) 5.9 (range 0.8 to 48.7)) but also F25L (median VAF 35.6, range 0.6 to 95.1) (similar frequency to that obtained by WES) and mutations reported in other cancers *i.e.* C16stop (median VAF 8.9, range 1.0 to 56.2) and G14V (median VAF 2.0, range 0.8 to 26.7). The two dominant RHOA variants (F25L and G17V) were validated by ddPCR assays and Sanger sequencing. *In silico* prediction suggested that F25L perturbed a pi-stack interaction with F171 to disrupt alpha-helix conformation and this conclusion was supported by the phenotype prediction programs, PolyPhen2 (score 1.0, probably damaging) and SIFT (0.02, deleterious). Is $RHOA^{F25L}$ detectable within lymphoma tissue? Of those patients with circulating $RHOA^{F25L}$ targeted sequencing of lymphoma tissue detected the mutation in only 50% of patients and at relatively low frequency (median VAF 4.5%, range 0.5-10.1%). Further sequencing from multiple tissue cores from two patients confirmed that mutations were not homogenous within tissue but were spatially separated. Therefore, RHOA exon 2 mutation in PTCL is more complex than previously believed. Mutations vary in frequency between lymph node and blood and also within lymph nodes. Finally, we analysed the mutational load in cfDNA in serial samples from a small number of patients and showed changes in the dominance of specific RHOA mutations associated with response and relapse and suggesting differential expansion of subclones during treatment.

Summary and Conclusions: Analysis of RHOA mutations in blood revealed a spectrum quite different to that observed in lymphoma tissue. Our findings, using PBMNC DNA and cfDNA, are likely to be the representation in the blood of intra-tumour heterogeneity. The data suggests differential contribution of mutations present in the tissues to those detectable in the circulation although the mechanisms underlying this need to be explored in future work. Blood-based detection of RHOA mutations could transform clinical practice impacting diagnostic pathways and predicting treatment response.

San Martino-IST, Genoa, [10]Department of Experimental and Clinical Medicine, University of Catanzaro Magna Graecia, Catanzaro, [11]Department of Oncology and Hemato-Oncology and Hematology Unit, University of Palermo School of Medicine Palermo, Palermo, [12]Dipartmento di Medicine Sperimentale, University of Genoa, Genoa, Italy

Background: Programmed death-1 (PD1) is expressed on T cells, B cells, and other immune effector cells and interacts with the PD1 ligand (PDL1) expressed on a wide variety of tumors. The PD1/PDL1 cross-link induces negative signals to the T cell, provides a T-cell exhaustion state and, ultimately, provokes neoplastic tolerance. PD1 is expressed on Hodgkin lymphoma (HL) and T-cells of B-cell non-HL. The tumor microenvironment (TME) is essential for supporting proliferation and survival of lymphoma cells and in resisting the effects of chemotherapy. Interrupting the signaling pathways mediated by cells or humoral factors might enhance the effects of chemotherapy and suggests that the TME is a target for therapy. Lenalidomide (LEN) is an oral immunomodulator (IMID) with direct antineoplastic activity and immunologic effects, including stimulation of T cell– and NK cell–mediated cytotoxicity in experimental models. Preclinical findings indicate that combination of IMIDs with immune checkpoint inhibitors may promote therapeutic synergy and long-term antitumor immunity to improve clinical outcome.

Aims: 1) To characterize the PD1, PDL1 and the lesser-known PDL2, phenotype in peripheral neoplastic CD19+ lymphocytes and T-cell subsets in patients with low-grade B-cell lymphoma; 2) to evaluate the role of the TME in supporting the PD1 axis; and 3) to determine whether LEN influences PD1 or cognate ligand expression.

Methods: Samples obtained from peripheral blood of patients with low grade lymphoma in leukemic phase attending participating Hematology Units in Southern Italy were used to determine PD1, PDL1, PDL2 phenotype by flow-cytometry (FC). Autologous activated T-cells (AAT) were obtained by *in vitro* co-culture of patient T-cells with anti-CD3/CD28 beads, rIL2, and with PBMCs. In selected experiments LEN (Celgene) was added to cell cultures.

Results: Twenty-eight cases of lymphoma were evaluated for PD1, PDL1 and PDL2 expression on malignant B- and T-cells by FC. The expression of PDL1 was practically undetectable, while PD1 and PDL2 were similarly expressed on B-cells. Significantly higher PD1 expression compared with very low levels of ligands were detected in CD4+ and CD8+ cells. Co-culture of lymphoma cells with AAT cells showed consistent formation of B/T-cell clusters. PD1 and PDLs expression significantly increased in AAT co-culture on B-cells. PD1 expression on CD3+ cells was unaffected by AAT, although the expression of both ligands increased significantly. Closer analysis of T-cell subsets showed that PD1 expression increased significantly following co-culture experiments only in CD4+ cells. Lymphoma-AAT co-culture experiments (n=4) indicated that LEN (0.5/1 uM) did not negatively influence the formation of AAT clusters. After 48 h of co-culture, the expression of CD19+CD5-PDL1+ cells increased in 4/4 cases following LEN treatment while, PDL2 expression remained unchanged. CD3+ cells showed a significant increase in PD1 expression by LEN, while the expression of both ligands remained unaffected. Evaluation of activated T-cell subsets showed similar results, with the exception of stronger induction of PD1 and PDL1 expression by LEN in CD8+ cells.

Summary and Conclusions: Our results suggest the potential involvement of the PD1/PDLs-axis in lymphoma patients. In particular, LEN further induces the expression of PD1 in CD8+ and CD4+ cells and may contribute to reactivate PD1 signaling under treatment. The PD1 pathway may be potentially targeted to overcome both the intrinsic and LEN-induced exhaustion phenotype.

Funding: Celgene to FM.

THE EFFECT OF DUVELISIB, A DUAL INHIBITOR OF PI3K-DELTA,GAMA ON COMPONENTS OF THE TUMOR MICROENVIRONMENT IN PREVIOUSLY UNTREATED FOLLICULAR LYMPHOMA

C. Casulo[1,*], A. Goy[2], K. Van Eygen[3], J. Sancho[4], S. Mercadal[5], R. Johnson[6], S. DeVos[7], K.-K. Bouabdallah[8], K. Sprott[9], N. Le[9], J. Pachter[9], D. Weaver[9]

[1]Wilmot Cancer Institute, University of Rochester Medical School, Rochester, [2]Hackensack University Medical Center, Hackensack, United States, [3]AZ Groeninge, Kortrijk, Belgium, [4]Hospital Universitario Germans Trias i Pujol, Badalona, [5]Department of Hematology, ICO L'Hospitalet-Hospital Duran i Reynals, L'Hospitalet de Ll., Barcelona, Spain, [6]St. James's Univ. Hospital Trust, Leeds, [7]Division of Hematology/Oncology, Ronald Reagan UCLA Medical Center, Los Angeles, United States, [8]University Hospital of Bordeaux, CHU Haut-Leveque, Bordeaux, France, [9]Verastem, Inc., Needham, United States

Background: Duvelisib (DUV), an oral dual inhibitor of PI3K-d,g, is clinically active in hematologic malignancies, including follicular lymphoma (FL), CLL, and T cell lymphoma (Flinn, 2017). PI3K-d inhibition directly targets malignant cells and PI3K-g inhibition disrupts the supportive tumor microenvironment (TME). In the CONTEMPO trial (NCT02391545), previously untreated FL patients (pts) treated with DUV+rituxumab had an ORR of 93% (36% CRR) and pts treated with DUV+obinutuzumab had an ORR of 89% (41% CRR). In both treatment arms chemokines reflective of the tumor microenvironment were inhibited (Casulo, 2016).

Aims: Herein we examine the effects of DUV on the TME via *in vitro* assays utilizing whole blood obtained from pts with treatment-naive follicular lymphoma.

Methods: *Ex vivo* whole blood assays were conducted from healthy volunteers and 32 FL pts enrolled in CONTEMPO [pre-and post-DUV]. *Ex vivo* and *in vitro* PI3K-g assays [(fMLP-stim monocyte and CXCL12-stim human T cell pAKT(S473), murine bone marrow monocyte migration, and macrophage polarization quantified by ARG1 expression] and PI3K-d assays [LPS-stimulated monocyte pAKT(S473)] with PI3K-d-selective [idelalisib (IDELA), TGR-1202, IPI-3063] and PI3K-g-selective [IPI-549] inhibitors were compared.

Results: DUV (IC_{50} 0.4 ±0.1 mM) and IDELA (IC_{50} 1.0±0.2 mM) potently inhibited LPS-induced human monocytes via PI3K-d compared with the PI3K-g selective IPI-549 (IC_{50} 12±0.5mM). For TGR-1202, the IC_{50} (25±8 mM) was below the RP2D clinical exposure. DUV (IC_{50} 0.5±0.2 mM) and IPI-549 (IC_{50} 1.6 ±0.2 mM) potently inhibited PI3K-g dependent fMLP-stimulated human monocytes compared to IDELA (IC_{50} 9.4±2.3) and TGR-1202 (IC_{50} 55±16 mM). In FL pts treated with DUV, these PI3K-g and PI3K-δ selective assays were inhibited 1-4 hours post treatment. Consistent with a PI3K-g mechanism, both DUV and IPI-549 inhibited macrophage polarization to M2, reduced CXCL12-induced macrophage migration (DUV IC_{50} 51 nM; IPI-549 IC_{50} 85 nM), and blocked CXCL12-induced T cell migration (DUV EC_{50} 128±39 nM; IPI-549 EC_{50} 17±17nM), which was not observed with PI3K-δ inhibitor IPI-3063 (IC_{50} 630±71nM).
Summary and Conclusions: The disruption of PI3K-d,g function in FL pts treated with DUV supports its inhibition of the tumor microenvironment through cancer-supportive macrophages and T cells.

PF647

INCORPORATION OF GENE EXPRESSION PROFILING FOR CELL-OF-ORIGIN DETERMINATION USING FORMALIN-FIXED PARAFFIN-EMBEDDED TISSUE SECTIONS IN ROUTINE WORK-UP OF DIFFUSE LARGE B-CELL LYMPHOMA CASES

R.S. Robetorye[1,*], C. Ramsower[1], A. Rosenthal[1], T. Yip[1], A. Wendel Spiczka[1], B. Glinsmann-Gibson[1], L. Rimsza[1]

[1]Department of Laboratory Medicine & Pathology, Mayo Clinic Arizona, Phoenix, United States

Background: Diffuse large B-cell lymphomas (DLBCL) represent a clinically heterogeneous group that is classified together based on similarities in morphology and immunophenotype. However, it was discovered that gene expression profiling (GEP) could classify DLBCL into distinct molecular subgroups based on cell-of-origin (COO), including germinal center B-cell type (GCB), activated B-cell type (ABC), and unclassified (UNC) type. COO assignment of DLBCL has important biological and prognostic significance, as well as potential therapeutic implications, with the ongoing development of selective agents for treatment of specific DLBCL subtypes.
Aims: Here, we describe the development of a clinical GEP assay (Lymph2Cx testing) to perform COO assignment in the routine work-up of DLBCL using FFPE tissue sections and summarize the results of the first 98 clinical DLBCL cases analyzed by the laboratory.
Methods: Lymph2Cx COO analysis was performed on 98 clinical DLBCL cases. RNA was extracted from macrodissected FFPE tissue sections and hybridized to the 20 fluorescently-labeled gene probes in the Lymph2Cx panel, including 8 genes overexpressed in ABC, 7 genes overexpressed in GCB, and 5 housekeeping genes. Probe/RNA complexes were purified on a NanoString® nCounter® Prep Station and transferred to a NanoString nCounter® Digital Analyzer for quantification. The counts were processed using the National Cancer Institute's Lymphoma/Leukemia Molecular Profiling Project Lymph2Cx DLBCL COO Classifier (patented algorithm) for subtyping. Minimum laboratory time required to perform the Lymph2Cx assay is approximately 28 hours/2.4 lab days.
Results: We have successfully analyzed 98 DLBCL cases from 66 male and 32 female patients using the Lymph2Cx assay and detected 46 GCB, 35 ABC, and 17 UNC cases. 85 of the 98 total cases were analyzed by immunohistochemistry using the Hans algorithm, and included 53 GCB and 32 non-GCB cases, with an overall concordance rate of 76%. 96 of the 98 DLBCL cases were also analyzed by FISH and detected 9 cases of high-grade B-cell lymphoma, with MYC and BCL2 and/or BCL6 rearrangements, including 6 cases with genetic double-hit type rearrangements and 3 triple-hit cases. Lymph2Cx analysis of these 9 cases detected 6 GCB type, 2 ABC type, and 1 UNC type lymphomas. The 98 DLBCL cases subjected to Lymph2Cx analysis included 37 nodal and 61 extranodal lymphomas. Most of the 17 total UNC cases were comprised of extranodal lymphomas, suggesting that UNC lymphomas may arise more frequently in extranodal sites. In addition, ABC cases occurred 2 times or more frequently at extranodal sites *versus* nodal locations in both male and female patients.
Summary and Conclusions: In summary, we have demonstrated that the Lymph2Cx COO assay can be performed relatively rapidly in the clinical laboratory and can be incorporated into the routine workflow for the workup of DLBCL cases. The assay is highly robust and reproducible and can provide valuable biological, prognostic, and potential therapeutic information for DLBCL patients.

PF648

DIFFUSE LARGE B CELL LYMPHOMA WITH CONCORDANT BONE MARROW INVOLVEMENT. UTILITY OF FLOW CYTOMETRY, CLINICAL AND BIOLOGICAL EVALUATION

L. Morais[1,*], C. Castañon[1], S. Alonso-Alvarez[1], M. Alcoceba[2], M. Garcia-Alvarez[2], O. Blanco[2], E. Perez[2], M. Baile[2], O. Lopez[2], M.B. Vidriales[2], E. Colado[1], A. Fonseca[1], M.D. Caballero[2], M. Gonzalez[2], N. Gutierrez[2], C. Nicolas[1], A. Martin[2]

[1]Hematology, HUCA, Oviedo, [2]Hematology, HUSAL, Salamanca, Spain

Background: Bone Marrow (BM) involvement by aggressive lymphoma is associated with poor prognosis.
Aims: We present the update of a Spanish series, and a prospective independent validation series, in which biological characteristics and prognostic of BM involvement have been analyzed.
Methods: Retrospective control series included 232 patients diagnosed of DLBCL (1999-2014) at HUSAL. Validation series includes patients diagnosed of DLBCL from 1/Jan/2016-31/Dec/2017 at HUCA. In both cohorts BM trephine biopsies were classified as "no involvement", "concordant" (DLBCL BM involvement) & "discordant" infiltration (low grade lymphoma BM involvement). Multyparameter Flow cytometry (MFC) analysis of parallel BM aspirates was performed, for improving tumoral clone detection and for phenotypically characterizing discordant cases. We analyzed *MYC, BCL2* and *BCL6* in DLBCL samples by FISH. Cumulative incidence of central nervous system (CNS) relapse was analyzed.
Results: ***Biology and clinical description*** In the control series 31 patients (13%) had concordant and 21 (9%) discordant BM involvement. MFC identified clonal lymphocytic populations in other 15 patients in whom histological studies were not diagnostic. In the validation series, 32 patients have been included; 7 (21%) with concordant and 1 (3%) with discordant BM involvement. MFC confirmed BM involvement in these patients and detected 2 extra cases: 1 DLBCL phenotype & 1 with low grade lymphoma BM involvement. MFC also accounted for 22% of the total of BM infiltration diagnoses. Thus, MFC allowed to observe phenotypes suggestive of different indolent lymphoproliferative disorders (Table 1). FISH analysis showed in both concordant BM groups a high percentage of *MYC* rearrangements:5/17 patients analyzed (29%) and 3/7 (43%) in the control and the validation series respectively. In both cohorts concordant BM disease was statistically associated with higher LDH values at diagnosis and higher risk IPI. ***CNS relapse*** 5-year-cumulative incidence of CNS relapse (occult and clinical leptomeningeal infiltration) in the control series was 33% in the concordant group, 6% in the discordant group,1% in non-infiltrated group (p<0.001). Concordant BM infiltration had an independent association with CNS relapse (HR:11.2;95%CI:2-61.2;p=0.006). In the validation series, we confirmed that all patients with concordant BM fulfilled high risk criteria for CNS relapse (CNS-IPI). Prophylaxis was recommended. No evidence of CNS relapse has been observed, maybe due to systematic CNS prophylaxis and intensive treatment. Three patients with concordant BM received frontline autologous stem cell transplantation.

Table 1.

Bone marrow histological and phenotypic description in patients diagnosed of DLBCL

	MFC									
Histology		CLL	FL	MZL	LPL	DLBCL	Composite	I	No
	Low grade (D)	4	4	2	-	1	1	5	4
	High grade (C)	-	-	-	1	2 1	6	-	-	9
	Unspecified lymphoid infiltrate	3	4	1	2	1	1	1	1	11	3	15

Bold: Hospital Universitario Central de Asturias
Regular: Hospital Universitario de Salamanca
CLL: Chronic lymphoid leukemia; FL: Folicular lymphoma; MZL-Marginal Zone Lymphoma; LPL: Linfoplasmocytic lymphoma; DLBCL: Diffuse large B cell lymphoma; I: Inespecific; D: Discordant; C:Concordant

Summary and Conclusions: Concordant BM infiltration in DLBCL defines a subtype of aggressive lymphoma, associated with high LDH, IPI, and a high rate of *MYC* translocations, which might explain the adverse prognosis recently reported. Concordant BM DLBCL patients were associated with a high

incidence of CNS relapse, reproducing coetaneous bibliography. CNS prophylaxis and aggressive therapy in this group should be considered. MFC helps to identify concordant BM cases at the moment of diagnosis of DLBCL, and it should be considered as part of BM initial evaluation in DLBCL in order to identify these patients.

PF649

DUVELISIB INHIBITION OF CHEMOKINES IN PATIENTS WITH CLL AND INHL

Background: Duvelisib (IPI-145) (DUV) is an oral dual inhibitor of phosphoinositide 3-kinase (PI3K)-δ and PI3K-γ being developed to treat B-cell malignancies. PI3K-δ inhibition directly targets proliferation and survival of malignant leukemia and lymphoma cells, while PI3K-γ inhibition modulates the tumor microenvironment (TME) through key support cells, including tumor-associated macrophages, nurse-like stroma and T cells, and via soluble factors stimulating tumor growth, survival and migration. The Phase 3 DUO study in relapsed/refractory (RR) CLL/SLL and the Phase 2 DYNAMO study in RR iNHL both met their primary endpoints (Flinn, ASH 2017; Zinzani EHA 2017).
Aims: Herein we present the effect of DUV on cytokines known to be involved in the TME in pts with RR CLL and RR iNHL.
Methods: DUO (NCT02004522) pts were randomized to DUV (n=160) or ofatumumab (OFA) (n=159). DYNAMO (NCT01882803) pts (n=129) received DUV. Serum from baseline and C2D1 was used for correlative studies of 24 chemokines, cytokines and serum factors. Bonferroni-Holm adjustment for multiple comparisons was applied.
Results: In DUO, CCL1, CCL17, CXCL9, CXCL10, CXCL11, and IL-10 were reduced in pts treated with DUV (median% inhibition=43.8%) but not in those treated with OFA ($p \leq 0.0009$). Eight chemokines were reduced in both treatment arms, but the level of reduction was significantly greater for DUV pts (median% inhibition, DUV 64.6% *vs* OFA 26.8%; $p \leq 0.001$). Many of the chemokines inhibited following DUV treatment are associated with the TME, including TNFα, IL-10, IL2Rα, IL12P40, CCL1, CCL17, CCL19, CXCL9, CXCL10, CXCL11, and CXCL13. In DYNAMO, 13 corresponding chemokines were also inhibited ($p \leq 0.008$), including TME factors. Reductions occurred rapidly (by C2D1) in both studies. In DUO, there was a correlation between duration of response and reduction (highest quartile) of the following chemokines: CCL17 (19.4 mo. Q4 *vs* 10.4 mo. Q1-3), CXCL11 (14.9 mo. Q4 *vs* 10.9 mo. Q1-3) IL-6 (16.6 mo. Q4 *vs* 10.9 mo. Q1-3), TRAIL (24 mo. Q4 *vs* 10.3 mo. Q1-3), VEGF_D (24 mo. Q4 *vs* 10.9 mo. Q1-3), TPO (14.9 mo. Q4 *vs* 10.9 mo. Q1-3).
Summary and Conclusions: Pts with CLL and iNHL treated with DUV monotherapy showed significant reduction of chemokines potentially derived from the tumor cells and TME. Further investigation of the effects of DUV on TME pharmacodynamic markers is warranted.

PF650

ACCURATE GCB/ABC CLASSIFICATION OF *DE NOVO* DIFFUSE LARGE B-CELL LYMPHOMA WITH ABERRANT CD10+ MUM1+ PHENOTYPE BY RT-MLPA

O. Laghmari[1], Y. Le Bris[2,*], A. Menard[3], A. Bonnet[4], A. Moreau[5], W. El Alami Thomas[6], A.-H. Pavageau[7], H. Maisonneuve[8], P. Ruminy[9], P. Guerzider[10], C. Copie-Bergman[11], T. Molina[12], M.-C. Bene[3], S. Le Gouill[4], C. Bossard[1]

[1]Pathology Department, [2]Hematology Biology, [3]Department of Hematology Biology, [4]Department of Hematology, [5]Department of Pathology, University Hospital Hotel Dieu, [6]Department of Pathology, Institut d'Histopathologie (IHP), Nantes, [7]Department of Pathology, [8]Department of Hematology, Centre Hospitalier de Vendée, La Roche sur Yon, [9]University Hospital, INSERM U1245, Rouen, [10]Department of Pathology, Centre Hospitalier de Saint Nazaire, Saint Nazaire, [11]Department of Pathology, University Hospital Henri Mondor, Créteil, [12]Department of Pathology, University Hospital Necker, Paris Descartes University, Paris, France

Background: The cell-of-origin (COO) determination of diffuse large B cell lymphoma (DLBCL) into germinal center B-cell like (GCB), and non-GCB (activated B-cell like (ABC) and unclassifiable) subgroups based on the Hans algorithm, the most commonly used immunohistochemical algorithm, remains an approximate approach compared with gene-expression profiling. The determination of this prognostic criterion needs to be improved in routine diagnosis practice.
Aims: The aim of this study was to verify at the mRNA level the COO classification of a subgroup of GCB DLBCL according to Hans algorithm but featuring an aberrant CD10+ MUM1+ phenotype. We addressed this issue using the RT-MLPA assay, a robust and sensitive method already successfully tested for the COO classification on archival paraffin-embedded formalin-fixed (FFPE) tissues.
Methods: We retrospectively identified 62 CD10+ GCB DLBCL according to Hans classifier from 255 *de novo* DLBCL with available FFPE tissue treated in our institution between 2006 and 2016, including 22 CD10+ MUM1+ (8.6% of DLBCL) and 40 CD10+ MUM1- cases. RNA was extracted from FFPE tissue from all 62 CD10+ GCB DLBCL and the RT-MLPA assay evaluated the expression of 14 genes to differentiate ABC from GCB molecular subtypes (Mareschal *et al.* JMD 2015).
Results: Interpretable expression profiles were obtained for 54 of 62 cases (87%, 33 CD10+ MUM1- and 21 CD10+ MUM1+). The 22 CD10+ MUM1+ DLBCL did not significantly differ from the 40 CD10+ MUM1- DLBCL in terms of main clinicopathological criteria (age, gender, stage, performance status, IPI, serum lactate deshydrogenase, overall and progression-free survivals. There was no difference either on immunohistochemical expression of BCL6, BCL2, cMYC, CD5 with 27% of double-expressor lymphomas in both subgroups. However, while the majority of CD10+ MUM1- DLBCL (29/33; 88%) were classified in the GCB subtype by RT-MLPA (4/33 unclassified), only a minority of CD10+ MUM1+ DLBCL (7/21; 33%) were classified in this molecular subtype and 10/21 (48%) were reclassified in the ABC subtype (4/21 unclassified). Interestingly, after molecular reclassification, the proportion of double-expressor lymphomas became more important in the ABC subtype (5/10, 50%) than in the GCB one (12/36, 33%), and patients with a GCB subtype featured a better progression-free survival than those with a ABC subtype (72% *vs* 60% respectively; p=0.5), in accordance with the literature. Finally, when we re-evaluated the percentage of MUM1+ tumor cells in the CD10+ MUM1+ subgroup, 8/9 cases reclassified in the ABC subtype harbored ≥80% of MUM1+ tumor cells (compared with only 2 cases with a maximum of 80% of MUM1+ tumor cells among the 6 cases classified in the GCB subtype).
Summary and Conclusions: This study shows that 67% of CD10+ MUM1+ DLBCL are misclassified in the GC subgroup according to the Hans algorithm since 48% of them were reclassified in ABC subtype by RT-MLPA. Consequently, the COO classification of CD10+ MUM1+ DLBCL based on Hans algorithm should be interpreted with caution in routine diagnosis. A high proportion of MUM1+ tumor cells by immunohistochemistry (>80%) could identify the majority of these non GC CD10+ MUM1+ DLBCL, and help to precise their COO classification.

PF651

IMMUNOGLOBULIN KAPPA DELETING ELEMENT (IGK-KDE) REARRANGEMENTS AS POSSIBLE TARGET FOR MINIMAL RESIDUAL DISEASE (MRD) EVALUATION IN MANTLE CELL LYMPHOMA (MCL)

[1]Department of Cellular Biotechnologies and Hematology, Hematology, Sapienza University, Rome, [2]Department of Molecular Biotechnologies and Health Sciences, Hematology, Turin University, Turin, [3]Department of Oncology, Hematology, Santa

Chiara Hospital, Pisa, Pisa, [4]Department of Medical Biotechnologies, Siena University, Siena, [5]Experimental OncoHematology, National Cancer Institute, Aviano, Aviano, [6]Medical Oncology and Hematology Division, Hematology, Istituto Clinico Humanitas Gavazzeni, Bergamo, Bergamo, [7]Department of Molecular Medicine, Sapienza University, Rome, [8]Division of Hematology, Azienda Ospedaliera SS Antonio e Biagio e Cesare Arrigo, Alessandria, Alessandria, Italy

Background: Minimal residual disease (MRD) assessment is of high clinical relevance in patients (pts) with mantle cell lymphoma (MCL). The real-time quantitative PCR (RQ-PCR) is currently the most sensitive, standardized and broadly applied method. However, in mature B-cell malignancies, the presence of somatic hypermutation (SHM) in VDJH rearrangements leads to frequent mismatches between primers, probes and the target, thus impairing tumor cells quantification. By contrast, in the immunoglobulin kappa-deleting-element (IGK-Kde) rearrangements, the JK-CK intron intervening sequences deletion removes the IGK enhancer, essential for the SHM process.
Aims: To evaluate the applicability of *IGK*-Kde rearrangements as targets for MRD RQ-PCR detection in MCL, to compare them to *IGH* and *BCL1/IGH*, and to perform a comparative RQ-PCR/digital-droplet-PCR (ddPCR) analysis.
Methods: Molecular IGK screening was performed (Pongers-Willemse, 1999) on two cohorts: the first from Turin (19 pts enrolled in the FIL-MCL0208 trial, NCT02354313), the second from Rome (17 outpts). The PCR products were examined by heteroduplex analysis (Langerak, 1997). The germline probes/primers and the clone specific primers were designed using two drawing strategies (Della Starza, 2014). RQ-PCR analyses followed the EuroMRD Consortium guidelines (van der Velden, 2007). The ddPCR was performed as published (Drandi, 2015; Cavalli, 2017).
Results: Of 36 MCL diagnostic BM samples from 36 pts, 3 showed poorly amplifiable DNA, so a total of 33 cases underwent IGK screening. Overall, 25/33 MCL cases were positive for at least one conventional target (*IGH* or *BCL-1/IGH*) and 8/33 were marker negative: 26/33 (79%) pts resulted positive for a *IGK* rearrangement, showing a 75% (6/8) target recovery for negative cases. Combining sequence analysis-molecular cloning, 19/26 (73%) suitable sequences for the ASO primer design were obtained and in 14/19 (74%) a useful primer for MRD monitoring was achieved. However, the analysis showed a high rate of non-specific amplification of normal mononuclear cells DNA (9/14 cases: 64%), thus hampering the sensitivity of the assay [71% (10/14) cases reached a sensitivity ≥10-4]. Based on the material availability, the MRD analysis was performed in 30 follow-up (FU) samples from 10 pts: a 100% concordance rate with both *BCL-1/IGH* and *IGH* was observed. [SF1] Finally, a comparative RQ-PCR/ddPCR analysis, carried out on 24 FU samples from 8 pts, showed a 79% (19/24) concordance. The discrepancies fell in the remaining 5 (21%), of which 4/5 resulted RQ-PCR positive not quantifiable and ddPCR negative. In this subgroup, no clinical relapses were observed. On the contrary, in 1/5 FU the ddPCR quantified the disease and the RQ-PCR was negative, but the FU is too short for a clinical correlation.
Summary and Conclusions: *IGK-Kde* rearrangements can be found in 79% of our MCL, representing a target marker in 75% of *no marker* cases. MRD RQ-PCR monitoring is possible in 54% (14/26) of cases, showing 100% concordance with the conventional targets. However, owing to the frequently observed background amplification, the sensitivity of this assay is lower in MCL compared with acute lymphoblastic leukemia (Van der Velden, 2002), and in line with multiple myeloma (Puig, 2012). Also in this setting ddPCR has a good concordance with RQ-PCR and it might help to identify false positive/negative results. From a clinical perspective, we suggest that *IGK-Kde* MRD monitoring deserves further evaluation in larger series of MCL pts as a supplementary tool that might integrate the standardized MRD strategies.

Platelets disorders

PF652

CIRCULATING MICRORNAS (MIRNAS) IN ITP PATIENTS BEFORE AND AFTER TREATMENT WITH THROMBOPOIETIN RECEPTOR AGONISTS (TPO-RAS)–DIAGNOSTIC AND PROGNOSTIC VALUE

L. Garabet[1,2,*], W. Ghanima[1], A. Rangberg[1], C. Furlund Nystrand[1], R. Teruel-Montoya[3], C. Martinez[3], M.L. Lozano[3], J. Bussel[4], P.M. Sandset[5], C. Monceyron Jonassen[1]

[1]Østfold Hospital Trust, Kalnes, [2]Akershus University Hospital, Lørenskog, Norway, [3]Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, Murcia, Spain, [4]New York Presbyterian Hospital, Weill Cornell Medical Center, New York, United States, [5]University of Oslo, Oslo, Norway

Background: Immune thrombocytopenia (ITP) is an autoimmune disease diagnosed clinically by isolated thrombocytopenia and exclusion of underlying diseases; there is no specific diagnostic test for ITP. TPO-RAs are effective treatment for ITP with response rates of 40-90%. MiRNAs are small, noncoding RNAs involved in post-transcriptional regulation of gene expression. Dysregulated expression of miRNAs is associated with different diseases such as cancer and autoimmune diseases. Circulating miRNAs are stable, easy to measure, and considered as potential disease biomarkers.
Aims: To characterize circulating miRNAs in ITP patients before and after treatment with TPO-RAs, and explore their diagnostic and prognostic value in ITP.
Methods: Ten miRNAs were selected for validation from our previous miRNA screening study where microRNA PCR panel was used to profile 179 miRNAs in 8 ITP patients before and after TPO-RAs and 8 controls. Validation was performed using droplet digital PCR (ddPCR), a technology allowing for absolute quantification of miRNAs, in 23 ITP patients before, 2 and 6 weeks after TPO-RA-treatment and 22 controls. The 10 miRNAs were: miR-423-5p, miR-26a-5p, miR-16-2-3p, miR-590-5p, miR-199a-5p, miR-382-5p, miR-195-5p, miR-92b-3p, miR-221-3p and miR-33a-5p.
Results: Mean age of patients was 58 years (controls 47 yrs), and 56% females (controls 59%); 22/23 patients had chronic ITP (cITP) with mean platelet count $38.7 \cdot 10^9$/L. Ten patients were on steroids and 3 on immune suppressants. Eltrombopag was initiated in 15 patients and romiplostim in 8. We identified 3 differentially expressed miRNAs in ITP patients compared to controls: miR-199a-5p (p=0.0001), miR-33a-5p (p=0.0002) and miR-195-5p (p=0.035). miR-199a-5p was down-regulated, while miR33a-5p and miR-195-5p were up-regulated; miR-195-5p did not change during TPO-RA-treatment and remained higher than in controls. ROC curve analysis comparing ITP patients and controls showed that area under the curve (AUC) for miR-195-5p, miR-33a-5p and miR-199a-5p was 0.66 (95% CI 0.49-0.81), 0.799 (0.66-0.93) and 0.814 (0.68-0.94) respectively. Logistic regression was used to determine the best combination of miRNAs to diagnose ITP; the combination of miR-33a-5p and miR-199a-5p provided a significantly increased AUC of 0.93 (0.86-0.99).
During TPO-RA-treatment, 6 of 10 miRNAs showed significant changes: miR-199a-5p (p=0.001), miR-33a-5p (p=0.003), miR-382-5p (p=0.004), miR-92b-3p (p=0.005), miR-26a-5p (p=0.008) and miR-221-3p (p=0.023). Of those, miR-33a-5p decreased 6 weeks after treatment, while the remaining 5 miRNAs increased after 2 weeks of treatment. Regression analysis revealed that pre-treatment levels of miR-199a-5p and miR-221-3p predicted platelet count 6 weeks after TPO-RAs (p=0.002, r^2 =0.40, and p=0.015, r^2=0.26, respectively) (Figure 1).

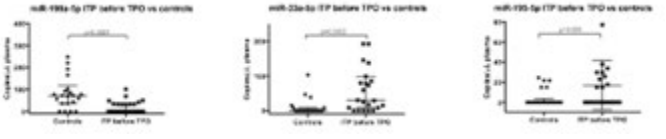

Figure 1.

Summary and Conclusions: Combining miR-199a-5p and miR-33a-5p demonstrated very good discrimination ability between ITP patients and controls and thus appears to be of diagnostic value in ITP. The unique expression of miR-195-5p being persistently upregulated in ITP patients regardless of TPO-RA-treatment and increased platelet count, may indicate a role in the pathophysiology of cITP. Finally, we propose that miR-199a-5p and miR-221-3p are candidate miRNAs to predict response to TPO-RAs. With the potential roles of these miRNAs in the diagnosis and pathophysiology of ITP, and apparent predictive ability of response to treatment with TPO-RAs, larger studies are needed to further explore and confirm the roles of miRNAs in ITP.

PF653

A SINGLE-ARM, OPEN-LABEL, LONG-TERM EFFICACY AND SAFETY STUDY OF SUBCUTANEOUS (SC) ROMIPLOSTIM IN CHILDREN WITH IMMUNE THROMBOCYTOPENIA (ITP)

J. Grainger[1], J. Bussel[2], M. Tarantino[3,4,*], N. Cooper[5], D. Beam[6], J. Despotovic[7], A. Maschan[8], N. Carpenter[9], M. Eisen[10], J. Park[10]

[1]University of Manchester, Manchester, United Kingdom, [2]Weill Cornell Medicine, New York, [3]The Bleeding and Clotting Disorders Institute, [4]University of Illinois College of Medicine-Peoria, Peoria, United States, [5]Imperial College, London, United Kingdom, [6]Cook Children's Medical Center, Fort Worth, [7]Texas Children's Hematology Center, Houston, United States, [8]Dmitry Rogachev National Research Center for Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation, [9]Amgen Ltd., Uxbridge, United Kingdom, [10]Amgen Inc., Thousand Oaks, United States

Background: Romiplostim was evaluated in children with ITP in phase 1/2 and 3 studies.
Aims: Here, we evaluate children with ITP receiving open-label SC romiplostim for ≤3 years.
Methods: Eligible children had ITP for ≥6 months, ≥1 prior ITP therapy, and screening platelet count ≤30×10^9/L or uncontrolled bleeding. Weekly dosing from 1-10 g/kg targeted platelet counts of 50-200×10^9/L. In Europe, bone marrows biopsies were evaluated at baseline and after 1 or 2 years (cohorts 1 or 2) and/or at end of treatment (if patients discontinued early).
Results: As of 20 Mar 2017, 203 patients received ≥1 dose. Baseline median (min-max) age was 10 (1-17) years, ITP duration 1.8 (0.5-13.8) years, and platelet count 14 (2-265)×10^9/L; 10 patients (5%) had had prior splenectomy. The median (Q1, Q3)% of time with a platelet response (platelet count ≥50×10^9/L; no rescue medications in the past 4 weeks) in months 0-6 was 50% (17%, 83%) (primary endpoint). Over the course of the study, 88% (179/203) of patients had a platelet response (Figure 1). From week 12 on, median platelet counts were >50×10^9/L. Four patients maintained platelet counts ≥50×10^9/L with no ITP medications (including romiplostim) for ≥24 weeks, starting 12, 14, 47, and 49 weeks after starting romiplostim. Fifty-two (26%) patients received rescue medications and 3 patients had splenectomy on study. Median (min-max) treatment duration was 53 (8-119) weeks, for a total of 226 patient-years. Median (min-max) average weekly dose over the course of the study was 6.9 (0.2-9.5) µg/kg. The median dose was 9 g/kg at 1 year (n=106) and 10 g/kg at 2 years (n=17) (Figure 1).

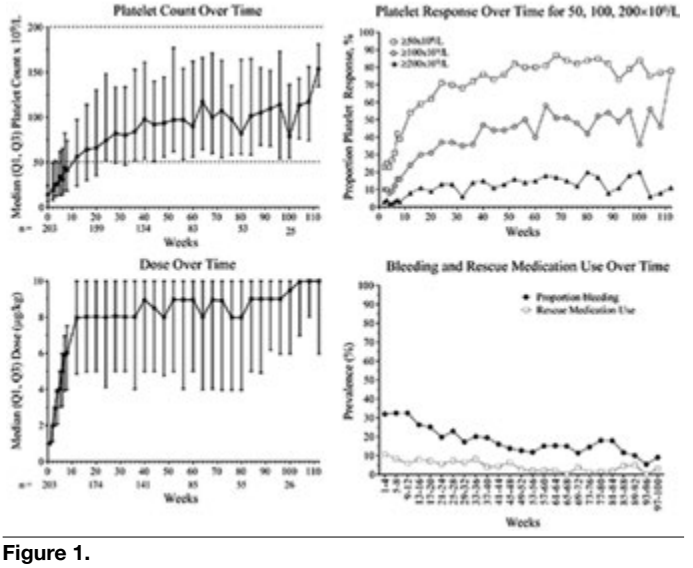

Figure 1.

Most (63%) patients initiated self-administration. Sixty-four patients (31%) discontinued treatment, most frequently for lack of efficacy (n=38), patient request (n=7), and adverse event (AE) (n=7). Forty-one (20%) patients had serious AEs (SAEs) including epistaxis (5%) and decreased platelet count (3%). Five patients had treatment-related SAEs: 2 headaches, 2 abdominal pain, and 1 each of presyncope and neutralizing antibodies (Ab). Bleeding was seen in 62% of patients and decreased over time. CTCAE grade ≥3 bleeding was seen in 17 patients (8%) and included epistaxis (4%), ecchymosis (1%), and contusion (1%); 2 patients had grade 4 bleeding events of "ITP". There were 6 cases of neutralizing Ab to romiplostim (of 201 patients tested), but none to TPO; 5/6 discontinued due to Ab, 5/6 had continued elevated platelet counts and in 2/6 cases Ab were not found on retesting. For cohort 1, of 30 patients with baseline bone marrow biopsies [all with modified Bauermeister scores of grade 0 (no reticulin), 1 (fine fibers), or 2 (fine fiber network)], 27 had evaluable on-study biopsies scheduled for 1 year; 1 patient had an increase from grade 0 to 2, 4 patients had an increase in 1 grade, 1 patient had a decrease in 2 grades, and 3 had a decrease in 1 grade. There were no findings of collagen or abnormalities.
Summary and Conclusions: In this interim datacut of an ongoing open-label study of romiplostim in children with ITP for ≥6 months, 88% of children had a platelet response at some point on study. Median platelet counts were >50×10^9/L from week 12 on, likely due to the time to escalate to the relatively high median dose. Overall, the median dose was 6.9 g/kg; the median romiplostim dose over time reached 10 g/kg. No new safety signals were observed over 226 patient-years. Future datacuts will provide more information on long-term efficacy and safety.

THE BURDEN OF DISEASE AND IMPACT OF IMMUNE THROMBOCYTOPENIA (ITP) ON PATIENT QUALITY OF LIFE AND PRODUCTIVITY: RESULTS FROM THE ITP WORLD IMPACT SURVEY (I-WISH)

N. Cooper[1,*], W. Ghanima[2], D. Provan[3], D. Arnold[4], M. Michel[5], C. Santoro[6], A. Kruse[7], S. Watson[8], M. Morgan[8], M. Hou[9], Y. Tomiyama[10], S. Laborde[11], B. Lovrencic[12], J. Waller[13], G. Taylor-Stokes[13], D. Judge[13], M. Stankovic[14], J. Bussel[15]

[1]Hammersmith Hospital, Imperial College London, London, United Kingdom, [2]Department of Medicine, Ostfold Hospital Trust, Kalnes, Norway, [3]Barts and The School of Medicine and Dentistry, London, United Kingdom, [4]Division of Medicine, McMaster University, Ontario, Canada, [5]Henri Mondor University Hospital, Créteil, France, [6]Department of Cellular Biotechnologies and Haematology, "Sapienza" University of Rome, Rome, Italy, [7]Platelet Disorder Support Association, Cleveland, United States, [8]ITP Support Association, Bedfordshire, United Kingdom, [9]Department of Hematology, Shandong University, Jinan, China, [10]Osaka University Hospital, Osaka, Japan, [11]O'Ctyo, Saint Loubes, France, [12]Italian Association Immune Thrombocytopenic Purpura, Caprino Veronese, Italy, [13]Bespoke Team, Adelphi Real World, Macclesfield, United Kingdom, [14]Novartis, Basel, Switzerland, [15]Division of Hematology/Oncology, Weill Cornell Medical College, New York, United States

Background: ITP is defined by isolated thrombocytopenia, with the diagnosis relying on exclusion of other causes of thrombocytopenia. Incidence rates range from 10-70 cases per 1,000,000 per year. Previous studies have highlighted fatigue as an important morbidity; however limited data are available on the overall impact of ITP on the patient's quality of life (QoL).
Aims: The I-WISh survey aims to understand the impact of ITP on patient (pt) QoL using a global patient and physician sampling frame. Here, we present the interim data from the pt survey.
Methods: I-WISh is a cross-sectional survey of ITP pts and physicians in 14 countries. Pts were recruited via physicians and pt support groups. Pts completed a 30-minute online survey providing information on demographics, diagnosis experience, symptoms, impact on daily living and emotional well-being, QoL and their treatment and management. Survey materials were designed and endorsed by a steering committee, including expert clinicians and pt advocacy leads specialising in ITP.
Results: 260 pts, 70% female, with a mean age (SD) of 55.3 (15.071) years completed the survey. Mean length of time since ITP diagnosis (SD, range) was 12.0 (11.3, 0.1-60) years. Pts reported their current health state using a 7-point Likert scale (7=excellent health), 67% of patients reported a score ≥5 and 11% a score ≤3. Mean time (SD) from initial presentation to a health care professional and ITP diagnosis was approximately 15.1 (77.5) weeks. Of all pts, 15% felt they experienced a delay in their ITP diagnosis and 65% wanted more support during their diagnosis. Initial presentation was made to a General Practitioner by 69% of pts, whereas diagnosis was by a haematologist for 81% of pts. The most frequently reported symptoms at diagnosis were bruising (of the skin/mucous membranes) (73%), fatigue (68%) and petechiae (65%); at the time of survey completion, they were fatigue (59%), bruising (31%) and petechiae (27%). Bruising, fatigue and petechiae were reported as the most severe symptoms when scored ≥5 on a 7-point Likert scale (7=worst imaginable) (57%, 71% and 48% at diagnosis; 22%, 64% and 30% at time of survey completion; respectively). ITP significantly impacted QoL and daily living; 44% of patients reported that ITP impacted their energy levels more than half the time; 28% said ITP had a negative impact on their normal capacity to exercise more than half the time; 21% reported that ITP impacted their undertaking of daily tasks more than half the time. 36% of pts stated ITP had a high impact on their emotional well-being (a score of ≥5 on a 7-point Likert scale, where 7 is a great deal). Additionally, pts reported a high impact of ITP on their work, with

28% of pts having reduced their hours at work due to ITP. Patients said "healthy blood counts" (79%) was their main treatment goal, followed by "increasing my energy levels" (55%) and "preventing episodes of worsening of my ITP" (46%).
Summary and Conclusions: This interim data analysis demonstrates the multifaceted burden of ITP on pts' lives. There was high symptom burden, and a negative impact on emotional well-being and pt's ability to work. Fatigue was the most severe symptom and pts indicated a desire to increase their energy levels, suggesting patients are primarily concerned with the impact of ITP on their QoL. These results highlight a need to further explore and define overall disease burden of ITP and to consider how these findings should affect the management of ITP in these patients.

PF655

FINAL SAFETY AND EFFICACY DATA OF LONG-TERM OPEN-LABEL DOSING OF SUBCUTANEOUS (SC) ROMIPLOSTIM IN CHILDREN WITH IMMUNE THROMBOCYTOPENIA (ITP)

M. Tarantino[12,*], J. Bussel[3], V. Blanchette[4], D. Beam[5], J. Roy[6,7], J. Despotovic[8], A. Raj[9], N. Carpenter[10], B. Mehta[11], M. Eisen[11]

[1]University of Illinois College of Medicine-Peoria, [2]The Bleeding and Clotting Disorders Institute, Peoria, [3]Weill Cornell Medicine, New York, United States, [4]Hospital for Sick Children, Toronto, Canada, [5]Cook Children's Medical Center, Fort Worth, United States, [6]The University of Queensland, Saint Lucia, [7]Children's Health Queensland & Pathology Queensland, South Brisbane, Australia, [8]Texas Children's Hematology Center, Houston, [9]Pediatric Cancer and Blood Disorders Clinic, Louisville, United States, [10]Amgen Ltd., Uxbridge, United Kingdom, [11]Amgen Inc., Thousand Oaks, United States

Background: Children with ITP for ≥6 months who completed a romiplostim phase 1/2 or 3 study could enter an open-label extension.
Aims: Final extension data for these children with ITP treated with romiplostim are described here.
Methods: All patients received weekly SC romiplostim, adjusted weekly by 1 µg/kg/week from 1–10 µg/kg to target platelet counts of 50–200×10^9/L. Incidence of adverse events (AEs) was the primary endpoint.
Results: Median (min–max) treatment for the 65 patients was 135 (5–363) weeks for a total of 182 patient-years, or 2.8 years / patient. Baseline median (min–max) age was 11 (3–18) years; 56% were female; 9.1% had prior splenectomy. Median (min–max) average weekly dose was 4.8 (0.1–10.0) µg/kg, including dose escalation; 20 patients started on 1 g/kg. All 65 patients received their doses per protocol >90% of the time; 21 missed ≥1 dose for noncompliance for a total of 65 times. Reasons for discontinuing romiplostim (n=28, 42%) included consent withdrawn (n=10), other therapy (n=6), and AE (n=2) (asthenia, headache, dehydration, and vomiting in one patient and anxiety in the other; per investigators, none were treatment related). Fifty-four serious AEs occurred in 19 patients but were treatment related in only one patient (concurrent grade 4 thrombocytopenia, grade 3 epistaxis, and grade 2 anemia). Bleeding AEs occurred in 57 patients; 3 were deemed treatment related (injection site hemorrhage, injection site bruising, and epistaxis). No thrombotic events were reported. Bone marrow biopsies were performed for 2 patients with additional cytopenias; both had iron-deficiency anemia. Upon leaving the study to receive other therapy, one patient had anti-romiplostim neutralizing antibody (Ab) which was absent on retesting 3 and 6 months later. No patients had anti-TPO neutralizing Ab. Median platelet counts were >50×10^9/L from week 2 on and >100×10^9/L from weeks 24-260 (Figure 1).Nearly all (94%, 61/65) patients had ≥1 platelet response (platelet counts ≥50×10^9/L, excluding counts ≤4 weeks after rescue medication). Most (72%, 47/65) patients had a platelet response ≥75% of the time and 58% (38/65) did ≥90% of the time. Sixty (92%) patients (or caregivers) self-administered romiplostim. Twenty-three (35%) patients received rescue medications; usage was highest in the first few months. Fifteen (23%) patients had treatment-free periods of platelet counts ≥50×10^9/L for ≥24 weeks (here also called remission; Table 1, Figure 1); these patients (9 girls, 6 boys) had had ITP for a median (min–max) of 3.5 (1.3–13) years, none had prior splenectomy, and had received romiplostim for 2.1 (0.7–6) years. All 15 of these patients had platelet counts over 100×10^9/L for ≥3 months and 12/15 for ≥6 months. The median (min–max) duration of being ≥100×10^9/L for these 15 patients was 42 (13–109) weeks. Of baseline characteristics such as sex, platelet counts, ITP duration, and number of past ITP treatments (1, 2, 3, >3), only age <6 years was predictive of developing treatment-free periods ≥24 weeks (p=0.0035).
Summary and Conclusions: Seven years of data from this open-label extension study of romiplostim in children with ITP show that >90% of children achieved a platelet response with romiplostim. Romiplostim was mostly well tolerated. Importantly, 23% of these patients with longstanding ITP (median 3.5 years) were able to discontinue all ITP medications (including romiplostim) for at least 6 months.

PREEMPTIVE RITUXIMAB HAS A FAVORABLE BENEFIT-RISK BALANCE IN THE PREVENTION OF LONG-TERM RELAPSES IN IMMUNE-MEDIATED THROMBOTIC THROMBOCYTOPENIC PURPURA

M. Jestin[1,*], Y. Benhamou[2], F. Provôt[3], L. Galicier[4], M. Hié[5], P. Poullin[6], S. Saheb[7], C. Deligny[8], S. Girault[9], T. Kanouni[10], A. Charvet Rumpler[11], M. Hamidou[12], A. Veyradier[13], P. Coppo[14]

[1]Hematology, Hôpital Saint-Antoine, PARIS, [2]Internal medicine, CHU, ROUEN, [3]Nephrology, CHRU, Lille, [4]Clinical immunology, Saint Louis, [5]Internal medicine, CHU La Pitié Salpétrière, Paris, [6]Hemapheresis, CHU La Timone, Marseille, [7]Hemapheresis, CHU La Pitié Salpétrière, Paris, [8]Internal medicine, CHU, Fort-de-France, [9]Hematology, CHU Dupuytren, Limoges, [10]Hematology, CHU, Montpellier, [11]Hematology, CHRU Jean Minjoz, Besançon, [12]Internal medicine, CHU, Nantes, [13]Biological hematology, Hôpital Lariboisière, [14]Hematology, Saint Antoine, Paris, France

Background: Immune thrombotic thrombocytopenic purpura (iTTP) is a fulminant and spontaneously fatal disease. Up to 50% of patients finally experience one or several relapses. Persistently undetectable ADAMTS13 activity in patients otherwise in remission represents a reliable early predictor of full clinical relapse (CR). Preemptive rituximab infusions prevent CR in iTTP by maintaining ADAMTS13 activity within normal values. However, the long-term outcome of these patients and the potential adverse events of this strategy need further investigations.
Aims: To evaluate the feasibility, efficacy and safety of preemptive rituximab in patients with iTTP in clinical remission but with a persistently undetectable ADAMTS13 activity.
Methods: We report the long-term outcome of 92 patients with iTTP in remission treated preemptively with rituximab for a biological relapse (BR) *i.e.* a severe ADAMTS13 deficiency (activity <10%) identified during follow-up, without CR. ADAMTS13 activity was systematically measured every 3 months. We compared in these patients the median number of iTTP episodes and the median cumulative incidence of annual relapse that occurred before and after preemptive rituximab. We also compared patients treated with preemptive rituximab to a distinct group of patients with a persistent severe ADAMTS13 deficiency but managed before the era of rituximab.

Results: Before rituximab, thirty-seven patients had experienced >1 episode of iTTP (median 3, IQR 2-3), and the median cumulated incidence of relapse was 0.33 episode/year (IQR, 0.23-0.66). Following preemptive rituximab, the median cumulated incidence of relapse in the whole population dramatically decreased (0 episode/year [IQR, 0-1.32], p<0.001) after a 35.8-month follow-up (IQR, 23.3-68). ADAMTS13 activity recovery was sustained in 34 patients (37%) following a single course of preemptive rituximab (comprising 1 to 4 infusions at 375mg/m^2/infusion), after a 31.5-month follow-up (IQR, 18-65). Forty-five patients (49%) had at least one new BR after initial improvement, which usually improved with further courses of rituximab. In these patients, the median time between 2 courses was 17.5 months (IQR, 12.6-25). Thirteen patients (14%) had a persistently undetectable ADAMTS13 activity after a first course of rituximab. Among them, 10 patients received repeated courses of rituximab and retreatment allowed ADAMTS13 improvement in 6 cases. Finally, only 7 patients/92 (7.6%) were refractory to preemptive rituximab. In total, 14 patients/92 (15%) experienced a CR after a median follow-up of 29 months (IQR, 20-57). Nineteen patients (20.7%) experienced benign adverse effects attributed to rituximab. From a historical group of 23 iTTP with a persistently undetectable ADAMTS13 activity and managed before the era of rituximab, 74% clinically relapsed after a 7-year follow-up (IQR, 5-11). These patients experienced significantly more relapses than patients treated with rituximab (p <0.001) (Figure 1).

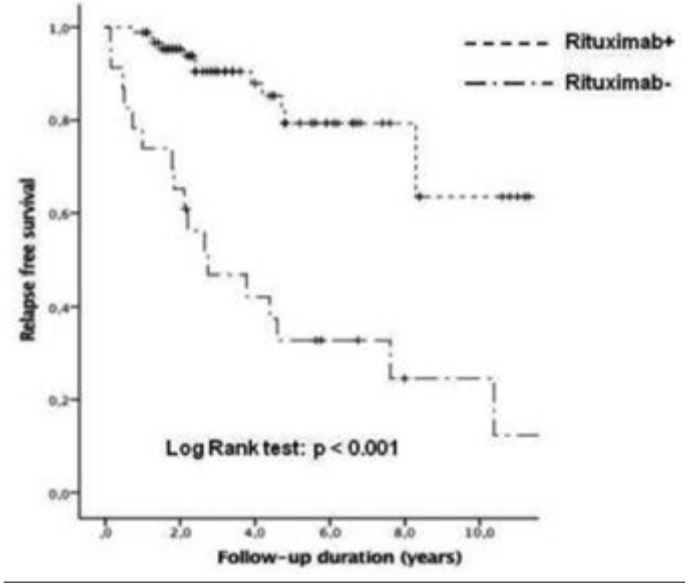

Figure 1.

Summary and Conclusions: In conclusion, a persistently undetectable ADAMTS13 activity in iTTP otherwise in remission is associated with a high relapse rate; in these patients, rituximab prevents CR by maintaining a detectable ADAMTS13 activity with an advantageous risk-benefit balance. However, half of patients require repeated courses to maintain a normal ADAMTS13 activity.

PF657

AVATROMBOPAG DEMONSTRATES SUPERIORITY TO PLACEBO FOR THE TREATMENT OF CHRONIC IMMUNE THROMBOCYTOPENIC PURPURA IN A PHASE 3, MULTICENTER, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL

W. Jurczak[1,*], K. Chojnowski[2], J. Mayer[3], B. Jamieson[4], W. Tian[4], L.F. Allen[4]

[1]Jagiellonian University, Kraków, [2]Medical University of Łódź, Lodz, Poland, [3]University Hospital Brno, Brno, Czech Republic, [4]Dova Pharmaceuticals, Durham, United States

Background: Avatrombopag (AVA) is an oral, 2nd generation thrombopoietin receptor agonist (TPO-RA) currently in development for the treatment of thrombocytopenia. Given the need for chronic administration, it is important to minimize treatment-related toxicities in patients with ITP. The once daily oral dosing of AVA, which can be taken with food, has no signal for hepatotoxicity, and a reliable pharmacokinetic-pharmacodynamic response profile due to limited metabolism of the parent molecule may provide advantages for its use in patients with ITP.

Aims: This trial investigated the efficacy and safety of AVA *versus* placebo (PBO) for the treatment of patients withchronic ITP in a multicenter, multinational, randomized, parallel group, PBO-controlled Phase 3 trial(NCT01438840).

Methods: Adult patients (age ≥18 years) with chronic ITP (Baseline platelet count <30 X 109/L) were randomized 2:1 to 20 mg/day AVA or PBO over the 6-month study period. The primary efficacy endpoint was the number of cumulative weeks with a platelet response defined as a plateletcount ≥50 x 109/L, in the absence of rescue therapy. Secondary endpoints included platelet response at Day8, and the proportion of patients with a reduction in concomitant ITP medications from Baseline.

Results: In total, 49 patients were included in the full analysis. The AVA treatment group included 32 patients; 22 (68.8%)completed the study. In the PBO group, which included 17 patients, only one (5.9%) completed the study. AVA was superior to PBO in the mean cumulative number of weeks with a platelet count ≥50 x 109/L duringthe 6-month treatment period (12.4 weeks *vs* 0 weeks; P<0.0001). Day 8 platelet responses were higher for patients who received AVA, 65.6% compared with 0% for PBO (P<0.0001). A durable platelet response was observed in more AVA-treated patients (34.3%) compared with PBO-treated patients (0%; P=0.009). Treatment emergent AEs (TEAEs) were reported by 31 patients (96.9%) in the AVA-treated group compared with 10 patients (58.5%) in the PBO-treated group; the incidence of TEAEs, Grade 3/4 TEAEs, and serious AEs were similar in the two treatment groups when adjusted for treatment exposure. The most commonly reported TEAEs included headache, contusion, upper respiratory tract infection, arthralgia, and epistaxis.

Summary and Conclusions: AVA is novel 2nd generation TPO-RA that has been shown to be well tolerated and superior to PBO in patients with chronic ITP may potentially provide an additional treatment option for patients with refractory chronic ITP.

PF658

A PHASE 1B, OPEN-LABEL, DOSE-ESCALATION STUDY OF PRTX-100, A HIGHLY PURIFIED FORM OF STAPHYLOCOCCAL PROTEIN A (SPA), IN ADULT PATIENTS WITH PERSISTENT/CHRONIC IMMUNE THROMBOCYTOPENIA (ITP)

N. Cooper[1,*], A. Newland[2], R. Kazmi[3], M. Scully[4], S. Audia[5], J.-F. Viallard[6], M. Hamidou[7], J.B. McClain[8], R. Francovitch[8], M. Marc[9]

[1]Haematology, Imperial College, Hammersmith Hospital, [2]Haematology, Queen Mary, University of London, London, [3]Haematology, University Hospitals Southampton NHS Foundation Trust, Southampton, [4]Haematology, University College London, London, United Kingdom, [5]Internal Medicine and Immunology, CHU Dijon, Dijon, [6]Internal Medicine, CHU Bordeaux, Bordeaux, [7]Internal Medicine, Hôtel Dieu University Hospital, Nantes, France, [8]Protalex, Inc., Florham Park, United States, [9]Internal Medicine, Henri Mondor University Hospital, AP-HP, Université Paris-Est Créteil, Créteil, France

Background: ITP is a rare autoimmune bleeding disorder characterized by isolated thrombocytopenia caused by antibody-dependent platelet destruction and impaired platelet production. Various therapies (eg glucocorticoids, IV immunoglobulin, and thrombopoietin receptor agonists) are available but are limited by inadequate efficacy, side effects and/or cost. PRTX-100 is a highly purified form of SpA that binds to human B-lymphocytes and monocytes and modulates immune processes. Preclinical data indicate that PRTX-100 may have the potential to treat ITP by reducing immune-mediated platelet destruction (Kapur *et al*., Br J Haematol 2017).

Aims: We present safety and efficacy data from the first four dosing cohorts of patients with refractory ITP enrolled in a phase 1b open-label study (PRTX-100-203).

Methods: Adults with persistent or chronic ITP who had received at least one prior ITP treatment and had either a platelet count <30,000/μL (if not receiving any ITP therapy) or <50,000/μL (if receiving a constant dose of permitted ITP treatment) were eligible. PRTX-100 was administered via a 30-min infusion (60 min if total dose >500 μg) on Days 1, 8, 15 and 22 in a standard 3+3 dose-escalation study design. Starting dose was 3 μg/kg with subsequent dose increases to 6, 12, 18 and 24 μg/kg. Primary objective: to characterize safety of up to five dose levels of PRTX-100. Safety analyses: adverse events (AEs), serious AEs, infusion reactions, clinical laboratory tests, vital signs, physical findings and electrocardiograms. Efficacy endpoints include platelet response (increased platelet count ≥30,000/μL and at least doubling of baseline count in patients with a baseline count <30,000/μL; or, in patients with a baseline count ≥30,000/μL and <50,000/μL, an increase in count to ≥50,000/μL and at least a doubling of baseline count or an increase to >100,000/μL). Secondary objectives include immunogenicity and pharmacokinetics.

Results: Data are available from 13 patients enrolled in the first four dosing cohorts: 3 µg/kg (n=3), 6 µg/kg (n=4), 12 µg/kg (n=3), and 18 µg/kg (n=3). There were 6 women and 7 men (10 Caucasian, 1 Asian, 2 other) with an age range of 21 to 81 years and most had a splenectomy. Two patients in the 6 µg/kg cohort discontinued the study (1 due to a serious unrelated grade 4 worsening of ITP after receiving 2 doses of PRTX-100; 1 due to non-compliance with study visits after receiving 3 doses of PRTX-100). All 11 remaining patients received 4 doses of PRTX-100. Two serious or higher-grade AEs were seen in this group: unrelated grade 4 mouth bleeding (n=1), unrelated grade 3 axonal neuropathy (n=1). Two grade 1 infusion reactions occurred: itching rash at the infusion site (n=1); pruritus (n=1). Laboratory events: grade 3/4 hyperglycaemia, grade 3 lymphocytopenia, and grade 4 abnormal urine glucose (n=1 patent); grade 3 hypophosphatemia and grade 4 abnormal urine glucose (n=1); grade 3 cholesterol increase (n=1). Five patients had increased platelet counts as early as Day 3. Two patients had a protocol-defined platelet response at the 3 µg/kg and 18 µg/kg doses (see Figure 1). A further 5 patients had an increase in their counts, although not to the level of response.

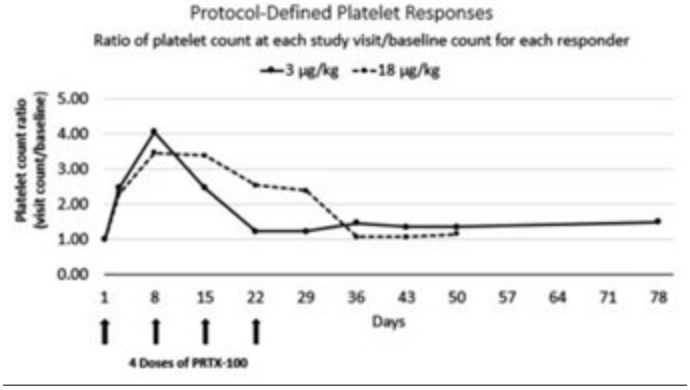

Figure 1.

Summary and Conclusions: Data from the first four cohorts of patients treated with PRTX-100 demonstrate an acceptable safety profile. Platelet counts were elevated in several patients and two patients so far have achieved a platelet response. Enrolment into the last dosing cohort (24 µg/kg) is ongoing and updated data will be included in any presentation.

PF659

RITUXIMAB IN ADULT PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA: STANDARD DOSE *VERSUS* LOW DOSE

S. Datta[1,*], S. Kalantri[1], S. Saha[1], N. Sinha[1], S.K. Samanta[1], S.S. Ray[1], M. Bhattacharyya[1]

[1]Clinical Haematology, Institute of Haematology and Transfusion Medicine; Medical College Hospital, Kolkata, India, Kolkata, India

Background: Rituximab 375 mg/m^2 weekly for 4 weeks has significant activity in adults with primary immune thrombocytopenia (ITP). Several evidences support that lower dose of rituximab (100 mgweekly for 4 weeks) is also effective in this setting. A randomized trial comparing standard dose and low dose rituximab in ITP is sparse in the literature.
Aims: To compare the efficacy of standard dose rituximab with that of low dose rituximab in previously treated adult patients with primary immune thrombocytopenia.
Methods: Fifty previously treated adult patients with primary immune thrombocytopenia were randomized to receive standard dose (375 mg/m^2 weekly for 4 weeks) or low dose (100 mg flat dose weekly for 4 weeks) rituximab in this single-center open-labeled trial conducted between August 2015 and August 2017. Platelet counts were measured weekly for the first month and then monthly. Patients with steroid dependency or active bleeding were allowed to continue steroids at the minimal effective dosage sufficient to maintain a safe number of platelets. However, only patients in whom steroid discontinuation was possible during or soon after rituximab therapy were considered responders.
Results: Each treatment arm had twenty-five patients. At one month, in standard dose (SD) arm Overall response (OR) and complete response (CR) rates were 60% (15 patients) and 36% (9 patients), respectively. In low dose (LD) arm OR and CR rates were 56% (14 patients) and 28% (7 patients) respectively. The difference of initial response between two treatment arm was not statistically significant (p=0.829). At six months standard-dose rituximab arm showed CR and OR rates of 28% (7 patients) and 44% (11 patients). Low-dose rituximab arm had CR and OR rates of 20% (5 patients) and 40% (10 patients). There was no statistically significant difference in response at six months between the two treatment groups (p=0.921). At one year, six patients (24%) of SD rituximab arm were in CR and rest of responders relapsed. In LD rituximab arm, at one year, CR and OR rates were 8% (2 patients) and 12% (3 patients), respectively (p=0.339). Relapse rates among responders at six months were 26.7% (4/15) and 28.6% (4/14) in SD and LD rituximab arm, respectively. At one year, relapse rates were 53.3% (8/15) in SD rituximab arm and 57.1% (8/14) in LD rituximab arm (p=0.837). Relapse rates after achieving CR were 22% in SD rituximab arm and 28% in LD rituximab arm. The relapse rates were very high in patients who achieved R (Response =platelet count ≥30 ×10^9 /L to <100 ×10^9 /L), 100% in SD arm and 85% in LD arm. The median duration of follow-up in non-relapse patients was 55 weeks (Range: 35-86 weeks) in SD arm and 47 weeks (Range: 34-98 weeks) in LD arm (Table 1).

Table 1.

Response after rituximab therapy

		Standard dose rituximab	Low dose rituximab	*P*
Patients (n)		25	25	-
One month	OR (%)	15 (60)	14 (56)	0.829
	CR (%)	9 (36)	7 (28)	
	R (%)	6(24)	7 (28)	
Six months	OR (%)	11 (44)	10 (40)	0.921
	CR (%)	7 (28)	5 (25)	
	R (%)	4(16)	5 (20)	
One year	OR (%)	6 (24)	3 (12)	0.339
	CR (%)	6 (24)	2 (8)	
	R (%)	0(0)	1 (4)	
Median time to response, in weeks (range)		2 (1-8)	3 (1-14)	0.246
Median time to CR, in weeks (range)		4 (2-24)	4 (2-20)	0.787
Relapse Rates in responders (%)		8 (53.3)	8 (57.1)	0.837
Relapse after CR (%)		2 (22.2)	2 (28.6)	0.979
Relapse after R (%)		6 (100)	6 (85.7)	
Median follow up in non relapse population, in weeks (range)		55 (35-86)	47 (34-98)	0.136

Summary and Conclusions: Low-dose rituximab has similar response rate and relapse rate compared to standard dose rituximab in previously treated adult patients with primary immune thrombocytopenia.

PF660

SAFETY PROFILE OF CAPLACIZUMAB DURING THE PHASE III HERCULES STUDY: FREQUENCY OF ADVERSE EVENTS ACCORDING TO STUDY PERIOD

P. Coppo[1,*], S. Cataland[2], F. Peyvandi[3], M. Scully[4], P. Knöbl[5], J.A. Kremer Hovinga[6], A. Metjian[7], J. de la Rubia[8], K. Pavenski[9], F. Callewaert[10], D. Biswas[10], H. De Winter[10], R. K. Zeldin[10]

[1]Department of Hematology, Saint-Antoine University Hospital, Paris, France, [2]Division of Hematology, Department of Internal Medicine, The Ohio State University, Columbus, United States, [3]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy, [4]Department of Haematology, University College London Hospitals NHS Trust, London, United Kingdom, [5]Department of Medicine 1, Division of Hematology and Hemostasis, Vienna University Hospital, Vienna, Austria, [6]University Clinic of Hematology and Central Hematology Laboratory, Bern University Hospital, Inselspital, Bern, Switzerland, [7]Division of Hematology, Duke University School of Medicine, Durham, United States, [8]Hematology Department, Universidad Católica de Valencia Hospital Doctor Peset, Valencia, Spain, [9]Department of Laboratory Medicine and Pathobiology, St. Michael's Hospital/Research Institute, Toronto, Canada, [10]Clinical Development, Ablynx NV, Zwijnaarde, Belgium

Background: Acquired (immune-mediated) thrombotic thrombocytopenic purpura (aTTP) is a life-threatening thrombotic microangiopathy, characterized by thrombocytopenia, hemolytic anemia, and organ ischemia. Results of the Phase 3 HERCULES study in aTTP patients demonstrated that caplacizumab reduces the time to platelet count response, the incidence of patients experiencing either aTTP-related death, recurrence of aTTP, or a major thromboembolic event during study drug treatment, recurrence of aTTP during the overall study, refractoriness to therapy, and healthcare resource utilization (Scully *et al.*, Blood 2017 130:LBA-1). Mucocutaneous bleeding was the most frequently reported adverse event (AE).
Aims: To analyze the frequency of treatment-emergent AEs (TEAE) according to timing of occurrence during the Phase III HERCULES study.

Methods: All reported TEAEs were classified according to the Medical Dictionary for Regulatory Activities Version 20.0. TEAEs were analyzed according to the following study periods: double-blind (DB) daily plasma exchange (PE) treatment period; DB post-daily PE treatment period; and the treatment-free follow-up (FU) period. Analysis was performed on the study's safety population (*i.e.*, all patients who received at least 1 administration of study drug).
Results: The safety population consisted of 71 caplacizumab-treated and 73 placebo-treated patients. The median (min; max) duration of DB study drug treatment was 35 (1; 65) days for the caplacizumab group and 23 (2; 66) days for the placebo group (*i.e.*, shorter in the placebo group due to the switch to open-label caplacizumab treatment for those with a recurrence, which may have impacted the incidence of TEAEs in the two groups). During the overall study period, at least one TEAE was reported in 69 patients (97.2%) in the caplacizumab group and 71 patients (97.3%) in the placebo group. Of these, TEAEs were reported in 57/71 (80.3%) *vs* 56/73 (76.7%) patients during the DB daily PE period, and in 52/65 (80.0%) *vs* 57/64 (89.1%) patients during the DB post-daily PE period, in the caplacizumab *vs* placebo group respectively. In the caplacizumab group, the most common reported TEAEs during the DB daily PE period were: epistaxis [9 patients (12.7%)], gingival bleeding [8 patients (11.3%)], and urticaria [11 patients (15.5%)], while during the post-daily PE period epistaxis [15 patients (23.1%)], headache [11 patients (16.9%)], and gingival bleeding [5 patients (7.7%)] were the most frequently reported TEAEs. In the placebo group, the most common TEAEs during the DB daily PE period were hypokalemia [11 patients (15.1%)], and insomnia, anxiety, chest pain, bruising, urticaria and pruritus (each in 5 patients (6.8%)], while during the DB post-daily PE period, TTP [28 patients(43.8%)], contusion [7 patients (10.9%)] and headache [5 patients (7.8%)] were the most frequently reported TEAEs. In the 28-day FU period, TEAEs were reported in 36/66 (54.5%) patients in the caplacizumab and 18/39 (46.2%) patients in the placebo group. The most commonly reported TEAEs in the caplacizumab group during the FU period were headache [5 patients (7.6%)] and TTP [6 patients (9.1%)]. During the FU period, all other TEAEs were reported in <5% of patients.
Summary and Conclusions: The safety profile of caplacizumab was generally favorable. In line with its pharmacology, treatment with caplacizumab was associated with an increased risk of mucocutaneous bleeding. These events were reported with a similar frequency during the daily PE period (*i.e.*, when platelet counts are low) and the post-daily PE period (*i.e.*, when platelet counts are normalized).

PF661

LOW-DOSE RITUXIMAB PLUS PREDNISOLONE YIELDS HIGHER SUSTAINED RESPONSE RATES THAN PREDNISOLONE MONOTHERAPY AS FRONTLINE THERAPY IN ADULT PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA

S. Datta[1,*], S. Kalantri[1], S. Saha[1], N. Sinha[1], S.K. Samanta[1], S.S. Ray[1], M. Bhattacharyya[1]

[1]Clinical Haematology, Institute of Haematology and Transfusion Medicine; Medical College Hospital, Kolkata, India, Kolkata, India

Background: Prednisolone is most widely used first-line therapy for treatment of newly diagnosed ITP. But most of the adults with ITP relapse after initial response to steroid. To intensify frontline therapy, Rituximab (375 mg/m^2, weekly for four weeks) in combination with high dose dexamethasone (HDD), was used in newly diagnosed ITP and showed higher long-term remission rates compared with dexamethasone alone. Subsequently, non-randomized trials used low-dose rituximab (100 mg, weekly for four weeks) in combination with HDD in treatment naïve adult patients with ITP. To date, there have been no randomized trials comparing low-dose rituximab plus prednisolone with prednisolone alone as frontline therapy in adult patients with ITP.
Aims: In this randomized trial we compared efficacy and safety of Low-dose rituximab plus prednisolone with prednisolone alone in newly diagnosed adult patients with ITP.
Methods: In this study, we enrolled newly diagnosed treatment naïve adult (≥18 years) ITP patients with symptomatic bleeding manifestations between February 2016 to October 2017. Total 60 patients were evaluated for eligibility and at randomization 8 patient were excluded from the study (pregnant=1, HIV positive=1, HBs Ag positive=1, ANA positive=1, three patient received IVIg, one received high dose methyl prednisolone). Fifty-two patients were randomly assigned to two treatment arms. Twenty-six patients received prednisolone 1 mg/kg for 4 weeks followed by tapering of prednisolone over another 4 weeks. Other twenty-six patients received additional rituximab 100 mg weekly, four doses.
Results: The initial responses were measured at one month. In Rituximab-Prednisolone arm 18 (69.2%) patients achieved CR and 3 (11.5%) achieved R, mounting an Overall response (OR) to 80.7%. In prednisolone arm, OR, CR, and R were achieved by 18 (69.2%), 13(50%), and 5(19.2%) patients, respectively. There was no statistically significant difference in initial response between two cohorts (p=0.368). At six months, in Rituximab-Prednisolone arm CR, R and OR were 65.4%, 11.5%, and 76.9%, respectively. Prednisolone arm showed CR, R, and OR of 26.9%, 11.5%, and 38.4%, respectively (p=0.013). One year response data was available for 19 patients of RP arm and for all the 26 patients of Prednisolone arm. At one year, Rituximab-Prednisolone arm and Prednisolone arm showed CR rates of 52.6% (10/19) and 15.4% (4/26), respectively (p=0.008). At three months, five patients (27.8%) of Prednisolone arm relapsed, whereas no patient of Rituximab-Prednisolone arm relapsed at 3 months (p=0.01). At six months, only one patient (4.8%) of Rituximab-Prednisolone arm relapsed, whereas 8 patients (44.4%) of Prednisolone arm relapsed at 6 months (p=0.003). One year relapse data were available for 14 patients of the Rituximab-Prednisolone arm and for all the 18 patients of Prednisolone arm. At one year, 4 patients (28.6%) of the Rituximab-Prednisolone arm and 14 patients (77.8%) of Prednisolone arm relapsed (p=0.002). Eleven patients (42.3%) of the Rituximab-Prednisolone arm and 10 (38.5%) patients of Prednisolone arm experienced adverse effects. All the adverse effects were grade 1 or grade 2 (Table 1).

Table 1.

Response rates at different point-of-time

		Rituximab-Prednisolone	Prednisolone	p
One month	CR (%)	18 (69.2)	13 (50)	0.368
	R (%)	3 (11.5)	5 (19.2)	
	OR (%)	21 (80.7)	18 (69.2)	
Three months	CR (%)	18 (69.2)	8 (30.8)	0.019
	R (%)	3 (11.5)	5 (19.2)	
	OR (%)	21 (80.7)	13 (50)	
	Relapse (%)	0/21 (0)	5/18 (27.8)	0.01
Six months	CR (%)	17 (65.4)	7 (26.9)	0.013
	R (%)	3 (11.5)	3 (11.5)	
	OR (%)	20 (76.9)	10 (38.4)	
	Relapse (%)	1/21 (4.8)	8/18 (44.4)	0.003
Nine months	CR (%)	15/24 (62.5)	5/26 (19.2)	0.005
	R (%)	2/24 (8.3)	2/26 (7.7)	
	OR (%)	17/24 (70.8)	7/26 (26.9)	
	Relapse (%)	2/19 (10.5)	11/18 (61.1)	0.001
One year	CR (%)	10/19 (52.6)	4/26 (15.4)	0.008
	R (%)	0/19 (0.0)	0/26 (0.0)	
	OR (%)	10/19 (52.6)	4/26 (15.4)	
	Relapse (%)	4/14 (28.6)	14/18 (77.8)	0.002

Summary and Conclusions: The combination of low-dose Rituximab plus Prednisolone as frontline therapy for adult patients with newly diagnosed primary immune thrombocytopenia is well tolerated and induces a higher long-term response and lower incidence of relapse than Prednisolone alone.

PF662

EXTENDED FOLLOW UP OF PATIENTS TREATED IN THE RITUXIMAB AS SECOND-LINE TREATMENT FOR ADULT IMMUNE THROMBOCYTOPENIA – THE RITP STUDY

E. Tjønnfjord[1], P.A. Holme[2], B. Darne[3], A. Khelif[4], A. Waage[5], W. Ghanima[6,*]

[1]Hematology, [2]Hematolgy, Rikshospitalet, OUS, Oslo, Norway, [3]Monitoring Force, Paris, France, [4]Hematology, CHU Farhat Hached, Sousse, Tunisia, [5]Hematology, St. Olavs Hospital, Trondheim, [6]Hematology, Sykehus Østfold, Kalnes, Sarpsborg, Norway

Background: Immune thrombocytopenia (ITP) is characterized by immune-mediated destruction of platelets and suboptimal production. **RITP** was a randomized placebo-controlled trial in which ITP patients who failed to achieve adequate response to steroids were randomized to receive rituximab or placebo plus standards of care (Ghanima *et al.* Lancet 2015; 385:1653-61). Study endpoints were treatment failure (splenectomy or meeting criteria for splenectomy), response rates and duration of response with a follow-up of 18 months. Apart from longer duration of response in the rituximab arm, the study showed no significant differences the other outcomes.
Aims: To provide long-term rates of splenectomy, death and duration of response based on extended open follow-up after completion of the RITP study.
Methods: Platelet counts, splenectomy status, ITP medication and death (after completion of RITP) were retrospectively collected. Response was defined as platelet count of ≥30X10 /L or at least a doubling of the platelet count from baseline without administration of any platelet increasing therapy except stable or decreasing doses of prednisone or prednisolone during the past 4 weeks;

or ≥100X10 /L for complete response (CR) after week 4 from first study drug administration. Relapse was defined as platelet count <30X10^9/L or reinstitution of ITP medication if this proceeded date of available platelet count. The study was approved by the ethics committees in Norway and Tunisia.
Results: Extended follow-up data were acquired from 90 of 109 patients participating in RITP. Median duration of follow-up from randomization to last observation was 72 months (IQR 62-82). Overall (double-blind and follow-up periods), 35 patients underwent splenectomy (13 in the rituximab; 22 in the placebo arm) with a no significant trend towards longer time to splenectomy in the rituximab arm (p=0.11) (Figure 1A). Eleven patients (10%) died during the extended follow-up: 5 in the rituximab and 6 in the placebo arms. Seventy-six of 109 patients achieved response (40 in the rituximab; 36 in the placebo arms) including complete response (28 in the rituximab; 21 in the placebo arms) during the RITP study. Figure 1B shows probability of first relapse in responding patients. Median duration of response, was 8.2 (5.2-16.7) after response and 17 (8-34) months after CR, in the rituximab arm, and 1.8 (1.3-3.7) and 11 (4.5- not reached) months respectively in the placebo arm. The difference in the duration of responses was not statistically significant (p=0.09). Notably, most of the relapses occurred during first 18 months after the administration of study medication. During the extended follow-up, 2 more patients in the rituximab arm relapsed after achieving response and 4 after achieving CR.

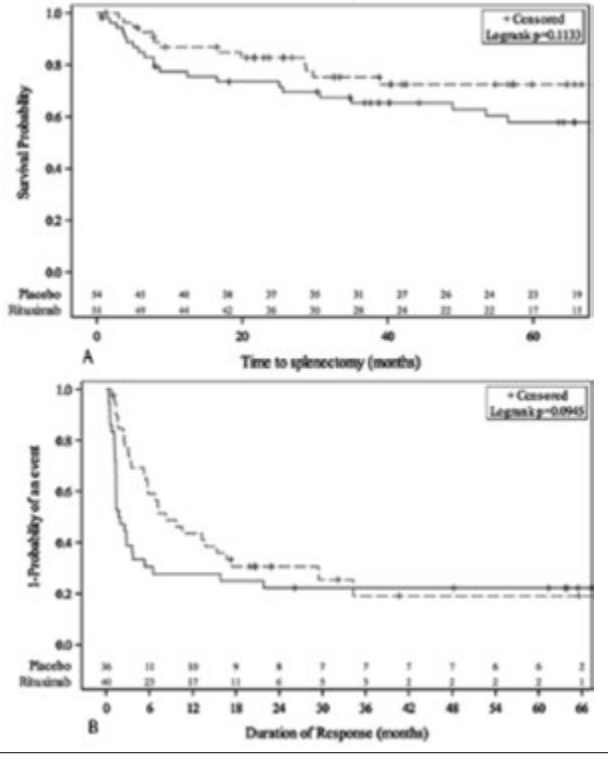

Figure 1.

Summary and Conclusions: To our knowledge, the data provided here represent the longest single study follow-up reported on the effect of rituximab in ITP. Although rituximab seemed to yield longer duration of response and CR, the effect was clearly transient and the two curves cross after 34 months. Around 20% of patients in both arms are still responders at 6 years. Interestingly a trend towards lower splenectomy rate was found in rituximab treated patients. The retrospective collection of data in the follow-up represent a limitation of the study. In the future, efforts should be made to augment the initial response to rituximab and to prolong the duration of response. Our ongoing PROLONG study will determine if the response can be prolonged by administration of maintenance therapy with rituximab.

PF663

EPIDEMIOLOGY AND MANAGEMENT OF PRIMARY IMMUNE THROMBOCYTOPENIA: REAL WORLD DATA FROM THE UK ITP REGISTRY

A. Zaidi[1,*], C. Gracie[2], U. Doobaree[2], D. Provan[2], M. Vickie[1]

[1]Haematology, Royal London Hospital, BartsHealth NHS Trust, [2]Department of Immunobiology, Queen Mary University of London, London, United Kingdom

Background: Immune thrombocytopenia (ITP) is a rare bleeding diathesis with an autoimmune background. Treatment practices vary considerably, there is a lack of epidemiological data and few large-scale randomised clinical trials to guide management.
Aims: We reviewed the UK Adult ITP registry, consisting of 89 sites across the United Kingdom who recruit cases of primary ITP, to describe real world characteristics of the population and evaluate management of ITP.
Methods: All clinical data from 2010- Jan 2018 was analysed for the diagnostic workup, bleeding symptoms, lines of treatment and clinical outcomes.
Results: 2920 patients (57% female) were entered into the registry in the time period. Median age at diagnosis was 50y (IQ range 35-66). The median platelet count at diagnosis was 19 x10^9/L (IQR 5 - 57). 66% had bleeding symptoms (18.3% - 1 episode; 14.8% - 2 episodes; 32.8% ≥3 episodes) whereas 34% (995 patient) never had any bleeding. The commonest bleeding sites were: subcutaneous/ soft tissue (58.8%), oral (13.3%), epistaxis (11.6%) and gynaecological (4.9%). Intracranial haemorrhage occurred in 0.65% (0.44% non-traumatic) and all occurred within 6 months of diagnosis.Median Hb at diagnosis was 14.6g/L (IQR 12.4-14.6) , WCC 7.2 x10^9/L (IQR 5.5-9.9), neutrophils 4.4 x10^9/L. Median PT was 11.7s (IQR 10.9- 14.5) and APTT was 28.5s (IQR 25-31.8). 1171 patient had Antinuclear antibodies (ANA) sent, of these 14.6% were positive. 270 had Direct Antiglobulin Test (DAT) testing of which 2.59% were positive. Lupus anticoagulant testing was positive in 13.8% (n=577). Insufficient data was recorded for bone marrow testing to draw conclusions. Twenty seven percent (787) never required therapy for ITP. 21.6% (631) received 1 line of therapy, 14.6% received 2 lines and and 19.9%% were treated with ≥3 lines of therapy. The most frequent treatment was steroids (65% prednisolone, 4.11% methylprednisolone and 9.25% dexamethasone) followed by IVIG (31.47%), rituximab (17.25%), MMF (11.7%), romiplostim (9.6%) and eltrombopag (5.99%). Splenectomy was performed in 9.83%.Outcomes and follow-up (6 months, 1 year, 5 years) are shown in Table 1. We compared partial response (PR, platelet count 30-100x10^9/L) and complete response (CR, platelet count >100 x10^9/L) in those who required no therapy, 1 and ≥2 lines of treatment over time.The proportion of patients in the total cohort with severe thrombocytopenia (platelet <10 x10^9/L) at 1 year was 3.1% and at 5 years, 2.7%. PR and CR rates one year from diagnosis were 44.7% and 41.9% respectively with 83.6% having a Platelet count >30 x10^9/L at 5 years. A greater percentage of patients were in PR/CR in those who were untreated *vs* those who required ≥2 lines of therapy (96% *vs* 79%). 1.37% of patients still had bleeding symptoms after 5 years.

Table 1.

Outcomes, bleeding symptoms and Platelet count at Diagnosis and up to 5 years from diagnosis for Overall cohort, Comparing untreated patients'yy those receiving1 line of therapy or 2+ lines of therapy

	Total Cohort				No Treatment				1 Line Of therapy				≥2 lines of therapy			
	Diagnosis	6 mo	1 Yr	5 Yr	Diag	6 mo	1 Yr	5 Yr	Diag	6 mo	1 Yr	5 Yr	Diag	6 mo	1 Yr	5 Yr
Median Platelet Count	19	91	82	76	68	83	79	85	16	126	106	66	11	87	78	73
% Patients with Platelets < 10 x10^9/L	37	3	3.1	2.7	11.8	0.45	0	1.8	38.5	1.2	0.6	0	48	4.5	4.9	3.4
% Patients with Platelets 11-30 x10^9/L	24	9.2	10.3	14	13.2	7.2	5.9	1.8	20.3	3.5	3.1	10	26	13.2	14	17.6
% Patients with Platelets 31-100 x10^9/L (PR)	33	43.3	44.7	44	61.3	43.9	40	41	36.8	34.1	43.6	37.5	23	40.4	40	38.2
% Patients with Platelets >100 x10^9/L (CR)	1	44.5	41.9	39	15	30.5	34	36	4.3	61.2	42.8	32.5	4.2	42.7	41	40.8
% Patients with Bleeding symptoms	29.7	4.25	3.42	1.4												
% Bleeding events requiring transfusion	11.5	1.7	0.7	0												

Summary and Conclusions: These data describe characteristics and outcome for patients with primary ITP in the UK population. Although limited by being observational and retrospective, they demonstrate that approximately 1/3 patients with primary ITP do not need treatment and currently, steroids and IVIG are the most common treatments used. Approximately 20% of patients require additional treatment beyond this including immunosuppressive therapy and thrombopoeitin agonists. Approximately 10% require splenectomy. Longer term follow up of upto 5 years from diagnosis shows more than 80% of patients will be at least PR (platelet count >30 x10^9/L) and fewer than 2% of patients will have ongoing bleeding symptoms.

Unit, University Hospital of Marseille, Marseille, [7]Pediatrics, University Hospital of Lille, Lille, [8]Pediatric Oncohematology Unit, University Hospital of Toulouse, Toulouse, [9]Pediatric Hematology Unit, University Hospital of Rennes, Rennes, [10]Pediatric OncoHematology Unit, University Hospital of Besançon, Besançon, [11]Pediatric Hematology Unit, University Hospital of Strasbourg, Strasbourg, [12]Pediatrics, University Hospital of Grenoble, Grenoble, France

Background: Chronic immunologic thrombocytopenic purpura (cITP), autoimmune hemolytic anemia (AIHA) and Evans syndrome (ES) in children are rare diseases, characterized in 20-70% of cases by recurrent outbreaks and treatment dependence. In children with cITP, as in adults, splenectomy remains one of the second-line treatments with the higher curative potential. Its role in rarest AIHA and ES is less known. The long-term risks and the potential spontaneous recovery of those diseases limit its use
Aims: The objective of this study is to identify predictive factors for successful splenectomy in the treatment of childhood autoimmune cytopenia (AIC).
Methods: In this national observational prospective cohort of children with AIC, all children who had a splenectomy before the age of 18 and followed for more than 12 months were analyzed. The failure of splenectomy was defined as the initiation of a subsequent second-line treatment. A uni and multivariate study of factors associated with failure was performed.
Results: Among the 1345 children included in the cohort, 196 were splenectomized for AIC, and 156 met the inclusion criteria: diagnosis of AIC between 1986 and 2014 ; 124 cITP (80%), 23 AIHA (15%) and 9 ES (5%). The sex ratio was 1, the median age at diagnosis was 7.6 years (0.6-17.4), the median age at splenectomy was 11 years (0.8-17.7) with a median time of 27 months (0,2-162,2) between diagnosis and splenectomy. The cytopenia was primary in 54 patients (48%) and associated with various immunological abnormalities (secondary) in 63 patients (45%). The mean number of pre-splenectomy treatments was 1 (0-11). With a median follow-up of 4.9 years (1-24) since the procedure, splenectomy was successful in 103 patients (66%), and 53% of the whole patients are in complete, sustained remission without relapses or pulses at the latest follow-up. The 53 patients (34%) in the failure group received further second-line treatments in a median delay of 1.5 years (0.01-19). Predictors of splenectomy failure in univariate analysis were the target AIHA or ES *vs* cITP (OR: 2.14, CI 95% [1.20, 3.81], p 0.01), and a context of secondary AIC (OR: 2.99, CI 95% [1.65, 5.43], p: 0.00003). In multivariate analysis, the context of secondary AIC remained significantly associated with failure (OR: 2.99, CI 95% [1.59, 5.67], p: 0.0007). During the follow-up, 19 patients (12%) had severe infections, 9 (6%) had thromboses, and 7 (4%) had died (median age 7, all had secondary cytopenia and had received multiple second lines).
Summary and Conclusions: For the first time long-term and comparative data on splenectomy for childhood AIC are provided. The benefit-risk ratio of the procedure seems lower in ES and AIHA than in cITP, in contexts where AIC are associated with other immunological abnormalities. The indication for splenectomy should be discussed on a case-by-case basis, and the best strategy to delay or avoid it, using alternative medical approaches, remains to be established.

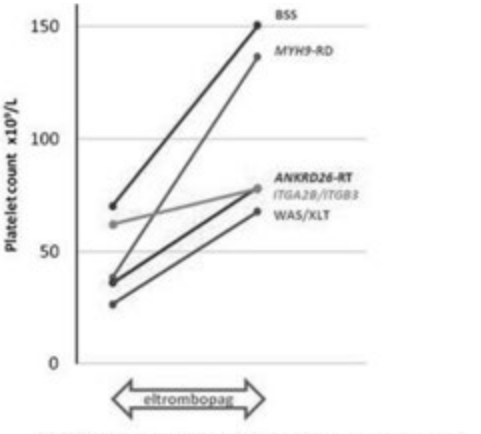
PF665

SHORT- AND LONG-TERM ELTROMBOPAG FOR THE TREATMENT OF INHERITED THROMBOCYTOPENIAS: A PHASE 2 CLINICAL TRIAL

C. Zaninetti[1,*], T. Fierro[2], A. Bertomoro[3], M.A. Alberelli[4], D. Veneri[5], V. Bozzi[1], S. Barozzi[1], P. Noris [1], F. Melazzini [1], E. De Candia[4], P. Minuz[5], F. Fabris[3], P. Gresele [2], C.L. Balduini[1], A. Pecci[1]

[1]Department of Internal Medicine, IRCCS Policlinico San Matteo Foundation, and University of Pavia, Pavia, [2]Department of Medicine, Section of Internal and Cardiovascular Medicine, University of Perugia, Perugia, [3]Department of Medicine-DIMED, University of Padova, Padova, [4]Department of Internal Medicine, Policlinico Gemelli Hospital, and Catholic University of Sacred Heart of Rome, Roma, [5]Department of Internal Medicine, University of Verona, Verona, Italy

Background: Inherited thrombocytopenias (ITs) are a group of rare disorders characterized by low platelet count (PC) and variable risk of bleeding. Until recently, platelet transfusion was the only effective measure for increasing PC. Thrombopoietin-receptor agonists represent an appealing therapeutic option to increase PC in patients with IT, but clinical data are limited.
Aims: To ascertain whether and in which forms of IT (a) short-term eltrombopag can transiently increase PC and reduce bleeding tendency, and (b) long-term eltrombopag can stably reduce bleeding symptoms in patients with clinically relevant spontaneous hemorrhages.
Methods: Patients initially received eltrombopag 50 mg/day for 3 weeks. Then, treatment was stopped in subjects who obtained a PC ≥100 x10^9/L, or continued at 75 mg/day for 3 further weeks (Phase 1). Major response was defined by the achievement of PC ≥100 x10^9/L with no bleeding tendency, minor response by the achievement of PC at least two times higher than the baseline value and reduction of bleeding tendency. Patients with clinically relevant bleeding symptoms at baseline (score ≥2 of the WHO bleeding scale), who completed the Phase 1 without side effects obtaining reduction of bleeding, entered the 16-week-long Phase 2. They initially received eltrombopag 25 mg/day and were re-evaluated for dose adjustments every 4 weeks. Major and minor responses were defined by a complete or a partial remission of bleeding, respectively (NCT02422394). All patients provided written informed consent for the study.
Results: We enrolled 24 patients (mean age 41 years, 58% males) affected with 5 forms of IT: *MYH9*-related disease (*MYH9*-RD, n=9), *ANKRD26*-related thrombocytopenia (*ANKRD26*-RT, n=9), X-linked thrombocytopenia/Wiskott-Aldrich syndrome (XLT/WAS, n=3), monoallelic Bernard-Soulier Syndrome (mBSS, n=2), and *ITGA2B*/*ITGB3*-related thrombocytopenia (*ITGA2B/ITGB3*-RT, n=1). Mean PC at baseline was 40 x10^9/L. All patients entered the Phase 1 and 23 of them completed the treatment. Eleven subjects (48%) obtained a major response, 10 (43%) a minor response, and 2 (9%) did not respond. The mean PC at the end of Phase 1 was 105 x10^9/L; the mean increase of PC with respect to baseline in responders was 70 x10^9/L. Among the 12 patients with spontaneous bleeding at baseline, 10 (83%) obtained complete remission of hemorrhages, 1 (8.5%) obtained reduction, and 1 (8.5%) did not obtain improvement. Four patients entered the Phase 2 (*MYH9*-RD, n=2; WAS, n=1; *ITGA2B/ITGB3*-RT, n=1) and 3 completed the treatment plan. All of them obtained a minor response associated with a stable increase of PC throughout the treatment period. Response to eltrombopag was associated with a stable improvement of quality of life in all the 3 cases. No major adverse events were recorded during the Phase 1 of the study. In one patient with WAS, treatment was discontinued during the Phase 2 because of exacerbation of a pre-existing cutaneous eczema; no other relevant adverse events were recorded during the Phase 2 (Figure 1).



Mean increase of platelet count obtained during the Phase 1 of the trial according to the different forms of IT.

Figure 1.

Summary and Conclusions: Short-term eltrombopag is safe and effective in transiently increasing PC in patients with *MYH9*-RD, *ANKRD26*-RT, XLT/WAS, and mBSS. Although the extent of platelet response was different between the different disorders, eltrombopag is expected to avoid or strongly limit the use of platelet transfusions in preparation for most surgical procedures in all these ITs. Long-term eltrombopag was safe and effective in reducing bleeding symptoms and improving quality of life in patients with *MYH9*-RD, WAS and *ITGA2B/ITGB3*-RT.

PF666

PHASE II, MULTIPLE-DOSE STUDY OF ANTI-FCRN ANTIBODY, ROZANOLIXIZUMAB (UCB7665), IN PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA: SECOND INTERIM ANALYSIS

T. Robak[1,*], I. Jarque[2], V. Musteata[3], P. Kiessling[4], U. Massow[4], J. Higginson[5], R. Snipes[6], S. Jolles[7]

[1]Medical University of Lodz, Lodz, Poland, [2]Hospital Universitario y Politécnico La Fe, Valencia, Spain, [3]Institute of Oncology, Chisinau, Moldova, Republic of, [4]UCB Pharma, Monheim, Germany, [5]UCB Pharma, Slough, United Kingdom, [6]UCB Pharma, Raleigh, United States, [7]University Hospital of Wales, Cardiff, United Kingdom

Background: Rozanolixizumab is a humanised, high-affinity, anti-human neonatal Fc receptor (FcRn) monoclonal antibody, developed with the aim

of reducing levels of pathogenic immunoglobulin G (IgG) in autoimmune and alloimmune diseases.

Aims: Report the safety, tolerability and efficacy from an ongoing Phase II, open-label study of rozanolixizumab in patients (pts) with primary immune thrombocytopenia (ITP) (NCT02718716). Interim analysis (8th Data Monitoring Committee review) data cut-off: 27 November 2017.

Methods: Eligibility criteria included: ≥18 years (y) of age; diagnosis of primary ITP for ≥3 months prior to screening; platelet count <30x10^9/L at screening and <35x10^9/L at baseline; current, or history of, peripheral blood smear consistent with ITP. Eligible pts received rozanolixizumab SC at 5x4 mg/kg or 3x7 mg/kg, weekly; the higher dose group was enrolled after review of pt safety data in the lower dose group.

Results: A total of 30 pts received rozanolixizumab: 4 mg/kg (n=15), 7 mg/kg (n=15). Median age was 55 y (range 20–86); 4 mg/kg, 66 y (21–86) and 7 mg/kg, 54 y (20–73). Median duration of disease at baseline was 6.5 y (range 0.3–36); 4 mg/kg, 7.1 y (1.7–29) and 7 mg/kg, 5.2 y (0.3–36). Of 27 pts who received prior ITP therapies, median number of therapies received was 4 (range 1–15); 4 mg/kg, 4 (1–15) and 7 mg/kg, 2 (1–12). Most common prior therapies: azathioprine (11/30 [37%] pts; 4 mg/kg, 40%; 7 mg/kg, 33%, romiplostim (10/30 [33%] pts; 4 mg/kg, 40%; 7 mg/kg, 27%), immunoglobulins (9/30 [30%] pts; 4 mg/kg, 27%; 7 mg/kg, 33%).

Overall, 21/30 (70%) pts reported ≥1 TEAE (66 TEAEs combined total): 12/15 (80%) pts in the 4 mg/kg group and 9/15 (60%) pts in the 7 mg/kg group. There was one serious TEAE (bleeding from genital tract, also classified as severe in intensity [CTCAE ≥Grade 3]) in the 4 mg/kg group, deemed unrelated to study medication by the investigator; all other TEAEs reported were mild/moderate (Grade 1/2). Two pts reported TEAEs (Grade 1) deemed related to study medication by the investigator: injection site reaction (4 mg/kg group) and headache (7 mg/kg group); the TEAEs did not interfere with subsequent dosing. The most frequently reported TEAE was headache (Grade 1): 3/15 (20%) pts in the 4 mg/kg group and 6/15 (40%) pts in the 7 mg/kg group (Table 1). No clinically relevant changes were observed in all other haematology, coagulation, clinical chemistry (including albumin), urinalysis, ECGs, vital signs or liver function tests. Changes were observed in total protein, as expected. No deaths or treatment discontinuations due to TEAEs were reported. At the interim analysis, maximum mean decreases in total IgG concentration were observed at Day 29 for rozanolixizumab 4 mg/kg (mean decrease from baseline 43.6%, range 21.9–68.6) and at Day 22 for rozanolixizumab 7 mg/kg (49.9%, 29.5–65.5). Clinically relevant improvements in platelet counts (count ≥50x10^9/L) were reported for 5/15 pts (33.3%) in the 4 mg/kg group (overall maximum value range: 52x10^9–198x10^9/L) and 5/15 pts (33.3%) in the 7 mg/kg group (52x10^9–133x10^9/L).

Table 1.

TEAEs occurring in >2 patients in total by preferred term

MedDRA (v20.0) Preferred term	Rozanolixizumab SC 5x4 mg/kg N=15 n (%)	Rozanolixizumab SC 3x7 mg/kg N=15 n (%)	All patients N=30 n (%)
Headache	3 (20)	6 (40)	9 (30)
Diarrhoea	1 (7)	2 (13)	3 (10)
Influenza-like illness	2 (13)	1 (7)	3 (10)

CTCAE, Common Terminology Criteria for Adverse Events; MedDRA, Medical Dictionary for Regulatory Activities; n, number of patients reporting at least 1 TEAE at the time of interim analysis; SC, subcutaneously; TEAE, treatment-emergent adverse event

Summary and Conclusions: From data available to date, multiple dosing with rozanolixizumab SC 4 mg/kg and 7 mg/kg has been well tolerated in pts with ITP, and initial platelet responses have been observed in both dose groups. The safety profile for rozanolixizumab SC reported in this trial is in line with the safety profile reported in the first in human trial (NCT02220153) with healthy participants receiving rozanolixizumab SC.[1]

PF667

SWI IDENTIFIES BRAIN MICROHAEMORRHAGES IN ASYMPTOMATIC PATIENTS WITH IMMUNE THROMBOCYTOPENIA (ITP)

C. Vladescu[1], G. Adams[12,*], M. Morrison[34], D. Paul[1], T. Young[1], M. Atta[1], A. Luqmani[1], A. Waldman[45], N. Cooper[12]

[1]Department of Haematology, Hammersmith Hospital, [2]Department of Medicine, Imperial College, London, United Kingdom, [3]Department of Radiology and Biomedical Imaging, UCSF, San Francisco, United States, [4]Division of Brain Sciences, Imperial College, London, [5]Centre for Clinical Brain Sciences, University of Edinburgh, Edinburgh, United Kingdom

Background: Immune thrombocytopenia (ITP) is an autoimmune disease characterised by a platelet count <100 x 10^9/L. Treatment is aimed at stopping bleeding and avoiding serious bleeding; options include steroids, immune-modulating drugs, thrombopoietin receptor agonists and splenectomy. Despite low platelet counts, many patients remain asymptomatic and morbidity and mortality is frequently from toxicities of treatment. There is therefore a trend to reduce the platelet target for treatment. Currently, there is no identifiable platelet count below which serious bleeds are known to occur, nor any method in place to assess whether patients develop internal bleeding at low platelet counts. Susceptibility-weighted imaging (SWI) is an MRI technique that exploits phase shifts due to magnetic susceptibility perturbation to generate tissue contrast; it is exquisitely sensitive to the presence of blood products, and is increasingly used in clinical practice to identify very small bleeds in the brain (microbleeds).

Aims: We propose the use of SWI to stratify ITP patients at risk of asymptomatic brain haemorrhage.

Methods: 44 adult ITP patients (median age=37.95, range=18 to 87) with at least one platelet count <30x10^9/L were recruited to a prospective MR study between 2014 and 2018 at the Hammersmith Hospital. No patient had neurological deficit at the time of neuroimaging. A dedicated MRI protocol including SWI was acquired at 3T (Siemens Verio, Erlangen, De; VB19). Microbleeds were detected with the aid of a semi-automated intensity-based detection algorithm and verified by an experienced neuroradiologist blinded to clinical details. Platelet count, bleeding scores, age of patient, duration of disease and treatment history was compared between patients with and without detectable microhaemorrhage.

Results: Intraparenchymal microhaemorrhages (of less than 3 mm diameter) were identified in 19 of 44 patients (43%) by semi-automated algorithm and 11 by visual inspection only. The majority had less than 5 microbleeds. These can occur in normal individuals with advancing age. Only 4 patients (9%) had greater than 5 microbleeds. Three of these patients had multi-refractory disease, two with disease of greater than 21 years. One patient had a head injury at a platelet count of 1 sustaining frontal bleeds. The fourth patient had not been treated for 10 years following diagnosis as a child. None had apparent neurological deficits. Bleeds were more likely in patients with lower platelet counts in an univariate model (p value 0.0094) as well as in logistic multivariate regression model (p value 0.046) when adjusted for age, gender and bleeding scores. Notably, severe thrombocytopenia was not always associated with microbleeds; 15 of 31 patients with counts less than 10 x 10^9/L did not have detectable microbleeds (Figure 1).

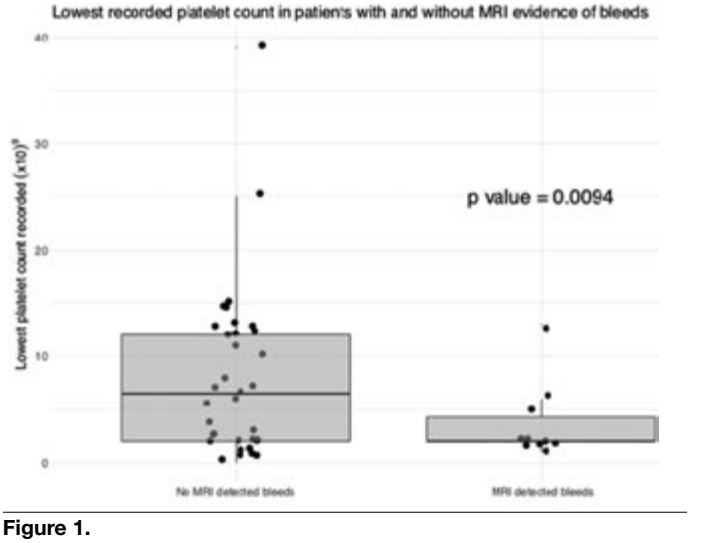

Figure 1.

Summary and Conclusions: ITP is associated with cerebral microhaemorrhage, which appears related to lower platelet count and refractory disease. There was no correlation with bleeding symptoms, although this requires further evaluation. The results of this preliminary study have potentially important implications for risk stratification and management of patients with ITP. They also provide proof of principle for using MRI to identify risk factors and functional consequences of haemorrhage in ITP and other thrombocytopenic disorders.

DEFINING TREATMENT SUCCESS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA RECEIVING THROMBOPOIETIN RECEPTOR AGONIST THERAPY: RESULTS FROM A MODIFIED DELPHI CONSENSUS PANEL

C.A. Bradbury[1,*], D. Provan[2], N. Cooper[3], J. Grainger[4], Q. Hill[5], J. Thachil[6], J.-P. Westwood[7], N. Ramscar[8], A. Roy[9]

[1]University of Bristol, Bristol, [2]Barts and the London School of Medicine, [3]Hammersmith Hospital, London, [4]Royal Manchester Children's Hospital, Manchester, [5]The Leeds Teaching Hospital, Leeds, [6]Central Manchester University Hospital, Manchester, [7]University College Hospital London, [8]Novartis UK, London, United Kingdom, [9]Novartis Pharmaceuticals, East Hanover, United States

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder causing reduced platelet counts <100,000/μL, with a range of potential bleeding consequences. Major bleeding episodes are less common when platelet counts are >30,000/μL, and treatment is generally reserved for patients with platelet counts <30,000/μL, bleeding, or a high risk of bleeding such as those undergoing surgery. Experimental and observational studies have suggested that thrombopoietin receptor agonist (TPO-RA) therapy may be tapered with the intent of discontinuation in patients with adequate response to treatment; however, there are no specific criteria for identifying treatment success, remission, and appropriate tapering strategies.
Aims: To gain consensus on parameters for defining sufficient TPO-RA treatment success in patients with ITP such that a tapering and discontinuation approach may be considered.
Methods: A consensus meeting using the modified Delphi method was held among UK ITP experts. Experts participated in a structured technology-based platform that captured individual uninfluenced opinion, followed by a panel debate and discussion in which consensus was sought. Expert panel participants responded to questionnaires in advance of the consensus meeting. Questionnaire topics focused on the appropriateness of the TPO-RA tapering and discontinuation approach; identifying suitable patients; outcomes to be expected from discontinuation; duration of remission; and evidence needed to further clarify treatment approaches and recommendations.
Results: Seven ITP experts participated in the June 2017 consensus meeting. Expert questionnaire responses indicated a high level of agreement that tapering of TPO-RA can be a rational approach to treatment and that in some patients who are deemed clinically improved and feel well, discontinuation of treatment is warranted. Experts agreed that a tapering approach may be considered after 6 months for patients with an adequate treatment response who are less likely to encounter a high-risk bleeding scenario, and after at least 12 months for those with a less clear treatment response who may need more time and continued monitoring. Regarding the definition of adequate treatment response, experts agreed that at a minimum, patients should have a stable platelet count of >50,000/μL without bleeding problems in the last 6 months. Similarly, experts agreed that tapering and discontinuation should not be continued if the platelet count fell below 30,000/μL or if patients experienced persistently worse quality of life due to anxiety, fatigue, or other humanistic factors. It was agreed that at present there are no clear predictive factors to identify those patients suitable for tapering. Also, consensus was reached on the need for prospective research based on clear eligibility criteria and tapering protocols.
Summary and Conclusions: This modified Delphi panel gained consensus on the potential merit of tapering and discontinuing TPO-RA therapy in patients with ITP. Platelet counts should remain consistently >50,000/μL without hospital encounters for at least 6–12 months depending on the patient. There is an important need for adequate new evidence regarding TPO-RA tapering and discontinuation.

PF669

MYH9-RELATED THROMBOCYTOPENIA: FOUR NOVEL VARIANTS AFFECTING THE TAIL DOMAIN OF THE NON-MUSCLE MYOSIN HEAVY CHAIN IIA ASSOCIATE WITH A MILD CLINICAL EVOLUTION OF THE DISEASE

C. Zaninetti[1,*], D. De Rocco[2], T. Giangregorio[3], V. Bozzi[1], J. Demeter[4], P. Leoni[5], P. Noris[1], S. Ryhänen[6], S. Barozzi[1], A. Savoia[7], A. Pecci[1]

[1]Department of Internal Medicine, IRCCS Policlinico San Matteo Foundation, and University of Pavia, Pavia, [2]Department of Medical Sciences, University of Trieste, [3]Institute for Maternal and Child Health, IRCCS Burlo Garofolo, Trieste, Italy, [4]First Department of Internal Medicine, Division of Hematology, Semmelweis University, Budapest, Hungary, [5]Hematology Clinic, Department of Clinical and Molecular Sciences, Università Politecnica delle Marche, Ancona, Italy, [6]University Central Hospital, University of Helsinki, Helsinki, Finland, [7]Department of Medical Sciences, Institute for Maternal and Child Health, IRCCS Burlo Garofolo, and University of Trieste, Trieste, Italy

Background: MYH9-related disease (MYH9-RD) is an autosomal-dominant syndromic thrombocytopenia caused by mutations in MYH9, the gene encoding the heavy chain of non-muscle myosin IIA (NMMHC-IIA). Patients present congenital thrombocytopenia, giant platelets, and inclusions of NMMHC-IIA in leukocytes, and have a variable risk of developing one or more non-congenital manifestations, namely proteinuric nephropathy often evolving to end-stage kidney failure, sensorineural deafness, presenile cataracts, and/or abnormalities of liver enzymes. NMMHC-IIA comprises two domains: the N-terminal globular head domain (HD), which binds actin and hydrolyzes ATP generating mechanical force, and the C-terminal tail domain (TD) mainly involved in the assembly of the myosin molecule. The TD is composed of a long coiled-coil region and a short non-helical tailpiece. The incidence and the severity of the non-congenital manifestations of MYH9-RD are predicted by the causative MYH9 mutation. Globally, variants affecting the HD of NMMHC-IIA correlate with a more severe clinical picture than those involving the TD. Moreover, recent studies demonstrated that different alterations of the TD associate with remarkably different disease evolution.
Aims: To enlarge the spectrum of mutations responsible for MYH9-RD and assess the prognostic significance of novel causative variants.
Methods: Nine subjects belonging to 4 Caucasian pedigrees, referred to our Institution because of chronic thrombocytopenia, were included in the study. All patients provided written informed consent. Diagnosis of MYH9-RD was confirmed in all the cases by the identification of NMMHC-IIA leukocyte inclusions through immunofluorescence analysis of blood smears. MYH9 variants identified in probands were tested in all the available relatives. Non-congenital features of the disorder were searched in all patients independently of the presence of a symptomatic disease.
Results: We identified a novel MYH9 mutation in each family. Two variants (c.3486G>C and c.4261G>A) lead to aminoacid substitutions in the coiled-coil region of the TD of NMMHC-IIA (p.Arg1162Ser and p.Glu1421Lys, respectively). The other two mutations are a splicing variant (c.5765+2T>G) and a single nucleotide deletion (c.5806del) both resulting in frameshift alterations of the non-helical tailpiece (p.Arg1922Argfs*43, and p.Arg1936Glyfs*12, respectively). The variants segregate with the phenotype within the respective families and are not reported in public databases. Bioinformatic prediction tools suggest that both missense mutations are likely to be pathogenic. Overall, patients have moderate thrombocytopenia with mild or absent bleeding symptoms. In 5 out of 9 subjects, audiometric examination disclosed a moderate, bilateral and symmetric hearing defect involving the middle and high tones. In 4 of such cases, the age at onset of deafness was above 40 years. Only one patient presents kidney damage at the stage of proteinuric nephropathy not associated with renal failure. Cataract was detected in only one case as well.
Summary and Conclusions: We report 4 novel variants affecting the TD of NMMHC-IIA and responsible for MYH9-RD in 4 families. Characterization of phenotypes of affected individuals showed that all of these mutations are associated with a mild clinical evolution of the disease.

PF670

REAL-WORLD TAPERING AND DISCONTINUATION OF THROMBOPOIETIN RECEPTOR AGONIST THERAPY IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA: A SURVEY OF HEMATOLOGISTS IN THE UNITED KINGDOM

N. Cooper[1,*], Q. Hill[2], J. Grainger[3], J.-P. Westwood[4], C. Bradbury[5], D. Provan[6], J. Thachil[7], N. Ramscar[8], A. Roy[9]

[1]Hammersmith Hospital, London, [2]The Leeds Teaching Hospital, Leeds, [3]Royal Manchester Children's Hospital, Manchester, [4]University College London Hospital, London, [5]University of Bristol, Bristol, [6]Barts and the London School of Medicine, London, [7]Central Manchester University Hospital, Manchester, [8]Novartis UK, London, United Kingdom, [9]Novartis Pharmaceuticals, East Hanover, United States

Background: Treatment of immune thrombocytopenia (ITP) with a thrombopoietin receptor agonist (TPO-RA) may improve platelet count, preventing major bleeding episodes and improving quality of life in 80–90% of patients. Many patients require continuous TPO-RA therapy in order to maintain adequate platelet levels. However, recent evidence suggests that some patients may have a durable remission of disease even after discontinuation of TPO-RA therapy. Observational and case studies of TPO-RA tapering and discontinuation have presented a range of practices and patient responses across many different countries and settings.

Aims: To better understand TPO-RA tapering practices and experience among UK practitioners treating patients with ITP.
Methods: Hematologists or hematologist/oncologists practicing in the UK were recruited using a panel methodology and invited to participate in a short survey regarding appropriateness of and experience with tapering and discontinuation of TPO-RAs in patients with ITP. A total of 495 physicians were approached, with a top threshold target of 60 survey completers, based on feasibility and time period (1 week) for response. The survey requested information related to how the practitioners determine appropriateness of a tapering strategy; how many of their patients have undergone a tapering strategy; and the reasons and modalities of treatment reinitiation after TPO-RA discontinuation based on their most recent 3 cases. Responses were collected and descriptive assessments conducted.
Results: Forty-nine hematologists (9.8%) completed the survey, having been in practice for an average of 12 years and managing an average of 47 patients with ITP over the past 6 months. Respondents were most often based in academic/teaching hospitals (84%) and reported spending most of their time (86%) in direct patient care. TPO-RA tapering and discontinuation practices were considered to be appropriate in 30–34% of patients with ITP overall. Less than half of practitioners applied these practices in patients determined to be well-controlled and appropriate candidates for TPO-RA tapering and discontinuation (35% for eltrombopag, 47% for romiplostim). Stable platelet count was the most common reason for tapering and discontinuing treatment (58–76%), followed by a lack of or reduced risk of bleeding (17–24%). Overall, 29–35% of patients reinitiated treatment after an average of 86–106 days in treatment-free remission. The biggest driver of the decision to reinitiate treatment was platelet count (100%), followed by clinical symptoms (67–75%). Patients who reinitiated treatment did so with TPO-RAs (85%), other pharmacological treatment (11%), surgery (6%), and/or another nonpharmacological treatment (2%).
Summary and Conclusions: Survey respondents discontinued TPO-RA therapy in approximately one-third of patients with ITP; patients had to have well-controlled ITP to be suitable candidates for this strategy. Respondents relied on both laboratory values and clinical symptoms when determining patient suitability for discontinuation and reinitiation of treatment. The majority of patients who discontinued did not require further treatment. Approximately one-third of patients reinitiated therapy, most frequently with TPO-RAs. Tapering and discontinuation practices among a sample of UK hematologists suggested a willingness to try in patients considered appropriate by the clinician. Larger observational studies are needed to better understand how this strategy is considered and applied in real-world clinical practice.

PF671

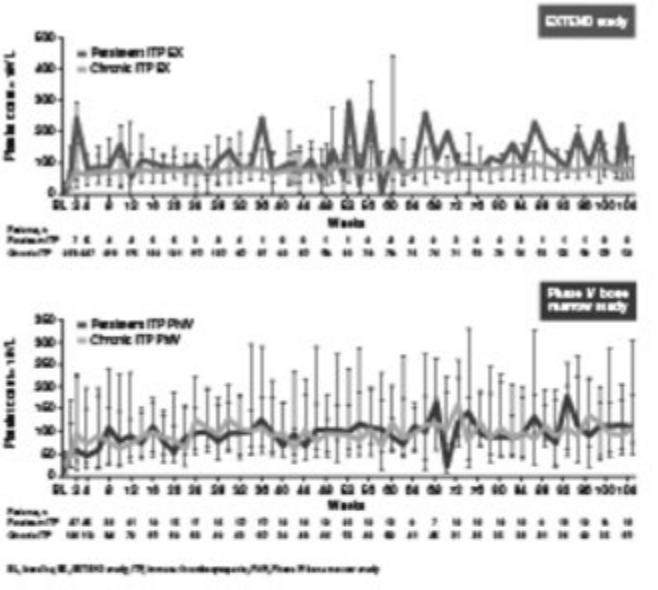
ELTROMBOPAG TREATMENT IN PATIENTS WITH PERSISTENT *VERSUS* CHRONIC IMMUNE THROMBOCYTOPENIA: COMPARISON OF EFFICACY AND SAFETY RESULTS FROM THE PHASE III EXTEND STUDY AND A PHASE IV STUDY

R.S. Wong[1,*], O. Meyer[2], T. Shamsi[3], R.K. Brynes[4], M.N. Saleh[5], A. Khelif[6], A. Orazi[7], Z. Aziz[8], A. Melikyan[9], O. Ocak Arikan[10], J. Maier[10], J.B. Bussel[11]

[1]Sir YK Pao Centre for Cancer & Department of Medicine and Therapeutics, Chinese University of Hong Kong, Shatin, NT, Hong Kong, [2]Institute of Transfusion Medicine, Charité-Universitätsmedizin Berlin, Berlin, Germany, [3]Research Department, National Institute of Blood Disease and Bone Marrow Transplantation, Karachi, Pakistan, [4]Department of Pathology, Keck School of Medicine, University of Southern California, Los Angeles, CA, [5]Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, United States, [6]Hôpital Farhat Hached, Sousse, Tunisia, [7]Department of Pathology, Weill Cornell Medical College, New York, United States, [8]Clinical Oncology, Hameed Latif Hospital, Lahore, Pakistan, [9]National Research Center for Hematology, Moscow, Russian Federation, [10]Novartis Pharma AG, Basel, Switzerland, [11]Pediatric Hematology/Oncology, Weill Cornell Medicine, New York, United States

Background: Primary immune thrombocytopenia (ITP), an acquired autoimmune-mediated disorder characterized by isolated thrombocytopenia, is classified as persistent between 3 and 12 months from diagnosis (perITP), and chronic (cITP) if ongoing for more than 12 months. Eltrombopag (EPAG) is an oral thrombopoietin receptor agonist approved for previously treated cITP patients ≥1 year old. To compare EPAG in perITP *vs* cITP, subanalyses were performed of EXTEND, a Phase III, open-label, extension study of long-term efficacy and safety of EPAG in adults with ITP ≥6 months who had participated in prior EPAG studies (Wong *et al. Blood* 2017;130:2527–2536), and a 2-year Phase IV, open-label, bone marrow safety study of EPAG in adults with ITP ≥6 months (Brynes *et al. Acta Haematol* 2017;137:66–72; Wong *et al. Blood* 2017;130:abst 3628).
Aims: Describe effects of EPAG on platelet counts and long-term safety in subsets of patients with perITP (ITP ≥6 months) or cITP (ITP ≥12 months).
Methods: Patients on EXTEND and the Phase IV study started EPAG at 50 mg/day, titrated to 25–75 mg/day or less often as required, based on a platelet count target range ≥50–200x10^9/L.
Results: In EXTEND, 7/265 (3%) patients had perITP and 258 (97%) patients had cITP at baseline. Median (range) treatment duration was 2.3 years (56 days–3.7 years) and 2.5 years (10 days–8.8 years); mean (range) daily dose was 32.0 (7–74) mg/day and 50.4 (1–75) mg/day. In the Phase IV study, 37/161 (23%) had perITP and 124 (77%) had cITP at baseline. Median (range) treatment duration was 2.0 years (31 days–2.1 years) and 2.0 years (21 days–2.2 years); mean (range) daily dose was 48.8 (11–75) mg/day and 48.8 (5–75) mg/day. Median platelet counts in all subsets of both studies increased to ≥50x10^9/L within 2 weeks (Figure 1A). In EXTEND, 6/7 (86%) perITP and 230/258 (89%) cITP patients achieved a platelet count ≥50x10^9/L without rescue therapy. In the Phase IV study, platelet counts ≥50x10^9/L were achieved by 31/37 (84%) perITP and 109/124 (88%) cITP patients, without rescue therapy. During EXTEND, 5/7 (71%) and 148/258 (57%) patients maintained platelets continuously ≥50x10^9/L for ≥28 weeks whilst on treatment; in the Phase IV study, this was achieved by 19/37 (51%) and 62/124 (50%) patients. During EXTEND, serious AEs occurred in 1/7 (14%) perITP patient and 86/258 (33%) cITP patients (Figure 1B). During the Phase IV study, serious AEs occurred in 12/37 (32%) perITP and in 29/124 (23%) cITP patients (Figure 1B).

A. Median platelet count over time to week 104 in persistent ITP and chronic ITP patients during EXTEND and Phase IV studies



B. Most frequently occurring adverse events (≥15% in any group) and serious adverse events (≥5% in any group), regardless of relationship to study drug during EXTEND and Phase IV studies

	EXTEND		Phase IV study

Nausea	–	–	2 (5)	–
Fatigue	–	–	2 (5)	–
Deaths (on treatment, +1 day), n (%)				
Any event	–	1 (<1)	–	3 (2)
Adenocarcinoma	–	1 (<1)	–	–
Cerebral hemorrhage	–	–	–	2 (2)
Acute respiratory distress syndrome	–	–	–	1 (1)

Figure 1.

Summary and Conclusions: In both studies, the overall effects of EPAG on platelet counts were similar in perITP and cITP patients; the rate of AEs and serious AEs were as expected for eltrombopag treatment in ITP. However, results should be interpreted with caution because of the relatively small number of perITP patients (only a total of 44 between both studies). Nonetheless, our study indicates that EPAG has the potential to be an effective treatment option for patients with perITP. Further investigation of outcomes in perITP patients would be of interest, with larger patient numbers, to confirm responses and advance our understanding of this patient population. Although not a focus of these analyses, moving forward it would also be of interest to explore outcomes in perITP patients with a 3–<6 month duration of ITP.

PF672

PERFORMANCE OF THE ISTH BLEEDING ASSESSMENT TOOL IN PREDICTING THE PRESENCE OF INHERITED PLATELET FUNCTION DISORDERS

M. Blaauwgeers[1,*], I. van Asten[2], A. Huisman[2], S. Korporaal[2], M. Coppens[3], M. Kruip[4], E. Beckers[5], J. Eikenboom[6], R. Tamminga[7], R. Urbanus[2], R. Schutgens[1]

[1]Van Creveldkliniek, [2]Clinical Chemistry and Hematology, UMC Utrecht, Utrecht, [3]AMC, Amsterdam, [4]Erasmus MC, Rotterdam, [5]Maastricht UMC, Maastricht, [6]LUMC, Leiden, [7]UMCG, Groningen, Netherlands

Background: The ISTH bleeding assessment tool (ISTH-BAT) was developed to standardize the documentation of bleeding symptoms, to guide further laboratory investigation and to help diagnose patients with possible bleeding disorders. Previous studies have shown that the BAT score was low in healthy volunteers and elevated in participants with clinical evidence of a bleeding disorder, but very few studies have assessed the clinical utility of the ISTH-BAT in predicting the presence of a platelet defect in patients with an increased bleeding tendency.
Aims: To evaluate the performance of the ISTH-BAT bleeding score (BS) in predicting the presence of platelet defects in patients with an increased bleeding tendency and (suspected) inherited platelet function disorders (PFDs).
Methods: Adult patients with an increased bleeding tendency, suspected for having a PFD, were included in a nationwide cross-sectional study on PFDs ('Thrombocytopathy in the Netherlands'). All participants gave written informed consent. The ISTH-BAT was administered by a physician prior to platelet function testing consisting of light transmission aggregometry (LTA), platelet nucleotide content analysis and flow cytometry. In addition, genetic analysis was performed on a 89-gene NGS platform.
Results: A total of 165 patients were enrolled in the study, of whom 135 were female (82%). Ninety-eight patients (59%) had an objective platelet defect based on abnormal results on LTA, platelet nucleotide content, flow cytometry and/or genetic analysis.The ISTH-BAT score was not significantly different between patients with an objective platelet function defect (median 10; interquartile range 7-15) and those with normal results (median 10; interquartile range 8-13) (p=0.78). The score was alsno not significantly different between men (median 9; interquartile range 5-13) and women (median 10; interquartile range 7-14) (p=0.07). The ISTH-BAT score could not discriminate between patients with and without a platelet function defect based on platelet function testing (area under the ROC curve=0.487 [95% CI 0.399-0.575]).
Summary and Conclusions: Although the ISTH-BAT is a useful tool for systematically documenting bleeding symptoms in patients with excessive bleeding, the BS obtained from the ISTH-BAT is unable to predict the presence of a platelet defect in patients with (suspected) platelet function disorders.

PF673

SPLENECTOMY IN COMPARISON WITH RITUXIMAB AS A SECOND LINE TREATMENT FOR RELAPSED OR REFRACTORY ITP

A. Boban[1,*], M. Morić-Perić[2], S. Zupančić-Šalek[3], D. Pulanić[3], S. Bašić-Kinda[4], M. Vodanović[4], I. Radman[4], R. Serventi-Seiwerth[4], N. Duraković[1], I. Zekanović[2], K. Benček[5], I. Aurer[1]

[1]Division of Haematology, Department of Internal Medicine, University Hospital Center Zagreb, School of Medicine University of Zagreb, Zagreb, [2]Haematology Unit, Department of Internal Medicine, Zadar General Hospital, Zadar, [3]Division of Haematology, Department of Internal Medicine, University Hospital Center Zagreb, School of Medicine University of Zagreb, School of Medicine Josip Juraj Strossmayer University of Osijek, [4]Division of Haematology, Department of Internal Medicine, University Hospital Centre Zagreb, [5]Division of Haematology, Department of Internal Medicine, School of Medicine University of Zagreb, Zagreb, Croatia

Background: Splenectomy has been used for the treatment of immune thromboctopenia (ITP) for more than a hundred years. However, the position of splenectomy in treating ITP has been questioned in the era of the new second line therapies, namely rituximab, anti-CD20 monoclonal antibody, and recently introduced thrombopoietin-receptor agonists.
Aims: The aim of this single-centre retrospective study was to re-evaluate the role of splenectomy as the second-line therapy for ITP.
Methods: We have retrospectively analysed efficacy and safety of splenectomy and rituximab used as the second line treatment of patients with relapsed/refractory ITP from our centre treated between 2000 and 2018. Patients with secondary ITP were excluded from the analysis.
Results: During the evaluation period, 48 patients with relapsed, refractory or corticosteroid dependent ITP received rituximab or had splenectomy as a second-line treatment. Twenty-four patients (50%) had splenectomy (19 female (79%), median age 38 (6-71) years) and 24 patients (50%) were treated with rituximab (12 female (50%), median age 30 (7-68) years). Median time from diagnosis of ITP and splenectomy was 2 (1-12) years and 1.5 (0.25-24) years for rituximab. Median follow-up period for splenectomy was 4 (0.5-16) years and 2 (0.3-10) years for rituximab.
Following splenectomy, eighteen patients (75%) achieved remission, while 12 patients (50%) achieved remission after rituximab. Relapse was observed in one patient 15 years after splenectomy, and in three patients following rituximab treatment, 12, 17 and 36 months later. Regarding side effects, one patient developed deep venous thrombosis related to splenectomy, whereas two patients had severe CMV infections after rituximab treatment.
Summary and Conclusions: The obtained results confirm that splenectomy is very efficient as a second line treatment of relapsed, refractory or corticosteroid-dependent ITP. Splenectomy is even demonstrating superiority in efficacy when compared with rituximab treatment in this indication. Complications following splenectomy and the rate of relapse were lower than among patients receiving rituximab. However, as splenectomy is an invasive procedure, further analysis is needed to identify a subset of patients that would have the most benefit from it.

PF674

IMMUNE THROMBOCYTOPENIA PURPURA (ITP) PATIENT JOURNEY – ROUTINE CLINICAL CARE FOR CHRONIC ITP IN DENMARK, 2009-2015

A. Ording[1], N. Kristensen[1], H. Frederiksen[2,*], M. Nørgaard[1], N. Alam[3], S. Bahmanyar[4], W. Ghanima[56], H. Toft Sørensen[1], C.F. Christiansen[1]

[1]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, [2]Department of Haematology, Odense University Hospital, Odense, Denmark, [3]Centre for Observational Research, Amgen Ltd., Uxbridge, United Kingdom, [4]Clinical Epidemiology Unit & Center for Pharmacoepidemiology, Karolinska Institutet, Stockholm, Sweden, [5]Department of Hematology, Institute of Clinical Medicine, University of Oslo, Oslo, [6]Department of Research, Østfold hospital, Sarpsborg, Norway

Background: Immune thrombocytopenia (ITP) is an autoimmune disease characterized by decreased production and increased peripheral destruction of platelets. Treatment is recommended for patients with persistent/recurrent bleeding and/or platelet count <30 x10^9/L.
Aims: We aimed to examine the clinical characteristics of routine clinical treatment of patients with chronic ITP (cITP) in Denmark.
Methods: This cohort study included all Danish patients aged ≥18 years diagnosed with incident cITP from April 1, 2009 to December 31, 2015 as reported to the Nordic Country Patient Registry for Romiplostim, which collects data on all cITP patients in Denmark. cITP was defined as ≥2 ITP diagnoses made >6 months apart, as recorded in the Danish National Patient Registry, and confirmed by medical record review. The date of the second ITP diagnosis was denoted cITP diagnosis date (index). Patients with secondary ITP were excluded. Patient distribution by nadir platelet count within 90 days before index and the percentage of patients who experienced ≥1 bleeding-related hospitalization within one year before index were reported. The overall proportion of patients treated with ITP drugs, splenectomy, and supportive treatments (including tranexamic acid and platelet transfusion) between first ITP diagnosis and index was estimated. Patients were followed for 12 months after their index date, with censoring at emigration or death. We calculated the 1-year cumulative risk of treatment initiation, with death as a competing risk, for patients previously untreated as of the index date.
Results: The study included 964 cITP patients (57% female, median age 58 years, interquartile range (IQR): 36-71). Median time from first ITP diagnosis to index was 7 months (IQR: 6-10). Nearly half (n=470, 48%) were treated between first diagnosis and index; of these 470 patients, 43% had a record of treatment with corticosteroids, 18% with rituximab, 12% with supportive treatment, 12% with IVIg, 3.7% with splenectomy, and 3.1%

with TPO-RA. For the 494 patients who did not receive any treatment prior to index date, the lowest platelet count within 90 days before index was <50×10^9/L for 20% of all patients; between 50 and 150 for 44%; and ≥150 for 7.1% (missing for 29%). For those treated prior to index date, corresponding proportions were 28%, 24%, 34% (missing for 14%), respectively. Bleeding events within one year prior to index date was reported for 32% of those who were treated, and for 26% of those not treated before index. Of the 494 patients not receiving therapy between first ITP diagnosis and index 9.2% (95% confidence interval (CI): 7.7, 11.0) (n=43) patients initiated therapy in the subsequent 12 months. The 12-month risk of therapy initiation for those unexposed to a given therapy prior to cITP diagnosis was: 6.3% (95% CI: 5.1, 7.7) for corticosteroids, 5.3% (95%CI: 4.4, 6.3) for rituximab, 3.1% (2.4, 4.0) for IVIg, 1.7% (95% CI: 1.2, 2.3) for TPO-RA, and 3.7% (2.9, 4.5) for splenectomy.
Summary and Conclusions: Nearly half of all patients diagnosed with cITP in routine clinical practice in Denmark had been treated for ITP before their cITP diagnosis; 3.7% of these patients with treatment before cITP were splenectomized and 3.1% were treated with TPO-RA. In the subsequent 12 months post-diagnosis, 9.2% of previously untreated patients commenced therapy.

DISEASE MANAGEMENT OF PATIENTS WITH IMMUNE THROMBOCYTOPENIA - RESULTS OF A REPRESENTATIVE RETROSPECTIVE SURVEY IN GERMANY

A.S. Kubasch[1,*], J. Kisro[2], J. Heßling[3], H. Schulz[4], H.-J. Hurtz[5], M. Klausmann[6], A. Ehrnsperger[7], U. Platzbecker[1]

[1]Medical Clinic and Policlinic I, University Hospital Carl Gustav Carus, TU Dresden, Dresden, [2]Lübecker onkologische Schwerpunktpraxis, Lübeck, [3]Onkologie am Segelfliegerdamm, Berlin, [4]Praxis internistischer Onkologie und Hämatologie, Frechen, [5]Onkolog. Gemeinschaftspraxis und Tagesklinik, Halle, [6]Gemeinschaftspraxis Dr. Klausmann, Aschaffenburg, [7]Novartis Pharma GmbH, Nuernberg, Germany

Background: Due to a better understanding of the disease pathology, treatment options for patients with immune thrombocytopenia (ITP) have increased over the last years. However, only few data exist on the real-life management of patients with ITP in Germany.
Aims: The current analysis of a national survey was undertaken to describe the diagnostic and treatment patterns of patients with ITP managed by hematologists in routine care.
Methods: A retrospective data collection using questionnaires was performed by 26 hematology practices distributed all over Germany. From 02/2016 until 12/2017, all patients diagnosed with ITP were documented. Documentation included patient characteristics, patient history and laboratory as well as clinical parameters at diagnosis and present, and previous and current therapeutic strategies. Next to the overall evaluation, patients were furthermore grouped by platelet count at diagnosis and results were compared between 4 groups: 1) 0-10 x 10^9/l; 2) 11-30 x 10^9/l; 3) 31-50 x 10^9/l; 4) 51-100 x 10^9/l.
Results: Data of 1,038 patients could be evaluated and a preliminary analysis was carried out. Overall, 47% of patients were female and 53% male. At diagnosis, more than half of the patients (56%) were >60 years. ITP was mainly diagnosed more than 3 years before the analysis (3-5 years: 28%; >5 years: 32%), and most patients (71%) suffered from primary ITP. An incidental finding was the main reason that led to the diagnosis of ITP (41%). Only 5% of all patients underwent splenectomy. The main strategies applied during 1st line treatment were steroids (45%) as well as "watch and wait" (40%), followed by intravenous immunoglobulins (IVIG; 6%). Multiple other treatment options were given to patients during 2nd and 3rd line therapy. Next to steroids and IVIGs, thrombopoietin receptor agonists (TPO-RAs) were increasingly used as 2nd (19%) or 3rd line treatment (26%).
Summary and Conclusions: According to the data analysis, steroids and a "watch and wait" strategy dominated 1st line treatment of patients with ITP. Most patients receive treatment with steroids as their first option. Only a minority of patients underwent splenectomy, which is probably due to better 2nd line therapies and an increased awareness of late remissions in ITP. A final analysis of the data will be presented at the conference, including data on subgroups.

PF676

PREDICTIVE FACTORS FOR SUCCESSFUL SPLENECTOMY OUTCOME – SYSTEMATIC REVIEW

M. Mitrovic[1,2,*], D. Antic[1,2], M. Virijevic[1,2], Z. Pravdic[1], N. Suvajdzic[1,2]

[1]Clinic of Hematology, Clinical Center of Serbia, [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background: Splenectomy may lead to a good response in 60-80% of adults with corticosteroid refractory immune thrombocytopenia (ITP). However, in the era of novel drugs the appropriate selection of patients for splenectomy is essential for optimization of the treatment outcome. Accordingly, it is important to identify both pre- and post-operative parameters predictable for the splenectomy outcome.
Aims: We analysed the large number of publications addressing this issues, in order to make systematic review of predictive factors for outcome of splenectomy in corticosteroid refractory ITP.
Methods: The Medline database was searched from January 1,1966, to January 1, 2018. using keywords: "splenectomy," "spleen and remov," "spleen and extract", "thrombocytopenia," "thrombocytopenic purpura," "ITP" or "AITP" as well as "predictor". The search was limited to English-language articles. The bibliographies of all retrieved articles were searched for additional relevant articles. Retrieved articles were selected for review if they reported ≥15 consecutive splenectomized ITP patients. Articles that reported data on children were included only if it could be determined that 75% or more of the patients were ≥14 years old.
Results: The literature search identified 410 articles; 335 articles did not meet our selection criteria and were not reviewed. We selected 75 articles with 6151 patients analizing three groups according to the type of response to the splenectomy: predictors of initial response (50 articles), predictors of sustained remission (35 articles) and predictors of relapse (11 articles).
Predictors of initial response: Age, duration of illness before splenectomy, platelet sequestration site, response to steroides and intravenous immunoglobulins (IVIg), preoperative and postoperative platelet count (PC), spleen size/weight were predictive in 62.5% (20/32), 14% (3/21), 63.3% (7/11), 42.9% (9/21), 20% (2/10), 50% (4/8), 100% (17/17), 20% (1/5) articles, respectively. Neither sex nor antiplatelet antibodies were predictive in analysed articles (19/19 and 11/11 articles).
Predictors of sustained remission: Age, duration of illness before splenectomy, platelet sequestration site, response to steroides and IVIg, preoperative and postoperative PC were predictive in 34.8% (8/15), 5.9% (1/17), 62.5% (5/8), 21.7% (5/23), 25% (1/4),71.4% (5/7), 70.6% (12/17) articles, respectively. Sex, spleen size/weight and antiplatelet antibodies were non-predictive in analysed articles (18/18, 2/2 and 6/6 articles).
Predictors of relapse: Age, response to steroides and IVIg, postoperative PC, spleen size/weight were predictive in 28.5% (2/7), 50% (2/4), 100% (1/1), 92.3% (12/13) and 2/6 (33.3%) articles, respectively. Sex, duration of illness before splenectomy, preoperative PC and antiplatelet antibodies were non-predictive in analysed articles (8/8, 5/5, preoperative PC 3/3 and 3/3 articles, respectively).
Summary and Conclusions: The reviewed articles used diverse criteria to evaluate patients' characteristics and to report outcomes. However, a comprehensive analysis of all published reports for predictive parameters for the outcome of splenectomy showed that the most reliabe predictor is postoperative PC. On the other hand, among preoperative variables, younger age and platelet sequestration site were related with response.

PF677

CARDIOVASCULAR AND BLEEDING OUTCOMES IN A NORDIC COHORT OF ADULT PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (CITP)

K. Adelborg[1,*], N.R. Kristensen[1], M. Nørgaard[1], S. Bahmanyar[2], W. Ghanima[3], K. Cetin[4], H.T. Sørensen[1], C.F. Christiansen[1]

[1]Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, [2]Clinical Epidemiology Unit & Center for Pharmacoepidemiology, Karolinska Institutet, Stockholm, Sweden, [3]Department of Medicine, Østfold Hospital Trust, Sarpsborg, Norway, [4]Center for Observational Research, Amgen Inc, Thousand Oaks, United States

Background: ITP is a rare condition associated with low platelet counts and an increased tendency to bleed. There is a paucity of real-world data on cardiovascular and bleeding outcomes according to platelet count levels in these patients, as well as how these events influence mortality.
Aims: To examine the incidence of cardiovascular events and bleeding in association with platelet count levels and the prognostic impact of these events in a population-based cohort of cITP patients.
Methods: Using data from the Nordic Country Patient Registry for Romiplostim, we studied adults diagnosed with cITP (1996-2015), defined as ITP lasting a duration of >12 months. Incidence of cardiovascular events and bleeding requiring inpatient, outpatient, or emergency room hospital contact (via cumulative incidence risk function with death as a competing risk) and all-cause mortality (via Kaplan-Meier method) were estimated. We constructed matched (age, sex, country, ITP duration) comparison cohorts of ITP patients without these events, and hazard ratios were com-

puted through Cox proportional hazard regression to examine the prognostic impact of cardiovascular events and bleeding.
Results: Among 3,584 cITP patients (median age 58; 58% women), absolute 1- and 5-year rates were 1.9% and 5.8% for arterial cardiovascular events, 1.2% and 3.2% for venous thromboembolism, 7.5% and 17.2% for bleeding, and 3.5% and 15.2% for all-cause mortality. After adjusting for important demographic and clinical factors, rates of cardiovascular events were similar across baseline platelet counts (measured within 90 days prior to cITP diagnosis), while patients with baseline platelet counts <50×10^9/L had more than 2-fold higher 1-year rates of bleeding and all-cause mortality than patients with baseline platelet counts in the normal range (150-249x10^9/L). Occurrence of arterial cardiovascular events, venous thromboembolism, and bleeding were associated with subsequent 7-fold, 6-fold, and 3-fold increased 1-year all-cause mortality, respectively, compared to the matched comparison cohorts.
Summary and Conclusions: In patients with cITP, rates of cardiovascular events were low; rates of bleeding and all-cause mortality were somewhat higher. Cardiovascular events occurred across all platelet count levels, while low platelet counts were associated with an increased risk of bleeding and all-cause mortality. Cardiovascular and bleeding events were strong adverse prognostic factors for all-cause mortality.

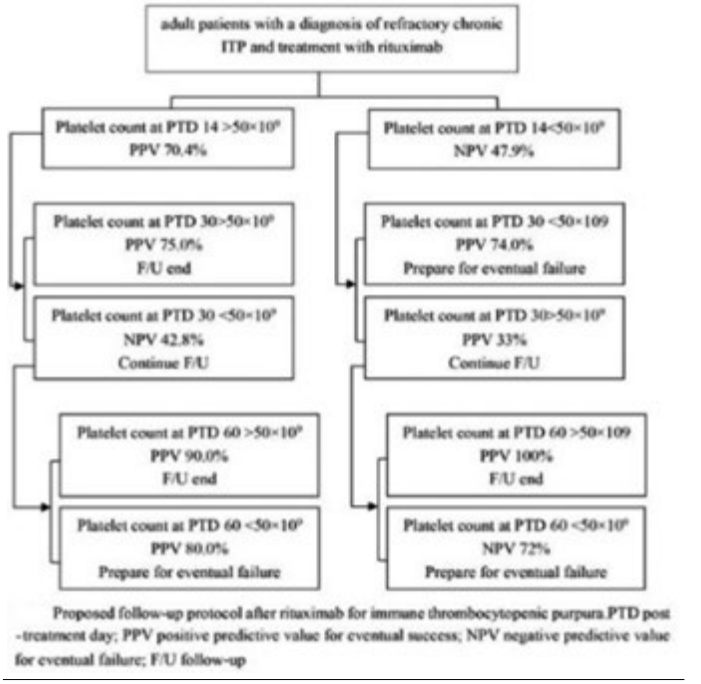
PF678

PLATELET COUNT EVOLUTION AS A PREDICTOR OF OUTCOME AFTER RITUXIMAB TREATMENT IN CHRONIC IMMUNE THROMBOCYTOPENIA

S. Wang[1,*], Y. Nie[2], M. Ju[1], T. Sun[1], H. Li[1], D. Zhang[1], L. Zhang[1], R. Yang[1]

[1]Institute of Hematology & Blood Disease Hospital, CAMS & PUMC, China, [2]Sinous Diagnostics, Tianjin, China

Background: Primary immune thrombocytopenia (ITP) is an autoimmune disorder in which a patient's immune system is activated by platelet-specific autoantigens produced by autoreactive B cells. Most adults with acute ITP will achieve an initial platelet count response to corticosteroid-based treatments; however, relapses are common within the first year and additional treatments are frequently required . Of the many available second-line alternatives, the anti-CD20 antibody rituximab are widely used.It depletes B cells, especially the memory B cell subset, and reverses regulatory T-cell dysfunction. Rituximab has been shown to provide initial response rates of about 60%; however, sustained responses lasting for more than 2 years occur in substantially fewer than 60% of patients. In this study, we want to present a prediction tool to identify eventual refractory ITP cases would aid patient counseling and management planning. The purpose of this study was to determine if responsive and refractory patients after treatment with Rituximab for ITP differ in terms of platelet count evolution, and to set a cut-off value for predicting response at the earliest possible time after treatment with Rituximab.
Aims: To determine whether platelet count evolution differs between patients with a successful or unsuccessful result after rituximab treatment in chronic ITP and to identify biological and clinical predictors of response.
Methods: A retrospective study was conducted in 103 chronic ITP patients hospitalized in our medical center between January 2012 and December 2014.Successes were defned to have a fnal platelet count of ≥50×10^9/L.Failures were defned to have a fnal platelet count of <50×10^9/L.The sensitivity, specificity, positive predictive value (PPV), negative predictive value(NPV) of platelet count in different time points were analyzed for the predictor of treatment response. Optimal cutoff values were established using ROC analysis.
Results: 1. Archived records of 103 consecutive patients that underwent Rituximab for ITP were reviewed. Multivariate analysis revealed that a lower absolute CD41$^+$megakaryocytes count <150 at diagnosis was an independent risk factor for treatment failure. (P=0.003; 95% confidence interval, 1.784~15.471; odds ratio, 5.253). long-term response (LTR) was higher in CD41$^+$megakaryocytes count >150 group *vs* <150 group patients.(P=0.001; 50.6% *vs* 17.5% after 48 months). 2. Successes and failures were found to have significantly different platelet counts from three days after treatment(PTD 3) with rituximab[74.4±104.1 ×10^9/L *vs* (37.3±37.4)×10^9/L,P=0.005], and remained different thereafter, with increasing significance[64.8±70.4 *vs* (31.2±24.9)×10^9/L, P=0.001 in PTD 14. In both groups, the different platelet counts stopped fluctuating and became raised gradually in PTD 60 107.1±62.0 ×10^9/L *vs* (22.6±18.4)×10^9/L, P<0.001 . 3. Patients were divided further using a optimal cut-off platelet count of 50×10^9/L on PTD 14, PTD 30, and PTD 60, and PPV and NPV values were calculated for predicting eventual success and failure (Figure 1).



Proposed follow-up protocol after rituximab for immune thrombocytopenic purpura.PTD post -treatment day; PPV positive predictive value for eventual success; NPV negative predictive value for eventual failure; F/U follow-up

Figure 1.

Summary and Conclusions: Response can be predicted by obtaining platelet counts at 14 days, 1 month, and 2 month after rituximab. We present a protocol that guides patient monitoring and management planning.

PF679

SUSTAINED PLATELET COUNTS ≥100X109/L DURING ELTROMBOPAG TREATMENT IN PATIENTS WITH PERSISTENT/CHRONIC IMMUNE THROMBOCYTOPENIA (ITP): RESULTS FROM A 2-YEAR, PHASE IV, OPEN-LABEL STUDY

T.S. Shamsi[1,*], R.S. Wong[2], A. Orazi[3], Z. Aziz[4], A. Melikyan[5], M. Stankovic[6], J. Maier[6], R.K. Brynes[7]

[1]Research Department, NIBD & BMT, Karachi, Pakistan, [2]Sir YK Pao Centre for Cancer and Department of Medicine and Therapeutics, Chinese University of Hong Kong, Shatin, NT, Hong Kong, [3]Department of Pathology, Weill Cornell Medical College, New York, United States, [4]Clinical Oncology, Hameed Latif Hospital, Lahore, Pakistan, [5]National Research Center for Hematology, Moscow, Russian Federation, [6]Novartis Pharma AG, Basel, Switzerland, [7]Department of Pathology, Keck School of Medicine, University of Southern California, Los Angeles, CA, United States

Background: Primary ITP is an acquired disorder of autoimmune-directed platelet reduction and impaired platelet production, defined as platelet counts <100x10^9/L in the absence of other causes of thrombocytopenia. The oral thrombopoietin receptor agonist (TPO-RA) eltrombopag (EPAG), approved for use in pts with previously treated (eg corticosteroids) chronic ITP aged ≥1 yr, has proven efficacy in increasing and maintaining platelet counts ≥50x10^9/L. However, few studies have evaluated how many pts achieve a platelet count ≥100x10^9/L with EPAG treatment. Here we report effects on platelet count during a Phase IV, open-label bone marrow safety study of EPAG in adults with ITP ≥6 months (Brynes *et al. Acta Haematol* 2017;137:66–72).
Aims: Evaluate effects on platelet counts, with a focus on counts ≥100x10^9/L, and long-term safety, during 2 yrs of EPAG treatment.
Methods: Adults ≥18 yrs old with ITP ≥6 months were enrolled in this safety study of the effects of EPAG on bone marrow fibrosis (NCT01098487). Pts with prior exposure to EPAG or romiplostim were eligible but treatment must have been completed ≥6 months before screening. Pts treated with any other TPO-RA were not eligible. All pts started EPAG at 50 mg/day (25 mg/day for East Asian pts), titrated to 25–75 mg dose as required to maintain platelet counts within the clinically indicated range. Platelet counts were prospectively recorded; weekly until pts reached a stable dose, then every 4 wks during the study.
Results: 162 pts (median [range] age 42 yrs [18–80]) were enrolled; 50% Caucasian, 49% Asian; 23% persistent (n=37) and newly diagnosed (n=1) ITP, 77% chronic ITP (n=124); 23% were splenectomized. 70% of pts had

received prior ITP therapy before enrollment; 57% were receiving ITP therapy at study initiation (baseline [BL]). 77% and 57% had platelet counts ≤50x10^9/L or <30x10^9/L at BL. Median daily EPAG dose was 49.7 mg (range 5–75); median treatment duration was 104 wks (range 2.4–112.6). 72% of pts attended all study visits and completed the study; 61% of pts completed ≥24 months of EPAG treatment. 80% (130/162) of pts achieved platelet counts ≥100x10^9/L at least once during EPAG treatment without rescue medication; 9% (14/162) had ≥100x10^9/L at BL. 51% (61/120) of those pts still on treatment maintained platelet counts ≥100x10^9/L for ≥13 wks without rescue therapy (Figure 1). 87% (141/162) of pts achieved platelet counts ≥50x10^9/L at least once during EPAG treatment without rescue medication; 23% had ≥50x10^9/L at BL. 51% (62/122) of those pts still on treatment maintained platelet counts ≥50x10^9/L for ≥43 wks without rescue therapy. Adverse events (AEs; any grade) were reported in 87% (141/162) of pts (most frequently headache; 19%; cough, arthralgia, diarrhea; 14% each). AEs considered drug-related occurred in 37% (60/162); 13% (21/162) discontinued because of an AE, including increased alanine aminotransferase (n=3), cerebral hemorrhage, hepatitis toxic, and increased blood bilirubin (n=2 each). Six (4%) pts experienced thromboembolic events (transverse sinus thrombosis, cerebral venous thrombosis, transient ischemic attack, deep vein thrombosis, pulmonary embolism, and thrombophlebitis).

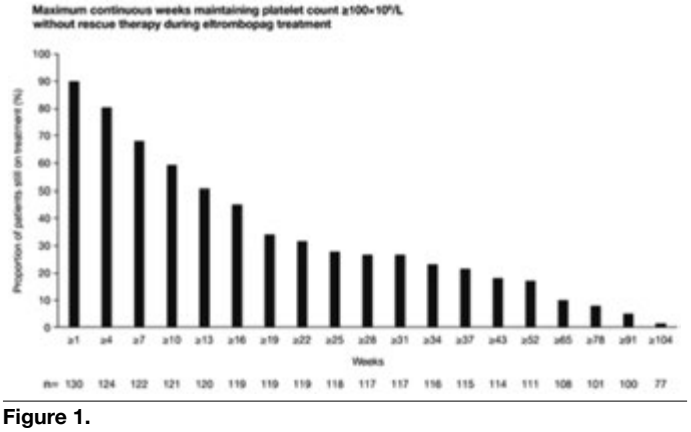


Figure 1.

Summary and Conclusions: During 2 yrs of EPAG, 80% of pts experienced at least one platelet count ≥100x10^9/L without rescue therapy, and 51% of pts still receiving EPAG maintained this platelet count for ≥13 wks. Reported AEs were consistent with the known EPAG safety profile, or underlying disease. These results further support the use of EPAG as an effective and well-tolerated treatment for pts with ITP.

PF680

LONG-TERM EFFICACY AND SAFETY OF ROMIPLOSTIM FOR TREATMENT OF CHRONIC IMMUNE THROMBOCYTOPENIA

E. Arshanskaya[1], S. Semochkin[2,*], V. Ivanova[1], V. Ptushkin[1,2]

[1]City Clinical Hospital n.a. S.P. Botkin, [2]Pirogov Russian National Research Medical University, Moscow, Russian Federation

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by transient or persistent decrease in platelet count due to decreased production and increased peripheral destruction of platelets secondary to antiplatelet antibodies. About 10% of patients do not respond to standard treatment including splenectomy. A new method of treatment for ITP is the use of thrombopoietin (TPO) mimetics to increase the rate of platelet production. Activation of the TPO receptor that is present on megakaryocytes and platelets leads to increased thrombopoiesis. Romiplostim is the first thrombopoietic agent that has been shown to be a highly effective treatment for both splenectomized and nonsplenectomized ITP patients.
Aims: The primary aims of the study were to determine the efficacy and safety of long-term romiplostim for treatment of chronic ITP on the patient's own population.
Methods: Seventy-five adult chronic ITP patients who were refractory to previous ITP treatments (platelet count <30.0x10^9/L) were enrolled in the study in the period from 01.2012 to 12.2015. Romiplostim was initiated at 1-3 mg/kg per week. The dose was then adjusted as needed based on the patient's platelet count weekly. The efficacy was evaluated based on platelet responses and the percentage of patients able to lower or discontinue their doses of concurrent ITP medications. A primary platelet response defined as a platelet count ≥50.0x10^9/L with at least the doubling of the baseline value, without any rescue intervention during the preceding 4 weeks. A complete response considered if achieved at a platelet level of ≥100.0 x 10^9/L. A sustained response diagnosed if the platelet count was 50.0 x 10^9/L for at least 6 months. This analysis performed as of 31 August 2017.
Results: The median age was 57 (range, 18.2-79.5) years. The median number of prior ITP treatments was one (range, 1-4). Seventy-two (96%) patients had previously been treated with glucocorticosteroids, per 6 (8%) patients with eltrombopag and rituximab, and 11 (16%) patients had undergone a splenectomy. The median ITP duration before eltrombopag treatment was 2.8 (range, 0.7-49.2) years. The median platelet count at baseline was 19.0 (range, 1.0-28.0) x 10^9/L. A primary platelet response to romiplostim was observed in 65 (87%) patients, complete platelet response in 39 (52%), and sustained platelet response in 38 (51%). Forty-eight (64%) patients continued treatment with romiplostim at the time of the current analysis with a median duration of therapy of 29.1 (range, 1.0-91.8) months. Two (2.7%) patients received a romiplostim shortly before performing surgical interventions. The mean starting dose of romiplostim was 2.1±1.0 g/kg, and the final dose - 4.6±2.1 g/kg. The reasons for the completion of the therapy were ineffectiveness in 11 (14.7%) patients, adverse events in 6 (8%) and achieving a sustained response, which allowed gradual withdrawal of treatment in 6 (8%) patients. An alternative TPO receptor agonist (eltrombopag) was used in 12 (16%) cases. Episodes of bleeding occurred in 35 (47%) cases, including ≥3 grade in 5 (7%). The need for a short-term appointment of glucocorticosteroid drugs occurred in 33 (44%) and *t*ransfusions of thromboconcentrates in 6 (8%) patients. The most common adverse events (all severity) were headache in 11 (14.7%), nasal bleeding in 10 (13.3%), arthralgia in 4 (5.3%), hypertension in 2 (2.7%) and thrombotic complications in 3 (4%) patients.
Summary and Conclusions: Our study confirms the high frequency of sustained platelet response (50.7%) on romiplostim and the safety of long-term use.

PF681

ITP SECONDARY TO ALEMTUZUMAB-INDUCED RENAL TRANSPLANT: OUTCOME OF 31 PATIENTS

E. Lucchini[1,2,*], A. Luqmani[3], M. Atta[3], S. Deplano[3], M. Layton[3], C. Vladescu[3], D. Paul[3], R. Charif[4], N. Cooper[2,3]

[1]Clinica Ematologica, University of Udine, Udine, Italy, [2]Department of Medicine, Imperial College, [3]Department of Hematology, [4]Nephrology, Hammersmith Hospital, London, United Kingdom

Background: Alemtuzumab (alem), a monoclonal antibody against CD52, causes profound depletion of T and B cells and as well as monocytes, NK and dendritic cells. Its effect is long-lasting; B cells recover after 12 months and T cells recover after more than 36 months. It is indicated for the treatment of multiple sclerosis and is used in chronic lymphocytic leukemia and in several solid organ transplantations, including renal, as induction therapy for the prevention of early rejection. Autoimmune complications after alem therapy include autoimmune thyroid disorders (17-26%), immune thrombocytopenia (ITP) (1-2%) and glomerulopathy (1%). In our experience at Hammersmith Hospital (HH) the incidence of ITP in alem-induced renal transplant patients (pts) is 1-2%.
Aims: To report the outcome of pts developing ITP after alem-induced renal transplants.
Methods: We retrospectively analyzed 31 pts attending the hematology clinic at HH, London, with ITP requiring treatment after an alem-induced renal transplant between 2002 and 2016. ITP was defined as a rapid onset of isolated thrombocytopenia (platelet count <100x10^9/L) with no other explanation. Pts with a platelet count <30x10^9/L or requiring a higher platelet count for other indications were treated. Response (R) was defined as platelet count >=30x10^9/L and at least doubling of baseline count. Complete response (CR) was defined as platelet count >=100x10^9/L.
Results: 21 (67.7%) pts were males, median age at transplant was 38.5 years and median age at ITP diagnosis was 52 years. 42% were deceased-donor transplants, 58% were living-donor transplants. All pts received tacrolimus as post-transplant immunosuppression, 6 (20%) in association with mycophenolate mofetil (MMF). Median time from renal transplant to ITP development was 33 months (range 1-161), median lowest platelet count was 5.5 x 10^9/L. 18 pts (58%) reported bleeding symptoms at diagnosis. One patient achieved spontaneous CR. Of the remaining 30 pts, 27 (90%) received steroids, IVIG or both as first-line treatment; 3 received additional therapy (IVIG+rituximab (rtx); IVIG+romiplostim (romi); rtx alone). The overall response (R) to first line therapy was 63% (53% achieving CR). After a median follow-up of 34 months (range 1-97), 11 pts (36.6%) are still in CR without further therapy. 19 pts required second line

therapy, ten required 3 lines, five 4 lines, two 5 lines and one 6 lines. All eventually responded: 4 to IVIG +/- steroids; 7 to thrombopoietin receptor-agonists (TPORA); 4 to rtx; 2 to MMF; 2 to combination therapy. 7 pts require ongoing treatment (TPORA/MMF). 16 pts (53%) experienced adverse events: 4 steroid-induced diabetes, 1 knee osteonecrosis, 3 thrombosis, 1 VZV encephalitis, 5 malignancies (3 PTLD and 2 solid tumors), 2 deaths from infectious complications (Table 1).

Table 1.

Treatment	1st line (n=30)	2nd line (n=19)	3rd line (n=10)	>3 lines (n=8)	response rate	relapse rate	adverse events (n=16)
TPO	0	2	4	4	80%	12.5%	2**
Steroids	12	3	2	0	64.7%	27.2%	7
IVIG	4	3	1	0	25%	100%	0
steroids + IVIG	11	3	1	0	73.3%	36.3%	4
RTX	1	5	1	0	71.4%	0%	0
TPO + RTX +/- steroids + IVIG	0	1	0	2	66.6%	50%	1**
MMF	0	0	0	2	100%	0%	0
RTX + IVIG +/- steroids	1	1	0	0	100%	50%	1*

*deaths in patients who received multiple lines of treatment before infectious events
**thrombosis

Summary and Conclusions: ITP is a non-negligible complication in pts who received alem as induction therapy for renal transplant. Most pts responded to first-line therapy and long-term response rates (RR) were similar to those expected with primary ITP (36.6%). This is a particularly frail subset of pts due to their chronic immunosuppression, with an increased risk of infections and malignancies, and many pts have an increased thrombotic risk. Balancing risks and benefits of each treatment remains the biggest challenge: steroid-sparing regimens should be preferred given the high toxicity in this cohort. TPORA and rtx had high RR and acceptable side effects, with risks of thrombosis or infection the primary factors driving the treatment choice. Further studies are needed to determine the best treatment pathway for these pts.

PF682

AN OBSERVATIONAL, NON-INTERVENTIONAL CLINICAL PRACTICE STUDY OF ROMIPLOSTIM IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIC PURPURA (ITP) – PLATON FINAL RESULTS

G. Mihaylov[1,*], B. Skopec[2], Z. Sninska[3], N. Tzvekov[4], D. Niepel[5], K. Bjorklof[6], V. Ivanushkin[7], P. Cernelc[2]

[1]Clinic of Hematology, Specialized Hospital for Active Treatment of Hematology Diseases AD, Sofia, Bulgaria, [2]Department of Hematology, University Medical Center Ljubljana, Ljubljana, Slovenia, [3]Deprtment of Hematoloty and Blood Transfusion, University Hospital St. Cyril and Metod, Bratislava, Slovakia, [4]Clinic of Hematology, University Multiprofile Hospital for Active Treatment "Dr. Georgi Stranski" EAD, Pleven, Bulgaria, [5]Global Medical Affairs, Amgen (Europe) GmbH, [6]EU Medical Affairs, Amgen (Europe North East), Zug, Switzerland, [7]Department of Biostatistics, Quartesian, Kharkov, Ukraine

Background: The thrombopoietin-receptor agonist romiplostim (rom) is indicated for adult chronic ITP patients (pts) who are refractory to other treatments (SmPC 2018). At the time of study, rom was approved for second line treatment of either non-splenectomized (splen) pts or pts with a contra-indication for splenectomy.
Aims: The aim of this study was to assess the use of rom in routine clinical practice in Bulgaria, Czech Republic, Slovenia, Slovakia, Romania and Russia.
Methods: This international single-arm, observational, non-interventional study enrolled adults with ITP, who had received ≥1 rom application. A period of 6 months prior to rom initiation was documented retrospectively from pt medical charts; the observation period started with rom initiation with a planned duration of 2 years. All pts provided written informed consent. Assessed parameters included pt demographics, rom application, dosage, adverse drug reactions (ADRs), reason of discontinuation, concomitant ITP therapies, clinically relevant bleeding events, and hospitalizations. Presented is the final analysis.

Results: Of 104 enrolled pts, 100 were analyzed (56% female, median age at diagnosis 45 [interquartile range, IQR: 26.5, 57.5] years, 36% splen, 64% non-splen). Of these, 73% completed the study, 27% discontinued prematurely (13 were lost to follow-up, 5 withdrew consent, 3 died [unrelated to rom], 4 stopped due to administrative reasons, 1 for severe ADR [thrombosis], 1 for other reasons). The median time from ITP diagnosis to rom initiation was 1.9 years (IQR: 0.3, 6.7); in pts with prior bleeding, the median time from start of bleeding to initiation of rom was 48 days (IQR: 25.0, 111.0). 49% had received ≥3 prior ITP therapies. During the 6 months before rom initiation the observation-adjusted event rate per 100 pt years was 131 (95% CI: 97.6, 171.4) for bleeding (122 [81.9, 175.6] in non-splen, 143 [90.7, 214.8] in splen pts) and 104 (95% CI: 86.9, 123.0) for ITP-related inpatient hospitalizations (145 [118.1, 175.8] in non-splen, 54 [36.5, 76.3] in splen pts). The median platelet count at rom start was 19 (IQR: 7.5, 42.0) x 10^9/L, increasing to 55 (IQR: 19.0, 100.0) x 10^9/L after 1 week and remaining above 50 x 10^9/L for the entire observation period (Figure 1). Pts received a median rom dose of 2.6 (IQR: 1.1, 4.5) µg/kg/week and a median of 60 (IQR: 14.5, 88.5) injections during a median duration of exposure of 23 (IQR: 6.7; 24.2) months. The observation-adjusted event rate per 100 pt years after rom initiation was 42 (95% CI: 32.9, 52.8) for bleeding (33 [22.8, 45.1] in non-splen, 58 [41.1, 80.6] in splen pts, no grade 3/4 events) and 47 (95% CI: 37.5, 58.6) for ITP-related inpatient hospitalizations (42 [30.5, 55.6] in non-splen, 57 [39.8, 78.7] in splen pts). 13% required splenectomy (*i.e.* 20% of non-splen) after initiation of rom. 4 pts experienced a total of 16 ADRs, with 1 pt experiencing 2 serious ADRs (thrombosis, dysphagia). At the end of study, 25% were in remission (per physician assessment), 45% had active, managed disease, 18% had active, untreated disease, and 3% had died (melanoma malignum, perianal abscess surgery, pneumonia, all unrelated to rom). For 9% ITP status was not reported.

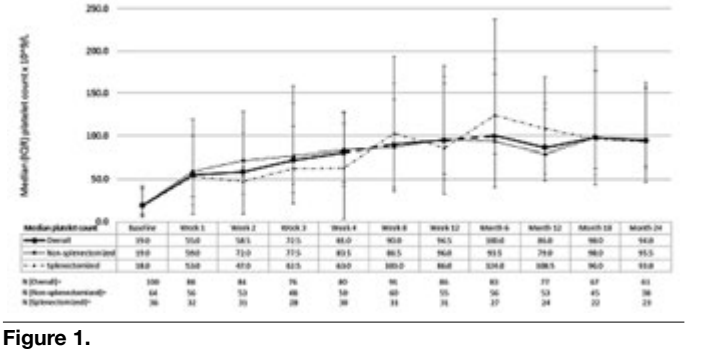

Figure 1.

Summary and Conclusions: In this study, rom increased platelet counts and reduced observation-adjusted rates of bleeding and hospitalizations. 25 pts achieved a remission and 13 pts required splenectomy after initiation of rom. Rom was generally well tolerated.

PF683

COMBINED/CONCOMITANT THERAPY FOR RAPID RECOVERY IN PATIENTS WITH REFRACTORY/RECURRENT IMMUNE THROMBOCYTOPENIA (ITP) AND MODERATE/SEVERE BLEEDING: AN OBSERVATIONAL STUDY

M. Napolitano[1,*], S. Raso[1], M. Santoro[2], A. Passannanti[1], L. LoCoco[3], M.R. Lanza Cariccio[2], S. Mancuso[1], S. Siragusa[1]

[1]Haematology Department, [2]Università di Palermo, [3]Central Laboratory, University Hospital "P. Giaccone", Palermo, Italy

Background: Sequential multiple agents treatment is frequent in patients with refractory/recurrent immune thrombocytopenia (ITP). So far, no data have been published about the use of combined/concomitant therapy in ITP patients in whom a fast increase in platelets count is needed due to severe thrombocytopenia and moderate/severe active bleeding. Primary aim of the current study was to evaluate the outcome of combined/concomitant treatment of adult patients with recurrent/refractory immune thrombocytopenia (ITP) and active moderate/severe bleeding.
Aims: Primary aim of the current study was to evaluate the outcome of combined/concomitant treatment of adult patients with recurrent/refractory immune thrombocytopenia (ITP) and active moderate/severe bleeding.
Methods: We have prospectively evaluated up to 12 months patients admitted to our Hematology Unit from January 2014 to January 2016 with a diagnosis of refractory/recurrent ITP, platelets count <10.000/mmc and active moder-

ate/severe bleeding. Combined/concomitant treatment was defined by a combination of two or more of the following agents, given at the same time: steroids, immunoglobulins, anti-CD20, Romiplostim. A historical cohort of patients diagnosed with relapsed/refractory ITP and treated with single agent was studied to evaluate any difference in 12 months prognosis.
Results: Overall, 18 patients (8F, 10M, mean age 50 years, range:18-87years), received a combined/concomitant treatment: 10 (55.5%) with two agents (High dose immunoglobulins,1g x 2 plus steroids, prednisone 1mg/kg for four weeks), 6 (33.3%) with three agents (Immunoglobulins, prednisone and Rituximab 375mg/mq weekly x 4 weeks) and 2 (11.1%) with four agents (Immunoglobulins, prednisone,Rituximab and Romiplostim). The overall response rate was 75%, with 60% of complete response, defined according to International criteria.2Median time to response was of four weeks; response rate was higher for recurrent (8/18) than refractory ITP (10/18). At Hospital admission three cases of life-threatening bleedings (2 gastro-intestinal and 1 intra-cerebral) were observed in 3 patients, they did not cause death and were succesfully managed with systemic haemostatic agents.Treatment-related adverse events were not reported in any case. Sequelae from intra-cerebral bleeding were observed in one case. After an analysis of the historical cohort, a faster complete response was reached (median response of 5.6 weeks *vs* 4 weeks, p=0.01) in the study group. There was no difference among groups at the12 months follow-up.
Summary and Conclusions: Combined/concomitant multi agent therapy may be a valid option for ITP patients in whom a rapid recovery from severe thrombocytopenia is needed.

Quality of life, palliative care, ethics and health economics

PF684

BRENTUXIMAB VEDOTIN IN RELAPSED/REFRACTORY SYSTEMIC ANAPLASTIC LARGE-CELL LYMPHOMA: A COST-EFFECTIVENESS ANALYSIS

G. Kay[1], C. Parker[1], E. Benson[2], T. Podkonjak[2], R. Selby[3], B. Wang[4], L.-I. Cheng[3,*]

[1]ICON Health Economics, ICON plc, Abingdon, [2]Takeda UK Ltd, Buckinghamshire, United Kingdom, [3]Global Patient Access, Takeda Oncology, [4]Oncology Statistics, Takeda Pharmaceuticals, Cambridge, United States

Background: Systemic anaplastic large cell lymphoma (sALCL) is a peripheral T-cell CD30+ non-Hodgkin lymphoma. CHOP chemotherapy is recommended for newly-diagnosed patients; however, 40-65% of patients will experience relapse/have refractory disease (R/R) after frontline treatment. High-dose therapy and autologous stem-cell transplantation (ASCT) can induce long-term remission in 30-40% of these patients. In 2012, the antibody-drug conjugate Brentuximab vedotin (ADCETRIS) was granted a European marketing authorisation for patients with R/R sALCL based on results from the pivotal Phase 2 study (SG035-0004; NCT00866047).
Aims: To evaluate the cost-effectiveness of brentuximab vedotin in patients with R/R sALCL using a UK payer perspective.
Methods: A partitioned survival model comprising three health states (progression-free survival [PFS], post-progression survival, and death) was developed. The relevant comparator was chemotherapy; this was implemented as a composite of five frequently used regimens (ICE, ESHAP, DHAP, GDP, and Gem-P) to reflect clinical practice. Patients achieving an adequate response to salvage therapy were assumed to undergo ASCT or allogeneic stem cell transplant (alloSCT). Data were obtained from 5-year follow-up from SG035-0004, a systematic literature review and clinical expert opinion. Clinical outcomes (PFS and overall survival [OS]) for brentuximab vedotin, ASCT and alloSCT were extrapolated over lifetime using cure modelling to reflect their curative potential. Clinical outcomes for chemotherapy were based on long-term follow-up for 89 patients in the British Columbia Cancer Agency Lymphoid Cancer database reported by Mak *et al.* (2013). Brentuximab vedotin and chemotherapy were compared naively given SG035-0004 was a single-arm study. Resource use included drug acquisition and administration; ASCT and alloSCT; adverse events; and long-term follow-up. Costs were based on a UK National Health Service (NHS) and Personal Social Services perspective. Sensitivity analyses included: varying the PFS and OS hazards for chemotherapy, using a self-control comparison to inform chemotherapy PFS and varying the rate of ASCT and alloSCT in both treatment arms. Probabilistic sensitivity analyses were also conducted.
Results: In the absence of ASCT/alloSCT, patients who received brentuximab vedotin experienced an additional 7.8 years mean PFS and additional 13.8 years mean OS compared to chemotherapy. Including ASCT/alloSCT in both arms yielded additional PFS and OS for brentuximab vedotin of 7.1 years and 11.9 years respectively. The base case incremental cost-effectiveness ratio (ICER) for brentuximab vedotin was £18,728 per quality-adjusted life-year (QALY) based on a drug acquisition cost of £2,500/vial. ICERs for brentuximab vedotin generated by the deterministic sensitivity analysis ranged between £13,000 and £27,000 per QALY. The probabilities of cost-effectiveness were 77% and 97% at decision thresholds of £30,000 and £50,000 per QALY respectively.
Summary and Conclusions: The ICER for brentuximab vedotin was below the threshold of £30,000 per QALY in the base case and all deterministic sensitivity analyses. As such, brentuximab vedotin is a cost-effective treatment for patients with R/R sALCL.

PF685

REAL-WORLD OUTCOMES ASSOCIATED WITH LENALIDOMIDE, BORTEZOMIB, AND DEXAMETHASONE *VERSUS* BORTEZOMIB AND DEXAMETHASONE IN THE TREATMENT OF NEWLY DIAGNOSED MULTIPLE MYELOMA WITHOUT STEM CELL TRANSPLANT

K. Parikh[1,*], Q. Ni[1], B. Ung[1], A. Agarwal[1], A. Chari[2]

[1]Celgene Corporation, Summit, United States, [2]Mount Sinai Hospital, New York, United States

Background: Recently, the use of triplet regimens featuring 2 novel agents, such as lenalidomide, bortezomib, and dexamethasone (RVd), has increased

for the treatment of multiple myeloma (MM) in the USA. Doublet regimens, such as bortezomib and dexamethasone (Vd), are still a first-line (1L) option for patients (pts) with newly diagnosed MM (NDMM), especially for those who are elderly and/or frail.
Aims: Using a large administrative claims database, this study aimed to evaluate real-world clinical and economic outcomes among pts with NDMM initiating RVd or Vd who had not received a stem cell transplant (SCT).
Methods: From the Truven MarketScan® data set, we identified adult pts with ≥2 claims for MM (International Classification of Diseases, Ninth/Tenth Revision, Clinical Modification codes: 203.0x and C90.0x, respectively) 30 days apart and ≥1 claim for a treatment of interest (index date) during the identification period (01Jan2011 to 31Dec2016). Pts were required to have continuous enrollment for 12 months pre- and post-index date, in addition to ≥1 full cycle of therapy with a valid 1L regimen. Pts were excluded if they had evidence of a prior MM diagnosis, treatment, or receipt of autologous SCT. Propensity score matching (PSM) was utilized to create balanced cohorts. The propensity score (the likelihood of receiving RVd) was estimated from a logistic regression model including age, gender, health plan, payer type, region, index year, medical cost and hospitalizations during baseline, and baseline clinical characteristics. A subgroup analysis of elderly pts (aged >70 years) was also conducted. Time to next treatment (TTNT) was defined as the duration from the index date until the initiation of a second-line therapy. Per patient per month (PPPM) total healthcare costs were calculated for the duration of the index treatment. Kaplan-Meier graphs were used to evaluate TTNT, whereas Wilcoxon rank-sum tests were utilized after PSM to assess differences in PPPM costs.
Results: 1,850 MM pts with ≥1 full cycle of a valid 1L regimen were identified in the database. Of these, 248 received RVd and 579 received Vd as 1L therapy. After PSM, 203 pts remained in each cohort (RVd and Vd) and no significant differences in demographics, clinical characteristics, or pre-medical events were observed. Pts initiating RVd induction therapy had a significantly longer median TTNT (Figure 1) and fewer RVd pts progressed to a second line of therapy (39.4% *vs* 49.3%; *P*=0.045) compared with Vd pts. Similar trends were observed in the elderly subgroup, with RVd pts having a significantly longer TTNT compared with Vd pts (not reached *vs* 34.4 months). Over the duration of the index treatment (time to treatment discontinuation [months] was 13.4 RVd *vs* 6.0 Vd), RVd pts had significantly higher total healthcare costs ($19,776 *vs* $15,028; *P* <0.0001) and pharmacy costs ($8,953 *vs* $517; *P* <0.0001) compared with Vd pts. However, they had significantly lower outpatient costs ($9,313 RVd *vs* $12,469 Vd; *P* <0.0001).

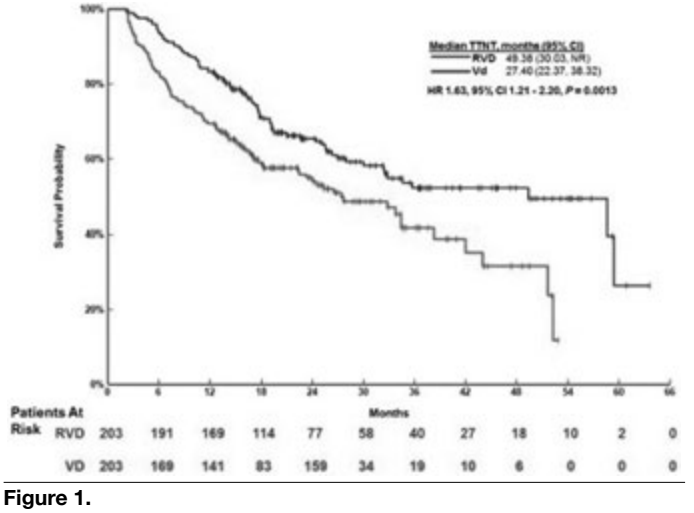

Figure 1.

Summary and Conclusions: This retrospective analysis of pts with NDMM, who had not received a SCT, initiating RVd induction therapy found that they had significantly longer TTNT and were less likely to progress compared with pts with NDMM treated with Vd. A subgroup analysis found that elderly pts (aged >70 years) saw similar benefits. While on therapy, RVd pts incurred higher total healthcare and pharmacy costs, but had fewer outpatient costs.

PF686

CPX-351 FOR THE TREATMENT OF NEWLY DIAGNOSED, THERAPY-RELATED ACUTE MYELOID LEUKEMIA (TAML) OR AML WITH MYELODYSPLASIA-RELATED CHANGES (AML-MRC): NUMBER NEEDED TO TREAT (NNT) TO PREVENT ONE DEATH

A.C. Louie[1,*], K.F. Villa[1], R.J. Ryan[1]

[1]*Jazz Pharmaceuticals, Inc., Palo Alto, CA, United States*

Background: CPX-351, a liposomal co-encapsulation of cytarabine and daunorubicin at a synergistic 5:1 molar ratio, is approved in the United States for the treatment of adults with newly diagnosed tAML or AML-MRC. In a randomized, phase 3 study of CPX-351 *versus* conventional cytarabine/daunorubicin (7+3), CPX-351 significantly prolonged survival and improved remission rates compared with 7+3 in adults aged 60-75 years with newly diagnosed tAML or AML-MRC.
Aims: The current analysis calculated the NNT to prevent 1 death at 2 years as a measure of efficacy of CPX-351 compared with a conventional 7+3 regimen.
Methods: In the phase 3 study (NCT01696084), patients were randomized 1:1 to receive 1-2 induction cycles with CPX-351 (100 units/m^2 [cytarabine 100 mg/m^2+daunorubicin 44 mg/m^2] on Days 1, 3, and 5 [2nd induction: Days 1 and 3]) or 7+3 (cytarabine 100 mg/m^2/day continuously for 7 days [2nd induction: 5 days]+daunorubicin 60 mg/m^2 on Days 1-3 [2nd induction: Days 1-2]). Responders could receive up to 2 consolidation cycles. The study's primary endpoint was overall survival; secondary endpoints included remission rate, duration of remission, and event-free survival. The NNT to prevent 1 death at 2 years with CPX-351 *versus* 7+3 was calculated as the reciprocal of the absolute risk reduction (1/ARR), where ARR equaled the control (conventional 7+3) death rate minus experimental (CPX-351) death rate.
Results: A total of 153 and 156 patients were randomized to receive CPX-351 and 7+3, respectively. Patient characteristics were generally balanced between cohorts; median age was 67.8 (range: 4.2) in the CPX-351 arm and 67.7 (range: 4.1) in the 7+3 arm. Median overall survival was 9.56 months in the CPX-351 arm and 5.95 months in the 7+3 arm (hazard ratio=0.69 [95% CI, 0.52-0.90]; 1-sided *P*=0.003). By 2 years, 84% of patients in the 7+3 arm had died *versus* 67% in the CPX-351 arm, for an NNT of 6 (1/(0.84 – 0.67)). Thus, on average, for every 6 patients treated with CPX-351, 1 death would be prevented over 2 years compared with 7+3. The safety profile of CPX-351 in this study was consistent with the known profile of conventional 7+3. The most common grade ≥3 adverse events in the CPX-351 and 7+3 arms were febrile neutropenia (68% *vs* 71%), pneumonia (20% *vs* 15%) and hypoxia (13% *vs* 15%).
Summary and Conclusions: In this randomized, phase 3 study, CPX-351 prolonged overall survival *versus* 7+3. Based on this survival benefit, the NNT to prevent 1 death at 2 years with CPX-351 *versus* 7+3 was 6 patients. The safety profile of CPX-351 was comparable to that of the conventional cytarabine/daunorubicin 7+3 regimen. These data support the treatment benefit of CPX-351 in adults with newly diagnosed tAML or AML-MRC.

PF687

QUALITY OF LIFE IN NEWLY DIAGNOSED AND RELAPSED DANISH MULTIPLE MYELOMA PATIENTS - A NATIONAL LONGITUDINAL STUDY OF DANISH MYELOMA STUDY GROUP

L.K. Nielsen[1,2,*], M. Jarden[3], C.L. Andersen[4], H. Frederiksen[1,2], H. Gregersen[5], A. Klostergaard[6], M.S. Steffensen[7], P.T. Pedersen[8], B. Broch[9], M. Frederiksen[10], B.A. Jensen[4], C. Helleberg[11], A.K. Mylin[3], N. Abildgaard[1,2]

[1]*Quality of Life Research Centre, Department of Haematology, Odense University Hospital,* [2]*Odense Patient data Explorative Network, Odense University Hospital, Odense,* [3]*Department of Haematology, Copenhagen University Hospital, Copenhagen,* [4]*Department of Haematology, Zealand University Hospital, Roskilde,* [5]*Department of Haematology, Aalborg University Hospital, Aalborg,* [6]*Department of Haematology, Aarhus University Hospital, Aarhus,* [7]*Department of Haematology, Regional Hospital West Jutland, Holstebro,* [8]*Department of Haematology, South West Jutland Hospital, Esbjerg,* [9]*Department of Haematology, Vejle Hospital, Vejle,* [10]*Department of Haematology, Hospital of Southern Jutland, Aabenraa,* [11]*Department of Haematology, Herlev Hospital, Herlev, Denmark*

Background: Multiple myeloma (MM) patients experience many symptoms and consequently report reduced health-related quality of life (QoL) compared to patients with other haematological malignancies or solid cancers. The prognosis of MM has improved markedly due to the introduction of new and more effective, but also potentially toxic therapies. The study, "Quality of life in Danish multiple myeloma patients" (QoL MM study) was initiated in late 2016 to investigate QoL in MM patients from diagnosis to late, advanced disease and throughout different treatments. With inclusion of the general population of MM patients the study offers "real world

data" on QoL in MM patients. This is the first analysis of data from the ongoing QoL MM study.
Aims: To compare QoL between patients with treatment-demanding relapsed or progressive MM (RMM) and patients with newly diagnosed, symptomatic MM (NDMM).
Methods: The QoL MM study is a prospective, national and observational study with additional retrospective data collection from Danish nationwide registers. All haematological departments in Denmark participate in the study. NDMM and RMM patients are eligible for study entry at the time of symptomatic or treatment demanding myeloma. Exclusion criteria are inability to understand the Danish language, or a mental or psychiatric disorder that prevents the patient from completing a questionnaire. Four validated QoL instruments: the European Organisation For Research And Treatment Of Cancer Quality Of Life Questionnaire (QLQ-C30), the Multiple Myeloma module (MY20), the Chemotherapy-Induced peripheral neuropathy questionnaire (CIPN20), and the Short-form health survey version 2-4-week recall (SF12v2) are used, starting at baseline prior to initiated therapy followed by every 4 weeks for 6 months and hereafter every 3 months until 24 months. Data on prior and initiated anti-myeloma treatments are collected from the Danish National Patient Registry. We report mean baseline score differences between the two groups adjusted for earlier identified confounding of gender, age and comorbidity. Data interpretation was based on both statistically significant and clinically relevant differences.
Results: The 1 December 2017, 239 patients had been screened and 144 patients included; 80 NDMM and 64 RMM patients. Of the NDMM patients, 21% were elderly (≥76 years) and 56% were Intermediate Fit or Frail according to the International Myeloma Working Group myeloma frailty score. 22% of the RMM patients were elderly and 31% were Intermediate Fit or Frail. 39% of the RMM patients were included at third or later relapse. For global QoL, physical, role, emotional function and future perspectives the RMM patients reported statistically significant better functioning of moderate or large clinical relevance compared to the NDMM patients. Also, for fatigue, pain, appetite loss and constipation the RMM patients reported statistically significant fewer symptoms of moderate or large clinical relevance compared to patients with NDMM. For none of the domains, the NDMM patients reported a clinical relevant better score than the RMM patients (Table 1).

Table 1.

Mean baseline scores, p-values for confounder adjusted between group comparisons and size of clinical relevant difference

Quality of life domains	NDMM Mean baseline scores (SD)	RMM Mean baseline scores (SD)	*p-value*	Clinically relevant difference
EORTC QLQ-C30				
Global quality of life	50.9 (26.9)	61.7 (19.8)	*0.006*[1]	Moderate
Physical functioning	65.2 (28.5)	76.9 (19.0)	*0.002*[1]	Moderate
Role functioning	48.1 (38.9)	66.9 (27.6)	*0.001*[1]	Large
Emotional functioning	68.0 (22.9)	81.4 (15.4)	*<0.001*[1]	Moderate
Fatigue	47.1 (30.2)	36.3 (21.8)	*0.007*	Moderate
Pain	51.7 (37.1)	30.2 (27.5)	*<0.001*	Large
Appetite loss	25.3 (30.8)	14.1 (21.3)	*0.022*[1]	Moderate
Constipation	19.4 (26.5)	9.9 (20.3)	*0.008*[1]	Moderate
EORTC QLQ-MY20				
Future Perspectives	47.8 (26.8)	62.8 (27.7)	*0.002*	Moderate

SD; standard deviation, [1]The regression analysis made is based on residuals without normal distribution.

Summary and Conclusions: RMM patients with treatment demanding disease report clinically relevant better scores than NDMM patients for nine QoL domains. The findings could be assigned to effective disease monitoring of known MM patients, but also to a psychological reaction caused by the cancer diagnosis in NDMM patients. Through the longitudinal follow-up, our study will address the impact on QoL during and after anti-myeloma treatments.

PF688

A QUALITATIVE ANALYSIS OF PSYCHOLOGICAL HEALTH MEASURES IN SURVIVORS OF PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA AFTER BEING TREATED WITH BFM-ALL PROTOCOLS

A. Iqbal[1,*], T. Kaur[2], S. Mukherjee[3], M. Bhattacharyya[1]

[1]Clinical Hematology, Institute of Haematology and Transfusion Medicine, [2]Clinical Psychology, Cankids India, [3]Clinical Hematology, NRS Medical College and Hospital, Kolkata, India

Background: Pediatric ALL is one of the curable childhood cancers. The remission rates after the intensive phase of all BFM-ALL trials approach 90% across risk categories and relapse rates are acceptable. The psychosocial consequences of successful treatment are an increasing concern as these children step into adolescence and adulthood. These concerns are amplified in countries like India because of the lack of social support groups, social stigma associated with cancer and because the treatment may also lead to significant life compromises like drop from school and vocational training.
Aims: - To analyze the psychosocial health of the participants objectively using a standard survey instrument
- To understand the social factors responsible for psychosocial illhealth in different dimensions
Methods: 104 survivors of pediatric ALL across 4 biggest centres catering to childhood cancers in Kolkata were analysed using a survey instrument called PedsQL™ generic core scale The 18 points PedsQL™ generic core measuring system encompasses 5 dimensions (general satisfaction, inclusion of family, communication, emotional needs, and academic and social attendance) as delineated to be measures of psychological health by the World Health Organisation. Each dimension had 3-4 questions and responses were recorded on a 5 point scale of 0-4. The survey was conducted by physical interview after prior appointment. The instrument was made available in English, Hindi and Bengali for participants' convenience. All the participants were documented cases of childhood ALL who had completed the entire therapy using one of the BFM protocols (BFM 90, 95 and 2002) and were treatment free for more than 5 years. The appointments and resource personnel were organised by an NGO called Cankids India.
Results: The participants were between 7 – 26 years of age. The median time from completion of therapy to participation was 7.1 years. Participants were grouped in three categories according to the age at interview: less than 10 years of age (A), 10-18yrs of age (B), and >18yrs (C). A used parent proxy report while B and C were analysed using self and parent report. In a scale of 1, the cumulative median score across all age groups was 0.70. Maximum score was found in C (0.8) followed by A (0.75), and B (0.66). Across the dimensions of psychological health, the lowest score was obtained in 'inclusion of family' in the A group and 'academics and social attendance' in B and C groups. Father's occupation, history of major treatment related comorbidities, treatment protocol violation, and absence of family support groups are found to be the main factors associated with lower scores while the specific protocol, age at treatment initiation, and use of cranial RT were not associated with adverse psychological health.
Summary and Conclusions: Psychological ill-health as a result of intensive, long duration treatment used in childhood ALL is profound, and its impact is maximum in the adolescent age group. Identification of age category specific factors is important to curb their effects and implement specific psychological and vocational measures.

PF689

COMBINED VISIBLE AND INFRA RED LOW LEVEL LASER THERAPY FOR PREVENTION OF ORAL MUCOSITIS IN PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION

F. Tabeie[1], M. Tabarraei[2,*], A. Tavakoli[2], L. Izadi[3]

[1]Nuclear medicine, [2]hematology oncology, Shahid Beheshti university of medical sciences and heath services, [3]Chemistry, Elm o sanat university, Tehran, Iran, Islamic Republic Of

Background: Oral mucositis (OM) is known to bea side effect of hematopoietic stem cell transplantation (HSCT).
Aims: The purpose of this study was to evaluate the efficacy of prophylactic combined visible and infra red low level laser therapy (LLLT) to reduce the incidence and sevierity of oral mucositis in patients undergoing hematopoietic stem cell transplantation (HSCT).
Methods: Fifty patients were randomly assigned into two LLLT and control groups. In LLLT group 25 patients received prophylactic LLLT prior to HSCT in addition to standard care for oral mucositis including administration of topical antimicrobial agents and mouth washes. LLLT were performed intraorally three times a week with a combined irradiation of 630 nm visible and 780 nm infra red laser with duration of 40 seconds for each lasers to the tongue and soft palate. The laser parameters used for each lasers were frequency of 100 Hz, power of 100 mW and an energy of 2.5 J. Patients were evaluated after the completion of HSCT for incidence and severity of oral mocositis. The control group underwent the same protocol for LLLT group, but with zerro intensity of lasers.
Results: Incidence of oral mocositis in LLLT and control groups were 25.9% and 70% respectively which was significantly lower in the LLLT group (p

= 0.003) and also mucositis scores were significantly lower in the LLLT group than in the control group (p = 0.004).
Summary and Conclusions: This study indicated that a combined protocol of visible and infra red application of LLLT can reduce the incidence and severity of oral mucositis in patients undergoing HSCT.

PF690

DETERMINANTS AND CLINICAL SIGNIFICANCE OF MUSCULOSKELETAL SYMPTOMS IN PATIENTS WITH CHRONIC GRAFT-*VERSUS*-HOST DISEASE

A. Zelic Kerep[1,2,*], F. Pirsl[1], S. Steinberg[3], S. Mitchell[4], L. Curtis[1], E. Cowen[5], D. Pichard[5], G. Joe[6], L. Comis[6], A. Im[7], A. Berger[8], L. Parsons-Wendell[1], M. Kenyon[1], J. Baruffaldi[1], S. Raja[9], J. Nashed[1], D. Pulanic[2,10,11], K. Baird[12], R. Gress[1], S. Pavletic[1]

[1]Experimental Transplantation and Immunology Branch, Center for Cancer Research (CCR), National Cancer Institute (NCI), National Institutes of Health, Bethesda, United States, [2]Division of hematology, University Hospital Zagreb, Zagreb, Croatia, [3]Biostatistics and Data Management Section, Center for Cancer Research, National Cancer Institute, [4]Outcomes Research Branch, Division of Cancer Control and Population Sciences, CCR, NCI, [5]Dermatology Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, [6]Rehabilitation Medicine Department, Clinical Center, National Institutes of Health, Bethesda, [7]Division of Hematology/Oncology, University of Pittsburgh Medica Center, Pittsburgh, [8]Department of Pain and Palliative Care, Clinical Center, [9]Center for Cancer Research, National Institutes of Health, Bethesda, United States, [10]School of Medicine, University of Zagreb, Zagreb, [11]Faculty of Medicine, University of Osijek, Osijek, Croatia, [12]Pediatric Oncology Branch, CCR, NCI, Bethesda, United States

Background: Muscle cramps, arthralgia and myalgia are common in chronic graft-*versus*-host disease (cGVHD) patients. However, the prevalence and associated factors have not been sufficiently investigated.
Aims: To determine the frequency of muscle cramps, joint and muscle aches and associated factors in cGVHD.
Methods: Data from 334 adult patients (pts) who participated in the NCI natural history study of cGVHD (NCT00092235) from 10/2004 to 5/2016 were analyzed. Five-point Lee cGVHD Symptom Scale (LSS) reported muscle cramps and joint and muscle aches was dichotomized (less symptom bother – 0,1,2; severe symptom bother – 3,4) and tested for associations with: Short Form 36 (SF36, physical (PS) and mental subscale (MS)), 2-minute walk test (2MW), grip strength, joint range of motion, and Human Activity Profile (HAP, maximum and adjusted (AAS)), clinical and laboratory data. Univariate analysis was followed by multivariable logistic regression (MLR) model identified by backward selection on a training set (n=167) and evaluated on the testing (n=167) set to determine its joint ability to predict the symptom category.
Results: In this cohort (median age 49 years, 72% severe NIH global severity - GSS), 75.4% reported joint and muscle aches (36.8% severe), 74.3% muscle cramps (33.5% severe), and 19.5% of pts reported having severe bother of both symptoms (LSS 3-4). In univariate analysis severe muscle cramps were associated with reduced SF36 PS and MS ($p<0.005$), Lee modified total score (total score reduced by the scores for muscle cramps, joint and muscle aches and muscle weakness) and a strong trend ($0.005<p<0.05$) towards association with skin sclerosis, LSS skin thickening (ST), itchy skin, limited joint movement (LJM), shortness of breath with exercise and loss of energy (LOE). MLR (Table 1) jointly identified variables as being at best, moderately predictive in both training and testing sets. Muscle cramps severity did not show associations with concomitant calcineurin inhibitor treatment, level of magnesium, use of statins and antidiabetics. In univariate analysis, severe joint and muscle aches were significantly associated ($p<0.005$) with reduced 2MW, HAP AAS, SF36 PS and MS, Karnofsky performance status, and with greater LSS for skin rash, ST, LJM, LOE, need to sleep more, depression, anxiety, difficulty in sleeping and decreased chloride. Factors jointly identified by MLR (Table 1) were reasonably predictive in both training and testing sets. There was no association with serum anti-CCP or rheumatoid factor. Muscle cramps and joint and muscle aches were not associated with NIH GSS, intensity of immunosuppression, or with the clinicians` therapeutic intent at the time of enrollment (active *vs* non-active).
Summary and Conclusions: These results show a notable burden of muscle cramps and joint and muscle aches in pts severely affected by cGVHD. Both symptoms of interest in this study did not show an association with NIH GSS, which indicates that these symptoms require special consideration when assessing disease severity and therapeutic response. A significant association with a host of potential etiological factors (calcineurin inhibitors, diabetes, serum auto-antibodies, statins) has not been identified, implying cGVHD as an etiological factor. Muscle weakness was also analyzed, however, numerous variables showed significant or a strong trend towards significance of association, likely indicating the complexity of this endpoint.

Table 1.

MUSCLE CRAMPS	JOINT AND MUSCLE ACHES
• *Limited joint movement*, **p=0.012**, OR 1.3 • *Shortness of breath with exercise* **p=0.05** OR 1.3 • *Itchy skin* **p=0.008**, OR 1.4	• *Short Form 36 Physical subscale*, **p=0.02**, OR 0.9 • *Need to avoid certain foods due to mouth pain*, **p=0.008**, OR 1.6 • *Limited joint movement*, p<0.0001, OR 3.0 • *Depression*, **p=0.01**, OR 1.6
• 50% of patients with severe muscle cramps identified in an independent set of data	• 56.9% of patient with severe aches identified in an independent set of data
• 75.9% of patients who did not have severe muscle cramps were correctly identified in independent data set	• 84.5% of patients who did not have severe aches were correctly identified in independent data set

Multivariable logistic regression results for muscle cramps and joint and muscle aches.

IMPACT OF CLINICAL AND SOCIAL FACTORS ON QUALITY OF LIFE (QOL) IN PATIENTS (PTS) WITH TRANSFUSION-DEPENDENT (TDT) AND NON-TRANSFUSION-DEPENDENT (NTDT) BETA-THALASSEMIA: A MULTICENTER STUDY

V. Viprakasit[1,*], M.D. Cappellini[2], A. Kattamis[3], P. Sutcharitchan[4], D. Mahmoud[5], J. Pariseau[5], A. Laadem[5], A. Khan[6], X.H. Hu[7], A. Taher[8]

[1]Siriraj Hospital, Mahidol University, Bangkok, Thailand, [2]Ca Granda Foundation, Ospedale Policlinico IRCCS, University of Milan, Milan, Italy, [3]Aghia Sophia Children's Hospital, Athens, Greece, [4]Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand, [5]Celgene Corporation, Summit, [6]Nathan S. Kline Institute for Psychiatric Research, Orangeburg, [7]Formerly of Celgene Corporation, Summit, United States, [8]American University of Beirut Medical Center, Beirut, Lebanon

Background: Life expectancy for pts with β-thalassemia has increased significantly in recent years. Improved survival is accompanied by considerable ongoing healthcare needs related to this chronic condition; therefore, QoL has emerged as a primary focus of comprehensive pt care.
Aims: To use data from a multicenter study to investigate the clinical and social factors that impact the difference in QoL outcomes between pts with TDT and NTDT β-thalassemia in the routine clinical care setting.
Methods: Adult pts with β-thalassemia were prospectively enrolled in an observational study from centers in Italy, Greece, Lebanon, and Thailand. All pts completed Short Form 36 Health Survey version 2 (SF-36v2) and Functional Assessment of Cancer Therapy (FACT)-Anemia (An) questionnaires at baseline, and then once every 3 weeks using a hand-held electronic device; this analysis evaluated QoL in pts with TDT and NTDT at study entry. Transfusion dependence was defined as receiving ≥6 red blood cell units in the 24 weeks prior to study entry with no transfusion-free period for ≥35 days during that time.
Results: In total, 102 pts were enrolled, of which 52 had TDT and 50 had NTDT. The mean age of pts was 31.2 years and 70 (68.6%) were female. On average, pts with TDT were 3.6 years younger (P=0.06) and had moderately higher hemoglobin levels at baseline (8.8 *vs* 8.2 g/dL; P=0.02). Of 102 pts enrolled, 65 (64%) were of White ethnicity (39 NTDT, 26 TDT) and 37 (36%) were of Asian ethnicity (11 NTDT, 26 TDT). Older pts (≥30 years) and pts with a long diagnosis history (≥25 years) had worse QoL *versus* younger pts and pts with a short diagnosis history (P <0.05). Currently married pts had better QoL (P <0.05). Pts transfused at baseline (100% of TDT pts; 10% of NTDT pts) had better QoL than non-transfused pts. Pts with NTDT reported lower QoL scores on all SF-36v2 domains and summary scores, except for Role-Physical. On average, pts with NTDT experienced lower QoL *versus* their TDT counterparts on the domains of General Health (39.5 *vs* 44.0; P=0.01), Vitality (49.3 *vs* 53.7; P=0.01), and Mental Health (46.8 *vs* 50.8; P=0.01), and in the Mental Component Summary Score (46.5 *vs* 50.8; P=0.01). Similarly, pts with NTDT reported lower FACT-An questionnaire QoL scores on all domains; statistically significant differences were observed for Emotional Well-Being (18.5 *vs* 20.0; P=0.02), Functional Well-Being (20.0 *vs* 23.2; P <0.01), and FACT-General (82.9 *vs* 89.4; P=0.01). Pts recruited by the Thai center reported higher QoL scores on the Functional Well-Being (23.11 *vs* 20.74; P <0.05) and Fatigue Scale domains (41.75 *vs* 38.27; P <0.05) compared with pts from centers in Italy, Greece, and Lebanon.

Summary and Conclusions: In the routine clinical care setting, there are critical unmet medical needs for pts with NTDT as they reported lower QoL scores compared with pts with TDT, as captured by two health questionnaires (SF-36v2 and FACT-An), across all domains except one. There is a need for new interventions to treat pts with NTDT and reduce their burden of disease. Significant differences between pt populations from different geographical locations were identified, suggesting social factors had an impact on difference in QoL between pts with TDT and NTDT. Pts from Thailand reported higher QoL scores for domains on the FACT-An questionnaire *versus* pts from centers in Italy, Greece, and Lebanon; half of the pts with TDT were from the Thai center.

PF692

RAPID AND COMPREHENSIVE GENOMIC CHARACTERIZATION OF HEMATOLOGICAL MALIGNANCIES USING A HYBRID-CAPTURE TARGETED SEQUENCING PANEL

M. Gruber[1,2,*], D. Alpar[3], G. Hoermann[4,5], N. Fortelny[1], B. Erguener[3], L. Muellauer[6], G. Greiner[4], H. Esterbauer[4], M. Schuster[3], I. Simonitsch-Klupp[6], M. Gurbisz[4], R. Kain[6], O. Wagner[4], U. Jaeger[2], C. Bock[1]

[1]CeMM Research Center for Molecular Medicine, [2]Department of Internal Medicine I, Division of Hematology and Hemostaseology, Medical University of Vienna, [3]Biomedical Sequencing Facility, CeMM Research Center for Molecular Medicine, [4]Department of Laboratory Medicine, Medical University of Vienna, Vienna, Austria, [5]MLL Munich Leukemia Laboratory, Munich, Germany, [6]Department of Pathology, Medical University of Vienna, Vienna, Austria

Background: Next-generation sequencing (NGS) fuels our knowledge of the genomic landscape of malignancies. Translating this into clinical management warrants comprehensive genomic characterization of tumor samples. To determine the disease-relevant genome of hematological malignancies, multiple assays are currently applied in parallel.
Aims: We here introduce a single hybrid-capture-based NGS workflow for the comprehensive characterization of clinically relevant alterations, comprising copy number aberrations (CNAs), insertions and deletions (InDels), structural rearrangements, single nucleotide variants (SNVs), T or B cell receptor (*TCR* and *BCR*) rearrangements and to assess *IGHV* somatic hypermutation rate.
Methods: Based on curation of literature and public databases, loci of 400 genes, 83 non-coding regions and all *BCR* and *TCR* segments were selected for customized Nextera panel design (Illumina). Fresh or FFPE-derived tumor samples from 26 patients with various hematologic malignancies and 7 reference standards (Horizon) were assessed. Libraries were prepared using Nextera Rapid Capture or an optimized TruSeq protocol and sequenced with 75bp (FFPE) or 150bp (fresh samples) paired-end protocols on HiSeq 3/4000 instruments (Illumina).
We identified SNVs and InDels by aligning sequencing reads to the reference genome, followed by somatic variant calling against a set of healthy controls. Pathogenic mutations were ranked based on low Exome Aggregation Consortium (ExAC)-frequencies in normal populations. CNAs were discovered based on genome-wide read-depth of on- and off-target reads, structural rearrangements were detected using svABA. *BCR* and *TCR* rearrangements were identified by MiXCR, followed by SPAdes for assembly of consensus sequences to determine somatic hypermutation rate using IMGT. Genomic profiles were manually curated for pathogenic relevance using database and literature research. Finally, results were compared with corresponding current diagnostic procedures
Results: Coverage of ≥100x was obtained in 98% percent of the target region, with mean target coverage of 750x-2000x across samples. Within reference standards, we detected all mutations at variant allele frequencies (VAF) of ≥2% and 93% at VAF <2%. Among patient samples, we found 71 putatively pathogenic SNVs (0-6/sample) and 42 InDels (0-4/sample). In addition, we identified 24 (0-3/sample) chromosomal and subchromosomal amplifications and deletions, confirming and extending FISH results in all samples that were provided with at least 25% tumor purity. We also found 5 (0-2/sample) large chromosomal rearrangements (*e.g. IGK-BCL2*) and 49 clonal B cell and T cell receptor rearrangements. In the latter, we identified clonal V(D)J rearrangements, and somatic hypermutation rate in the *IGHV* segment highly correlated with results of Sanger sequencing (r^2=0.9989). In summary, our panel could independently reproduce all results obtained by various conventional methods and detected numerous additional variants of potential pathogenic or therapeutic relevance (Figure 1).
Summary and Conclusions: We introduce a NGS-based assay for highly comprehensive and versatile characterization of hematological patient samples. For all specimens with ≥25% tumor cell purity and appropriate DNA quality, we were able to obtain detailed genomic profiles including somatic SNVs, CNAs, clonality assessment and *IGHV* mutation rate. Our panel therefore represents a powerful tool to facilitate an efficient and streamlined patient stratification with the goal to improve personalized treatment strategies.

PF693

UNTANGLING HOSPITALIZATIONS IN SYSTEMIC AMYLOIDOSIS: PATIENT CHARACTERISTICS, ECONOMIC COST AND CLINICAL OUTCOMES

T.P. Quock[1,*], T. Yan [2], R. Tieu[2], A. D'Souza[3], M. Broder[2]

[1]Prothena Biosciences Inc, South San Francisco, [2]Partnership for Health Analytic Research, LLC, Beverly Hills, [3]Medical College of Wisconsin, Milwaukee, United States

Background: The amyloidoses are a group of rare protein-folding disorders characterized by extracellular tissue deposition of misfolded and aggregated autologous proteins as ß-pleated sheet fibrils. Although many organs can be affected, the heart is frequently involved in two forms of systemic amyloidosis: light chain (AL) and transthyretin (ATTR) amyloidosis. Patients with systemic amyloidosis frequently require hospital care.
Aims: To understand patient characteristics, healthcare resource utilization, costs, and clinical outcomes associated with systemic amyloidosis treated in US hospitals.
Methods: This retrospective analysis used 2014-2016 data from the Premier Perspective® Database. The study population comprised of hospitalized patients aged ≥18 years with ≥1 inpatient claim consistent with systemic amyloidosis [International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) codes: 277.30, 277.39; International Classification of Diseases, 10th Revision, Clinical Modification (ICD-10-CM) codes: E85.4x, E85.8x, E85.9x] in any diagnosis field; the first qualifying hospitalization was included. Patients with evidence of other types of amyloidosis (ICD-9-CM codes: 277.31; ICD-10-CM codes: E85.0x-E85.3x) or chronic inflammatory diseases that may lead to other types of amyloidosis were excluded. Study outcomes included hospitalization costs (in 2016 USD), length of stay (LOS), intensive care unit (ICU) use, and mortality.
Results: 7,533 patients were admitted to the hospital with a diagnosis consistent with systemic amyloidosis; mean (SD) age was 72.8 (11.7) years, 46.3% were female, 68.0% were White, and 78.0% had Medicare. The mean (SD) Charlson Comorbidity Index was 3.2 (2.1), and 59.5% of patients had either, or both, cardiac involvement or renal disease. Among patients with cardiac involvement, 74.6% had congestive heart failure. For all amyloidosis-related admissions, the mean (SD) total hospitalization cost was $18,110.70 (25,245.78) and mean (SD) LOS was 7.4 (9.9) days. 90.1% of patients had urgent/emergent admission. During the hospital stay, 30.7% of patients were admitted to the ICU, with a mean (SD) ICU LOS of 4.1 (5.4) days. In-hospital mortality was 6.7%.
Summary and Conclusions: Disease burden and hospital costs associated with AL or ATTR amyloidosis are high. Based on hospital discharge records, almost 60% of the patients had cardiac and/or renal disease. Mean hospitalization costs were >$18,000 per patient and many patients were admitted to ICU. New therapies aimed at improving organ response have the potential to reduce disease burden and to yield substantial cost savings.

PF694

ERECTILE DISFUNCTION IN HEMATOLOGICAL MALIGNANCIES

F. Krstanoska[1,*]

[1]General Hospital Slovenj Gradec, Slovenj Gradec, Slovenia

Background: Erectile disfunction (ED) is a sexual disfunction, usually in men over forty years old. It is defined as a disability to get an erection enough hard for penetration and to sustain that erection until the the end of intercourse, it is present in most of the cases in last 6 months and make the individual stress and unsatisfaction. Erectile disfunction can be primary (from the beginig of sexual life) or secondary (become later after normal sexual activity).

Aims: The aim of the study in 2016 - 2017 is to find prevalence and severity of erectile disfunction in male patients with hematology malignancy diseases: chronic lymfocytic leukemia, multiple myeloma and myeloproliferative neoplasm at diagnosis and after 1 year of treatment. Patients were classified into three groups based on diagnosis, the WHO performance status, hemoglobin level, renal function, present or absent another vascular disease (cerebral stroke, peripheral occlusive disease, coronary disease and diabetes mellitus).
Methods: All the patients answered at diagnosis questionary 5 item version of the International index of erectile function IIEF- 5 with specificity 0,88 and sensitivity 0,97. After one year of therapy, survivors answered the same 5 questions, each of them has 0 - 5 point and max 25 points. The score depends on severity of erectile disfunction and classified like severe ED 1-7points, moderate 8- 11, mild to moderate 12 -16, mild 17 - 21, normal erectile function 22 - 25 points. The study includes 60 male patients, 20 with chronic lymphatic leukemia, 20 with multiple myeloma and 20 with myeloproliferative neoplasm.
Results: At the diagnosis in group with CLL the average age was 75 years old, 55% of patients had severe ED, moderate 35% and 10% had mild ED. After one year of treatment the results were - 3 patients died, 70% had severe ED and 30% patients had moderate ED. In patients with multiple myeloma at diagnosis the average age of men was 55 years old, the results were: severe ED 30%; mild ED 45%, mild 20%, no ED 5%. After one year patients had: severe ED 50% , moderate 40%, mild 10%.Group of myeloproliferative neoplasm included patients with chronic myeloid leukemia and policitemia rubra vera, average age 65 y, the prevalence at diagnosis: severe ED 70%, moderate 20%, mild 10%.After one year 5 patients died, the others had: severe ED 50%, moderate 20%, mild 30%
Summary and Conclusions: In our patients with hematological malignancy at diagnosis only one patient had not erectile disfunction. After therapy for one year the number of patients with ED raised, only in group with myeloproliferative diseases due to chemotherapeutic agens an supportive care declines severe ED from 70 to 50%,in this group 5 patients died in that group become smaller for 25%. In the group with MM 70% patients after chemotherapy and autologous stem cell transpltion were in complete remission, still after one year the severe ED was found in 70% of them. The possible reason for erectile disfunction in hematological malignancy are: chemoimunotherapy, anemia, renal disease, fatigue, psychological stress, depression, isolation and absence of or fear of partner after the confirmation of malignant disease.

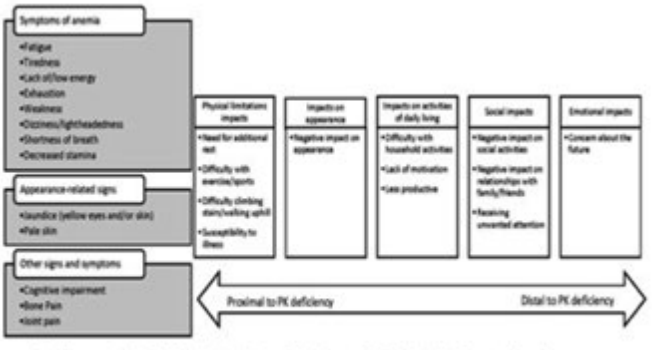
PF695

THE BURDEN OF DISEASE IN PYRUVATE KINASE DEFICIENCY: PATIENTS' PERCEPTION OF THE IMPACT ON HEALTH-RELATED QUALITY OF LIFE

S. Salek[1,*], J. Cohen[2], S. Egan[3], T. Wells[4], B. Witherspoon[4], A. Ryan[4], S. Bodie[5], R. Klaassen[6], R. Grace[7]

[1]School of Life and Medical Sciences, University of Hertfordshire, Hatfield, United Kingdom, [2]Patient Advocate, Wrentham, [3]Endpoint Outcomes, Long Beach, [4]Endpoint Outcomes, Boston, [5]Agios Pharmaceuticals, Inc., Cambridge, United States, [6]Division of Hematology/Oncology, Children's Hospital of Eastern Ontario, Ottawa, Canada, [7]Pediatric Hematology/Oncology, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, United States

Background: Pyruvate kinase (PK) deficiency is a rare hemolytic anemia caused by mutations in the *PKLR* gene. Though the clinical features of PK deficiency in individual patients can vary substantially, common signs and symptoms may include: fatigue, dyspnea, jaundice, and splenomegaly. Due to the rarity of PK deficiency, an understanding of its burden on patients' lives remains limited and there is no published research that describes the overall experience of living with PK deficiency.
Aims: The aim of this qualitative study was to explore how signs and symptoms of PK deficiency impact adult patients' health-related quality of life (HRQoL).
Methods: Interviews were conducted with twenty-one adults with PK deficiency and symptomatic anemia in the United States, the Netherlands, and Germany. All transcripts were coded using processes guided by established qualitative research methods, including grounded theory and constant comparison method. Conceptual saturation was achieved for nearly all concepts.
Results: Participants were a mean age of 38.9 (19-58), 52% female, and 86% splenectomized. The most common signs and symptoms reported were yellow eyes (90.5%), tiredness (85.7%), yellow skin (81.0%), fatigue (71.4%), low energy (61.9%), and shortness of breath (61.9%). Fifty-nine impacts of PK deficiency were reported and divided into nine major themes: physical, appearance, social, emotional, activities of daily living (ADL), leisure activities, work (or school), sleep, and cognitive deficit. The most commonly reported impacts were a need for additional rest (85.7%), difficulty with exercise or sports (76.2%), susceptibility to illness (66.7%), negative impact on appearance (61.9%) receiving unwanted attention (57.1%), and negative impact on social activities (52.4%). A conceptual model was developed to demonstrate the profound impact that signs and symptoms of PK deficiency have on dimensions of patients' HRQoL (Figure 1).



Conceptual model for pyruvate kinase (PK) deficiency showing impacts found to be most directly related (proximal) to a participants' symptom experience.

Figure 1.

Summary and Conclusions: This is the first study that provides patient perspective on the burden of living with PK deficiency. The development of tools to capture patient-report of signs and symptoms of PK deficiency and their impact on HRQoL will lead to greater appreciation of the challenges that living with PK deficiency presents, and allow examination of the effects of future treatments and pharmacologic interventions on HRQoL of patients with PK deficiency.

PF696

RELEVANT REDUCTION OF POMALIDOMIDE-RELATED NEUTROPENIA BY INTENSIVE USE OF MYELOID GROWTH FACTOR

M.S. Parisi[1,*], V. Calafiore[1], E. Martino[1], V. Del Fabro[1], A. Romano[1], G. Sapienza[1], C. Conticello[1], F. Di Raimondo[1]

[1]hHmatology, Policlinico Universitario, Catania, Italy

Background: Neutropenia and complications of neutropenia such as febrile neutropenia (FN) or pneumonia, are one of major hematological toxicity associated with cancer chemotherapy. It often results in drug dose reduction or delay or interruption, thus leading to morbidity, mortality, and high costs of patient management. Granulocyte colony-stimulating factor (G-CSF) is a myeloid growth factor able to reduce the risk of neutropenia and its complications, enabling safe and effective chemotherapy dose intensity. Hematological and not hematological toxicity of immunomodulatory drug pomalidomide has been studied in association with dexamethasone particularly in three main clinical trials (MM02, MM03 and MM10) in relapsed refractory multiple myeloma (RRMM) patients. The most frequent hematological adverse event of grade 3/4 is neutropenia (between 48% and 50%), followed by anemia (22% to 32%) and thrombocytopenia (between 19 and 31%). Among non-hematological grade 3/4 adverse events pulmonary infections have an incidence between 10% and 20%. In the same clinical trials the frequency of dose reduction was about 30% and treatment was temporary interrupted in about 60%, of patients, while it was definitively interrupted in about 5% (3-6%) of patients.
Aims: In order to limit Pomalidomide and Dexametasone (PomaD) reduction and/or interruption and prevent neutropenia-related adverse events we tried to use G-CSF prophylaxis in our RRMM patients.

Methods: Here we describe the analysis of a total of 51 RRMM patients treated with PomaD. G-CSF was used (mean dose 60 MU) one week after starting pomalidomide therapy when leukocyte counts were ≤2.5· 109/L and neutrophils ≤1.5· 109/L. Median age was 68 years (range 42-78), median number of prior therapies was 4 (range 2-7) and the majority of patient (33/51) were treated for almost 6 cycles (overall treatment duration mean 7.7 months). We decided to maintain a >2.0· 109/L leukocyte count with ANC >1.5· 109/L in attempt to reduce the incidence of neutropenia and its complications.
Results: In our cohort of patients, hematological adverse events occurred at a reduced rate. In particular, neutropenia was present only in 9% of cases, anemia in 5,5% of cases and thrombocytopenia in 3,5% of cases. Reduced frequency of neutropenia among our patients should be attributable to the use of prophylaxis with G-CSF one week after starting of PomaD in that patients with leukocyte counts ≤2.5· 109/L and ANC ≤1.0· 109/L. In this way, we maintained for almost 6 cycles a median of >3.5· 109 leukocyte count (mean 4· 109/L) with a median of neutrophils >1.5 · 109/L (mean 2· 109/L). Table 1 describes mean and median of leukocyte count and ANC for every cycle till the sixth in 33/51 RRMM patients that were treated for almost six cycles with PomaD. We also obtain a significant reduction of the incidence of FN, present only in 11% of patients. In addition, in this setting of prophylaxed patients, the dose of pomalidomide was reduced only in 12.5% and temporary interrupted in less than 20%.

Table 1.

	pre-treatment	I cycle	II cycle	III cycle	IV cycle	V cycle	VI cycle	Total
Median of leukocyte count· 10^9/L	3,76	3,94	4,04	4,1	4	4,28	4,12	4,04
Median of ANC · 10^9/L	2,04	1,95	1,62	1,86	1,91	1,79	1,71	1,86
Mean of leukocyte count · 10^9/L	4,11	4,26	4,07	4,17	4,26	4,23	4,02	4,16
Mean of ANC· 10^9/L	2,42	2,46	1,79	2,04	2,06	2,03	1,86	2,09

Summary and Conclusions: Our data suggest that intensification of G-CSF prophylaxis in RRMM patients during PomaD therapy can reduce frequency of serious adverse events and enable full dosage of pomalidomide with limited reduction or interruption of this drug.

REAL WORLD EVIDENCE BASED COST-EFFECTIVENESS ANALYSES (CEA) OF NILOTINIB *VERSUS* IMATINIB AS FIRST-LINE TREATMENT IN THE MANAGEMENT OF CHRONIC MYELOID LEUKEMIA (CML) IN CHINA

H. Zhu[1], S. Chen[2], J. Xuan[3], J. Wu[4], Y. Zhang[5], Y. Song[5,*], J. Luo[6], J. Tan[2], C. Liu[7], S. Qu[8], T. Xiong[8], J. Ming[8]

[1]West China Hospital of Sichuan University, Chengdu, [2]The First Affiliated Hospital of Soochow University, Suzhou, [3]Sun-Yat-Sen University, Guangzhou, [4]Tianjin University, Tianjin, [5]Henan Cancer Hospital, Zhengzhou, [6]The Second Hospital of Hebei Medical University, Shijiazhuang, [7]Novartis Pharmaceuticals (China) Oncology, Beijing, [8]IQVIA, Shanghai, China

Background: Nilotinib (NIL) is the only second-generation TKI recommended in Chinese guidelines for first-line treatment of CML-CP [1]. Discontinuation of TKI therapy (treatment-free remission [TFR]) in CML-CP patients with a sustained deep molecular response is a treatment goal that is recommended in the Chinese guidelines [1]. TFR is an approved indication for NIL based on two registration studies (ENESTop: NCT01698905; ENESTfreedom: NCT01784068) demonstrating a favourable risk-benefit ratio for this approach.
Aims: The aim of this study was to understand the impact of TFR on clinical outcomes and costs using a CEA model comparing NIL and IM as first-line treatments. This has not been previously evaluated in China.
Methods: Real world clinical and cost data were obtained from top-tier hospitals in China. A Markov model based on a previously published structure [2] was applied to simulate and evaluate the long term clinical and economic outcomes associated with different CML treatments (NIL or IM). Treatment discontinuation was modelled on the ELN (2013) and Chinese guidelines (2016), and time to first $MR^{4.5}$and sustained first $MR^{4.5}$were based on the results of ENESTnd (NCT00471497). TFR data were extracted from ENESTfreedom, and the frequency of molecular monitoring was based on the FDA approved recommendations.
Results: The incremental cost-effectiveness ratio (ICER) was dominant for TAS. The cost-savings were primarily driven by reduced drug cost associated with NIL first line TFR, and more patients in the NIL arm remaining on first line treatment, which was less costly than the second line treatment (*i.e.*, dasatinib). A sensitivity analysis was conducted varying key model assumptions (*e.g.* treatment benefits and costs), nonetheless NIL remained dominant.
Summary and Conclusions: The RWE and CEA support that first line NIL use can result in greater opportunity for patients to be eligible for TFR, reduced treatment costs and is a cost-effective option for patients when TFR is considered.

LIVING AND COPING WITH CHRONIC LYMPHOCYTIC LEUKEMIA: A QUALITATIVE STUDY OF GREEK PATIENTS' EXPERIENCES ON BEHALF OF ERIC, THE EUROPEAN RESEARCH INITIATIVE ON CLL

C. Karamanidou[1], A. Xochelli[1,*], P. Ghia[2], P. Panayiotidis[3], K. Stamatopoulos[1]

[1]Institute of Applied Biosciences, CERTH, Thessaloniki, Greece, [2]Division of Experimental Oncology, IRCCS San Raffaele Scientific Institute and Università Vita-Salute San Raffaele, Milan, Italy, [3]First Department of Propaedeutic Medicine, University of Athens, Athens, Greece

Background: Chronic illnesses require complex management that includes patients' active participation and engagement in care. Chronic lymphocytic leukemia (CLL) is a paradigmatic chronic hematologic malignancy whose management and nature are hard for both patients to understand and physicians to explain. Therefore, understanding CLL patients' perspective is an essential first step towards communicating effectively, responding to needs and promoting active engagement in care thus enhancing quality of life (QoL).
Aims: To explore the illness experience of Greek CLL patients within the context of ERIC's CLL patient empowerment program.
Methods: An in-depth qualitative study with semi-structured interviews was conducted with CLL patients from all over Greece (n=30; both treated and untreated). Data collection was considered as complete by the investigators when saturation was reached *i.e.* no new themes emerged. Interpretative Phenomenological Analysis (IPA) was performed separately by a health psychologist and a hematologist with a 98% inter-rater reliability score. IPA looks for patterns of convergence and divergence across cases. Main themes are generated from all participants' accounts but an idiographic approach is maintained so that individual variations within a theme are not lost.
Results: Seven main themes emerged from the participants' accounts. (i) *Diagnosis*: The announcement of the word leukemia and its association with an aggressive disease cause patients concern, insecurity, depression, anxiety as well as worry for loved ones. (ii) The *illness*: Most patients consider themselves fortunate to be diagnosed with 'the good leukemia'. However, CLL still causes uncertainty in patients who are baffled by the lack of symptoms and anxious about the efficacy, availability and cost of therapy. (iii) *Causes:* Patients attribute their illness to environmental factors *e.g.* exposure to chemicals; lifestyle factors *e.g.* consumption of certain foods; but also emotional factors like sadness or stress after negative life experiences. (iv) *Life with CLL:* Changes are experienced by patients on a social, professional, emotional and personal level. Most view their illness experience as an important life lesson and hold a positive outlook on life. (v) *Relationship with physician:* Patients clearly appreciate their physician, whom they regard as "a friend", "a family member" and sometimes referred to him/her as "god". They emphasize the need for a holistic approach including practical and emotional support, empathy, truth, trust, and equality (vi) *Coping and self-management:* Patients use a spectrum of strategies to cope with their illness and manage their emotions. These include active coping strategies such as information seeking, lifestyle changes, creative hobbies or volunteering; also, emotion-focused coping strategies such as humor, acceptance, positive thinking, social support etc. (vii) *Past and current needs:* A variety of elements mentioned would have helped patients

throughout the course of the illness namely, reliable information regarding the disease and treatment, peer contact, experience exchange, psychological support and emergency preparedness.
Summary and Conclusions: This study's findings have captured an insider's perspective into the CLL illness experience and identified patient needs throughout the illness course. More studies are ongoing within ERIC at an international level so as to identify CLL patient needs in different healthcare contexts that will guide and inform the design of CLL specific patient empowerment programs.

PF699

COMPARISON OF THE PAPER-BASED AND ELECTRONIC VERSION OF A NEW PATIENT-REPORTED OUTCOME MEASURE IN HAEMATOLOGICAL MALIGNANCY FOR USE IN CLINICAL PRACTICE, HM-PRO: AN EQUIVALENCE STUDY

P. Goswami[1,*], T. Ionova[2], E. Oliva[3], M. Salek[1]

[1]Life and Medical Sciences, University Of Hertfordshire, Hatfield, United Kingdom, [2]University Clinic, St.Petersburg State University and Multinational Centre for Quality of Life Research, St Petersburg, Russian Federation, [3]Haematology Unit, Grande Ospedale Metropolitano, Reggio Calabria, Italy

Background: The use of quality of life (QoL) information in patients with haematological malignancies (HM) in routine clinical practice is of value to evaluate risks/benefits of treatment, capture unmet patient's needs, and facilitate physician-patient communication. The new developed HM-PRO is a specific instrument for such use. It is undergoing assessment to meet the minimum standards set out by the FDA for PRO instruments. The use of an electronic patient-reported outcome version not only provides a quick and mostly reliable assessment of QoL but also would enhance the integrity and accuracy of data and is also incited by regulatory authorities.
Aims: To assess the equivalence between paper-based & electronic application of the newly developed HM-PRO.
Methods: Following ISPOR ePRO Guidelines, patients diagnosed with different HM at different stages of disease or treatments were recruited from inpatient/outpatients setting of 7 secondary care hospitals in the UK. The paper-based and electronic versions of the HM-PRO were completed with a 30-minute interval to minimise crossover effect. Relevant treatment & demographic data were collected. Instrument version and order effects were tested on total score of the two parts (Part A: Quality of life & Part B: Signs & symptoms) of HM-PRO in a 2-way ANOVA with patients as random effects. Intra-class correlation coefficients (ICC, 95% CI) and Spearman's rank correlation coefficients were used to evaluate test-retest reliability and reproducibility. 10 patients were randomly selected for cognitive interviewing and content analysis of transcribed interviews was carried out qualitatively.
Results: 193 patients with different HM (ALL-12; AML-28; CLL-17; CML-13; MM-33; INHL-16; ANHL-22; HL-14; MDS-15; and MPN- 23), and median time since diagnosis of 1.7 years (IQR 0.002-25.8) were recruited into the study (Table 1).

Table 1.

Demographic characteristics (n=193), HM-PRO scores, test-retest reliability and reproducibility

Characteristic			Median	IQR
Age (Years)			66.5	17.9-89.1
Time since diagnosis (years)			1.7	0.002 – 25.8
			n	%
Sex		Male	118	61.5
		Female	72	37.5
Inpatient/outpatient		Inpatients	13	6.8
		Outpatient	180	93.8

Domain/Scale (no. Of Items)	Paper mean score (SD)	IQR	Electronic mean score (SD)	IQR	Mean Difference	$r(r_s)$	ICC (95% CI)	P Value*
Physical Well-being (7)	4.80 (3.7)	2-8	4.94 (3.7)	2-8	0.14	0.95 [0.95]	0.97 [0.97-0.98]	0.17
Social Well-being (3)	1.48 (1.6)	0-2	1.50 (1.6)	0-3	0.02	0.88 [0.88]	0.94 [0.92-0.96]	0.45
Emotional Behaviour (11)	8.08 (4.9)	4-11	8.19 (5.0)	4-12	0.10	0.95 [0.95]	0.98 [0.97-0.98]	0.40
Eating & Drinking (2)	1.42 (1.3)	0-2	1.41 (1.4)	0-2	0.02	0.92 [0.93]	0.96 [0.95-0.97]	0.52
Part A (QoL) (23)	15.61 (9.6)	7.5-23	15.89 (9.6)	8-23	0.28	0.97[0.97]	0.98 [0.98 -0.99]	0.07
Part B (Signs and Symptoms) (17)	7.49 (5.2)	4-10	7.64 (5.2)	4-10	0.15	0.96 [0.96]	0.98 [0.97-0.98]	0.22

a – Wilcoxon signed rank test
r – Pearson's correlation coefficient
r_s – Spearman's rank correlation coefficient

A total of 192 cases were used to assess effects of the type of the questionnaire and the order of the administration. No interactions between the type of questionnaire and administration were found for both Part A (*P=0.95*) and Part B *P=0.72*) respectively. Similarly, there was no effect of the type of the questionnaire Part A *(P=0.76*)& Part B (*P=0.78*) and of the order of administration, Part A (*P=0.75*) and Part B (*P=0.058*). The reliability indices (Table 1) were in the acceptable range, with Spearman's correlations greater than 0.9, and ICC ranging from 0.94 to 0.98. The Wilcoxon signs rank test for paired samples showed that the mean scores for each domain and the scale were not statistically different, even without Bonferroni correction for multiple testing. With respect to cognitive interviews, all the 10 patients were able to understand the items in the way they were intended and were able to respond to both electronic and paper version of the instrument spontaneously and without any difficulty.The difference between the completion time for paper (6.4 min) and electronic (7.3 min) versions of the instrument was not statistically significant (P=0.11).
Summary and Conclusions: There were no significant differences between Part-A & Part-B scores of the HM-PRO for paper-based and electronic application. Also, instrument version and administration order effects were not significant. The electronic application possesses good reliability & face validity with minor modifications to its format compared to the original paper-based version.

PF700

A SEER-MEDICARE ANALYSIS OF NOVEL TREATMENT USE AND ASSOCIATED OUTCOMES AMONG AFRICAN AMERICAN PATIENTS WITH MULTIPLE MYELOMA

S. Ailawadhi[1,*], Z. Clancy[2], Z.-Y. Zhou[3], W. Tang[3], C. Cheung[3], Z. Zhou[3], J. Xie[3], K. Parikh[2]

[1]Mayo Clinic Florida, Jacksonville, [2]Celgene Corporation, Summit, [3]Analysis Group, Inc., Boston, United States

Background: Multiple myeloma (MM) is the most common blood cancer among African Americans (AA). Recent advances in novel therapies and autologous stem cell transplants have increased treatment options for patients with MM and improved overall survival (OS).
Aims: To compare clinical and economic outcomes in AA patients with newly diagnosed MM who received novel *vs* non-novel agents as first-line treatment for MM.
Methods: Patients with MM in the Surveillance, Epidemiology, and End Results (SEER)–Medicare database, which links the Medicare claims database and the National Cancer Institute's SEER database at the patient level, from 2007 to 2013 were included. Continuous Medicare enrollment for 6 months before (baseline) and after the date of first-line treatment initiation (index date) was required, except in the case of patient death. Recipients of novel agents (eg, lenalidomide, pomalidomide, bortezomib, or carfilzomib) and non-novel agents were identified based on the first-line treatment patients received. OS, myeloma-specific survival (MSS), and healthcare costs were compared between AA patients who received novel agents and AA patients who received non-novel agents. Multivariable regression models were used to control for baseline characteristics. Among AA patients who received novel agents, outcomes were further compared between those who received lenalidomide plus a steroid agent (Rd) *vs* bortezomib plus a steroid agent (Vd) as first-line treatment. Steroid agents included dexamethasone and prednisone.
Results: Among the 657 AA patients included, 398 (61%) received novel agents as first-line treatment. This proportion was significantly lower compared with Caucasian patients (66%; P=.02). AA patients who received novel agents were significantly younger than those who received non-novel agents (mean, 70 *vs* 73 years; P <.001). Both median OS (3.1 *vs* 1.8 years; P <.001) and MSS (not reached *vs* 4.8 years; P <.01) were significantly longer in AA patients who received novel agents than in those who received non-novel agents. After adjusting for baseline characteristics, the risk of all-cause death remained lower in the group of AA patients who received novel agents (adjusted hazard ratio [HR]=0.77; P=.01). AA patients who received non-novel agents had numerically higher monthly medical costs than did those who received novel agents (adjusted mean difference, $951), which were driven by significantly higher inpatient ($2571) and emergency room ($38) costs (both P <.05). Total healthcare costs (medical plus pharmacy) were comparable between the 2 cohorts. Among AA patients receiving novel agents, 102 (26%) and 147 (37%) received first-line treatment with Rd and Vd, respectively. Duration of treatment (DOT) was longer with Rd than with Vd (median, 4.6 *vs* 4.0 months; adjusted HR=0.72; P=.04). A trend of longer time to next-line treatment initiation or death (a proxy of progression-free survival) was observed among those who received Rd (median, 17.6 *vs* 12.1 months; P=.06).
Summary and Conclusions: AA patients with MM who received novel

agents as first-line treatment for MM had significantly longer OS and MSS than did AA patients who received non-novel agents. Among AA patients who received novel agents, the use of Rd as first-line treatment was associated with longer DOT. There was also a trend toward longer time to next-line treatment initiation or death with first-line Rd *vs* Vd. These results suggest that increasing the use of regimens with novel agents, particularly Rd, may improve outcomes among AA patients with MM.

PF701

USE OF PATIENT-CENTRED OUTCOMES IN THE MANAGEMENT OF ANEMIA: A SYSTEMATIC REVIEW

P. Staibano[1,2,*], I. Perelman[2,3], J. Lombardi[12], A. Davis[4], A. Tinmouth[2,4], M. Carrier[2,4], C. Stevenson[2], E. Saidenberg[2,4]

[1]Faculty of Medicine, [2]Ottawa Hospital Research Institute, [3]School of Epidemiology and Public Health, University of Ottawa, [4]The Ottawa Hospital, Ottawa, Canada

Background: Patient-centred outcomes (PCOs) evaluate the impact of disease on patient wellbeing and are critical for managing chronic disease and understanding the impact of medical therapies from a patient perspective. Anemia is a common consequence of many acute and chronic illnesses. Therapies for anemia, including iron supplementation, erythropoietin-stimulating agents (ESAs), and transfusion, improve hematological parameters and survival. The efficacy of anemia therapies has been widely studied, however the impact of anemia and its management on PCOs remains largely unknown.
Aims: To characterize and assess the literature addressing the usage of PCOs to investigate the effect of anemia management on PCOs in patients with various underlying medical conditions.
Methods: We conducted a search of the PUBMED, EMBASE, PsychInfo, and CINAHL databases for studies published until January 2017. Eligibility criteria included full-text observational cohorts, case series (N >10), and clinical trials published in English. Inclusion criteria were any studies with patients with anemia who were undergoing any treatment for anemia, and measured at least one PCO before and after anemia intervention. Risk of bias was assessed for all studies and all studies were reviewed by two or more independent reviewers. Descriptive statistics were employed to analyze study characteristics, PCO tool use, the quality of PCO reporting, and to assess the effect of anemia treatment on patient wellbeing from a PCO perspective.
Results: Of the 3224 articles identified in the initial search, 130 eligible articles were included in the qualitative synthesis. We report that 62% of studies were RCTs, of which 44% were open-label, and 30% were observational cohort studies. Most studies (46%) assessed anaemia in oncology patients. Other studies included renal, hematologic, cardiac, and gastrointestinal patients. Most studies (78%) investigated ESAs as the anaemia treatment, while 21% investigated either iron supplementation or transfusion. Only 25% of studies reported a PCO as a primary endpoint. A wide variety of PCO tools were used, the FACT/FACIT questionnaires being the most common tools (33%), followed by the linear analogue scale (18%), and the SF-36 (14%). Moreover, 53% of studies utilized one PCO tool, whereas 47% utilized two or more PCO tools. The quality of PCO reporting varied greatly across studies, with some presenting all PCO subscales in great detail, while other studies had incomplete or limited reporting of PCOs. Among the studies reporting hemoglobin outcomes, 68% reported an increase in patient haemoglobin levels. Of these studies, 51% also reported an improvement in PCOs. Moreover, 7% of studies did not report an improvement in haemoglobin; of these studies, 63% reported an improvement in PCOs while 38% did not.
Summary and Conclusions: Studies of PCOs in anemia have largely focused on oncology patients administered ESAs. Other anemic patient groups and other anemia treatments are less well studied from a patient-centred perspective. While the majority of studies were RCTs, a large subset was open-label, only employed a single PCO tool, and did not report PCOs as a primary endpoint. Only half the studies reported a concordant improvement in both haemoglobin levels and PCOs following anemia treatment. Future studies should standardize the use and reporting of PCOs to better understand the patient-centred impact of treatments for anemia.

PF702

COST UTILITY ANALYSIS OF THE USE OF LETERMOVIR FOR THE PROPHYLAXIS OF CYTOMEGALOVIRUS IN PATIENTS UNDERGOING ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANT – TWO SCENARIO ANALYSES FROM ITALY

F. Ciceri[1,2,*], U. Restelli[3], D. Croce[3], V. Pacelli[3], C. Girmenia[4]

[1]Hematology and BMT Unit, IRCCS San Raffaele Scientific Institute, [2]University Vita-Salute San Raffaele, Milan, [3]Center for Health Economics, Social and Health Care Management, LIUC - Università Cattaneo, Castellanza, [4]Department of Haematology, Oncology and Dermatology, Azienda Policlinico Umberto I - Sapienza University, Rome, Italy

Background: Cytomegalovirus (CMV) is a common infection that can be asymptomatic during its latency phase. Immune system dysfunctions, as hematologic malignancies and hematopoietic stem cell transplant (HSCT), solid organ transplantation, and HIV infection, can lead to CMV disease. Current standard of care for CMV infections is represented by preemptive strategy, based on antiviral treatment triggered by CMV detection in blood by different methods. Letermovir is an orphan drug recently approved by European Medicines Agency for CMV prophylaxis in adults CMV seropositive recipients (R+) undergoing allogeneic HSCT.
Aims: The analysis aimed at estimating, from the Italian National Health Service (NHS) perspective, the cost-effectiveness of the use of letermovir CMV prophylaxis in adult R+ patients receiving an allogenic HSCT, compared with a no-prophylaxis strategy assuming preemptive antiviral administration in both groups.
Methods: A cost-effectiveness decision analytic model was adapted to the Italian context in a lifetime horizon, considering costs and effectiveness (quality adjusted life years - QALYs) of two different strategies: use of letermovir prophylaxis for CMV infection followed by preemptive in patients experiencing CMV reactivation despite prophylaxis *vs* no-prophylaxis (current standard practice). The effectiveness of letermovir was based on a phase III clinical study and estimated in the model considering the incidence of clinically significant CMV infection, CMV disease, CMV-related hospitalisations, opportunistic infections, graft-*versus*-host disease (GVHD), and mortality. Utility values were derived from the results of a clinical study and refers to the mean EQ-5D index at week 14, 24 post-transplant in the two scenarios letermovir and no-letermovir arms and in the post-trial period. The direct medical costs considered (2017) are related to drugs and to the clinical events reported upon. Due to lack of cost data published in literature related to the Italian context, the cost of each event was estimated considering its management as in real clinical practice, considering the opinion of two Italian experts of two distinct stem cell transplantation programs. Both costs and QALYs were discounted at a 3% annual rate.
Results: CMV prophylaxis would lead to per capita incremental costs between 13,500 € and 14,300 €, and to per capita incremental QALYs of 0,432. The incremental cost effectiveness ratio (ICER) is between 31,400 and 33,100 €/QALY. In a hypothetical cohort of 1,000 patients, CMV prophylaxis would lead to a reduction of significant CMV infections (-240; -60.0%), of cases of CMV disease (-4.8; -66.7%), and of CMV-related hospital admissions (-45.7; -59.8%). Probabilistic sensitivity analysis showed a percentage of ICERs below a 40,000 €/QALY threshold of 61.8% and 67.2%.
Summary and Conclusions: Letermovir use is cost-effective for the Italian NHS with an ICER consistently below the threshold of 40,000 €/QALY identified by the Italian Health Economics Association. Its use for CMV prophylaxis in adults R+ patients undergoing a HSCT would represent a substantial step forward, compared with current standard of care, for patients management in terms of better outcomes.

PF703

ERN-EUROBLOODNET: THE EUROPEAN REFERENCE NETWORK IN RARE HEMATOLOGICAL DISEASES. 1ST YEAR OF IMPLEMENTATION

M.D.M. Mañú Pereira[1,*], V. Gutierrez Valle[1], M. Pellegrini[2], B. Gulbis[3], P. Fenaux[2]

[1]Josep Carreras Leukaemia Research Institute / Hôpital St. Louis, Barcelona / Paris, Spain, [2]Hôpital St. Louis, Paris, France, [3]Hôpital ERASME-CUB, LHUB-ULB, Brussels, Belgium

Background: Due to the scarcity of patients and knowledge, rare diseases, affecting less than 1 in 2000 individuals, are the area in public health in which joint efforts among European Member States is most crucial. ERN-EuroBloodNet, the ERN in Rare Hematological Diseases (RHD), results from a joint effort of the European Network on Rare and Congenital Anaemias (ENERCA), the European Hematology Association (EHA), and European hematology patient organisations represented in both the EURORDIS European Patient Advocacy Groups (ePAGS) and the EHA Patient Organisations Workgroup. ERN-EuroBloodNet gathers 66 highly skilled and multidisciplinary healthcare teams in 15 Member States. Aimed at facing the challenges of RHD, it gathers also advanced specialized medical equipment and infrastructures which will facilitate concentration of resources for the design, validation and implementation of high-quality and cost-effective services.
Aims: ERN-EuroBloodNet's main goal is to improve the healthcare and

overall quality of life of patients with a rare hematological disease: 1) Give equal access to highly specialized healthcare delivery across Europe 2) Promote the best practices in prevention, diagnosis and safe clinical care across Europe 3) Disseminate cutting-edge knowledge and facilitate continuous medical education 4) Provide inter-professional consultation by sharing of expertise and safe exchange of clinical information 5) Foster European cooperation in highly specialized procedures for diagnosis, promotion of clinical trials and innovative treatments and research.
Methods: RHD are covered in two main thematic groups: non-oncological and oncological diseases that have been divided into 4 and 2 sub-thematic areas, respectively *i.e.* 1) Rare red blood cell defects 2) Bone marrow failure (BMF) and hematopoietic disorders 3) Rare Bleeding-Coagulation disorders and related diseases and 4) Haemochromatosis and hereditary iron metabolism disorders; 1) Myeloid malignancies and 2) Lymphoid malignancies. Methods and tasks aiming to achieve ERN-EuroBloodNet specific objectives have been splitted into five categories of Transversal Field of action (TFA): 1)Cross border health 2)Best practices 3)Continuing medical education 4)Telemedicine 5)Clinical trials and research.
Results: Based on common unmet needs to all RHDs identified during the 1st year of the network, activities developed were focussed to map the existing expertise, services and facilities available for RHD across ERN-EuroBloodNet Members as starting point for network objectives deployment in the consecutive phases.
Summary and Conclusions: Based on the results, the annual programme for the second year of ERN-EuroBloodNet is structured in two main branches: a) Expanding and exploiting the dynamic European repository of ERN-EuroBloodNet members profiles, diseases covered, existing guidelines for RHD, patient registries implemented at the regional, national or EU level, on-going clinical trials and collaborative research initiatives launched in the first period of the network. b) Establishing an educational programme identifying areas requiring continuing medical education in order to contribute to solving inequalities among Member States in the delivery of best care, contributing also to the consolidation of the Clinical Patients Management System by the promotion of its use among ERN-EuroBloodNet members as the space for inter professional consultation of complex cases within the ERN.

PF704

PALLIATIVE CARE INDICATION IN NON-HODGKIN'S LYMPHOMA PATIENTS: A COMPARISON TO SOLID TUMOR PATIENTS

L. Morais[1,*], E. Fernandez[2], L. Fernandez[2], S. Garcia[2], S. Alonso-Alvarez[1], E. Colado[1], T. Bernal[1,2]

[1]Servicio de Hematología, Hospital Universitario Central de Asturias, [2]Departamento de Medicina, Universidad de Oviedo, Oviedo, Spain

Background: The prognosis of diffuse large B cell lymphoma (DLBCL) in patients who are not candidates for autologous stem cell transplant (SCT) is poor, with an expected median overall survival of 6 months. According to actual end-of-life care (EOL) standards, this population should receive early palliative care (PC) integrated with standard oncologic care when relapse is documented. Conversely, recent evidence shows an excess of aggressiveness in this population compared with the EOL care in solid neoplasms. The reasons for this difference remain to be determined.
Aims: To compare EOL care in DLBCL and stage-IV lung cancer in a tertiary care center and identify factors related to late or no PC referral.
Methods: Consecutive relapsed DLBCL not candidates for SCT and stage-IV lung cancer patients were studied. Data are shown as percentage or median (interquartilic range). Univariant comparisons of the main indicators of EOL aggressiveness between the 2 cohorts were performed using Chi-square or Wilcoxon tests as appropriate. Overall survival was calculated from the date of relapse of lymphoma and the date of lung cancer diagnosis until last follow up or death using the Kaplan-Meier method.
Results: From 1st October 2004 to 1stAugust2017, 51 patients with relapsed DLBCL not candidates to autologous SCT and 98 stage-IV lung cancer patients were recorded. Median age at diagnosis was 73 (69-76) and 63 (59-71) years respectively (p<0.001). Male sex was more frequent in lung cancer (68% *vs* 47%, p=0.02). ECOG and number of comorbidities according to the Charlson comorbidity index were similar in the two cohorts. Ninety-two percent lymphoma patients were treated with R-CHOP as first line therapy. At relapse, all but 2 lymphoma patients received chemotherapy again, with no patient included in a clinical trial. Survival for lymphoma patients was significantly lower than for lung cancer patients (8[4-13] *vs* 12[9-19] months respectively, p=0.047). Discussion between patients and physician about prognosis was documented in 8% DLBCL patients as opposed to 85% lung cancer patients (p<0.001). Patients with lymphoma spent more days in hospital as compared to lung cancer patients (23[14-49] *vs* 14[6-24] days, p<0.001). Referral to PC Unit was documented in 14% DLBCL compared to 48% lung cancer patients (p<0.0001). There were no differences in the percentage of patients receiving chemotherapy in their last 14 days of life between cohorts. More lymphoma patients were transfusion dependent in their last 2 months of life (28% *vs* 3%, p<0.0001). Lymphoma patients died more frequently in hospital compared to lung cancer patients (63% *vs* 44%) but this difference was not statistically significant (p=0.08).
Summary and Conclusions: Palliative Care is seldom prescribed in relapsed diffuse large B cell lymphoma patients. This may lead to a more aggressive, suboptimal treatment at EOL in this population. Efforts must be made to improve the process of information between patient and physician and to avoid unavailing hospitalizations.

PF705

EVALUATING THE CORRELATION BETWEEN FATIGUE AND QUALITY OF LIFE IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES AND TREATED WITH BIOSIMILAR EPOETIN ALFA FOR CHEMOTHERAPY-INDUCED ANEMIA: THE CIROCO STUDY

K. Laribi[1,*], P. Rodon[2], E. Kfoury[3], M. Hacini[4], R.-F. Soumoudronga[5], S. Choquet[6]

[1]Centre Hospitalier du Mans, Le Mans, [2]Centre Hospitalier de Périgueux, Périgueux, [3]Centre Hospitalier Dubois Brive, Brive La Gaillarde, [4]Centre Hospitalier Métropole Savoie, Chambéry, [5]Sandoz S.A.S., [6]AP-HP, Hôpitaux Universitaires Pitié-Salpêtrière, Paris, France

Background: Anemia is common in patients with cancer who are receiving treatment with chemotherapies. Symptoms of anemia, the most common of which is fatigue, can have a substantial negative impact on the quality of life (QoL) of affected patients.
Aims: To determine the correlation between fatigue and QoL in patients with hematological malignancies and treated with biosimilar epoetin alfa (Sandoz) for chemotherapy-induced anemia (CIA).
Methods: This was a non-interventional, prospective, multicenter study conducted in France (66 centers). Key inclusion criteria included: age >18 years; ≥2 cycles of chemotherapy planned after inclusion in the study; CIA and receiving treatment with biosimilar epoetin alfa. Data were collected on the first day of the chemotherapy cycle (inclusion, T0), after 2–3 chemotherapy cycles (follow-up; T1), and following 4–6 chemotherapy cycles (end of follow-up; T2). Fatigue (patient-reported outcome) was measured using a Visual Analog Scale (VAS; range 0–10) and QoL was evaluated using the EORTC QLQ C30 questionnaire.
Results: Data are reported for a subgroup of patients with hematological malignancies (FAS population; n=104): non-Hodgkin lymphoma, n=48; multiple myeloma, n=28; chronic lymphoid leukemia, n=18; Hodgkin lymphoma, n=7; other, n=3. At T0, the type of chemotherapy included: induction treatment, n=87; consolidation treatment, n=2; and salvage treatment after relapse, n=15. Mean (SD) hemoglobin level at baseline was 9.5 (±0.9) g/dL. Mean (SD) increase in hemoglobin between T0 and T1 was 1.3 (±1.8) g/dL, and 0.7 (±1.4) g/dL between T1 and T2. Improvements in fatigue and QoL were observed: mean (standard deviation [SD]) change in fatigue VAS score between T0 and T2 was –37.2 (±76.6)% and mean (SD) improvement in QoL between T0 and T2 was 58.6 (±88.4)%. The Pearson correlation co-efficient for fatigue and QoL was –0.255 at T0 (p=0.0001), –0.6459 at T1 (p<0.0001) and –0.7910 at T2 (p<0.0001). Assessment of fatigue by treating physicians was consistent with patients' perceptions of fatigue at T0 (5.1±1.7 *vs* 4.7±2.3), T1 (4.1±2.1 *vs* 4.3±2.2) and T2 (3.1±2.4 *vs* 2.7±2.3). Of the 108 patients in the safety population, 17 (15.7%) had adverse events (N=67 events) and of these, 49 AEs in 13 (12.0%) patients were serious. No AEs were considered related to the study treatment.
Summary and Conclusions: A correlation between reduced fatigue and improvement in QoL was observed. Treatment of CIA with biosimilar epoetin alfa in patients with hematological malignancies was well tolerated and effective, leading to improvements in fatigue and QoL.

PF706

DIAGNOSIS DISCLOSURE IN PATIENTS WITH HEMATOLOGICAL CANCERS IN INDIA

C. Cherian Philip[1,*], S. Singh[1], A. Mathew[1], A. Jindal[2], N. Kakkar[3], M.J. John[1]

[1]Clinical Haematology, [2]Immunohematology and Blood Transfusion, [3]Laboratory Haematology, Christian Medical College & Hospital, Ludhiana, India

Background: Disclosure of diagnosis is a challenge for health care providers in India(1). With family playing the significant role in healthcare decisions, there is often collusion between the doctor and the family to withhold information from the patient(2). This is however in good intent and stems from the societal belief that it benefits the patient (3). The fear of discrimination and stigma is further accentuated when the diagnosis is cancer, often perceived with a pervading sense of inevitability that relatives often request the doctor to withhold information(4). However, honest disclosure is reported to establish a satisfactory relationship between the doctor, patient and family members(5).
Aims: To estimate the percentage of patients with haematological cancers wanting complete diagnosis disclosure at our tertiary care centre and their attitude towards disclosure.
Methods: This prospective study involved a questionnaire based interview that assessed patient demographics, the information provided about cancer, patient preference about the diagnosis disclosure, and the roles of family and finances in treatment planning. Consecutive inpatients beginning August 2016 through June 2017 were interviewed in the absence of their relative with the intent to derive genuine patient response**.** The questionnaire was derived and modified from extensive literature search and its components had been validated elsewhere in the country. An informed consent was obtained prior to the interview.
Results: The patient demographics of the 100 patients who were interviewed are detailed in Table 1. The majority (80) had been to other treatment centres earlier for the current diagnosis. Ninety seven were satisfied with the diagnosis discussion and information they had been provided. Most (92 and 91) patients did not want to enquire further about their disease and treatment respectively. 72 preferred that the physician disclose their illness to relatives. 85 patients responded as being aware of the nature of their disease but only 35 were aware that they had cancer. The attitude of patients appears to approve of a paternalistic role for physicians in India. The patients who liked disclosure of diagnosis were younger [(36 (25-51) *vs* 55 (43-62)] and had a higher education (33 *vs* 13),P<0.05.

Table 1.

Patient demographics (N=100)

Variable	Patients (N=100) n or %/ Median (IQR)/Mean ±SD			
Age	46 (28-57)			
Gender (Male)	59			
Monthly family Income (€)	€375 (€187.5 – €500)			
Family history of Malignancy (Yes)	5			
Treatment decision maker (Spouse)	35			
Patient attitude towards diagnosis disclosure				
Question	Don't mind to know	Absolute need to know	Disclose to relative	Trust doctor's choice
What is your disease?	62	17	16	5
What is your specific medical illness?	40	19	14	27
What is your weekly progress?	43	20	29	8
What are the chances of cure?	46	23	24	7
What are the possible treatments?	32	13	19	36
What are the possible side effects of treatment?	48	18	14	20
How does the treatment work?	26	12	5	57
₹80 = 1€				

Summary and Conclusions: Our study though limited by patient numbers and being single centred, reveals some useful insights. In our analysis, most patients are neither aware nor in want of complete diagnosis disclosure. Despite only a minority of patients being aware of the exact nature of their illness, the majority of patients were satisfied with the information provided. There exist differences in regards to attitude and preference of patients towards diagnosis disclosure in cancer across societies. Personal beliefs and social practices possibly govern patient choice. Gaining an understanding of factors that influence decision making and diagnosis disclosure for each population should guide physicians on disclosure.

Sickle cell disease

PF707

NATIONAL EVALUATION OF QUALITY OF CARE DURING THE 5 FIRST YEARS OF LIFE FOR CHILDREN DIAGNOSED BY THE NEWBORN SICKLE CELL SCREENING PROGRAMME IN FRANCE: RESULTS OF EVADREP STUDY

Background: The aims of newborn SCD screening programmes are to reduce early mortality from infection and acute splenic sequestration as well as morbidity especially stroke. Introduction of pneumococcal conjugate vaccines (PCV) and of Transcranial Doppler (TCD) are the main recent progress allowing to further improve outcome.
Aims: The goal of this national retrospective study was to evaluate at 5 years of age the performance of the French newborn SCD screening programme by describing the residual risks of death, stroke, and bacterial meningitis/septicaemia as well as TCD use and pneumococcal vaccines coverage.
Methods: Evadrep study (NCT 03119922) was approved by the French National Committee for Computerized Databases (CNIL-127020) and by EC/CCTIRS (12319). Data were collected from the patients' medical files up to the age of 5 years, including age first prescribed penicillin, occurrence of death/overt stroke/bacterial meningitis and septicaemia, use of pneumococcal vaccines/chronic TF programme / hydroxycarbamide/ HSCT and DTC results. Between 01/01/2006 and 31/12/2010, 1792 consecutive babies with SCD were identified through newborn screening programme by AFDPHE (Association Francaise de Depistage et de Prevention des Handicaps de l'Enfant). 152/1792 patients (8.5%) could not be located during the period of data collection (2014-2015), of whom 64 were known to be back to their country of origin. 1620 patients followed in 69 centres were included in EVADREP study, 71.8% with sickle-cell anaemia (SS) or sickle beta°-thalassemia (Sb°). 20.3% had SC disease. 59.6% were resident in Paris area, 9.4% in the French West Indies.
Results: Probability of survival at 5 years was 98.9% (95%CI: 98.2-99.3). 18 deaths occurred, 12 related to SCD (11 patients SS or SB0). Probability of overt stroke at 5 years for the whole study population was 0.8% (95%CI: 0.5-1.4%) and 1.1% (0.6%>1.9%) in SS/Sb° patients. All 12 patients with stroke had the SS genotype and 6 have not been investigated by DTC before. In the SS/Sb° group DTC was performed before 2 and 3 years of age in 56% and 81% of patients. The median number of annual TCD was 0.8. The probability of experiencing abnormal TCD (velocities ≥200cm/s) at 5 years was of 10.4% [8.6%>12.4%]. 26 patients underwent a severe infection (meningitis or septicaemia), lethal in 8 cases. Streptococcus pneumonia was identified in 8/26 cases. More than 99% of patients were prescribed prophylactic penicillin, started at a median age of 2.2 months of life. 87% of children received at least 3 injections of PCV during their first year of life. The 23-valent pneumococcal polysaccharide vaccine was less well administered (only 90% before 5 years). For patients SS and Sb°, probabilities at 5 years to be treated with hydroxycarbamide or to receive chronic transfusion programme were of 13.7% [11.7%>15.9%] and 18.4% [16.2%>20.8%]. Only 9 patients underwent a HSCT before 5 years of age. Vaccination and DTC coverage, use of TF programme were significantly higher in larger centers.
Summary and Conclusions: In this national newborn SCD screening cohort of children born between years 2006-2010 the residual risks under the age of 5 years of death, stroke and invasive infection were very low. Almost all infants benefited from PVC and a vast majority of children from TCD monitoring before 3 years reflecting an efficient access to French care system. These national results are near to those observed in SCD expert centres cohorts. Nonetheless national coverage with Pneumovax and TCD can be further improved.

PF708

VISUAL CORTEX CHANGES IN CHILDREN WITH SICKLE CELL DISEASE: A MULTIMODAL MRI STUDY

R. Manara[1], A. Dalla Torre[2], M. Lucchetta[2], M. Ermani[2], A. Favaro[2], C. Baracchini[2], S. Favaretto[2], F. Viaro[2], V. Munaretto[3], S. Sartori[2], S. Ponticorvo[4], A. G. Russo[4], G. Basso[3], L. Sainati[3], R. Colombatti[3,*]

[1]University of Salerno, Salerno, [2]Department of Neurosciences, [3]Clinic of Pediatric Hematology Oncology, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, Italy, Padova, [4]Department of Neurosciences, University of Salerno, Salerno, Italy

Background: The neural tissue is typically affected in the Sickle Cell Disease (SCD) SS-Sβ° genotype due to its vulnerability to micro and macrocirculation failure. Recently, advanced imaging analyses have revealed several structural and functional brain changes (white matter volume loss, cortical thinning, neural function impairment of cognitive- or pain-related networks) that go beyond silent infarcts and stroke (1-2). Among several neural systems, vision is known to be primarily affected by SCD and regular eye examination (visual acuity and dilated eye examination) since late childhood is recommended in SCD management guidelines. Retinal abnormalities include proliferative and non-proliferative retinopathy. As the retina is a visible and easily assessed part of brain tissue, retinal changes might represent a valuable "window" on the mechanisms of brain injury in SCD. On the other hand, neurons of the retina are subjected to the same interactivity that characterizes neurons in all parts of the brain. Subclinical retinal changes might have an effect on the entire neural visual system and reciprocally, brain changes in the visual network might affect the the retina. So far, all studies focused on the retina neglecting the changes that might be present in the cortical portion of the visual system
Aims: The aim of the present study was to investigate, with multimodal MRI analyses, structural and functional changes in the cerebral part of the visual system of children with SCD, using a control group for comparison and taking into account age-related changes
Methods: 25 SCD children and 31 healthy controls -mean age (yrs) 12.3±1.9 *vs* 12.7±1.6- underwent: MR-angiography and axial FLAIR for determining vascular and parenchymal lesion burden, 3D-T1-weighted scan and resting-state fMRI for cortical thickness and neural network connectivity analyses. SCD children had a routine ophthalmologic evaluation
Results: Ophthalmologic examination revealed: 3/25 SCD children with mild visual acuity deficits (8-9/10), none with biomicroscopy abnormalities, 2/25 with mild tortuosity of the retinal vessels (both children had normal acuity) at dilated eye examination. None had occipital infarcts at MRI nor abnormal Transcranial Doppler, while 6/25 disclosed posterior cerebral artery stenosis (5 mild, 1 severe) at MR-angiography. Compared to controls, SCD children had increased posterior pericalcarine cortical thickness (Table 1) with a different trajectory of cortical maturation and decreased connectivity within both medial and ventral visual neural networks (Figure 1).

Table 1. Cortical thickness whole brain analysis: showing clusters (>50 mm2) of different values in the primary visual cortex: increased thickness in SCD patients compared to controls.

Thickness	Hemisphere	Annotation	Size (mm^3)	TalX	TalY	TalZ
Increased	Left	Pericalcarine	714	-12.4	-88.0	6.2
Increased	Right	Pericalcarine	274	5.8	-79.6	11.3
Increased	Right	Lingual	134	4.6	-86.4	-6.5

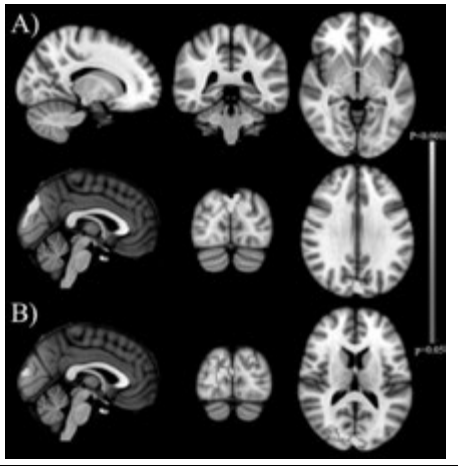

Figure 1.

Summary and Conclusions: Our findings provide novel evidence that SCD affects the development and tuning of the visual cortex leading to significant anatomical and functional changes in childhood, even without retinopathy at standard ophthalmologic examination. Longitudinal multimodal MRI (fMRI) and advanced ophthalmologic tools (i.e OCT) could determine if these changes can be predictors of visual impairment in adulthood, biomarkers of disease progression or treatment response

PF709

RESULTS FROM A PHASE 2A STUDY (GBT440-007) EVALUATING ADOLESCENTS WITH SICKLE CELL DISEASE TREATED WITH MULTIPLE DOSES OF VOXELOTOR (GBT440), A HBS POLYMERIZATION INHIBITOR

C. Brown[1,*], C. Hoppe[2], A. Inati[3], W. Wang[4], L.L. Hsu[5], V.R. Gordeuk[5], R. Liem[6], G. Woods[7], C. Piccone[8], E. Fong[9], G. Balaratnam[9], S. Dixon[9], M. Tonda[9], C. Washington[9], Y. Yaron[9], J. Lehrer-Graiwer[9]

[1]Children's Healthcare of Atlanta, Atlanta, GA, [2]UCSF Benioff Children's Hospital Oakland, Oakland, CA, United States, [3]Rafik Hariri University Hospital Beirut, Beirut, Lebanon, [4]St. Jude Children's Research Hospital, Memphis, TN, [5]University of Illinois at Chicago, Chicago, IL, [6]Ann and Robert Lurie Children's Hospital of Chicago, Chicago, IL, [7]Children's Mercy Hospital, Kansas City, MO, [8]UH Rainbow Babies and Children's Hospital, Cleveland, OH, [9]Global Blood Therapeutics, South San Francisco, CA, United States

Background: Sickle cell disease (SCD) is an autosomal recessive inherited disorder in which deoxygenated sickle hemoglobin (HbS) polymerizes and triggers downstream effects including red blood cell deformation (sickling), hemolysis, vaso-occlusion, and inflammation. Ischemic injury from SCD starts in infancy and accumulates over a lifetime, causing pain, fatigue, vaso-occlusive crisis (VOC), progressive end-organ damage, and other clinical complications that are associated with decreased quality of life and early death. Voxelotor (GBT440) is a first-in-class, oral, once-daily therapy that modulates hemoglobin (Hb) affinity for oxygen, thereby inhibiting HbS polymerization.
Aims: To assess the efficacy and safety of voxelotor at 900 mg in pediatric patients with SCD (HbSS or HbS ^{0} thalassemia) in the ongoing phase 2a study (GBT440-007).
Methods: This study is being conducted in 2 parts. Part A was single-dose voxelotor (600 mg) in pediatric (6-11 years) and adolescent (12-17 years) patients. PK data from part A have been completed and were reported previously. Part B includes treatment of adolescents for 24 weeks with multiple doses of voxelotor (900 and 1500 mg/d). The primary objective of part B is to assess the effect of voxelotor on anemia. Secondary objectives include measures of hemolysis, daily symptoms using an electronic patient-reported outcome (PRO) measure, and safety.
Results: Enrollment in part B of the 900 mg cohort is complete. As of 29Jan2018, 25 patients (11 females) have received voxelotor for up to 24 weeks (range, 3-24). Median age was 14 years (range, 12-17), median weight 50 kg (range, 31-93), and median baseline Hb value was 8.9 g/dL (range, 6.3-11.0). In this cohort, 88% of patients were receiving hydroxyurea (HU) and 44% had ≥2 VOC (range, 2-8) in the year prior to enrollment. Data for measures of hemolysis are available for 12 patients (92% on HU at study entry) who received voxelotor 900 mg for 24 weeks. Five of the 12 patients (42%) achieved Hb response of >1 g/dL increase (Figure 1), which was associated with improved measures of hemolysis. Median reduction in reticulocytes (32%) and indirect bilirubin (38%) was consistent with previous results in adults with SCD. Data collected from the PRO measure indicate total SCD symptom scores trended lower from screening to week 24. Among the 25 patients treated for up to 24 weeks, the majority of treatment-related adverse events (AEs) were grade 1 or 2, and there were no treatment-related serious AEs or drug discontinuations due to AEs. The most common treatment-related AEs included nausea (12%), vomiting (8%), headache (8%), and rash (8%). Data for all 25 patients treated with voxelotor 900 mg for 24 weeks will be presented. Statistical results will be available for presentation at the meeting.
Summary and Conclusions: Voxelotor at 900 mg was well tolerated in all 25 adolescents. Data from 12 adolescents at 24 weeks demonstrated sustained and durable improvement in Hb and reduction in clinical measures of hemolysis in patients already maximally managed with HU. PRO data suggest that clinical symptoms may improve with voxelotor. Overall, these results are consistent with *in vivo* inhibition of HbS polymerization by voxelotor and support the ongoing clinical evaluation of voxelotor as a potential disease-modifying therapy for adults and adolescents with SCD.

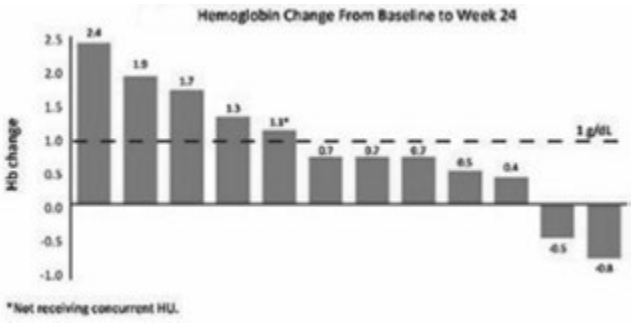

Figure 1.

PF710

EVALUATION OF CEREBRAL TISSUE OXYGENATION USING NIRS DURING TRANSFUSION EXCHANGES IN SICKLE CELL PATIENTS WITH CEREBRAL VASCULOPATHY.

F. Romain[1], Z. Fouzia[2], C. T. Rym[3], M. Dehbia [3], P. Sadaf [3], H. Anoosha [4], G. Frederic[4], P. France [3], R. Thomas [5], B. Pablo[4,*]

[1]Rhône, Service de Médecine Interne, Hôpital Edouard Herriot, HCL, Lyon, [2]Paris, Service d'Hématologie biologique, Hôpital Antoine Béclère, APHP, Clamart, [3]Paris, Etablissement Français du Sang, Hôpital Henri Mondor, APHP, Créteil, [4]Paris, Centre de Référence des Syndromes Drépanocytaires Majeurs, Hôpital Henri-Mondor, AP-HP, Créteil, Paris, [5]Savoie, Laboratoire Interuniversitaire de Biologie de la Motricité, Université Savoie Mont Blanc, EA 7424, Chambéry, Chambery, France

Background: Sickle cell disease is a genetic disorder caused by a mutation of beta globin, characterized by chronic hemolysis and vascular dysfunction. Stenosis of the large intracranial vessels represents one of the most serious complications, responsible for cerebrovascular accidents with a prevalence between 4 and 13% before the age of 20 years old, and a recurrence rate of approximately 46%. These lesions are preferentially localized to the internal carotid, middle and anterior cerebral arteries. Primary and secondary prevention of stroke is based on long-term transfusion exchange (TE) with an HbS goal <30%. However no evaluation was made on the benefit of cerebral tissue perfusion during TE.
Aims: The aim of this study was to evaluate the benefit of cerebral tissue perfusion during TE in sickle cell patients with cerebral vasculopathy.
Methods: We conducted a pilot, monocentric, observational, prospective study in adult sickle cell patients under TE protocol by erythrapheresis. Real-time evaluation of tissue oxygenation throughout the procedure was performed transcutaneously using a near-infrared spectroscopy (NIRS) system. Several parameters were analyzed at the muscular level and the two cerebral hemispheres: 1) quantification of tissue oxygen saturation (TSI%); 2) oxyhemoglobin (HbO2) with high level reflecting better cerebral perfusion; 3) deoxyhemoglobin (HHb); and 4) total hemoglobin (HbT).
Results: 21 patients were included, including 11 men and 10 women, with an average age of 36 years. 14 of them had cerebral vasculopathy (8 unilateral and 6 bilateral). The cerebral perfusion after TE was significantly improved, as shown by the increase of HbO2 (p=0.004) and HbT (p=0.003), without modification of the HHb. At the muscular level there was only a significant increase in HbO2 (p=0.03). Interestingly, the improvement in perfusion concerned only cerebral hemispheres with vasculopathy. Finally, TSI% did not differ during TE.
Summary and Conclusions: This is the first study to demonstrate the benefit of TE on cerebral perfusion in sickle cell patients with cerebral vasculopathy. These results confirm 1) the feasibility of evaluating real-time cerebral perfusion with NIRS; and 2) the need to maintain a transfusion therapy in patients with cerebral vasculopathy. It would be then interesting to perform respiratory maneuvers during the NIRS, in order to evaluate the vascular reserve which is an early marker of the risk of cerebral hypoperfusion.

PF711

COMPASSIONATE-USE VOXELOTOR (GBT440) FOR PATIENTS WITH SEVERE SICKLE CELL DISEASE (SCD) AND LIFE-THREATENING COMORBIDITIES

G. Blyden[1], K. Bridges[2,*], L. Bronte[1]

[1]Foundation for Sickle Cell Disease Research, Hollywood, FL, [2]Global Blood Therapeutics, South San Francisco, CA, United States

Background: Voxelotor (GBT440) is a first-in-class, oral, once-daily therapy designed to modulate the affinity of hemoglobin (Hb) for oxygen and prevent sickle hemoglobin polymerization, thereby blocking subsequent red blood cell damage and complications from SCD. Seven patients with severe SCD ineligible for ongoing clinical trials because of high mortality risk from comorbidities, including renal dysfunction, frequent hospitalizations for vaso-occlusive crisis (VOC), extreme anemia, and multiorgan failure, were provided compassionate-use access to voxelotor by the US Food and Drug Administration single-patient investigational new drug program.
Aims: To report the efficacy and safety of voxelotor administered to 7 patients with severe SCD and high mortality risk owing to multiple comorbidities.
Methods: Once-daily voxelotor began at 900 mg, with possible increase to 1500 mg. Baseline echocardiograms were performed. Initial assessments at 2 and 4 weeks were followed by routine evaluations at least monthly. Key data captured included Hb levels, reticulocyte count, indirect bilirubin, resting oxygen saturation (PO_2), pain level on 0 to 10 scale, transfusions, and hospitalizations for VOC. Patient Health Questionnaire-9 (PHQ-9) assessed depression.
Results: Four female and 3 male patients aged 22 to 67 years had severe comorbidities at baseline, including iron overload in all patients, frequent transfusions in 5/7, severe fatigue in 4/7, chronic oxygen supplementation in 2/7, progressive severe renal dysfunction (1/7), and multiorgan failure (1/7). In 5/7 patients, baseline Hb was ≤6.4 g/dL, with three <6 g/dL. Hb level increased in all 7 patients by 24 weeks of receiving voxelotor, with 5 reaching ≥1.0 g/dL. Hb increase from voxelotor was clearest in 3 patients, who had 1.0 to 5.4 g/dL rises without transfusion. The number of transfusions fell by 60% in all 7 patients. VOC hospitalizations fell by 67%. Baseline PO_2 improved to 98% to 99% from <95% in 4 patients following voxelotor treatment, permitting discontinuation of long-term supplemental oxygen in 2 patients. Improved overall well-being, typically 2 to 3 weeks after treatment initiation, occurred in all patients, and the PHQ-9 score registered reduced depression. Voxelotor was well-tolerated with no discontinuations during treatment periods of up to 17 months. There was 1 dose reduction because of grade 2 diarrhea. Two patients with advanced end-stage organ injury died of SCD complications unrelated to treatment.
Summary and Conclusions: Seven patients given compassionate-use voxelotor after exhausting all treatment options achieved substantial improvements in clinical, laboratory, and mental health parameters. Controlled clinical trials will be needed to confirm the benefit of voxelotor in patients with severe SCD and multiple comorbidities.

PF712

CRIZANLIZUMAB TREATMENT IS NOT ASSOCIATED WITH THE DEVELOPMENT OF PROTEINURIA AND HEMATURIA IN PATIENTS WITH SICKLE CELL DISEASE: A SAFETY ANALYSIS FROM THE SUSTAIN STUDY

K.I. Ataga[1,*], A. Kutlar[2], R. Cancado[3], D. Liles[4], L. Velez-Nandayapa[5], J. Lincy[5], A. Bruederle[5], J. Kanter[6]

[1]Division of Hematology–Oncology, University of North Carolina, Chapel Hill, NC, [2]Sickle Cell Center, Medical College of Georgia, August University, Augusta, GA, United States, [3]Department of Hematology–Oncology, Santa Casa Medical School of São Paulo, São Paulo, Brazil, [4]Division of Hematology–Oncology, East Carolina University, Greenville, NC, United States, [5]Novartis Pharma AG, Basel, Switzerland, [6]Division of Pediatrics, Medical University of South Carolina, Charleston, SC, United States

Background: Patients with sickle cell disease (SCD) are at risk of multiorgan complications, including renal disease. Sickle cell nephropathy is caused primarily by cortical hyperperfusion, medullary hypoperfusion and the renal vascular response to the stress of SCD, leading to renal vaso-constriction and vaso-occlusion. Renal complications of SCD include proteinuria, hematuria and renal failure. Crizanlizumab, a humanized anti-P-selectin monoclonal antibody, is under investigation for reducing the frequency of, or preventing, vaso-occlusive crises (VOCs) in patients with SCD. In the Phase II SUSTAIN study, crizanlizumab 5.0 mg/kg significantly reduced the median annual rate of VOCs by 45.3% *vs* placebo (median absolute difference of –1.01 *vs* placebo, 95% CI [–2.00, 0.00]; *P*=0.01). Crizanlizumab 5.0 mg/kg was also associated with longer Kaplan-Meier estimated median time to first VOC *vs* placebo (4.07 *vs* 1.38 months). The incidence of adverse events (AEs) and serious AEs was similar in patients receiving crizanlizumab and placebo (Ataga *et al. N Engl J Med* 2017). Although proteinuria (n=3) and hematuria (n=1) were rarely reported as AEs, and all were mild or moderate, the overall incidence across treatment groups (computed from the laboratory sample results) was 34.2% and 26.6%, respectively.

Aims: To compare the risk of developing proteinuria or hematuria during SUSTAIN for patients receiving crizanlizumab or placebo.
Methods: SUSTAIN was a Phase II, randomized, double-blind, placebo-controlled, 52-week study (NCT01895361). Patients (aged 16–65 years) with SCD were randomized 1:1:1 to receive intravenous crizanlizumab 5.0 mg/kg, 2.5 mg/kg or placebo. This safety subanalysis from SUSTAIN was performed with risk ratios (RR) as a measure of effect. The analysis compared two groups: patients receiving crizanlizumab (2.5 and 5.0 mg/kg combined) *vs* those receiving placebo, in patients without proteinuria or hematuria at baseline. Proteinuria and hematuria were each defined as a positive result for protein or red blood cells in dipstick urinalysis, respectively. Incidences of abnormal estimated glomerular filtration rate and increase in serum creatinine were also assessed.
Results: 192 patients received at least one dose of crizanlizumab 5.0 mg/kg (n=66), 2.5 mg/kg (n=64) or placebo (n=62). In total, 161 patients had no proteinuria at baseline (crizanlizumab, n=109; placebo, n=52) and 156/161 (n=106 and n=50) had available post-baseline protein data. During the study, proteinuria was reported in 35/106 (33.0%) patients receiving crizanlizumab *vs* 17/50 (34.0%) receiving placebo (RR=0.97, 95% CI [0.61–1.56]). At baseline, 109 patients did not have hematuria (crizanlizumab, n=77; placebo, n=32) and 100/109 (n=73 and n=27) had available post-baseline hematuria data. During the study, hematuria was reported in 18/73 (24.7%) patients receiving crizanlizumab *vs* 11/27 (40.7%) receiving placebo (RR=0.61, 95% CI [0.33–1.11]). The incidence of glomerular filtration abnormalities and increased serum creatinine was low.
Summary and Conclusions: This analysis suggests there is no association between the use of crizanlizumab and the risk of developing proteinuria or hematuria in patients with SCD in SUSTAIN. As such, the observed cases of proteinuria and hematuria in patients treated with crizanlizumab are likely associated with the underlying disease. These findings further support the use of crizanlizumab as a well-tolerated treatment for preventing VOCs in SCD. Further studies are needed to evaluate the effect of crizanlizumab in reducing proteinuria/hematuria in SCD.

PF713

PHARMACOKINETICS (PK) OF VOXELOTOR (GBT440) USING POPULATION PHARMACOKINETIC (PPK) AND PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODELING IN PEDIATRIC SUBJECTS WITH SICKLE CELL DISEASE (SCD)

Background: SCD is an autosomal recessive inherited disorder caused by a mutation in hemoglobin (Hb) that leads to the production of sickle hemoglobin (HbS). When deoxygenated, HbS polymerizes and deforms and damages red blood cells. These damaged red blood cells block capillaries and undergo hemolysis, which triggers downstream effects of anemia, fatigue, tissue ischemia, vaso-occlusive crisis, vascular injury, and organ damage leading to a decreased quality of life. Currently, pharmacologic treatments do not address the primary pathogenesis of SCD by direct inhibition of HbS polymerization. Voxelotor is a first-in-class, oral, once-daily therapy that is designed to modulate Hb's affinity for oxygen, thereby inhibiting HbS polymerization. GBT440-007 is a phase 2a study designed to assess the safety, PK, and efficacy of voxelotor in pediatric patients with SCD and consists of 2 parts: Part A (single-dose) and Part B (multiple-dose).
Aims: To report the single-dose PK of voxelotor in children (6 to <12 years; Part A) and multiple-dose PK of voxelotor in adolescents (12 to <18 years; Part B) with SCD.
Methods: Children and adolescents in Part A received a single oral dose (600 mg) of voxelotor. Adolescents in Part B received multiple once-daily oral doses (900 or 1500 mg) of voxelotor for up to 24 weeks. PK samples to measure whole blood and plasma voxelotor concentrations were collected up to 15 days following single-dose administration and up to 24 weeks following multiple-dose administration. Separate PPK models were developed to describe the concentration *versus* time profiles of voxelotor in whole blood and plasma using nonlinear mixed effects modeling (NONMEM, version 7.3). Additionally, PPK models and PBPK modeling were used to simulate voxelotor PK parameters and support dose selection for future evaluation in younger children (<12 years).
Results: Enrollment in Part A and Part B (900-mg cohort) is complete. Part A included 6 children (3 females; median age 8.5 years [range, 6-10]). Mean weight was 21.1 kg (range, 16-38 kg). Part B included 25 adolescents (11 females; median age 14 years [range, 12-17]. Mean weight was 49.9 kg (range, 31-93 kg). A 2-compartment model with first-order absorption best described the PK of voxelotor and is the same model structure previously used for adults with SCD. The half-life was similar in children, adolescents, and adults (Table 1). The% Hb occupancy following multiple 900-mg doses (~23%) was similar in adolescents and adults. Voxelotor PK exposures in adolescents were comparable to those observed in adults. However, as expected, higher PK exposures were observed in children supporting a weight-based dosing approach in this population. PPK and PBPK simulations resulted in similar dosing schemes for children <12 years.

Table 1.

Model PPK Parameter Estimates for Voxelotor in Children, Adolescents, and Adult Participants with SCD

PK Parameters/n	n = 6	n = 25	n = 42
	Children	Adolescents	Adults
Voxelotor Whole Blood PK Parameters			
CL/F, L/h	0.24	0.4	0.43
V/F, L	9.55	18.9	21.4
$T_{1/2}$, h	27.8	32.7	34.5
Voxelotor Plasma PK Parameters			
CL/F, L/h	3.67	5.48	7.63
V/F, L	140	267	373
$T_{1/2}$, h	26.4	33.8	33.9

CL/F, apparent clearance; h, hours; L, liters; $T_{1/2}$, half-life; V/F, apparent volume of distribution.

Summary and Conclusions: Voxelotor was well tolerated following single doses (600 mg) in children and multiple doses (900 mg) in adolescents. Multiple-dose PK were similar in adolescents and adults. PK exposures were higher in children compared with adolescents and adults, so lower doses are recommended in children (<12 years). The integrated PPK and PBPK strategy provides an innovative approach to minimize the need for clinical PK evaluation in children and to accelerate dose selection.

PF714

ACCESS TO EMERGENCY DEPARTMENT AND IDENTIFICATION OF SUBJECTS WITH SICKLE CELL DISEASE AND OTHER HEMOGLOBINOPATHIES IN REFUGEES

Background: The number of refugees coming to Europe has considerably increased since the beginning of the Syrian conflict which started in 2011. Hundreds of migrants still arrive on a daily basis along the Mediterranean coasts of southern European countries. The arrival of refugees in Italy represents a humanitarian emergency with needs which are still largely unmet. There are currently no signs of these fluxes slowing down or being interrupted. In hot-spot and in secondary level centers, refugees are routinely screened for communicable diseases and undergo vaccinations based on WHO recommendations. However, no screening for non-communicable disorders such as sickle cell disease (SCD) is currently in place. As indicated in a recent document from the US Department of Health and Human service

– division global migration and quarantine, screened in refugees coming from endemic areas for SCD is recommended.
SCD is a worldwide distributed red cell disorder defined as a global health priority issue by the African Union and WHO. Life-threatening complications of SCD include acute vaso-occlusive crisis (VOCs), which require early identification and intensive clinical management. Dehydration, psychologic stress, and exposition to high/low temperature can trigger VOCs and other severe complications in SCD patients.
Aims: To evaluate as hemoglobinopathies impact refugees
Methods: Here, we carried out a retrospective study on new diagnosis of SCD in refugees at their access to emergency departments for acute events in Italy. Data were collected from 2014-2017 by National reference centers for SCD and hemoglobinopathies, which are part of the SITE (Italian society for hemoglobinopathies studies) and ERN-Euroblood network (https://www.eurobloodnet.eu/).
Results: A total number of 67 patients were identified as first diagnosis of SCD related to acute event at their access to the emergency department (ED). SCD patients were 52% adults (86% male/14% female) and 48% children (81% male/19% female). Genotype distribution was as follow: SS (*n*=48), SC (*n*=9), bS (*n*=3), CC (*n*=2), AS (*n*=1). We also identified 4 subjects with non-transfusion dependent b-thalassemia. Patients identified came from a wide range of countries, including Nigeria (32%), Gambia (20.9%), Mali (7.5%), Senegal, Ghana (6%), Guinea, Syria (4.5%), Bangladesh (3%), Benin (1%), Burkina Faso (1%), Guinea Bissau (1%) and Kenya (1%). The main causes of access to the ED were: VOC (35.8%), anemia (19.4%), fever (7.5%), acute chest syndrome (4.5%), pneumonia (3%) and abdominal pain (3%). 60% of the identified SCD patients were then followed-up by the comprehensive Centers for hemoglobinopathies after their first access to ED.
Summary and Conclusions: Collectively, our data support the recommendation that SCD as a non-communicable disease should be screened in refugees coming from endemic areas for SCD. To address this health and humanitarian crisis, we propose (i) to develop flow-charts for the early and systematic identification of SCD patients at the arrival and second level refugee camps; (ii) to educate health operator in early identification and treatment of acute VOCs; (iii) to send SCD or symptomatic HbS-carrier refugees to the regional comprehensive SCD reference center for treatment and follow-up. Recent low-costs point-of-care screening devices could potentially play a more role in ensuring the implementation of such a program, which would allow to identify affected patients early and to prevent severe complications.

PF715

AN ANALYSIS OF PAIN CRISIS PATTERNS IN DIFFERENT GEOGRAPHIC REGIONS OF THE WORLD: ANALYSIS FROM THE CASIRE STUDY

R. Colombatti[1,*], B. Andemariam[2], I. Tartaglione[3], C. Antwi-Boasiako[4], C. Strunk[5], D. Manwani[6], C.M. Piccone[7], E.V. Asare[8], S. Perrotta[9], I. Ekem[8], L. Sainati[1], S. Rao[10], D. Boruchov[11], W. Zempsky[11], F. Sey[8], C. Segbefia[10], B. Inusa[12], A. Campbell[13]

Background: Sickle cell disease (SCD) is global blood disorder affecting over 1 million people. It is characterized by chronic hemolysis, unpredictable pain crises(PCs), and chronic organ damage which leads to early death in patients affected by the disorder. Pain crisis frequency varies widely between patients and is directly related to disease severity and increased mortality (O Platt et al). Pain crises resulting in emergency room (ER) or day hospital visits and or hospitalizations have been used in many studies as an indicator of disease phenotype and inclusion criteria for eligibility for Phase II/III clinical drug trials in SCD.
Aims: To determine the pain phenotype across different geographic regions of the world.
Methods: The CASIRE group is an international multi-institutional collaboration of researchers studying the clinical severity of patients with sickle cell anemia on a global scale through a validated questionnaire, chart review and laboratory studies with 868 patients enrolled to date. Patients were enrolled into the CASIRE study after informed consent and assent was obtained from either the parent or patient when appropriate. The study was approved at each participating institution's IRB. A questionnaire was answered by the parents and/or patient, and baseline and current laboratory studies were collected. We investigated the sickle cell disease pain crisis patterns in three geographic regions of the world (USA, Europe [Italy, United Kingdom], and Africa (Ghana). Secondary data analyses of crises per year requiring ER/day hospital clinic visit (PC-ER/DH) or requiring hospitalization (PC-Hosp) were performed within each geographic region to assess PC frequency and care utilization variability.
Results: We analyzed 867 patients in this study for Pain crises per year requiring ER/day hospital clinic visit (PC-ER/DH) and requiring Hospitalization (PC-Hosp). We stratified patients based on age (pediatrics, n=443 *vs* adults, n=424) disease genotype: Severe (Hgb SS or Sickle Beta-Thal-Zero, n=678, 79%) *vs* Mild (Hgb SC /Hgb Sickle Beta thal-plus, n=189, 21%). Subjects included were receiving care either in Ghana (n=365), Italy/United Kingdom (n=258), or the United States (n=244). Fifty-two percent were female (n=446) while 49% were male (n=419). Overall, the Ghanaian pediatric patients had a significantly higher PC-ER/DH rate than the pediatric patients from the U.S. and U.K./Italy groups. Among patients with the severe disease genotypes, those receiving care in Europe experienced higher PC-Hosp rates than those who were receiving care in either the U.S. or in Ghana. Among pediatric patients with a mild SCD genotype, those from the U.S. experienced significantly lower rates of pain than the European and Ghanaian groups. When analyzing the adult SCD patients with severe genotype, Ghanaian patients experienced significantly lower PC-Hosp rates than their U.S./UK/Italy counterparts with a p<0.001. Conversely Adult American patients reported significantly higher PC-Hosp rates than their Ghana/European cohorts (Table 1).

Table 1.

Ghana : mean PC(sd)	n=57 1.51 (2.2)	**.028	N=57 1.27 (1.94)	0.114	N=204 2.15(3.08)	0.509	N=204 1.20(2.2)	** <0.001
UK/Italy: meanPC(sd)	n=200 0.81 (1.96)	0.153	n=200 2.35(4.3)	**.036	N=31 0.65(1.1)	**.017	N=31 1.97(4.0)	0.525

U.S. : Mean PC (sd)	n=35 0.37(0.843)	0.153	n=35 0.77(1.19)	**.036	n=23 2.17(3.1)	0.913	n=23 2.04(2.2)	**.031

*One Way Anova: PC per year: Index Countries compared to all other countries combined;
p= <0.05; * N/A: number too small(N=2) for statistical analysis

Summary and Conclusions: A different pattern of admission to ER and inpatient services seem to be present in the various regions: Children in Europe presented more hospitalizations for SCD related painful crisis while adults in the USA seem to present more ER and hospital admissions compared to other areas. Whether this is related to disease phenotype, genetic modifying factors, environment characteristics or organization of health care needs to be investigated.

PF716

CHARACTERISTICS OF EPISODES OF ACUTE CHEST SYNDROME IN ADULTS PATIENTS WITH SICKLE CELL DISEASE IN GUADELOUPE AND PREDICTIVE FACTORS OF SEVERITY: A RETROSPECTIVE STUDY

M. Etienne-Julan[1,*], C. Mitaut[2], C. Lebouc[2], V. Tarer[3], O. Hippomene-Jerier[4], N. Lemonne[5], C. Charneau[6], M. Billaud[1], B. Pons[7], B. Tressieres[8]

[1]Unité transversale de la drépanocytose (Sickle cell Unit), Sickle cell reference centre,

[2]Unité transversale de la drépanocytose (Sickle cell Unit), [3]Reference centre for Sickle cell disease, [4]Service de médecine polyvalente, [5]Unité transversale de la drépanocytose (Sickle cell Unit), Sickle cell reference center, CHU de la Guadeloupe, Pointe-a-Pitre cedex, [6]Unité de la drépanocytose (Sickle cell Unit), Sickle cell competence center, Centre Hospitalier de la Basse-Terre, Basse-Terre, [7]Service de réanimation (Intensive Care Unit), [8]Centre d'Investigation Clinique Antilles-Guyane CIC 1424, CHU de la Guadeloupe, Pointe-a-Pitre cedex, France

Background: Acute chest syndrome (ACS) is the second leading cause of hospitalization and the most common cause for death among adult patients with sickle cell disease (SCD). It is a lung injury syndrome. Its pathophysiology is complex and associates, at different levels, vaso-occlusion, fat embolism, infection, *in situ* thromboembolism, hemolysis related vasoconstriction, hypoventilation. The evolution can be severe and drive to acute respiratory distress syndrome and/or acute pulmonary hypertension with acute cor pulmonale. Treatment is symptomatic. It is still difficult to predict which patients will have severe disease or develop life-threatening hypoxemia.
Aims: The goals of this non-interventional retrospective study were to describe the characteristics of ACS in an SCD affected adult population attending the referral centre for sickle cell disease in Guadeloupe and to identify predictive factors of severity
Methods: The CHU de Guadeloupe has the agreement (CNIL-2006302 v) from the French national Committee for computerized Databases for MR3 non interventional Studies. All patients with SCD, who were hospitalized at the University Hospital of Guadeloupe or at the Hospital of la Basse-Terre from January 1st 2011 to december 31st 2014 because of the occurrence of ACS, were included. The data were collected from the patients'medical files and included demographic data, sickle cell and non-sickle cell related medical antecedents, current treatment, the more recent biological steady state values, clinical symptoms before admission and at admission, radiological signs at admission, clinical evolution after admission, biological parameters evolution during hospitalization, transfer or not to Intensive Care Unit (ICU), transfusion therapy and the issue of the episode. Two groups were compared, according to the occurrence of a severe ACS, defined by clinical worsening, and/or an ICU stay of more than 48h, and/or the need for ventilatory support.
Results: During the study period, 71 episodes of ACS with 41 (58%) severe episodes were recorded. To be a younger adult (p=0.01), to have lower steady hematocrit level (p=0.013), long term treatment for SCD-related nephropathy by angiotensin-converting enzyme (ACE)-inhibitors and/or angiotensin receptor blockers (p=0.035), pregnancy for women patients (p=0.016), higher heart rate at admission (p=0.004), higher temperature at admission (p=0.01), lower limb located pain (p=0.035), higher leukocytes count (p=0.042), higher serum bilirubin, lacticodehydrogenase and C reactive protein levels at admission (p=0.002, 0.046 and 0.013 respectively) were associated with severe episodes. The multivariate analysis showed that to be younger than 28 years old, to have steady state hematocrit level lower than 25% and long term treatment for SCD-related nephropathy by angiotensin-converting enzyme (ACE)-inhibitors and/or angiotensin receptor blockers are independent factors associated with the severity of this complication in our population
Summary and Conclusions: Younger adults, pregnancy in SCD women, SCD nephropathy, and higher hemolysis level were associated with more severe ACS in adults with SCD in our study. A large-scale prospective study is needed to investigate the influence of these factors on the development of severe ACS in order to identify the patients who should benefit from early aggressive treatment in order to reduce mortality associated with this severe complication.

PF717

COULD LIVER INVOLVEMENT BE EARLY DETECTED IN SICKLE CELL DISEASE?

M. Bortolotti[1,*], R. D'Ambrosio[2], M. Fraquelli[3], P. Pedrotti[4], D. Cattaneo[5], M. D. Cappellini[6], G. Graziadei[7]

[1]Rare Diseases Center, General Medicine Unit, Department of Clinical Sciences and Community Health, University of Milan, [2]Gastroenterology and Hepatology Department, [3]Division of Gastroenterology and Endoscopy, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, [4]Cardiac Magnetic Resonance Laboratory, Cardiology 4, ASST GOM Niguarda, [5]Department of Clinical Sciences and Community Health, University of Milan, [6]Rare Diseases Center, General Medicine Unit, Department of Medicine and Medical Specialties - Department of Clinical Sciences and Community Health, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico - University of Milan, [7]Rare Disease Center, General Medicine Unit, Department of Medicine and Medical Specialties, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy

Background: Liver damage is a severe and frequent complication in Sickle Cell Disease (SCD), mainly characterized by intra-hepatic cholestasis. So far, no effective approaches to prevent or treat this condition are established.
Aims: Clinical, laboratory and imaging findings are evaluated longitudinally in SCD patients, comparing different sickle-genotypes, in order to identify possible early predictors of liver involvement.
Methods: Sixty-eight SCD patients were studied: 17 Sickle Cell Anemia (SCA, median age 42.8±10.3yrs, M:F 4:13), 38 Sickle Cell Thalassemia (HbS-βThal, 45.2±9.4yrs, M:F 14:24) and 13 HbS/HbC (HbSC, 35.6±8.7yrs, M:F 5:8). Patients with at least two Stiffness data (Transient Elastography TE) (T0 and T1), measured out of sickle crisis, were retrospectively evaluated (2007-2016). Liver function tests, HBV, HCV, iron status, and hemolytic indices, were recorded. Abdominal ultrasound (US) and Magnetic Resonance Imaging (MRI) T2* were also collected.
Results: In SCA pts Hb were 9±0.92 g/dL, HbS% 67.9±18.2% and HbF% 8.08±5.36; in HbS-βThal Hb 10±1.59, HbS 63.4±14.2% and HbF% 12.1±9.03; in HbSC Hb 11.9±1.1 (25.9-83.1), HbS 46.4±1% and HbF% 1.53±1.3 (SCA *vs* HbSC and HbS-βThal *vs* HbSC <0.0001).
Considering clinical manifestations, 76.5% of SCA, 60.5% of HbS-βThal and 30.8% of HbSC pts had >1 vaso-occlusive crisis during the decade (VOCs)/yr (SCA *vs* HbSC p=0.02; SCA *vs* HbS-βThal p=0.36; HbS-βThal *vs* HbSC p=00.1). Occasional transfusions (<4 RBCs Units/yr) occurred in 88.2% of SCA, 84.2% of HbS-βThal and 61.5% of HbSC pts. Hydroxy-Carbamide was prescribed to 58.8% of SCA, 65.8% of HbS-βThal and 15.4% of HbSC pts and iron-chelators to 23.5% of SCA, 23.7% of HbS-βThal and none of HbSC pts. At T0 AST, ALT, LDH were statistically higher in SCA pts than in HbS-βThal and HbSC (ALT p<0.0001) and in HbS-βThal compared to HbSC (ALT p=0.01). GGT, ALP were higher in SCA than in HbS-βThal and HbSC (GGT p=0.013; ALP p=0.006), but without statistical significance in HbS-βThal compared to HbSC (GGT p=0.23; ALP p=0.44). Liver synthesis indices were similar in the three subgroups; none was neither HbsAg nor HCV-RNA positive. No differences were found comparing laboratory indices at T0 and T1. TE Stiffness was statistically higher in SCA (KPa 8.3±6.86) than in HbSC pts (KPa 5.33±2.15; p=0.014). In HbS-βThal (KPa 6.17±2.58) was increased but not statistically significant compared to either SCA and HbSC pts (p=0.2). Liver Iron Concentration (LIC) (derived from MRI T2*) was higher in HbS-βThal than in SCA and HbSC pts (HbS-βThal *vs* HbSC p=0.0145) and in SCA comparing HbSC (p=0.018). Univariate analysis was performed to correlate GGT with ferritin (p=0.02), TE (p=0.002), US (p=0.107) and LIC (p=0.511) in all SCD pts. A good correlation between GGT and US liver echogenicity was present in SCA and HbS-βThal pts, with GGT values respectively 20% and 160% higher than normal. TE and US (p=0.045) in all SCD pts correlated positively. No differences were found in TE and MRI T2* at T0 and T1. US showed significant differences at T0 compared with T1 in HbS-βThal (p=0.04) and in HbSC pts (p=0.001), but not in SCA pts (p=0.46) probably because of higher Stiffness since T0. Multivariate analysis showed as independent risk factors: sex (male), low HbF values, high ferritin values, more severe sickle genotype as predictors of liver involvement.
Summary and Conclusions: Function liver tests associated with US, TE and when possible to MRI T2* taking into account sex, percentage of HbF, and SCD genotypes, are important to early detect and follow the sickle hepatopathy.

Stem cell transplantation – Clinical

SAFETY AND IMPROVED SUSTAINED RESPONSE RATES IN PATIENTS WITH CHRONIC GRAFT *VERSUS* HOST DISEASE TREATED WITH IBRUTINIB: 1-YEAR UPDATE OF A PHASE 1B/2 STUDY

E. Waller[1,*], D. Miklos[2], C. Cutler[3], M. Arora[4], M. Jagasia[5], I. Pusic[6], M. Flowers[7], A. Logan[8], R. Nakamura[9], J. Dubovsky[10], S. Chang[10], F. Clow[10], I. Lal[10], L. Styles[10], S. Jaglowski[11]

[1]Winship Cancer Institute of Emory University, Atlanta, GA, United States, [2]Stanford University, Stanford, CA, United States, [3]Dana Farber Cancer Institute, Boston, MA, United States, [4]University of Minnesota, Minneapolis, MN, United States, [5]Vanderbilt-Ingram Cancer Center, Nashville, TN, United States, [6]Washington University School of Medicine, St. Louis, MO, United States, [7]Fred Hutchinson Cancer Research Center, Seattle, WA, United States, [8]University of California San Francisco, San Francisco, CA, United States, [9]City of Hope, Duarte, CA, United States, [10]Pharmacyclics LLC, an AbbVie Company, Sunnyvale, CA, United States, [11]The Ohio State University Comprehensive Cancer Center, Columbus, OH, United States

Background: Ibrutinib, a once-daily inhibitor of Bruton's tyrosine kinase, demonstrated clinically meaningful sustained responses and an acceptable safety profile in a phase 1b/2 study involving patients with active chronic graft *versus* host disease (cGVHD) and inadequate response to corticosteroid-containing therapies (median follow-up, 1.2 years; Miklos *et al.*, *Blood* 2017). Observations from this study led to the approval of ibrutinib in US patients who failed ≥1 lines of systemic therapy.
Aims: To report updated data from the phase 1b/2 clinical study of ibrutinib in patients with inadequate response to corticosteroid-containing therapies.
Methods: Phase 1b/2, open-label, single-arm, multicenter study (PCYC-1129-CA; NCT02195869). Patients with steroid-dependent or -refractory cGVHD who received ≤3 prior therapies for cGVHD and had either a National Institutes of Health (NIH)-defined 25% body surface area erythematous rash or 4 total mouth score received ibrutinib 420 mg/day until progression or unacceptable toxicity. The primary endpoint was best overall cGVHD response by 2005 NIH Consensus Panel Response Criteria with modification based on the 2014 NIH Consensus Panel Response Criteria. Secondary endpoints included sustained response rate, changes in Lee cGVHD symptom Total Summary Score, steroid doses over time, and safety. All patients provided written informed consent.
Results: After a median follow-up of 2.1 years, the best overall cGVHD response rate was 69% (n=29/42; complete response [CR], 31% [n=13]; partial response [PR], 38% [n=16]). Among the 29 patients who responded, 20 (69%), 18 (62%), and 16 (55%) had sustained responses ≥20, ≥32, and ≥44 weeks, respectively. A total of 19/26 (73%) patients who responded and had ≥2 organs involved at baseline had a response in ≥2 organs and 6/10 (60%) patients who responded and had ≥3 organs involved at baseline had a response in ≥3 organs. The cGVHD response rate in patients with sclerosis at baseline was 61% (n=11/18; CR, 39%; PR, 22%). By week 52, 26/42 (62%) patients had a reduced steroid dose to <0.15 mg/kg/d; 8 patients discontinued steroids. A clinically meaningful (≥7 point) decrease in the Lee cGVHD Symptom Total Summary Score was observed in 12 (29%) patients on ≥2 consecutive visits. At 1 year, 16/29 patients who responded (55%) compared with 1/13 patients who did not respond (8%) showed an improvement in Lee cGVHD Symptom Total Summary scores. Common grade ≥3 adverse events (AEs) were pneumonia (n=6), fatigue (n=5), and diarrhea (n=4). Serious AEs (SAEs) were reported in 22 patients (52%); grade ≥3 SAEs occurred in 19 patients (45%) and included 6 patients with pneumonia. One patient with pneumonia died. The onset of new grade ≥3 AEs decreased from 71% in the first year of treatment to 25% in the second year of treatment (n=12). A total of 15 patients discontinued treatment because of AEs and 5 discontinued because of progressive cGVHD; 4 patients discontinued ibrutinib after cGVHD resolution.
Summary and Conclusions: An additional 1 year of follow-up of ibrutinib's activity and safety in adult patients with cGVHD that failed ≥1 lines of systemic therapy demonstrated durable responses and continued improvements from the previously reported 1-year results: CR rates increased from 21% to 31%, sustained response rates for ≥32 weeks increased from 48% to 62%, and patients with improvement in Lee cGVHD Symptom Total Summary Score on ≥2 consecutive visits increased from 24% to 29%. These results support ibrutinib's recent approval in the United States in this pretreated, high-risk population.

Background: The best alternative donor for allogeneic HCT (alloHCT) candidates without a matched sibling remains to be defined. In the absence of prospective randomized trials, additional data are needed to inform donor choice in these patients. Recently, Milano et al (N Engl J Med 2016;375:944-53) showed that cord blood HCT may improve relapse rates and overall survival compared to unrelated donors (UD) in patients with high-risk acute leukemia (AL) and residual disease prior to HCT.
Aims: We present a retrospective case-controlled study by the Grupo Español de Trasplante Hematopoyético y Terapia Celular (GETH) of first alloHCT for high-risk AL including 94 alloHCT recipients of single cord-blood units plus third-party donor CD34+ cells (haplo-cord) compared (1:2) with 188 recipients of UD alloHCT.
Methods: Case and controls were matched for age, gender, WHO diagnosis, disease status at HCT, time from diagnosis to HCT, prior auto-HCT, TBI use in conditioning and year of HCT. Haplo-cord cases included 57 men (61%) and 37 women (39%), median age 34 years (range 16-64), median weight 70 kg (42-111), 51 AML and 43 ALL, 49 in first CR, 16 in CR2 and 29 more advanced, including 23 with detectable disease. Six had a prior autologous HCT. Median time from diagnosis to alloHCT was 8.3 months (range 2-66).
Results: Overall outcomes for the whole series at 6 years are comparable between haplo-cord and UD-controls for non-relapse mortality (33.0%, 95CI: 24.7-44.0 *versus* 34.4%, 95CI: 28.1-42.0, respectively; n.s.), and show a statistical trend in favour of haplo-cord in relapse rate (24.5%, 95CI:17.2-34.9 in haplo-cord *versus* 30.7%, 95CI:24.7-38.2 in UD-controls; p=0.135) and overall survival (47.7%, 95CI: 37.6-57.8 in haplo-cord *versus* 37.0%, 95CI: 29.9-44.0 in UD-controls; p=0.079). In addition, grade II-IV acute GvHD was significantly lower in the haplo-cord group (12.1% *vs* 40.7%, p=0.001; 35.8% in matched *vs* 45.6% in mismatched controls) as well as chronic GvHD (29.9% *vs* 50.0%, p=0.02; 43.6% in matched *vs* 55.8% in mismatched controls).
Of note, high-risk AL patients transplanted with advanced disease (CR3 or later, partial remission or refractory disease), had significantly better 6-year outcomes following haplo-cord alloHCT than their UD-controls: relapse rate was 37.9% (95CI: 23.8-60.4) *versus* 47.8% (95CI: 35.4-64.7), respectively (p=0.069), progression-free survival was 24.1% (95CI: 8.6-39.7) *versus* 13.0% (95CI: 3.3-22.8), respectively (p=0.046), and overall survival was 31% (95CI: 14.2-47.9) *versus* 13.0% (95CI: 3.3-22.8), respectively (p=0.046). Patients with ALL had a particular benefit from the use of haplo-cord HCT. Their progression-free survival with haplo-cord at 6 years significantly improved compared with UD (43.6% (95CI: 28.0-59.2) *vs* 24.4% (95CI: 14.6-34.3); p=0.05) (Figure 1).
Summary and Conclusions: With the increase availability and use of alternative donors for alloHCT, data to inform donor choice are needed. It is unlikely that any single type of alternative donor will be the best choice for all patients lacking a matched related donor. Our data with haplo-cord HCT, in line with recent findings by Milano *et al.*, contribute to the evidence to suggest that unrelated CB reduces the incidence of GvHD while controlling the underlying AL, and might be a preferable donor choice with improved overall survival for patients with AL and a high-risk of relapse, especially in ALL patients.

Background: Salvage autologous stem cell transplantation (ASCT) is used in selected patients with relapsed multiple myeloma (MM) after up-front ASCT. However, there are limited data on the optimal induction therapy before salvage ASCT. There is strong support for the use of maintenance therapy after upfront ASCT in newly diagnosed MM whereas data on maintenance therapy after salvage ASCT are sparse.

The Nordic Myeloma Study Group (NMSG) initiated the CARFI trial (NCT02572492), an open randomized phase II study, to investigate the efficacy and safety of carfilzomib as part of induction and conditioning in salvage ASCT and to evaluate the role of carfilzomib/dexamethasone maintenance after salvage ASCT. Here we report safety and response data before start of maintenance on the first 118 included patients that have undergone induction and salvage ASCT.

Aims: To report safety and response data on the first 118 included patients that have undergone carfilzomib-cyclophosphamide-dexamethasone (CAR-CY-DEX) induction and salvage ASCT.

Methods: Patients with first relapse more than one year after up-front ASCT can be included. A total enrollment of 200 patients is planned. Induction therapy is four cycles of CAR-CY-DEX (iv carfilzomib 20 mg/sqm 36 mg/sqm on days 1, 2, 8, 9, 15 and 16, tablet cyclophosphamide 300 mg/sqm on days 1, 8 and 15 and tablet dexamethasone 20 mg on days 1, 2, 8, 9, 15 and 16 in each 28-days cycle). The conditioning regimen consists of iv carfilzomib 27 mg/sqm on day –2 and –1, and iv melphalan 200 mg/sqm on day –2. Two months after ASCT patients are randomized (1:1) to either observation or maintenance therapy with iv carfilzomib 27 mg/sqm 56 mg/sqm every second week and tablet dexamethasone 20 mg every second week.

Results: By January 15, 2018, 173 out of 200 planned patients have been enrolled in the study. 129 patients have completed CAR-CY-DEX induction and 118 patients have completed salvage ASCT. Twelve patients went off study during the induction phase (four discontinued due to progression, five due to serious adverse events (two infections, acute myocardial infarction, intracerebral hemorrhage and pulmonary insufficiency), two due to withdrawal of consent and one due to sub-optimal response (SD)). Two patients died due to serious infections during induction. Five patients went off study during the ASCT phase or within the following two months (two patients due to progression, one due to fatal Candida septicemia, one due to withdrawal of consent and one due to small cell lung cancer) (Table 1). A total of 53 Grade 3/4 serious adverse events were reported in 40 patients (31.0%) during the CAR-CY-DEX induction therapy (Table 1).

Responses after CAR-CY-DEX induction and after salvage HDT are summarized in Table 1. After CAR-CY-DEX induction ≥VGPR and ≥CR were observed in 46.5% and 9.3%, respectively, and at disease evaluation 2 months after salvage ASCT ≥VGPR and ≥CR were achieved in 64.4% and 16.9%, respectively. The corresponding figures for the same patients after upfront induction therapy were ≥VGPR in 46.6% and ≥CR in 10.9%, and after up-front ASCT ≥VGPR in 78.0% and ≥CR in 31.4%.

Summary and Conclusions: At first relapse after upfront ASCT CAR-CY-DEX induction therapy was feasible, tolerable and equally effective as induction at front-line.

THE ROLE OF COLLATERAL RELATED DONORS IN HAPLOIDENTICAL HEMATOPOIETIC TRANSPLANTATION: A COMPARATIVE STUDY BETWEEN COLLATERAL RELATED DONORS AND PARENTAL DONORS

X.-D. Mo[1,*], Y.-Y. Zhang[1], X.-H. Zhang[1], L.-P. Xu[1], Y. Wang[1], C.-H. Yan[1], H. Chen[1], Y.-H. Chen[1], K.-Y. Liu[1], X.-J. Huang[1]

[1]Peking University People's Hospital, Institute of Hematology, Beijing, China

Background: Human leukocyte antigen (HLA)-haploidentical related donor HSCT (haplo-HSCT) has become a valuable option in transplant procedures.Immediate family donor and the collateral relative donor (CRD) could both be a potential haploidnetical donor. But the role of CRDs in the donor selection for haplo-HSCT is unclear
Aims: We aimed to analyze the clinical outcomes and prognostic factors for patients receiving haplo-HSCT from CRDs. We also wanted to compare the clinical outcomes among patients receiving haplo-HSCT from CRDs, maternal donors (MDs), and paternal donors (PDs).
Methods: A total of 929 consecutive subjects with hematological malignances receiving haplo-HSCT January 2005 through December 2014 were considered; including CRDs (n=60), PDs (n=573), or MDs (n=296).
Results: Female donor/male recipient (FDMR) combination was significantly associated with higher non-relapse mortality (NRM) and poorer survival rates of CRDs. The 5-year cumulative incidence of relapse was comparable among the PD, MD, and CRD groups. The 5-year cumulative incidence of NRM was higher in CRD (25.0%) and MD (23.1%) groups compared with that of PD (12.5%) group (P<0.001). The 5-year probabilities of DFS (66.1%) and OS (72.2%) of PD group were both better than those of CRD (DFS: 53.2%; OS, 56.6%) and MD group (DFS: 59.5%; OS, 61.6%). All of the clinical outcomes were comparable between CRD and MD groups. FDMR CRD was associated higher platelet engraftment failure (HR=3.58, P=0.028), higher extensive chronic graft-*versus*-host disease (cGVHD) (HR=6.33, P=0.010), higher NRM (HR=13.20, P<0.001), lower DFS (HR=6.79, P<0.001) and lower OS (HR=8.89, P<0.001) compared with MD. The clinical outcomes of non-FDMR CRD group were comparable to those of MD. PD showed the best clincial outcomes.
Summary and Conclusions: Our results showed that for the patient without sibling or offspring donor, choosing PD was the most optimal selections. For those who were not available to choose PD, choosing MD or non-FDMR CRD is reasonable. Transplants from FDMR CRD should probably be avoided considering the low platelet engraftment, high GVHD, high NRM, and low survival rates.

PF722

EFFICACY OF BONE MARROW DERIVED MSC FOR STEROID REFRACTORY ACUTE GVHD ASSOCIATES WITH AGE AND A DEFINED MOLECULAR PROFILE OF MSC DONORS

L. Van Der Wagen[1,*], F. Fernando[2], N. Appukudige[2], A. Janssen[2], K. Westinga[3], R. Admiraal[4], M. Lorenowicz[5], P. Coffer[5], G. Huls[6], S. Zeerleder[7], J. Janssen[8], A. Broers[9], W. van der Velden[10], R. van Marwijk Kooy[11], J.J. Boelens[12], J. Kuball[1]

[1]Hematology, [2]Laboratory of Translational Immunology, [3]Cell Therapy Facility, [4]BMT Unit Pediatric Department, UMC UTRECHT, [5]Center for Molecular Medicine & Regenerative Medicine Center, UMC Utrecht and Utrecht University, Utrecht, [6]Hematology, UMC Groningen, Groningen, [7]Hematology, AMC Amsterdam, [8]VU MC, Amsterdam, [9]Erasmus MC, Rotterdam, [10]Radboud MC, Nijmegen, [11]Internal Medicine, Isala klinieken, Zwolle, [12]UMC UTRECHT, Utrecht, Netherlands

Background: Acute graft *versus* host disease (aGVHD) remains a life-threatening complication and substantially reduces efficacy of allo-HSCT. The outcome of patients with severe steroid-refractory aGVHD continues to be poor. Administration of Mesenchymal Stromal Cells (MSC) has been reported by others and us as an interesting treatment option (Le Blanc, Frassoni *et al.* 2008, von, Stolzel *et al.* 2009, Lucchini, Introna *et al.* 2010, Te Boome, Mansilla *et al.* 2015). Though insurance and fast track approval has recently been granted to MSC products in Japan and USA, variability arising from donor variability and the inability to link surrogate markers of the product to clinical efficacy could prove to be a major obstacle in daily clinical practice.
Aims: To evaluate the impact of individual MSC donors as well as MSC donor properties such as age on clinical response in a cohort of 102 patients with grade II-IV steroid refractory aGVHD treated within a prospective study as well as an extended hospital exemption program (Te Boome, Mansilla *et al.* 2015).
Methods: Bone marrow derived MSC from third party non-HLA matched donors were administered at day 1, 8, and 21 as reported (Te Boome, Mansilla *et al.* 2015). Primary outcome measures were 1-year overall survival (OS) and GVHD response. Cox proportional hazards models, competing risk analyses (Gray's test) and Kaplan Meier estimates were used for analyzing response and OS respectively. Two R statistical packages for RNA-seq analysis were used for calculating differentially expressed genes (DEGs) (DeSeq & EdgeR). DEGs were considered significant based on the overlap across the two methods and a False Discovery Rate/adjusted p-value<0.05.
Results: 102 patients received in total 299 MSC infusions derived from 10 different BM donors. Median number of infusions was 3 (range 1-4). 75,5% of patients received all MSC infusions from the same donor, 20,6% MSC from 2 donors and 3,9% MSC from 3 different donors. Two donors were used to treat 28,4% and 43,1% of patients respectively. When testing retrospectively impact on 1-year OS of an individual product no differences between patients treated with either the 2 main contributing donors or the patients treated with the 'other' MSC donors could be observed. However, a survival benefit was observed for patients treated with young donors (MSC donor age <10 years, Figure 1). Competing risk analysis also revealed a significant benefit for patients only treated with young donors. Furthermore, in multivariate analysis, MSC donor age remained predictive for OS (HR 2,00, p-value 0,025). RNA sequencing analysis was used to further dissect molecular differences between individual donors and allowed to identify a distinctive molecular profile in MSC which associated with improved clinical outcome.

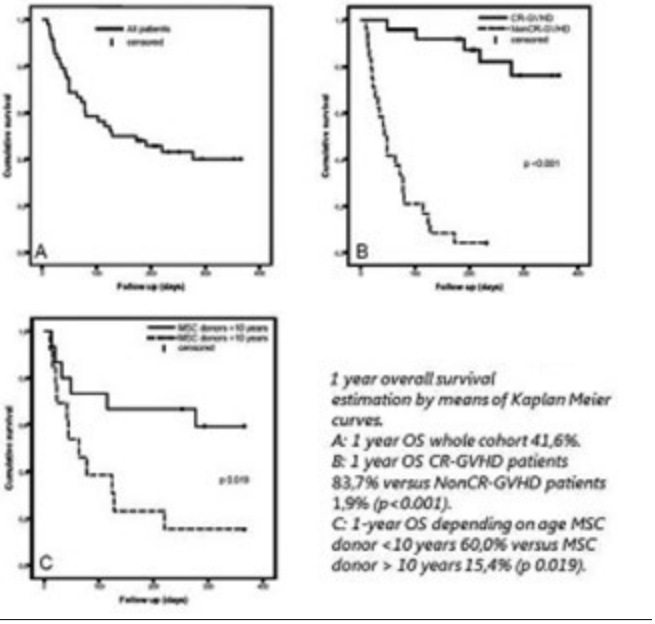

Figure 1.

Summary and Conclusions: In our cohort of 102 patients with steroid refractory acute GVHD that were treated with MSC we observed in this retrospective study differences in achieving both complete resolution of GVHD symptoms and 1 year OS. Patients only treated with MSC derived from young bone marrow donors (<10 years old) had significantly better resolution of GVHD symptoms as well as an improved OS. Furthermore we identified a distinctive molecular profile by means of RNA sequencing which associates with improved clinical outcome. These findings may have implications for approval of current products entering the market as well as on future and currently ongoing trials with MSC.

Background: Generally, the outcomes of hematopoietic cell transplantation (HCT) in patients with non-remission acute myeloid leukemia (AML) have been poor. Particularly, the detection of cohorts with extremely poor prognosis is important, because medicosociological issues, including escalation of medical costs or donor burden, remain unresolved.
Aims: A multicenter retrospective study was performed to design a prognostic scoring index and to detect a population with lowest survival in patients with relapsed or refractory AML, who underwent HCT.
Methods: Patients with non-remission AML who received HCT between 2005 and 2015 at attending institutions were eligible. Using a clinical research form, further clinical information, such as the reason of non-remission or biomarkers prior to HCT, was collected. Inclusion criteria were the blast fraction in bone marrow ≥5% or detection of blast cell in peripheral blood prior to HCT. Extramedullary sarcoma without bone marrow involvement and untreated leukemia were excluded.
Results: A total of 639 patients with non-remission AML were found in the registry data. After excluding 120 patients, 519 patients were included in the analysis. The whole cohort was randomized for training (n=256) and validation (n=263). The median age of a training cohort was 50 years (range: 16–70). Disease status included primary induction failure in 145 patients and relapse after remission in 111 patients. The median blast fractions of peripheral blood and bone marrow were 3% (range: 0–99) and 20% (range: 0-99), respectively. The median duration from diagnosis to HCT was 7 months (range: 0–78). Donors came from related bone marrow in 26 patients, related peripheral blood in 50, an unrelated donor in 115, and a single unit of umbilical cord in 65, respectively. An HLA antigen-matched donor was used for 150 patients. Myeloablative and reduced intensity conditioning regimen was used for 150 and 106 patients, respectively. Cumulative incidence of engraftment at 50 days, grade to of acute graft-*versus*-host disease (GVHD) at 100 days, and chronic GVHD at 1 year was 85.5%, 48.3%, and 34.9%, respectively. With a median follow-up period of 36.7 months (range: 2.5–129), overall survival (OS), non-relapse mortality, and relapse mortality at 1 years was 42% and 36%, and 41%, respectively. Multivariate analysis demonstrated independent predictors for OS included C-reactive protein ≥1 mg/dL (hazard ratio [HR]=1.84, 95% confidence interval [CI]: 1.35–2.50, P <0.001), peripheral blood blast fraction ≥20% (HR=1.99, 95%CI: 1.48–2.69, P <0.001), poor-risk karyotype (HR=1.75, 95%CI: 1.30–2.35, P <0.001), performance status ≥2 (HR=1.74, 95%CI: 1.17–2.57, P=0.006), and bone marrow from unrelated donor (HR=1.56, 95%CI: 1.16–2.09, P=0.003). Scoring one point for each factor, a prognostic scoring index was designed. At 2 years, OS was 46%, 24%, 8%, and 0% for Good (Score 0, 1: n=118), Intermediate-1 (Score 2: n=75), Intermediate-2 (Score 3: n=39), and Poor (Score 4: n=24), respectively (P <0.001)(Figure 1A). Applying the index to the validation cohort, OS at 2years was 40%, 18%, 12%, and 0% for Good (n=133), Intermediate-1 (n=61), Intermediate-2 (n=49), and Poor (n=20), respectively (P <0.001). The index was reconfirmed in a validation cohort (Figure 1B).

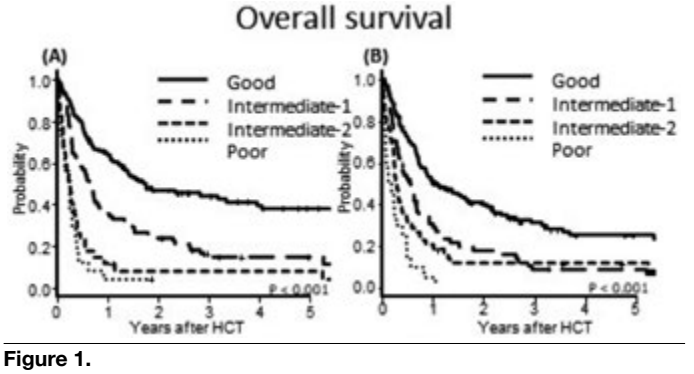

Figure 1.

Summary and Conclusions: Although further validation study is warrant, the scoring index may be useful to predict survival and to detect the population with the lowest survival prior to HCT in patients with relapsed or refractory AML.

PF724

IMPROVED SURVIVAL FOLLOWING OMS721 TREATMENT OF HEMATOPOIETIC STEM CELL TRANSPLANT-ASSOCIATED THROMBOTIC MICROANGIOPATHY (HCT-TMA)

A. Rambaldi[1,*], S. Khaled[2], M. Smith[3], M. Zecca[4], Y. L. Kwong[5], K. Claes[6], N. Leung[7], S. Whitaker[8]

[1]Bone Marrow Transplant Unit ASST Papa Giovanni XXIII, Bergamo, Italy, [2]City of Hope, Duarte, United States, [3]Canterbury District Health Board - Te Poari Hauora o Waitaha, Christchurch, New Zealand, [4]Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [5]University of Hong Kong, Hong Kong, Hong Kong, [6]UZ Leuven, Leuven, Belgium, [7]Mayo Clinic, Rochester, [8]Omeros Corporation, Seattle, United States

Background: Thrombotic microangiopathy is a potentially fatal complication of HCT. Mortality greater than 90% has been reported in high-risk cases. HCT-TMA is an endothelial injury syndrome associated with complement pathway activation. Other endothelial injury syndromes include graft *versus* host disease (GvHD) and diffuse alveolar hemorrhage (DAH). OMS721 is a human monoclonal antibody that inhibits mannan-binding lectin-associated serine protease-2 (MASP-2), the effector enzyme of the lectin pathway. OMS721 may improve patient outcomes by inhibiting complement-mediated injury during TMA.
Aims: This study's aims were to evaluate the efficacy and safety of OMS721 in patients with HCT-TMA.
Methods: OMS721 was evaluated in a 3-stage, uncontrolled Phase 2 study of patients with TMA, including HCT-TMA. Stage 1 evaluated 3 dose levels. One dose level was selected for cohort-expansion Stages 2 and 3. The protocol allowed 4 or 8 once-weekly IV doses of OMS721. Additional ½ doses could be administered to patients who received plasma therapy. HCT-TMA patients had persistent TMA defined as TMA that did not resolve following immunosuppression modification. One patient received OMS721 under compassionate use and received thrice-weekly dosing. A best-matched historical control from the literature was identified for comparison to the outcomes of HCT-TMA patients treated with OMS721. References were chosen to match OMS721-treated patients based on age, allogeneic transplantation, and reports that TMA did not resolve following immunosuppression modification. The references included individual patient survival data and were published in 2000 or later. Kaplan-Meier estimated mean survival was compared between OMS721-treated patients and historical control patients.
Results: A total of 19 patients were included in the analysis, 18 from the study and 1 from compassionate use. Nine OMS721-treated patients died, 4 during study participation. Figure 1 demonstrates a significant increase in median overall survival between OMS721-treated patients and historical controls (347 days *vs* 21 days from TMA diagnosis, respectively; Log-Rank p <0.0001).

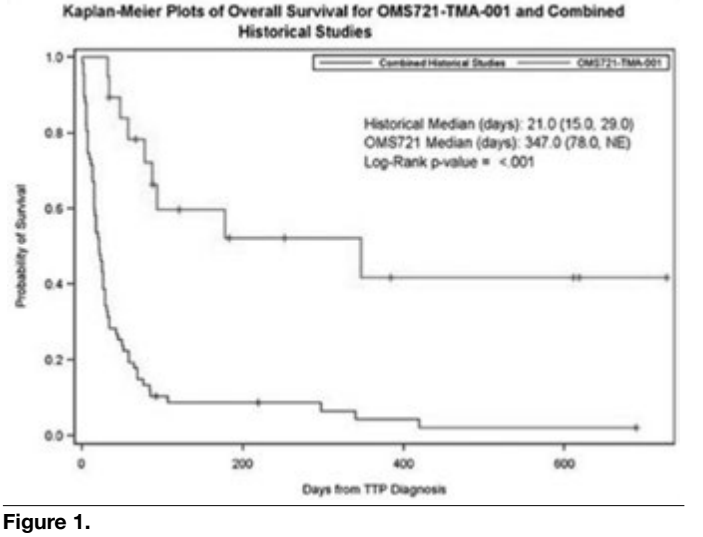

Figure 1.

Two patients from this population were previously presented. The compassionate-use patient's course was complicated by DAH and she did not tol-

erate previous eculizumab treatment. She responded well to OMS721 and was able to discontinue oxygen therapy, hemodialysis, and platelet transfusions. Another patient had steroid-refractory GvHD post-transplant. He developed TMA with co-existing GvHD and multiple disabling neurological complications. Following OMS721 treatment, his TMA and GvHD resolved, his neurological complications improved, and he was discharged and returned to work. OMS721 was well tolerated. The most common adverse events were diarrhea and neutropenia. One fatal adverse event of infection-related acute respiratory and renal failure was considered possibly related to OMS721 treatment because the investigator could not definitively rule out possible causation.

Summary and Conclusions: In this study, patients with high-risk HCT-TMA had significantly improved overall survival compared to best-matched literature controls. The safety profile was acceptable. This study shows positive outcomes with lectin pathway blockade by MASP-2 inhibition to treat HCT-TMA and other HCT-related complications (*i.e.*, GvHD and DAH) linked to endothelial injury.

PF725

TRANSPLANT-ASSOCIATED THROMBOTIC MICROANGIOPATHY: INCIDENCE, PROGNOSTIC FACTORS, MORBIDITY AND MORTALITY IN ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION

E. Gavriilaki[1,*], I. Sakellari[1], D. Mallouri[1], I. Batsis[1], Z. Bousiou[1], A. Vardi[1], E. Yannaki[1], V. Constantinou[1], A. Tsompanakou[1], C. Vadikoliou[1], P. Kaloyannnidis[1], G. Bamihas[2], A. Anagnostopoulos[1]

[1]Hematology Department - BMT Unit, [2]Nephrology Department, G. Papanicolaou Hospital, Thessaloniki, Greece

Background: Transplant-associated thrombotic microangiopathy (TA-TMA) is a severe complication of allogeneic hematopoietic cell transplantation (HCT). Renewed interest has emerged in the field with the introduction of novel prognostic, diagnostic and treatment algorithms.

Aims: Therefore, we aimed to investigate the incidence, prognostic factors, morbidity and mortality of TA-TMA in allogeneic HCT recipients.

Methods: We enrolled consecutive patients who underwent HCT from 1990 to 2017 in our center. TA-TMA diagnosis was based on the International Working Group Criteria. Anti-thymocyte globulin (ATG, rabbit) was used as part of the conditioning in almost all non-sibling transplants. Graft-*versus*-host disease (GVHD) prophylaxis consisted of cyclosporine or tacrolimus plus methotrexate in myeloablative and mycophenolate mofetil plus cyclosporine in reduced intensity or toxicity conditioning transplants. Upon identification of TA-TMA, all possible causative factors were fully investigated. Management included withdrawal of calcineurin inhibitors, plasma infusion and plasma exchange combined with corticosteroid administration. Patients refractory to conventional management received humanized anti-CD20 monoclonal antibody (rituximab) until 2015 and since 2015, terminal complement inhibitor (eculizumab).

Results: Among 758 alloHCT recipients (transplanted from 451 sibling, 259 unrelated, 40 haploidentical, 2 twin donors and 6 cord blood), 116 (15.5%) patients were diagnosed with TA-TMA.

Regarding pre-transplant characteristics (age, gender, disease type and phase, lines of previous treatments, type of conditioning, ATG or TBI administration, type of donor, HLA matching), TA-TMA was associated only with TBI-based conditioning (34.4% *versus* 20.6%, p=0.004). TA-TMA patients also showed significantly increased rates of viral (p=0.001) and fungal (p=0.002) infections post-transplant, as well as severe acute (grade III-IV) and extensive chronic GVHD (p<0.001 for both). In the multivariate analysis, TBI-based conditioning (p=0.020), viral infections (p=0.024), acute (p=0.010) and chronic (p=0.004) GVHD remained independent predictors of TA-TMA. With a median follow-up of 23 (range 0.1-329) months, TA-TMA resulted in significantly lower overall survival (OS Figure 1, p=0.016). In the multivariate analysis, TA-TMA (p=0.029) remained an independent predictor of OS, along with relapse (p<0.001), acute (p<0.001) and chronic (p=0.002) GVHD. Among 116 TA-TMA patients, 70 developed renal (56) and/or neurologic (26) dysfunction that would be necessary for TA-TMA diagnosis according to the Bone Marrow Transplant Clinical Trials Network criteria. TA-TMA patients with renal dysfunction showed increased rates of acute GVHD (p=0.010), but no difference in OS compared to TA-TMA patients without renal dysfunction. However, neurologic dysfunction resulted in significantly lower OS (p=0.033) in TA-TMA patients.

Summary and Conclusions: Our results confirm that TA-TMA is associated with increased morbidity and mortality in allogeneic transplant recipients, irrespectively of pre-transplant characteristics (except for TBI). Successful prevention and treatment strategies of infections and GVHD need to be timely employed to improve survival in this complex setting. Novel diagnostic criteria are also warranted to early recognize patients that would benefit from novel treatment options.

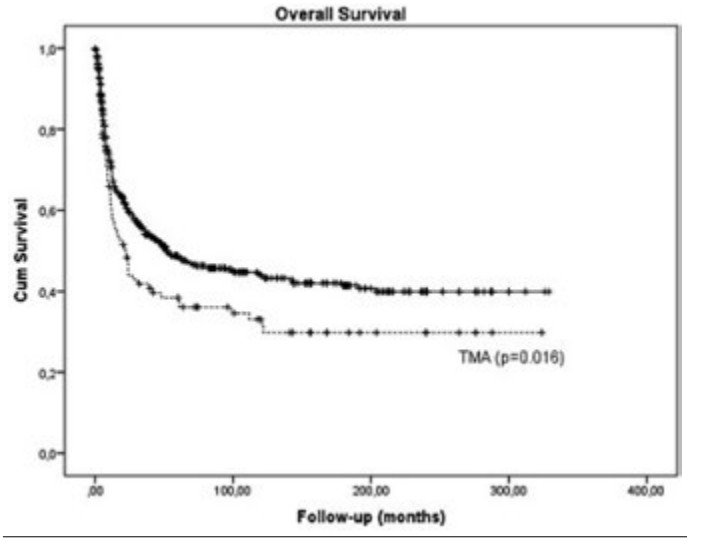

Figure 1.

PF726

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANT IN THE OUTPATIENT SETTING: A SINGLE CENTER EXPERIENCE OF 924 CONSECUTIVE TRANSPLANTS

S. Saadeh[1,*], U. Durani[1], A. Kansagra[2], H. Alkhateeb[1], M. Shah[1], K. Ewert[3], S. Kendarian[1], S. Hashmi[1], M. Patnaik[1], M. Litzow[1], W. Hogan[1]

[1]Hematology, Mayo Clinic, Rochester, [2]Internal Medicine, UT Southwestern Medical Center, Dallas, [3]Information Technology, Mayo Clinic, Rochester, United States

Background: In most centers, allogeneic transplant patients are admitted for follow-up until engraftment and hematopoietic recovery a median length of stay of up to 31 days (Majhail *et al.*, 2013). Prolonged admissions can increase risk of nosocomial infections, deconditioning, in addition to associated financial toxicity. At our institution, patients are not routinely admitted and transplant followed outpatient with scheduled daily follow-up. Some require planned admissions for completion of conditioning or GVHD prophylaxis regimen among other reasons. During follow-up, patients are admitted for management of complications when deemed unsafe or high risk for management as outpatient

Aims: We aim to report on feasibility and outcomes of outpatient allogeneic stem cell transplant during the first 100 days

Methods: We retrospectively analyzed records of all adult allogeneic transplants performed from January 1989 to March 2017. Non-routine hospital admissions within 100 days after transplant were included. Descriptive statistics and multivariable logistic regression were used to characterize the cohort and determine predictors of admission

Results: A total of 924 transplants were identified. Males were 58%, median age was 51 (IQR 39-58), and 55.3% received myeloablative conditioning. There were 1,098 non-routine admissions with 32.7% of patients never requiring admission. Median number of admissions for the entire cohort was 1 (inter-quartile range (IQR) 0-2), and median time from transplant to admission was 23 days (IQR 9-54). Median length of stay was 6 days per admission (IQR 3-13) and in-hospital mortality was low at 5%. Direct admission to an intensive care unit occurred in 6.6% of admissions. In the cohort requiring admissions, median total number of days spent in the hospital was 17 (IQR 9-34). Most patients had an absolute neutrophil count greater than $0.5x10^9$/L and a platelet count greater than $20x10^9$/L prior to admission; 57% and 58%, respectively. Baseline characteristics and cause of admission are highlighted in Table 1 and Figure 1, respectively. patients with CLL were the least likely to require admission, and in a multivariable logistic regression (adjusted for age, sex, conditioning), patients with ALL (OR 2.66, p<0.01), AML (OR 2.44, p<0.01), benign disease (OR 3.25, p<0.02), lymphoma (OR 2.49, p<0.03), MPN (OR 2.93, p<0.02), and MM (OR 4.63, p<0.01) were more likely to be admitted compared to CLL. Bone marrow graft (*versus* peripheral blood) was a negative predictor of admission (OR 0.22, p<0.01) while unrelated donor was a positive predictor (OR 2.23, p<0.01).

Summary and Conclusions: Allogeneic stem cell transplant in the outpatient

setting is feasible with 32.7% of patients never requiring admission. Median number of in-hospital days was decreased to a median of 17 days compared to a reported median of 31 days. Interestingly, conditioning intensity was not a predictor of admission.

Table 1. Patient characteristics.

	Transplants (N=924)
Diagnosis	
ALL	124 (13%)
AML	352 (38%)
CLL	60 (4%)

PF727

PHASE II STUDY EVALUATING THE SAFETY AND EFFICACY OF BL-8040 FOR THE MOBILIZATION OF DONOR HEMATOPOIETIC STEM CELLS AND ALLOGENEIC TRANSPLANTATION IN PATIENTS WITH ADVANCED HEMATOLOGICAL MALIGNANCIES

M.P. Rettig[1,*], G.L. Uy[1], A. Bashey[2], S.M. Devine[3], S. Jaglowski[3], A. Vainstein-Haras[4], E. Sorani[4], H. Chen[4], O. Bohana-Kashtan[4], P. Westervelt[1], J.F. DiPersio[1]

[1]Washington University School of Medicine, St. Louis, [2]Blood and Marrow Transplant Group of Georgia, Northside Hospital Cancer Institute, Atlanta, [3]The Ohio State University Comprehensive Cancer Center, Columbus, United States, [4]BioLineRx Ltd., Modi'in, Israel

Background: Mobilization of hematopoietic stem and progenitor cells (HSPCs) with G-CSF requires 4-5 days of treatment prior to collection and is associated with bone pain and splenic rupture in donors, and higher rates of chronic GVHD in allogeneic hematopoietic cell transplant (alloHCT) recipients. Here, we sought to test BL-8040, a novel high affinity CXCR4 antagonist with rapid mobilizing kinetics and long receptor occupancy, in donors for alloHCT.
Aims: To assess the safety and tolerability of BL-8040 and the ability of a single BL-8040 injection to mobilize HSPCs for use in alloHCT.
Methods: This phase 2 study consists of 24 donor/recipient pairs. Part 1 enrolled HLA-identical pairs and donors were treated with a single SC dose of 1 mg/kg BL-8040. Part 2, following demonstration of safety, is enrolling both HLA-identical and haploidentical pairs and treating donors with 1.25 mg/kg BL-8040. Leukapheresis (LP) was performed 3 hours after injection and could be repeated the next day. When less than $5x10^6$ CD34 cells/kg recipient weight were collected, a second injection of BL-8040 and LP collection was performed the next day. The primary endpoint was collection of $\geq 2x10^6$ CD34 cells/kg recipient weight after up to 2 LP sessions.
Results: As of Feb. 2018, 22 healthy donors (16 HLA-identical and 6 haploidentical) with a median age of 54 (range 20-69) years have been enrolled in the study. One donor was not evaluable due to difficulties with vascular access and was replaced. 11 out of 13 donors (85%) treated at the 1 mg/kg dose and 8/8 donors (100%) treated at the 1.25 mg/kg dose of BL-8040 reached the primary goal of $\geq 2x10^6$ CD34 cells/kg recipient in up to 2 LP. 15 donors out of the 21 (71%) collected $\geq 2x10^6$ CD34 cells/kg in the primary LP and 13 (62%) collected $\geq 5x10^6$ CD34 cells/kg in up to 2 LP. The median CD34 cells/kg recipient in the primary LP collection was 2.3×10^6 (range 0.5×10^6 - 9.4×10^6; N=13) and 3.8×10^6 (range 1×10^6 - 8.7×10^6; N=8) in the 1 and 1.25 mg/kg BL-8040 group, respectively. The median CD34 cells/kg recipient in 2 LP collections was 5.2×10^6 (range 1.2×10^6 - 9.4×10^6; N=13) and 6.9×10^6 (range 2.3×10^6 – 13.8×10^6; N=8) in the 1 and 1.25 mg/kg BL-8040 group, respectively. Evaluation of CD34 kinetics following BL-8040 administration demonstrated stable CD34 cell concentration in the peripheral blood (15-21 cells/μL) throughout LP collection time. The most common BL-8040-related adverse events were injection site reactions and transient systemic reactions (mild to moderate hives). No serious adverse events were observed. 19 recipients, median age 51 years (range 26-69), with hematological malignancy (13 AML, 3 ALL, 1 MDS, 1 MPN and 1 HD), were transplanted with BL-8040-mobilized grafts. All transplanted recipients successfully engrafted with a median time to neutrophil engraftment (ANC≥500 cells/mm3) of 13 days (range 11-25 days) and to platelet engraftment (PLT≥20,000/mm3) 18 days (range 14-37 days). 13 out of 19 recipients passed day 100 post-transplant. Grade II acute GVHD was observed in 2 out of the 19 recipients (11%) and was resolved in one patient. Grade III-IV GVHD was observed in 3 out of 19 recipients (16%), of which 2 were resolved and 1 was downgraded to Grade 1.
Summary and Conclusions: BL-8040 as a single agent is a safe, rapid and effective HSPC mobilizing agent which results in prompt hematopoietic recovery after alloHCT with shortened collection time relative to G-CSF. Effects of BL-8040 on rates of chronic GVHD and relapse await longer follow up.

PF728

NON-HLA MATCHED, *EX-VIVO* EXPANDED CORD BLOOD PRODUCT SIGNIFICANTLY IMPROVES THE KINETICS OF HEMATOPOIETIC RECOVERY AND RESULTS IN EXCELLENT SURVIVAL IN PATIENTS UNDERGOING CORD BLOOD TRANSPLANTATION

F. Milano[1,*], E. Cox[1,2], S. Heimfeld[1,2], I. Bernstein[1], F. Appelbaum[1], C. Delaney[1,2]

[1]Clinical Research Division, Fred Hutchinson Cancer Research Center, [2]Nohla Therapeutics, Inc., Seattle, United States

Background: Allogeneic hematopoietic cell transplantation remains the only known curative approach for patients with high-risk leukemia; however, access is limited by donor availability. Umbilical cord blood (CB) has emerged as an important source of donor stem cells, particularly due to a decreased risk of graft-*versus*-host disease (GVHD) and potential improvement in graft *versus* leukemia effect. However, the low number of $CD34^+$ cells in CB grafts can lead to delayed hematopoietic recovery, resulting in increased risk of morbidity and mortality post-transplant.
Aims: With the goal of enhancing the kinetics of hematopoietic recovery and improving transplant outcomes, we developed methods to *ex-vivo* expand CB-derived hematopoietic stem/progenitor cells (HSPC) using an engineered Notch ligand to increase the number of rapidly repopulating HSPC for clinical applications. The final expanded product (NLA101) is a cryopreserved, non-HLA matched product for use as a T-cell depleted, universal donor graft source.
Methods: Between 2010 and 2012, 15 patients with hematologic malignancies were enrolled in a single center, Phase 2 trial to assess safety and feasibility of infusing NLA101 to augment myeloablative CB transplant (CBT). All patients received conditioning of fludarabine 75 mg/m^2; cyclophosphamide 120 mg/kg; and 13.2 Gy TBI. On transplant day, the unmanipulated CB unit(s) was infused first followed 4 hours later by NLA101. GVHD prophylaxis consisted of Cyclosporine/MMF. Hematopoietic recovery was analyzed using cumulative incidence (CI) rates to accommodate competing risks and was compared to a concurrent control cohort of 50 patients enrolled on a standard of care protocol who were treated identically. No significant differences between the two cohorts were found

with respect to age, sex, weight, disease, and MRD status. Disease-free survival (DFS) and overall survival (OS) were analyzed using Kaplan-Meier estimates. We herein report long-term follow-up data from this study.
Results: Fifteen patients, median age 21 years (range 5-45), being treated for ALL (n=8), AML (n=6) and MDS (n=1) were enrolled and included in this analysis. The median $CD34^+$ and TNC cell doses of NLA101 were 5.3 (range 3.1-11.6) $x10^6$ cells/kg and 5.8 (range 2.2-10.9) $x10^7$ cells/kg, respectively. Median follow-up for this study is now 6.5 years (range 5.6-7.4). As reported previously, time to neutrophil and platelet recovery was significantly improved over the control. CI at day 100 of neutrophil recovery was 100% *vs* 94% (p=0.005), with a median time of 19 days (range 9-31) *vs* 25 days (range 14-45) in the control. CI at day 100 of platelet recovery was 93% *vs* 74% (p=0.02), with a median time of 35 days (range 21 to 86) *vs* 48 days (range 24-158) in the control (Figure 1). No patients experienced transplant related mortality (TRM) or severe grade 3-4 acute GVHD. Two of the 15 patients (13%) relapsed post-transplant and subsequently died. Of the 13 evaluable patients, 9 patients (69%) were off immunosuppression therapy at 2 years post-CBT. DFS and OS remained excellent at 5 years post-CBT at 86%.

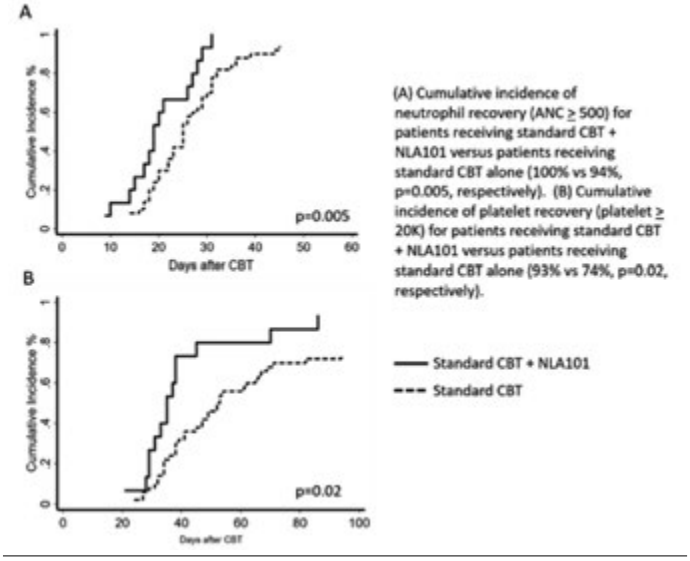

Figure 1.

Summary and Conclusions: These results demonstrate that infusion of NLA101 to augment myeloablative CBT was safe and led to faster neutrophil and platelet recovery, but more importantly showed excellent long-term outcomes of survival, with no TRM or severe grade 3-4 acute GVHD. The non-HLA matched NLA101 can be infused to enhance the kinetics of hematopoietic recovery, resulting in reduction of early transplant related mortality.

PF729

INCIDENCE AND RISK FACTORS OF ANTIBODIES TO HUMAN LEUKOCYTE ANTIGENS IN HAPLOIDENTICAL STEM CELL TRANSPLANTATION CANDIDATES: A MULTI-CENTER STUDY

M.-R. Huo[1], Y.-J. Xu[2], S.-Z. Zhai[1], M. Lv[1], Y. Wang[1], L.-Q. Cao[1], L.-P. Xu[1], X.-H. Zhang[1], H. Chen[1], Y.-H. Chen[1], F.-R. Wang[1], W. Han[1], Y.-Q. Sun[1], C.-H. Yan[1], F.-F. Tang[1], X.-D. Mo[1], M.-F. Zhao[3], K.-Y. Liu[1], X.-J. Huang[4], Y.-J. Chang[5,*]

[1]Peking University Institute of Hematology, Peking University People's Hospital, Beijing, [2]Department of Hematology, Xiangya Hospital, Changsha, [3]Department of Hematology, Tianjin First Central Hospital, Tianjin, [4]Peking University Institute of Hematology,Peking-Tsinghua Center for Life Sciences, Collabrative Innovation Center of Hematology, Peking University People's Hospital, [5]Peking University Institute of Hematology, Collabrative Innovation Center of Hematology, Peking University People's Hospital and Peking University Institute of Hematology, Beijing, China

Background: Currently, the incidence of and risk factors for antibodies to human leukocyte antigen (HLA) in haploidentical allograft candidates have not been thoroughly elucidated.
Aims: To investigate the incidence of and risk factors for antibodies to HLA
Methods: We investigated the incidence of and risk factors for antibodies to HLA in 1,663 haploidentical transplant candidates.
Results: Among these cases, 349 (21.0%) showed positive panel-reactive antibody (PRA) either for class I or class II HLA. Multivariate analysis showed the following: i) risk factors associated with the prevalence of PRA either for class I or class II HLA were female gender (P=0.018), prior transfusions (P<0.001) or pregnancy (P<0.001), and cases with MDS (P=0.018); compared to other patients, subjects with ALL had a lower incidence of class I antibodies (P=0.017); and ii) risk factors associated with the prevalence of PRA both for class I and class II HLA were female gender (P=0.014), prior transfusions (P=0.003), previous pregnancy (P<0.001), and diagnosis with MDS (P=0.035). The percentages of anti-HLA antibodies against a single locus, including HLA-A, -B, -C, -DP, -DQ, and -DR, among all cases were 15.6%, 17.3%, 10.5%, 5.6%, 8.5%, and 9.7%, respectively. Risk factors associated with specific antibodies against HLA-A, -B, -C, -DP, -DQ, and -DR were female gender, prior transfusion, previous pregnancy, and underlying disease. The median number of antibodies to a specific HLA locus was 28 (range, 1 to 148). Multivariate analysis showed a correlation between pregnancy and higher numbers of anti-HLA antibodies (P=0.004).
Summary and Conclusions: Our findings suggest that gender, prior pregnancy, previous transfusion and underlying diseases are risk factors for HLA sensitization. These findings could guide clinical monitoring for HLA antibodies and provide help with donor selection.

PF730

SAFETY AND EFFICACY OF VEDOLIZUMAB IN PATIENTS WITH STEROID REFRACTORY ACUTE GASTROINTESTINAL GRAFT-*VERSUS*-HOST DISEASE: A RETROSPECTIVE CHART REVIEW

Y. Fløisand [1], V. Lazarevic[2], J. Maertens[3], J. Mattsson[4], N. Shah[5], P. Zachée[6], A. Taylor[7,*], M. Akbari [8], S. Quadri[8], Y.-B. Chen[9]

[1]Department of Hematology, Oslo University Hospital, Oslo, Norway, [2]Department of Hematology, Oncology and Radiation Physics, Skåne University Hospital, Lund University, Lund, Sweden, [3]Department of Hematology, University Hospitals Leuven, Leuven, Belgium, [4]Department of Oncology-Pathology, Karolinska Institutet, Stockholm, Sweden, [5]Division of Hematology and Oncology, Medical College of Wisconsin, Milwaukee, United States, [6]Hematology Service, ZNA Stuivenberg, Antwerp, Belgium, [7]Takeda Development Centre Europe Ltd., London, United Kingdom, [8]Takeda Pharmaceuticals International Co, Cambridge, [9]Blood and Marrow Transplant Program, Massachusetts General Hospital, Boston, United States

Background: Allogeneic hematopoietic cell transplantation (allo-HCT) can be curative in patients with hematological malignancies but carries a significant risk of acute and chronic graft-*versus*-host disease (GvHD). Acute GvHD of grades II–IV and grades III–IV have been reported in 39–71% and 14–32% of allo-HCT recipients, respectively, despite standard prophylaxis. Corticosteroids are first-line treatment, but are effective in only approximately half of patients, with durable responses in one-third. Steroid refractory (SR) acute GvHD is associated with high rates of morbidity and mortality, especially when there is lower intestinal involvement. There are no approved treatments for acute gastrointestinal (GI) GvHD, but published case series suggest that vedolizumab, a gut-selective immunomodulator approved for treatment of inflammatory bowel diseases, may be effective in reducing ongoing tissue damage in patients with this disease.
Aims: The aims of this international retrospective cohort study are to evaluate the off-label use of vedolizumab for treatment of patients with SR acute GI GvHD, and to assess key clinical outcomes of these patients, including safety and effectiveness.
Methods: Data from medical charts of patients from seven sites in Belgium, Norway, Sweden and the USA were analyzed. To be eligible for inclusion, patients must have received only one allo-HCT and ≥1 dose of vedolizumab as treatment for SR acute GI GvHD, which was defined as active stage 1–4 GI GvHD following ≥1 previous treatment regimen containing ≥1 mg/kg methylprednisolone or equivalent for acute GvHD. Any donor source, conditioning regimen intensity and GvHD prophylaxis was allowed. Descriptive analyses were performed on collected data for treatment, acute GvHD response rate, overall survival (OS) and serious adverse events (SAEs).
Results: We identified 29 patients who met the inclusion criteria. Median age was 50 years (range 19–69). Median time from allo-HCT to diagnosis of acute GvHD was 36 days (range 20–131). Median duration of treatment with steroids before vedolizumab treatment was 15 days (range 1–236). Patients received 1–10 doses of intravenous vedolizumab 300 mg (median, 3 doses) as treatment for acute GI GvHD. The overall response rate (partial response or better), measured at 6–10 weeks after the first dose of vedolizumab, was 64%. The corresponding complete response rate was 28%. Three patients experienced relapse of their primary malignancy. OS at 6 and 12 months after the first dose of vedolizumab was 54% and 47%, respectively. After initiation of treatment with vedolizumab, there were 29

identified SAEs; 12 were infections (two of which were reported as possibly related to vedolizumab treatment), four were GI (one case of bleeding from the colon, with ileus and obstruction was possibly related to vedolizumab treatment), four were hematological, two were cardiovascular, two were in the central nervous system, two were respiratory, one was psychological, one was multiple organ failure and one was renal. Thirteen of these SAEs were fatal, of which seven were infections or sepsis (one of which was possibly related to vedolizumab treatment) (Figure 1).

Patient characteristics (N = 29)

Age, mean years (SD)		48.0 (15.3)
Age, median years (range, IQR)		50 (19–69, 37–59)
Female, n (%)		7 (24%)

[a]Aplastic anemia (1 patient), chronic lymphocytic leukemia (1), CMML converted to AML (1), CMML/MF (1), Hodgkin disease (2), multiple myeloma (1), very severe aplastic anemia (1).
aGvHD, acute graft-versus-host disease; allo-HCT, allogeneic hematopoietic cell transplantation; AML, acute myeloid leukemia; B-cell, B lymphocyte; CMML, chronic myelomonocytic leukemia; IQR, interquartile range; MF, myelofibrosis; NK-cell, natural killer cell; SD, standard deviation; T-cell, T lymphocyte.

Figure 1.

Summary and Conclusions: Evidence from this international retrospective cohort study suggests that treatment of patients with vedolizumab for SR acute GI GvHD leads to a 64% overall response rate at 6–10 weeks after the first dose and OS of 54% at 6 months after the first dose. These data support the ongoing prospective clinical trials designed to characterize fully the efficacy and safety of vedolizumab in this indication.

Background: The administration of high dose cyclophosphamide post-transplant (HD-Cy) has improved the outcome of patients who receive an unmanipulated haploidentical graft. Mobilized peripheral blood (PB) is increasingly used as it is more convenient.

Aims: We report the French experience of haploidentical transplantation using HD-Cy and unmanipulated bone marrow (BM) or PB.

Methods: From 2012 to 2015, 176 patients with hematologic malignancy received a haploidentical transplant in 21 centers. We compared the outcome of patients who received a BM graft (n=89) with those receiving a PB graft (N=87). Median age at transplant was 44 year-old (2.5-72). One hundred thirteen (64%) patients had myeloid disease, 19 (11%) had acute lymphoblastic leukemia and 44 (25%) had lymphoid neoplasm. Prophylaxis of GVHD consisted in anticalcineurin and mycophenolate in 94% of the cases. All patients received HD-CY post-transplant (100 mg per kg total dose).

Results: The 2 groups were comparable for age, disease status at transplant, type of conditioning regimen (RIC 71% *vs* 80% for BM *vs* PB respectively; p=0.16), recipient cytomegalovirus (CMV) status, ABO mismatch. PB recipients were more likely to receive antithymocyte globulin (ATG) (N=19 *vs* 1) and to have a higher disease risk index (DRI). The number of CD34+ and CD3+ infused cells was higher in PB grafts (median 2.64x10^6 CD34/Kg and 26 x10^6 CD3/Kg for BM and 6.03x10^6 CD34/Kg and 191 x10^6 CD3/Kg for PB). Median follow-up was 525 days (94-1851). In univariate analysis, the rate of patients who recovered neutrophils and platelet (>50G/L) were similar in both groups. However, median time to neutrophil engraftment was significantly longer with BM than PB (20 days *vs* 18 days respectively, p=0.004). Median time to platelet recovery was not significantly different (30 days *vs* 24 days in BM and PB, p=0.14). At one year, OS, progression free survival (PFS) and relapse were similar in the 2 groups (OS=64% *vs* 53% (p=0.1), PFS= 53% *vs* 46% (p=0.17) and relapse rate 28% *vs* 34% (p=0.2) in BM and PB respectively). Acute GVHD II-IV or III-IV and chronic GVHD were similar in both groups (aGVHD II-IV= 18% *vs* 28% (p=0.09) and aGVHD III-IV=7% *vs* 9% (p=0.48), cGVHD=13% *vs* 15% (p=0.6) in BM and PB respectively), resulting in a similar GVHD-free relapse-free survival (GRFS) at 1 year (48% *vs* 37% (p=0.09)). High DRI and the lack of complete remission at transplant had a significant pejorative effect on OS, PFS, relapse, GRFS and platelet recovery. As ATG was mainly used with PB, patients who had received ATG were excluded and the same analysis was performed on the 156 remaining patients. One-year PFS was 52% for BM *vs* 42% for PB (p=0.06), aGVHd was 18% for BM *vs* 31% for PB (p=0.07) resulting in a better 1-year GRFS for BM (48% *vs* 33%; p=0.02). One year OS was 63% for BM *vs* 51% for PB (p=0.05).

Summary and Conclusions: In this retrospective study the use of PB instead of BM does not significantly impact the outcome of patients who received a haploidentical unmanipulated graft with HD-CY. However, GRFS and OS might be better with BM compared to PB without ATG. Prospective randomized studies are needed to evaluate the effect of PB *vs* BM in haploidentical settings.

PF732

G-CSF/ATG-BASED REGIMEN IS SUPERIOR TO PTCY-BASED REGIMEN IN TERMS OF ENGRAFTMENT AFTER MYELOABLATIVE HAPLOIDENTICAL TRANSPLANTATION FOR HEMATOLOGIC MALIGNANCIES

F.-F. Tang[1], H.-R. Chen[2], Y.-J. Xu[3], L.-P. Xu[1], X.-H. Zhang[1], Y. Wang[1], Q.-F. Liu[4], D.-P. Wu[5], X.-J. Huang[1,*]

[1]Peking University People's Hospital, Peking University Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China, [2]PLA Army General Hospital, Beijing, China, Beijing, [3]Xiangya Hospital, Central South University, Changsha, Hunan, China, Changsha, [4]Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong, China, Guangzhou, [5]The First Affiliated Hospital of Soochow University, Suzhou, Jiangsu, China, Suzhou, China

Background: The protocol in which granulocyte colony stimulating factor(G-CSF) mobilized marrow and blood grafts and anti-thymocyte globulin (ATG) in the conditioning is the most commonly used haploidentical hematopoietic stem cell transplantation (haplo-HSCT) regimen in China. The use of post-transplantation cyclophosphamide (PTCy) is a new emerging optional strategy for haplo-HSCT abord over the past decade. Data comparing the two regimens in myeloablative haplo-HSCT for hematologic malignancies are lacking.

Aims: We aim to compare these two approaches in patients with hematologic malignancies receiving haplo-HSCT.

Methods: We compared PTCy-based and G-CSF/ATG-based regimens after myeloablative haplo-HSCT for hematologic malignancies between January 2013 and March 2017 who were reported to the Chinese Bone Marrow Transplantation Registry. For each PTCy patient, G-CSF/ATG-based subjects (1:4) were randomly selected using the nested case-pair method.

Results: A total of 175 patients were analyzed: 35 in the PTCy group and 140 in the G-CSF/ATG group. Incidences of neutrophil engraftment at day

30(91.4% *vs* 96.4%, P=0.007) and platelet engraftment at day 180(85.7% *vs* 95%, P=0.04) were significantly lower in the PTCy group. Median times to neutrophil (17 days *vs* 12 days, P=0.000) and platelet (22 days *vs* 17 days, P=0.001) engraftment were prolonged in the PTCy group. In the PTCy and G-CSF/ATG groups, the cumulative incidences of grade 2-4 and grade 3-4 acute graft-*versus*-host disease(GVHD)at day 100 were 20% *vs* 27.2%(P=0.29) and 8.6% *vs* 9.4%(P=0.86), respectively; incidences of chronic and severe chronic GVHD at 3 years were 26.2% *vs* 42.3%(P=0.11) and 5.7% *vs* 9.5%(P=0.51), respectively. The 3-year cumulative incidences of non-relapse mortality(20.5% *vs* 10.2%,P=0.08), relapse (9.6% *vs* 15.7%, P=0.35),GVHD-free, relapse-free survival(58.7% *vs* 65.1%,P=0.46),progression-free survival(69.7% *vs* 73.3%, P=0.56), and overall survival(72.2% *vs* 78.4%, P=0.39) were comparable between two groups. In multivariate analysis, the incidences of neutrophil and platelet engraftment were lower in the PTCy group (Figure 1).

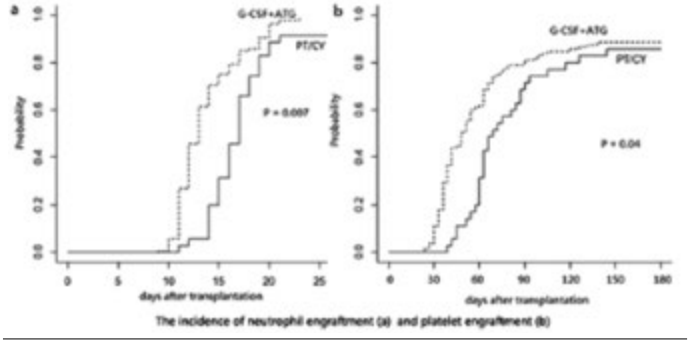

Figure 1.

Summary and Conclusions: G-CSF/ATG-based regimen is superior to PTCy-based regimen in terms of engraftment after myeloablative haplo-HSCT for hematologic malignancies.

Background: A major drawback affecting clinical trials of high-dose therapy (HDT) followed by autologous stem cell transplant (ASCT) in lymphomas is the high heterogeneity of histological entities. As a consequence, the statistical power is reduced when we focus on a specific histological subset, and data are often not conclusive.
Aims: We designed a phase II multicenter study to evaluate the efficacy of the BeEAM high-dose therapy regimen (bendamustine 200 mg/m2 on days -7,-6, cytarabine 400 mg/m2 days -5-4-3-2, etoposide 200 mg/m2 days -5-4-3-2, melphalan 140 mg/m2 day-1) followed by ASCT (day 0) in resistant/relapsed diffuse large B-cell (DLBC) non-Hodgkin lymphoma patients.
Methods: The study was registered at European Union Drug Regulating Authorities Clinical Trials (EudraCT) with the number 2011-001246-14. Until now, 76 out of 88 pre-planned patients (median age 55 years, range 19-69) with resistant/relapsed DLBCL were enrolled. The primary end-point of the study is to evaluate the 1-year complete remission rate.
Results: Briefly, 59/76 patients had advanced stage disease (III-IV); 25 were primary refractory and 51 had relapsed. 38/76 patients were in II or subsequent CR after salvage therapy, whereas 31 were in PR and 7 in progressive disease. A median number of 5.63x10^{6}CD34+/kg cells (range 2.21-11.40) collected from peripheral blood was reinfused to patients. All patients engrafted, with a median time to ANC>0.5x10^9/l of 10 days. Median times to achieve a platelet count >20x10^9/l and >50x10^9/l were 12 and 17 days respectively. Twenty-four out of 76 patients presented a FUO (32%), whereas 25 patients (34%) presented a clinically documented infection. All patients received G-CSF after transplant for a median time of 8 days (range: 8-13). One patient died due to an incomplete hematological recovery after transplant, for an overall transplant related mortality of 2.7%. Sixty-six patients are evaluable for response: 55/66 (72%) obtained a CR, 4/66 (5%) a PR, whereas 7/66 (9%) did not respond to therapy. The median follow-up after transplant was 20 months (range 0-69).
Summary and Conclusions: The stringent inclusion criteria at enrollment might allow to accurately evaluate the impact of BeEAM HDT regimenfollowed by ASCT in a highly selected population of DLBCL patients. Accordingly, our data provide the evidence that the Benda-BEAM regimen is highly effective in resistant-relapsed aggressive diffuse large B cell lymphoma, with a maneageble toxicity profile. **Acknowledgements:** The study was supported in part by AIL Pesaro Onlus. Mundipharma Italy provided Bendamustine free of charge.

PF734

A HIGH PRE-TREATMENT BONE MARROW CD34+/CD38- CELL BURDEN IN PATIENTS WITH MYELODYSPLASTIC SYNDROME IS A PROGNOSTIC FACTOR FOR DISEASE PROGRESSION AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

M. Jentzsch[1,*], U. Geus[1], J. Grimm[1], S. Beinicke[1], J. Häntschel[1], V. Vucinic[1], W. Pönisch[1], G. Behre[1], G.-N. Franke[1], D. Niederwieser[1], S. Schwind[1]

[1]Hematology and Oncology, Universitätsklinikum Leipzig, Leipzig, Germany

Background: Myelodysplastic syndrome (MDS) is a highly heterogeneous clonal hematopoietic disorder. Allogeneic stem cell transplantation (HSCT) remains the only curative treatment, especially with respect to patients (pts) at high risk for progression to acute myeloid leukemia (AML). It has been shown that in MDS, CD34+/CD38- cells possess MDS stem cell potential & secondary AML (sAML) clones originate from MDS disease stage. To date no study evaluated the prognostic impact of a high MDS stem cell burden prior to therapy.
Aims: To analyze the impact of a high pre-treatment CD34+/CD38- cell burden in MDS pts on outcome after HSCT.
Methods: We retrospectively analyzed 124 MDS (n=105) or myelodysplastic/myeloproliferative neoplasm (n=19) pts receiving HSCT at our institution (median age at HSCT 61.3 [range 22.2-74.4] years [y]) after reduced-intensity (RIC, 44%; Fludarabine with Busulfan or Treosulfan) or non-myeloablative (NMA, 56%; Fludarabine with 2Gy or 3Gy total body irradiation)-conditioning. Prior to HSCT, 59% of pts received cytoreductive therapy with hypomethylating agents (25%), AML chemotherapy (24%) or both (10%). Median follow up after HSCT was 4.3 y. Karyotype analyses were performed centrally at our institution. IPSS-R was 0% very low, 7% low, 28% intermediate, 21% high, 36% very high & 7% unknown. CD34+/CD38- cell burden was evaluated by flow cytometry in untreated bone marrow (BM) material. A cut-off of 1% CD34+/CD38- cells was determined using R's OptimalCutpoint package & divided the cohort in pts with high (34%) or low (66%) CD34+/CD38- cell burden.
Results: A high pre-treatment BM CD34+/CD38- cell burden associated with higher expression of CD13 (P<.001), CD33 (P<.001) & CD117 (P<.001) in BM, an excess of blasts (P<.001) & worse IPSS-R (P=.03) risk group. Pts with a high CD34+/CD38- cell burden also had worse IPSS-R genetic risk (P=.02), were more likely to harbor an abnormal (P=.04), complex (P=.002) or monosomal (P=.004) karyotype & more often received cytoreductive treatment prior to HSCT (P=.008). Pts with a high CD34+/CD38- cell burden had a significantly higher cumulative incidence of relapse/progression (CIR, P<.001, Figure 1A), sAML (CIsAML, P<.001, Figure 1B) & shorter overall survival (OS, P=.12) by trend. In multivariate analyses, a high CD34+/CD38- cell burden was an independent factor for higher CIR (Hazard ratio [HR] 2.9, Confidence Interval [CI] 1.4-6.1, P=.005) after adjustment for IPSS-R genetic risk, for higher CIsAML (HR 4.6, CI 2.0-10.8, P<.001) after adjustment for age at HSCT & HLA match & for shorter OS (HR 2.1, CI 1.2-3.8, P=.01) after adjustment for HLA match & donor type. Analyzing IPSS-R low/intermediate & high/very high risk MDS pts separately, a high CD34+/CD38- cell burden indicated patients with higher CIR (P<.001, Figure 1C), higher CIsAML (P<.001, Figure 1D) & a trend for shorter OS (P=.07) irrespective of the IPSS-R risk group.
Summary and Conclusions: A high pre-treatment CD34+/CD38- cell burden associated with higher CIR, higher CIsAML & a trend for shorter OS after

HSCT. Despite the correlation with high risk disease a high CD34+/CD38- cell burden provided independent prognostic information for all endpoints in multivariable analyses & in separate analyses for IPSS-R low/intermediate & high/very risk pts. The observed prognostic impact is likely mediated by MDS stem cells within the CD34+/CD38- cell population initiating MDS relapse or progression to AML. New therapeutic strategies targeting MDS stem cells might improve outcomes.

Background: Therapy-related myelodysplastic syndrome (t-MDS) after autologous stem-cell transplantation (ASCT) is uncommon and there is no curative treatment. Allogeneic hematopoietic stem cell transplantation (HSCT) may be considered in eligible patients.
Aims: The aim of the study was to evaluate the results of alloHSCT in patients with secondary MDS who have received an ASCT for lymphoid neoplasms.
Methods: Data were extracted from ProMISe for patients from French, Belgian, and Swiss centers, who received an alloHSCT between 2006 and 2016 for t-MDS after an ASCT for lymphoid neoplasms. Secondary acute myeloid leukemias were excluded. Overall survival (OS), relapse-free survival (RFS), and non-relapse mortality (NRM) were evaluated.
Results: We present 47 patients (37 males and 10 females), with a median age of 58 years (range: 30-71). Initial lymphoid neoplasm was Hodgkin's lymphoma in 8 patients (17%) and Non-Hodgkin Lymphoma in 36 (77%). 10 patients received more than two lines of chemotherapy before ASCT. Conditioning regimen was mostly BEAM (80.8%). CR was achieved in 37 patients (78.7%). The median time from ASCT to the diagnosis of t-MDS was 74.4 months (range 2.2 - 259). MDS type was MDS-EB-1 in 11 patients (23.5%) and MDS-EB-2 in 12 patients (25.6%), while 22 patients (46.7%) had other MDS. 2 patients (4.2%) had normal cytogenetics and 39 patients (82.9%) had at least one cytogenetic abnormality. Eleven patients (23.4%) were considered lower-risk (Low/Int-1 IPSS) and 28 (59.6%) higher-risk patients (Int-2 and High IPSS).32 patients (68%) received treatment before allo HSCT: 16 patients (34%) hypomethylating agents and 11 patients (23.4%) AML-like treatment. Ten patients (21.2%) achieved CR before alloHSCT. The median time interval from diagnosis of t-MDS to alloHSCT was 7.9 months (range 2.5-16.8). A myeloablative conditioning was used in 9 patients (19.1%) and a reduced intensity conditioning in 38 patients (80.9%). 19 patients (40.5%) had an HLA-identical donor, 17 patients (36.2%) had an matched unrelated donor and 10 patients (21.2%) an mismatched unrelated donor. The most frequent GvHD prophylaxis was cyclosporine (CsA) and mycophenolate mofetil (MMF) in 18 patients (38.3%) and 11 patients (23.4%) received cyclosporine and methotrexate (MTX). The Karnofsky score was equal or higher to 90 in 29 patients (61.8%) before alloHSCT. The median duration of post-transplant follow-up was 21.4 months (range 0 – 105.7) and median OS was 6.9 months (95% CI 0-14.6). OS rates was 45% (29–60%) and 30% (15-45%) in the first and third year after transplantation. In univariate analysis, prior therapy of MDS before alloHSCT (p=0.02) and mismatch HLA donors (p=0.004) were associated with poor OS. NRM and relapse rates were 44% (25-63%) and 41% (22-61%) at 3 years, respectively. The graft type (p=0.02) and mismatch HLA donors (p<0.001) were associated with higher NRM and MDS type at diagnosis (p=0.008) with higher relapse risk. On multivariable analysis, mismatch HLA was associated with higher NRM (HR 6.21; 95% CI 1.63- 23.62; p=0.007).
Summary and Conclusions: Although the number of patients is small, the results suggest that patients receiving an ASCT for a lymphoid neoplasm and developing a t-MDS have a short OS after alloHSCT, with few long-time survivors. The use of mismatched donors with standard GvHD prophylaxis should be avoided in such indication for alloHSCT. It will be worth to see if the implementation of CY post-transplantation will improve the outcome with mismatched donors.

PF736

A PHASE I/II STUDY OF PEGYLATED-INTERFERON-2ALPHA FOR RELAPSED HAEMATOLOGICAL MALIGNANCY AFTER ALLOGENEIC HAEMATOPOIETIC PROGENITOR CELL TRANSPLANTATION

A. Henden[1,2,*], J. Leach[2], E. Sturgeon[2], J. Avery[2], S. Olver[1], L. Samson[1], S. Durrant[2], J. Butler[2], J. Morton[2], A. Misra[2], S. Tey[1,2], E. Subramoniapillai[2], C. Curley[2], G. Kennedy[2], G. Hill[1,2]

[1]Bone Marrow Transplantation Laboratory, QIMR Berghofer Medical Research Institute, [2]Department of Haematology and Bone Marrow Transplantation, Royal Brisbane and Women's Hospital, Brisbane, Australia

Background: Relapse of hematologic malignancy after allogeneic hematopoietic progenitor cell transplantation (HPCT) reflects failure of immune-mediated graft-*versus*-malignancy (GVM) and is associated with very poor survival outcomes. In pre-clinical models of HPCT type I Interferons have capacity to regulate GVM and graft-*versus*-host disease (GVHD) by sensitizing residual malignancy to cytotoxicity and augmenting donor T and NK cell cytotoxic responses (Robb R *et al.*, Blood 2011, 118:3399 and Robb R *et al.*, Blood 2012, 119:5918). We sought to test the ability of pegylated-Interferon-2α (peg-IFN2a), a long acting type I Interferon, to improve outcomes in clinical transplantation.
Aims: To test safety and efficacy of peg-IFN2α when added to therapy for relapse of any haematological malignancy post HPCT.
Methods: Patients between 18 and 70 years with both haematological and minimal residual disease (MRD) relapse post HPCT were eligible. The study received approval from institutional HREC and informed consent was obtained for all participants. Treatment schema included cessation of immune suppression (where applicable) and those with haematological relapse received cytoreduction with Fludarabine and Cytarabine (FLAG). Upon count recovery peg-IFN2α was given in escalating weekly doses for up to 6 months, with stipulated dose adjustment based on cytopenias and toxicity. Those without grade II-IV acute GVHD or progressive chronic GVHD were eligible to receive DLI. 29 patients were planned for accrual. The primary endpoint is 2 year OS.
Results: Accrual is complete, the final patient having commenced therapy

on 31/03/2017. Current 2 year OS is 30% with median OS 330 days (median follow-up 1089 days). Median disease free survival (DFS) is 183 days (median follow-up 857 days). Peg-IFN2α was able to be given safely; 11 patients (38%) experienced grade 3 or greater adverse events however only 4 were thought probably or likely related to peg-IFN2α administration. 18 patients (62%) have had acute (11%) or chronic (89%) GVHD whilst on trial, 11 (61%) after administration of peg-IFN2α alone. 7 of 11 (64%) patients receiving DLI subsequently developed GVHD. GVHD was induced with peg-IFN2α in 7 of 12 (58%) patients who had not had any prior GVHD. 13 patients had measureable MRD or mixed chimerism after FLAG cytoreduction and prior to administration of peg-IFN2α and 8 of these (62%) demonstrated disease responses to peg-IFN2a, including 6 complete remissions (75%). Immune profiling demonstrates persistence of a high proportion of cytolytically active Tc1 cells (CD8+ T cells with Interferon γ secreting capacity and granzyme B positivity) in those patients who develop GVHD relative to those who do not.

Summary and Conclusions: Current 2 year OS of 30% compares favorably with an institutional control cohort who did not receive peg-IFN2α where 2 year OS was 9% (Curley C *et al.,* Int J Lab Haematol 2014, 36:197). Peg-IFN2α administration was associated with expected and manageable toxicity. Our data support the addition of peg-IFN2α to standard strategies of cytoreduction±DLI in patients that relapse after allo-HPCT. Patients who do not experience GVHD within 3 months of peg-IFN2α are candidates for alternative strategies. In the modern era, our cytokine-dependent approach to enhance GVL seems particularly well suited to patients with relapsed myeloid malignancies, where CAR based therapies are not available.

PF737

OUTCOME OF MESENCHYMAL STROMAL CELL TREATMENT IN CHRONIC GVHD PREDICTED BY THYMIC FUNCTION: A PHASE II CLINICAL STUDY

E. Boberg[1,2,*], L. von Bahr[1,2], N. Heldring[3], G. Afram[4,5], E. Iacobaeus[6,7], C. Lindström[1], K. Garming-Legert[8], E. Alici[5], P. Ljungman[4,5], R. Sugars[8], N. Kadri[2], K. Le Blanc[2,4]

[1]Department of Hematology, Karolinska University Hospital, [2]Department of Laboratory Medicine, [3]Center for Hematology and Regenerative Medicine, Karolinska Institutet, [4]Center for Allogeneic Stem Cell Transplantation (CAST), Karolinska University Hospital, [5]Department of Medicine, [6]Department of clinical neuroscience, Karolinska Institutet, [7]Department of Neurology, Karolinska University Hospital, [8]Department of Dental Medicine, Karolinska Institutet, Stockholm, Sweden

Background: No treatment for patients unresponsive to first line therapy for chronic graft *versus* host disease (cGvHD) has been established. Infusion of mesenchymal stromal cells (MSCs) is a promising alternative in this situation but treatment efficacy and mechanism of action have not yet been determined.

Aims: To evaluate the clinical and immunological effects of repeated MSC infusion treatment on steroid refractory (SR) cGvHD patients.

Methods: In this study, 11 patients with severe SR cGvHD were treated with repeated infusions of MSCs. The treatment consisted of 6 to 9 infusions (once every month) of $2x10^6$ allogeneic bone marrow MSCs/kg. Clinical response was evaluated using the National Institutes of Health (NIH) criteria. Immunophenotyping and cytokine analysis was conducted on blood samples taken before, and at several time points shortly after each infusion. Skin biopsies were also taken before and after treatment and blindly evaluated by an external pathologist.

Results: Nine patients completed the treatment protocol and were evaluated for response. Six patients responded (R) to MSC therapy according to NIH criteria. Five of the six showed long-lasting improvement 12 months after MSC treatment. Analysis of the immune cell distribution in R and the non-responders (NR) revealed significantly higher proportions and absolute numbers of naive CD4+ T-cells (CD3+ CD4+ CD45RA+ CD27+) and activated naïve B cells (CD19+ IgD+ CD38low) prior to MSC treatment in R compared to NR. A similar trend was observed for absolute numbers of immature NK-cells (CD56bright, p=0.066). These differences remained unchanged throughout the treatment. Further, in R, absolute numbers of these naïve lymphocyte subsets, as well as regulatory T-cells (Tregs, Figure 1A) increased 7 days after each MSC infusion, which returned to baseline by the next infusion. No such increases were seen in NR. Levels of four miRNAs increased one hour after MSC infusion in both R and NR, suggesting a MSC-specific effect. Multiplex analysis revealed long term improvements in the levels of the pro-inflammatory cytokines CXCL2 (Figure 1B) and CCL2 in R, while the levels of CXCL9, CXCL10 (Figure 1B), CXCL12, TNFa, IL-6 increased in NR. In skin biopsies, we observed resolution of epidermal inflammatory changes (keratinocyte apoptosis, vacuolization and mononuclear infiltration). Finally, we ascertained that differences in naïve T cell numbers and the short term increases after MSC infusion were due to mobilisation from the thymus, as the proportion of Ki67+ naïve CD4+ T-cells was similar in both R and NR. A significant difference in the percentage of recent thymic emigrants among naïve CD4+ T-cells suggested improved thymic function in the R (Figure 1C).

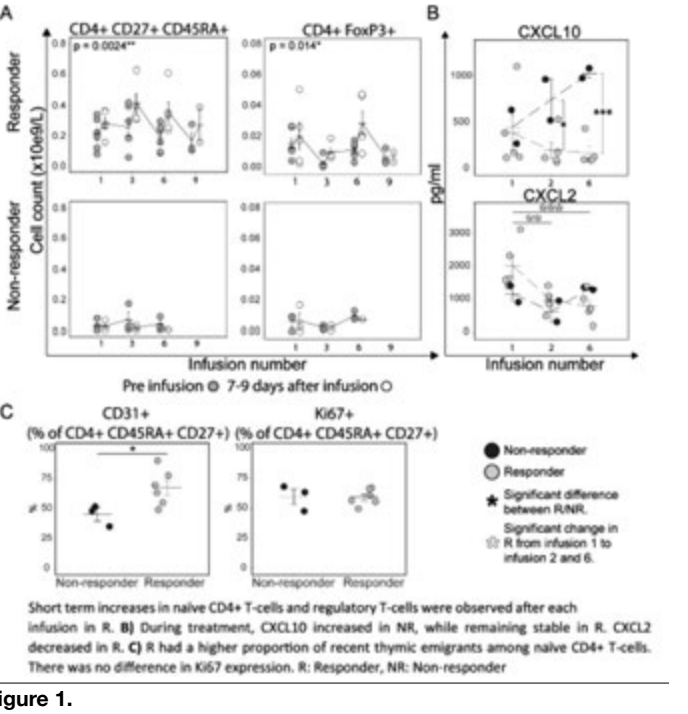

Figure 1.

Summary and Conclusions: In the current study, MSC treatment induced durable responses in patients with severe refractory cGvHD, as well as long term improvements in cytokine profile and skin pathology. Further, our data suggest that success of MSC treatment for patients with refractory cGvHD is dependent on the immunological characteristics of the individual patient. More specifically, we propose that sufficient thymic function, generating sufficient numbers of naïve T-cells and naïve Tregs, is required for responsiveness to MSC treatment in these patients.

PF738

IMPAIRED BONE MARROW ENDOTHELIAL PROGENITOR CELLS ARE INVOLVED IN THE PATHOGENESIS OF ACUTE GRAFT-*VERSUS*-HOST DISEASE AFTER ALLOTRANSPLANT

X.-N. Cao[1,*], Y. Kong[1], Y. Song[1,2], M.-M. Shi[1,2], H.-Y. Zhao[1], Q. Wen[1], Z.-S. Lyu[1,2], C.-W. Duan[3], Y. Wang[1], L.-P. Xu[1], X.-H. Zhang[1], X.-J. Huang[1,2]

[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Beijing, [3]Key Laboratory of Pediatric Hematology and Oncology Ministry of Health and Pediatric Translational Medicine Institute, Shanghai Children's Medical Center, Shanghai, China

Background: Graft-*versus*-host disease (GVHD) is a major complication that is frequently associated with bone marrow (BM) suppression after allogeneic hematopoietic stem cell transplantation (allo-HSCT), and the clinical management is challenging. While traditionally considered to be induced through an immune-mediated mechanism, GVHD is also associated with circulating endothelial cells (ECs) injury, which determines the severity of GVHD. BM endothelial progenitor cells (EPCs), the precursors of ECs, play crucial roles in the regulation of hematopoiesis and thrombopoiesis. We recently reported that impaired BM EPCs and hematopoietic stem cells (HSCs) contribute to the occurrence of prolonged isolated thrombocytopenia and poor graft function after allo-HSCT. However, little is known regarding the functional roles of BM EPCs in acute GVHD (aGVHD) patients.

Aims: To evaluate whether the number and function of BM EPCs and HSCs in allo-HSCT patients with aGVHD differed from those without aGVHD. Furthermore, to explore whether the severity of aGVHD and GVHD-mediated cytopenia was associated with impaired BM EPCs and HSCs in aGVHD patients.

Methods: In the current prospective case-pair study, we evaluated whether the percentages and functions of BM EPCs and HSCs in aGVHD patients differed from those in patients without aGVHD. In order to explore whether the severity of aGVHD was associated with impaired BM EPCs and HSCs in aGVHD patients, the percentages and functions of BM EPCs and HSCs were compared between patients with aGVHD >grade II and aGVHD ≤grade II. Moreover, to evaluate whether aGVHD-associated cytopenia was correlated with the impairment of primary BM EPCs and HSCs, the percentages and functions of BM EPCs and HSCs were compared between aGVHD patients with cytopenia and patients without cytopenia as well.
Results: Human BM EPCs were demonstrated as the spindle shape and the similar expression of CD34, VEGFR2 and CD133 at day 7 of cultivation among the enrolled subjects. Reduced and dysfunctional BM EPCs, characterized by decreased migration and angiogenesis capacities and higher levels of ROS and apoptosis, were found in aGVHD patients. Meanwhile, reduced and dysfunctional BM HSCs, characterized by higher levels of ROS and apoptosis, were identified in patients with aGVHD compared with those without aGVHD. In PB, increased frequency of ECs and decreased HSCs with higher levels of ROS and apoptosis were detected in patients with aGVHD compared to those without aGVHD. In addition, the frequencies of BM EPCs and HSCs in patients with the onset of aGVHD ≥grade II were significantly lower than those with aGVHD <grade II. By contrary, the levels of ROS and apoptosis in BM EPCs and HSCs in patients with the onset of aGVHD ≥grade II were remarkably higher than those with aGVHD <grade II. Moreover, the GVHD-mediated cytopenia was associated with BM EPCs impairment in aGVHD patients. And the EPCs impairment positively correlated with the ROS level, which may have led to the GVHD-associated cytopenia.
Summary and Conclusions: Taken together, our results suggest that reduced and dysfunctional BM EPCs may be involved in the pathogenesis of aGVHD. Although these findings require validation, our data indicate that improvement of BM EPCs represents a promising therapeutic approach for aGVHD patients.

PF739

PHASE II PROSPECTIVE STUDY OF DIFFERENT ATG DOSING IN ADDITION TO STANDARD HAPLOIDENTICAL TRANSPLANT CONDITIONING WITH POST-TRANSPLANT CYCLOPHOSPHAMIDE (PT-CY)

M. Hassanein[1,*], A. Alshomar[1], A. kotb[1], S. Al-Otaibi[1], S. Ahmed[1], F. Alfraih[1], F. Almohareb[1], H. Alzahrani[1], F. Alsharif[1], M. Shaheen[1], S. Alhayli[1], N. Chaudhri[1], A. Hanbali[1], S. Hashmi[1], G. Aldawsari[1], M. Aljurf[1], R. El Fakih[1]

[1]Adult Hematology/BMT, KFSHRC, Riyadh, Saudi Arabia

Background: Haploidentical stem cell transplant (Haplo-SCT) is accompanied by intense bidirectional alloreactivity due to the HLA mismatch between the donor and the recipient. Immunosuppression to control this alloreactivity is essential for the success of transplant. Currently 2 platforms for haploidentical transplant exist. The post-transplant cyclophosphamide (PT-CY) is the most frequently used regimen in the west (Europe and North America). The GIAC (Gcsf+Intense immunosuppression+ATG+Combined bone marrow and peripheral blood graft) is the most frequently used in China. We adopted the PT-CY after myeloablative conditioning as our standard haploidentical transplant platform.
Aims: To assess the risk of developing acute GVHD after the addition of ATG at different doses to standard Haplo-SCT conditioning with post-transplant PT-CY.
To study the impact of adding ATG on relapse risk, OS, CMV reactivation, and the risk of developing hemorrhagic cystitis (HCYST).
Methods: In this phase II prospective clinical trial we studied a total of 39 patients, who underwent Haplo-SCT at our institution. All studied patients (12 ALL, and 27 AML) had no active disease at time of transplant. Our first 12 patients received myeloablative conditioning (MA) with PT-CY without ATG. As we recognized the higher rates of aGVHD, we added ATG at a dose of (3mg/kg) (ATG-3) to our conditioning regimen. A total of 15 patients received ATG-3, and our first interim analysis revealed a marked decrease in the risk of aGVHD in the expense of a significant increase in post-transplant infections. We decided to cut down the ATG dose to be 2mg/kg (ATG-2), 12 of our studied patients received conditioning with this dose, and this is our second interim analysis.
Results: Our Haplo-SCT results showed that the probability of death without aGVHD is less than 11% at 100 days (Figure 1A), patients who received ATG-3 had a significantly lower risk of aGVHD 6.7%, compared to patients who received ATG-2 or no ATG (41.7% and 58.3%, respectively) p-value= 0.01 (Figure 1B). There was no significant difference in the cumulative incidence of relapse between the 3 groups of patients p-value= 0.4, and with longer follow it seems that the addition of ATG at a dose of 3mg/kg didn't affect the relapse risk 42% compared with 33.3% for no ATG (Figure 1C), and resulted in an even better median DFS when compared with no ATG (19 months and 9 months, respectively), but the difference was not statistically significant (p-value=0.7) (Figure 1D). Furthermore, the median OS was not reached for the patients who received ATG-3, but it was 18 months for patients who didn't receive ATG at 2 years follow up (Figure 1E). The rates of developing CMV reactivation and HCYST were not significantly different between the 3 patient groups (p-value= 0.2 and 0.4 respectively), with lower rates of non-relapse mortality (NRM) in patients who received ATG-3 (14%), compared to 25% for no ATG, and 32% for ATG-2 (Figure 1F).

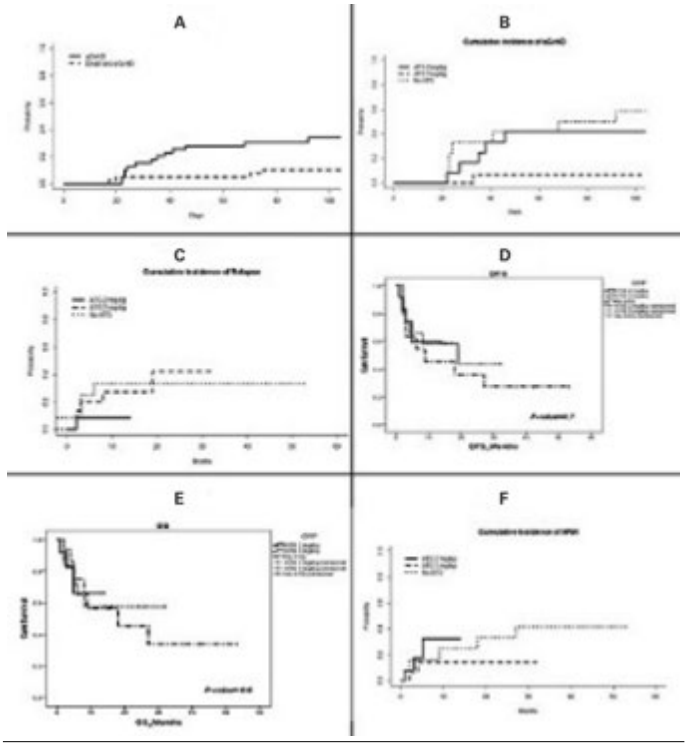

Figure 1.

Summary and Conclusions: ATG at a dose of 3mg/kg as a part of Haplo conditioning can significantly decrease the risk of aGVHD without increasing the risk of relapse or NRM, and with promising survival outcomes on longer follow up. However, decreasing the dose of ATG to 2mg/kg didn't seem to reduce the risk of aGVHD, but longer follow up is required to evaluate its long term effect on the relapse risk and overall survival.

PF740

EXTENSIVE TELOMERE SHORTENING IN MONONUCLEAR CELLS IS ASSOCIATED WITH INFERIOR OVERALL SURVIVAL AFTER NON-MYELOABLATIVE ALLO-HCT

J.H. Petersen[1,2,3,*], S.E. Bojesen[1,2,4], B. Kornblit[5], B.G. Nordestgaard[1,2,4], S.L. Petersen[5], H. Sengeløv[4,5]

[1]Department of Clinical Biochemistry, [2]The Copenhagen General Population Study, Herlev and Gentofte Hospital, Copenhagen University Hospital, Herlev, [3]Department of Hematology, Zealand University Hospital, Roskilde, [4]Faculty of Health and Medical Sciences, University of Copenhagen, [5]Department of Hematology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark

Background: After allogeneic hematopoietic cell transplantation (allo-HCT), transplanted cells rapidly undergo multiple rounds of division. This may cause extensive telomere shortening, which could potentially prohibit further cell division and lead to increased mortality.
Aims: We characterized the development in mononuclear cell telomere length after non-myeloablative allo-HCT and tested the hypothesis that when compared to pre-transplant donor telomeres, extensive telomere shortening in recipients post-transplant is associated with low overall survival.
Methods: We studied 240 unselected consecutive patients undergoing non-myeloablative allo-HCT due to hematologic malignancies. Telomere length

was measured using quantitative polymerase chain reaction in mononuclear cells obtained from donors and recipients pre-transplant and in follow-up samples obtained from recipients post-transplant. Percentwise telomere length at 1 year post-transplant was calculated as the recipient telomere length at 1 year post-transplant in percent of donor pre-transplant telomere length.
Results: Although allo-HCT led to shorter mean telomere length in recipients when compared to donors, recipients had longer mean telomere length at 1 year post-transplant than they had pre-transplant. When compared to donor pre-transplant telomeres, recipients with extensive telomere shortening post-transplant had low overall survival (10-year survival from 1 year post-transplant an onwards 68% in the tertile with the longest percentwise telomere length at 1 year post-transplant, 57% in the middle tertile, and 39% in the shortest;p for trend=0.004). Similarly, when adjusting for potential confounders, recipients with extensive telomere shortening had high all-cause mortality (multivariable adjusted hazard ratio 1.84 per standard deviation shorter percentwise telomere length at 1 year post-transplant;95% confidence interval 1.25-2.72;p=0.002) and high relapse-related mortality (subhazard ratio 2.07;1.14-3.76;p=0.02). Neither donor nor patient pre-transplant telomere length were associated with overall survival.
Summary and Conclusions: Recipients with extensive telomere shortening post-transplant had low overall survival and high relapse-related mortality, indicating that telomere shortening may potentially be a clinically relevant marker for identifying patients at high risk of mortality.

PF741

G-CSF MOBILIZED MACROPHAGES POLARIZATION MAY PREVENT ACUTE GRAFT-*VERSUS*-HOST DISEASE AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Q. Wen[1,2,*], Y. Kong[2], H.-Y. Zhao[2], Y.-Y. Zhang[2], T.-T. Han[2], L.-P. Xu[2], X.-H. Zhang[2], X.-J. Huang[1,2]

[1]Nanfang Hospital, Southern Medical University, Guangzhou, [2]Peking University People's Hospital, Peking University Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Collaborative Innovation Center of Hematology, Beijing, China

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is an effective treatment for malignant hematopoietic diseases. Granulocyte colony-stimulating factor (G-CSF) application in a healthy donor can modulate the balance between Th1/Th2/Th17 cells, promote regulatory T cell and tolerogenic dendritic cell differentiation, as well as affect myeloid-derived suppressor cells induction. Therefore G-CSF induced immune tolerance has been shown to play a critical role in allo-HSCT. Macrophage (MΦ) is an important population of immune cells. MΦs are now classified as M1 (classic) MΦs, which produce pro-inflammatory cytokines, and M2 (alternative) MΦs, which produce anti-inflammatory cytokines. The unbalanced polarization of MΦs has been shown to play a critical role in the occurrence and development of disease, such as cancer and diabetes. Therefore repolarization of MΦs may be a novel therapeutic option to treat diseases. The impact of endogenous G-CSF on MΦs induction has been described in mouse models, but no study focus on the function of G-CSF on MΦs in human. Moreover, little is known about the association of MΦs subgroups in allografts with the occurrence of acute graft-*versus*-host disease (aGvHD) in patients who underwent allo-HSCT.
Aims: To determine the effect of G-CSF on MΦs in healthy donors. Moreover, to investigate the association of MΦ subgroups in allografts with the occurrence of aGvHD in patients after allo-HSCT.
Methods: We investigated the effects of G-CSF on the percentages of M1(CD68+CCR2+), M2(CX3CR1+CD163+) MΦs both in bone marrow(BM) and peripheral blood(PB) of healthy donors by flow cytometry. Moreover, the effects of G-CSF on MΦs function, including DiI-Ac-LDL uptake, DAPI binding assay, migration assay and mixed-lymphocyte reaction were investigated *in vitro*. Subsequently, we evaluated the association of M1/M2 MΦs ratio with the occurrence of aGvHD in patients who underwent allo-HSCT.
Results: We found that G-CSF mobilized MΦs polarization in both PB and BM. A decrease in pro-inflammatory M1 MΦs were found in the G-CSF mobilized-BM (G-BM, 4 days after G-CSF) and G-CSF mobilized-PB (G-PB, 5 days after G-CSF) compared to the stable-BM (S-BM) and stable-PB (S-PB) pre-G-CSF administration. Moreover, a decrease in anti-inflammatory M2 MΦs were observed in the G-PB, whereas a reciprocal increase in anti-inflammatory M2 MΦs in the G-BM. As a result, the M1/M2 MΦs ratio was markedly decreased in G-PB and G-BM. After G-CSF mobilization *in vivo*, BM MΦs showed reduced migration and increased phagocytic activities. In the mixed lymphocyte reaction, G-CSF mobilized MΦs can promote the apoptosis of activated T cells, but inhibit the proliferation of T cells. Furthermore, after G-CSF mobilization, MΦs increased the percentage of Th2, Tc2 and regulatory T cell lineages, but depleted the percentage of Th1, Tc1 and Th17 lineages. Moreover, patients who received a higher ratio of M1/M2 MΦs infusion exhibited higher incidence of grade II–IV aGvHD.
Summary and Conclusions: These findings suggested that G-CSF induced immune tolerance may be mediated by MΦs polarization in allo-HSCT. The ratio of M1/M2 MΦs in bone marrow graft may be used to predict the occurrence of grade II–IV aGvHD. Moreover, G-CSF mobilized MΦs promise to be a novel immunotherapeutic strategy against aGvHD in the future.

PF742

INTERFERON-A IS EFFECTIVE FOR TREATMENT OF MINIMAL RESIDUAL DISEASE IN PATIENTS WITH T(8;21) ACUTE MYELOID LEUKEMIA AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

X.-D. Mo[1,*], X.-H. Zhang[1], L.-P. Xu[1], Y. Wang[1], C.-H. Yan[1], H. Chen[1], K.-Y. Liu[1], X.-J. Huang[1]

[1]Peking University People's Hospital, Institute of Hematology, Beijing, China

Background: *RUNX1-RUNX1T1* transcript levels were established as a powerful marker for predicting relapse in patients with t(8;21) acute myeloid leukemia (AML). Monitoring of minimal residual disease (MRD) during chemotherapy can identify high-risk patients with t(8;21), and our prospective multicenter study demonstrated that allogeneic hematopoietic stem cell transplantation (allo-HSCT) significantly improved clinical outcomes of the high-risk patients.
Aims: We aimed to identify the efficacy of MRD-directed interferon-alpha (IFN-α) treatment in patients with t(8;21) AML who were positive for MRD after allogeneic hematopoietic stem cell transplantation (allo-HSCT) ($n = 42$).
Methods: MRD-positive status was defined as that a <4.5-log reduction from diagnosis in *RUNX1-RUNX1T1* transcripts and/or the loss of a ≥4.5-log reduction after 3 months post-HSCT. Patients with positive MRD received six cycles of IFN-α treatment (twice or thrice weekly of every 4 weeks cycle).
Results: The 1-year cumulative incidence of severe acute and chronic graft-*versus*-host disease after MRD-directed IFN-α treatment was 7.1% and 4.8%, respectively. After the treatment, 15 (35.7%), 5 (11.9%), 3 (7.1%), 3 (7.1%), and 6 (14.4%) patients achieved MRD negativity at 1, 2, 3, 4, and >4 months, respectively. Three patients relapsed after the IFN-α treatment, where the 1-year cumulative incidence of relapse was 7.2%. One patient died of severe infection at 460 days after treatment. The 1-year probabilities of event-free survival, disease-free survival, and overall survival post treatment were 76.0%, 92.4%, and 92.5%, respectively. The clinical outcomes in patients who received MRD-directed IFN-α treatment were significantly better than those of the MRD-positive patients without any interventions in the historical cohort.
Summary and Conclusions: MRD-directed IFN-α treatment is effective for patients with t(8;21) AML who were MRD-positive after allo-HSCT. The study was registered at http://clinicaltrials.gov as # NCT02027064.

PF743

EFFICACY AND SAFETY OF AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) IN ELDERLY MULTIPLE MYELOMA (MM) PATIENTS AGED ≥65 YEARS: A SINGLE CENTRE EXPERIENCE

J. Er[1], H. Rose[1], D. Routledge[1], D. Kipp[1], H. Fairweather[1], S. Ratnasingam[1], A. Friebe[1], J. Hempton[1], P. Campbell[1,*]

[1]Haematology, University Hospital Geelong, Geelong, Australia

Background: MM is a disease of the elderly, with a median age at diagnosis of 66 years. Induction chemotherapy followed by high-dose melphalan ASCT is considered the standard of care in patients aged <65 years without significant comorbidities. Transplant eligibility has historically been determined according to age, based on studies of young MM patients and the perceived risks associated with ASCT in the elderly. However, recent studies suggest that ASCT is both efficacious and safe in the latter group. Here, we report our single-centre experience of ASCT in elderly MM patients.
Aims: To evaluate the efficacy and safety of ASCT in 2 groups of patients aged ≥65 years and <65 years.
Methods: We identified 91 MM patients who underwent a single ASCT at our institution between 2008 and 2016. These patients were analysed based on age at ASCT. The "younger group" included patients aged <65 years, while the "elderly group" included patients aged ≥65 years. Patient charac-

teristics and comorbidity indices were collected including the haematopoietic cell transplantation-specific comorbidity index (HCT-CI). Patients were also retrospectively assessed using the recently developed revised myeloma comorbidity index (R-MCI). Response assessment included overall response rate (ORR), transplant-related mortality (TRM), progression-free survival (PFS) and overall survival (OS). The Kaplan-Meier method was used to estimate OS and PFS, and compared using the log-rank test. Multivariate analysis using the Cox proportional hazards model was used to identify factors independently associated with survival.

Results: Of 91 patients, 25 were in the elderly group (median age 66 years; range, 65-74) and 66 were in the younger group (median age 58 years; range, 38-64). Median follow-up time was 49 months. There were no differences in gender, ISS stage, cytogenetic risk status, or HCT-CI (p=0.359) between the 2 groups. More patients in the elderly group had R-MCI scores of 4-6 (intermediate fit) (44% *vs* 12%; p=0.011), while more patients in the younger group had R-MCI scores of 0-3 (fit) (83% *vs* 52%; p=0.004). 90% of patients in each group received the standard dose of melphalan (200 mg/m^2) as conditioning. Four patients received a dose of 140 mg/m^{2}due to elderly age, heavy pre-treatment, or reduced lung function, while 1 patient received a dose of 100 mg/m^{2}due to renal impairment. Overall response rates pre-ASCT were similar (elderly group, 96% *vs* younger group, 91%; p=0.4159) while the ORR post-ASCT also did not differ (88% *vs* 89%; p=0.8370). Toxicity, time to engraftment, and days of hospitalization were not significantly different between the 2 groups and TRM was low (3-4%) in both groups. The median PFS for the elderly group was non-inferior to the younger group (46 months *vs* 30 months; p=0.9390), while the median OS did not show any significant difference between the 2 groups (74 months *vs* not reached; p=0.2636) (Figure 1). In the uni- and multivariate analysis, higher ISS stage (hazard ratio [HR], 2.4; p=0.007) and high-risk cytogenetics (HR 7.8; p=0.005) were poor prognostic factors for OS. In the univariate analysis, higher R-MCI scores (HR 1.4; p=0.016) were also associated with inferior OS.

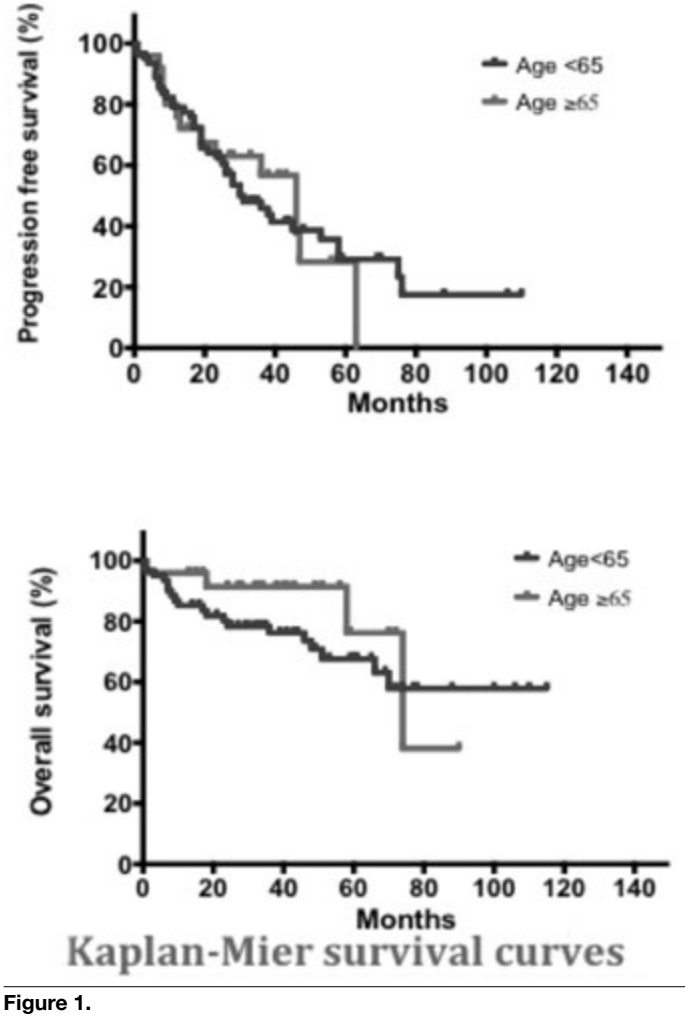

Figure 1.

Summary and Conclusions: This study suggest that ASCT is safe and effective in MM patients aged ≥65 years and should be considered based on performance status and comorbidities rather than age alone. In addition, this study suggests that the R-MCI could be useful in predicting outcomes for elderly MM patients undergoing ASCT.

PD-1 CONTRIBUTES TO THE DEVELOPMENT OF ACUTE GRAFT-*VERSUS*-HOST DISEASE IN PEDIATRIC PATIENTS RECEIVING HAPLOIDENTICAL STEM CELL TRANSPLANTATION

E. You[1], S. Jang[1], Y.-U. Cho[1], C.-J. Park[1], Y.J. Lee[2], N.-R. Park[2], E.S. Choi[3], H. Kim[3], K.N. Koh[3], H.J. Im[3], A. Ahn[4,*]

[1]Laboratory medicine, [2]Asan Clinical Research Center, [3]Department of Pediatrics, Asan medical center and University of Ulsan College, Seoul, Korea, Republic Of, [4]Department of Laboratory Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: In a tumor microenvironment, overexpression of PD-1, an inhibitory receptor on the surface of T cells, can lead to dysfunction of anti-tumor effector cells. Recent studies show PD-1 is associated with graft-*versus*-host disease (GVHD) and relapse after stem-cell transplantation (SCT). However, studies on PD-1 in patients received SCT are rare.

Aims: The aim of this study was to evaluate pediatric patients undergoing haploidentical hematopoietic stem-cell transplantation (HHSCT) to determine expression levels of PD-1 and to investigate the association between PD-1 and GVHD and relapse.

Methods: Between April 2017 and February 2018, a total of 153 peripheral blood samples with 34 patients with hematologic malignancies (n=18) and non-malignancies (n=16) were enrolled. Seventeen patients were experienced acute GVHD and 4 patients were experienced engraftment failure and 2 patients were expired. Flow cytometric analysis of PD-1 expression on T cells was performed by means of a Navios™ flow cytometer and Kaluza® Flow Analysis Software (Beckman Coulter, Miami, FL, USA).

Results: Patients within 14 days after graft infusion showed significantly lower level of PD-1 on CD8+ and CD4+ T cells than before HHSCT (P=0.000 and P=0.009). However, PD-1 expressions were not correlated with time after HHSCT. However, PD-1 expressions on CD8+ T cells and CD4+ T cells were significantly correlated quantitative chimerism results (P=0.000 and P=0.000). PD-1 expression on CD8+ T cells was higher in hematologic malignancies patients than non-malignancies patients (P=0.028). To investigate the relationship between PD-1 expression and acute GVHD, we analyzed the samples within 100 days after HHSCT. PD-1 expression in CD8+T cells and CD4+ T cells were significantly increased in the patients with acute GVHD (P=0.010 and P=0.034). However, no difference in PD-1 was observed between patients with engraftment and patients with engraftment failure.

Summary and Conclusions: In this study, the correlation between PD-1 expressions and quantitative chimerism results suggests that it might be associated with relapse after SCT. Blockade of PD-1 immune checkpoint may be an option of immunotherapeutic strategies for patients with increased quantitative chimerism results after HHSCT.

In particular, expression of PD-1 was found to be increased in patients with acute GVHD compared to non-GVHD patients and might be helpful in understanding the relationship between PD-1 and acute GVHD. However, the role of PD-1 in post-SCT patients should be evaluated in larger patient cohorts in future studies.

A PHASE 1 PILOT STUDY OF ULTRA-LOW DOSE IL-2 AS GVHD PROPHYLAXIS IN HAPLO-IDENTICAL STEM CELL TRANSPLANTATION

S. Ito[1,*], P. Jain [1], S. Cordes[1], X. Tian[2], C. Cantilena[1], C.P. Bradley[1], R. Panjwani[1], Q. Yu[1], S. Hauffe[1], J. Superata[1], D. Stroncek[3], J. Chen[4], M. Battiwalla[1], J. Barrett[1]

[1]Hematology Branch, [2]Office of Biostatistics Research, National Heart, Lung, and Blood Institute National Institutes of Health, [3]Department of Transfusion Medicine, Clinical Center, [4]Center for Human Immunology, Autoimmunity, and Inflammation, National Institutes of Health, Bethesda, United States

Background: Post-graft cyclophosphamide dramatically improved the outcomes of haplo-identical stem cell transplantation (haplo-SCT) by reducing the life-threatening graft *versus* host disease (GVHD). However, the optimal duration and choice of systemic immunosuppression in haplo-SCT remain undetermined especially for the subjects of high-risk hematologic malignancies requiring maximal benefit of graft *versus* leukemia (GVL) effects. Ultra-low dose interleukin 2 (ULD IL-2) can simultaneously prevent GVHD

and potentiate GVL through its unique biological properties to expand regulatory T cells (Tregs) and natural killer (NK) cells.
Aims: We updated our report of a phase 1 study evaluating the safety and feasibility of ULD IL-2 as GVHD prophylaxis in haploidentical allo-SCT (NCT02226861) with correlative biological data.
Methods: Twelve subjects (median age 35, range 22-66 years) with high-risk hematological malignancies were enrolled in the study receiving a myeloablative conditioning regimens of fludarabine 120mg/m^2 (day -10 to day -8) and total body irradiation (TBI; 600-1200 cGy, day -10 to day -6). Donor lymphocyte infusion (DLI) products (2x10^8 CD3+/kg) was infused on day -6, followed by post-DLI cyclophosphamide 120mg/kg on days -3 and -2. CD34$^+$ selected, peripheral blood stem cell product was infused on day 0. For GVHD prophylaxis, ULD-IL2 (aldesleukin, 100,000 IU/m^2) was given from day +1 subcutaneously daily for 12 weeks with a concurrent use of sirolimus for the first 60 days. The subsets of memory T cells, Tregs, NK cells were characterized by flow cytometry and plasma GVHD biomarkers (ST2, Reg3α, sTNFR1, ANG2) were measured by multiplex microfluidic channel assay. Virus and leukemia antigen specific T-cells were evaluated by both Elispot and flow cytometry. ULD IL-2-dependent transcriptome landscape was further analyzed at single cell level using 10x™ Chromium™ Single Cell Platform.
Results: Eight subjects were classified as high or very high risk by Disease Risk Index (DRI) and most subjects had high-risk EBMT score (median 5) and high HCT co-morbidity index (median 5). All subjects achieved successful engraftment and 100% donor myeloid and lymphoid chimerism by day 21. At the median follow up of 2 years, the overall survival and relapse-free survival was 56.2% and 37.5%, respectively. All evaluable subjects tolerated ULD-IL2 without significant toxicities. Grade II-IV and III-IV acute GVHD (aGVHD) were only observed in 25% and 8% respectively during ULD IL-2 treatment. However, five subjects experienced either *de-novo* or rapid exacerbation of aGVHD after discontinuation of ULD IL-2, resulting in the cumulative incidences of grade II-IV and III-IV aGVHD of 58% and 25% respectively (Figure 1A). ULD IL-2 expanded both Helios$^+$Tregs as well as CD56^{bright}NK cells. The onset of aGVHD was correlated to rapid decrease in Helios$^+$Tregs population with a sharp increase of ST2 (Figure 1B). Single cell RNAseq confirmed dynamic transcriptome changes in various cell populations induced by ULD IL-2 discontinuation, suggesting significant homeostatic roles of ULD IL-2 in GVHD prophylaxis. Both leukemia and virus antigen specific T cells were detectable as early as day 100 after haplo-SCT.

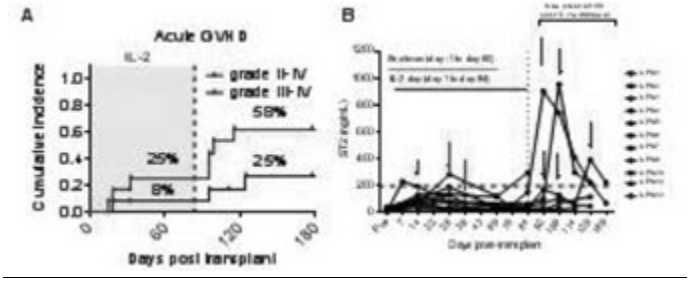

Figure 1.

Summary and Conclusions: This is the first study to demonstrate the safety and feasibility of ULD IL-2 as GVHD prophylaxis in haplo-SCT. Our study implies an acquired dependency of donor-derived Tregs to exogenous ULD IL-2 and the possible need of prolonged administration of ULD IL-2 after haplo-SCT.

PF746

THE IMPACT OF CMV REACTIVATION ON HSCT OUTCOMES IN CHILDREN WITH MALIGNANCIES: A 13 YEARS SINGLE CENTER EXPERIENCE

F. Baccelli[1,*], A. Di Gangi[2], S. Bernasconi[3], M. Nardi[3], L. Coccoli[3], G. Casazza[3], C. Favre[4], M. Menconi[3]

[1]University of Pisa, [2]Sant'Anna School of Advanced Studies, [3]Azienda Ospedaliera Universitaria Pisana (AOUP), Pisa, [4]Azienda Ospedaliera Universitaria Meyer, Firenze, Italy

Background: After the introduction of pre-emptive therapy, the incidence of CMV disease (CMVD) dramatically decreased in HSCT recipients, while indirect effects of CMV infection (CMVI) are still under investigation.
Aims: To critical evaluate indirect effects of CMVI and the incidence of CMVD in pediatric HSCT for malignancies.
Methods: We retrospectively analyzed children (aged<18 years) who underwent first allogeneic HSCT for malignancies at our institution between 01/2003 and 12/2016. CMVI was defined as virus isolation or detection of viral proteins (antigen pp65) or nucleic acid in any body fluid or tissue specimen while the definition of CMVD required specific organ signs/symptoms combined with CMV documented in the involved tissue by virus isolation, rapid culture, histopathology, immunohistochemistry or DNA hybridization techniques. Patients were classified according to the presence of CMVI. 5-years probabilities of OS, DFS, GVHD-free relapse-free survival (GRFS) and infection were calculated using the Kaplan-Meier method and the log-rank test. Cumulative incidence procedure and Gray's test were used to assess differences in relapse, NRM, aGVHD grades 2-4 and extensive cGVHD (e-cGVHD). Major endpoints are reported in Table 1 together with standard errors (SE).
Results: 92 patients were included (CMVI N=40). Groups were homogeneous for age, sex, diagnosis, donor (MSD N=13, MUD N=31, MMUD N=22, haploidentical (HAPLO) N=12, UCBU N=15), stem cell source and graft composition with the exception of lower median cellularity in UCBU. Eleven HAPLO were lymphocyte-depleted (6 α/β+ and 5 CD3+/CD19+) while one received post-transplantation cyclophosphamide. No significant differences were reported for OS, DFS, infections, GRFS, relapse and NRM (p>0.05). The mean day of CMVI diagnosis was 39.6 (28.2-51.0). Although statistically non-significant, aGVHD grade 2-4 was higher in CMVI+, suggesting a possible association. As reported in Figure 1, aGVHD has often preceded CMVI (N=7 *vs* N=1). In contrast, e-cGVHD was less frequent in CMVI+ patients. Remarkably, infections were slightly higher in the early period in CMVI+. Noticeable, only three patients have suffered of CMVD (all of them with gastrointestinal involvement) and two of them are alive at the time of the last follow-up.

Table 1.

Endpoints (SE)	Global	CMV infection	No CMV infection	p
OS	67.2 (0.05)	70.0 (0.07)	64.5 (0.07)	n
DFS	62.0 (0.05)	59.9 (0.08)	64.1 (0.07)	s
Relapse	24.6 (0.05)	25.1 (0.07)	24.2 (0.06)	
NRM	4.6 (0.03)	5.0 (0.04)	4.1 (0.03)	
Extensive cGVHD	9.7 (0.04)	6.3 (0.04)	13.1 (0.07)	
GRFS	41.4 (0.05)	35.0 (0.08)	46.4 (0.07)	
Infections	52.8 (0.06)	58.3 (0.09)	47.8 (0.08)	

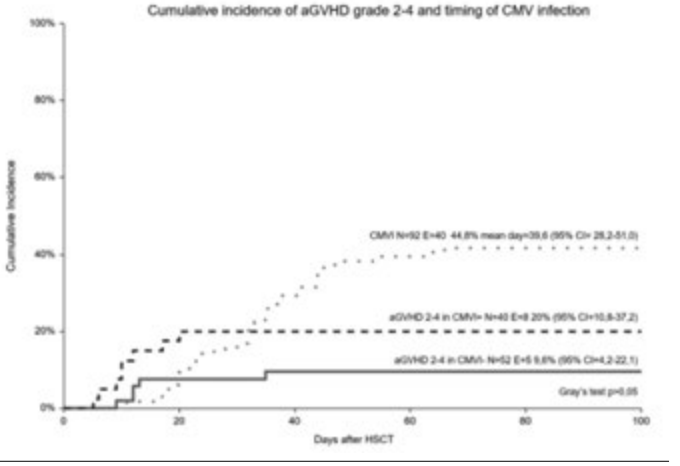

Figure 1.

Summary and Conclusions: Our data confirm low rates of CMVD in modern HSCT. Despite variations in HSCT procedures and the limited sample size, pre-emptive therapy determined a dramatical decrease in CMV indirect effects. Moreover, aGVHD is a possible risk factor for CMVI but not vice versa. However, further evidences are needed to enlighten the role of CMV in the modern era of pediatric HSCT.

PF747

A REAL-LIFE SINGLE CENTER RETROSPECTIVE ANALYSIS TO EVALUATE EBMT RISK INDEX AS A PROGNOSTIC FACTOR IN PEDIATRIC HSCT

A. Di Gangi[1,*], F. Baccelli[2], S. Bernasconi[3], L. Luti[3], E. De Marco[3], G. Casazza[3], C. Favre[4], M. Menconi[3]

[1]Sant'Anna School of Advanced Studies, [2]University of Pisa, [3]Azienda Ospedaliera Universitaria Pisana (AOUP), Pisa, [4]Azienda Ospedaliero Universitaria Meyer, Florence, Italy

Background: EBMT risk index (EBMT-RI) is a well-established tool for risk assessment in HSCT. Although it has been validated in children and adults as a predictor of OS and TRM, its association with other endpoints has not been extensively investigated in pediatric HSCT performed with more recent protocols.
Aims: To retrospectively investigate the role of EBMT-RI as a predictor of outcomes in modern pediatric HSCT.
Methods: We included patients <18 years who underwent first allogeneic HSCT between 01/2004 and 01/2017 for ALL, AML, MDS, CML and NHL. EBMT-RI was calculated following EBMT guidelines and patients were accordingly stratified: low risk (LR, score 0-3), intermediate risk (IR, score=4) and high risk (HR, score>4). Kaplan-Meier and log-rank tests were applied to estimate probabilities of 5-years OS, DFS and GRFS. Relapse, aGVHD grades 2-4, cGVHD, TRM were assessed by cumulative incidence accounting for competing risks and Gray's test. Donor types, donor and patient age, HSC source, AB0 compatibility, conditioning regimens, CMV infection and serostatus were included in univariate and multivariate Cox regression analyses.
Results: We analyzed data from 88 patients (LR N=62, IR N=19, HR N=7). Diseases were not uniformly represented within the sample (ALL N=51, AML N=24, MDS N=6, CML N=5, NHL N=2) and among groups. Matched sibling donors were present only in the LR group. 6 Haploidentical HSCT were lymphocyte-depleted (3 α/β+ and 3 CD3+/CD19+) and one received post-HSCT cyclophosphamide. TBI-based MA regimens and BM grafts were used in HSCT with the exception of haploidentical HSCT which were conducted with RIC regimens and PBSC grafts. Results with standard errors (SE) are reported in Table 1. Only 4 patients experienced TRM (LR N=3, IR N=1). OS and DFS were significantly associated with EBMT-RI (p<0.05). Relapse (Figure 1) and GRFS may show an association with EBMT-RI which is not statistically significant probably because of the nature of the study (p=0.06). Other endpoints did not differ between groups. Due to the small sample size, univariate Cox regression have demonstrated only weak correlations. Remarkably, a possible correlation was observed between DFS and EBMT-RI (p=0.08), donor types (p=0.02), HSC source (p=0.06) or AB0 compatibility (p=0.02). Similarly, correlation between OS and either donor types (p=0.03) or EBMT-RI (p=0.047) was observed. Multivariate analysis did not show any significant correlation.

Table 1.

Endpoints, % (SE)	All	LR	IR	HR	p
OS	65.7 (.05)	73.0 (.06)	57.4 (.12)	28.6 (.17)	<0.02
DFS	60.3(.05)	66.7 (.06)	51.5 (.12)	28.6 (.17)	0.05
GRFS	38.7 (.05)	44.2 (.07)	31.6 (.11)	14.3 (.13)	0.06
Relapse	25.7 (.05)	19.9 (.05)	32.8 (.11)	57.1 (.19)	0.06
aGVHD	14.8 (.04)	16.1 (.05)	10.5 (.04)	14.3 (.13)	>0.05
cGVHD	28.7 (.06)	28.0 (.07)	30.7 (.12)	20.0 (.18)	

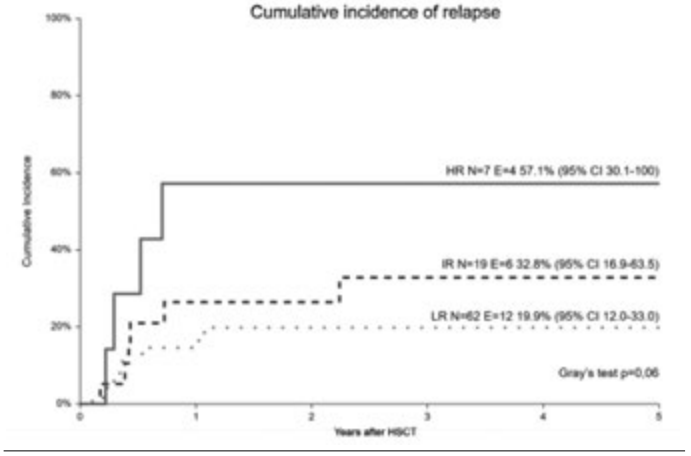

Figure 1.

Summary and Conclusions: EBMT-RI is a good predictor of OS and DFS. Furthermore, we found a putative association between the score and relapse and GRFS. Due to the low incidence of TRM, it was not possible to study correlation between TRM and EBMT-RI. Sample size and lack of homogeneous groups are important limiting factors of our study. Since EBMT-RI was not specifically developed for children, a reformulation of this score for pediatric HSCT may significantly improve risk stratification in this peculiar context. However, further studies are needed.

PF748

THE EXPERIENCE OF USING DEFIBROTIDE FOR THE PREVENTION AND TREATMENT OF HEPATIC VENO-OCCLUSIVE DISEASE AFTER PEDIATRIC HEMATOPOIETIC STEM CELL TRANSPLANTATION; A SINGLE CENTER EXPERIENCE

B. Antmen[1,*], H.I. Sasmaz[1,2], B. Karagun[1], M. Serbest[1]

[1]Pediatric Bone Marrow Transplantation Unit, Department of Pediatric Hematology, Adana Acibadem Hospital, [2]Pediatric Hematology, Cukurova University, Adana, Turkey

Background: Hepatic veno-occlusive disease (VOD) is a common and serious complication of hemotopoietic stem cell transplantation (HSCT) in children. Çorbacıo lu et al reported that, defibrotide prophylaxis seems to reduce incidence of VOD.
Aims: We aimed to assess prospectively the use of prophylactic defibrotide in pediatric patients undergoing HSCT and present of treatment results.
Methods: In this study, 157 patients who underwent HSCT were given defibrotide prophylaxis as 25 mg/kg per day in four divided intravenous infusions over 2h, starting on the same day as the pre-transplantation conditioning regimen. The mean duration of use of defibrotide is 25 days as a prophylaxis.
Results: In this study, 157 patients were recruited, 95 male patients and 62 female patients, with the average of 8.7 years, range 1-20; 9% infants, 58% children and 33% adolescent. There were 69 patients with thalassemia major, 58 patients with leukemia, 12 patients with aplastic anemia, one patient with Diamond Blackfan anemia, two patients with congenitale dyserythropoetic anemia, one patient with osteopetrosis, five patients with famial hemophagocytic lymphohistiocytosis, three patients with severe immune deficiency, threee patients with sickle cell disease and threee patients with Kostman syndrome. All transplants were allogeneic. No serious side effects were seen. In 13 patients developed clinical VOD (Seattle criteria). In these patients, defibrotide dose was increased to a treatment dose of 40-60 mg/kg per day. One infant patient with Kostman syndrome died due to hepatic and pulmonary veno-occlusive disease. After 48 months of follow up, 12 patients who developed VOD are being well and no patient have transplant related complications
Summary and Conclusions: Hepatic veno-occlusive disease, which is caused by hepatocyte and sinusoidal vessel endothelium damage, can ocur usually early phase after HSCT, and in its severe form, may lead to liver failure, hepatorenal syndrome, portal hypertension, and eventually death from multiorgan faillure. In this prospective study, we demonstrated that the use of defibrotide is safe and effective in preventing and treating VOD in pediatric patients at high risk group.

PF749

THE HEMATOPOIETIC CELL TRANSPLANTATION COMORBIDITY INDEX IN THE CONTEXT OF AUTOLOGOUS STEM CELL TRANSPLANTATION CAN PREDICTS CLINICAL OUTCOMES

A. Martínez-Roca[1,*], C. Talarn Forcadel[1], L. G. Rodríguez-Lobato[2], L. Escoda Teigell[1], R. Vallansot[1], M. Cervera Calvo[1], J. Do Nascimento[1], R. Aguinaco Culebras[1], T. Giménez Pérez[1], C. Araguás Arasanz[1], A. Vicen[1], M. Sola[1], J. Sarrà Escarre[1]

[1]Hematology, ICO-Hospital universitari Joan XXIII., Tarragona, [2]Hematology, Hospital Clinic, Barcelona, Spain

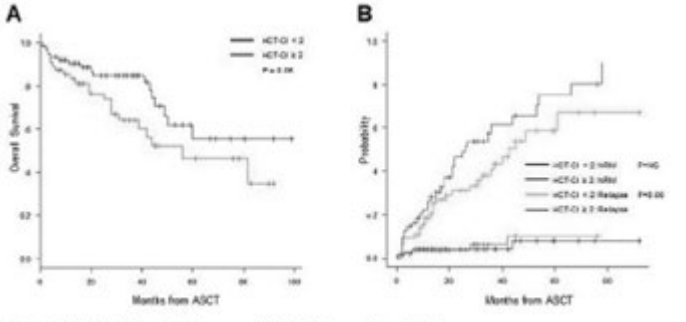
Background: Autologous stem cell transplantation (ASCT) is a standard of care in patients with multiple myeloma and lymphoma, nevertheless is associated with morbidity and mortality. The Hematopoietic cell transplant comorbidity index (HCT-CI) is a score used to evaluate the comorbidities for outcomes after allogenic hematopoietic cell transplant (HCT), proving to be a predictor of non-relapse mortality (NRM) after allogenic HCT. There are few publications that evaluate the use of HCT-CI in the setting of ASCT with heterogeneous results on the score ability to predict NRM and overall survivor (OS) in this group of patients.
Methods: We analyzed 130 ASCT performed in our center between November 2008 and April 2017. Individual comorbidities were prospectively collected at the time of ASCT. All patients were assigned an HCT-CI score. We tested the utility of HCT-CI as a predictor of NRM and survival in patients undergoing ASCT. Survival curves and probabilities were estimated using the Kaplan-Meier method and log-rank analysis. Multivariate analysis was performed using Cox proportional hazard regression model. Variables analyzed included HCT-CI, age, gender, type of disease (myeloma and lymphoma), disease stage and Karnofsky performance score

(KPS) (Table 1). NRM was defined as mortality after transplant in the absence of disease relapse/progression Thus, the cumulative incidence probabilities for NRM were calculated accounting for relapse as a competing risk.

Table 1. Patient Characteristics of the 2 Groups (HCT-CI Score <2 and ≥2).

Characteristic	TOTAL	HCT-CI <2	HCT-CI ≥2	P
Transplants	130	96	34	
Age at transplant (range) ≥ 50	94 (72.3)	47 (62.7)	47 (85.5)	0.004
Gender (%) Male	71 (54.6)	39 (52)	32 (58.8)	0.48
KPS (%) <90	74 (56.9)	40 (53.3)	34 (61.8)	0.33
Diagnose (%) Myeloma	70 (53.8)	36 (48)	34 (61.8)	0.12
Lymphoma	60 (46.2)	39 (52)	21 (38.2)	
Disease stage (%) CR	54 (41.5)	31 (41.3)	23 (41.8)	0.95

Results: Median follow-up was 29,5 months (CI, 11-44,25). Patients with a HCT-CI score ≥2 presented a median OS of 56 months (P=0.06) and trend towards to an inferior OS. In the multivariate analysis HCT-CI score ≥2 retained its independence adverse prognostic factor (HR=2.34; 95% CI, 1.166-4.71; P=0.016). NRM was 43 months in HCT-CI score <2, and 26 months in the HCT-CI score ≥2 group (P=0.083) (Figure 1).



OS and NRM of the 2 risk groups (HCT-CI Score <2 and ≥2).

Figure 1.

Summary and Conclusions: A higher HCT-CI score did not predict NRM but was associated with inferior survival in patients undergoing ASCT in our cohort.

PF750

INTRA-BONE CORD BLOOD TRANSPLANT WITHOUT *IN-VIVO* T-CELL DEPLETION: RESULTS IN 12 PATIENTS.

E. Xue[1,*], F. Giglio[1], R. Greco[1], D. Clerici[1], L. Lazzari[1], M. Bernardi[1], S. Piemontese[1], M.T. Lupo Stanghellini[1], J. Peccatori[1], F. Ciceri[1]

[1]Hematology and Bone Marrow Transplantation Department, IRCCS San Raffaele Scientific Institute, Milan, Italy

Background: Cord Blood Transplant (CBT) represents a valid option in patients affected by hematological malignances without HLA-matched donors. Anti-thymoglobulin (ATG) has been largely used as an *in vivo* T-cell depletion to reduce the risk of GVHD and prevent graft rejection, but its use is associated with a slow post-transplant immune recovery, which might lead to higher infection and relapse rate.
Aims: Aims of this study was to demonstrate the efficacy and safety of CBT without *in vivo* T-cell depletion in high-risk hematological disease.
Methods: Since 2015 our Center adopted a policy of GvHD prophylaxis without *in-vivo* T-cell depletion, based on sirolimus and mycophenolic acid. Twelve patients received a CBT: diagnosis were AML=8, T-ALL=2, NHL=2; median age was 45 years (range 22 - 65), and 5 pts were in active disease (AD) at transplant. None of them have received prior auto-SCT, whereas four have received prior allo-SCT (MUD=2, MRD =1, MMRD=1). In all but one case, CB was transplanted directly intra-bone to improve the speed and efficacy of engraftment. Conditioning regimens were based on full myeloablative doses of Treosulfan and fludarabine; Donor/recipient HLA matching were 5/8, 6/8, 7/8 in 4, 2, 5 cases respectively, and in one case 4/6. Antifungal prophylaxis included voriconazole (n=7), posaconazole (n=3), amphotericin (n=1) or micafungin (n=1), antimicrobial prophylaxis was based on quinolones (n=12), and antiviral prophylaxis included acyclovir (n=5) or acyclovir plus foscarnet (n=7).
Results: After thawing, median mono-nucleated CD45+ cells was 1.3 x 10e7/kg (range 0.69 – 2.9), median CD34+ cells infused was 0.08 x 10e6/kg (range 0.02 – 0.23), and median CD3+ cells was 2.75 x 10e6/kg (range 1.29 – 4-9). Neutrophils engraftment was documented in all but two cases (who died within one week after graft injection) with a median time of 25 days (range 16–59 days); platelets engraftment in seven out of 12 cases (median time=50 days, range 24 – 221 days). Median follow up is 206 days (range 9 – 1016 days). Three pts transplanted in active leukemia died from disease relapse, which occurred at 90, 180 and 305 days after CBT respectively; 3 pts died early from TRM (GvHD n=1, probable IFD n=3). In ten pts at least one viral reactivation was documented (CMV n=7, HHV6 n=10, others n=5), with a first reactivation median time of 25 days from CBT, in 7 cases with organ involvement (encephalitis n=2, gastrointestinal infection n=6). Two pts also had EBV reactivation, in one case associated to lymphoproliferative disorder. Three pts developed probable invasive fungal disease (IFD), treated with amphotericin (n=1) and voriconazole (n=2). One patient developed acute GvHD (overall grade 4; 59 days after CBT), whereas 4 pts developed a peri-engraftment syndrome (median time 13 days after CBT) which recovered after a short steroid course. Sirolimus and mycophenolic acid were withdrawn at a median time of 175 (range 64–353) and 27 days (range 27–31) respectively. No pts developed chronic GvHD. Interestingly, immune reconstitution of lymphocytes subsets was obtained at 3 months after CBT, showing a median of 157/μL CD3+ cells, 142/μL CD3+CD4+ cells, 38/μL CD3+CD8+ cells, 35/μL CD19+ cells, 129/μL NK cells at 3 months. Six pts are alive and in complete remission at last follow up (median FU 316 days, range 53-1016 days).
Summary and Conclusions: Intra-bone CBT without *in vivo* T-cell depletion is associated with fast hematopoietic engraftment and immune reconstitution, with low rate of GvHD.

PF751

HEMATOPOIETIC REGENERATION AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION WITH ACTUAL BODY WEIGHT BASED DOSING OF CONDITIONING CHEMOTHERAPY

D. Fuchs[1,*], R. Greul[1], K.J. Krenosz[1], M.A. Fridrik[1]

[1]Department of Internal Medicine 3 - Hematology and Oncology, Kepler University Hospital, Johannes Kepler University Linz, Linz, Austria

Background: The incidence of obesity is increasing, but it is unclear how to dose chemotherapy in these patients, especially in autologous stem cell transplantation (ASCT). Obese patients have more comorbidities and different pharmacokinetics than non-obese patients, which may put them at a higher risk for complications of ASCT. A majority of centers adjust dose for obese patients, but methods are heterogeneous and include using ideal body weight (IBW) or adjusted actual body weight (ABW) (*i.e.* IBW plus 25 or 40% of ABW minus IBW) and/or capping the calculated body surface area (BSA) at $2.0m^2$. In patients undergoing conventional chemotherapy, guidelines recommend full dosing based on ABW, because myelosuppression is not more pronounced in obese patients and adequate doses are need for optimal efficacy. In ASCT, there is little data and no consensus on how to dose conditioning chemotherapy in obese patients.
Aims: We aimed to examine whether ABW-based dosing of chemotherapy before ASCT leads to a prolongation in the time to hematopoietic reconstitution in patients with a BSA over $2.0m^2$.
Methods: We performed a retrospective analysis of patients with an ASCT from 2004 to2017 at our center, which uses full, ABW-based dosing of chemotherapy. In patients with a BSA of >=$2.0m^2$ those with a BSA <$2.0m^2$, reconstitution of leukocytes (days from ASCT to leukocytes >1.0 G/l) and thrombocytes (>20 and >100 G/l) were compared. We also examined overall survival (OS), 100-day OS and transplant associated mortality (TRM). Time to event analysis was summarized using Kaplan Meier curves and results were compared using the log rank test.
Results: We included 60 patients and 76 autologous transplants from 2004 to 2017. 69.7% were male, with a median age of 50.5±12.9 years (range 25.7-63.1, 95%CI 25.7-63.1). Median BMI was 25.3±4.4 (range 16.7-44.5, 95% CI 19.7-33.5). A majority was overweight (43.4%) or obese (10.5%; 40.3% normal weight, 5.3% underweight). 50.0% had a BSA over $2.0m^2$ (median 2.0±0.24, range 1.4-2.5, 95% CI 1.5-2.4). Chemotherapy protocols were BEAM (31.6%), carboplatin/etoposide (21.1%), melphalan (42.1%) and busulfan/cyclophosphamide (5.2%). Diagnoses were lymphoma (33.0%; Hodgkin's, 7.9%; follicular lymphoma, 13.2%, diffuse large B-

cell-lymphoma, 5.3%, other, 6.6%), testicular cancer (19.7%), multiple myeloma (42.1%) and acute myeloid leukemia (5.3%). Median time to reconstitution of leukocytes (>=1.0 G/l) was 10.0±0.354 days for BSA <2.0 and 10.0±0.233 days for BSA >=2.0 (p=0.643). There was no significant difference between reconstitution of thrombocytes >20 G/l (median 10.0±0.42 *vs* 10.0±0.328 days, p=0.481) or thrombocytes >100 G/l (median 18.0±0.581 *vs* 19.0±1.50 days, p=0.497). Similar results were seen when comparing BMI (underweight/normal weight *vs* overweight/obese; p=0.051 for leukocytes, p=0.624 and 0.729 for thrombocytes >20 and >100). Grade 3-4 infections were numerically higher in patients with BSA >=2.0, but this was not statistically significant (78.9% *vs* 92.0%, p=0.191). The same was true for other complications of grade 3 and higher (51.0 *vs* 65.8%, p=0.245). Therapy associated deaths were rare (n=1) and there was no difference regarding 100-day-OS (median N.R. *vs* N.R., p=0.558), but patients with a BSA >2.0 had a trend for a higher OS (N.R. *vs* 94.8 months, p=0.075) (Figure 1).

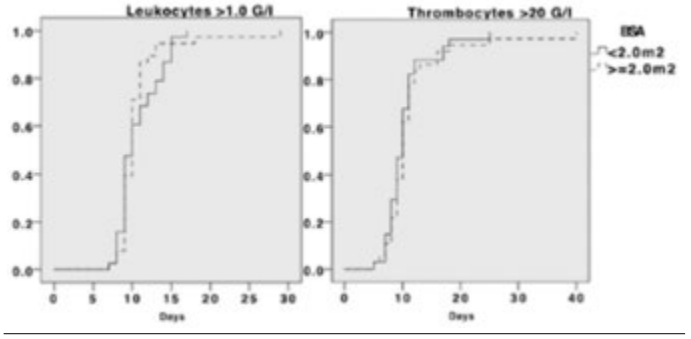


Figure 1.

Summary and Conclusions: Although this was a retrospective study and findings need to be validated, there was no difference in time to hematopoietic reconstitution, OS or TRM. ABW-based dosing of chemotherapy prior to ASCT was safe in patients with BSA >2.0m^2.

PF752

IMPACT OF MIXED CHIMERISM IN T REGULATORY CELLS ON RELAPSE RATE IN ACUTE LEUKEMIA PATIENTS AFTER ALLO-HSCT

D. Dubnyak[1,*], N. Risinskaya[2], M. Drokov[1], N. Kostritsa[3], J. Davydova[4], L. Kuzmina[1], N. Kapranov[4], V. Vasilyeva[1], N. Popova[1], E. Mikhaltsova[1], O. Koroleva[1], A. Sidorova[1], E. Usikova[1], Z. Konova[1], I. Galtseva[4], A. Sudarikov[2], E. Parovichnikova[1], V. Savchenko[1]

[1]Bone marrow transplant, [2]Molecular biology laboratory, National Research Center for Hematology, Moscow, Russian Federation, [3]School of Medicine, Lomonosov Moscow State University, [4]Immunophenotyping laboratory, National Research Center for Hematology, Moscow, Russian Federation, Moscow, Russian Federation

Background: It is known that T-regulatory cells (Treg) play an important role in maintaining tolerance after allo-HSCT. Tregs prevent the development of acute graft-*versus*-host disease (aGVHD) (Beres & Drobyski, 2013). At the same time these T-cell populations can limit the antitumor response (graft-*versus*-leukemia, GVL) and that limitation may cause relapses. Here we report the analysis of mixed chimerism in T-reg population and the frequency of relapse in patients with acute leukemia (ALL and AML) after allo-HSCT with comparable levels of donor chimerism.
Aims: To evaluate a possible relationship between the mixed chimerism in Treg cells and the rate of relapses in acute leukemia patients after allo-HSCT.
Methods: The study included 31 patients after allo-HSCT (ALL n=6, AML n=25). The median age was 38 years (19-66). Peripheral blood samples for analysis were taken on day 30 after transplantation. Immunomagnetic separation (Miltenyi Biotec, Germany) was used to isolate population with CD4+CD25+ phenotype which is predominantly associated with Treg cells. Extraction of DNA was performed from the obtained cells. Chimerism in DNA samples was determined using the STR-PCR method. The percentage of donor chimerism was calculated using standard procedures (Nollet *et al.*, 2001) Statistical analysis of the data was carried out using SPSS ver 23. (IBM, Chicago, Ill., USA). xact Fisher's test was used to analyze the 2 × 2 contingency tables.
Results: In the patients group with less than 11% of cells with host genotype (more than 89% of cells of donor origin) the relapse rate was significantly higher - 52.6% (10 of 19) than in the other group of patients with 11% and more cells with host genotype - 8.3% (1 of 12), (p=0.02). At the same time donor chimerism in the unselected bone marrow did not significantly differ between the groups (p=0.36) and amounted to 100% (75-100%) and 97.5% (90-100%). The study groups were balanced for all other factors that could affect the relapse rate: disease status, graft source, GVHD.
Summary and Conclusions: According to our data we proposed that host's Treg cells are not capable of suppressing GVL that explains significant differences in the frequency of relapses in patients with acute leukemia after allo-HSCT. Predominance of host's Treg cells may serve as a favorable prognostic sign but this hypothesis needs to be confirmed in the largest cohort of patients.

PF753

REDUCED-INTENSITY CONDITIONING WITH FLUDARABINE AND BUSULFAN *VERSUS* FLUDARABINE AND MELPHALAN FOR T DEPLETED ALLOGENEIC TRANSPLANT IN MYELOID MALIGNANCIES: AN EXPERIENCE OF A TERTIARY CENTRE

M.S. Lopes[1,*], P. Krishnamurthy[2], K. Tawana[2], J. Craig[2], B. Uttenthal[2], C. Crawley[2]

[1]Clinical Haematology, Centro Hospitalar Porto, Porto, Portugal, [2]Haematology, Cambridge University Hospitals, Cambridge, United Kingdom

Background: Fludarabine with busulfan (FB) and fludarabine with melphalan (FM) are two widely used reduced-intensity conditioning (RIC) regimens that are well tolerated in older patients and those with comorbidities. Until 2015, our centre has routinely used oral busulfan based regimens. Following data suggesting more favourable outcomes for acute myeloid leukaemia (AML) patients undergoing FM conditioning (Baron *et al.* 2015) we elected to switch to this regimen for all transplants for myeloid malignancies.
Aims: To review overall and progression free survival (OS and PFS) for patients undergoing T-cell depleted RIC FB or FM transplants for myeloid malignancies.
Methods: Data was collected retrospectively for myeloid patients who underwent allogeneic haematopoietic stem cell transplant (aHSCT) with FB or FM at our centre between February 2014 and December 2017. Busulfan 8mg/kg was given orally over 2 days and a single dose of melphalan (140 mg/m2) was given intravenously. All patients received aHSCT from a fully-matched sibling or an unrelated donor (VUD). All received alemtuzumab as graft-*versus*-host disease (GvHD) prophylaxis at 30-50mg total dose. Results were analysed using SPSS with Kaplan-Meier methodology for survival assessments.
Results: Of 78 patients observed, 46 (56%) were male, with a median age at transplantation of 59 years (range 35-71). The HCT comorbidity index (HCT-CI) score (Sorror 2005) was more than 3 in 25 patients (32%). Patients received transplants from a sibling (n=22, 28.2%) or VUD (n=56, 71.8%). The groups were matched for age, sex, HCT-CI, donor type, EBMT risk score (Gratwohl 2012) and months between diagnosis and transplantation. Patients were transplanted for AML (n=57, 73%) or MDS/MPN (n=21, 27%) and were equally distributed between groups. Fourteen patients (18%) had secondary AML (sAML). The median follow-up for FBC (FB+alemtuzumab) cohort was 39.1 months (range 26.7-48.6) and 11.5 months (range 1.7-47) for FMC (FM+alemtuzumab). Thirty-seven patients received FBC and 41 patients received FMC conditioning. Amongst the FBC group, there were 30 AML patients (*de novo*, n=20 (67%) and sAML, n=10 (33%)); amongst FMC patients, 27 were transplanted for AML (*de novo*, n=23 (85%), sAML n=4 (15%)) with a statistical difference (p=0.21). High risk AML patients by the ELN classification (Döhner *et al.* 2017) were equally distributed (p=0.14) between both conditioning groups (14/30 AML in FBC, 8/27 AML in FMC). Twenty-one MDS/MPN patients were equally distributed and classified in terms of IPSS-R as poor and very poor risk. Acute GvHD was observed in 23 (29.5%) patients and chronic GvHD in 14 (18%) patients, no significant differences between groups. Median OS was 19.7 months for FBC and not reached for FMC patients (p=0.005). Median PFS was 18.5 months for FBC and not reached for FMC (p=0.001). No other factors significantly influenced OS and PFS (Figure 1).
Summary and Conclusions: We demonstrate inferior OS and PFS in patients receiving FBC (oral Busulfan) when compared with patients who received FMC conditioning for transplantation in myeloid malignancies. Reasons for this could include the bioavailability and pharmacokinetics of oral busulfan. Whilst the data represents a small sample with short follow-up on FMC cohort, the earlier and greater number of relapses in the FBC cohort is significant. These results suggest that FBC (oral busulfan) is a suboptimal con-

ditioning for our data. Studies with longer follow-up and larger samples will be necessary to achieve major conclusions.

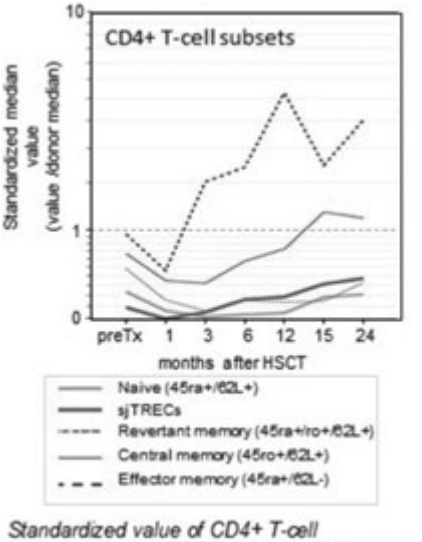
Città della Salute e della Scienza di Torino, Torino, Italy

Background: The use of post-transplant cyclophosphamide (PTCY) has expanded the application of haploidentical haematopoietic stem cell transplantation (haplo-HSCT). Post-transplant immune-deficiency, especially in the T-cell compartment, may lead to increased risks of opportunistic infections and reduced graft-*vs.*-tumor effects. Adequate reconstitution of a near-normal/normal T-cell immunity may play a key role. The thymus is the primary source of naïve T-cells and highly contributes to maintain the peripheral T-cell pool.

Aims: To evaluate the kinetics of long-term thymus-dependent immune-reconstitution after PTCY haplo-HSCT.

Methods: The study population consisted of 29 consecutive haplo-HSCT patients of median age 53 (r 28-70) years. Donor median age was 39 (r 18-66). Blood samples were collected before conditioning and at 1, 3, 6, 12, 18, 24 months after transplant. Analysis of T-cell subsets (naïve, central, memory, revertant) by flow-cytometry was correlated with Real-Time PCR quantification of signal joint T-cell receptor excision DNA circles (sjTRECs), specific marker of naïve T-cells thymopoiesis. SjTRECs real-time PCR was performed on genomic DNA extracted from sorted CD4 and CD8 T-cells. Associations between sjTRECs and T-cell subsets and trends over time were evaluated by Generalized Linear Models.

Results: Following PTCY induced T-cell depletion, a constant gradual increase in absolute numbers of all T-cell subsets and of sjTRECs from the first month up to two years post-transplant was observed Patient median counts of T cell subsets at 1, 3, 6, 12, 15, 24 months were as follows: **naive CD4+CD45RA+CD62L+**: 1,9/ul; 2,3/ul; 5,5/ul; 9,3/ul; 31,9/ul, 40,2/ul; **central CD4+CD45RO+CD62L+**: 17,6/ul, 50,7/ul, 89,8/ul, 127,0/ul, 202,8/ul, 197,6/ul; **effector CD4+CD45RO+CD27-**: 5,2/ul, 41,37ul, 72,7/ul, 125,4/ul, 109,8/ul, 179,9/ul; **revertant CD4+CD45RA+/45RO+**: 3,9/ul, 11,1/ul, 36,6/ul, 62,2/ul, 42,2/ul, 55,4/ul. Median values of **sjTREC copies**/100 ng DNA from sorted CD4+ cells were: 2,8; 5,9; 36,2; 25,8; 22,4 at 3, 6, 12, 15, 24 months, and 84,6 in healthy donors respectively (Figure 1).



Standardized value of CD4+ T-cell subsets and sjTRECs reconstitution at different time-points after HSCT.

Figure 1.

Median values of healthy donor T cell counterparts were 284,3 /ul, 161,9/ul, 37,0/ul, and 152,6/ul respectively. Similar patterns of immune-recovery was observed in CD8+ T cell subsets. Overall, at two years, CD4 and CD8 T-cell levels and sjTRECs levels were lower than those observed in healthy donors. Molecular analysis of the sjTRECs kinetics was associated with the increase in CD4+ naïve T-cells (global p <0,008). This correlation clearly suggests that most of naïve T-cells derives from thymic re-education of donor precursor stem cells. Furthermore, an increase in revertant CD4 and CD8 memory T-cells was also significantly correlated with sjTRECs kinetic (p 0,041 and <0.001 respectively). By contrast, central and effector memory T-cells showed a faster thymic-independent expansion. Importantly, sjTRECs levels and overall thymic dependent immune-reconstitution were more robust in a cohort of 63 adult patients undergoing HSCT from HLA identical donors (data not shown).
Summary and Conclusions: Our results provide evidence of active thymic function despite age-dependent involution that substantially contributes to T-cell reconstitution after PTCY haplo-HSCT. Lower production of sjTRECs as compared after HLA identical sibling transplants may partly be due to a higher degree of "mismatching" of MHC molecules during thymic re-education after PTCY haplo-HSCT. Correlation between immune-reconstitution and clinical outcomes will be presented at the meeting.

PF755

A MESENCHYMAL STROMAL CELL (MSC)-DERIVED COMBINATION OF CXCL5 AND ANTI-CCL24 IS SYNERGISTIC AND SUPERIOR TO MSC AND CYCLOSPORINE FOR THE TREATMENT OF GRAFT-*VERSUS*-HOST DISEASE

X. Fan[1,*], D. Guo[1], A. Cheung[2], Z. Y. Poon[2], C. S. Yap[3], S. Goh[1], H. Li[4], S. Bari[2], S. Li[5], K.H. Lim[6], W. Hwang[7]

[1]Clinical Translational Research, [2]Hematology, Singapore General Hospital, [3]KK Research Centre, KK Women's and Children's Hospital, [4]Division of Medicine, Singapore General Hospital, [5]Cancer & Stem Cell Biology, Duke-NUS Medical School, [6]Department of Pathology, Singapore General Hospital, [7]National Cancer Centre Singapore, Singapore, Singapore

Background: The immunosuppressive properties of mesenchymal stromal cells (MSCs) have been clinically proven to be effective in treating graft-*versus*-host disease (GVHD). However, MSC therapy is limited by the need for laborious and expensive manufacturing processes that are fraught with some batch-to-batch variabilities.
Aims: Substitution of MSC therapy with key MSC-mediated immunomodulatory factors could be an option for GVHD treatment.
Methods: Cytokines presenting in the bone marrow-MSCs/mixed lymphocytes co-culture were identified with a cytokine antibody array. The key MSC-mediated immunosuppressive factors were screened out through serial factorial designs. The immunosuppressive efficacy of these key factors was validated in xenograft model of GVHD created by infusing human peripheral blood mononuclear cells to NOD.Cg-*Prkdc*^{scid} *Il2rg*^{tm1Wjl}/SzJ (NSG) mice. Human cell engraftment and cytokine/chemokine expression in mouse peripheral blood were measured by flow cytometry and Luminex assay.
Results: We identified a synergistic two-factor combination (2FC) of CXCL5 and anti-CCL24 from a panel of over 100 immunomodulatory factors as being equivalent to MSC in the modulation of mixed lymphocyte reactions. This 2FC was superior to cyclosporine in ameliorating both moderate and severe GVHD, while being equivalent to MSC in moderate GVHD and superior to MSC in severe GVHD. Its immunosuppressive efficacy could be further improved by extended treatment. Mechanistic studies revealed that, *in vitro*, the 2FC could only reduce the proliferation of T_H1 cells and T_H17 cells; while *in vivo*, CXCL5 acts in concert with anti-CCL24 antibody to reduce not only human T_H1 cells, T_H17 cells but also cytotoxic T lymphocytes and NK cells, increase mouse immunosuppressive neutrophils and without affecting human hematopoietic stem cell reconstitution. Concurrently, it reduced circulating human pro-inflammatory cytokines IFN-γ, IL-6, IL-17A, IL-8, MIP-1β and MCP-1.
Summary and Conclusions: Both *in vitro* and *in vivo* data suggest that CXCL5 and anti-CCL24 antibody act in concert to ameliorate GVHD via T_H1 and T_H17-triggered immunosuppression. We propose that this novel 2FC could substitute for MSC therapy in GVHD treatment.

GENERATION OF IMMORTAL MURINE HEMATOPOIETIC STEM/PROGENITOR AND LEUKEMIC STEM CELL LINES FROM TRANSGENIC MICE

E. Doma[1,*], F. Pfleger[1], A. Hoelbl-Kovacic[1], V. Sexl[1]

[1]Department of Biomedical Sciences, Pharmacology and Toxicology, University of Veterinary Medicine, Vienna, Austria

Background: Research on hematopoeitic and leukemic stem cells (LSCs) is currently limited as these cells are infrequent and their immortalization is hardly achieved.
Aims: We aimed to establish a long term *ex-vivo* culture system that allows maintenance and expansion of immortalized and functional LSK (lin$^-$, Sca-1$^+$, c-Kit$^+$) cells and LSCs, which trigger leukemia upon transplantation.
Methods: We adapted a technique described by the L. Carlsson lab and transduced high-purity sorted murine LSKs with *Lhx2*, a LIM-homeobox transcription factor, which has been reported to facilitate *ex vivo* expansion of immature hematopoietic cells.
Results: Lhx2 expressing- hematopoietc progenitor cell (HPC^{LSK}) lines require SCF (stem cell factor) and IL-6 and they can be maintained in a feeder-independent culture. They preserve LSK markers despite continuous proliferation and represent functional stem/progenitor cells. HPC^{LSK} cells differentiate *in vitro* upon stimulation with cytokines and repopulate lethally irradiated mice, where they reconstitute the entire hematopoietic cell compartment. HPC^{LSK} cell lines were established from a range of transgenic mice, underlining the overall applicability of this model. Using this system, we also established LSC lines that express BCR/ABL^{p210}, MLL-AF9, or Flt3-ITD; Nras^{G12D} and which do induce disease *in vivo*. These LSCs home to the bone marrow, differentiate and drive myeloid leukemia, when injected into NSG mice. To test the applicability of the model system for drug sensitivity tests we employed Imatinib mesylate (IM). As in people, HPC^{LSK}-BCR/ABL^{p210} cells show partial IM resistance and leads to the enrichment of undifferentiated LSKs.
Summary and Conclusions: We created a robust method of culturing functional hematopoietic stem/progenitor cells which are immortalized and can be expanded indefinitely. By oncogenic transformation we created leukemia triggering LSCs. Our model is a versatile tool allowing the investigation of hematopoietic and leukemic stem cells of any given genotype. Our system thereby represents a valuable tool for (cancer) stem cell biology and may assist in the development of new therapeutic avenues to combat LSCs.

Background: Allogeneic hematopoietic stem cell transplantation (AHSCT) is a curative therapeutic approach for different hematological diseases. Currently, little is known about the biology of HSCs after transplant in terms of homing, self renewal and differentiation, as well as about the role of bone marrow (BM) microenvironment. Since DNA methylation is involved in the balance between HSC self-renewal and differentiation into lymphoid and myeloid lineages, this epigenetic modification may play a role in the reconstitution of the hematopoietic system after AHSCT.
Aims: We explored genome DNA methylation dynamics in BM HSCs aiming to describe the general pattern of methylation after AHSCT.
Methods: A total of 10 patients, affected by acute myeloid leukemia (n=6), acute lymphoblastic leukemia (n=3), Hodgkin lymphoma (n=1) and receiving BM AHSCT, were included in our study. CD34+ cells were sequentially collected from BM of donors (t0) and matched recipients at different time points, at day +30 (t1), +60 (t2), +120 (t3), +180 (t4), +360 (t5). DNA, extracted from CD34+ cells, was used to perform array-based methylation (Infinium Methylation EPIC, Illumina). M-values (log2 Methylated/Unmethylated signals) were used for analysis.
Results: We generated genome wide methylation profiles of donors and recipients interrogating about 850.000 CpG sites. We firstly analyzed global methylation level of all samples. Specifically, we applied principal component analysis to the most variable probes, observing that samples were uniformly distributed; moreover, unsupervised hierarchical clustering showed that, generally, each patient profiled into a specific methylation cluster; some donors clustered together, while others separated with their respective recipient. We

also observed that global methylation level was similar in all times (t0-t5), when considering all samples. Subsequently, to assess methylation changes after transplant, we compared methylation profiles of donor and recipient HSCs at different times. First, we evaluated differentially methylated probes (DMPs) observing the major differences in t1 *vs* t0 (n=12043 DMPs, 70% hyper- and 30% hypo-methylated); this data suggested that, after 30 days, CD34 recipient cells consistently modified their methylation pattern respect to donor cells. We also identified differential methylated regions (DMRs) observing a higher number of DMRs in t1 samples *vs* t0 (n=292). Genomic methylation distribution showed that percentage (%) of hyper-methylated DMPs resulted higher in CpG islands, shores and 3'UTR in all time points *vs* t0, while% of hypo-methylated DMPs was higher in open sea regions. To understand if DMPs maintained a long term modification (t5) or had a short term effect only present in t1, we generated two different signatures: (i) DMPs both in t1 and t5 against t0 (368 DMPs, 276 hyper- and 92 hypo-methylated) representing a long term signature (Figure 1), (ii) DMPs at t1 but not in t5 against t0 (2604 DMPs, 1987 hyper- and 617 hypo- methylated), defined as short term signature. Functional enrichment of both signatures revealed that differentially methylated genes were associated with hematopoiesis.

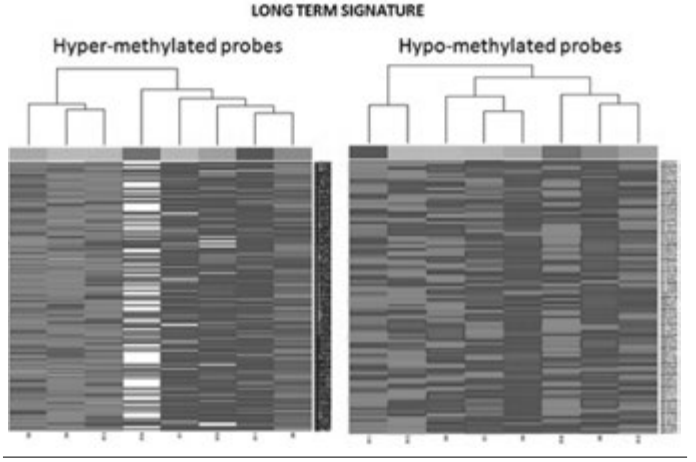

Figure 1.

Summary and Conclusions: Our study shows that global methylation pattern of HSCs prevalently changes in an early time after BM AHSCT, possibly, as a consequence of the adaptation of donor cells in recipient BM niche. Moreover, after 12 months, HSCs partially restored methylation pattern, similarly to donor cells at baseline. Ongoing studies on status and dynamic of HSC methylation could define methylation role in AHSCT outcome.

PF758

TYPE-I-INTERFERON INDUCING MICROBIAL METABOLITES PROTECT FROM INFLAMMATORY TISSUE DAMAGE

E. Thiele Orberg[1], H. Poeck[1,*]

[1]3. Medizinische Klinik; Klinikum Rechts der Isar, Technische Universität München, München, Germany

Background: Recent studies have demonstrated that signals of the innate immune system and the composition of local microbial communities (*i.e.*, the bacterial microbiota) in the gastrointestinal (GI) tract are linked to the outcome of graft-*versus*-host disease (GVHD) following allogeneic hematopoietic stem cell transplantation (allo-HSCT). Yet, the specific contribution of selected innate immune pathways and factors that mediate microbiota-dependent GVHD regulation remain poorly understood. Therefore, a better mechanistic understanding of microbiome-host interactions is needed for the development of clinical strategies based on targeted microbial interventions in patients. Recent work suggests a protective function of Type I Interferons (IFN-I) at epithelial surfaces and in the preventon of GVHD. Consistent with this, we have recently shown that activation of nucleic acid sensing pathways including RIG-I/MAVS and cGAS/STING during genotoxic stress and allo-HSCT results in protective type-I-interferon (IFN-I) signaling that maintains gut epithelial barrier integrity. Thus, we propose a key role for IFN-I signaling and nucleic acid sensor-mediated pathways for the maintenance and restoration of epithelial homeostasis during acute intestinal tissue damage. Notably, new research suggests naturally-occurring microbial-derived metabolites in the GI tract play an important role in protection against viruses in an IFN-I dependent manner.
Aims: We therefore aimed at characterizing the role of these microbial metabolites on intestinal homeostasis and self-renewal during genotoxic tissue damage and whether these metabolites can be harnessed for promotion of intestinal barrier function and prevention of GVHD.
Methods: We used intestinal organoid cultures derived from small intestine and colon to address tissue regeneration (proliferation assay, histology, FACS) and signaling (qPCR, immunoblot) in response to IFN-I-inducing metabolite treatment. We also studied treatment responses using a murine model of chemotherapy -induced gut epithelial damage.
Results: We found that treatment of intestinal organoid cultures with IFN-I-inducing metabolite (i) induced growth and proliferation, (ii) increased expression of interferon stimulated genes (ISG) and of antimicrobial peptides (RegIIIγ), (iii) enhanced NF-kB signaling (p65) and (iv) reduced apoptosis via inhibition of caspase-3 cleavage. In addition, mice receiving the respective metabolite were less sensitive to a chemotherapy (CTx)-mediated model of gut epithelial damage and showed improved recovery of intestinal stem cells (ISCs).
Summary and Conclusions: Our data suggest that prophylactic administration of IFN-I inducing metabolites coupled with maintenance of a permissive microbiome may improve the outcome of allo-HSCT recipients via maintenance of intestinal homeostasis.

PF759

EX-VIVO GENERATED HUMAN CORD BLOOD MYELOID-DERIVED SUPPRESSOR CELLS (HCB-MDSCS) ATTENUATE MURINE CHRONIC GRAFT-*VERSUS*-HOST DISEASES

J.-Y. Lim[1], D.-B. Ryu[1], M.-Y. Park[2], S.-E. Lee[1], G. Park[3], T.-G. Kim[2], C.-K. Min[1,*]

[1]Department of Internal Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, [2]Catholic Hematopoietic Stem Cell Bank, College of Medicine, The Catholic University of Korea, [3]Department of Pathology, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Myeloid derived suppressor cells (MDSCs) are a heterogeneous population of immature myeloid cells with anti-inflammatory activity. Although it has been shown that expanded murine MDSCs are capable of attenuating acute GVHD (AGVHD) severity, it is unclear whether *ex-vivo* cultured human cord blood-MDSCs (hCB-MDSCs) have therapeutic effects in preclinical chronic graft-*versus*-host disease (CGVHD) models.
Aims: We used two mouse CGVHD models to evaluate preventive and therapeutic effects of hCB-MDSCs.
Methods: First, GVHD recipients surviving in a classical C57BL/6 into MHC-mismatched BALB/c AGVHD model developed CGVHD. Second, donor pretreatment with G-CSF induced CGVHD. hCB-MDSCs ($1x10^6$) were intravenously injected to determine their preventive effects (on days 5, 7, 10 and 21) or therapeutic effects (on days 21, 28, and 35).
Results: In the first model, the onset of clinical cutaneous CGVHD was significantly delayed in preventive hCB-MDSCs-treated allogeneic recipients. Pathologic scoring of target organs confirmed these clinical results. Importantly, thymic tissues of GVHD mice treated with hCB-MDSCs were less severely damaged, showing higher number of double (CD4 and CD8) positive T cells with reduced expansion of donor-type CD4 and CD8 T cells. Moreover, late infusion of hCB-MDSCs controlled the severity of established CGVHD that had occurred in control recipients. In the second model, allogeneic recipients of G-CSF-mobilized stem cell graft had CGVHD with Th17 differentiation and due to promotion of Th2 differentiation, at least in part. hCB-MDSCs attenuated clinical and pathologic CGVHD severity. Increased production of IL-17 and more infiltration of T cells and macrophages in CGVHD mice were markedly reduced after hCB-MDSCs treatment. Importantly, $Foxp3^+$ regulatory T cells and IFN-γ-producing T cells were expanded while IL-17- and IL-4-producing T cells were decreased in allogeneic recipients of hCB-MDSCs.
Summary and Conclusions: Taken together, these results showed that hCB-MDSCs have preclinical capability of attenuating CGVHD by preserving thymus function and regulating Th17 signaling, suggesting a possible therapeutic strategy for clinical application.

PF760

EFFICACY OF DEFIBROTIDE FOR PREVENTION AND TREATMENT OF ACUTE GRAFT-*VERSUS* HOST DISEASE IN A FULLY MHC-MISMATCHED MURINE MODEL OF ALLOGENEIC BONE MARROW TRANSPLANTATION

D. García-Bernal[1,*], M. Blanquer[1], C.M. Martínez[2], A.I. García-Guillén[1], J.E. Millán-Rivero[1], R. Sackstein[3], J.M. Moraleda[1]

[1]Hematopoietic Transplant and Cellular Therapy Unit, [2]Experimental Pathology Unit,

Instituto Murciano de Investigación Biosanitaria, Murcia, Spain, [3]Departments of Dermatology and Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, United States

Background: Allogeneic bone marrow transplantation (allo-BMT) is an intensive therapy used for the treatment of high-risk hematological malignant disorders and other life-threatening hematological and genetic diseases. Acute graft *versus* host disease (aGvHD) remains the most frequent and adverse complication following allo-BMT and limits its extensive clinical application. Current pharmacologic agents used for prophylaxis and treatment of aGvHD have variable rates of success or provoke serious secondary side effects, arising the need for discovery and development of more effective and innocuous pharmacotherapies. Defibrotide is a drug clinically employed for the prophylaxis and treatment of veno-occlussive disease after allo-BMT. However, recent preliminary clinical evidences suggest that this drug could be also effective to prevent the occurrence and/or severity of aGvHD after allo-BMT.
Aims: Using a fully MHC-mismatched murine model of allo-BMT, we analyzed if defibrotide, either in prophylaxis or treatment, could reduce aGvHD incidence and severity in mice after allo-BMT.
Methods: On day +0 C57BL/6 recipient mice were transplanted with $1x10^7$ bone marrow cells from BALB/C donor mice (BM transplant), or with $1x10^7$ bone marrow cells and $1.5x10^7$ donor splenocytes to induce aGvHD. Control mice received syngeneic BMT by transplanting $1x10^7$ bone marrow cells and $1.5x10^7$ splenocytes, both from C57BL/6 mice. After aGvHD onset (from day +7 after allo-BMT), mice were treated with a daily infusion of 25 mg/kg of defibrotide for 20 days, or with 25 mg/kg of prophylactic defibrotide from 2 days before allo-BMT to 20 days after. Untreated mice received same volume of saline solution. Survival after allo-BMT was monitored daily and clinical aGvHD was graded using a previously described score. Histopathological aGvHD score was evaluated in distant areas of skin, liver, colon and oral mucosa (tongue) of mice by H&E staining. Also, T $CD3^+$ cell inflammatory infiltrate in same organs was detected by standard ABC anti-CD3 immunohistochemistry procedure.
Results: Mice with ongoing aGvHD and treated daily with defibrotide displayed a significantly lower aGvHD-related mortality and improved clinical aGvHD score than untreated mice group ($p<0.001$) (60% survival at day +60 post-allo-BMT). Control mice transplanted only with donor bone marrow cells w/o splenocytes (BM Transplant) or with syngeneic bone marrow plus splenocytes (Syngeneic Transplant) did not develop aGvHD. When defibrotide was used in prophylaxis, mice displayed a significant higher survival than untreated mice group ($p<0.001$) (87.5% survival at day +60 post-allo-BMT), also showing a significant reduced aGvHD clinical score from the aGvHD onset compared to untreated group of animals. Histopathologically, aGvHD-target organs revealed significant differences in the severity of aGvHD between the different experimental groups: liver, colon and tongue of untreated animals showed a higher degree of tissue damage than those receiving prophylactic defibrotide (liver: grade III *vs* grade I; colon: grade II/III *vs* grade I; tongue: grade I/II *vs* grade 0). Finally, we observed that liver, colon and tongue of allo-BMT recipient mice that received administration of prophylactic defibrotide displayed a substantial and significant decrease of $CD3^+$ T cells counts compared to untreated animals, mainly in the colon ($p<0.001$).
Summary and Conclusions: Defibrotide could represent a promising clinical alternative for both prophylaxis and treatment of aGvHD after allo-BMT, thereby opening new therapeutic strategies.

CONSTRUCTION OF A GFP KNOCK-IN CELL LINE FOR STUDYING GAMMA-GLOBIN CIS-ACTING ELEMENTS

M. Banan[1,*], S. Hesami[1], M. Safi[1], F. Ghasemi[1]

[1]Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Iran, Islamic Republic Of

Background: K562 is an erythroid cell line which expresses the γ-globin gene. In addition, its γ-globin expression is induced in response to several widely-studied chemicals. Therefore the K562 cell line is deemed to be a good model system for studying the γ-globin cis-acting regulatory elements (*i.e.* via CRISPR/Cas9 genome editing).
However, K562 cells have three normal copies and an abnormal copy of chromosome 11, where the β-locus is located (*i.e.* 4 Gγ and 4 Aγ copies). Thus in all likelihood, all eight putative cis-acting elements have to be edited in order to detect a robust effect on γ-globin expression. Given this limitation, K562 cells harboring a single copy of a reporter gene integrated into either γ-globin gene could be of great value.
Aims: The aim of the present study was to create K562 cells harboring a single copy of a GFP-(IRES)-Neo^R cassette integrated into either γ-globin gene by using CRISPR/Cas9 and HDR. Unlike previous studies (using TALENs), we wanted to avoid integrating an extra promoter (*i.e.* from PGK-Neo^R) into the locus.
Methods: Two sgRNAs binding upstream of the γ-globin start codon were cloned into the PX459 plasmid and screened in HEK 293T cells for functionality. The HDR construct was assembled in pBluescript by amplifying and cloning the GFP.Neo^R.pA cassette (from pSUPER.neo+GFP plasmid), and ~850 bp homology arms amplified from K562 cells. The homology arms precisely flanked the sgRNA-2 break site. K562 cells were co-transfected with the CRISPR/Cas9 and HDR constructs, selected, passaged, expanded, and characterized.
Results: Targeted integration of the cassette was verified by PCR. Subsequently, qPCR experiments showed the presence of ~2 GFP copies/cell, with a reciprocal decrease in the number of amplified γ-globin copies at the break junction. Expression of GFP was detected at both the RNA and protein (fluorescence) level. Of note, reporter gene expression was apparently higher than those detected in similarly created cell lines (by using TALENs and a td-Tomato/PGK-Neo^R cassette). Furthermore, reporter gene expression was induced upon both hydroxyurea and sodium butyrate treatment.
Summary and Conclusions: Our results suggest that the cell line hereby created could be useful for studying γ-globin cis-acting elements. However, further characterization of this cell line (*e.g.* interaction of the LCR with the γ-globin promoter adjacent to GFP) may be required for certain studies.

PF763

LONG-TERM LONGITUDINAL PROSPECTIVE CMR STUDY IN PATIENTS WITH THALASSEMIA MAJOR

Background: According to the International Guidelines, thalassemia major (TM) patients should perform a complete cardiac evaluation, including a CMR scan, every year. However, prospective CMR studies are limited beyond 3 years and longer-term studies are, therefore, important.
Aims: We aimed to determine longitudinal changes in cardiac iron and function assessed by CMR over 6 years in a large cohort of TM patients.
Methods: We considered 426 TM patients (205 males; 30.87±8.21 years) consecutively enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) Network with a CMR follow-up (FU) study at 72 months (6 years). The T2* in all 16 myocardial segments was quantified and 4 patterns of myocardial iron overload (MIO) were identified: no MIO (all segments with T2*≥20 ms), heterogeneous MIO (some segments with T2*≥20 ms and other segments with T2*<20 ms) and global heart T2*≥20 ms, heterogeneous MIO and global heart T2*<20 ms, and homogeneous MIO (all T2*<20 ms). Risk classes were defined on the basis of the patterns of MIO from worst to normal: homogeneous MIO heterogeneous MIO with global T2*<20 ms heterogeneous MIO with global T2*≥20 ms no MIO.
Biventricular function was quantified by cine images.
Results: In the 254 patients with baseline MIO (at least one segment with T2*<20 ms), the following changes were detected at the FU: - improvement, defined as a transition to a better risk class, in 182 (71.7%); - stabilization, defined as no change in the risk class, in 62 (24.4%); - worsening, defined as a transition to a worse risk class, in 10 (3.9%). Among the 172 patients without baseline MIO, 30 (17.4%) worsened, that is developed MIO at the FU. Biventricular end-diastolic volume indexes (EDVI) were significantly lower at the FU CMR. In patients with significant baseline MIO (global heart T2*<20 ms) a significant decrease in all biventricular volumes and a significant increase in left ventricular ejection fraction (EF) (mean difference: 3.83±8.48%, P<0.0001) as well as in right ventricular EF (mean difference: 1.79±9.04%, P=0.042) were detected with a concordant improvement of MIO status. The 50.7% of the patients changed the type of chelator during the FU based on CMR results. The percentage of patients who changed the chelation therapy was significantly higher in patients with significant MIO than in patients without MIO (60.2% *vs* 46.2%; P=0.008).
Summary and Conclusions: Over a period of 6 years, the continuous monitoring of cardiac iron levels and a tailored chelation therapy allowed an improvement in more than 70% of patients with baseline MIO and a consequent improvement of biventricular function.

PF764

CEREBROVASCULAR DISEASE IN BETA-THALASSEMIA: NOT A DISEASE RELATED COMPLICATION?

Background: Little is known about brain involvement in beta-thalassemia: chronic hypoxia and thrombophilic state could be responsible of an increased risk of cerebrovascular disease (CVD). Silent cerebral infarcts and intracranial artery abnormalities have been recently studied in hemoglobinopathies, but their importance in beta-thalassemia has not been clarified, yet. Asymptomatic white matter lesions (WML) have been shown in both transfusion dependent thalassemia (TDT) and non transfusion dependent thalassemia (NTDT) while intracranial artery stenosis have been detected in NTDT (Karimi *et al.*, 2016; Karimi *et al.*, 2012; Pazgal *et al.*, 2016; Musallam *et al.*, 2011).
Aims: To define prevalence, severity and distribution of WML and intracranial artery stenosis, their impact on cognitive function, and to identify any possible risk factor for CVD in beta-thalassemia.
Methods: this cross-sectional study enrolled TDT and NTDT beta-thalassemic patients and healthy controls from 4 major Centers in the South of Italy. FLAIR and intracranial time-of-flight MR-angiography were performed with a 3T MR scanner. Three neuroradiologists blinded of clinical data evaluated the MR-exams. Both patients and controls were administered the Wechsler Adult Intelligence Scale-Fourth Edition (WAIS-IV) to detect cognitive ability, and Intelligence Quotient (IQ) was measured. Clinical and laboratory data were collected to correlate neuroradiologic and psychometric findings with disease history and severity.

Results: Seventy-four thalassemic patients (46/74 females, mean-age 35.2±11.4 years, range 16-66; 51 TDT and 23 NTDT; mean hemoglobin 9.3±1.4 g/dl, range 7.5-12; 41 splenectomized; 34 on prophylactic aspirin) and 56 controls (36/56 females, mean-age 34.2±11.7 years, range 17-66) were enrolled. No intracranial artery stenosis was detected; no difference between patients and controls with regards to aneurysms prevalence (9.46% *vs* 9.67%). WML were found both in patients and controls, and the prevalence (35/74; 47.30% *vs* 28/56; 50.0%), the mean-number (4.1 *vs* 4.6), the size and the Fazekas score did not differ between the groups. No differences in WML were found between TDT and NTDT, nor between patients on aspirin and others. Splenectomy was associated with an increased lesion burden only in TDT (mean 5.56 *versus* 1.53, p= 0.048); in splenectomized patients on aspirin the number and prevalence of WML was lower compared to those splenectomized not on prophylaxis, but the difference was not statistically significant. Patients with WML did not differ from others in terms of comorbidities, hemoglobin, platelets, erythroblasts, ferritin, hemolysis markers and chelation therapies. The presence of WML did not correlate with cognitive impairment as measured by IQ, both in patients and healthy controls. Patients' IQ was significantly lower than controls, and this finding remained significant after correction for education (82.75±11.11 *vs* 93.96±SD13.22, p=0.032).
Summary and Conclusions: beta-thalassemia patients present lower cognitive performances compared to healthy controls despite no difference in terms of WML and intracranial artery abnormalities. Cognitive impairment did not correlate with the presence of WML. Further analyses are warranted to understand the pathogenesis of cognitive impairment in beta-thalassemia.

PF765

CO-INHERITANCE OF SOUTHEAST ASIAN OVALOCYTOSIS WITH B-THALASSEMIA OR HEMOGLOBIN E HETEROZYGOTE LEAD TO ANEMIA IN CHILDREN

P. Banjerdlak[1,*], P. Sripornsawan[1], T. Chotsampancharoen[1], M. Wongchanchailert[1], N. Songthawee[1], S. Duangchu[1]

[1]Pediatric, Prince of Songkla University, Hat Yai, Songkhla, Thailand

Background: Southeast Asian Ovalocytosis (SAO) is an autosomal form of hereditary elliptocytosis wide spread in Southeast Asia, with an allele frequency of 0.01 in Southern Thailand. In this region Thalassemia is also prevalent, about 30% of Thai population being carriers of these abnormal genes. However, co-inheritance of SAO with β-thalassemia heterozygote has rarely been reported. It is still not known how SAO and β-thalassemia interact, nor its effect on clinical phenotype.
Aims: To determine the effects of co-inheritance of SAO with β-thalassemia, or Hb E heterozygote on clinical severity, hematological parameters compared to SAO patients without these mutations.
Methods: We conducted a cross-sectional analytic study on a total of 128 SAO patients during july - december 2017. Demographic data, clinical presentations, hematological parameters, peripheral blood smears and hemoglobin typing of patients were reviewed. The diagnosis of SAO was made based on peripheral blood smears that; had a presence of more than 25% of elliptocytes, macro-ovalocytes and stomatocytes(so called Theta cells " "). The molecular analysis confirmed that all patients were heterozygous 27bp-deletion of *AE1 gene.* β-thalassemia and Hb E heterozygote were diagnosed by use of a high performance liquid chromatography technique. Patients with other concomitant diseases such as; ABO incompatibility, G6PD deficiency, feto-maternal hemorrhage and thalassemia diseases were excluded. Student's t-test was used to compare continuous data, Chi-squared and Fisher exact test was used to compare categorical data.
Results: There were 77 patients who were diagnosed as SAO during the newborn period. Of these, 18 patients had co-inheritance of SAO with thalassemia (5 β-thalassemia trait & 13 Hb E trait), while the rest of these 59 patients were typical SAO cases. There was no significant difference in the incidence of neonatal anemia and jaundice between two groups. However, there was a higher degree of anisocytosis and poikilocytosis in the patients who had a co-inheritance of SAO and β-thalassemia (Figure 1). This finding correlated with a higher RDW in the co-inheritance group compared to the typical SAO (18.9±2.2 *VS* 18±1.3%, P= 0.03). Other hematological parameters (Hb, Hct, MCV, MCH) at birth were of no significant difference. At one year of age, there were 70 patients, whose hematological parameters were available for comparison. We found that all RBC parameters from 20 patients in the co-inheritance group (6 β-thalassemia trait & 14 Hb E trait), were significantly difference from those of the typical SAO group at: Hb (10.9±0.9 *VS* 11.9±0.8 g/dL, P<0.001), Hct (31.5±2.1 *VS* 33.5±2.1%, P<0.001), RBC count (4.8±0.4 x10^6 *VS* 4.5±0.3 x10^6/μL, P= 0.001), MCV (65.9±3.7 *VS* 74.7±2.8 fL, P<0.001), MCH (22.9±1.6 *VS* 26.5±1.2 pg, P<0.001), MCHC (34.7±1.1 *VS* 35.5±0.8 g/dL, P<0.001), respectively. More importantly, the co-inheritance group had a significant higher incidence of anemia at 1 year of age (60% *VS* 18%, P= 0.001). In addition there were more anisocytosis in the co-inheritance group as shown by a higher RDW (16.6±1.3 *VS* 15.3±1%, P<0.001).

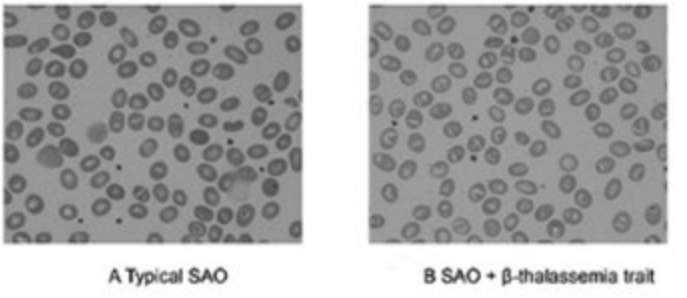

Figure 1.

Summary and Conclusions: Co-inheritance of SAO coupled with β-thalassemia did not affect the degree of neonatal anemia and jaundice at birth, however it lead to a higher incidence of anemia when patients reached one year of age. The presence of β-thalassemia mutation within the SAO population significantly increased the degree of anisocytosis.

PF766

DAILY ALTERNATING DEFERASIROX AND DEFERIPRONE AS NEW THERAPEUTIC SCHEME FOR IRON OVERLOAD IN UNTREATABLE TRANSFUSION DIPENDENT THALASSEMIA PATIENTS

V. Pinto[1,*], M. Balocco[1], S. Quintino[1], L. Bacigalupo[2], B. Gianesin[1], M. Rizzi[3], R. Malagò[4], L. De Franceschi[3], G. L. Forni[1]

[1]Centro della Microcitemia, [2]Radiology, Ospedale Galliera, Genoa, [3]Medicine, Policlinico GB Rossi, University of Verona and AOUI, [4]Radiology, University of Verona AOUI Verona, Verona, Italy

Background: Chelation therapy for treating iron overload has changed the prognosis for patients (pts) with Transfusion Dependent Thalassemia (TDT). Up to now, three drugs are available to reduce iron overload in these patients: deferoxamine (DFO), which is given subcutaneously, and the oral agents deferasirox (DFX), and deferiprone (DFP). The efficacy of combined chelation treatment has been shown to be additive and to increase the probability of success in patients, who previously fail on monotherapy. However, a small portion of patients do not tolerate mono or combined therapy, resulting in worsening iron over-load and in poor prognosis in term of life-expectancy.
Aims: To evaluate the impact of daily alternating regimen of DFP-DFX in otherwise untreatable TDT patients on iron-overload, determined by complementary approaches.
Methods: A total of eight TDT pts (4 males and 4 females) were placed on daily DFP (starting dose 75 mg/Kg/day)-DFX (starting dose 25 mg/Kg/day) alternating chelation therapy. Pts were defined as intolerant to monotherapy or classical combined therapy based on the following criteria: (i) significant proteinuria persistent after re-challenges; (ii) arthralgia with functional limitation; (iii) persistent neutropenia resolved after DFP discontinuation; (iv) gastrointestinal intolerance; (v) systemic reaction. Mean age was 28 years (ranging from 17 to 36). Medical records of TDT pts on daily alternating DFP-DFX were evaluated using serum ferritin and magnetic resonance imaging (MRI).
Results: Mean dose of DFP and DFX were 74 and 26 mg/kg/day, respectively and the median compliance was 90% (calculated as the percentage of drug taken in respect to that administered). Median iron intake from blood transfusions was 9.9 mg/year. Mean follow-up was 52 months (ranging from 12 to 104). The mean value of serum ferritin levels was 1632 at baseline and 1045 ng/ml at follow-up (p 0.2). The mean value of cardiac MRI-T2* was 27 and 37 millisecond (ms) at baseline and follow-up, respectively (p 0.21). Three patients showed at baseline cardiac iron overload (1 severe, 1 moderate and 1 mild) that was removed at follow-up. The mean value of the MRI-T2* of the liver was 5.8 and 12.8 ms at baseline and follow-up, respectively (p 0.19). Five patients showed at baseline liver iron overload (1 moderate-severe, 4 mild) that was removed at the follow-up. The mean value of the MRI-T2* of pancreas was 12.6 and 17 ms at baseline and follow-up, respectively (p 0.47). None of patients developed iron overload in the liver and heart during the treatment. No adverse events were reported. One patient was excluded from analysis due to lack of MRI follow-up (Table 1).

Table 1.

A. Demographic & clinical conditions of TDT patients on daily alternating chelation therapy

CASES	Gender	AGE (years)	Weight (Kg)	Splenectomy	Received Iron Via Blood Transfusion (g/year)	Chelation therapy (mg/kg/die)		Ferritin Levels (µg/dL)		Adverse events
						DFX	DFP	BASAL	FU	
1	F	17	51	Yes	9.9	28	79	4823	2564	No
2	F	36	63	Yes	8.7	18	68	298	407	No
3	F	24	60	Yes	8.5	34	94	2371	348	No
4	M	35	58	Yes	11.4	25	90	547	182	No
5	F	35	50	Yes	9.2	30	75	592	918	No
6	M	32	62	No	11.7	20	69	1500	1510	No
7	M	28	65	No	9.7	28	72	1300	1387	No

CASES	Follow up (months)	HEART			LIVER			PANCREAS		
		BASAL	FU	Difference	BASAL	FU	Difference	BASAL	FU	Difference
1	46	28	26	-2	8.7	6.1	2.6	11.5	16.3	4.8
2	104	28.2	34.3	6.1	13.8	6.8	-6.5	20.1	10.9	-9.2
3	88	8.3	35	26.8	3.4	30.8	27.4	4.9	36.2	31.3
4	70	11.6	48.5	36.9	4.1	23.7	19.6	6.5	7.2	0.7
5	32	19.1	36.4	17.3	10.5	7	-3.5	8.3	8.6	0.3
6	12	47.8	40.3	-7.5	3.3	10.3	9	-	16.7	-
7	12	48.2	37.3	-10.9	4.3	4.5	0.2	24.5	23.2	-1.3

Summary and Conclusions: In this case series, daily alternating regimen of DFP and DFX has been found effective in removing iron from heart and liver as well as maintaining the requested MRI-T2* in heart, liver and even pancreas during the follow-up period. None of the patients experienced moderate to severe adverse events with a safety profile. This new schedule of administration of oral iron chelators exploits the peculiarity of pharmacokinetic and pharmacodynamics of DFP and DFX, making these molecule synergizing and reducing their possible side effects. Our data generate the rationale to design larger studies to investigate this regimen as a potential treatment option for a broader spectrum of TDT patients.

PF767

DENOSUMAB EFFECTS ON SERUM LEVELS OF THE BONE MORPHOGENIC PROTEINS ANTAGONIST NOGGIN IN PATIENTS WITH BETA-THALASSEMIA MAJOR AND OSTEOPOROSIS

E. Voskaridou[1], J. Ntanasis-Stathopoulos[2], D. Christoulas[3], L. Sonnleitner[4], A. Papaefstathiou[5], M. Dimopoulou[1], A. Missbichler[4], N. Kanellias[2], K. Repa[1], A. Papatheodorou[6], M. Peppa[5], G. Hawa[4], E. Terpos[2,*]

[1]Thalassemia and Sickle Cell Disease Center, "Laiko" General Hospital, [2]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, [3]Department of Hematology, 251 General Air-Force Hospital, Athens, Greece, [4]FIANOSTICS GmbH, Vienna, Austria, [5]Endocrine Unit, Second Department of Internal Medicine-Propaedeutic, Research Institute and Diabetes Center, National and Kapodistrian University of Athens, School of Medicine, [6]Department of Biomedical Research, 251 General Air-Force Hospital, Athens, Greece

Background: Osteoporosis is a common complication of beta-thalassemia major (TM). Denosumab (DMB) is a fully human monoclonal antibody that binds RANKL, decreases osteoclast formation and function and is used for the treatment of osteoporosis. NOGGIN (NOG), a secreted homodimeric glycoprotein, is an antagonist of bone morphogenetic proteins (BMPs) that predominantly binds BMP-4 and BMP-2 and antagonizes their bioactivities by preventing their binding to the respective receptors. Thus, NOG seems to have a profound impact on osteogenesis and may be influenced by anti-resorptive therapy.
Aims: The aim of the study was to evaluate NOG in patients with TM and osteoporosis under DMB therapy.
Methods: NOG was measured in 63 TM patients with osteoporosis who participated in a randomized, placebo-control, phase 2b study. In that study, patients received either 60 mg DMB, sc, every 6 months for 12 months for a total of 2 doses (n=31) or placebo (group B, n=32). Measurement of bone mineral density (BMD) of three body sites (L1-L4, Femoral Neck, Wrist) was performed using DXA before treatment and after 12 months, along with a series of bone remodeling indices: sRANKL and OPG, Dkk-1 and SOST, CTX and RACP-5b, bALP and osteocalcin. NOG was measured, for the first time in TM patients, on days 0 and 180, using a recently developed high sensitivity fluorescent immunoassay based on plasmonic microtiter plates which increase the signal of fluorescent dyes several hundred-fold. Briefly the assay protocol includes: adsorptive coating of capture antibody in 50mM phosphate buffer (PBS)/150mM NaCl pH 7.4, overnight at 4°C followed by washing with PBS containing 0,1% Triton x100. Blocking of unspecific binding was achieved with a proprietary solution of FIANOSTICS containing synthetic polymers and mercapto-compounds. After another washing step, 20ul duplicates of standards/samples (serum) together with 25ul of anti-human NOG antibody labeled with AlexaFluor680 were incubated over night at RT temperature in the dark. Measurements were done using a standard fluorescence micro-plate reader. Samples reading above 100 pmol/l NOG were diluted with assay buffer and re-run to check for linearity of the signal.
Results: The effects of DMB on BMD were presented in EHA 2017 meeting. Regarding bone remodeling indices, patients of group A (DMB arm) achieved a dramatic decrease of sRANKL, sRANKL/OPG, CTX, TRACP-5b, bALP between baseline and after 12 months ($p<0.01$ for all comparisons), while there were no changes in Dkk-1, SOST and OC. On the contrary, patients of group B had an increase of sRANKL, OPG, Dkk-1, CTX, TRACP-5b, bALP ($p<0.01$ for all comparisons) and a slight increase of SOST and OC. Both groups showed an increase in Noggin serum levels after 12 months (mean±SD: 44.2±112.4 *vs* 19.4±49.1 for group A, $p<0.001$; 120.3±478.0 *vs* 12.2±22.1 for group B, $p<0.0001$). This increase was higher in the placebo group. In DMB group there was a strong correlation between NOG with WR T-score ($r=0.797$, $p<0.001$) and WR BMD ($r=-0.641$, $p=0.002$); this was not observed in the placebo group.
Summary and Conclusions: This is the first study where NOG is measured in TM. NOG elevation was lower in DMB than in placebo patients. Only in DMB group NOG changes correlated with WR-BMD. Since our assay detects free, bioactive NOG, higher NOG levels reflect more BMP inhibition, which in turn led to less bone formation of placebo group. Mechanistically these results suggest that denosumab possibly regulates NOG and leads to increased BMD in TM patients with osteoporosis via another mechanism of action.

PF768

FERRITN LEVELS BELOW 500 NG/ML IN TRANSFUSION DEPENDENT THALASSEMIA PATIENTS: HOW TO MODULATE CHELATION TREATMENT?

N. Scaramellini[1,*], E. Cassinerio[2], A. Marcon[3], N. Cieri[2], M. Bortolotti[2], G. Graziadei[2], M.D. Cappellini[2,3]

[1]Rare Disease Center, Department of Medicine and Medical Specialities, Ca' Granda Foundation IRCCS Ospedale Maggiore Policlinico, University of Milan, [2]Rare Disease Center, Department of Medicine and Medical Specialities, Ca' Granda Foundation IRCCS Ospedale Maggiore Policlinico, University of Milan, [3]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy

Background: Trasfusional iron overload is a major target of care in patients with transfusion dependent thalassemia (TDT) because accumulation of iron due to ineffective erythropoyesis and transfusions lead to multiorgans disfunctions; cardiac and hepatic iron overload is the preminent cause of morbidity and mortality in thalassemia patients. Serum ferritin (SF), iron intake, liver iron concentration (LIC) and cardiac T2* values are the parameters used to define when starting chelation: specific guidelines are available in literature for TDT. Three iron chelators are available for a tailored chelation therapy in clinical practice: Deferoxamine (DFO), administered intravenously or subcutaneously, and two oral iron chelators, Deferiprone (DFP) and Deferasirox (DFX). How to treat TDT with iron overload is clear, how to treat TDT with no signs of iron overload is blurred. For these reasons many specialists decide to stop chelation therapy when SF is below 500 ng/ml in absence of evident signs of iron overload thinking that side effects of chelation prevail on good effects.
Aims: We analysed patients with serum ferritin below 500 ng/ml of at least three years in whom we choose to modulate chelator's doses to prevent iron overload and adverse effects.
Methods: One-hundred thirty-two TDT patients were regularly followed at Rare Disease Center, Ca' Granda Foundation Ospedale Maggiore in Milan. All patients were transfusion-dependent and were treated with iron chelators. In a retrospective cohort study we analyzed data of 30 patients (10 males, 20 females, aged 40±6 years) who showed SF below 500 ng/ml from 2014 to 2016 and were treated with DFX (the most used chelator). All the participants underwent periodical evaluation of Hb, renal and hepatic function, SF, iron intake, and yearly T2* magnetic resonance imaging (T2*MRI) for regular follow-up of hepatic and cardiac iron overload. LIC (mg/g/dw) was calculated using the appropriate formulas. We registered the mean used doses of DFX, and their changes during time.
Results: We divided patients into 2 groups based on ferritin levels: group A (8 patients with SF <300 ng/ml) and group B (22 patients with SF between 300-500 ng/ml). Patients of both groups had a steady iron intake and a steady hemoglobin during all three years of observation. Moreover LIC and cardiac T2* values were normal at entering the study and they remained within the normal range over time. No major adverse effects related to DFX were documented during the observetional period. Overall 21 patients maintained a stable dose of DFX (mean dose of 20.6 +/- 6.93 mg/kg/day). In

group A, 3 patients had a reduction of dosage: one because of a slight increase of serum creatinine, one because of SF below 150 ng/ml. Only 1 patient had to increase the dosage because LIC had a mild increase (4.43 mg/g/dw) . In group B, 4 patients had a reduction of dosage for SF<150 ng/ml and only 1 patient had to increase the dosage due to a mild increase of serum ferritin without iron overload.
Summary and Conclusions: These data showed that iron chelation therapy is safe in patient with SF below 500 ng/ml. Chelators don't worsen renal and liver function if regularly monitored, and the reduction of ferritin levels below 300 ng/ml don't determine a reduction of Hb level during time or an increased in chelator's adverse events. More data are needed to support how to modulate chelation treatment in patients under transfusion but without iron overload and very low ferritin levels.

PF769

COMPARAISON OF MORBIDITIES BETWEEN NON TRANSFUSION AND TRANSFUSION DEPENDENT THALASSEMIA PATIENTS OLDER THAN 45 YEARS

A. Marcon[1,*], J. Sleiman[2], A. Tarhini[2], G. Graziadei[3], R. Bou-Fakhredin[2], E. Cassinerio[3], A. Taher[2], M.D. Cappellini[1]

[1]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy, [2]Department of Internal Medicine, American University of Beirut Medical Center, Beirut, Lebanon, [3]Rare Disease Center, Department of Medicine and Medical Specialities, Foundation IRCCS "Ca' Granda" Ospedale Maggiore Policlinico, Milan, Italy

Background: The survival of Transfusion Dependent Thalassemia (TDT) patients over the last two decades dramatically improved, becoming similar to that of Non Transfusion Dependent Thalassemia (NTDT) patients.
Aims: To describe and compare clinical complications in TDT and NTDT patients older than 45 followed in two different Centers (Italy and Lebanon).
Methods: Clinical parameters and complications were evaluated in 90 (56 NTDT and 34 TDT) patients who are currently alive. All TDT patients aged >45 years were included in this study. For NTDT patients we included all patients >45 years except those with mild genotype (alpha gene triplication associated with one beta mutation).
Results: male to female ratio were similar in NTDT and TDT patients (33/23 and 18/16 respectively), mean age was higher in NTDT group (53.8±6 *vs* 47.9±3.6 years; p<0.05). The rate of splenectomized patients was higher in TDT group (85.3 *vs* 62.5%; p<0.05). Mean hemoglobin (Hb) was 8.9±1.5 in NTDT and 9.5±0.7 g/dl in TDT group. Mean ferritin levels were similar in both groups (807±567 *vs* 881±742 ng/ml) despite blood transfusion. Liver Iron Concentration (LIC) was higher in NTDT group (6.69±6.1 *vs* 3.52±4.9 mg Fe/g dw; p <0.05). Mean cardiac T2* was 42.05±9.76 ms in NTDT and 37.86±9.8 ms in TDT group; only 2 patients (both TDT) had myocardial iron overload (T2* <20 ms). All TDT and 40/56 (71.4%) NTDT patients were on Iron Chelation Therapy (ICT). Overall the most used drug was Deferasirox (55.5%) followed by Desferal (27%) and Deferiprone (13.5%); only 3 TDT patients (4%) were on combined ICT. The most commonly observed complications in both TDT and NTDT patients were bone disease and cholelithiasis (more than 50% of patients affected in both groups) followed by cardiac involvement, ocular disease and hypoacusia (more than 33% of patients affected in both groups). No statistically significant differences were observed between TDT and NTDT groups regarding fractures (44.1 and 35.7% respectively), in most cases due to traumatic events, cholecystectomy (32.3 and 39.2% respectively), and arterial hypertension (5.9 and 10.7% respectively). In TDT group we observed a higher prevalence of arrhythmic events (29.4 *vs* 10.7%) and nephrolithiasis (35.3 *vs* 14.3%). All endocrinopathies but adrenal insufficiency had higher prevalence in TDT group (p <0.05). Adrenal insufficiency was, so far, observed in 3/34 (8,8%) TDT and 3/56 (5.36%) NTDT patients. HCV infection had higher prevalence in TDT group (52.9% *vs* 8.9% p <0.05). Two TDT and 1 NTDT patients had hepatocellular carcinoma (HCC). Leg ulcers, pulmonary hypertension (PHT) extramedullary hematopoiesis (EMH) and venous thrombotic events were higher in NTDT group (p <0.05).
Summary and Conclusions: the comparison of morbidities in elderly TDT *vs* NTDT patients is still scanty so far. In TDT patients older than 45 years iron related comorbidities remain prevalent due to a long lasting transfusional iron accumulation not regularly counterbalanced by iron chelation. On the contrary NTDT patients showed higher rate of complications related to ineffective erythropoiesis, and anemia. The elderly NTDT patients also experience liver damage due to long lasting iron absorption. Based on these observations, preventive therapeutic strategies are mandatory in young patients.

PF770

A RANDOMIZED, CONTROLLED, PHASE III STUDY TO EVALUATE S-303/GLUTATHIONE PATHOGEN-INACTIVATED RED BLOOD CELLS IN THALASSEMIA MAJOR PATIENTS (SPARC)

Y. Aydinok[1,*], R. Origa[2], N. Huang[3], A. North[3], A. Erikson[3], N. Mufti[3], C. Ernst[3], J.-S. Lin[3], R. J. Benjamin[3], L. Corash[3], A. Piga[4]

[1]Ege University Hospital, Izmir, Turkey, [2]Ospedale Pediatrico Microcitemico, Calgieri, Italy, [3]Cerus Corporation, Concord, United States, [4]University of Torino, Torino, Italy

Background: Life expectancy of Thalassemia major patients is improved by chronic Red Blood Cell component (RBCC) transfusion support combined with iron chelation therapy, but longer duration transfusion exposure increases lifetime risk of acquiring transfusion transmitted infections, including HIV, hepatitis and emerging pathogens (*e.g.*, Zika, Chikungunya, Dengue). The INTERCEPT Blood System for Red Blood Cells (Cerus Corporation) is an investigational device that uses S-303 (amustaline) and glutathione (GSH) in an *ex vivo* treatment step to inactivate a broad spectrum of viruses, bacteria, protozoa and T-cells.
Aims: To evaluate the efficacy and safety of S-303/GSH RBCC in regularly transfused patients with Thalassemia.
Methods: A randomized, controlled, double-blind, non-inferiority, two-treatment period (6 transfusion episodes each), crossover study was conducted with informed consent to evaluate leukocyte-reduced (LR) S-303/GSH RBCC in comparison to conventional LR-RBCC, in >70 evaluable subjects ≥11 years old. Each patient maintained the same transfusion threshold as medically indicated before and during the study period (pre-transfusion hemoglobin (Hb) levels 9-10 g/dL). The primary efficacy endpoint was RBC Hb consumption during transfusion episodes #3-6 in each treatment period (the efficacy evaluation period) measured as the total Hb mass transfused per subject adjusted for body weight (kg) and time (Hb g/kg /day). Non inferiority was defined by a predetermined margin of 15% of the mean consumption of Hb in the Control efficacy evaluation period. The primary safety endpoint was treatment-emergent antibodies to S-303/GSH RBCC.
Results: 86 subjects were enrolled and 81 transfused with study RBCC at two sites in Italy (n=14) and one site in Turkey (n=67). Mean age was 26.1 ±8.1 years (range: 10-44), 45.7% were male, and 18.5% were aged ≤18 years. Eleven percent of patients had pre-existing RBC alloantibodies. In the intention to treat (ITT) population, mean RBCC exposure to S-303/GSH RBC was 12.5 components (range 3-18) and 12.5 (range 6 -18) with conventional RBCC, with a mean transfusion interval of 19.4 (Test) and 19.5 (Control) days. Total transfused Hb (per protocol (PP)+off-study RBCC) dose in the Test period was 687 ±97 grams (g) *versus* 700±116 g Hb (p =0.127) in the Control period. Total mean Hb consumption in the efficacy evaluation period was 0.113±0.04 g/kg/day for S-303/GSH RBCC, and 0.111±0.04 g/kg/day for conventional RBCC. Non inferiority was robustly achieved with a treatment difference of 0.002 g/kg/day, with upper bound of 95% 1-sided confidence interval (CI) for mean Test-Control difference in both ITT and PP populations of 0.005 g/kg/day (<0.017g/kg/day, the predetermined 15% non-inferiority margin). No treatment-emergent RBC alloantibodies or antibodies specific for S-303/GSH RBCC were detected. Adverse events occurred in 56/81 (69.1%) Test and 57/81 (71.3%) Control subjects, and were balanced between Test and Control periods. There were no deaths, grade 4 adverse events, or events deemed certain or likely related to S-303/GSH RBCC.
Summary and Conclusions: In transfusion-dependent patients with Thalassemia, S-303/GSH-RBCC are non-inferior to conventional RBCC based on Hb consumption and therefore transfusion iron burden. The safety profile was not different from conventional RBCC and no antibodies were detected to S-303/GSH-treated RBC. These results support the application of effective and safe pathogen inactivation in the clinical setting of Thalassemia major.

PF771

EVALUATION OF VASCULAR HEALTH OF E-BETA THALASSEMIA PATIENTS: EFFECT OF IRON OVERLOAD

D. De[1,*], U.K. Nath[2], P. Chakrabarti[3]

[1]Dept of Hematology, The Mission Hospital, Kolkata, [2]Aiims Rishikeh, Rishikeh, 3nrs Medical College, Kolkata, India

Background: Hb E-β thalassemia is the most common form of hemoglobinopathy in Southeast Asia and eastern India. Iron overload resulting from blood transfusion and increased intestinal iron absorption promotes the formation of reactive oxygen species (ROS), leading to oxidative stress, organ dysfunction, and tissue damage. Of these, cardiovascular complications are the leading cause of mortality. Impaired endothelial function is a biomarker of vascular

health in patients with cardiovascular risks. Therefore, assessment of endothelial function is a useful prognostic tool.
Aims: To determine the presence of vasomotor dysfunction and subclinical atherosclerosis in patients of E β thalassemia and its relationship with serum ferritin.
Methods: In the present study, 60 E- β thalassemia patients and 60 healthy, age, sex matched control subjects were taken. The mean hemoglobin and ferritin of thalassemic patients were 7.43gm/dl and 1032 mcg/dl respectively. The vascular health was compared by measuring flow-mediated vasodialation (FMD), arterial elastic parameters, and carotid intima-medial thickness (CIMT).
Results: There was lower FMD (7.49%) and higher CIMT (0.46mm) in thalassemic group than control (10.52% and 0.36mm respectively) (p value<0.05). Also arterial stiffness is elevated and arterial distensibility is lower in thalassemic patients than control. Among the thalassemic patients FMD or CIMT did not correlate with serum ferritin value.There was lower FMD (7.49%) and higher CIMT (0.46mm) in thalassemic group than control (10.52% and 0.36mm respectively) (p value<0.05). Also arterial stiffness is elevated and arterial distensibility is lower in thalassemic patients than control. Among the thalassemic patients FMD or CIMT did not correlate with serum ferritin value.
Summary and Conclusions: So, the E- β thalassemia patients had poor vascular health and are at a higher risk of developing atherosclerosis and cardio-vascular complication than normal population. The vascular dysfunction does not correlate with serum ferritin value, so regular monitoring with Doppler study is required for early diagnosis of subclinical atherosclerosis in this group of patients. However the effects of chelation therapy, Hydroxyurea, or other targeted therapies needs to be validated by further study.

PF772

CHRONIC HEPATITIS C VIRUS INFECTION IN THALASSEMIA MAJOR: A NEW CARDIOVASCULAR RISK FACTOR?

A. Meloni[1,*], L. Pistoia[1], R. Renni[2], S. Macchi[3], A. Quota[4], L. Tedesco[5], P. Giovangrossi[6], V. Carrai[7], S. Pulini[8], T. Grippo[9], M.P. Smacchia[10], G. Peritore[11], R. Righi[12], V. Positano[1], A. Pepe[1]

[1]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Ospedale Civile "F. Ferrari", Casarano (LE), [3]Ospedale "Santa Maria delle Croci", Ravenna, [4]Ospedale "V. Emanuele III", Gela (CL), [5]Presidio Ospedaliero Locri - A.S.P di Reggio Calabria, Locri (RC), [6]Ospedale S. M. Goretti, Latina, [7]Azienda Ospedaliero - Universitaria Careggi, Firenze, [8]Ospedale Civile "Spirito Santo", Pescara, [9]Azienda Ospedaliera Regionale San Carlo di Potenza, Potenza, [10]Policlinico Umberto 1, Roma, [11]"ARNAS" Civico, Di Cristina Benfratelli, Palermo, [12]Ospedale del Delta, Lagosanto (FE), Italy

Background: Hepatitis C virus (HCV) infection is associated with a number of important extrahepatic manifestations.
Aims: The aim of this multicentric study was to assess the relationship between HCV infection and some traditional cardiovascular risk factors (CRF) and its predictive value and cardiovascular complications (CC) in thalassemia major (TM) patients.
Methods: We considered 827 TM patients (435 F) consecutively enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) network.
At the baseline assessment mean age of the patients, all free of CC, was 29.65±8.89 years and a categorization in 4 groups was performed: negative patients (group 0), patients who spontaneously cleared HCV (group 1), patients who eradicated the virus after treatment with antiviral therapy attaining a sustained virological response-SVR (group 2), and patients with chronic HCV infection (group 3).
Results: Patients in group 0 were significantly younger than patients in all the other three groups (P<0.0001) and had a significant lower frequency of diabetes than patients in group 3 (3.6% *vs* 11.0%; P=0.006).
Patients were followed-up for 79.53±28.71 months and 84 cardiovascular events (42 arrhythmias, 29 heart failure, and 13 vascular diseases) were registered. Table 1 shows the results of the univariate Cox regression analysis. Patients with chronic HCV infection had a significant higher risk of developing CC than negative patients.

Table 1.

	N(%) in Group	N(%) with CC	Univariate analysis HR(95%CI)	P
HCV group				
Group 0	290 (35.1)	19 (6.6)	Reference	0.258
Group 1	241 (29.1)	24 (10.0)	1.42 (0.78-2.59)	0.225
Group 2	43 (5.2)	5 (11.6)	1.84 (0.69-4.93)	0.006
Group 3	253 (30.6)	36 (14.2)	2.18 (1.25-3.79)	

Summary and Conclusions: HCV chronic infection is associated with a significant higher risk of CC in TM patients and, as a consequence, it should be analyzed as a systemic disease in which extrahepatic consequences increase the weight of its pathological burden.

PF773

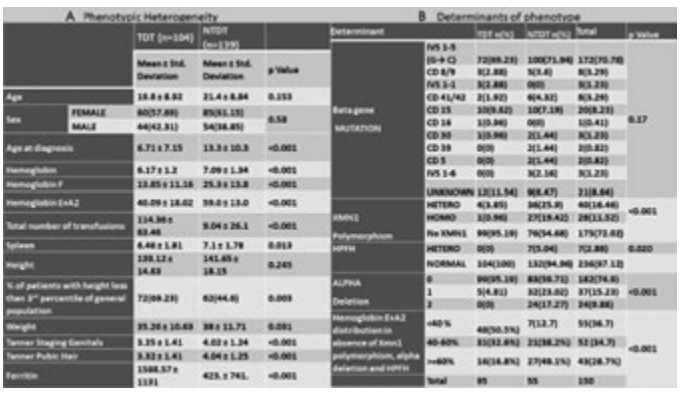
PHENOTYPIC HETEROGENEITY OF HAEMOGLOBIN E BETA THALASSEMIA AND ITS DETERMINANTS- IT'S NOT ONLY HAEMOGLOBIN F!

S. Kalantri[1,*], R. Ray[1], S. Choudhuri[1], S. Datta[1], M. Bhattacharyya[1]

[1]Clinical Hematology, Institute of Hematology and Transfusion Medicine, Medical College Kolkata., Kolkata, India

Background: HbE/ Beta Thalassemia is common problem(50 percent symptomatic thalassemias) in south-east asia and is phenotypically Highly diverse.Various factors influence the natural history of this disorder (example- XMN1 polymorphism, presence of HPFH, type of beta gene mutation, alpha deletion). Researchers have always focused on haemoglobin F and its induction in ameliorating severity of this disorder. Very few studies have focused on importance of haemoglobin E in modifying severity of this disease.
Aims: To document phenotypic heterogeneity and to investigate role of Haemoglobin E as determinant of severity.
Methods: This was comparative study. Diagnosed cases of HbE/ Beta Thalassemia, attending Thalassemia clinic and day care centre of IHTM between March 2015 and August 2016 were included in this study after obtaining informed consent. Patients were divided into two groups. 1) Requiring more than 8 transfusions/ year- **TDT (Transfusion dependent group).** 2) Requiring less than 8 transfusion/ year - NTDT **(Non- Transfusion dependent group).** Evaluation of patients comprised of a) Clinical Assessment B) Routine Laboratory evaluation & C) Molecular analaysis **(PCR) for** β-thal mutations, alpha deletion, HPFH gene persistence, XMN 1 polymorphism in both the arms.
Results: Two forty three HbE- Beta Thalassemia patients were included in the study. Various phenotypic parameters were compared in TDT and NTDT arm (Table 1A). Age at presentation was significantly lower in TDT arm (p value <0.001). TDT arm lagged in terms of linear and pubertal growth (Table 1A). Mean baseline haemoglobin, haemoglobin E percent, haemoglobin F percent were higher in NTDT arm (Table 1A).
It was observed that 7.91 percent (n=11) cases in NTDT arm had Haemoglobin E less than 40 percent and 50.36 percent (n=70) cases in this arm had greater than 60 percent of Haemoglobin E. As against this, only 16.35 percent (n=17) cases in TDT arm had haemoglobin E greater than 60 percent and 48.08 percent (n=50) cases had haemoglobin E less than 40 percent in this arm (p- value <0.001[u1]). In multivariate analysis higher haemoglobin E percentage was documented in NTDT arm; suggesting high haemoglobin E may be independently responsible for reducing severity (p value <0.001).
For beta mutation status no statistically, significant difference was found for frequency of various types of beta mutation (Table 1B). When subgroup analysis was done by excluding patients having xmn1 polymorphism, HPFH mutation and alpha deletion, higher prevelance of severe beta mutation IVS 1-5 (G C) mutation { 64(61.54 percent) *vs* 38(27.34) ; p value<0.001} was found in TDT arm.Xmn1 polymorphism, presence of HPFH mutation and alpha deletion were more prevalent in NTDT arm *vs* TDT arm (Table 1B).

Table 1.



Summary and Conclusions: We conclude that phenotype is not only modified by haemoglobin F percent but also by haemoglobin E percent. Further studies are warranted to detect the exact mechanism.

PF774

EFFICACY AND SAFETY OF RESVERATROL, AN ORAL HBF AUGMENTING AGENT, IN PATIENTS WITH BETA THALASSEMIA INTERMEDIA

M. Karimi[1,*], S. Haghpanah[1], T. Zarei[1], P. Eshgi[2], M. Bordbar[1], O. Zekavat[1], M. Hoormand[3], S. Parand[1]

[1]Hematology Research Center, Shiraz University of Medical Sciences,, Shiraz, [2]Pediatric Congenital Hematologic Disorders Research Center, Shahid Beheshti University of Medical Sciences,, [3]Department of Pharmacology, Iran University of Medical Sciences,, Tehran, Iran, Islamic Republic Of

Background: Recently, Resveratrol, (trans-3, 4, 5-trihydroxystilbene), showed induction of γ-globin mRNA synthesis in human erythroid precursors and reducing oxidative stress in red cells of thalassemia patients in many *in-vitro* studies.
Aims: We aimed to investigate the efficacy and safety of Resveratrol, for the first time, in non-transfusion dependent beta-thalassemia intermedia (B-TI) in Southern Iran.
Methods: In this double blind randomized clinical trial, 54 patients with B-TI were investigated from a total of 290 patients during 6 months between October 2016 and March 2017. Patients were randomly allocated into 3 groups by simple randomization method. Group 1 (hydroxyurea (HU) and placebo # 18 patients), group 2 (Resveratrol/Piperine and placebo #16 patients) and group 3(HU and Resveratrol/Piperine # 20 patients). HU was given with a dose of 8 15 mg per kg body weight per day and Resveratrol/Piperine, 2gram/10 mg per day orally. Primary end point was considered as change in hemoglobin levels and need for blood transfusion. Drug safety was considered as a secondary end point.
Results: Mean age of the patients was 28.2±5.6 (18-42) years. Response rate was not significantly different among the three groups (P>0.05). Higher percentages of adverse events were detected in groups 2 (31.3%) and 3 (25%) compared to group 1 (5.6%). However, the difference was not statistically significant (P>0.05). All reported adverse events were gastrointestinal symptoms.
Summary and Conclusions: Resveratrol showed a similar efficacy with HU in the small population of non-transfusion B-TI patients during a 6-month follow-up. Complications, mostly gastrointestinal, were observed more frequent in Resveratrol groups compared to the HU group. Although it was not statistically significant, more attention should be given to safety and efficacy of Resveratrol as an oral HbF augmenting agent.

PF775

HYPERURICEMIA, URINE URIC EXCRETION AND ITS COMPLICATIONS IN THALASSEMIA PATIENTS

J. Chaloemwong[1], A. Tantiworawit[1,*], T. Rattanathammethee[1], C. Chai-Adisaksopha[1], E. Rattarittamrong[1], L. Norasetthada[1], P. Charoenkwan[2], W. Louthrenoo[1]

[1]Internal Medicine, Division of Hematology, [2]Pediatric, Chiang Mai University, Maung, Thailand

Background: Thalassemia patients has high cell turnover rate due to its chronic hemolysis and ineffective erythropoiesis. Hyperuricemia is anticipated as complication.
Aims: To identify the prevalence of hyperuricemia, gout and nephrolithiasis, factor associated with high serum uric acid (SUA), urine uric acid excretion (UUA) and correlation to its complications in thalassemia patients.
Methods: This was a cross-sectional study in 15 years or older thalassemia patients at hematology clinic, Chiang Mai University. All patients had SUA and 24 hours UUA collection test. Renal ultrasound was performed in hematuria cases. Categorical variables were compared using the Chi-squared test or Fisher exact test. Continuous variables were compared by T-test or Mann-Whitney test.
Results: Of 112 thalassemia patients, there was female in 67.0%, beta thalassemia/Hb E in 64.3%, transfusion dependent in 76.8% and post splenectomy in 59.8%. The median age was 29 (range 16-58) years. Mean SUA was 6.7±2.0 mg/dl and hyperuricemia (SUA>6.8 mg/dl) was found in 47 cases (45.2%). The hyperuricemia was significantly identified in patients with intact spleen (51.1% *vs* 28.1%, p= 0.01), higher nRBC (222.7±155.8 *vs* 152.6±117.9 per 100 WBC, p=0.05), higher serum creatinine (0.6±0.2 *vs* 0.5±0.1 mg/dl., p=0.03) and lower fraction excretion of uric (FE uric) (7.9±2.6% *vs* 10.3±3.6%, p= 0.01) but reverse in deferasirox use (4.2% *vs* 19.3%, p= 0.019) compared with normal SUA. Seven (6.3%) had gouty arthritis and 9(8%) had microscopic hematuria which 1 case confirmed calyceal stone. The mean UUA excretion was 981.3± 335.0 mg/day which UUA hyperexcretion (>700 mg/24hours) was found in 83.3%. Renal hyperfiltration (eGFR>135 ml/min/1.73m^2) was documented in 46%, glomerular dysfunction (proteinuria and microalbuminuria) in 84% and renal tubular dysfunction (high urine neutrophil gelatinase-associated lipocalin (uNGAL)) in 7.7% from those who had UUA hyperexcretion. Mean uNGAL was 21.0± 8.2 mcg/L. The high uNGAL level that more than 37 mcg/L was significant correlated with higher serum creatinine (0.8± 0.4 *vs* 0.6± 0.1 mg/dl, p= 0.01), lower eGFR (89.9± 63.4 *vs* 127.9± 32.3 ml/min/1.73m^2, p= 0.04), higher FE phosphate (13.9± 4.9 *vs* 10.1± 3.3%, p= 0.04) and higher serum ferritin (2,659.1± 1,340.0 *vs* 1,434.2± 1,041.8 mcg/L, p= 0.03).
Summary and Conclusions: Hyperuricemia was found approximately forty percent but gouty arthritis was occurred only in six percent in thalassemia patients which may be explained by urinary hyperexcretion of uric acid which found in over eighty percent of thalassemia patients. The significant risk factor for hyperuricemia were intact spleen, higher serum creatinine and lower in fraction excretion of uric acid. The various renal abnormalities such as hyperfiltration, glomerular and tubular dysfunction were also detected in most cases.

PF776

THE VALUE OF MAGNESIUM LEVELS IN THE HAEMOSTASIS OF PATIENTS WITH B-THALASSAEMIA.

A. Kerimov[1], N. Aliyeva[1,*], T. Mamedova[1]

[1]Azerbaijan Scientific research hematology and transfusiology institute, Baku, Azerbaijan

Background: The study investigated the role of magnesium in hypercoagulation in different forms of β-thalassaemia patients.
Aims: The study was aimed to investigate the relationship between magnesium levels and hypercoagulation disorders of haemostasis in patients with different forms of β-thalassaemia.
Methods: The study involved 100 women aged 18-40 years with different clinical forms of β-thalassaemia (30 major, 25 intermedia and 45 minor). The diagnosis of β-thalassaemia was verified by haemoglobin fractions and characteristic clinical manifestation. Serum levels of magnesium and thrombinemia markers - D-dimer and soluble fibrin monomer complex (SFMC) have been identified. The patients had no clinical symptoms of hypercoagulation. The control group consisted of 30 healthy women of comparable age. Statistical analysis was done by variation statistics via standard software packages.
Results: β-thalassaemia major (β-TM) and intermedia (β-TI) patients exhibited decreased levels of magnesium, respectively, 0,73±0,04mmol/L (p<0,001) and 0,74±0,07mmol/L (p<0,001), ranging between 0,21 to 1,53 mmol/L. Magnesium levels of individuals with β-thalassemia trait (β-TT) were normal - 0,84±0,02mmol/L, ranging from 0,80 to 1,1mmol/L. Thrombinemia markers of β-TM and β-TI patients were increased: D-dimer - 496,0±5,1ng/mL (p <0,001) and 530,0±4,1ng/mL (p<0,001); SFMC - 5,83±0,2% (p<0,001) and 6,07±0,3% (p<0,001), respectively. 11 β-TM and 8 β-TI patients had hypercoagulation. Patients with latent hypercoagulation exhibited more expressed changes: magnesium levels of β-TM were 0,65±0,03mmol/L (p<0,001), D-dimer - 652,0±4,2ng/mL (p<0,001), SFMC - 6,81±0,18% (p<0,001); magnesium levels of β-TI were 0,63±0,05mmol/L (p<0,001), D-dimer - 690,0±7,1ng/mL (p <0,001), SFMC - 7,10±0,4% (p<0,001). No signs of latent hypercoagulation were detected in β-TT (no statistically significant difference with control values).
Summary and Conclusions: The plasma magnesium levels of β-TM patients was 1,6 times, and β-TI was 2,1 times less than control values. One-third of patients with β-TM and β-TI had latent hypercoagulation and lower magnesium levels. Based on our data, it can be concluded that, the low serum magnesium level of β-thalassemia patients is associated with an increased thrombosis risk.

PF777

ASYMPTOMATIC MALARIA IN CASES OF HBE BETA THALASSEMIA: A PILOT STUDY FROM EASTERN INDIA

S. Kalantri[1,*], R. Ray[1], S. Datta[1], S. Choudhuri[1], M. Bhattacharyya[1]

[1]Clinical Hematology, Institute of Hematology and Transfusion Medicine, Medical College Kolkata., Kolkata, India

Background: Haemoglobin E Beta thalassemia is the commonest symptomatic haemoglobinopathy in South East Asia & phenotype of this disease is heterogeneous. Many genetic and non genetic factors determine pheno-

type of this disease. Malaria is one such factor which was postulated to be important in affecting phenotypic severity of these patients. [O'Donnell *et al.* A 2009]The effect of thalassaemia on malaria parasite has been studied extensively but reverse is not true. Nancy F Olivieri opined in a review article that if studies from Asia and particularly from India also show higher frequency of asymptomatic malaria as shown in Sri Lanka it would be the basis for initiating anti malarial prophylaxis in these patients.[2]It has been observed that erythrocytes from subjects with homozygous and heterozygous haemoglobin E (HbE) infected with Plasmodium falciparum *in vitro* were phagocytosed to a greater extent by human monocytes than infected erythrocytes from normal subjects. [Bunyaratvej AH 1986] This gives protection against malaria but whether this excessive phagocytosis contributes to anemia and severity of thalassemia needs to be studied.

Aims: To document prevalence of asymptomatic malarial infection in patients with HbE Beta Thalassemia and compare the prevalence in transfusion dependent and non-transfusion dependent groups.

Methods: In a pilot study we evaluated 90 cases of HbE beta Thalassemia from Eastern India for detection of prevalence of asymptomatic malarial infection. Multiplex PCR was done using the primer set and protocols followed by Padley et al (2003). Both transfusion dependent (TDT) (those requiring more than 8 transfusions per year) and non-transfusion dependent (NTDT) (those requiring less than 8 transfusions per year)HbE – beta thalassaemia patients were included in the study. Result were compared in two arms.

Results: Prevalence of asymptomatic malarial infection in the total population was 35.5%. It was noted that out of 37 patients in the TDT arm 16 (43.24%) had asymptomatic malarial infection. In the NTDT arm of 53 patients 16 (30.19%) had asymptomatic malarial infection. When two arms were compared there was no statistically significant difference in prevalence of malarial infections (both Vivax and Falciparum). It is important to note that 43.24% and 30.19% cases in TDT and NTDT arm respectively had either falciparum or vivax infection. None of these patients gave past history of infection by malaria. Malarial infection was more prevalent in TDT arm though it was not statistically significant (Table 1).

Table 1.

Prevalence of Asymptomatic Malaria

		Group		Total N(%)= 90(100%)	p Value
		TDT N = 37	NTDT N=53		
Malaria PCR	FALCIPARUM	7(18.92%)	3(5.66%)	10(11.11%)	0.065
	VIVAX	9(24.32%)	13(24.53%)	22(24.44%)	0.982

TDT: transfusion dependent, NTDT: non- transfusion dependent

Summary and Conclusions: In a study from the same region where this study was also done, prevalence of asymptomatic falciparum malaria among general population using PCR was reported to be 8.4% (81/963) from Bandowan block of Purulia District. This was the block with highest prevalence of asymptomatic falciparum malaria of various others block included in that study. In the same block only 4 cases were detected to have asymptomatic vivax infection(0.41 percent). In the study from Sri Lanka authors reported that 28.6% of the children had DNA-based evidence of current infection with P. Vivax. Though this is a small pilot study it has clearly shown that prevalence of asymptomatic malaria is high in HbE- beta thalassaemia and its more in transfusion dependent group. More studies with larger sample size should be undertaken to understand the effect of malaria on phenotype of Hb E beta thalassemia particularly in South East Asian countries where both the conditions are common problem.

ANTICOAGULATION IN THE OBESE - A PROSPECTIVE REGISTRY

G. McCaughan[1,2,*], H. Crowther[1,3], L. Pasalic[4,5,6,7], P. Rebeiro[8], J. Curnow[1,7]

[1]Department of Haematology, Westmead Hospital, [2]Sydney Medical School, [3]Department of Haematology, Blacktown Hospital, [4]Haematology, NSW Health Pathology, [5]Haematology, ICPMR, Westmead Hospital, Sydney, [6]Haematology, Westmead Hospital, Westmead, [7]Sydney Centres for Thrombosis and Haemostasis, [8]Haematology, Blacktown Hospital, Sydney, Australia

Background: The optimal anticoagulation strategy in the obese remains unclear. There is limited data to guide prescribing of low molecular weight heparin (LMWH) and direct oral anticoagulants (DOAC) in this population, particularly those with class III obesity (body mass index [BMI] ≥40kg/m^2).

Aims: To examine anticoagulant prescribing patterns in the obese in Australia and New Zealand; determine the most appropriate dosing strategy for LMWH; determine whether obese patients achieve appropriate peak and trough DOAC drug levels and evaluate clinical efficacy and safety of these agents in the obese.

Methods: We are prospectively registering all patients with a BMI ≥35kg/m^2 or weight >120kg receiving anticoagulants at 5 study sites in Australia and New Zealand (with 5 further sites in the process of submitting or awaiting ethics approval). Demographic data, weight, height, indication, anticoagulant choice, efficacy, adverse events and drug specific levels are being collected at registration and follow-up.

Results: As of abstract submission date we have recruited 21 patients at two sites with BMI ≥35kg/m^{2}with 3 sites commencing recruitmentthis month. Median BMI was 43kg/m^2 (range 39 - 80) and median weight was 132kg (range 108-229kg). 14/21 patients were female with a median age of 47 years (range 27-81). Indication for anticoagulation was deep vein thrombosis (11), pulmonary embolus (7), superior mesenteric vein thrombosis (1), extensive superficial vein thrombosis (1) and atrial fibrillation (1). Of those with venous thrombosis, 10/20 had a provoking factor and 7/20 had a prior history of DVT. Initial anticoagulation was: rivaroxaban (8), apixaban (6), dabigatran (1), enoxaparin (6) with transition to warfarin for 4/6. Of the four patients who received enoxaparin during the study period, 3 patients had a weight ≥200kg (BMI 70-80kg/m^2) and required 0.65-0.75mg/kg to achieve therapeutic Anti-Xa. The final patient had a weight of 108kg (BMI 43.2kg/m2) and required a dose of 0.92mg/kg. With regards to rivaroxaban 15mg twice daily, one peak level of 338ng/ml and three trough levels (<25, 37 and 55ng/ml) were available. There are no published 'on therapy' ranges for the rivaroxaban 15mg BD dose. For the 20mg dose, peak levels (n=4) ranged from 177-561 and median trough level (n=5) was 31ng/ml (range 28-122). 3/4 peak levels and 5/5 trough levels fell within the 5th to 95th percentile of published 'on therapy' ranges. For apixaban 5mg twice daily, median peak level (n=4) was 112ng/ml (range 97-156) and median trough level (n=5) was 40ng/ml (range 25-68). All peak levels and trough levels fell within the 5th to 95th percentile of published 'on therapy' ranges. 2 patients were changed from rivaroxaban to apixaban, due to menorrhagia in one patient and an undetectable trough rivaroxaban level in another. All patients that had progress imaging had radiological improvement and no patients had a symptomatic recurrent thrombotic event (median follow up 6 months).

Summary and Conclusions: There is limited data to guide prescribing of anticoagulation in the obese. Published 'on therapy' ranges have not been validated with clinical outcomes and there is no data to guide dose adjustment on the basis of drug levels. This makes interpreting the clinical significance of drug levels in the obese population difficult. The measured drug levels within this cohort appear appropriate relative to published 'on therapy ranges' and reassuringly no patients had a recurrent thrombotic event. Further data is required and we are now recruiting across multiple sites in Australia and New Zealand.

PF779

CHARACTERISTICS OF PLATELET COUNT AND SIZE AND DIAGNOSTIC ACCURACY OF MEAN PLATELET VOLUME IN PATIENTS WITH VENOUS THROMBOEMBOLISM. A SYSTEMATIC REVIEW AND META-ANALYSIS

S. Kovács[1], Z. Csiki[2], K. S. Zsóri[3], Z. Bereczky[4], H.A. Shemirani[5,6,*]

[1]Research Methodology and Statistics, Sectorial Economics and Methodology, [2]Medicine, Debrecen University, Debrecen, [3]Central Pharmacy, Erzsébet hospital, S.ujhely, [4]Laboratory Medicine, Debrecen University, [5]Laboratory Medicine, Dberecen

University, Debrecen, [6]Central Laboratory, Erzsébet hospital, S.ujhely, Hungary

Background: Venous thromboembolism (VTE) (pulmonary embolism and deep venous thrombosis) is the third most common cause of cardiovascular disease. Platelets play an active role in the thrombotic process and they contribute to the pathogenesis of atherothrombosis. There is strong evidence indicating that larger platelets are metabolically and enzymatically more active with higher thrombotic potential. Mean platelet volume (MPV) is potentially an important biomarker of platelet reactivity.
Aims: The purpose of this study was to evaluate the association between platelet (PLT) count and mean platelet volume (MPV) and venous thromboembolism (VTE). Thus, this study reviewed and perform a quantitative synthesis on data from the literature.
Methods: This meta-analysis was conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. 18 studies were included in this paper. A random-effect meta-analysis was conducted for the assessment of heterogeneity using thrombosis place, type of analyzer, type of anticoagulant and incubation time of samples as covariates. A mixed-effect meta-regression was performed based on the subgroup for the whole samples using thrombosis place and method of measurement as moderators for MPV and PLT, respectively. The cumulative estimates and 95% confidence interval (95%CI) of specificity, sensitivity, area under the receiver operator characteristic curve (AUC) and diagnostic odds ratio (DOR) for MPV were calculated using a random effect model. The quality assessments were evaluated according to the quality assessment and diagnostic accuracy tool-2 (QUADAS-2). The primary outcome was the occurrence of VTE. Secondary outcomes included PLT and MPV.
Results: Patient with deep vein thrombosis is likely to have a higher value of MPV than control group (P <0.001). The presence of pulmonary embolism (PE) had no significant effect on the standardized mean difference of MPV between patients and controls. Patients are likely to have less PLT than the control group regarding all studies. However, subgroup analysis demonstrated that this effect was significant for patients with PE (P <0.05). The summary receiver operating characteristic (SROC) curve indicated that AUC was 0.745 (95% CI: 0.672-0.834). The DOR for MPV was 4.76 (95%CI: 2.3-9.85), with diagnostic accuracy of 0.66.
Summary and Conclusions: In our meta-analysis, significantly increased MPV and significantly decreased PLT were identified in patients with VTE. Additional studies are needed to investigate the clinical relevance of such relatively small but significant differences. Further studies are warranted in order to establish whether an increased MPV is either the cause or the consequence of venous occlusion in patients with VTE.

PF780

TISSUE PLASMINOGEN ACTIVATOR GENE POLYMORPHISM AND RECURRENCE OF VENOUS THROMBOEMBOLISM IN YOUNG PATIENTS FROM THE NORTH-WEST REGION OF RUSSIA

A. Chechulova[1,*], S. Kapustin[2], K. Svetlana[3], V. Shmeleva[3], V. Soldatenkov[3], L. Papayan[3], V. Soroka[1], P. Chechulov[4]

[1]Vascular surgery, Dzhanelidze Research Institute of Emergency Medicine, St. Petersburg, [2]laboratory of biochemistry, [3]Russian Research Institute of Hematology and Transfusiology, [4]Dzhanelidze Research Institute of Emergency Medicine, St. Petersburg, St. Petersburg, Russian Federation

Background: Tissue plasminogen activator (TPA) is an important component of fibrinolytic system. Inhibition of fibrinolysis can lead to venous thromboembolism (VTE). However, the role of TPA gene polymorphism in pathogenesis of VTE remains controversial.
Aims: To assess the role of TPA gene polymorphism in the risk of recurrence of VTE in young patients from the North-West region of Russia.
Methods: We analyzed 205 patients under 45 years old (101 men and 104 women, mean age – 37,4 years) with at least one confirmed episode of deep vein thrombosis (DVT) or/and pulmonary embolism (PE). The patients were genotyped for the 311 bp insertion/deletion (Ins/Del) TPA gene polymorphism by PCR. The differences in distribution of TPA genotypes were estimated by Fisher's exact method. Odds ratios (OR) together with their 95% confidence intervals (CI) and p-values were determined by using the SPSS software version 17,0 (SPSS Inc, Chicago, IL, USA).
Results: Recurrent VTE was diagnosed in 102 (49,7%) patients. The comparison group consisted of 103 patients without disease recurrence. The group with recurrent VTE included 71 (69,6%) patients with isolated DVT and 31 (30,4%) patients with the signs of PE. The frequency of the "normal" genotype TPA Del/Del was more than 2-fold decreased in patients with recurrent VTE when compared to those with single thrombotic episode (13,7% *vs* 29,1%, respectively; OR=0,4; 95% CI: 0,2-0,9; p=0,026). Moreover, in the group with non-recurrent isolated DVT, the frequency of the TPA Del/Del genotype was three times higher than in patients with recurrent DVT (28,5% *vs* 9,3%; OR=3,8; 95% CI: 1,6-9,1; p=0,005). At the same time, the TPA Del/Del genotype was almost equally represented in patients with or without recurrence of PE (20.8% *vs* 25.0%, p=0.68).
Summary and Conclusions: The presence of homozygous TPA Del/Del variant could have a significant protective effect against the risk of DVT recurrence and probably is not associated with the frequency of thromboembolic complications.

PF781

SEASONAL VARIATION IN PULMONARY EMBOLISM BUT NOT DEEP VEIN THROMBOSIS INCIDENCE: A KOREAN NATIONWIDE VENOUS THROMBOEMBOLISM EPIDEMIOLOGY STUDY

J. Hong[1,*], J. H. Lee[2], H. Park[3], J. Y. Lee[2], J.-O. Lee[2], W.-I. Choi[4], S. Ahn[5], Y.-H. Lim[6], S.-M. Bang[2], D. Oh[7]

[1]Department of Internal Medicine, Seoul National University Hospital, Seoul, [2]Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, [3]Department of Internal Medicine, Inha University Hospital, Incheon, [4]Department of Internal Medicine, Keimyung University Dongsan Medical Center, Daegu, [5]Medical Research Collaborating Center, Seoul National University Bundang Hospital, Seongnam, [6]Environmental Health Center, Seoul National University College of Medicine, Seoul, [7]Department of Internal Medicine, CHA University School of Medicine, Seongnam, Korea, Republic Of

Background: Seasonal variation is an environmental factor proposed to affect the incidence of venous thromboembolism (VTE). However, VTE seasonal variation is not well studied in Asian populations, which have different genetic determinants of VTE compared to Westerners.
Aims: The present study aimed at investigating seasonal variation of VTE occurrence and the effect of various demographic factors (*i.e.*, age, gender, and co-morbidities) on variation.
Methods: VTE seasonal variation was evaluated in 59,626 index cases (from January 2009-December 2013) in the Korean Health Insurance Review and Assessment Service (HIRA) database, a nationwide healthcare claims database basically covers near a whole Korean population (49,989,620 subjects registered in 2013). We quantified and compared VTE occurrence across four seasons, and additionally assessed monthly through a chronobiological analysis.
Results: VTE incidence varied both seasonally and monthly, with new cases peaking in the winter (January and February) and the lowest incidence in the summer (August and September). After adjusting for sex, age, type of VTE, and combined cancer diagnosis, winter remained a significant independent factor driving VTE incidence. Additionally, seasonal variation was prominent in patients aged 60 years or older and in patients with pulmonary embolism, but not in patients of aged less than 60 years and patients with deep vein thrombosis (Table 1).

Table 1.

Result of multivariate Poisson regression analysis of seasonality and VTE, DVT, and PE

	Venous thromboembolism			Deep vein thrombosis			Pulmonary embolism		
Subgroups	RR	95% CI	p	RR	95% CI	p	RR	95% CI	p
Male	1			1			1		
Female	1.20	1.18-1.22	<0.001	1.18	1.15-1.21	<0.001	1.22	1.20-1.25	<0.001
Age < 60	1			1			1		
Age ≥ 60	8.42	8.26-8.58	<0.001	6.07	5.90-6.26	<0.001	10.67	10.48-10.95	<0.001
Non-cancer	1			1			1		
Cancer	53.25	52.30-54.23	<0.001	58.20	56.53-59.91	<0.001	50.39	49.23-51.57	<0.001
Winter	1			1			1		
Spring	0.94	0.92-0.97	<0.001	0.97	0.93-1.00	0.0580	0.93	0.90-0.95	<0.001
Summer	0.91	0.89-0.93	<0.001	0.98	0.95-1.02	0.3743	0.86	0.84-0.89	<0.001
Autumn	0.94	0.92-0.96	<0.001	0.96	0.92-0.99	0.0143	0.93	0.90-0.96	<0.001

RR, relative risk; CI, confidence interval

Summary and Conclusions: Seasonal variation was a weak but independent contributor to VTE incidence in a Korean population diagnosed from 2009 to 2013, especially in those individuals suffering from a pulmonary embolism.

PF782

BLEEDING AND THROMBOTIC EVENTS RELATED TO PERIOPERATIVE CESSATION OF DIRECT ORAL ANTICOAGULANTS

S. Lam[1,*], D. Pepperell[1], S. P'ng[1]

[1]Haematology Department, Fiona Stanley Hospital, Perth, Australia

Background: Direct acting oral anticoagulants (DOACs) are increasingly prescribed long-term for atrial fibrillation or venous thromboembolism. These patients often require peri-procedural interruption of anticoagulation. The current management of DOACs perioperatively is based on expert consensus guidelines, with little published supporting evidence, particularly in the Australian population.
Aims: We aimed to assess the appropriateness of current perioperative DOAC cessation guidelines by measuring drug levels, physician compliance, and patient-centred outcomes.
Methods: Patients with planned invasive procedures were recruited to this single-centre observational study from haematology, cardiology and preoperative anaesthetic outpatient clinics. Perioperative anticoagulation management was at the discretion of the treating physicians, who were encouraged to utilise the guidelines by Tran (IMJ 2014).
Plasma DOAC levels were measured on the day of procedure and, when possible, within 24hrs after drug cessation. Peri-procedural bleeding events, and thrombotic events up to day 30 postoperatively were recorded.
Results: 36 patients with a mean age of 68 years (range 39-88) were recruited. The DOAC was apixaban in 21 patients (58%), rivaroxaban in 10 (28%) and dabigatran in 5 (14%). The indication for anticoagulation was atrial fibrillation in 92% of patients and venous thromboembolism in 8%. The timing of drug cessation preoperatively was consistent with guidelines in all patients undergoing high-risk procedures (n=13; mean 60hrs, range 40-107). However, 43% of patients undergoing a low-risk procedure had early cessation of anticoagulation (n=10; mean 59hrs, range 36-120).
Plasma DOAC levels were measured 24hrs following drug cessation in 12 patients, and were <50µg/mL in all but one (92%). On the day of procedure, plasma DOAC levels were <50µg/mL in 34 patients (94%). Both patients with plasma DOAC levels exceeding recommended limits underwent uncomplicated cardiac ablations; one patient had a rivaroxaban level of 72µg/mL (24hrs post-cessation, normal renal function), and the other did not cease rivaroxaban preoperatively and had a level of 192µg/mL 5hrs post-dose (at time of procedure).
There was one significant bleeding event in our cohort. The patient underwent cardiac ablation with a dabigatran level of 40 on the day of the procedure. This was complicated by cardiac tamponade with pericardial drain insertion required. There were no thrombotic complications.
Summary and Conclusions: In our observational study of perioperative DOAC cessation, plasma DOAC levels at the time of procedure were considered safe in almost all patients. The timing of DOAC cessation was consistent with guidelines in all patients undergoing high-risk procedures, however cessation was earlier than required in almost half of patients undergoing low-risk procedures. 2 patients had levels >50µg/mL at the time of procedure, but no immediate bleeding complications occurred in these patients. These findings are suggestive that the guidelines are overly cautious in DOAC cessation prior to high-risk procedures. Replication of these findings in a larger cohort may suggest that 50µg/mL is too conservative as a safety threshold. Perioperative interruption of anticoagulation did not result in any thrombotic events at 30-day follow-up.

PF783

TROMBOSIS IN LYMPHOMA, INCIDENCE, RISK FACTORS AND MANAGEMENT.

V. Pradillo[1,*], M. Bastos[1], E. Landete[1], D. Carbonell[1], J. Menarguez[1], P. Balsalobre[1], J.L. Diez-Martín[1], C. Pascual[1]

[1]Haematology, Hospital General Universitario Gregorio Marañón., Madrid, Spain

Background: Thrombosis is a frequent complication in patients with cancer. The incidence of thrombosis in patients diagnosed with lymphoma is estimated at 5%. These events increase the co-morbidity of these patients. New risk scores have been recently developed, and are being validated to predict thrombosis in this population.
Aims: The main objective of our study was to identify the risk factors associated with thrombosis disease in patients with lymphoma as well as to analyse the management in a single centre.
Methods: This is a retrospective unicentric study, all patients with diagnosis of non-Hodgkin lymphoma (NHL) and Hodgkin lymphoma (HL) were included consecutive since January 2014 to November 2017. A total of 250 patients were included. Basal characteristics of the patients are shown in Table 1A. Demographic, clinical and laboratory data and tumour characteristics were collected. Thrombotic events were assessed from diagnosis up to 6 months after. Likewise, thrombosis at the time of relapse was also assessed. In the incidence analysis, we defined as competitive event for thrombosis relapse, death and second neoplasm. We used R software for statistical analysis.

Results: For newly diagnosed patients we found 23 thrombotic events, with accumulative incidence of 8.7% at six months. At relapse, we found 5 events. The basis characteristics of the thrombosed patients are shown in Table 1B. Eight of the thrombosed patients (34%) presented the event at the moment of diagnosis, and in 15 patients (29%) thombotic event developed during chemotherapy. Among relapsed patients, we found 5 events in a total of 24 relapse patients (20%). In a univariate analysis, central venous catheter, ECOG and higher steroids dose were associated with thrombosis. In a multivariate, the variables independently associated with thrombosis risk were high aggressive lymphoma, previous thrombosis, platelet count at diagnosis, concomitant neoplasia and previous immobilization. Interestingly, the leucocytes or haemoglobin count were not associated with thrombosis; however we found increased risk with the highest platelet counts. Adenopathy location, bulky disease or extranodal involment were not associated with the event. No thrombosis was documented in patients under observation (16%) (p=0.034).Thirteen patients (5.2%) received antithrombotic prophylaxis, with LMWH. Thirty six patients were on antithrombotic treatment at diagnosis (14,4%): 10 anticoagulated and 26 anti-aggregated. None anticoagulated patients developed thrombosis, but six patients under anti-aggregant therapy did it. Rethrombosis was observed in two patients, both after treatment suspension (one with severe trombopenia in relapse and the other after complete anticoagulant treatment in complete remission). Regarding treatment, 27 of the thrombosed patients (75%) were treated with LMWH at full doses. Treatment adjustments were required in 10 patients due to thrombocytopenia (6), renal failure (1) or haemorrhagic events (3). Two patients under treatment had mild haemorrhagic complications (gluteal hematoma and fracture). No bleeding was observed in patients under prophylaxis.

NEUTROPHILS MEDIA	5095		1	NS		
CENTRAL VENOUS CATHETER	17	74	2.87	0.026	1.85	NS
TREATMENT						
CHEMOTHERAPY (QT)	21	92				
QT+RT	2	8				

Summary and Conclusions: In our study, variables independently associated with thrombosis were: disease treatment, previous thrombosis, histology, immobilization, and a concomitant neoplasm. Also, a higher platelet count could confer an increased risk. Anti-aggregate therapy does not adequately protect patients. The adjustment of therapeutic doses has not been associated with rethrombosis. Relapse is a risk factor to consider.

PF784

PLATELET HYPERREACTIVITY AND POSTOPERATIVE VENOUS THROMBOEMBOLISM IN KNEE REPLACEMENT ARTHROPLASTY

J. Kim[1,*], Y. Kim[2]

[1]Laboratory Medicine, [2]Orthopaedics, Chungnam National University Hospital, Daejeon, Korea, Republic Of

Background: It is suggested that platelet hyperreactivity plays a role in the pathophysiology of arterial thrombi, such as myocardial infarction and

stroke, but the link between platelet hyperaggregability and venous thromboembolism is not well defined. The aggregometry using a submaximal concentration of epinephrine is proposed as a reliable method to detect hyperreactivity. Postoperative vein thromboembolism (VTE) in knee replacement arthroplasty (KRA) is a serious complication.
Aims: The aim of this study was to examine whether platelet hyperreactivity affects the development of VTE.
Methods: Seventy-six patients (71.2±5.4 years, 61 women and 15 men) without previous venous thrombotic history were enrolled. The unilateral KRA was performed by one surgeon. The complete blood count, coagulation assay and platelet function were checked in automated analyzers. We performed platelet aggregation using Chrono-log (Chrono-log Corporation, USA) in the presence of agonist epinephrine (0.4 mM) in duplicate and measured maximal aggregation (%) for 10 minutes.
Results: In aggregation response to 0.4 mM epinephrine, 53 (69.7%) exhibited relatively low platelet aggregation (<40%) and 11 (14.5%) demonstrated more than 60% aggregation, consistent with platelet hyperreactivity. The aggregation in 12 patients was distributed between 40% and 60%. Platelet hyperreactivity showed higher platelet count (P=0.040) and mean platelet volume (P=0.024) compared to group with low aggregation. The VTE was detected in 4 patients (5.3%) showing aggregation of 40% or more. The frequency of VTE was significantly lower in hyporeactivity phenotype group (P=0.008). The decrease of hemoglobin, RBC transfusion unit, CRP increase, and hospitalization time after surgery were similar among groups.
Summary and Conclusions: We conclude that platelet reactivity is a useful biological marker for the prediction of postoperative VTE. Postoperative transfusion requirement and the degree of inflammation are not related with platelet phenotype.

PF785

THROMBOEMBOLISM IN CHILDREN WITH CANCER; A RETROSPECTIVE MULTICENTER STUDY IN KOREA

H.S. Choi[1,*], H.J. Kim[1], C.R. Hong[2], H.J. Kang[2], J.W. Lee[2], H.Y. Shin[2], B.-K. Park[3], H.J. Park[3], Y.H. Lee[4], J.A. Lee[5], Y.-J. Lim[6], K.D. Park[2]

[1]Pediatrics, Seoul National University Bundang Hospital, Seongnam, [2]Pediatrics, Seoul National University Hospital, Seoul, [3]Pediatrics, National Cancer Center, Goyang, [4]Pediatrics, Hanyang University Hospital, [5]Pediatrics, Korea Cancer Center Hospital, Seoul, [6]Pediatrics, Chungnam National University Hospital, Daejeon, Korea, Republic Of

Background: Thromboembolism (TE) has been recognized as a significant cause of morbidity and mortality in adult cancer patients, however there is less knowledge about TE in pediatric cancer patients.
Aims: This study aims to determine the epidemiology of TE in Korean children with cancer.
Methods: During the period between January 2000 and July 2015, we retrospectively analyzed pediatric patients (0 to 18 years of age) newly diagnosed with cancer at six tertiary hospitals in Korea. Medical records were reviewed to evaluate the incidence, risk factors, treatment and outcome of TE.
Results: Among 3689 children with cancer, TE occurred in 33 patients (0.89%). Patients with acute lymphoblastic leukemia (n=12), brain tumors (n=5), lymphoma (n=4), and bone/soft tissue sarcomas (n=5) had a significantly higher incidence of developing TE. The male-female ratio was 17 to 16, and median age at diagnosis was 10 year 2 months (range 2 months-18 year 1 month). Symptoms including pain and swelling were present in 18 out of 33 patients (54.5%). Doppler ultrasonography was the most frequently used diagnostic method followed by computed tomography and magnetic resonance imaging. Locations of TE included three intracerebral, 23 upper venous, six lower venous and one combined upper and lower venous system. Additional risk factors for TE included central venous lines (CVL) in 11 patients, steroid and/or L-asparaginase in nine patients, and CVL and steroid and/or L-asparaginase in seven patients. Treatments included the use of unfractionated heparin, low-molecular-weight heparin, and warfarin according to the protocols of each institute. Of 33 patients, 23 exhibited complete resolution of TE, six partial resolution, two persistent disease and two recurrent disease. Aggravation of chronic subdural hemorrhage was occurred in one patient following warfarin treatment.
Summary and Conclusions: The incidence of TE is very low (0.89%) in Korean children with cancer but higher than general pediatric population and children hospitalized for diseases other than cancer. Further investigation of a larger pool of patients is warranted to determine the most effective strategies to prevent and treat TE in Korean children with cancer.

PF786

A RETROSPECTIVE ANALYSIS OF UTILISATION OF DIRECT ORAL ANTICOAGULANT LEVELS FROM A TERTIARY HAEMATOLOGY CENTRE

N. Denny[1,*], H. Belli[2], L. Keighley[2], M. Nash[1]

[1]Department of Haematology, [2]Department of Laboratory Haematology, Manchester University Foundation Trust, Manchester, United Kingdom

Background: Specialised laboratory tests for the measurement of direct oral anticoagulants (DOAC) are discussed in a number of international guidelines. Although DOAC may not require routine laboratory monitoring there are a number of situations in which measuring drug levels is useful. Our hospital is a tertiary centre for haematology and is the only hospital to process DOAC levels 24/7 in the area.
Aims: To assess the utilisation of these tests and to analyse the variation in DOAC levels in a real world setting.
Methods: We identified all DOAC levels requested at our institution over a 2 year period from 01/01/2016 to 31/12/2017 inclusive. Patient notes were reviewed and relevant blood results that were measured at the same time as DOAC levels were recorded. Levels were defined as peak if a DOAC had been taken within the last 12 hours. Dabigatran levels were measured using the Hemoclot® assay. Rivaroxaban and apixaban levels were measured using a chromogenic anti-Xa assay. Edoxaban levels were not available. Statistics were performed using SPSS and where appropriate the Mann Whitney U test was used.
Results: 220 levels were requested in 127 patients. 17 patients and 50 levels were excluded as they were from a different hospital and information was unavailable. 170 levels and 110 patients were included in the final analysis. The mean age was 67 years and DOAC use was as follows; apixaban 59 patients, rivaroxaban 38 and dabigatran 12. 1 patient had a DOAC level measured but was receiving LMWH. AF was the indication for DOAC use in 63 patients, VTE in 42 and in 5 use was off license. The reason for DOAC level requests is shown in Table 1. Bleeding and emergency surgery were the leading causes. A reversal agent was used in 27 patients; Praxbind in 6 and PCC in 21. Reversal agents were given prior to obtaining a result in all cases. The most common indication for reversal agent use was bleeding. 11 of the patients died during their admission and 7 received reversal agents. GI bleeding and polytrauma were the main reasons for death.
55% of DOAC levels were measured out of working hours. The mean turnaround time from receipt of sample to result was 108 minutes out of hours and 97 minutes in hours (no sig diff p=0.89). 84 apixaban levels were measured; 41 peak, 42 trough and 1 overdose. Mean peak apixaban level was 192ng/mL and mean trough level was 46ng/ml (sig diff p<0.00001). 61 rivaroxaban levels were measured; 19 peak and 42 trough. Mean peak rivaroxaban level was 290ng/ml and mean trough level was 43ng/ml (sig diff p<0.00001). 24 dabigatran levels were measured; 11 peak, 11 trough and 2 overdose. Mean peak dabigatran level was 86ng/ml (st dev 64ng/ml) and mean trough level was 55ng/ml (no sig diff p=0.178). There was minimal correlation between apixaban level and PT (r=0.11) or aPTT (r=0.39). There was moderate correlation between rivaroxaban level and PT (r=0.43) or aPTT (r=0.44). There was strong correlation between dabigatran level and both PT (r=0.98) and aPTT (r=0.94).

Table 1.

Reason for DOAC level request	Number of tests (n=170)
Bleeding	58
Pre-operative (emergency)	36
Monitoring efficacy	34
No clear reason	20
Change in renal function	13
Pre-operative (elective)	9

Summary and Conclusions: Our real world data show that DOAC levels are used clinically and provide helpful information about patients taking these drugs. Levels were predominantly requested in an emergency context and they are feasible in and out of hours with a turnaround time of under 2 hours. Interestingly, for direct Xa inhibitors, measured peak and trough levels correspond with expected levels in the BCSH guideline. There was minimal correlation between direct Xa inhibitor level and PT/aPTT highlighting the usefulness of measuring DOAC levels directly.

PF787

LONG- TERM MANAGEMENT OF RECURRENT VENOUS HROMBOEMBOLISM IN BLOOD CANCER PATIENTS AT HIGH BLEEDING RISK

M. Napolitano[1,*], S. Raso[2], S. mancuso[1], A. Passannanti[2], M. Santoro[2], L. LoCoco[3], S. Siragusa[1]

[1]Haematology Department, [2]Università di Palermo, [3]University Hospital "P.Giaccone", Palermo, Italy

Background: Recurrent venous thromboembolism (VTE), bleeding, and severe thrombocytopenia are frequently observed in haematological cancer patients. The optimal management of anticoagulation in such instances presents a major challenge to clinicians.
Aims: We here report efficacy and safety of anticoagulant treatment in patients with active haematological malignancies, a history of recurrent venous thromboembolism and stable thrombocytopenia
Methods: We here report results of a 12 months observational cohort study of patients with active haematological malignancies, a history of recurrent venous thromboembolism, at high bleeding risk for concomitant stable thrombocytopenia (Platelets count <50 x 10^9/L for at least three consecutive days), diagnosed between January 2014 and January 2017 at the Reference Regional Centre for Thrombosis and Haemostasis of University Hospital "P. Giaccone", Palermo. Haematological malignancies were either acute or chronic. Recurrent venous thromboembolism included two or more episodes of: deep vein thrombosis (DVT) of upper or lower extremities; atypical sites vein thrombosis; pulmonary embolism (PE) and catheter-related thrombosis. Long-term anticoagulant treatment was defined by continuous administration of anticoagulants.
Results: A total of 45 patients with a history of recurrent VTE were included (15 with chronic myeloproliferative neoplasms; 12 with acute leukemia; 8 with non-Hodgkin Lymphoma; 8 with multiple myeloma; 2 with Hodgkin Lymphoma). Twenty-five subjects had a history of recurrent DVT of the lower limbs, ten had sinus cerebral vein thrombosis and catheter-related thrombosis; five had PE and DVT of the lower limbs; 5 had mesenteric vein thrombosis and DVT of the lower limbs. All subjects received long-term anticoagulant treatment with Low Molecular Weight Heparin (LMWH) at reduced dose (50% of therapeutic dose),discontinued in case of severe thrombocytopenia (PLT<30 x10^9/L), active bleeding or new acute episodes of recurrent VTE. At 12 months follow-up, 27 (60%) subjects were still under treatment with a good compliance to daily LMWH. Among them, short-term discontinuation of LMWH was needed in 12 patients for severe thrombocytopenia secondary to chemotherapy and in 3 cases for active bleeding (2 recurrent epistaxis, 1 gum bleeding). At 12 months follow-up, seven subjects (15.5%) experienced recurrences while under treatment, in 4 (8.8%) patients a major bleeding occurred (2 gastro-intestinal bleeding, 1 genito-urinary bleeding, 1 intra-cerebral), six (13.3%) patients died of cancer.
Summary and Conclusions: Waiting for ad hoc studies, a patient oriented LMWH treatment tapering may be appropriate for the management of haematological cancer patients at high risk.

PF788

A MULTICENTER EXPERIENCE WITH IDARUCIZUMAB "IN REAL WORLD" AS REVERSAL ANTICOAGULATION OF DABIGATRÁN

M. Villalba Montaner[1,*], R. Martínez Fernández[2], O. Gavín Sebastián[2], I. Cuesta Gallardo[3], J.M. Real Campaña[4], L.I. Sancho Val[5], A.R. Millán Acero[6], I. Larrode Leciñena[4], E. Salvador Rupérez[7], S.F. Pinzón Mariño[7], G. Ferrer Garrido[7], B. Sánchez Quiñones[2], N. Fernández Mosteirín[7], J.M. Calvo Viñas[7]

[1]Hematology, Hospital Miguel Servet, Zaragoza, Spain, [2]Hematology, Hospital Clínico Universitario, Zaragoza, [3]Hematology, Hospital Obispo Polanco, Teruel, [4]Pharmacist, Hospital Miguel Servet, Zaragoza, Spain, Zaragoza, [5]Hematology, Hospital De Alcañiz, Teruel, [6]Hospital San Jorge, Huesca, [7]Hematology, Hospital Miguel Servet, Zaragoza, Spain

Background: Idarucizumab has been recently approved as reversal agent of anticoagulant effect of dabigatran in major bleeding and emergency surgeries however there is not patients reported outcomes of using idarucizumab "in real world.
Aims: Analyze the use of idarucizumab as reversal agent of dabigatran in current clinical practice in the hospitals of Aragón (Spain) from 2016 up to now.
Methods: From January-16 to date, 16 patients were registered in this multicenter prospective/retrospective study. We analyzed clinical variables and laboratory tests; efficacy, safety and thrombogenic capacity of the idarucizumab and related mortality with its use.
Results: The indications of dabigatran in patients were non-valvular auricular fibrillation in 15 patients and aortic valve prosthesis in 1 pt. The indications of idarucizumab were emergency surgeries in 11 pts, major bleeding in 4 pts and 1 pt with severe renal failure requiring dialysis received the drug off-label. Time from the last dose of dabigatran to the administration of idarucizumab was <12h in 15 patients.
Surgeries requiring reversal anticoagulation were 1 splenic rupture, 2 aortic dissections, 1 cardiac transplant, 1 cholecystectomy, 1 stroke fibrinolysis, 1 nephrectomy, 2 lower limb thrombectomies, 1 stroke thrombectomy, and 1 ankle osteosynthesis. One patient was at renal failure (clearance creatinine <30 ml/min). Activated partial thromboplastin time (aPTT) and prothrombin time (PT) were prolonged in 7 patients prior to idarucizumab infusion. Two hemorrhagic complications related with surgery: retrocardiac hematoma and cerebral hemorrhage, were registered.
The use of the drug in major bleeding was 2 pts with intracerebral hemorrhage, 1 with retroperitoneal hemorrhage and 1 lower gastrointestinal bleeding. aPTT and PT were prolonged, and one patient was at renal failure. Neither adverse effects nor thrombotic events were identified.
Four patients died in relation with intraventricular hemorrhage, heart transplant complications, septic shock and multi-organic failure respectively.
Summary and Conclusions: Our series includes 16 patients treated with idarucizumab to reverse the anticoagulation effect of dabigatran in hospitals of Aragon. In our experience "in real world" idarucizumab reversed immediately, completely, sustainably and safely the anticoagulation with dabigatran. The implementation of multidisciplinary protocols would optimize the cost/effectiveness ratio of idarucizumab in the approved clinical indications.

PF789

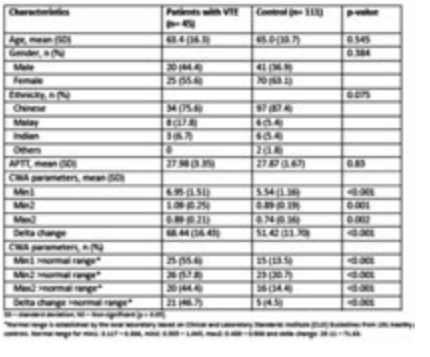
THE ASSOCIATION BETWEEN APTT-BASED CLOT WAVEFORM ANALYSIS AND ACUTE VENOUS THROMBOEMBOLISM

I.Q. Wu[1,*], C.W. Tan[2], H.H.M. Cheen[3], W.H. Wong[2], L.W.B. Chua[1], A.S. Hameed[4], C.K.L. Ng[1], M.H.Y. Chu[2], S.S. Lim[2], H.J. Ng[2]

[1]Singapore Health Services, [2]Haematology, [3]Pharmacy, Singapore General Hospital, [4]Ministry of Health Holdings, Singapore, Singapore

Background: Hypercoagulability contributes to the formation of venous thromboembolism (VTE). Increased levels of certain individual clotting factors and global hemostatic markers have been implicated as risk factors for VTE. Clot waveform analysis (CWA), as a global hemostatic assay, has been evaluated mainly in bleeding disorders, and its value in thrombotic conditions has not been explored.
Aims: We sought to evaluate the relationship between CWA parameters with acute VTE. We postulated that increased CWA parameters reflect a hypercoagulable state which will be present in patients with acute VTE compared with normal controls.
Methods: This project received institutional IRB approval prior to data collection. Inclusion criteria for this study included patients referred to the inpatient Hematology service at a tertiary hospital for objectively proven acute VTE with an activated partial thromboplastin time (aPTT) performed prior to initiation of anticoagulation. aPTT-based CWA was then performed on the CS2100i automated analyser using Dade Actin FSL reagent as per manufacturer's instructions. CWA parameters obtained were maximum velocity (min1), maximum acceleration (min2), maximum deceleration (max2) and delta change. Results from control patients were compared and retrospectively analysed. We also calculated the odds ratio for VTE based on comparison with the normal ranges for CWA parameters established by our laboratory.
Results: Whilst the baseline demographics and aPTT between VTE patients (n=45) and controls (n=111) were similar, all CWA parameters in the patients with VTE were significantly higher compared to the control groups (Table 1).

Table 1.



Similarly, there were significantly more cases within the VTE group exhibiting CWA values above the normal ranges of the respective CWA parameters than those within the control group (Table 1). In patients who had a CWA value above the normal range of that particular CWA parameter, the odds ratios for VTE were 8.0 (95% confidence interval [CI]: 3.6-17.8) for min1, 5.2 (95% CI: 2.8-11.1) for min2, 4.8 (95% CI: 2.2-10.5) for max2 and 18.6 (95% CI: 6.4-54.1) for delta change.
Summary and Conclusions: We have shown that increased aPTT-based CWA parameters were associated with hypercoagulability and were independent risk factors for acute VTE. aPTT-based CWA might be a potential diagnostic marker for acute VTE.

Transfusion medicine

PF790

A TERTIARY INSTITUTION BLOOD BANK EXPERIENCE AFTER THE IMPLEMENTATION OF A UNIFIED NATIONAL MASSIVE TRANSFUSION PROTOCOL (MTP) IN SINGAPORE.

C.-T. Lee[1,2,*], Y.L. Khng[3], S.T. Lim[3], E.S. Sumardi[3], K.P. Lim[3], S.Y. Lee[1,3], L.K. Tan[1,3]

[1]Department of Haematology-Oncology, NCIS, [2]Department of Medicine, Yong Loo Lin School of Medicine, National University Singapore, [3]Blood Transfusion Service, Department of Laboratory Medicine, National University Hospital, Singapore, Singapore

Background: Blood Services Group of the Singapore Health Sciences Authority had introduced a unified national massive transfusion protocol (MTP) to provide a standardized mechanism for prompt delivery of blood products to massively haemorrhaging patients in 6 acute general hospitals island-wide since 2012. Prior to this, within these hospitals, there was individual transfusion workflow in place for haemorrhaging patients.
Aims: To demonstrate the feasibility, usage, wastage, and patients' mortality after implementation of a nationwide MTP.
Methods: This is a retrospective analysis of blood bank data on blood product usage, returns and wastage of each MTP activation from 2012-2017. Clinical data of patients were analyzed to determine survival and Assessment of Blood Consumption (ABC) scores that was to used guide MTP activation in trauma. Our MTP consists of 3 packages. They are MTP1 and MTP3 which consist of 4 packed red cells (pRBC), 4 units of fresh frozen plasma (FFP) and 4 units of platelets pooled into 1 bag (pPLT). As for MTP2, additional 10 units of cryoprecipitate (CRYP) are added. After MTP1 is issued, the attending physicians will decide if MTP2 and MTP3 are required. Other components of the MTP included use of adjunctive anti-fibrinolytics to arrest bleeding.
Results: There were 401 MTPs activated, of which the median age was 52 years (13 - 93years). 185(46.1%) cases were trauma, 89(22.2%) gastrointestinal (GI) bleeding, 47(11.7%) peri-operative bleeding, 20(5.0%) ruptured aortic aneurysm (AAA), 11(2.7%) peripartum hemorrhage and 49 (12.3%) massive bleeding due to other causes. A total of 261(65.1%) MTP1, 87(21.7%) MTP2, 46(11.5%) MTP3 were activated, and 7(1.7%) cases required more than MTP3.This accounted for 5.8% of total blood products issued hospital-wide from 2012-2017. 5036(47.2%) of the blood units were issued to the EMD, 3394(31.8%) to ICUs, 1996(18.7%) to operating theatres, and 242(2.3%) to general wards with the median time of 9 minutes (interquartile range: 4-14 minutes). 1557(14.6%) units of blood products were returned unused including 568 units pRBC (5.3%), 121 units pPLT (1.1%), 693 units FFP (6.5%) and 175 units CRYP (1.6%). 72(17.9%) MTP activation had 528(4.9%) of the blood products issued returned due to patient's death. From 2014-2017, of the returned blood units, 9 out of 348 pRBC (2.6%), 67 out of 543 FFP (12.3%), 0 out of 89 pPLTs and 22 out of 155 CRYP (14.2%) were discarded after return, whereas the rest which met proper storage conditions were reissued. Overall calculated wastage was 1.8%. 300(74.8%) patients survived more than 1 day after MTP activation. The overall survivorship at 1 month was 139 (75.1%) for trauma cases, 48 (53.9%) GI bleeding, 31(66.0%) perioperative bleeding, 8(40.0%) ruptured AAA and 11 (100%) peri-partum bleeding. 37(9%) of all the patients who survived after activation expired within a month.
Summary and Conclusions: MTP packs are feasible and allow rapid and coordinated delivery of blood products to bleeding patients. Although return rates are moderately high at 14.6%, the overall wastage can be lower if proper storage conditions are maintained, thus, allowing product reuse. Our overall wastage was 1.8% which is lower than reported (*Dunbar et al.*) FFP and CRYP had the highest wastage, likely due to short expiry time after thawing. Development of better clinical predictive scoring to aid decision for MTP activation may also reduce return rates. MTP survivorship is acceptable and justifies the unified MTP as an adequate way for efficient blood product delivery in tertiary care hospitals.

PF791

DURATION OF RED BLOOD CELL STORAGE IS SIGNIFICANTLY ASSOCIATED WITH HEMOGLOBIN INCREASE AFTER BLOOD TRANSFUSION

J. Rydén[1,2,*], M. Clements[3], E. Hellström-Lindberg[1,2], P. Höglund[1,4], G. Edgren[3,5]

[1]Department of Medicine, Karolinska Institutet, Huddinge, Stockholm, [2]Department

of Hematology, Karolinska University Hospital, [3]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, [4]Department of Clinical Immunology and Transfusion Medicine, Karolinska University Hospital, [5]Department of Cardiology, Stockholm South General Hospital, Stockholm, Sweden

Background: Red blood cells are commonly stored for up to 42 days. There has been conflicting evidence on the effect of red blood cell storage duration and clinical outcomes. Previous research has focused on determining the association between duration of storage time and risk for adverse outcomes including mortality, but most data has not supported such association. Surprisingly few studies have addressed the association between red blood cell storage and component efficacy.
Aims: The main aim of this study was to determine the effect of red blood cell storage duration with regard to hemoglobin increment in the transfusion recipient.
Methods: Transfusion data on a well-defined cohort of myelodysplastic syndromes were linked to hemoglobin measurements taken within 2 days before until 28 days following the transfusion. We applied a mixed effect regression model to study the impact of storage duration (categorized as <10, 10-19, 20-29 or ≥30 days) on the hemoglobin yield, per red blood cell unit.
Results: The study population consisted of 243 unique patients who were transfused at 4,419 transfusion occasions. Compared to patients who received units stored 1-9 days receipt of blood units stored 10-19, 20-29, or ≥30 days resulted in a hemoglobin increase that were 0.26 (95% confidence interval [CI], -0.11-0.63), 0.75 (95% CI, 0.26-1.23), and 1.12 (95% CI, 0.4-1.85) g/L lower, respectively, per red blood cell unit. Results were consistent in sensitivity analyzes.
Summary and Conclusions: We observed a gradual drop in the mean hemoglobin increase with prolonged red blood cell storage. Although the effect was statistically significant, the effect was modest and if this is clinically relevant in subgroups of patients must be investigated further.

PF792

RED CELL TRANSFUSION THRESHOLDS IN PATIENTS RECEIVING INDUCTION CHEMOTHERAPY FOR ACUTE MYELOID LEUKEMIA

A. Trottier[1,*], J. Tay[1]

[1]Department of Medicine, Division of Hematology, University of Calgary, Calgary, Canada

Background: Recent studies from a variety of clinical settings have provided evidence in favour of the use of a restrictive red cell transfusion strategy, however, data for patients with hematologic malignancies remains sparse. Patients undergoing chemotherapy for hematologic malignancies, such as induction chemotherapy for acute myeloid leukemia (AML), are high users of red cells and differ from other patient populations for numerous reasons such as, the presence of concurrent anemia and thrombocytopenia as well as a compromised immune system. The limited evidence available for the impact of red cell transfusion on clinical outcomes for these patients has been conflicting and unclear.
Aims: The aim of this study was to evaluate the impact of red cell transfusion threshold on clinically relevant outcomes for patients undergoing induction chemotherapy for AML.
Methods: This was a single-centre retrospective exploratory analysis of consecutive adult patients admitted between 2011 and 2016 for induction chemotherapy for newly diagnosed *de novo* or secondary AML. Baseline information including, age, gender, admission duration, induction regimen, and disease characteristics were collected. Transfusion data was compiled for each patient including the mean hemoglobin pre-transfusion (transfusion threshold) and the number of red cell units and platelet doses transfused during admission. Clinically relevant outcomes examined included remission status and 30-day mortality as well as WHO grade 3-4 bleeding events, myocardial infarction (MI), heart failure (HF), and venous thromboembolism (VTE) occurring during the admission period. Statistical analysis was performed using Stata 15.1 (StataCorp LLC). Comparison of the transfusion threshold for a given outcome was done using the two-sided two-sample unpaired t-test with a significance level of $p < 0.05$.
Results: 168 patients were included in the analysis. Baseline characteristics, transfusion data, and outcomes are shown in Table 1. The median transfusion threshold was 76 g/L (range: 64 – 86 g/L). The median number of red cell units and platelet doses transfused during admission were 10 and 7, respectively. The mean red cell transfusion threshold did not differ significantly between patients who suffered an MI, experienced HF, or had a VTE compared with those who did not (73 *vs* 75.3 g/L, p=0.1), (75.5 *vs* 75.2 g/L, p=0.8), (75.9 *vs* 75.2 g/L, p=0.3), respectively. There was no difference between patients who achieved a complete remission (CR) and those who did not (75.2 *vs* 76.1 g/L, p=0.1) or between patients who died within 30 days of starting induction and those alive (74 *vs* 75.3 g/L, p=0.2). There was no statistically significant difference in mean red cell transfusion threshold between patients who had a serious bleeding event and those who did not (74.3 *vs* 75.4 g/L, p=0.06). Younger patients (<56 years, the median cohort age) had a lower transfusion threshold than their older counterparts (≥56 years), however the magnitude of difference was small and unlikely to be clinically significant (74.8 *vs* 75.7 g/L, p=0.03).

Table 1.

Baseline characteristics, transfusion data, and outcomes

Characteristic (n=168)	Value
Median age, years (range)	56 (18 - 77)
Male sex (%)	95 (57%)
De novo AML (%)	150 (89%)
3+7 based induction	144 (86%)
Median admission duration, days (range)	32 (2 - 56)
Median Hgb threshold, g/L (range)	76 (64 – 86)
Median RBC units per pt (range)	10 (0 - 47)
Median Plt doses per pt (range)	7 (0 - 40)
CR* (%)	128 (76%)
30-day mortality (%)	13 (8%)
WHO grade 3-4 bleeding (%)	26 (15%)
Myocardial infarction (%)	3 (2%)
Heart Failure (%)	11 (7%)
VTE (%)	16 (10%)

*Complete remission (CR) = CR or Cri

Summary and Conclusions: In this single-centre retrospective analysis of patients with newly diagnosed AML admitted for induction chemotherapy, there were no significant differences in the mean red cell transfusion thresholds between patients who experienced severe bleeding, MI, HF, or VTE and those who did not. There was also no difference between patients who did and did not achieve CR or suffer 30-day mortality. Our results suggest that a restrictive red cell transfusion threshold is safe.

PF793

DEVELOPMENT OF HUMANIZED MOUSE MODELS TO EVALUATE AND PREVENT MOTHER-TO-CHILD HTLV-1 TRANSMISSIONS

T. Mizukami[1,*], K. Nojima[1], E. Sasaki[1], Y. Hiradate[1], K. Furuhata[1], Y. Sato[1], S. Matsuoka[1], K. Okuma[1], M. Satake[2], H. Akari[3], K. Uchimaru[4], I. Hamaguchi[1]

[1]Department of Safety Research on Blood and Biologicals, National Institute of Infectious Diseases, [2]Central Blood Institute, Japanese Red Cross, Tokyo, [3]Primate Research Institute, Institute for Virus Research, Kyoto University, Kyoto, [4]Department of Computational Biology and Medical Sciences, Graduate School of Frontier Sciences, The Institute of Medical Science, The University of Tokyo, Tokyo, Japan

Background: Human T-cell leukemia virus type 1 (HTLV-1) is a retrovirus that infects mature T cells and causes adult T-cell leukemia (ATL) and a chronic inflammatory central nervous system disease called HTLV-1-associated myelopathy/tropical spastic paraparesis (HAM/TSP). HTLV-1 transmissions in children mainly occur via the breast milk of HTLV-1(+) carrier mothers. Thus, avoiding long term breastfeeding (over 3 months) is recommended in the endemic areas of Japan. This political decision resulted in a drastic decrease in new HTLV-1 infections; however, new infections (5-8%) continued to occur even when HTLV-1(+) carrier mothers bottle fed infants. This suggested the possible involvement of alternative HTLV-1 transmission routes, such as placental or birth canal transmission. However, the transmission route most important to HTLV-1 vertical infection is still unknown.
Aims: In this study, we developed a humanized mouse model to evaluate HTLV-1 transmission mechanisms and to provide a platform that prevented mother-to-child transmissions.
Methods: NOD/SCID/gammac(null) (NOG) pregnant mice were intraperitoneally injected with human PBMCs before being transplanted into a mitomycin C-treated HTLV-1-infected cell line (MT-2).
Results: Although no HTLV-1-infected T cells were detected in the peripheral blood of newborn mice at day 30, HTLV-1-infected cells were exclusively observed in the liver tissues via FACS and PCR. To evaluate the importance of HTLV-1 infections via breastfeeding or before birth, we designed a study that switched HTLV-1-infected carrier mother (CM) mice with non-infected healthy mother (HM) mice. After switching, CM mice were maintained with HM mice pups (potentially HTLV-1(-)), and HM mice were maintained with CM mice pups (potentially HTLV-1(+)). This switching at birth resulted

in 30% of the potentially HTLV-1(-) pups becoming HTLV-1(+) since they were breastfed by an HTLV-1(+) mother. Similarly, 30% of the potentially HTLV-1(+) pups were HTLV-1(+) at 40 days after switching as they were breastfed by an HTLV-1(-) mother. These results suggested that both breast-feeding and canal or placental transmissions demonstrated equal risks with respect to HTLV-1 infections. Currently, we are trying to evaluate the efficacy of our anti-HTLV-1 immunoglobulin usage in this model.
Summary and Conclusions: In this study, we successfully developed the new humanized mouse models of mother-to-child HTLV-1 Transmissions. This model will provide platform to evaluate the mechanism of mother-to child HTLV-1 transmission and prevention.

PF794

A DESCRIPTIVE STUDY OF TRANSFUSION-RELATED ACUTE LUNG INJURY (TRALI) IN THE CANARY ISLANDS

C. Acosta Fleitas[1,*], L.M. Guerra Domínguez[1], L.M. González del Castillo[1], S. Fumero Guersi[2], R. López Hernández[3], A. Geijo Rodríguez[1], J. López Brito[1], P. Pecos Dorta[4], T. Marrero Quintana[5], E. Herrero[5], A. Oliva[6], T. Molero Labarta[1]

[1]Hematology, Hospital Universitario de Gran Canaria Doctor Negrín, [2]Hematology, Instituto Canario de Hemodonación y Hemoterapia, [3]Inmunology., Hospital Universitario de Gran Canaria Doctor Negrín, Las Palmas de Gran Canaria, [4]Hematology, Hospital Universitario de Canarias, Tenerife, [5]Hematology, Complejo Hospitalario Insular Materno Infantil, Las Palmas de Gran Canaria, [6]Hematology, Hospital Nuestra Señora de la Candelaria, Tenerife, Spain

Background: TRALI is a very relevant, but frequently infradiagnosed complication, that can result in potentially fatal consequences derived from blood-transfusion. It is associated with the presence of anti-leucocyte antibodies in the donor's plasma.
Aims: Hemovigilance programs have helped us establish more precisely its incidence, and whatsmore, they have opened the way to the development of preventive measures. The exclusive use of male plasma for transfusional purpose has shown its efficacy in reducing the incidence, even though it has not eliminated the diagnosed cases.
Methods: A review of the clinical history was performed. TRALI-cases taken place in Canarias between 2008-2016 were communicated. Luminex technology was used for the immunological study (Table 1).
Results: Demographic data were available for only 23 out of the 28 communicated cases. There were 12 male patients and 11 female. The age interval went from the neonatal period up to 97 years old, being 60 the median of the sample. The patients' diagnoses were heterogeneous, being mostly patients that had recently undergone surgery (10 cases), had an active infectious disease (7), or were suffering from a hematological condition (5). 89% cases presented a clinical and radiological presentation that was compatible with TRALI, with a severity of 2 and an imputability of 2-3 in 66% cases. 64% of the blood components that were related with TRALI were RBCs. When performed the determination of antiHLA and antiHNA antibodies in affected recipients, it was observed that only 6 of them had completed the study (31%), obtaining a positive result in at least one of them, being able to demonstrate a 100% "antigen-antibody" correlation with the involved donors. In Canarias, it has been possible to demonstrate the implication of 76 donors in various cases of TRALI, being able to complete the study in just 37 of them (49%), with a positive antiHLA and/or antiHNA result in 6 of them (25%) (Table 1).

Table 1.

Age	Gender	Diagnosis	Blood component	Severity / Imputability	Donor studied? (anti-HLA and/or HNA)	Recipient studied? (anti-HLA and/or HNA)
0	M	Respiratory distress	RBC	2/3	Negative	ND
69	F	MDS	RBC	2/3	Positive result	Anti-HLA I & II
ND	ND	Colitis	ND	2/3	Positive result	Anti-HLA II & Anti-HNA3
77	M	Tetraplegia	RBC	2/3	Anti-HNA3 & anti-HNA4	Negative
66	M	Renal cancer	RBC	2/2	Anti-HNA4 positive	Negative
80s	M	Cardiac surgery	RBC	2/3	Positive result	Anti-HLA II
30	M	Renal cancer	RBC	2/3	NO	NO
ND	ND	Cardiac surgery	RBC	2/3	Positive result	Anti-HNA3c
61	F	Cholecystectomy	RBC	2/3	NO	NO
67	M	Unstable angina	RBC	2/2	Anti-HLA II	No
ND	ND	Sepsis	ND	2/2	Negative	No
76	M	Burn oil	RBC	2/3	Negative	Negative
42	M	AML	RBC	2/3	Negative	Negative
75	F	Colon cancer	RBC	2/2	NO	No
ND	ND	Kidney donor	RBC	2/2	Negative	Negative
77	M	Aortic aneurysm	RBC	2/2	Anti-HNA3A & Anti-HNA3B	No
44	M	Abdominal sepsis	RBC	2/2	NO	Negative
60	M	Splenectomy	Platelets	2/2	Anti-HLA II & Anti-HNA3	Negative
ND	ND	Renal failure	ND	2/2	NO	No
47	F	Septic shock	FFP	2/3	Negative	Negative
57	F	Hip fracture	RBC	2/3	Positive result	Anti-HLA II
72	F	Peritonitis	RBC	2/2	Negative	Negative
56	F	MDS	Platelets	2/2	Negative	Negative
17	F	Tetraplegia	RBC	2/3	Negative	No
36	M	TTP	Plasma	2/3	Not considered	Negative
80	F	Colon cancer	RBC	2/3	Not considered	Negative
68	M	Brain aneurysm	RBC	2/3	Anti-HLA I & II	Negative
69	F	MDS	Platelets	2/3	Positive result	Anti-HLA I & II

Summary and Conclusions: TRALI's incidence in Canarias is 0.003%. The fact that most of the cases were communicated by HUDGCDN could be justified not only by the creation of a multidisciplinary formation program based on this matter, via the Hospital Transfusion Committee, but also due to the qualified nursing staff assigned to hemovigilance tasks. Independently of the severity of the case, 89% patients evolved favorably. 31% of the studied recipients presented antiHLA antibodies, with a 100% correlation with respect to donors-HLA-antigens. We could also establish, in case of donors carrying antiHLA/antiHNA antibodies, a 100% "antigen-antibody" correlation in relation to affected recipients. In spite of the study's limitation (as we could only analyze 49% implied donors), this study has led us identify the presence of anti-leucocyte antibodies in 6 frequent donors, finding that has led to their definite exclusion from the donation program as a preventive measure. Because of this, we have come to the conclusion that it is extremely important to establish training programs on this matter, as well as pursue an active formation in Hemovigilance and screen recipients at risk.

PF795

DYE-LIGANDS AFFINITY CHROMATOGRAPHY IN PROCESS OF FACTOR VIII PURIFICATION

N. Shurko[1,*], T. Danysh[1], V. Novak[1]

[1]State Institution «Institute of Blood Pathology and Transfusion Medicine NAMS of Ukraine», Lviv, Ukraine

Background: Industrial chromatographic fractionations have been used increasingly in the last few years for plasma fractionation. This has led to the emergence of a new generation of products derived of blood, especially factor coagulation. The commercial concentrates of factor VIII (FVIII) are used for the treatment of Hemophilia A. The main method of obtaining of plasma concentrates of FVIII remains the method of ion-exchange chromatography. The active dyes are important alternatives to natural ligands for specific affinity chromatography. We have developed a method for obtaining of FVIII by using dye-ligand affinity chromatography.
Aims: describe the main properties of FVIII concentrate obtained by a combination of different methods of purification.
Methods: Precipitation of proteins, ion-exchange on DEAE-Sepharose, dye-ligands affinity chromatography.
Results: To create a scheme for obtaining a highly purified preparation of the blood coagulation factor VIII from blood plasma, the research was conducted on combinations of the pre-fractionation method with the method of negative affinity sorption. It was determined that the pre-fractionation with barium citrate, aluminum hydroxide (III), and PEG-4000, provides removal of factors of prothrombin complex, fibrinogen, fibronectin, lipoproteins, denatured proteins, albumin etc. At this stage, we have reached hundredfold purification of the factor VIII preparation (for example, from 0.017±0.001 IU/mg protein to 1.88±0.11 IU/mg protein for sorbent Diasorb-Active purple 4GT). It has also been demonstrated that the use of ion-exchange chromatography on DEAE-Sepharose and affinity chromatography on selected sorbents (Diasorb-Active purple 4GT, Diasorb-Procion Gelb M4R, Diasorb-Procion Blue HB, Diasorb-Procion Blue MXR and Diasorb-Active bright blue KX) allows obtaining factor VIII from Cryoprecipitate with a degree of purification of 129 to 242 times and preservation of up to 73-76% of the initial procoagulant activity. The main losses from the initial activity of factor VIII and the von Willebrand's factor (up to 27%) occurred at the stage of ion-exchange chromatography.The phenomenon of negative affinity sorption provides almost 100.0% (96.34%) yield of the product. This is significant advantage of this method in the technology of obtaining a purified preparation of the coagulation factor VIII. It has been found that the combination of pre-fractionation, ion-exchange and affinity chromatography stages provides a purification rate of 239–700 times, depending on the type of selected sorbents. The best result was achieved when using Diasorb-Active purple 4GT.
Summary and Conclusions: The proposed method of purification of the blood coagulation FVIII, combining the stages of pre-fractionation, ion-exchange and affinity chromatography. A concentrate of FVIII with a specific activity of 50.58±1.68 IU/mg protein, vWF:R_{cof} – 3.07±0.18 IU/ml, FVIII/vWF:R_{cof} – 1.73±0.21 was obtained using the suggested method. The activity of thrombin and factor IX, as well as fibrinogen residues in the resulting preparation was not detected.

PF796

TEN YEAR EXPERIENCE OF RED BLOOD CELL TRANSFUSION ADEQUACY INDEX AS PART OF PATIENT BLOOD MANAGEMENT PROGRAM

G.D.C. Duarte[1,2,*], A. Celso Vigorito[1,2], F.J. P. Aranha[1,2], M. Veiga Rodrigues[1,2], J.F.C. Marques Jr[1,2]

[1]Hematology, Vera Cruz Hospital, [2]Hemotherapy, Cellular Hemotherapy Center in Medicine, Campinas, Brazil

Background: Transfusion is a vital and life-saving therapy. To achieve improved patient outcomes by avoiding unnecessary exposure to blood products through effective conservation and management of a patient's own blood, Patient Blood Management (PBM) program have been created. This program aims to promote medical education associated with blood transfusion alternatives in patient care and rationale blood utilization.
Aims: To optimize this task we have been studying the "Red Blood Cell Adequacy Index" since 2008, and this report demonstrate it's value in providing a useful tool for PBM program.
Methods: In our Institution, all transfusion requests are audited by staff physicians and classified as "proper" or "non-proper" based on internationally-adopted guidelines. "Non-proper" requests are then adapted to suit these protocols. From April to October 2008, requests for red blood cells (RBC), were identified that pre-transfusion hemoglobin higher than 9.0 g/dl, and absence of information on hemoglobin levels were associated with a higher likelihood of "non-proper" indication. These two characteristics were then used to calculate the so-called "RBC transfusion adequacy index" (RAI), which represents the proportion of RBC transfused in which any of these two characteristics was present. RAI was monitored prospectively is six different health care institutions of Campinas, Brazil, as a tool from the PBM program, providing information to promote interventions in the Institution practices.
Results: During the first part of the study, 1495 transfusions requests were analyzed, of which 12,9% were classified as "non-proper". In the second part of the study, from January 2008 until December 2017, 101.879 blood units were transfused and the RAI was monitored. The results are shown in Table 1. The data can show that the overall global RAI, assessing the whole six units, have a positive correlation regression value (R^2=0,49), but when each unit individually is evaluated, different realities are shown, with different patterns and tendencies (Table 1). For example, the Unit E shows an improvement in annual RAI and in the SD, unlike Unit A that has worse results in the last two years in both. The acceptable RAI can vary significantly from service to service according to Institutional focus and to local patterns of RBC transfusion. But the real value of the tool is to enable to follow the progress of each Institution during time and measure the efficacy of the PBM program. Another contribution of this tool, is that it makes possible to measure this index in any hierarchic level, *e.g.*, all the hospitals supplied by the blood bank, each hospital unit, a surgery specialty or even a specific physician. Therefore continuous monitoring of the RAI allows one to identify deviations from the established standards, identifying the focus of the deviation and providing information to more accurate interventions, ultimately improving transfusion safety.

Table 1.

Red Blood Cell Adequacy Index						
	Unit A Median ± SD (Monthly Range)	Unit B Median ± SD (Monthly Range)	Unit C Median ± SD (Monthly Range)	Unit D Median ± SD (Monthly Range)	Unit E Median ± SD (Monthly Range)	Unit F Median ± SD (Monthly Range)
2008	82 ± 6,9 (68,5-88,1)	85 ± 3,2 (81,5-93,4)	76,8 ± 6,2 (65,9-86,5)	*	85 ± 12,8 (66,67-100)	92 ± 12,3 (75-100)
2009	79,6 ± 5,9 (71,6-87,3)	91,7 ± 3,5 (85,4-96,7)	80,6 ± 6,2 (71,2-89,3)	*	84,9 ± 8,7 (70,6-100)	91,4 ± 8,6 (73,0-100)
2010	85,6 ± 5,6 (78,2-96,8)	89,6 ± 3,5 (82,6-93,8)	70,3 ± 7,4 (56,9-79,7)	*	90,7 ± 13,1 (60-100)	87,6± 6,9 (76-100)
2011	84,7 ± 5,2 (75,1-90,9)	90,5 ± 4,0 (84,3-94,7)	75,5 ± 5,0 (76,2-86,2)	*	85 ± 11 (53,8-100)	86,6 ± 3,9 (82,5-95,5)
2012	82,8 ± 5,7 (70,6-88,0)	87,0± 4,6 (77,9-95,2)	71,1 ± 6,9 (58,1-85,5)	*	69,6 ± 12,3 (56,2-93,1)	92,7 ± 4,6 (80,4-98,4)
2013	83,3 ± 7,1 (73,9-81,5)	92,0 ± 3,0 (85,0-92,1)	79,0 ± 5,0 (73,3-83,3)	*	91,6 ± 6,3 (78,1-100)	90,9 ± 6,2 (79,5-100)
2014	83,2 ± 5,5 (71,6-91,4)	92,2 ± 2,7 (89,7-98,1)	74,6 ± 1,3 (73,3-75,9)	*	89,4 ± 4,8 (79,7-96,3)	90,7 ± 9,4 (76,9-100)
2015	84,9 ± 7,8 (72,7-91,4)	88,3 ± 5,2 (78,9-97,0)	*	88,0 ± 5,2 (86,2-97,3)	87,9 ± 4,4 (81,1-94,3)	74,1 ± 12,9 (57,6-90)
2016	79,8 ± 6,3 (70,1-89,9)	92 ± 3,6 (83,9-95,1)	*	82,9 ± 10,2 (59,2-100)	89,9 ± 6,1 (75,7-95,4)	82,3 ± 4,5 (74-88,3)
2017	79,3 ± 7,6 (70,4-90,5)	85,7 ± 4,5 (76,2-94)	*	85,4 ± 8,2 (70,7-100)	85,1 ± 6,7 (71,7-92)	85,9 ± 5,7 (74-94,8)

Table 1. Red Blood Cell Adequacy Index per year, in each of the health units. *Indicates the period that the blood bank didn't supplied blood for that specific health unit. Median ± Standart deviation (Monthly RAI)

Summary and Conclusions: The optimal management of blood transfusion and patient related risks are an on course task. The RAI as part of a PBM programs can be a helpful tool in this process.

PF797

A 3-PART DIFF POCT CELL ANALYZER AT THE HEMATO-ONCOLOGY WARD FOR CLINICAL DECISION MAKING OF PLATELET TRANSFUSION AND CHEMOTHERAPY

N. Van den Eede[1,*], M.-B. Maes[1], R. Malfait[1], J. Van den Bossche[1], K. Deiteren[1]

[1]Laboratory of Hematology, UZA, Edegem, Belgium

Background: In our hospital a 3-part DIFF ABX Micros ES60 analyzer (Horiba, Kyoto, Japan) is used for screening of the patients' peripheral blood in follow up of their therapy at the hemato-oncology ward. The measurements are made by well-educated nurses. Clinical decisions such as platelet transfusion and start/stop of chemotherapy are based on the platelet count (PLT) and absolute neutrophil count (ABNEU) respectively of the POCT device.
Aims: In this study we compared the PLT and ABNEU POCT results with the 5-part DIFF ADVIA 2120 (Siemens, Munic, Germany) and Sysmex XN-1000 (Sysmex, Kobe, Japan) analyzers of the laboratory and we evaluated how many transfusions were not given or given erroneously based on a PLT threshold of 20x10E9/L or 10x10E9/L. At last we evaluated how many times the absolute neutrophil count was (in)correctly <0.5x10E9/L.
Methods: A 5 ml EDTA blood tube (BD) was analyzed for a complete blood count and differentiation on a POCT ABX Micros ES60 by a nurse at the hematology-oncology ward. Afterwards the tube was sent to the laboratory for reanalysis on the Advia 2120 and/or Sysmex XN-1000.
Results: A total of 20470 samples were analyzed using the POCT device during 2017. Investigation of unnecessary transfusion of platelet units showed that this occurred in ≤0,05% of samples (threshold ≤20 x10E9/L) or ≤0,02% (threshold ≤10 x10E9/L). In 0,6% or 0,4% of samples platelet transfusion was not given because PLT were >20 x10E9/L with POCT and ≤20 x10E9/L using Advia or Sysmex, respectively. When the threshold was lowered to 10 x10E9/L this number was reduced to 0,3%. A very small number of samples falsely indicated severe neutropenia (ABNEU <0.5x10E9/L) (0,03% and 0,06% in comparison with ADVIA and Sysmex, respectively). This observation may have resulted in unnecessary cessation of chemotherapy. In contrast, severe neutropenia was not detected using POCT in 0,6% and 0,3% of samples in comparison with ADVIA and Sysmex, respectively.
Summary and Conclusions: Only a minimum of cases were found discrepant for low platelet and absolute neutrophil count between POCT and high throughput hematoloy analysers Advia and Sysmex. We conclude that a small and easy-to-use 3-DIFF POCT device is a useful tool for obtaining fast and accurate results appropriate for clinical decision making of platelet transfusion or chemotherapy at the hemato-oncology ward.

PF798

EVALUATION OF OXYGEN TRANSPORT OF BLOOD IN PATIENTS WITH ANEMIA ON THE BACKGROUND OF THE RED BLOOD CELLS TRANSFUSIONS

N. Romanenko[1,*], A. Chechetkin[2], G. Grishina[3]

[1]Clinical Hematology, [2]Transfusiology, [3]Experemental Transfusiology, Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Anemia frequently decreases survival rate and overall Quality-of- life in patients with hematological malignancies (HM). Red blood cell transfusions (RBCTs) can quickly correct severe symptoms of anemia, increase hemoglobin (Hb) and improve oxygen transport of blood.
Aims: To study efficacy of RBCTs in anemic patients with anemia before and after RBC transfusions.
Methods: The first group included patients (n=28) with hematological malignancies (acute myeloid leukemia (n=7), primary myelophibrosis (n=2), chronic myeloid leukemia (n=4), MDS (n=4), multiple myeloma in II and III st. (n=7), Non-Hodgkin's lymphoma in III-IV st. (n=4)), aged 65 years. The second group included patients with massive hemorrhage of traumatic genesis (n=12) at the age of 36 years. The indication for RBCTs was anemia with a hemoglobin level <8.0 g/dl, hematocrit <25%, target Hb was >8.0 g/dl in every groups. The efficiency of RBCTs was estimated as reduce clinical symptoms of anemia, increase concentration of hemoglobin and hematocrit, as well as to increase the saturation of venous blood (SvO_2).

Results: Mean baseline Hb concentration in our patients was <8.0 g/dl. During the hospitalization period were transfused 1-8 (Me=2 units) in both groups. There were revealed increasing of hemoglobin concentration and hematocrit: in the 1st group the Hb concentration increased from 6.41±0.27 g/dl to 9.02±0.17 g/dl, Ht – from 20.1±0.8% to 28.9±0.7%; in the second group the Hb concentration increased from 6.59±0.30 g/dl to 8.83±0.32 g/dl, Ht increased from 19.6±0.9% to 26.7±1.4%. Also observed an increasing of SvO_2: in the first group – from 42.0±3.3% to 57.6±4.1%; in the second group – from 51.3±1.9% to 69.0±1.3%. However, to compare of the frequency of achieving SvO_2 ≥60% in the 1st group was observed in 67.9% of patients after RBCTs, in the second group was in all (100%) patients. These data indicate that after RBCTs 32.1% of patients with hematological malignancies may persist tissue's hypoxia, despite the achievement of Hb >8.0 g/dl, Ht >25%.

Summary and Conclusions: In this study were shown the importance to access the saturation of venous blood in anemic patients, and in cases low SvO_2 (<60%) the patients should be continued RBCTs to increase of Hb concentrations to 9.5-10.0 g/dl, Ht to 33%.

Background: Tisagenlecleucel is a chimeric antigen receptor (CAR) T-cell therapy with a high rate of durable complete responses and a manageable safety profile in adult patients (pts) with R/R DLBCL.
Aims: To report long-term follow up of safety and efficacy in a single-arm, open-label, global phase 2 trial of tisagenlecleucel in pts ≥18 y with R/R DLBCL (JULIET; NCT02445248).
Methods: Eligible pts had r/r DLBCL, received ≥2 lines of therapy, including rituximab and anthracycline, and were ineligible for/failed autologous stem cell transplant (ASCT). Centrally manufactured CAR T cells were provided using cryopreserved apheresis and a global supply chain. The primary endpoint was best ORR (CR + PR) per independent review committee. Efficacy results are reported for pts in the main cohort with ≥3 mo follow-up or earlier discontinuation; safety is reported for all infused pts.
Results: At data cutoff (8 Dec 2017), 165 pts were enrolled and 111 infused (95 with US-manufactured [main cohort] and 16 with EU-manufactured [cohort A] tisagenlecleucel) with a single dose of tisagenlecleucel (median, 3.0×10^8 [range, $0.1\text{-}6.0\times10^8$] cells). 92% of pts received bridging therapy and 93% received lymphodepleting chemotherapy. Median time from infusion to data cutoff, 13.9 mo. Median age, 56 y (range, 22-76; 23% >65 y). At study entry, 76% of infused pts had stage III/IV disease, 17% had double/triple hits in MYC/BCL2/BCL6. 57% had germinal center B-cell; 41% had activated B-cell molecular subtypes. Median number of prior lines of antineoplastic therapy, 3 (range, 1-6; 95% had ≥2); 49% had prior ASCT. 93 pts had ≥3 mo and 81 pts had ≥12 mo of follow-up or discontinued earlier and were evaluable for efficacy. Best ORR was 52% (95% CI, 41-62) with 40% CR and 12% PR. Response rates were consistent across prognostic subgroups (including prior ASCT and double-hit lymphoma). Median duration of response was not reached; the 12-mo probability of being relapse-free was 65% (95% CI, 49-78; max follow-up, 17.3 mo). Median OS among all infused pts was 11.7 mo (95% CI, 6.6-NE); OS probability at mo 12, 49% (95% CI, 38.5-59). No pts proceeded to allo/ASCT while in remission. Tisagenlecleucel was detected in peripheral blood by qPCR for ≤693 days in responders. Grade (G)3 or 4 AEs of special interest ≤8 weeks of infusion included cytokine release syndrome (CRS; 14% G3 and 8% G4 by the Penn grading scale and managed by a protocol-specific algorithm), neurologic AEs (12%, managed with supportive care; no cases of cerebral edema were observed), cytopenias lasting >28 days (32%), infections (20%), and febrile neutropenia (14%). 15% received tocilizumab for CRS management. 3 pts died ≤30 days of infusion (all disease progression). No deaths were attributed to tisagenlecleucel or CRS. Since previous reports, no new deaths occurred due to causes other than disease progression. Analyses to better characterize and predict severe CRS, including relationships with baseline clinical/laboratory parameters, cytokines, dose, cellular kinetics and neurologic events will be presented.
Summary/Conclusion: Tisagenlecleucel produces high response rates in a cohort of highly pretreated adult pts with r/r DLBCL. With longer follow-up, these results confirm findings of an earlier primary analysis and show prolonged durable responses can be achieved. Centralized manufacturing was feasible in the first global study of CAR T cell therapy in DLBCL. CRS and other AEs could be effectively and reproducibly managed by appropriately trained investigators without treatment-related mortality.

S800

UPDATED SAFETY & LONG TERM CLINICAL OUTCOMES IN TRANSCEND NHL 001, PIVOTAL TRIAL OF LISOCABTAGENE MARALEUCEL (JCAR017) IN R/R AGGRESSIVE NHL

J. Abramson[1,*], L. Gordon[2], M. L. Palomba[3], M. Lunning[4], J. Arnason[5], A. Forero-Torres[6], M. Wang[7], D. Maloney[8], A. Sehgal[9], C. Andreadis[10], E. Purev[11], S. Solomon[12], N. Ghosh[13], T. Albertson[14], B. Xie[14], J. Garcia[14], T. Siddiqi[15]

[1]Massachusetts General Hospital, Boston, [2]Northwestern University Feinberg School of Medicine, Chicago, [3]Memorial Sloan-Kettering Cancer Center, New York, [4]University of Nebraska Medical Center, Omaha, [5]Beth Israel Deaconess Medical Center, Boston, [6]University of Alabama at Birmingham, Birmingham, [7]MD Anderson Cancer Center, Houston, [8]Fred Hutchinson Cancer Research Center, Seattle, [9]University of Pittsburgh Medical Center, Pittsburgh, [10]University of California San Francisco, San Francisco, [11]University of Colorado School of Medicine, Denver, [12]Blood and Marrow Transplant Group of Georgia, Atlanta, [13]Carolinas Healthcare Group Levine Cancer Institute, Charlotte, [14]Juno Therapeutics, Inc., Seattle, [15]City of Hope National Medical Center, Duarte, United States

Background: Lisocabtagene maraleucel (liso-cel; JCAR017) is a CD19-directed 4-1BB CAR T cell product administered in defined composition at a precise dose of CD8 and CD4 CAR T cells. A multicenter, seamless design pivotal phase 1 trial of liso-cel in R/R B-NHL (NCT02631044) has enrolled.
Aims: Long-term follow up of the initial cohort is presented herein.
Methods: Pts with R/R DLBCL, PMBCL, FL3B, or MCL and adequate organ function are eligible. Treatment includes lymphodepletion with fludarabine and cyclophosphamide, followed by liso-cel. Multiple dose levels (DLs) and administration schedules were evaluated; DL2 (10^8 CAR T cells) was chosen for the pivotal cohort. The FULL dataset includes all pts in the initial DLBCL cohort (DLBCL NOS, PMBCL, FL3B) treated with liso-cel at all DLs; CORE dataset includes only pts meeting inclusion criteria for the pivotal cohort, including DLBCL NOS (*de novo* or transformed from FL) and high grade lymphoma. Study objectives include safety, PK, and antitumor response.
Results: As of Oct 9, 2017, 91 pts were treated and evaluable for safety, 88 for efficacy. Pt characteristics were previously reported(Abramson ASH 2017). CRS was seen in 35% of pts; a single pt (1%) developed grade 3-4 CRS. Neurotoxicity (NT) developed in 19% of pts including 12% grade 3-4; all but one event resolved at time of data snapshot. Median onset of CRS and NT was 5 and 10 days respectively. Nineteen pts (21%) received tocilizumab and/or dexamethasone. Long term safety, including B cell aplasia, infections, and cytopenias, will be reported. Best ORR in FULL and CORE was 74% (65/88) and 80% (52/65), respectively; best CR was 52% (46/88) in FULL and 55% (36/65) in CORE. A higher rate of durable response at DL2 was observed in the CORE population, with 6-month ORR and CR of 50% and 50% (7/14), vs 40% (8/20) and 30% (6/20) at DL1. Long term efficacy, including 6-/12-month follow up from ~95/~55 pts, will be reported.
Summary/Conclusion: Liso-cel shows durable responses in pts with heavily pretreated R/R DLBCL and trends toward more durable responses at DL2. Observed acute toxicities have been manageable at all DLs tested and long-term safety from the initial cohort will be reported.

S801

AXICABTAGENE CILOLEUCEL (AXI-CEL) IN PATIENTS WITH REFRACTORY LARGE B CELL LYMPHOMA: OUTCOMES BY PRIOR LINES OF THERAPY IN ZUMA-1

F.L. Locke[1], A. Ghobadi[2], L.J. Lekakis[3], D. B. Miklos[4], C.A. Jacobson[5], E. Jacobsen[5], I. Braunschweig[6], O. O. Oluwole[7,*], T. Siddiqi[8], Y. Lin[9], P. Reagan[10], U. Farooq[11], A. Deol[12], A. Bot[13], J.M. Rossi[13], Y. Jiang[13], A. Xue[13], W.Y. Go[13], S.S. Neelapu[14]

[1]Moffitt Cancer Center, Tampa, [2]Washington University School of Medicine, St. Louis, [3]University of Miami Health System, Sylvester Comprehensive Care Center, Miami, [4]Stanford University, Stanford, [5]Dana-Farber Cancer Institute, Boston, [6]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, [7]Vanderbilt-Ingram Cancer Center, Nashville, [8]City of Hope National Medical Center, Duarte, [9]Mayo Clinic, [10]University of Rochester School of Medicine, Rochester, [11]University of Iowa, Iowa City, [12]Karmanos Cancer Center, Wayne State University, Detroit, [13]Kite, a Gilead company, Santa Monica, [14]The University of Texas MD Anderson Cancer Center, Houston, United States

Background: In ZUMA-1 (NCT02348216), axi-cel, an anti-CD19 chimeric antigen receptor (CAR) T cell therapy, demonstrated significant benefit in patients with refractory large B cell lymphoma with an objective response rate (ORR) of 82% (complete response [CR] 58%; Neelapu & Locke et al. *N Engl J Med.* 2017). These results supported the recent approval of axi-cel by the US FDA for the treatment of adult patients with relapsed or refractory large B cell lymphoma after ≥ 2 prior lines of systemic therapy.
Aims: To assess outcomes of axi-cel by prior lines of therapy (LoT) in patients from Phases 1 and 2 of ZUMA-1.
Methods: All patients provided written informed consent. Patients with refractory large B cell lymphoma were leukapheresed and received 2×10^6 CAR T cells/kg after low-dose conditioning chemotherapy (Neelapu & Locke et al. *N Engl J Med.* 2017). Patients were evaluated by number of prior LoT: 2–3 vs ≥ 4. Autologous stem cell transplant (ASCT) was considered a prior LoT.
Results: As of 8/11/17, median follow-up was 15.4 months for the 108 patients treated with axi-cel. Sixty-two (57%) patients had 2–3 prior LoT and 43 (40%) had ≥ 4. Patients with 2–3 and ≥ 4 prior LoT had median ages of 60 and 55 y, 65% and 47% of patients had ECOG performance status 1, 18% and 42% had prior ASCT, and 76% and 93% had disease stage III/IV, respectively. ORRs were 94% and 67% for patients with 2–3 and ≥ 4 prior LoT, respectively, with CR rates of 65% and 53%; 44% and 42% of patients had ongoing responses as of the data cutoff (Table 1). Overall survival (OS) at 12 months was 65% and 51% for patients with 2–3 and ≥ 4 prior LoT, respectively. Grade ≥ 3 treatment-emergent adverse events (AEs) were reported for nearly all (100% and 93%) patients with 2–3 and ≥ 4 LoT, with similar rates of Grade ≥ 3 cytokine release syndrome (11% and 12%) and neurologic events (32% and 30%). There were 1 and 3 Grade 5 AEs unrelated to disease progression in the 2–3 and ≥ 4 LoT groups, respectively.

Table 1.

Response, % (95% CI)	LoT 2 – 3 (n = 62)	LoT ≥ 4 (n = 43)
ORR	94 (84 – 98)	67 (51 – 81)
CR rate	65 (51 – 76)	53 (38 – 69)
Ongoing ORR	44 (31 – 57)	42 (27 – 58)
6-month PFS[a]	49 (36 – 61)	51 (35 – 65)
12-month OS[a]	65 (51 – 75)	51 (35 – 65)

[a]Kaplan-Meier estimate.

Summary/Conclusion: Axi-cel demonstrated long-term clinical benefit for patients with refractory large B cell lymphoma, regardless of the number of prior LoT.

S802

ADDING POLATUZUMAB VEDOTIN (POLA) TO BENDAMUSTINE AND RITUXIMAB (BR) TREATMENT IMPROVES SURVIVAL IN PATIENTS WITH RELAPSED/REFRACTORY DLBCL: RESULTS OF A PHASE 2 CLINICAL TRIAL

This abstract is embargoed until Saturday, June 16, 08:30 local time.

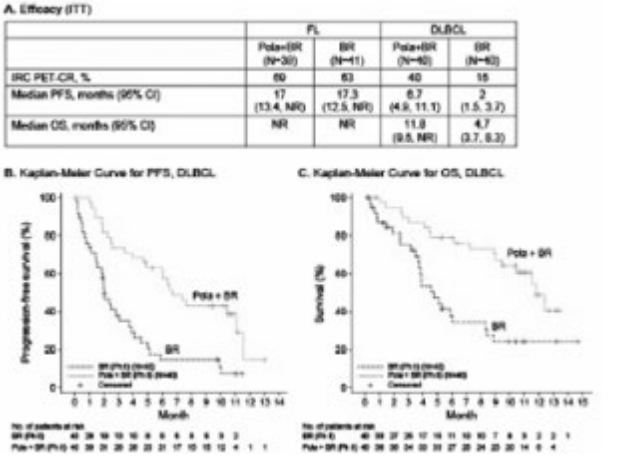
Background: Pola is an antibody-drug conjugate targeting CD79b+ cells in B-NHL. Early results led to FDA breakthrough therapy status and EMA PRIME designation. We now report combined results for safety and efficacy from the randomized r/r FL and DLBCL cohorts of a phase 1b/2 study (ClinicalTrials.gov NCT02257567).
Aims: The primary objective is complete response rate by PET scan (PET-CR) 6-8 weeks after end of treatment by independent review committee (IRC) using modified Lugano criteria (PET-CR required PET score 1-3 and negative bone marrow if positive at screening).
Methods: After informed consent was obtained, 80 FL and 80 DLBCL transplant-ineligible patients (pts) were randomized 1:1 to pola 1.8 mg/kg + BR (B: 90mg/m^{2}x 2 days; R: 375mg/m^2) or BR for 6 cycles (q28 days FL, q21 days DLBCL). Pts were stratified by duration of response to last treatment ≤12 mo or >12 mo. FL pts were also stratified by high vs low disease burden.
Results: For FL pts (pola+BR *vs* BR), median age was 65 *vs* 63 years, both arms had median 2 prior therapies, 41% *vs* 42% were refractory to last therapy, and 64% *vs* 37% had FLIPI 3–5. As of 24 Oct 17, median follow up was 15 months. DLBCL characteristics and follow up were previously described (Sehn, ASH 2017). Safety: The most common grade 3–5 adverse events (AEs) that were higher in pola+BR *vs* BR in both FL and DLBCL were cytopenias, febrile neutropenia, and infections. Serious AEs higher in pola+BR *vs* BR were febrile neutropenia (FL, DLBCL) and infection (FL). Grade 5 AE rates were similar between treatment arms per histology: 5% (FL) and 18% (DLBCL). Efficacy: PET-CR by IRC and progression-free survival (PFS) by investigator (INV) were similar between FL arms (Figure 1 A). In DLBCL, pola+BR showed significantly higher IRC-PET-CR rates (p=0.012) and longer median (m) INV-PFS (p<0.0001) and overall survival (mOS; p=0.0008) (Figure 1 A,B,C). Also in DLBCL, longer PFS and OS were seen for pola+BR in 2nd-line (2L), 3rd-line plus (3L+), relapsed, and refractory pts. mPFS (pola+BR *vs* BR in months): 2L (11.1 *vs* 3.7), 3L+ (6.0 *vs* 2.0), relapsed (11.1 *vs* 5.1), refractory (6.0 *vs* 1.9). mOS: 2L (not reached [NR] *vs* 5.9), 3L+ (11.5 *vs* 3.8), relapsed (NR, NR), refractory (11.5 *vs* 3.8).

Figure 1.



Summary/Conclusion: The toxicity of pola+BR was manageable and as expected. In FL, pola+BR showed similar PET-CR rate compared to BR. Time-to-event endpoints are immature at this time due to low event rate. In contrast, in DLBCL, pola+BR led to significantly higher PET-CR rate and notably longer PFS and OS compared to BR regardless of prior treatment status.

S803

ATEZOLIZUMAB PLUS R-CHOP SHOWS ENCOURAGING ACTIVITY AND ACCEPTABLE TOXICITY IN PREVIOUSLY UNTREATED PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL): AN INTERIM ANALYSIS OF A PHASE I/II STUDY

Hoffmann-La Roche Ltd, Basel, Switzerland, [16]Willamette Valley Cancer Institute, Eugene, Oregon, United States

Background: Rituximab (R) plus CHOP (R-CHOP) is standard of care for pts with previously untreated DLBCL. Although most pts have long-term responses, up to 40% relapse or fail to achieve a remission. Atezolizumab (atezo) is a fully humanised anti-programmed death-ligand 1 (PD-L1) antibody with a complementary mechanism of action to R. An ongoing phase I/II study (NCT02596971) is evaluating the safety and efficacy of atezo in combination with R-CHOP (R-CHOP-atezo) in DLBCL pts. We report interim data.

Aims: To assess the safety and preliminary efficacy of R-CHOP-atezo in previously untreated pts with DLBCL.

Methods: Pts (aged ≥18 years, ECOG PS 0–2) with advanced DLBCL (Ann Arbor stage III/IV, International Prognostic Index [IPI] score ≥2 or stage II with bulky disease [at least one lesion ≥7cm]) received 8 cycles (each 21 days) of induction treatment with R-CHOP-atezo (R 375 mg/m^2 IV on Day 1 [Cycles 1–8], atezo 1200 mg IV on Day 1 [Cycles 2–8], CHOP [6 or 8 cycles as determined by the investigator (INV)]). Pts who achieved a CR at end of induction (EOI) received consolidation treatment with atezo 1200 mg IV on Day 1 of Cycles 9–25, every 21 days for 12 months. The primary endpoints were safety, and efficacy as determined by CR rate at EOI by independent review committee (IRC) using modified Lugano 2014 criteria. Secondary endpoints included CR rate at EOI assessed by INV using modified Lugano 2014, and by IRC and INV using Cheson 2007. An interim analysis was pre-planned after 15 consecutive pts had completed the EOI response assessment. The data cut-off was 20 November 2017.

Results: In total, 42 pts were enrolled and received treatment (safety population). At the time of data cut-off, 20 pts were receiving ongoing induction treatment, 5 had discontinued (3 AEs, 1 protocol violation, 1 withdrawal) and 17 had completed induction, of whom 14 had entered consolidation. Median (range) observation time was 5.3 (0.7–7.2) months for induction and only 1.6 (0.7–5.1) months for consolidation. Therefore, this report focuses on preliminary data from the safety population during induction only. Pt demographics and disease characteristics are shown in Table 1. Among 15 pts evaluable for response (efficacy population), 13 (87%) achieved a CR, and 2 (13%) had PD according to IRC and INV using modified Lugano 2014. Response assessment using Cheson 2007 showed 11 (73%) CRs, 2 (13%) PRs and 2 (13%) pts with PD, consistent between INV and IRC review. Preliminary safety data from induction therapy showed that all pts had ≥1 AE and 27/42 pts (64%) had a grade (gr) 3–4 AE. Regardless of causality, the most common gr 3–4 AEs were neutropenia (16 pts [38%], 6 received G-CSF prophylaxis) and febrile neutropenia (4 pts [9.5%], 3 received G-CSF prophylaxis). No deaths were reported. Serious AEs were reported in 13 pts (31%). AEs led to dose reduction in 8 pts (19%) (gr 4 neutropenia, gr 3 pancytopenia, gr 1–2 peripheral neuropathy) and withdrawal of any component in 3 pts (7%) (gr 3 neutropenia, gr 3 transaminase and asymptomatic lipase increases, gr 2 hyperthyroidism). Three pts had atezo-related AEs (gr 3 lipase and transaminase increases).

Table 1.

Pt demographics and disease characteristics for the safety population (n=42) and the efficacy population (n=15)

Characteristic, n (%)	Safety population (n=42)	Efficacy population (n=15)
Median age (range) at baseline, years	65 (22–84)	65 (31–78)
Age ≥65 years	22 (52)	9 (60)
Male	26 (62)	10 (67)
Ann Arbor stage III/ IV at diagnosis	39 (93)	15 (100)
IPI risk group at baseline		
Low (2)	13 (31)	3 (20)
High (≥3–5)	29 (69)	12 (80)
ECOG PS 0–1 at baseline	37 (88)	14 (93)
Bone marrow involvement at baseline	6 (14)	3 (20)
Extranodal involvement at baseline	30 (73)	11 (73)
LDH elevated at baseline	28 (67)	9 (60)
Bulky disease (≥7 cm) at baseline	26 (62)	7 (47)

Summary/Conclusion: Interim data demonstrate that first-line R-CHOP-atezo shows encouraging efficacy and acceptable toxicity in untreated pts with DLBCL. Updated results, including minimal residual disease and cell of origin data, will be presented.

Combination treatment with targeted agents in CLL

Background: Achievement of CR with undetectable residual disease (uMRD) may be associated with a longer survival in CLL. New therapeutic agents have recently emerged, including new anti-CD20 antibodies and agents targeting BCR signaling.
Aims: We conducted a multicenter phase II trial aimed to explore the efficacy of an induction treatment associating obinutuzumab and ibrutinib, followed by immunochemotherapy only in case of PR or detectable MRD. The primary objective of this study was to obtain 30% of CR (according to IWCLL 2008 guidelines) with uMRD in BM at month 16.
Methods: FIT treatment-naïve patients with active Binet stage A to C CLL and no *TP53* mutation/deletion were eligible if CIRS score was < 7 and ECOG 0 or 1. Induction treatment consisted of 6 courses of obinutuzumab (1000 mg D1, D8, D15 for cycle 1 and D1 for cycles 2 to 6) along with ibrutinib 420 mg daily for 9 months. A first assessment of response was performed at month 9, including CT-scan, bone marrow (BM) biopsy and peripheral blood (PB) and BM MRD testing. Patients in CR with uMRD ($<10^{-4}$, by 8-color cytometry) received ibrutinib alone for 6 additional months whereas the others received 4 courses of fludarabine + cyclophosphamide and obinutuzumab while continuing ibrutinib. Patients with stable or progressive disease were taken off study. Final evaluation of response was performed at Day 1 Month 16.
Results: Between November 2015 and May 2017, 135 planned patients were enrolled including 89 males and 46 females; 7% were Binet stage A, 67% stage B and 26% stage C. The median age was 62 years (range, 35-80 years) and 57% have an unmutated mutational status. Patients with del11q, del13q and trisomy 12 were 20%, 51% and 22% respectively; and 13% had a complex karyotype (>3 abnormalities). A total of 37 serious AEs were observed with 24 related to the treatment. Two patients died during the study at the cut-off date, one sudden death and one of brain hemorrhage due to accidental fall not reliable to therapy. Among the other AE, 57% of the patients have presented, at least one G3-4 toxicity along the 6 cycles. Hematological toxicity was neutropenia (24% G3-4) and mainly during cycle 1 anemia and thrombocytopenia for respectively 6% and 31% of the patients. Infusion Related Reaction (IRR) only occurred during cycle 1 at day 1 for 69.5% of the patients (8% G3). Other significant toxicity was digestive (nausea, vomiting and diarrhea) occurring in 35% of the patients (grade 1 and 2) but only during cycle 1. At Month 9, 92% of the patients had received the 8 planned infusions of obinutuzumab; Ibrutinib dosage was reduced for 4 patients and definitively stopped in 3 out of them due to AE (atrial fibrillation, atrial flutter and neutropenia). One hundred twenty three are evaluable so far for the response at M9. The ORR was 100% with 41% in CR (IWCLL criteria) and 59% in PR. Only 16 patients (12.5%) had uMRD in PB and BM including 9 patients in CR and 7 in PR (2 bone marrow not evaluable but normal CT scan; 5 patients with lymph nodes > 15 mm respectively: 15, 17, 19, 20 and 21).
Summary/Conclusion: These preliminary results indicated that this 9 month « chemo-free » induction is associated with a high CR rate (41%) without excess of toxicity. However, the majority of the patients required subsequent immuno-chemotherapy because of detectable BM MRD.

S805

HIGH, DURABLE MINIMAL RESIDUAL DISEASE (MRD) NEGATIVITY WITH VENETOCLAX + RITUXIMAB IN RELAPSED/REFRACTORY CLL: MRD KINETICS AND RESPONSES IN CYTOGENETIC RISK GROUPS IN PTS FROM PHASE 3 MURANO STUDY

P. Hillmen[1,*], J. F. Seymour[2], A. W. Langerak[3], B. Eichhorst[4], C. Owen[5], S. Assouline[6], A. Janssens[7], P. Marlton[8], X. Badoux[9], R. Mous[10], B. Chyla[11], R. Humerickhouse[11], M. Hoffmann–La Roche, Welwyn Garden City, United Kingdom, [13]Genentech, Inc., South San Francisco, United States, [14]Academic Medical Center Amsterdam, Amsterdam, Netherlands

Background: Improved survival outcomes with chemoimmunotherapy in patients with chronic lymphocytic leukemia (CLL) are associated with minimal residual disease negativity (MRD–; <1 CLL cell in 10,000 leukocytes [$<10^{-4}$]), but the importance of MRD with targeted agents and in the relapsed/refractory (R/R) setting remains unclear, mostly due to low MRD– rates with these agents. In the Phase 3 MURANO study, venetoclax + rituximab (VenR) showed superior PFS (hazard ratio 0.17) and higher peripheral blood (PB) and bone marrow (BM) MRD– vs bendamustine + R (BR) in R/R CLL patients.
Aims: To report MRD kinetics (percent of patients achieving MRD $<10^{-4}$, 10^{-4} to $<10^{-2}$, and $\geq 10^{-2}$, at various timepoints), and MRD response in CLL cytogenetic and molecular risk groups in patients from MURANO.
Methods: Patients were randomized to VenR for 6 months followed by single-agent Ven ≤1.5 years, or to BR for 6 months. PB samples were serially collected whereas BM samples were collected at the end of combination treatment assessment (EOCT; Month 9) or at best response; MRD was analyzed centrally by ASO-PCR and/or flow cytometry.

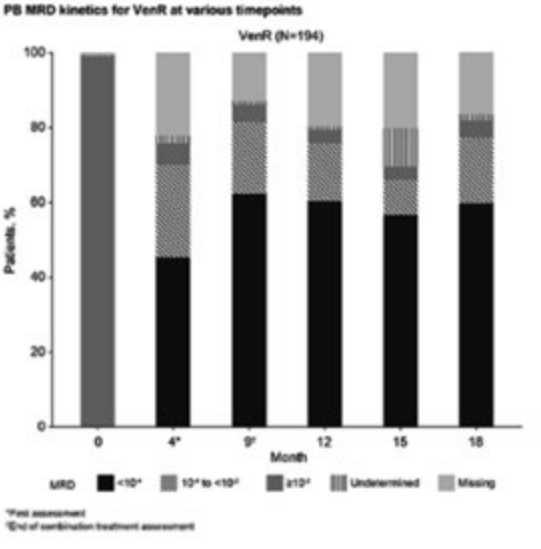

Figure 1.

Results: High concordance was observed between PB and BM MRD status (84%) in patients with paired samples. Higher agreement in MRD– between BM and PB was seen with VenR (45/50 [90%] PB MRD– were also BM MRD–) compared with BR (3/10 [30%]). Given this concordance and availability of serial PB sampling, we focus on PB MRD and outcome.
Best MRD– (at any time on study) rates were higher with VenR (84% *vs* 23% in BR), and were independent of high-risk cytogenetic and molecular factors only for VenR: del(17p) present vs absent: 83% vs 87%; *TP53* mutated vs unmutated: 73% vs 88%; IGVH unmutated vs mutated: 82% vs 89%.

PB MRD kinetics for VenR are shown in the Figure 1. Among 121/194 (62%) patients who were MRD– at EOCT with VenR: 100 (83%) maintained MRD– and were PFS free at a median follow-up of 13.8 (5.6–23.0) months; 2 patients developed progressive disease (PD); 2 died (unrelated); and 2 patients developed Richter's syndrome (with one MRD+ directly before). The remaining 15/121 (12%) patients converted to confirmed MRD+ (2 serial assay-positive assessments) at a median MRD+ follow-up of 5.6 (0.03–11.2) months; 1 patient had MRD ≥10^{-2} with PD, 14 patients had MRD 10^{-4} to <10^{-2}, 2 of which had PD, 1 patient died, and 11 patients remained PFS free. MRD kinetics by patient including treatment status will be presented.

Summary/Conclusion: The robust PB MRD and high concordance with BM MRD with VenR confirms the value of PB MRD for correlation with clinical outcome in patients with R/R CLL treated with this regimen. VenR achieves high, early, deep and durable PB MRD– regardless of risk features, unlike BR. Some reemergence of MRD+, mainly intermediate (10^{-4} to <10^{-2}) level, is seen only in a small number of patients, and may not lead to clinical PD, consistent with the PFS benefit observed in the MURANO study. *NCT02005471*

S806

IBRUTINIB LEAD-IN FOLLOWED BY VENETOCLAX IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA: PHASE 2 CAPTIVATE EARLY SAFETY AND EFFICACY RESULTS

P. Ghia[1,*], C. Tam[2], T. Siddiqi[3], I. Flinn[4], X. Badoux[5], T. Kipps[6], J. Allan[7], A. Tedeschi[8], J. Pagel[9], B. Kuss[10], E. Gonzalez-Barca[11], K. Eckert[12], C. Zhou[12], J. Ninomoto[12], J. Dean[12], D. James[12], W. Wierda[13]

Background: Ibrutinib (ibr), a first-in-class, once-daily BTK inhibitor, is approved in the US for CLL/SLL and in the EU for CLL treatment, including patients with del(17p). Single-agent ibr results in improved survival; however, rates of complete remission (CR) are low, and continuous therapy is required. Ibr and venetoclax (ven), a BCL-2 inhibitor approved by FDA, have complementary therapeutic activity, and synergistic anti-tumor activity has been shown in preclinical and clinical studies with these agents. Ven improves CR rates and can lead to minimal residual disease-negative (MRD(-)) responses in CLL, but increases tumor lysis syndrome (TLS) risk. Tumor debulking by single-agent ibr lead-in followed by combination ibr + ven (I+V) may improve clinical outcomes and lower TLS risk.

Aims: PCYC-1142 (CAPTIVATE) is a phase 2, multicenter study of I+V in first-line CLL (NCT02910583). The study is conducted in 2 phases. The first phase evaluates the MRD(-) clinical response rate of I+V, followed by MRD status-guided randomized treatment discontinuation. The overall objective is to evaluate whether achievement of MRD(-) remission after I+V allows for treatment holidays.

Methods: PCYC-1142 (CAPTIVATE) is a phase 2, multicenter study of I+V in first-line CLL (NCT02910583). The study is conducted in 2 phases. The first phase evaluates the MRD(-) clinical response rate of I+V, followed by MRD status-guided randomized treatment discontinuation. The overall objective is to evaluate whether achievement of MRD(-) remission after I+V allows for treatment holidays.

Results: At time of analysis, a total of 163 patients (median age, 58 years) were enrolled. The first 14 patients had completed the safety run-in of ibr lead-in and ≥6 cycles of I+V; 97 patients (including the safety run-in patients) had completed ibr lead-in and had initiated ven treatment (I+V Exposed). No dose-limiting toxicities occurred during safety run-in. At baseline, 14% of patients had del(17p), 15% had del(11q), and 33% had bulky disease with longest lymph node diameter (LDi) ≥5 cm. Of the 14 safety run-in patients, ORR was 100% (14/14; CR confirmed in 1/5 patients with early BM results at time of analysis and 13/14 confirmed PR); 9/11 assessed patients had MRD(-) status in PB. Common AEs (occurring in ≥20% of I+V Exposed patients) were diarrhea (39%), fatigue (23%), nausea (23%), and arthralgia (21%); grade ≥3 AEs in ≥3% were neutropenia (10%), hypertension (3%), and thrombocytopenia (3%). No patients met the clinical criteria for TLS; laboratory TLS was seen in 1/163. Of 30 I+V Exposed patients with baseline LDi ≥5 cm, 19 (63%) were reduced to LDi <5 cm after ibr lead-in. TLS risk was reduced to medium/low in 17/22 of high risk patients (77%). Overall, the proportion of patients with high-risk TLS decreased from a baseline of 23% to 3% after ibr lead-in.

Summary/Conclusion: These early study results support the safety, activity, and TLS risk reduction potential of ibr lead-in. The early data show promising activity of an I+V oral regimen with MRD(-) responses in 82% in first-line CLL. Safety profiles were consistent with AE profiles of single-agent ibr or ven. The protocol-specified efficacy analysis in the first 30 patients (including ORR) will be presented.

S807

A PHASE IB/II STUDY OF DUVELISIB IN COMBINATION WITH FCR (DFCR) FOR FRONTLINE THERAPY OF YOUNGER CLL PATIENTS

M. Davids[1,*], D. Fisher[1], S. Tyekucheva[1], H. Kim[1], M. McDonough[1], J. Hanna[1], K. Francoeur[1], J. Bazemore[1], J. Hellman[1], O. Odejide[1], P. Armand[1], J. Arnason[2], J. Brown[1]

[1]Medical Oncology, Dana-Farber Cancer Institute, [2]Medical Oncology, Beth Israel Deaconess Medical Center, Boston, United States

Background: FCR is a common initial therapy for younger CLL patients (pts); however, only about 20% will achieve CR/CRi with MRD negativity in the bone marrow (BM-MRD-). Duvelisib (formerly IPI-145) is a delta/gamma PI3K inhibitor with promising efficacy in CLL. We report on an investigator-initiated, phase Ib/II study of dFCR as initial treatment for younger CLL pts (NCT02158091).

Aims: The primary objectives in phase Ib were to determine duvelisib safety and the RP2D, and in phase II to assess the rate of CR/CRi with BM MRD- after dFCR. Secondary objectives included efficacy assessments.

Methods: A standard 3 + 3 phase I design included 2 dose levels of duvelisib (25 mg qd and 25 mg bid). Duvelisib was given for 1 week with FCR added on day 8. Up to 6 cycles of dFCR were given, followed by up to 2 years of duvelisib maintenance. Growth factor support, antimicrobial prophylaxis, and CMV monitoring were mandatory. Eligibility criteria included: age ≤ 65, requiring treatment by IW-CLL criteria, ECOG PS ≤1, and adequate organ function. Toxicity evaluations were performed by CTCAE v4.03/IW-CLL. Response evaluations by 2008 IW-CLL criteria occurred after 3 cycles, 2 months after final FCR, and q6 months thereafter. MRD was assessed by four-color flow cytometry (sensitivity of 10^{-4}).

Results: 32 pts were enrolled, including 6 pts treated with duvelisib 25 mg QD and 26 pts treated with duvelisib 25 mg bid. The median age at enrollment was 55 yrs (range 45-65). By FISH, 8 pts (25%) had del(11q), and 3 (9%) had del(17p). Unmutated *IGHV* was present in 18 pts (56%) and *TP53* mutation in 2 pts (6%). Gr3 febrile neutropenia at 25 mg QD (n=1) was the only DLT, and the RP2D of duvelisib was 25 mg bid. Heme toxicity included thrombocytopenia (69%; 34% gr 3-4), neutropenia (56%; 47% gr 3-4), and anemia (34%, 16% gr 3). Non-heme toxicities included nausea (72%, all gr 1/2), fatigue (69%, 3% gr 3), fever (53%, all gr 1/2), diarrhea (47%, 3% gr 3), transaminitis (34%, 28% gr 3/4), anorexia (34%, all gr 1/2), vomiting (28%, all gr 1/2), pruritus (16%, 3% gr 3), and inflammatory arthritis (9%, all gr 2). SAEs included transaminitis (n=5 gr 3, n=4 gr 4), febrile neutropenia (n=7, all gr 3), pneumonia (n=6, including 3 cases of PJP despite planned prophylaxis), colitis (n=1 gr 2, n=1 gr 3), gr 3 pruritus and gr 3 CMV infection (n=1 each). A median of 5.5 cycles of FCR were given, and 10 pts (31%) discontinued chemotherapy early due to toxicity. Nine pts (28%) required duvelisib dose-reduction. In the 29 pts evaluable for post-FCR response, the ORR was 97%, with 28% achieving CR (n=4) or CRi (n=4), and 69% achieving PR. The best rate of MRD- in the BM in pts with at least one evaluation was 21/26 (81%). The rate of CR/CRi with BM-MRD- (primary efficacy endpoint) was 28%. Two pts with del(17p) achieved MRD+ PR and one achieved MRD+ CR after 12 mo. of duvelisib maintenance. With a median follow-up among survivors of 21 mo. (range 6-42), 2 pts have progressed, including 1 with asymptomatic progression 6 mo. after maintenance ended and 1 with baseline del(17p) and complex karyotype who developed Richter's Syndrome and died 29 mo. after starting on study. Two other pts died, including 1 with metastatic melanoma (at 15 mo.) and 1 with glioblastoma (at 36 mo.). 2-year PFS and OS are both 97%. 8 pts have now completed 2 yrs of duvelisib maintenance.

Summary/Conclusion: dFCR is an effective regimen for the initial therapy of younger, fit CLL pts, leading to a high rate of BM-MRD negativity of 81%, although infectious and immune-mediated toxicities were observed.

S808

A PHASE 2 STUDY TO ASSESS THE SAFETY AND EFFICACY OF UMBRALISIB (TGR-1202) IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) WHO ARE INTOLERANT TO PRIOR BTK OR PI3K DELTA INHIBITOR THERAPY

A.R. Mato[1,*], S.J. Schuster[2], N. Lamanna[3], I.W. Flinn[4], J. Barrientos[5], S. Kambhampati[6], B.D. Cheson[7], P. M. Barr[8], J.M. Pagel[9], J.A. Reeves[10], F. Lansigan[11], J.J. Pu[12], A. Background: Although kinase inhibitor (KI) therapies such as ibrutinib are generally well tolerated, intolerance is the most common reason for discontinuation (~50%, Mato et al, Blood 2016). Therefore, patients (pts) who respond to a KI but discontinue due to intolerance represent an unmet medical need. Umbralisib (TGR-1202) is a novel, highly-specific PI3K- inhibitor that also uniquely inhibits CK-1ε (Casein Kinase-1ε). Umbralisib is well-tolerated with a discontinuation rate due to Adverse Events (AEs) of < 10% as demonstrated in a safety analysis of 347 pts (Davids et al, ASH 2017).
Aims: This trial evaluates the safety/efficacy of umbralisib in CLL pts who are intolerant to prior BTK or PI3K- inhibitor therapy.
Methods: KI intolerant is defined as: ≥ 1 grade 3 or ≥ 2 grade 2 non-heme toxicities, ≥ 1 grade 3 neutropenia with infection or fever, and/or ≥ 1 grade 4 heme toxicity leading to KI (BTK and/or PI3K inhibitor) discontinuation. Toxicities must resolve to ≤ grade 1 prior to umbralisib. Prior KI must be discontinued for ≥ 14 days without CLL progression; however, pts could have progressed after 14 days of KI discontinuation. Pts must start umbralisib within 12 mos of discontinuing prior KI. All pts are treated with umbralisib (800 mg oral daily) until progression, toxicity, or study conclusion. The primary endpoint is progression-free survival (PFS). Secondary endpoints include duration of response, time to treatment failure, and umbralisib safety profile. Peripheral blood samples are being collected for correlative analyses to identify markers associated with KI intolerance.

Table 1.

Umbralisib AEs in > 15% pts (n=40)				
Adverse Events (All Causality)	All Grades	% All Grades	GR 3/4	% GR 3/4
Diarrhea	17	43%	3	8%
Nausea	17	43%		
Thrombocytopenia	11	28%	4	10%
Insomnia	9	23%		
Neutropenia	9	23%	7	18%
Dizziness	8	20%		
Fatigue	8	20%		
Rash	7	18%	1	3%

Results: 40 pts were treated as of 2/2018 (36 BTK & 4 PI3K intolerant). Baseline demographics include: median age 69 yrs (range 52-96), median prior therapies 2 (1-7), 55% were male, ECOG 0-1 (92%), del17p (20%), del11q (23%), IGHV unmutated (60%). 80% required treatment within 6 mos of prior KI discontinuation. Most AEs leading to prior KI discontinuation were: arthralgia, rash (9 events each), A-fib (6 events), diarrhea (4 events), bleeding, fatigue and weight loss (3 events each). AEs reported in 40 patients on umbralisib (regardless of causality) are listed in Table 1. Common GR ≥3 PI3K -associated AE's were limited: AST/ALT elevation (3%); diarrhea (7.5%); rash (3%). Four pts discontinued umbralisib due to intolerance (rash, pneumonia, pneumonitis, pancreatitis), and 1 patient due to study noncompliance. No patient has discontinued umbralisib as a result of a prior KI intolerant AE, and only 4 pts had recurrence of an AE that led to intolerance on their prior KI, however all recurrences were of lesser severity, and none led to discontinuation or dose-modification of umbralisib. Three pts (7.5%) had dose reductions (headache, hematologic, and colitis) and were successfully re-challenged (colitis patient on study in PR now 12 mos). Median PFS has not been reached with 90% of pts progression-free at a median follow up of 7 mos (range 1–16). No deaths were observed.
Summary/Conclusion: Umbralisib appears to be safe and effective in a KI intolerant CLL population. These are the first prospective data to confirm that switching from ibrutinib, acalabrutinib or idelalisib to an alternate PI3K- (umbralisib) can result in durable responses without recurrence of prior KI intolerance toxicities. Pre-umbralisib dosing samples are being analyzed for BTK resistance mutations and CYP-3A4 polymorphisms. Study enrollment is expected to be completed with 50 pts by the meeting.

S809

FINAL RESULTS OF THE DESTINY STUDY OF DE-ESCALATION AND STOPPING TREATMENT IN CHRONIC MYELOID LEUKAEMIA

Background: The British study of De-Escalation and Stopping Treatment with Imatinib, Nilotinib or sprYcel (DESTINY) recruited from December 2013 until April 2015. Entrants were aged 18 or over, in first chronic phase, on the same tyrosine kinase inhibitor (TKI) for at least 3 years since original diagnosis (except that 1 change was permitted if intolerant to the initial TKI), and with all *BCR-ABL* qPCR transcript levels (minimum of 3) < 0.1% in the 12 months before entry. If all these results were also <0.01%, they were assigned to the 'MR4 group' (as studied in many other studies); patients with one or more result between 0.1% and 0.01% were allocated to a 'MMR but not MR4 group' (not previously studied in a stopping trial). Entry criteria were thus virtually identical to the EUROSKI study except that patients with MMR but not MR4 were also separately eligible.
Aims: TKI treatment was de-escalated to 50% of the standard dose (imatinib 200mg daily, dasatinib 50mg daily or nilotinib 200mg twice daily) for 12 months, then stopped altogether for a further 24 months. Centralised PCR monitoring was carried out 1-2 monthly, expressed according to International Scale. Molecular recurrence was defined as the first of 2 consecutive samples >0.1%; this required recommencement of the relevant TKI at full dose.
Methods: 174 patients (male 98; female 76) were recruited after giving informed consent from 20 UK centres. At entry, 148 patients were receiving imatinib, 16 nilotinib and 10 dasatinib, for a median duration of 6.8 years.
Results: We previously reported that after 24 months on study, molecular recurrence was lower in patients with stable MR4 at entry (29 of 125 patients; 23.2%) than in those in MMR but not MR4 (29 of 49 patients; 59.2%) (p<0.001). We now show in the Figure 1 that during the subsequent 12 months of complete treatment cessation (i.e. months 25-36 of study), only 5 further recurrences have occurred, all in patients with stable MR4 at entry, giving a recurrence free survival (RFS) of 72% (90% CI: 65-79%) at 36 months follow-up in this group of patients. The overall recurrence rate is higher in the MMR but not MR4 group (20 of 36 patients during cessation; 39% RFS overall (90% CI: 29-52%); p=< 0.001), though no new recurrences have been seen in months 25-36 in this group.
Multivariable Cox proportional hazards modelling revealed that the baseline entry PCR result did not add to the predictive effect on RFS of the PCR pattern in the 12 months prior to trial entry; however the duration of TKI treatment was an additional predictive factor (p=0.047; HR 0.93), as shown in other studies. The RFS probability remains unrelated to age, gender, performance status or prior TKI (imatinib vs second generation). No progression to advanced phase was seen; two deaths occurred due to unrelated causes, and one case lost haematological response. All relapsing patients have regained MMR within 4 months of resuming full dose TKI. No difference in RFS was seen between patients with a PCR level <0.0032% (MR4.5) at entry and those not.
Summary/Conclusion: The present finding of minimal (only 5) recurrences in the second stopping year, thus sustaining the excellent previously reported RFS out to 24 months of stopping, suggests that initial de-escalation is not simply delaying recurrence, though the mechanism of its benefit is not yet clear. Possibilities include gradual mobilisation of leukaemic stem cells into cycle and/or gradual improvement in the anti-leukaemic immune response at a time when TKI is still present. These require further study.

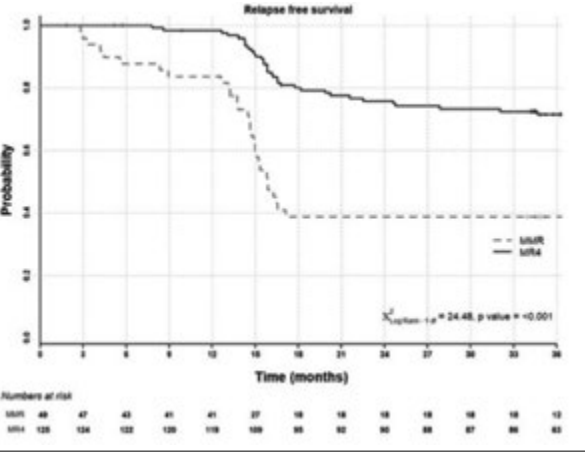

Figure 1.

[1]Paul O'Gorman Leukaemia Research Centre, University of Glasgow, [2]Cancer Research UK Clinical Trials Unit, Glasgow, United Kingdom, [3]Hematology Department, CH Annecy-Genevois, Pringy, France, [4]Faculty of Medicine & Health Sciences, The University of Nottingham, Nottingham, [5]Royal Liverpool University Hospital, Liverpool, [6]Imperial College London, London, United Kingdom, [7]Hematology department, Centre Léon Bérard, Lyon, France

Background: It is well documented that residual BCR-ABL positive leukemia stem cells are responsible for disease persistence in chronic phase CML (CP-CML), despite TKI therapy. Autophagy is rapidly induced following TKI treatment *in vitro* in CP-CML. Pharmacological autophagy inhibition, using lysosomotropic chloroquine (CQ), enhances the effect of TKIs in CP-CML, compared to Imatinib (IM) or CQ alone. Here, we report the results of the largest clinical trial of autophagy inhibition [CHOICES (CHlorOquine and Imatinib Combination to Eliminate Stem cells] trial. CP-CML patients in major cytogenetic response (MCyR) with residual disease detectable after at least one year of IM treatment were treated with IM and hydroxychloroquine (HCQ) or IM alone.
Aims: The primary study end-point was the proportion of treatment 'successes', defined as patients who had >0.5 log reduction in their 12-month (mth) qPCR level from baseline. The secondary study end-points were the proportion of treatment 'successes' at 24 mth, molecular response and progression at 12 and 24 mth, comparison of IM levels between study arms, and the proportion of patients who achieved whole blood HCQ levels >2000ng/ml.
Methods: CHOICES was an international multicentre, two-arm, parallel, randomised phase II trial with a safety run-in, designed to study the safety and efficacy of IM+HCQ. Patients were randomly assigned, using one-to-one allocation, to receive either IM alone, or IM+HCQ. IM was continued at the same dose that was taken prior to trial entry. At the end of 12 cycles, IM was continued. HCQ was initially started at 800mg/day.
Results: From 2010 to 2014, 62 patients were randomized to IM or IM+HCQ. Demographic data at study entry are listed in Table 1. The success rate in the IM+HCQ arm at 12 mnth was 1.2% lower than with IM alone (95% CI 21.1% lower to 18.4% higher; 1-sided p=0.58). MMR was achieved in 80% of IM alone vs 92% in IM+HCQ arm (p =0.21). At 24 mth, the 'success' rate in the IM+HCQ arm was 20.8% higher than the IM alone arm (p=0.059), and MMR was achieved in 79.2% IM and 88% in thr IM+HCQ (p=0.1) group. Within the IM+HCQ experimental arm, HCQ levels were determined over time and analysed by the 12 and 24 mth 'success' and 'failure' status. There was no correlation between achieving 'success' and achieving HCQ concentrations of >2000ng/ml at either time point.

During the trial period, 17 adverse events were reported; four were serious adverse reactions: 1 within the IM arm (dyspepsia), and 3 with IM+HCQ. Of these, 1 was unrelated, and 2 had a potential association, namely dyspnea and heart failure. An *in vitro* assessment of autophagy was performed within the CD34+ stem/progenitor and mononuclear populations from peripheral blood and bone marrow at each time point. Basal autophagy, assessed by LC3B-II levels, was higher in CD34+ stem/progenitor cells compared to mononuclear populations (p=0.002). Additionally, LC3B-II levels at 6 and 12 mth were higher in IM/HCQ arm than the IM arm, suggesting a block in autophagy flow (i.e. inhibition of autophagy-mediated degradation of LC3B-II), although this was not statistically significant.

Table 1.

Selected Demographics	IM	IM+HCQ
Age (years)	49.5 (21-79)	50 (20-78)
Male (%)	66.7	71.9
ECOG 0 (%)	93.1	87.5

Summary/Conclusion: We confirm that IM+HCQ is a tolerable combination in CP-CML, with significant improvement in overall qPCR levels and MMR at 24 mth. This suggests that there may be a potential long-term benefit of combined therapy on qPCR levels and achievement of deep molecular response. Longer follow-up will be required to confirm this.

Background: The European Treatment and Outcome Study (EUTOS) registry contains data on adult patients with chronic-phase (CP) chronic myeloid leukaemia (CML). In 2,205 imatinib-treated patients, the EUTOS long-term survival score (ELTS) was developed to discriminate three risk groups with different probabilities of dying from CML. Still, many investigators continue to apply the Sokal score for the prognostic discrimination of CML-patients treated with tyrosine kinase inhibitors (TKIs).
Aims: The Sokal score had allocated 23% of patients to the high-risk group, the ELTS score 12%. Long-term outcome of TKIs suggests that allocating >20% CP CML patients into a high-risk group is too pessimistic. The aim of this analysis was to compare risk group allocations and prognosis between the two scoring systems.
Methods: Due to the success of TKIs, the number of deaths from CML has distinctly declined. To optimise power, 2,949 patients from other registry sections were added. Survival was calculated from the date of start of treatment to death and censored at the latest follow-up. Cumulative incidence probabilities (CIPs) of dying of CML were compared with the Gray test and overall survival probabilities (OS) with the log-rank test. Only death after confirmed disease progression was regarded as "death due to CML". Progression was defined in accordance with the current ELN recommendations (Blood 2013). Level of significance was 0.05.
Results: The 5,154 patients in the combined registry sections had a median observation time of 5.3 years. Six-year OS probability was 90% (95% confidence interval (CI): 89-91%). Of 429 deceased patients, in 175 CML progression prior to death was confirmed (40%). The 6-year CIP of dying of CML was 4% (CI: 4-5%). From low to high risk groups, the Sokal score resulted in 6-year CIPs of 3% (n=1,982 (38% of 5,154), CI: 2-3%), 4% (n=1,975 (38%), CI: 3-5%), and 8% (n=1,197 (23%), CI: 6-10%) and the ELTS score in 6-year CIPs of 2% (n=3,037 (59%), CI: 2-3%), 5% (n=1,449 (28%), CI: 4-7%), and 12% (n=668 (13%), CI: 9-15%). Of the 1,197 patients allocated to high risk by the Sokal score, the ELTS score classified 671 (56%) as non-high-risk. Compared to the 526 high-risk patients according to both scores (6-year CIP of dying: 12%, CI: 9-16%), the CIPs of dying were lower for the non-high risk patients (p=0.0003, 6-year CIP: 5%, CI: 3-7%). The Sokal high but ELTS non-high-risk patients (6-year OS: 88%. CI: 85-91%) showed higher OS than the 526 common high-risk patients (p=0.0036, 6-year OS: 81%, CI: 76-85%). Of the 3,037 patients identified as low risk by the ELTS score, the Sokal score allocated 1,200 (40%) to non-low-risk groups. Without significant CIP differences to the latter group, at 6 years, the CIP of dying was 2% (CI: 1-3%) in the 1,837 low-risk and 2% in the 1,200 non-low-risk patients (CI: 2-4%). OS of the Sokal non-low-risk patients (6-year OS: 92%. CI: 90-94%) was lower than in the cases classified as low-risk by both scores (6-year OS: 95%. CI: 94-96%, p=0.0186).
Summary/Conclusion: The Sokal score allocated 13% (n=671) more patients to the high-risk group than the ELTS score. As these patients had significantly and clinically relevant lower CIPs of death and higher OS probabilities, the allocation of the Sokal score was not appropriate. OS probabilities but not the CIPs of 1,200 patients assessed as low-risk by the ELTS and non-low-risk by the Sokal score were different from the probabilities of 1,837 assessed as low-risk patients by both scores. For prediction of long-term survival, the use of the ELTS score is recommended.

S812

PHASE 2 STUDY OF RUXOLITINIB IN COMBINATION WITH 5-AZACITIDINE IN PATIENTS WITH MYELOFIBROSIS

L. Masarova[1,*], S. Verstovsek[1], J. Cortes[1], N. Pemmaraju[1], E. Jabbour[1], P. Bose[1], M. Ohanian[1], L. Zhou[1], S. Pierce[1], R. Gergis[1], G. Borthakur[1], Z. Estrov[1], G. Garcia-Manero[1], H. Kantarjian[1], N. Daver[1]

[1]Leukemia, UT MD Anderson Cancer Center, Houston, United States

Background: Ruxolitinib (RUX) is effective in controlling symptoms and organomegaly in patients with myelofibrosis (MF). Combination with azacitidine (AZA) may further improve its efficacy.
Aims: To evalute efficacy and safety of RUX and AZA combination.
Methods: This was a single insitutional, phase 2 study. RUX 15 or 20 mg orally twice daily was given continuously since cycle 1. AZA 25 to 75 mg/m^2 on days 1-5 of each 28-day cycle was added starting cycle 4. Responses were assessed per International Working Group for Myelofibrosis Research and Treatment 2013 criteria (IWG-MRT).
Results: Forty nine patients were enrolled on study between 03/2013 and 08/2017. After median follow-up of 18.5+ months (range, 1-56+); 14 patients (29%) remain on therapy with a median overall follow-up of 28+ months. 41 patients (84%) received AZA on study, with a median of 15 cycles (range, 1-52). Median age was 66 years (range, 48-87), 37 patients (76%) had int-2/high DIPSS score, 37 (76%) had spleen ≥5cm, and 26 (53%) were JAK2^{V617F} positive (Figure 1, Part I). Twenty six patients (53%) were previously treated. Thirty-six patients (73%) achieved an IWG-MRT 2013 objective response (Figure 1, Part II). Median time to response was 1.7 months (range, 0.7-19). Eight responses (22% of responders) occurred

after the addition of AZA with median time to response from start of AZA of 4 months (range, 1-16.5). In total, 25 (68%) and 22 (59%) patients had palpable spleen reduction by > 50% at any time on study, and at week 24, respectively. Spleen responses occurred after AZA introduction in 6 patients with a median time of 1.8 months from start of AZA. Mean percentage spleen reduction by palpation was 73% (95% CI 59-86%) and 63% (95% CI 25-100%) at any time on study and at week 24, respectively. $JAK2^{V617F}$ allele reduction was noted in 14 (82%) of 17 evaluable patients, including > 50% reduction in 3 patients (18%). Thirty-one patients (63%) had bone marrow biopsies available for sequential evaluation. Sixteen patients (52%) had a documented improvement in bone marrow fibrosis by at least one grade per European grading (EUMNET) including 4 (13%) by two grades or more, with median time to first documented fibrosis improvement of 12 months (range, 6-18). Additionally, 12 (48%) and 9 (41%) achieved improvement in initially abnormal collagen (n=25) or osteosclerosis (n=22), respectively (Figure 1, Part III).

Overall, 31 patients (63%) experienced grade 3/4 toxicity while on therapy. New onset of G3/4 anemia, thrombocytopenia and neutropenia occurred in 33%, 24% and 22% of patients, respectively. Only 4 (8%) discontinued therapy due to toxicities.

The most common reasons for therapy discontinuation were elective stem cell transplantation (n=12), and uncontrolled disease (n=8), including progression to AML in 4 patients.

PART I.

Patient clinical characteristics	N (%) or median [range]
White blood cells x 10^9 / L	12.1 [2.2 - 79.8]
Hemoglobin g / dL	10.4 [6.8 - 16.2]
Platelets x 10^9 / L	272 [125 – 1070]
Peripheral blood blast ≥ 1%	31 (63)
Spleen ≥ 5 cm below costal margin	37 (76)
Total symptom score (TSS)	32 [1 - 84]
Bone marrow fibrosis grade: Gr 1 vs 2 vs 3+	4 / 24 / 21
JAK2 V617F positive	26 (53)
MPL / CALR positive	3 / 5
Karyotype abnormal	21/49 (43)
Additional molecular mutations by 28-gene panel	15/33 (45)

PART II.

IWG-MRT 2013	N (%)
Overall response	36 (73)
Partial remission (PR)	2 (4)
Clinical improvement (CI) spleen + TSS	9 (18)
CI TSS + CI hemoglobin	2 (4)
CI TSS + CCyR	1 (2)
CI spleen + TSS + molecular PR (JAK2)	2 (4)
CI TSS only	11 (22)
CI spleen only	9 (18)

PART III.

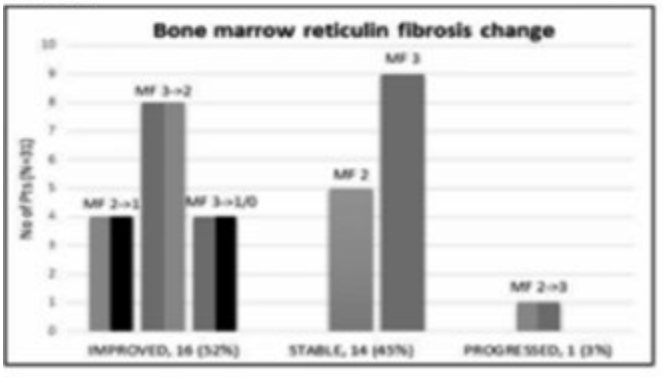

Figure 1.

Summary/Conclusion: Concomitant RUX with AZA was well tolerated with overall IWG-MRT response rate of 73%, including >50% spleen length reduction in 59% of patients at week 24. Moreover, 52% of patients achieved an independent pathologist committee reviewed, objective improvements in bone marrow fibrosis grade with a median time to improvement of 12 months, which compares favorably to single RUX. ClinicalTrials.gov Identifier: NCT01787487

Background: Mastocytosis is a clonal mast cell disease which, in adults, most commonly affects skin, bone marrow and other organs. Symptoms and serum tryptase levels vary, and there are patients with pure cutaneous mastocytosis (CM). It is generally appreciated that all adult patients with MIS require a bone marrow biopsy (BMB) in order to confirm the presence of SM. Although BMB is safe, it may be painful and cause complications. Existing risk scores are based on relatively few patients and a limited set of parameters.

Aims: We aimed at creating a simple and solid risk score to predict SM in adult patients with MIS. We hypothesized that there are patients at low risk of SM which may be relevant in clinical practice.

Methods: The European Competence Network on Mastocytosis (ECNM) registry is the largest collection of data on patients with mastocytosis. 1145 patients of at least 18 years with MIS who had a BMB within six months of diagnosis were included. Patients with advanced mastocytosis (ASM, MCL, SM-AHN) were excluded. We identified significant variables in univariate analysis and created a multivariate regression model using the whole population as a training and validation set (bootstrapping). A risk score was derived and the model and score were validated with receiver operating curve (ROC) area under the curve (AUC).

Results: Of 1145 patients, 944 had SM and 201 had CM. Among these 1145 patients, 63.7% were female, with a median age of 44±13.3 years (18-81 years) and good performance status (ECOG 0-1, 97.6%). They were highly symptomatic (skin symptoms, 81.4%; other, 65.5%). Almost all patients had typical skin lesions (>97%) and tryptase levels varied greatly (median 29.3±81.9 ng/ml, range: 1-885). In a univariate analysis to determine predictors of SM in patients with MIS, significant variables were typical MIS (p=0.001), a positive Darier's sign (p=0.020), constitutional/cardiovascular symptoms (p=0.002), bone symptoms/osteoporosis (p<0.001), gastrointestinal symptoms (p=0.004), serum tryptase (p<0.001), palpable spleen (p=0.003), age >65 years (p=0.009), lactate dehydrogenase (p=0.003),

monocytes (p=0.001) and beta2-microglobulin (p=0.047). In the multivariate regression model, tryptase level (p<0.001), constitutional/cardiovascular symptoms (p=0.014) and bone symptoms/osteoporosis (p<0.001) were identified as independent predictors of SM (p<0.001, Nagelkerke R2=0.462, Hosmer-Lemeshow p=0.177). The model correctly classified 88.1% of the cases as SM (sensitivity 90.7%, specifity 69.1%, positive predictive value 95.5%, negative predictive value 50.3%). A risk score was derived and points were assigned to all variables, creating a six-point scale with a risk of SM ranging from 10.7% to 98.0% (Figure 1). ROC AUC was 0.871 for the model and 0.867 for the risk score. Bootstrap validation (k=1000) led to an optimism-corrected AUC of 0.853 for the model and 0.849 for the score. Of all MIS patients, 17.4% (n=199) were at low risk (-1 and 0 points, 10.7 and 24.7% risk of SM), 14.5% (n=166) at medium risk (1 and 2 points, 47.1 and 70.7%) and 68.1% (n=779) at high risk (3-5 points, 86.8-98%).

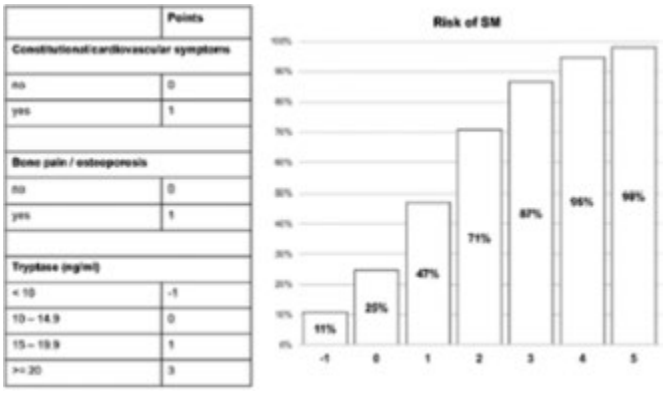

Figure 1.

Summary/Conclusion: Using a large data set of the ECNM registry, we created a risk score to better predict SM in patients with MIS. Although it will need validation in independent cohorts, our score seems to be valid and may discriminate between patients with SM and CM. Our new score may thus have clinical implications and may assist in the decision to recommend a BMB in adults with MIS.

IL1RAP POTENTIATES MULTIPLE ONCOGENIC SIGNALING PATHWAYS IN AML

K. Mitchell[1,*], L. Barreyro[1], T.I. Todorova[1], S. J. Taylor[1], I. Antony-Debré[1], S.-R. Narayanagari[1], L. A. Carvajal[1], J. Leite[1], Z. Piperdi[1], G. Pendurti[1], I. Mantzaris[1], E. Paietta[1], A. Verma[1], K. Gritsman[1], U. Steidl[1]

[1]Albert Einstein College of Medicine–Montefiore Medical Center, Bronx, United States

Background: Our group and others previously identified the surface molecule Interleukin 1 receptor accessory protein (*IL1RAP*) as one of the most significantly upregulated genes in hematopoietic stem and progenitor cells (HSPC) from AML patients and found that its overexpression is correlated with a poor prognosis. IL1RAP is emerging as a novel target for immunotherapy in AML and other myeloid malignancies, however, the cell-intrinsic functions and mechanism of action of IL1RAP in AML cells are largely unknown.
Aims: To investigate therapeutic targeting and the functional and mechanistic role of IL1RAP in AML.
Methods: We used complementary approaches to target IL1RAP (genetic knockout, RNA-interference, and antibody targeting), and measured the functional effects (cell growth, apoptosis, differentiation) of IL1RAP targeting *in vitro* in AML cell lines, AML patient samples (including leukemic stem cell-enriched populations), and healthy HSPC, and *in vivo* in AML xenograft models. We generated retrovirally induced leukemias in the *wt* vs. *Il1rap*$^{-/-}$ setting and performed competitive transplants of *wt* vs. *Il1rap*$^{-/-}$ normal bone marrow cells. Using western blotting, phospho-flow cytometry, EdU incorporation, co-immunoprecipitation and flow cytometric-based Förster resonance energy transfer (FRET), we assessed the molecular effects of IL1RAP targeting and the cellular role of IL1RAP.
Results: We found that IL1RAP targeting inhibited AML growth and viability and promoted differentiation in a cell-intrinsic manner and in the absence of immune effector cells, but did not have inhibitory effects on healthy HSPC. *in vivo*, IL1RAP targeting inhibited AML xenografts, and *Il1rap* knockout decreased leukemic stem cell function in an MLL-AF9 AML mouse model. Meanwhile, *Il1rap* knockout did not perturb healthy stem cell function in competitive transplantation experiments. In exploring the cell-intrinsic molecular bases for these effects, we unexpectedly found that IL1RAP is a promiscuous co-receptor in AML and its function is not restricted to its canonical role in the IL-1 receptor pathway. Specifically, studies by co-immunoprecipitation, FRET, and biochemical assays revealed that IL1RAP physically interacts with and mediates signaling and pro-proliferative effects through FLT3 and c-KIT, two receptor tyrosine kinases with known key roles in AML pathogenesis. Consistent with these mechanistic findings, we found differential sensitivity to IL1RAP targeting of FLT3-mutant and FLT3-wildtype AML cells, a finding with important implications for currently ongoing immunotherapeutic and precision oncology approaches targeting IL1RAP.
Summary/Conclusion: Our study reveals novel functional and mechanistic cell-intrinsic roles of IL1RAP in AML, and provides important insight for currently ongoing and future therapeutic strategies targeting IL1RAP.

S815

ARRAYED MOLECULAR BARCODING IDENTIFIES TNFSF13 AS A POSITIVE REGULATOR OF ACUTE MYELOID LEUKEMIA-INITIATING CELLS

M. Chapellier[1,*], P. Peña-Martínez[1], R. Ramakrishnan[1], M. Eriksson[1], M. Safaee Talkhoncheh[2], C. Orsmark-Pietras[1], H. Lilljebjörn[1], C. Högberg[1], A. Andersson Hagström[1], T. Fioretos[1], J. Larsson[2], M. Järås[1]

[1]Clinical Genetics, [2]Molecular Medicine and Gene Therapy, Lund Stem Cell Center, Lund University, Lund, Sweden

Background: Acute myeloid leukemia (AML) is characterized by an accumulation of immature myeloid blasts in the bone marrow. By providing cell-cell interactions and secreted factors, the bone marrow niche supports AML and normal hematopoietic stem and progenitor cells (HSPCs). A dysregulation of cytokines in the bone marrow microenvironment upon AML development contributes to the selective advantage of leukemia stem cells, a self-renewing population of leukemia cells that constitutes a chemo-resistant reservoir responsible for disease relapse.

Aims: To identify factors that regulate AML cells, we recently developed an *in vitro* cytokine screen using fluorescently labeled c-Kit$^+$ leukemia cells mixed with corresponding normal bone marrow cells, allowing us to successfully identify both negative and positive regulators of AML cells (Peña-Martínez *et al*., Leukemia 2017). However, to assess effects on leukemia stem cells, there is a strong demand to improve such screens to evaluate the impact of cytokines on the leukemia-initiating capacity of cells more directly using an *in vivo* readout. A major challenge for combining *ex vivo* screens with *in vivo* read-out of stem cell function is the large number of experimental animals needed to provide meaningful data. Hence, new methods that allow for a multiplexed *in vivo* read-out of leukemia-initiating activity are needed.
Methods: To identify cytokines that regulate AML stem cells using a competitive *in vivo* read-out of leukemia-initiating activity, we generated lentiviral vectors harboring 11 genetic barcodes in an arrayed setting. This approach allows for labeling of leukemia cell populations with distinct molecular barcodes followed by exposure to separate experimental conditions. Each labeled cell population was stimulated with one cytokine *ex vivo* and after culture, leukemia cells from up to 11 cytokine conditions were pooled prior to *in vivo* competition. To trace the effects of the cytokines to the leukemia-initiating capacity of barcoded cells, the representation of individual barcodes *in vivo* was assessed using next-generation sequencing (NGS).
Results: With this approach, we assessed the effect of 114 murine cytokines on *MLL-AF9* AML mouse cells and identified the tumor necrosis factor ligand superfamily member 13 (TNFSF13) as a positive regulator of leukemia-initiating cells. By using a *Tnfsf13*$^{-/-}$ mouse, we confirmed that TNFSF13 supports leukemia initiation and also normal myelopoiesis by regulating granulocyte and macrophage progenitor (GMP) cell levels in the bone marrow. TNFSF13 was secreted by normal myeloid cells but not by AML mouse cells, suggesting that mature myeloid bone marrow cells support AML cells by secreting TNFSF13. TNFSF13 supported leukemia cell proliferation in an NF-κB-dependent manner and suppressed apoptosis. Moreover, TNFSF13 supported the growth and survival of several human myeloid leukemia cell lines, demonstrating that our findings translate to human disease.
Summary/Conclusion: Taken together, using arrayed molecular barcoding, we identified a previously unrecognized role of TNFSF13 as a positive regulator of primitive AML cells. The arrayed barcoded screening methodology is not limited to cytokines and leukemia, but can be extended to other types of *ex vivo* screens, where a multiplexed *in vivo* read-out of stem cell functionality is needed.

S816

INVESTIGATING THE ROLE OF INPP4B AS A THERAPEUTIC TARGET IN AML

J. Woolley[1,2,3,*], M.H. Son[2], I. Dzneladze[2], R. He[2], A. Rashid[2], M. Minden[2], L. Salmena[2,3]

[1]Molecular and Clinical Pharmacology, University of Liverpool, Liverpool, United Kingdom, [2]Ontario Cancer Institute, Princess Margaret Hospital, [3]Pharmacology & Toxicology, University of Toronto, Toronto, Canada

Background: Our studies have focused on characterizing a role for the lipid phosphatase Inositol polyphosphate 4-phosphate Type II (INPP4B) in Acute Myeloid Leukemia (AML). We have previously published data showing that elevated INPP4B expression in AML patients is predictive of lower response rates to induction chemotherapy and lower overall survival. We have since revealed that INPP4B protein plays a critical role in both human and murine HSC maintenance
Aims: To investigate the role of INPP4B in hematopoiesis and leukemia and how this contributes to leukemogenesis, both *in vitro* and *in vivo*.
Methods: We make use of *Inpp4b*$^{-/-}$ C57/BL6 mice to study the contribution of Inpp4b to the HSC niche. Functional studies of *Inpp4b*$^{-/-}$ HSCs were carried out *in vivo* (competitive transplant into CD45.1 B6.SJL mice) and *in vitro* (CFC assays). Leukemia models of Inpp4b-loss were generated by retroviral transduction of bone-marrow with MLL-AF9. A combination of *in vivo* transplants, *in vitro* CFC assays, mass cytometry and next-generation sequencing were utilized to study the contribution of *Inpp4b* to leukemia.
Results: We show compelling evidence that INPP4B expression is significantly enriched in human and mouse hematopoietic stem and progenitor cells (HSPC). *Inpp4b*$^{-/-}$ mice show a disrupted bone-marrow stem-niche with reduced long-term HSC, MPP and GMP compared to *wild-type* controls (49.1%, 32.4% and 19.7% respectively). Functional studies of *Inpp4b* in HSPC by competitive transplant of bone marrow demonstrated that *Inpp4b*$^{-/-}$ cells show a greatly diminished contribution to the myeloid compartment in secondary and tertiary transplants. Similarly, serial 5'-fluorouracil injections demonstrate a reduced overall survival of *Inpp4b*$^{-/-}$ mice compared to *wild-type* controls, indicating an impaired ability of *Inpp4b*$^{-/-}$ HSCs to repopulate the hematopoietic system post-insult.
Investigating *INPP4B* expression in a human primary AML patient sample grown in culture, we show its expression correlates with more primitive populations (CD34$^+$CD38$^-$). To further study the role of INPP4B in primitive leukemia populations we modeled Inpp4b-loss in an MLL-AF9 murine leukemia model. Transplanting MLL-AF9 leukemias into recipient mice in limiting dilution showed that loss of Inpp4b reduces the frequency of leukemia initiating cells (LICs), and increases disease latency. We also show in this model of Inpp4b-loss sensitizes the leukemia model to a 7-day regimen of cytarabine treatment *in vivo*. Mass-cytometry analysis showed that Inpp4b-loss leads to a more differentiated phenotype, with altered surface marker expression such as Gr-1, c-Kit, Flt3, CD117 and CD44. Also, next-generation sequencing demonstrated a transcriptional profile associated with loss of stem-related genes and upregulation of genes associated with differentiation in *Inpp4b*$^{-/-}$ MLL-AF9 leukemias.
Summary/Conclusion: Our results indicate that Inpp4b plays a role in maintaining stemness, and that Inpp4b loss leads to differentiation and chemosensitization of leukemia *in vivo*. We hypothesize that INPP4B plays a critical role in HSC maintenance and contributes to worse leukemia, and that its stem-related function is responsible for the poor therapy response observed in patients with elevated INPP4B.

RAS MUTATIONS ARE THE DOMINANT MECHANISM OF SECONDARY RESISTANCE TO GILTERITINIB THERAPY FOR RELAPSED/REFRACTORY FLT3-MUTATED AML

C.M. McMahon[1,*], T.T. Ferng[2], J. Canaani[3], B. Rea[4], R.L. Sargent[4], J. Morrissette[4], D.B. Lieberman[4], C. D. Watt[4], R. Durruthy-Durruthy[5], M. Pellegrino[5], D.J. Eastburn[5], E.S. Wang[6], N.P. Shah[2], M. Carroll[1], C.C. Smith[2], A.E. Perl[1]

[1]Hematology-Oncology, University of Pennsylvania, Philadelphia, [2]Hematology-Oncology, University of California, San Francisco, San Francisco, United States, [3]Hematology, Sheba Medical Center, Givatayim, Israel, [4]Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, [5]Mission Bio, Inc, South San Francisco, [6]Medicine, Roswell Park Comprehensive Cancer Center, Buffalo, United States

Background: Gilteritinib is a potent, selective FLT3 inhibitor with substantial single-agent clinical activity in relapsed/refractory (R/R) AML patients with FLT3 internal tandem duplication (ITD) and/or FLT3-D835 tyrosine kinase domain mutations (Perl AE, et al *Lancet Oncol* 2017). However, gilteritinib monotherapy is not curative and, like other FLT3 inhibitors, our data suggest acquired sequence mutations eventually arise and contribute to drug resistance (McMahon CM, et al, ASH 2017 abstract #295). In some cases, FLT3-wild type leukemic populations are selected during gilteritinib therapy and establish clonal dominance at clinical progression; in others, the original FLT3 mutation persists but is accompanied at progression by new mutations, often N-RAS or FLT3-F691L. Higher gilteritinib doses might combat resistance from FLT3-F691L, but combinatorial strategies are likely needed to circumvent other mechanisms of resistance and optimize response quality and duration.
Aims: We sought to describe and clarify mechanisms of secondary resistance to gilteritinib therapy.
Methods: Adults with R/R FLT3-mutated AML who received at least 80 mg/day of gilteritinib on a phase 1/2 study (NCT02014558) at 3 institutions provided leukemia samples at baseline, scheduled study time points, and at study withdrawal; all clinical molecular and cytogenetic data were reviewed. Baseline and progression samples were tested by a 66-gene next generation sequencing (NGS) panel; a subset with treatment-emergent mutations at disease progression were analyzed by a 24-gene single-cell NGS technique (Tapestri). Dual FLT3-ITD+/NRAS+ cell lines (MOLM14-NRAS) were generated through long-term culture of MOLM14 cells in low concentrations of the FLT3 inhibitor quizartinib. Effects of gilteritinib and/or the MEK inhibitor trametinib on the *in vitro* growth and apoptosis of MOLM14-NRAS cells were studied.
Results: 29 subjects (median age 62) have complete, evaluable cytogenetic and/or NGS data; an additional 7 have data currently being analyzed. At study enrollment 26/29 (89.7%) had a FLT3-ITD mutation, including 5 (17.2%) with both FLT3-ITD and FLT3-D835 mutations. Three subjects (10.3%) had a FLT3-D835 mutation only. 23/29 progressed during gilteritinib therapy, 5 were withdrawn for transplant or toxicity, and one remains on gilteritinib in remission. 10/21 subjects (47.6%) with serial cytogenetic data developed new cytogenetic abnormalities during therapy, including a new BCR-ABL1 fusion at progression in 1 subject. Cytogenetic evolution

did not always correlate with disease progression. New gene mutations developed on gilteritinib in 12/27 subjects (44.4%) with available NGS data, including NRAS (n=7), KRAS (n=2), FLT3-F691L (n=3), IDH2 (n=1), PTPN11 (n=2), TBL1XR1 (n=1), and CBL (n=1). Single-cell NGS confirmed that treatment-emergent RAS mutations indeed occur in FLT3-mutated cells. MOLM14-NRAS cells were resistant *in vitro* to either gilteritinib or trametinib alone, but remained sensitive to the two drugs in combination. Both serial single cell genotyping to determine whether NRAS mutations precede gilteritinib therapy and whole exome sequencing of progression samples lacking new mutations by targeted NGS are ongoing and will be updated for presentation.
Summary/Conclusion: Ras mutations are the most common mechanism of acquired mutational resistance to gilteritinib and can occur through clonal selection for FLT3-WT or clonal evolution of FLT3-mutated cells. Combining gilteritinib and MEK inhibitors is a promising strategy to prevent or delay clinical resistance.

Stem cell transplantation – Experimental

REDUCED FIBROBLASTIC RETICULAR CELL EXPRESSION OF TISSUE-RESTRICTED ANTIGENS IMPAIRS PERIPHERAL REGULATION OF SELF-REACTIVE T CELLS DURING ACUTE GRAFT-VERSUS-HOST DISEASE

S. Dertschnig[1,*], P. Evans[1], C. Bennett[1], R. Chakraverty[1]

[1]*Cancer Institute and Institute of Immunity and Transplantation, University College London, London, United Kingdom*

Background: Acute graft-versus-host disease (GVHD) is a known risk factor for the later development of chronic GVHD. Although thymic injury during acute GVHD leads to the *de novo* generation of self-reactive T cells, the "two hit" hypothesis proposes that the additional loss of peripheral mechanisms is required for autoimmunity. Non-hematopoietic lymph node stromal cells (LNSC) provide a platform for peripheral tolerance by expressing and directly presenting tissue-restricted antigens (TRAs) to T cells.
Aims: The aim of this work was to test the hypothesis that alloreactive T cells could directly kill LNSC in the GVHD recipient, thus disrupting a critical mechanism for preventing injury by auto-aggressive donor T cells.
Methods: To test this concept, we used a clinically relevant model of MHC-matched, B6 female → B6 male bone marrow transplantation (BMT) where GVHD is induced by the co-transfer of anti-HY TCR-transgenic MataHari $CD8^+$ T cells.
Results: We found that fibroblastic reticular cells (FRC), a LNSC subset identified as $CD45^-CD31^-gp38^+$, were reduced ~15-fold in mice with GVHD whereas other LNSC, including lymphatic or blood endothelial cells were less affected. FRC injury was associated with a profound loss of type 3 innate lymphoid cells (ILC3). Consistent with injury to FRC, transcription of both *Il-7* and *Ccl19* genes was significantly reduced in LN stroma of mice with GVHD. Furthermore, the repertoire of putative TRAs expressed by FRC was also substantially reduced. To test the hypothesis that acute GVHD interferes with FRC capacity to express TRAs and induce peripheral tolerance, we exploited the iFABPtOVA model where truncated ovalbumin (tOVA) antigen is expressed by intestinal epithelial cells and ectopically by FRC; in the steady state, direct presentation of tOVA by FRC induces clonal elimination of antigen-specific T cells. Transfer of HY-specific T cells into iFABPtOVA male BMT recipient reduced intranodal tOVA expression by 15-fold compared to no GVHD controls. To test whether acute GVHD-mediated FRC damage impairs tolerance induction, 10^6OT-I T cells (a surrogate for self-reactive T cells) were adoptively transferred to GVHD+ or GVHD- iFABPtOVA recipients at 6 weeks following BMT. Transferred OT-I T cells were efficiently tolerized and clonally deleted in GVHD- iFABPtOVA recipients. However, in GVHD+ iFABPtOVA, OT-I T cells were not eliminated, and a large number of $IFN\gamma^+$ effector cells expanded in LN and intestinal epithelium, leading to severe weight loss and intestinal injury.
Summary/Conclusion: Taken together, our data demonstrate that acute GVHD reduces TRA display by FRC and induces loss of a critical peripheral tolerance mechanism that prevents expansion and pathogenicity of autoreactive T cells. These findings provide a potential mechanism to explain the link between acute GVHD and the succeeding autoimmunity observed in chronic GVHD.

S819

MICRORNA-155 (MIR-155) INHIBIT T LYMPHOCYTE PRENYLATION TO PROTECT AGAINST ACUTE GRAFT VERSUS HOST DISEASE (AGVHD)

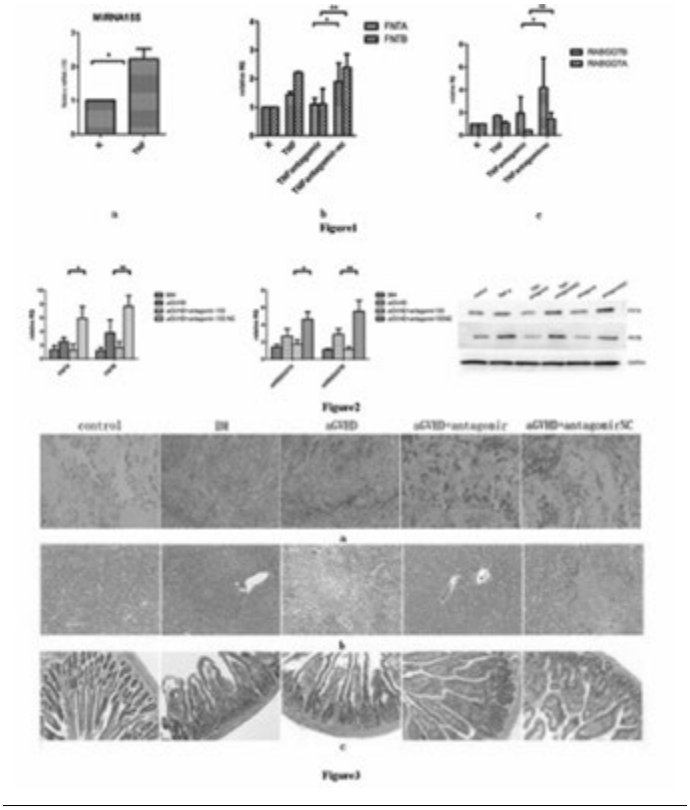
X. Wang[1,*], L. Xia[1]

[1]*Union Hospital, Tongji Medical College, Huazhong University of Science & Technology, WuHan, China*

Background: It is reported that farnesyl-transferase and geranylgeranyl-transferase inhibitors could help to reduce graft-versus-host (GVHD) disease significantly without having a negative impact on immune reconstitution. Previously, we have reported that miR-155 levels in T lymphocyte from peripheral blood of acut GVHD (aGVHD) patients and mice were significantly elevated and the inhibition of miR-155 can relieve the severe murine aGVHD.
Aims: we show a novel mechanism that inhibition of miR-155 protects against aGVHD via effects on prenylation of T cells.
Methods: TNF-α, which participates in the initiating events that culminate in aGVHD as well as amplifies the disease process once established. There-

fore, TNF-α induced T cell injury was used to simulate the course of aGVHD *in vitro*. To assess the contribution of miR-155 to prenylation of human T lymphocyte, T lymphocyte from human peripheral blood mononuclear cells (PBMCs) was selected through negative selection using magnetic bead, which was effected for 48h with antagomir-155 and antagomir-NC before stimulated with TNF-α (100 ng/ml) for 24h. To assess the contribution of miR-155 to prenylation *in vivo*, a well-established MHC mismatched bone marrow transplantation (BMT) model (C57BL/6 to BALB/c) was used to investigate the effect of deficiency of miR-155 on prenylation *in vivo*. 800 cGy X-rays irradiated BALB/c mice transplanted with 1×10^7 BM cells and 2×10^7 spleen cells from C57BL/6 mice, were treated with antagomir-155 and antagomir-NC at a loading dose of 25 mg/kg on +7d, 5 mg/kg intravenously twice weekly up to +21d post-transplant. Mice T lymphocyte magnetically isolated from PBMCs. we examined expression of prenyltransferase of both human T lymphocyte and mice T lymphocyte by Realtime quantitative-PCR and western blotting. We evaluated the severity of aGVHD using a histopathology scoring system and the farnesyltransferase activity by immunohistochemistry.

Results: The results indicated TNF-α stimulated T cells to imitate aGVHD *in vitro* induced a higher expression of miR-155 (Figure 1a, $p<0.05$), coincidentally, TNF-α stimulated T cells resulted a higher expression of farnesyltransferase(FT) subunits farnesyltransferase-α FNTA which is common to geranylgeranyltransferase -α and farnesyltransferase-β FNTB mRNA (Figure 1b) and protein levels(Figure 3), similarly increased geranylgeranyltransferase (GGT) subunits RABgeranylgeranyltransferase-α(RABGGTA) and RABgeranylgeranyltransferase-β(RABGGTB) mRNA expression (Figure 1c). Intriguingly, the suppression of miR-155 could reverse this phenomenon, which not only restrained FNTA, FNTB mRNA and protein expression (Figure 1b, $p<0.01$), but also decreased RABGGTA and RABGGTB (Figure 1c, $p<0.05$) mRNA levels. Simultaneously, in aGVHD mice models, compared with control groups, aGVHD group caused higher expression of FNTA, FNTB, REBGGTA and RABGGTB, however, which exacerbation can be reversed by inhibition of miR-155 (Figure 2a,b, $p<0.05$), all of this suggested that during the initiation and development of aGVHD, prenyltransferase and miR-155 levels were both increased, the suppression of miR-155 decreased th xpression of prenyltransferase *in vivo* and *in vitro*. Next, we consistently discovered that the miR-155 deficient aGVHD mice which had a lower histopathology score of live(Figure 3b) and small intestine(Figure 3c) possessed of decreased farnesylated proteins and farnesyltransferase activity in spleen (Figure3 a).



Figures 1,2,3.

Summary/Conclusion: this results confirmed that miR-155 simulate the role of farnesyl-transferase and geranylgeranyl-transferase inhibitors to relieve the effect of aGVHD.

PIM1 INHIBITION EFFECTIVELY ENHANCES AMD3100-INDUCED HSC MOBILIZATION

T. Müller[1,*], S. Pennisi[1], A. Zwick[1], S. Decker[1], C. Klein[1], B. Rister[1], A. Rudorf[1,2], S. Kissel[1], M. Follo[1], R. Wäsch[1], A.L. Illert[1,2], C. Waskow[3], R. Oostendorp[4], D. Christine[1,5], J. Duyster[1,2]

[1]Department of Hematology and Oncology, University Medical Center Freiburg, Freiburg, [2]German Cancer Consortium (DKTK) and German Cancer Research Center (DKFZ), Heidelberg, [3]Regeneration in Hematopoiesis and Animal Models in Hematopoiesis, Institute for Immunology, Medical Faculty Carl Gustav Carus, TU Dresden, Dresden, [4]Department of Internal Medicine III, Klinikum rechts der Isar, Technical University Munich, Munich, [5]Center for Biological Signaling studies, EXC294, BIOSS, Freiburg, Germany

Background: The interaction between hematopoietic stem cells (HSCs) and the bone marrow (BM) niche is best described for CXCR4 and its ligand, SDF-1/CXCL12. Therefore, CXCR4 antagonists like AMD3100 are used in the clinic for the collection of HSCs from patients who fail to mobilize HSCs in response to G-CSF. However, their effects are short-lived, limiting the collection time to only 4-6h and 30 % of the patients fail to collect the required amounts of CD34+ cells for autologous transplantation. We have previously demonstrated that the PIM1 kinase regulates CXCR4 receptor recycling and surface expression on HSCs. Consequently, deletion of *Pim1* results in reduced migration of HSCs towards a CXCL12 gradient and reduced homing to the BM.

Aims: We aimed to improve HSC mobilization by combining CXCR4 and PIM inhibition and demonstrate that the mobilized stem cells are capable of homing to the bone marrow niche.

Methods: In order to study the mobilization efficiency in the murine model, mice were treated with AMD3100 alone or in combination with LGB321, a novel pan-PIM inhibitor. The mice were sacrificed at various timepoints and peripheral blood (PB) was isolated. The percentage of HSCs was then determined by flow cytometry and colony-formation assays. To rule out long-term effects of PIM inhibition on stem cell engraftment, we transplanted mobilized cells into lethally irradiated recipient mice. The mechanism of HSC mobilization was studied in isolated HSC and stroma populations by analyzing mRNA levels of *Cxcl-12* and surface expression of CXCR4.

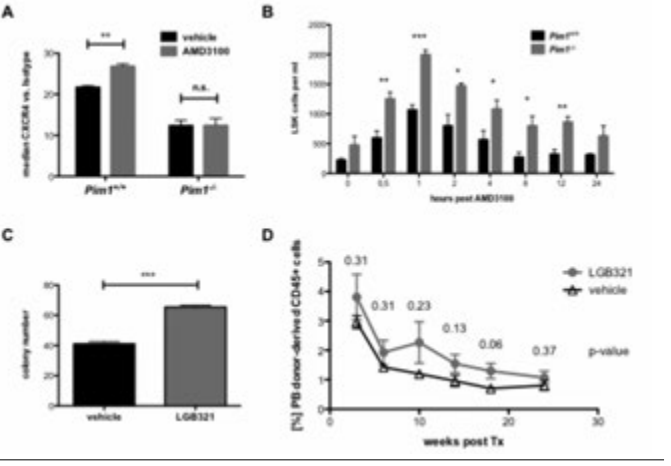

Figure 1.

Results: We found that CXCR4 inhibition using AMD3100 leads to a compensatory upregulation of CXCR4 surface expression on total BM cells as well as HSCs. This effect can be reverted by deficiency or inhibition of PIM1 (Figure 1A). As a consequence, HSC mobilization using AMD3100 is strongly enhanced and prolonged in *Pim1*-deficient mice compared to WT animals (Figure 1B). Likewise, treatment of WT animals with AMD3100 in combination with LGB321 leads to increased and prolonged HSC mobilization compared to animals treated only with AMD3100. Moreover, colony formation potential of LGB321/ AMD3100-mobilized LSKs was significantly elevated compared to AMD3100-only mobilized cells (Figure 1C). LSK cells mobilized with LGB321 and AMD3100 showed long-term engraftment (>1% donor-derived cells in 5/8 mice after week 18) after transplantation into lethally irradiated recipient mice. These cells even exhibited a strong

trend towards higher repopulating capacity compared to LSK cells mobilized only with AMD3100 (Figure 1D). Besides the downregulation of CXCR4 on HSCs, we found that the *Cxcl-12* expression as well as CXCR4 surface expression in CXCL12-abundant reticular (CAR) cells is dramatically decreased in *Pim1*-deficient mice, which even further increases the mobilization capacity of Pim1-deficient mice.
Summary/Conclusion: Our findings indicate, that PIM1 inhibition counteracts the compensatory upregulation of the CXCR4 receptor on HSCs after AMD3100 treatment and decreases CXCL12 levels within the bone marrow niche. Furthermore, PIM inhibition does not interfere with stem cell engraftment in the murine model. Therefore, targeting PIM kinases in combination with CXCR4 inhibition could improve the collection of stem cells in patients at risk for poor mobilization.

Marks[11], J. Apperley[3], V. Potter[12], K. Raj[12], M. Bornhauser[5,6], H. Walczak[4], C. Bennett[4], F. Dazzi[1,12]

[1]School of Cancer & Pharmaceutical Sciences, King's College London, [2]Institute of Immunity and Transplantation, University College London, [3]Imperial College Healthcare NHS Trust, [4]University College London, London, United Kingdom, [5]University Hospital Carl Gustav Carus, Dresden, Germany, [6]King's College London, London, [7]Plymouth Hospitals NHS Trust, Plymouth, [8]Royal Hallamshire Hospital, Sheffield, [9]Central Manchester University Hospital, Manchester, [10]University Hospital Southampton, Southampton, [11]University Hospitals Bristol, Bristol, [12]King's College Hospital NHS Trust, London, United Kingdom

Background: Mesenchymal stromal cells (MSCs) exhibit therapeutic activity in steroid-resistant acute Graft versus Host Disease (aGvHD). However, MSC efficacy is completely unpredictable.
Aims: We investigated the fate of infused MSCs and used our findings to design an assay to predict clinical responses
Methods: MSCs were used in a mouse model of GvHD where the disease was mediated by $CD8^+$ cells from Matahari mice (GvHD group) or defective cytotoxic $CD8^+$ cells from Matahari/perforin$^{-/-}$ mice (GvHD perf$^{-/-}$ group). Apoptosis in infused MSCs was evaluated 1 hour after infusion and infiltration of GvHD effector cells in spleen and lungs was assessed 4 days after. We then examined the cytotoxic activity against MSCs of Peripheral Blood Mononuclear Cells (PBMCs) obtained from 31 steroid-resistant aGvHD patients treated with MSCs. When performing the assay, the operator was blind to patients' clinical details. Informed consent was obtained from all patients in accordance with the local ethics committee requirements. Finally, MSCs made apoptotic *in vitro* (apoMSCs) before the infusion were tested for their ability to induce immunosuppression in our GvHD mouse model
Results: After infusion, we found that MSCs were induced to undergo apoptosis within the first hour but only in the presence of functional cytotoxic GvHD effector cells: mean caspase activation in MSCs was 26.1±7.4 and 6.2±5.6 in GvHD mice and GvHD perf$^{-/-}$ mice, respectively (p=0.0006). Notably, when we assessed the immunosuppressive activity of MSCs, we found that MSCs were able to reduce the infiltration of GvHD effector cells in lungs and spleen only in the GvHD group (Figure 1A-D). Taken together, our data demonstrate that cytotoxic cells are required to induce MSC apoptosis which is instrumental for the delivery of immunosuppression. Therefore, we inferred that the presence of cytotoxic cells in the recipient could be predictive of MSC therapeutic activity. PBMCs from 31 patients with steroid-resistant GvHD collected the day before MSC treatment were co-cultured with MSCs and MSC apoptosis was assessed using Annexin V and 7-AAD after 4 hours. The clinical overall response rate to MSCs was 37.5%. PBMCs from responders exhibited a significantly higher cytotoxicity against MSCs in comparison to non-responders (mean: 21.9%±15.4% versus 6.9%±4.7%, respectively (p<.0001) and a cut-off of 11.5% was predictive of response with 91.7% sensitivity and 90.0% specificity. The importance of the cytotoxic assay in predicting the response and its impact on the overall survival (OS) was then assessed. Higher cytotoxicity (>11.5%) was significantly associated with the response in multivariate logistic regression analysis (p<.001) and the median OS was longer in responders than in non-responders: median survival times were not reached and 60.5 days, respectively (log-rank test, p<.03). Finally, to further confirm the role played by MSC apoptosis, we tested the immunosuppressive activity of apoMSCs and we found that the infiltration of GvHD effector cells was significantly reduced both in lungs and spleen after apoMSC infusion (Figure 1E, F)
Summary/Conclusion: We propose the innovative concept that the presence of functional cytotoxic cells is required to induce MSC apoptosis which in turn is necessary to deliver immunosuppression. Therefore, patients should be stratified for MSC treatment according to their ability to kill MSCs. Alternatively, all patients may be treated with *ex vivo* apoptotic MSCs

Background: Clonal hematopoiesis of indeterminate potential (CHIP) occurs in the peripheral blood of approx. 20% of people > 60 years of age without history of hematologic disorders. CHIP associates with an increased risk of hematologic cancer, atherosclerotic disease and shorter overall survival. Case reports indicate that donor CHIP may lead to donor cell

leukemia in the recipient. Collectively, these data might raise worries about the eligibility of a stem cell donor with CHIP.
Aims: We performed a comprehensive investigation to elucidate how donor CHIP - transferred from the donor to the recipient - affects the outcome of allogeneic hematopoietic stem cell transplantation (HSCT).
Methods: We included PB or BM samples from 488 healthy HSCT donors aged ≥55 years (median 63y) collected prior to or at the time of donation. Whole blood DNA was subjected to targeted sequencing using a 60-gene panel. Clinical data from the 488 transplant recipients were collected using a standardized catalogue of HSCT outcome parameters. AML was the most frequent diagnosis leading to HSCT (n=239), followed by MPN (n=55), MDS (n=53), multiple myeloma (n=41), lymphoma (n=40), ALL (n=24), and CLL (n=18). Due to their elevated age, the majority of donors were related to the recipient (98.6 %).
Results: We identified 89 clonal mutations in 77/488 elderly donors (15.8%). The median VAF was 6.1% (range 2–43.0%) with 24 variants in 18 donors being present at a VAF ≥ 10%. 67 donors harbored one single CHIP mutation. Most frequently mutated genes were *DNMT3A* (37/488; 7.6%), *TET2* (2.3%), *ASXL1* (1.4%), *SF3B1* and *SRSF2* (0.8% each). Donor CHIP status was evenly distributed when looking at demographic, disease and transplantation characteristics of the recipient. Transplant failure, aGvHD and CMV reactivation were not affected by donor CHIP status, but cGvHD was significantly more often after HSCT with donor CHIP (54% vs. 39%; p=.018). Multivariate analysis confirmed donor CHIP as an independent risk factor for cGvHD (OR=1.8, 95% CI=1.05–2.95; p=.032). This was mainly attributed to *DNMT3A* mutations, which were associated with cGvHD in 64% of recipients (p=.004). Competing risk analysis identified donor CHIP to be associated with lower cumulative incidence of relapse/progression (CIR/P) in the recipient (p=.022) while non-relapse mortality was similar. Risk reduction was predominantly observed in recipients allografted in non-CR (n=297). Multivariate analysis confirmed donor CHIP as an independent risk factor for decreased CIR/P together with AML, cGvHD, CMV reactivation, donor age, ECOG performance and disease remission status (Fine and Gray test: HR=0.58; 95% CI=0.36–0.94; p=.029) in the entire cohort and in the subgroup of patients transplanted in non-CR (HR=0.36; 95%>CI = 0.151–0.842; p=.019). With respect to OS (median follow-up time for patients alive: 3.3y), neither donor CHIP status nor any single gene mutation affected survival, except for the MPN subgroup. MPN patients allografted with a clonal mutation (n=14) showed a reduced OS (p=.026). Serial quantification of 14 donor mutations in 50 follow-up samples suggests disproportionate expansion in most cases (Figure 1).

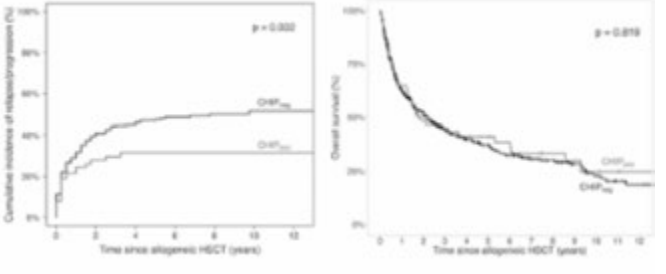

Figure 1.

Summary/Conclusion: Allogeneic HSCT from a donor with CHIP appears safe and results in similar OS in the setting of elderly and related donors. Surprisingly, donor CHIP may increase cGvHD rates and reduce relapse/progression risks. Future studies in younger and unrelated donors are warranted to confirm these results.

Acute lymphoblastic leukemia – Translational research

SYNTHETIC LETHAL SCREENING IDENTIFIES CHK1 INHIBITION AS AN EXPLOITABLE VULNERABILITY IN EZH2 DEFICIENT T-CELL ACUTE LYMPHOBLASTIC LEUKAEMIA

T.E. Leon[1,*], T. Rapoz-D'Silva[1], C. Bertoli[2], S. Rahman[1], M. Magnussen[1], N. Farah[1], J. Guerra-Assunção[3], R. Gupta[4], E. Nacheva[5], R. de Bruin[2], D.C. Linch[1], M.R. Mansour[1]

[1]Department of Haematology , UCL Cancer Institute, [2]MRC Laboratory for Molecular Cell Biology, [3]Bill Lyons Informatics Centre, UCL, [4]Stem Cell Laboratory, [5]Health Service Laboratories LLP, UCL Cancer Institute, London, United Kingdom

Background: Loss of function mutations of Enhancer of Zeste (Drosophila) homolog 2 (EZH2), the enzymatic component of Polycomb Repressive Complex 2 (PRC2), are recurrently found in T cell - Acute Lymphoblastic Leukaemia (T-ALL) and deregulation of PRC2 has been strongly associated with the pathogenesis of T-ALL. Moreover, PRC2 mutations are independent predictors of poor survival across all T-ALL subtypes and *EZH2* mutations alone are associated with a 60% risk of relapse in paediatric T-ALL, emphasizing the need for identification of drugs that selectively target PRC2 deficient leukemic cells.
Aims: Our aim was to identify specific synthetic lethal vulnerabilities induced by EZH2 deficiency, that can be exploited using drugs targeting other dependency pathways, potentially resulting in a clinically meaningful therapeutic strategy in T-ALL.
Methods: We used double-nicking CRISPR Cas9 to generate isogenic Jurkat T-ALL cells, with and without EZH2-inactivating mutations, and performed a cell-based drug screening using 220 well-characterized compounds, enriched for drugs targeting epigenetic, cell cycle and DNA repair machinery.
Results: Strikingly, we observed that *EZH2*-knock out (KO) cells are hypersensitive to checkpoint kinase 1 (CHK1) inhibition by the clinical-grade small molecule MK8776, showing an IC50 reduction of over 2-fold. To determine the specificity of this observation, we tested two different *EZH2*-KO cells against other CHK1 inhibitors (LY2603618 and CHIR-124) obtaining a similar sensitisation to CHK1 inhibition. Moreover, when we transduced the cells with shRNAs that specifically targeted CHK1 expression, we observed a significant reduction of cell growth in *EZH2*-KO cells compared to the parental control. Furthermore, pharmacological inhibition of EZH2 methyltransferase activity by its potent inhibitor GSK126 in other human T-ALL cell lines resulted in sensitization to CHK1 inhibition by MK8776. Notably, MK8776 resulted in apoptosis of EZH2-deficient cells as determined by Annexin V-PI staining. To investigate the mechanism, gene expression of two *EZH2*-KO Jurkat clones was compared to their isogenic parental control by RNA-seq. EZH2-KO cells showed a marked upregulation of genes associated with human ETP-ALL including *LYL1*, *MYCN*, *KIT* and *HHEX*, a finding that could be recapitulated with GSK126 treatment. Gene set enrichment analysis (GSEA) showed significant changes of expression in MYC target genes. Importantly, MYCN protein was markedly upregulated in both *EZH2*-KO and GSK126 treated cells. We speculated that increased MYCN expression induces high levels of replication stress and increased dependency on CHK1 for cell survival. In fact, EZH2 deficient cells showed a significant reduction in replication fork speed, compared with WT control, as determined by DNA fiber assay. In line with this observation, *EZH2*-KO cells exhibited markedly elevated levels of the ssDNA binding protein RPA and MK8776 treatment resulted in higher yH2AX expression in these cells.
Summary/Conclusion: Our findings suggest that specific inhibition of the CHK1 pathway can preferentially target PRC2-deficient leukemic cells, providing a potentially less toxic and more effective treatment for this high-risk subgroup of patients.

Background: *PAX5*, a gene encoding a key transcription factor in B cell differentiation, is altered in one third of B-cell acute lymphoblastic leukemia

(B-ALL). Its structural alterations (point mutations and translocations) are considered as primary oncogenic events of B-ALL while its deletion can be considered as an additional hit in leukemia process. Our previous work reported a new chromosomal t(7;9)(q11;p13) translocation in human B-ALL that juxtaposes *PAX5* and the sequence of elastin *ELN*. The resulting protein showed a dominant negative effect on the wild type PAX5 protein in patients cells.
Aims: Despite the well-known role of *PAX5* as haploinsufficient tumour suppressor gene in human B-ALL, the function of PAX5 fusion proteins in B-ALL initiation and transformation is less defined. The aim of this work is to study the impact of PAX5-ELN fusion protein in murine B cell development, decipher its molecular role and determine if the PAX5-ELN expression is a *princeps* event in the B-ALL process.
Methods: We have generated a transgenic mouse model in which PAX5-ELN is expressed from the *IgH* locus to ensure its early and restricted expression in B cell compartment.
Results: PAX5-ELN transgenic mice efficiently developed B-ALL with an incidence of 80%. Leukemic transformation systematically occurs with a minimal latency of 3 months suggesting requirement of additional oncogenic events. Indeed, exome sequencing revealed that mouse B-ALL induced by PAX5-ELN is associated with recurrent secondary mutations on *PTPN11*, *KRAS*, *PAX5* and *JAK3* genes affecting key signalling pathways required for cell proliferation. At the pre-leukemic stage, PAX5-ELN induces a partial blockade of B-cell differentiation *in vivo* characterized by an aberrant expansion of the pro-B cell compartment in steady state and in transplantation assay. At the molecular level, we showed that PAX5-ELN downregulates endogenous Pax5 expression and its canonical target genes in pro-B cells, consistent with a dominant-negative effect. At the functional level, PAX5-ELN is not able to restore B-cell differentiation of *Pax5*-deficient pro-B cells in an *ex vivo* complementation assay. Together, our functional studies demonstrate that PAX5-ELN perturbs PAX5 activity in pro-B cells to affect B-cell development before malignant transformation.
Summary/Conclusion: Our work strongly supports the role of PAX5-ELN as a potent oncoprotein in leukemia development and provides a valuable *in vivo* model recapitulating the multistep leukemogenesis process of human B-ALL.

S825

HIGH RECURRENCE OF FUSION GENES IN PHILADELPHIA-LIKE CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

G. Fazio[1,*], S. Bresolin[2], D. Silvestri[3], E. Vendramini[2], F. Locatelli[4], M.G. Valsecchi[3,5], G. Basso[2], A. Biondi[6], G. te Kronnie[2], G. Cazzaniga[1]

[1]Centro Ricerca Tettamanti, Fondazione Tettamanti, Monza, [2]Dept. Health of Woman and Child, Univ. of Padua, Padua, [3]CORS, Fondazione Tettamanti, Monza, [4]Dep. of Pediatric Hematology and Oncology , IRCCS Ospedale Pediatrico Bambino Gesù, Roma, [5]Medical Statistics, Medicine and Surgery, University of Milano-Bicocca, [6]Pediatric Dept., Univ. Milano Bicocca, Monza, Italy

Background: *Ph-like* (or *BCR/ABL-like*) ALL subtype encompasses 10-15% of BCP-ALL patients, predicts high incidence of relapses and defines a candidate subgroup for targeted treatment.
Aims: (i) To identify BCP-ALL Ph-like cases in patients treated in Study Protocols of the Italian Association of Pediatric Hematology and Oncology (AIEOP); (ii) to assess their prognosis; and (iii) to characterize their genetics basis, in terms of CNV and fusion genes.
Methods: Gene expression profiling was successfully performed on 400 Italian childhood BCP-ALL cases enrolled in AIEOP-BFM ALL2000/R2006 protocols. Of them, 142 negative for common fusion transcripts, non-high hyperdiploid and non-Down Syndrome, were defined as B-others. We implemented IKZF1-P335 MLPA kit (MRC Holland), in combination with ERG PCR to identify cases with an 'IKZF-plus' profile. RNA-target-NGS (panel with 1385 cancer-associated genes, Trusight RNA Pan Cancer, Illumina) has been setup to identify fusion genes involving recurrent genes with novel partners.
Results: Out of 142 B-other cases, 43 (30.3%, and 11% of the total BCP-ALL cohort) presented as a cluster with a gene expression signature close to the BCR/ABL signature, therefore referred to as Ph-like. Among B-others, Ph-like cases had a significantly increased proportion of males, age>10 years and WBC>20x10^9/L. The 5y event-free survival (EFS) of Ph-like patients was 54.8% (SE 8.2) vs 83.1% (3.9) in the remaining B-others patients (p<0.001), mostly due to an increased cumulative incidence of relapse (CIR: 33.9% (7.4) vs. 14.9% (3.7); p=0.009). Overall, 33 out of 142 cases experienced relapse, 14 Ph-like (33%) and 19 B-others not Ph-like (19%).
We analyzed 138/142 B-others by MLPA (in 59 cases also by DNA array), and detected 11/142 IKZF-plus patients (7/11 Ph-like and 6/7 experienced relapse). Regarding the *CLRF2* status, 15/142 cases resulted rearranged, 11/15 within Ph-like and 4/15 relapsed (exclusively in the Ph-like group). By NGS, we analyzed 61/142 patients, including all the Ph-like cases plus relapsed cases B-other not Ph-like. Among the 14 Ph-like relapsed cases, 11 were positive for a fusion gene, while the three cases negative were IKZF-plus. We detected four cases carrying *P2RY8/CLRF2*, 1 case with *TCF3/HLF*, 1 with *EBF1*-fusion, 1 with *IKZF1*-fusion, 1 with a *TTYH3*-fusion and 3 cases with *PAX5*-fusions. Considering the 28 Ph-like not relapsed patients, we detected 10 cases with various fusion genes and 4 additional cases with *PAX5*-fusion genes. Moreover, we detected two cases with *EBF1/PDGFRB*, 1 carrying *MEF2D/BCL9*, 1 positive for *RB1*-fusion, 1 with *DOT1L*-fusion and 1 patients with a noncanonical *MLL* fusion. Strikingly, the *PAX5* rearrangements are over-represented in the Ph-like subgroup (N=7), followed by *P2RY8/CRLF2* (N=6). We further identified IgH-CRLF2 (FISH) in two cases, one with a concomitant *PAX5*-fusion. Overall, 21/43 Ph-like cases were carrying a pathogenetic relevant fusion gene. Among relapsed B-others not Ph-like patients, only one carried a fusion gene, *ZNF384/CREBBP* originated from translocation t(12;16).
Summary/Conclusion: We dissected the Ph-like subgroup in the Italian cohort of children with BCP-ALL Ph-like patients, showing that, independently of other known risk features, these patients have a poor outcome and can be considered eligible for alternative treatments, in particular when they have high levels of MRD after induction. The genetic characterization of this subgroup revealed a high recurrence of fusion genes, this finding underlining the urgent need to define the pathogenetic mechanisms, with the aim to identify novel, maybe targeted, therapies.

COMPREHENSIVE SCREENING OF B-OTHER ADULT ALL PATIENTS TREATED ON UKALL14 ESTIMATES FREQUENCY AND PROGNOSTIC IMPACT OF GENE ALTERATIONS AND IDENTIFIES JAK-STAT ABNORMALITIES AS MARKERS OF POOR OUTCOME

A. Moorman[1,*], E. Barretta[1], A. Kirkwood[2], C. Schwab[1], T. Creasey[1], P. Patrick[2], L. Clifton-Hadley[2], B. Patel[3], T. Menne[4], A. McMillan[5], C. Harrison[1], C. Rowntree[6], D. Marks[7], A. Fielding[8]

[1]Northern Institute for Cancer Research, Newcastle University, Newcastle upon Tyne, [2]Cancer Research UK & UCL Cancer Trials Centre, University College London, [3]Department of Haematology, Queen Mary University of London, London, [4]Department of Haematology, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, [5]Department of Haematology, Nottingham University Hospital NHS TRUST, Nottingham, [6]Department of Haematology, Cardiff And Vale University Health Board, Cardiff, [7]Department of Haematology, University Hospitals Bristol NHS Foundation Trust, Bristol, [8]UCL Cancer Institute, London, United Kingdom

Background: Chromosomal abnormalities are established prognostic markers in adult ALL. In the UKALL14 clinical trial patients with *BCR-ABL1*, *KMT2A-AFF1*, low hypodiploidy or a complex karyotype were classified as having high risk (HR) genetics. All remaining patients, including those lacking an established chromosomal abnormality (B-other ALL) were classified as having standard risk (HR) genetics. Recent genomic studies have identified a plethora of new gene fusions within B-other ALL.
Aims: The aim of this study was to screen UKALL14 patients with B-other ALL for ABL-class (*ABL1, ABL2, PDGFRB, CSF1R*), JAK-STAT (*CRLF2, JAK2*), *ZNF384*, and *MEF2D* rearrangements and determine their outcome to assess whether or not future such patients should be re-classified as HR.
Methods: Fixed cells left-over from diagnostic marrow samples were screened using commercially available and/or custom made dual colour break apart or dual fusion probes to detect gene rearrangements using standard methods. Endpoints were defined as per the trial protocol and analysed using standard methods. Patients were followed-up for a median of 2 years.
Results: Among 648 patients with B-cell precursor (BCP) ALL treated on UKALL14 (ISRCTN 66541317), 329 (51%) had HR genetics: *BCR-ABL1* (n=196), *KMT2A-AFF1* (n=47), low hypodiploidy (n=51) or a complex karyotype (n=35). The remaining 319 (49%) patients were classified as having SR genetics. Forty-seven patients had specific SR abnormalities: high hyperdiploidy (n=17), t(1;19) (n=15), other *KMT2A* (n=10), iAMP21 (n=4), *ETV6-RUNX1* (n=1)]. The remaining patients were classified as B-other (n=190) or had failed cytogenetics (n=82). Patients with B-other ALL, complex or failed cytogenetics were screened and rearrangements were detected at the following frequencies: *ABL1* (3/294, 1.0%), *ABL2* (0/185), *PDGFRB* (3/187, 1.6%), *CSF1R* (0/187), *CRLF2* (24/188, 13%), *JAK2* (3/190, 1.6%), *ZNF384* (11/145, 7.6%) and *MEF2D* (3/137, 2.2%). The following partners have been confirmed to date: *EBF1-PDGFRB* (n=1), *IGH-CRLF2* (n=19), *P2RY8-CRLF2* (n=5), *BCR-JAK2* (n=1), *PAX5-JAK2* (n=1) and *TCF3-ZNF384* (n=6). Among 19 cases with a complex karyotype, none

harboured an ABL-class or JAK-STAT abnormality but three had *ZNF384* (n=2) or *MEF2D* (n=1) rearrangements.
The Table 1 shows the demographic, clinical and outcome features of patients with ABL-class, JAK-STAT and *ZNF384* abnormalities. Patients with *ZNF384* or ABL-class abnormalities had a lower median age at diagnosis compared to other BCP-ALL cases (p=0.003 & p=0.06 respectively). Patients with JAK-STAT abnormalities had significantly inferior responses to initial treatment with higher rates of MRD positivity after phase 1 and phase 2 induction (p=0.015 & p<0.001, respectively). This poor response translated to a lower EFS and OS compared with other BCP-ALL patients (both p=0.01) due to higher rates of relapse/death and death: hazard ratio 1.74 (95% CI 1.10-2.73), p=0.017 and 1.81 (1.12-2.92), p=0.015, respectively. No patient with a *ZNF384* abnormality suffered a relapse or death after a median follow-up time of 2 years (10 months to 4.9 years). EFS and OS rates for the 11 patients identified were significantly higher than other BCP-ALL patients (p=0.005 & p=0.014).

Table 1.

	Total*	SR-Cyto	HR-Cyto	B-other**	ABL-class	JAK-STAT	*ZNF384*
Total	648	237	329	225	6	27	11
% Male	55%	58%	52%	59%	33%	56%	82%
Mean age (years)	45	43	46	43	37	43	35
Median WCC	8.0	6.1	13.6	5.9	9.3	12	4.6
% CR PP1	85%	87%	83%	84%	100%	77%	81%
% CR PP2	91%	94%	89%	92%	100%	85%	91%
% MRD positive PP1	62%	54%	68%	61%	50%	89%	64%
% MRD positive PP2	36%	35%	40%	38%	25%	81%	50%
EFS @ 3 y	42%	48%	36%	49%	50%	18%	100%
OS @ 3y	51%	56%	45%	55%	67%	27%	100%

* All patients with B-cell precursor ALL and available genetic data. ** Includes patients with complex karyotype. CR, complete remission PP1, post-phase 1 induction; PP2 post-phase 2 induction

Summary/Conclusion: The frequency of ABL-class abnormalities was <1% in BCP-ALL. Approximately 5% of patients harboured a *CRLF2* or *JAK2* abnormality and collectively had a significantly inferior outcome. We suggest that patients with a JAK-STAT abnormality should be classified as high-risk. Finally, 11 patients with a *ZNF384* fusion had 100% 3 years OS and EFS despite the lack of 100% MRD response.

S827

THE RIBOSOMAL RPL10 R98S MUTATION DRIVES IRES-DEPENDENT BCL-2 TRANSLATION IN T-ALL

[1]Laboratoryfor Disease Mechanisms in Cancer, Oncology, [2]Laboratory for Disease Mechanisms in Cancer, Oncology, KU leuven, [3]Center for Cancer Biology, VIB-KU Leuven, [4]Department of Pediatric Oncology & Hematology, University Hospitals Leuven, Leuven, Belgium, [5]Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands, [6]Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle-upon-Tyne, United Kingdom, [7]Department of Gastroenterology-Hepatology and Metabolic Center, University Hospitals Leuven, [8]Laboratory of Molecular Biology of Leukemia, VIB-KU Leuven, [9]Department of Laboratory Medicine, University Hospitals Leuven, Leuven, Belgium

Background: While outcomes of pediatric T-ALL improved with the induction of multi-agent chemotherapy, event-free survival rates of 75% and long-term toxicity remain major problems of the current therapies. Thus, targeted treatments that specifically interfere with genetic subgroups are needed. As such, the R98S mutation in ribosomal protein L10 (RPL10 R98S) was identified in 8% of pediatric T-ALL cases.
Aims: Better delineation of the oncogenic role of RPL10 R98S in order to identify targeted therapies for RPL10 R98S positive T-ALL.
Methods: RPL10 R98S engineered Jurkat T-ALL cells, lineage negative (lin-) bone marrow (BM) cells from an RPL10 R98S knock-in mouse, and T-ALL PDX samples were used as models to study the effect of R98S on cell functions. Cell viability assays using PI exclusion or ATP measurements. Colony forming cell assays. Growth curves. Luciferase reporter assays. Treatment of T-ALL PDX models.
Results: A previously published quantitative proteomics screen showed that the peroxisome, the cellular organelle in which b-oxidation of very long-chain fatty acids occurs, as well as associated metabolic pathways were upregulated in RPL10 R98S Ba/F3 cells. The observed increase in peroxisomal protein expression was confirmed in RPL10 R98S JURKAT cells, in lin- RPL10 R98S mouse BM cells, and in T-ALL PDX samples. Peroxisomal β-oxidation produces high levels of the reactive oxygen species (ROS) hydrogen peroxide (H_2O_2). All RPL10 R98S mutant cell models presented a 20-40% increase in ROS expression as compared to RPL10 WT cells, causing mitochondrial dysfunction and the hypoproliferation defect of RPL10 R98S cells. Elevated ROS levels are a known source of DNA damage and may induce genomic instability in RPL10 R98S leukemia patients. Cells that encounter high ROS levels typically undergo programmed cell death, as observed in RPL10 WT cells. In contrast, RPL10 R98S cells showed enhanced survival phenotypes, especially under nutrient poor conditions. Proteomics data presented elevated levels of anti-apoptotic BCL-2 expression, which was confirmed by a 2-fold increased protein expression in all RPL10 R98S cell models, while other proteins regulating apoptosis were unchanged. BCL-2 has previously been shown to be regulated by stress-induced IRES-mediated translation. BCL-2 IRES reporter assays in Jurkat cells indicated that RPL10 R98S mutant ribosomes have an intrinsically higher capability to drive IRES-dependent BCL-2 translation, independent of oxidative stress. Elevated BCL-2 expression in RPL10 R98S cells may provide therapeutic opportunities, as BCL-2 inhibitors such as ABT-199/venetoclax are clinically used for other leukemias. We examined the efficacy of ABT-199 (50 mg/kg, once/week i.p.) on RPL10 WT and R98S mutant T-ALL PDX models. ABT-199 treatment completely suppressed appearance of human leukemia cells in the blood, prevented the occurrence of splenomegaly, and decreased the bone marrow engraftment by 30-50% in RPL10 R98S xenografted T-ALL animals, while RPL10 WT T-ALL PDX *in vivo* responses were undetectable at most leukemic infiltration sites (Figure 1).

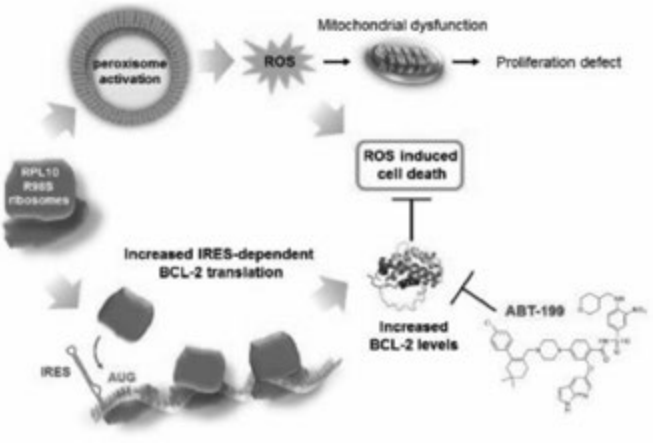

Figure 1.

Summary/Conclusion: The RPL10 R98S mutation enhances peroxisomal β-oxidation, resulting in accumulation of ROS, mitochondrial dysfunction and cellular hypoproliferation. Selective preference of RPL10 R98S mutant ribosomes for IRES-dependent BCL-2 translation allows R98S cells to survive under high oxidative stress. Finally, we demonstrate that RPL10 R98S positive T-ALL samples represent a subgroup that is highly sensitive to BCL-2 inhibitor ABT-199.

Lymphoma biology

TH17 CELLS IN CLASSICAL HODGKIN LYMPHOMA ARE SUPPRESSED VIA THE PD1-PDL1 AXIS AND MAY PLAY AN IMPORTANT ROLE IN THE ACTION OF PD1 CHECKPOINT INHIBITORS

J. Taylor[1,2,*], A. Clear[1], P. Greaves[1], M. Poynton[1], M. Caporale[1], M. Calaminici[1], J. Gribben[1]

[1]Centre for Haemato-Oncology, Barts Cancer Institute, [2]Haematology , St Barts Hospital, London, United Kingdom

Background: Exciting responses are reported with Programmed Death 1 inhibitors (PD1i) in Classical Hodgkin Lymphoma (CHL). It is widely believed that PD1i act by reversing CD8 T cell exhaustion, however, predictors of PD1i response in CHL are elusive. Neither CD8 infiltration, PD1 expression nor lymphoma MHC1 expression are predictive as might be expected with a CD8-dependent mechanism of action (MOA). Instead, lymphoma MHC2 expression is associated with response and Programmed Death Ligand 1 (PDL1)-expressing tumor associated macrophages (TAM) interact primarily with PD1+CD4+ not CD8+ cells. These data suggest that CD4+T cells are central to the activity of PD1i in CHL and may be key to identifying better predictors of response.
Aims: To evaluate T cell subsets in CHL and their relationship to the PD1-PDL1 axis.
Methods: We assessed 146 patients with CHL and 24 reactive lymph node (RLN) controls. Immunohistochemistry (IHC) and novel phenotyping and spatial analysis methods were used to assess TAM, T subsets, lymphoma cells and the PD1 axis. Phenotyping was performed using IHC followed by stripping and re-staining of the same section, allowing accurate assessment of dual-positivity. Spatial analysis was performed using dual-staining on serial sections. CD4+T subset frequency by distance from the lymphoma cell was determined using HALO analysis software. To assess lymphoma influence on TAM, monocyte-derived macrophages (MdM) were differentiated from healthy PBMCs and treated with KMH2 CHL cell line supernatant.

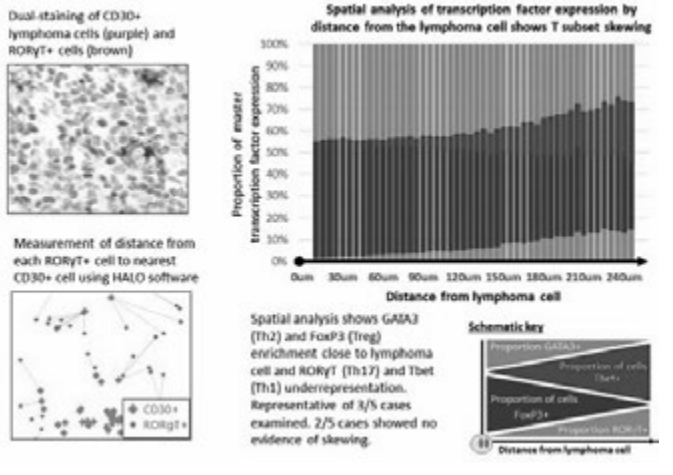

Figure 1.

Results: CD8+ lymphocytes were frequent, but PD1+ tumour-infiltrating lymphocytes (TIL) were absent or seen at low levels in CHL (median 33% vs 0.08% of nucleated cells). No correlation was seen between PD1+ TIL and PDL1. The absence of a significant PD1+ CD8 population or correlation to PDL1 is inconsistent with a central role for CD8 exhaustion. Expression of the Th17 transcription factor RORγT was reduced in CHL compared to RLN (p=0.001). Having identified that Th17 suppression was seen in CHL we assessed the role of Th17-suppressing factors; PDL1, Gal1 and IDO1 were upregulated on lymphoma cells and TAM. PDL1+TAM were enriched in areas proximal to lymphoma cells and MdM treatment with CHL cell line supernatant led to PDL1 upregulation (p=0.009) suggesting that TAM PDL1 expression is lymphoma induced. We observed an inverse correlation between RORγT+ TIL and PDL1 (p=<0.001) but no correlation between RORγT+ TIL and IDO1 or Gal1. No correlation was seen between PDL1 and other CD4+T-related transcription factors: Tbet (Th1), GATA3 (Th2) or FoxP3 (Treg). Spatial analysis revealed skewing of the T cell infiltrate by distance from the lymphoma cell. Skewed cases revealed enrichment of FoxP3+ and GATA3+ and underrepresentation of Tbet+ and RORγT+ TIL around lymphoma cells (Image, p=<0.0001). This powerful method corrects for variations in tumour content and highlights patterns that are hard to assess by eye. The finding of a distribution similar to Th1 suggests a Th17 anti-tumour role (Figure 1).
Summary/Conclusion: The data presented support a model of lymphoma suppression of Th17 cells via the PD1-PDL1 axis. This would explain PD1i activity despite a lack of observed PD1 expression. This is supported by: i) low Th17 numbers, ii) lymphoma-induced expression of Th17-suppressing factors, iii) an inverse correlation to PDL1 expression that is not seen with other CD4+ subsets and iv) a spatial distribution pattern similar to Tbet+ TIL. These data in conjunction with reports of an association between MHC2 with a response to PD1 inhibition highlight a central role for Th17 cells in the MOA of PD1i in CHL.

S829

EFFICACY OF VENETOCLAX AS A SINGLE AGENT AND IN COMBINATION WITH IBRUTINIB IN REFRACTORY OR RELAPSED T-PROLYMPHOCYTIC LEUKEMIA

C. Kornauth[1,*], B. Boidol[2], J. Koller[1], A. Ringler[2], E. van der Kouwe[1], L. Kazianka[1], G. Hörmann[3], I. Simonitsch-Klupp[4], U. Jäger[1], S. Kubicek[2], P. Staber[1]

[1]Clinical Department of Haematology, University Clinic for Internal Medicine I, Medical University of Vienna, [2]Center of Molecular Medicine (CeMM), Austrian Academy of Science, [3]Department of Laboratory Medicine, [4]Department of Pathology, Medical University of Vienna, Vienna, Austria

Background: T-cell prolymphocytic leukemia (T-PLL) is a rare and aggressive T-lymphoid malignancy usually refractory to current treatment strategies or complicated by relapse and associated with short overall survival.
Aims: We set out to identify novel effective treatments for T-PLL patients, especially new combinatorial treatment strategies.
Methods: We applied next-generation functional testing of primary patient-derived leukemia cells using a library 106 FDA approved anticancer drugs or compounds currently in clinical development. Combinatorial functional testing of T-PLL patient samples with venetoclax in combination with 14 other agents such as ibrutinib, idelalisib, 5-azacytidine, 6-mercaptopurin, alitretinoin, bendamustine, bortezomib, and cisplatin was performed. Bliss' independence was used to assess synergistic or antagonistic effects of the respective combination partners *ex vivo*.

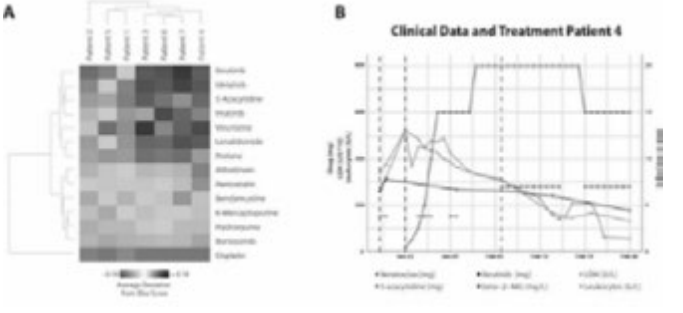

Figure 1.

Results: We found that the B-cell lymphoma 2 (BCL-2) inhibitor venetoclax (ABT-199) demonstrated the strongest T-PLL-specific response *ex vivo* when comparing individual drug response in 86 patients with refractory hematologic malignancies. Based on these results, off-label venetoclax treatment was commenced in 2 late-stage refractory T-PLL patients resulting in striking clinical responses (Boidol et al., Blood 2017). The most promising candidates for combination were the Bruton tyrosine kinase inhibitor ibrutinib, the PI3K-inhibitor idelalisib, and the DNA methyltransferase inhibitor 5-azacytidine, whereas cisplatin antagonized the effect of venetoclax across all patient samples tested (Figure 1A). Off-label co-treatment of venetoclax and 5-azacytidine was commenced in a T-PLL patient at third relapse after a failed re-treatment attempt with alemtuzumab presenting with dyspnea, leukocytosis, splenomegaly and reduced clinical condition. Combination of 5-azatiidine and venetoclax demonstrated modest clinical and laboratory improvement. In contrast, after initiating co-treatment with ibrutinib and venetoclax a dramatic response was observed as evidenced in significant clinical improvement, significant decrease in spleen size and disease related laboratory values such as leukocytosis, LDH, and B2-MiG (Figure 1B). At time of report the response is ongoing.

Summary/Conclusion: Our findings demonstrate first evidence of single-agent activity of venetoclax. Furthermore, we identify ibrutinib as an effective combination partner both *ex vivo* and in patients, offering a novel treatment concept in T-PLL.

REFINING DIFFUSE LARGE B CELL LYMPHOMA SUBGROUPS USING INTEGRATED ANALYSIS OF MULTI-LEVEL MOLECULAR PROFILES IN A PROSPECTIVE COHORT: A LYSA STUDY

S. Dubois[1,2,*], B. Tesson[3], P.-J. Viailly[2], S. Mareschal[2], E. Bohers[2], P. Ruminy[2], P. Peyrouze[4], C. Copie-Bergman[5], J.-P. Jais[6], C. Haioun[7], G. Salles[8], R. Delarue[9], T.J. Molina[10], H. Tilly[2], F. Jardin[2]

[1]CHU de Rouen, [2]Centre Henri Becquerel, Rouen, [3]Institut Carnot CALYM, Paris, [4]Université de Lille 2, Lille, [5]IMRB – Inserm U955, AP-HP Hôpital Henri Mondor, Créteil, [6]Inserm UMRS 872, AP-HP Hôpital Necker, Paris, [7]Unité Hémopathies Lymphoïdes, AP-HP Hôpital Henri Mondor, Créteil, [8]CNRS UMR5239, Hospices Civils de Lyon, Lyon, [9]Department of Hematology, [10]Pathology Department, AP-HP Hôpital Necker, Paris, France

Background: Gene expression profiling has enabled the identification of three distinct DLBCL subtypes: ABC, GCB and PMBL. More recently, techniques such as Next Generation Sequencing (NGS) and Copy Number Variation (CNV) analysis have led to an increasingly detailed characterization of the genomic profiles of DLBCL.
Aims: The aim of this study was to perform a fully integrated analysis of mutational, genomic, and expression profiles of DLBCL to refine disease subtypes using molecular tools.
Methods: 215 patients with *de novo* DLBCL from the prospective, multicenter and randomized LNH-03B LYSA clinical trials were included. Gene expression profiling (GEP) was obtained with HGU133+2.0 Affymetrix GeneChip arrays. Mutational profiles were established by Lymphopanel NGS, targeting 34 key genes (Dubois *et al*., CCR 2016). CNV were analyzed by array Comparative Genomic Hybridization. FISH was performed to identify BCL2, BCL6 and MYC rearrangements. IHC was performed on CD10, BCL6, MUM1, BCL2, FOXP1, IgM and MYC. We applied unsupervised independent component analysis (ICA) to GEP data and identified 38 gene signatures (components) reflecting transcriptomic variability across our DLBCL cohort. SignatureDB and MSigDB databases were used to interpret the biological function of each component.

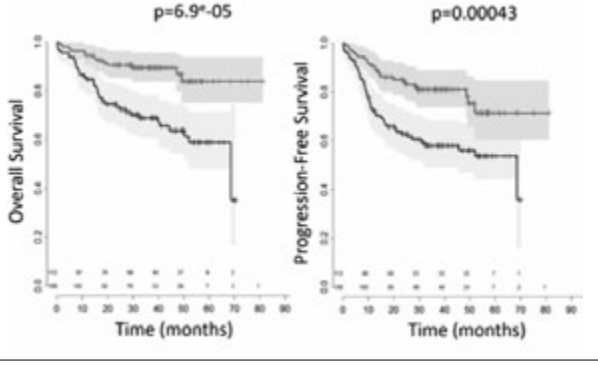

Figure 1.

Results: Many of the components were closely related to well-known DLBCL features such as cell of origin, stromal and MYC signatures, as evidenced by gene set overrepresentation analyses. Correlation of the components' expression with gene mutational status, CNV data, IHC and FISH identified interesting associations. Stromal components correlated positively with *B2M* and *TNFAIP3* mutations (FDR≈0.02) and negatively with *CD79B* mutations (FDR≈0.008). The GCB/ABC signature correlated positively with *EZH2*, *BCL2*, *STAT6* and *GNA13* mutations (FDR <10^{-3}-0.06) and negatively with *CD79B* and *PIM1* mutations (FDR 0.005 - 0.06). PMBL and interferon components shared numerous correlations with mutations including *SOCS1*, *B2M*, *ITPKB*, *STAT6*, *CD58*, *XPO1* and *TNFAIP3* (FDR <10^{-3}- 0.04). Both components were also linked to gain/amplification of the 9p24 locus containing *PDL1*/*PDL2*. Interestingly, PMBL with high interferon component expression also presented low T cell component expression, in keeping with the negative regulation of T lymphocytes by PDL1/2 during the immune response. ICA also identified variability among the GCB subgroup, delineating proliferation-high / T cell-low GCB patients versus GCB patients with the opposite phenotype. The Myc component was strongly linked to FOXP1, MUM1, IgM and MYC IHC expression, as well as to MYC rearrangement, showcasing a poor prognosis non-GCB population. Stromal components were strongly correlated with better OS ($p<10^{-4}$- $p<0.05$) and PFS ($p<10^{-3}$) (Figure 1). Another component correlated with *MYD88* and *CD79B* mutations as well as gain of 19q13 locus was found to be correlated with poor OS and PFS (p=0.01): gain of 19q13 locus has previously been shown to be linked to reduced event-free survival.
Summary/Conclusion: ICA is an unsupervised approach, which is sensitive and efficient for the analysis of DLBCL expression profiles. We characterized components linked to gene mutational status, to the presence of CNV, to IHC and FISH results and, notably, to patient outcome. The results of this type of integrated analysis should enable a global and multi-level view of DLBCL, as well as improve our understanding of DLBCL subgroups.

S831

EVIDENCE FOR INTERCLONAL TUMOR COOPERATIVITY IN MEDIATING IBRUTINIB RESISTANCE BY BTK-C481SER EXPRESSING MYD88 MUTATED LYMPHOMA CELLS

G. Yang[1,*], J. Chen[1], X. Liu[1], M. Munshi[1], L. Xu[1], N. Tsakmaklis[1], M. Demos[1], A. Kofides[1], M. L. Guerrera[1], G. Chan[1], C. Patterson[1], K. Meid[1], J. Gustine[1], T. Dubeau[1], P. Severns[1], J. Castillo[1], Z. Hunter[1], J. Wang[1], S. Buhrlage[1], N. Gray[1], S. Treon[1]

[1]Dana-Farber Cancer Institute, Boston, United States

Background: Acquired ibrutinib resistance due to BTKCys481 mutations occurs in B-cell malignancies, including those with MYD88 mutations. BTKCys481 mutations are usually sub-clonal, and their relevance to clinical progression remains unclear.
Aims: We sought to define the signaling pathways that promote ibrutinib resistance in MYD88 mutated WM and ABC DLBCL cells. Furthermore, we sought to delineate mechanisms responsible for promoting ibrutinib resistance in neighboring BTK wild-type tumor cells.
Methods: We engineered BTKCys481Ser and BTKWT expressing MYD88 mutated WM and ABC DLBCL cells, and performed signaling studies that included pathways responsible for aberrant MYD88 signaling, and downstream BTK signaling. Furthermore, cytokine release was evaluated by multiplex assay and correlated to findings in patients who progressed on ibrutinib after acquisition of BTK Cys 481 mutations. Lastly, co-culture experiments with BTK Cys 481 mutated and unmutated cells were performed and viability assessed.
Results: Comparing to BTK^{WT}, $BTK^{Cys481Ser}$ expressing cells re-activates BTK–PLCγ2–ERK1/2 signaling in the presence of ibrutinib. Use of ERK1/2 inhibitors triggered apoptosis in $BTK^{Cys481Ser}$ expressing cells, and showed synergistic cytotoxicity with ibrutinib. ERK1/2 re-activation in ibrutinib treated $BTK^{Cys481Ser}$ cells was accompanied by release of many pro-survival and inflammatory cytokines, including IL-6 and IL-10 that were also blocked by ERK1/2 inhibition. To clarify if cytokine release by ibrutinib treated $BTK^{Cys481Ser}$ cells could protect non-transduced BTK^{WT} MYD88 mutated malignant cells, we used a Transwell™ co-culture system, and showed that non-transduced BTK^{WT} MYD88 mutated WM or ABC DLBCL cells were rescued from ibrutinib induced cell death when co-cultured with $BTK^{Cys481Ser}$ but not their BTK^{WT} expressing counterparts (Figure 1). Use of IL-6 and/or IL-10 blocking antibodies abolished the protective effect conferred on non-transduced BTK^{WT} by co-culture with $BTK^{Cys481Ser}$ expressing WM or ABC DLBCL cell counterparts. Rebound of IL-6 and IL-10 serum levels also accompanied disease progression in WM patients with acquired BTK^{Cys481} mutations.

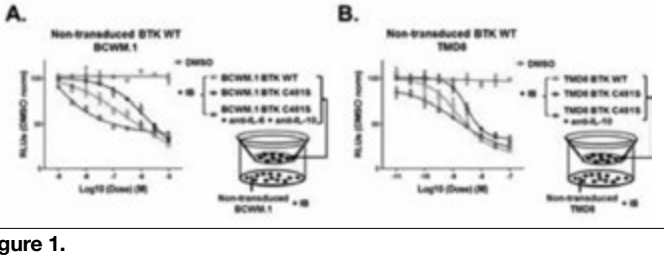

Figure 1.

Summary/Conclusion: Our findings show that the $BTK^{Cys481Ser}$ mutation drives ibrutinib resistance in MYD88 mutated WM and ABC DLBCL cells through re-activation of ERK1/2 activation, and can confer a protective effect on BTK^{WT} cells through a paracrine mechanism. The findings provide evidence for interclonal tumor cooperativity in mediating ibrutinib resistance.

Cell and gene therapy: Clinical results

S832

EFFICACY AND SAFETY OF CD22-DIRECTED CAR-T CELL THERAPY IN 15 PEDIATRIC REFRACTORY OR RELAPSED B ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS

This abstract is embargoed until Saturday, June 16, 08:30 local time.

J. Pan[1,*], B. Deng[2], S. Liu[1], J. Wang[1], T. Wu[3], Z. Gao[3], Y. Lin[1], Y. Zhao[3], Y. Zhang[3], X. Tan[3], A. H. Chang[4], C. Tong[1]

[1]Department of Hematology, [2]Department of Immunotherapy, [3]Department of bone marrow transplantation, Beijing Boren Hospital, Beijing, [4]Clinical Translational Research Center, Shanghai Pulmonary Hospital, Shanghai, China

Background: Many patients with refractory or relapsed B cell acute lymphoblastic leukemia (rrB-ALL) have disease progressed again in one year after initial successful CD19-directed chimeric antigen receptors T (19-CAR-T) cell therapy. Most of them are probably refractory to secondary 19-CAR-T therapy. The relapse rate in rrB-ALL is still high even after allogeneic hematopoietic stem cell transplantation (allo-HCT). Therefore, new modalities are needed.
Aims: The efficacy and safety of a novel CD22-directed CAR-T (22-CAR-T) cell therapy in pediatric patients with rrB-ALL were evaluated.
Methods: Between July 6, 2017 and January 8, 2018, consecutive 15 pediatric patients (pts) with rrB-ALL who received 22-CAR-T cell therapy were enrolled in Beijing Boren Hospital. The median age was 8 (2-18) years old. The median disease course was 21 (5-84) months. 4/15 pts relapsed post-allo-HCT and 11/15 pts relapsed after chemotherapy. 14/15 pts received 19-CAR-T therapy before. One patient had weak CD19 expression on leukemia cells when relapsed. 11/15 pts had hematologic relapse with 42 (5-95.5) % blasts in bone marrow (BM), 2 pts remained minimal residual disease (MRD) positive by flow cytometry (FCM-MRD), and 2 pts developed extramedullary diseases (EMDs) only. All pts had CD22 expression on leukemia cells. A lentiviral vector was used to carry a second-generation CAR including anti-CD22 scFV derived from a humanized CD22 antibody, 4-1BB co-stimulatory and CD3z signaling domains. Manufacture of CAR-T cells from peripheral blood mononuclear cells commenced on day of leukapheresis and was completed in 7-8 days. The median doses of 22-CAR-T cells infused were 8.2 (0.5-34.7) × 10^5/kg in non-transplant pts, and 0.9 (0.7-5.0) × 10^5/kg in transplant pts. The 22-CAR-T cell expansion and cytokine releasing syndrome (CRS) were monitored after infusion. The efficacy in BM was evaluated on day 30, and EMDs were examined by imagine tests (ultrasonography, MRI and PET-CT) on day 30 as well. Long term follow-up was carried out and the outcome depended on several factors.
Results: Peak expansion of CAR-T cells (3.2%-71.7% of $CD3^+$ cells) was detected at day 11±1.8. On day 30, 13/15 (86.7%) pts had response. 10/11 hematologic relapsed pts achieved CR or CR with incomplete count recovery (CRi), and 9 of them became FCM-MRD negative. 1/2 $FCM\text{-}MRD^+$ case turned to $FCM\text{-}MRD^-$. 1/ 2 EMDs pts achieved CR, but the other patient had only partial response (PR) (mass size: from 10.0×5.3×5.9 cm to 6.2×2.3×3.1 cm). Both 2 pts with no response to 22-CAR-T therapy remained strong CD22 expression on leukemia cells. All pts experienced mild to moderate (grade 0-2) CRS only and 2 pts occurred grade 1 neurotoxicity. There was no significant difference in CRS between pts with and without allo-HCT (p=0.41). With a median follow-up time of 108 (46-199) days, 6 pts had been bridged to allo-HCT after 22-CAR-T cell therapy.11/12 CR/CRi pts achieved progression-free survival (PFS), and 1 of 12 CR/CRi pts had relapsed on day 50. The 6-month PFS rate was 91.7 (91.5-91.9) %.
Summary/Conclusion: Our results indicate that CD22-directed CAR-T cell therapy is quite effective and safe for treating pediatric rrB-ALL, and could be valuable especially for those who have failed to previous 19-CAR-T therapy. Extended observation period will be required to determine the long-term outcome and whether subsequent allo-HCT could further reduce the relapse rate after CAR-T cell therapy.

Lurie Children's Hospital of Chicago, Chicago, United States

Background: LentiGlobin Drug Product (DP) contains autologous CD34+ hematopoietic stem cells (HSCs) transduced *ex vivo* with the BB305 lentiviral vector (LVV) encoding β-globin with the T87Q point mutation which permits quantification of transgenic hemoglobin (Hb) in transduced cells. The safety and efficacy of LentiGlobin in patients with transfusion dependent β-thalassemia (TDT) was evaluated in the phase 1/2 Northstar (HGB-204; NCT01745120) study where 9/10 patients with non-$β^0/β^0$ genotypes were free from chronic packed red blood cell (pRBC) transfusions for a median of 29 months with a median Hb of 10.2 g/dL (Kwiatkowski, ASH 2017). To further improve clinical results, the LentiGlobin DP manufacturing process was modified to increase transduction rates.
Aims: To evaluate the efficacy and safety of LentiGlobin DP with these refinements in patients with TDT and non-$β^0/β^0$ genotypes in the ongoing phase 3 Northstar-2 study (HGB-207; NCT02906202).
Methods: Patients with TDT (≥100 mL/kg/yr of pRBCs or ≥8 pRBC transfusions/yr) underwent HSC mobilization with G-CSF and plerixafor. Collected HSCs were transduced with the BB305 LVV. Patients underwent myeloablative conditioning with pharmacokinetic-adjusted busulfan dosage, were infused with transduced cells, and were followed for engraftment, pRBC transfusion independence, VCN, HbA^{T87Q}, adverse events (AEs), vector integration profile, and evidence of replication competent lentivirus (RCL). Summary statistics are presented as median (min – max).
Results: As of 13 October 2017, 7 patients with TDT and non-$β^0/β^0$ genotypes (age 20 [15 – 24] yrs) have been treated in Northstar-2 with a median follow-up of 3 (1 – 9) months. Data are reported for 6 treated patients with > 1 month follow-up. The time to neutrophil and platelet engraftment was 21.5 (17 – 26) and 44 (35 – 46) days, respectively. All patients successfully engrafted with no graft failure or death. AEs were consistent with myeloablative conditioning and no DP-related AEs were observed. Serious AEs after DP infusion included one AE each of transfusion reaction (grade 2) and hypotension (grade 3). No evidence of clonal dominance or RCL has been observed. As of 1 December 2017, 11 DP lots had been manufactured for 10 patients in Northstar-2 of which 9 could be assessed for % transduced CD34+ cells. In Northstar, 22 DP lots were manufactured for 18 patients. The refined manufacturing process used in Northstar-2 yielded higher DP VCNs (median 3.3 vs 0.7) and higher % transduced cells (median 82% vs 32%). In Northstar-2, peripheral blood VCN was 0.25 – 2.3 in 6 treated patients with 3 – 9 months of follow-up. The 3 patients with ≥ 6 months of follow-up have been transfusion-free for 7.5, 4.2, and 5.3 months with total Hb levels of 12.5, 8.4, and 11.5 g/dL at last visit. The first patient treated began phlebotomy 6 months post-infusion. By month 3, 5/6 patients had HbA^{T87Q} levels of ≥ 6.5 g/dL, and total Hb of 10.4 – 12.5 g/dL with HbA^{T87Q} contributing 58 – 91% of total Hb.
Summary/Conclusion: The refined manufacturing process for LentiGlobin in Northstar-2 has yielded higher DP VCNs and % transduced CD34+ cells. Early data suggest that these improved DP parameters translate into clinically significant levels of HbA^{T87Q} that can result in near-normal or normal total Hb production allowing patients to be free of transfusions. The safety profile to date is similar to that observed in Northstar. Longer follow-up and results observed in additional patients in Northstar-2 will be presented.

S834

LONG-TERM OUTCOME OF A COHORT OF ELDERLY ACUTE MYELOID LEUKEMIA PATIENTS, NOT ELIGIBLE FOR ALLOGENEIC STEM CELL TRANSPLANTATION, INFUSED WITH ALLOREACTIVE NATURAL-KILLER CELLS AS CONSOLIDATION THERAPY

Orsola-Malpighi Hospital, University of Bologna, Bologna, [2]Department of Medicine, Division of Hematology and Clinical Immunology, University of Perugia, Ospedale Santa Maria della Misericordia, Perugia, [3]Immunohematology Service and Blood Bank, S.Orsola-Malpighi Hospital, Bologna, [4]Department of Hematology, Istituto Scientifico Romagnolo per Studio e Cura dei Tumori, Meldola, Forlì-Cesena, [5]Department of Medical and Surgical Sciences, University of Bologna, Bologna, [6]Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, IRCCS Azienda Ospedaliera Universitaria S. Martino-IST, Genova, Italy

Background: Several pre-clinical and clinical studies revealed the potential of adoptive immunotherapy with alloreactive, natural-Killer (NK) cells in acute myeloid leukemia (AML) patients. Indeed, adoptively transferred NK cells can be successfully expanded *in vivo* and significantly impact on leukemic cells killing.
Aims: Aim of this work is to establish the impact on long-term survival and relapse rate of adoptive immunotherapy with alloreactive NK cells in a cohort of AML patients, who had been infused with alloreactive NK cells in CR, as post-consolidation therapy.
Methods: Seventeen AML patients, with a median age of 64 years (range 53-73), were enrolled in our study. Patients were in first complete remission (CR) after standard chemotherapy regimens and were unfit for allogeneic stem cell transplantation (ASCT). Patients in morphologic or better CR with an haploidentical KIR-L–mismatched donor, received NK cells after an immunosuppressive chemotherapy regimen based on fludarabine 25 mg/mq from day 7 to 3 and cyclophosphamide 4 g/mq on day 2. Two days after cyclophosphamide administration, patients received the NK cell infusion (day 0), which was followed by subcutaneous administration of IL-2 ($10x10^6$ IU/day, 3 times weekly) for 2 weeks (6 doses total). To correlate donor NK cell activity with clinical response, donor NK cells were assessed before and after infusion.
Results: As previously reported, NK cell infusion was well-tolerated and no signs of GVHD were described. The median follow-up is now extended to 55.5 months (range 6-125 months) *vs* 22.5 (range 6-68 months) in the original publication. Eight out of 16 evaluable patients (50%) are alive disease-free. Among relapsing patients (8 of 16), median time to relapse was 9 months (range 5-51 months). Three of the relapsed patients maintained a prolonged CR for 15, 24 and 51 months, respectively. Among them, the patient relapsing after 51 months received a second NK infusion, thus obtaining a second CR. All patients treated with molecular disease achieved molecular CR. Based on these data, 11 of 16 (69%) patients were considered as responders, whereas 5 of 16 (31%) were non-responders. These long-term clinical results were compared with the outcome of patients from a historical control cohort, treated with standard chemotherapy regimen and who did not receive NK immunotherapy. In the latter group, 14 out of 15 patients (93%) relapsed, with a median time to relapse of 11 months (range 3-79). Due to the low numbers of evaluable patients, the difference in terms of DFS between the two groups of patients is not statistically significant, although a trend toward an increase of DFS for patients who received NK infusion may be observed. In agreement with our previous work, the predictive impact of higher alloreactive NK donor repertoire on clinical outcome was confirmed also when a longer-follow up was evaluated.
Summary/Conclusion: In conclusion, adoptively transferred alloreactive NK cells have the potential to induce prolonged control of AML in the non transplant setting. Moreover, the composition of NK graft in terms of frequency of alloreactive NK cells is likely to influence the long-term clinical response.

S835

CART19-BE-01: A EUROPEAN ACADEMIC TRIAL ON THE USE OF ARI-0001 CELLS (A3B1:CD8:4-1BB:CD3Z CAR19 CELLS) IN PATIENTS WITH CD19+ RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA

J. Delgado[1,*], S. Rives[2], M. Castella[3], M. Caballero-Baños[3], V. Ortiz-Maldonado[1], A. Boronat[3], E. Garcia-Rey[4], T. Baumann[1], M. Torrebadell[2], J. Cid[5], M. Lozano[5], C. [1]Hematology, Hospital Clinic, [2]Hematology, Hospital Sant Joan de Deu, [3]Immunology, Hospital Clinic, [4]Banc de Sang i Teixits, [5]Apheresis Unit, Hospital Clinic, [6]Clinical Trials, Hospital Sant Joan de Deu, [7]University of Barcelona, Barcelona, Spain

Background: The prognosis of relapsed/refractory acute lymphoid leukemia (R/R ALL) is very poor, particularly in patients relapsing after allogeneic hematopoietic cell transplantation (alloHCT). New agents, such as inotuzumab or blinatumomab, have improved the complete response rate (CRR) in R/R ALL, but with a progression-free survival (PFS) shorter than 6 months. In the last decade, several chimeric antigen receptor anti-CD19 (CAR19) constructs have been developed. One of them (tisagenlecleucel) was approved by the FDA for pediatric or young adults with R/R ALL. The approval was based on a CRR around 80% with a 6-month PFS around 70%.
Aims: To develop our own academic CAR19 construct for clinical use.
Methods: We selected the anti-CD19 A3B1 hybridoma licensed by our institution, identified the scFv sequence and incorporated the CD8, 4-1BB and CD3z modules next to it. We cloned it into a 3rd generation lentiviral vector and transduced PBMCs from buffy coats after activation with CD3 and CD28 TransACT polymeric nanomatrix (ARI-0001 cells). Once cytotoxicity and specificity were confirmed *in vitro* and *in vivo* (in NALM6-xenograft NSG murine models), we scaled-up both lentiviral and cell production, the latter using the CliniMACS Prodigy System (Miltenyi). After reaching all pre-specified acceptance criteria in lymphoapheresis from 3 healthy donors, the Spanish Agency of Medicines approved our IND and also our first pilot clinical trial (clinicaltrials.gov NCT03144583) on May/2017. Eligibility criteria included R/R ALL (adult and pediatric), NHL and CLL who had failed all standard available therapy, but in this abstract we will only report the outcome of patients with R/R ALL.
Results: As of February 2018, we have recruited 8 patients with R/R ALL, all but one relapsing after alloHCT. Median age was 19.5 years (range 3-34) and 50% were female. Patients were included in the trial in first (1), second (5), and third (2) relapse. Two patients were in CR with negative minimal residual disease (MRD) at study inclusion. The median percentage of blasts in bone marrow was 92% (range 73-96%) for the remaining 6 patients. We successfully prepared ARI-0001 cells in all patients, although two patients required two procedures (2/10 [20%] production failure rate globally). After fludarabine (90 mg/m^2) and cyclophosphamide (900 mg/m^2) chemotherapy, we infused $0.5\text{-}5x10^6$ ARI-0001 cells/kg to 7 patients. In one patient the infusion was delayed due to pneumonitis. Only 4 patients are evaluable at this time (two were in MRD negative CR upon recruitment, one has not been evaluated yet), and all achieved CR with negative MRD (100% CRR) at day +28. Median follow-up is 114 days (range 13-219 days). All 6 patients have developed absolute B-cell aplasia, and none has relapsed so far. Cytokine release syndrome (CRS) has been observed in all 7 patients, but it was of grade III-IV in only one of them (14%). This patient's grade IV CRS was fully reversible with tocilizumab. Grade I neurotoxicity (confusion and tremor) has been observed in 2 (29%) patients but resolved spontaneously.
Summary/Conclusion: It is feasible to prepare CART19 (ARI-0001) cells in a purely academic setting using the automated CliniMACS Prodigy System and home-made lentiviral vectors. The treatment was safe, with only one case (14%) of severe but reversible CRS. The treatment was also efficacious, with a 100% CRR and no relapses so far, although with very limited median follow-up.

RECENT PROGRESS IN GENE THERAPY FOR SEVERE SICKLE CELL DISEASE: UPDATED INTERIM RESULTS FROM A PHASE 1 CLINICAL STUDY OF LENTIGLOBIN GENE THERAPY

J. Kanter[1,*], A. Thompson[2], M. Mapara[3], M. Walters[4], J. Kwiatkowski[5], L. Krishnamurti[6], M. Schmidt[7], A. Miller[8], F. Pierciey[8], W. Shi[8], M. Asmal[8], J. Tisdale[9]

[1]Division of Pediatrics, Medical University of South Carolina, Charleston, [2]Division of Hematology, Oncology & Stem Cell Transplant, Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, [3]Division of Hematology/Oncology, Columbia University Medical Center, New York, [4]Blood and Marrow Transplant Program, Division of Hematology/Oncology, UCSF Benioff Children's Hospital Oakland, Oakland, [5]Division of Hematology, Children's Hospital of Philadelphia, Philadelphia, [6]Department of Pediatrics, Division of Hematology/Oncology/BMT, Emory University School of Medicine, Atlanta, United States, [7]German Cancer Research Center (DKFZ), National Center for Tumor Diseases (NCT), Heidelberg, Germany, [8]bluebird bio, Inc. , Cambridge, [9]Sickle Cell Branch, National Heart, Lung and Blood Institute, National Institutes of Health, Bethesda, United States

Background: The purpose of β-globin gene transfer into hematopoietic stem progenitor cells (HSPCs) is to express a functional adult β-globin that reduces or eliminates sickle cell disease (SCD) symptoms. The investigational gene therapy LentiGlobin Drug Product (DP) contains autologous CD34+ HSPCs transduced with the BB305 lentiviral vector, which encodes β-globin with an anti-sickling mutation (HbA^{T87Q}). Initial results from a Phase 1 HGB-206 study (NCT02140554) of LentiGlobin in patients with severe SCD treated with CD34+ HSPCs from bone marrow harvesting (BMH) showed acceptable safety, but suboptimal HbA^{T87Q} production. The revised protocol instituted pre-harvest RBC transfusions, increased target busulfan levels, increased the DP VCN after manufacturing, and investigated plerixafor-mediated mobilization/apheresis for DP manufacturing.
Aims: To investigate the safety and efficacy of a revised LentiGlobin gene therapy protocol with plerixafor-mobilized HSPCs in severe SCD.
Methods: Adult patients with severe SCD (history of recurrent vaso-occlusive crisis, acute chest syndrome, stroke, or tricuspid regurgitant jet velocity of >2.5 m/s) were enrolled. In lieu of BMH-derived HSPCs for back-up and DP manufacturing (Group [Grp] A), the revised protocol instituted ≥2 months of RBC transfusions before plerixafor mobilization/apheresis for back-up HSPC collection but retained BMH for DP manufacturing (GrpB). A GrpC evaluated DP and back-up prepared with plerixafor-mobilized HSPCs. Following HSPC collection, patients received myeloablative conditioning, followed by DP infusion. Adverse events (AEs), engraftment, vector copy number (VCN) and HbA^{T87Q} production were monitored.
Results: As of Nov 30, 2017, 10 patients (18-42 yrs) received LentiGlobin DP. In 7 GrpA patients, the median DP VCN and cell dose were 0.6 (0.3-1.3) copies/diploid genome and 2.1 (1.6-5.1)×10^6CD34+ cells/kg, with 8% - 42% CD34+ cells transduced. Median follow-up was 21.6 (17.8-26.7) months, as of Oct 26, 2017. At last visit, the median peripheral blood (PB) VCN, total Hb and HbA^{T87Q} levels were: 0.1 (0.1-0.2), 9.7 (7.5-10.9) g/dL and 0.7 (0.5-2.0) g/dL. In 2 GrpB patients, DP VCN and cell dose improved: DP VCNs were 1.4/3.3 and 2.9/5.0 (2 DP lots per patient) and total cell doses were 2.2 and 3.2×10^6 CD34+ cells/kg, with 46% - 95% cells transduced. At 9 (pt 1313; GrpB) and 6 months (pt 1312; GrpB) follow-up, PB VCNs were 0.5 and 2.5, total Hb levels were 10.4 and 12.6 g/dL, and HbA^{T87Q} levels were 3.0 and 6.4 g/dL. Of 11 patients enrolled in GrpC, 6 completed plerixafor mobilization/apheresis. DPs in 4 GrpC patients had median VCN and cell dose of 3.3 (2.8-4.6) and 6.9 (3-8)×10^6 CD34+ cells/kg, with 78% - 88% cells transduced. One GrpC patient received DP and at 1-month follow-up (as of Dec 6, 2017) had a PB VCN of 2.5. Additional follow-up results will be presented. There were 17 Grade 3-4 AEs reported in 5 patients after BMH (N=9). There were 5 Grade 3-4 AEs reported in 3 patients after plerixafor mobilization/apheresis (N=7). The AEs that were Grade 3-4 after DP infusion were consistent with myeloablative busulfan. To date, there was no graft failure and no Grade 3-4 DP-related infusional toxicity/AEs.
Summary/Conclusion: Patients enrolled and treated in a revised protocol had improvements in DP VCN and HbA^{T87Q} levels with no new significant safety events to date. Plerixafor mobilization in patients with severe SCD appears safe and can result in DPs with VCNs comparable to, and cell doses higher than, BMH. Longer follow-up and additional experience will clarify the effect of protocol changes.

Thrombosis – Risk factors and treatment

S837

PLATELET ADHESION UNDER FLOW CONDITION IS SIGNIFICANTLY AFFECTED BY HEMATOCRIT LEVELS IN POLYCYTHEMIA VERA PATIENTS

S. Gamba[1,*], A. Vignoli[1], M. Marchetti[1], P.E. van der Meijden[2], C. Giaccherini[1], S. Tessarolo[1], F. Swieringa [2], H. ten Cate[3], G. Finazzi[4], A. Rambaldi[4], J.W. Heemskerk[2], A. Falanga[1]

[1]Division of Immunohematology and Transfusion Medicine, ASST Papa Giovanni XXIII, Bergamo, Italy, [2]Department of Biochemistry, [3]Department of Internal Medicine, CARIM, Maastricht University, Maastricht , Netherlands, [4]Division of Hematology, ASST Papa Giovanni XXIII, Bergamo, Italy

Background: Polycythemia Vera (PV) is complicated by a high rate of thromboembolic events. Aspirin therapy (81–100 mg once-daily) + phlebotomy with a target hematocrit (HCT) of 45% is currently recommended in all PV patients regardless of risk status. Recently, a novel mechanism by which elevated HCT can lead to an increased risk of thrombosis has been described. The red blood cells push the platelets closer to the vessel wall, increasing the probability of their adhesion and activation via von Willebrand factor and collagen (Blood 19: 2537, 2017). This may occur in PV, where multiple cellular events may be needed to trigger thrombosis.
Aims: In a cohort of PV patients, we aim to characterize the *in vitro* platelet thrombus formation capacity under flow conditions at arterial shear rate in relation to HCT levels.
Methods: Fifty-two PV patients (26 M/26F; median age 65 years, range: 38-87) were enrolled after giving informed consent. Measurement of whole blood thrombus formation was performed in a parallel plate flow-chamber for 4' at 1,000 s^{-1}shear-rate over a collagen-coated surface. Thrombi were then stained with an anti-P-selectin-FITC antibody to evaluate the platelet activation status, and annexinV-AlexaFluor647 to detect procoagulant phosphatidylserine (PS) exposure. Results are expressed as mean±SEM of the % of area covered by thrombi or the % of adherent platelets positive for either P-selectin or AnnexinV.
Results: Platelet adhesion was significantly increased in PV (48.9±1.6%) compared to healthy controls (37.5±1.7%, $p<0.01$). In both PV and controls, almost all platelets forming the inner thrombus core expressed P-selectin, while PS was expressed by some platelets at the external thrombus border. Patients' thrombi were usually larger and more often interconnected forming a network while thrombi from controls are smaller and well isolated from each other. Considering the total population analyzed, a significant positive correlation ($p<0.005$) was found between HCT levels and either platelet adhesion and P-selectin positive platelets. Differently, no significant correlation was found between platelet adhesion and platelet count in either PV or controls. On the basis of the median value of HCT of our patient population (43.7%), subjects with an HCT value above the median had a significantly higher adhesion than the subjects with an HCT below the median (42±1.9 vs 51±2.3%, $p<0.05$). After a multivariate analysis adjusted for sex, age, therapy and JAK2-V617F allele burden, the HCT value was still significantly associated with platelet coverage and p-selectin expression.
Summary/Conclusion: Our study demonstrates that an elevated HCT increases platelet adhesion to the vessel wall. This is likely favored by local rheological factors coming from the increased red blood cell count typical of this disease. These findings support the concept that an elevated HCT is a very relevant thrombotic mechanism in PV.

S838

COMPLEMENT C3 AND C4 ARE ASSOCIATED WITH POSTNATAL VENOUS THROMBOSIS

A.E.A. Dahm[1,2,*], A.F. Jacobsen[3], E.M. Jacobsen[4], H. Skuterud Wik[4], P.M. Sandset[2]

[1]Haematology, Akershus University Hospital, Lørenskog, [2]Institute of Clinical Medicine, University of Oslo, [3]Obstetrics and Gynaecology, [4]Haematology, Oslo University Hospital, Oslo, Norway

Background: Venous thrombosis (VT) is one of the most serious complications to pregnancy in developed countries. The complement system is part of the innate immune system. It has been suggested that the complement system and the coagulation system cross-talks and that high levels of C3 is associated with VT in the general population.

Aims: To investigate if high levels of complement C3 or C4 were associated with pregnancy related VT.
Methods: We investigated women in the Norwegian VIP study which is a population based case-control study of VT in pregnancy or within 3 months post partum (cases, n=313) and women without pregnancy related VT (controls, n=353). Blood samples were taken 3-16 years after the index pregnancy. We first investigated determinants of C3 and C4 in the control women with univariate linear regression. We then calculated the odds ratio (OR) for pregnancy related VT with multiple logistic regression including adjustments for other risk factors for pregnancy related VT associated with C3 or C4.
Results: In the control women C3 and C4 were associated with BMI. Control women pregnant at blood sampling had higher C3 than non-pregnant women. Both C3 and C4 were associated with CRP; the coagulation factors fibrinogen, factor VIII or factor IX; and with the coagulation inhibitors protein C, protein S, antithrombin, and free tissue factor pathway inhibitor. The strongest associations were seen between C3 and CRP (standardized regression coefficient beta 0.67), C3 and protein C (beta 0.49), C3 and free TFPI (beta 0.40), C3 and fibrinogen (beta 0.56), C3 and factor IX (beta 0.56). The crude OR for pregnancy-related VT was 1.8 (95% confidence interval (CI) 1.1-3.0) for C3 above the 90th percentile and 2.0 (95% CI 1.2-3.2) for C4 above the 90th percentile. Further stratification in antenatal and postnatal VT showed that the OR for antenatal VT for C3 above the 90th percentile was 0.87 (95% CI 0.43 to 1.7), and for C4 above the 90th percentile it was 1.4 (95% CI 0.73-2.6). For postnatal VT, the OR for C3 above the 90th percentile was 3.0 (95% CI 1.8-5.0), and for C4 above the 90th percentile 2.6 (95% CI 1.5-4.6). Adjustment for CRP, BMI, protein S, fibrinogen, factor VIII or factor IX only changed the odds ratios marginally.
Summary/Conclusion: Complement C3 and C4 were associated with several coagulation factors and coagulation inhibitors. High levels of C3 and C4 were associated with postnatal, but not antenatal VT.

S839

EFFECT OF COVARIATES IN THE PHARMACOKINETIC/PHARMACODYNAMIC MODEL OF ANDEXANET ALFA USED TO PREDICT THE REGIMEN FOR REVERSAL OF ANTICOAGULATION BY FXA INHIBITORS IN PATIENTS WITH ACUTE MAJOR BLEEDING

J.M. Leeds[1,*], Y. Xiong[2], M. Lovern[2], K. Der[1], J.W. Mandema[2], G. Lu[1], J.T. Curnutte[1], T.J. Milling[3], M. Crowther[4], S.J. Connolly[4], P. Yue[1], P.B. Conley[1]

[1]Portola Pharmaceuticals, Inc., South San Francisco, CA, [2]Certara, Menlo Park, CA, [3]Seton Dell Medical School Stroke Institute, Austin, TX, United States, [4]McMaster University, Hamilton, Canada

Background: Andexanet alfa (andexanet) is a recombinant protein that acts as a factor Xa (FXa) decoy to bind and sequester FXa inhibitors (apixaban, rivaroxaban, edoxaban, and betrixaban). A naïve-pooled pharmacokinetic (PK)/pharmacodynamics (PD) model, developed in Phase 2 studies in healthy subjects, predicted the andexanet regimen required to reverse anticoagulation by FXa inhibitors. Preliminary analysis of the ongoing Phase 3b/4 study (ANNEXA-4) demonstrated that the naïve-pooled model was predictive of the anti-FXa activity reversal in patients with acute major bleeding who were anticoagulated with FXa inhibitors. It is not known whether patient characteristics (e.g., impaired renal function, advanced age) may alter PK and affect the accuracy of the model.
Aims: The first interim data from the ANNEXA-4 study in patients with acute major bleeding was compared to predictions from the naïve-pooled PK/PD model. Additionally, enhanced analyses of the model that include evaluation of intrinsic factors that might affect both FXa inhibitor and andexanet levels in this patient population are ongoing.
Methods: In ANNEXA-4, an ongoing prospective, open-label study, bleeding patients anticoagulated with a FXa inhibitor received IV andexanet bolus (400 or 800 mg) followed by 120-min infusion (4 or 8 mg/min). Anti-FXa activity was measured before andexanet administration (baseline), at end of bolus (EOB), end of infusion, and 4, 8, and 12 h after infusion. The relationship between baseline anti-FXa activity and reversal in healthy subjects was used to develop the naïve-pooled PK/PD model and then to predict the percent reversal of anti-FXa activity for patients with acute major bleeding. Refinement of the PK/PD model includes assessment of intrinsic factors such as renal function, age and body weight on both FXa and andexanet exposure.
Results: In the first interim analysis of ANNEXA-4, 73 patients (apixaban, 39; rivaroxaban, 34) had plasma levels available for model qualification. The mean observed percent reversal of anti-FXa activity for rivaroxaban and apixaban was well predicted by the healthy subject PK/PD model; the point estimates fell within the 90% confidence intervals of predicted values (Table 1). The predicted reversal fit closely the observed confidence intervals through the first 4 h for rivaroxaban and apixaban; it extended through all evaluated time points for rivaroxaban but only through the post 4-h time points for apixaban, possibly due to higher baseline anti-FXa activity levels seen in some apixaban patients. The revised PK/PD model identified body weight as a significant covariate for andexanet exposure, and incorporated published covariates for rivaroxaban and apixaban, including renal function, age and lean body mass. This revised model is being used in all subsequent PK/PD analysis in samples from bleeding patients.

Table 1.

Comparison of mean predicted percentage of anti-FXa reversal vs. observed reversal (with 95% with 95% CI) for rivaroxaban and apixaban at different time points

Time	N	Predicted % reversal	Observed % reversal [95% CI]
Rivaroxaban			
EOB	32	76.4	74.4 [58.3 to 90.4]
EI	33	78.3	77.4 [67.6 to 87.2]
4 hrs	32	31.8	32.0 [18.0 to 45.9]
8 hrs	33	40.7	43.6 [35.0 to 52.2]
12 hrs	32	51.0	56.9 [50.2 to 63.7]
Apixaban			
EOB	34	84.1	83.9 [75.3 to 92.5]
EI	36	81.4	84.2 [77.3 to 91.1]
4 hrs	33	34.4	27.6 [10.2 to 45.0]
8 hrs	32	40.2	30.6 [25.1 to 36.1]
12 hrs	36	48.6	32.8 [26.1 to 39.5]

Summary/Conclusion: The naïve-pooled PK/PD model in healthy subjects closely predicted the percent reversal of anti-FXa activity by andexanet in patients receiving apixaban or rivaroxaban who presented with acute major bleeding. At later time points, the observed apixaban anti-FXa activity reversal did not overlap with that predicted by the naïve-pooled model. Incorporation of intrinsic factors (renal function and age) into the PK/PD model may provide more robust prediction of anti-FXa activity reversal in patients initially seen as outliers.

S840

A SYSTEMATIC REVIEW OF PREDICTORS OF VENOUS THROMBOEMBOLISM IN ACUTE LEUKEMIA

F. Al-Ani[1], A. Ahrari[1], P. Wang[2], A. Lazo-Langner[1,*]

[1]Medicine, [2]Western University, London, Canada

Background: The impact of venous thromboembolism (VTE) on morbidity and mortality is significant in hematological cancer patients, including acute leukemia (AL). Identifying risk factors for the development of VTE among patients with AL will enable clinicians to stratify patients according to their VTE risk and consider individualized approaches for anticoagulant prophylaxis.
Aims: We aimed to identify potential predictors of VTE in AL patients in previoslu published studies.
Methods: We conducted a systematic review of randomized trials and observational studies assessing VTE in the setting of AL including acute myeloid leukemia (AML), acute promyelocytic leukemia (APL) or acute lymphoid leukemia (ALL). Studies were included if they contained information on total VTE events, catheter related thrombosis (CRT) and cerebral vein thrombosis (CVT). Relative Risks (RR) for all VTE events, CRT and CVT were calculated among AL subgroups.
Results: A total of 30 studies were included (29 cohort and 1 case control) with 15,491 AL participants. Of the total participants, the number of evaluable patients was 10,788 for AML, 3,242 for ALL, and 1,031 for APL. The median time for VTE occurrence from AL diagnosis was reported in 22 studies, ranging between 5 and 92 days. The median time of VTE occurrence from AL diagnosis was <1 month in 14 studies (64% of evaluable studies); 1-2 months in 7 studies (32%); and only 1 study reported a median time of 3 months (~4%). The risk of VTE was higher in ALL patients compared to AML patients (excluding APL) [RR: 1.8; 95%CI: 1.58-2.10; p<0.00001]. When comparing APL patients to other AML subtypes, the risk was 1.5-fold significantly higher in APL [RR: 1.56; 95%CI: 1.24-1.97; p=0.0001]. The risk of thrombosis was higher with the presence of catheter [RR: 1.2; 95%CI: 1.04-1.36; p=0.0074]. A subgroup analysis of CRT comparing AL subgroups showed that the risk of CRT is similar between AML vs. ALL [RR: 0.9; 95%CI: 0.72-1.13; p=0.405]. The risk was also similar between peripherally inserted central line vs. central venous catheter [RR: 1.08; 95%CI: 0.81-1.45; p=0.557]. When comparing APL with ALL patients, the risk of CRT was higher among APL [RR: 1.54; 95%CI: 1.10-2.18;

p=0.0122]. Finally, the risk of CVT was 4-fold higher with ALL patients receiving l-asparaginase compared to AML patients [RR: 4.1; 95%CI: 1.75-9.73; p=0.0012].
Summary/Conclusion: Factors that seem to influence VTE risk in AL patients include leukemia phenotype, the presence of catheters, and probably the use of l-asparignase. The risk of thrombosis seems to be higher in the initial period following the diagnosis. Due to the lack of available data in published studies, other potential predictors could not be identified. A thrombosis risk prediction model study is warranted to develop risk stratification criteria for AL patients.

S841

PULMONARY EMBOLISM SEVERITY INDEX (PESI) SCORE AS A PREDICTOR FOR READMISSION IN ACUTE PULMONARY EMBOLISM IN EMERGENCY DEPARTMENT?

D. Prajapati[1,*], D. Suryanarayan[1], E. Lang[2]

[1]Department of Medicine, Devision of Hematology, [2]Department of Emergency Medicine, University of Calgary, Calgary, Canada

Background: Pulmonary Embolism (PE) management in Emergency Department (ED) confers a substantial cost burden representing opportunities for improvements in decision-making. The "Pulmonary Embolism Severity Index (PESI)" is a validated tool to prognosticate patients with PE supporting admit versus (vs.) discharge decisions from the ED. Despite existing evidence, PESI is under-used in patients with PE.
Aims: Our aim is to to evaluate PESI scores and patient disposition from 4 EDs within Calgary to determine discordance between them and the effect of the discordance on readmission and mortality.
Methods: Retrospective review of adult patients ≥18 years, diagnosed with PE between January-June 2016 at 4 EDs in Calgary Health Region. Patients were divided into high-risk PESI (score>85) and low-risk PESI (score 0-85). Chi-Square (χ^2) test was used for comparison between the groups. Primary outcome measure was rate of discordance between PESI risk and disposition decision and identify factors driving the discordance. Secondary outcome measures included comparing 30-day readmission rate, 30-day and 90-day mortality between the discordant PESI groups.
Results: 365 patients were diagnosed with PE in the study period with 60% being admitted and 40% discharged. The median PESI score in admitted patients was 85 (26-172) vs. 68 (20-163) in discharged patients. 51% of admitted patients had a low-risk PESI score and 24% of the discharged patients were high-risk PESI. 30-day readmission rate was 22.9% vs 5.3% (p=0.002) in discharged patients with high-risk PESI vs. discharged patients with low-risk PESI. Hypoxemia was the most common (62%) justification for admission in low-risk PESI groups. Among discharged patients we noted an 8.6% 90-day mortality in the high-risk vs. 0% in the low-risk PESI groups.
Summary/Conclusion: Discharging a PE patient from the ED with a high PESI score carries a significant risk of ED revisit and readmission. Hypoxia was the reason for admission in majority of low risk PE patients.

Thalassemia

S842

LUSPATERCEPT INHIBITS PSMAD2/3 SIGNALING AND PROMOTES ERYTHROID MATURATION THROUGH A GATA1 DEPENDENT MECHANISM

P. Martinez[1,*], M. Bhasin[2], R. Li[1], S. Pearsall[1], R. Kumar[1], R. Suragani[1]

[1]Preclinical, Acceleron Pharma, [2]Genomics and Proteomics Center, Beth Israel Deaconess Medical Center, Harvard Medical School, Cambridge, United States

Background: Previously, we reported elevated Smad2/3 signaling in diseases characterized by erythroid maturation defects (Ineffective Erythropoiesis; IE) such as MDS and β-thalassemia. Luspatercept (an erythroid-maturation agent [EMA]) binds and inhibits signaling by certain Smad2/3 ligands such as GDF11, activin B, and corrects IE/anemia in a murine model of thalassemia and MDS (Suragani et. al, 2014). However, the molecular mechanism through which Smad2/3 ligands negatively regulate erythroid maturation is not completely understood.
Aims: We investigated the molecular mechanism of action through which Smad2/3 ligands such as GDF11 inhibit erythroid maturation *in vitro*, *in vivo*, and how luspatercept prevents this inhibition.
Methods: β-thalassemic mice (*Hbb*$^{th3/+}$) were used to obtain splenic basophilic erythroblasts to be used for RNA-seq. MEL cells were treated with GDF11 in the presence or absence of luspatercept. *In vivo* studies were conducted using transgenic mice with inducible GDF11 overexpression under a ROSA26Cre promoter. CBC and erythroid differentiation analysis were carried out following 3-weeks of inducing GO (N= 5).
Results: To investigate the effect of GDF11 *in vivo*, we used transgenic mice with inducible GDF11 overexpression (GO). RBC and hemoglobin (Hgb) levels were significantly decreased in GO mice. RBC levels were 6.83×10^6/ l in GO mice vs. 8.7×10^6/ l in WT ($p<0.05$). Hgb levels were 9.92 g/dl in GO mice vs. 12.96 g/dl in WT ($p<0.05$). Additionally, bone marrow TER119+ cells were significantly reduced in GO mice (5.294%) compared to WT (29.16%, $p<0.001$) suggesting IE. Furthermore, we found that GATA1+ cells in splenic TER119+ erythroid cells was significantly reduced in GO mice (2.876%) compared to WT (7.342%; $p<0.05$).
Transcriptome analysis of sorted β-thalassemic erythroblasts identified 74 genes that were differentially expressed in RAP-536 (murine version of luspatercept) treated samples vs. VEH. Analysis of the significantly upregulated genes by RAP-536 revealed increased activity of GATA1. We investigated whether elevated pSmad2/3 levels by GDF11 affects GATA1 expression using MEL cells and found that GATA1 was decreased in both mRNA and protein levels, and importantly luspatercept treatment prevented the decrease. We also found increased nuclear accumulation of GATA1 in these cells consistent with increased transcriptional activity in β-thalassemic mice *in vivo*. Furthermore, we found that the expression of Transcription Intermediary Factor (TIF) 1γ in β-thalassemic erythroid tissues was significantly lower in VEH vs. RAP-536 treated mice. TIF1γ has been reported to compete with Smad4, binding pSmad2/3 and leading to erythroid differentiation (Wei *et. al*, 2006), and may act as a molecular link between pSmad2/3 and GATA1.
Summary/Conclusion: In this study, we showed that pSmad2/3 negatively regulates the levels of GATA1 protein, and prevents RBC maturation. We have emerging data to show TIF1γ as a link between pSmad2/3 and GATA1. Thus by preventing elevated pSmad2/3, and restoring GATA1 availability through TIF1γ, luspatercept treatment causes upregulation of genes involved in promoting terminal erythroid maturation, and consequently corrects anemia in β-thalassemia. Luspatercept is currently in phase 3 studies in patients with MDS and β-thalassemia.

S843

HEPCIDIN MIMETIC PTG-300 FOR TREATMENT OF INEFFECTIVE ERYTHROPOIESIS AND CHRONIC ANEMIA IN HEMOGLOBINOPATHY DISEASES

G. Bourne[1,*], L. Zhao[2], A. Bhandari[2], B. Frederick[2], J. McMahon[1], V. Tran[2], J. Zhang[1], A. Stephenson[1], R. Taranath[2], J. Tovera[2], T. Annamalai[2], L. Mattheakis[2], D. Patel[2], M. Smythe[1], D. Liu[2]

[1]Protagonist Therapeutics Pty Ltd., Brisbane, Australia, [2]Protagonist Therapeutics Inc., Newark, CA, United States

Background: Hepcidin is a 25–amino acid peptide synthesized by hepatocytes and is involved in iron homeostasis. The known molecular-target of hepcidin is the ferroportin receptor, which functions as the major transmembrane channel for the export of cellular iron. Hepcidin induces endo-

cytosis and proteolysis of ferroportin and thereby decreases the export of iron to plasma. Hepcidin is prone to aggregation and is difficult to synthesize, characteristics that hinder its future development. The hormone is a complex 4-disulfide bonded beta-hairpin structure that is highly conserved. Protagonist used a proprietary 'scaffold hopping' approach (Vectrix™) to identify a novel peptidic scaffold that matches key pharmacophores of hepcidin. After further optimization PTG-300 was selected as a clinical development candidate, based on its simpler structure and drug-like characteristics, such as human plasma stability $t_{1/2}$>24h and aqueous solubility >100 mg/mL. It reduces cell surface expression of human ferroportin with an EC_{50} of 5 nM and in healthy cynomolgus monkeys causes >80% sustained reduction of serum iron over 48 hr after a single subcutaneous dose of 1 mg/kg.
Aims: To evaluate the impact of the hepcidin mimetic PTG-300 on anemia in a mouse model of β-thalassemia
Methods: Wild-type control (WT) C57B6 and b-thalassemia intermedia (*Hbb$^{th3/+}$*) mice aged between 4 to 6 weeks were treated with PTG-300 by sc injection at various frequencies and doses. Hematological and iron parameters were examined, including analysis of erythropoiesis, molecular studies of sorted erythroid precursors, indices of hemolysis, various biomarkers (including EPO and liver expression) were carried out.
Results: PTG-300 was injected subcutaneously at several dosing frequencies (Q2D to Q5D) for 4 weeks in six week old *Hbb$^{th3/+}$*mice. This resulted in significant erythropoiesis as evidenced by a hemoglobin increase > 1.5 g/d, after Q5D dosing, reticulocyte count and spleen size reductions, and an increase in peripheral red cell number. The minimum effective dose (MED) was determined by comparing various doses levels between the acute mouse model (pharmacodynamic reduction in serum iron) and the Hbb$^{th3/+}$ mouse chronic model (erythropoietic increase in hemoglobin, peripheral red cell number and the decrease in reticulocytes). Using conditions of optimal dosing frequency and MED in *Hbb$^{th3/+}$* mice, flow cytometry studies of bone marrow and spleen erythroid populations from PTG-300 treated animals demonstrated an increase in the relative proportion of mature erythroid cells. Accumulation of tissue iron was also significantly reduced in the liver and spleen but not in the heart and duodenum. RBC survival increased in *Hbb$^{th3/+}$* mice to similar levels as in WT mice while EPO expression was decreased.
Summary/Conclusion: Our data suggest that PTG-300 ameliorates ineffective erythropoiesis as a treatment for chronic anemia in a mouse model of β-thalassemia. In conditions characterized by low endogenous hepcidin levels and high serum iron levels, such as β-thalassemia and myelodysplastic syndrome (MDS) patients, we believe that PTG-300 has the potential to treat the dysregulation of iron metabolism thereby reducing iron toxicity in the erythropoietic cascade and the chronic anemia. Ultimately PTG-300 has the potential to treat secondary iron overload by reducing the need for transfusions and by decreasing excessive dietary iron absorption.

IMPROVEMENTS IN HEMOGLOBIN, QUALITY OF LIFE, AND SIX-MINUTE-WALK DISTANCE IN ADULTS WITH β-THALASSEMIA TREATED WITH LUSPATERCEPT: LONG-TERM PHASE 2 STUDY

A. Piga[1,*], I. Tartaglione[2], M. R. Gamberini[3], E. Voskaridou[4], A. Melpignano[5], P. Ricchi[6], V. Caruso[7], A. Pietrangelo[8], J. Reynolds[9], C. Barron[9], X. Zhang[9], A. Laadem[10], P. G. Linde[9], M.L. Sherman[9]

[1]Turin University, Turin, [2]Università della Campania "L. Vanvitelli, Naples, [3]Arcispedale S. Anna, Cona, Ferrara, Italy, [4]Laiko General Hospital, Athens, Greece, [5]Ospedale "A. Perrino", Brindisi, [6]AORN "A. Cardarelli", Naples, [7]ARNAS Garibaldi, Catania, [8]CEMEF, Medicina 2 , Modena, Italy, [9]Acceleron Pharma Inc, Cambridge, [10]Celgene, Summit, United States

Background: Serious hematologic conditions such as β-thalassemia are associated with an erythroid maturation defect leading to anemia and other clinical sequelae. Luspatercept (ACE-536) is being developed as an erythroid-maturation agent (EMA) for treatment of β-thalassemia. Luspatercept binds to select TGF-β superfamily ligands, reducing aberrant Smad2/3 signaling and promoting late-stage erythroid maturation and increased hemoglobin (Hgb); it has corrected the effects of ineffective erythropoiesis in a mouse model of thalassemia (Suragani R, Blood, 2014), and increased Hgb and was well tolerated in a phase 1 study in healthy volunteers (Attie K, Am J Hematol, 2014).
Aims: This ongoing, phase 2, multicenter, open-label study followed by a long-term extension (ext) evaluates the effects of luspatercept in patients (pts) with either transfusion-dependent (TD) or non-transfusion dependent (NTD) β-thalassemia. Key endpoints include Hgb increase, pt-reported quality-of-life (QoL) and assessment of functional improvement in 6-minute walk distance (6MWD) in NTD pts, and reductions in RBC transfusion burden in TD pts.
Methods: Inclusion: age ≥18 yr and either NTD (<4 RBC U/8 weeks prior to first dose with baseline Hgb <10 g/dL) or TD (≥4 RBC U/8 weeks prior to first dose, confirmed over 6 months). Pts treated every 3 weeks subcutaneously for up to 5 doses (titration up to 1.25 mg/kg) in the base study were then eligible for treatment up to 5 additional years (base completed NCT01749540; ext ongoing NCT02268409).
Results: Data (as of 31Aug2017) were available for 63 pts treated at dose levels ≥0.6 mg/kg. 31 NTD, 32 TD; median (range) age (yr) was 38 (20-62); 67% had prior splenectomy. For NTD pts, at baseline, median (range) Hgb (g/dL) was 8.5 (6.5-9.8); mean (SD) liver iron concentration (LIC, mg/g dw) was 5.1 (3.6). For TD pts, at baseline, median (range) transfusion burden was 8 U/12 weeks (4-18 U); mean (SD) LIC (mg/g dw) was 4.7 (4.7). 22/31 (71%) NTD pts achieved mean Hgb increase of ≥1.0 g/dL and 17/31 (55%) achieved an even greater increase of ≥1.5 g/dL in mean Hgb over any 12-week period compared to baseline. Increases in mean Hgb over a 12-week period correlated positively with improvement in both a pt-reported QoL questionnaire (FACIT-F) and with improvements in 6MWD at weeks 16 and 48. At week 48, a statistically significant improvement from baseline in mean (SD) 6MWD was seen in NTD pts (n=9), 484 (121) vs 408 (68) meters, p=0.02. 22/32 (69%) TD pts achieved ≥33% reduction in transfusion burden over any 12-week interval compared to baseline. 12/29 (41%) achieved ≥33% reduction in transfusion burden over a fixed 12-week interval (weeks 13-24) compared to baseline, and 12/29 (41%) continued to have a response at a fixed interval of weeks 37-48 on study. Luspatercept was generally well tolerated, with no related serious adverse events and few grade 3 related AEs: bone pain (n=3), asthenia (n=2), and headache (n=1). The most frequent related AEs (≥10%) were bone pain, headache, myalgia, arthralgia, musculoskeletal pain, asthenia, injection site pain, and back pain.
Summary/Conclusion: In this phase 2 open-label study, long-term luspatercept treatment in pts with β-thalassemia was generally safe and well tolerated up to 2 years. Clinically relevant measures of luspatercept efficacy were observed in both NTD pts (increased Hgb levels and improved QoL) and TD pts (decreased transfusion burden).

IMPAIRMENT OF THE MESENCHYMAL STROMAL NICHE OF BETA-THALASSEMIA PATIENTS: IMPLICATIONS OF PROLONGED IRON EXPOSURE

S. Crippa[1,*], V. Rossella[1], S. Rivis[1], L. Silvestri[2], A. Aprile[2], S. Scaramuzza[2], M.A. Avanzini[3], M. Zecca[4], S. Marktel[2], F. Ciceri[2], A. Aiuti[1], G. Ferrari[2], M.E. Bernardo[1]

[1]San Raffaele-Telethon Institute for Gene Therapy (SR-TIGET), Pediatric Immunohematology, [2]Ospedale San Raffaele, Milano, [3] Fondazione IRCCS Policlinico "San Matteo", [4]Fondazione IRCCS Policlinico "San Matteo", Pavia, Italy

Background: Bone marrow (BM) contains a population of mesenchymal stromal cells (MSCs) that, together with endothelial cells and osteoblasts, provide a specific microenvironment to support hematopoietic stem cell (HSC) homeostasis. Beta-thalassemia (BT) is a hereditary blood disorder characterized by reduced or absent synthesis of hemoglobin beta-chains amenable to allogeneic HSC transplantation and HSC-gene therapy (HSC-GT). Data on the mesenchymal compartment in BT patients are scarce.
Aims: Aim of this work is to characterize the mesenchymal compartment in BT patients before transplant procedures and to test whether these cells are functionally altered in their ability to support HSC.
Methods: We isolated MSCs from the BM of 12 BT patients (9 pediatric and 3 adults) and age-matched healthy donor (HD: 1:1). MSCs were characterized for their classical properties (clonogenic, proliferative and differentiation capacity, immunophenotype analyses) and for their functional properties in terms of BM niche supportive functions and response to iron overload.
Results: BT-MSCs showed a reduced clonogenic capacity (CFU-Fs), delay in colony formation and longer population doubling time. Similarly, we observed an altered differentiation capacity into adipocytes and osteoblasts both by immunohystochemical staining and RT-qPCR. Both HD- and BT-MSCs expressed canonical mesenchymal markers (positive for CD105, CD90, CD73; negative for hematopoietic markers). On the contrary, the expression of CD146 and CD271 was extremely reduced in BT-MSCs, indicating a pauperization of the most primitive stem cell pool. We measured a higher iron content in the BT BM microenvironment; moreover, we demonstrated that MSCs expressed iron transporters (TFR1, ZIP14, ZIP18, DMT1) and were able to uptake iron. Iron overload correlated with increased ROS level in BT-MSCs and robust decrease of primitive MSCs.

We showed that ROS levels were increased possibly due to altered anti-oxidant response caused by prolonged iron exposure associated with chronic blood transfusions. Indeed, at basal level BT-MSCs showed a reduced expression of anti-oxidant genes, which were not properly induced in response to iron. Moreover, we found that the expression of genes involved in the crosstalk between MSCs and HSCs (*Cxcl12*, *SCF* and *Angp1)* was reduced in BT-MSCs, leading to an altered capacity to attract CD34+ hematopoietic stem progenitors cells (HSPC) in transwell migration assays and impaired capability to maintain primitive HSPCs in *in vitro* 2D co-culture models. We demonstrated that iron dependent demethylases were more active in BT-MSCs, leading to an epigenetic remodeling of BT-MSCs associated with an altered MSC functionality.
Summary/Conclusion: In conclusion, we showed an impairment in the mesenchymal niche of BT-BM possibly associated with prolonged iron exposure and reduced anti-oxidative response. This underlines the importance of iron level for normal MSC function. Whether the ability of MSC to up-take iron represents a mechanism of protection for the BM niche and how the BT stromal niche impairment influences engraftment and HSC support after allogeneic HSC transplantation and HSC-GT is currently being investigated.

S846

A NOVEL BAEVRLESS-PSEUDOTYPED GLOBIN LENTIVIRAL VECTOR DRIVES HIGH AND STABLE FETAL HEMOGLOBIN EXPRESSION IMPROVING THALASSEMIC ERYTHROPOIESIS *IN VITRO*

E. Drakopoulou[1], M. Georgomanoli[1], C.W. Lederer[2], M. Kleanthous[3], C. Costa[4], O. Bernadin[4], F.-L. Cosset[4], E. Verhoeyen[4], E. Voskaridou[5], E. Papanikolaou[6], N.P. Anagnou[1,*]

[1]Cell and Gene Therapy, Biomedical Research Foundation of the Adademy of Athens, Athens, Greece, [2]Molecular Genetics Thalassemia Department , [3]The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, [4]International Centre for Infectiology Research, Inserm, Lyon, France, [5]Thalassemia Centre, Laikon General Hospital, [6]Laboratory of Biology, University of Athens, School of Medicine, Athens, Greece

Background: Ineffective erythropoiesis in β-thalassemia occurs primarily as a result of an early erythroid progenitor apoptosis, due to precipitation of the excess of α-chains at the polychromatic normoblast stage, becoming more profound upon enhanced activation of the autophagy pathway [Ann Hematol 90:7, 2011]. We have previously demonstrated that the self-inactivating γ-globin lentiviral vector GGHI, can significantly increase HbF ($\alpha_2\gamma_2$) in erythroid cells of thalassemia patients and improve the disease phenotype *in vitro*, by reducing apoptosis and restoring thalassemic erythropoiesis [Hum Gene Ther 23:1, 2012]. Furthermore, we have recently shown that the alternative baboon envelope glycoprotein BaEVRless specifically targets hCD34$^+$ cells and increases transduction at low multiplicity of infection (MOI) [Blood 119:5, 2012; Blood 124:8, 2014].
Aims: To this end, we generated a novel, improved, γ-globin vector designated as GGHI-mB-3D by 1) incorporating two regulatory novel elements, i.e the 3D HPFH-1 enhancer and the 3' β-globin UTR and 2) pseudotyping with the BaEVRless envelope glycoprotein, and assessed its potency to specifically target hCD34$^+$ cells from normal and thalassemic donors and its ability for stable and high transgene expression at low MOIs.
Methods: Both VSVG and BaEVRless envelope glycoproteins were used for pseudotyping γ-globin and GFP lentiviral vectors, while titration was carried out in 293T cells, using FACS and/or qPCR. Peripheral blood CD34$^+$cells from normal and thalassemic donors were isolated, transduced at low MOIs and cultured for up to 14 days in liquid and methylcellulose cultures. Assessment of HbF expression at both protein and mRNA levels was carried out at the terminal differentiation stage. Improvement of erythropoiesis was evaluated by both Annexin/7AAD staining and orthochromatic erythroblast determination, while *ATG5* expression at the mRNA level was determined using qPCR.
Results: We documented high and stable HbF expression in thalassemic cells for the novel GGHI-mB-3D/BaEVRless vector, exhibiting increased transduction efficiency, compared to the conventional GGHI-mB-3D/VSVG, with a concomitant 119% mean HbF increase (p=0.029, n=9), a mean VCN/cell of 0.86 and a mean transduction efficiency of 56.4%. Transduced populations also exhibited a trend towards late-erythroid, orthochromatic differentiation and reduced apoptosis, a further indication of a successful gene therapy treatment. Monitoring expression of *ATG5*, a key link between autophagy and apoptosis, showed that gene correction correlated with reduction of enhanced autophagy activation, a typical feature of thalassemic polychromatophilic normoblasts.
Summary/Conclusion: The novel GGHI-mB-3D regulatory elements, coupled with BaEVRless pseudotyping, can lead to efficient transduction and potentially therapeutic HbF levels, which can have significant implications for the clinical efficiency of the currently ongoing clinical trials.

SIMULTANEOUS SESSIONS III

New therapeutic strategies to improve the outcome of relapse/refractory plasma cell disorders

Background: Despite recent therapeutic advances, multiple myeloma (MM) remains an incurable plasma cell malignancy. Pomalidomide (POM) is a standard-of-care treatment in relapsed or refractory MM (RRMM) and has demonstrated synergistic anti-myeloma activity with dexamethasone (DEX) and proteasome inhibitors, as well as cytotoxic effects in lenalidomide (LEN)-resistant cells. POM + DEX is approved in the European Union for patients with RRMM who received ≥ 2 prior therapies, including LEN and bortezomib (BORT), and has been investigated after LEN-based treatment. As LEN becomes increasingly established in up-front treatment of MM, patients who have exhausted the benefit of LEN represent a clinically relevant unmet medical need. Here we report final progression-free survival (PFS) and safety data from a phase 3 triplet trial in an entirely post–LEN-treated population, comparing POM, BORT, and low-dose DEX (PVd) vs BORT and low-dose DEX (Vd) in patients who received 1 to 3 prior therapies.
Aims: To compare the efficacy and safety of PVd vs Vd in LEN-exposed patients with RRMM.
Methods: Key eligibility criteria included 1 to 3 prior regimens and ≥ 2 cycles of prior LEN therapy. Patients were randomized 1:1 to receive PVd or Vd treatment in 21-day cycles: POM 4 mg/day on days 1-14 (PVd arm only); BORT 1.3 mg/m^2 on days 1, 4, 8, and 11 of cycles 1-8 and on days 1 and 8 of cycle 9 and beyond; and DEX 20 mg/day (10 mg/day if aged > 75 years) on the days of and after BORT. The primary endpoint was PFS. All pts provided informed consent.
Results: A total of 559 patients were enrolled: 281 patients in the PVd arm and 278 in the Vd arm. Demographic, baseline, and prior disease characteristics were generally well balanced between the 2 treatment arms. Median age was 67 and 68 years, respectively. All patients had prior LEN (71% vs 69% were LEN refractory), 72% vs 73% had prior BORT, and 70% vs 66% were refractory to their last treatment. Median number of prior lines of therapy was 2; 40% and 41% had 1 prior line of treatment in the PVd and Vd arms, respectively. Median follow-up was 16 months. Compared with Vd, PVd treatment significantly reduced the risk of progression or death by 39% and resulted in deeper responses in the intention-to-treat (ITT) population (Table 1). Median PFS was 11.20 vs 7.10 months in the ITT population and 20.73 vs 11.63 months in patients with only 1 prior treatment including LEN. Data for the overall survival analysis are not yet mature. Neutropenia (42% vs 9%), infections (31% vs 18%), and throm-

bocytopenia (27% vs 29%) were among the most frequently reported grade 3/4 treatment-emergent adverse events.

Table 1.

Efficacy	ITT		1 Prior Treatment Line	
	PVd n = 281	Vd n = 278	PVd n = 111	Vd n = 115
PFS, mos				
Median	11.20	7.10	20.73	11.63
HR (95% CI)	0.61 (0.49-0.77)		0.54 (0.36-0.82)	
P	< .0001		NA	
ORR (≥ PR), %	82.2	50.0	90.1	54.8
≥ VGPR, %	52.7	18.3	61.3	22.6

HR, hazard ratio; ITT, intention-to-treat; NA, not applicable; ORR, overall response rate; PFS, progression-free survival; PR, partial response; PVd, pomalidomide, bortezomib, and low-dose dexamethasone; Vd, bortezomib and low-dose dexamethasone; VGPR, very good partial response.

Summary/Conclusion: The OPTIMISMM phase 3 study in early RRMM reported a significant and clinically meaningful PFS improvement in patients who were entirely LEN exposed, including 70% of patients who were refractory to LEN. Of note, the PFS and overall response rate results showed improved benefit with PVd over Vd in patients who had only 1 prior line of treatment. Follow-up for long-term survival is ongoing. The safety of POM-based treatment was manageable and consistent with its well-established profile.

S848

MOR202 WITH LOW-DOSE DEXAMETHASONE (DEX) OR POMALIDOMIDE/DEX OR LENALIDOMIDE/DEX IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA (RRMM): A PHASE I/IIA, MULTICENTER, DOSE-ESCALATION STUDY

M. Raab[1,*], M. Chatterjee[2], H. Goldschmidt[3], H. Agis[4], I. W. Blau[5], H. Einsele[2], M. Engelhardt[6], B. Ferstl[7], M. Gramatzki[8], C. Röllig[9], K. Weisel[10], T. Jarutat[11], D. Weinelt[11], M. Winderlich[11], R. Boxhammer[11], C. Peschel[12]

[1]Department of Medicine V, University Hospital Heidelberg, Heidelberg, [2]Department of Internal Medicine II, University Hospital of Wuerzburg, Wuerzburg, [3]Department of Medicine V, University Hospital Heidelberg and the National Center for Tumor Diseases, Heidelberg, Germany, [4]Department of Medicine I, University Hospital of Internal Medicine – AKH Wien, Vienna, Austria, [5]Department of Internal Medicine III, Charité Campus Benjamin Franklin, Berlin, [6]Hematology & Oncology Department, Medical University Hospital, Freiburg, [7]Department of Internal Medicine 5 - Hematology and Oncology, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, [8]Department of Medicine, University Hospital Schleswig-Holstein Division of Stem Cell Transplantation and Immunotherapy, Kiel, [9]Department of Medicine I, University Hospital Carl Gustav Carus, Dresden, [10]Department of Hematology, Oncology, Immunology, Rheumatology and Pulmonology, University Hospital of Tuebingen, Tuebingen, [11]Morphosys AG, Planegg, [12]Department of Internal Medicine III, Technical University of Munich, Munich, Germany

Background: CD38 is a type II transmembrane glycoprotein expressed by MM cells. MOR202, a human IgG1 CD38 monoclonal antibody, has shown high single-agent activity in preclinical models of MM and synergy in combination with immunomodulatory drugs (IMiDs®), lenalidomide (LEN) and pomalidomide (POM).
Aims: The primary objectives of the study were to evaluate the safety, maximum tolerated dose (MTD)/recommended phase II dose of MOR202 in patients with relapsed or refractory multiple myeloma.
Methods: This is an analysis of a multicenter, dose-escalation phase I/IIa study of MOR202 with data presentation from patient (pt) cohorts treated with clinically relevant doses of MOR202 (2-hour IV infusion; 4, 8 and 16 mg/kg q1w) + Dex (≤40 mg), or at 8 or 16 mg/kg q1w with an IMiD+Dex combination.
Results: As of September 2017, 91 pts had been treated, including 56 in clinically relevant cohorts: 18 received MOR202 + Dex, 17 MOR202 + LEN/Dex and 21 MOR202 + POM/Dex. Pts received a median of 3, 2 and 3 prior treatment lines, respectively. The MTD of MOR202 was not reached. Combinations were generally well tolerated, with grade ≥3 adverse events (AEs) of mainly hematological nature. 2 pts discontinued due to a MOR202-related AE (one patient with a grade 4 thrombocytopenia and one patient with a grade 3 bacterial infection complicated by acute kidney failure). Infusion-related reactions (all grade 1 or 2) were observed in 4/56 (7%) pts. These mainly occurred during the first infusion. In the MOR202 + Dex cohort, 5/18 (28%) pts showed a response: 3 partial responses (PRs) and 2 very good PRs (VGPRs). Responses were also observed in 11/17 (65%, 7 PRs, 3 VGPRs, 1 complete response [CR]) pts in the MOR202 + LEN/Dex cohort and 9/21 (43%, 3 PRs, 4 VGPRs and 2 CRs) in the MOR202 + POM/Dex cohort. Longest response duration was 25 months (MOR202/Dex). Preliminary results indicate preservation of high CD38 levels on MM cells under MOR202 therapy.
Summary/Conclusion: 2-hour infusions of MOR202 administered at up to 16 mg/kg with Dex or in combination with an IMiD/Dex in heavily pretreated pts with RRMM showed a favorable safety profile, including excellent infusion tolerability. Promising preliminary efficacy and long-lasting tumor control were observed.

S849

ONCE-WEEKLY VS TWICE-WEEKLY CARFILZOMIB DOSING PLUS DEXAMETHASONE IN PATIENTS WITH RELAPSED AND REFRACTORY MULTIPLE MYELOMA (RRMM): RESULTS OF THE RANDOMIZED PHASE 3 STUDY A.R.R.O.W.

M.-V. Mateos[1,*], P. Moreau[2], J.R. Berenson[3], K. Weisel[4], A. Lazzaro[5], K. Song[6], M. A. Dimopoulos[7], M. Huang[8], A. Zahlten-Kumeli[8], A.K. Stewart[9]

[1]Hematology, Hospital Clinico Universitario de Salamanca-IBSAL, Salamanca, Spain, [2]Hematology Department, University of Nantes, Nantes, France, [3]Institute for Myeloma and Bone Cancer Research, West Hollywood, United States, [4]Universitatsklinikum Tubingen, Tubingen, Germany, [5]Department of Clinical Oncology and Hematology, Division of Hematology and Bone Marrow Transplant Center, Hospital Gulielmo da Saliceto, Piacenza, Italy, [6]Leukemia/Bone Marrow Transplant Program of British Columbia, Vancouver, Canada, [7]National and Kapodistrian University of Athens, Athens, Greece, [8]Amgen Inc., Thousand Oaks, [9]Division of Hematology/Oncology, Mayo Clinic, Scottsdale, United States

Background: Twice-weekly carfilzomib (K) at 20/27 mg/m^2 is approved for the treatment of RRMM. To develop a more convenient K regimen, once-weekly K plus dexamethasone (d) was assessed in the phase 1/2 CHAMPION-1 study, establishing a maximum tolerated dose of K 20/70 mg/m^2 for RRMM pts.
Aims: To present results from the pre-planned interim analysis of the phase 3 study A.R.R.O.W. comparing Kd once-weekly at 20/70 mg/m^2 (once-weekly group) vs twice-weekly at 20/27 mg/m^2(twice-weekly group).
Methods: Pts with 2–3 prior therapies and prior exposure to proteasome inhibitor and immunomodulatory agent were eligible. Pts were randomized 1:1 to receive either once- or twice-weekly K plus d. The once-weekly group received K (30-min IV) on days (D) 1, 8, and 15 of all cycles (20 mg/m^2 on D1 [cycle 1]; 70 mg/m^{2}thereafter). The twice-weekly group received K (10-min IV) on D1, 2, 8, 9, 15, and 16 (20 mg/m^2 on D1 and 2 during cycle 1 and 27 mg/m^2 thereafter). All pts received d at 40 mg on D1, 8, 15 (all cycles), and 22 (cycle 1–9 only). Treatment was given in 28-day cycles until disease progression or unacceptable toxicity. The primary endpoint was progression-free survival (PFS). Secondary endpoints were overall response rate (ORR), overall survival, safety, and pharmacokinetics.
Results: Baseline characteristics were generally balanced. Median PFS (once- vs twice-weekly) was 11.2 mo vs 7.6 mo (hazard ratio = 0.69; 1-sided p=0.0014). ORR (once- vs twice-weekly) was 62.9% vs 40.8% (p<0.0001); 7.1% vs 1.7% had a complete response or better. Grade ≥3 adverse events (AEs) occurred in 67.6% (once-weekly) and 61.7% (twice-weekly). Treatment-related grade 5 AEs occurred in 5 pts (2.1%) (once-weekly) and 2 pts (0.9%) (twice-weekly). The incidence of grade ≥3 hypertension and cardiac failure (once- vs twice-weekly) was 5.9% vs 5.5% and 2.9% vs 4.3%, respectively.
Summary/Conclusion: Once-weekly Kd at 20/70 mg/m^2 significantly improved PFS and ORR vs twice-weekly Kd at 20/27 mg/m^2. The incidence of AEs was comparable between groups. No new safety risks were found in the once-weekly group. Overall, once-weekly Kd showed favorable benefit-risk profile with a convenient dosing regimen vs twice-weekly Kd.

S850

FINAL RESULTS OF A PHASE IB STUDY OF ISATUXIMAB PLUS POMALIDOMIDE AND DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

J. Mikhael[1,2,*], P. Richardson[3], S. Usmani[4], N. Raje[5], W. Bensinger[6], C. Karanes[7], F. Dubin[8], Q. Liu[9], O. Vitse[10], K. Anderson[3]

[1]Mayo Clinic, Phoenix, [2]International Myeloma Foundation, Los Angeles, [3]Dana-Farber Cancer Institute, Harvard Medical School, Boston, [4]Levine Cancer Institute/Carolinas Healthcare System, Charlotte, [5]Massachusetts General Hospital, Boston, [6]Swedish Cancer Institute, Seattle, [7]City of Hope National Medical Center, Duarte, United States, [8]Sanofi, Vitry-sur-Seine, France, [9]Sanofi Oncology, Cambridge, United States, [10]Sanofi, Montpellier, France

Background: Isatuximab (ISA) is a monoclonal antibody targeting CD38-expressing tumor cells via several modes of action. We report final data from a Phase Ib dose-escalation/expansion study of ISA in combination with pomalidomide (Pom)/dexamethasone (dex) in patients (pts) with relapsed/refractory multiple myeloma (RRMM) (NCT02283775).
Aims: To evaluate combination therapy with ISA plus Pom/dex in pts with RRMM.
Methods: Pts with RRMM (≥2 prior MM therapies; includes lenalidomide and a proteasome inhibitor [PI]) received 5, 10, or 20 mg/kg ISA (4 weekly [QW] doses, then every 2 weeks until disease progression/intolerable toxicity), Pom 4 mg (Days 1–21), and dex 40 mg (QW; 20 mg if ≥75 yrs old) in 28-day cycles. All pts provided written informed consent to participate in the study. The primary objective was to determine the recommended dose of ISA plus Pom/dex. Secondary objectives included efficacy (International Myeloma Working Group criteria), safety, and pharmacokinetics (PK).
Results: Forty-five pts received ISA at 5 (n=8), 10 (n=31), or 20 (n=6) mg/kg. Median age was 67 (42–82) yrs. Median 3 (2–10) prior lines; 41 (91%), 37 (82%), and 38 (84%) pts were refractory to their last regimen, immunomodulatory drugs (IMiDs), or PIs, respectively. Six pts had high-risk (HR) cytogenetics. Median time on treatment was 9.6 mos; 19 (42%) pts remain on treatment. Two pts (10 mg/kg) discontinued due to an adverse event (AE) (grade [Gr] 5 intestinal perforation [due to underlying MM]; Gr 3 infusion-associated reaction [IAR]). One pt at each dose reported a dose-limiting toxicity; the maximum tolerated dose was not reached. The expansion cohort was initiated at 10 mg/kg based on efficacy, safety, and PK data. The most common treatment-emergent AEs besides IARs/hematologic abnormalities were fatigue (62%), upper respiratory tract infection (42%), and dyspnea (40%). Gr ≥3 neutropenia was observed in 83% of pts (Gr 4, 56%); all cases proved manageable with dose modification (dose delay in 16 [35.6%] pts and dose reduction in 22 [48.9%] pts) and/or granulocyte colony stimulating factor support. IARs occurred in 19 (42%) pts (Gr ≥3, 1 pt): 18 (40%) pts during the first infusion, 3 (7%) pts at later infusions. Overall response rate (ORR) was 62%; ORR in HR cytogenetics: 33%; IMiD refractory: 57%; PI refractory: 63%. Twelve (27%) pts achieved ≥ very good partial response (1 complete response; 1 stringent complete response). Median time to first response was 0.95 mos and median duration of response was 18.7 mos (95% confidence interval [CI] 12.5–not calculable). Median progression-free survival was 17.6 mos (95% CI 6.8–20.5). ISA PK is unaffected by co-administration with Pom/dex.
Summary/Conclusion: These final results confirm the promising clinical activity and manageable safety profile of ISA in combination with Pom/dex in heavily pretreated RRMM. A Phase III confirmatory trial is ongoing with results expected later in 2018.
Funding: Sanofi

A PROSPECTIVE PHASE II STUDY OF DARATUMUMAB IN PREVIOUSLY-TREATED SYSTEMIC LIGHT- CHAIN (AL) AMYLOIDOSIS

A. Jaccard[1,*], B. Arnulf[2], A. M. Stoppa[3], L. Karlin[4], A. Perrot[5], M. Macro[6], A. Huart[7], L. Frenzel[8], P. Morel[9], V. Dorvaux[10], G. Merlini[11], G. Palladini[11], D. Lavergne[1], F. Bridoux[12], M. Rousselle[13]

[1]Hematology, CHU Limoges, Limoges, [2]Hematology, APHP, Saint Louis, Paris, [3]Hematology, IPC Marseille, Marseille, [4]Hematology, CHU Lyon, Lyon, [5]Hematology, CHU Nancy, Nancy, [6]Hematology, CHU Caen, Caen, [7]Nephrology, CHU Toulouse, Toulouse, [8]Hematology, APHP Necker, Paris, [9]Hematology, CHU Amiens, Amiens, [10]Hematology, CHU Metz-Thionville, Metz, France, [11]Hematology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [12]Nephrology, CHU Poitiers, Poitiers, [13]Hematology, CHU Toulouse, Toulouse, France

Background: Daratumumab (DARA), is a novel, high-affinity, IgG1κ human monoclonal antibody that specifically recognizes CD38. It has emerged as a breakthrough targeted therapy for patients with multiple myeloma. Monoclonal plasma cells in AL amyloidosis (AL) are similar to plasma cells in myeloma and express CD38.
Aims: We report here the preliminary results of a prospective multi-center, phase II study of DARA in AL (NCT02816476).
Methods: Forty patients will be recruited in this trial. Patients aged ≥18 years with evaluable AL amyloidosis, who have received ≥1 prior therapy and are not in very good partial response (VGPR) or better with a measurable plasma cell dyscrasia with dFLC >50 mg/L (difference between involved and uninvolved free light chain levels), with at least one major vital organ involvement, with ECOG performance status 0, 1 or 2, no chronic atrial fibrillation, a supine blood pressure >100 mmHg and NT-proBNp<8500 ng/L are eligible. They receive DARA intravenously in a standard schedule and dose: 16 mg/kg weekly during the first two 28-day cycles and every other week during cycles 3 through 6 for a total of six 28-day cycles. Hematologic responses are measured after 1 injection of DARA, at day 1 of each cycle and at the end of treatment visit. The objectives are to assess hematologic responses, organ responses and safety.
Results: To date 38 of the 40 planned patients have been enrolled in 11 French and 1 Italian centers. Here are the characteristics of the 36 patients included at data cut-off (Nov 13th, 2017). The median age is 69 years (range, 45-83). The median number of organ system involvement is 2 (range, 1-5). Twenty-three patients (64%) have cardiac and 21 patients (58%) renal involvement. The median time from diagnosis to enrolment is 24 months (range, 3.5-122). Median number of prior therapies is 3 (range, 1-5), 20 patients (56%) have received Melphalan and Dexamethasone, 34 patients (94%) bortezomib, and 19 patients (53%) lenalidomide. Nineteen patients (53%) have received 3 or more lines of treatment. There were two on-study deaths due to cardiac progression and lung cancer. Three other patients have discontinued study treatment before 6 cycles due to disease progression. Nine patients (25%) experienced at least one grade ≥3 AE (any cause) and only one was considered as drug related (lymphopenia). The most common drug-related AEs were infusion reaction seen in 11 patients (30%), all grade I or II. Very good partial response or better (VGPR) was observed in 14 of 32 evaluable (completing at least 1 cycle) patients (44%), and partial response in 5 patients (16%). The overall response rate is 59%. Responses were usually very rapid, after a single DARA injection, all 17 patients, with available dFLC measurement, who finally reached partial response or better had a dFLC decrease of more than 35 % with a median dFLC decrease after only 1 injection in these 17 responding patients of 70% (range 35-96).
Summary/Conclusion: Monotherapy with DARA demonstrates encouraging efficacy in previously-treated patients with AL amyloidosis with deep and rapid hematological responses. The administration of DARA in these patients is associated with a good safety profile and non-severe adverse events occurring mostly after the first infusion. The data, in particular hematological and organ responses, will be updated at the meeting. A prospective randomized international phase III study (AMY3001) in naive patients with DARA in combination with bortezomib, cyclophosphamide and dexamethasone is ongoing.

Waldenström's macroglobulinemia, mantle-cell lymphoma and hairy cell leukemia – Clinical

S852

MULTINATIONAL, RANDOMIZED PHASE 3 TRIAL OF IBRUTINIB-RITUXIMAB VS PLACEBO-RITUXIMAB IN PATIENTS WITH WALDENSTRÖM'S MACROGLOBULINEMIA

This abstract is embargoed until Friday, June 15, 08:30 local time.

Background: Waldenström's macroglobulinemia (WM) is an incurable B-cell lymphoma with several treatment choices, however, there have been few randomized trials to help identify treatment standards. Single-agent ibrutinib is highly active in relapsed WM with reported PFS rates of 86% (at 18 mo) and 69% (at 24 mo) (Dimopoulos, Lancet Oncol. 2017; Treon, NEJM 2015) and is approved in the United States and Europe for WM.
Aims: To report the safety and efficacy of ibrutinib-rituximab (IR) vs placebo-rituximab (R) at a preplanned interim analysis in treatment naïve and relapsed patients who were not refractory to prior rituximab-containing therapies.
Methods: Patients with confirmed WM and symptomatic disease requiring treatment were randomized to daily ibrutinib (420 mg) or placebo, both with rituximab (375 mg/m^2/wk IV for infusions at wks 1-4 and 17-20). Patients previously treated with a rituximab-based regimen were required to have a response (≥MR) to the last rituximab therapy. The primary endpoint was progression-free survival (PFS) as assessed by an independent review committee (IRC). We also report response rates, sustained improvement in hemoglobin levels, time to next treatment (TTnT), overall survival (OS), and safety. All patients provided written informed consent.

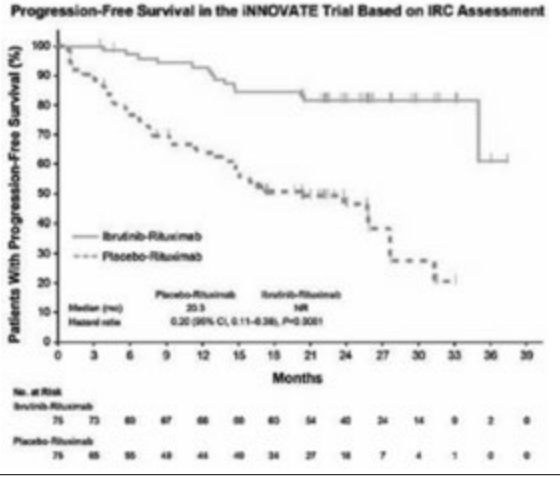

Figure 1.

Results: For 150 randomized patients, median age was 69 y, 38% had a high IPSSWM risk score, and 45% were treatment-naïve. Of 136 patients with available mutation data, MYD88^{L265P} and CXCR4^{WHIM} mutations were identified by target exome sequencing assay in 85% and 36%, respectively. At a median follow-up of 26.5 mo, IR significantly prolonged PFS compared with R representing a five-fold reduction in the risk of progression or death (median PFS, not reached vs 20 mo; hazard ratio [HR], 0.20; 95% CI: 0.11-0.38, p<0.0001; Figure 1). The 30-mo PFS rates were 82% vs 28% in each arm. Improvements in PFS were consistently reported in all relevant subgroups, including treatment-naïve (HR, 0.34; 95% CI: 0.12-0.95), relapsed (HR, 0.17; 95% CI: 0.08-0.36), MYD88^{L265P}/CXCR4^{WT} (HR, 0.17; 95% CI: 0.06-0.49), MYD88^{L265P}/CXCR4^{WHIM} (HR, 0.24; 95% CI: 0.09-0.66), and MYD88^{WT}/CXCR4^{WT}(HR, 0.21; 95% CI: 0.04-1.1). Overall (≥MR) and major (≥PR) response rates were significantly higher for IR vs R, 92% vs 47% (p<0.0001) and 72% vs 32% (p<0.0001), respectively. Improvements in hemoglobin were observed in 73% vs 41% of IR and R patients (p<0.0001). At the time of this analysis, 75% of IR patients continued on treatment. Median TTnT was not reached for IR and 18 mo for R (HR, 0.096; *P* <0.0001). The 30-mo OS rates were 94% vs 92% in the 2 arms. With a median time on treatment of 25.8 mo for IR, grade ≥3 treatment-emergent adverse events (AEs) occurred in 60% vs 61% of patients on on IR vs R. Serious AEs occurred in 43% vs 33% of patients on each arm. No fatal AEs occurred with IR vs 3 with R. Meaningful reductions in any grade IgM flare (8% vs 47%) and grade ≥3 infusion reactions (1% vs 16%) were observed with IR vs R.
Summary/Conclusion: The efficacy of the ibrutinib-rituximab combination was superior to that of placebo-rituximab, producing improvements in PFS for all WM patients regardless of prognostic or genotypic factors. The IR combination had a manageable toxicity profile and no new or unexpected AEs were observed. Based on these results, IR should be considered a standard therapeutic option for patients with WM.

S853

ACALABRUTINIB IN PATIENTS WITH WALDENSTRÖM MACROGLOBULINEMIA

R. Owen[1,*], H. McCarthy[2], S. Rule[3], S. D'sa[4], S. Thomas[5], F. Forconi[6], T. Anderson[7], M.J. Kersten[8], P.L. Zinzani[9], S. Iyengar[10], J. Kothari[11], M. Minnema[12], E. Kastritis[13], R. Izumi[14], J.G. Slatter[14], D. Mittag[15], H. Wei[14], D.-Y. Chen[14], P. Patel[14], R.R. Furman[16]

Background: Bruton tyrosine kinase (BTK) is a clinically validated target in Waldenström Macroglobulinemia (WM). Acalabrutinib is a highly selective, potent, covalent BTK inhibitor.
Aims: The efficacy and safety of acalabrutinib was evaluated in a Phase 2 study of patients with treatment-naive (TN) or relapsed/refractory (R/R) WM.
Methods: Patients with TN or R/R WM received 100 mg acalabrutinib BID (or 200 mg QD [n=6], later switched to 100 mg BID) in 28-day cycles until progressive disease (PD) or intolerance. The primary endpoint was investigator-assessed overall response rate (ORR). Secondary endpoints included duration of response (DOR), progression-free survival (PFS), overall survival (OS), safety and pharmacokinetics (PK).
Results: One hundred six patients (14 TN and 92 R/R) were treated. In all patients, the median age was 69 years (range 39-90), 94% had ECOG PS ≤1, and median serum IgM level was 3615 mg/dL (range 291-9740). R/R patients had a median of 2 prior therapies (range 1-7). At a 25-mo median follow-up, 7 (50%) TN patients and 70 (76%) R/R patients remain on treatment. Discontinuations were primarily due to PD (TN: 0 patients; R/R: 9 patients), adverse events (AEs; TN: 3 patients; R/R: 3 patients), and investigator decision (TN: 2 patients; R/R: 4 patients). BTK occupancy and PK parameters were consistent with previous acalabrutinib studies. Efficacy outcomes are listed in Table 1. The most common AEs of any grade were headache (39%), diarrhea (31%), contusion (29%), and dizziness (25%). The most common Grade 3/4 AEs were neutropenia (16%), pneumonia (7%), anemia, increased alanine aminotransferase, and hyponatremia (each 5%). Atrial fibrillation occurred in 3 patients; 1 case was Grade 3. Bleeding events occurred in 57% of patients, the most common of which were contusion (29%) and epistaxis (13%). Four bleeding events were Grade 3/4:

epistaxis, hematuria, dysfunctional uterine bleeding, and retinal hemorrhage. There were 5 Grade 5 events: pneumonia, glioblastoma multiforme, esophageal carcinoma, myocardial ischemia, and intracranial hematoma.

Table 1.

	Modified 3rd International Workshop on WM Criteria (Kimby 2006)	
	TN (n=14)	R/R (n=92)
ORR (≥ minor response [MR]), n (%)	13 (93)	86 (94)
95% CI	66, 100	86, 98
Major response rate (≥ partial response [PR])	11 (79)	72 (78)
95% CI	49, 95	68, 86
Complete response	0	0
Very good PR	1 (7)	29 (32)
PR	10 (71)	43 (47)
MR	2 (14)	14 (15)
24-mo rate, % (95% CI)		
DOR	90 (47, 99)	84 (73, 90)
PFS	90 (47, 99)	82 (72, 88)
OS	92 (54, 99)	89 (80, 94)

Summary/Conclusion: Acalabrutinib is a highly effective treatment for WM with durable responses and limited toxicity.

S854

PROSPECTIVE PHASE II STUDY OF VENETOCLAX (VEN) IN PATIENTS (PTS) WITH PREVIOUSLY TREATED WALDENSTROM MACROGLOBULINEMIA (WM)

J. Castillo[1,*], J. Gustine[1], K. Meid[1], T. Dubeau[1], J. Allan[2], R. Furman[2], T. Siddiqi[3], R. Advani[4], J. Lam[4], Z. Hunter[1], G. Yang[1], L. Xu[1], M. Davids[1], S. Treon[1]

[1]Dana-Farber Cancer Institute, Boston, [2]Weill Cornell Medicine, New York, [3]City of Hope, Duarte, [4]Stanford Cancer Institute, Stanford, United States

Background: Ven is an oral BCL2 antagonist approved for the treatment of chronic lymphocytic leukemia. However, the role of venetoclax in WM is unknown. Immunophenotypic and genomic sequencing studies have shown that BCL2 is highly expressed and activated in WM cells (Chng Blood 2006; Hunter Blood 2016). In a study of pts with non-Hodgkin lymphoma, ven showed efficacy in 4 pts with WM (Davids J Clin Oncol 2017).
Aims: We initiated a phase II study to evaluate the safety and efficacy of ven monotherapy in previously treated pts with WM (NCT02677324).
Methods: Treatment was given in the outpatient setting and followed a ramp-up of 200 mg daily days 1-7, 400 mg daily days 8-14, then 800 mg daily thereafter, for maximum of 2 years. Pts were closely monitored for tumor lysis syndrome (TLS) during the first 24 hours of each dose escalation. Toxicity was graded per CTCAE v.4.03. Response was assessed based on IWWM6 criteria.
Results: 30 pts with symptomatic WM were enrolled. Median follow-up time is 8 months (range 0.2-18 months). Median age was 66 years (range 39-80 years) and 17 pts (57%) were men. Indications to treat were constitutional symptoms (52%), anemia (44%), neuropathy (15%), extramedullary disease (11%) and thrombocytopenia (7%). Median number of previous lines of therapy was 2 (range 1-10), and 15 pts (50%) were previously exposed to BTK inhibitors (BTKi). The $MYD88^{L265P}$ mutation was detected in all pts, and CXCR4 mutations in 16 (53%). At baseline, median serum IgM was 3,543 mg/dl (range 642-7,970 mg/dl), median bone marrow involvement was 35% (range 4-95%) and median hemoglobin was 10.6 g/dl (range 6.4-13.5 mg/dl). All pts were successfully escalated to target dose of 800 mg. At 6 months, median serum IgM declined to 1,640 mg/dl (range 49-5,220 mg/dl), median bone marrow involvement declined to 5% (range 0-20%) and median hemoglobin increased to 12.6 g/dl (range 10-15.1 g/dl) ($p<0.001$ for all variables against baseline). At best response, very good partial response (VGPR) was attained in 5 pts (17%), partial response in 11 (37%), minor response in 8 (27%) and stable disease in 6 (20%), for overall response rate of 80% and major response rate of 53%. Major response rate was not statistically different based on relapsed or refractory disease, prior BTKi exposure or CXCR4 mutation status. However, VGPR rate at best response was lower in pts with previous BTKi exposure (7% vs. 27%), and those with CXCR4 mutations (6% vs. 29%). Median time to response (TTR) was 9 weeks and was slower in pts with prior BTKi exposure than in pts without (19 vs. 6 weeks; $p=0.02$). TTR was not impacted by relapsed vs. refractory disease or CXCR4 mutations. Only one instance of disease progression has been observed thus far, in a patient with MYD88, CXCR4 and TP53 mutations. Grade 4 neutropenia ocurred in 4 pts, who received G-CSG support; ven was dose reduced to 600 mg in 2 pts. Grade 3 adverse events included neutropenia (n=7), anemia (n=2), back pain (n=1), constipation (n=1), diarrhea (n=1), headache (n=1), upper respiratory infection (n=1). One instance of laboratory TLS occurred in a patient with significant extramedullary disease. No clinical TLS was seen. Most common grade 2 adverse events included anemia (n=5), nausea (n=4), neutropenia (n=3). Most common grade 1 adverse events included nausea (n=9), diarrhea (n=6), rash (n=5). No instances of IgM flare were observed, and there have been no deaths.
Summary/Conclusion: Our interim results show that venetoclax provides a safe and effective treatment option for pts with symptomatic, previously treated WM, including those previously exposed to BTKi.

S855

EFFICACY OF VENETOCLAX MONOTHERAPY IN PATIENTS WITH RELAPSED, REFRACTORY MANTLE CELL LYMPHOMA POST BTK INHIBITION THERAPY

T. Eyre[1,*], H. Walter[2], S. Iyengar[3], G. Follows[4], C. Fox[5], M. Dyer[2,6], N. Morley[7], G. Collins[1]

[1]Haematology, Oxford University Hospitals NHS Foundation Trust, Oxford, [2]Haematology, Leicester Royal Infirmary, Leicester, [3]Haematology, The Royal Marsden Hospital, London, [4]Haematology, Addenbrooke's Hospital NHS Trust, Cambridge, [5]Haematology, Nottingham University Hospitals NHS Trust, Nottingham, [6]The Ernest and Helen Scott Haematological Research Institute, Leicester, [7]Royal Hallamshire Hospital, Sheffield, United Kingdom

Background: Patients (pts) with relapsed, refractory (R/R) mantle cell lymphoma (MCL) have a typical survival of 2 years despite the recent approval of active novel agents including lenalidomide, ibrutinib and acalabrutinib. Although ibrutinib monotherapy provides impressive efficacy (overall response rate (ORR) 68% (complete response (CR) 21%)) and tolerability in R/R MCL, primary resistance (i.e. lack of response) occurs in 30% and most pts ultimately relapse, representing a cohort with clear unmet need. Documented responses post-ibrutinib are seen in <1/3 of patients and median overall survival (OS) following cessation of ibrutinib 4 months. Venetoclax is a potent, selective and orally bioavailable BCL2 inhibitor. A phase 1 first-in-human trial of venetoclax (n=106) included 28 Bruton tyrosine kinase inhibitor (BTKi)-naïve MCL pts; toxicity was minimal and an impressive ORR 75% (21% CR) was demonstrated.
Aims: There are no data regarding venetoclax efficacy in R/R MCL outside these initial data and none available in the post-BTKi setting. We provide data from the UK compassionate use programme.
Methods: 20 R/R MCL pts who had failed BTKi received venetoclax monotherapy in UK and Ireland between 03/2016-02/2018. Data at diagnosis and relapse were collected from hospital records by the treating physician. Response to and duration of BTKi and reasons for stopping BTKi were collected. Baseline data collected prior to venetoclax included LDH, performance status, extranodal disease/sites, stage, histological subtype, and KI67%.
Results: The median age was 69 years (range 43-84) with 86% male gender. Pts received a median of 3 prior lines (range 2-5). 38% received a Rituximab(R)-Maxi-CHOP/Ara-C-based induction, and 29% were consolidated with ASCT in 1st remission. Others pts received chemotherapy (fludarabine or CHOP-based) +/- R 1st line. At relapse (2nd or subsequent line), all but 1 pt received BTKi (ibrutinib (n=17), ibrutinib with DLI (n=1), tirabrutinib (n=2)). The ORR to BTKi was 55% (CR 15%), with a median progression free survival (PFS) of 4.8 months (95% CI 3.1-29.3 months). 9/20 pts did not respond to BKTi. 18 pts stopped BTKi due to disease progression and 2 for toxicity. Following BTKi, 4 pts relapsed with documented blastoid MCL and the median Ki67% was 45% (n=11). ECOG PS 0-1 (n=11) and PS 2-3 (n=9) were noted. LDH was raised in 75%. ORR to venetoclax monotherapy in the 20 BKTi exposure pts was 60% (20% CR). The median PFS was 2.6 months (95% confidence interval (CI) 1.5-9.9 months) and the median OS was 4.3 months (95% CI 2.1-16.0 months). The median duration of response was not reached (Figure 1). Although the ORR to venetoclax varied according to prior BTKi response (primary resistance to BKTi (n=9): ORR 44.4% *vs* response to prior BTKi (n=11): ORR 72.7%) differed ($p=0.198$)), this did not translate to an improved PFS (Figure 1). There were no cases of clinical tumour lysis syndrome (TLS) and 5 asymptomatic biochemical TLS. Venetoclax was otherwise well tolerated. 3 pts required dose reductions (800 mg to 600 mg od) due to adverse events (AEs) (Grade (G) 2 fatigue (n=1), G2 diarrhoea (n=2)). There were 13 AEs

reported including pneumonia (G3; n=3), sepsis (G4; n=2), fatigue (G2; n=2) and diarrhoea (G2; n=2). 11 pts have died; 9 from PD and 2 from the combination of PD and infection.

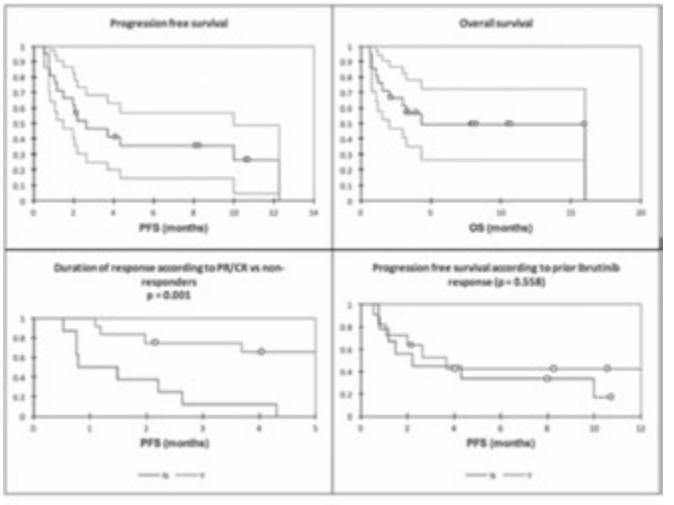

Figure 1.

Summary/Conclusion: In summary, venetoclax monotherapy provided an ORR of 60% with 20% CR in a poor-risk R/R BTKi-resistant MCL. Venetoclax was relatively non-toxic and provides scope for rational novel combination therapies in this setting.

Background: Moxetumomab pasudotox, a first-in-class recombinant immunotoxin targeting CD22, is composed of an immunoglobulin light chain variable domain and a heavy chain variable domain genetically fused to a truncated form of *Pseudomonas* exotoxin PE38.
Aims: This pivotal multicenter, single-arm study evaluated the rate of durable complete response with moxetumomab pasudotox in patients with relapsed/refractory hairy cell leukemia (HCL).
Methods: Eligible patients had ≥2 prior systemic therapies, including ≥1 purine nucleoside analog. Patients received moxetumomab pasudotox 40 µg/kg intravenously on days 1, 3, and 5 of 28-d cycles, up to 6 cycles. Disease response and immunohistochemistry (IHC) minimal residual disease (MRD) status were determined by blinded independent central review. The primary end point was durable complete response (CR), defined as CR with hematologic remission (HR; blood count normalization) for >180 days.
Results: Eighty patients (63 male; median age 60 years) received moxetumomab pasudotox. The median number of prior systemic therapies was 3 (2–11); 39 patients (49%) had >3 prior lines of therapy and 60 (75%) had prior rituximab. At 16.7 months median follow-up, objective response (OR) rate was 75% (60/80), HR rate was 80% (64/80), CR rate was 41% (33/80), and durable CR rate was 30% (24/80). Of 33 patients achieving CR, 27 (82%) had IHC MRD negative status. Median time to HR was 1 month. Median duration of OR and median PFS were not reached. Most frequent treatment-related adverse events (AEs) were nausea (28%), peripheral edema (26%), headache (21%), and pyrexia (20%); 8% had infections and 3% had neutropenia deemed treatment related. Three deaths occurred; none were treatment related. Treatment-related AEs leading to discontinuation were hemolytic uremic syndrome (HUS; n=4 [5%]), capillary leak syndrome (CLS; n=2 [3%]), and increased blood creatinine (n=2 [3%]). Seven patients (9%) had CLS (grade 2: n=5; grade 4: n=2), 7 (9%) had HUS (grade 2: n=2; grade 3: n=3; grade 4: n=2), and 4 (5%) had both. Both CLS and HUS were manageable and reversible with dose interruption and discontinuation in severe cases (no plasma exchange in HUS). Median immunoglobulin levels remained unchanged after treatment. Median CD4 cell counts were stable or improved after the first week of treatment.
Summary/Conclusion: Moxetumomab pasudotox achieved a high rate of independently assessed durable CR, with the ability to eradicate MRD in heavily pretreated HCL patients, and showed a favorable safety profile without immuno/myelosuppression.

Intensive and immune therapy in AML

PROSPECTIVE STUDY OF HLA-MATCHED DONOR AVAILABILITY AND SURVIVAL IN REMISSION AFTER AML IN OLDER ADULTS: 1ST PLANNED ANALYSIS FROM ECOG-ACRIN E2906 PHASE III RANDOMIZED TRIAL IN PATIENTS AGE ≥60 YEARS

J. Foran[1,*], Z. Sun[2], D. Claxton[3], H. Lazarus[4], E. Paietta[5], J. Godwin[6], S. Luger[7], J. Rowe[8], J. Altman[9], K. Pratz[10], M. Litzow[11], M. Tallman[12]

[1]Mayo Clinic Cancer Center, Mayo Clinic Florida, Jacksonville, [2]ECOG-ACRIN Biostatistics Center, Dana-Farber Cancer Institute, Boston, [3]Penn State Hershey Cancer Institute, Hershey, [4]University Hospitals Cleveland Medical Center, Cleveland, [5]Montefiore Medical Center, Bronx, [6]Providence Portland Medical Center, Portland, [7]Abramson Cancer Center, University of Pennsylvania, Philadelphia, United States, [8]Hematology, Shaare Zedek Medical Center, Jerusalem, Israel, [9]Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, [10]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Baltimore, [11]Hematology, Mayo Clinic, Rochester, [12]Leukemia, Memorial Sloan-Kettering Cancer Center, New York, United States

Background: This is the 1st report of the planned analysis of donor availability and outcome in the E2906 phase III trial of intensive therapy in patients (pts) age ≥60 years with newly-diagnosed AML.
Aims: Determine availability of HLA-matched donor and its impact on relapse & survival from 1st remission in the E2906 prospective study of 'curative' therapy with integrated allogeneic transplantation (AlloBMT).
Methods: 727 pts were registered (2011-2015) to receive induction therapy on E2906, with results previously presented (Foran, ASH 2015, #217). All pts in 1st 'remission' [complete remission (CR), CRi (platelets (plts) <100K), or leukemia-free state] with 10/10 HLA-matched donor were eligible for protocol AlloBMT using a busulfan-fludarabine reduced intensity conditioning (RIC) regimen. Living siblings, intent to initiate donor search, & comorbidity (HCT-CI) score at AML diagnosis was recorded for all pts. Survival from remission was determined by Kaplan-Meier method, and we performed a multivariate analysis using Cox models to determine impact of matched donor availability on Overall (OS) & Leukemia-Free survival (LFS; relapse or death from remission) with established AML risk factors.
Results: 360 patients in 'remission' (centrally reviewed) were included in this pre-specified analysis; 135 (37.5%) had a donor identified (sibling 42%, unrelated 58%), & 225 did not. Patients with donor were more likely baseline age<70yrs (p<0.01), performance status (PS)=0 (p=0.03), & plts≥50K (p<0.01). 61/135 (45%) underwent protocol-specified RIC AlloBMT in 1st remission, and 55 additional pts underwent *non*-protocol AlloBMT, including 25 in the No Donor group. The median follow-up is 37.7 months, and OS by Donor status is noted in Figure 1 (p=0.013). On multivariate analysis, favorable risk cytogen., PS, & plts≥50K were significantly associated with OS (Table 1). After stratification by age, secondary (vs. *de novo*) AML & induction treatment, and adjusted for cytogenetics, plts, PS & HCT-CI, availability of matched Donor was associated with 24% reduction OS risk, however did not meet statistical significance on multivariate analysis (HR: 0.76, 95% CI [0.56, 1.04], p=0.09). Similar results were observed for LFS in multivariate model (HR: 0.76, 95% CI [0.56, 1.03], p=0.07).

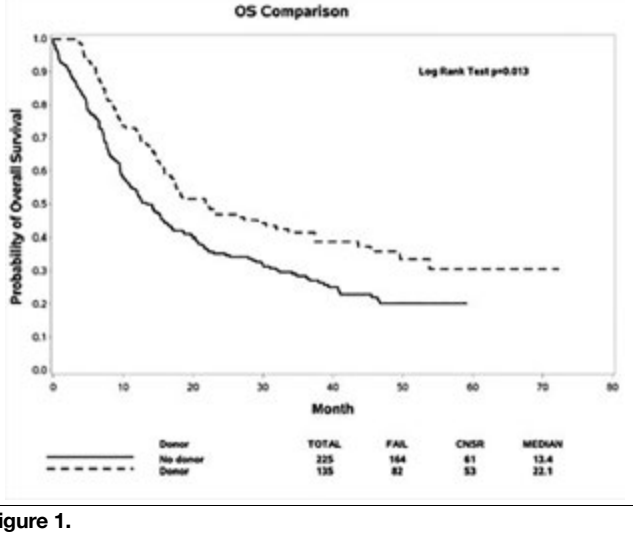

Figure 1.

Table 1.

Multivariate Cox Model – OS	P Value	Hazard Ratio (HR)	95% HR CI	
Donor vs. No donor	0.09	0.76	0.56	1.04
Baseline HCT-CI 0 vs. >2	0.33	0.82	0.56	1.22
Favorable vs. Unfavorable Risk Cytogenetics	0.002	0.25	0.11	0.59
Platelet <50K vs. ≥50K	<.0001	1.89	1.39	2.55
Performance status 2 vs. 0	0.02	1.68	1.07	2.63
Performance status 3 vs. 0	0.004	5.32	1.70	16.65
Unfavorable Risk Cytogen., Donor vs. No Donor	0.13	0.65	0.38	1.13

Summary/Conclusion: An OS advantage was observed in this 1st prospective Donor vs. No Donor analysis from E2906 in older adults, although matched donor status was not significant in the multivariate model. Further analysis is being performed to identify barriers to AlloBMT in this population, and its impact in CR1 vs. conventional therapy.

S858

PANOBINOSTAT, DECITABINE, AND DONOR LYMPHOCYTE INFUSION POST ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: THE HOVON 116 STUDY IN NEWLY DIAGNOSED POOR-RISK AML PATIENTS

J. Cornelissen[1,*], Y. van Norden[1], B. Kalin[1], M. van Gelder[2], D. Breems[3], J. Maertens[4], M. Jongen-Lavrencic[5], A. Broers[5], T. Grob[5], W. Zeijlemaker[6], G. Ossenkoppele[6], E. Meijer[6]

[1]Erasmus MC, Rotterdam, [2]Maastricht University Medical Center, Maastricht, Netherlands, [3]Ziekenhuis Netwerk Antwerpen, Antwerp, [4]University Hospital Leuven, Leuven, Belgium, [5]ErasmusMC, Rotterdam, [6]VUMC, Amsterdam, Netherlands

Background: Although the allogeneic graft versus leukemia (GVL) effect is operational in poor-risk AML, the relapse rate remains high. In order to exploit GVL more effectively, we explored the early initiation of epigenetic therapy after alloHSCT, interspersed with successive, low dosage donor lymphocyte infusion (DLI).
Aims: 1. First, feasibility of epigenetic therapy, consisting of either panobinostat (PNB) alone or PNB combined with decitabine, was evaluated with toxicities and DLT as endpoints. 2. Following the feasibility phase, the study continued as phase II focusing on outcome after transplantation.
Methods: Pts were registered early after diagnosis. Patients qualifying for alloHSCT all received standard reduced intensity conditioning (Flu/TBI). GVHD prophylaxis consisted of post-transplant (PT) cyclophosphamide and a short course of ciclosporine. First, feasibility of epigenetic therapy, consisting of either panobinostat (PNB) alone (20 mg orally at days 1, 4, 8, 11 of a 4 wk-cycle) or PNB combined with decitabine (DCB, either 10 or 20 mg/m^2 i.v. at days 1-3 of every 4 wk-cycle) was evaluated. After the feasibility phase, the study continued as phase II focusing on toxicities, GVHD, non-relapse mortality (NRM), relapse, residual disease (MRD), overall survival (OS), and relapse free survival (RFS) as from alloHCT.
Results: 140 Pts were registered early after diagnosis and 110 actually proceeded to alloHSCT at a median number of 110 days (range: 56-205) after diagnosis. 67 pts were in hematological CR, 38 in CR without complete blood recovery, and 5 in PR. Median age was 59 years (18-71). Donors included 41 sib and 69 MUD. Combining PNB with DCB at a dose of 20 mg/m^2 proved not feasible due to prolonged cytopenia, which was a dose limiting toxicity (DLT), but either PNB alone or the combination of PNB/DCB 10 mg/m^2 did prove feasible. Altogether, 87 out of 110 transplanted pts received PT epigenetic therapy, including 39 PNB alone, 13 PNB/DCB (20 mg/m^2), and 35 PNB/DCB (10 mg/m^2). Pts started at a median time point of 33 days (range: 27-90) after transplantation. CTC grade 3 and 4 side-effects after the first cycle of PNB/DCB included nausea in 7 pts (5 grade 3; 2 grade 4)), febrile neutropenia in 1 pt and general fatigue in 1 pt. No CTC grade 3 or 4 opportunistic infections were observed after the first 2 cycles of PNB/DCB. Outcome of 110 transplanted pts showed OS at 12 and 24 months from transplantation of 71% (se 5%) and 49% (se 6%), respectively. 44 Pts died, including 17 due to NRM and 27 due to relapse. RFS at 12 and 24 months was 64% (se 5%) and 46% (se 6%), comparing favourably to historical matched HOVON-pts with RFS of 43% and 39% at 12 and 24 m, respectively. So far, DLI could be administered in 62 pts, including 38 pts receiving 2 DLI's, and 20 pts a third DLI. None of the pts developed grade 3 or 4 acute GVHD before DLI. Out of 62 recipients of DLI, severe chronic GVHD occurred in 15 (24%) pts.

Summary/Conclusion: Collectively, these results suggest that: 1. alloHSCT with GVHD-prophylaxis by cyclophosphamide PT allows for early initiation of epigenetic therapy and DLI, and 2. as compared to a matched historical HOVON-cohort, encouraging results with respect to relapse, RFS, and OS were observed. 3. Limited side effects were observed in recipients of PNB alone or the combination of PNB and DCB at a dose of 10 mg/m^2; the incidence GVHD also appeared limited. Altogether these results might suggest enhanced GVL and, therefore, will be followed by an international prospective randomized study in (very) poor-risk AML patients.

S859

PHASE 1 FIRST-IN-HUMAN TRIAL OF AMV564, A BIVALENT BISPECIFIC (2×2) CD33/CD3 T-CELL ENGAGER, IN PATIENTS WITH RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA (AML)

P. Westervelt[1,*], G.J. Roboz[2], J.E. Cortes[3], H. M. Kantarjian[3], S. Lee[2], M.P. Rettig[1], T.H. Han[4], J. Guenot[4], E.J. Feldman[4], J.F. DiPersio[1]

[1]Washington University, St. Louis, MO, [2]Weill-Cornell Medical College, New York, NY, [3]MD Anderson Cancer Center, Houston, TX, [4]Amphivena Therapeutics Inc, South San Francisco, CA, United States

Background: AMV564 is a novel bivalent, bispecific (2x2) CD33/CD3 targeted immunotherapy that binds both CD33 and the invariant CD3ε on T-cell receptors with strong avidity, thus creating an immune synapse between CD33-expressing cells and T cells, initiating T-cell directed lysis of CD33 expressing cells, and inducing expansion, differentiation and proliferation of T cells. By design, AMV564 has reduced renal clearance and therefore has a longer half-life ($t_{1/2}$) than monovalent, bispecific T-cell engagers. In preclinical investigations using both leukemic cell lines and primary cells from AML patients, AMV564 eliminated myeloid blasts with picomolar potency and broad activity independent of cytogenetic risk, CD33 expression level, and disease stage, with no nonspecific activation of T cells (Reusch U et al. *Clin Cancer Res* 2016;22:5829-38). AMV564 also selectively eliminated myeloid-derived suppressor cells (MDSC) in myelodysplastic bone marrows at low doses with restoration of immune homeostasis and hematopoiesis (Cheng P *et al. Blood* 2017;130:51).
Aims: The primary objectives of this study are to characterize the safety, tolerability, and preliminary anti-leukemic activity of AMV564. Evaluation of AMV564 pharmacokinetics (PK) is a secondary objective.
Methods: This is an ongoing Phase 1 study with a 3+3 dose-escalation design (NCT03144245). Key inclusion/exclusion criteria are: adults with relapsed and/or refractory AML after 1-2 prior induction regimens (with a standard anthracycline-based regimen or hypomethylating agent) and no more than 2 prior salvage regimens. AMV564 is administered by continuous intravenous infusion (CIV) for 14 consecutive days for up to 2 induction cycles.
Results: Twelve patients (7M/5F) with a median age of 71 years (range 24-84) have been enrolled in 1 of 4 dosing cohorts: (0.5, 1.5, 5.0, and 15 mcg/day×14 days). Overall, 83% (10/12) had secondary AML and/or adverse cytogenetics, 75% (9/12) had received at least one prior salvage regimen, and 58% (7/12) had received one or more prior intensive chemotherapy-based regimens. No dose-limiting toxicity, cytokine release syndrome, or treatment-related grade ≥3 adverse events (AE) have been reported. The most common treatment-emergent grade ≥3 AE has been febrile neutropenia in 25% (3/12) of patients, but each case was considered unrelated to study drug. The 30-day mortality rate is 0% (0/12). AMV564 PK were linear with a terminal $t_{1/2}$ of 2-3 days. Plasma concentrations increased gradually, with time to steady-state concentrations of 3-7 days. Reductions in bone marrow blasts ranging from 13% to 38% were observed in 6 of 9 evaluable patients. Two of 3 patients with progression after cycle 1 had a reduction in bone marrow blasts after cycle 2. One patient with prior myelodysplastic syndrome had stable disease with a significant rapid rise in hemoglobin (>4 g/dL), achievement of transfusion-independence, and a rise in the absolute neutrophil count to >2,400/mm^3. Preliminary data demonstrated clearing of MDSC from the peripheral blood.
Summary/Conclusion: AMV564 is well-tolerated and can be administered without the need for incremental dosing and/or pre-medication. AMV564 has a unique PK profile compared to monovalent T-cell engagers, demonstrating a gradual increase in drug concentration and thus the potential for controlled T-cell activation. In a limited number of patients at the lowest dose levels, AMV564 demonstrated anti-leukemic activity. Dose escalation continues and correlation with T-cell expansion, T-cell activation, cytokine release, and other pharmacodynamic endpoints is ongoing.

S860

DECREASED INCIDENCE OF INFECTION, USE OF ANTIBACTERIALS AND DAYS IN HOSPITAL AFTER ADMINISTRATION OF CLT-008 MYELOID PROGENITOR CELLS TO SUBJECTS RECEIVING AML INDUCTION THERAPY: PHASE 2 STUDY RESULTS

P. Desai[1,*], L. Akard[2], C. Andreadis[3], J. Foran[4], O. Frankfurt[5], J. Hsu[6], S. Gill[7], J. Lister[8], J. Pagel[9], G. Schiller[10], M. Solh[11], C. Ustun[12], M. Wieduwilt[13], J. Brown[14], A. Wong[15], L. Kellerman[16], R. Van Syoc[16], D. Zimmerman[16], S. Panuganti[16], S. Solish[16], R. Mandalam[16], R. Mamelok[16], C. Abboud[17]

[1]Weill Cornell Medicine, New York, [2]Indiana Blood and Marrow Transplantation, Indianapolis, [3]University of California, San Francisco, San Francisco, [4]Mayo Clinic, Jacksonville, [5]Northwestern University, Chicago, [6]University of Florida, Gainesville, [7]University of Pennsylvania, Philadelphia, [8]Western Pennsylvania Hospital, Pittsburgh, [9]Swedish Cancer Institute, Seattle, [10]University of California, Los Angeles, Los Angeles, [11]Northside Hospital - The Blood & Marrow Transplant Group of Georgia, Atlanta, [12]University of Minnesota, Minneapolis, [13]Moores University of California, San Diego Cancer Center, La Jolla, [14]Stanford University Medical Center, Palo Alto, [15]Celllerant Therapeutics, Inc, [16]Cellerant Therapeutics, Inc, San Carlos, [17]Washington University, St. Louis, United States

Background: Standard induction chemotherapy (7+3) for AML results in prolonged neutropenia with a high risk of infection. CLT-008 is an off-the-shelf human allogeneic myeloid progenitor cell (MPC) preparation manufactured by ex vivo culture expansion of CD34+ cells. Following infusion, MPCs are expected to home to bone marrow (BM) and produce neutrophils.
Aims: Study the effect of CLT-008 on the reduction of infections during AML induction therapy.
Methods: 94 *de novo* AML subjects (age ≥55) receiving 7+3 induction therapy were randomized on Day 0 (first day of induction) to receive a regimen of CLT-008 ($7.5x10^6$ cells/Kg) on Day 9 + GCSF daily starting on Day 14 (intervention) or GCSF alone daily starting on Day 14 (control) until ANC recovery to ≥500/μL. The primary endpoint was days in a febrile episode (DFE) and secondary endpoints included clinically diagnosed (CDI) and microbiologically diagnosed (MDI) bacterial or fungal infection (adjudicated by a blinded independent committee), use of antimicrobials, and days in hospital (to Day 42). Data are reported for 2 periods: From infusion of CLT-008 on Day 9-28 and from 6 days after infusion of CLT-008 (1 day after start of GCSF) – Day 28 (denoted as Day 15-28). This is the period when CLT-008 derived neutrophils are likely to be circulating. Intervention and control subjects were evaluable if they received respectively CLT-008 or GCSF alone, were on study ≥28 days, and did not receive additional chemotherapy before Day 28. One-sided p-values are reported.
Results: The baseline characteristics, including mean age, mean WBC, and ECOG status were balanced between the intervention and control groups. The mean DFE during Day 9-28 in the intervention and control was 7.37 and 9.11 days respectively (p=0.099). The mean DFE for Day 15-28 was 3.24 and 4.77 days in the intervention vs. control respectively (p=0.057). The incidence of MDI or CDI during Day 9-28 was 33% vs 51% in the intervention vs. control, a decrease of 35% (p=0.058) and during Day 15-28 was 7.6% vs 28% in the intervention vs. control, a decrease of 73% (p=0.010). Mean number of days in hospital were 27.1 vs 30.6 days in intervention vs. control groups (p=0.003). Remission rates and days to ANC recovery were similar in the two groups. Eleven subjects assessed for chimerism had CLT-008 cells detected in peripheral blood (PB) on the day of infusion. Post infusion, chimerism was observed on day 13 or 14 in bone marrow in 5/6 subjects and in PB in 5/11 subjects between days 13 and 21 prior to ANC recovery. No infectious deaths were observed in the intervention group; there were two deaths attributed to pneumonia in the control group. CLT-008 was generally tolerated well (Table 1).

Table 1.

	Incidence of Subjects Receiving Antibacterial Agents	
	Empiric therapy with IDSA Group 2[a] Intervention (N = 39) vs Controls (N = 39)	Antibacterial treatment of MDI/CDI Intervention (N=39) vs Control (N=39)
Days 9-28	38% vs 54% p=0.084	38% vs 67% p=0.007
Days 15-28	31% vs 54% p=0.021	36% vs 64% p=0.007

[a]IDSA2: antimicrobials added to initial treatment of neutropenic fever due to suboptimal response to initial treatment.

Summary/Conclusion: The incidence of infections, use of antibacterial agents and days in hospital were decreased in subjects receiving CLT-008. Myeloid progenitors may provide a new option to reduce infections in AML patients undergoing induction therapy.

Background: Seven days of cytarabine plus three days of anthracycline, most commonly daunorubicin, remains the standard approach for curative treatment of acute myeloid leukemia (AML). Two randomized trials have shown a survival benefit for a daunorubicin dose of 90 mg/m^2 versus 45 mg/m^2 as part of a standard 7+3 schedule using seven days of continuous cytarabine (c.i.) and three subsequent days of daunorubicin. However, a daunorubicin dose of 60 mg/m^2 rather than 45 mg/m^2 has been an established standard in many countries, posing the question if 90 mg/m^{2}would still be a superior approach. The NRCI-AML 17 study explored 90 mg/m^2 versus 60 mg/m^2 in a 10+3 induction using cytarabine bolus infusion twice daily plus daunorubicin on days 1, 3, 5 followed by diverse induction and consolidation options, but showing no differences in complete remission (CR) rates, early death or survival.
Aims: In order to compare 90 mg/m^2 versus 60 mg/m^2 in a standard 7+3 induction regimen, we set up the randomized multicenter DaunoDouble trial.
Methods: Patients with newly diagnosed AML without previous anthracycline treatment, normal cardiac and organ function and 18-60 years of age were randomly assigned to receive induction treatment with seven days of cytarabine 100 mg/m^2 c.i. plus daunorubicin infusion on days 3-5, either with 90 mg/m^2 (Dauno90) or with 60 mg/m^2 (Dauno60). Response assessment in bone marrow was done 15 days after commencement of chemotherapy. A blast count <5% was defined as good response. Responses were compared using Chi squared test and multivariable logistic regression analyses accounting for established prognostic factors. Incidence and grade of adverse events and early mortality were compared between Dauno90 and Dauno60. Patients with good response were eligible for a second randomization to proceed to a routinely administered second induction with 7+3 or to no further induction. This second part of the DaunoDouble trial is ongoing and results will be presented in the future.
Results: Between April 2014 and August 2017, 314 patients were randomized, 157 in each arm. The median age was 48 years, 87% had *de novo* AML, NPM1 mutation was present in 41% of patients, FLT3-ITD in 20%, CEBPA double mutation in 5%; favorable, intermediate and adverse risk (ELN 2017) was present in 7%, 73% and 20% of patients, respectively. No significant imbalances were observed between the two treatment arms. Response rates after 7+3 induction with 90 mg/m^2 daunorubicin were 47.8% (95%>CI, 39.7-55.9) versus 42,7% (95%>CI, 34.8-50.8) with 60 mg/m^2 (p=0.29). Adverse events (AE) were documented in 89.8% of patients in Dauno90 and 86.6% in Dauno60. AEs ≥ grade 3 were registered in 20.3% and 16.2%, respectively. The incidence of early deaths within 14 days after start of induction was 1.3% and 0.6%, whereas 28-day early mortality was 3.2% and 1.3% in Dauno90 and Dauno60, respectively (p=0.251).
Summary/Conclusion: Our results provide randomized evidence that in a standard 7+3 induction, a dose escalation of daunorubicin from 60 to 90 mg/m^2 does not result in a significant increase in response rates. The tolerability was similar in both dose levels with no obvious signs of excess toxicity. Survival follow-up is ongoing. Our preliminary results support the use of 60 mg/m^2 daunorubicin in 7+3 induction.

Acute lymphoblastic leukemia – Biology

[1]Center for Translational Cancer Research (TranslaTUM), Technische Universität München, [2]Department of Medicine II, Klinikum rechts der Isar, Munich, [3]German Cancer Consortium (DKTK), German Cancer Research Center (DKFZ), Heidelberg, [4]Equal, contribution, Germany, [5]Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom, [6]Instituto de Medicina Oncólogica y Molecular de Asturias (IMOMA), Oviedo, Spain, [7]Institute of Pathology, Technische Universität München, Munich, [8]Institute of Pathology, University of Tuebingen, Tuebingen, Germany, [9]Equal senior, contribution, United Kingdom, [10]Institute of Virology, Technische Universität München, Munich, Germany

Background: Insertional mutagenesis by the *PiggyBac* transposon can be used for cancer gene discovery in mice. Previously, we have shown that transposon based genetic screening can overcome the challenge of pinpointing cancer drivers that are not mutated, but are among the thousands of transcriptionally, epigenetically, or posttranslationally dysregulated genes in cancer. Although the majority of transposon insertions are detected in intergenic regions, the consequence of these insertions for tumor development has not yet been investigated systematically.
Aims: We used *PiggyBac* for the identification of novel cancer genes, but also to decipher the role of non-coding regulatory elements in leukemogenesis and lymphomagenesis.
Methods: Using *PiggyBac* transposon mutagenesis in mice, we performed genome-wide surveys for cancer drivers and regulatory elements across distinct hematologic malignancies (n=256 cancers), including T cell, B cell, and myeloid neoplasms.
In addition, using intergenic knockout mouse models, we validated these newly identified regulatory elements *in vivo*.
Results: In line with previous studies more than 90% of *RosaPB;ATP2* mice developed hematopoietic malignancies. The subgroup of T cell lymphoblastic lymphomas/ T cell acute lymphoblastic leukemia (T-LBL/T-ALL, n=53) demonstrated a significantly reduced survival compared to other subgroups or single-transgenic control mice. Using semi-quantitative transposon insertion site sequencing (Friedrich *et al.*, *Nature Protocols* 2017) we found genes already known to be important in T cell malignancies (e.g., *Notch1*, *Ikzf1*, *Pten*, *Myb*) as well as potential novel candidate genes. Moreover, systematic genome-wide analyses of intergenic insertions identified cancer-relevant regulatory regions, including high-coverage insertions on chromosome 12 downstream of *Bcl11b* in the T-LBL/T-ALL subgroup. Two of these intergenic common insertion sites show an overlap with markers for open chromatin such as H3K27ac, H3K4me1, and DNase hypersensitivity sites confirming their potential role as regulatory elements. Knockout of two such intergenic regions (105 kb and 1 Mb) in novel mouse models resulted in lymphoma and solid cancer development in 30-40% of cases. Whereas the 105 kb knockout mice (n=148) showed a diverse tumor spectrum, the knockout of the 1 Mb region (n=47 mice) mainly led to the development of lymphomas (70% T-LBL/T-ALL). Consistent with this observation, the mRNA expression of *Bcl11b* was more prominently reduced in mice with the knockout of the 1 Mb region, thereby indicating a role of this region in *Bcl11b* regulation and T-LBL/T-ALL development. Importantly, the common insertion sites found downstream of *Bcl11b* share over 80% sequence similarity to the concordant human region and might therefore also play a role in human *BCL11B* regulation.
Summary/Conclusion: Taken together, our studies give comprehensive novel insights into the coding and regulatory landscapes in malignant hematopoiesis and show that an intergenic knockout model can recapitulate the phenotype of the transposon mice.

S863

MODELING HIGH RISK ACUTE LEUKEMIA WITH COMBINED T-CELL AND MYELOID PHENOTYPE CAUSED BY THE ETV6-NCOA2 FUSION GENE

H. Fishman[1,*], B. Vase[2], W. Van Loocke[3], Y. Kirschenbaum[1], I. Ganmore [1], P. Van Vlierberghe[3], J. Mulloy[2], S. Izraeli[1]

[1]Dept. of Human Molecular Genetics and Biochemistry, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, [2]Cincinnati Children's hospital, Cincinnati , United States, [3]Ghent University, Ghent , Belgium

Background: Mixed-phenotype acute leukemia (MPAL) is a rare subtype of leukemia in which there is co-expression of myeloid and lymphoid markers on the same malignant cells. The pathogenesis of these leukemias is unknown and their treatment is challenging. This research is based on our discovery of the recurrent t(8;12)(q13;p13) chromosomal translocation in children with acute leukemia. The translocation generates a transcript in which the PNT domain of the transcriptional repressor ETV6 fuses with the epigenetic-modification domains of the co-activator NCOA2. Remarkably, this genetic event is always associated with acute leukemia co-expressing T-lymphoid and myeloid (T/M) markers and often presents with activating mutations of Notch1.
Aims: We hypothesize that ETV6-NCOA2 (EN2) fusion protein is a major driver of MPAL and of Early T-cell leukemia (ETP) with a T/M phenotype through transcriptional dysregulation.
Methods: To examine whether EN2 directly contributes to leukemogenesis we transduced lineage-negative BM progenitors with EN2 and performed *in vitro* and *in vivo* assays: methylcellulose replating assay to assess self-renewal; co-cultures on OP9DL4 to examine T-cell differentiation ability and transplantation into C57B/6 mice to examine leukemia development. Cord blood derived CD34+ hematopoietic stem and progenitor cells (HSPCs) were co-transduced with EN2 and a Notch1 allele with a weak activating mutation (L1601PdP) and transplanted into immunodeficient mice. To understand the initiating changes in gene expression we conducted RNA-sequencing of HSPCs transduced with EN2. To reveal the effect of EN2 fusion protein on wt-ETV6 we preformed CO-IP experiments to explore this interaction and luciferase reporter assay to examine changes in transcription.
Results: *In vitro* experiments demonstrated enhanced self-renewal ability and T-cell differentiation arrest at the DN1/DN2 stage. C57B/6 mice transplanted with lin- transduced with EN2 cells developed a lymphoma/leukemia malignancy characterized by extra medullary infiltration including spleen, liver, lungs and lymph nodes. Immunophenotypic analysis displayed a mixed T/M phenotype. Several leukemic/lymphoma cells developed spontaneous Notch1 mutations similarly to those found in human EN2 patients. The tumors were propagated in secondary transplantations. Immunodeficient mice transplanted with HSPCs co-expressing EN2 and Notch1-L1601PdP developed leukemia with co-expression of T-cell and myeloid markers. RNA-seq of CD34+ cells transduced with EN2 after five days in culture with myeloid and stem cell cytokines revealed that EN2 induces an early T-cell precursor's transcriptional program. We detected a significant up-regulation of ETV6 target genes. We hypothesize that EN2 has a dominant negative effect on wt-ETV6 through dimerization with its PNT domain and recruitment of histone acetylase EP300 to ETV6 targets. COIP experiments confirmed that EN2 and ETV6 interacts and Luciferase assay showed that EN2 expression can abolish ETV6's repression.
Summary/Conclusion: ETV6-NCOA2 is a driver of T/M MPAL by inducing a T-cell program in early hematopoietic progenitors, possibly by de-repression of ETV6 genes. These findings are consistent with an earlier report on dominant negative mutations in ETV6 in early T-cell ALL, characterized by a T/M phenotype. The development of the first preclinical model of T/M acute leukemia will contribute to the understanding of this disease and may serve as a future model for therapeutics. Furthermore, this research could shed more light on the lineage choice decisions of early hematopoietic progenitors.

S864

SYK TARGETING AS A POTENTIAL THERAPEUTIC STRATEGY FOR HIGH RISK TEL-AML1 PATIENTS

V. Serafin[1,*], E. Porcù[1], G. Cortese[1], E. Mariotto[1], S. Bresolin[1], G. Basso[2], B. Accordi[1]

[1]University of Padova, Padova, Italy, [2]Dipartimento della Salute della Donna e del Bambino, University of Padova, Padova, Italy

Background: The most frequent chromosomal rearrangement in childhood B acute lymphoblastic leukemia (B-ALL) is the reciprocal translocation t(12;21)(p13;q22) (ETV6-RUNX1). Although the presence of ETV6-RUNX1 appears to be a strong independent predictor factor of a favorable prognosis, relapses still occur in the 10% of patients, usually near the end of treatment and occasionally many years later. A distinctive marker able to distinguish, already at diagnosis, ETV6-RUNX1 patients at risk of relapse is still missing.
Aims: To identify new potential biomarker and/or therapeutic targets that could predict and/or prevent already at the moment of diagnosis ETV6-RUNX1 patients' relapse.
Methods: By Reverse Phase Protein Arrays (RPPA) we performed the phosphoproteomic profiling of pediatric ETV6-RUNX1 B-ALL patients. We evaluated by MTT assay the effects of treatment with selected inhibitors in cell lines and primary samples. We assessed by phosphoflow the phosphorylation of SYK.
Results: We performed a phosphoproteomic profiling at diagnosis of 62 pediatric ETV6-RUNX1 B-ALL patients. We analysed the activation status of several signaling pathways and we identified SYK as hyperactivated (SYK Y525) in patients who will experience relapse (n=11) compared to non-relapsed ones (n=51, p=0.02). Total SYK and *SYK* RNA were not differentially expressed in the two subgroups. We also evaluated the activation of SYK at relapse occurrence and we observed an increase of SYK Y525 compared to diagnosis (n=8, p=0.009). SYK is a non-receptor tyrosine kinase which mediates signal transduction downstream of a variety of transmembrane receptors including classical immunoreceptors such as the B-cell receptor. Thus, we first functionally validated SYK as a new therapeutic target by treatment of cell lines and primary cells from pediatric ETV6-RUNX1 patients with SYK inhibitors. We treated t(12;21) REH, AT-1 and AT-2 cell lines, that display SYK hyperphosphorylation, with Entospletinib, Fostamatinib and PRT-060318. After 48hours of treatment, all the compounds were able to decrease both cell proliferation and SYK Y525 phosphorylation. We also tested inhibitors in combination with conventional chemotherapeutic compounds (Vincristine, Dexamethasone and Cytarabine-Ara-C), and Entospletinib resulted the one with the best synergistic effect. This result was also confirmed combining all the three chemotherapeutic compounds (VDA) together with Entospletinib. We also validated SYK as a therapeutic target by treating primary cells from t(12;21) patients at diagnosis with Entospletinib and VDA alone or in combination. At diagnosis we observed an augmented response to Entospletinib in samples from patients who will experience relapse (n=3) compared to non relapsed ones (n=7, p=0.03), and more importantly an increased cell death with Entospletinib+VDA compared to VDA alone (p= 0.1) in patients who will relapse. Finally, we are now setting up the analysis of activated SYK by phosphoflow to validate it as a prognostic marker. We will screen an independent cohort of t(12;21) patients, and preliminary results seem to confirm what previously observed by RPPA.
Summary/Conclusion: SYK is hyperactivated in t(12;21) B-ALL patients who will experience relapse and also at relapse occurrence. Its inhibition using Entospletinib, a phase 2 inhibitor for Chronic Lymphocytic Leukemia treatment, is able to potentiate the effects of conventional chemotherapeutics. Thus, SYK could be considered as a new potential marker of relapse occurrence and as a new therapeutic target for t(12;21) pediatric patients.

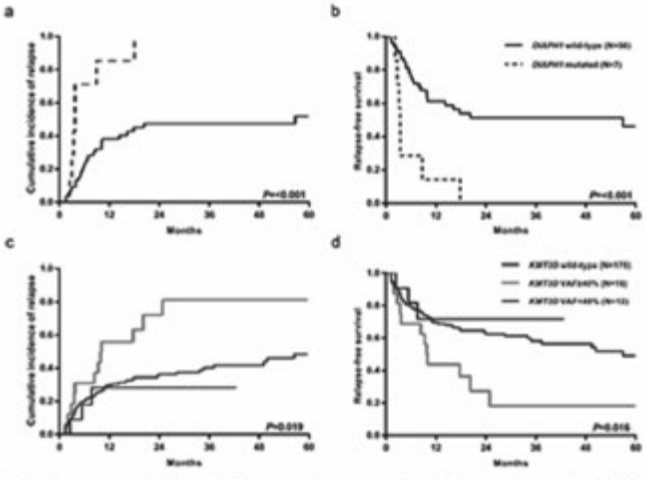
GENOMIC LANDSCAPE OF ADULT B-CELL ACUTE LYMPHOBLASTIC LEUKAEMIA

L.-X. Wu[1,*], R.-Q. Lu[1], K.-Y. Liu[1], R. Peter Gale[2], Q. Zheng[3], J. Zhou[1], J.-L. Li[1], S.-J. Wang[1], H. Jiang[1], Q. Jiang[1], B. Jiang[1], X.-H. Zhang[1], L.-P. Xu[1], Y. Wang[3], C.-L. Song[3], Y.-R. Liu[1], X.-J. Huang[1#4], G.-R. Ruan[#1]

[1]Peking University People's Hospital, Beijing, China, [2]Haematology Research Center, Division of Experimental Medicine, Department of Medicine, Imperial College London, London, United Kingdom, [3]Novogene Bioinformatics Institute, [4]Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Beijing, China

Background: The overall prognosis of adults with B-cell acute lymphoblastic leukaemia (ALL) remains worse than that of children. One of the bottlenecks leading to the poor outcome of adults is that molecular analyses of risk cohorts in adult B-cell ALL has lagged behind progress in pediatric B-cell ALL.
Aims: Interrogate the genomic landscape of adult B-cell ALL and variants associating with leukaemogenesis and prognosis.
Methods: 226 consecutive, newly-diagnosed adults with B-cell ALL seen in Peking University People's Hospital between April, 2007 and December, 2015 were enrolled in the study. Whole-genome sequencing was performed for 8 paired samples (at diagnosis and at complete remission), whole-exome sequencing for 13 paired samples and target DNA sequencing for 210 samples including 88 paired samples. For validation, 5 paired samples were sequenced both by whole-exome and target DNA sequencing. Clonal evolution of 7 paired samples (at diagnosis and at relapse) was detected by whole-exome sequencing.
Results: We identified 2285 mutations in 791 genes (median, 11 mutations *per* subject) with ≥2 mutations identified in 190 subjects (84%; 95% confidence interval [CI], 79, 89%). *KMT2D*, also termed *MLL2*, represented

the most frequent significantly mutated gene in our cohort (N=31; 14% [9, 19%]). We also found 4 new mutated genes, *PRB2* (N=13; 6% [3, 9%]), *NBPF10* (N=12; 5% [2, 8%]), *TSFM* (N=8; 4% [1, 7%]) and *DIAPH1* (N=8; 4% [1, 7%]). 7 *DIAPH1* mutated subjects with remission were matched by 56 controls according to age (<35y *vs.* ≥35y), t(9;22)/*BCR-ABL* (+ *vs.* -) and time to CR1 (≤33 d *vs.* >33d) to compare CIRs and RFSs. *DIAPH1* mutation had a significantly higher CIR *vs.* those without a mutation (p=<0.001; Figure 1a) and worse RFS (p=<0.001; Figure 1b). In multivariate analyses *DIAPH1* mutation was independently-associated with CIR (hazard ratio [HR]=4.6 [1.7, 12.7], p=0.004) and RFS (HR=4.5 [1.6, 12.6], p=0.004). Besides, 90% of the samples showed 14q32.33 loss, validating by a long non-coding RNA, *KIAA0125* in this area. Mutation burden (40% VAF as a watershed) showed more importance in B-ALL development and patient survival than mutation itself. *KMT2D* mutation with VAF≥40% indicated higher relapse risk compared with the wild-type ones(Figure 1 c,d). Multivariate analyses also revealed that *KMT2D* mutation with VAF≥40% was an independent risk factor for CIR (HR=2.4 [1.3, 4.3], p=0.006) and RFS (HR=2.3 [1.2, 4.4], p=0.013). Moreover, genes with VAF ≥40% predispose them to persistence at relapse.



Univariate analyses. CIR (a) and RFS (b) analyses subjects with *DIAPH1* mutations and matched subjects without *DIAPH1* mutations; CIR (c) and RFS (d) analyses of subjects with *KMT2D* mutations VAF ≥40%, <40% and without *KMT2D* mutations.

Figure 1.

Summary/Conclusion: These data provide insights into the genomic landscape of adults with B-cell ALL, identify diverse mutations with 4 new mutated genes and frequent copy number loss in 14q32.33, which may highly correlate with leukaemogenesis. Besides, targeting mutations with VAF ≥40% may benefit patients as more clinically relevant. (Trial registered in the Beijing Municipal Health Bureau Registration N: 2007–1007 and the Chinese Clinical Trial Registry [ChiCTR-OCH-10000940 and ChiCTR-OPC-14005546]; http://www.chictr.org.cn)

MESENCHYMAL STROMAL CELLS PROTECT ACUTE LYMPHOBLASTIC LEUKAEMIA CELLS FROM CYTARABINE INDUCED APOPTOSIS BY TRANSFER OF MITOCHONDRIA VIA TUNNELLING NANOTUBES IN A TREATMENT RESISTANT NICHE MODEL

R. Burt[1,*], A. Dey[1], K. Ng[1], C. Pospori[2,3], S. Hooper[4], C. Lo Celso[2,3], E. Sahai[4], A. Fielding[1]

[1]Cancer Institute, UCL, [2]Stem Cell Biology, The Francis Crick Institute, [3]Stem Cell Biology, Imperial College, [4]Cancer microenvironment, The Francis Crick Institute, London, United Kingdom

Background: In acute lymphoblastic leukaemia (ALL) models, mesenchymal stromal cells (MSC) can form a 'protective niche' critical for treatment resistance (Ebinger, 2016; Duan, 2014).
Aims: We set out to determine the existence of such a niche in primary human bone marrow from patients with ALL and to understand the mechanism by which MSC may support ALL cell survival in this niche, following standard chemotherapy drugs.
Methods: We used both primary MSC and blasts from bone marrow of 152 patients enrolled on the UKALL14 trial as well as B-ALL cell lines and HS27a stromal cell line. We employed immunocytochemistry, gene expression profiling, ELISA, cytokine bead assay, MTS assays, apoptosis assays, quantification of reactive oxygen species (ROS), assays of mitochondrial number and various live cell imaging techniques.
Results: Immunostaining for f-actin, a gene expression profile panel and ELISAs showed that a significant proportion of primary patient bone marrow specimens contained MSC with an irreversible, activated phenotype, analagous to cancer associated fibroblasts (ALL-CAF). We demonstrated that both primary ALL cells, ALL cell lines and cytarabine (AraC) were able to generate ALL-CAF *de novo* from both healthy donor MSC and HS27a cells. ALL-CAF formation was closely associated with an increase in reactive oxygen species (ROS). It was functionally significant; pre-treatment of HS27a with AraC before co-culture with ALL cells led to increased cell proliferation and chemotherapy resistance. This phenomenon was not observed in untreated, or VCR or DEX pre-treated HS27a. Given AraC induces apoptosis by increasing ROS, we postulated MSC may protect ALL cells by 'rescuing' them from oxidative stress. We exposed SEM cells to AraC for 48 hours and observed a 1.4 fold increase in intracellular ROS (p=0.01), a 2-fold increase in apoptosis (p=0.0009) and cell death (p=0.01) at 48 hours compared to an untreated control. When SEM cells (a B-ALL cell line that didn't induce ALL-CAF) were co-cultured with MSC in the presence of AraC, ROS reduced 4-fold (p = 0.0002) compared to SEM in mono-culture which correlated with a 2.5-fold reduction in apoptosis (p=0.02) and a 3.4-fold reduction in cell death (p=0.0001). The observations couldn't be replicated in a transwell system, suggesting a contact-dependent mechanism. Next, using a mitotracker flow cytometry assay, we showed transfer of mitochondrial from HS27a to ALL cell lines, proportionate to the ROS level of the ALL cell line. Mitochondrial transfer to healthy donor B-cell controls was minimal. Passive transfer was excluded in a transwell system. Treatment of the MSC and ALL cell co-cultures with AraC increased mitochondrial transfer to ALL cells 3-fold at 72 hours compared to an untreated control (p<0.0001) and was AraC dose-dependent. Treatment with DEX and VCR did not impact mitochondrial transfer. We confirmed mitochondria were transferred along tunnelling nanotubes (TNT) using time-lapse confocal microscopy. As further evidence for transfer via TNT, the actin inhibitor latrunculin B and the microtubule damaging agent nocodazole both significantly blocked the phenomenon (Figure 1).

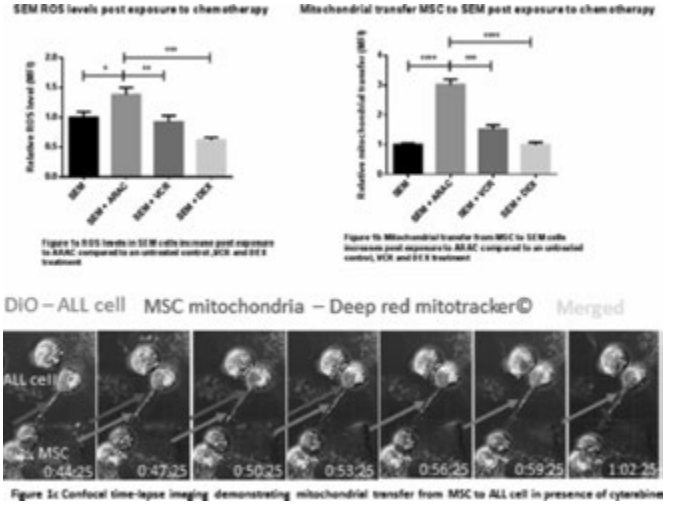

Figure 1.

Summary/Conclusion: We have shown that CAF-like MSC can provide support to ALL cells under oxidative stress by mitochondrial transfer via TNT. Our data may explain the ineffectiveness of ROS-inducing chemotherapy at eradicating residual disease at this niche and provide an explanation of why low dose non-ROS-inducing, microtubule damaging agents such as VCR used in maintenance therapy are effective in ALL.

Molecular mechanisms underlying CLL biology and response to treatment

MULTIPLE MECHANISMS OF KRAS ACTIVATION IN TRISOMY 12 CHRONIC LYMPHOCYTIC LEUKEMIA

E. Vendramini[1,*], R. Bomben[1], F. Serra[1], F. Pozzo[1], D. Benedetti[1], F.M. Rossi[1], G. Del Poeta[2], F. Zaja[3], A. Chiarenza[4], G. Pozzato[5], V. Gattei[1], A. Zucchetto[1]

[1]Clinical and Experimental Onco-Hematology Unit, CRO Aviano National Cancer Institute, Aviano, [2]Division of Hematology, S. Eugenio Hospital and University of Tor Vergata, Rome, [3]Clinica Ematologica, Centro Trapianti e Terapie Cellulari "Carlo Melzi" DISM, Azienda Ospedaliera Universitaria S. Maria Misericordia, Udine, [4]Division of Hematology, Ferrarotto Hospital, Catania, [5]Department of Internal Medicine and Hematology, Maggiore General Hospital, University of Trieste, Trieste, Italy

Background: Trisomy 12 (Tri12) chronic lymphocytic leukemia (CLL) identifies a cytogenetic subset with a peculiar clinical behavior (Bulian *et al*, Haematologica, 2017) and specific biological features, including high frequency of stabilizing *NOTCH1* mutations (*NOTCH1-mut*) (Rossi et al, Blood, 2013). Moreover, *KRAS* and its transcriptional regulator *HNRNPA1*, key components of Ras-Raf-MEK-ERK pathway are both hosted in the trisomic chromosome 12.
Aims: To investigate the role of KRAS expression and/or activation in Tri12 and *NOTCH1-mut* CLL.
Methods: Tri12 was assessed by FISH. *NOTCH1* and *KRAS* mutations were assessed by either Sanger or NGS. QRT-PCR and western blot were employed to evaluate HNRNPA1 and KRAS expression and down-stream signaling in primary CLL or CLL cell line models. Active GTP-bound RAS pull-down was performed by Raf1 RBD agarose beads assay. CI and MEC-1 cell lines were used as human *in vitro* model of Tri12 *NOTCH1-mut* CLL and non-Tri12 *NOTCH1-wild type* (*wt*) CLL, respectively. Mann-Whitney test, unpaired t-test or Chi-Square test were used to compare differences between groups.

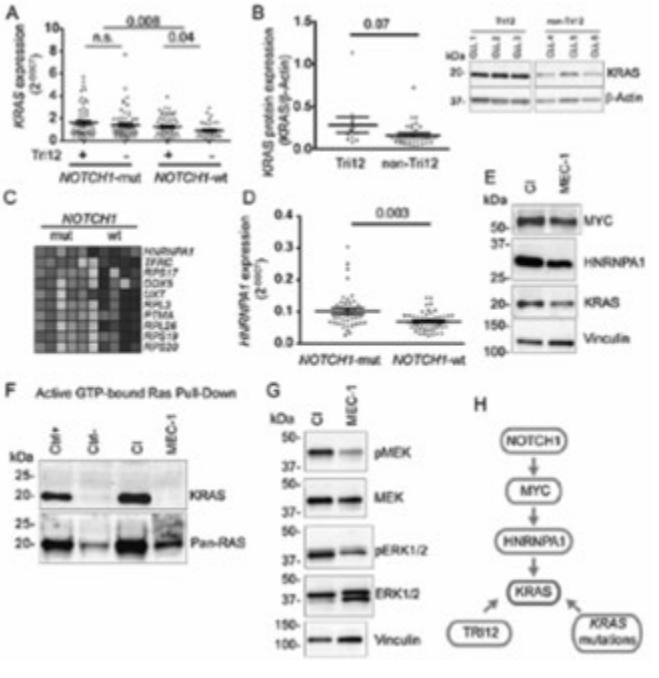

Figure 1.

Results: *KRAS* transcript was analyzed in 215 cases purposely enriched in Tri12 (118) and *NOTCH1-mut* (121). As shown in Figure 1 A, Tri12 were characterized by higher *KRAS* level in the context of *NOTCH1-wt* CLL (p=0.04); conversely, no differences in KRAS expression were found between Tri12 and non-Tri12 in the context of *NOTCH1-mut* CLL cases, which however expressed higher *KRAS* transcript compared to *NOTCH1-wt* CLL (p=0.008). Consistently, KRAS protein level was higher in Tri12 vs. non-Tri12 in the context of *NOTCH1-wt* CLL (Figure 1 B). A gene expression profiling identified *HNRNPA1* as the top ranked gene among MYC target genes upregulated in *NOTCH1-mut* vs. *NOTCH1-wt* CLL. Accordingly, higher *HNRNPA1* levels were found by QRT-PCR in additional 41 *NOTCH1-mut* vs. 47 *NOTCH1-wt* CLL samples (p=0.003, Figure 1 C,D) without differences between Tri12 (42) and non-Tri12 (46) CLL. In line with a KRAS transcriptional activation mediated by NOTCH1-MYC-HNRNPA1 axis, higher MYC, HNRNPA1 and KRAS protein levels were found in the Tri12 *NOTCH1-mut* CI cell line when compared to the non-Tri12 *NOTCH1-wt* MEC-1 cells. Furthermore, higher levels of active GTP-bound KRAS and higher phosphorylation levels of MEK and ERK were found in CI cells (Figure 1 E,F,G), supporting the hypothesis of sustained Ras-Raf-MEK-ERK signaling in Tri12 and *NOTCH1-mut* CLL. Finally, analysis of *KRAS* genomic aberrations revealed higher mutations incidence in Tri12 CLL (10/77, 13%) when compared to non-Tri12 CLL (2/68, 2.9%, p=0.03). Altogether, these data foster the hypothesis of multiple mechanisms of KRAS overexpression/activation occurring in Tri12 CLL via the NOTCH1-MYC-HNRNPA1 axis in *NOTCH1-mut* cases, or due to a higher incidence of KRAS mutations or an overexpression of KRAS by the supernumerary chromosome 12 (Figure 1 H).
Summary/Conclusion: Our data, by describing a synergism between Tri12, *NOTCH1-mut* and *KRAS-mut* in boosting KRAS expression and activity in CLL, indicate the Tri12 subset as particularly addicted to the Ras-Raf-MEK-ERK signaling pathway and likely to benefit of ERK/MEK inhibitors, as recently emphasized (Dietrich *et al*, J Clin Invest, 2018).

Background: Treatment of high-risk chronic lymphocytic leukemia (CLL) patients remains an unmet clinical need. Disease aggressiveness can be ascribed to intrinsic features of the tumor cells (i.e. *TP53* disruption) and to the interaction of CLL cells with stromal cells (SC) of the microenvironment. HIF-1 is a transcription factor implicated in cell adaptation to hypoxia and is involved in the regulation of genes implicated in tumor progression. In CLL cells, the α subunit of HIF-1 (HIF-1α) is constitutively expressed even in normoxia and regulates the protective interactions that the leukemic cells establish with the microenvironment.
Aims: The aims of this study were to understand HIF-1α regulatory pathways in CLL cells from *TP53* disrupted ($TP53^{dis}$) and wild type ($TP53^{wt}$) patients, and to evaluate the ability of HIF-1α inhibition to exert synergistic cytotoxic effects in combination with fludarabine and ibrutinib.
Methods: Del(17p) in CLL cells was assessed by fluorescence in situ hybridization and the presence of *TP53* gene mutations was evaluated by Sanger sequencing. CLL patients with mutation of the *TP53* gene, or >40% del(17p) in the absence of *TP53* mutation, were included in the $TP53^{dis}$ subset. Patients with <10% del(17p) and without *TP53* mutation were considered $TP53^{wt}$. In selected experiments, CLL cells were cultured in the presence or absence of M2-10B4 SC, and exposed to PD98059, Y27632, LY249002, BAY87-2243, F-ara-A or ibrutinib. Culture conditions were 21% (normoxia) or 1% (hypoxia) O2, 5% CO2 at 37°C. Ras, ERK1-2, Akt, HIF-1α, Elk3 and pVHL expression was evaluated by Western Blot. RhoA and RhoA kinase acitivity was measured by specific immunoassays. *HIF-1A*, *p21* and *ENO1* gene expression was assessed by RT-PCR. Cell viability was analyzed by AnnexinV/propidium Iodide immunostaining.

Results: We found that primary CLL cells from patients carrying *TP53* abnormalities (*TP53*^{dis} CLL cells) had constitutively higher transcriptional activity and expression levels of the α subunit of HIF-1 compared to CLL cells isolated from *TP53*^{wt} samples (*TP53*^{wt} CLL cells). HIF-1α upregulation detected in the *TP53*^{dis}subset was due to a reduced expression of the HIF-1α ubiquitin ligase von Hippel-Lindau protein (pVHL) and more active PI3K/Akt and Ras/ERK1-2 signalling pathways. Hypoxia and SC further enhanced HIF-1α accumulation in both *TP53*^{dis} and TP53^{wt} CLL cells. Hypoxia-mediated HIF-1α upregulation was due to a decreased pVHL expression and to the activation of PI3K/Akt and Ras/ERK1-2 signalling pathways. SC did not affect pVHL expression, but induced an increased activity of Ras/ERK1-2, RhoA/RhoA kinase and PI3K/Akt pathways, leading to HIF-1α accumulation. Interestingly, *in vitro fludarabine-resistant* CLL cells were mostly *TP53*^{dis} and expressed significantly higher levels of *HIF-1A* mRNA compared to *fludarabine-sensitive* cells. The HIF-1α inhibitor BAY87-2243 reversed the constitutive fludarabine resistance of leukemic cells isolated from patients carrying *TP53* abnormalities, and counteracted the fludarabine resistance induced by SC. BAY87-2243 also elicited a strongly synergistic cytotoxic effect in combination with ibrutinib.
Summary/Conclusion: Overall, our data indicate that HIF-1α is overexpressed in CLL cells, especially in the presence of *TP53* abnormalities, and is susceptible of positive regulation by hypoxia and SC. From the translational standpoint, HIF-1α can be regarded as a crucial target whose inhibition warrants further evaluation, also in combination with currently available therapies.

Background: The B-cell receptor (BCR) is one of the most important surface molecules that CLL cells use to gain oncogenic signals from the microenvironment. The critical role of BCR signaling for the pathogenesis of CLL is supported by the therapeutic success of ibrutinib, a targeted agent that disrupts the BCR pathway. Beside microenvironment-promoted oncogenic signals, the biology of CLL is also driven by molecular lesions and clonal evolution, that mark CLL progression and treatment resistance. The interconnection between microenvironment-promoted oncogenic signals and clonal evolution has been postulated in CLL but never proven because of the lack of suitable *ex vivo* models.
Aims: Ibrutinib allows the unprecedented opportunity of assessing the contribution of BCR to cancer clonal evolution directly *in vivo* in patients.
Methods: The IOSI-EMA-001 study (NCT02827617) is an observational, non-interventional, multicenter study consisting in the prospective and longitudinal collection of peripheral blood samples and clinical data from high risk CLL patients treated with ibrutinib monotherapy. Tumor DNA derived from sorted CLL cells (purity >99%) and germline DNA derived from sorted T cells were used for somatic mutation identification by CAPP-seq targeted deep next generation. A gene panel including 133 genes recurrently mutated in mature B-cell tumors or targeted by the aberrant somatic hypermutation process, was used. The number of the libraries loaded in the NexSeq500 sequencer (Illumina) was tailored at obtaining at least a coverage >2000x in >80% of the region of interest. A stringent bioinformatic pipeline was applied to suppress the background noise allowing to call variants with a sensitivity of $3x10^{-3}$. To track clonal trajectories across serial samples, we first measured the variant allele fraction (VAF) of all mutations identified across the different timepoints per patient. VAFs were transformed to cancer cell fractions (CCFs) using the ABSOLUTE tool. For each patient, we compared the clonal composition of the baseline sample with all the available longitudinal samples (up to 72 weeks of therapy).
Results: The study cohort comprised 31 high risk CLL patients, including 15 treatment naïve, 16 relapsed, 80% IGHV unmutated, 42% 17p deleted and 55% TP53 mutated (Figure 1A). Median duration of ibrutinib treatment was 45 weeks (range 24-72 weeks). Overall, 285 individual mutations were longitudinally discovered and monitored across a total of 119 sequential timepoints collected during ibrutinib treatment. Significant changes in CCF over time, defined as a FDR adjusted p value of <0.1 for change in CCF >0.1 in the largest rising or falling clone was observed in 21/31 (67.7%) cases (Figure 1B), a proportion that is superimposable to the clonal evolution rate previously documented in CLL treated with chemoimmunotherapy. Clonal evolution appeared to be puzzled and involved different genes without a stereotypic targeting (Figure 1C). Consistently, none of the main driver gene mutations was homogeneously selected or suppressed by ibrutinib. Clonal evolution rate neither associated with IGHV or TP53 mutation status (Figure 1D), nor changed over time (Figure 1E).

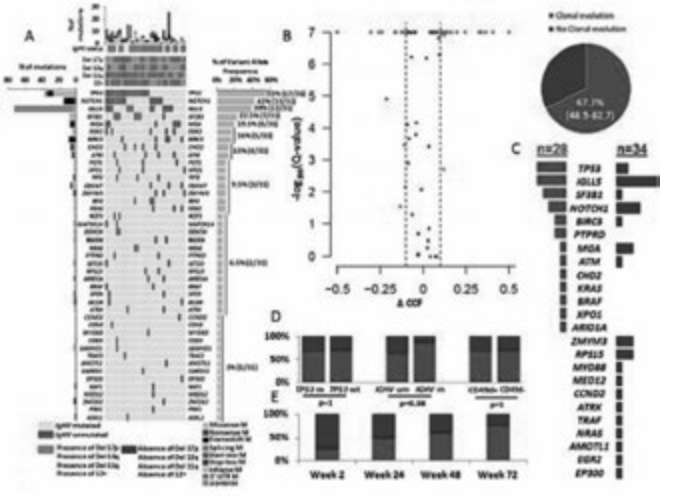

Figure 1.

Summary/Conclusion: Our results suggest that clonal evolution, a known pathogenic mechanism of progressive CLL: i) is not abrogated by ibrutinib; and ii) is quantitatively similar, but qualitatively different, than clonal evolution under chemoimmunotherapy, without specific pathways being targeted.

S870

RITUXIMAB INDUCES A PRO-INFLAMMATORY MICROENVIRONMENT THAT INCREASES NOTCH1 SIGNALLING IN CHRONIC LYMPHOCYTIC LEUKAEMIA CELLS

J. Edelmann[1,*], K. Holzmann[2], J. G. Gribben[1]

[1]Centre for Haemato-Oncology, Barts Cancer Institute, London, United Kingdom, [2]Genomics Core Facility, Ulm University, Ulm, Germany

Background: The addition of the anti-CD20 monoclonal antibody (mAb) rituximab to chemotherapy improves responses in almost all chronic lymphocytic leukaemia (CLL) patients, with the exception of those having *NOTCH1* mutations. NOTCH1 is a cell surface receptor releasing its intracellular domain (NICD1) after two ligand-induced cleavage steps performed by metalloproteases and γ-secretase. NICD1 acts as transcription factor and *NOTCH1* mutations in CLL lead to longer lasting transcription factor activity.
Aims: To understand the relationship between rituximab and NOTCH1, we studied the effects rituximab treatment has on NOTCH1 signalling.
Methods: Freshly isolated peripheral blood mononuclear cells (PBMCs) from CLL patients attending St. Bartholomew's Hospital, London were enriched for CD19+ cells and treated with rituximab. Whole protein lysates were obtained after 15, 30 and 60 min of mAb treatment; RNA was isolated after 150 min. NICD1 was semi-quantitatively assessed by western blot. Expression of *HES1*, the best established NICD1 target gene, and *CCL2* was quantified by TaqMan-probe-based quantitative PCR. Rituximab

F(ab')2 fragments and trastuzumab were used as controls.
Results: Peripheral blood CLL cells showed low NOTCH1 signalling activity. Following *in vitro* treatment with rituximab, we observed NOTCH1 receptor activation with NICD1 release in a time-dependent manner. In line with this, *HES1* gene expression was up-regulated after rituximab treatment. The extent to which *HES1* expression was up-regulated varied in between individual samples. Samples had variable amounts of residual non-tumour PBMCs and the sample with the highest up-regulation of *HES1* expression had the highest amount of residual non-tumour cells. We therefore reasoned that activation of immune effector cells via the Fc-fragment of rituximab might be involved in activating NOTCH1. Since relative effector cell numbers were low (≤4%), physical contact between CLL cells and activated ligand-expressing effector cells was unlikely to serve as only explanation. Effector cells such as monocytes secrete matrix metalloproteases (MMPs) upon activation. Therefore, we hypothesised that secreted metalloproteases might contribute to cleavage of the NOTCH1 receptor. Particularly MMP9 and MMP8 were found in the supernatant of healthy donor PBMCs treated with rituximab. Using this supernatant, NOTCH1 activation could be evoked in SU-DHL4 cells, which did not show NOTCH1 activation when adding rituximab to their standard culture medium. Also, the supernatant of trastuzumab treated PBMCs led to NOTCH1 activation in SU-DHL4 cells, whereas using rituximab F(ab')2 fragments had no impact. MMP9 and MMP8 are mainly secreted by monocytes. In line with this, up-regulation of *HES1* expression after rituximab treatment correlated well with up-regulation of *CCL2* expression. CCL2 is mainly produced by monocytes and secreted upon their activation.
Summary/Conclusion: Our data shows that rituximab treatment increases NOTCH1 signalling. In B-cells, only cell surface bound ADAM10 and ADAM17 were so far associated with first cleavage of NOTCH1. Here we show that proteins secreted by activated immune effector cells contribute to activate NOTCH1. MMP8 and MMP9 are the most likely candidates and active recombinant proteins will be used to prove their involvement. Activation of NOTCH1 in a pro-inflammatory environment occurs independent of the NOTCH1 mutation status, but abnormally long activity of mutant NICD1 probably has a different/stronger impact on the CLL transcriptome than wild-type NICD1.

Stem cell transplantation – Clinical II

ADMINISTRATION OF BPX-501 CELLS FOLLOWING ALPHA/BETA T-CELL AND B-CELL-DEPLETED HLA HAPLOIDENTICAL HSCT (HAPLO-HSCT) IN CHILDREN WITH PRIMARY IMMUNODEFICIENCIES

D. Pagliara[1,*], A. Bertaina[1], M. Slatter[2], N. Kapoor[3], L. Krishnamurti[4], W. Qasim[5], S. Naik[6], V. Aquino[7], S. Baumeister[8], A. Woolfrey[9], P. Woodard[10], F. Locatelli[1]

[1]Department of Onco-Hematology and Cell and Gene Therapy, Ospedale Pediatrico Bambino Gesu, Rome, Italy, [2]Paediatric Immunology, Allergy, and Infectious Disease , Great North Children's Hospital, Newcastle upon Tyne, United Kingdom, [3]Hematology, Oncology, and Blood and Marrow Transplantation, Children's Hospital Los Angeles, Los Angeles, CA, [4]Blood and Marrow Transplant Program, Children's Healthcare of Atlanta, Atlanta, GA, United States, [5]Cell and Gene Therapy Program, Great Ormond Street Hospital, London, United Kingdom, [6]Bone Marrow Transplant/Stem Cell Transplant, Texas Children's Hospital, Houston, TX, [7]Pediatric Hematology and Oncology, University of Texas-Southwestern, Dallas, TX, [8]Hematology/Oncology, Boston Children's Hospital, Boston, MA, [9]Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, WA, [10]Clinical Development, Bellicum Pharmaceuticals, Inc., Houston, TX, United States

Background: Allogeneic Hematopoietic Stem Cell Transplantation (HSCT) is a well-established treatment for children with a wide range of primary immunodeficiencies (PIDs). HLA partially-matched (haplo) donors are a suitable alternative option for children who lack a matched donor.
Aims: To evaluate the safety and efficacy of BPX-501 T cells administered after a T-cell receptor αβ and B-cell depleted haplo-HSCT in pediatric patients with PIDs. The purpose of this clinical trial is to determine whether BPX-501 infusion can enhance immune reconstitution and reduce the risk of life-threatening infections.
Methods: Fifty-nine (59) patients (EU:42, US:17; 34 males, 25 females; median age 4.6 years) with PIDs were enrolled in a multicenter, prospective trial utilizing αβ-T-cell and B-cell-depleted haplo-HSCT, followed by infusion of donor lymphocytes genetically modified to include the inducible Casp9 suicide gene (iCasp9; BPX-501 T cells). The study included, SCID: 19 patients, WAS: 9 patients, CGD: 7 patients, HLH: 6 patients, CID: 4 patients, and other immune deficiencies: 14 patients. In the EU, the conditioning regimen was primarily-treosulfan-based (used in 47.5% of all patients), whereas in the US conditioning was most frequently busulfan-based (used in 39% of all patients). All patients received rabbit anti-thymocyte globulin (Grafalon/Neovii® or Thymoglobulin/Sanofi® in the EU and US, respectively) as graft rejection prophylaxis. Patients received 0.25-1 x 10^6 BPX-501 cells/kg. The median time to BPX-501 infusion was 15 days (11.00 - 56.00).
Results: The median time for neutrophil and platelet engraftment was 16 and 11 days, respectively. Six children (10.1%) experienced primary graft failure (3 HLH, 1 CID, 2 CGD). Five patients engrafted after a successful second transplant (4 haplo, 1 unrelated cord blood). Twenty patients developed Grade I-IV aGVHD (cumulative incidence [CI] 35.1% [95% confidence interval (CoI): 22.6-47.6]). Ten patients developed Grade II-IV aGVHD (CI 17.0% [95% CoI: 7.4-26.6]). Three patients developed Grade III-IV aGVHD (CI 5.5% [95% CoI: 0-11.6]). Two patients developed mild to severe cGVHD (CI of 5.1% [95% CoI: 0-12.2]). The dimerizing agent AP1903 activating iCasp9 was administered in 6 patients (2 CRs, 2 PRs, 1 NE, 1 NR). Three of the 59 patients experienced transplant-related mortality (TRM CI 5.9%; 95% CoI 0-12.4%). Disease-free survival (DFS) was 88.1% (95% CI, 79.9-96.3%) after a median follow-up of 487 days (32-1147 days). The probability of overall survival was 88.6%. CD3+ and CD3+CD4+ T cells above 500 cells/ml were achieved by 90 and 180 days, respectively. IgA and IgM levels achieved normal values by 270 and 180 days, respectively. CD3+CD19+ cell counts above 100 cells/ml were achieved by day 90.
Summary/Conclusion: These data suggest that αβ-T-cell and B-cell depleted haplo-HSCT followed by infusion of BPX-501 cells represents a novel and highly effective transplantation strategy for many different PIDs, leading to a success rate comparable to that of matched-donor HSCT.

GRAFT-VERSUS-LEUKEMIA EFFECTS IN SECONDARY ACUTE MYELOID LEUKEMIA: A RETROSPECTIVE STUDY FROM THE ACUTE LEUKEMIA WORKING PARTY OF THE EBMT

F. Baron[1,*], E. Beohou[2], M. Labopin[2], B. Savani[3], D. Niederwieser[4], A. Ganser[5], V. Potter[6], N. Kröger[7], D. Beelen[8], G. Socie[9], M. Itala-Remes[10], M. Bornhäuser[11], M. Mohty[12], A. Nagler[13]

[1]GIGA, ULiege, Liege, Belgium, [2]EBMT Paris Office, Paris, France, [3]Vanderbilt University Medical Center, Nashville, United States, [4]University Hospital Leipzig, Leipzig, [5]Hannover Medical School, Hannover, Germany, [6]GKT School of Medicine, London, United Kingdom, [7]University Hospital Eppendorf , Hamburg, [8]University Hospital Essen, Essen, Germany, [9]Hopital St. Louis, Paris, France, [10]HUCH Comprehensive Cancer Center, Helsinki, Finland, [11]Universitaetsklinikum Dresden, Dresden, Germany, [12]AP-HP, Hématologie Clinique et Thérapie Cellulaire, Hôpital Saint-Antoine, Paris, France, [13]The Chaim Sheba Medical Center, Tel-Hashomer, Israel

Background: The efficacy of allogeneic hematopoietic cell transplantation (HCT) in patients (pts) with acute myeloid leukemia (AML) depends both on chemo/radiotherapy given in the conditioning regimen and on immune-mediated graft-versus-leukemia (GVL) effects. Previous studies have observed an association between occurrence of acute (a) and chronic (c) graft-versus-host disease (GVHD) and a lower risk of AML relapse in pts with *de novo* AML (GvL effects).
Aims: It is well established that, in comparison to *de novo* AML, secondary AML (sAML) is less sensitive to chemotherapy. However, its susceptibility to GvL effects has not been studied in large cohorts of pts. This is the focus of the current study.
Methods: The study population included adult pts with sAML in first or second CR, bone marrow (BM) or peripheral blood stem cells (PBSC) as stem cell source, HLA-identical sibling or 10/ 10 (MUD) or 9/10 (MMUD) HLA-matched unrelated donor, no ex vivo T-cell depletion, and transplantation between 2005 and 2016. Previous studies might have overestimated the beneficial impact of GVHD on relapse prevention given the tight association between GVHD and non-relapse mortality (NRM) (since relapse and NRM are competing events). Thus, here we assessed the evolution of relapse rate over time according to GVHD condition by calculating the relapse rate per pt-year within sequential 90-day intervals, as previously reported (Baron *et al*., J Intern Med 2018, 283(2):178-18). The smoothed rates were plotted as curves for each GVHD condition. The impact of GVHD on relapse, NRM and overall survival (OS) was also assessed with classical multivariate Cox models modeling GVHD as time-dependent covariates.
Results: 3303 pts met the study inclusion criteria. Status at transplantation was CR1 in 2919 pts (88%) and CR2 in the remaining 384 ps. 1517 pts received grafts from MSD, 1427 from MUD and 359 from MMUD. 41% of the pts received a myeloablative conditioning (MAC), and 49% anti-thymocyte globulin (ATG). Stem cell source was PBSC in 90% of the patients. The proportion of patients with grade II and III-IV aGVHD was 15% and 10%, respectively. At 2 years, the cumulative incidence of cGVHD was 43% (18% extensive), the cumulative incidence of relapse 30% and OS 53%. Relapse rates declined gradually over time and were significantly lower in pts with cGVHD than in those without (p=0.009). In multivariate Cox models, grade III-IV aGVHD and cGVHD were each associated with a lower risk of relapse but not grade II aGVHD. Other factors associated with a lower risk of relapse included absence of poor-risk cytogenetic (p=0.008), MAC versus reduced-intensity (RIC) conditioning (p<0.001), and MUD (p=0.01). Interestingly, while there was a trend for better OS in pts with limited cGVHD (p=0.07), all other forms of GVHD were associated with lower OS. Other factors associated with increased mortality included high pt age (p<0.001), intermediate (p=0.01) and poor (p<0.001) risk cytogenetics, and MMUD (p=0.01).
Summary/Conclusion: Although this study showed that limited cGVHD was associated with lower risk of sAML relapse and a trend to a better OS, all other form of GVHD were associated with lower OS. In addition, while MUD recipients had a lower risk of relapse, they had higher NRM offsetting any potential OS benefit. Further studies should focus at optimizing the conditioning regimens and administering post-transplant maintenance therapies in an attempt to further reduce sAML relapse post HCT.

S873

KD025-208: A PHASE 2 OPEN-LABEL TRIAL OF KD025-208 FOR STEROID-DEPENDENT CHRONIC GRAFT-VERSUS-HOST DISEASE (CGVHD)

M. Jagasia[1,*], A. Lazaryan[2], A. Salhotra[3], B. Zoghi[4], J. Essell[5], C. Bachier[6], B. MacGillivray[7], O. Schueller[7], D. Eiznhamer[7], J. Ryan[7], S. Lee[8]

[1]Vanderbilt University, Nashville, TN, [2]University of Minnesota, MN, Minneapolis, [3]City of Hope, Duarte, CA, [4]Sarah Cannon Research Institute, San Antonio, TX, [5]Oncology/Hematology Care, Cincinnati, OH, [6]Sarah Cannon Research Institute, Nashville, TN, [7]Kadmon Corporation, LLC, New York, NY, [8]Fred Hutchinson Cancer Research Center , Seattle, WA, United States

Background: KD025 is a ROCK2-selective inhibitor in Phase 2 development for chronic graft-versus-host disease (cGVHD). By downregulating Th17 and Tfh cells while upregulating regulatory T cells and decreasing myofibroblast formation and proliferation, KD025 targets inflammatory and fibrotic components of cGVHD.
Aims: The aim is to evaluate the safety and activity of KD025 in subjects with steroid-dependent cGVHD.
Methods: KD025-208 is an open label, Phase 2 study in patients with steroid-dependent or refractory cGVHD. Three cohorts (200 mg QD, 200 mg BID, and 400 mg QD) of 16 patients each are planned, followed by an expansion cohort. The primary endpoint is the overall Complete and Partial Response rate, defined per the 2014 NIH Consensus criteria.
Results: Patients enrolled in Cohorts 1 (n=17) and 2 (n=16) had received a median of 3 and 2 prior lines of cGVHD therapy, respectively. The median corticosteroid dose (mg/kg/day) at baseline was 0.22 in Cohort 1 and 0.19 in Cohort 2. The most frequently involved organs in Cohorts 1 and 2, respectively, are eyes (82%, 69%), skin (76%, 75%), mouth (76%, 69%), joints (71%, 69%), and lung (24%, 38%). Forty-seven percent (47%) of patients in Cohort 1 and 69% in Cohort 2 had involvement of ≥ 4 organs. Sixteen patients (8 in each cohort) remain on treatment with KD025, with a median treatment duration of 37 and 28 weeks, respectively. As of a data cutoff date of January 3, 2018, the Overall Response Rate was 65% in Cohort 1 and 69% in Cohort 2. Responses were rapid, with 68% of responders achieving a response by the first assessment (at 8 weeks). Seven of 17 patients 41%) in Cohort 1 have sustained a response for ≥20 weeks. In responders with ≥4 organs involved, 75% and 33% in Cohorts 1 and 2, respectively, showed response in ≥4 organs. Responses were observed across all affected organ systems, including CRs in upper GI, lower GI, esophagus, mouth, skin, joints, eyes, and liver. The median corticosteroid dose reduced by 40% in Cohort 1 and 26% in Cohort 2 while on study. Four patients completely discontinued corticosteroid treatment while receiving KD025. Sixty-five percent (65%) and 38% of patients in Cohorts 1 and 2, respectively, achieved an improvement (≥7 point reduction) in the Lee cGVHD Symptom Scale Score. KD025 was well tolerated. Commonly reported AEs were AST/ALT elevations, anemia, nausea, diarrhea and URTI. Grade 3 or higher AEs were reported in 16 patients and SAEs in 9 patients. No apparent increase in incidence of infection was observed. Eleven of 33 patients discontinued treatment due to progression of cGVHD, 1 due to an adverse event, 2 due to recurrence of underlying malignancy, 2 due to voluntary withdrawal, and 1 due to investigator decision.
Summary/Conclusion: Treatment with KD025 has resulted in clinically meaningful and durable overall responses across all affected organ systems. Corticosteroid doses were reduced in both responders and non-responders. KD025 treatment was well tolerated with an AE profile consistent with that expected in cGVHD patients receiving corticosteroids. There was no apparent increased risk of infection observed with KD025. Enrollment targets in all three cohorts have been reached and treatment is ongoing. Updated follow-up data will be presented at the meeting.

S874

PREDICTION OF LEUKEMIA FREE SURVIVAL FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANTATION IN AML: A RISK SCORE DEVELOPED BY THE ALWP OF THE EBMT

R. Shouval[1,*], M. Labopin[2], D. Bomze[3], M. Houhou[2], D. Blaise[4], T. Zuckerman[5], G. Baerlocher[6], R. Foa[7], E. Forcade[8], A. Huynh[9], R. Saccardi[10], M. Martino[11], N. Schaap[12], D. Wu[13], M. Mohty[2], N.C. Gorin[2], A. Nagler[1]

[1]Sheba Medical Center, Tel-HaShomer, Ramat-Gan, Israel, [2]Department of Haematology, Saint Antoine Hospital, EBMT Paris study office / CEREST-TC, Paris, France, [3]Sackler School of Medicine, Tel-Aviv University, Tel-Aviv, Israel, [4]Institut Paoli Calmettes, Marseille, France, [5]Rambam Medical Center, Haifa, Israel, [6]University Hospital Bern, Bern, Switzerland, [7]Univ. La Sapienza, Rome, Italy, [8]CHU Bordeaux Hôpital Haut-Leveque, Pessac, [9] Institut Universitaire du Cancer Toulouse, Oncopole, I.U.C.T-O, Toulouse, France, [10]Azienda Ospedaliera Universitaria Careggi, Firenze, [11] Grande Ospedale Metropolitano Bianchi Melacrino Morelli, Reggio Calabria, Italy, [12]Radboud University Medical Centre, Nijmegen, Netherlands, [13]First Affiliated Hospital of Soochow University, Suzhou, China

Background: Autologous stem cell transplantation (ASCT) has been proposed as consolidation therapy for patients with acute myeloid leukemia

(AML). Concern regarding the risk of relapse has led to decreasing use of this procedure. However, ASCT has been shown to be a putative strategy for reducing relapse and is associated with reduced non-relapse mortality (NRM) and a better quality of life compared to allogeneic SCT.
Aims: Develop a prediction model for Leukemia Free Survival (LFS) in AML patients treated with an ASCT.
Methods: This was a retrospective study of adult AML patients in complete remission (CR), treated with ASCT as consolidation therapy between 2000 and 2015 in European Society for Blood and Marrow Transplantation (EBMT) centers. The primary outcome was LFS, defined as death or relapse following ASCT. To develop a nomogram for prediction of 3-year and 5-year, we first performed a univariate analysis, introducing statistically significant ($p<0.1$) variables into a Cox regression multivariable model. The final model was chosen according to the Akaike information criterion. The performance was assessed using time-dependent c-statistic.
Results: A total of 2,298 AML pts, with a median age of 49 (IQR: 38-58) were included. The majority of pts were in CR1 (90%) and had intermediate risk cytogenetics (75%), followed by good (18.5%), and poor (6.5%). Peripheral blood was the cell source in 93% of the cases. TBI was used as the backbone of conditioning in 86% of the pts. The final variables included in the multivariable model were age, cytogenetic risk group (Medical Research Council classification), cell source, year of transplantation, and disease status and time from diagnosis to transplantation as an interaction term. The nomogram is present in Figure 1A. The cumulative points a patient receives corresponds with 3-year and 5-year LFS probability, described in the bottom rows. Prognostic discrimination was performed by dividing the predicted survival probabilities into quartiles that were then used to plot Kaplan-Meier curves (Figure 1B). Patients in the highest and lowest quartiles had a 60.8% and 27.7% probability of 5-year LFS. The c-statistic of the model for 5-year LFS was 0.64.

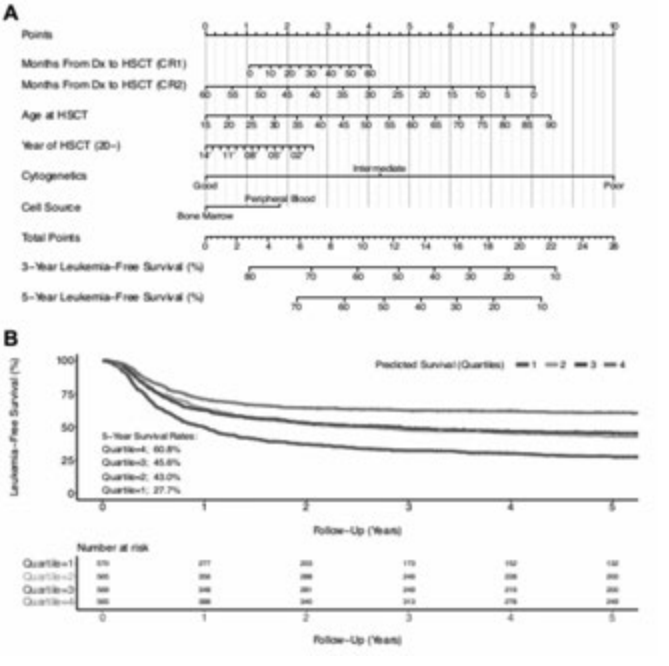

Figure 1.

Summary/Conclusion: We present the first predictive score for AML patients treated with ASCT. The score may help to better define patients who benefit from autologous transplantation as post-remission treatment.

Background: Allogeneic stem cell transplantation for peripheral T-cell lymphomas: a study of 284 patients from the Société Francophone de Greffe de Moelle et de Thérapie Cellulaire.
Aims: The aim of the current study was to analyse the outcomes (overall survival, relpase/progression, non relapse mortality) in a cohort of patients who underwent an allo-HSCT for peripheral T cell lymphoma.
Methods: Based on the SFGM-TC database and on clinical files, we performed a retrospective multicentric analysis of adult patients who underwent an allo-SCT for non cutaneous PTCL between 2006 and 2014 in 34 centers. Primary cutaneous T cell lymphomas were excluded.
Results: A total of 284 patients with PTCL (NOS-T cell lymphomas: 39%, angioimmunoblastic T lymphomas: 29%, anaplastic T cell lymphomas 15%, others: 17%) were allo-transplanted in a median time of 12.6 months after diagnosis (3-322). Median age at transplant was 50 years (15 to 60) and 67% were males. At the time of transplant, 62% were in complete remission (CR), 27% in partial response (PR) and 11% in progressive disease (PD). Twenty-eight percent were transplanted in front line treatment, 36% after 2 lines of treatment and 35% after 3 or more lines of treatment; 23% had relapsed after a first autologous HSCT. Karnofsky index was up to 80% in 94% of the patients. Donors were matched related in 45%, matched unrelated in 36% and alternative in 19% (haplo-identical n=7, cord blood n=33, mismatched 9/10 n=13) and SC source was peripheral blood in 71% of the patients. Reduced intensity regiment was given in 147 patients (52%), myeloablative in 106 (38%) and non myeloablative (NMA) in 27 (10%). Fifty percent of the patient received an ex-vivo T cell depletion (ATG) whereas only 1% had an *ex vivo* T -depletion. Fourteen patients (14%) developed grade III-IV acute GvHd, and 34% developed chronic GvHd (extensive for 13%). Median follow up was 33 months. One and 2 year -OS were 68% (95% 0.62-0.73) and 64% (95% 0.58-07). Cumulative incidence (CI) of relapse was 18% at 1 year and 22% at 2 years. The median time from transplant to relapse was 94 days and only 10% of the relapse occurred after the first year post transplant. Non relapse mortality (NRM) was 22% at 1 year and 24% at 2 years. The main causes of death were relapse (35%), infection (27%) or GvHD (22%). In multivariate analysis, 5 year OS was significantly adversely influenced by the occurrence of grade III-IV aGvhd (HR: 2.52 (1.52-4.19), *p<0.01)*, low karnofsky score at the time of transplant (HR 2.22 (1.32-3.71), p:0.002), cord blood transplant compared to bone marrow (HR 2.01 (1.00-4.01), p:0.049). The main factor associated with NRM were patient's age (HR:1.02, p:0.084[MTR3]) a low Karnofsky score (HR 2.03 (1.08-3.83) p:0.029), female donor to male recipient (HR:1.87 (1.07-3.28), p: 0.027). The conditioning regimen intensity (RIC or MAC) was not found to have impact on OS. Among thirty patients transplanted in PD, 50% reached CR after allo-HSCT and 2 year-OS was 51% in this subgroup (Figure 1).

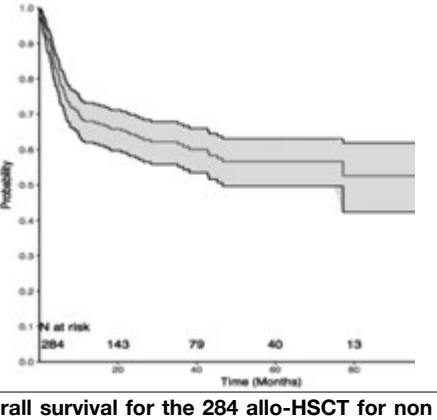

Figure 1. Overall survival for the 284 allo-HSCT for non cutaneous T-cell Lymphoma.

Summary/Conclusion: This is to our knowledge the largest cohort of allo-HSCT patients for T cell lymphoma, showing encouraging results in both MAC and RIC.

Myelodysplastic syndromes – Biology

INTRINSIC DEFECTS CAUSED BY COMBINED CSNK1A1/RPS14 AND MIRNA145/146A DEFICIENCY DIRECTLY ALTER THE MICROENVIRONMENT IN A NOVEL MOUSE MODEL FOR DEL(5Q) MDS

F. Ribezzo[1,*], I. Snoeren [2], J. Stoelben [1], S. Ziegler[1], P. Olofsen[2], G. Buesche[3], U. Platzbecker[4], M. Raaijmakers[2], B.L. Ebert[5], R.K. Schneider[2]

[1]Department of Hematology, Oncology, Hemostaseology, and Stem Cell Transplantation, RWTH Aachen University , Aachen, Germany, [2]Department of Hematology, Erasmus MC Cancer Institute , Rotterdam, Netherlands, [3]Institute of Pathology, Hannover Medical School, Hannover, [4]Department of Hematology, University Hospital Carl Gustav Carus Technical University Dresden, Dresden, Germany, [5]Division of Hematology, Brigham and Women's Hospital, Department of Medicine, Harvard Medical School, Boston, United States

Background: Hemizygous, interstitial deletion of chromosome 5q is the most common cytogenetic abnormality in myelodysplastic syndrome (MDS) and has been the focus of functional analysis. Some patients with this molecular lesion have the 5q– syndrome, a disorder with a highly consistent clinical phenotype, characterized by a distinct clinical phenotype including severe macrocytic anemia, a high or elevated platelet count with hypolobulated megakaryocytes in the bone marrow and a low rate of progression to acute myelogenous leukemia. The full clinical phenotype is likely caused by the integration of effects from allelic insufficiency for multiple genes. *RPS14*, *CSNK1A1* and *mir-145* are universally co-deleted in 5q-syndrome but mouse models of each gene deficiency recapitulate only a subset of the composite clinical features of del(5q) MDS.
Aims: We aimed to dissect the combinatorial effect of haploinsufficiency for *Rps14*, *Csnk1a1* and *miRNA-145* on the hematopoietic stem cell function in a novel murine model for del (5q) MDS We hypothesized that compound loss of *Rps14*, *Csnk1a1* and *miRNA145/146a* has additive effects leading to recapitulation of the del(5q) MDS phenotype and an aggravated inflammatory response resulting in a more severe erythroid phenotype.
Methods: For *in vivo* studies, hematopoietic stem and progenitor cells (HSPCs) from compound haploinsufficient *Rps14*, *Csnk1a1* mice were retrovirally transduced and miR-145/146a were stably knocked down, followed by transplantation of the cells into lethally irradiated recipient mice. In order to further dissect the mechanisms, we generated granulocyte-macrophage colony-stimulating factor (GM-CSF) estrogen-receptor (ER)-Hoxb8 cells and Fms-related tyrosine kinase 3 ligand (FL) ER-Hoxb8 cells from the del (5q) murine models.
Results: We demonstrate that compound deficiency has high fidelity to human MDS and recapitulates the del(5q) MDS phenotype including 1) anemia, 2) thrombocytosis, 3) hypolobulated megakaryocytes and 4) clonal dominance. Macrophages, regulatory cells of erythropoiesis and the innate immune response, were significantly increased in *Rps14/Csnk1a1/miR-145/146a* deficient mice as well as in del(5q) MDS patient bone marrows and showed activation of the innate immune response, reflected by increased expression of S100A8, and decreased phagocytic function.
The bone marrow microenvironment is abnormal in MDS, but whether this is a direct consequence of changes in hematopoietic cells or instead independent of the disease has not been determined. Using 1) our new mouse model, 2) co-culture models with a defined mesenchymal stromal cell population, 3) immunohistochemistry and RNA-sequencing in del(5q) MDS patient samples, we demonstrate that increased expression of S100A8 in MDS-derived macrophages induces S100A8 expression in neighboring mesenchymal stromal cells. We show that S100A8-expression in stromal cells leads to loss-of their hematopoiesis-supporting capacity.
Summary/Conclusion: In conclusion, our data support the hypothesis that the combined haploinsufficiency of multiple genes on 5q has additive effects in the del(5q) phenotype and in the activation of the innate immune system. Our data indicate that intrinsic defects of the del(5q) MDS hematopoietic stem cell directly alter the surrounding microenvironment, which in turn negatively affects hematopoiesis as an extrinsic mechanism.

EZH2 AND RUNX1 MUTATIONS COLLABORATE TO INITIATE DISTINCT HEMATOLOGICAL MALIGNANCIES DEPENDING ON THE TARGET CELL

Adam Mead and Sten Eirik Jacobsen contributed equally to this work.

Background: How the identity of the cells targeted by oncogenic lesions impacts on the clinical picture of the resulting cancer has not been established. In myelodysplastic syndrome (MDS), all mutations in a malignant clone can be tracked back to the hematopoietic stem cells (HSCs) (Woll et al., Cancer Cell 2014). This suggests that MDS originates within and is propagated by the malignant counterparts of normal HSCs. However, the human phenotypically-defined HSC compartment also contains substantial numbers of non-HSCs, and it remains to be established to what extent also non-HSCs may be targeted and transformed by MDS-associated mutations. As well as in MDS (Papaemmanuil et al., Blood 2013), co-occurrence of inactivating mutations in EZH2 and RUNX1 is frequently observed in early thymic progenitor (ETP) leukemia, a clinically and molecularly distinct subtype of T cell acute lymphoblastic leukemia (Zhang et al., Nature 2012).
Aims: To determine the distinct impacts of inactivation of Ezh2 and Runx1 in different hematopoietic stem and progenitor populations in mice.
Methods: We used Mx1Cre, Flt3Cre and Rag1Cre to target conditional inactivation of Ezh2 and Runx1 to HSCs, multipotent progenitors (MPPs) or early lymphoid progenitors respectively.
Results: In agreement with previous studies using inactivation of Ezh2 combined with expression of a dominant-negative Runx1 mutant (Sashida *et al.*, Nat Commun 2014), we found that targeting of Ezh2 and Runx1 inactivation to HSCs using Mx1Cre induced an MDS phenotype. Competitive transplantation experiments demonstrated a clonal advantage of mutant cells over wild-type cells, combined with an extrinsic suppression of wild-type HSCs in recipient bone marrow.
Surprisingly, targeting of the same mutations to MPPs using Flt3Cre resulted in development of the same MDS phenotype with a similar latency to that induced by Mx1Cre. Absolute numbers of $Lin^-Kit^+Sca1^+CD48^-CD150^+$ HSCs were reduced in these mice, while $Lin^-Kit^+Sca1^+CD48^+CD150^-$ MPPs were expanded compared to wild-type controls, suggesting that MPPs rather than HSCs could represent the MDS-propagating malignant stem cells in this model. We confirmed this using transplantation of purified E13.5 fetal liver MPPs. Unlike wild-type MPPs, MPPs from Flt3Cre-induced Ezh2 and Runx1-inactivated embryos were able to engraft and reconstitute long-term hematopoiesis and an MDS phenotype in recipient mice, while transplanted MPPs from Flt3Cre-negative littermate controls showed no engraftment.
In striking contrast, when Ezh2 and Runx1 inactivation was targeted to early lymphoid progenitors using Rag1Cre, we did not observe development of an MDS phenotype. Rather, absolute numbers of ETPs within the thymuses of these mice were markedly expanded compared to wild-type controls. This expanded ETP population showed transcriptional signatures characteristic of human ETP leukemia. Addition of Flt3-ITD, a constitutively activating RAS signalling mutation recurrently found in ETP leukemia, induced an acute T cell/myeloid leukemia which could be propagated by the expanded ETP population.
Summary/Conclusion: Our findings reveal that targeting the same clinically relevant mutations to different hematopoietic stem and progenitor populations can induce distinct and clinically relevant malignant phenotypes. This provides experimental evidence that the identity of the target cell of specific oncogenic lesions might be a crucial factor for the phenotype, prognosis and therapeutic response of the resulting malignancy.

Background: Myelodysplastic syndromes (MDS) are hematological disorders at high risk of progression to acute myeloid leukemia (sAML). Previous high-throughput sequencing studies have provided insight into the mutational dynamics and clonal evolution underlying disease progression. However, large longitudinal sequencing genomic studies are still required to define which mutations or combinations of them are important in disease progression.
Aims: To study the mutational profiles and mutational dynamics underlying progression from MDS to sAML.
Methods: A total of 846 samples of myeloid malignancies, divided in 3 cohorts, were examined: 1) a **discovery cohort** consisting of 94 serially collected samples from 47 MDS/CMML patients evolving to sAML that were studied two different time-points: at the time of diagnosis (disease presentation) and at sAML progression (disease evolution); 2) a control cohort consisting of 10 samples from 5 MDS/CMML patients who did not progress to sAML (median follow-up of 3 years); and 3) a validation cohort comprising 742 myeloid malignancies samples. Sequencing studies were performed by a combination of whole-exome sequencing (WES) and targeted-deep sequencing (TDS). WES was carried out, as first screening, on 40 diagnosis/progression-matched samples of the discovery cohort, and driver mutations were identified, after variant calling by a standardized bioinformatics pipeline, by using the novel tool "Cancer Genome Interpreter". Secondly, TDS was performed on these 40 samples of the initial discovery cohort, in order to validate WES results, and in additional 806 samples from all of the cohort (including 66 extra serial samples), using a custom MDS/AML-related capture enrichment panel (Illumina ®) of 117 genes.
Results: As a first result, all patients, progressing (discovery cohort) and not progressing (control cohort), presented similar number of mutations at diagnosis (p=0.15). However, patients who evolved to sAML displayed a statistically significant increase of mutations after progression (p=0.001) while control cohort did not during follow-up time (p=0.88). Thus, this greater number of mutations at second sampling may be indicative of a higher genomic instability during disease evolution. Then, to study the mutational dynamics during disease progression (discovery cohort), we compared the variant allele frequencies (VAFs) of mutations detected at both time-points in each patient. We identified 4 different clonal dynamics: mutations that were initially present but increased (type-1) such as *STAG2* mutations; decreased (type-2); were newly acquired (type-3) such as *NRAS/KRAS* and *FLT3* mutations; or persisted with similar allelic burden (type-4) at sAML stage, namely *SRSF2*, *TET2* and *DNMT3A* mutations. Interestingly, 13% of patients (6/47) included in this cohort showed co-occurrence of type-1 *STAG2* and type-3 Ras signaling mutations indicating this mutational combination could play an important role during disease progression. To confirm this hypothesis, we searched this combination in all patients of the validation cohort and we found that was present in 8 patients, and 7 of them were MDS patients who finally progressed to sAML.
Summary/Conclusion: Progression from MDS to sAML could be explained by different mutational processes, as well as by the occurrence of unique and complex changes in the clonal architecture of the disease during the evolution. Co-occurrence of *STAG2* and Ras signaling mutations could play an important role during disease progression.

COMPARED ANALYSIS OF MUTATIONAL LANDSCAPE IN PEDIATRIC AND ADULT PATIENT WITH MYELODYSPLASTIC SYNDROMES

W. An[1,*], B. Li[2], C. Liu[1], Y. Wan[1], Z. Xiao[2], X. Zhu[1]

[1]Pediatric blood diseases center, [2]MDS/MPN center, Institute of Hematology and Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: Myelodysplastic syndromes (MDS) are uncommon in children. There are limited known on the gene mutations landscape in pediatric patients with MDS and the differences between pediatric and adult patients.
Aims: We aimed to elucidate the mutational landscape in pediatric MDS and compared with adult cases.
Methods: We performed both whole exome sequencing and targeted sequencing on 30 pediatric MDS patients and targeted sequencing on 57 pediatric cases and 510 adult patients. The diagnosis was according to the 2016 revised criteria of the WHO for childhood MDS. To be comparable with adult and on the basis of difficulty of precisely diagnosing of low-risk RCC, only pediatric patients who also meet the diagnostic criteria for adult MDS were included. DNA was obtained from bone marrow. Germline status was analyzed by CD3+ T-cell or oral epithelial cells.

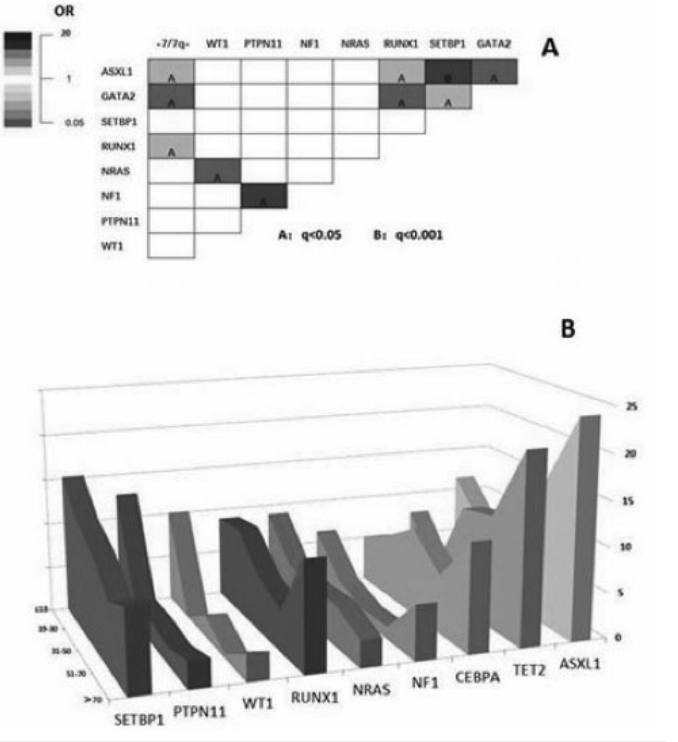

Figure 1.

Results: We found 208 mutations in 54 distinct genes with variant allelic frequency (VAF) from 2% to 100%. 83% patients had at least 1 gene mutation. 11 genes were mutated in more than 5% of patients, including *SETBP1* 15%, *PTPN11* 13%, *ASXL1* 10%, *WT1* 9%, *RUNX1* 8%, *NRAS* 8%, *TET2* 7%, *NF1* 7%, *CEBPA* 5%, *GATA1* 5%, *FLT3* 5%. Germline mutation of *GATA2* and *SAMD9/SAMD9L* were detected in 9% and 5% of the patients. Mutation of *DNMT3A*, *TP53*, *SF3B1*, *SRSF2* were rare (1%, 2%, 0%, 2%,). The most frequent pathways were the epigenetic modification (37%) and the RAS pathway (30%). In univariate analysis, somatic mutated *SETBP1*, *ASXL1*, *RUNX1* and deletion of chromosome 7 were significantly enriched in germline *GATA2* mutated subjects (p<0.05). And *NRAS* and *NF1* were significantly associated with *WT1* and *PTPN11* mutated subjects, respectively (Figure 1A). The multivariate analysis showed *ASXL1* was significantly enriched in *GATA2* mutated subjects, and *NRAS* and *NF1* were significantly associated with *WT1* and *PTPN11* subjects, respectively (p<0.05). According to the above results, the cohort could be divided into three subgroups, namely *GATA2/ASXL1/SETBP1/RUNX1* group, the *WT1/NRAS* group and the *PTPN11/NF1* group. Using copy number-adjusted VAF, we reconstructed the clonal architecture to explore ancestral and subclonal mutations. *ASXL1*, *NRAS*, and *PTPN11* were more likely to be an ancestral mutation. The 5-year overall survival (OS) was 57%. For patients with and without HSCT, the 5-year OS was 92% and 40% (p<0.001). Patients with deletion of chromosome 7, mutation of *PTPN11* and *SETBP1* tend to have worse OS. However, for patients accepted HSCT, there was no significant association between the genetic mutation and OS. In adult patients from our institution, the most common mutated genes were spliceosome and epigenetic associated genes. Pediatric patients had higher VAF than adult patients in *SETBP1*, *PTPN11*, *RUNX1*, *TET2*, *CEBPA* (the average VAF was 37.4% v.s. 20.2%; 38.3% v.s.18.6%; 38.3% v.s.18.6%; 44.0% v.s. 22.9%; 43.7% v.s. 17.0%; 36.2% v.s. 16.2%, p<0.001).We also found that *SETBP1*, *PTPN11*, *WT1*, *FLT3* more frequently occurred in pediatric and young adult patients, while, *TET2* and *ASXL1* were more likely existing in patients more than 70 years old (Figure 1B).
Summary/Conclusion: In this study, we found that mutations frequent encountered in adult MDS and in age-related clonal hematopoiesis were

rare in children. We also verified that germline mutations like *GATA2* and *SAMD9/SAMD9L* are common in pediatric patients. Somatic mutations in *SETBP1*, *ASXL1*, *RUNX1*, *WT1* and the RAS oncogenes define the genomic landscape of the pediatric MDS. Collectively, our results help define the mutational landscape in MDS in children.

Background: Although patients with chronic myelomonocytic leukemia (CMML) have surprisingly diverse genomic alterations, these events tend to occur in a limited number of pathways. The prognostic impact of pathway activation in CMML is poorly investigated. Recently we were able to show that the spontaneous *in vitro* growth of myeloid colonies (CFU-GM) may be a useful functional parameter of RAS pathway activation (Geissler K et al, Leukemia 2016).
Aims: To investigate the prognostic impact of RAS pathway activation in patients with CMML.
Methods: In this study we analyzed CMML patient samples which were collected in the "Austrian Biodatabase for CMML" (ABCMML) with regard to the presence of molecular aberrations in RASopathy genes by targeted next generation sequencing (NGS) and the presence of high spontaneous myeloid colony formation using semisolid *in vitro* cultures as described previously (Geissler K et al, J Exp Med 1996). From 225 CMML patients 288 samples (BMMNC or PBMNC) were analyzed by NGS and 207 samples (PBMNC) were used for *in vitro* cultures. Mutations with a VAF ≥5% were considered as positive in this study and autonomous CFU-GM formation ≥100/10^5 PBMNC was considered as high colony growth. Survival analysis was calculated from the sampling date. Molecular and functional data were correlated with patient survival using Cox regression analysis.
Results: Figure 1a shows the Kaplan-Meier plots, hazard ratios and p-values of the prognostic impact of RASopathy gene mutations including NRAS (23.3%), KRAS (11.6%), CBL (16.5%), NF1 (10.2%), and PTPN11 (8.0%), respectively. If the presence of a mutation in at least one of the RASopathy genes was used as a composite molecular parameter (55.5%) the prognostic impact was most significant with a p value = 0.00006. The prognostic impact of RAS pathway activation could be also demonstrated at a functional level. As shown in Figure 1b high autonomous colony formation (CFU-GM ≥100/10^5 PBMNC; 27.0%) was significantly associated with inferior survival (p <0.00001).
Summary/Conclusion: Our data show that RAS pathway hyperactivation, which was demonstrated at the molecular and at the functional level, is associated with inferior survival in patients with CMML. These data may be important for better understanding the pathogenesis of CMML, for improving risk stratification of individual patients and for the design of targeted treatment concepts.

Myeloproliferative neoplasms – Biology

S881

A NOVEL INHIBITORY MUTATION FOR JAK2 V617F TARGETING THE AROMATIC INTERACTION AROUND F617 RESTORES NORMAL FUNCTION FOR MOST OF JAK2-UTILIZING CYTOKINE RECEPTORS EXCEPT IFNGR

E. Leroy[1,2,*], A. Dusa[1,2], C. Pecquet[1,2], D. Colau[1,2], S.N. Constantinescu[1,2]

[1]Ludwig Cancer Research, [2]Université catholique de Louvain, Brussels, Belgium

Background: Dysfunction of JAK2 signaling is associated with hematopoietic malignancies. The JAK2 V617F mutation, which constitutively activates JAK2, is found in over 95% of Polycythemia Vera patients. JAK2 has a pivotal physiologic role in triggering several signaling pathways by binding to several cytokine receptors; therefore specific targeting of the mutant protein is absolutely required. Currently, no drug can discriminate between the mutant and the normal protein in myeloproliferative neoplasms. We have previously shown that an aromatic interaction between F617 and F594/F595 of pseudokinase domain helix C is required for constitutive signaling of JAK2 V617F, which constitutes the first molecular step in triggering hyperactivation in JAK2.
Aims: We aimed to find novel inhibitory strategies that directly destabilize the initial molecular step in V617F-mediated activation, namely the aromatic stacking between F617 and F594/F595 that only exist in the mutant conformation. We also aim to assess these approaches on the homologous JAK1 V658F, associated with ALL, and in the context of distinct cytokine receptors.
Methods: Via structure-guided mutagenesis, we assessed the role of key residues around the F617 aromatic interaction and used a combination of transcriptional activity luciferase-based assays, biochemical assays and cellular growth to measure the activity of JAKs in reconstituted JAK2 and JAK1 deficient cells.
Results: We created several aromatic mutations (S591F, A597F, A598F, S599F, V615F) strategically localizing around this aromatic interaction. We show that the specific mutation A598F preferentially inhibits JAK2 V617F over JAK2 WT, and without altering the normal function of the protein. Of importance, the inhibitory mutation A598F suppressed the hyperactivity of JAK2 V617F and other disease-associated JAK2 mutants such as JAK2 T875N and R683G, but not the JAK2 exon 12 mutant K539L. We found that the mutation A598F and the homologous A639F can inhibit basal JAK2 V617F and JAK1 V658F, respectively, in the context of distinct cytokine receptors, such as IL2-R, IL9-R, IFNGR and type I IFN receptor (IFNAR). Surprisingly, we found that the A598F mutation, as well as several other inhibitory mutations for JAK2 V617F, when in the background of the wild-type protein, drastically altered the cytokine responsiveness of the IFNGR, while it preserved normal cytokine response for EpoR, IL2-R, IL9R and IFNAR. This was even more compelling for JAK1 signaling with IFNGR; when these homologous inhibitory mutations were present in JAK1, they completely blocked the IFNγ signal transduction. Thus, it appears that the region of the JH2 helix C, which is required for JAK2 V617F and JAK1 V658F hyperactivation mechanism, is also crucial in specifically relaying the activation by cytokine in the heterodimeric IFNGR complex. Finally, we also show an unexpectedly low effect of JAK2 V617F on IFNGR complex compared to other cytokine receptors that physiologically utilize JAK2 (Figure 1).

Left, the pseudokinase domain (JH2) αC of JAK2 V617F is shown (PDB: 4FVR) with the three phenylalanine residues (pink) involved in the aromatic interaction. Right, modeling of substitution A598F (yellow) on the αC of JH2-V617F and the putative break of the aromatic interaction between F617-F595-F594.

Figure 1.

Summary/Conclusion: We identified a novel strategy to specifically inhibit JAK2 V617F and homologous JAK1 mutants, and we described an unexpected requirement for pseudokinase domain helix C specifically in the function of IFNGR. Inhibitory mutations localizing in the vicinity of JH2 helix aromatic interaction of JAK2 V617F restore normal function for most of JAK2-utilizing cytokine receptors except for the IFNGR.

S882

DELETION OF STAT2 INCREASES THROMBOCYTOSIS AND SURVIVAL IN A JAK2 V617F MOUSE MODEL OF MPN VIA A NON CELL-AUTONOMOUS MECHANISM

G. Vertenoeil[1,*], C. Pecquet[1], Y. Rahmani[1], J.-L. Villeval[2], W. Vainchenker[2], S.N. Constantinescu[1]

[1]Signal Transduction Unit, Ludwig Institute for Cancer Research Ltd Brussels Branch, Brussels, Belgium, [2]Hématopoïèse normale et pathologique (UMR 1170), Institut de cancérologie Gustave Roussy, Villejuif, France

Background: Myeloproliferative neoplasms are clonal hematopoietic disorders characterized by increased production of terminally differentiated myeloid cells. These diseases that encompass Polycythemia Vera (PV), Primary Myelofibrosis (PMF) and Essential Thrombocythemia (ET) are associated with drivers mutations inducing constitutive activation of JAK2/STAT signaling pathway.
The most prevalent driver mutation is the *JAK2*V617F mutation. During the last years, murine models of *JAK2*V617F-induced disease were developed and recapitulate the disease. These models have increased the understanding of the pathogenesis and have provided tools for preclinical testing of new therapies. Among those, interferon (IFN) alpha treatment is widely used in patients and induces significant hematologic and molecular responses. In mouse models, it was shown to target the mutated clone but the mechanism remains unknown.
Aims: STAT2 activation and formation of ISGF3 complex is the hallmark of IFN alpha signaling pathway, while STAT1 homodimer formation is shared by the signaling of many other cytokines and STATs. Thus, we wanted to assess the role of STAT2 in MPN phenotype induced by *JAK2* V617F knock-in and to evaluate the role of STAT2 in normal hematopoiesis.
Methods: We crossed our previously described *JAK2*V617F knock-in mice (based on cre-loxP system, with the use of the vav promoter) with STAT2 knock out mice to obtain $STAT2^{-/-}JAK2^{V617F}$ mice.
Results: The heterozygous KI JAK2V617F homozygous KO STAT2 mice exhibit a stronger myeloproliferative phenotype- regarding the blood counts, especially on the megakaryocyte lineage. However, mice exhibited a better survival compared to KI JAK2V617F mice, which was surprising, given the very high platelet and granulocyte levels. Myelofibrosis was apparently reduced in mice that do not express STAT2. The study of megakaryopoeisis in $STAT2^{-/-}JAK2^{V617F}$ mice compared to the $STAT2^{+/+}JAK2^{V617F}$ mice showed no significant increases in CFU-Mk and CD41+CD42+ cell numbers, suggesting that STAT2 deficiency targets the latter stages of megakaryopoeisis. To test whether this late effect on MK differentiation was due to an intrinsic or extrinsic effect, we performed bone marrow reconstitution assays. These experiments showed no differences in blood counts between mice reconstituted with $STAT2^{+/+}$ $JAK2^{V617F}$ and those reconstituted with $STAT2^{KO/KO}$ $JAK2^{V617F}$. Thus, the observed impact of STAT2 KO is due to the absence of STAT2 in non-hematopoietic cells. Survival also did not differ between the two types of reconstituted mice and was improved compared to the KI *JAK2*V617F mice resulting after the vav-cre crossing. The latter result suggests that mortality related to *JAK2*V617F in our knock-in model is probably related to its expression in endothelial cells (cre expression being under the control of vav promoter).
We will further use these murine models to assess the impact of STAT2 in interferon alpha response via competitive bone marrow reconstitution.
Summary/Conclusion: We report that in the vav-dependent *JAK2*V617F knock-in mouse model, the knock-out of STAT2 protects against myelofibrosis, increases survival, while leading to an increased thrombocytosis. These effects were extrinsic to the hematopoietic system. This raises the possibility that administration of type I IFN, in IFN-resistant patients, may enhance myelofibrosis by activation of STAT2 in non-hematopoietic cells and points to a potential extrinsic pro-inflammatory role of STAT2.

S883

A HISTIDINE PATCH IN THE N-DOMAIN OF MUTANT CALRETICULIN IS REQUIRED FOR MPN PATHOGENESIS

J. Rivera[1,*], A. Baral[1], R. Smyth[1], R. Mehta[1], E. Chen[1]

[1]Faculty of Biological Sciences, University of Leeds, Leeds, United Kingdom

Background: Recurrent somatic mutations in exon 9 of the calreticulin (CALR) gene are found in a majority of JAK2-unmutated myeloproliferative neoplasms (MPNs). All known mutations result in a +1-frameshift in the CALR reading frame that creates a novel C-terminal domain encoded by an alternative reading frame. We and others have previously demonstrated that mutant CALR binds to and activates the thrombopoietin receptor MPL and

confers cytokine-independent growth. Moreover, we showed that these oncogenic activities of mutant CALR are dependent on a threshold of basic amino acid residues in the mutant C-terminus. However, relatively less is known regarding the role of the N-domain of mutant CALR in oncogenic transformation.
Aims: We aim to identify key features of the N-domain of mutant CALR which are required for its oncogenic activity.
Methods: Mutations in the FLAG-tagged human CALR cDNA harbouring a "type I" del52 mutation ($CALR^{MUT}$) were introduced by site-directed mutagenesis. Transforming activity of $CALR^{MUT}$ variants was assessed based on their ability to confer cytokine-independence to Ba/F3 cell line expressing human MPL (Ba/F3-MPL). Interaction between $CALR^{MUT}$ variants and MPL was assessed by FLAG-pulldown experiments.
Results: We previously demonstrated that the lectin binding motif of $CALR^{MUT}$ was essential for oncogenic activity. The crystal structure of the CALR globular domain reveals that the carbohydrate binding pocket is proximal to a patch of histidine (His) residues which are required to coordinate Zn^{2+} and mediate regional domain structure of wild-type CALR. Here, we undertook a systematic mutagenesis screen to test the role of 3 His residues (His^{82}, His^{128} and His^{153}) and their effects on Zn^{2+} homeostasis in $CALR^{MUT}$ oncogenic activity. We observed that $CALR^{MUT}$ harbouring of any single His residue retained the ability to confer cytokine-independence, bind to MPL and activate Stat3/5. In contrast, $CALR^{MUT}$ harbouring loss of His^{82} in combination with either His^{128} or His^{153} (but not His^{25} which resides on the opposite face of the CALR N-domain) were compromised in their capacity to confer cytokine independence and bind MPL, suggesting that His^{82} needs to cooperate with other nearby Zn^{2+}-coordinating His residues on the carbohydrate binding face of $CALR^{MUT}$to facilitate oncogenic activity. The stability of all $CALR^{MUT}$ His variants exhibited comparable stability and folding *in vitro*, suggesting these changes in $CALR^{MUT}$ activity likely reflect a disruption of a critical domain within CALR rather than affecting protein stability. Finally, given the role of the His residues in wild-type CALR in regulating Zn^{2+} binding, we tested that $CALR^{MUT}$ activity may be affected by intracellular Zn^{2+} levels. We used CRISPRi to repress expression of metallothionein 1a (MT1a) which is required for Zn^{2+} uptake, and observed that MT1a depletion rendered CALR mutant cells more sensitive to the JAK inhibitor ruxolitinib. These data suggest that Zn^{2+} homeostasis is able to regulate MPN pathogenesis.
Summary/Conclusion: We show that Zn^{2+} binding by histidine residues are essential for $CALR^{MUT}$ to bind to MPL and engender transformation, and that disrupting intracellular Zn^{2+} levels has the potential to sensitise $CALR^{MUT}$-expressing cells to existing MPN therapies such as ruxolitinib.

CALRETICULIN DEL52 KNOCK-IN MICE DEVELOP A DOSE-DEPENDENT THROMBOCYTOSIS AND PROGRESSION TO MYELOFIBROSIS

C. Marty[1,*], C. Benlabiod[1], L. Touchard[2], B. Panneau-Schmaltz[1], L. Lamrani[1], P. Gonin[2], J.-L. Villeval[1], H. Raslova[1], S. Constantinescu[3], P. Isabelle[1], W. Vainchenker[1]

[1]Inserm UMR1170, [2]Unité Mixte de Service 3655/US23, Gustave Roussy, Villejuif, France, [3]Ludwig Institute, de Duve Institute, Université catholique de Louvain, Brussels, Belgium

Background: The acquisition of somatic mutations in the hematopoietic stem cell (HSC) compartment leading to the constitutive activation of the JAK-STAT signaling pathway drives the development of myeloproliferative neoplasms (MPNs). Besides *JAK2*V617F, recurrent genetic abnormalities in the exon 9 of *calreticulin* (*CALR*) gene are the second most frequent driver mutations found in essential thrombocythemia (ET) and primary myelofibrosis (PMF). All CALR mutants induce a +1-bp frameshift of the same alternative reading frame and generate a common novel C-terminus tail. Retroviral models have shown that these mutants are driver of a MPN phenotype in mice dependent on the thrombopoietin receptor.
Aims: We investigated the consequences of physiological expression of one of the most frequent *CALR* mutations, the 52-bp deletion (*del52*) or type 1, in the pathophysiology of MPNs.
Methods: We generated a knock-in (KI) mouse model. As the analogous 52-bp deletion found in human patients would generate a mutated C-terminus tail with a different amino acid sequence in mice, our approach was to introduce fused mouse exons 8 and 9 framed with loxP sites and to humanized the C-terminal mutant tail in mouse exon 9. Floxed KI mice were crossed with tamoxifen-inducible Scl-$CreER^T$ (and Vav-Cre) mice to generate murine calr with the human mutated C-terminus sequence. Blood parameters and the different bone marrow and spleen hematopoietic compartments were analyzed over one year.
Results: Both heterozygous and homozygous KI *del52* mice were produced and developed a *del52* dose-dependent increase in both platelet and white blood cell counts. In contrast to heterozygous mice, ET-like phenotype in the homozygous *del52* mice progressed towards mild myelofibrosis in bone marrow (BM) but not in spleen after one year of induction. Myelofibrosis was accompanied with a decrease BM cellularity and splenomegaly. Both BM and spleen from heterozygous and homozygous mice presented megakaryocytic (MK) hyperplasia revealed using von willebrand factor staining and flow cytometry. *In vivo*, MKs achieved significantly higher ploidy in KI mice than in WT littermates (modal ploidy of 32N compared to 16N in WT). In BM, MK frequency increased mostly at the expense of erythroid ($CD71^+$Ter-119^+) cells. In spleen, increased MK frequency was associated with an increased frequency of erythroid cells resulting in a decreased frequency of B ($B220^+$) and T ($CD3^+$) cells. We observed a *del52* dose-dependent increase in the frequency of immature progenitors (SLAM cells) and MK progenitors (MkP) both in BM and spleen as well as a thrombopoietin-independent growth of the MK progenitors (CFU-MKs) in BM. Finally, using competitive BM transplantation with different ratios of homozygous *del52* KI cells and WT GFP^+ cells we found that the homozygous *del52* BM cells were able to outcompete WT BM cells and induce thrombocytosis from an initial 25% competitive engraftment.
Summary/Conclusion: Altogether, these results demonstrate that CALR del52 is sufficient to dose-dependently induce a thrombocytosis progressing to myelofibrosis in KI mice, thus mimicking the natural history of MPN patients. It will offer a good *in vivo* model to investigate therapeutic approaches for *CALR*-positive MPNs or cooperation with others mutated molecules.

S885

UNEXPECTED PREVALENCES OF THE JAK2V617F AND CALR MUTATIONS IN THE GENERAL POPULATION

S. Cordua[1,*], L. Kjaer[1], V. Skov[1], C. Ellervik[23], N. Pallisgaard[4], H.C. Hasselbalch[1]

[1]Department of Hematology, Zealand University Hospital, Roskilde, [2]Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, [3]Department of Research, Production, Innovation, Zealand Region, Soroe, [4]Department of Pathology, Zealand University Hospital, Roskilde/Naestvaed, Denmark

Background: The JAK2V617F mutation (JAK2) and calreticulin mutations type 1 and 2 (CALR) are predominantly found within the chronic Philadelphia-negative myeloproliferative neoplasms (MPN). Few studies have assessed the JAK2 prevalence in the general population with very limited reports on the association with MPN over time. To our knowledge, no corresponding studies of CALR exist.
Aims: 1) to determine the prevalence of JAK2 and CALR mutations in a Danish population study 2) to assess the kinetics of the allele burden and blood cell counts over time by inclusion of mutated citizens in a follow up program.
Methods: Inclusion of participants in the general population study in Region Zealand took place during 2010-2013 (N=20,000). When included, a broad range of blood samples were collected as well as DNA to be stored in a biobank, and all participants were asked for a written consent to allow the data and DNA to be used in future research. This DNA was in our study analyzed for JAK2 and CALR by digital droplet PCR. The assays used have high accuracy and sensitivity with a detection level of allele burden at 0.01%. Part of our ongoing follow up program during 2017-2018 on citizens with mutation includes blood samples and a current allele burden for JAK2/CALR, thereby obtaining a follow up time of 5-8 years.
Results: In a preliminary mutational analysis of 9,000 individuals, 285 (3.2%) were JAK2 positive and 18 (0.2%) were CALR positive corresponding to a JAK2:CALR ratio of 16. Among the citizens with mutation, median age was 63 years (range 23-93), and 82% presented low allele burden less than 1%. These proportions were similar when looking at the JAK2- and CALR-mutated groups separately. We noticed that 40% of the citizens concurrently with their mutation had an aberrant blood cell count – leukocytosis (defined as $>8.8\times10^9$/L) being the most frequent and present in 54% of the cases.
Summary/Conclusion: To our knowledge, we are the first to determine the prevalence of JAK2 and CALR in the general population with such a sensitive method, and our preliminary results indicate that the true prevalence of JAK2 in the general population is much higher than previously reported with dominance of low allele burdens. On the contrary, we find the CALR prevalence low compared to JAK2. The difference cannot entirely be explained by the distribution of the mutations within the MPN diagnoses. The long-term perspective of this study is to reduce thrombotic and hemorrhagic events in today's pre-MPN diagnosis phase by diagnosing MPN in earlier disease stages in the future. Thus, we find the high prevalence of low allele burden and mild cytosis intriguing, and we hope that the follow up program can elucidate whether we can discriminate between early signs of MPN and clonal hematopoiesis of indeterminate potential; though these two wordings in time might turn out to be two sides of the same coin.

Platelet and bleeding disorders II

A STRATEGY WITH CHAPERONE-LIKE COMPOUNDS TO RESTORE EXPRESSION OF FACTOR IX VARIANTS AFFECTED BY FREQUENT MISSENSE MUTATIONS CAUSING HEMOPHILIA B

S. Pignani[1], A. Todaro[1], M. Ferrarese[1], S. Marchi[2], S. Lombardi[1], D. Balestra[1], P. Pinton[2], F. Bernardi[1], M. Pinotti[1], A. Branchini[1,*]

[1]Department of Life Sciences and Biotechnology, [2]Department of Morphology, Surgery and Experimental Medicine, University of Ferrara, Ferrara, Italy

Background: Missense mutations, representing the most frequent gene alteration associated with human disease including coagulation factor disorders, exert the most detrimental effect by impairing protein folding and intracellular trafficking. These effects at the protein level may be counteracted by small molecules with chaperone-like activity, with a concomitant improvement of the affected intracellular processes. Although some evidence exists for missense mutations associated with disorders involving intracellular proteins, only very few attempts have been made for secreted proteins, in particular in the coagulation field. Noticeably, a correction approach with chaperone-like compounds could be of relevance for coagulation factor disorders, where even modest increases of functional protein levels could have therapeutic implications.
Aims: The aims of our study were to i) detail the altered intracellular processing of a panel of factor IX (FIX) missense variants causing severe type I Hemophilia B (HB), and ii) to rescue their intracellular processing, secretion and activity through chaperone-like compounds.
Methods: Transient and stable expression of recombinant FIX (rFIX) variants in Human Embryonic Kidney (HEK) 293 cells, and evaluation of secreted/intracellular protein levels (ELISA, Western Blotting), intracellular trafficking (immunofluorescence) and activity (coagulant assays) before and after treatment of cells with chaperone-like compounds.
Results: As model mutation we selected the *F9* p.R294Q, representing the most frequent substitution (~100 patients) associated with severe/moderate type I HB. As comparison we chose other recurrent *F9* missense mutations (p.Y115C, n=9; p.Y161C, n=5; p.Y305C, n=9; p.F424L, n=3). Transient expression studies indicated that the selected mutations severely impair rFIX secretion (0.2-0.8% of wild-type rFIX), thus recapitulating findings in HB patients (antigen levels <1%). Immunofluorescence studies on stably expressing cells revealed that, at variance from wild-type rFIX, missense variants mainly co-localized in the ER and scarcely with Golgi, thus indicating impaired intracellular trafficking. This pattern was comparable to that of the rFIX-450C variant, previously demonstrated by us to cause severe type I HB and here chosen as additional control. These observations were in accordance with the very low secreted levels observed in expression studies. Screening of a panel of chaperone-like compounds identified sodium phenylbutyrate (NaPBA) as active in improving trafficking to Golgi and in appreciably promoting secretion (from 0.3±0.1% to 1.5±0.3%) of the rFIX-294Q variant in a dose-dependent manner. Noticeably, the rFIX-294Q variant revealed a remarkable specific coagulant activity that was higher (~2.0) than that of wild-type rFIX in all treatment conditions (0.5, 1.0 and 2.0 mM NaPBA). Importantly, activity after treatment was improved in terms of shortening of coagulation times (from 80±0.1 to 62±3 seconds at 2 mM NaPBA), with increased levels (~3%) that, if achieved in patients, would approach the therapeutic threshold.
Summary/Conclusion: Altogether our data contribute to detail molecular mechanisms underlying type I HB and candidate NaPBA as a potential "personalized" option for the high number of patients affected by the frequent p.R294Q mutation. In addition, our expression platform is proposed for other missense mutations leading to severe type I Hemophilia to select those being responsive to chaperone-like compounds.

S887

NLRP3 INFLAMMSOME ACTIVATION IN PBMCS CONTROLS THE T CELL RESPONSE IN ADULT PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA

M. Hua[1,*], X. Li[1], M. Hou[1], J. Peng[1]

[1]Department of Hematology, Qilu Hospital, Shandong University, Jinan, China

Background: Immune thrombocytopenia (ITP) is an acquired autoimmune disorder, which is characterized by imbalanced adaptive immunity of T cells. NLRP3 inflammasome has recently been reported to be involved in diverse inflammatory or immune diseases. However, NLRP3 inflammasome activation in the pathophysiology of ITP remains unclear.
Aims: To explore the effects of NLRP3 inflammsome activation on the T cells in adult patients with chronic ITP.
Methods: Peripheral blood was obtained from 28 adult patients with chronic ITP. PBMCs were isolated using Ficoll density-gradient centrifugation and the CD4+ cells were purified by positive immuno-magnetic microbeads selection. The PBMCs, CD4+ or CD8+ cells were primed with LPS, then stimulated with ATP and finally cultured in plate-bound anti-human CD3 and soluble anti-human CD28 plus IL-2. After four days, the percentage of CD4+ cells and CD8+ cells, the T helper cell subsets (Th cells) of Th1, Th2, Th17 and T-reg cells, the inhibitory molecules, PD1 and CTLA4, and the CFSE-labeled cells were analyzed by flow cytometry. IFN-γ, IL-4, IL-17 and TGF-β in cultured supernatants were assayed by ELISA. The mRNA expression level of cytokines associated with Th cells (*Ifn-γ, Il-6, IL-10, Il-17*), the key transcription factors of Th cells (*T-bet, Gata3, Foxp3, Ror-γt*) and the inhibitory molecules (*Ctla-4, Btla, Tim3, Lag3, Pd1 and Vista*) was determined by Real-Time PCR.
Results: We found that NLRP3 inflammasome activation in PBMCs initiated caspase-1–dependent IL-1β secretion, and thereby weakened the Th1 cell differentiation (unstimulated control 13.3% vs. stimulation 5.3%; p=0.015), which can be restored, at least in part, by caspase-1 inhibitor Z-YVAD-FMK (Figure 1). The production of IFN-γ and the expression of *Ifn-γ*, were significantly down-regulated after NLRP3 inflammsome activation. However, the percentage of Th2 or Th17 was not significantly different between the stimulated and unstimulated groups. Meanwhile, the percentage of T-reg cells was also decreased after stimulation by LPS plus ATP in PBMCs (unstimulated control 6.67% vs. stimulation 4.39%; p=0.033). More importantly, NLRP3 inflammasome activation significantly suppressed the proliferation but didn't induce the apoptosis of CD4+ cells and CD8+ cells (Figure 2). Accordingly, the mRNA expression of inhibitory molecules (*Ctla-4, Btla, Tim3, Pd1 and Vista*) of T cells and the PD1 or CTLA4 (Figure 3) on the membrane surface of CD4+ and CD8+ cells were up-regulated after the activation of NLRP3 inflammasome in PBMCs. Furthermore, the percentage of CD8+ cells significantly decreased after NLRP3 inflammasome activation in PBMCs. However, LPS plus ATP took no effect on purified CD4+ or CD8+ cells in contrast with PBMCs.

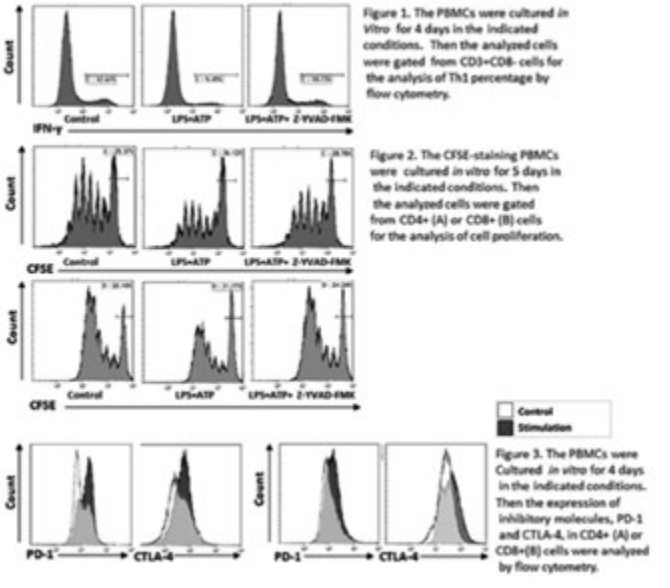

Figure 1.

Summary/Conclusion: NLRP3 inflammsome-mediated innate immune reaction may play an important role in controlling the T cell responses of adaptive immunity by the inhibitory molecules and might prevent disease progression in adult chronic ITP.

S888

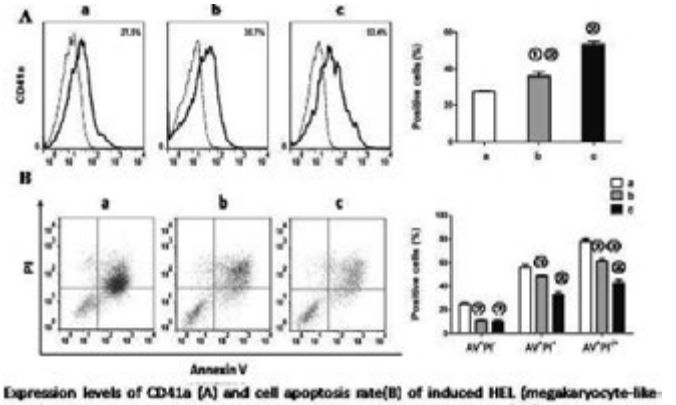
EFFECTS OF BONE MARROW MESENCHYMAL CELLS FROM IMMUNE THROMBOCYTOPENIA PATIENTS ON THE BIOLOGICAL BEHAVIORS OF MEGAKARYOCYTES

J. Wang[1], X. Li[1], T. Yin[2], J. Liu[2], X. Wang[3], L. Xu[1], A. Wang[1], H. Zhong[1,*]

[1]Department of Hematology, Ren Ji Hospital, South Campus,School of Medicine, Shanghai Jiao Tong University, [2]Department of Hematology, Ren Ji Hospital, School

of Medicine, Shanghai Jiao Tong University, [3]Department of Rheumatology, Ren Ji Hospital, South Campus,School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Background: Immune thrombocytopenia(ITP) is an autoimmune disease characterized by increased platelet destruction as well as impaired production. The pathogenesis of impaired platelet production in ITP is still ill-defined. The bone marrow microenvironment plays the critical role in platelet generation. As the important component of the bone marrow microenvironment, bone marrow mesenchymal cells(BMCs) also play a critical role in regulating platelet production. BMCs can sustain MK differentiation and platelet formation through multiple mechanisms, including expressing many of the cytokines that are involved in megakaryocytic developments, as well as providing mechanical supports through adhesion molecules mediated direct contact. A series of studies have demonstrated the defective BMCs from ITP patients. However, whether the effects of BMCs in regulating megakaryopoiesis have changed in ITP is still not clear. In this study we focused on the interaction of BMCs and megakaryocytes, compared many aspects of BMCs from ITP and Normal controls, in order to deepen our understanding of the pathogenesis of ITP.
Aims: To investigate changes in the proliferation, survival and cytokines expression of BMCs derived from ITP patients, as well as to evaluate their influences on the biological behaviors of megakaryocytes.
Methods: Bone marrow samples were obtained from 7 ITP patients and 5 normal controls, and BMCs were cultivated by the whole marrow adherent method. The surface markers of BMCs and the basal cell apoptosis rate were analyzed by flow cytometry. Proliferation of BMCs were assessed by Cell Counting Kit-8 method. HEL cells were induced to undergo megakaryocytic differentiation by using nanomolar concentrations of Phorbol 12-myristate 13-acetate (PMA). The induced HEL cells were grouped and co-cultured with BMCs from different resources, followed by surface protein CD41a detection and apoptosis analysis through FCM. The expression levels of IL6 IL11 TPO SCF mRNA and protein in BMCs were detected by Real-time Fluorescent quantitative PCR and Enzyme Linked Immunosorbent Assay.
Results: BMCs from ITP patients grew progressively slowly, and cell basal apoptotic rates were higher than that of normal controls. BMCs from normal controls significantly promoted the CD41a expression as well as reduced the apoptosis rate of induced HEL(megakaryocyte-like cells) by co-culture *in vitro*. Whereas, this ability was much weaker in BMCs from ITP patients; The expression Levels of IL6, SCF mRNA and IL6 protein were significantly decreased in ITP BMCs (Figure 1).



Expression levels of CD41a (A) and cell apoptosis rate(B) of induced HEL (megakaryocyte-like cells) after co-cultured with BMCs from either ITP or normal controls(NC). a. Induced HEL cultured alone; b. Induced HEL co-cultured with ITP-BMCs; c: Induced HEL co-cultured with NC-BMCs. ①P=0.015, ②p=0.000, compared with group a; ③P=0.000, compared with group c

Figure 1. Effects of BMCs on the biological behaviours of megakaryocytes.

Summary/Conclusion: BMCs from ITP patients exhibited impaired proliferation and excessive apoptosis when cultured *in vitro*. BMCs from ITP also show defects in supporting megakaryocytic differentiation and survival under co-culture condition, which may be resulted from their deficiencies in expressing cytokines IL6 and SCF.

S889

ATRA COULD CORRECT THE IMPAIRED PROPLATELET FORMATION CAUSED BY THE TUBULIN β1 SINGLE NUCLEOTIDE POLYMORPHISM R307H IN CORTICOSTEROID-RESISTANT ITP PATIENTS

C.-C. Wang[1,2,3,*], Y.-N. Wang[1,2,3], Y. He[1,2,3], Q. Chen[1,2,3], X. Liu[1,2,3], J.-M. Zhang[1,2,3], J. Xue[1,2,3], H.-X. Fu[1,2,3], X.-S. Zhao[1,2,3], X.-Y. Zhao[1,2,3], Y. Kong[1,2,3], Y.-J. Chang[1,2,3], K.-Y. Liu[1,2,3], X.-J. Huang[1,2,3], X.-H. Zhang[1,2,3]

[1]Peking University Institute of Hematology, Peking University People's Hospital, [2]Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, [3]Collaborative Innovation Center of Hematology, Peking University, Beijing, China

Background: Primary immune thrombocytopenia (ITP) is an autoimmune disorder with reduced platelet production, and increased platelet destruction is considered to be the main pathogenic mechanism. However, the mechanism of corticosteroid-resistant ITP is still unclear. It is reported that single nucleotide polymorphisms (SNPs) in tubulin β1 in patients with ITP is related to the response of corticosteroid therapy (Paul A. Basciano et. al. 2013) and proplatelet formation (PPF) (Shinji Kunishima *et al.* 2013). Our study revealed that all-trans retinoic acid (ATRA), which has demonstrated to be a promising candidate for corticosteroid-resistant/relapsed ITP patients in our previous study (Feng FE *et al.* 2017), could correct the abnormal function of tubulin β1 in ITP patients with SNP and promote megakaryocyte maturation and PPF.
Aims: To explore the effect of ATRA on megakaryocyte maturation and PPF in ITP patients with tubulin β1 SNP R307H.
Methods: Thirty corticosteroid-resistant/relapse ITP patients and 10 healthy donors were enrolled in this study. MKs were isolated by cell sorting from bone marrow samples obtained by aspiration from the posterior iliac crest, and bone marrow samples were collected again after ITP patients received a 16-week oral ATRA (10 mg twice daily) therapy. The identification of R307H substitution in TUBB1 (the gene encoding tubulin β1) was performed by polymerase chain reaction (PCR) and Sanger sequencing. CD34+ cells were isolated from bone marrow samples by cell sorting for *in vitro* culture with TPO, and on day 8, differentiated MKs were enriched. Western blot (WB) was performed to verify the expression level of tubulin β1 in differentiated MKs. Immunofluorescence staining was performed for tubulin β1 and observed by inverted confocal fluorescence microscopy. In the ITP group, ATRA was added to the differentiating culture process. Proliferation, GPIIb/IIIa–GPIbIX expression, ploidy distribution and PPF were observed in the different groups.
Results: The allelic frequencies between a group of 30 ITP patients and the healthy control group showed no difference. The protein levels of tubulin β1 in cultured differentiated MKs from ITP patients with homozygote SNPs were significantly decreased compared with patients with wild type tubulin β1, and heterozygote patients also showed a similar trend, but no significant difference. The *in vitro* culture-differentiated MKs from ITP patients with homozygote SNPs displayed normal proliferation but decreased GPIIb/IIIa–GPIbIX expression and ploidy distribution, as well as impaired and decreased PPF compared with the control groups and patients with WT tubulin β1. Immunofluorescence results of the differentiated MKs showed that the expression of tubulin β1 and the distribution of microtubules were abnormal both in MKs and in pro-platelets from ITP patients with homozygote SNPs. In the homozygote SNP group, when ATRA was added to the culture, tubulin β1 expression was recovered, and as a result, the GPIIb/IIIa–GPIbIX expression, ploidy distribution and PPF was increased. Additionally, after receiving ATRA therapy, the expression and distribution of tubulin β1 in megakaryocytes and proplatelets returned to nearly normal compared with those before therapy.
Summary/Conclusion: The megakaryocytes of ITP patients with homozygote SNPs showed a decreased expression and abnormal distribution, which might lead to its dysmaturity and impaired PPF. ATRA might correct the function of impaired tubulin β1 and promote megakaryocyte maturity and PPF.

S890

VERY LOW DOSE PROPHYLAXIS IN CHILDREN WITH HAEMOPHILIA A: A RURAL INDIAN EXPERIENCE

D. De[1,*], S.S. Datta[1], B. Basak[2], S. Halder[2], P. Chatterjee[2]

[1]Department of Hematology, [2]Department of Pathology, The Mission Hospital, Kolkata, India

Background: Prophylactic therapy with factor concentrates administered 2 to 3 times a week on a regular basis is the gold standard treatment for haemophilia[1]. In countries with limited resources, initiating prophylaxis

with very low dose and at reduced frequency could be recommended.
Aims: We report our single centre experience from a Hemophilia Treatment Centre at rural eastern India with very low dose once weekly prophylaxis regimen in children with haemophilia A.
Methods: It was an open label prospective trial using historical data as control. Children with severe haemophilia A, below the age of 15 years, were included. The patients received very low dose prophylaxis with recombinant F-VIII, at the dose of 15 IU/kg once weekly. The dose was approximated to nearest 250 IU or 500 IU F-VIII, for optimal use of Factor vials. The Anti Hemophilic Factors (AHF) were provided by Hemophilia Federation of India on compassionate ground free of cost. The patients were followed up for 6 months (June 2017- November 2017) and clinical and joint evaluation parameters were compared with historical data in previous 6 month period. APTT-based Inhibitor screening was done at study entry and then at the end of 6 month.
Results: Altogether 18 patients were included in the study, but 3 patients were excluded from calculation, as they discontinued the prophylaxis because of logistics issues. The mean age of patients was 9.47 years (Range 3-15 years) and mean body weight were 28 Kg, (range 12-40 Kg). All the patients were previously exposed to AHF infusion as On Demand Therapy. There was significant reduction of ABR during prophylaxis therapy (23.73 before prophylaxis vs 1.87 after prophylaxis, P value <0.001). Similarly, no. of days of hospitalisation for rescue therapy was also reduced significantly. No patient developed inhibitor during the study period. The Social and functional parameters like PedQL score and days of school absenteeism also reduced significantly. The AHF use was about 1235 IU/Kg/year during on demand therapy, which came down to 821 IU/Kg/year during prophylaxis (Figure 1).

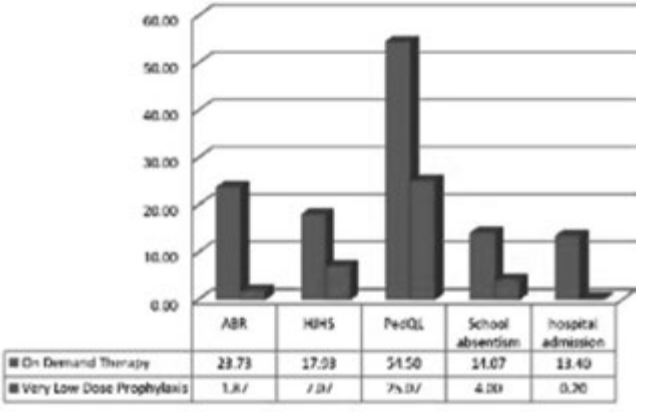


Figure 1.

Summary/Conclusion: Prophylaxis in haemophilia is a big challenge in resource constrained developing countries. Also the limited access to haemophilia treatment centre in rural India, difficulty in using public transport facility by haemophiliacs and lack of knowledge about self infusion and home based therapy makes prophylaxis program more difficult. The very low dose prophylaxis regimen of 15 units/kg once a week AHF was quite convenient and acceptable to the children with haemophilia. It is effective in preventing joint bleeds and overall bleeds and also is cost effective. Significantly less emergency visits, lesser days of school absenteeism and improved quality of life can be achieved in children with very low dose prophylaxis.

Iron: From basic science to clinical application

S891

INVESTIGATING THE ROLE OF NCOA4 IN ACUTE AND CHRONIC IRON RELEASE FROM STORES

A. Nai[1,2,*], M. R. Lidonnici[3], G. Federico[4], M. Pettinato[12], I. Artuso[15], G. Mandelli[3], G. Ferrari[23], C. Camaschella[1], F. Carlomagno[4], L. Silvestri[12]

[1]Division of Genetics and Cell Biology, San Raffaele Scientific Institute, [2]Vita-Salute San Raffaele University, [3]SR-TIGET – San Raffaele Telethon Institute for Gene Therapy, San Raffaele Scientific Institute, Milan, [4]CNR Endocrinology and Experimental Oncology Institute-Department of Molecular Medicine and Medical Biotechnology, University of Naples Federico II, Naples, [5]Department of Biotechnology and Biosciences, University of Milano-Bicocca, Milan, Italy

Background: Nuclear Receptor Coactivator 4 (NCOA4) has been recently identified as the cargo receptor that promotes the autophagic ferritin degradation in conditions of iron deficiency (ID). Depletion of *NCOA4* increases ferritin aggregates and C57Bl/6 *Ncoa4-ko* mice show mild microcytic anemia and increased susceptibility to ID. Previously published *in vitro* and *ex vivo* data suggest a direct role of NCOA4 in erythroid differentiation and hemoglobinization.
Aims: We will address the role of NCOA4 in response to chronic and acute iron demand and we will identify the cell type mostly affected by *Ncoa4* deficiency *in vivo.*
Methods: The iron response has been studied in Sv129/J *Ncoa4-ko* and wt mice that were maintained in iron-balance (IB) or ID diet for 6 months. Complete blood count was periodically measured and the iron phenotype was evaluated at sacrifice. Ferritin degradation was also assessed *ex vivo* in hepatocytes and BM macrophages isolated from wt and *Ncoa4-ko* mice and treated with desferrioxamine. Moreover, in order to unambiguously elucidate the function of NCOA4, we lethally irradiated *Ncoa4-ko* mice for transplantation of bone marrow cells (BMT) from wt and *Ncoa4-ko* mice, and manipulated the dietary iron content of the transplanted animals. Two months after BMT, animals were fed an ID diet for 3 months and subsequently analyzed for hematological parameters and iron content.
Results: Sv129/J *Ncoa4-ko* mice, that are particularly enriched in iron content, showed microcytosis without anemia. The ID diet induced slight changes in hemoglobin (Hb) levels in wt mice, but severe microcytic anemia with very low transferrin saturation in *Ncoa4-ko* mice. Hepatic (LIC) and splenic (SIC) iron content were reduced by ID in both genotypes. On the other hand, acute iron chelation *ex vivo* induced progressive ferritin degradation in wt but not in *Ncoa4-ko* hepatocytes and macrophages.
In the transplantation model, red blood cells count and Hb levels were comparable between mice transplanted with wt and *Ncoa4-ko* BM at 2 months after BMT, while mean corpuscular volume was higher in the former. The ID diet caused a more severe anemia in mice transplanted with *Ncoa4-ko* cells than in animals transplanted with wt cells. High SIC and ferritin levels were observed in mice transplanted with *Ncoa4-ko* cells, while LIC was unchanged.
Summary/Conclusion: Our results demonstrate that Sv129/J *Ncoa4*-ko mice, although not anemic in basal conditions, are more susceptible to iron-deficiency anemia. Their hematological phenotype is due to a defect of BM-derived cells. *Ncoa4-ko* BM cells are able to reconstitute almost normal Hb levels in transplanted animals and this, accompanied by a normal erythropoiesis, indicates that *in vivo Ncoa4* deficiency has a limited, if any, effect on the erythroid lineage differentiation. On the contrary, the reduced iron recycling capacity of *Ncoa4-ko* macrophages *in vivo*, confirmed by *ex vivo* experiments, supports the role of NCOA4 in mobilizing the iron stores. Still, a prolonged ID diet leads to a substantial splenic and hepatic iron mobilization in *Ncoa4-ko* mice, and this suggests that other mechanisms of ferritin degradation are likely activated in chronic conditions. Therefore, to verify the role played by NCOA4 in response to acute increased iron demand *in vivo*, *Ncoa4-ko* mice are under study, exploiting an EPO based treatment protocol that induces rapid changes of iron bound transferrin, to analyse their ability to restore normal circulating iron levels after an acute erythropoietic expansion.

delberg, [2]MMPU - Molecular Medicine Partnership Unit, [3]EMBL - European Molecular Biology Laboratory, Heidelberg, Germany

Background: The hepcidin-ferroportin regulatory system is crucial to maintain physiological systemic iron levels. Ferroportin is the only known iron exporter and mediates the release of iron from reticuloendothelial macrophages and from duodenal enterocytes. Mutations that affect ferroportin protein stability or its targeting to the cell surface cause iron retention in iron exporting cells and reduced systemic iron levels. Gain of function ferroportin mutations that cause resistance to hepcidin binding generate systemic iron overload. Hepcidin is a small hormone produced by the liver in response to iron levels. Hepcidin binds to and degrades ferroportin thereby reducing the amount of iron released into the blood stream. Recent evidences have shown that hepcidin is activated by the bone morphogenetic proteins BMP2 and BMP6, predominantly expressed by liver sinusoidal endothelial cells (LSECs). How iron levels are sensed by the liver to control BMP2 and BMP6 expression and the consequent hepcidin production is still unknown.
Aims: Study the impact of the haploinsufficiency of ferroportin on iron homeostasis and identify how iron levels are sensed by the liver to control BMP2 and BMP6 production and hepcidin synthesis.
Methods: Slc40a1(wt/trp) mice have been generated via homologous recombination by inserting into the 6th intron of the *Slc40a1* locus a promoterless bGEO selection marker cassette containing an upstream splicing acceptor. LSEC have been isolated from the liver via magnetic sorting using the CD146 magnetic beads. Gene expression analysis has been performed using SYBR-green qRT-PCR.
Results: We have generated and analysed mice with a heterozygous loss of the ferroportin allele (Slc40a1$^{wt/trp}$). In this mouse model we observed normal haematological parameters and plasma iron levels, while liver iron content is strongly decreased. In addition, plasma hepcidin levels are dramatically reduced suggesting a response to hepatic iron deficiency. Analysis of sinusoidal endothelial cells (LSECs) from the liver of Slc40a1$^{wt/trp}$ mice revealed a strong decrease of BMP6 levels compared to wild-type mice. Consistently, hepatic SMAD1/5/8 phosphorylation is decreased in Slc40a1$^{wt/trp}$ mice explaining low hepcidin expression. Reduced hepcidin in Slc40a1$^{wt/trp}$mice explains similar ferroportin protein expression in duodenal enterocytes and splenic macrophages compared to wild-type mice. As a consequence plasma iron is maintained within the physiological range to satisfy the demand for erythropoiesis.
Summary/Conclusion: Our results show that the hepatic iron content dominates over plasma iron levels in regulating BMP6 expression in LSECs and hepcidin expression in hepatocytes. Furthermore, low hepcidin expression can compensate for the lack of one ferroportin allele. This may explain why patients with heterozygous ferroportin null mutations have not been yet identified.

S893

DEVELOPMENT OF A GALNAC SIRNA CONJUGATE TARGETING TMPRSS6 FOR THE TREATMENT OF IRON OVERLOAD DISORDERS, SUCH AS B-THALASSEMIA

U. Schaeper[1,*], S. Altamura[2], S. Dames[1], S. Schubert[1], C. Frauendorf[3], M. Aleku[4], M. Muckenthaler[2], G. Grigoriadis[5], J. Vadolas[5], U. Zügel[1]

[1]Drug Discovery, Silence Therapeutics GmbH, Berlin, [2]Molecular Medicine, University of Heidelberg, Heidelberg, [3]Chemistry Manufacturing Controls, [4]Non Clinical Development, Silence Therapeutics GmbH, Berlin, Germany, [5]Centre for Cancer Research, Hudson Institute of Medical Research, Melbourne, Australia

Background: Hyperferremia is a major health problem in hemochromatosis, thalassemia and sickle cell anemia. Severe symptoms of excess iron can lead to liver cirrhosis, diabetes, and heart failure. In hereditary hemochromatosis, gene mutations in the hepcidin-ferroportin axis controlling iron homeostasis, lead to hepatic iron overload. In thalassemia major patients, iron overload develops as a consequence of frequent blood transfusions to ameliorate severe anemia. In addition, iron overload develops in patients with b-thalassemia intermedia, due to gastrointestinal iron hyperabsorption. Thus, in both indications iron overload is caused by dysregulation or dysfunction of the hepcidin-ferroportin axis. Importantly, expression of the peptide hormone hepcidin, which is the key player in iron homeostasis, is abnormally low and unable to block ferroportin-mediated intestinal iron absorption. Hepcidin is predominantly produced by the liver and is induced by activation of the BMP/SMAD signalling pathway. Hepcidin is furthermore under the negative control of the transmembrane protease matriptase 2, encoded by the TMPRSS6 gene. RNA interference is a powerful technology for inhibiting the expression of disease associated targets. Silence Therapeutics has developed siRNA conjugate technology for the selective inhibition of target gene expression in the liver. siRNAs conjugated to a GalNAc ligand bind efficiently to the asialoglycoprotein (ASGP) receptor expressed predominantly by hepatocytes. Thereby they provide a safe and efficient delivery technology for targeting disease modifying genes in the liver for therapeutic purposes. Here we report on the identification and pharmacological evaluation of SLN124, a GalNAc-siRNA conjugate targeting TMPRSS6 expression, for the treatment of iron overload disorders, such as b-thalassemia. Moreover, this study demonstrates that our GalNAc-conjugated siRNAs provide a safe and efficient delivery system and hold great promise for the targeted knock-down of modifier gene expression in the liver for therapy.
Aims: Identification and characterization of SLN124, a GalNAc-siRNA conjugate targeting TMPRSS6 expression, for treatment of b-thalassemia and iron overload.
Methods: Lead identification and pharmacological characterization of siRNA conjugates in cell based assays, in rodent disease models and in non-human primates.
Results: We will present the identification and pharmacological characterization of SLN124, the GalNAc-siRNA conjugate targeting TMPRSS6 expression. A single subcutaneous administration is sufficient to achieve significant modulation of target gene expression in mice and in non-human primates over several weeks. SLN124 reduces systemic iron levels, transferrin saturation and tissue iron levels in rodent models for hereditary hemochromatosis. In addition, we show the therapeutic efficacy of SLN124 in an animal model for b-thalassemia intermedia on erythropoiesis and anemia. Safety and tolerability are assessed in relevant preclinical models. SLN124 shows dose-dependent and long-lasting effects on target expression as well as on modulation of iron stores and normalization of erythropoiesis in b-thalassemia mice and was well tolerated.
Summary/Conclusion: GalNAc-siRNA conjugate SLN124 is a promising candidate for treatment of iron overload and anemia in b-thalassemia and related disorders. SLN124 is in preclinical development and we plan to enter clinical development by end of 2018.

S894

A PHASE 1, OPEN-LABEL STUDY TO DETERMINE THE SAFETY, TOLERABILITY, AND PHARMACOKINETICS OF ESCALATING DOSES OF LJPC-401 (SYNTHETIC HUMAN HEPCIDIN) IN PATIENTS WITH IRON OVERLOAD

A. Lal[1], A. Piga[2], V. Viprakasit[3,*], J. Maynard[4], A. Kattamis[5], D. Yaeger[6], B. Byrnes[6], L. Chawla[6], G. Tidmarsh[6]

[1]University of California San Francisco Benioff Children's Hospital, Oakland, United States, [2]Università degli Studi di Torino, Torino, Italy, [3]Siriraj-Thalassemia Center, Bangkok, Thailand, [4]CTI Clinical Research Center, Cincinnati, United States, [5]National and Kapodistrian University of Athens, Athens, Greece, [6]La Jolla Pharmaceutical Company, San Diego, United States

Background: Iron overload is a significant complication in patients with hereditary hemolytic anemia (esp. sickle cell disease and thalassemia) and hereditary hemochromatosis. LJPC-401, a synthetic form of endogenous human hepcidin, is being developed as a therapeutic intervention for iron overload in these conditions.
Aims: To determine the safety, tolerability, and pharmacokinetics (PK) and pharmacodynamics (PD) of escalating doses of LJPC-401 in patients at risk for iron overload.
Methods: This was a phase 1, multicenter, open-label, dose-escalation study. Patients (aged 18-85 years) were eligible for enrollment if they had one of the following: transfusion-dependent anemia (with blood transfusion [≥2 units in the past 2 months or 4 units in the past 6 months]; iron chelation therapy in the past 6 months; serum ferritin >1000 g/L, or hemochromatosis (requiring phlebotomy at least once every 2 months or iron chelation therapy in the past 6 months). Patients were assigned to receive LJPC-401 at doses of 1, 5, 10, 20, or 30 mg. A single subcutaneous injection was administered on day 1, and dose cohort escalations occurred only after the final patient at each dose level had been observed for ≥3 days with no evidence of study drug–related toxicity. Safety assessments included treatment-emergent adverse events (TEAEs), physical and laboratory evaluations, and immunogenicity. PK parameters of baseline corrected serum LJPC-401 were obtained by noncompartmental analysis, with blood samples collected at predose and at 0.5, 2, 4, 8, 24, 48, and 168 hours postdose. PD endpoints included effects on serum iron, ferritin, transferrin, iron-binding capacity, and transferrin saturation.
Results: Eighteen patients (55.6% female; 66.7% white) were enrolled and completed the study; 7 had hemoglobinopathies (sickle cell disease or thalassemia) and 11 had hemochromatosis. Sixteen patients (88.9%) reported TEAEs (34 mild and 4 moderate in severity). Rates of TEAEs were similar

across dose groups. The most frequently occurring AEs were injection site reactions (66.7%), nausea (11.1%), increased alanine aminotransferase (11.1%), decreased appetite (11.1%), and hypoesthesia (11.1%). There were no severe TEAEs, no TEAEs leading to early discontinuation, and no deaths during the study. One serious AE (sickle cell crisis) was reported but was not considered treatment related. Following LJPC-401 doses of 1 to 20 mg (but not 30 mg), the maximum serum concentration and area under the serum concentration-time curve from time 0 to 24 hours postdose increased with dose. Peak concentrations occurred at ~2 to 4 hours postdose for all doses. A larger reduction in serum iron was generally associated with increasing LJPC-401 doses up to 20 mg (Figure 1); at 30 mg, the magnitude of serum iron reduction was lower than that at 20 mg. Overall, there was a statistically significant dose response across the 5 dose groups (p=0.0478). Serum iron reductions were sustained up to day 8 in most patients. Data from other iron parameters will be presented.

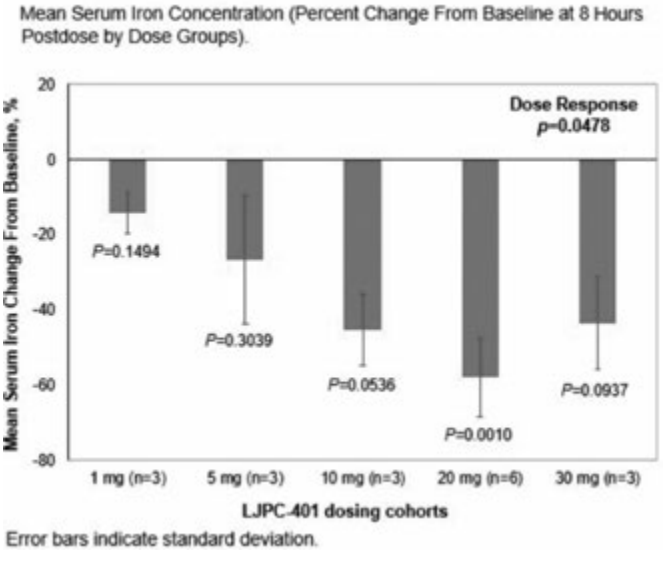

Figure 1.

Summary/Conclusion: LJPC-401 was well tolerated at doses between 1 and 30 mg in iron-overload patients, and showed significant decreases in serum iron levels compared with baseline, which were sustained in most patients up to 8 days. In healthy adults (abstract submission by Yaeger et al), LJPC-401 showed decreased serum iron levels that returned to baseline levels within 48 h. Additional studies are planned to further explore the iron-regulating effects of LJPC-401 in patients with iron-overload disorders.

S895

HEPCIDIN MIMETIC PTG-300 INDUCES DOSE-RELATED AND SUSTAINED REDUCTIONS IN SERUM IRON AND TRANSFERRIN SATURATION IN HEALTHY SUBJECTS

A. Nicholls[1], J. Lickliter[2], L. Tozzi[1], D. Liu[1], R. Shames[1,*]

[1]Protagonist Therapeutics. Inc., Newark, United States, [2]Nucleus Network Ltd., Melbourne, Australia

Background: PTG-300, an injectable peptide hepcidin mimetic, is being developed as a potential therapeutic agent for the treatment of hematologic diseases characterized by ineffective erythropoiesis, chronic anemia and iron overload including beta-thalassemia and myelodysplastic syndromes (MDS). PTG-300 improved anemia in a mouse model of beta-thalassemia and was well-tolerated in non-clinical studies.
Aims: A first-in-human (FIH) study of subcutaneous (sc) PTG-300 was conducted in normal healthy volunteers (NHV) to evaluate the safety/ tolerability, pharmacokinetics (PK) and the effect on serum iron parameters.
Methods: This was a randomized, double-blind, placebo-controlled single-ascending (SD) and repeat (RD) dose study of PTG-300 in 62 healthy male subjects. Eligible subjects had no recent history of oral iron, transfusion or blood donation and had normal baseline hematologic parameters. Informed consent was obtained and subjects randomized to cohorts of 10 subjects (single doses 1 to 40 mg, active: placebo 8:2) or 6 subjects (80 mg SD or 40 mg weekly×2; 5:1). Subjects consumed a standard diet throughout the study. PTG-300 was given as a single dose (1 mL sc) over 1-80 mg dose range or placebo. Subjects were followed for one week after dosing. In the RD cohort, two 40 mg doses were administered one week apart to further assess exposure-response. Blood sampling (iron studies, hematology and clinical chemistry), clinical observations and adverse event (AE) assessments were performed at frequent intervals after dosing.
Results: PTG-300 induced a dose-related reduction in serum iron with a maximum mean reduction of approximately 60% from baseline. The effect on iron appeared to plateau at a dose of 20 mg and was sustained for at least 72 h at higher doses. Recovery to pre-dose concentrations occurred at 144 h for the 20 mg dose while the 40 and 80 mg dose groups had not completely returned to baseline at this time point (Figure 1). Changes in serum iron were associated with a reduction in transferrin saturation; no changes in hematologic indices were observed in SD cohorts. In the RD cohort, the effects on iron were comparable for both administered doses. A small reduction in mean hemoglobin and a reticulocytosis were observed at 480 h, consistent with the return of available iron following PTG-300-induced iron restriction in subjects undergoing repeat blood sampling. PTG-300 was generally well-tolerated with no dose-limiting toxicities or serious AEs. The most frequent AEs were injection site reactions (ISRs), consisting mainly of transient erythema without systemic effects, headache and URIs. The maximum concentration in peripheral blood samples was observed up to 24 h after dosing. The decay in PTG-300 followed a simple exponential pattern, with AUC and Cmax increasing with dose; however, the increases were less than proportional to dose. Mean $t_{1/2}$ was 36.5 h (SD 17.6, n=24) for the 10-40 mg dose range.

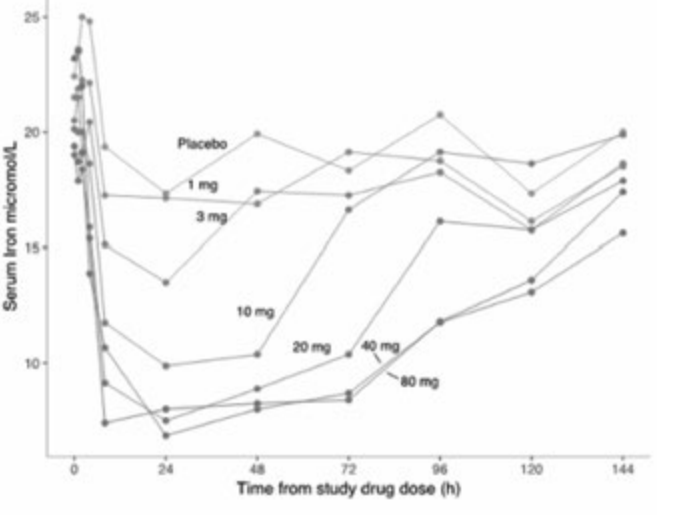

Figure 1.

Summary/Conclusion: PTG-300 was well-tolerated following single and repeat dose sc injection in NHV and demonstrated marked and sustained dose-related effects on iron distribution consistent with known activities of hepcidin and pre-clinical studies of PTG-300. This FIH study establishes PD-based proof of concept and provides a range of doses that could be evaluated in the treatment of iron-loading anemias, such as beta-thalassemia and MDS.

INFLAMED BM-MSCS HIGHLY ATTRACT TEL-AML1+ PRE-LEUKEMIC CELLS AND PROVIDE A SUSTAINING NICHE FOR THEIR EMERGENCE

L. Beneforti[1,*], E. Dander[1], S. Bresolin[2], G. te Kronnie[2], T. Ford[3], G. D'Amico[1], A. Biondi[4], C. Palmi[1], G. Cazzaniga[1]

[1]Centro Ricerca Tettamanti, Fondazione Tettamanti, Monza, [2]Dept. Health of Woman and Child, Univ. of Padua, Padua, Italy, [3]Centre for Evolution and Cancer, Division of Molecular Pathology, The Institute of Cancer Research, Sutton, United Kingdom, [4]Pediatric Dept., Univ. Milano Bicocca, Monza, Italy

Background: Epidemiological and experimental data indicate that infections and inflammation play an important role in the conversion from TEL-AML1 positive pre-leukemia to leukemia. We showed that TGFβ, a pleiotropic cytokine produced after inflammation, limited the proliferation of normal B-precursors, favoring the TEL-AML1+ clone. Moreover, TEL-AML1+ Ba/F3 showed altered expression of adhesion molecules and an impaired migration towards SDF-1α, suggesting possible dysregulated interactions within the BM-niche, where MSCs are key regulators of HSPCs homeostasis. Moreover, MSCs posses pro- and anti-inflammatory properties representing a bridge between hemopoiesis and inflammation. In this complex equilibrium, pre-malignant cells are often characterized by oncogene induced senescence (OIS), which represents an anti-tumor barrier alternative to apoptosis. An important mediator of OIS is the CXCL1-CXCR2 axis; however, due to its link with inflammation, this pathway can also exert protumoral effects.
Aims: Aim of the study is to better elucidate intrinsic/extrinsic mechanisms favoring the TEL-AML1+ clone in the BM-niche, focusing on OIS, MSCs and inflammation.
Methods: Murine BM-derived MSCs were isolated, characterized and cultured for limited passages. Inflammatory conditions were reproduced by treating cells for 48-72-96h with IL6/IL1β/TNFα. Competitive growth assays were performed by mixing control and TEL-AML1+ Ba/F3 in presence of MSCs and/or cytokines.
Results: TEL-AML1 expression induces OIS in murine Ba/F3 proB cells, and accordingly, one of its mediator, the CXCL1-CXCR2 axis, is upregulated in pre-leukemic cells, as shown by GEP analysis and by the overexpression of CXCR2 receptor (MFI: TA=1378±807; ctr=284±167). Interestingly, preleukemic cells highly migrate toward recombinant CXCL1 respect to controls (% migrated cell/input: TA=21.5±6.7; ctr=2.2±1.7). Moreover, both murine and human BMMSCs basally produce CXCL1, but they dramatically increase its secretion after inflammatory stimulation (pg/mL: unstimulated=78±28; inflamed=30162±4760). Accordingly, TEL-AML1+ cells are more attracted by inflamed, but not unstimulated, BM-MSCs supernatants respect to control cells (% migrated cell/input: TA=30.2±9.1; ctr=14.3±9.6). Co-culturing control and TEL-AML1+ cells on unstimulated MSC doesn't provide any advantages to the latter; on the contrary, preleukemic cells increase if inflammatory cytokines are added to the MSC co-cultures (fold-increase=1.76±0.27). The advantaging effect depends on BM-MSCs, as inflammatory cytokines do not impact on Ba/F3 cells themselves, and it's mediated by soluble factors. Indeed, the inflammatory milieu in MSC co-cultures induces a strong anti-proliferative effect on normal B precursor (FI, CSFE-MFI: TA=1.18±0.49; ctr=2.34±0.58) and reduce their viability (FI,% ANN-V/7AAD: 0.76±0.18), while it exerts an anti-apoptotic effect on TEL-AML1+ cells (FI,% ANN-V/7AAD: 1.42±0.09). Blocking CXCL1 in inflammatory co-cultures doesn't affect results; TGFβ isn't likely implicated as well, as it doesn't increase in inflamed MSCs supernatants.
Summary/Conclusion: TEL-AML1+ murine B-progenitors are strongly attracted by inflamed BM-MSC, which provides at the same time an advantageous microenvironment for their emergence. While CXCL1 is fundamental for migration, it doesn't represent a pro-survival or pro-proliferative stimulus. However, blocking CXCL1/CXCR2 axis could avoid pre-leukemic cells to reach a sustaining niche, therefore representing a potential strategy to eradicate TEL/AML1+ pre-leukemic cells.

TRANSLATOME ANALYSIS REVEALS ALTERED SERINE METABOLISM IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

K. Kampen[1,*], L. Fancello[1], T. Girardi[1], S. O. Sulima[1], F. Loayza-Puch[2], B. Verbelen[1], S. Vereecke[1], G. Rinaldi[3], J. Verbeeck[1], J. Op de Beeck[1], J. Royaert[1], P. Vermeersch[4], D. Cassiman[5], S.-M. Fendt[3], R. Agami[2], M. Fiers[6], K. De Keersmaecker[1]

[1]Laboratoryfor Disease Mechanisms in Cancer, Oncology, KU leuven, Leuven, Belgium, [2]Division of Oncogenomics, The Netherlands Cancer Institute, Amsterdam, Netherlands, [3]Center for Cancer Biology, VIB-KU Leuven, [4]Department of Laboratory Medicine, [5]Department of Gastroenterology-Hepatology and Metabolic Center, University Hospitals Leuven, [6]Center for human Genetics, KU leuven, Leuven, Belgium

Background: Recurrent somatic mutations occur in ribosomal protein L10 (RPL10) at residue R98 (R98S missense mutation) in approximately 8% of pediatric T-ALL.
Aims: Integrate multi-omics approaches to define the overall changes in transcriptional and translational control of RPL10 R98S defective cells.
Methods: Merge multiple datasets to compare RPL10 WT and R98S cells; Quantitative proteomics by mass spectrometry analysis (published), RNA sequencing (3 datasets), Polysome profiling (published), and Ribosome footprinting. Immunoblot validation. $^{13}C_6$-Glucose metabolic tracing analysis. Genetic interference of T-ALL cells by shRNA
Results: RPL10 R98S was associated with 798 transcriptional gene changes. We consulted iRegulon to predict transcriptional regulators that may cause this R98S linked transcriptome. Ikzf2 (Helios) was predicted to control upregulated transcripts and was overexpressed at mRNA and protein level. The NKX2 family was a predicted mediator for downregulated mRNAs, which is of interest as RPL10 R98S mutant T-ALL cases are known to be enriched for NKX2 translocations. The RPL10 R98S associated translatome highlighted phosphoserine phosphatase (Psph), showing a significant increase in all datasets with enhanced translational efficiency (3-fold) on top of increased mRNA expression (6-fold), leading to a 5-fold increase in protein expression by mass spectrometry. PSPH is an enzyme catalyzing the third and last step in *de novo* serine synthesis. The transcriptional and translational upregulation of PSPH were confirmed by increased mRNA and protein expression in Ba/F3 and Jurkat T-ALL RPL10 R98S cell models. In line with these findings, $^{13}C_6$-Glucose tracing revealed enhanced incorporation of ^{13}C labeled carbons into serine and glycine in our RPL10 R98S cell models, supporting increased branching towards *de novo* serine/glycine synthesis. High PSPH protein expression was observed in all T-ALL cases and was not restricted to R98S cases, while low PSPH levels were observed in CD34+ normal bone marrow cells and other leukemia's, such as pediatric AML. Besides the involvement of RPL10 R98S mutations in controlling PSPH expression, preliminary data revealed an association between high PSPH expression and occurrence of PHF6 mutations in pediatric T-ALL. Knockdown (KD) of PSPH expression using two different shRNAs in three different T-ALL cell lines revealed that PSPH was required for T-ALL cell proliferation. PSPH KD T-ALL cells were blocked in their cell cycle progression potential by reduced phosphorylation of CDK2 (Thr160) and increased p21/p27 protein expression. This was not merely an *in vitro* effect, as PSPH KD reduced *in vivo* T-ALL xenograft growth by suppression of engraftment to the bone marrow and spleen. In addition, elevated PSPH levels in T-ALL PDX samples were associated with enhanced blood plasma serine/glycine levels in mice. Interestingly, supplementation of serine and/or glycine increased the survival of bone marrow niche cell types. These data indicate that not only T-ALL cells themselves, but also their surrounding niche may benefit from enhanced *de novo* serine synthesis in T-ALL (Figure 1).

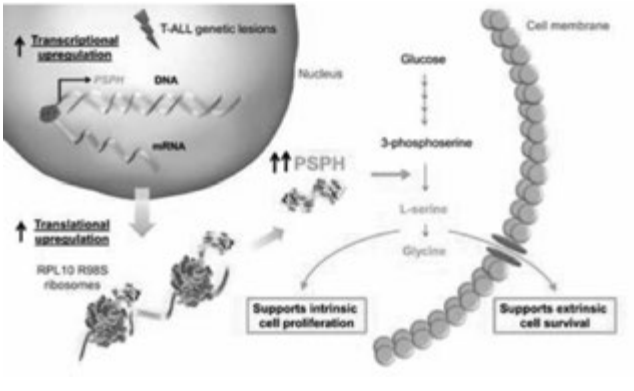

Figure 1.

Summary/Conclusion: Enhanced PSPH-driven serine/glycine synthesis is a common phenotype in T-ALL that can be mediated by specific mechanisms such as the RPL10 R98S mutant ribosome. Our results highlight the importance of PSPH for T-ALL proliferation and expansion capabilities, revealing for the first time a serine/glycine dependency of T-ALL cells.

PS898

MIR-497~195 CLUSTER IS ASSOCIATED WITH FAVORABLE OUTCOME AND HAS A TUMOR SUPPRESSIVE FUNCTION IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA

E. Boldrin[1,*], E. Gaffo[2], S. Demir[1], K.-M. Debatin[1], G. te Kronnie[3], S. Bortoluzzi[2], L.-H. Meyer[1]

[1]Department of Pediatrics and Adolescent Medicine, Ulm University Medical Center, Ulm, Germany, [2]Department of Molecular Medicine, [3]Department of Women's and Children's Health, Padua University, Padua, Italy

Background: Despite high rates of successful treatment of B-cell precursor acute lymphoblastic leukemia (BCP-ALL), relapse is still associated with poor outcome. Previously, we found that rapid engraftment of BCP-ALL patient cells transplanted into NOD/SCID mice (short time to leukemia, TTL^{short}) is indicative of early relapse, while slow engraftment (TTL^{long}) is associated with favorable outcome. MicroRNAs (miRNAs) are short non-coding regulatory RNAs, which are deregulated in different cancers.
Aims: In this study, we analyzed miRNA expression profiles in BCP-ALL associated with distinct engraftment and outcome and addressed the functional impact of identified candidate miRNAs on leukemia development.
Methods: MiRNA expression was investigated in 13 patient-derived xenograft (PDX) BCP-ALL samples by small RNA sequencing, validated by qRT-PCR and associated with outcome data. Identified candidate miRNAs were lentivirally overexpressed in BCP-ALL cell lines and PDX samples. *in vitro* proliferation was analyzed by flow cytometry (eFluor and cell counting). *In vivo* leukemia development was assessed upon transplantation of transduced cells into NOD/SCID mice compared to empty vector (EV) control.
Results: We identified 18 differentially expressed miRNAs in ALL samples associated with distinct engraftment and patient outcome. Among the most significantly regulated miRNAs, the miRNA cluster miR-497~195 was overexpressed in TTL^{long}/good outcome ALL. This finding was validated in a large cohort of N=57 BCP-ALL xenograft samples, identifying significantly lower miR-497 levels in poor outcome ALL as compared to good outcome ALL (U-test; p=0.016). In addition, increasing miR-497 levels were significantly associated with longer remission duration (N=11; Spearman r=0.68; p=0.025). Interestingly, the miR-497~195 cluster has previously been reported to have tumor suppressive functions in solid cancers, in line with the high miR-497~195 expression we identified in good outcome ALL. Moreover, upon analysis of putative targets and biological functions associated with miR-497~195, we found cellular proliferation as the most enriched biological process (DAVID, p=0.004), further emphasizing a tumor-suppressor function in ALL. To address the functional impact of miR-497~195 on leukemia proliferation and growth, miR-497~195 were stably overexpressed in the BCP-ALL cell line EU-3. No differences in cell death and *in vitro* proliferation were observed as compared to control EV transduced cells. However, lower leukemia loads were observed in recipient animals transplanted with miR-497~195 overexpressing EU-3 cells as compared to EV control (N=5 per group, U-test p=0,008). We further addressed the functional role of miR-497~195 in leukemia growth of PDX-ALL *in vivo* and stably overexpressed miR-497~195 in an ALL with short engraftment, poor patient outcome and low miR-497~195 expression. Upon transplantation, high leukemia infiltration of EV control cells was observed (49% BM, 60% spleen, mean, N=4 in two independent experiments), whereas miR-497~195 overexpressing cells showed a clear delay in leukemia engraftment and lower ALL infiltration in both, spleen and BM (below 1%), indicating that miR-497~195 negatively regulated ALL growth *in vivo*.
Summary/Conclusion: We found that high miR-497~195 expression is significantly associated with good patient outcome in BCP-ALL. Overexpression of miR-497~195 in cell line and primary PDX BCP-ALL led to clearly prolonged ALL development and reduced ALL infiltration *in vivo*, indicating a tumor suppressor role of miR-497~195 in BCP-ALL.

PS899

MICRORNA-142 IS AN ESSENTIAL REGULATOR OF B CELL DEVELOPMENT AND MALIGNANT TRANSFORMATION

W.-L. Wang[1,*], N. Magilnick[2], E. Reyes[3], M. Boldin[4]

[1]Molecular and Cellular Biology,Irell & Manella Graduate School of Biological Sciences-City of Hope, Los Angeles, [2]Irell & Manella Graduate School of Biological Sciences-City of Hope, Los Angels, [3]Beckman Research Institute of the City of Hope, [4]Irell & Manella Graduate School of Biological Sciences-City of Hope, Los Angeles, United States

Background: MicroRNA-142 (*miR-142*) is predominantly expressed in cells of hematopoietic origin and plays a crucial role in the regulation of both innate and adaptive immune responses. Accumulating evidence suggests that *miR-142* dysregulation is associated with hematological malignancies. Acute myeloid leukemia (AML) patients were shown to carry somatic *miR-142* mutations that occur in the seed sequence of *miR-142* and therefore interfere with target repression. In addition, approximately 20% of patients with diffuse large B cell lymphoma (DLBCL) display *miR-142* lesions. Nevertheless, the role of *miR-142* in aberrant leukocyte proliferation is poorly understood.
Aims: Our previous findings indicated that abrogation of *miR-142* expression in mice results in a significant expansion of the immature and mature B cell compartments in part due to the upregulation of B-cell activating factor receptor (*BAFF-R*), a *bona fide* target of miR-142. We therefore hypothesize that *miR-142* deficiency confers developmental and proliferative advantages to B cell progenitors and promotes malignant transformation.
Methods: To better understand the role of *miR-142* in B cell ontogenesis, we examined early B cell development in *miR-142*$^{-/-}$ mice using Hardy fraction analysis. Since genetic lesions that disrupt control of B cell development frequently drive malignant transformation of B cells, we wondered whether *miR-142* dysregulation contributes to proliferative B cell disorders. To address this question, we bred *miR-142*$^{-/-}$ mice with Eμ-myc transgenic mice, which spontaneously develop a mix of precursor B cell lymphoblastic leukemia and mature B cell lymphoma.
Results: Here we show that *miR-142* deletion results in a significant increase in the frequency of pro-B, large pre-B and immature B cells (Fractions B, C and E), while the pre-pro-B cell population (Fraction A) decreased. In addition, *miR-142*-deficient pro-B cells displayed a significant proliferative advantage over the wild-type cells in *in vitro* differentiation assay in the presence of IL-7. Our data linked accumulation of pro-B and large pre-B cells in *miR-142*$^{-/-}$ bone marrow to an increase in their survival capacity. Furthermore, we found that *miR-142* haploinsufficiency dramatically accelerated development of leukemia/lymphoma and significantly shortened survival of Eμ-myc transgenic mice. We are currently testing a hypothesis that *miR-142* exerts its tumor suppressor activity in B cells by controlling BAFF-R and IL-7R signaling. This notion is supported by our *in vitro* observations that *miR-142*-deficient B cells display more robust proliferation than wild-type cells in response to BAFF or IL-7 treatments.
Summary/Conclusion: Collectively, our results establish *miR-142* as an essential molecular brake on B cell development and malignancy. Besides, it also demonstrates a great potential of using this miRNA as a biomarker to classify patients with dysregulated *miR-142* expression, and then corrects *miR-142*-directed target repression in malignant B cells e.g. BAFF-R signaling.

Background: T-cell Acute Lymphoblastic Leukemia (T-ALL) is caused by malignant transformation of T cells showing differentiation arrest and uncontrolled proliferation. The checkpoints during T-cell development are dominated by pre-T-cell receptor (pTCR) for β-selection and T-cell receptor (TCR) for positive/negative selection. Gene lesions with proximity to these checkpoints are found in T-ALL such as *NOTCH, FBXW7, PTEN* and *NRAS*. As shown in B-cell Precursor Leukemia, kinases of the pre-B-cell receptor signaling complex (SYK and BTK) have been validated as drug targets, but whether critical components of the pTCR/TCR signaling such as LCK or ZAP70 play a similar role in T-ALL remains unclear. LCK (lymphocyte-specific kinase) is a central molecule in pTCR/TCR signaling transduction. The important role for LCK has been shown in Chronic Lymphoblastic Leukemia, however, the role of LCK in T-ALL has not been studied.
Aims: To investigate the importance of pTCR/TCR complex for T-ALL cell proliferation and survival.
Methods: We performed limited screens targeting six components of the pTCR/TCR signaling complex *in vitro* and *in vivo* in 4 T-ALL cell lines

and 2 T-ALL patient-derived xenografts (PDXs). To validate the screening results we conducted gene knockdown experiments in T-ALL cell lines using GFP-expressing lentiviral shRNA vectors and evaluated cell proliferation by competitive assays *in vitro* and *in vivo*. The activation and expression of LCK were determined in 11 T-ALL cell lines and 10 PDXs by qPCR, western blotting and Phosflow. The kinase activity of LCK was abrogated using Dasatinib. Synergism between Dexamethasone and Dasatinib was evaluated by drug matrix assays. The *ex-vivo* expansion of PDXs was achieved by co-culture with OP9-DL1 feeder cells and proliferation was assessed by Cell Trace Violet.

Results: A targeted *in vitro* and *in vivo* shRNA screen targeting central components of the pTCR/TCR signalling complex (*PTCRA*, *CD3ε*, *LCK*, *FYN, ZAP70* and *LAT*) in T-ALL cell lines and PDXs identified LCK to be crucial for T-ALL maintenance and engraftment. Knockdown of LCK in SUP-T1, CUTLL1 and MOLT4 cells revealed a significant loss of at least 50% of GFP+/*LCK* shRNA transduced cells over a time period of 2-3 weeks. This was also confirmed *in vivo* in competitive assays with MOLT4 cells showing a growth advantage of control shNTC cells over LCK knockdown cells in bone marrow, spleen and liver. Mechanistic analyses indicate that knockdown or inhibition of LCK by Dasatinib impairs cell proliferation by inducing G1/G0 arrest in both T-ALL cell lines and PDXs, but has little effect on the induction of cell death. The sensitivity of T-ALL cell lines towards Dasatinib seems to correlate positively with activated LCK (LCK p-Y394). Moreover, *LCK* knockdown significantly sensitizes T-ALL cells to Dexamethasone (Dex) and strong synergistic lethal effects between Dex and Dasatinib have been observed in various T-ALL cell lines and PDXs. Importantly, both Dex-sensitive and Dex-resistant T-ALLs are highly sensitive to Dex/Dasatinib combination treatment. To evaluate this further we currently perform a randomized phase- like mini-trial in NSG mice with 10 PDXs comparing four treatment arms including control, Dex, Dasatinib and combination.

Summary/Conclusion: Overall, our data demonstrate that LCK plays a critical role in T-ALL cell proliferation and engraftment. LCK inhibition with Dasatinib, in conjunction with Dex, reverses glucocorticoid resistance and induces cell death. The Dex/Dasatinib combination might provide a novel treatment strategy for refractory and relapsed T-ALL patients.

Background: In B-lineage acute lymphoblastic leukemia (B-ALL) lacking the major fusion genes (i.e. *BCR-ABL1*, *ETV6-RUNX1*, *TCF3-PBX1* and r-*KTM2A)*, defined B-NEG, the outcome is negatively influenced by the *BCR-ABL1*-like profile, *CRLF2* overexpression, JAK/STAT and RAS pathway mutations. However, their prognostic value in the setting of a pediatric-oriented, Minimal Residual Disease (MRD)-driven trial for adult ALL has not been fully dissected.

Aims: To evaluate - within B-NEG ALL patients enrolled in the GIMEMA LAL1913 front-line protocol for adult Ph-negative ALL - the prognostic role of: i) *BCR-ABL1*-like profile, ii) *CRLF2* overexpression, iii) RAS and JAK/STAT pathway mutations.

Methods: Within a total of 120 B-NEG ALL patients enrolled in the GIMEMA LAL1913 protocol, 92 (median age 38.5 years, range 18.1-64.6) were screened for the *BCR/ABL1*-like profile (Chiaretti *et al*., BJH, in press), *CRLF2* expression levels (Chiaretti *et al*., Leuk Res, 2016), JAK/STAT (*JAK1*, *JAK2*, *JAK3*, *IL7R*, *CRLF2*) and RAS pathway (*FLT3*, *NRAS*, *KRAS*, *PTPN11*) mutations, the latter by Truseq custom amplicon kit and Illumina MiSeq (CA, USA). Molecular markers were correlated with clinical variables (age, gender, WBC count), complete remission (CR) achievement, disease-free and event-free survival (DFS, EFS) at 12 months.

Results: By applying the *BCR/ABL1*-like predictor, we identified 25 (27.2%) *BCR/ABL1*-like cases. *CRLF2* overexpression was found in 19 cases (20.6%) and was associated with a *BCR/ABL1*-like signature (40% *BCR/ABL1*-like *vs* 13.4% of non-*BCR/ABL1*-like ALL, p=0.008). Similarly, JAK/STAT pathway mutations, detected in 14 (15.9%) patients, were more frequent in *BCR/ABL1*-like (33.3%) than in non-*BCR/ABL1*-like cases (11.5%) (p=0.035). RAS pathway mutations were documented in 43 (48.8%) cases, with a higher incidence in non-*BCR/ABL1*-like cases (51.9%) than *BCR/ABL1*-like (33.3%) cases. No association was found between *BCR/ABL1*-like signature, *CRLF2* overexpression, JAK/STAT or RAS mutations and clinical correlates. Among the molecular markers evaluated, only the *BCR/ABL1*-like profile and RAS mutations impacted on outcome. Indeed, there was a trend towards an inferior CR rate in *BCR/ABL1*-like compared to non-*BCR/ABL1*-like cases (78.3% *vs* 90.6%). Consistently, survival analyses showed that *BCR/ABL1*-like cases had a significantly inferior EFS and DFS than non-*BCR/ABL1*-like (49.2% *vs* 74.4%, p=0.02 - Figure 1 - and 60.3% *vs* 82.6%, p=0.047, respectively). Clonal RAS pathway mutations did not impact on CR achievement, whereas they affected DFS: RAS-M cases had a significantly lower DFS than RAS-WT (58.6% *vs* 85%, p=0.04); subclonal (VAF <20%) RAS mutations did not influence patients' outcome. In a multivariate model for EFS, the only statistically significant variables were the *BCR/ABL1*-like profile (p=0.017, HR=0.4 CI 95% 0.2-0.85) and age (p=0.003, HR=1.03, CI 95% 1.01-1.06). The impact of the *BCR/ABL1*-like profile on MRD achievement will be presented.

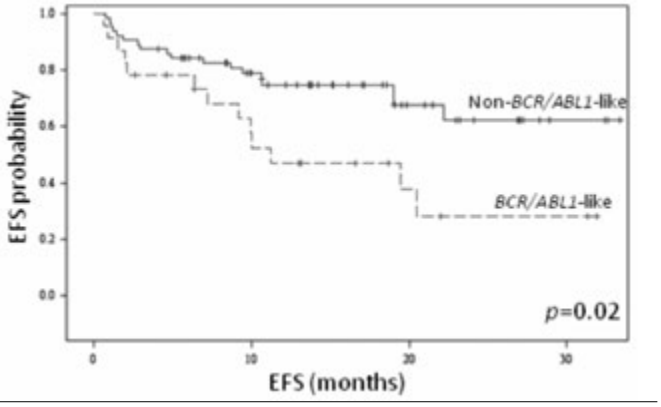

Figure 1.

Summary/Conclusion: In this first analysis of the GIMEMA LAL1913 protocol, our model identified as *BCR/ABL1*-like 27.2% of B-NEG ALL cases and showed that also in a pediatric-oriented and MRD-driven clinical trial adult *BCR/ABL1*-like ALL patients are characterized by a lower CR rate, EFS and DFS. RAS pathway mutations also negatively influenced DFS. In multivariate analysis, only the *BCR/ABL1*-like profile retained statistical significance. These findings further underline the need to identify *BCR/ABL1*-like ALL cases at presentation in order to allow a proper risk stratification and that treatment of this unfavorable subset of patients should include novel strategies upfront.

Background: Genetic profiles of pediatric T-cell acute lymphoblastic leukemia (T-ALL) have been well studied and we reported recurrent *SPI1* fusions associated with dismal prognosis. However, the epigenetic profiles and their potential contribution to clinicopathological features of T-ALL remain largely elusive.
Aims: To describe epigenetic landscape of T-ALL, we performed methylation array analysis.
Methods: Seventy-nine pediatric T-ALL samples mainly obtained from Tokyo Children's Cancer Study Group (TCCSG) and Japan Association of Childhood Leukemia Study (JACLS) including 7 cases with *SPI1* fusions were analyzed using Illumina HumanMethylation EPIC array, and conducted combined analysis whole transcriptome sequencing (WTS) and targeted-capture sequencing for 158 ALL-related genes.
Results: After normalization, 939 probes were selected to identify the most variable methylated probes. Unsupervised consensus clustering clearly identified 4 distinct sample clusters, characterized by *TAL1* fusions/high expression with intermediate methylation (M1 cluster; n=39), high TLX/HOX expression with intermediate methylation (M2 cluster; n=20), high TLX//HOX expression with high methylation (M3 cluster; n=11), and *SPI1* fusions/high expression with low methylation (M4 cluster; n=9), respectively. In M1 cluster, *PTEN* alterations were especially enriched, indicating a crucial role of PI3K-AKT pathway in this cluster. In M2 cluster, genes related to chromatin remodeling and JAK-STAT pathway were frequently mutated. *DEPTOR* related to activation of PI3K-AKT1 pathway was highly expressed. Mutation status of M3 cluster was similar to the M2 cluster, and frequent mutations of epigenetic regulators and JAK-STAT related genes were also observed in M3. Intriguingly, all *SPI1* fusion cases were classified into M4 cluster with 2 *SPI1* highly expressed cases without *SPI1* fusions. In M4 cluster, *SPI1* and *RASGRP4* were differentially expressed, and significant enrichment in RAS and NF-kB pathways was observed. Importantly, patients in M4 cluster showed significantly poor prognosis (Log-rank $p=4.4\times10^{-7}$). Next, we investigated cell surface markers of each methylation cluster. Cases in M1 cluster exhibited a late cortical thymocyte profile after T-cell receptor gene rearrangement (CD4+CD8+TCRαβ+), whereas most cases in M3 cluster did not show TCRαβ expression (CD4+CD8+TCRαβ–). In M2 and M4 clusters, most cases showed an uncommitted double negative T-cell profile (CD4–CD8–Myeloid+). Furthermore, most cases in M2 cluster represented more early stage of development (M2; CD1a–, M4; CD1a+). Finally, we analyzed CpG island methylator phenotype (CIMP) status of our cohort using previously reported 450K CIMP panel (1176 probes). As previously reported, two distinct CIMP groups were identified. Cases in M1 and M4 clusters were classified as CIMP–, exhibiting a similar methylation profile to normal CD3+ T-cells. In contrast, cases in M2 and M3 clusters were classified as CIMP+. Importantly, patients with a CIMP– profile had an significantly inferior prognosis (Log-rank $p=8.0\times10^{-4}$).
Summary/Conclusion: Based on DNA methylation profiles, pediatric T-ALL is clustered into 4 distinct subtypes, which exhibited remarkable correlation with genetic signatures, expression features, and clinical outcomes as well as profiles of T-cell development. Our results suggested that the biological phenotype of T-ALL is mediated by both genetic and epigenetic regulations, and explorations for aberrant DNA methylation along with genetic alterations might be helpful for a new therapeutic strategy for T-ALL.

PS903

THE PHILADELPHIA-LIKE SUBTYPE IN CHILDREN WITH FIRST RELAPSE OF B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA: A STUDY OF THE GERMAN ALL-REZ BFM 2002 TRIAL

M. Pogodzinski[1,*], J. Toedling[1], A. von Stackelberg[1], C. Eckert[1], R. Kirschner-Schwabe[1]

[1]Department of Pediatric Oncology and Hematology, Charite - Universitaetsmedizin, Berlin, Germany

Background: Philadelphia-like acute lymphoblastic leukemia (Ph-like ALL) is characterized by a gene expression profile similar to that of Philadelphia chromosome positive (*BCR/ABL* rearranged) ALL. Ph-like ALL lacks the *BCR/ABL* rearrangement, but frequently harbors other kinase activating gene fusions that can be targeted by kinase inhibitor treatment. Patients with Ph-like ALL have an elevated risk of relapse after primary treatment. However, the frequency of Ph-like ALL in children with relapsed ALL and the outcome of this subgroup after relapse treatment is currently unknown.
Aims: We investigated the frequency, clinical presentation and outcome of Ph-like ALL in relapsed patients of the German ALL-REZ BFM 2002 relapse trial to determine the eligibility of this subgroup for kinase inhibitor treatment during second-line therapy.
Methods: We performed gene expression profiling of 97 leukemic samples from children with first bone marrow relapse of B-cell precursor ALL by Affymetrix HG-U133 Plus 2.0 microarrays. For the identification of Ph-like cases, we used the previously established *Prediction Analysis of Microarrays* (PAM) method.
Results: Our study cohort comprised 11 *BCR/ABL*-positive and 86 *BCR/ABL*-negative samples. Within the BCR/ABL-negative group, 26 samples had defined cytogenetic aberrations (*ETV6-RUNX1, KDMT2A*-rearrangement, hyper- or hypodiploidy) that are in large parts mutually exclusive with the Ph-like subtype. Therefore, we used this subgroup (hereafter referred to as cytogenetic group) together with the *BCR/ABL*-positive group to train a *BCR/ABL* classifier. The classifier contained 351 genes and achieved a prediction accuracy of 100% for *BCR/ABL*-positive ALL. As a proof of concept, the same approach was applied to a published data set from primary ALL (GSE79533), where the classifier also reached a prediction accuracy of 100% and contained 732 genes. Next, we used the BCR/ABL classifier built on our ALL relapse training set to predict Ph-like ALL in the remaining 60 ALL relapse samples (test set). Using a PAM coefficient cut-off of ≥85%, the classifier predicted 31 of 60 relapse samples to be highly similar to *BCR/ABL* positive ALL, that is Ph-like ALL. In agreement with primary ALL, relapses of the Ph-like subtype were associated with an increased rate of *IKZF1* deletions (65%, p=0.004) and *JAK* mutations (*JAK2* and *JAK3*, 30%, p=0.006) and with an increased proportion of *CRLF2* high expressing samples (36%, p=0.004) compared to other cases of the study cohort. Interestingly, the rate of deletions in the PAR1 region leading to the kinase activating P2RY8-CRLF2 fusion was only slightly increased in our relapsed Ph-like ALL patients (13.3%, non-significant). A more in depth genetic analysis of the Ph-like relapses is currently ongoing. With respect to their clinical presentation, relapsed ALL patients with the Ph-like subtype comprised a heterogeneous group that did not significantly differ from the total ALL-REZ BFM 2002 trial cohort. Similarly, the probability of event-free survival (pEFS) of relapsed Ph-like patients was highly similar to the overall pEFS of the total ALL-REZ BFM 2002 trial cohort (pEFS 0.452±0.089 vs. 0.517±0.022; p=0.368).
Summary/Conclusion: In conclusion, we found that the Ph-like subtype is present in more than 30% (31/97) of children with relapsed B-cell precursor ALL. In contrast to primary ALL, the Ph-like subtype is not linked to inferior prognosis after relapse treatment. However, tyrosine kinase inhibitor treatment may still improve the currently intermediate outcome of relapsed Ph-like ALL patients.

PS904

HUMAN T CELL ACUTE LYMPHOBLASTIC LEUKEMIA DEVELOPS HYPOXIA-RELATED CHEMORESISTANCE THROUGH HIF1A AND MTOR PATHWAY INTERACTIONS

L. Fahy[1,*], J. Calvo[1], R. Kulkarni[1], I. Naguibneva[1], J. Rucci[1], S. Chabi[1], M.-L. Arcangeli[1], F. Pflumio[1], B. Uzan[1]

[1]CEA/UMR967, Fontenay-aux-Roses, France

Background: T cell acute lymphoblastic leukemia (T-ALL) is a malignant hematological disorder characterized by an increased proliferation of T lymphocytes precursors unable to complete their maturation. These leukemic cells accumulate in bone marrow, blood, thymus and/or lymph nodes and interfere with the production and function of normal hematopoietic cells. T-ALL treatment is based on intensive chemotherapy, which is effective in 80% of cases in children. However, children with relapse have a very poor prognosis as well as current treatments have significant side effects that should ideally be reduced. Besides the involvement of intracellular oncogenic pathways in leukemic development, extracellular signals from the microenvironment also participate in the development and progression of T-ALL. These data highlight the importance of targeting tumor cells as well as their environment to achieve sustainable results in patients. Bone marrow microenvironment, a crucial site of propagation and maintenance of leukemia, is hypoxic with oxygen levels varying from 0.1 to 5%.
Aims: We studied the consequences of a hypoxic environment on T-ALL growth and chemoresistance.
Methods: Growth, apoptosis, cell cycle, chemoresistance and graft capacity in NSG mice were quantified using human pediatric T-ALL cells cultured in

normoxia (21% O_2) or in hypoxia (3.5% or 1% O_2). Hypoxia target gene expressions were measured in T-ALL cells and HIF1α knock down (KD) was obtained using a lentiviral vector encoding shRNA specific to HIF1α (shHIF1α). Activation of mTOR and its direct targets (S6K and 4EBP1) was measured by flow cytometry. Efficiency of combining drugs with Rapamycine was tested on the growth and chemoresistance of T-ALL.
Results: We observed that hypoxia inhibits T-ALL cell growth by slowing down cell cycle progression, decreasing their metabolism and increasing apoptosis. Nevertheless leukemic cells recovered from hypoxia cultures keep their ability to propagate leukemia after transplantation into immune deficient NSG mice. In addition, T-ALL cells treated with vincristine, dexamethasone or cytarabine (drugs commonly used in T-ALL treatment) *in vitro* are better protected in hypoxia than in normoxia as they maintain their growth *in vitro* and are able to initiate leukemia *in vivo*. As expected HIF1α signaling pathway is activated in hypoxic T-ALL cells whereas HIF1α and hypoxia target gene expressions (*VEGF*, *Glut3* and *CXCR4*) are decreased in shHIF1α/T-ALL cells cultured in hypoxia. Functionally HIF1α KD in T-ALL reverses the drug resistance observed in hypoxia. Because mTOR is a potential therapeutic target in aggressive T-ALL, and as mTOR is indirectly regulated by HIF1α, we measured mTOR pathway activation. We observed that mTOR phosphorylation is decreased in T-ALL cells in hypoxia compared to normoxia. Importantly treatment of T-ALL with the mTOR inhibitor Rapamycine during cultures in normoxia mimicked the chemoresistance effects observed in hypoxia and drug treated T-ALL cells are more chemoresistant in hypoxia with Rapamycine than without. These results highlight a mechanistic loop between HIF1α and mTOR in hypoxia-related T-ALL chemoresistance.
Summary/Conclusion: Our results show that hypoxic niches may play a protective role during T-ALL treatment and induce chemoresistance. Inhibition of HIF1α and/or activation of the mTOR pathway would help abolishing the chemoresistance. A better understanding of the signaling pathways involved in T-ALL chemoresistance will undoubtedly allow more efficient therapeutic targeting of chemoresistant cells.

PS905

METABOLOMIC ANALYSIS REVEALS CEREBROSPINAL FLUID CREATINE AND XANTHINE CONCENTRATIONS AS POTENTIAL BIOMARKERS FOR CENTRAL NERVOUS SYSTEM INVOLVEMENT IN ACUTE LYMPHOBLASTIC LEUKAEMIA

A. Cousins[1,*], D. Sumpton[2], G. MacKay[2], J.H.M. Däbritz[2], A. Michie[1], E. Gottlieb[2], C. Halsey[1]

[1]Institute of Cancer Sciences, University of Glasgow, [2]Cancer Research UK Beatson Institute, Glasgow, United Kingdom

Background: Prevention and treatment of central nervous system (CNS) relapse remains a major challenge in childhood acute lymphoblastic leukaemia (ALL). The ability to colonise the leptomeninges (the site of CNS relapse) appears to be a common feature of pre-B ALL cells, and without CNS-directed therapy up to 80% of children will experience CNS relapse. The standard test for CNS involvement in ALL– cerebrospinal fluid (CSF) cytology – has poor sensitivity. Better tests for detecting and quantifying disease in the CNS are needed to assess individual risk of CNS relapse to enable accurate risk-adapted CNS-directed therapy. ALL cells in the CNS reside in a normally hypocellular environment, bathed in nutrient-poor CSF. We hypothesised that the presence of leukaemic cells in this environment would cause detectable alterations in the metabolome of CSF, creating opportunities for identification of metabolic biomarkers of CNS disease in ALL.
Aims: To detect metabolic signatures of leptomeningeal ALL using metabolomic analysis of CSF .
Methods: Metabolomics using high-performance liquid chromatography - mass spectrometry (LC-MS) was carried out on CSF of 20 children at pre-B ALL diagnosis (i.e. with high disease burden and prior to CNS-directed therapy) and while on maintenance chemotherapy (in complete remission, n=19), and of 17 unmatched control CSF samples (from patients investigated for possible neurological illnesses with negative test results). Promising compounds with differences in abundance between groups were confirmed with standards, and validated using LC-MS analysis of CSF and plasma from a human leukaemia xenotransplantation model in NSG mice, and of CSF from children at CNS relapse. LC-MS analysis was also performed on the intracellular matrix of human ALL cells retrieved from the CNS and spleen in the xenotransplantation model.
Results: Untargeted metabolomic analysis of CSF shows clear differences between children with ALL (either at diagnosis or on maintenance therapy) and non-ALL controls, and between children with ALL at diagnosis and the same children on maintenance therapy. Xanthine and creatine abundances were significantly different in children with ALL at diagnosis (xanthine 5-fold higher, creatine 1/3 lower at diagnosis than either patients on maintenance or non-ALL controls, $p<0.0001$). There was no correlation between allopurinol therapy or CSF allopurinol concentration and CSF xanthine abundance. In a murine xenotranplantation model of human leukaemia we detected a clear reduction in CSF creatine in the presence of CNS leukaemia (1/3 lower in leukaemic *vs.* control CSF, $p=0.0056$) but no change in xanthine concentration. Analysis of leukaemic cells retrieved from the CNS and spleens of these mice showed increased intracellular creatine in CNS ALL (9-fold higher, $p=0.02$). In our analysis of CSF from 4 children at CNS relapse, there was a reduction in creatine in the sample closest to relapse in 3 children, but a wide baseline creatine concentration. There was a clear increase in xanthine in the CSF in 3 children at the time of CNS relapse.
Summary/Conclusion: LC-MS metabolomic analysis is a powerful tool for investigating clinical samples. We identified clear changes in the CSF metabolome related to both ALL and ALL therapy, and present two new potential biomarkers for the presence of CNS ALL. Prospective analyses in independent cohorts are required to determine the clinical utility of these novel biomarkers for prediction of CNS relapse risk.

Unit, Karolinska University Hospital, Stockholm, [8]Dept. of Medical Biosciences, Umeå University, Umeå, [9]Dept. of Women's and Children's Health, Pediatric Oncology, Uppsala , [10]Dept. of Medical Biochemistry and Biophysics, Karolinska Institute, Stockholm, Sweden

Background: Acute lymphoblastic leukemia (ALL) is the most frequent pediatric cancer. ALL originates from the malignant transformation of B- or T-cell lymphocyte progenitors into leukemic cells. ALL cells are characterized by large-scale chromosomal aberrations that define genetic subtypes of the ALL patients. Relapsed ALL presents a survival rate of ~45% and remains one of the leading causes of cancer-related death in children. Our previous results of whole genomes (WGS) and transcriptomes (RNA-seq) of diagnostic ALL samples (Lindqvist *et al*., 2015) and targeted sequencing of 872 cancer genes of diagnostic and relapse ALL samples (Lindqvist *et al*., 2016) revealed KMT2D and ATRX as novel putative driver genes in ALL, and EP300, ARID1A and SH2B3 as novel relapse-associated genes.
Aims: To determine clonal heterogeneity and clonal evolution patterns in ALL patients from diagnosis to relapse, using whole-genome sequencing, transcriptome sequencing and "linked-read" single-cell RNA sequencing and to increase the understanding of the molecular mechanisms that lead to relapse in pediatric ALL.
Methods: Here, we have performed WGS and RNA-seq of samples collected at diagnosis and relapse and at remission of ALL from 29 patients of six different BCP-ALL subtypes and T-ALL. For 9 of the patients, relapse samples at two time points were sequenced. RNA-seq will be used to determine the expression of somatic mutation in protein-coding regions and non-coding regions regulating gene expression. To resolve large, complex structural rearrangements in the ALL cells that remain undetected in the WGS data, we will use "linked-read" sequencing (Chromium, 10xGenomics) for genome-scale phasing (haplotyping).
Results: We have found 10 driver genes in our diagnostic cohort including 7 previously known in ALL, such as *NRAS, KRAS, ETV6, PTPN11, PTEN, FBXW7, SH2B3* and three that appear to be novel candidate driver genes in ALL. In the current study, we identified somatic driver mutations in coding and non-coding regions of the ALL genomes, aided by recently established genomic resources with data on functional genomic regions in relevant cell types, including ALL cells.
Summary/Conclusion: By combining the results from WGS, RNAseq and SNP-genotyping data for each individual, our results will provide novel insight into the mechanisms such as clonal competition and evolutionary adaptation that govern the treatment resistance in ALL.

Background: Structural chromosomal rearrangements that may lead to in-frame gene-fusions represent a leading source of information for diagnosis, risk stratification, and prognosis in pediatric acute lymphoblastic leukemia (ALL). The information on genetic variation from standard whole-genome sequencing (WGS) remains incomplete due to the inability of short sequence reads to accurately detect or phase large-scale chromosomal aberrations to the individual chromosome of each homologous pair in diploid ALL genomes.
Aims: To evalute "linked-read" WGS (lrWGS) for the detection of pathogenic structural aberrations in a set of well-characterized patients with pediatric ALL.
Methods: By sequencing library preparation from single DNA molecules (10X Genomics) in combination with short-read WGS (Illumina) we performed "linked-read" WGS (lrWGS) for unbiased detection of somatic chromosomal rearrangements in an ALL cell line (REH) and primary samples of varying DNA quality from 12 patients diagnosed with ALL. By analysis of the data from lrWGS we assessed the effect of input DNA quality on phased haplotype block size and the detectability of copy number aberrations (CNAs) and structural variants (SVs).
Results: We successfully detected all known pathogenic variants in the 13 analyzed DNA samples using lrWGS. By analysis of high-molecular weight DNA (~127 Kb average size) we detected phased haplotype blocks spanning over 18 megabases of genomic DNA with up to 99% of phased SNPs at a WGS coverage over 20x. Biobanked DNA isolated by standard column-based extraction methods (~56 Kb average size) was sufficient to detect chromosomal rearrangements associated with ALL pathogenesis even at as low as 10x sequencing coverage, as well as aneuploidy assessment comparable to that of microarrays. The genomic breakpoints of two balanced translocations involving the *ZNF384* gene were detected at single base-pair resolution. With use of haplotype information from the linked-reads, we also identified previously unknown structural variants, such as compound heterozygous deletions of *ERG* in a patient with the *DUX4-IGH* fusion gene.
Summary/Conclusion: Linked-read WGS allows detection of pathogenic variants in ALL genomes at a resolution beyond that of traditional karyotyping or short-read WGS. Refined accuracy at ALL diagnosis will allow more precise risk stratification of the ALL patients and will potentially translate into more effective therapy with less adverse drug effects in the future.

PS908

AMPLICON-BASED NGS AS A TOOL FOR THE IDENTIFICATION OF NEW MARKERS WITH POOR PROGNOSIS IN B-ALL

Background: B-cell precursor Acute Lymphoblastic Leukemia (B-ALL) is a neoplasm that can present both children and adults, being more frequent in childhood (80%). Despite the increase in the survival rate in patients, it is necessary to identify new markers that explain the cases with relapse or that do not respond to treatment.
Aims: Evaluation of an amplicon-based next-generation sequencing panel for detection of mutations in ALL patients.
Methods: A total of 116 samples with B-ALL were analyzed at the time of diagnosis or prior to treatment. All patients were treated according to PETHEMA and SEHOP protocols and minimal residual disease (MRD) data were available in more than 70% of cases. Sequencing was carried out by means of a panel of amplicons (Illumina) that allowed the analysis of 52 genes with importance in B-ALL.
Results: 1) A mutation rate of 84.4% was identified. The genes most frequently mutated were: *KRAS* (17.5%), *NRAS* (14.6%), *PTPN11* and *STAG2* (10.7%) and *JAK2* and *JAK3* (9.7%). There were differences between children and adults. In children, the most recurrent mutations were in *KRAS* (28.3%) and *NRAS* (19.6%), *JAK3* and *STAG2* (13%). While in adults the most frequently mutated genes were *TP53* (14%), *JAK2* (12.3%), *NRAS*, *PAX5* and *PTPN11* (10.5%). 2) Mutations in *RAS* pathway were frequently detected in *BCR-ABL1* negative cases (p=0.001). The univariate survival analysis in whole B-ALL cohort showed that mutations in *TP53* were associated with lower OS (p=0.001), EFS (p=0,005) and RFS (p=0.001), *JAK2* mutations with a decreased EFS (p=0.034) and RFS (p=0.017), NF1 mutations were associated with lower OS (p=0.006), EFS (p=0.017) and RFS (p=0.017), while mutations in epigenetic regulators and chromatin structure modifiers (*SETD2*, *PHF6*, *IDH2*, *EZH2* and *CREBBP*) showed a lower OS (p=0.05) (Figure 1). In the multivariate analysis of the whole B-ALL cohort, mutations in *NF1* were an independent risk factor associated with shorter OS (HR=11.583; p=0.015), EFS (HR=11.310; p=0.006) and RFS (HR=24.718; p=0.002). Mutations *TP53* and *JAK2* were an independent risk factor associated with shorter EFS (HR=10.439; p=0.047) and RFS (HR=4.598; p=0.018) and mutations in *TP53* were an independent risk factor associated with shorter RFS (HR=13.830; p=0.034).

Figure 1.

Summary/Conclusion: The mutations in *NF1*, *JAK2* and *TP53* could be considered as novel biomarkers associated with poor prognostic in B-ALL patients.

PS909

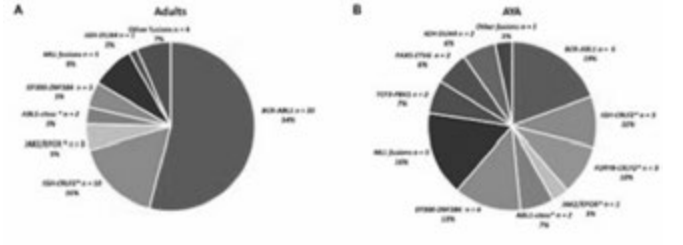
EXPLORING THE GENOMIC DIVERSITY OF AYA AND ADULT HIGH-RISK B-ALL CASES BY MRNA SEQUENCING

S.L. Heatley[1,2,3,4,*], B. Mayne[1], B.J. McClure[1,2], C. Kok[1,2], T. Sadras[1,2], P. Dang[1], M. Osborn[4,5,6], T. Revesz[4,5], N. Shanmuganathan[1,6], T.P. Hughes[1,2,6,7], D.T. Yeung[1,2,6,7], D.L. White[1,2,4,7,8]

[1]Cancer Theme, South Australian Health & Medical Research Institute, [2]Faculty of Health & Medical Science, University of Adelaide, Adelaide, [3]The Kids' Cancer Project, Sydney, [4]Australian Children's Haematology/Oncology Group , Melbourne, [5]Dept of Haematology, Women's & Children's Hospital, [6]Dept of Haematology, Royal Adelaide Hospital, Adelaide, [7]Australasian Leukaemia & Lymphoma Group, [8]Australian Genomics Health Alliance, Melbourne, Australia

Background: Acute lymphoblastic leukemia (ALL) remains one of the most challenging malignancies in adults, with more than 60% of patients suffering disease relapse. A comprehensive understanding of the genomic factors that influence leukaemogenesis and disease relapse is required to both improve outcomes in high-risk subtypes and guide the development of new therapeutic approaches.

Aims: The aim of this study was to identify the frequency of genomic alterations in adolescent/young adults (AYA) (16-39 years) and adults (>40 years) with B-ALL.
Methods: Samples from 63 AYA (ranged between 16-39 years, with a median age of 21) and 63 adult patients (40-88 years, median age of 59) underwent mRNA sequencing (mRNAseq). The cohort also contained Philadelphia (Ph)+ samples (n=33 adults, n = 6 AYA) but these were not sequenced. Fusions were identified using FusionCatcher, SOAPfuse and JAFFA. Variants were called using GATK HaplotypeCaller and underwent several filtering steps to eliminate possible germline alterations and common SNPs.
Results: Structural genomic abnormalities were identified in 112/126 (89%) samples by mRNAseq, including a number of clinically relevant, known oncogenic lesions associated with high-risk malignancy. Many of these lesions are considered to be Ph-like (15/63, 24% of adults and 9/63, 14% of AYA), with the majority of these being *CRLF2* rearrangements (*CRLF2*r) (n = 16). Together with Ph+ ALL, these two subsets define the bulk of the adult cohort. *MLL* rearrangements were also found in both AYA (n=5) and adults (n=5). Other recurrent high-risk lesions include variants identified in *NRAS, KRAS, PTPN11, NF1, TP53, JAK2, CSF1R, RB1, CREBBP, RUNX1, FLT3, NOTCH1* and *NOTCH2* with an average of 1-2 variants per patient and slightly more occurrences found in adults (n=90) than AYA (n=73). Broadly, many of these lesions inactivate tumor suppressor genes or activate kinase, cytokine or other pathways likely to be involved in leukemogenesis. Of significance, 21/63 (33%) AYA patients harbored *RAS* mutations compared to 10/63 (16%) adults (p=0.037). *TP53* mutations were found in only 2/63 (3%) AYA yet were present in 13/63 (21%) adults (p=0.004). Somatic *TP53* mutations have been reported in hypodiploid ALL patients and all *TP53* mutations reported here occurred within the DNA-binding domain, critical to biological activity. Interestingly, in patients with *TP53* mutations no concomitant gene fusions could be identified. While Ph+ and some Ph-like ALL patients may benefit from adding appropriate tyrosine kinase inhibitors to their chemotherapy, for many of the other gene fusions and alterations identified here, suitable targeted agents may not yet be clinically available (Figure 1).



Gene fusions identified in adults and AYA B-ALL patients. Fusions found in (A) adults and (B) AYA by mRNA seq and including Ph+ patients. Fusions that may be considered as Ph-like ALL are indicated by a *. Other fusions in adults included *TCF3-PBX1, IGH-MYC, TRIM24-FGFR1* and *DDX3-CXCR4* (one each) and in AYA 1 x *TCF3-MKNK2*.

Figure 1.

Summary/Conclusion: In this adult/AYA cohort we demonstrate that the majority of high-risk B-ALL cases harbor rearrangements or mutations in genes associated with malignant transformation. Importantly, Ph+ and Ph-like ALL, both high-risk subtypes, represent the majority of adult B-ALL cases. In the remaining patients, significant associations were found with *RAS* mutations in AYA and *TP53* mutations in adults. Furthermore, mRNAseq may eliminate discrepancies seen with different algorithms currently used to identify Ph-like ALL and may provide a deeper understanding of the genomic alterations associated with high-risk B-ALL. The increasing genomic complexity of high-risk B-ALL highlights the need for continued efforts to identify appropriate targeted therapies.

PS910

FUNCTIONAL CHARACTERIZATION OF ABERRANT FAT1 EXPRESSION IN T-ALL

S. Liebig[1,*], M. Neumann[1,2,3], J. Ortiz Tanchez[1], K. Isaakidis[1], C. Schlee[1], M.P. Schroeder[1], L. Bastian[1,2,3,4], L. Mochmann[1], C.D. Baldus[1,2,3,4]

[1]Department of Hematology and Oncology, Charité, University Hospital Berlin, Campus Benjamin Franklin, Berlin, [2]German Cancer Research Center (DKFZ), [3]German Cancer Consortium (DKTK), Heidelberg, [4]Berlin Institute of Health, Berlin, Germany

Background: T-cell acute lymphoblastic leukemia (T-ALL) has an unfavorable outcome in adult patients. The protocadherin FAT1 is frequently mutated and aberrantly expressed in many cancer types, including acute lymphoblastic leukemia (ALL). We have previously described FAT1 mutations in 16% of T-ALL patients. Aberrant expression occurred in 54% of T-ALL patients, in contrast to T-cells and progenitors from healthy donors lacking FAT1 expression. Moreover, it has been reported that FAT1 expression was associated with a shorter relapse-free and overall survival in ALL. Thus, FAT1 is considered a promising candidate for future targeted therapy, yet its functional consequences are unclear in T-ALL.
Aims: This study investigates the functional role of FAT1 in T-ALL.
Methods: FAT1 gene expression profiles were generated using a microarray dataset of adult T-ALL (Affymetrix U133 Plus 2.0; GSE78132, n=83) and an independent cohort of adult T-ALL samples analyzed by RNA-seq (n=84). Gene Set Enrichment Analyses (GSEA) and pathway enrichment analyses for genes coexpressed with FAT1 (ANOVA, p<0.01) were performed. The effect of FAT1 expression was studied by knockdown of FAT1 with siRNA and FAT1 overexpression of a functional truncated protein (kindly provided by Morris, L.G. *et al.*, 2013) in T-ALL cell lines. WNT pathway activity was modulated by treatment with 6-Bromoindirubin-3'-oxime (BIO), XAV-939 and CHIR00921 at 1μM, 5μM and 10μM for 48h in T-ALL cell lines. Proliferation was assessed by WST-1 assay. Downstream gene expression effects were analyzed by RT-PCR.
Results: RNA-seq based profiling revealed high expression of FAT1 in 53% of T-ALL patients (defined as FAT1$^+$, median TPM 155, range 36-1368) whereas 47% had negative FAT1 expression (FAT1$^-$, median TPM 0.5, range 0-27). GSEA using the Affymetrix data set and validated by the RNA-seq data, exhibited a positive enrichment for mature T-cell signatures (p=0.025) in FAT1$^+$ samples. In contrast, FAT1$^-$ samples correlated with early T-cell precursor ALL (p<0.001) and hematopoietic stem cell (p=0.064) signatures. FAT1$^+$ T-ALL samples had higher levels of immunophenotype maturation markers CD4 (p<0.001), CD8 (p=0.003) and CD1 (p=0.005) harboring a distinct expression pattern. Pathway enrichment analyses revealed coregulated genes with a strong enrichment for DNA replication (p<0.001), cell cycle (p<0.001), T cell receptor signaling (p<0.001), pathways in cancer (p=0.011) and WNT signaling pathway (p=0.036) compared to FAT1$^-$ samples. FAT1 was expressed in 6/7 tested T-ALL cell lines with significantly higher mRNA expression in the more mature T-ALL cell lines Jurkat, HPB-ALL and MOLT4 in contrast to immature cell lines RPMI-8402, BE13, Loucy and PER117. Functional analyses for FAT1 knockdown led to a FAT1 downregulation of 64% (p<0.01) compared to control siRNA in Jurkat, resulting in 14% reduction (p=0.02) of proliferation after 72h. FAT1 overexpression resulted in a proliferative advantage with a 42% increase (p=0.02) compared to WT controls in Jurkat. Furthermore, FAT1 knockdown mediated a downregulation of WNT target genes CCND1 (p=0.005), LEF1 (p=0.016), JUN (p=0.036) and IGF2 (p=0.02) compared to controls. Treatment of T-ALL cell lines with WNT pathway activating drugs BIO and CHIR00921 caused a dose-dependent upregulation of FAT1, yet WNT pathway inhibitor XAV-939 led to a FAT1 downregulation.
Summary/Conclusion: Aberrant FAT1 expression, associated with maturation, induces proliferation and WNT pathway interaction in T-ALL. This study contributes to understanding the role of FAT1 in T-ALL biology aiding in further therapeutic approaches.

PS911

"TRIPLE NEGATIVE" ACUTE GENE EXPRESSION CLUSTERING IDENTIFY NEW ADULT LYMPHOBLASTIC LEUKEMIA SUBGROUPS

Hernández-Rivas[5], C. Baldazzi[1], M. Abbenante[1], S. Paolini[1], N. Testoni[1], G. Castellani[2], E. Sabattini[3], M. Cavo[1], D. Remondini[2], G. Martinelli[6]

[1]DIMES, Institute of Hematology "L. e A. Seràgnoli", [2]Fisica e Astronomia, Bologna University, [3]DIMES, Hematopathology Unit, Bologna, [4]Hematology, A.O. Ospedali Riuniti Villa Sofia-Cervello, Palermo, Italy, [5]Fundación de Investigación del Cáncer , Universidad de Salamanca, Salamanca, Spain, [6]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori , IRST-IRCCS, Meldola (FC), Italy

Background: Although the remarkable progress, there is a need in improving the molecular dissection of subtypes, identifying genetic alterations that predict the risk of treatment failure and developing novel and targeted therapies. B-ALL patients (pts) that doesn't have the most recurrent adult rearrangements (*BCR-ABL1* t(9;22)*; TCF3-PBX1* t(1;19); *MLL-AF4* t(4;11)) are collectively referred to as "triple negative" (Ph-/-/-) ALL.
Aims: Biological characterization of Ph-/-/- ALL considering *CRLF2* overexpression event (that represents near to 57% of B-ALL; Roberts KG, J Clin Oncol. 2016), in in order to define and assess biomarkers in this subgroup to test new drugs.
Methods: Gene Expression Profiling (GEP; HTA 2.0 Affymetrix) were per-

formed on 60 Ph-/-/- ALL, 30 B-ALL Ph+ at different time point of the disease and on 7 mononuclear cell of healthy donors. Data were normalized and analyzed with the Expression Console and the Transcriptome Analysis Console (TAC) Software (Affymetrix). Successively we cluster triple negative GEP data with our validated pipeline, based in a top ten gene list. Ph-/-/- ALL samples were then characterized for the presence of gene fusions, Copy Number Alterations (CNAs) and mutations using different approaches (TruSight Pancancer-Illumina; MLPA and/or dMLPA-MRC-Holland; SNP Array-Affymetrix and PCR).

Results: Comparing all GEP of Ph-/-/- to donors we found some top upregulated genes to focus on (e.g. *EBF1, PDLIM1, PXDN, TCL1A, BLNK, CD19, RASD1, NAV1, DNTT, SOCS2, CTGF, CD200, CRLF2*). In triple negative ALL GEP top upregulated gene analysis we identify a defined 2-clusters-subdivision (Gr1 and Gr2; Figure 1) furthermore a third group, in the Gr1, can be identified by the algorithm without ambiguous assignments. The Gr2 is characterized by *CTGF, CRLF2* and *CD200* overexpression and it represents 12.2% of all B-ALL. Two groups t-test has been performed between Ph+ and the isolated subgroups of Ph- to determine the similarity of these two groups to Ph+. The Gr2 GEP is similar to Ph+ one. Fusion and mutational screening done, detected that Gr2 has a higher frequency of Ph-like associated lesions, that mainly affect JAK-STAT pathway. Also *IKZF1* deletion are significantly associated to Gr2 (p=0.0028).

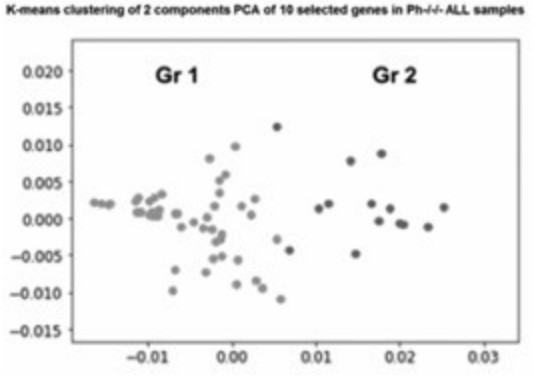


Figure 1.

Summary/Conclusion: We identified a new signature, related to *CRLF2* high expression, to classify Ph-/-/- ALL B-based on 10 genes. Gr2 represents 12.2% of all B-ALL and it is characterized by a) high co-expression of three main genes: *CRLF2*, *CTGF* and *CD200;* b) *IKZF1* deletion (CDK2 inhibitor downregulate *CRLF2* overexpression in *IKZF1* deleted ALL); c) JAK-STAT pathway mutations/fusions/deletions. Gr1 represents 45.4% of all B-ALL. Gr2 GEP similarity to Ph+ one, suggests that this Gr2 could contain Ph-like pts. This new Ph-/-/- subclassification identify new potential therapeutic targets with available drug (α-CTGF, α-CD200, CDK2 inhibitor; tyrosine kinase inhibitors already effective on Ph+ and Ph-like) to test as a single agent or in combination. Supported by: ELN, AIL, AIRC, project Regione-Università 2010-12 (L. Bolondi), FP7 NGS-PTL project, HARMONY project, Fondazione del Monte BO e RA project.

Background: Minimal residual disease (MRD) is the most important prognostic factor in acute lymphoblastic leukemia (ALL) at all ages. However, around 25% of MRD-negative adult patients ultimately relapse, suggesting that MRD has limitations for prognostic assessment. Molecular characterization may contribute to more precise risk stratification. Unfortunately, reliable molecular prognostic markers are still warranted, especially for Ph-negative B-cell precursor ALL (Ph-neg BCP-ALL).

Aims: To identify molecular abnormalities with prognostic significance in a series of homogeneously treated adult Ph-neg BCP-ALL patients.

Methods: Multiplex Ligation-dependent Probe Amplification (MLPA) was performed for the most recurrent copy number alterations in 128 adult Ph-neg BCP-ALL patients treated according to PETHEMA protocols. MRD was centrally evaluated by flow cytometry and good early response was considered when MRD was $<10^{-3}$ at the end of induction (End Ind). Outcome was also assessed in cases with MRD$<10^{-4}$ at End Ind.

Table 1.

Outcome variable	Variables	HR (IC95%)	p
Overall Survival including $<10^{-3}$ MRD at the end of induction	Age	**1,036** (1,013 ; 1,060)	0,002
	WBC	**1,007** (1,003 ; 1,011)	<0,001
	MRD≥10^{-3}	**2,223** (1,121 ; 4,410)	0,022
Overall Survival including $<10^{-4}$ MRD at the end of induction	Age	**1,048** (1,020 ; 1,076)	0,001
	WBC	**1,006** (1,003 ; 1,009)	0,001
	MRD≥10^{-4}	**2,605** (1,267 ; 5,355)	0,009
	CDKN2A/B	**2,003** (1,001 ; 4,006)	0,050
Disease Free Survival including $<10^{-3}$ MRD at the end of induction	Age	**1,026** (1,005 ; 1,047)	0,015
	WBC	**1,007** (1,003 ; 1,010)	<0,001
Disease Free Survival including $<10^{-4}$ MRD at the end of induction	Age	**1,022** (1,002 ; 1,043)	0,033
	WBC	**1,006** (1,003 ; 1,010)	<0,001
Cumulative Incidence of Relapse including $<10^{-3}$ MRD at the end of induction	WBC	**1,007** (1,004 ; 1,01)	<0,001
Cumulative Incidence of Relapse including $<10^{-4}$ MRD at the end of induction	WBC	**1,007** (1,004 ; 1,01)	<0,001

Results: At baseline, patients with intragenic IKZF1 deletion showed higher cumulative incidence of relapse (CIR) than patients without deletion (5-year CIR 83% [45%; 96%] vs. 43% [31%; 54%] p=0.005). Patients with CDKN2A/B deletion had poorer outcomes than those without deletion (5-year OS 34% [20%; 48%] vs. 57% [43%; 71%], p=0.042; 5-year DFS 25% [12%; 38%] vs. 47% [33%; 61%], p=0.029; 5-year CIR 56% [40%; 70%] vs. 41% [27%; 54%], p=0.090). Patients with both IKZF1 and CDKN2A/B deletions had an extremely high CIR (5-year CIR 91% [29%; 99%] vs. remaining, p=0.003).

MRD data at End Ind were available for 75/128 patients. Patients with MRD ≥10^{-3} (n= 19/75, 25%) showed a trend for poorer OS than those with good early response (5-year OS 26% [5%; 47%] vs. 56% [35%; 63%], p=0.175). Fewer patients with IKZF1 deletion achieved CR than patients without deletion (18/25 vs. 77/88, p=0.064) and more patients with IKZF1 deletion had MRD>10^{-3} at End Ind compared to patients without deletion (5/11 vs. 13/53, p=0.150). Among patients with good early response (MRD<10^{-3}) at End Ind, those with CDKN2A/B deletion had lower OS and DFS than those without CDKN2A/B loss (5-year OS 37% [19%; 55%] vs. 61% [42%; 80%], p=0.062 and 5-year DFS 24% [7%; 41%] vs. 51% [32%; 70%], p= 0.041). Patients with MRD<10^{-4} at End Ind, showed better outcome than those with MRD≥10^{-4} (5-year OS 48% [31%; 65%] vs. 29% [12%; 46%], p=0.136). CDKN2A/B deletion was also a significant marker of poor prognosis among patients with MRD<10^{-4} at End Ind (5-year OS DEL 32% [11%; 53%] vs WT 70% [45%; 95%], p= 0.018; 5-year DFS

DEL 9% [0%; 24%] vs. WT 66% [42%; 90%], p=0.006; 5-year CIR DEL 70% [36%; 89%] vs. WT 27% [(%; 52%], p=0.048) and showed independent prognostic significance in multivariate analysis (Table 1).
Summary/Conclusion: Molecular markers such as CDKN2A/B add prognostic information independent of MRD in adult patients with Ph-negative BCP-ALL. Combined MRD and molecular data should be used for risk stratification and treatment assignment.

PS913

TCR ALPHA GENE REARRANGEMENTS AS A NEW TYPE OF CLONAL MARKERS IN PEDIATRIC T-LINEAGE ACUTE LYMPHOBLASTIC LEUKEMIA

A. Komkov[1,2,*], A. Miroshnichenkova[1], G. Nugmanov[2], Y. Lebedev[2], Y. Olshanskaya[1], I. Mamedov[2], M. Maschan[1]

[1]National Research Center of Pediatric Hematology, Oncology and Immunology, [2]Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation

Background: Relapse is still the major cause of poor outcome in therapy of T-lineage acute lymphoblastic leukemia (T-ALL) in children. According to the previously published data, up to 30% cases of T-ALL relapses in T-ALL are accompanied by changing of the major leukemic clones because of the "bottle-neck" caused by chemo-therapy. At the present time the most reliable markers for analysis of clonal architecture of T-ALL in debut as well as in relapse are rearrangements of immunoglobulin and T-cell receptors (TCR) genes: TCR beta, TCR gamma and TCR delta. However, involvement of rearrangements of fourth TCR genes family – TCR alpha genes – in clonal diversity formation in T-ALL remains unclear.
Aims: The main purposes of this study are identification and characterization of clonal TCR alpha locus rearrangements in pediatric T-ALL and analysis of possibilities to use them for precise reconstruction of clonal structure of T-ALL together with other TCR genes (first of all TCR beta) rearrangements.
Methods: Detection of TCR alpha and TCR beta genes rearrangements was based on targeted high-throughput sequencing (HTS). Amplicons for HTS was obtained in series of multiplex PCRs with genomic DNA isolated from bone marrow (BM) and degenerate primers covering the vast majority of all V- and J-genes combinations of both TCR alpha and TCR beta loci. Identification of rearrangements specific for leukemic clones was performed based on analysis of clone frequencies in obtained TCR repertoires using 5% cut-off.
Results: We analyzed a cohort consisted of 75 patients aged 2-18 years with T-ALL diagnosis. We identified over 90 clonal rearrangements of TCR alpha locus and over 120 clonal rearrangements of TCR beta locus in total. 15 samples contained TCR alpha rearrangements with clonal rate more than 40%, 37 samples contained 1-4 TCR alpha rearrangements with clonal rate 5-35%, 23 samples didn't contain any leukemia specific TCR alpha rearrangements. In the same time, 53 analyzed samples contained 1-2 TCR beta rearrangements with clonal rate above 40%, 10 samples contained TCR beta rearrangements with clonal rate 5-35% and the rest ones didn't contain leukemia specific TCR beta rearrangements. The vast majority of TCR alpha rearrangements was detected in samples with dominant TCR beta rearrangements. Samples without TCR beta rearrangements also didn't contain rearranged TCR alpha loci.
Summary/Conclusion: For the first time we evaluated frequency of occurrence of clonal rearrangements of TCR alpha locus in pediatric T-ALL. This type of clonal markers is presented in more than half of T-ALL cases what makes them fully applicable for analysis of clonal structure of T-ALL along with other TCR genes rearrangements. Detection of rearranged TCR alpha loci with rearranged TCR beta loci in the same samples allow to increase resolution of clonal structure reconstruction in T-ALL in both onset and relapse. This research was supported by Russian Science Foundation grant #17-75-10113, Russian Foundation for Basic Research grants #17-04-01280 and # Russian President's Fellowship SP-4059.2016.4.

Milano Bicocca, Monza, [5]Ematologia ed Oncologia Pediatrica, Presidio Ospedaliero Ciaccio-De Lellis, Catanzaro, [6]Pediatric Dept., Presidio S. Fermo, ASST Lariana, Como, Italy

Background: Cornelia de Lange syndrome (CdLS) is a rare genetic disorder characterized by pre- and post-natal growth retardation, mental retardation, facial dysmorphism and upper limb abnormalities. The main causes of the disease are mutations in *NIPBL*, *SMC1A*, *SMC3*, *HDAC8* and *RAD21* genes, which encode proteins of cohesin complex or associated to it. *NIPBL* is involved in about 55% of CdLS cases, while the others account for 5%. Mutations in the cohesin genes have recently been identified in AML, CML and myelodysplastic syndromes.
Aims: The present study aims to describe the first case of a CdLS pediatric patient who developed precursors B-cell Acute Lymphoblastic Leukemia (BCP-ALL). Furthermore, we investigated the presence of cohesin variants in pediatric BCP-ALL patients not affected by CdLS.
Methods: RNA NGS-Targeted Capture strategy was setup, by implementing the TruSight Pan-Cancer (Illumina, 1385 genes), which included cohesin genes complex, such as *NIPBL*, *SMC1A*, *SMC3*, *RAD21*, *STAG2*.
Results: The patient was previously diagnosed as CdLS based on clinical features, but without genetic characterization. When he was 8-years old, he developed the B-cell precursor ALL and was enrolled in the AIEOP-BFM ALL 2009 study protocol. The biological investigations performed on bone marrow blasts at onset did not reveal any prognostically relevant cytogenetic abnormalities and was enrolled to high risk treatment group for MRD analysis. Through NGS Trusight Pan-Cancer analysis, we identified two mutations in heterozygosity of *JAK3* in exon 1 (shared only with the father) and in exon 16 (shared with whole family in heterozygosity), respectively noted as rs7254346 (benign) and rs3213409 (known as benign if germline and somatic in ALL and AML). A germline mutation of *TP53* exon4, rs1042522, known as benign and potentially involved in chemotherapeutic resistance mechanisms was identified. This mutation is present in homozygosity also in the mother. More importantly, we have identified variants in cohesin genes, in particular in exon 46 of *NIPBL*, in heterozygosity. This *NIPBL* variant is a new mutation that causes frameshift and a premature stop codon. This anomaly was confirmed on the patient's bone marrow DNA both at diagnosis and in remission of leukemia and in a buccal smear sample. Both parents and brother are negative, phenotypically normal and not affected by hematological diseases. We further analyzed 86 pediatric BCP-ALL cases after the first CdLS-ALL patient. We analyzed cohesin complex genes, including *NIPBL*, *RAD21*, *SMC1A*, *SMC3*, *STAG2*, and overall we detected 36 variants, including recurrent known variants in addition to 10 novel variants, mainly affecting the *NIPBL* gene. PCR/Sanger validation is ongoing and already confirmed three variants out of ten.
Summary/Conclusion: It has commonly accepted that cancer originates by two or more mutations accumulated in somatic cells, and there is growing evidence of the association of germline genetic aberrations and cancer. Some cancer predisposing syndromes have been associated with ALL in children as for example Down syndrome, Noonan syndrome and Li- Fraumeni syndrome.
Although mutations in cohesins have been found in many tumor cells, in particular in AML, only few cases of cancer have been reported in patients affected by cohesinopathies. Nevertheless, the present study reports a CdLS pediatric patient with concomitant ALL. The role in leukemogenesis of the new NIPBL gene mutation, identified in the first CdLS pediatric patient with BCP-ALL, and the biological role in leukemia of cohesin genes deserves further investigation.

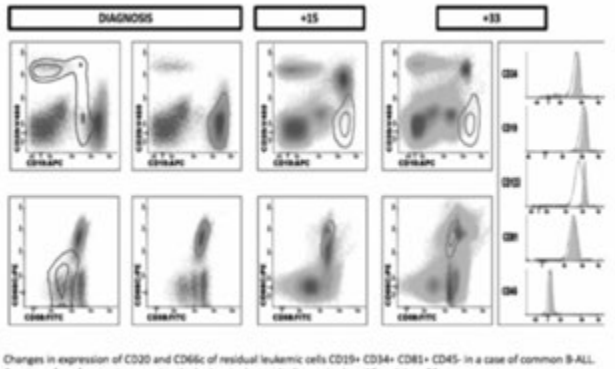
PS916

EVALUATION OF SAMPLE QUALITY AND CREATION OF DATABASES FOR FOLLOW-UP ASSESSMENT OF BLAST INFILTRATION AT DAY +15 IN CHILDHOOD B CELL ACUTE LYMPHOBLASTIC LEUKEMIA

P. Manresa[1,*], J. López[1], H. Sarmiento[1], F. López[1], O. Alda[1], E. Arranz[1], V. Rodríguez[1], I. Molina[1], M. Pérez[1], P. Ruiz-Sogorb[1], L. Blázquez[1], C. García[1], J.J. Verdú[1], F. De Paz[1], M. Del Cañizo[2], M. Tasso[2], C. Esquembre[2], P. Marco[1], F. Tarín[1]

[1]Department of Hematology, [2]Department of Pediatrics, Hospital General Universitario de Alicante, Alicante, Spain

Background: Evaluation of blast percentage on day +15 (BM+15) is critical in decision-making in patients with childhood B acute lymphoblastic leukemia (B-ALL). The current protocols establish risk criteria based on the optical count and minimal residual disease (MRD) evaluated by flow cytometry (FCM), both being critical in therapeutic decisions. However, different studies show the existence of relevant discordances in both optical and immunophenotypic count. These discrepancies are due to different aspects, highlighting sample contamination by peripheral blood (PB), lack of consensus in panels and strategies used, subjective interpretation of the results, and antigenic modulation produced by the active treatment, all of which can hinder the identification of residual population.
Aims: Investigate the significance of sample quality and immunophenotypic changes in residual/neoplastic populations, in data interpretation and final results in BM+14 samples.
Discuss the usefulness of the new multidimensional analysis tools applicable to the 8-color standardized FCM in the resolution of discrepancies.
Methods: Patients: 51 patients diagnosed of B-ALL (August 2013-February 2018) and treated according to the current SEOP-PETHEMA protocols. Estimation of contamination degree: evaluation of total cellularity (nucleated cells/µl) in bone marrow (BM) (ncBM) and PB (ncPB) measured the same day in order to estimate the BM contamination percentage by PB (% = ncPB /ncBM). Optical count: infiltration percentage evaluated by 3 independent observers. FCM panels: B-ALL panel proposed by Euroflow standards. Residual blasts count measured with 8 color FCM evaluated by 3 independent observers. FCM images are compared with normal sample databases (normal lymphoid maturation) and pathological (individual samples of each patient with the original pathological populations) (Figure 1).
Results: 1) The average percentage PB sample contamination was 26.03% (+/- 22.08%) almost 4 times higher than the day of control+33 (6.82 +/- 11.62%) reaching> 75% in 10% of the samples. The PB contamination degree correlated inversely with the erythroid precursors percentage (R2 = 0.613, p <0.05). 2) Optical count correlation was low among three different observers (R2 = 0.22 p= 0.06) and was not significant with FCM count (p> 0.1). 3) Relevant immunophenotypic changes were observed compared to the original leukemic population, highlighting an increased expression of CD20 (almost X10 more intense in 95% of cases) and CD45 (75%) as well as a decrease in CD10 (90%), CD66c (75%) and CD34 (60%). The antigenic expression of CD19, CD38, CD58 and CD123 remained stable. 4) Nonetheless, the FCM count correlation was very high among the different observers (R2 = 0.87 p=<0.01) using the tools previously described, as residual populations continued showing identifiable aberrant expression patterns when compared with databases of the different stages of normal lymphoid maturation.



Changes in expression of CD20 and CD66c of residual leukemic cells CD19+ CD34+ CD81+ CD45- in a case of common B-ALL. Creation of a reference image using the leukemic cluster. At diagnosis, day +15 and day +33

Figure 1.

Summary/Conclusion: 1) BM+15 samples present a relevant degree of PB contamination that can be evaluated by simple parameters such as PB/BM ratio and erythroid precursors percentage. 2) Identification of the residual population using "similarity criteria" to the original leukemic cells is exposed to relevant pitfalls that can be overcome using the new FCM interpretation tools. 3) The generalization of FCM standardized procedures and tools as well as the consensus of minimum sample quality criteria are necessary in order to reach diagnostic concordance and reproducibility.

GENETIC ALTERATIONS OF T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA IN TAIWAN: A COMPARISON BETWEEN PEDIATRIC AND ADULT COHORTS

Y.-J. Huang[1,*], T.-C. Yeh[2], H.-C. Liu[2], M.-C. Kou[1,3], T.-H. Jaing[3,4], S.-H. Chen[3,4], P.-N. Wang[1], T.-L. Lin[1], J.-Y. Hou[2], Y.-S. Hung[1], H. Chang[1,3], C.-P. Yang[4], L.-Y. Shih[1,3]

[1]Division of Hematology-Oncology, Chang Gung Memorial Hospital at Linkou, Taoyuan, [2]Division of Pediatric Hematology-Oncology, Mackay Memorial Hospital, Taipei, [3]College of Medicine, Chang Gung University, [4]Division of Pediatric Hematology-Oncology, Chang Gung Memorial Hospital at Linkou, Taoyuan, Taiwan, Republic of China

Background: T-cell acute lymphoblastic leukemia (T-ALL) is an aggressive hematologic disease and caused by multistep processes of genetic lesions. Recently, many recurrent genetic alterations have been identified by genome-wide approaches in children, however, those in adult T-ALL remain to be defined. There may be existence of significant differences between children and adults.
Aims: We aimed to analyze the frequencies of genetic alterations of different pathways involved in both children and adults with T-ALL in Taiwan and to determine whether different genetic lesions existed in the two cohorts.
Methods: Bone marrow samples obtained from 102 children (< 18 years) and 70 adult patients with T-ALL between 1994 and 2015 were examined. Fusion transcripts including *SIL-TAL1, CALM-AF10,* and *KMT2A*-rearranged (*KMT2A*-R) were detected by RT-PCR. RQ-PCR with TaqMan assay was used to measure the expression of transcription factor oncogenes, including *HOX11* (*TLX1*), *HOX11L2* (*TLX3*), *TAL1,* and *LYL1.* Detection of gene deletion or amplification was carried out with multiplex ligation dependent probe amplification kit (SALSA MLPA P383 T-ALL). The hotspot regions of *NOTCH1, FBXW7*, *JAK1*, *JAK2*, *PHF6*, *RUNX1*, *WT1*, *NRAS* and *KRAS* were amplified by PCR-based assays and followed by direct sequencing.
Results: Totally, 32 genetic alterations involving bHLH family, Homeobox family, LMO family, NOTCH1 pathway, cell cycle, signaling pathway, transcription factors, and epigenetic regulators were analyzed in Taiwanese children and adult patients with T-ALL. The frequency of genetic alterations involving NOTCH1 pathway (*NOTCH1* and *FBXW7* mutations) and transcription factors (*WT1* mutation, *RUNX1* mutation, *LEF1* deletion, *MLLT3* deletion, and *MYB* duplication) was similar in both cohorts. The four most common genetic abnormalities were *TAL1* over-expression, *P16* deletion, *P15* deletion, and *NOTCH1* mutation occurring in 74.7% and 64%, 63.3% and 35.6%, 50.0% and 35.3%, and 46.9% and 43.5%, respectively, of children and adults with T-ALL. Among bHLH, Homeobox and LMO family genes, *SIL-TAL1* fusion was more frequently detected in children (19.2% vs. 7.5%, p=0.043), whereas the frequencies of other genetic abnormalities including presence of *CALM-AF10, KMT2A-R,* or *RAG2-LMO2,* expression of *HOX11*, *LYL1*, and *TAL1* oncogenes, or *LMO1* amplification were not significantly different in both cohorts. A trend of *HOX11L2* over-expression in children compared with adults (17.2% vs. 6.0%, p=0.07) was observed. Of the cell cycle-related genes, *P16* deletion was more common in children than adults (p=0.001) and there was no difference in the frequency of *P15* or *MTAP deletion* between children and adults. Among the genetic alterations of signaling pathway (deletion of *NF1*, *CASP8AP2*, *PTEN*, or *PTPN2*, or mutations of *NRAS*, *KRAS*, *JAK1*, *JAK2*, or *NUP214-ABL1* fusion), only the frequency of *NF1* deletion was significantly different in the two cohorts (8.8% in adults vs. 0% in children, p=0.028). Of the three epigenetic regulator genes (*EZH2*, *PHF6*, and *SUZ12*), adult patients had a higher rate of *PHF6* mutation/deletion (34.1% vs. 16.5%, p=0.038) and *SUZ12* deletion (11.8% vs. 0%, p=0.008) than children, and a comparable frequency of *EZH2* deletion.
Summary/Conclusion: The present study showed that the genetic alterations in T-ALL were different between children and adults. *SIL-TAL1* fusion and *P16* deletion occurred more frequently in children whereas *PHF6* mutation and *NF1* or *SUZ12* deletion were more frequently present in adults.

Acute lymphoblastic leukemia – Clinical

PROGNOSTIC VALUE OF IKZF1 DELETIONS ON THE UKALL14 TRIAL; SIGNIFICANT ROLE OF BCR-ABL1 STATUS

R. Mitchell[1,*], A.A. Kirkwood[2], S. Lee[1], K. Zuborne Alapi[1], N. Zareian[3], P. Patrick[2], E. Lawrie[2], L. Clifton-Hadley[2], D.I. Marks[4], A. Douglas[2], C.J. Rowntree[5], T. Menne[6], A. K. McMillan[7], B. Wrench[8], A.V. Moorman[9], A.K. Fielding[1]

[1]UCL Cancer Institute, [2]CRUK and UCL Cancer Trial Centre, University College London, [3]Departmant of Haemato-Oncology, King's College, London, [4]Bristol Haematology and Oncology Centre, University Hospitals Bristol NHS Foundation Trust, Bristol, [5]Department of Haematology, University Hospital of Wales , Cardiff, [6]Department of Haematology, Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne, [7]Centre for Clinical Haematology, Nottingham University Hospitals NHS Trust, Nottingham, [8]Barts Cancer Institute, QMUL, London, [9]Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle Upon Tyne, United Kingdom

Background: *IKZF1* deletions *(ΔIKZF1)* are common in acute lymphoblastic leukaemia (ALL), with the most frequent, Δ4-7 exerting a dominant negative (DN) effect, with others causing loss of function (LOF). There are varying reports on the role of *ΔIKZF1* in prognosis.
Aims: We determined the prognostic impact of DN and LOF *ΔIKZF1* in 655 patients with B-precursor ALL aged 23-65 years UKALL14 (ISRCTN 66541317).
Methods: Samples were screened for Δ4-7, Δ2-7, Δ4-8, and Δ2-8 using a multiplex PCR assay with primer sites located in intron 1, intron 3, intron 7 and 3' UTR close to the breakpoints. All deletions were confirmed as unique by Sanger sequencing. At a median follow up of 29 months, we analysed the impact of any, LOF, DN or both *ΔIKZF1*, on CR, presence of minimal residual disease (MRD) at >1x10^{-4} (Ig/TCR or BCR-ABL1 quantitation, using EuroMRD criteria) after phases 1 and 2 of induction therapy, EFS, time to relapse (TTR) and OS.

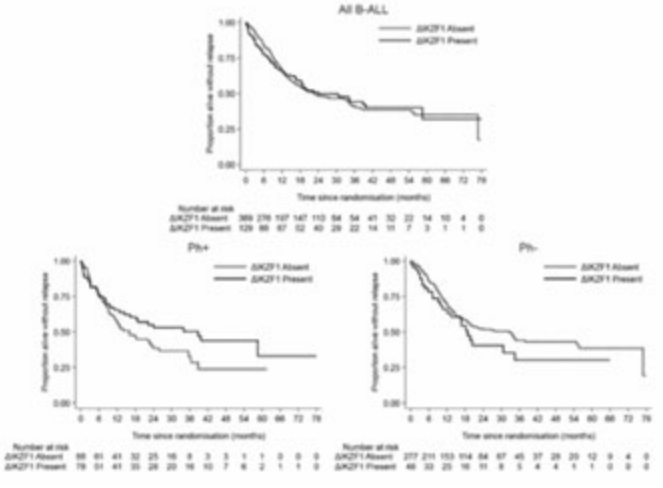

Figure 1.

Results: Diagnostic DNA was available from 498/655 (76%) patients enrolled with B-ALL. The median age of those screened was 46 years (range 23-65) and was not different from that of the trial population overall. The only difference between the screened and total population was presenting WCC (9.7 vs. 8.0 p<0.001) and a higher proportion of patients with Ph+ ALL (34% vs 31%, p=0.003). 142 *ΔIKZF1* lesions were detected in 129 (26%) patients. As expected, Δ4-7 was the most common (n=83, 59%) of deletions followed by Δ2-7 (n=31, 22%), Δ4-8 (n=22, 15%) with Δ2-8 (n=6, 4%) being the rarest deletion. Seventy-one (14%) patients harboured a DN deletion, 46 (9%) a LOF deletion, and 12 (2%) carried both DN and LOF. The frequency of *ΔIKZF1* was 78/166 (47%) of Ph+ cases and 48/325 (15%) of Ph- cases. Overall, patients with any *ΔIKZF1* were significantly less likely to reach CR (84.4% vs 93.4%, p=0.009) and significantly more likely to be MRD positive after both one (68.5% vs 53.5% p=0.016) and two (45.9% vs 32.2%, p=0.03) courses of therapy. However, when analysing these data by Ph status, this finding was strongly driven by Ph-data; as an example, 57.1% vs. 28.8% were MRD+ after 2 courses (p=0.004) in Ph- specimens as compared to 40.7 vs. 41 p=0.98 in Ph+ specimens. We did not find a significant impact of *ΔIKZF1* on EFS, OS and TTR. A subanalysis of *ΔIKZF1* impact by Ph status showed hazard ratios (HR) entirely >1 in the Ph- setting and largely <1 in the Ph+ setting, although none of the HR differences were statistically significant. For EFS: all patients *ΔIKZF1* HR 1.02, (0.76-1.36) p=0.92, Ph- only *ΔIKZF1* HR 1.34 (0.87–2.06), p= 0.18 and Ph+ only *ΔIKZF1* HR 0.7 (0.45 – 1.08) p=0.01. The Kaplan-Meier survival curves shown illustrate the differential relationship of *ΔIKZF1* to EFS by Ph status and show a significant interaction effect, p=0.038. A multivariable analysis (MVA) for EFS showed a negative prognostic impact of age in 10 year increments (HR 1.45, p<0.001) and high-risk cytogenetics (HR 1.91 p= 0.001). Among the Ph+ cohort the HR for EFS was 0.69 (0.39-1.24) for patients with a *ΔIKZF1* (p=0.21) compared to 1.67 (1.23-2.45) for Ph+ patients who did not have a *ΔIKZF1* (p=0.01). Conversely, when patients with *ΔIKZF1* were considered, the HR was 1.56 (0.92-2.62) p=0.096 among Ph- ALL and 0.65 (0.42-0.99) p=0.046 in Ph+ ALL. Thus, the MVA also implies a different prognostic impact of *ΔIKZF1* depending on Ph status (Figure 1).
Summary/Conclusion: *ΔIKZF1* are readily screened by multiplex PCR, a highly sensitive method. On the UKALL14 trial *ΔIKZF1* best predicts adverse early outcomes in patients with Ph- ALL. The impact of *ΔIKZF1* in Ph+ ALL is, at best, neutral and may be positive.

Background: In adult ALL, pediatric-type treatment (PTT) in association with risk/MRD (minimal residual disease)-oriented strategy for allogeneic stem cell transplantation (SCT) can improve outcome, as documented by recent studies. One such pilot program yielded a 55% 5-year overall survival (OS) rate (Bassan R *et al.*, Blood 128:176;2016). This regimen was adopted and modified by the GIMEMA by adding pegylated-asparaginase (PegASP, 2000 IU/m^2×4 doses).
Aims: A first trial analysis was performed to assess the feasibility and reproducibility in a wider national context (vs NILG study), by examining the complete remission (CR) rate and early survival in different age and disease subsets.
Methods: The GIMEMA LAL1913 protocol (Clinical.Trials.gov NCT02067143) for adults aged 18-65 years with Ph- ALL combined PTT together with MRD evaluation for MRD/risk-guided SCT decision. This program consisted of a 5-drug remission induction phase including PegASP, followed by three modified BFM-like blocks (two with pegASP), three lineage-targeted MTX blocks (5 g/m^2 for T-ALL and 2.5 g/m^2 for B-ALL [1.5 g/m^2 if age >55 years]; two with high-dose Ara-C and one with PegASP) and reinduction, plus twelve triple prophylactic intrathecal injections. Bone marrow MRD monitoring was studied centrally by quantitative PCR at the end of courses 1 (TP1, week 4, w4), 3 (TP2, w10), 5 (TP3, w16) and 7 (TP4, w22). Patients achieving a CR were risk-stratified for SCT (high-risk, HR) or maintenance (standard-risk, SR). The HR group was defined by WBC >100x10^9/l (T-ALL), highly adverse cytogenetics or pre-T/mature T-

ALL; by late CR, WBC >30x10^9/l (B-ALL) or pro-B phenotype if MRD not available; by MRD ≥10^{-4} at TP2/TP3 or positive at TP4. The SR group was defined by MRD <10^{-4} at TP2/TP3 and negative at TP4, or by the absence of above risk factors in patients without MRD.

Results: Between 2014 and 2016, 203 patients were eligible for the study. Median age was 39.8 years (range 18-65, 19.2% ≥55 years), 58% were male, 64 had T-precursor lymphoblastic leukemia/lymphoma (32%) and 76 expressed HR clinical features (41.8%). The CR rate was 89.6% (n=182), correlating with T-cell phenotype (98.4% vs 88.6% in B-ALL, p=0.02) but not with the clinical risk profile (95% SR vs 87.8% HR, p=0.09) or age (p=0.80). After a median follow-up of 17.4 months (range 1.8-34.7), the 1-year OS and disease-free survival (DFS) rates are 80% and 77.9%, respectively. OS was slightly better in patients aged ≤40 years: 92.5% <25 years (n=44) and 86% 25-40 years (n=58) *vs* 72.3% 40-55 years (n=61) and 73.2% >55 years (n=39) (p=0.08, Figure 1). OS was significantly better in patients with T-cell disease: 89.3% *vs* 77.6% (p=0.04) and very similar among clinical risk groups: 83.9% SR *vs* 79.7% HR (p=0.19). The DFS rate was 77.9%, with better results in patients aged ≤40 years: 89.3% <25 years (n=42) and 87.4% 25-40 years (n=52) *vs* 69.6% 40-55 years (n=53) and 62.8% >55 years (n=34) (p=0.006); and no/minor differences between different diagnostic (B *vs* T, p=0.29) and clinical risk (SR *vs* HR, p=0.97) groups. Results of MRD evaluations and related treatment allocation will be analyzed and presented.

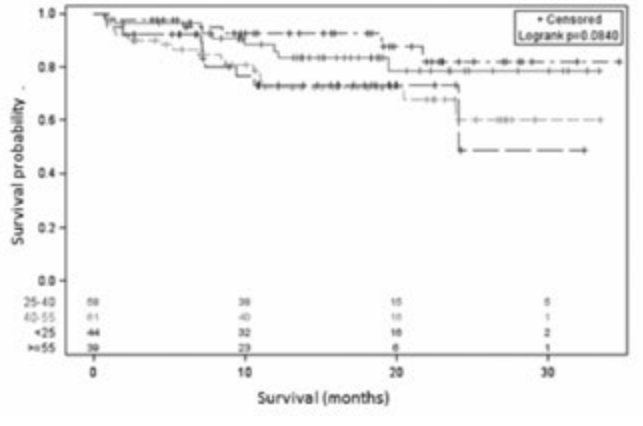

Figure 1.

Summary/Conclusion: The first analysis of the GIMEMA LAL1913 trial has documented a high CR rate with very favorable early OS and DFS, reproducing data from the interim analysis of the reference trial. The outcome seems excellent in T-ALL and younger adults, while HR patients fared no worse than clinical SR, to validate the adopted post-remission strategy. These results could be partly related to the use of PegASP in the present study.

PS920

LOW MIR-151 AND MIR-451 LEVELS IN BONE MARROW AT DIAGNOSIS IS CONFIRMED AS A PROGNOSTIC FACTOR FOR RELAPSE OF B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS FROM THE AIEOP 2000 CLINICAL TRIAL

[1]Curewize Health Ltd., Yokneam, [2]Molecular Oncology, Felsenstein Medical Research Center, Petach-Tikva, [3]Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, [4]Pediatric Hematology Oncology, Schneider Children's Medical Center of Israel, Petach-Tikva, Israel, [5]Haematology-Oncology Division, Department of Women's and Children's Health, University of Padova, Padova, Italy

Background: Previous findings showed that the microRNA (miRNA) expression profile of miR-151-5p, miR-1290 and miR-451 measured at diagnosis in bone marrow (BM) aspirations can predict risk of relapse in pediatric precursor B-cell acute lymphoblastic leukemia (B-ALL) patients treated according to BFM-based protocols and DCOG protocols (Avigad *et al.*, Genes, Chromosomes & Cancer; 55:328–339, 2016).

Aims: Confirm miR-151-5p, miR-451 and miR-1290 expression profile measured in BM aspirations at diagnosis, as a prognostic factor for B-ALL and standardize the classifier on a new platform method for measuring miRNA.

Methods: The miRNA expression was measured in BM samples from a subcohort of B-ALL patients (n=272) from the Associazione Italiana di Ematologia Oncologia Pediatrica (AIEOP) enrolled in the AIEOP-BFM 2000 study under inform consent (Sep-1, 2000 to Jul-31, 2006). Patients' clinical status was unknown to the lab. A fixed amount of synthetic non-human miRNA (Ref-miR) was spiked in total miRNA extracted from BM samples before reverse transcription (RT) for quality control. RT was performed with stem-loop primers. Relative quantities (RQ) of the miRNA, measured by RT-qPCR, were calculated by the ddCt method using the Ref-miR as a reference, and a mix of synthetic miRNAs as a calibrator. Kaplan-Meier was performed for testing event and relapse-free-survival (EFS and RFS). Cox proportional-hazards regression was performed to investigate the relationship of the miRNA with other prognostic factors.

Results: Forty-nine of the 272 patients had an event (38 relapses, 2 second malignancies and 9 deaths). Optimal cutoffs for predicting an event (positive biomarker) was determined at < median level of miR-151-5p and < upper quartile level of miR-451 of whole population. Analysis of miR-1290 didn't continue due to nonsignificant association with EFS. Low levels (positive biomarker) of the miRNAs predicted worse EFS compared to high levels: miR-151-5p (75% vs. 89%, p=0.003) and miR-451 (79% vs. 92%, p=0.02). Combining miR-151-5p/miR-451 to a single classifier led to a linear decrease in EFS with increasing number of positive miRNA: 0 positive (96%), 1 positive (86%), 2 positive (74%) (p=0.0005, logrank trend). Combined miR-151-5p/miR-451 associated with PCR-MRD risk classification: 2 positive miRNA in 25/80 (31%) standard risk (SR), 50/123 (41%) medium risk (MR) and 11/13 (85%) high risk (HR), whereas <2 positive in 55/80 (69%) SR, 73/123 (59%) MR and 2/13 (15%) HR (p=0.002, chi^2 for trend). The combined miR-151-5p/miR-451 classifier (HR 2.0, 95%CI 1.3-3.3, p=0.004) was an independent predictor of EFS when testing in relation to white blood cell (WBC) count, age (1-6 yrs. vs. >6 yrs.) and AIEOP-BFM final risk stratification. An incremental classifier was created by the summation of miR-151-5p/miR-451 positive status (0, 1 or 2), WBC count 3 levels (1, 2 or 3), and age > 6 (0 or 1) leading to a score of 0 to 6. There was a linear decrease in EFS and RFS (p<0.0001) as the score increased. Subcohort analyses showed the predictive power of the classifier in AIEOP-BFM HR patients, PCR-MRD MR patients and patients negative for TEL/AML or t(4;11) mutations (Figure 1).

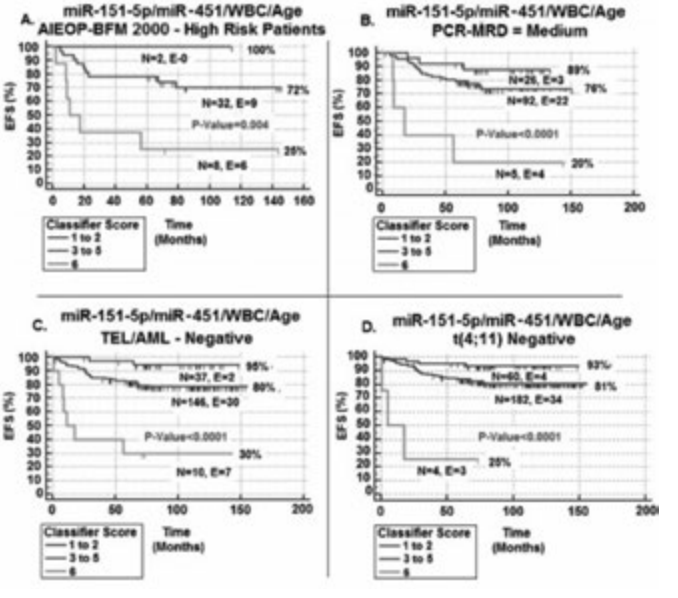

Figure 1.

Summary/Conclusion: The mir-151-5p/miR-451 classifier was confirmed as an independent prognostic factor for EFS and RFS of B-ALL patients from the AIEOP-2000 cohort. To confirm the prognostic independent value, these results should be validated in another independent cohort using this standardized method for the semi-quantification of miR-151-5p and miR-451.

Bourquin[1]

[1]Oncology, University Childrens Hospital Zurich, Zurich, Switzerland, [2]Alacris Theranostics , Berlin, [3]Department of Pediatrics, University Hospital Schleswig-Holstein, Kiel, [4]Pediatric Hematology and Oncology, Charité University Hospital, Berlin, Germany, [5]St. Anna Children's Hospital and Children's Cancer Research Institute, Vienna, Austria, [6]Department of Pediatric Hematology and Oncology, Charles University Hospital Motol, Prague, Czech Republic, [7]Department of Pediatrics, University of Padova, Padova, Italy, [8]Pediatric Hematology and Oncology, Hannover Medical School, Hannover, [9]Department of Vertebrate Genomics, Max Planck Institute for Molecular Genetics, Berlin, Germany

Background: The *in vivo* response to treatment assessed by minimal residual disease (MRD) during induction therapy is the most applicable predictor of the risk of relapse in acute lymphoblastic leukemia (ALL) of childhood. However, most relapses occur within an MRD-intermediate risk group, and better predictors are needed to stratify the patients at risk for targeted agents.
Aims: The aim of this project was to identify cell surface markers that are associated with MRD persistance and increased risk of relapse for possible inclusion in diagnostic immunophenotyping.
Methods: We have mapped the cell surface proteome of 11 good prognosis and 8 high risk ALL samples using a chemoproteomic cell surface capture technology. This revealed exclusive identification of the cell surface glycoprotein and fetal liver hematopoietic stem cell marker Vanin-2 (VNN2) in high risk ALL samples. In retrospective (by qPCR) and prospective (by flow cytometry) analyses performed in 5 different centres within the AIEOP-BFM ALL study group we validated this association of VNN2 positivity with high risk disease. We performed low coverage whole genome and whole exome sequencing in 26 VNN2-positive ALL cases and transcriptome sequencing in 16 VNN2-positive cases to identify lesions that associate with VNN2 positive ALL.
Results: Comparative analysis of the ALL high and low risk surfaceome revealed association of VNN2 with very high risk of relapse cases. Using mRNA analysis of VNN2 levels by qPCR, we evaluated the risk association of VNN2 high ALL in 776 cases retrospectively (ALL-BFM 2000 study). Very high levels of VNN2 transcripts were enriched in MRD intermediate and high risk ALL. Overall, the median event-free survival probability of VNN2-high ALL was significantly lower than in VNN2-low ALL, in particular in IR-ALL. To validate this association with risk, we have prospectively integrated VNN2 in the flow cytometry diagnostics of our international cooperative study group (AIEOP-ALL-BFM 2009) and have so far detected VNN2 positivity in about 10% of pediatric ALL patients (62/468), with an enrichment in MRD-high risk (20/35 = 57%) and MRD-intermediate risk (10/35 = 29%) cases. Immunophenotypic analysis of VNN2-positive cases did not show a pattern of myeloid co-expression, indicating that only a low percentage of cases were classified as biphenotypic (6/42 = 14%) or mixed-phenotype acute leukemia (3/42 = 7%). Genomic analysis of 26 VNN2-positive ALL cases revealed heterogeneous genotypes with frequent deletions of PAX5 or IKZF1, which were often combined with CDKN2A/B deletions and single nucleotide variants in RAS pathway genes. Indeed, around 25% of the cases were IKZF1+ (7/26), a recently described poor outcome subgroup. In a few cases known fusions such as JAK2-BCR (1/26 = 4%), TCF3-ZNF384 (2/26 = 8%) and PAX5-ESRRB (1/26 = 4%) were detected. The fatal ALL subtype positive for the translocation TCF3-HLF was always strongly positive for VNN2 (11 cases tested), providing a biomarker for rapid and early identification of such cases. Surprisingly, over 50% of all VNN2 positive cases had recurrent mutations in epigenetic regulators, such as EZH2, MLL2 and KDM6A.
Summary/Conclusion: VNN2 positive leukemia is a genetically heterogeneous group, appears associated with high risk of relapse, is always detected on poor risk TCF3-HLF ALL and has high frequency of mutations in epigenetic regulators. Prospective evaluation of VNN2 by flow cytometry in the upcoming AIEOP-BFM-ALL study will clarify the significance of this marker for risk stratification in ALL and will be useful for early detection of TCF3-HLF positive cases.

NILOTINIB COMBINED WITH LOWER-INTENSITY CHEMOTHERAPY FOR FRONT-LINE TREATMENT OF YOUNGER ADULTS WITH PH-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA (ALL): INTERIM ANALYSIS OF THE GRAAPH-2014 TRIAL

Y. Chalandon[1,*], P. Rousselot[2,3], J.-M. Cayuela[4], X. Thomas[5], E. Clappier[4,6], V. Havelange[7], P. Chevallier[8], F. Huguet[9], N. Boissel[4,6], C. Berthon[10], G. Stüssi[11], S. Maury[12], S. Chantepie[13], F. Pasquier[14], I. Plantier[15], V. Lhéritier[16], N. Ifrah[17], S. Chevret[6,18], H. Dombret[4,6]

[1]HUG, Geneve, Switzerland, [2]CH, [3]UVSQ University, Versailles, [4]University Hospital Saint-Louis, AP-HP, Paris, [5]CHU Lyon Sud, Lyon, [6]University Paris Diderot, Paris, France, [7]UC, Louvain, Belgium, [8]CHU, Nantes, [9]IUCT-Oncopole, Toulouse, [10]CHRU, Lille, France, [11]Oncology Institute, Bellizona, Switzerland, [12]University Hospital Henri Mondor, AP-HP, Creteil, [13]CHU, Caen, [14]Institut Gustave Roussy, Villejuif, [15]CH, Roubaix, [16]GRAALL Coordination, Lyon, [17]CHU, Angers, [18]Biostatistics, University Hospital Saint-Louis, AP-HP, Paris, France

Background: The introduction of tyrosine kinase inhibitors (TKIs) to treat patients with Philadelphia chromosome-positive (Ph+) ALL allows reducing the intensity of associated chemotherapy. In our previous randomized GRAAPH-2005 trial with imatinib, we have reported better short-term results when patients received lower-intensity chemotherapy (vincristine, dexamethasone and intrathecal chemotherapy infusions [ITs] only) during the first treatment cycle (Y. Chalandon *et al.* Blood 2015).
Aims: In this ongoing GRAAPH-2014 trial with nilotinib, we are pursuing random evaluation of reducing chemotherapy intensity by omitting high-dose cytarabine during the second treatment cycle. We are also repeating cycles 1 and 2 for a total of 4 cycles in order to prolong TKI exposure and reach a deeper response prior to allogeneic or autologous stem cell transplantation (SCT) in these patients.
Methods: After a common steroid prephase, patients aged 18-59 years old with newly diagnosed previously untreated *de novo* Ph+ ALL and an ECOG-PS ≤3 are eligible for randomization. Treatments are detailed in Figure 1. Primary study endpoint is non-inferiority of major *BCR-ABL1* molecular response (MMR) in the no-cytarabine arm after cycle 4, defined as *BCR-ABL1/ABL1* ratio <0.1% in the bone marrow. Secondary endpoints are hematologic complete remission (CR), early mortality, progression-free survival (PFS), per protocol event-free survival (EFS, also including initiations of unplanned subsequent therapies as events) and overall survival (OS). An interim analysis was planned after the first 60 patients enrolled became evaluable to make sure that the overall MMR rate does not significantly differ from the anticipated 80% rate.

Figure 1.

Results: This analysis included thus 60 patients randomized between March 2016 and June 2017 (M/F, 29/31; median age, 47 years; minor *BCR-ABL1* breakpoint, 72%). The median follow-up was 14 months (IQR, 11.6-16.2) and the minimal follow-up of alive patients was 3.8 months. All patients but one who early died from a septic shock achieved hematologic CR after

cycle 1 (CR rate, 98%). During the initial 4-cycle period of time, 4 additional CR patients discontinued the planned therapy during cycle 1 (1 septic shock, 1 chest pain, 1 paraplegia, 1 cannabis arteritis) and 1 during cycle 3 (prolonged cytopenia). In intent to treat analysis, the MMR rate was 43/54 patients (80%) after cycle 2 and 38/41 patients (93%) after cycle 4. Based on these as good as expected MMR rates, the trial is continuing in order to randomize the 265 patients needed to answer the no-cytarabine question. At the time of analysis, 31 and 13 patients had received allogeneic and autologous SCT in first CR, respectively (transplant rate, 73%). Seven out of the 59 CR patients relapsed (including 4 post-SCT relapse) and 3 patients died (including 2 deaths in CR, 1 of whom after SCT). At one year, resulting PFS and OS were estimated at 84.5% (95% CI, 75.0-95.2) and 95.9% (95% CI, 90.3-100), respectively. When taking into account initiation of unplanned therapies prior to SCT as events (3 dasatinib, 1 imatinib), per protocol EFS was estimated at 79.7% (95% CI, 69.5-91.4) at one year.
Summary/Conclusion: Front-line combination of nilotinib and lower-intensity chemotherapy appears to be a promising option to treat adult patients with Ph+ ALL, associated with a high major molecular response rate and a good short-term outcome.

PEDIATRIC PATIENTS WITH ACUTE LEUKEMIA AND MLL REARRANGEMENT SHOW A DISTINCTIVE EXPRESSION PATTERN OF HISTONE DEACETYLASES

N. Vega-Garcia[1,2,*], R. Malatesta[1,2], C. Estella[1,2], S. Pérez-Jaume[3], E. Esperanza-Cebollada[1,2], M. Torrebadell[1,2,4], A. Català[2,4,5], S. Gassiot[1,2], S. Pont[1,2], S. Rives[2,4,5], M. Camós[1,2,4]

[1]Hematology Lab, Hospital Sant Joan de Deu, [2]Institut de Recerca Hospital Sant Joan Deu, [3]Developmental Tumor Biology Laboratory,, Barcelona, [4]CIBERER, Instituto de Salud Carlos III, Madrid, Madrid, [5]Pediatric Hematology Oncology Depart, Hospital Sant Joan de Deu, Barcelona, Spain

Background: Histone deacetylase inhibitors (HDACi) have emerged as potential drugs. However, the lack of target specificity makes it difficult to predict their toxicities, limiting their use. There is a need to elucidate the role of HDACs.The study of *HDAC* expression in pediatric leukemia has been scarcely addressed and could help to tailor treatment with HDACi in a more personalized approach.
Aims: To analyze the expression of *HDACs*, *MEF2C* and *MEF2D* in pediatric patients with acute leukemia.
Methods: We analyzed HDACs MEF2C and MEF2D mRNA expression in pediatric patients with acute leukemia from 2003 to 2017 uniformly treated according to the SEHOP consecutive protocols.
Results: We studied 211 patients (57% males, median age 5.8 years, range 0-17.4), including 134 B-cell precursor acute lymphoblastic leukemia (BCP-ALL) cases, 33 T-ALL and 44 patients with acute myeloid leukemia (AML). We observed a global overexpression of *HDACs* and nearly all patients expressed class I *HDACs* homogeneously. In T-ALL patients, high *HDAC4* expression correlated with a poor prednisone response at day +8 of induction therapy, although not significantly (p=0.053). Interestingly, *MEF2C* expression seemed to reflect the oncogenic pathway of leukemic blasts. Thus, all patients with absent expression of *MEF2C* were *NOTCH1/FBXW7* mutated, while all but one patients with high *MEF2C* expression were wild-type; the only *NOTCH1*-mutated patient who expressed *MEF2C* gene had an immature pre-T phenotype. Noticeably, we identified a distinctive signature for patients with *MLL* rearrangement, with high *HDAC9* and *MEF2D* expression, regardless of age, *MLL*partner and lineage (p=0.005 and p=0.034, respectively). Regarding outcome, in BCPALL patients, low *HDAC2* expression (cut-off 3.29, around percentile 50) and very high *HDAC9* (cut-off 3.62, around p65) impacted negatively on event-free survival (EFS) at 5 years (70.5±7% *vs.* 95.4±3%, p=0.002; 69±1% *vs.* 97.9±2%, p<0.001, respectively). *HDAC9* expression was an adverse prognostic factor both in *MLL*-rearranged and in *MLL* wild-type cases. AML patients with *HDAC8* expression above the median (cut-off 2.34, p55), had a significantly worse EFS at 5 years (30.1±12% *vs.* 61±11%, p=0.015).
Summary/Conclusion: We identified an HDAC signature for MLL-rearranged patients,with overexpression of HDAC9 and MEF2D.Our results provide useful knowledge on HDACs in childhood leukemia and support the use of more specific HDACi.

PS924

PROTEOLYTIC L-ASPARAGINASE DEGRADATION AS A MECHANISM FOR NON-ANTIBODY-RELATED DRUG INACTIVATION

J. Walenciak[1,*], E. Polakowska[2], K. Wyka[2], W. Mlynarski[1], B. Zalewska-Szewczyk[1]

[1]Department of Pediatrics, Oncology, Hematology and Diabetology, [2]Laboratory of Immunopathology and Genetics, Medical University of Lodz, Lodz, Poland

Background: Immune-mediated L-asparaginase (L-asp) inactivation is the major process limiting the efficacy of the drug. Apart from clinical allergy, in some proportion of patients occurs a phenomenon called 'silent inactivation', where L-asp activity is below its therapeutic level, while the recipient does not present symptoms of hypersensitivity. Interestingly, approximately 1/3 of patients with inadequate activity of the drug are negative for the presence of anti-L-asp antibodies (Willer *et al*., 2011). The mechanism responsible for L-asp inactivation in this case remains unknown. We hypothesized that proteolytic enzymes involved in *in vitro* L-asp degradation (Patel *et al*., 2009) may influence drug activity *in vivo*.
Aims: The aim of our study was to evaluate an effect of L-asparaginase-degrading enzymes on L-asp treatment efficacy. For that reason, we evaluated serum concentrations of AEP, CTSB and its secreted proenzyme, procathepsin B (proCTSB), as well as their inhibitor, cystatin C (CysC), in 44 L-asp recipients undergoing induction remission therapy for ALL.
Methods: Serum concentrations of L-asp degrading enzymes: asparaginyl endopeptidase (AEP) and cathepsin B (CTSB) and its proenzyme – procathepsin B (proCTSB) were assessed prior to L-asp therapy and at the end of induction remission using immunoenzymatic method. At the same time the level of the main serum protease inhibitor – cystatin C (CysC) was assessed using the same technique. Ratios of the evaluated proteases to CysC and to serum total protein were evaluated. L-asp activity was assessed prior each drug administration according to the treatment protocol using spectrophotometric method. Inadequate L-asp activity was defined as mean activity below 100 U/l from all measurements.

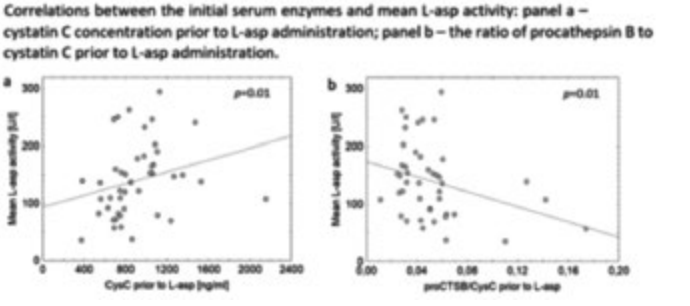

Figure 1.

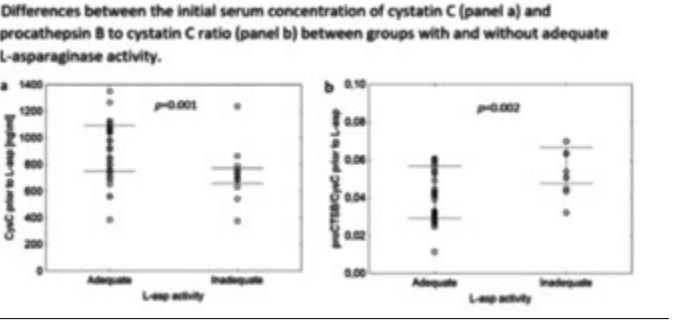

Figure 2.

Results: At the end of L-asp therapy we found an increase in the concentration of proteolytic enzymes (median of 1.29 vs. 1.41 ng/ml for AEP, 46.97 vs. 36.92 ng/ml for proCTSB and 0.51 vs. 0.30 ng/ml for CTSB) whereas their inhibitor level decreased (698.34 vs. 816.94 ng/ml for CysC). The proCTSB/CysC and CTSB/CysC ratio also increased significantly during the treatment. Mean L-asp activity correlated with initial CysC concentration (R=0.34, p=0.01) and initial proCTSB/CysC ratio (R=-0.35, p=0.01) (Figure 1). We did not observed any case of clinical hypersensitivity to L-asp, although inadequate activity of the drug was present in 13/44 patients (29%). In the group with inadequate L-asp activity we noted significantly lower CysC concentrations at the beginning of L-asp treatment (731.41 ng/ml vs. 977.34 ng/ml, p=0.001) and a higher initial proCTSB/CysC ratio (0.067 vs. 0.045, p=0.002, see also Figure 2).

Summary/Conclusion: Our results provide, for the first time *in vivo*, a possible explanation for the mechanism of L-asp inactivation apart from the development of anti-L-asparaginase neutralizing antibodies. To our knowledge, this is the first study demonstrating changes in the protease-antiprotease equilibrium upon L-asparaginase administration that may be involved in clinically significant blood L-asp clearance.

PS925

EVALUATION OF CORRELATION BETWEEN EARLY IMMATURE T-ALL IMMUNOPHENOTYPE, ABSENCE OF BIALLELIC DELETION OF TCR-Γ AND MEF2C EXPRESSION

S. Jay[1,*], N. Rajpoot[1], D. Verma[1], R. Kumar[1], S. Bakshi[2], R. Seth[3], J. Kumar[4], A. Sharma[2], A. Chopra[1]

[1]Laboratory Oncology, [2]Medical Oncology, [3]Pediatrics, [4]Biochemistry, all India Institute of Medical Sciences New Delhi, New Delhi, India

Background: T-ALL is an aggressive hematologic malignancy. Though it is generally associated with more unfavorable clinical features compared with B-lineage ALL, the prognostic markers in this disease are relatively inadequate for risk stratification and treatment planning. Because of this, there is interest in finding markers of poor risk disease that would indicate the likelihood of failure of remission induction on standard chemotherapy. Three potential markers of bad risk disease that show very poor treatment response, in the overall disease category of immature T-ALL (CD5+/-, CD1a-, CD8-; EGIL pro- and pre-T ALL), have emerged from recent work. The first is the presence of immunophenotypic characteristics that define the newly described entity of early thymic precursor T-ALL (ETP-ALL). The second is the absence of biallelic deletion of TCRγ chains (ABD) which also is a marker of immaturity. The third is overexpression of transcription factor, MEF2C, the driving oncogene for immature ETP T-ALL cases. In this study,we determined the correlation between T-ALL immunophenotype, ABD and MEF2Cexpression.
Aims: To determine how the three parameters of immaturity in T-ALL – immunophenotypically defined ETP-ALL, and molecularly determined absence of biallelic deletion of TCR y chains (ABD) and MEF2C, correlate with each other.
Methods: A total of 118 T-ALL cases, including 91 pediatrics and 27 adults, were included.Immunophenotyping was done on bone marrow/peripheral blood samples using CD3, CD7, CD45, CD5, CD8, CD1a, CD13, CD33, CD117, HLA-DR, CD34, CD65 and CD11b antibodies. ABD was done in 92 patients in which DNA was available by quantitative DNA PCR (Q-PCR) for TCR-γ rearrangements. *MEF2C* gene expression was quantified in patients (n=86) in which RNA was available by Q-PCR. Kruskal-Wallis test followed by Mann-Whitney test was performedto determine the correlation of *MEF2C* Expression with immunophenotypes and TCRγ chain status. Pearson's chi-squared test and Fisher exact test was performed to determine the significance of TCRγ chain status among various T-ALL immunophenotypes.
Results: Immunophenotypically, T-ALL cases were classified into mature(n=28), cortical(n=40) and immature(n=49) groups. Immature consists of ETP-ALL (n=17), Pro-TALL (n=9) and Pre-TALL(n=23) subgroups.As compared to mature and cortical, *MEF2C* expression was increased in immature group($p<0.05$).Within the immature group, *MEF2C*gene was found to be significantly over expressed in ETP-ALL subgroup as compared to mature and cortical ($p=0.004$ and 0.002; respectively). While comparing between ETP-ALL and non-ETP-ALL, *MEF2C* had high expression in ETP-ALL cases ($p=0.004$). Out of 92 patient analyzed for TCRγchains status, ABD was found in 29.3% (n=27) of patients. Also in comparison to mature ABD, it was significantly present in Pro-TALL and ETP-ALL groups ($p= 0.02$). Patients having ABD had higher expression of *MEF2C*($p<0.05$).
Summary/Conclusion: Taken together, ABD, MEF2C and immunophenotype can be used interchangeably to identify and risk stratify T-ALL cases.

Background: Despite significant improvement of childhood acute lymphoblastic leukemia (ALL) outcome, disease recurrence remains the most important cause of treatment failure. ALL relapse occurs more frequently during treatment or within the first 2 years from primary diagnosis; following, the risk gradually reduces.
Aims: Herein, we report the AIEOP experience on late (>30 months from first diagnosis) ALL relapse with atypical extramedullary localizations.
Methods: We retrospectively analyzed late relapses with atypical extramedullary localizations among ALL patients enrolled in subsequent AIEOP study protocols (ALL91, ALL2000, ALL2006 and ALL2009). Clinical data about primary diagnosis, relapse, treatment and outcome, were recorded by filling a data collection form in each AIEOP centers. We considered atypical, both extramedullary isolated and combined relapses, excluding central nervous system (CNS) and testicular involvement.
Results: We collected 19 patients (11 female and 8 male), from 12 AIEOP centers, with late atypical extramedullary relapse diagnosed within 21 years. Mean age at relapse was 13 years (range 6-22) and mean time from primary diagnosis was 59 months (34-93). The most frequent involved sites were the ovary (n=5), pelvis (n=3), mediastinum (n=3), kidney (n=2) and lymph nodes (n=2). Other localizations were liver, abdomen, skin, bladder, maxillary sinus, nasopharynx, parotid and retina, each involved in 1 patient. Four patients had extramedullary localizations, already at the time of first diagnosis. Minimal residual disease (MRD) evaluation on bone marrow, at disease recurrence, was available only in 9 patients, and was positive in 5. Patients received different treatment protocols: 10 were enrolled in the AIEOP REC 2003, 6 in the IntReALL SR 2010, 2 in the AIEOP 9503 and 1 in the AIEOP LNH-97 protocols. Patients with ovary involvement were submitted to ovariectomy and local radiotherapy was performed in 2 other cases. Allogenic hematopoietic stem cell transplant (HSCT) was performed in 8 patients, while 2 received autologous HSCT. Second complete remission (CR) was obtained in 18 patients. After a median follow-up of 48 months (7-158), 14 patients (73,6%) are alive, in second CR (2 still on treatment, 2 completed follow-up after 10 and 13 years, and 12 continue controls). All but one patient (sepsis death), treated with allogenic HSCT are alive. Overall, 5 patients dead, 4 from progression disease and 1 from post-transplant complications. The estimated overall survival probability was 60%.
Summary/Conclusion: The Italian experience confirms that extramedullary ALL localizations, other than CNS and testicles, have a very low incidence (<1%); the most frequent involved sites are ovary, pelvis, kidney and lymphnodes, while mediastinum prevails in T-ALL, as expected. Patients have a good prognosis: 94,7% achieved a second CR, and 73,6% are in continuous CR after a median time of 48 months. Sixteen patients, at relapse, received a risk-adapted protocol with MRD monitoring, according to which treatment intensification with allogenic HSCT was established. Since most of the transplanted patients are alive, we underline the importance of MRD evaluation during salvage treatment in order to identify patients at high risk who can benefit from HSCT. Further study on specific genetic abnormality, microenvironment and adhesion molecules could clarify pathogenesis of these atypical relapse and the specific tropism for some tissues of leukemic cells.

PS927

INCIDENCE AND OUTCOME OF RELAPSES IN YOUNG ADULTS (18-60 YR) WITH PH—POSITIVE ALLTREATED WITH IMATINIB, CHEMOTHERAPY AND ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION (PETHEMA ALLPH08 TRIAL)

J. M. Ribera[1,2,*], O. Garcia[1,2], M.J. Moreno[3], P. Barba[4], I. García-Cadenas[5], S. Mercadal[6], P. Montesinos[7], M. Barrios[8], T. Bernal[9], J. Ribera[2], S. Vives[12], M. Cervera[10], E. Lavilla[11], E. Abella[12], M. Tormo[13], E. Genescà[2], M. Calbacho[14], E. Feliu[12]

[1]ICO-Hospital Germans Trias i Pujol, [2]Josep Carreras Leukaemia Research Institute (IJC), Badalona, [3]Hospital Clínico de Málaga, Málaga, [4]Hospital Vall d'Hebron, [5]Hospital de Sant Pau, Barcelona, [6]ICO Duran i Reynals, Bellvitge, [7]Hospital Universitario y Politécnico de La Fe, Valencia, [8]Hospital Carlos Haya, Málaga, [9]Hospital Central de Asturias, Oviedo, [10]ICO-Hospital Joan XXIII, Tarragona, [11]Hospital Lucus Augusti, Lugo, [12]Hospital del Mar, Barcelona, [13]Hospital Clínico Universitario de Valencia, Valencia, [14]Hospital Ramón y Cajal, Madrid, Spain

Background: The concomitant use of tyrosine kinase inhibitors (TKI) and chemotherapy has improved the prognosis of patients with Philadelphia chromosome-positive (Ph+) acute lymphoblastic leukemia (ALL) allowing them to achieve a high rate (>95%) of complete remission (CR) and to perform allogeneic hematopoietic stem cell transplantation (HSCT) in a high proportion of patients (>70%), most of them in good molecular status. However, relapses occur in around 30% of young adults, their treatment and outcome has not been extensively analyzed.
Aims: The aim of this study was to analyze the incidence, characteristics and outcome of relapses in young adults with Ph+ ALL treated with imatinib, chemotherapy and allogeneic HSCT according to the PETHEMA ALLPh08 trial (NCT01491763)
Methods: The PETHEMA ALL Ph08 trial included 120 patients aged 15-60 yrs. CR was achieved in 111 (93%), and allogeneic HSCT was performed in 91 patients (82%) in first CR (Leuk Lymphoma 2018; 59:146-154). Twenty-six out of 111 patients (23%) experienced relapse. The following characteristics were analyzed: type of relapse (molecular/clinical), timing (before/after HSCT), location (BM/CNS/combined), presence of kinase domain mutations at relapse, type of treatment and outcomes (response, DFS and OS).
Results: 17/26 patients were male, with a median age of 42 years (range 17-56). At the time of relapse the median value of Hb was 116 g/L (85-134), WBC count 5.1 x10^9/L (0.97-111.4), platelet count 122x10^9/L (9-1125) and BM blast percentage of 4% (0%>90%). Four relapses (15%) occurred before HSCT and 22 (85%) after HSCT; 10 (39%) were molecular and 16 (61%) were systemic (BM [n=11], CNS [n=2], combined [n=3]). Mutations were studied in 12 patients (T315I [n=4], E225K [n=3], Y253H + E255V + E355G [n=1], no mutations [n=4]). Table 1 shows the results of treatment according to the type of relapse. Two patients did not receive treatment and one patient died during rescue therapy. At the time of analysis 12/20 patients who achieved a second CR relapsed and 16/26 patients died. The median of DFS was 8.5 months (95% CI: 2.1-14.9), and the median of OS was 15.3 months (95% CI: 6.7-23.9). DFS and OS probabilities were significantly higher for those patients with molecular relapse than for those with systemic relapse.

Table 1. Response to rescue therapy according to the type of relapse.

	Molecular relapse (n=10)	Systemic relapse (n=16)
Type of treatment	Increase imatinib dose (n=2) Change TKI (n=8)	TKI+Intensive chemotherapy (n=10) Intensive chemotherapy only (n=1) Change TKI (n=3) No treatment (n=2)
CR	-	13/13*
Molecular CR	7	9/10
Second HSCT after CR2	0	7
Relapse	3/7	9/13
DFS (median, 95%CI), months**	NA	6.3 (2.2-10.3)
Dead	4/10	12/16
OS (median, 95% CI), months***	NA	11.5 (8.4-14.6)

*early death in 1 patient; ** p=0.014; ***p=0.031

Summary/Conclusion: One fifth of young adults with Ph+ ALL treated in the ALLPh08 trial relapsed, most of them after allogeneic HSCT, and 40% of relapses were molecular. Mutations at relapse were detected in two thirds of patients. Although the response to rescue therapy was high, most patients showed a second relapse. The outcome of patients with molecular relapse was significantly better than that of patients with systemic relapse.

PS928

VENETOCLAX AND NAVITOCLAX WITH CHEMOTHERAPY IS EFFICACIOUS IN PATIENTS WITH RELAPSED ACUTE LYMPHOBLASTIC LEUKEMIA

T. Alexander[1,*], N. Lacayo[2], S. L. Khaw[3], J. Rubnitz[4], M. Schmidt[5], Y. Zhou[5], J. Ross[5], L. Rosenwinkel[5], S. Y. Kim[5], E. Jabbour[6], W. Stock[7]

[1]Department of Pediatrics, University of North Carolina School of Medicine, Chapel Hill, NC, [2]Lucile Packard Children's Hospital, Stanford University, Palo Alto, CA, United States, [3]Royal Children's Hospital, Melbourne, Australia, [4]Department of Oncology, St. Jude Children's Research Hospital, Memphis, TN, [5]AbbVie, Inc, North Chicago, IL, [6]Department of Leukemia, University of Texas MD Anderson Cancer Center, Houston, TX, [7]Section of Hematology/Oncology, Department of Medicine, University of Chicago and University of Chicago Cancer Research Center, Chicago, IL, United States

Background: Children and adults with relapsed or refractory (R/R) acute lymphoblastic leukemia (ALL) continue to have poor prognosis despite intensive chemotherapy regimens and novel therapeutic approaches. There remains significant unmet medical need for patients with ALL that are unsuitable for, or progress on, available therapies. In preclinical models of ALL, venetoclax (Ven; a highly selective BCL-2 inhibitor) has shown synergistic antitumor effects when combined with navitoclax (Nav; BCL-2, BCL-X_L and BCL-W inhibitor).
Aims: To present preliminary efficacy data, evaluating Ven and Nav in combination with chemotherapy in patients with R/R ALL.
Methods: This is an open-label, phase 1, multicenter dose escalation study (NCT03181126) in patients (4 45 years; ≥20 kg) who have R/R ALL. Patients receive the weight-adjusted equivalent of 200 mg daily Ven exposure on day 1, and 400 mg daily equivalent thereafter. Daily oral Nav administration is initiated on day 3 and given in three dose levels: 25, 50, or 100 mg weight-based equivalent for weight ≥45 kg. Patients may also receive chemotherapy: peg-asparaginase (1,250 IU/m^2 intravenous [IV] on days 9 and 22), vincristine (1.5 mg/m^2 IV on days 9, 15, 22 and 29), and dexamethasone (20 mg/m^2/day orally on days 9–13 and 22–26). Chemotherapy administration can be delayed, repeated for a second cycle, or not administered based on investigator discretion. Bone marrow aspirate and/or biopsy is required on days 8 and 36 for disease assessment and minimal residual disease (MRD; 10^{-4} cutoff) evaluation by flow cytometry before and after the first dose of chemotherapy, respectively. Absolute neutrophil counts (ANC) and platelet counts are reported 10^3 cells/mL.
Results: Baseline characteristics and prior therapies of the first three patients enrolled and treated are shown in the Table 1; all three patients had B-cell ALL. Patient A had a CRi with 1% MRD in the bone marrow on day 8; chemotherapy was not started to allow for count recovery. At day 36, this patient achieved a CR and was MRD-negative with an ANC of 2.74 and platelet count of 212. Patient B had stable disease (SD) with persistence of bone marrow blasts on day 8; by day 36 following one cycle of chemotherapy, this patient achieved CRp (platelet count of 62) and 0.7% MRD. Patient C had SD at treatment day 8 with persistence of bone marrow blasts. After one cycle of chemotherapy at day 36, this patient had achieved an MRD-negative CRi (ANC of 0.17).

Table 1. Baseline characteristics and disease response.

	Patient A	Patient B	Patient C
Age (years)	45	19	25
Sex	Male	Female	Male
Date of Diagnosis	Oct 2015	Jan 2013	Jun 2012
No. of prior therapies	6	7	3
Prior Therapy	1. intensive chemotherapy; 2. blinatumomab, cytarabine; 3. inotuzumab; 4. maintenance chemotherapy; 5. CAR-T; 6. SCT	1. intensive chemotherapy; 2. intensive chemotherapy; 3. blinatumomab, chemotherapy; 4. intensive chemotherapy, vorinostat, decitabine; 5. intensive chemotherapy, bortezomib, dasatinib; 6. fludarabine, cyclophosphamide; 7. CAR-T	1. intensive chemotherapy; 2. SCT; 3. SCT
Time on study	79 days	63 days	43 days
Day 8			
Response	CRi	SD	SD
MRD	1.0%	88%	90%
Day 36			
Response	CR	CRp	CRi
MRD	Negative	0.7%	Negative

CAR-T, chimeric antigen receptor therapy; SCT, stem cell transplant; CR, complete remission; CRi, CR with incomplete blood count recovery; CRp, CR with incomplete platelet recovery; SD, stable disease

Summary/Conclusion: Preliminary data suggest that the combination of

Ven and Nav is efficacious in patients with relapsed ALL that have failed multiple lines of therapy. The efficacy of Ven and Nav is potentiated by the addition of chemotherapy, and led to CR, CRi or CRp in all patients and MRD-negativity in 2 of the 3 patients. Long term follow-up to assess durability of response in these patients is ongoing. Results from this trial, along with data from an ongoing phase 1 study using Ven monotherapy followed by chemotherapy (NCT03236857) will help assess the overall contribution of Nav to the activity of Ven in this patient population.

PS929

IDENTIFICATION OF BCR-ABL-LIKE PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) PATIENTS BY REAL-TIME PCR

G. Tsaur[1,*], T. Mukhacheva[2], Y. Olshanskaya[3], S. Kovalev[2], O. Soldatkina[3], A. Druy[3], P. Sibiryakov[4], A. Vlasova[4], L. Vakhonina[1], O. Arakaev[1], L. Saveliev[5], L. Fechina[1]

[1]Regional Children's Hospital [1], Research institute of Medical Cell Technologies, [2]Ural Federal University named after the First president of Russia B.N. Yeltsin, Ekaterinburg, [3]National medical research centre of Pediatric Hematology, Oncology and Immunology named after D. Rogachev, Moscow, [4]Regional Children's Hospital [1], [5]Ural State Medical University, Ekaterinburg, Russian Federation

Background: Current strategy of *BCR-ABL*-like ALL identification is based on gene expression profile either by microarray, next-generation sequencing or TaqMan low-density array. All techniques are laborious and hardly transferrable. However easy and reliable characterization of *BCR-ABL*-like ALL is of high demand.
Aims: To work out the real-time PCR system for the identification of *BCR-ABL*-like ALL patients and to estimate clinical and genetic characteristics of pediatric *BCR-ABL*-like ALL cases
Methods: Based on previously published data (*R. Harvey et al. ASH 2013 abs #826.*) we estimated expression of *IGJ, SPATS2L, MUC4, CRLF2* and *CA6* genes in bone marrow samples of *BCR-ABL*-positive childhood ALL patients (n=9) obtained at the time of initial diagnosis by real-time PCR. Genes' expressions were estimated by ΔCt method in relation to *ABL* expression. Based on obtained results we made a classifier that was later applied on 97 pediatric 'B-others' ALL patients aged 1.2-17.0 years (median 4.0 years). 'B-others' group were formed after exclusion of translocations t(9;22)(q34;q11), t(12;21)(p13;q22), t(1;19)(q23;p13), 11q23/*MLL* rearrangements, high hyperdiploidy, hypodiploidy. In case of having expression results similar to *BCR-ABL*-positive cases, patients with *BCR-ABL*-negative ALL were attributed as *BCR-ABL*-like ALL. In 97 'B-others' ALL we evaluated *IKZF1* status by MLPA using P335 kit (MRC-Holland). We tested *BCR-ABL*-like ALL group for the presence of *ABL1, ABL2, CRLF2, IgH, JAK2, PDGFRb/CSFR1* gene rearrangements by FISH. Prognostic significance of *BCR-ABL*-like expression profile was estimated in 77 'B-others' patients treated according to the ALL-MB 2008 protocol. Informed consent was obtained in all cases.
Results: Hierarchical cluster analysis and principal component analysis showed that 15 cases out of 97 pediatric 'B-others' ALL patients were clustered together with 9 *BCR-ABL*-positive ones. In concordance with previously published data our *BCR-ABL*-like group identified by 5-genes approach was enriched by *IKZF1* deletions, *JAK2* and *CRLF2* rearrangements. *IKZF1* gene deletions were found more frequent in *BCR-ABL*-like ALL patients (67%) in comparison to non-*BCR-ABL*-like cases (11%) (p<0.001). Among 9 *BCR-ABL*-like cases *JAK2* rearrangements by FISH were found in 2, *CRLF2* in 4 (2 cases of *CRLF2-IgH* and 2 *CRLF2-P2RY8*). In 2 patients none of tested gene rearrangements were revealed. Moreover, in one case of *BCR-ABL*-like signature iAMP21 was identified, which is also in line with earlier published results (*J. M. Boer et al., Oncotarget 2017*). *BCR-ABL*-like profile in the observed cohort of patients was associated with female gender (80% vs. 57% p=0.011), high initial WBC (≥30*10^9/L) (67% vs. 18%, p=0.001), M3 bone marrow status on day 15 of induction remission (27% vs. 4%, p=0.010). As a results of high initial tumor load, *BCR-ABL*-like ALL patients more often were stratified to high-risk group (40% vs. 9%, p=0.001). *BCR-ABL*-like ALL patients had significantly worse outcome. Event-free survival in this cohort of patients was lower compared to non-*BCR-ABL*-like group (0.25±0.14 vs. 0.89±0.04, p<0.001) while cumulative incidence of relapse was remarkably higher (0.55±0.16 vs. 0.03±0.02, p<0.001).
Summary/Conclusion: Thus, we showed that real-time PCR technology based on expression data of 5 genes allowed us to detect the group of pediatric *BCR-ABL*-like ALL patients, enriched with *IKZF1* gene deletions, *JAK2, CRLF2* rearrangements. The observed group of patients had initial high-risk features, slower treatment response and as a consequence the unfavorable outcome within ALL-MB 2008 protocol.

PS930

DELIVERY OF INTRATHECAL METHOTREXATE CHEMOPROPHYLAXIS TO ADULTS AND TYA PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKAEMIA – AN AUDIT OF FACTORS AFFECTING PROTOCOL ADHERENCE

S.A. Sommerfeld[1,*]

[1]Haematology, Christie Hospital, Manchester, United Kingdom

Background: ALL is a curable disease in 30-40% of adults up to 60 years and 60-70% of young adults aged 16-25 years. CNS relapse is associated with a poorer prognosis. Intrathecal chemoprophylaxis with methotrexate (IT MTX) is a standard of care and integral part of modern treatment protocols. In the UK, protocol schedules like UKALL14 and UKALL 2011 define total numbers of IT MTX. Keeping up with scheduled IT MTX prior to maintenance can be challenging and we recognize this in our clinical practice
Aims: Objective 1: Compare numbers of administered IT MTX with protocol scheduled doses to determine compliance. Objective 2: Examine factors leading to cancellation of IT MTX
Methods: Included were patients aged 16 to 60 years with a diagnosis of B or T – ALL or LBL who received IT MTX following either the UKALL 2011 or the UKALL 14 protocol. Excluded were patients with CSF disease at presentation, systemic or CSF relapse or cessation of protocol guided treatment for other reasons. Objective 1: EPR data from 31.8.2011 to 31.8.2017 were reviewed for IT MTX. Compliance with the IT MTX schedule as per current protocol phase was assessed by a compliance score (number of administered doses divided by protocol defined doses). Objective 2: Cancellations of protocol scheduled prescribed IT MTX between 1.1.2016 and 31.7.2017 were reviewed.
Results: Objective 1: 56 patients were identified. Of these, a total of 29 (51.8%) were TYA patients (16-25 years of age at time of commencing treatment) and 27 (48.2.7%) were adult patients (26 – 60 years). Of scheduled IT MTX doses, 135/176 (76.7%) were given in adults and 221/279 (79.8%) in TYA (78.6% in total). Compliance scores in adult and TYA did not differ significantly. Objective 2: 75 events leading to 70 cancellations were identified and separated in categories (Platelets, Coagulation, Rescheduled, Did not attend/communication issues, Infection, Toxicity, Vincristine administration, Anticoagulated, Failed lumbar access, Other). There were 56 events in 16 TYA and 19 in 10 adult patients. The 3 patients with the most events had overall compliance scores of 72.7%, 81.8% and 90.9%, respectively. Comparing TYA and adult events for "coagulation" by chi square test for independence, there was a statistically non-significant relationship that cancellation of an IT MTX due to abnormal coagulation parameters differed between the TYA group and the adult group (p-value 0.143538) (Figure 1).

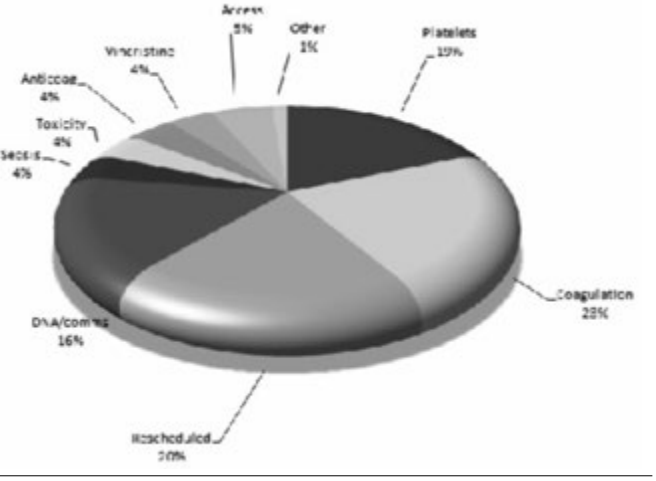

Figure 1. Causes for cancellation of IT MTX.

Summary/Conclusion: We believe this is the first audit examining IT MTX compliance in defined treatment schedules. The strength of this work lies in review of real life data. Limitations are a relatively small case numbers and bias. Data from objective 1 suggest IT MTX following a trial protocol is deliverable. The analysis of events in objective 2 shows compelling clinical reasons for most cancellations, but also scope for improvement. We suggest that targeting scheduling issues by integration of records into a single information system may improve overall efficacy of IT MTX. More data by other centres and re-audit are encouraged.

PS931

THE PROGNOSIS FOR PATIENTS WITH PHILADELPHIA CHROMOSOME POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA WHO WERE INELIGIBLE FOR ALLOGENEIC STEM CELL TRANSPLANTATION IN THE TKI ERA

A. Shigematsu[1,*], K. Minauchi[1], S. Takahashi[1], J. Iwasaki[1], T. Yamakawa[1], M. Ogasawara[1], M. Imamura[1], N. Kobayashi[1], S. Ota[1]

[1]Department of Hematology, Sappro Hokuyu Hospital, Sapporo, Japan

Background: The survival of the patients with Philadelphia chromosome positive acute lymphoblastic leukemia (Ph+ALL) has improved by the introduction of tyrosine kinase inhibitors (TKIs), especially for those who received allogeneic stem cell transplant (allo-HSCT). However, there has been a few data about the prognosis for patients with Ph+ALL who were ineligilble for allo-HSCT.
Aims: We conducted a retrospective analysis of prognosis for patients with Ph+ALL who were ineligible for allo-HSCT.
Methods: Clinical data of patients were retrospectively collected from medical records in Sapporo Hokuyu Hospital. The patients' eligibility criteria were as follows: diagnosed as Ph+ALL since 2003 and aged more than 25 years. Descriptive statistical analysis was performed using the Fisher's exact test for categorical variables and using the 2-sided Wilcoxon rank sum test for continuous variables. The probability of survival was estimated using the Kaplan-Meier method. All P-values were two-sided and a P-value of 0.05 was used as the cutoff for statistical significance.
Results: Sixty-four patients were eligible for the study, and median age of the patients was 41 years (range; 31-89). Median count of WBC at diagnosis was 11000/μL (860- 367300), and 31 of the patients had additional chromosomal abnormalities. Sixty-one patients received induction therapy including a TKI (Imatinib, n=44; Dasatinib, n=17), and 57 patients achieved complete remission. Thirty-five of the patients were received allo-HSCT (HSCT group) and the remaining 29 were did not receive allo-HSCT (non-HSCT group). Age was significantly higher in the non-HSCT group (non-HSCT, 65 years; HSCT, 45 years, p<0.001), and other characteristics of the patients; such as sex, WBC count at diagnosis and additional chromosome did not differ between the two groups. At the median follow-up days of 955 (range: 305-5077 day), overall survival was significantly worse in the non-HSCT group (p=0.009). The median day of death of the non-HSCT group was 451 (15-1284), and the major cause of death was relapse (81.0%). Only five of the fifteen relapsed patients achieved CR2, and all of the 5 patients relapsed early after achievement of CR2 (Figure 1).

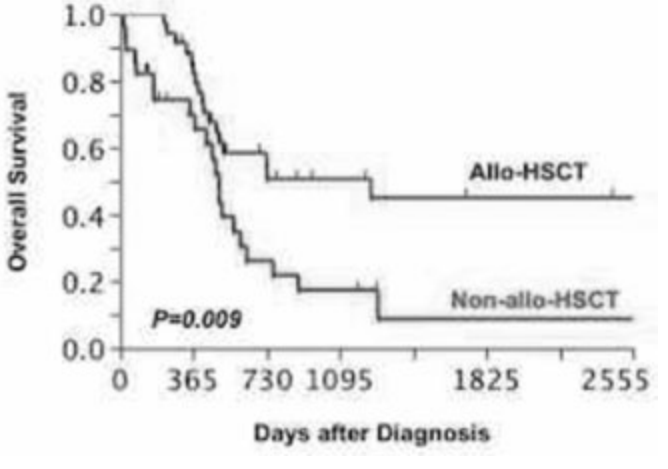

Figure 1. Overall survival according to allo-HSCT.

Summary/Conclusion: Our analysis suggests that overall survival was inferior for the Ph+ALL patients who did not received allo-HSCT, and the major cause of death was relapse. Few patients achieved CR2 after relapse, and more effective consolidation therapy is therefore needed for improvement of survival for patients who are ineligible for allo-HSCT.

PS932

COMPARISON OF NEXT GENERATION SEQUENCING AND RT-PCR APPROACHES FOR MINIMAL RESIDUAL DISEASE MONITORING IN ACUTE LYMPHOBLASTIC LEUKEMIA

A. Miroshnichenkova[1,*], A. Komkov[1,2], E. Zerkalenkova[1], I. Mamedov[2], Y. Olshanskaya[1]

[1]Laboratory of Cytogenetics and Molecular genetics, Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology, [2]Laboratory of Comparative and Functional Genomics, Shemyakin-Ovchinnikov Institute of bioorganic chemistry, Moscow, Russian Federation

Background: Being the major cause of relapse in leukemia, minimal residual disease (MRD) is considered to be the strongest prognostic factor, allowing to evaluate the efficiency of a treatment, and to make a decision on the subsequent therapy. Detection of MRD by Next generation sequencing (NGS) is proven to be one of the most efficient and sensitive techniques. Detection of clonal rearrangements of immunoglobulin (Ig) and T-cell receptor (TCR) genes is widely used for clonality assessment and for MRD monitoring along with RT-PCR of fusion transcripts, and unlike the latter one, is applicable in most cases of lymphoblastic malignancies.
Aims: The purpose of this study is to compare a new approach for monitoring MRD in acute lymphoblastic leukemia (ALL) by targeting massive sequencing of clonal rearrangements of immunoglobulin (IG) and T-cell receptor (TR) genes with MRD monitoring via RT-PCR of fusion transcripts.
Methods: A cohort of uniformely treated patients consisted of children aged 4 to 13 years diagnosed with ALL. DNA was extracted from patients' bone marrow (BM) samples on the 1st and 36th day of treatment. Initial detection of patient specific clonal rearrangements was carried out by 8 multiplex PCRs of Ig and TCR loci followed by NGS. MRD detection included targeted NGS of previously detected rearrangements in post-treatment follow-up samples in serial dilutions. The rearrangements chosen for future MRD diagnostics were chosen using 5% cut-off. Quantitative analysis was based on "Digital PCR"-like statistical approach.
Results: We identified over 500 leukemic rearrangements in 97 patients using NGS technique. All cases had detectable Ig and/or TCR rearrangements with a median number of 3 per sample. 65% of samples contained rearranged TCRG, and in 85% of samples IGH was rearranged. Complete VDJ rearrangements dominated over incomplete DJ rearrangements in both IGH and TRB. We compared the MRD levels of 21 follow-up samples with data obtained by RT-PCR of fusion transcripts including t(12;21)(p13;q22) ETV6/RUNX1, t(5;14)(q35;q32) BCL11B/TLX3, and t(4;11)(q21;q23) KMT2A/AFF1. Three KMT2A/AFF1 positive cases revealed a strong correlation between MRD level measured by RT-PCR and NGS. Among 17 RT-PCR negative results, 14 were confirmed negative by NGS, however 3 of those follow-up samples showed significant MRD level, verified by flow cytometry.
Summary/Conclusion: RT-PCR of fusion genes is a reliable and widely used MRD detection technique, however, it is only applicable for patients with known fusion transcripts. Moreover, our data showed that in 17% of cases MRD negativity by RT-PCR was not confirmed by NGS, clearly showing the presence of tumor clones in analysed samples, undetectable by RT-PCR. Therefore, NGS-based detection of rearrangements of Ig and TCR loci, being a sensitive, specific, and widely applicable method, allowing for clonality evaluation and MRD quantification, is likely to become a routine procedure for MRD diagnostics in the nearest future.

PS933

ENHANCING MANAGEMENT OF PH+ ALL BY MONITORING WITH AN ANALYTICALLY VALIDATED MULTIPLEX ASSAY FOR BCR-ABL1 MINOR BREAKPOINT (E1A2) WITH HIGHLY SENSITIVE DETECTION OF 1:40,000 (0.0025% OR 4.6 LOGS)

J. Brown[1,*], M. Dodge[1], I. Beldorth[1], S. Filipovic-Sadic[1], K. Jefferson[1], M. Fahey[1], J. hedges[1]

[1]Asuragen, Austin, United States

Background: Management of ALL requires MRD quantification to assess response dynamics. For Philadelphia-chromosome-positive acute lymphoblastic leukemia (Ph+ ALL), such assessment of tumor burden can be achieved through flow cytometry and molecular monitoring (PCR-based) of the BCR-ABL1 fusion transcript of t(9;22), frequently e1a2 (minor break-

point, m-BCR). MRD is valuable post-induction and to assess eligibility for stem cell transplantation (SCT) after consolidation. For Ph+ ALL, prolonged monitoring of BCR-ABL1 MRD levels is recommended by the ESMO Clinical Practice Guidelines to guide changing TKI. As therapeutic progress results in deeper clinical responses, analytical sensitivity has become a critical topic for reliable measurement of complete molecular remission (MolCR), the most important prognostic factor for disease-free and overall survival. This level requires an MRD assay for minor breakpoint that confidently and consistently calls molecular responses of ≥1:10,000 (≥4 logs or ≤0.01%).

Aims: We describe the analytical validation and method comparison of a CE-marked IVD multiplex system reporting continuous BCR-ABL1:ABL1%ratio values via automated analysis.

Methods: Encapsidated RNA molecules form blends of nuclease-resistant BCR-ABL1 and ABL1 transcripts to calibrate and control the system. Multiplexed 4-point curves using such blends provide copy values and account for the relative run-specific efficiency of the RT step. Controls (high, low, negative) were also developed using encapsidated RNAs. cDNA generation and qPCR were optimized to allow high mass of nucleic acid without inhibition to drive analytical sensitivity. Cell line RNA was diluted into non-leukemic human RNA to create challenge panels for most validation studies. RNAs negative for e1a2 tested specificity. Peripheral blood from e1a2-positive ALL patients were collected (n=13) with informed consent from age range 33-73 (median 59) across the 4 groups: 15-35 (1), 36-55 (5), 56-70 (6), and >70 (1). They were tested against a second CE-marked IVD kit capable of e1a2 detection as a comparator. The software includes a logic algorithm that flags any specimen requiring further review. Statistical analyses were carried out after log transformation to achieve normal distributions. Specifically, we introduced "Log Reduction" (LR) values as the log reduction from theoretical totality of 100% (LR = log10(100%÷%ratio)), similar to Molecular Response (MR) values for Major breakpoints.

Results: Our gains in analytical sensitivity allowed detection of background e1a2 mRNA in non-leukemic specimens. Specifically, an LOB was determined both for BCR-ABL1 copy number of 1 copy/qPCR and for%ratio of 0.0010% (LR5.00, 1:100,000). The LOD (classical parametric) and LOQ were statistically distinct from LOB at 0.0025% (LR4.61, 1:40,000) and 0.0039% (LR4.45, 1:26,000), respectively. Despite deep analytical sensitivity, this system maintains analytical specificity ("below LOD" for BCR-ABL1-negative samples); however, it does demonstrate the expected low-level crosstalk from contrived clonal specimens of extremely high BCR-ABL1 Major breakpoint transcripts. Linearity was validated to encompass 4 logs, from 0.0025% to 25% (LR4.61 to LR0.61).

Summary/Conclusion: The newly developed test kit quantifies deep response dynamics to 1:40,000 (4.6 log) and improves workflow with streamlined reagent formulation, multiplex format, and automated software analysis.

PS934

THE RISK OF DEVELOPING HEPATIC TOXICITY FROM PEGYLATED-ASPARAGINASE IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS IS HIGHLY AFFECTED BY CONCOMITANT MEDICATIONS

P. Minetto[1,*], N. Bisso[1], F. Guolo[1], M. Clavio[1], R. Marcolin[1], M. Miglino[1], F. Ballerini[1], R.M. Lemoli[1], M. Gobbi[1]

[1]*Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, Policlinico San Martino, IRCCS per l'Oncologia, Genoa, Italy*

Background: The application of pediatric-inspired regimens for treating adult acute lymphoblastic leukemia (ALL) has led to a significant improvement in clinical outcome. However, concerns about the use of pegilated L-Asparaginase (PEG-ASP) have emerged. While patient-related risk factors as high BMI or hepatic steatosis have already been identified, few data are available on the role of concomitant drugs potentially contributing to PEG-ASP toxicity.

Aims: To identify patients and therapy-related factors related to PEG-ASP toxicity in a cohort of adult ALL patients.

Methods: Since 2013, 26 adult ALL patients received PEG-ASP in our Center. Median age was 47 years (range 19-76); 19 patients were treated in frontline setting (13 according to a full pediatric protocol) whereas 7 patients received PEG-ASP during salvage therapy for relapsed/refractory disease. We analyzed each course of therapy including PEG-ASP administration as an independent event, accounting 51 episodes. Patients' features, concomitant therapies were analyzed as factors potentially affecting PEG-ASP toxicity. The incidence of grade III-IV thrombotic/bleeding, hepatic or pancreatic toxicity was recorded.

Results: No grade III-IV pancreatic, thrombotic or hemorrhagic adverse event were observed. Grade III hepatotoxicity was observed in 5 patients; 3 patients had grade IV hepatotoxicity and experienced unexplained severe weight gain and painful hepatomegaly, a clinical picture resembling sinusoidal occlusive disease. Ultrasonography showed the onset of acute liver steatosis. All 3 patients had received concomitant therapy with Idarubicin (IDA), vincristine (VCR) and vancomycin. In univariate analysis age > 45 yrs, administration of PEG-ASP therapy with active leukemia or BMI >25 were not related with an increased incidence of grade III-IV hepatotoxicity which was instead significantly higher when a cumulative dose of IDA of at least 20 mg/sqm (p 0.047, HR 1.49) was administered. Cumulative dose of VCR of at least 2 mg/sqm determined a borderline increase in toxicity risk (p 0.055, HR 4.75). No increase was observed with any dose of steroids, daunorubicin, cyclophosphamide, cytarabine, methotrexate, and 6-mercaptopurine. Among antimicrobial therapies, vancomycin administration increased the risk of grade III-IV hepatotoxicity (p 0.009, HR 1.86). No significant increase in the risk of toxicity was observed with carbapenems and azoles. Notably, none of the patients undergoing full pediatric induction, which contains higher cumulative doses of PEG-ASP, experienced grade IV hepatotoxicity, regardless of age (range: 19- 55). A multivariate logistic regression analysis disclosed that administration of IDA or vancomycin were independent predictors of grade III/IV hepatotoxicity (p 0.004, 0.054; Table 1).

Table 1. Factors affecting Hepatic Toxicity.

	Grade III/IV hepatic toxicity (%)	HR	p (univ)	p (multiv)
Age >45	5/22 (23)	-	0.440	-
BMI >25	2/15 (13)	-	1.000	-
Full pediatric schedule (higher PEG-ASP dose)	3/27 (11)	-	0.440	-
Daunorubicin	4/23 (17)	-	1.000	-
Vincristine	7/26 (27)	4.75	0.055	0.137
Cyclophosphamide	5/23 (22)	-	0.698	-
Idarubicin	3/6 (50)	1.49	0.047	0.004
Cytarabine	1/15 (7)	-	0.406	-
Mercaptopurine	0/12 (0)	-	0.173	-
Methotrexate	0/9 (0)	-	0.322	-
Steroids	8/37 (22)	-	0.173	-
Vancomycin	4/7 (57)	1.86	0.009	0.054
Azoles	6/23 (26)	-	0.125	-
Carbapenems	5/15 (33)	-	0.086	0.543
Overall	8/41 (20)			

Summary/Conclusion: In our experience the toxicity profile of PEG-ASP in adult patients is overall manageable and even higher dose of PEG-ASP were administered without excess toxicities. However, our data suggest that concomitant drugs play a crucial role contributing to PEG-ASP hepatotoxicity.

Acute myeloid leukemia – Biology & Translational Research

PS935

CELL OF ORIGIN INFLUENCES DISEASE AGGRESSIVENESS AND CHEMOTHERAPY RESISTANCE IN A MOUSE MODEL OF MLL-AF9 REARRANGED ACUTE MYELOID LEUKEMIA

C. H. Nguyen[1,*], K. Bauer[1], R. Wieser[1]

[1]Department of Medicine I, Medical University of Vienna, Vienna, Austria

Background: The cell from which a cancer originates has a profound impact on its clinical properties. This has also been suggested for acute myeloid leukemia (AML), where the presence of a stem-cell like gene expression signature in leukemic blasts was associated with a poor prognosis. Especially AML with rearrangements of the MLL locus in 11q23 is thought to be able to arise from either stem or progenitor cells, and the cell of origin appears to influence the course of disease
Aims: Using a mouse model of MLL-AF9 (MA9) driven AML, we further investigate the impact of the cell of origin on clinical properties of resultant AML.
Methods: A well-established and clinically relevant model of AML driven by expression of the fusion oncogene MA9 was used. The hematopoietic stem cell-enriched $Lin^-Sca\text{-}1^+c\text{-}kit^+$ (LSK) cell and the common myeloid progenitor (CMP) populations were retrovirally transduced with MA9 and transplanted into sub-lethally irradiated mice. Leukemic cells were harvested from terminal ill mice and subjected to flow cytometric analysis to determine the frequency of leukemic stem cells (LSCs) and of mature myeloid ($Mac\text{-}1^+$ and $Gr\text{-}1^+$) cells. Cell cycle analysis of LSCs was performed by intracellular staining with Ki-67 and DAPI. Furthermore, cell renewal capacity was determined using the serial replating assay, and sensitivity to drugs used in standard chemotherapy (cytarabine and daunorubicin) of AML was measured using a metabolic activity assay.
Results: LSK_MA9 cells were more potent in inducing AML in mice than CMP_MA9 cells, indicated by a shorter disease latency and a higher white blood cell count at the time of sacrifice. LSK_MA9 derived AML cells had a significantly higher frequency of LSCs and a lower frequency of mature myeloid cells as determined by cell surface marker phenotype. Also, LSCs derived from LSK_MA9 was more quiescent in G_0 phase of cell cycle. Accordingly, LSK_MA9 derived AML cells formed more colonies than CMP_MA9 derived AML cells through 4 serial replatings. Furthermore, high expression of *Evi1*, a stem-cell associated proto-oncogene linked to a poor prognosis in AML, was found in LSK_MA9 but not CMP_MA9 derived AML. Finally, LSK_MA9-derived AML cells were less responsive to cytarabine and daunorubicin than those derived from CMP_MA9.
Summary/Conclusion: Our data lend further support to the notion that the cell of origin influences the clinical outcome of AML. Specifically, expression of MA9 in LSK cells resulted in more aggressive and chemotherapy resistant AML as compared to AML derived from MA9 transduced CMPs.

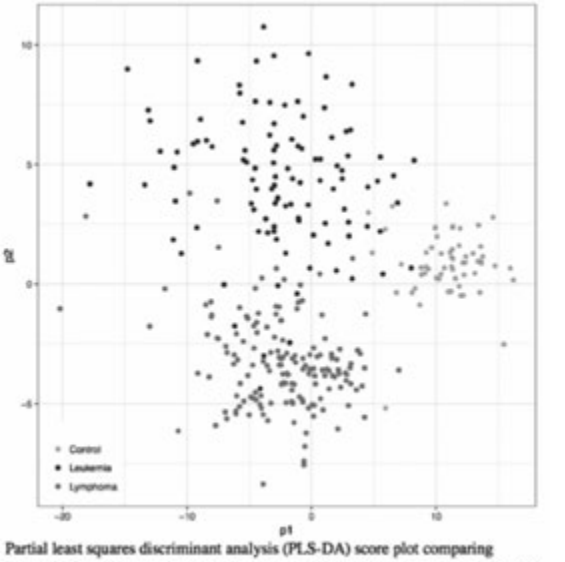
PS936

PLASMA PROTEOME IN PATIENTS WITH LEUKEMIA AND LYMPHOMA REVEALS MAJOR DIFFERENCES RELATED TO HEMOSTASIS, INFLAMMATION AND STROMA

A. Eriksson[1,*], A. Abu Sabaa[2], Q. Shen[2], E. Bergfelt Lennmyr[1], A. Enblad[1], G. Gammelgård[2], A. Hein[2], E. Freyhult[3], M. Kamali-Moghaddam[2], M. Höglund[1], G. Enblad[2]

[1]Department of Medical Sciences, [2]Department of Immunology, Genetics & Pathology, [3]Department of Medical Sciences, National Bioinformatics Infrastructure Sweden, Science for Life Laboratory, Uppsala University, Uppsala, Sweden

Background: Acute leukemias and lymphomas are highly malignant disorders associated with poor prognosis and high frequency of relapse.
Aims: In order to increase the knowledge of the disease biology, and to investigate the diagnostic and prognostic value of plasma proteins for these diseases, a large number of proteins were analyzed in plasma samples from consecutive acute leukemia and lymphoma patients and compared to healthy controls
Methods: Multiplex proximity extension assays (PEA) were utilized to assess plasma samples (1 µL), from leukemia and lymphoma patients included in the U-CAN biobank as well as age-matched healthy controls, using two Olink™ multiplex protein panels (ONCII and CVDIII). In multiplex PEA, each target protein is recognized by a pair of proximity probes that in proximity are hybridized to each other allowing enzymatic DNA polymerization and subsequent DNA amplification. In total, 183 proteins were measured in 265 plasma samples taken at diagnosis; 113 acute leukemias (Acute Myeloid Leukemia, AML: 69, Acute Lymphoblastic Leukemia, ALL: 35, Acute Promyelocytic Leukemia, APL: 9) 158 lymphomas (Diffuse Large B-Cell Lymphoma, DLBCL: 105, Hodgkin's Lymphoma, HL: 53) and 60 healthy controls. Results were obtained as Normalized Protein Expression (NPX) on a log2 scale where a high NPX value corresponds to a high protein concentration. For each protein, the difference in NPX between groups (leukemia vs controls, lymphoma vs controls and leukemia vs lymphoma) was assessed using a linear regression model, adjusting for age and gender. In addition, multivariate modeling (PLS-DA) was performed.
Results: Highly significant differences were observed for plasma protein levels between leukemia and lymphoma patients and healthy controls. Comparing the leukemia samples to controls, the 10 most significantly differentiating proteins were: vWF, SYND1, TNF-RSF6B, MPO, VIM, TNF-R1, IL-6, CTSD, ADAM-TS15 and FURIN; all with higher levels in leukemias except for ADAM-TS15. When lymphoma samples were compared to controls, the top 10 differentiating proteins were: PAI, MMP-9, VIM, AZU-1, MPO, HGF, PDGF subunit A, S1000A11, TGF-α and FURIN; all with higher levels in lymphomas. The analysis also allowed distinguishing between patients with leukemia and lymphoma, for which the top 10 identified proteins were MMP-9, PDGF subunit A, SPARC, PGLYRP1, vWF, TNFRSF10C, PAI, TR, TGF-α and GPNMB. The PLS-DA model distinguished between leukemia and lymphoma with very few patients being misclassified. Of the 5 ALL patients clustering with the lymphomas, 4 out of 5 samples had lymphoblastic lymphomas. For the 2 DLBCL cases misclassified as leukemias, both had bone marrow involvement by lymphoma. When the subgroups of leukemias and lymphomas were compared, major differences were observed between AML, APL and ALL as well as between HL and DLBCL (Figure 1).



Partial least squares discriminant analysis (PLS-DA) score plot comparing leukemia, lymphoma and controls. The cross-validated average error rate is 0.028.

Figure 1.

Summary/Conclusion: Using the highly specific and sensitive PEA technology, we identified sets of plasma proteins significantly distinguishing samples from patients with leukemia, lymphoma, and healthy controls. Samples from patients with acute leukemia had higher levels of proteins associated with hemostasis, cell to matrix integration and inflammation, whereas samples from lymphoma patients had higher levels of proteins associated with stroma and neutrophil activation. This technology appears to be a feasible screening technique for plasma protein biomarkers in minute sample volumes, and may be a valuable tool in the diagnostics and prognostics of various subgroups of acute leukemias and lymphomas.

PS937

IDENTIFICATION OF CALM/AF10 (PICALM/MLLT10) COOPERATING MUTATIONS IN A ZEBRAFISH LEUKAEMIA MODEL

O. Delfi[1,*], Y.J. Sung[1], P.J. Browett[1], P.M. Kakadia[1], S. Bohlander[1]

[1]Department of Molecular Medicine and Pathology, University of Auckland,

Leukaemia & Blood Cancer Research Unit, Auckland, New Zealand

Background: Acute Myeloid Leukaemia (AML) is one of the most frequent and aggressive types of blood cancer and can lead to the death of patients just a few weeks after diagnosis. AML is caused by somatic genetic aberrations, such as recurring chromosomal translocations and point mutations. The *PICALM/AF10* fusion gene results from the t(10;11)(p12;q14) that is found in about 1% of AML cases as well as in some acute lymphoblastic leukaemia cases.
Aims: Establish a CALM/AF10 transgenic zebrafish leukaemia model using the minimal fusion of CALM/AF10 (CA-MF), which has been shown to induce leukaemia in mice.
Methods: In our model, CA-MF is expressed under the control of the murine Runx1+23 promoter, which restricts CA-MF expression to zebrafish hematopoietic stem cells. Two transgenic constructs (pTol2-Runx1+23_CA-MF_IRES-EGFP and oTol2-Runx1+23_CA-MF_IRES-mCherry) were injected into fertilized zebrafish eggs at the one cell stage. Two days after injection, embryos were sorted based on the expression of the heart marker.
Results: More than 85% of the transgenic embryos died in the first 5 days after injection and only about 5% of F0 zebrafish reached four months of age. Between 3 to 8 months, 50% (5 out of 10 fish) fish developed signs of disease. They became less active, sat at the bottom of the tank and their abdomens became distended. At this stage, the fish were euthanized and dissected. The autopsies showed tissue overgrowth around the kidney and histological sections revealed increased cellularity of the kidney and liver with massive infiltration of hematopoietic cells in the tissue sections of these organs. In flow cytometry, the cells from the kidney marrow from the transgenic fish showed a different pattern in the forward scatter (FSC) and side scatter (SSC) profile compared to the FSC/SSC profile of normal zebrafish kidney marrow cells. The changed FSC/SSC profile was compatible with an expansion of the hematopoietic progenitor cell population in the transgenic F_0 zebrafish. These findings strongly suggest that the fish had developed a leukaemia-like disease. Currently, we are establishing tissue transplantation to determine whether the disease is transplantable.
To identify potentially cooperating mutations, we performed whole exome sequencing (WES) of the tumor cells and germline tissue (muscle) of six CA-MF zebrafish. We obtained about 10 gigabases of sequence per exome. Preliminary analysis of the WES data identified somatic mutations among others in genes whose human homologues are frequently mutated in patient samples, like *kras*, *dnmt3*, and *ezh1*. The identification of somatic mutations was complicated by the fact that the tumor and germline DNA samples that we used for our sequencing experiments only had a purity of between 70 to 80% (i.e. the germline DNA samples contained between 20 to 30% tumor DNA and the tumor DNA samples contained about 20 to 30% of germline DNA).
Summary/Conclusion: While the flow cytometry, histology and sequencing data from our transgenic zebrafish are strongly suggestive of leukaemia, additional experiments are required to further characterize our model and confirm the malignant nature of the observed tumors (e.g. by performing transplantatioan experiments).
To date only a handful of zebrafish leukaemia models have been established. Our new CA-MF zebrafish model together with the ease with which additional genetic manipulation can be performed in zebrafish will be a helpful tool to understand leukaemia biology.

PS938

FLT3-ITD ANALYSIS ON RNA CONFERS ENHANCED SENSITIVITY AND ALLOWS EARLIER RELAPSE PREDICTION

E. Oppliger Leibundgut[1,2,*], R. Joncourt[1], N.A. Porret[1], U. Bacher[1], M. Andres[1], G. Baerlocher[1,2]

[1]Hematology, University Hospital Bern, [2]Biomedical Research, University of Bern, Bern, Switzerland

Background: *FLT3* internal tandem duplications (ITD) are reported in ~30% of patients with acute myeloid leukemia (AML) and have been associated with a high relapse rate and poor outcomes. The FLT3 inhibitor midostaurin has been approved for targeted therapy of *FLT3* mutated AML, conferring a survival benefit. Thus, rapid molecular testing for *FLT3*-ITD is required as well as techniques for more sensitive molecular monitoring of response and minimal residual disease (MRD) assessment. *FLT3*-ITD analysis is currently performed by fragment length analysis (FA) that has a limited sensitivity of 2-5%. There is no consensus on whether DNA or RNA is the specimen of choice. Newer protocols are based on DNA including the FDA-approved companion test (Leukostrat *FLT3*). Due to *FLT3* overexpression on AML blasts, we hypothesized that use of RNA might increase the sensitivity of FA.
Aims: We compared the sensitivity of *FLT3*-ITD detection by FA on paired DNA and RNA samples.
Methods: Bone marrow (BM) or peripheral blood (PB) samples from 42 patients with AML were collected at diagnosis and follow-up. Samples were subjected to DNA and RNA extraction followed by PCR and FA using the Leukostrat Assay 2.0 (Murphy KM, *et al.* JMD 2003). ITD mutations and allelic ratios (ITD-mutated/wildtype) were determined. The assay was validated down to a limit of detection (LOD) of 2%.
Results: Eighty-two paired samples from 42 patients with AML (median age 62 y, 45% females, 33 ITD-mutated, 9 wildtype) were assessed including 31 BM and 51 PB samples. 30 were diagnostic and 52 follow-up samples from patients with a known ITD. 20 samples (24%) showed corresponding ITDs in RNA and DNA, and 52 (63%) were negative for ITD on RNA and DNA. In 12 samples, ITDs were only detected on RNA but not on DNA. McNemar's chi-squared test for symmetry was highly significant (p=0.00053), indicating that higher sensitivity with the RNA-based method outweighed potentially false negative cases. Of the 12 samples with ITD only on RNA, 4 had ITDs on DNA below the detection limit of 0.05 and therefore were reported as ITD negative. Allelic ratios across all samples ranged between 0.02 and 23.5. Differences of allelic ratios between RNA and DNA were 0.3-226-fold (mean 16-fold). Higher ratios on RNA were found in 75% of cases with positivity on both materials. Three patients with early hematological relapses were studied in detail. In two ITD-mutated patients, ITDs on DNA became undetectable during treatment, and relapses occurred at 5 and 7 months with reappearance of ITDs. On RNA, both patients had detectable ITDs at all time points under treatment and high levels at relapse. The 3rd patient had wildtype *FLT3* on DNA at diagnosis and a relapse after 7 months with 2 ITDs. On RNA, both ITDs were retrospectively detectable already at diagnosis at low levels of 0.02 and 0.04.
Summary/Conclusion: In the era of FLT3 inhibitors, sensitive detection of *FLT3*-ITD at diagnosis and monitoring of response to therapy and MRD are important prerequisites for therapy guidance. Systematic comparison of DNA and RNA analysis revealed positivity on RNA in 12 (15%) cases that were missed on DNA. Follow-up analyses showed that 1) persistence of ITD clones under treatment was relevant for prognosis and associated with earlier relapses, and 2) small initial ITD clones can evolve and require reevaluation of therapy. Higher sensitivity of *FLT3*-ITD detection by using RNA for FA will allow optimizing of therapeutic strategies and elucidate the dynamics of clonal evolution from diagnosis to relapse.

PS939

PHARMACOLOGIC INHIBITION OF CELLULAR METABOLIC PROCESSES IMPACTED BY AGING SENSITIZE ACUTE MYELOID LEUKEMIA (AML) CELLS TO THE NOVEL LIPOATE DERIVATIVE CPI-613

R. Anderson[1], K. Pladna[1], T. Pardee[1,2,*]

[1]Internal Medicine, Section on Hematology and Oncology, Wake Forest Baptist Health, Winston-Salem, [2]Rafael Pharmaceuticals , Cranbury, United States

Background: Altered metabolism is a hallmark of cancer cells, including AML. CPI-613 is a novel lipoate derivative in clinical development by Rafael Pharmaceuticals that inhibits the TCA cycle enzymes, pyruvate dehydrogenase (PDH) and α-ketoglutarate dehydrogenase. In a phase one study, CPI-613 in combination with high dose cytarabine and mitoxantrone demonstrated encouraging efficacy especially in older AML patients. One possible explanation is that the cellular metabolic pathways affected by aging contribute to the increased response. Two well documented pathways are the decline in mitochondrial electron transport chain quality that occurs with aging and the decline in autophagy.
Aims: To determine if pharmacological inhibition of the electron transport chain and autophagy would increase the response to CPI-613.
Methods: To determine the effect of TCA cycle inhibition on autophagy and mitochondrial membrane potential a Pdha deleted murine AML cell line was created using CRISPER/Cas9. Human and murine AML cell lines were treated with CPI-613, the electron transport chain inhibitor metformin and the autophagy inhibitor chloroquine alone and in combination. The effects of PDH loss or CPI-613 on autophagy were assessed by Western blotting for p62 and LC3B. The effect of metformin on mitochondrial membrane potential was assessed by TMRM staining. In vivo effects of combination treatment were assessed in a syngeneic, orthotopic, therapy resistant murine AML model.
Results: The murine Pdha deleted cells were significantly more sensitive to autophagy inhibition with chloroquine. They also displayed a decrease in mitochondrial membrane potential and were more sensitive to CPI-613 treatment. In PDHA wild type cells CPI-613 treatment induced autophagy in all AML lines tested. Inhibition of autophagy with chloroquine significantly sensitized AML cells to CPI-613 *in vitro*. *In vivo*, animals treated

with the combination of chloroquine and CPI-613 had a significantly improved survival compared to controls and singly treated animals. In addition, metformin treatment decreased mitochondrial membrane potential and significantly sensitized all AML cells to CPI-613 cell killing *in vitro*. *In vivo*, treatment with CPI-613 and metformin conferred a significant survival benefit.

Summary/Conclusion: These data suggest that response to the novel lipoate analog CPI-613 is influenced by metabolic pathways that are affected by aging. This may help explain the increased benefit seen in older patients treated with CPI-613 in combination with high dose cytarabine and mitoxantrone in a phase I trial. These data further support that AML cells containing less functional mitochondria or those with reduced autophagy capacity may be particularly susceptible to this approach. Future studies will be needed to determine if pretreatment assessment of these functions can be used as a biomarker to predict which patients will most benefit from CPI-613.

PS940

GENOMIC CHARACTERIZATION OF DIAGNOSTIC AND REFRACTORY/RELAPSED ACUTE MYELOID LEUKEMIA SAMPLES THROUGH A NEXT GENERATION SEQUENCING (NGS) PANEL OF 62 GENES

D. Carbonell[1,2,*], C. Martínez-Laperche[1,2], J. Suárez-González[2,3], M. Chicano[1,2], M. Bastos[1,2], G. Rodríguez-Macías[1], M. Kwon[1,2], J.L. Díez-Martín[1,2], I. Buño[1,2,3]

[1]Department of Hematology, Gregorio Marañón General University Hospital (HGUGM), [2]Gregorio Marañón Health Research Institute (IiSGM), [3]Genomics Unit, Gregorio Marañón General University Hospital (HGUGM), Madrid, Spain

Background: Acute myeloid leukemia (AML) is an entity with a complex clonal structure, which presents from 3 to 5 driver mutations at diagnosis. These alterations may be useful as diagnostic and prognostic biomarkers; moreover, during follow-up, they may provide information about treatment response and clonal evolution within the disease. Thus, the study of these variants is becoming essential in a routine clinical practice. During the last years, advances in next generation sequencing (NGS) have revolutionized the world of genetics and cancers

Aims: The aim of this study is to characterize, using NGS, the genomics of AML at diagnosis and at refractoriness/relapse

Methods: Thirty-eight patients diagnosed of AML (non-promyelocytic) were consecutively included in a prospective observational study between November 2015 and February 2018. Samples were obtained from the entire cohort at diagnosis, at refractoriness in a subgroup of 12 of these patients and at relapse in another subgroup of seven patients. As a whole, 57 samples were analyzed. Therefore, two groups of paired samples were obtained: diagnosis-refractoriness and diagnosis-relapse. For NGS analysis, an enrichment-capture custom panel (LMA-GeneSGKit® 62 Genes, GeneSystems, Valencia, Spain) was used. This panel, designed with collaboration of our team, can detect SNP and short indels (<30 bp) in 62 AML-related genes. A mean depth of 300x was reached, obtaining a 10% sensitivity. The GeneSystems software was used for the bioinformatics analysis, and the variant classification was performed according to the American College of Medical Genomics (ACMG) 2015 score. All variants were confirmed by Sanger sequencing or GeneScan fragment analysis

Results: Non-benign variants were detected in 37 of the 38 diagnostic samples. A total of 194 variants in the 70.97% (44/62) of the genes analyzed were found; 99 of these variants were classified as unknown significance (VUS) and 95 as pathogenic or likely pathogenic variants (PV). The most frequently altered gene with VUS was *NF1* and with PV, *DNMT3A*, *FLT3* and *NPM1*. The median number of variants per sample was 5 (range 0-10). In refractoriness and relapse samples, 99 variants in the 53.23% (33/62) of the genes were found, 53 VUS and 46 PV. The main gene with VUS was, as in the case of diagnostic samples, *NF1*. In contrast to diagnostic samples, the most frequent genes with PV were DNMT3A and ASXL1. The median number of variants per sample, as in diagnosis, was 5 (range 2-10). Gain or loss of variants was observed in 73.68% of patients with paired samples (14/19), being *NF1* the gene with the most changing behavior in VUS, followed by *ASXL1*, *FLT3* and *IDH1*, which are affected by variants of pathogenic nature (Figure 1).

Summary/Conclusion: The use of NGS gene panels is useful at diagnosis of AML for an appropriate risk-group classification and at determining the heterogeneity of the diverse subpopulations taking into account the allele frequency of each variant. Moreover, the study of refractory or relapsed samples and its comparison with those at diagnosis, could add to the understanding of the clonal evolution of the disease. Thus, identifying leukemic cells that have a resistance-related variant, treatment selection could be more effective by targeting all potentially malignant clones. However, the lack of consensus in the interpretation of variants makes it a very subjective endeavor, being VUS a very frequently type of variant detected. Functional studies are therefore needed to test the actual cellular consequences of such variants which would lead to a better clinical management of AML patients.

HEMATOPOIETIC FUNCTIONS OF R396Q AND R204X GATA2 MUTANTS SUGGEST DISTINCT MECHANISMS LEADING TO THE GATA2 SYNDROME

M. Pasquet[1], S. Lagarde[2], N. Prade[2], L. Jamrog[3], A. Carrette[3], N. Rouquie[3], S. Hebrard[3], P.-Y. Juvin[3], P. Bories[3], C. Bellanne Chantelot[4], J. Donadieu[5], B. Gerby[3], C. Broccardo[3], E. Delabesse[2,*]

[1]Haematology, CHU Toulouse, [2]Haematology, Institut Universitaire de Cancérologie de Toulouse, site Oncopôle CHU de Toulouse, [3]Team [16], CRCT, Toulouse, [4]CHU Pitié, [5]CHU Trousseau, Paris, France

Background: Germline *GATA2* mutations have been identified in patients associated with predisposition to hematological, immunological and vascular disorders. Few data are available regarding the molecular pathogenesis of these mutations.

Aims: We analyze two representative germline GATA2 mutations, R204X leading to a premature stop codon before the N-terminal zinc finger and R396Q, a missense mutation located after the C-terminal zinc finger.

Methods: Human GATA2 coding region was cloned upstream of the IRES of the MSCV-IRES-EGFP retroviral vector. Retroviral particles were produced. Bone marrow cells from C57BL/6 8-week female mice were sorted and infected twice with retroviral vector. Infected lineage-negative cells were plated in triplicate in multipotential methylcellulose.

Results: The cellular location of these mutant proteins is distinct, nuclear for the R396Q mutant and restricted to the cytoplasm for the R204X mutant protein. *in vitro* differentiation of hematopoietic progenitors showed that the cells transduced with the GATA2 R396Q mutant remain blocked at an early stage of granulo-monocytic differentiation in contrast to the GATA2 R204X mutant which has no effect compared to cells transduced with wild type GATA2. The R396Q mutant, unlike R204X, specifically induces leukemic transformation of cells *in vitro* after serial replating of transduced progenitors leading to leukemia cell lines. The R396Q mutant although behaving as a null allele demonstrates a distinct and specific activation of *Runx1t1*.

Summary/Conclusion: Our *in vitro* experiments demonstrate that the heterogeneity of the GATA2 syndrome relies on biological distinct defects, the R204X mutant acting only as a complete loss of function mutant in contrast to the R396Q mutant combining to its loss of the normal GATA2 function a specific oncogenic activation of *Runx1t1* explaining the increased risk of myeloid transformation of this mutant In epidemiological studies.

PS942

SYNERGISTIC INHIBITORY EFFECT OF HYDROXYUREA AND DECITABINE ON THE PROLIFERATION OF AML CELLS

K. Byrgazov[1,*], P. Valent[2,3], T. Lion[1,4]

[1]Children's Cancer Research Institute, [2]Department of Internal Medicine I, [3]Ludwig Boltzmann Cluster Oncology, [4]Department of Pediatrics, Medical University of Vienna, Vienna, Austria

Background: Treatment of acute myeloid leukemia (AML) in patients who are unable to tolerate standard intensive chemotherapy remains a challenge. Hydroxyurea (HU) and decitabine (DCB) have been used in palliative treatment of AML, and several studies have examined drug efficacy in this setting, but the combination of both drugs has not been studied in detail.
Aims: We examined the individual and combined effects of HU and different small molecules, including DCB, on intracellular molecular pathways, implicated in differentiation and proliferation of AML cells, as a potential basis for the development of improved treatment strategies in AML patients who are unfit for intensive therapy.
Methods: Six different AML cell lines (HL-60, ML-2, THP-1, MV4-11, KASUMI-1, U937) were treated with HU *in vitro*, and alterations in various signalling pathways involving over 20 proteins and genes previously identified as hallmarks of cancer were assessed by Western blot analysis (Figure 1A) and qPCR. Several small molecules targeting oncogenic pathways and epigenetic drugs, including DCB, were selected for further testing of potential synergism with HU.
Results: In four of the cell lines tested (HL-60, ML-2, THP-1, MV4-11), HU down-regulated the Hedgehog transcription factor GLI-1 and its downstream target MYC (Figure 1A). By contrast, HU induced expression of the differentiation factor SPI-1/PU.1 which is putatively repressed by MYC. Among various small molecules tested, DCB showed the most prominent synergy with HU in all AML cell lines examined (Figure 1B), as calculated by the "bliss-over-excess" method. Combined exposure to HU and DCB was efficient in killing HL-60, ML-2, THP-1, and MV4-11 cells, whereas drug combination effects on U937 and KASUMI-1 cells were moderate.

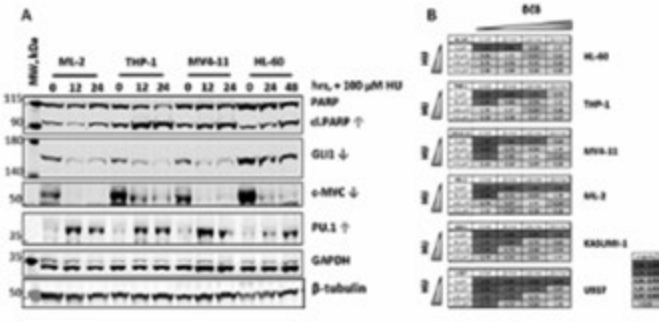

Figure 1.

Summary/Conclusion: HU and DCB are cytoreductive agents widely used in AML patients who cannot tolerate intensive therapy. Our data show that HU inhibits production of the MYC protein in AML cell lines. Moreover, we show that the combination of HU and DCB exerts synergistic anti-leukemic effects on AML cells which may pave the way for the development of new therapeutic strategies for AML patients, who are not amenable for intensive therapy, after tests on primary AML cells and *in vivo*.

MINIMAL RESIDUAL DISEASE IN ACUTE MYELOID LEUKEMIA USING MULTIPARAMETRIC FLOW CYTOMETRY IS HIGHLY PREDICTIVE OF OUTCOME

C. Kakirde[1,*], R. Kodgule[1], G. Raval[1], S. Kadechkar[1], Y. Badrinath[1], S. Ghoghale[1], N. Deshpande[1], D. Shetty[2], S. Chaudhary[1], S. Joshi[1], R. Mascarenhas[1], A. Gokarn[3], H. Jain[3], B. Bagal[3], H. Menon[4], M. Sengar[3], N. Khattry[3], P. Tembhare[1], P. Subramanian[1], S. Gujral[1], N. Patkar[1]

[1]Haematopathology, [2]Cytogenetics, [3]Adult Haematolymphoid Disease Management Group, Tata Memorial Center, Navi Mumbai, [4]Haemato-Oncology, Cytecare Cancer Hospitals, Bangalore, India

Background: One of the mainstays of chemotherapy in acute myeloid leukaemia (AML), other than acute promyelocytic leukaemia, is induction with a goal to achieve morphological complete remission (CR) as evident by less than 5% blasts. Post-remission strategies then focus on either consolidation chemotherapy or allogeneic bone marrow transplantation (aBMT). However, not all patients with this remission criterion achieve long-term remission and a subset of patients relapse. Detection of minimal residual disease (MRD) following chemotherapy, early in the course of treatment, is highly predictive of outcome and offers a window of opportunity to intensify treatment and prevent relapse.
Aims: Determining the prognostic outcome for Acute Myeloid Leukemia (AML) by Minimal Residual Disease (MRD) detection using multiparametric flow cytometry.
Methods: We accrued 311 consecutive patients of adult (>18 years) AML, other than with t(15;17), over a 32 month period (May 2015-Feb 2018) after obtaining consent. These patients were treated with standard 3+7 induction followed by high dose cytarabine MRD testing was done post induction and if feasible, post 1st Cycle HiDAC using a two tube 10 colour assay (CD15, CD13, CD19, CD34, CD56, CD7, CD45, CD11b, HLA-DR, CD117, CD14, CD123, CD64, CD33, CD36 & CD38). A minimum of 1.6 million events were acquired per tube on a Navios flow cytometer. An identical panel was used at MRD time points as well as on the diagnostic sample. Analysis of MRD was done using Kaluza 1.3. Conventional karyotyping and FISH was done as per standard recommendations and patients were classified into cytogenetic risk groups. The presence of *FLT3*-ITD, *NPM1* and *CEBPA* mutations was detected by a fragment length analysis based assay. Overall survival (OS) was calculated from the date of diagnosis to time of last follow up or death. Relapse-free survival (RFS) was calculated after achieving of 1st remission (CR) till relapse or death or last follow up if in CR. Results were analyzed for their impact on OS and RFS using Log Rank test of Kaplan–Meier survival analysis.
Results: Based on cytogenetics, 29.9% were classified as favourable risk whereas 59.4% and 10.6% were intermediate and poor risk respectively. FLT3-ITD, NPM1 and CEBPA mutations were harboured by 20.9%, 26.3% and 10.6% of patients respectively. The median follow-up was 8.2 months. Of these, 40 had induction death and 49 had refractory disease. Median OS was 5.1 months and RFS was 6.15 months. Post induction MRD was assessed in 264 patients of which 124 (46.9%) had a detectable residual disease (range 0.01-66.5%, median:0.35%). Post-consolidation MRD was assessed in 123 patients of which 28 (22.7%) were MRD positive (range 0.002-12.9%, median: 0.03%). Favorable risk and Intermediate risk cytogenetics were predictive of better OS than Poor risk patients (p=0.028) and (p=0.051) respectively and also provided a better outcome for RFS (p<0.001) and (p=0.001) respectively. The patients harbouring MRD at the end of induction were associated with inferior OS (p<0.001) and RFS (p=0.004), whereas post consolidation positive MRD status did not show a significant change in OS and RFS.
Summary/Conclusion: Our data is in agreement with other studies that determination of immunophenotypic MRD is extremely important in predicting an outcome. AML MRD is a very useful guide for guiding post remission strategies in AML and should be incorporated into routine treatment algorithms.

PS944

EXPRESSION OF CD25 FLUCTUATES IN THE LEUKEMIC STEM CELL POPULATION OF CD25-POSITIVE AML

Y. Kageyama[1,*], H. Miwa[1], R. Arakawa[2], K. Ohishi[3], M. Masuya[1], K. Nakase[4], F. Ishikawa[5], N. Katayama[1]

[1]Hematology and Oncology, Mie University Graduate School of Medicine, [2]School of Medicine, Mie University, [3]Blood Transfusion Service, [4]Cancer Center, Mie University Hospital, Tsu, [5]Laboratory for Human Disease Models, RIKEN Center for Integrative Medical Sciences, Yokohama, Japan

Background: A small but distinct population of leukemic stem cells (LSCs) is responsible for the initiation and propagation of acute myeloid leukemia (AML) and its recurrence. IL-2 receptor α chain (CD25), which is expressed on leukemia cells of 10 to 20% cases of AML, has been reported to be associated with poor prognosis of AML (Nakase *et al*., PLoS One, 2015). CD25 is also demonstrated to be one of the LSC-specific surface antigens that are not expressed on normal hematopoietic stem cells (Saito *et al*., Sci Transl Med, 2010). It is possible that CD25-targeting may be a promising novel therapy against AML.
Aims: We elucidated the relationship between CD25 expression and stem cell property using patient-derived xenograft model.
Methods: We examined nine CD25-positive AML samples with the detectable CD34 expression. CD25-positive or -negative cells in $CD34^{+}CD38^{-}$ population when this population was detected or otherwise

$CD34^+$ population were transplanted into 120 to 150 cGy irradiated newborn NOD.Cg-*Prkdc*^{scid}*Il2rg*^{tm1Wjl}/Sz (NSG) mice *via* facial vein within 48 hours of birth. Then engraft rate and phenotype of the engrafted cells were analyzed. Engrafted leukemic cells were subjected to secondary transplantation.
Results: Leukemic engraftment was observed with both $CD34^+CD25^+$ and $CD34^+CD25^-$ populations in three of nine CD25-positive AML samples. Phenotypical analyses of bone marrow cells from mice with leukemic engraftment revealed that those engrafted cells had both $CD34^+CD25^+$ and $CD34^+CD25^-$ populations. Engrafted cells of these cases were again divided into CD25-positive and -negative $CD34^+$ populations, each of which reconstituted both fractions again in the secondary recipient mice.
Summary/Conclusion: LSC has been defined as having the abilities to initiate leukemia in a recipient mouse and to grow out after re-transplantation into secondary recipients and preferably in tertiary recipients (Lapidot *et al.*, Nature, 1994). LSC-specific markers should satisfy the following conditions: 1) low or undetectable expression in normal tissues, especially normal HSCs, which ensures no or negligible adverse effects upon target therapy, 2) universally expressed in LSCs, which leads to eradication of LSCs by target therapy. Our results demonstrate that LSCs of CD25-positive AML reside in both CD25-positive and CD25-negative populations and that CD25 is not a *bona fide* LSC-specific marker of AML.

PS945

INTEGRIN ALPHA 7 EXPRESSION IS ASSOCIATED WITH PHENOTYPE AND GROWTH OF ACUTE MYELOGENOUS LEUKEMIA

N. Kobayashi[1,*], M. Takizawa[2], T. Ishizaki[1], K. Honma[3], H. Shimizu[1], A. Yokohama[4], T. Saitoh[3], N. Tsukamoto[5], H. Handa[1]

[1]Department of Hematology, Gunma University Graduate School of Medicine, [2]Medical Security and Safety Management Center, Gunma University Hospital, [3]Gunma University Graduate School of Health Science, [4]Blood Transfusion Service, [5]Oncology Center, Gunma University Hospital, Maebashi, Japan

Background: Acute myelogenous leukemia (AML) with granulocytic sarcoma (GS) at diagnosis is related to poor prognosis. A study using an established GS cell line demonstrated that a 92 kDa type IV collagenase enhances tissue invasiveness. However, other factors that promote the formation of extramedullary lesions are unknown.
Aims: To clarify the mechanism of tissue invasion and proliferation in local lesions of AML cells and its clinical prognosis.
Methods: A total of 77 AML patients participated in this study after informed consent. RNA was extracted from the bone marrow mononuclear cells of seven AML patients, with clinical complications of GS and seven AML-M2 patients (French-American-British classification; FAB) without GS, in Gunma university hospital. The RNA was subjected to RNA sequencing (RNA-seq) using NextSeq500 (Illumina) to evaluate the variations in gene expression between the AML groups with and without GS. The expression of integrin α7 (ITGA7) was evaluated using RT-qPCR and RNA extracted from the bone marrow mononuclear cells. Protein expression was confirmed using immunohistochemical staining of formalin fixed paraffin embedded (FFPE) specimens of the bone marrow clot. We also analyzed the clinical prognosis of these patients. As well, AML cell lines including PL21, THP1, and HL60 were evaluated for ITGA7 gene and protein expression using RT-PCR and flow cytometry, respectively. Cell proliferation assays were performed using the WST-8 cell proliferation cytotoxicity assay kit.
Results: Analysis of the RNA-seq results using Gene Set Enrichment showed that the genes expressed on the cell surface were significantly different in the group with GS (FDR q-value <0.005). We focused on ITGA7, which has a relatively higher expression in the GS group, because of its role in cell-to-cell interaction. RT-PCR analysis of the clinical specimens confirmed that the expression of ITGA7 was significantly higher in the GS group (p=0.00168) and AML M5 group (p=0.000108). Immunostaining of the FFPE specimen from the bone marrow also validated ITGA7 expression. Flow cytometry confirmed ITGA7 expression on PL21 and THP1 cell surfaces. ITGA7 has been shown to be expressed mainly in the muscle and is involved in cell proliferation, migration, and adhesion. Therefore, we examined PL21 and THP1 cells in a cell culture assay using a dish coated with the extracellular matrix laminin 211 isoform – a ligand of integrinα7β1. Proliferation of these cells was significantly enhanced in the presence of laminin 211 compared to that of laminin 411 or in an uncoated dish. However, ITGA 7 expression level was not associated with the prognosis of AML patients. No significant differences were seen in 64 patients, except for the rates of overall survival (p=0.918) and disease-free survival (p=0.398).
Summary/Conclusion: The proliferation of an AML cell line expressing ITGA7 was enhanced by laminin 211. However, the association of ITGA7 expression and the clinical prognosis was unclear. The formation of GS occurs more frequently in AML classified as M4 and M5 in the FAB classification than in other subtypes of AML. Clinically, these AML types are often accompanied by organ infiltration at diagnosis. Interaction of ITGA7 and laminin demonstrates the mechanism of infiltration and local growth of these AML subtypes.

PS946

THE ROLE OF STAT3B IN ACUTE MYELOID LEUKEMIA

P. Aigner[1,*], T. Mizutani[1], J. Horvath[1], H. Sill[2], K. Lind[2], V. Just[1], E. Casanova[1], D. Stoiber[1]

[1]Ludwig Boltzmann Institute for Cancer Research, Vienna, [2]Division of Hematology, Medical University of Graz, Graz, Austria

Background: Signal transducer and activator of transcription 3 (STAT3), a multifunctional transcriptional regulator, plays a central role in proliferation, differentiation and oncogenic transformation. It is expressed in two alternatively spliced isoforms, STAT3α and truncated STAT3β, which lacks the C-terminal transactivation domain. In addition to the C-terminal transactivation domain, which is crucial for the recruitment of nuclear cofactors, STAT3β is lacking the additional STAT3 phosphorylation site, serine 727, and instead carries a tail of seven unique amino acids. STAT3β recently gained attention as a powerful anti-tumorigenic molecule and protective prognostic marker. This has been shown in patients with esophageal squamous cell carcinoma, as well as in mouse models for breast, skin and colon cancer. Deregulated STAT3 signaling is frequently observed in leukemogenesis and generally associated with a poor clinical outcome in patients with acute myeloid leukemia (AML). Furthermore, it has been shown that the expression ratios of STAT3α and STAT3β change upon myeloid differentiation. However, the exact role of STAT3β in AML patients and during disease progression remains unknown.
Aims: The aim of our study is to gain a better understanding of STAT3β and its specific function in acute myeloid leukemia.
Methods: Hence, we analyzed more than 50 AML patient samples for *STAT3β/STAT3α* mRNA expression levels and its correlation with clinical prognosis and overall survival. Moreover, we generated an inducible *Stat3β* transgenic mouse model and crossed it with *Pten*-deficient mice, a previously described model for AML. In addition, we used fetal liver-derived stem cells from *Stat3β* transgenic mice, transduced with a retrovirus encoding for the MLL-AF9 translocation, in a transplant model for AML.
Results: We observed a correlation between clinical prognosis and *STAT3β/STAT3α* expression ratio. Specifically, we found elevated levels of *STAT3α* in all AML samples compared to healthy CD34-positive cells and only low levels of *STAT3β*. Similarly, we detected higher levels of *STAT3α* in patients with an adverse prognosis. A higher *STAT3β/STAT3α* ratio was further associated with a favorable clinical prognosis and a significantly increased overall survival.
In both *in vivo* models we could demonstrate that the expression of STAT3β impairs leukemogenesis and delays disease progression. In particular, we observed a significant decrease of leukemic cell infiltration into hematopoietic organs. The STAT3β-dependent delay in disease progression and leukemic infiltration resulted in a significant increase of overall survival. Additionally, *in vitro* colony formation assays with bone marrow cells (BMCs) derived from *Stat3β* transgenic mice, transformed with MLL-AF9, revealed lower numbers of colonies in *Stat3β* transgenic BMCs compared to the wild-type control.
Summary/Conclusion: In conclusion, our results indicate that STAT3β can serve as an anti-tumorigenic molecule in AML mouse models and the *STAT3β/STAT3α* ratio correlates with a more favorable outcome in AML patients. This study helps to unravel the role of STAT3-mediated signaling in the development of acute myeloid leukemia.

DISSECTING INTRA-TUMOR HETEROGENEITY IN ACUTE MYELOID LEUKEMIA THROUGH LEUKEMIA STEM CELL-ASSOCIATED MIRNA SIGNATURES AND SINGLE-CELL RNA TRANSCRIPTIONAL PROFILING

M. M. Naldini[1,*], F. Pavesi[2], A. Cammarata[3], M. Volpin[3], G. Casirati[2], G. Desantis[3], C. Caserta[1], A. Cosentino[3], D. Cittaro[4], E. Montini[3], F. Ciceri[2], B. Gentner[5]

[1]UNISR - SRTIGET, [2]Hematology and Bone Marrow Transplant Unit, San Raffaele Scientific Institute, [3]San Raffaele Telethon Institute for Gene Therapy, [4]Center for Translational Genomics and BioInformatics, San Raffaele Scientific Institute, [5]Hematology and Bone Marrow Transplant Unit, San Raffaele Telethon Institute for Gene Therapy, Milan, Italy

Background: Despite recent advances in risk-adapted treatment of AML, a large proportion of patients relapses. Recent findings suggest that relapse-promoting clones are already present at diagnosis and often show features of leukemic stem cells (LSC), which may persist through chemotherapy as minor subpopulations later leading to relapse. LSC-associated mRNA and miRNA signatures have shown promise in measuring LSC content in clinical samples.
Aims: To exploit miRNAs as new biomarkers of LSC and chemotherapy resistance in AML.
Methods: We have set up a droplet PCR assay for miRNA quantification in patient samples, as well as lentiviral reporter vectors to measure the activity of miR-126 (stem cell-associated miRNA), miR-21 and miR-22 (associated with chemotherapy resistance) in patient-derived xenografts (PDX) allowing prospective isolation of miRNA(high) AML subpopulations. Vector integration site (IS) analysis was used to identify single AML clones and track blast ontology in serial PDX transplantation. Single-cell RNA sequencing (scRNAseq) of AML blasts and residual HSPC at diagnosis was obtained by drop-seq technology.
Results: Based on previous data describing a panel of LSC-enriched and depleted miRNAs that correlate with clinical outcome, we verified the predictive power of the top 4 LSC miRNAs in an independent cohort of AML patients (n=55). Excluding CBF leukemia, higher miR-126 expression was associated with adverse ELN2017 risk. We investigated miR-126 and miR-21/22 activity in PDX by transducing patient blasts with miRNA reporters and transplanting them into NSG mice for prospective isolation of LSC enriched/miRNA(high) populations. miRNA(high) cells were enriched for CD34+ blasts (n=5 AML), and clonal tracking by vector IS analysis (n=1 disease) revealed higher sharing of miR-126(high) IS between primary and secondary PDX, further suggesting enrichment of leukemia-propagating cells within such population. We then sought to measure miR-126 expression in longitudinal patient samples at time-points putatively enriched for LSC, either early after chemotherapy (day 14) or at relapse. When sorting CD45dim blasts, we found increased levels of miR-126 with respect to the diagnosis samples. Furthermore, we sorted day 14 BM samples for residual AML based on leukemia-associated phenotype (LAIP+), and for non-leukemic HSPC (LAIP-CD34+CD90+) (n=5 pts). While we confirmed an increased LSC miRNA score in the LAIP+ blasts at day 14, we surprisingly found an even higher score within the HSPC compartment. We next performed scRNAseq on diagnostic blasts from 2 NPM1+AML patients: patient 1 achieved a long-lasting CR, while patient 2 had primary refractory disease. Since miRNAs cannot be evaluated with this technology, we calculated the extensively validated mRNA-based LSC17 score. Preliminary data show a higher LSC17 score in CD117+blasts from patient 2 than patient 1. Unexpectedly, the highest LSC17 score was detected within CD34+ cells from patient 1, which turned out NPM1(negative) and resulted in a multilineage graft when transplanted into NSG mice.
Summary/Conclusion: We show the feasibility of identifying LSC-enriched populations *in vivo* by LSC-associated microRNA reporters. We also highlight promiscuous expression of stem cell associated microRNA and mRNA signatures within LSC and residual healthy hematopoiesis in AML patients, hinting to shared transcriptional programs associated with stemness and underlining the need to separate blasts from regenerating HSPC for accurate interpretation of LSC signatures in post-treatment samples.

PS948

CLINICAL AND BIOLOGICAL CHARACTERISTICS OF TWO DISTINCT T(16;21) FUSIONS IN PEDIATRIC ACUTE MYELOID LEUKEMIA: A RETROSPECTIVE ANALYSIS BY THE I-BFM STUDY GROUP

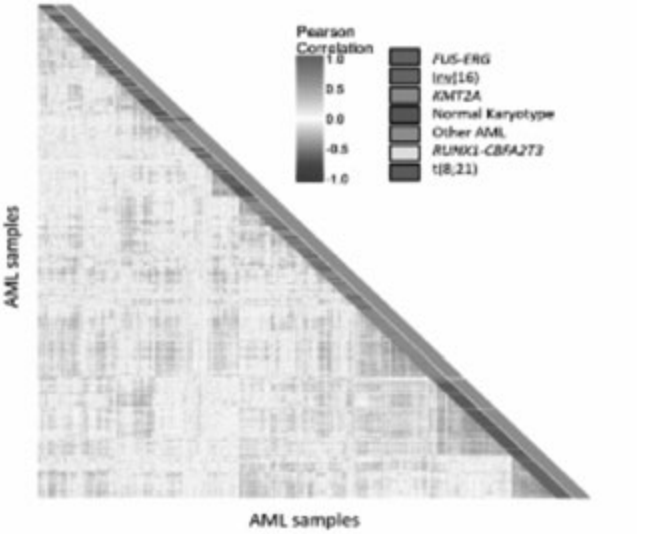
Background: Despite the use of intensive chemotherapy and allogeneic stem cell transplantation (HSCT) in selected patients, children with acute myeloid leukemia (AML) have 5-year overall survival (OS) rates of about 65%. Apart from early clinical response, cytogenetic and molecular aberrations are the most reliable prognostic factors for survival. It is clinically important to identify prognostic subgroups to stratify patients in future trials. Studies on rare AML subtypes can be facilitated by international collaborations. Herein, we focus on AML with t(16;21) rearrangements, including 2 different translocations: t(16;21)(p11;q22) resulting in the *FUS–ERG* fusion, and t(16;21)(q24;q22) resulting in the *RUNX1–CBFA2T3* fusion.
Aims: To define clinical and biological characteristics of pediatric AML with t(16;21) rearrangements.
Methods: Clinical data from children with t(16;21) AML were collected from 14 study groups participating in the international Berlin–Frankfurt–Munster (I-BFM) network. Patients (age 0–18 years) diagnosed from January 1, 1995, to January 1, 2016, were included. The AML-BFM study group provided data for 1326 unselected patients diagnosed between 1997 and 2013 as a reference cohort. All karyotypes were centrally reviewed by 2 independent cytogeneticists according to the international system for human cytogenetic nomenclature 2005. For gene expression analysis, the Children's Oncology Group (COG) provided RNAseq data for 1035 patients in AAML1031.



Unsupervised hierarchical clustering of pediatric AML. Fractional counts were normalized to trimmed mean of m-values and counts per million mapped reads (CPM), log2 transformed and filtered for genes with at least 1 CPM in 5% of samples. The relative level of expression per gene in each sample was determined by mean centering the expression values, using the geometric mean. Pairwise sample correlations (Pearson's R) were used for hierarchical clustering.

Figure 1.

Results: Clinical data were collected from 54 patients with t(16;21): 32 with *FUS–ERG* and 22 with *RUNX1–CBFA2T3*. Patients with *FUS–ERG* had no predominant French–American–British (FAB) type, whereas

76.4% of those with *RUNX1–CBFA2T3* had a granulocytic FAB type (M1, M2) compared with 42.1% in the reference cohort (p=0.004). Event free survival, OS and cumulative incidence of relapse at 4 years were 51% [standard error (SE)=1%], 68% (SE=1%), and 32% (SE=1%), respectively, for the reference cohort. The corresponding numbers for *FUS-ERG* were 7% (SE=5%, p<0.0001), 21% (SE=8%, p<0.0001) and 74% (SE=8%, p<0.0001), and for *RUNX1–CBFA2T3* were 77% (SE=9%, p=0.06), 81% (SE=8%, p=0.34) and 0%, respectively. In multivariate analysis with age, white blood cell count at diagnosis, and cytogenetic risk group as co-variables and allogeneic HSCT as the time-dependent variable, presence of *FUS–ERG* and *RUNX1–CBFA2T3* were independent risk factors for EFS, with hazard ratios of 1.93 (p<0.0001) and 0.325 (p=0.025), respectively. Hierarchical clustering analysis of RNAseq data showed that *FUS–ERG* and *RUNX1–CBFA2T3* clustered separately. *RUNX1–CBFA2T3* clustered with t(8;21) cases (Figure 1). Comparison of gene expression of *FUS–ERG* and *RUNX1–CBFA2T3* with other AML cases revealed 1314 and 119 differentially expressed genes, respectively. Of differentially expressed genes of *RUNX1–CBFA2T3*, 63 overlapped with differentially expressed genes in t(8;21) AML.

Summary/Conclusion: We identified two clinically relevant, distinct subtypes of pediatric AML patients with different t(16;21) rearrangements: those with *FUS–ERG* had poor outcomes, and those with *RUNX1–CBFA2T3* had favorable outcomes. *RUNX1–CBFA2T3* should be considered a core binding factor (CBF) AML, as the fusion involves *RUNX1*. RUNX1 is a subunit of CBF, a transcription factor that is an essential regulator of normal hematopoiesis. Disruption of CBF subunits by cytogenetic rearrangements leads to CBF AML. Patients with *RUNX1–CBFA2T3* might benefit from inclusion in the standard-risk group, along with other CBF AMLs, whereas those with *FUS–ERG* should be included in the high-risk group.

NUP98-KDM5A FUSION GENE IS AN INDEPENDENT PREDICTOR OF POOR PROGNOSIS WITH A DISTINCT HOX GENE EXPRESSION PATTERN

S. Noort[1,*], T. A. Alonzo[2], J. Smith[3], R. E. Ries[4], R. B. Gerbing[2], E. Sonneveld[5], F. Locatelli[6], D. Reinhardt[7], A. Baruchel[8], J. Stary[9], M.M. van den Heuvel-Eibrink[10], C.M. Zwaan[1], S. Meshinchi[311]

[1]Pediatric Oncology/Hematology, Erasmus MC/Sophia Childrens Hospital, Rotterdam, Netherlands, [2]Children's Oncology Group, Monrovia, California, [3]Fred Hutchinson Cancer Research Center, Seattle, Washington, [4]Fred Hutchinson Cancer Research Center, Seattle, Washington, United States, [5]Dutch Childhood Oncology Group, The Hague, Netherlands, [6]Italian Association of Pediatric Hematology and Oncology, University of Pavia, Pavia, Italy, [7]AML-BFM Study Group, Pediatric Hematology and Oncology, Essen, Germany, [8]Pediatric Hematology-Immunology Department, University Hospital Robert Debré and Paris Diderot University, Paris, France, [9]Czech Pediatric Hematology/Oncology, University Hospital Motol and Charles University, Prague, Czech Republic, [10]Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands, [11]Department of Pediatrics, Seattle Children's Hospital, University of Washington, Seattle, Washington, United States

Background: *NUP98* rearrangements are recurrent genetic events in pediatric acute myeloid leukemia (AML). We identified *NPU98-NSD1* as a recurrent poor risk abnormality (Hollink *et al.*, Blood 2011). Another recurrent fusion is *NUP98-KDM5A*, which was found in pediatric acute megakaryocytic leukemia (AMKL) and associated with poor clinical outcome (de Rooij *et al.*, Nature Genetics 2017).

Aims: The aim of this study was to determine the incidence of *NUP98-KDM5A* in large pediatric AML cohort not restricted to AMKL, and to define the biological and clinical characteristics of this subgroup.

Methods: The study comprised a COG and a European cohort of patients, and included 975 patients from COG trials 03p1 and 0531 (Gamis *et al.*, Blood 2013) and 343 European pediatric AML patients, previously described by Balgobind *et al.* in Haematologica, 2011. *NUP98-KDM5A* rearrangements were detected either by paired-end RNA sequencing or RT-PCR. Patients with FAB M3 and Down AML were excluded from this study. The Cox proportional-hazard model was used for multivariate analysis, considering as co-variates age, white blood cell count, cytogenetic risk group, allogeneic hematopoietic stem cell transplant as time dependent variable and study group (COG vs European cohort). Gene expression analysis was performed using RNAseq data of patients enrolled in the AAML1031 trial.

Results: *NUP98-KDM5A* rearrangements were detected in 31 out of 1348 patients (2.3%). Three NUP98-KDM5A+ patients had to be excluded due to inconclusive analysis. There was no significant difference in prevalence between the COG and European cohorts. The median age of *NUP98-KDM5A* patients was significantly lower as compared to patients without this fusion gene (5.4 vs 9.4 yrs; p=0.017). *NUP98-KDM5A* occurred in all FAB types, as only 37% of the *NU98-KDM5A+* cases had an M7 FAB type. The 5-year EFS and OS of *NUP98-KDM5A+* patients was 28.6±18.9% and 33.0±20.2%. This was significantly lower as compared to the *NUP98-KDM5A-* patients with EFS of 48.1±2.8% (p=0.015) and OS of 63.9±2.8% (p=0.001). In multivariate analysis, *NUP98-KDM5A* was an independent risk factor for OS, but not for EFS, with hazard ratios of 1.89 (p=0.025) and 1.53 (p=0.122), respectively.

Gene expression analysis of RNAseq data of 1,035 patients, of which 16 *NUP98-KDM5A+* patients, revealed 2252 differentially expressed genes between *NUP98-KDM5A+* and *NUP98-KDM5A-* cases, of which 1542 upregulated genes. However, unsupervised hierarchical clustering did not cluster the majority of *NUP98-KDM5A+* cases together, but scattered them among samples with normal and other karyotypes. The top 3 most differentially expressed genes when comparing gene expression between NUP98-KDM5A+ and NUP98-KDM5A- cases were 3 *HOXB* genes, i.e. *HOXB5*, *HOXB6* and *HOXB9*. When we performed HOX-gene based clustering, several subgroups were revealed (Figure 1), separating the MLL-rearranged cases with a *HOXA* profile from the *NUP98-KDM5A* and *NUP98-NSD1* cases, characterized by *HOXA* and *B* expression.

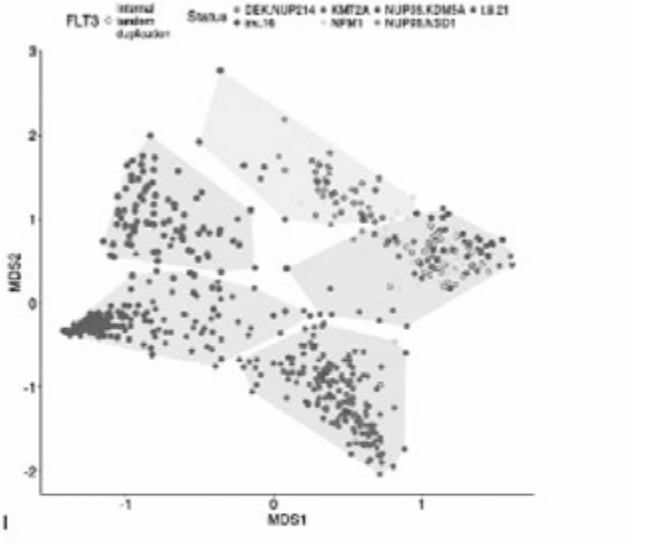

Figure 1: *HOXA and HOXB gene expression in pediatric AML. HOXA and HOXB gene expression was examined using principal coordinates analysis. Five distinct groups(clusters) were determined using k-means clustering and are depicted in convex hulls. Samples with very rare or unknown driving aberrations have been excluded for this analysis. The NUP98-KDM5A samples all cluster in the purple hull, together with NPM1 and DEK-NUP214, whereas most NUP98-NSD1 samples cluster separately.*

Figure 1.

Summary/Conclusion: This study shows that *NUP98-KDM5A* is an aberration that occurs in all FAB types and not exclusively in AMKL. *NUP98-KDM5A* is an independent risk factor for OS, but not for EFS, and identifies a relatively poor prognostic subgroup. Gene expression analysis revealed upregulation of *HOXB* genes, similar to results previously found in *NUP98-NSD1* rearranged AML (Hollink *et al.*, Blood 2011). However, *NUP98-NSD1* and *NUP98-KDM5A* positive patients do not cluster together in *HOX*-gene based clustering analysis.

PS950

TARGETED THERAPY FOR AML EXPRESSING SOMATIC OR GERMLINE MUTATION IN RUNX1

K. Bhalla[1,*], C. DiNardo[1], C. Mill[1], W. Fiskus[1]

[1]Leukemia, MD Anderson Cancer Center, Houston, United States

Background: RUNX1 is the DNA-binding subunit of the core binding factor complex and a transcription factor involved in normal and malignant hematopoiesis. Somatic mutations in RUNX1 commonly occur in secondary or *de novo* AML (~10%). Presence of mtRUNX1 confers relative therapy-resistance and poorer survival in patients with AML. Germ-line, intragenic mutations and deletions in RUNX1 cause the highly penetrant (~40%), autosomal dominant, Familial Platelet Disorder (FPD) that evolves into myeloid malignancy (FPD-MM), i.e., MDS or AML. Majority of mutant

(mt) RUNX1 are missense, large deletions or truncation-mutations, behaving mostly as loss of function mutations. RUNX1 transcription is controlled by a conserved +24-kb-enhancer within a super-enhancer (covering the intron 1 of RUNX1) that demonstrates high occupancy by the BET protein BRD4. Hi-C analysis showed high interaction scores between +24-kb-enhancer and P2 promoter of RUNX1.
Aims: Following knockdown of RUNX1 or BRD4, the effects on RUNX1 and its targets, as well as on survival of AML cells expressing mutant versus WT RUNX1 were determined.
Methods: Following knockdown of RUNX1 or BRD4, the effects on RUNX1 and its targets, as well as on survival of AML cells expressing mutant versus WT RUNX1 were determined.
Results: Our findings confirmed that, as compared to the luciferase-containing P2 promoter or the enhancer alone, the +24kb-enhancer-driven P2 promoter exhibited superior luciferase induction, representing increased transcriptional activity of RUNX1. We also determined that shRNA-mediated knockdown of RUNX1 depleted RUNX1 targets c-MYC and PU.1, as well as induced significantly more apoptosis of cultured cell line and patient-derived (PD) AML blast progenitor cells (BPCs) expressing mtRUNX1, as compared to the PD AML BPCs expressing wild-type (WT) RUNX1. Doxycycline-inducible, shRNA-mediated *in vivo* knockdown of RUNX1 in engrafted OCI-AML5 cells expressing mtRUNX1 markedly reduced AML burden and improved survival of the immune-depleted (NSG) mice. Knockdown of BRD4 (via shRNA) also attenuated expression of RUNX1 and its targets, as well as inhibited growth and induced apoptosis of OCI-AML5 cells. We also found that BETP-PROTACs (proteolysis targeted chimera) ARV-825 and ARV-771 (20 to 250 nM) caused degradation and depletion of BRD4, reduced BRD4 occupancy at the +24-kb-enhancer and P2 promoter of RUNX1, thereby repressing RUNX1 and its targets, and potently inducing apoptosis of AML BPCs expressing mtRUNX1. Treatment with ARV-771 (30 mg/kg SQ daily for 3 weeks also inhibited AML growth and improved survival of NSG mice engrafted with OCI-AML5 cells. CRISPR-Cas9 mediated editing of the +24-kb RUNX1 enhancer markedly depleted levels of RUNX1 in the surviving fraction of slow growing OCI-AML5 cells expressing mtRUNX1. By utilizing the RNA-seq mRNA signature from RUNX1-depleted AML cells we also queried for expression mimickers (EMs) through LINCS1000-CMap (Connectivity Mapping) analyses. This uncovered several novel agents as EMs, e.g., narciclasine, anisomycin, cinobufagin and fenbendazole. These EMs, at nanomolar levels, inhibited mRNA and protein expressions of RUNX1, c-Myc and PU.1 and induced more apoptosis of the AML cells expressing somatic or germ-line mtRUNX1, as compared to FPD hematopoietic progenitor cells (HPCs) that solely expressed mtRUNX1 or of CD34+ normal HPCs.
Summary/Conclusion: These findings highlight RUNX1-targeted novel agents that exert preferential lethal activity against AML BPCs expressing somatic or germline mtRUNX1.

PS951

DECIPHERING THE GENETIC LANDSCAPE OF ACUTE MYELOID LEUKEMIA WITH COMPLEX KARYOTYPE BY TRANSCRIPTOME ANALYSIS USING RNA SEQUENCING

F. G. Rücker[1,*], X. Gong[2], A. Dolnik[1], M. Hoyos[1], J. Biscocho[2], T.J. Blätte[1], J. Swoboda[1], A. S. Pollack[2], A. Turchiano[1], H. Döhner[1], K. Döhner[1], J.R. Pollack[2], L. Bullinger[1,3]

[1]Department of Internal Medicine III, University Hospital of Ulm, Ulm, Germany, [2]Department of Pathology, Stanford University, Stanford, United States, [3]Department of Hematology, Oncology and Tumorimmunology, Charité University Medicine, Berlin, Germany

Background: Acute myeloid leukemia with complex karyotype (CK-AML) represents approximately 15% of adult AML. CK-AML is the least understood cytogenetic subgroup at molecular level, except that about two-thirds of cases carry *TP53* alterations. In particular, as cytogenetic alterations are distinct among patients, it is unclear whether they are cause of leukemogenesis, or whether they merely reflect genomic instability.
Aims: We hypothesized that cytogenetic aberrations in CK-AML create gene fusions (GF) that, although not recurrent, nonetheless deregulate cancer genes contributing to leukemogenesis.
Methods: We performed Illumina paired-end (101bpx2) RNA-seq transcriptome analysis of 65 CK-AML to identify GF using multiple independent algorithms. GF were in part independently validated by array-based genomic profiling and/or long range PCR followed by long-read Oxford Nanopore sequencing technology.
Results: RNA-seq uncovered 55 high-evidence GF in 30 (46% of) CK-AML with up to four per case. Nearly all fusions were previously unreported in AML, except *RUNX1-MECOM*, *CBFA2T3-GLIS2*, *MN1-ETV6*, *and ETV6-MN1*. No GF were recurrent, though some genes recurred as 5' or 3' partners. About 35% were in-frame, encoding chimeric proteins. The remainder encoded either C-terminally truncated 5' fusion partners, or else N-terminally truncated (or rarely full-length) 3' fusion partners in instances where the 5' partner contributed only the 5'UTR. Many fusions were predicted to lead to overexpression or chimeric activation of known or putative novel cancer genes. Most frequently affected genes were *RUNX1* (n=5) leading to truncation in 4/5 fusions, *KMT2A*, and *MECOM* (n=3 each). Due to affected genes, fusions could be categorized into five functional clusters. Many fusions (n=17) contained at least one known AML gene (e.g. *RUNX1*, *MECOM*, *DEK*, *ETV6*, *KMT2A*) or oncogenes (e.g. *MYB*) and a novel fusion partner, clearly suggesting pathogenic relevance. Others were predicted to disrupt tumor suppressors (n=4; e.g. *TP53*, *NF1*). The majority of fusions comprised partners where neither was previously associated with AML, though many had plausible leukemic roles or targetable domains (n=34, e.g. cell surface receptors, kinases, enzymes). To elucidate the correlation between gene fusions (GF) and gene mutations in $TP53^{altered}$ CK-AML, we performed a targeted mutation calling for 36 known AML genes delineating only 1.1 mutations per $TP53^{altered}$ CK-AML (range: 0-6 mutations) and 2.6 mutations per $TP53^{unaltered}$ CK-AML (0-8 mutations) (p<.001), respectively. Compared to GF-/CK-AML, GF+/CK-AML exhibited significantly less gene mutations per case [1.4 (range: 0-4 mutations) vs 2.0 (0-8 mutations), p=.038] and was significantly correlated with chromothripsis (p=.001), a plausible mechanism underlying GF. GF seem not to be only of leukemogenic, but also prognostic relevance in $TP53^{altered}$ CK-AML since GF+ cases had significantly worse overall survival (p=.018).
Summary/Conclusion: Detailed molecular characterization of CK-AML revealed a high incidence of novel GF and demonstrated that $TP53^{altered}$ CK-AML is rather characterized by the acquisition of genomic aberrations leading to novel GF than the accumulation of gene mutations. While GF might play an important role in CK-AML pathogenesis, identifying GF could lead to more effective, personalized treatment strategies and provide valuable patient-specific biomarkers to track leukemic burden within the monitoring of disease remission and early prediction of relapse.

PHOSPHO-PROFILING LINKING AML-BIOLOGY AND RESPONSE PREDICTION IN PEDIATRIC MYELOID LEUKEMIA

M. Prchal-Murphy[1,*], A. Hoelbl-Kovacic[1], M. Dolezal[2], S. Fajmann[1], A. Schumich[3], M. Kauer[3], V. Sexl[1], M. Dworzak[3]

[1]Department for Biomedical Science, Institute of Pharmacology and Toxicology, VetMed university Vienna, [2]Department for Biomedical Science, Institute of Population Genetics, [3]St.Anna Children's Hospital and Children's Cancer Research Institute, Medical University of Vienna, Vienna, Austria

Background: Acute myeloid leukemia (AML) accounts for 15-20% of all pediatric leukemias. Treatment outcome has significantly been improved and reached 65-70% survival rate due to better risk classifications, advances in chemotherapy, stem cell transplantation and accessory treatment with signal interceptors. Nevertheless the high frequency of 25-30% in relapse is rooted in the genetic heterogeneity of the disease that brings a broad diversity in aberrant protein expression and activation. Those mainly pro-survival and proliferation-inducing factors get phosphorylated for their full activation. Proof of phosphorylation points at a disease-propagating role of a given factor and renders it a promising drug target. In adults, the inhibition of FLT-3 signaling by Midostaurin in combination with chemotherapy was recently shown to prolong event-free survival. In pediatric patients, a comparable breakthrough is still lacking. To identify new drug targets in pediatric AML, we analyzed a detailed picture of phospho-profiles in individual subtypes and cases of relapse.
Aims: We aimed at deriving a detailed picture of phospho-profiles in AML samples, at stratifying them according to individual subtypes of the disease and at identifying vulnerable nodes for future patient-tailored therapies.
Methods: We established a high-throughput FACS-based screening method and characterized phospho-profiles of cells derived from 116 pediatric AML patients. We compared basal and cytokine-induced phosphorylation patterns. Cytokine stimulation was included to evaluate influences provided by the *in vivo* milieu. Pathways that were identified to be deregulated were blocked with specific inhibitors *in vitro*. Their efficacy was determined by a FACS-based cytotoxicity assay. Furthermore we established a mouse xenograft model to amplify limited patient material and to validate the efficacy of inhibitors that were identified in the *in vitro* studies to block leukemic cell proliferation. In parallel, we correlated individual activation of proteins to the incidence of relapse.
Results: We demonstrate a novel high-throughput FACS-based screening method to determine AML sub-type specific alterations of signaling path-

ways. Independent from the AML subtype, the transcription factor STAT5 was prominently activated. Leukemic cell survival could be blocked by Midostaurin, a PKC - and Flt-3 inhibitor. Of note, we found that Midostaurin also blocks STAT5 activation. In line, high levels of pSTAT5 correlated with an increased cumulative incidence of relapse in pediatric patients.
Summary/Conclusion: The transcription factor STAT5 is over-activated in all AML subtypes tested. Activation of STAT5 negatively influences the incidence of relapse and can be blocked by Midostaurin. These data suggest that the applicability of Midostaurin extends to pediatric patients suffering from AML, irrespective of the AML subtype.

PS953

TOWARDS IMPROVING OF SURVIVAL IN AML BY REPURPOSING EXISTING DRUGS AS NOVEL SAMHD1 INHIBITORS

N. Tsesmetzis[1,*], S. Rudd[2], C. Paulin[2], K. Sanjiv[2], J. Kutzner[3], I.H. Myrberg[1], H. Axelsson[4], A. Rasti[2], R.M. Branca[5], E. Witta[2], J. Lehtiö[5], G. Rassidakis[6], U. Warpman-Berglund[2], K. Pokrovskaja Tamm[6], M. Heyman[1], S. Lehman[7,8], T. Lundbäck[4], T. Helleday[2], J.-I. Henter[1,9], T. Schaller[3], N. Herold[1,9]

Background: Despite highly toxic chemotherapy regimens, seven out of ten patients with acute myelogenous leukaemia (AML) still succumb to their disease. The antimetabolic nucleoside analogue cytarabine (ara-C) is, together with anthracyclines, the single most important drug in the treatment of AML, and its clinical efficacy directly correlates with AML blasts' ability to accumulate its active metabolite ara-CTP. We have previously shown that SAM and HD domain-containing protein 1 (SAMHD1) hydrolytically inactivates ara-CTP, conferring resistance to ara-C in primary AML blasts and animal models. More importantly, SAMHD1 expression is significantly associated with worse survival in paediatric and adult AML. Notably, SAMHD1 has no impact on the efficacy of induction therapy, but rather limits the outcome of high-dose ara-C consolidation courses. We verified these findings in a total of three adult and two paediatric patient cohorts (n=600).
Aims: Hence, combining ara-C with a SAMHD1 inhibitor promises to greatly improve outcome for children with AML during consolidation chemotherapy.
Methods: We therefore screened a large library of small molecules in a phenotypic screen to identify compounds that increase ara-C toxicity in SAMHD1-wildtype, but not SAMHD1-knockout cells. Activity was validated in AML mouse models. Using *in vitro* activity together with cellular thermal shift and cross-linking assays we furthermore addressed the mode of action of inhibition of SAMHD1 ara-CTPase activity (allosteric vs catalytic).
Results: Excitingly, we found two FDA- and EMA-approved substances for which patens have expired and for which extensive safety data exists in both adults and children. These drugs completely abolished SAMHD1-mediated ara-C resistance in primary AML samples and resensitised animal models of AML to ara-C.
Summary/Conclusion: We thus advocate clinical studies that prospectively test the ability of these novel SAMHD1-inhibitors to improve survival when combined with high-dose ara-C consolidation courses.

Background: Altered cellular metabolism participates to acute myeloid leukemia (AML) pathogenesis, predicts response to therapy and can be targeted. Mutated enzymes, oncogenes or tumor suppressors can drive metabolic dependency of patients' subgroups
Aims: To map potential connections between genetic lesions and metabolism in AML and identify metabolic alterations underlying druggable pathways.
Methods: Whole exome sequencing was performed on 78 AML. Variants were called by MuTect and Varscan2. Metabolites were quantified by mass spectrometry of bone marrow (BM) cells (35 CD34$^+$, 16 CD33$^+$ AML), CD34$^+$ cord blood and CD33$^+$ healthy blood cells (n=21, Metabolon) and compared by Welch's *t*-Test ($p<0.05$). Gene expression profiling was performed on 56 BM (AML and healthy donors, Affymetrix). Cell specific metabolic reconstructions derived with iMat and mCADRE algorithms were studied for data integration.
Results: Metabolism-related genes were mutated in 67% AML (47% of lesions rated as damaging). The most represented pathways were lipid (24% mutations) and nucleotide metabolism (11%), with mutations in the pyrimidine-related gene *AK9* and the pentose phosphate pathway (PPP) gene *H6PD*; bioenergetics pathway (9%), with the respiratory chain genes *NNT* and *ADCK3*; amino acid metabolism (8%), with the tryptophan-related gene *IDO2*; carbohydrate and glucose metabolism (6%), with altered *PKM* and *HK3*; response to stress (4%), with mutated *SOD2*. AML cells showed distinct metabolic profiles compared with healthy cells, while little differences were observed between AML subgroups. The top 30 ranking biochemicals suggested differences in lipid, nucleotide and amino acid metabolism between AML and controls, in line with genomic data. The bioenergetic pathway was also altered in CD34$^+$ AML, with reduced glycolytic intermediates (FDP, 3PG, PEP) and enzymes (GPI, PFKFB3). The Krebs cycle intermediates citrate, aconitate, succinate and malate were decreased in CD34+ AML. The PPP metabolite S7P and intermediates of purine/pyrimidine synthesis/salvage were increased, suggesting elevated demands in DNA/RNA synthesis and repair. Half AML cases displayed high 4-HNE-glutathione, that was undetectable in normal cells, indicating elevated detoxification of 4-HNE. 4-HNE-glutathione significantly correlated with GSH and GSSG levels. Moreover, CD34$^+$ and CD33$^+$ AML showed distinct glutamine/glutamate-dependence: increased NAAG and NAA in CD33$^+$ AML, along with GLS upregulation, and decreased NAAG and elevated glutamine in CD34$^+$ AML. To investigate the relations between genomic and metabolomic alterations, we sought to identify the most fitting metabolic model. Metabolites, reactions and genes annotated in BM, blood, CD14$^+$ cells and monocyte subsystems by mCADRE were largely overlapping and shared a core with an iMat hematological model. 69% of altered metabolites and 14% of differentially expressed genes were mapped in the RECON model: of them, 31% and 69% metabolites and 28% and 26% genes, on average, were present in mCADRE and iMAT models, respectively.
Summary/Conclusion: Mutations of metabolic genes are common in AML. Despite their heterogeneity, genomic-driven and functional metabolic alterations converge to common pathways. Dissecting the link between genomic and metabolic alterations, by simultaneous consideration of datasets for the construction of cell specific models may help define AML subtypes sensitive to antimetabolic therapies, as PPP inhibition and 4-HNE treatment.

PS955

THE CALCIUM BINDING PROTEIN S100A8/S100A9 COMPLEX IS ASSOCIATED WITH DRUG RESISTANCE IN ACUTE MYELOID LEUKEMIA

M. Liu[1,*], R. Karjalainen[1], A. Kumar[1], A. Parsons[1], L. He[1], D. Malani[1], K. Porkka[2,3], C. A. Heckman[1]

[1]Institute for Molecular Medicine Finland (FIMM), [2]Hematology Research Unit Helsinki, University of Helsinki, [3]Department of Hematology, Helsinki University Hospital Comprehensive Cancer Center, Helsinki, Finland

Background: Despite the development of novel therapy options for acute myeloid leukemia (AML), the overall cure rate remains low with most patients succumbing to relapse or refractory disease. Better understanding of the molecular mechanisms responsible for drug resistance could lead to development of improved treatment strategies, as well as the means to monitor patients at risk for developing drug resistance. S100A8 and S100A9 are members of the S100 family of calcium-binding proteins. Expression of

S100A8 and *S100A9* have been studied in many different tumor types. In AML, expression of S100A8 is considered to be a poor prognostic indicator (Nicolas *et al.*, 2011). Although these proteins are known to have a role in myeloid cell development, little is known about their function in myeloid malignancies and treatment response.
Aims: In this study, we investigated the expression of *S100 genes* in RNA sequence data from AML patients with matching *ex vivo* drug sensitivity and resistance data. Integrating the datasets allowed us to identify associations between *S100A8* and *S100A9* and response to drugs currently being used or under development for the treatment of AML.
Methods: RNA-sequencing was used to determine *S100* gene expression in a cohort of AML samples (n = 112) and healthy individuals (n = 4). Sensitivity of MNCs from AML patient samples was assessed to 304 different small molecule inhibitors tested in 5 concentrations in a 10,000-fold concentration range by measuring cell viability after 72 h incubation using the CellTiter-Glo (CTG) assay. Free cytosolic calcium was measured using the calcium assay kit (BD Biosciences). Statistical dependence between gene expression and DSRT data was assessed by Pearson's correlation coefficient modelling.
Results: Among the S100 members, *S100A8* and *S100A9* were the most highly expressed genes in a cohort of AML samples (n = 112) compared with healthy individuals. Integrated analysis of *S100A8* and *S100A9* gene expression and *ex vivo* drug sensitivity data showed high and moderate correlation with the selective BCL2 inhibitor venetoclax and the FLT3 inhibitor quizartinib, respectively. Both drugs are in development for AML and have shown promising activity in clinical investigations. We further validated and confirmed the high expression of *S100A8* and *S100A9* by qRT-PCR in the venetoclax resistant samples. We also observed a similar association between *S100A8* and *S100A9* expression and venetoclax sensitivity in AML cell line models. Mechanistically, over-expression of *S100A8* and *S100A9* in venetoclax-resistant cell lines (OCI-AML3, SHI-1, SKM-1) was associated with failure to release free-cytosolic Ca^{2+} compared with venetoclax-sensitive cell lines (MOLM-13, Kasumi-1, ML-2). By binding free Ca^{2+}, the S100A8/S100A9 complex can inhibit mitochondrial membrane depololarization and the initiation of apoptosis, which may contribute to the development of venetoclax resistance in *S100A8* and *S100A9* high-expressing AML.
Summary/Conclusion: Our *ex vivo* and *in vitro* data show high correlation between the expression level of calcium binding proteins (S100A8/S100A9) with resistance to the BCL2 inhibitor venetoclax. This study suggests that S100A8/S100A9-mediated calcium pathway may play a role in the development of resistance to venetoclax in AML patients.
ML and RK equeal contribution.

A HIGH RISK PEDIATRIC AML SUBTYPE PRESENTS A DIAGNOSTIC CHALLENGE-A REPORT FROM THE CHILDREN'S ONCOLOGY GROUP AAML0531 STUDY

S. Kahwash[1], L. Brodersen[2,*], T. Alonzo[3,4], R. Gerbing[3], A. Gamis[5], M. Loken[2], S. Meshinchi[3,6]

[1]Nationwide Children's Hospital, Columbus, [2]Hematologics, Inc, Seattle, [3]Children's Oncology Group, Monrovia , [4]University of Southern California, Los Angeles, [5]Children's Mercy Hospitals & Clinics, Kansas City, [6]Fred Hutchinson Cancer Research Center, Seattle , United States

Background: A new subtype of pediatric acute myeloid leukemia, RAM, identified by immunophenotype, has been previously reported from the Children's Oncology Group (COG) AAML0531 phase 3 study. Patients harboring RAM phenotype AML are predominantly under the age of 2, with an over representation of acute megakaryoblastic leukemia (AMKL), and a 3 year EFS of 16%. Patients harboring the chimeric fusion gene, CBFA2T3-GLIS2, share several of these features and both have recently been included as high-risk prognostic markers in the enhanced risk stratification strategy from COG.
Aims: To improve diagnostic testing algorithms among pediatric AML patients by properly identifying these rare yet high-risk patients by correlating RAM status, CBFA2T3-GLIS2 status, and morphologic features.
Methods: We correlated the RAM and CBFA2T3-GLIS2 status among 821 patients meeting eligibility requirements who participated in AAML0531. Although FAB classification was completed at diagnosis and centrally reviewed, the unique morphologic features of a patient with RAM phenotype overlapping with metastatic solid tumor malignancies were not yet described. Blast features include: 1) cohesive clumps showing nuclear molding, 2) bi- or multinucleation, 3) cytoplasmic blebs or detached cytoplasmic fragments, 4) lack of cytoplasmic granules and/or Auer rods, and 5) bone marrow architecture consisting of patchy islands of blasts with alternating areas of less affected hematopoietic bone marrow.
Blinded retrospective analysis assessing these morphologic features was completed for 72 patients that included those with RAM phenotype, positive CBFA2T3-GLIS2 status, randomly selected AMKL patients, and other randomly selected patients. Each of the morphologic features was scored with one point given for each of the above characteristics, with a point deducted if cytoplasmic granules or Auer rods were identified. Patients were stratified based on morphologic scores: ≥4 or, ≤3.
Results: Of the 821 patients, 26 patients (3.2%) harbored either RAM phenotype or CBFA2T3-GLIS2 fusion transcripts with 19/25 (61%) defined as RAM+ (no data for 1 patient), while 18/24 (75%) were CBFA2T3-GLIS2+ (no data for 2 patients). Data for both markers were available for 23 patients; where 11 patients were dual positive (48% RAM+/ CBFA2T3-GLIS2+), while 6 were RAM+/CBFA2T3-GLIS- (26%) and 6 were RAM-/CBFA2T3-GLIS2+ (26%).
Morphologic analysis revealed 20/72 patients had scores ≥4 while 53/72 patients were ≤3. 12/20 (60%) of patients with scores ≥4 harbored RAM phenotype, 8 of these were also CBFAT23-GLIS2+. No RAM-/CBFA2T3-GLIS2+ patients had scores ≥4. 5/20 patients with scores ≥4 had previously been classified as classic AMKL (and these were RAM-/CBFA2T3-GLIS2-). Morphologic identification of patients exhibiting RAM phenotype demonstrated a sensitivity of 80% [95% CI=51.9-95.7] and specificity of 86% [95% CI=74.2-93.7]. When morphologic identification of patients with RAM phenotype or CBFA2T3-GLIS2+ status is considered, the sensitivity decreased to 63% [95% CI=38.4-83.7], while the specificity remained at 86%.
Summary/Conclusion: Proper identification of these high-risk features is essential because of the poor prognosis of patients with RAM phenotype and/or the CBFA2T3-GLIS2 fusion transcript. Given the overlap of the morphologic features with metastatic solid tumors and other challenging acute leukemias, these data suggest that patients with these morphologic features should be screened for RAM phenotype and CBFA2T3-GLIS-2, particularly patients under the age of 5.

PS958

TARGETED COMBINATION THERAPY AGAINST ONCOGENIC PI3K/AKT/MTOR AND NFKB SIGNALLING PATHWAYS USING ACUTE MYELOID LEUKEMIA AS A CANCER MODEL

M. Estruch[1,*], K. Reckzeh[1], A. Søgaard Helbo[1], K. Theilgaard-Mönch[1]

[1]Finsen Laboratory, Biotech Research and Innovation Centre, Univesrity of Copenhagen, Copenahgen, Denmark

Background: Various cancer entities are addicted to aberrant activity of an "oncogenic" signalling pathway in order to maintain their malignant phenotype. As a consequence, cancer patients treated with therapeutics that effectively target such a pathway often demonstrate robust initial clinical responses. However, chronic treatment frequently gives way to relapse, due to various escape mechanisms including loss of negative feedback regulation promoting activation of a "bypass" signalling pathway, that render cancer cells independent of their primary oncogenic signalling pathway.
Aims: We aim to unravel the molecular mechanisms of a hitherto undescribed crosstalk of the PI3K/AKT/MTOR and NFKB signalling pathways and define how combinatorial as compared to individual targeting of these pathways will affect growth and survival of primary cancer cells, as a promising strategy to improve clinical responses to targeted therapies.
Methods: In order to identify small molecule inhibitors targeting PI3K/AKT/MTOR and NFKB signalling pathways, we use acute myeloid leukaemia (AML) as a cancer model and apply AML mouse models that accurately mimic the genetics of AML patients to conduct initial drug screening experiments that can be applied in preclinical trials using AML patient cells from our biobank in xenograft assays. Specifically, we are currently focussed on the inv(16) AML subtype showing poor (15-20%) survival rates. For this, our group has specifically implemented the inv(16)/KitD816Y mouse model mimicking the genetics of these AML patients.
Results: So far, we have identified PI3K inhibitors (BKM120 and CAL-101) that abrogate phosphorylation of PI3K substrates (Western Blot analysis) and inhibit growth and survival of clonogenic primary murine inv(16)/KitD816Y AML cells *in vitro*. Moreover, we have identified proteasome inhibitors (Bortezomib/Carfilzomib/Oprozomib) that abrogate NFKB translocation to the nucleus in primary murine inv(16) AML cells

(confocal microscopy) leading to inhibition of the constitutively active NFKB pathway as well as inhibition of survival and clonogenic growth of AML cells (CFC- assays). Significantly, co-inhibition of both PI3K/AKT/MTOR and NFKB signalling pathways demonstrated a strong synergistic inhibitory effect on growth and survival of clonogenic murine inv(16) AML cells *versus* normal clonogenic haematopoietic stem/progenitor cells (HSC/HPCs), suggesting potential crosstalk and the need of co-inhibition of oncogenic signalling pathways (*i.e.* PI3K/AKT/MTOR and NFKB) rather than inhibition of a single pathway to effectively kill AML cells. Based on these *promising results*, we are currently conducting *in vivo* studies in inv(16)/KitD816Y mouse model to assay the effects of the single versus the combinatorial treatment on decreasing AML cell progression and thereby promoting an increase on survival (Figure 1).

Summary/Conclusion: Significantly, the present results not only shed new light on how PI3K/AKT/MTOR and NFKB signalling pathways crosstalk in AML but also highlight the importance of identification and combinatorial therapeutic targeting of interconnected oncogenic signalling pathways in order to improve clinical outcome of patients suffering from AML as well as other cancer entities.

IDENTIFICATION OF GENE COPY NUMBER ABERRATIONS AS PROGNOSTIC MARKERS OF SURVIVAL IN ACUTE MYELOID LEUKEMIA (AML) PATIENTS BY EXOME SEQUENCING OF LEUKEMIA DNA IN THE MAYO CLINIC AML EPIDEMIOLOGY COHORT

Y. Asmann[1,*], M. Heckman[1], N. Diehl[1], V. Sarangi[2], R. Ketterling[3], L. Sproat[4], L. Jiang[5], B. Eckloff[6], L. Finn[7], K. Robertson[8], J. Foran[9]

[1]Department of Health Sciences Research, Mayo Clinic, Jacksonville Florida, [2]Department of Health Sciences Research, [3]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester Minnesota, [4]Department of Oncology and Hematology, Mayo Clinic, Phoenix Arizona, [5]Department of Laboratory Medicine and Pathology, Mayo Clinic, Jacksonville Florida, [6]Medical Genome Facility, Mayo Clinic, Rochester Minnesota, [7]Oncology and Hematology, Ochsner Medical Center, New Orleans, LA, [8]Department of Molecular Pharmacology and Experimental Therapeutics, Mayo Clinic, Rochester Minnesota, [9]Department of Oncology and Hematology, Cancer Center, Mayo Clinic, Jacksonville Florida, United States

Background: Chromosomal aberrations are the strongest genetic markers for AML prognosis. Studies have identified genomic abnormalities at whole chromosome, arm, and band levels that are associated with outcomes in AML patients. However little is known about the role of specific gene copy number (CN) aberrations.

Aims: We performed exome sequencing of AML DNA collected at the time of diagnosis from Mayo clinical epidemiology cohort and evaluated associations between gene level CN and survival after AML diagnosis.

Methods: The Mayo Clinic AML Epidemiology cohort comprises a highly annotated, unselected, and consecutive patients diagnosed and treated at Mayo Clinic Florida and Arizona. All patients received standard of care intensive remission induction chemotherapy with curative intent. We obtained AML DNA from remnant diagnostic cytogenetic pellets identified in 98 patients and performed exome sequencing . Approximately 100 million paired-end 100bp reads per sample were mapped to human reference genome build hg19 using BWA-MEM. The gene level copy numbers were called using patternCNV method. Separately for each gene, comparisons of survival after AML onset between CN neutral patients and patients with a gain, and also between normal patients and patients with a loss, were made using Cox proportional hazards regression models that were adjusted for chemotherapy regimen. Comparisons were made only if there were greater than five patients in both of the given comparison groups in order to avoid performing non-informative tests. In order to correct for the 38,138 total statistical tests that were performed, we utilized a false-discovery rate (FDR) correction (assuming a FDR of 5%), after which p-values < 7.90E-06 were considered as statistically significant. All statistical tests were two-sided.

Tables 1, 2 and Figure 1.

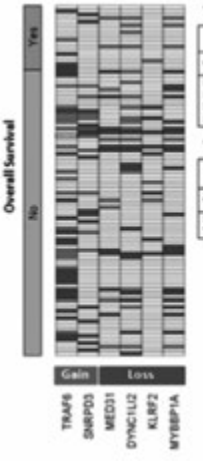

Table 1. Genes with Copy Number (CN) Loss as Prognostic Marker

Gene	Chr	Band	Patient Counts and CN Status: Loss	Neutral	Gain	Kaplan-Meier 12-month Survival: Loss	Neutral	HR (Loss vs. Neutral)	Adjusted p Values
DYNC1LI2	16	q22.1	12	70	18	8.0%	50.0%	8.40	2.410E-06
MYBBP1A	17	p13.2	20	73	5	5.0%	48.0%	4.25	1.310E-06
MED31	17	p13.1	10	80	8	0.0%	43.6%	5.73	8.330E-06
KLRF2	12	p13.31	8	87	3	0.0%	44.1%	6.68	8.670E-06

Table 2. Genes with Copy Number (CN) Gains as Prognostic Marker

Gene	Chr	Band	Patient Counts of CN Status: Loss	Neutral	Gain	Kaplan-Meier 12-month Survival: Neutral	Gain	HR (Gain vs. Neutral)	Adjusted p Values
SNRPD3	22	q11.23	14	74	10	45.9%	0.0%	6.86	7.030E-07
TRAF6	11	p12	24	56	18	50.9%	5.6%	4.96	1.680E-06

Figure 1. heat-map of the copy numbers from genes associated with 12-month survival. Rows are patients, and columns are genes. The red, white, and blue cells of the heat map indicate copy number gain, neutral, and loss, respectively. The copy number losses of 4 genes are associated with poor survival (the right 4 columns of the heat-map, and Table 1); and the copy number gains of 2 genes were associated with poor survival (the left 2 columns of the heat-map, and Table 2); and There were 18 patients (the top 18 rows of the heat-map) achieved and 80 patients (bottom 80 rows of the heat-map) failed 12-month survival.

Results: We found significant associations of CN losses of DYNC1LI2, MYBBP1A, MED31, and KLRF2 with poorer overall survival (OS) (Table 1). DYNC1LI2 is a microtubule-associated motor protein with unknown significance in AML. However the expression of DYNC1LI2 is correlated with BICD1, a potential biomarker for prognosis and therapy response in glioblastoma. MYBBP1A is a nucleolar transcriptional regulator involved in cell cycle control, and the dysregulation of MYBBP1A is functionally associated with RUNX1 in inducing leukemia. KLRF2 is reported to regulate MYC expression, and MED31 is a transcription cofactor with unknown function in AML. In addition, we observed significant associations of CN gains of SNRPD3 and TRAF6 with poorer OS after AML diagnosis (Table 2). Report showed that mice transplanted with TRAF6-expressing marrow progressed either to marrow failure or AML and acquired 5q-syndrome. This is intriguing since 5q deletion is a known marker for poor prognosis in AML. The role of SNRPD3 gain in AML is unclear but it is involved in local aggressiveness and metastatic behavior in soft tissue tumor (Figure 1).

Summary/Conclusion: Exome sequencing was for the first time successfully performed on archived diagnostic cytogenetic cell pellets, and we identified CN gain or loss of 6 genes as potential biomarkers located outside of the previous known large chromosomal aberration regions associated with survival after therapy for AML. Functional roles of these genes provided important insights into the mechanism of AML clinical outcome and will guide prospective studies to determine the mechanism AML prognosis and therapy response.

NEO2734, A NOVEL HIGHLY POTENT ORAL DUAL BET AND P300/CBP BROMODOMAIN INHIBITOR FOR TREATMENT OF HEMATOLGICAL MALIGNANCIES

B. Brown[1,*], C. Wahlestedt[2], D. Chiche[1], F. Giles[3]

[1]NEOMED Therapeutics 1 Inc., Montreal, Canada, [2]University of Miami, Miami, [3]Developmental Therapeutics Consortium, Chicago, United States

Background: The Bromodomain (BRD) and Extra-Terminal domain (BET) family of proteins are key regulators of epigenetic control. Modulation of epigenetic 'readers' such as BRDs is a recognized developmental therapeutics priority. Cyclic AMP response element binding protein (CREB)-binding protein (CBP) and E1A interacting protein of 300 kDa (EP300 or P300) are highly homologous BRD-containing transcriptional co-activators that regulate a number of important cellular events through their acetyltransferase activity. We have developed a series of molecules that exhibit dual inhibition of BET and CBP/P300 from which NEO2734 has emerged as lead clinical candidate.

Aims: To study NEO2734 a dual inhibitor of BET and CBP/P300 in AML and other hematolgical malignancies
Methods: NEO2734 was initially profiled against the BET inhibitor iBET762 in cellular assays and in multiple human cancer xenograft models including leukemia (MV-4-11).
Results: Table 1 shows NEO2734 *in vitro* antiproliferative activity against a variety of leukemia cell lines. NEO2734 has major activity at 10mg/kg (p.o.) in a leukemia xenograft model whereas iBET762 has minimal activity at 30mg/kg (p.o.) both dosed once daily for 18 days. For example, MV-4-11 xenograft mice were treated by oral gavage with NEO2734 (1 mg/kg, 3mg/kg and 10mg/kg) and the reference compound iBET762 (10 mg/kg and 30mg/kg) for 18 days. In this model, NEO2734 led to potent tumor regression in a dose dependent manner. Much weaker activity was observed for iBET-762 at either 10 or 30 mg/kg (Figure 1).

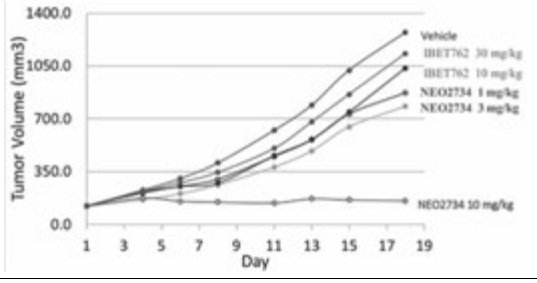

Figure 1.

Table 1.

Cell line	Tissue Type	IC50 (μM) (72h)		
		NEO2734	iBET762	Cisplatin
Molt-4	Blood	0.56	2.4	0.49
KG-1		0.11	0.58	1.9
THP-1		0.29	1	1.2
KHYG-1		0.18	1.1	0.46
Daudi		0.3	1.2	0.27
Raji		0.32	1.8	0.91
RL		0.13	0.84	2
U-937		0.28	1.1	1.2

Summary/Conclusion: NEO2734, an oral potent novel dual inhibitor of BET and CBP/P300, has pre-clinical activity in a spectrum of human hematoligical malignancies. Clinical studies are in preparation.

ACUTE MYELOID LEUKEMIA INDUCED TRANSFORMATION OF THE HUMAN BONE MARROW MICROENVIRONMENT PREDICTS CLINICAL OUTCOME

Y. Chen[1,2,*], Y. Zaun[1,2], L. Arnold[1,3], K. Weissenfels[1,2], K.W. Schmid[2,4], L. Klein-Hitpass[2,5], A. Squire[2,6], S. Bertram[2,4], U. Dührsen[1,2], M. Hanoun[1,2]

[1]Department of Hematology, University Hospital Essen, [2]University of Duisburg-Essen, [3]University Hospital Essen, Essen, Germany, [4]Institute of Pathology and Neuropathology, [5]Institute of Cell Biology (Cancer Research), [6]Institute for Experimental Immunology and Imaging and Imaging Center Essen (IMCES), University Hospital Essen, Essen, Germany

Background: Acute myeloid leukemia (AML) is an aggressive hematological malignancy which is characterized by a high relapse rate, suggesting that leukemic stem cells escape chemotherapeutic treatment. Recently, different murine models gave insight how leukemia infiltration alters the bone marrow microenvironment to reinforce disease. However, little is known about the bone marrow architecture in human. Further, if these alterations have an impact on clinical outcome in AML patients so far remained unsolved.
Aims: We aimed at dissecting the bone marrow architecture in human AML, characterize distinct niche constituents and uncover its clinical significance for the course of disease.
Methods: We combined immunohistochemical stainings with global gene expression analyses as well as protein analyses from human AML patients at first diagnosis and matching non-leukemic donors. To assess the bone marrow architecture, we automatically quantified CD271+ mesenchymal stem and progenitor cells (MSPCs) as well as reticular fibers on bone marrow sections. Bone marrow MSPCs were freshly isolated by fluorescence-activated cell sorting (FACS), herewith avoiding culture-induced artefacts and were used for microarray analyses (Clariom™ S Human Assay). The bone metabolism was evaluated by measuring serum osteocalcin levels. Final findings were correlated with clinical outcome.
Results: Here, we found that AML bone marrow infiltration induced a 2-fold increase in CD271+ MSPCs which correlated with loss of quiescence as indicated by gene expression analysis of freshly isolated bone marrow MSPCs. Increase in MSPCs in AML bone marrow significantly correlated with an increase in reticular fiber, an extracellular matrix protein produced by mesenchymal stroma cells (AML mean 4.50±2.28% vs. Control, 2.39±1.50%, p=0.0038), which negatively correlated with hemoglobin, thrombocytes and neutrophils. Alongside, MSPCs showed decreased expression of hematopoietic stem cell-regulating genes, particularly *CXCL12* and *KITLG*. Also the niche capacity of isolated bone marrow MSPCs from AML patients differed with respect to osteoblast differentiation as indicated by impaired expression of bone growth and mineralization related genes. To assess the bone metabolism in AML patients at first diagnosis we quantified serum osteocalcin levels. In fact, AML patients showed a significant reduced expression of osteocalcin indicating impaired bone turnover (AML mean 13.14±7.74ng/ml vs. Control 17.88±9.00ng/ml, p=0.0152). Ongoing *in vitro* studies demonstrated that AML cells specifically inhibit osteoblast mineralization. Strikingly, the level of osteocalcin expression proved to be of clinical significance. Patients with low osteocalcin level showed inferior median overall survival of 280 days, while the median overall survival of high osteocalcin level was not reached.
Summary/Conclusion: In summary, our data show how AML severely alters the human bone marrow architecture and the fate of MSPCs. These alterations proved to be of high clinical significance and allowed us to detect new prognostic markers. This increasing understanding of the human AML bone marrow niche might open the window for new niche-targeted therapies to eradicate leukemic stem cells and eventually decrease the high relapse rate in AML.

IMMUNOPHENOTYPIC PROFILING OF LEUKEMIC STEM CELLS TO TRACK FLT3-ITD POSITIVE, CHEMO-RESISTANT CLONES IN ACUTE MYELOID LEUKEMIA

T. Ottone[1,2,*], V. Alfonso[1], D. F. Angelini[2], G. Guerrera[2], L. Iaccarino[1], S. Lavorgna[1,2], M. Divona[1], M. Irno Consalvo[1], L. Cicconi[1], S. Travaglini[1], M. De Bardi[2], B. Neri[3], V. Martini[4], L. Fianchi[5], L. Battistini[2], A. Venditti[1], F. Buccisano[1], M. T. Voso[1], F. Lo-Coco[1,2]

[1]Department of Biomedicine and Prevention, University of Rome Tor Vergata, [2]Fondazione Santa Lucia, Laboratorio di Neuro-Oncoematologia, [3]Hematology Unit, Sant' Eugenio Hospital, Rome, [4]Hematology Unit, F. Spaziani Hospital, Frosinone, [5]Department of Hematology, Università Cattolica del Sacro Cuore, Roma, Italy

Background: Persistence of leukemia stem cells (LSCs) in AML patients achieving complete remission after chemotherapy is known to lead to disease recurrence and poor outcome. Therefore, the identification of LSCs driving resistance to therapy represents an important challenge. A widely accepted hypothesis is that LSCs reside within the CD34+/CD38- cell fraction and several groups have identified cell surface antigens preferentially expressed on LSCs. We recently demonstrated a strong correlation between the CD123/CD99/CD25+ population within CD34+ cells and the presence of the *FLT3*-ITD mutation, notoriously associated with higher risk of relapse in AML.
Aims: The aim of this study was to better characterize the LSCs of *FLT3*-ITD positive patients and to track, through flow-cytometry and semiquantitative-PCR, the expansion of mutated clones.
Methods: Bone marrow (BM) samples from 9 patients with *de novo* AML harbouring *FLT3*-ITD were analysed by 8-color flow cytometry. A sequential gating strategy was carried out to identify and purify the hematopoietic precursor fraction CD34/CD45/CD123+,CD38-, the LSCs enriched fraction CD34/CD123/CD99/CD25+, the CD34+ stem cell subset lacking CD123/CD99/CD25 expression, and T-lymphocytes. BM cells from UPN9 were sorted at diagnosis, at several follow-up time points during treatment and at the time of relapse. Cells were purified by a high-speed cell sorter. *FLT3*-ITD was monitoring was carried out through PCR followed by capillary electrophoresis.
Results: Enrichment of *FLT3*-ITD positive population, defined as a significantly higher *FLT3*-ITD mutation load, was observed within the CD34+ compartment of CD123/CD99/CD25+ cells, as compared to the MNC (p=0.001) and the lymphoid/myeloid precursors which showed a low or absent CD123/CD99/CD25 expression (p=0.004) (Figure 1A). In one patient with 2 different *FLT3*-ITD mutated clones at diagnosis (UPN1), we identified a LSC population defined by CD34/CD123/CD99/CD25+ with one ITD mutated clone in homozygous, likely originated by loss of heterozygosity (LOH) of the mutated allele (Figure 1B). Based on several studies indicating that LSCs are enriched in CD34+/CD38- cells, we investigated whether *FLT3*-ITD mutation was enriched in the LSCs CD34/CD123/CD99/

CD25+/CD38- compartment. As shown in Figure 1C, in UPN7 the CD34+/CD38- LSCs fraction, characterized by CD123/CD99/CD25 co-expression, represented the dominant *FLT3*-ITD mutated population in comparison with the CD34+/CD38+ counterpart. Finally, to trace the clonal evolution of LSCs carrying *FLT3*-ITD mutation, we sorted different BM-cell fractions at diagnosis and during follow-up from a patient (UPN9) who underwent disease relapse 8 months after the initial diagnosis. As shown in Figure 1D, a progressive increase of the *FLT3*-ITD allele burden was detected in the CD34/CD123/CD99/CD25+ subset as compared to the CD34+ cells lacking CD123/CD99/CD25 expression and the total MNC population. In this patient, a high *FLT3*-ITD mutant allele burden in CD34/CD123/CD99/CD25+ fraction was detected already at time of complete morphologic remission and 2 months before haematological relapse.
Summary/Conclusion: Our study shows that *FLT3*-ITD mutation represents a founding clone occurs at an early LSC level as defined by CD34/CD123/CD99/CD25+,CD38- immunophenotype. Prospective studies are needed to assess whether monitoring of this cell subset may allow early identification of patients at higher risk of relapse.

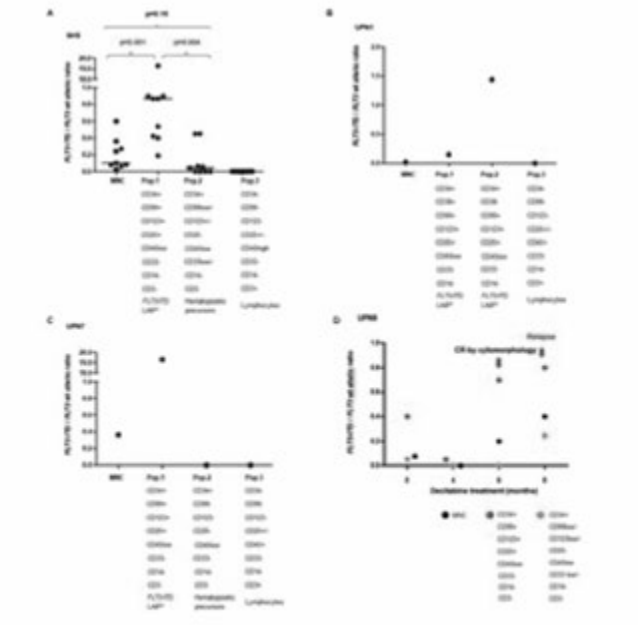

Figure 1 *FLT3*-ITD allele ratio analysed in several BM AML samples
(A) *FLT3*-ITD allelic ratio analysis in 9 AML patients collected at diagnosis and in particular in (B) UPN1, (C) UPN7 and (D) UPN9. The *FLT3-ITD* mutant allele burden, defined as the ratio of the area under the curve of mutant and wild type alleles, was performed both in total MNC and in several BM high-purified cells. The antibody combination used for cell sorting is indicated. *P* values were calculated by a paired Student's *t*-test.

[1]Internal Medicine III, University Hospital of Ulm, Ulm, [2]Third Department of Medicine, University Medical Center of the Johannes Gutenberg University Mainz, Mainz, [3]Department of Hematology, Oncology and Tumor Immunology, Charité University Medicine, Campus Virchow-Klinikum, Berlin, [4]Department of Medicine, Division of Hematology and Oncology, University Hospital of Freiburg, Freiburg, [5]Department of Medicine, Haematology and Oncology, Ruhr-University of Bochum, Knappschaftskrankenhaus, Bochum, [6]Department of Hematology/Oncology, Caritas Krankenhaus Lebach, Lebach, Germany, [73]rd Medical Department, Paracelsus Medical University Salzburg, Salzburg Cancer Research Institute, Cancer Cluster Salzburg, Salzburg, Austria, [8]Department of Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany

Background: In 2010 an international expert panel (European LeukemiaNet, ELN) published recommendations for diagnosis and management of acute myeloid leukemia (AML) including a risk stratification by genetics, subdividing AML in four risk groups. Emerging data on molecular markers in AML has led to an introduction of new stratification criteria by ELN in 2017 including the recommendation for screening of the high-risk (HR) molecular markers *ASXL1, RUNX1,* and *TP53* that have been shown to be associated with poor prognosis.
Aims: To assess the prevalence of the HR molecular markers *ASXL1, RUNX1,* and *TP53* in patients with newly diagnosed AML previously classified as intermediate-I and -II risk (inter-I/-II) based on the 2010 ELN criteria.
Methods: Using a next-generation targeted sequencing approach [HaloPlex HS (Agilent) on a Miseq (Illumina)], we performed a prospective analysis of all coding regions of *ASXL1*, *RUNX1*, and *TP53* in 200 newly diagnosed intermediate risk AML patients all enrolled in the AMLSG Biology and Outcome (BiO)-Project of the German-Austrian AML Study Group (AMLSG). Patient genetic features were as follows: Inter-I: normal karyotype n=124 (62%); inter-II: trisomy 8 (sole) n=12 (6%), nullisomy Y (sole) n=5 (2.5%), others n=59 (30%); *FLT3*-internal tandem duplication (*FLT3*-ITD^{+}) n=38 (19%), mutations in tyrosine kinase domain of *FLT3* (*FLT3*-TKD^{mut}) n=7 (3,5%), in *NPM1* n=32 (16%), in IDH1/2 19.5% (*IDH1*^{mut} *n=13*, *IDH2*^{mut} n=26); median age was 67 yrs (range: 21-89 yrs).
Results: Overall, 137 HR mutations in 98 patients (49%) were identified (one HR marker mutated, n=73; two HR markers mutated, n=25). Most frequently co-mutated partners were *ASXL1* and *RUNX1* accounting for 20/25 cases with two concurrent mutated genes, whereas co-mutations in *RUNX1/TP53* and *ASXL1/TP53* were seen in only 3/25 and 2/25 cases, respectively. Mutations in *ASXL1* occurred in 32% (64/200; inter-I: n=37, inter-II: n=27), followed by *RUNX1* in 22% (44/200; inter-I: n=23, inter-II: n=21), and *TP53* in 7.5% (15/200; inter-I: n=7, inter-II: n=8). Patients with mutation in one of the three HR markers exhibited lower WBC (median 5.92 vs 13.9, p=.031), lower hemoglobin value (median 8.6 vs 9.35 g/dl, p=.008), and lower LDH serum level (median 324 vs 510 U/l, p<.0001). Furthermore, HR markers correlated with male gender (66% HR+ vs 51% HR-, p=.044). HR marker mutations were inversely correlated with *FLT3*-ITD^{+} (4% vs 34%, p<.0001), *NPM1*^{mut} (1% vs 31%, p<.0001), and the genotype *NPM1*^{mut}/*FLT3*-ITD^{+} (1% vs 30%, p<.0001). Moreover, HR marker mutations were in trend inversely correlated with normal karyotype (60% vs 72%, p=.087). There were no correlations with regard to age, platelet count, *FLT3*-TKD, or *IDH1/2* mutation. Further analyses of cooperating mutations and survival data are currently ongoing.
Summary/Conclusion: In this prospective study, we show that 50% of AML patients classified by 2010 ELN criteria as intermediate risk AML harbor at least one HR marker. This high prevalence clearly demonstrates the clinical importance of HR marker screening by 2017 ELN criteria in this AML subgroup resulting in a shift of the prognostic stratification towards adverse risk. Screening for *ASXL1, RUNX1,* and *TP53* mutations in previously intermediate-risk patients with newly diagnosed AML allows the identification of those who potentially benefit from more intensive therapy or novel treatment approaches.

Background: Treatment strategies of Acute Myeloid Leukemia (AML) patients are based on clinical features as well as the molecular and cytoge-

netic profile of each patient. For patients with a normal karyotype (NK) the final risk classification is also defined by the identification of somatic mutations that have been recently described and impact on patient survival.
Aims: To describe the clinical impact of the gene mutation profile of NK AML patients treated within the prospective NILG trial 02/06 [ClinicalTrials.gov Identifier: NCT00495287].
Methods: The 02/06 trial enrolled a total of 572 patients, 250 of them having a NK AML. Molecular profiling was prospectively obtained with standard approach and subsequently with Next Generation Sequencing (NGS) on available material (207). Two commercial NGS kits were applied: Trusight Myeloid panel (Illumina) and Sophia Myeloid Solution (Sophia genetics) investigating 54 and 30 gene regions, respectively. Variants were identified with dedicated software and pathogenicity was verified in public repository.
Results: The median age of the 207 NK AML studied was 52 years (19-74) and 30% of them had >50.000 White Blood Cell (WBC) count. The 5-year overall survival (OS) and Disease Free Survival (DFS) were 52% and 51%, respectively. The most frequently mutated genes in this cohort were NPM1 (50%) followed by DNMT3A (38%), FLT3-ITD (26%), CEBPA (20%), (single allele mutation in 9% and double mutated in 11%), TET2 (16%), RUNX1 (15%), IDH2 (12%), FLT-TKD (11%), ASXL1, IDH1 (10%), PTPN11, SRSF2, MLL-PTD (9%), NRAS (8%), STAG2, BCOR (7%), GATA2, KRAS (6%), WT1 (5%), SF3B1, U2AF1 (4%), PHF6, RAD21 (3%), CBL, BCORL1, KDM6A, SMC3, CSF3R (2%), ETV6, EZH2, ZRSR2, SETBP1, CUX1, GATA1, SMC1A (1%), TP53, HRAS, JAK2, CDKN2A, FBXW7, GNAS, JAK3, KMT2A, MID88, NOTCH1 (<1%). We verified whether the incidence of co-occurring mutations was different among NPM1mutated (NPM1m) and NPM1 wild type (NPM1wt) groups of patients. DNMT3A, FLT3-ITD, FLT3-TKD, IDH1, PTPN11 and RAD21 mutations were more frequently detected in the NPM1m group ($p<0.05$) while double mutated CEBPA (CEBPAdm), RUNX1, IDH2, ASXL1, SRSF2, MLL-PTD, STAG2, BCOR, GATA2, WT1, SF3B1, U2AF1 mutations were mostly associated to the NPM1wt group. Univariate analysis showed that FLT3-ITD negatively affected the OS of both NPM1m and NPM1wt patients while DNMT3A, RUNX1, TET2, IDH1, NRAS, U2AF1, determined a worse OS in the NPM1wt group ($p<0.05$). In this latter, the presence of CEBPAdm was associated to a favorable clinical outcome while ASXL1 had an adverse effect, only in the absence of RUNX1 mutation. The 5-year OS of NPM1m group with or without FLT3-ITD were 38% and 72%, respectively ($p=0.0002$, Figure 1A), while the 5-year OS of NPM1wt group with or without any of the above described prognostically detrimental gene mutations were 26% and 72%, respectively ($p<.0001$, Figure 1B). The same results were obtained by multivariate analysis with the exception of IDH1 and NRAS that did not affect the outcome of NPM1wt patients. Interestingly, by univariate analysis allogeneic stem cell transplantation was associated to a better OS and DFS in both the NPM1m and NPM1wt cohort. By multivariate analysis, the beneficial effect of transplant was confirmed only in the NPM1m group.

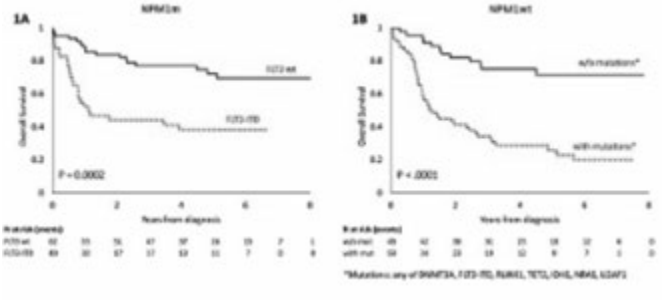

Figure 1.

Summary/Conclusion: Molecular profiling of NK AML is crucial for a precise definition of the relapse risk in AML patients, particularly those lacking the NPM1 mutation. High throughput NGS provides timely information on a growing set of genes and may improve treatment strategies.

PS965

SINGLE CELL SIGNALING PHARMACODYNAMICS AND CLONAL EVOLUTION IN A PHASE 1/2 CLINICAL TRIAL OF SELECTIVE AXL INHIBITOR BEMCENTINIB (BGB324) IN R/R ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROME

M. Hellesøy[1,*], S.-E. Gullaksen[2,3], R.B. Forthun[1], O.H.E. Fagerholt[2,3], B.S. Tislevoll[2,3], H. P. Brodal[1], R. Hovland[4], H. Reikvam[1], A.O. Kittang[1], J. Cortez[5], J. Skavland[2,3], J. Lorens[6], D. Micklem[6], M. Yule[6], S. Loges[7], B.T. Gjertsen[1,2,3]

[1]Department of Internal Medicine, Section of Hematology, Haukeland University Hospital, [2]Department of Clinical Science, [3]Centre for Cancer Biomarkers CCBIO, Department of Clinical Science, Faculty of Medicine and Dentistry, University of Bergen, [4]Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway, [5]Department of Leukemia, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, United States, [6]BerGenBio AS, Bergen, Norway, [7]Department of Oncology and Hematology with Sections BMT and Pneumology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Overexpression and activation of Axl is found in many cancers, and is linked to increased proliferation, invasion and resistance to apoptosis. It is also a poor prognostic marker, linked to acquired resistance to chemotherapy and other anticancer therapies in many malignancies, including AML. Bemcentinib (BGB324) is a first-in-class orally available highly selective small molecule inhibitor of Axl, currently being investigated in a ph 2 clinical trial in patients with refractory/relapsed AML and MDS (BGBC003, NCT02488408). Here we report results from phospho-flow cytometry and mass cytometry analyses of PB and BM samples from the clinical trial.
Aims: We aimed to investigate the effect of bemcentinib on the Axl signaling pathway and on clonal evolution in treated patients.
Methods: The dose escalation part of the study evaluating bemcentinib monotherapy followed a standard 3+3 design. PB sampled at frequent intervals was analyzed by flow- and mass cytometry to investigate the effects of bemcentinib treatment on signaling proteins known to be downstream of Axl, such as pPLCγ, pAkt and pErk. Sequential BM samples were also analyzed by mass cytometry for extensive single cell immune profiling using a 35 marker panel. Clonal evolution was analyzed by TruSight myeloid panel (Illumina) sequencing of sequential BM samples.
Results: PhosphoFlow and CyTOF analyses of PB showed altered signaling in circulating leukemic blasts relative to pre-treatment in several proteins downstream of Axl, including pPLCγ1, pErk and pAkt. Changes in signaling relative to pre-treatment were seen within 4-24 hours of treatment start in all patients. The time point of signaling response correlated with drug exposure. Signaling responses were heterogeneous in the cohort examined. Two distinct patient groups were identified; one with high and one with low basal signal profiles in PB leukemic blasts pre-treatment. Patients with high basal signaling profiles tended to have reduced signaling with treatment, whereas patients with low basal profiles showed increased signaling with treatment. However, correlation to treatment response was not apparent. TruSight myeloid panel sequencing of sequential BM samples from 5 patients showed little or no clonal drift during treatment (median treatment time 5,5 mo, min 3 mo, max 27 mo), indicating that the clonal composition of the leukemic blast populations could be conserved during treatment. Deep single cell immune profiling of BM samples from 7 patients by mass cytometry revealed the presence of blast populations with composite immune phenotypes in all patients, with moderate drift during treatment. Blast immune phenotypic composition was more complex than what was reflected by the clonal composition. The mutational profiles will be validated via using exome sequencing.
Summary/Conclusion: Bemcentinib has unique pharmacodynamic properties, and signaling responses to exposure can be observed in peripheral blood leukemic blasts by phospho-flow and mass cytometry within hours of ingestion of the first treatment dose. Further studies may establish whether single cell signal profiling can discriminate responders from non-responders and provide information about dose-response. Bemcentinib appears to stabilize the clonal distribution in AML and MDS an effect that may be exploited in combination therapy with hypomethylating agents.

PS966

FURTHER EVIDENCE FOR GPR56, BUT NOT CLL-1 (CLEC12A) AS A MARKER FOR LEUKEMIC STEM CELLS IN CD34-POSITIVE ACUTE MYELOID LEUKEMIA

S. Daga[1,2,*], A. Rosenberger[1,2], N. Krisper[1,2], B. Prietl[2], A. Reinisch[1], A. Zebisch[1], H. Sill[1], A. Wölfler[1,2]

[1]Division of Hematology, Medical University of Graz, [2]CBmed Center of Biomarker Research in Medicine, Graz, Austria

Background: Acute myeloid leukemia (AML) is characterized by a hierarchical cellular organization with a minor fraction of self-renewing leukemia stem cells (LSCs) at the apex of this hierarchy. The clinical importance of LSCs has been implied not only in leukemia initiation, but also in relapse

and drug resistance. Within CD34-positive leukemias, which comprise about three quarters of all AMLs, LSCs have been shown to predominantly reside in the $CD34^+38^-$ cell fraction. Several surface markers including GPR56 and CLL-1 have been reported to be up-regulated on $CD34^+38^-$ LSCs or to mark AML cells with high repopulating activity in immunocompromised mice. However, the immunophenotype of LSCs as well as their prognostic value still remain controversial.

Aims: In this study, we aimed for a detailed analysis of putative LSC markers using multi-color flow cytometry with a strictly standardized protocol and a focus on cellular compartments of AML specimens defined by their CD34/38 expression patterns. In addition, expression of distinct surface markers was correlated with expression of LSC-associated genes as well as with outcome of patients after intensive therapy.

Methods: Bone marrow or peripheral blood samples from 150 newly diagnosed AML patients were analyzed for 24 surface markers including several putative LSC markers using flow cytometry with a strictly standardized protocol including distinct backbone markers per tube allowing simultaneous expression analysis of all markers. Expression of 17 genes associated with leukemic stemness (LSC17 profile; Ng *et al.*, Nature 2016;540:433-437) was determined by qPCR after sorting CD34+38-AML cells according to their GPR56 and CLL-1 surface expression levels. Differences in fluorescence intensity as well as gene expression between specimens and/or sub-populations were calculated using the nonparametric Mann-Whitney U or Wilcoxon test. Overall survival (OS) was estimated using the Kaplan-Meier method.

Results: GPR56 and CLL-1 proved to be differentially expressed. While GPR56 exhibited an elevated expression in CD34-positive AML specimens (n=108), CLL-1 expression was higher in CD34-negative AMLs (n=42). Within CD34-positive AML samples, GPR56 levels were highest in the $CD34^+38^-$ LSC-containing subpopulation and lowest in the $CD34^-$ compartment ($p<0.001$). In contrast, CLL-1 was significantly up-regulated in the more mature $CD34^+38^+$ and $CD34^-$ leukemic cells as compared to the $CD34^+CD38^-$ compartment ($p<0.01$). All other markers tested were not differentially expressed among CD34/38 leukemic subpopulations. To determine whether GPR56 or CLL-1 marks cells with an LSC-associated gene expression signature, we sorted $CD34^+38^-$ leukemic cells according to their GPR56 as well as CLL-1 surface levels and determined the expression of genes included in the LSC17 panel. While nine out of 17 genes were significantly up-regulated in $GPR56^{hi}$ versus $GPR56^{lo}$ $CD34^+38^-$ leukemic cells, none of the genes was higher expressed in CLL-1^{hi} as compared to CLL-1^{lo} cells. Finally, in a cohort of 102 AML patients receiving intensive chemotherapy high GPR56 surface expression at diagnosis was associated with significantly lower OS ($p=0.0325$), while expression of CLL1 did not show prognostic significance.

Summary/Conclusion: Our data indicate that GPR56 may serve as a potential prognostic marker, but also as a promising marker for LSC activity in CD34-positive AML. In contrast, CLL-1 has limited potential as LSC marker in AML.

PS967

MOLECULAR ABNORMALITIES IN THERAPY-RELATED ACUTE MYELOID LEUKEMIAS

G. Balatzenko[1,*], B. Spassov[2], M. Jagurinoski[3], M. Stoychov[2], S. Ivanova[1], V. Madzharova[3], T. Dikov[3], Y. Petrov[4], M. Donchev[2], P. Ganeva[4], G. Arnaudov[4], K. Ignatova[2], M. Guenova[3]

[1]Laboratory of Cytogenetics and Molecular Biology, [2]Department of Clinical Hematology, [3]Laboratory of Hematopathology and Immunology, [4]Department of Hematopoietic Stem Cells Transplantation, National Specialized Hospital for Active Treatment of Hematological Diseases, Sofia, Bulgaria

Background: Therapy-related acute myeloid leukemias (t-AML) are one of the most serious long-term complications of anti-cancer treatment. These neoplasms are considered to be the direct consequence of genetic abnormalities induced by chemotherapy and/or radiotherapy. In contrast to *de novo* (dn) AML, t-AMLs are associated with resistance to standard chemotherapy and poorer overall prognosis. Despite that t-AMLs are a relatively frequent subtype of AML, accounting for approximately 10% of the cases, the molecular events, associated with the pathogenesis and unfavourable prognosis of t-AML are still poorly defined.

Aims: To analyze the spectrum of molecular abnormalities in adult patients (pts) with t-AML.

Methods: Over a 15 years period, 582 AML pts were tested for leukemia-associated abnormalities by RT-PCR. Among these, 52 (9.2%) pts (25 females; 27 males; at a median age of 60 years, range 22 - 83 years) had a history of antecedent chemotherapy/radiotherapy. The panel of routinely screened by RT-PCR molecular abnormalities in all pts included fusion transcripts: *BCR-ABL1, PML-RARA, RUNX1-RUNX1T1, CBFb-MYH11*; and *FLT3*-ITD. In addition, several other molecular abnormalities with a proven or suggestive role in malignant transformation were also tested in a significant proportion of pts, including: *KMT2A-MLLT3, KMT2A -MLLT4, DEK-NUP214, KMT2A*-PTD gene; aberrant overexpression of *Survivin, EVI1, BAALC, PRAME, MDR1* genes, and type A mutation of *NPM1* gene.

Results: In 15/52 (29%) pts with t-AML, recurrent fusion mRNAs were identified, as follows: 5 *RUNX1-RUNX1T1* (9.6%); 4 *CBFb-MYH11* (7.7%); 4 *PML-RARA* (7.7%); and 3 *KMT2A-MLLT3* (3.8%) . The incidence of the same abnormalities in dnAML was similar: 24/530 *RUNX1-RUNX1T1* (4.5%) ; 21/530 *CBFb-MYH11* (3.9%); 35/530 *PML-RARA* (6.6%); 4/235 *KMT2A-MLLT3* (1.7%). No significant differences were also found in regard to the incidence of *NPM1*-A mutation in t-AML and dnAML: 4/30 (13.3%) vs. 27/129 (20.9%). The frequency of *KMT2A*-PTD was only slightly higher in t-AML compared to dnAML: 4/27 (14.8%) vs. 10/228 (4.6%) [p=0.054]. In contrast, the incidence of *FLT3*-ITD was significantly lower in t-AML - 4/48 (8.3%) vs. in dnAML - 109/429 (25.4%) [p=0.038], while the frequency of *EVI1* gene overexpression was higher in t-AML compared to dnAML - 9/31 (29.0%) vs. 8/77 (10.4%) [p=0.037]. Results from an extended panel testing in 32 pts revealed 3 distinctive patterns of the molecular abnormalities: (i) 31.2% of pts were characterized by "favourable" fusion transcripts *PML-RARA*, *CBFb-MYH11*, or *RUNX1-RUNX1T1*, generally without any other molecular abnormalities, with the exception of *PRAME* gene overexpression in half of the cases; (ii) 25.0% of pts were characterized by the presence of unfavourable high *BAALC* and/or *EVI1* gene expression, generally in association with other unfavourable molecular abnormalities, such as *KMT2A*-PTD and *Survivin* gene overexpression; (iii) in the remaining 43.8% of pts no characteristic molecular profile was detected, with the exception of the elevated *Survivin* expression in about half of the cases (6/14). *MDR1* overexpression was found in 62.5% of pts, being the most common abnormality in t-AML. None of the pts was positive for *BCR-ABL1*, *KMT2A-MLLT4*, and *DEK-NUP214* mRNA.

Summary/Conclusion: t-AML pts are heterogeneous in regard to the spectrum of genetic abnormalities and in general, 3 groups of t-AMLs pts with a distinctive pattern of molecular abnormalities could be distinguished: with "favourable" fusion transcripts; with a high incidence of unfavourable *BAALC* and/or *EVI1* gene overexpression, and with no characteristic molecular profile.

CD123 REDIRECTED NK92 CELLS FOR ACUTE MYELOID LEUKEMIA

L. Zhou[1,2,*], C. Zheng[2], X. Song[1]

[1]Center for Cell and Gene Therapy, Baylor College of Medicine, Houston, United States, [2]Hematology, The First Affiliated Hospital of University of Science and Technology of China, Anhui provincial hospital, Hefei, China

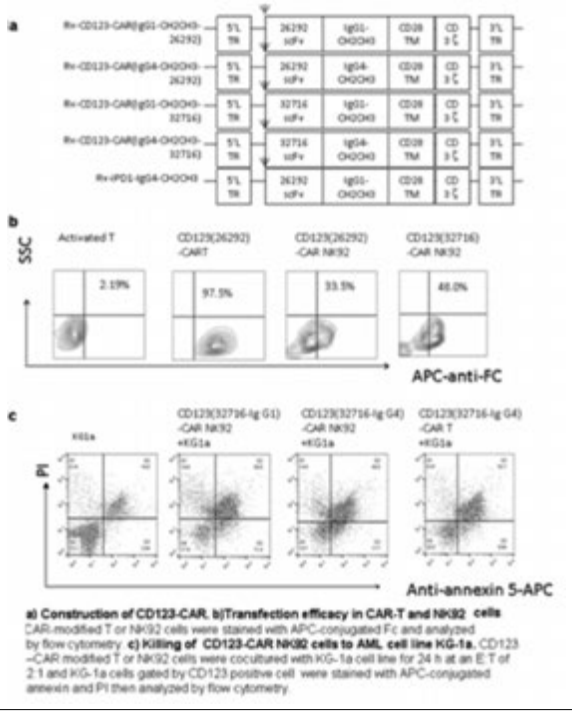
Background: Hematopoietic stem cell transplantation (HSCT) has been increasingly used as a curative treatment for acute myeloid leukemia (AML). However, relapse rates after HSCT in complete remission (CR) are reported between 30% and 70%. Currently, chimeric antigen receptor (CAR)-based T cells have been approved to able to treat ALL and lymphoma effectively in clinical studies. However, there are concerns that CAR-T therapy may induce severe cytokine release storm. By contrast, Natural killer (NK) cell-based cellular therapies have shown safety advantages in clinical studies, because of lack of in vivo clonal expansion and cytokine storm. Thus it would be desirable to develop CAR-NK cells targeting AML relapse. The human NK cell line, NK-92, that expresses a high affinity variant of the IgG Fc receptor (FcγrIII), has been demonstrated to kill leukemia primary blasts and leukemia cell lines *in vitro* and in clinical studies.hIgG1-CAR engineered NK92 cells, are likewise activated by FcγR binding resulting in cytokine secretion (cytokine storm) and lysis of monocytes and NK cells. To reduce the unwanted "off-target" effect, we designed a new CD123-CAR with human IgG4 CH2CH3 spacer domain without affecting CAR expressing and antigen binding.

Aims: To produce CD123-CAR-NK92 cells using NK92 cells engineered to express CAR for a specific AML cell-surface antigen CD123. Then to study the CD123-CAR-NK92 cell's specificity against CD123-positive AML cell lines *in vitro*.

Methods: We developed chimeric antigen receptors (CARs) containing a single polypeptide chain with an CD123-specific antibody-derived single chain fragment (scFv) and human IgG1 or IgG4 hinge-CH2CH3 spacer domain in the extracellular moiety for binding and combined CD28–CD3ζ signaling domain in the intracellular moiety for NK92 cells(hIgG1-CD123-CAR or hIgG4-CD123-CAR). We produced retrovial vector expressing hIgG1-CD123-CAR or hIgG4-CD123-CAR and retrovirus were transduced to NK92 cells. hIgG1-CD123-CAR or hIgG4-CD123-CAR engineered

NK92 cells were then co-cultured with CD123-positive AML cell lines including MOLM13, KG-1a. CD123-negative CML cell line K562 was used as negative control. The cytotoxicity of CD123-CAR NK92 was compared *in vitro* using flow cytometry.

Results: We successfully produced CD123-CAR-NK92 using NK92 cells engineered to express CAR for a specific AML cell-surface antigen CD123. We demonstrated that CD123-CAR-NK92 retained the specificity against CD123-positive AML cell lines MOLM13 and KG-1a *in vitro* (Figure 1).



a) Construction of CD123-CAR. b)Transfection efficacy in CAR-T and NK92 cells CAR-modified T or NK92 cells were stained with APC-conjugated Fc and analyzed by flow cytometry. **c) Killing of CD123-CAR NK92 cells to AML cell line KG-1a.** CD123 –CAR modified T or NK92 cells were cocultured with KG- 1a cell line for 24 h at an E:T of 2:1 and KG- 1a cells gated by CD123 positive cell were stained with APC-conjugated annexin and PI then analyzed by flow cytometry.

Figure 1.

Summary/Conclusion: Our results suggested that CD123-CAR-NK92 might be a valuable candidate to simultaneously prevent or treat relapse in AML HSCT recipients.

PS969

THE DIFFERENTIAL EXPRESSION OF DNMT3A SPLICE VARIANTS AND THEIR PROGNOSTIC RELEVANCE IN ACUTE MYELOID LEUKEMIA

S. Beinicke[1,*], M. Jentzsch[1], J. Grimm[1], J. Häntschel[1], M. Bill[1], K. Goldmann[1], J. Schulz[1], M. Cross[1], G.-N. Franke[1], G. Behre[1], V. Vucinic[1], W. Pönisch[1], D. Niederwieser[1], S. Schwind[1]

[1]Hematology and Oncology, University Leipzig, Leipzig, Germany

Background: Acute myeloid leukemia (AML) is associated with aberrant DNA methylation patterns. DNA methyltransferase 3A (DNMT3A) catalyzes DNA methylation & is frequently mutated in AML. Five *DNMT3A* splice variants with the same catalytic domain & different N-terminus - important for DNA binding – are known. Different *DNMT3A* splice variants may lead to different DNA methylation patterns & influence the AML phenotype & outcome of AML patients (pts). Here we assessed the diagnostic expression of the two main *DNMT3A* splice variants *DNMT3A1* & *DNMT3A2* in AML pts.

Aims: To assess the *DNMT3A1* & *DNMT3A2* expression & analyze associations with clinical & molecular features & evaluate the prognostic relevance in AML pts.

Methods: We analyzed 146 pts who received allogeneic hematopoietic stem cell transplantation (HSCT; median age at HSCT 64 years [y]; range 32-76y) in complete remission (CR) or CR with incomplete peripheral recovery (CRi) after intensive chemotherapy. At diagnosis, cytogenetics & the mutation (mut) status of *CEBPA*, *DNMT3A*, *IDH1*, *IDH2*, *NPM1*, presence of *FLT3*-ITD & *EVI1* expression were assessed. At diagnosis, *DNMT3A1*, *DNMT3A2* & *ABL1* expressions were absolutely quantified in diagnostic bone marrow by digital droplet PCR (ddPCR). R's OptimalCutpoint package was used to determine optimal cut-offs according to *DNMT3A1*, *DNMT3A2* & *DNMT3A1*/*DNMT3A2* expression. Median follow up after HSCT for pts alive was 4.7y.

Results: Using ddPCR both main splice variants were detected in all pts, but *DNMT3A1* was higher expressed compared to *DNMT3A2* (p=0.02). No correlation of *DNMT3A1* & *DNMT3A2* expression was found (Pearson correlation 0.28). AML pts with higher expression of *DNMT3A1* or *DNMT3A2* associated with monosomal (*DNMT3A1* p=.02, *DNMT3A2* p=.002), complex (*DNMT3A1* p=.03, *DNMT3A2* p=.05) karyotypes & were less often *IDH2* mutated (*DNMT3A1* p=.07, *DNMT3A2* p=.002) at diagnosis. Pts with high *DNMT3A1* expression had by trend a higher platelet count (p=.07) & lower *EVI1* expression (p=.01). Pts with high *DNMT3A2* expression less often had a normal karyotype (p=.002) & more% bone marrow blasts (p=.02) &% blood blasts (p=.06) by trend & were less likely to be *NPM1* mutated (p=.001) at diagnosis. While pts with high *DNMT3A1* expression had a higher cumulative incidence of relapse (CIR, p=.05) & shorter overall survival (OS, p=.01), *DNMT3A2* expression did not associate with CIR (p=.36) or OS (p=.88). Combining the expression information for both splice variants pts with a high *DNMT3A1*/*DNMT3A2* expression ratio had lower% bone marrow blasts (p=.002) &% blood blasts (p=.007) at diagnosis. A high *DNMT3A1*/*DNMT3A2* expression ratio associated with higher CIR (p=.028, Figure 1A) & a trend for shorter OS (p=.055, Figure 1B). Using the Bayesian information criterion we found the model containing the *DNMT3A1*/*DNMT3A2* expression ratio to be the preferred model compared to a model with the *DNMT3A1* expression information. In multivariate analysis, a high *DNMT3A1*/*DNMT3A2* ratio was an independent factor for a higher CIR (Hazard ratio [HR] 2.09, Confidence Interval [CI] 1.0-4.25, p=.04).

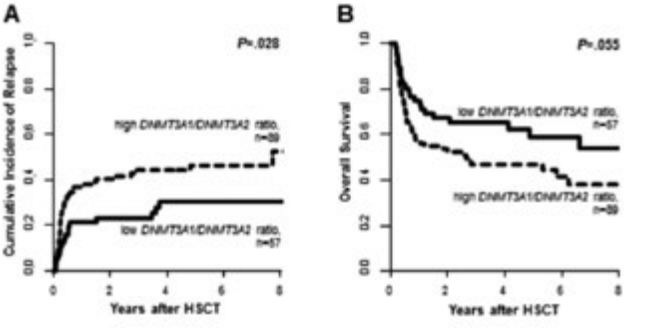


Figure 1.

Summary/Conclusion: In AML pts the two main *DNMT3A* splice variants are expressed at different levels. The differential expression of *DNMT3A* splice variants & their ratio may lead to aberrant DNA methylation patterns & specific AML phenotypes. Expression levels of *DNMT3A1* & *DNMT3A2* associate with distinct clinical & biological features. Especially a high *DNMT3A1*/*DNMT3A2* expression ratio was identified as a negative prognostic factor that independently associated with a higher CIR in AML pts.

PS970

P53(D281G) MUTATION CAUSES CYTARABINE RESISTANCE VIA PROMOTING WARBURG EFFECT IN ACUTE MYELOID LEUKEMIA CELLS

K. M. Ng[1,*], C.-Y. Hu[1], H.-A. Hou[2], C.-Y. Chen[2], D.-L. Ou[3], H.-F. Tien[2], L.-I. Lin[1]

[1]Clinical Laboratory Sciences And Medical Biotechnology, National Taiwan University, [2]Internal Medicine, National Taiwan University Hospital, [3]Oncology, National Taiwan University, Taipei, Taiwan, Republic of China

Background: It is widely accepted that cancer cells tend to "ferment" glucose into lactate even in the presence of sufficient oxygen to support mitochondrial oxidative phosphorylation, so-called Warburg effect. However, the mechanistic links between p53 mutation-mediated Warburg effect and drug resistance in human acute myeloid leukemia (AML) remains to be established. We established a cytarabine-resistant human leukemic MV4-11 derivative (MV4-11-R) from parental MV4-11 (MV4-11-P) cells. The IC_{50} of cytarabine in resultant in MV4-11-R cells increases from 0.2 μM in MV4-11-P cells to 340.2 μM. Molecule alterations in several signaling pathways have been characterized, including p53. Exon sequencing and pyrosequencer analysis revealed that there were similar p53 R248W mutation burdens in MV4-11-P and -R cells; but D281G mutation increased from 1% in MV4-11-P cells to 41% in MV4-11-R cells.

Aims: To investigate the extent of D281G p53-associated metabolic alterations contribute to the cytarabine resistance in MV4-11-R cells.

Methods: The differential expression genes (DEGs) were examined using

RNA-Seq (Illumina NextSeq-500). Alterations of metabolites were profiled by using Liquid Chromatography-Time of Flight Mass Spectrometry (LC-TOF-MS) coupled with True ion pick (TIPick) algorithm in MV4-11-P and -R cells. Metascape resource and KEGG (Kyoto Encyclopedia of Genes and Genomes) pathway analyses were performed to predict the biological functions of DEGs. Real-time quantitative PCR (RT-qPCR) were used to validate the RNA-seq results. To assess the effect of p53 D281G mutation on glycolysis and mitochondria respiration, the extracelluar acidification rate (ECAR) and oxygen consumption rate (OCR) were measured using Seahorse bio-analyzer.

Results: We identified a total of 869 DEGs between the MV4-11-P and -R cells. Among them, 210 DEGs were up-regulated, while 659 DEGs were down-regulated. Metascape enrichment analyses revealed the highest ranked pathway associated with down-regulated DEGs was p53-signaling pathway in MV4-11-R cells, in line with vanished wt p53 and decreased p21, a transcriptional target of wt p53. Moreover, KEGG mapper analyses showed that the highest ranked up-regulated DEGs are *ASNS, ASS1, CBS, GOT1, PSPH, PHGDH, UPB1, ALDOC, ARG2, SLC27A5, PTS, ME1, CYP27B1, PCK2, COQ3, and DGAT2*, relevant to the metabolic pathways. Metabolomic analyses revealed a total number of 56 increased and 25 decreased metabolites in MV4-11-R, compared to MV4-11-P, cells. Of them, three metabolites: malate (with 1.94x increase), glutamate (with 56410x increase) and serine (with 12083x increase) were the corresponding reaction product or intermediate of ME1, GOT1 and PSPH/PHGDH, respectively. Furthermore, MV4-11-R cells showed higher glucose uptake, GAPDH activity, lactate production and ATP content than MV4-11-P cells. Consistent with increased lactate production, ECAR analyses showed a significant increase in glycolysis, glycolytic capacity and glycolytic reserve in MV4-11-R cells. In addition, we showed increased basal mitochondrial and ATP-coupled respiration in MV4-11-R, compared to MV4-11-P, cells by OCR analyses. Lastly, decreased OCR/ECAR ratio indicated the relatively higher reliance on glycolysis in MV4-11-R cells.

Summary/Conclusion: In this study, transcriptomic and metabolomic profiles of cytarabine-sensitive and -resistant MV4-11 myeloid leukemia cells were analyzed. Our investigation highlights that the emerged p53 D281G mutation may contribute to the cytarabine-resistance of MV4-11-R cells via promoting Warburg effect.

PS971

SINGLE-CELL DNA ANALYSIS OF MUTATIONAL HETEROGENEITY IN ACUTE MYELOID LEUKEMIA TUMORS WITH HIGH-THROUGHPUT DROPLET MICROFLUIDICS

D. Eastburn[1,*], M. Pellegrino[1], A. Sciambi[1], S. Treusch[1], L. Xu[2], R. Durruthy-Durruthy[1], K. Gokhale[1], J. Jacob[1], T. Chen[1], W. Oldham[1], J. Matthews[3], H. Kantarjian[3], A. Futreal[3], K. Patel[3], K. Jones[1], J. Zehnder[2], K. Takahashi[3]

[1]Mission Bio, Inc., South San Francisco, [2]Stanford School of Medicine, Stanford, [3]UT MD Anderson Cancer Center, Houston, United States

Background: Current tumor sequencing paradigms are inadequate to fully characterize many instances of AML (acute myeloid leukemia). A major challenge has been the unambiguous identification of potentially rare and genetically heterogeneous neoplastic cell populations, with subclones capable of critically impacting tumor evolution and the acquisition of therapeutic resistance. Standard bulk population sequencing is often unable to identify rare alleles or definitively determine whether mutations co-occur within the same cell. Single-cell sequencing has the potential to address these key issues and transform our ability to accurately characterize clonal heterogeneity in AML

Aims: Our goal was to remove existing barriers to performing high-throughput single-cell DNA sequencing and make possible the routine characterization of genetic diversity within heterogeneous cancer cell populations. Insights provided by this type of analysis could ultimately lead to better patient stratification, disease monitoring and therapy selection.

Methods: We developed a novel multi-step microfluidic droplet workflow that enables efficient and massively-parallel single-cell PCR-based genomic barcoding for single-cell DNA sequencing applications. We demonstrate that the multi-step microfluidic approach is required for robust DNA amplification on thousands of individual cells per run with high coverage uniformity and low allelic dropout of targeted genomic loci. To apply our single-cell sequencing technology to human tumor samples, we developed a targeted panel to partially sequence 26 genes frequently mutated in acute myeloid leukemia (AML) including *TP53, DNMT3A, FLT3, NPM1, NRAS, IDH1* and *IDH2*.

Results: Using this panel, we were able to sensitively identify SNV and indel-defined clones within AML samples and assess their distribution at the time of diagnosis, remission and relapse. In total, more than 35,000 cells were successfully genotyped for variant alleles likely to play a role in the progression of the disease. Significant clonal remodeling with both expansion and contraction of clones was seen when comparing the diagnosis and relapse samples in some patients. Additionally, our approach was able to detect rare clones during complete remission (CR) and identified clonal populations that were missed with bulk sequencing inference. We also used single cell SNVs to monitor host and donor cell populations during bone marrow transplantation (BMT), which allowed us to accurately evaluate engraftment and disease relapse.

Summary/Conclusion: Collectively, our single-cell data indicates that clonal populations inferred from VAFs obtained from bulk sequencing data may not fully resolve the heterogeneity within tumors; moreover, the single-cell nature of our approach enabled the sensitive and unambiguous identification of multiple co-occurring mutations within subclones that is not possible with bulk measurements. Our results also show a greater degree of heterogeneity in AML tumor samples than is commonly appreciated with traditional sequencing paradigms and demonstrate the value of single-cell analysis for AML. Additionally, our single-cell method can be applied to build custom panels of interest and to solid tumor specimens.

PS972

CANDIDATE FDA-APPROVED DRUGS THAT MAY MIMIC HOXA CLUSTER DELETION IN MLL-AF9 LEUKEMIA

L. Kettyle[1,*], C.-É. Lebert-Ghali[2], J. Bijl[3], D. Simpson[4], K. Mills[1], G. Sauvageau[5], A. Thompson[16]

[1]CCRCB, Queen's University Belfast, Belfast, United Kingdom, [2]Division of Hematology, Maisonneuve-Rosemont Hospital Research Center, Montreal, QC, Canada, [3]Division of Hematology, Maisonneuve-Rosemont Hospital, Montreal, Canada, [4]Centre for Experimental Medicine, Queen's University Belfast, Belfast, United Kingdom, [5]Institute for Research in Immunology and Cancer, University of Montreal, Montreal, Canada, [6]Cancer and Stem Cells, University of Nottingham, Nottingham, United Kingdom

Background: Gene rearrangements involving *MLL*, termed *MLLr*, are among the most potent oncogenic drivers of leukemia. *HOX* genes are well established as downstream targets of MLL and their high expression is a hallmark of high-risk, refractory AML.. Whilst several studies indicate a need for *HOXA* expression in the establishment of MLLr leukemia, their absolute requirement for disease progression and maintenance is less clear. Currently, there are no specific therapies approved for MLLr-AML and identifying target and pathway dependencies and candidate drugs is critical to improving clinical outcome for these patients. The HOXA-axis is a potential target in MLLr-AML if candidate drugs that mimic HOXA repression/deletion can be identified.

Aims: 1. Determine the criticality of *HoxA* to disease maintenance in established leukemia. 2. Identify FDA-approved drugs with the potential to mimic *HoxA* deletion for repurposing in AML

Methods: Transgenic mice: *Hoxaflox/WT* mice were backcrossed to generate *Hoxaflox/flox* mice. These were subsequently crossed into the MxCre background to generate compound *MxCre$^{+/}$ Hoxaflox/flox* mice.

Generation of Leukemia: Haematopoietic stem and progenitor cells enriched from bone marrow were transduced with MLL-AF9 virus by spinoculation. Colonies were grown and serially re-plated in Methocult M3434 prior to being transplanted intravenously into sub-lethally irradiated recipient mice.

Deletion of the Hoxa cluster and analysis: Deletion of the *Hoxa* cluster was achieved *in vitro* by IFNα, *ex vivo* by direct exposure to *Cre*-recombinase and *in vivo* by IP injection of PolyI:C. Treated leukemic cells were subsequently analyzed for cell/colony growth and gene expression by RNAseq. The *Hoxa-del* signature was further analyzed by Ingenuity® Pathway Analysis (IPA) and connectivity mapping software to identify key processes and FDA-approved drugs within the LINCS database.

Results: Aggresssive MLL-AF9 models were generated and homozygous deletion of the *HoxA* cluster was not tolerated by the leukemia cells. A *Hoxa-del* signature including Cxcl12, Tgfb2, Notch4 and Mmp9 was obtained. Analysis of the *Hoxa-del* signature identified cell cycle, polo-like kinase activity, DNA damage regulation, and aryl hydrocarbon receptor signaling as associated processes and canonical pathways. Further bioinformatics analysis using connectivity mapping identified candidate FDA-approved drugs, including Albendazole and Homoharringtonine for potential repurposing in *HOXA* expressing leukemias.

Summary/Conclusion: *Hoxa* deletion, within a MLL-AF9 leukemia background, resulted in reduced proliferation, colony formation and repopulating ability in transplanted mice. Surviving leukemic cells retained at least one copy of the *Hoxa* cluster, indicating dependency, in contrast to the normal hematopoiesis setting in which biallelic deletion of the *Hoxa* locus is

tolerated [Lebert-Ghali *et al.* Blood 2016; 127(1):87-90]. Comparative RNA-seq analysis identified a unique *Hoxa-del* signature, further bioinformatics analysis of which identified a number of FDA-approved drugs for potential repurposing in MLL-AF9 leukaemias.
In conclusion our findings demonstrate, for the first time, dependency on the *Hoxa* locus for the maintenance of MLL-AF9 leukemias and in the absence of direct inhibitors identifies candidate FDA-approved drugs for further pre-clinical validation and redeployment to this highly refractory disease.

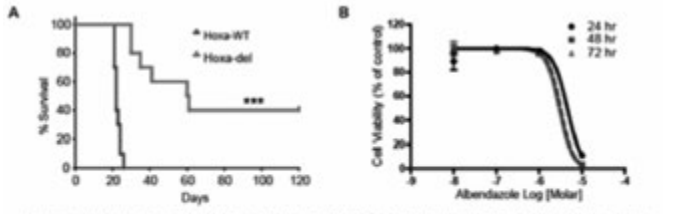

Figure. A Kaplan meier plot demonstrating that deletion of the Hoxa cluster in MLL-AF9 leukemia results in significantly improved survival compared to wild type in transplantation models (A). A dose response curve for the connectivity mapped candidate FDA-approved drug Albendazole shows anti-leukemia properties in MLL-AF9 primary cell lines in the uM range (B).

Background: *Nucleophosmin1* mutated (*NPM1*^{mut}) based minimal residual disease (MRD) monitoring allows the early identification of patients (pts) with acute myeloid leukemia (AML) at high risk of relapse. However, its predictive value, in particular with regard to the type of post-remission therapy [high-dose cytarabine, (HIDAC) versus (vs) allogeneic stem cell transplantation, (alloSCT)] has not been investigated yet.
Aims: To exploratory evaluate the predictive value of the *NPM1*^{mut} MRD status after two cycles of treatment with respect to the type of post-remission therapy (HIDAC vs alloSCT) in a large cohort of younger AML pts [18 to 60 years (yrs)] harboring *NPM1*^{mut}. Indication for alloSCT was performed according to institutional algorithms.
Methods: In total, 611 *NPM1*^{mut} pts were enrolled in one of four AMLSG treatment trials. Treatment comprised 1 to 2 cycles of induction therapy followed by HIDAC (n=363, 59%), autologous (n=19, 3%) or alloSCT (n=162, 27%). Overall, 3527 bone marrow (BM) and 2812 peripheral blood (PB) samples were analyzed at diagnosis, during treatment and follow-up (FU). *NPM1*^{mut} transcript levels (ratio of *NPM1*^{mut}/*ABL1* transcripts×10^4) were determined by RQ-PCR with a sensitivity of 10^{-5} to 10^{-6}; the median FU for all pts was 3.2 yrs.
Results: We first compared the outcome of pts (n=63) who achieved RQ-PCR-negativity (RQ-PCR^{neg}) in the BM after two cycles of intensive chemotherapy with respect to the type of post-remission therapy (HIDAC vs alloSCT). Here, 4-yr overall survival (OS) was significantly superior in pts treated with HIDAC (100% vs 46%; p<.00001) compared to pts who received alloSCT; median survival was not reached for pts after HIDAC and was 3.06 yrs in pts after alloSCT. When stratifying pts according to the 2017 European LeukemiaNet (ELN) risk stratification with regard to *FLT3*-ITD mutation (wildtype / allelic ratio < 0.5 vs allelic ratio ≥ 0.5) this survival benefit was sustained. In addition, there was no significant difference in the cumulative incidence of relapse (CIR) at 4 yrs between HIDAC and alloSCT (p=.18). The predictive value of the MRD status was also observed when only PB samples (129 pts) were analyzed. However, the results were slightly different when looking at pts being RQ-PCR-positive (RQ-PCR^{pos}) in the BM after two treatment cycles (n=332). Here we still found a significant difference in OS in favor of the HIDAC group (68% vs 54% at 4 yrs, p=.0001) but when stratifying according to the *FLT3*-ITD status this difference only remained significant in pts with wildtype / allelic ratio < 0.5 while OS in pts with an allelic ratio ≥ 0.5 was equivalent for the two groups (HIDAC 53% vs alloSCT 49% at 4 yrs; p=.89). This was mainly due to a higher 4-yr CIR rate in RQ-PCR^{pos} pts which was 47% in HIDAC pts vs 22% in the alloSCT group (p=.007). In pts with *FLT3*-ITD wildtype / allelic ratio < 0.5 CIR at 4 yrs was 46% for HIDAC pts vs 21% for the alloSCT group (p=.03); alloSCT treatment was also associated with a significantly lower CIR in pts with an allelic ratio ≥ 0.5 (alloSCT 26% vs HIDAC 50%; p=.04). Again, the predictive value of the MRD status could be confirmed when PB (164 pts) samples were analyzed.
Summary/Conclusion: In this retrospective exploratory analysis of *NPM1*^{mut} AML pts, outcome of pts who became MRD negative or remained positive but had a 2017 ELN favorable risk profile was superior after HIDAC consolidation versus alloSCT. Our data provide strong support for the importance of *NPM1*^{mut} MRD monitoring after two cycles of intensive chemotherapy to inform type of post-remission therapy.

PS974

MUTATIONAL LANDSCAPE OF RELAPSED ACUTE PROMYELOCYTIC LEUKEMIA

L. Iaccarino[1,*], T. Ottone[1], V. Alfonso[1], L. Cicconi[1], M. Divona[1], S. Lavorgna[1], A. Ferrantini[1], C. Baer[2], M. Usai[3], F. Forghieri[4], M.T. Voso[1], T. Haferlach[2], F. Lo Coco[1]

[1]Biomedicine and Prevention, University of Tor Vergata, Rome, Italy, [2]Munich Leukemia Laboratory, Munich, Germany, [3]Department of Medical Sciences and Public Health, University of Cagliari, Cagliari, [4]Department of Surgical and Medical Sciences, University of Modena and Reggio Emilia, Modena, Italy

Background: Acute promyelocytic leukemia (APL) is characterized by the unique PML/RARA oncoprotein, whose role in disease pathogenesis and diagnostics is well established. Additional genetic abnormalities have also been detected in APL both at diagnosis and at time of relapse; however, their biologic and clinical significance remains unclear. Recent reports, including one from our group, suggested that mutations in *PML* and *RARA* genes play an important role in development of resistance to arsenic trioxide (ATO) and/or all-*trans* retinoic acid (ATRA).
Aims: We hypothesize that deciphering the molecular mechanisms involved in APL relapse and resistance may be important for the early identification of patients in need of salvage pre-emptive therapy.
Methods: An NGS-based approach was used to analyze a total of 30 APL patients who underwent disease relapse after treatment (15 following ATRA-ATO, and 15 after ATRA-chemotherapy). The NGS assay included both a 31-target gene panel and a customized assay to specifically identify mutations in *PML* and *RARA*. Twenty one patients in continuous complete remission (CCR) at a median follow-up of 42 months (range 12-85), were analysed as controls.
Results: A high prevalence of mutations in *PML* and *RARA* genes was found in relapse samples (8/30, 27%). Comparing the initial mutation burden of patients who relapsed with those who remained in CCR, we found that the number of concomitant mutations *per* patient was significantly higher in the former group (median n=2 per patient) compared to controls (median n=1 per patient, p=0.02). Moreover, APL patients with multiple relapses after ATRA-ATO showed a significantly higher number of mutations (median n=2 per patient, p=0.04), and an accumulation of mutations during disease progression. In particular, we detected in relapsing patients alterations associated with clonal hematopoiesis such as *ASXL1, DNMT3A, JAK2, SRSF2, TET2*

and mutations in *TP53* (Figure 1A). *PML* and *RARA* mutations were mutually exclusive with *FLT3*-mutations. The identified mutational patterns suggested different models of disease progression. In 8 patients, relapse apparently derived from a mutated subclone present at diagnosis. In particular, we observed the co-occurrence of at least one driver mutation in addition to *PML/RARA,* which was detected both at disease onset and relapse (Figure 1B). In contrast, in 3 patients, relapse probably emerged from *PML*-mutated ATO-resistant subclones likely arising under selective pressure of ATO. During clonal selection, these subclones may acquire mutations in genes, such as *ASXL1, DNMT3A, JAK2, SRSF2, TET2, TP53, WT1*, which confer advantages in self-renewal and proliferation (Figure 1C).

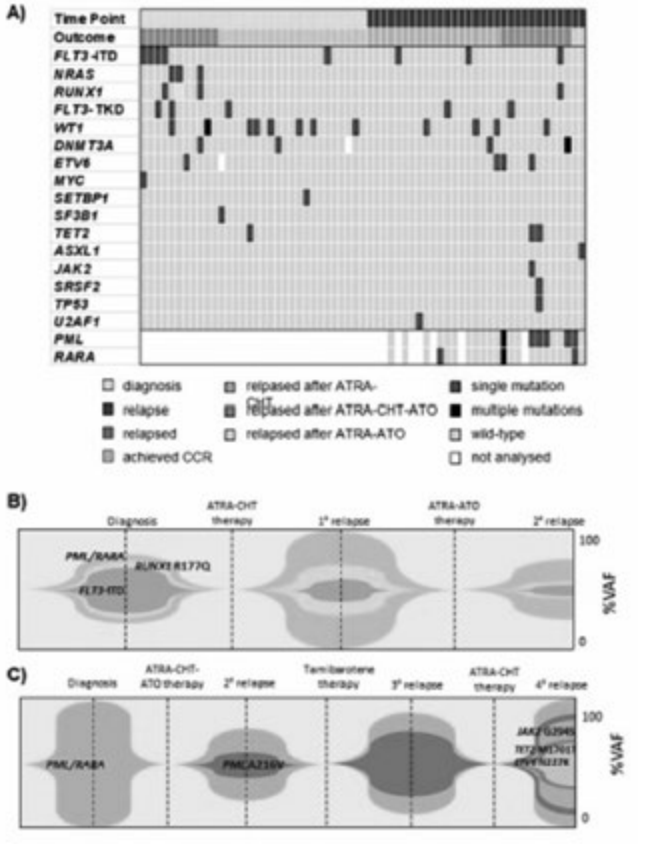

Figure 1.

Summary/Conclusion: The two proposed mechanisms of disease relapse could explain why *PML* and *RARA* mutations in our series were mutually exclusive with driver mutations, such as *FLT3*-ITD and TKD. Deep molecular sequencing at the time of relapse in APL may help to identify patients with a high mutational burden, and/or with PML-mutated subclones resistant to ATO. This may help informing treatment decisions, including the choice anti-CD33 antibodies or allogeneic stem cell transplantation for cases with unfavorable genetic profile.

PS975

THE ROLE OF THE TRANSCRIPTION FACTOR GFI1 IN LEUKEMIA GENOME STABILITY AND EVOLUTION

D. Frank[1,2,*], T. Liehr[3], U. Pascheberg[4], U. Dührsen[1], C. Khandanpour[1,2]

[1]Department of Hematology, University Hospital Essen, Westdeutsches Tumorzentrum, Essen, [2]Medical Clinic A, University Hospital Muenster, Muenster, [3]Institute of Human Genetics, Jena, [4]MVZ Dr. Eberhard & Partner, Dortmund, Germany

Background: Genetic and cytogenetic aberrations are one of the key players in the development of leukemia. Our team is interested to find new pathways with participation of GFI1 which regulate the genetic stability of leukemia. Growth Factor Independence 1 (GFI1) is a transcriptional repressor which regulates the proliferation and differentiation of hematopoietic stem cells (HSCs). We have previously shown that less expression levels of Gfi1 promotes the development of *myelodysplastic syndrome* (MDS) and acute myeloid leukemia (AML) in patients as well as in murine models. Low expression of GFI1 leads to failure to repress efficiently genome wide GFI1 target genes; among them a number of AML related oncogenes. Additional, a single nucleotide polymorphism variant of GFI1, named GFI1-36N (whereby the Serine on position 36 is exchange with an Asparagine) also contributes to the development of MDS and AML by failing to induce certain genome wide epigenetic changes. AML patients which feature a low expression level of GFI1 or presence of GFI1-36N have a poor prognosis. A low expression level and presence of GFI1-36N can be detected in around 30% of all AML patients: Our group reanalyzed the available genomic data of MDS and AML patients with low expression of GFI1 or expression of GFI1-36N. We found that this patient cohort showed significantly more frequent mutation and cytogenetic aberrations (around 50% had a complex karyotype, meaning more than 3 chromosomes were altered) than MDS/AML patients with increased "wild type" level of GFI1-36S. This indicates that low expression level of GFI1 or presence of GFI1-36N are associated with genomic instability.
Aims: Our aim was to determien which role GFI1might play in the regulation of genome stability.
Methods: Using different methods such as comet assay, yH2Ax staining, gene expression analysis and murine models of human AML we examined the role of GFI1 in DNA repair and stability.
Results: . To investigate the DNA repair and DNA damage after irradiation (X-rays) we using different methods such as comet assay and γH2AX assay. We could show that reduced level of GFI1 and presence of GFI1-36N impedes the DNA repair and increase the DNA damage after irradiation. On molecular level, low expression of GFI1 or presence of GFI1-36N is associated with a reduction of the homologous and non-homologous DNA repair capacity. Moreover we found that GFI1 regulates activation of different DNA repair pathways by inducing demethylation and therefore activate PRMT1 or MGMT. On a functional level, we serially transplanted murine AML cells expressing either hGFI1-36N or low level of hGFI1-36S or normal level of hGFI1-36S. After four rounds the leukemic cells with low level of GFI1-36S or presence of GFI1-36N showed a significantly higher number of cytogenetic aberrations and mutation load than the leukemic GFI1-36S control cells. In addition we treated GFI1-36N expressing, low GFI1-36S expressing and GFI1-36S leukemic cells with Temozolomide a drug which affects the MGMT pathway and is used in glioblastoma. We could see that the leukemic cells with low level of GFI1-36S and presence of GFI1-36N are susceptible to low doses of Temozolomide compared to the leukemic GFI1-36S control cells.
Summary/Conclusion: In summary, low expression level of GFI1 as well as expression of GFI1-36N leads to a clonal genetic evolution of about 30% of all human AML cases by impeding DNA-repair and GFI1 could be a new target in leukemia therapy.

PS976

VEGFC ANTIBODY TREATMENT: A NEW DIFFERENTIATION THERAPY FOR AML

K. R. Kampen[1,2,*], F. J. Scherpen[2], H. Mahmud[2], A. Ter Elst[2], A.B. Mulder[3], V. Guryev[4], H. J. Verhagen[5], K. De Keersmaecker[1], L. Smit[5], S.M. Kornblau[6], E. S. de Bont[2]

[1]Laboratory for Disease Mechanisms in Cancer, Oncology, KU leuven, Leuven, Belgium, [2]Pediatric Oncology, [3]Department of Laboratory Medicine, [4]European Research Institute for the Biology of Ageing, University Medical Center Groningen, Groningen, [5]Department of Hematology, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, Netherlands, [6]Department of Leukemia , M.D. Anderson Cancer, Houston, Texas, United States

Background: High VEGFC levels were identified as an independent prognostic factor in AML and associated with decreased complete remission rates and a reduced survival. Exogenous VEGFC can protect AML cells from chemotherapy induced apoptosis. We previously showed that endogenous VEGFC expression is associated with decreased drug responsiveness in childhood AML.
Aims: We hypothesized that VEGFC is an important autocrine growth factor involved in CD34+ AML blast maintenance.
Methods: Reverse Phase Protein Array analysis. Immunoblot analysis. Genetic shRNA interference. Quantitative RT-PCR. NSG systemic AML PDX xenografts. Immunohistochemistry. Flow cytometry.
Results: The VEGFC/KDR axis was shown to be selectively expressed by AML blasts. The CD34+ and CD34- cell populations within primary AML patient samples expressed significantly higher levels of VEGFC as compared to NBM controls and associated with elevated KDR membrane protein expression levels, while FLT-4 membrane protein expression was absent. These findings, challenged us to explorer VEGFC targeting effects on AML cell functions by using monoclonal antibody treatment (30 µg/mL). VEGFC targeting antibody treatment reduced the expansion potential of primary CD34+ AML

blasts by 25-50% reduction in short-term and long-term colony forming cell assays and especially in clonal limiting dilution assays. Interestingly, VEGFC antibody treated induced a significant 3-fold enahnced differentiation along the myelocytic lineage. Differentiation marker analysis confirmed that increasing percentages of cells stained positive for CD38, CD11b and CD14 or CD15, while CD34 percentages were decreased. In addition, VEGFC antibody treated cultures presented increased percentages of apoptotic cells. FLT3-ITD fragment analysis showed identical ratios of heterozygous FLT3-ITD mutant cells in control and VEGFC antibody treated cultures, supporting that anti-VEGFC treatment affects the leukemic clone. Proteomics analysis revealed that VEGFC antibody treatment reduced proliferative signals via inhibiting the phosphorylation of Erk and STAT5. The VEGFC antibody treatment induced differentiation phenotype was shown to be controlled by FOXO3A suppression, as FOXO3A overexpression could repress the VEGFC antibody treatment induced differentiation. *In vivo* targeting of VEGFC in an EVI1 ASXL1 AML PDX model is characterized by reduced circulating white blood cell counts, decreased splenic AML blast infiltration, and induced myelomonocytic differentiation in the bone marrow (Figure 1).

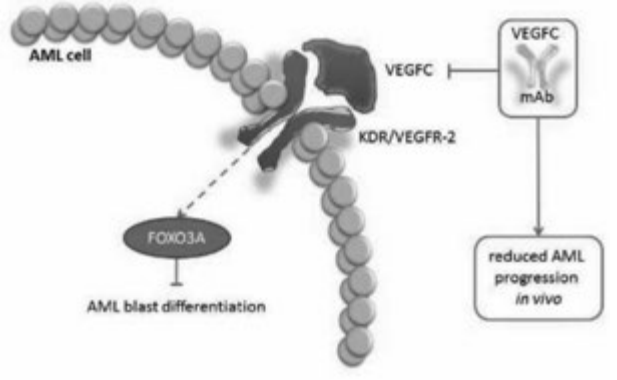

Figure 1.

Summary/Conclusion: This study shows that VEGFC antibody therapy suppresses the AML progression *in vivo* via enforced myelocytic differentiation.

Acute myeloid leukemia – Clinical

PS977

EVALUATION OF THE DRUG INTERACTION POTENTIAL OF PRACINOSTAT, A NOVEL HISTONE DEACETYLASE (HDAC) INHIBITOR, WITH CYP1A2 INDUCER CIGARETTE SMOKING AND CIPROFLOXACIN, A CYP1A2 INHIBITOR

A. Bernareggi[1,*], O. Moreno[2]

[1]R&D Innovation and Strategy, Helsinn Healthcare, Lugano , Switzerland, [2]Research & Development, MEI Pharma, San Diego, United States

Background: Pracinostat (PRAN) is a novel oral HDAC inhibitor in Phase 3 clinical development for patients with acute myeloid leukemia (AML). *in vitro* metabolism studies indicate that PRAN is metabolized mainly by CYP1A2 and CYP3A4, making it susceptible to drug-drug interactions (DDIs) when co-administered with relevant inhibitors or inducers.
Aims: Two studies were conducted to determine the potential risk for DDIs when PRAN was co-administered with a representative CYP1A2 inducer and inhibitor. As tobacco smoke contains substances, such as polycyclic aromatic hydrocarbons which are potent inducers of CYP1A2, Study 1 evaluated the effect of cigarette smoking on the pharmacokinetics (PK) of PRAN. Study 2 evaluated the effect of ciprofloxacin, a strong CYP1A2 inhibitor, on the PK of PRAN.
Methods: Study 1 was an open-label, single-dose, parallel study in 28 adult healthy males/females (14 non-smokers in Cohort 1 and 14 moderate-to-heavy smokers in Cohort 2). A single 60 mg oral dose of PRAN was administered, with blood samples collected for PK evaluation at specified times through 48 hours post-dose. Study 2 was an open-label, 2-period crossover study in 16 nonsmoking adult healthy males/females, with a 10-day washout period between periods. In Period 1 subjects received a single 60 mg dose of PRAN with PK blood sampling for 48 hours post-dose; in Period 2, subjects received 500 mg ciprofloxacin BID for 7 days with a single dose of PRAN on the morning of Day 4 with PK sampling for 96 hours after the PRAN dose.
Results: In Study 1, peak concentration (C_{max}), and exposure to last measurable concentration (AUC_{0-t}) and to infinity ($AUC_{0-\infty}$) of PRAN were 52%, 57% and 55% lower, respectively, in smokers (Table). In Study 2, PRAN C_{max}, AUC_{0-t}, $AUC_{0-\infty}$ and $t_{1/2}$ were comparable following administration of PRAN alone or in combination with ciprofloxacin (Table 1).
A single dose of PRAN, when administered alone in both studies or in combination with ciprofloxacin in Study 2 was well-tolerated.

Table 1.

PRAN PK Parameters	Study 1, Means (SD)		Study 2, Means (SD)	
	Non-Smokers	Smokers	PRAN	PRAN + Ciprofloxacin
C_{max} (ng/mL)	108.2 (32.2)	51.6 (18.1)	97.3 (24.8)	97.5 (35.0)
t_{max} (hr) median (min, max)	1.3 (0.99, 1.5)	1.3 (1.0, 2.0)	1.50 (0.99, 2.0)	2.0 (1.5, 3.0)
AUC_{0-t} (ng*hr/mL)	599.5 (198.0)	257.6 (92.5)	623.6 (130.1)	690.1 (148.1)
$AUC_{0-\infty}$ (ng*hr/mL)	609.2 (198.7)	271.5 (87.7)	637.3 (131.5)	702.2 (14.2)
$t_{1/2}$ (hr)	7.6 (1.5)	6.4 (2.0)	9.6 (1.6)	10.5 (2.9)

Summary/Conclusion: The results of Study 1 suggest that exposure to PRAN is reduced in smokers, which may result in reduced benefit to patients who choose to smoke while receiving treatment. In the ongoing Phase 3 AML trial, smokers are excluded. There was no indication of DDI when PRAN and ciprofloxacin, a strong CYP1A2 inhibitor, were co-administered.

PS978

SINGLE CENTRE REAL-LIFE EXPERIENCE OF HYPOMETHYLATING AGENTS WITH OR WITHOUT DLI AS SALVAGE THERAPY FOR ACUTE MYELOID LEUKEMIA RELAPSING AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

D. Lazzarotto[1,*], A. Candoni[1], C. Filì[1], M.E. Zannier[1], M.V. Dubbini[1], N. Rabassi[1], A. Sperotto[1], M. Cerno[1], A. Geromin[1], M. Battista[1], F. Patriarca[1], R. Fanin[1]

[1]Division of Hematology and Stem Cell Transplantation, Azienda Sanitaria Universitaria Integrata di Udine, Udine, Italy

Background: Acute Myeloid Leukemia (AML) relapsing after allogeneic stem cell transplantation (Allo-SCT) carries a very poor prognosis and there are very few therapeutic options outside clinical trials, even nowadays.
Aims: We wanted to analyze the outcome of patients with AML relapsing after Allo-SCT and treated with hypomethylating agents (HMA) with or without Donor Lymphocytes Infusions (DLI).
Methods: We report the outcome of 19 patients (pts) with AML relapsed after Allo-SCT (89% with cytologic relapse) and treated with HMA, either Decitabine or Azacytidine, with or without DLI.
Results: Eleven cases (58%) had an unfavorable karyotype at diagnosis and 2 (11%) cases were FLT3-ITD positive. Median age was 51 years (range 24–66), 12 were male and 7 were female; 4/19 pts underwent Allo-SCT from an HLA-identical sibling donor, 13 from a Matched Unrelated donor (MUD) and 2 from an Haploidentical donor. The median time from SCT to relapse was 6,9 months (range 2,2–72,5), 17/19 pts had a cytologic relapse (with a bone marrow average blast count of 40%), while 2/19 had a molecular relapse. Twelve pts (63%) received salvage therapy with Azacytidine while 7 (37%) received Decitabine. Nine cases (47%) received concomitant HMA and Donor Lymphocytes Infusions (DLI) according to DLI availability. Pts received a median of 2 cycles of HMA therapy (range 1-9) and a median of 3 DLI doses (range 1-9) with a median dosage of $3x10^6$/kg (range 0,05 $x10^6$/kg – 35 $x10^6$/kg). After a median follow-up of 3,1 months (range 1-38) from the beginning of the HMA therapy, 14 (74%) pts died, of these 10 (71%) due to AML and 4 (29%) due to TRM. Five pts (26%) are alive, of these 3 (60%) in complete remission (CR) and 2 with active, but stable, disease. One pts received a second Allo-SCT procedure and maintains a CR status. No pt experienced a GvHD > grade I after DLI. The median OS of this population was 6,7 months with a 1-year OS probability of only 18%. We observed a significant survival improvement in pts that received concomitant DLI (median OS 9,3 months vs 2,2 months, p=0,05) and in pts that achieved a CR with HMA (median OS 12,3 months vs 2,9 months, p=0,01). The concomitant use of DLI was the only variable to retain statistical significance in multivariable analysis (p=0,03). Notably, the type of HMA and the timing of relapse from the previous Allo-SCT did not influence OS.
Summary/Conclusion: Our real-life experience suggests that salvage therapy with HMA is feasible and safe. We observe a clear OS benefit in pts who received a combination of HMA and DLI suggesting a synergistic effect. Prospective studies are needed to explore the benefit of HMA combinations with DLI and/or new drugs for AML relapsing after Allo-SCT. Given the unfavorable probability of OS at 1-year of this population (18%) we strongly suggest using this therapeutic approach early after Allo-SCT as a preemptive strategy to prevent cytologic relapse.

PS979

CONSOLIDATION CHEMOTHERAPY PREVENTS RELAPSE BY INDIRECTLY REGULATING BONE MARROW ADIPOGENESIS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

H. Liu[1,*], Y. Zhai[2], W. Zhao[3], J. Shi[4], Z. Li[5]

[1]Hematology, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, [2]Hematology , Shanghai Jiao Tong University School of Medicine Affiliated Tongren Hospital, [3]Hematology, Shanghai Jiao Tong University Affiliated Sixth People's Hospital South Campus, [4]Hematology, [5]Blood Transfusion, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China

Background: Consolidation chemotherapy is still the mandatory strategy to prevent relapse of acute myeloid leukaemia (AML) during complete remission (CR), including those patients acquiring molecular level elimination of leukemia cells. This implicates that an working mechanism may exist in addition to killing residual leukemia cells using chemotherapy.
Aims: As the most abundant stromal component in bone marrow (BM), marrow adipocytes have been previously identified to be the promoter in leukemogenesis. We hypothesized that consolidation chemotherapy may regulate adipogenesis to maintain remission.
Methods: A retrospective study of BM biopsies from 80 patients with AML in remission and 71 control subjects was applied to quantitatively analyse marrow adipocyte volume. Toxicity tests were used to assess the effect of chemotherapy drugs on BM cells. The possible mechanisms by which chemotherapy regulated the reduced marrow adipocyte content were investigated using antibody neutralization experiments, with an emphasis on growth differentiation factor 15 (GDF15), and a correlation analysis was performed to assess the relationship between the GDF15 level and the adipocyte volume in AML-CR patients.
Results: Our retrospective analysis indicated the marrow adipocyte volume in AML patients after consolidation chematherapy was significantly lower than that in the controls ($p<0.001$). Moreover, the patients with an adipocyte content lower than 21.5% exhibited a longer relapse-free survival ($p<0.001$). However, the chemotherapeutic drug cytarabine was neither sufficient to kill the mescenchymal stem cells (MSCs) or MSCs-derived adipocytes, nor was it directly inhibit the adipogenic capability of MSCs *in vitro*. Instead, the condition medium from cytarabine -treated hematopoietic cells (HCs), which was the main ingredient in BM during CR period, partially blocked the adipogenic differentiation of MSC. RNAseq analysis showed that transcription of GDF15 was higher in treated HCs than the controls. The antibody against GDF15 neutralized the effects of cytarabine-treated HCs, whereas rhGDF15 treatment potentiated the effects. Finally, a higher GDF15 level in bone marrow (BM) aspirates was associated with the reduced marrow adipocyte content in AML patients after consolidation chemotherapy, suggesting that GDF15 secreted by chemotherapy-induced HCs plays an important role in adipogenesis.
Summary/Conclusion: chemotherapy indirectly inhibits adipogenesis by promoting secretion of GDF15 from HCs in BM , which strengthens consolidation chemotherapeutic efficacy in AML patients during CR.

CONTINUING ENASIDENIB TREATMENT FOR PATIENTS WITH MUTANT-IDH2 RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA (R/R AML) WITH STABLE DISEASE MAY RESULT IN IMPROVED RESPONSES AND SURVIVAL OVER TIME

E.M. Stein[1,2,*], R.M. Stone[3,4], D.A. Pollyea[5,6], G.J. Roboz[2,7], J.K. Altman[8], C. D. DiNardo[9], S. de Botton[10,11], A. Tosolini[12], N. Tu[12], A.S. Swern[12], J. VanOostendorp[12], S.V. Agresta[13], A.T. Fathi[3,14]

[1]Memorial Sloan Kettering Cancer Center, [2]Weill Cornell Medical College, New York, [3]Harvard Medical School, [4]Dana-Farber Cancer Institute, Boston, [5]University of Colorado School of Medicine, [6]University of Colorado Denver, Aurora, [7]New York Presbyterian Hospital, New York, [8]Robert H. Lurie Comprehensive Cancer Center, Northwestern University Feinberg School of Medicine, Chicago, [9]The University of Texas MD Anderson Cancer Center, Houston, United States, [10]Gustave Roussy, Villejuif, France, [11]Univ Paris Sud, Université Paris-Saclay, Le Kremlin-Bicêtre, [12]Celgene Corporation, Summit, [13]Agios Pharmaceuticals, Inc., Cambridge, [14]Massachusetts General Hospital Cancer Center, Boston, United States

Background: Enasidenib (AG-221) is a small-molecule, oral inhibitor of mutant IDH2 (mIDH2) proteins. The clinical efficacy of enasidenib is derived in part by differentiation of immature leukemic cells. Unlike cytotoxic therapies, lower-intensity therapies, including differentiating agents such as enasidenib, can induce first responses months after treatment (Tx) initiation.
Aims: Investigate efficacy outcomes for patients (pts) with R/R AML in the phase 1/2 AG221-C-001 study (NCT01915498) who maintained stable disease (SD) during early Tx with enasidenib.
Methods: Response and overall survival (OS) were assessed for pts with m*IDH2* R/R AML who received enasidenib 100 mg/day and maintained SD, defined by the European LeukemiaNet (Döhner, *Blood*, 2017) as no formal IWG response and no evidence of progressive disease (PD) during the first 90 days on-study.
Results: Of 214 pts with R/R AML who received enasidenib 100 mg/day, 82 pts (38%) maintained SD during the first 90 days of Tx. As of data cutoff (1-Sep-2017), 25 pts (30%) achieved an IWG-defined response after day 90 ("Late Responders"), including 16 pts who attained complete remission. Twenty-nine pts (35%) retained SD at all subsequent response assessments ("SD Only"), and 28 pts (34%) developed PD after day 90 (Table 1). Median time to response for Late Responders was 121 days (range 91-286). Median Tx duration for Late Responders was 259 days, for SD Only pts was 164 days, and for pts who developed PD after day 90 was 107 days. At baseline, Late Responders were less likely than pts who later developed PD to have received >2 prior anti-cancer Tx (8% *vs* 32%, respectively) or to have poor-risk cytogenetics (8% *vs* 43%). Seven Late Responders (28%) went to transplant. Median OS for Late Responders was 15.1 months (95%CI 10.7, not reached [NR]), for SD Only pts was 9.0 months (7.7, 11.4), and for pts who developed PD after day 90 was 5.8 months (5.4, 8.3); estimated 1-year survival rates were 57.7%, 23.9%, and 8.2%, respectively. Risk of death was significantly reduced in Late Responders by 59% compared with SD Only pts (hazard ratio [HR] 0.41; 95%CI 0.21, 0.82), and by 79% compared with pts who later developed PD (HR 0.21; 0.10, 0.42). Similarly, maintaining SD after day 90 was associated with a significant 51% reduction in risk of death vs early SD followed by PD (HR 0.49; 0.28, 0.87).

Table 1.

Outcomes after day 90 for patients with m*IDH2*-R/R AML receiving enasidenib 100 mg/day with sustained stable disease during the first 90 days of Tx (N=82)	
	n (%)
CR + CRp	20 (24.4)
CR	16 (19.5)
CRp	4 (4.9)
Partial remission	3 (3.7)
Morphologic leukemia-free state	2 (2.4)
Stable disease	29 (35.4)
Progressive disease / not evaluable / unknown	28 (34.1)
CR, Complete remission; CRp, CR with incomplete platelet recovery	

Summary/Conclusion: SD may represent sustained but controlled proliferation of leukemic cells that, in some cases, later differentiate and lead to clinical responses. In the first 90 days of enasidenib Tx, 38% of pts with m*IDH2* R/R AML maintained SD. Of them, almost one-third responded after day 90 during continued Tx. Late Responders had a significant OS benefit compared with pts with no later response. However, pts who maintained SD at all response evaluations received a median of ~5.5 months of enasidenib Tx and had a median OS of 9 months. These data suggest pts who sustain SD during early enasidenib Tx should continue Tx for at least 6 cycles or until PD. SD during early enasidenib therapy does not predict Tx failure, and pts who maintain SD may benefit from continuing enasidenib Tx.

PS981

PH II TRIAL WITH SELECTIVE ORAL AXL INHIBITOR BEMCENTINIB (BGB324) IN RELAPSED/REFRACTORY AML AND MDS: IDENTIFICATION OF PREDICTIVE AND PHARMACODYNAMIC BIOMARKER CANDIDATES ASSOCIATED WITH PT BENEFIT

S. Loges[1,*], B. T. Gjertsen[2], M. Heuser[3], J. Chromik[4], C. E. Vigil[5], P. Paschka[6], I. Ben-Batalla[1], N. Akyüz[1], D. Micklem[7], R. Holt[7], A. Brown[7], M. Yule[7], J. Lorens[7], M. Kebenko[1], M. Janning[1], M. Binder[1], W.M. Friedler[1], J. Cortes[8]

[1]University Medical Center Hamburg- Eppendorf, Hamburg, Germany, [2]Department of Clinical Science, Translational Hemato-Oncology group, University of Bergen, Bergen, Norway, [3]Hamatologie, Hamostaseologie, Onkologie und, Stammzelltransplantation, Medizinische Hochschule Hannover, Hannover, [4]Frankfurt Medizinische Klinik II, Hamatologie/Onkologie, Johann-Wolfgang-Goethe Universität , Frankfurt/Main, Germany, [5]University of Iowa Hospitals and Clinics, Iowa City, United States, [6]Universitätsklinikum Ulm, Ulm, Germany, [7]BerGenBio ASA, Bergen, Norway, [8]The University of Texas M.D. Anderson Cancer Center, Houston, United States

Background: Bemcentinib is a first-in-class, selective, orally bioavailable, Axl kinase inhibitor which is being evaluated as a therapy for solid tumours and myeloid malignancies in multiple phase II clinical trials. Bemcentinib has shown anti-leukaemic activity and immune activation in pre-clinical models of AML and other cancers and selective blockade of Axl via bemcentinib in patients with relapsed / refractory AML and int-2 and high-risk MDS is currently being evaluated in the Phase II trial BGBC003 (NCT02488408).
Aims: To identify the safety and tolerability of BGB324 both as a single agent and in combination with cytarabine. To identify biomarkers for monitoring target inhibition, to collect evidence of immune activation and to discover and validate predictive biomarkers which may be used as companion diagnostics
Methods: The dose escalation part of the study evaluating bemcentinib monotherapy followed a standard 3+3 design, cohort expansion was carried out the recommended phase 2 dose. Plasma protein biomarker levels were measured using the DiscoveryMap v3.3 panel (Myriad RBM) at pre-dose and after one cycle of treatment. Gene expression analysis was carried out on RNA extracted from BM-MNCs by qPCR using TaqMan. Levels of sAxl were measured in patient peripheral blood plasma as well as bone marrow plasma using a custom ELISA assay. The presence of phosphorylated Axl was measured using Western blotting and a custom Luminex assay. The TCRß repertoire was quantified by NGS of DNA isolated from PBMNCs using an Illumina MiSeq sequencer. TCRß genes and the IGH repertoire were analysed with BIOMED2-TCRß-A and –B and BIOMED2-FR1/-FR3 primer pools, respectively. Using genomic DNA as template, the amplicons were tagged with Illumina adapters and indices in two consecutive PCR reactions. Demultiplexing and FastQ formated data output was generated by the MiSeq reporter. Analysis of TCRß and IGH data was performed on a Microsoft Cloud using our in-house analysis pipeline Pippa.
Results: A loading dose of 400 mg on days one to three followed by 200 mg daily thereafter has been established as safe and recommended phase 2 dose. Most adverse events were mild or moderate in severity congruent with bemcentinib monotherapy being well-tolerated in this patient population. 2 pts (6%) achieved complete responses with incomplete recovery of peripheral counts (CRi) and 5 (14%) achieved partial responses (PR). 8 pts (23%) reported disease stabilisation for more than 4 months. Immune activation was observed by T- and B-cell receptor diversification. PhosphoFlow analysis of AXL and downstream signaling intermediates demonstrated target pathway inhibition. Levels of plasma soluble AXL (sAxl) and angiogenin as well as bone marrow SLFN-11 expression correlated with pt benefit. sAxl levels were strongly correlated in bone marrow plasma and blood plasma.
Summary/Conclusion: Bemcentinib is well tolerated in relapsed / refractory MDS and AML pts and exhibits anti-leukemic activity through multiple mechanisms including immune modulation. Pt benefit (CRi/PR/SD > 4 mths) is predictable by measurement of plasma markers soluble AXL and angiogenin. These predictive biomarker candidates may be developed as companion diagnostics to select patient populations that are more likely to respond to bemcentinib treatment. In addition, the identification of Axl and Axl-mediated pathways as predictive biomarkers, demonstrates the 'on-target' activity of bemcentinib.

PS982

CYTOGENETIC AND MOLECULAR DRIVERS OF OUTCOME WITH VENETOCLAX-BASED COMBINATION THERAPIES IN TREATMENT-NAÏVE ELDERLY PATIENTS WITH AML

S. Strickland[1,*], B. Chyla[2], R. Popovic[2], A. Bhathena[2], M. Dail[3], Y. Sun[2], A. Wei[4], W. Fiedler[5], K. Pratz[6], J. Hayslip[2], J. Potluri[2], C. DiNardo[7], D. Pollyea[8]

[1]Vanderbilt-Ingram Cancer Center, Vanderbilt University Medical Center, Nashville, TN, [2]AbbVie, Inc, North Chicago, IL, [3]Genentech, Inc, South San Francisco, CA, United States, [4]The Alfred Hospital and Monash University, Melbourne, Australia, [5]Hubertus Wald University Cancer Center, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [6]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Baltimore, MD, [7]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX, [8]University of Colorado School of Medicine, Aurora, CO, United States

Background: Acute myeloid leukemia (AML) is highly heterogeneous and tumor-related genetic abnormalities have been shown to be key prognostic factors affecting outcomes to standard treatments. Although AML treated with low-intensity therapies has a poor prognosis, recent studies suggest higher response rates may be achievable in combination with venetoclax (Ven)—an oral BCL-2 inhibitor. Therefore, identifying cytogenetic and molecular factors that influence outcome to these novel combinations is of high importance.
Aims: To evaluate the impact of molecular profiles in elderly, untreated AML patients in response to front-line Ven combination therapies.
Methods: This analysis includes data from two open-label multicenter trials assessing the safety and efficacy of Ven in combination with azacitidine or decitabine (NCT02203773; phase 1b; data cutoff July 7, 2017), or low-dose cytarabine (NCT02287233; phase 1/2; data cutoff August 15, 2017) in treatment-naïve patients with AML. Patients (≥65 years) were classified into ten molecular subgroups based on cytogenetic or molecular mutations identified using next-generation sequencing in baseline bone marrow or blood samples (Table 1). Response to Ven combination therapies was evaluated in patients with intermediate and poor cytogenetic risk, as well as in patients within the three most common molecular subgroups: those with mutated chromatin/RNA-splicing genes, those with mutated *TP53*/aneuploidy, and those with *NPM1* mutation. Determination of minimal residual disease (MRD) used standardized multicolor flow cytometry, centrally analyzed.
Results: Patients with intermediate cytogenetic risk had higher rates of CR/CRi than those with poor risk, regardless of Ven therapy combination (Table 2). There was no significant difference in rates of CR/CRi across Ven combinations among subgroups with concordant cytogenetic risk. Rates of CR/CRi were high (range: 68–100%) for patients with chromatin spliceosome, or *NPM1* mutations across all Ven doses and combination backbones. In comparison, those with chromosomal aneuploidy and/or *TP53* mutations had lower rates of CR/CRi (50–55%). Of patients with CR/CRi and available MRD data, 43% (34/80) and 32% (12/38) achieved MRD below 10^{-3} threshold when treated with Ven + Aza/Dec and Ven + LDAC, respectively. Additional univariate and multivariate analyses are ongoing to determine significant drivers of Ven therapeutic response in elderly AML patients. OS will be presented at the meeting.

Table 1.

Genomic subgroup*	Patients, n (%)	Class-defining mutations
Mutated chromatin, RNA splicing genes, or both	71 (37)	*RUNX1, ASXL1, BCOR, STAG2, EZH2, SRSF2, SF3B1, U2AF1, ZRSR2, or MLL*[PTD]

Table 2.

Outcomes after day 90 for patients with m*IDH2*-R/R AML receiving enasidenib 100 mg/day with sustained stable disease during the first 90 days of Tx (N=82)	
	n (%)
CR + CRp	20 (24.4)
CR	16 (19.5)
CRp	4 (4.9)
Partial remission	3 (3.7)
Morphologic leukemia-free state	2 (2.4)
Stable disease	29 (35.4)
Progressive disease / not evaluable / unknown	28 (34.1)
CR, Complete remission; CRp, CR with incomplete platelet recovery	

Summary/Conclusion: Mutated chromatin and RNA splicing genes, chromosomal aneuploidy or *TP53* mutations, and *NMP1* mutations were identified as the most common molecular drivers in treatment-naïve elderly AML patients. Preliminary data suggest that venetoclax combination therapies induce high rates of response compared to historical rates of response to standard chemotherapy; this includes all tested cytogenetic risk and molecular subgroups, including those with *TP53* mutations.

PS983

RANDOMIZED OPEN-LABEL, PHASE III MULTICENTER TRIAL TO EVALUATE AZACITIDINE POST-REMISSION THERAPY IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA

Background: In elderly patients with acute myeloid leukemia (AML), complete remission (CR) rate following intensive chemotherapy is approximately 45%, considerably lower than in younger patients, with a shorter duration of remission and high treatment-related mortality. Median survival is 7 to 12 months. Several studies have suggested that maintenance therapy may improve survival.

Aims: This phase III, prospective, randomized, multicenter trial assesses the efficacy of post-remission treatment with Azacitidine (Aza) versus best supportive care (BSC) in 54 AML patients >60 years of age in CR after induction and consolidation chemotherapy. Primary endpoint is the difference in disease free survival (DFS) at 2 and 5 years between arms; secondary endpoints are the difference in overall survival (OS) at 2 and 5 years, the number and length of hospitalizations and quality of life in the 2 arms in the 2-year post-remission period.

Methods: Newly diagnosed AML patients with >30% blasts, "*de novo*" or evolving from myelodysplastic syndrome and fit for intensive chemotherapy have been included. Induction consisted of two courses of "3+7" (Daunorubicin 40 mg/m^2 daily days 1-3 and cytarabine 100 mg/m^2 daily continuous IV infusion days 1-7). Patients in CR received cytarabine 800 mg/m^2 3 hour infusion bid days 1-3 and were randomized 1:1 to recieve BSC or Aza according to the following schema: 50 mg/m^2 s.c. or i.v. for 7 days every 28 days and dose increase after 1st cycle to 75 mg/ m^2 for further 5 cycles, followed by cycles every 56 days for 4.5 years.

Results: Enrollment has been completed with 149 patients of median age 69 years, interquartile range (IQR) 65-74 years, male/female 78/71. During chemotherapy, 59 patients were relapsed/refractory, 22 died, 10 refused to continue, 3 were excluded for protocol violation, and 1 was lost to follow-up. Fifty-four randomized patients (27 Aza, 27 BSC) are included in this interim analysis. At 2-years, the median period of observation was 15 months (IQR: 6-24 months) with 18 patients in CR. Nineteen BSC patients (median DFS 5 months) have relapsed versus 17 Aza patients (median DFS 11 months) (p=0.23, see Figure 1a). Twenty patients have died, all after relapse: 10 in BSC arm (median OS not reached) versus 10 in AZA arm (median OS not reached) (p=0.40, see Figure 1b). Age modified the effect of Aza on both relapse (P for effect modification=0.001) and mortality (P for effect modification=0.01), its effect versus BSC being not significant in patients in the 1st (<65 years) and 2nd (65-73 years) age tertiles (relapse, p=0.38 and p=0.47, respectively; mortality, p=0.23 and p=0.81, respectively) but highly significant in patients in the highest age tertile (>73 years) (relapse, p<0.001, Figure 1c; mortality, p=0.015, Figure 1d). Cytogenetics and minimal residual disease did not modify the effect of AZA on survival. At 4.5 years from randomization (median 15 months, IQR: 6-32 months), 15 patients are in CR and the effect modification by age on the effect of AZA *versus* BSC is confirmed with AZA showing significant efficacy only in patients >73 years of age (relapse, p<0.001; mortality, p=0.005). Grade 3-4 adverse events (mainly neutropenia) were more frequent in the AZA (18%) than in the BSC arm (0%)(p=0.051).

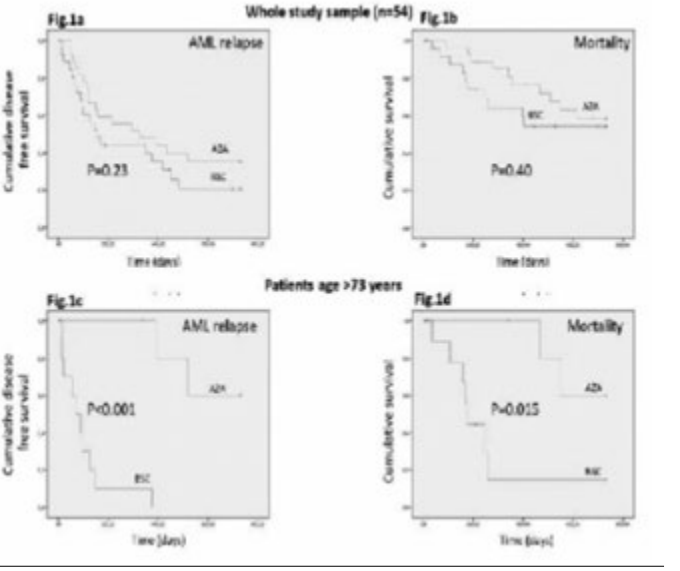

Figure 1.

Summary/Conclusion: Preliminary results indicate that in elderly AML patients receiving standard induction-consolidation chemotherapy, 5-Aza post-CR is well-tolerated and significantly prolongs DFS and OS. The trial is ongoing and may provide further insight on the impact of post-remission 5-Aza treatment on OS in this elderly population.

Background: L-asparaginase (ASNase) is a key drug in the treatment of ALL. ASNase therapy aims to lower serum asparagine (ASN) levels, which in turn inhibits the protein synthesis, resulting in cell cycle arrest and apoptosis.

A synergistic effect of ASNase has been demonstrated in both children and adult patients with acute myeloblastic leukemia (AML) when given in combination with chemotherapy and especially cytarabine. However, L-asparaginase is poorly tolerated in elderly patients due to severe toxicities.

Eryaspase, ASNase encapsulated in red blood cells (RBCs) is an investigational product under development. Following infusion, ASN is actively transported into RBCs, where it is hydrolyzed by the encapsulated ASNase.

Aims: The primary endpoint was overall survival (OS). The key secondary endpoints included progression free survival (PFS), objective response rate (ORR), toxicity as well as pharmacokinetic and pharmacodynamic profile of eryaspase.

Methods: This open-label, multicenter phase 2 study enrolled 123 patients (65 to 85 years-old) with newly diagnosed AML and unfit for intensive chemotherapy, randomized 2:1 to receive subcutaneous low-dose cytarabine – LDAC (D1 to D10 of 4-wk regimen) in combination with eryaspase (100 U/Kg Day11) versus LDAC alone.

Results: The median age of the patients enrolled in this study was 78 years. Baseline characteristics were well balanced between the two treatment arms. The adjusted OS Hazard Ratio (HR) was 0.98 (95% CI; 0.70, 1.61). The adjusted PFS HR was 1.15 (95% CI; 0.75, 1.76) and the ORR was 25.3% and 22.5% in the eryaspase and control arms, respectively (p=0.74).

Forest plots for OS and for PFS showed relatively consistent results across the population as a whole.

The incidence of adverse events (AE) was similar between both groups except for hypersensitivity reactions, coagulopathic, pancreatic and hepatic events that occurred at a higher frequency during in the eryaspase arm. These events are generally considered to be class-effects relevant to asparaginase and were consistent with previously reported AEs for eryaspase.

Summary/Conclusion: This is the largest prospective study to date to evaluate the efficacy of ASNase in elderly AML patients. The addition of eryaspase did not improve survival in this difficult-to-treat patient population. Patient selection is likely the most important factor. The study enrolled unfit patients, who remained briefly on treatment to achieve a potential drug effect. Individualized risk stratification based on multiparameter assessment tools and comorbidity burden, should be considered for older adults with AML participating in clinical trials.

PS985

AN EVALUATION OF CONTROL REGIMENS IN A GROUP OF HIGH RISK OLDER PATIENTS WITH ACUTE MYELOID LEUKAEMIA FROM TWO COOPERATIVE GROUPS: DATA FROM THE UK NCRI AND DUTCH HOVON STUDIES

R. Hills[1,*], G. Ossenkoppele[2], A. Burnett[3], B. Lowenberg[4], G. Stussi[5], D. Breems[6], P. Gradowska[4], N. Russell[7]

[1]Centre for Trials Research, Cardiff University, Cardiff, United Kingdom, [2]Department of Haematology, VU University Medical Center, Amsterdam, Netherlands, [3]Blackwaterfoot, Isle of Arran, United Kingdom, [4]Department of Haematology, Erasmus Medical Center, Rotterdam, Netherlands, [5]Department of Haematology, Oncology Institute of Southern Switzerland, Bellinzona, Switzerland, [6]Department of Haematology, Hospital Network Antwerp, Antwerp, Belgium, [7]Department of Haematology, Nottingham University Hospitals, Nottingham, United Kingdom

Background: Outcomes for older patients with AML with high risk features are poor, even with intensive chemotherapy (typically ara-C plus an anthracycline). The multifactorial Wheatley index found 1-year survival with standard chemotherapy of only 30% in high risk patients. There is a need for better treatments in this population. A recent phase 3 trial of CPX-351, a liposomal daunorubicin/ara-C combination, found significant benefit in a high-risk population with prior MDS or CMML, therapy related AML, or with an MDS-related karyotype (median survival 9.6 vs 6.0 months p=0.005). Enrolment was at US and Canadian sites: we therefore examined the European experience to contextualise the results when placed against European standard of care.

Aims: To evaluate the outcomes of high-risk patients aged 60-75 enrolled in successive European AML trials from the UK NCRI and Dutch HOVON Group.

Methods: Patients treated with standard anthracycline/ara-C chemotherapy recruited to collaborative group trials since 2002 were included if they satisfied the eligibility criteria corresponding to those for the Phase III CPX-351 trial: age 60-75, WHO/ECOG performance status 0-2, and exhibiting one of the adverse risk features above. NCRI patients were treated with daunorubicin/ara-C for two courses in a 3+10/3+8 schedule; HOVON patients received daunorubicin/ara-C or idarubicin/ara-C in a 3+7 schedule for course 1 and regimens based upon ara-C 1g/m^2 for course 2. Patients were hierarchically grouped by type of AML: therapy-related, prior MDS, prior CMML, and MDS-like karyotype. Survival was evaluated using the Kaplan-Meier method and compared using logrank tests and Cox regression for multivariate analyses. Median follow-up was 61.3 months for NCRI and 107.5 months for HOVON.

Results: A total of 669 patients (NCRI 465 patients in 2 trials, HOVON 204 patients in 4 trials) were identified. Median age was 65 years (NCRI) vs 66 years (HOVON, p=0.5); 61% were male (63% MRC vs 56% HOVON, p=0.13); and median WBC was 5.0x10^9/L (5.1 vs 4.4 p=0.2). Distribution of disease type was similar between groups (p=0.9); overall 18% had t-AML; 23% prior MDS; 4% prior CMML; and 55% an MDS-like karyotype. Remission rates CR/CRi were 59% for NCRI and 47% for HOVON patients (OR 0.61 (0.44-0.85) p=0.004). However, overall survival was similar between trial groups (median OS 8.9 vs 8.3 m; 1-year OS 40% vs 38%; 3 year OS 13% vs 13%, HR 0.96 (0.81-1.14) p=0.6). In the entire cohort, there was no significant difference in survival by type of AML (p=0.14). In a multivariable analysis with age, sex, white blood cell count, type of AML and study group as candidate variables, only white cell count (HR 1.20 (1.05-1.37) per 10-fold increase, p=0.03) and type of AML (p=0.05) were significantly prognostic with patients with MDS-like karyotype performing worst. Transplant rates were similar between trial groups with 15% of NCRI and 17% of HOVON patients receiving stem cell transplantation. In a landmark analysis at 120 days, SCT gave better survival (34% vs 15% at 3 yrs, p<.0001) (Figure 1).

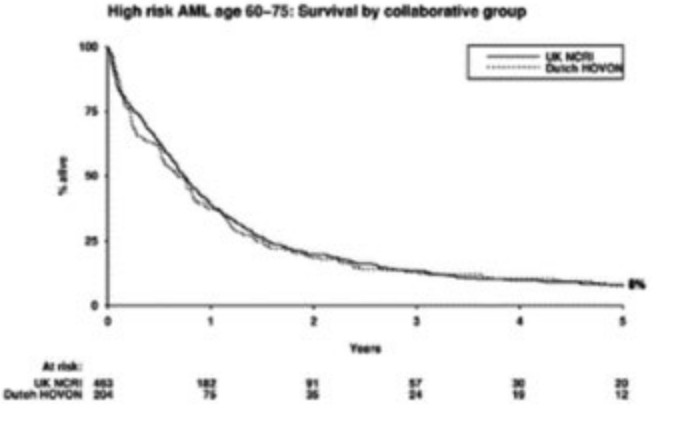

Figure 1.

Summary/Conclusion: Despite the different chemotherapy regimens used by two large European groups, survival in this group of patients is equally poor. In particular, a 10+3 regimen, produces more remissions, does not show better survival. Median survival is approximately 9 months, and continues to decrease with only 13% alive at 3 years, about half that in the pivotal CPX-351 trial. Although the median survival is similar to the pivotal trial, we do not see evidence of a plateau. Stem cell transplant is associated with prolonged survival.

PS986

TP53 ALTERATIONS AND MONOSOMAL KARYOTYPE IN OLDER UNFIT PATIENTS WITH ACUTE MYELOID LEUKEMIA TREATED WITH DECITABINE

H. Becker[1,2,*], D. Pfeifer[1,2], G. Ihorst[2,3], B. Rüter[1], L. Bullinger[4,5], B. Hackanson[1,2,6], U. Germing[7], A. Kündgen[7], U. Platzbecker[8], K. Döhner[4], A. Ganser[9], P. Wijermans[10], H. Döhner[11], J. Duyster[1,2], M. Lübbert[1,2]

[1]Department of Medicine I, Medical Center - University of Freiburg, [2]Faculty of Medicine, University of Freiburg, [3]Clinical Trials Unit, Medical Center - University of Freiburg, Freiburg, [4]University of Ulm, Ulm, [5]Charite University Hospital, Berlin, [6]Interdisciplinary Cancer Center Augsburg, Augsburg, [7]Heinrich-Heine-University, Düsseldorf, [8]University Hospital Dresden, Dresden, [9]Hannover Medical School, Hannover, Germany, [10]Haga Ziekenhuis, The Hague, Netherlands, [11]University of Ulm, Freiburg, Germany

Background: Monosomal karyotype (MK+), particularly in case of multiple monosomies (MK2+), and *TP53* mutations have been described to be predictive for a favorable response to decitabine (DAC) in acute myeloid leukemia (AML) (Lübbert *et al.* Haematologica 2012;97:393; Welch *et al.* NEJM 2016;375:2023).
Aims: To assess clinical features and outcome associated with gene and chromosome alterations of *TP53* in AML patients treated with DAC within a phase II trial.
Methods: Briefly, 227 AML patients >60 years ineligible for intensive therapy were enrolled (Lübbert *et al.* Haematologica 2012;97:393). Patients received DAC 3x15 mg/m^2/day on 3 days, every 6 weeks. Patients with antileukemic effect (ALE) or stable disease after course 1 additionally received all-trans retinoic acid (ATRA, 45 mg/m^2/day) for 28 days in course 2; those with complete remission (CR), partial remission (PR) or ALE after course 4 qualified for maintenance with DAC 20 mg/m^2/day on 3 days, every 6-8 weeks. Karyotypes were centrally reviewed (A. Hagemeijer, University Leuven). Sequencing was performed using Illumina TruSight panels. Subclones were defined as cell fractions >20% smaller than the major clone.
Results: Gene mutations were assessed in 45 patients with material available. Median patient age was 75 years, 27 had AML secondary to MDS. Patients harbored a median of 3 mutations (range, 0-9); 9 patients had >1 mutation in a given gene. Most frequently mutated were: *ASXL1* (29%), *RUNX1* (24%), *SRSF2* (24%), *IDH1/2* (22%), *TET2* (18%), *TP53* (18%). Of the 8 *TP53* mutated patients 4 were MK+, two of whom had a -17. *TP53* mutated patients had received a median of 1 DAC course (range 1-6), *TP53* wild-type (wt) patients 2 (range 1-11) (p=.22); 24 patients had additionally received ATRA. Patients with *TP53* mutations had similar CR/PR/ALE rates (38% vs 50%) but shorter OS than those with *TP53* wt (p=.036; median 1.8 vs 4.4 months). Moreover, patients with a subclone (n=9) had shorter OS than those without (n=24; p=.05), while a subclone was present in only one *TP53* mutated patient; *TP53* mutations were all present in the major clone. Next, we sought to evaluate the impact of chromosomal loss of *TP53* (ie, -17/del(17p)) in the context of MK+. Of 178 patients with cytogenetics available, 38 were MK+. Of these, 22 were MK2+, while 16 had one monosomy and ≥1 structural aberration (MK1). Overall, 17 patients had a -17, all of whom were MK+ and had a complex karyotype (CK+). Among the MK+ patients, those with -17 differed from those without -17 by higher platelet counts (p=.01), by trends for lower blood blasts but higher marrow blasts and by more often being MK2+ (p=.05). We evaluated the outcome according to -17 in all patients with cytogenetic data and restricted to CK+ and MK+ patients. Patients with -17 had higher rates of CR/PR/ALE than those without in all subsets (82% vs 41-53%). However, the favorable responses did not translate into prolonged OS. Considering only patients who received ATRA in addition to DAC, there were also no OS differences according to -17. We previously observed that MK2+ patients treated with DAC had better outcome than MK1 patients. Thus, to further dissect the impact of -17, we compared the outcomes of MK2+ patients with -17 (n=13) and those without (n=9) but observed no differences in response rates or OS.
Summary/Conclusion: *TP53* mutations did not impact response, but were associated with shorter OS. In contrast, -17 was associated with favorable responses, even among MK+ patients, but not among MK2+ patients. Our data suggest that monosomies rather than *TP53* alterations may sensitize for DAC treatment.

PS987

IDENTIFYING A GENETICALLY DEFINED RISK GROUP OF PEDIATRIC AML PATIENTS THAT CANNOT BE RESCUED AT ALL AFTER THE FAILURE OF THE FIRST LINE TREATMENT

N. Niktoreh[1,*], C. Walter[1], M. Zimmermann[2], N. von Neuhoff[1], M. Rasche[1], U. Creutzig[2], H. Hanenberg[1], D. Reinhardt[1]

[1]Department of Pediatrics III, Pediatric Hematology and Oncology, University Children's Hospital Essen, University of Duisburg-Essen, Essen, [2]Department of Pediatric Hematology and Oncology, Hannover Medical School, Hannover, Germany

Background: Pediatric acute myeloid leukemia (AML), a rare and heterogeneous disorder, is currently treated with intensive risk-adaptive chemotherapy regimens combined with myeloablative therapies. These treatments are assigned based on various clinical and cytogenetic characteristics of patients at the time of diagnosis which define risk of the disease. Genetic alterations of the leukemic blasts at initial diagnosis are one of the most important indicators currently used for the risk group stratification in pediatric AML. Mutations in the *WILMS TUMOR 1 (WT1)* gene and the internal tandem duplication of the juxta-membrane domain of *FLT3* gene (*FLT3-ITD*) frequently co-occur in myeloid blasts of children at diagnosis.
Aims: Two pediatric treatment optimization studies demonstrated before that this genetically defined subgroup of patients had poor survival when treated on protocols before 2005. To reevaluate this finding in newer protocols, 346 patients (<18 years) treated in Germany since 2005 in the BFM-AML 2004 trial (ClinicalTrials.gov Identifier: NCT00111345) or AML-BFM Registry 2012 (EudraCT number: 2013-000018-39) were included in this report.
Methods: We retrospectively reviewed medical records of patients with 0–18 years of age with *de novo* AML (excluding FAB M3 and Down Syndrome) and identified patients with *WT1* mutations and *FLT3-ITD* at the time of diagnosis. As confirmation, material from patients with *WT1* and *FLT3-ITD* was re-analyzed by next-generation sequencing using the TruSight Myeloid Panel (Illumina).
Results: We identified 45 (13%) patients with 60 *WT1* mutations and 52 (15%) with *FLT3-ITD.* Other mutations in *NPM1*, *NRAS* and *c-KIT* were present in 9, 18 and 10% of patients' blasts, respectively; however, *WT1* and *FLT3-ITD* frequently co-occurred with each other and predominantly were detected in older children with blasts belonging to the FAB M1/M2 subtype and having normal cytogenetics. Analysis of the patient outcomes showed that *WT1* and *FLT3-ITD*, but not *NRAS*, *NPM1* or *c-KIT* mutations significantly reduced the probability of 3-year overall survival (OS) as single factors. However, presence of both mutated *WT1* and *FLT3-ITD* resulted in a 3-year event-free survival of 34±12% compared to 67±3% for patients with none of these mutations (p=0.0009) and 56±9% or 70±10% for patients with only *FLT3-ITD* (p=0.08) or *WT1* mutation (p=0.013), respectively. Importantly, the probability of 3-year OS in patients with co-occurrence of *WT1* and *FLT3-ITD* mutations was only 35±12% compared to patients without these mutations (84±2%, p<0.0001), patients with only mutated *WT1* (91±6%, p=0.0004) or only *FLT3-ITD* (77±8%, p=0.004). This poor survival outcome demonstrated that also our current second line treatment completely failed to rescue at least some of these patients and our multivariate analysis identified the effect of these two factors to be dependent on each other (Figure 1).

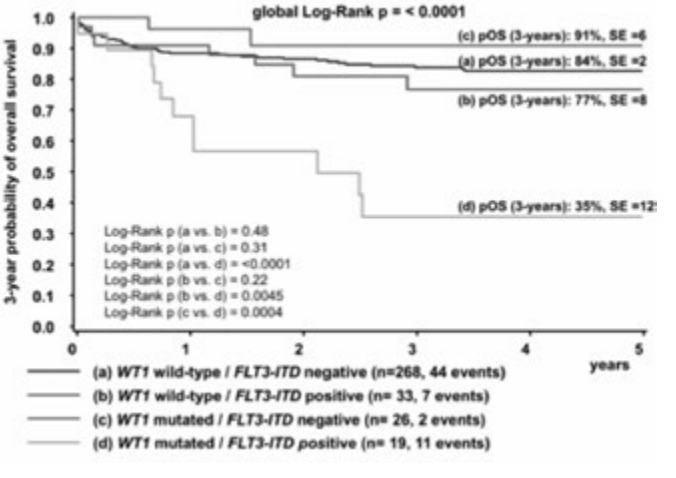

Figure 1.

Summary/Conclusion: We conclude that co-occurrence of *WT1* mutation and *FLT3-ITD* is still predictor of poor response in contemporary first and especially second line treatment for pediatric AML.

PS988

A PHASE II STUDY OF THE AURORA A KINASE INHIBITOR ALISERTIB COMBINED WITH 7+3 INDUCTION CHEMOTHERAPY IN PATIENTS WITH HIGH-RISK ACUTE MYELOID LEUKEMIA

A. Brunner[1], T. Blonquist[2], D. DeAngelo[2], M. McMasters[3], E. Winer[2], G. Hobbs[1], P. Amrein[1], H. Hock[1], D. Steensma[2], J. Garcia[2], M. Luskin[2], R. Stone[2], K. Ballen[4], J. Rosenblatt[3], D. Avigan[3], S. McAfee[1], J. Moran[1], J. Foster[1], C. Bertoli[1], M. Bergeron[1], K. McGregor[1], K. Fishman[1], M. MacRae[1], M. Burke[1], T. Behnan[1], T. Som[1], A. Ramos[1], J. Lombardi Story[1], C. Connolly[1], D. Neuberg[2], Y.-B. Chen[1], T. Graubert[1], A. Fathi[1,*]

[1]Massachusetts General Hospital, [2]Dana-Farber Cancer Institute, [3]Beth Israel Deaconess Medical Center, Boston, [4]University of Virginia, Charlottesville, United States

Background: Increased expression of aurora A kinase occurs in hematologic malignancies, including myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML). We previously conducted a phase I study of alisertib combined with "7+3" induction chemotherapy as upfront treatment of AML; this combination appeared to be particularly promising for the patient cohort with high-risk disease, who typically have poor induction outcomes and remission rates of 45% or less. We therefore conducted a phase II study of alisertib and induction chemotherapy in patients with high-risk AML.
Aims: To evaluate the efficacy of alisertib combined with conventional induction in high-risk AML.
Methods: We enrolled patients with high-risk AML, defined as those with adverse-risk karyotype (as per European Leukemia Net Guidelines), secondary AML, or aged ≥ 65 years, in a phase II study. We used a Simon two-stage design, assuming a null composite remission rate (complete remission [CR] and complete remission with incomplete count recovery [CRi]) rate of 45% with induction chemotherapy alone. Patients with favorable cytogenetics were removed prior to day 8 and replaced. All patients received 7+3 induction (continuous infusion cytarabine 100mg/m^2 on days 1-7 [D1-7] and idarubicin 12mg/m^2 [or daunorubicin 60mg/m^2] D1-3). On D8-15, alisertib 30mg BID was administered. All underwent a mid-induction bone marrow biopsy to assess for residual disease, which, if present, was treated with 5+2 re-induction without alisertib. Following remission, patients could receive up to 4 consolidation cycles with cytarabine (3g/m^2 BID D1,3,5 for age <60 and 2g/m^2 daily D1-5 for age ≥60) followed by alisertib on D6-12. Patients could come off study for stem cell transplant (SCT).
Results: 39 eligible patients were treated on study. The median age was 68 (range 33-83); 25 (64%) were male, and 33 (85%) were Caucasian. Twenty one patients (51%) had secondary AML (18 with antecedent MDS, 2 with antecedent CMML, and 1 with antecedent MPN). Two (5%) had therapy related AML. Thirteen (33%) exhibited adverse risk karyotype. *FLT3* mutations were seen in 7 (18%), *NPM1* in 7 (18%), *IDH1* in 5 (13%), *IDH2* in 5 (13%), *CEBPA* in 3 (8%), and *TP53* mutations in 4 (10%) patients. 33 patients (84%) demonstrated an ablated marrow at mid-treatment, and six (15%) received re-induction at mid-treatment. 8 patients (21%) were refractory to induction, and five (13%) died prior to response assessment due to infection or bleeding. The 30-day and 60-day mortality were 8% and 13%, respectively. Patients experienced expected grade 4 toxicities of leukopenia, anemia, thrombocytopenia, and febrile neutropenia; no new safety signals were detected. The CR+CRi rate was 64% (2-stage 95% CI 47.45-79.44%) with 20 patients (51%) achieving CR and 5 (13%) achieving CRi. One (3%) patient achieved a partial remission. Based on this composite remission rate, the combination was deemed effective per study design. The CR+CRi rate for P53 mutated patients was 75% (3 of 4). Survival data is maturing and is expected to be available at time of presentation. Four patients have relapsed and 17 patients have died to date. 16 patients (41%) have gone on to SCT. Ten have received at least 1 cycle of consolidation.
Summary/Conclusion: Alisertib, a novel aurora A kinase inhibitor, combined with conventional induction, is efficacious and demonstrates a promising rate of remission, particularly among patients with high-risk AML. Larger randomized studies are under consideration to better assess the promise of this novel combination.

PS989

ADMINISTRATION OF BPX-501 CELLS FOLLOWING ALPHA/BETA T-CELL AND B-CELL-DEPLETED HLA HAPLOIDENTICAL HSCT (HAPLO-HSCT) IN CHILDREN WITH ACUTE MYELOGENOUS LEUKEMIA

N. Kapoor[1,*], P. Merli[2], M. Algeri[3], V. Aquino[4], D. Jacobsohn[5], S. Naik[6], E. Nemecek[7], P. Woodard[8], F. Locatelli[3]

[1]Hematology, Oncology, Blood and Marrow Transplantation, Children's Hospital Los Angeles, Los Angeles, United States, [2]Department of Onco-Hematolgy and Cell and Gene Therapy, [3]Department of Onco-Hematology and Cell and Gene Therapy, Ospedale Pediatrico Bambino Gesu, Rome, Italy, [4]Pediatric Hematology-Oncology, University of Texas-Southwestern, Dallas, [5]Blood and Marrow Transplantation, Children's National Medical Center, Washington, DC, [6]Bone Marrow Transplant/Stem Cell Transplant Program, Texas Children's Hospital, Houston, TX, [7]Pediatric Bone Marrow Transplantation Program, Oregon Health Sciences University, Portland, OR, [8]Clinical Development, Bellicum Pharmaceuticals, Inc., Houston, TX, United States

Background: Allogeneic Hematopoietic Stem Cell Transplantation (HSCT) is an established treatment for children with either high-risk or relapsed Acute Myelogenous Leukemia (AML). HSCT from a partially-HLA matched (haplo) relative is a suitable option for children who lack an HLA-matched donor.
Aims: To evaluate the safety and efficacy of BPX-501 T cells administered after ab T-cell and B-cell depleted haplo HSCT in pediatric patients with AML. In particular, we investigated whether BPX-501 cells administered post-haplo HSCT can enhance immune reconstitution, reduce the risk of infections and of relapse in children with AML.
Methods: Thirty-eight (38) patients (EU:25, US:13; 21 males, 17 females; median age 7.9 years) with AML were enrolled in a multicenter, prospective trial utilizing ab-T-cell and B-cell-depleted haplo-HSCT, followed by infusion of donor lymphocytes genetically modified to include the inducible caspase 9 (iCasp9) suicide gene (BPX-501 T cells). Conditioning regimens included, TBI (n=19; 50%), busulfan (n=15; 39.5%) and other regimens (n=4; 10.5%). Patients received rabbit anti-thymocyte globulin either as Grafalon/Neovii® or Thymoglobulin/Sanofi® in the EU and US, respectively. The median HSCT CD34+ and ab TCR+ cell doses were 12×10^6 /kg and 0.4×10^5 /kg, respectively. The donor was a parent in 31 children (81.6%), a sibling in 5 (13.2%), and a half-sibling in the remaining 2 (5.3%). The median time to BPX-501 infusion was 18.5 days (range 12-147).
Results: The median time for neutrophil and platelet engraftment was 13 and 11 days, respectively. The median time to discharge was 23.5 days, with 61% (23/38) of patients not requiring re-hospitalization. The median follow-up period was 374 days (range, 26-1024). Eleven patients developed Grade I-IV aGVHD (cumulative incidence [CI] 31.9% [95% confidence interval (CoI): 16.3-47.5]). Six patients developed Grade II-IV aGVHD (CI 17.7% [95% CoI: 4.8-30.6]). Two patients developed Grade III-IV aGVHD (CI 6.7% [95% CoI: 0-15.7]). There were no cases of cGVHD. Four patients received rimiducid for aGVHD not responsive to standard treatment and 3 had complete resolution 4-31 days after rimiducid. One patient died after HSCT, translating into a TRM CI of 2.8% [95% CoI: 0.0-8.2]. Two patients relapsed (CI 6.1% [95% CoI: 0-14.2]) post-HSCT. In patients that received a chemo-based (n=19) or a TBI-based conditioning regimen (n=19), the relapse-free survival (RFS) was 100% and 84.2%, respectively . CR1 (n=13) and CR2 (n=25) AML patients exhibited a RFS of 91.7% [95% CI: 76.1-100.0] and 91.3% [95% CI: 79.8-100.0], respectively. One patient expired, leading to a 1-year overall survival probability of 97.2%. BPX-501 cells expand after infusion and persist through the duration of follow-up.
Summary/Conclusion: Although longer follow-up is needed to validate these data, current results suggest that ab T-cell and B-cell depleted haplo-HSCT followed by BPX-501 represents and effective therapeutic strategy to achieve high curability rates in childhood AML.

PS990

NATIONAL EARLY WARNING SCORE (NEWS), QUICK SEQUENTIAL (SEPSIS-RELATED) ORGAN FAILURE ASSESSMENT (QSOFA) AND MICROBIOLOGICAL EVALUATION IN FEBRILE NEUTROPENIA OF ACUTE MYELOID LEUKEMIA

B. Nicolino[1,*], E. Audisio[1], S. Aydin[1], A. Busca[2], S. D'Ardia[1], C. Dellacasa[2], C. Frairia[1], G. Iovino[2], U. Vitolo[1]

[1]Hematology, [2]Bone Marrow Transplant Unit, AOU Città della Salute e della Scienza di Torino, Turin, Italy

Background: Chemotherapy induced neutropenia in acute myeloid leukemia (AML) patients is at high risk for life threatening infections. Early diagnosis and prompt interventions are associated with better outcomes that, however, is hampered by a lack of diagnostic tools. Recently, the quick Sequential (Sepsis-related) Organ Failure Assessment (qSOFA) as well as the National Early Warning Score (NEWS) were proposed predicting in-hospital mortality.
Aims: The aim of the present study was to analyze the predictive validity of the NEWS and the qSOFA in a large cohort of homogeneous AML patients during neutropenia.
Methods: The NEWS is a warning clinical score that evaluates seven clinical parameters. The qSOFA score consists of three parameters, each allocated with one point: respiration rate of ≥22/min, altered mental status and sys-

tolic blood pressure of ≤ 100 mmHg. The ability of the NEWS and the qSOFA score on prediction of early mortality was analyzed by calculating the area under the curve using a logistic regression model (AUROC). Further, we assess the incidence and microbiological spectrum of febrile neutropenia.

Results: A total of 1048 neutropenic episodes in 334 consecutive adult patients were analyzed. After induction chemotherapy, a complete remission was achieved in 238 patients (71%); 74 were resistant (22%) and 22 died (7%). In 418 cycles no fever was observed; fever of unknown origin (FUO) occurred during 230 neutropenia periods; clinically documented infection was noted in 106 aplasia courses, whereas a microbiologically documented infection was evident in 272 cases and an invasive fungal infection (IFI) in 22. We analized the risk for life threatening infections using NEWS and qSOFA. Both scores were evaluated during a total of 2792 days of neutropenic fever. In addition, clinical conditions such as septic shock, amine necessity, ventilation support, intensive care unit (ICU) admission and death were analyzed. In our study, the determination of the NEWS and qSOFA significantly predicted ICU admission on the same day (NEWS AUROC 0.917, qSOFA AUROC 0.916) as well as death on the day of score determination (NEWS AUROC 0.984, qSOFA AUROC 0.969). Further, both scores were able to significantly predict ICU admission after 24 hours ((leg-1 analysis) NEWS AUROC 0.929, qSOFA AUROC 0.913) and as well as death after 24 hours (NEWS AUROC 0.928, qSOFA AUROC 0.887). Further, analyzing the microbiological spectrum of the infections, a significant difference was documented. Incidence of Gram positive bacteria were significantly more evident during the first induction cycle compared to Gram negative bacteria, that were significantly increased after consolidation treatments (66/119 versus 67/93), p=0.001.

Summary/Conclusion: To the best of our knowledge, the present analysis is the first validation of the NEWS and the qSOFA during neutropenia in a large homogeneous AML patient cohort. The NEWS and qSOFA may be valid tools to evaluate critical patients in intensive chemotherapy induced aplasia. Furthermore, the pattern of infections changed during the ongoing chemotherapeutic treatment. This may be attributed to the prophylactic and therapeutic use of antibiotics that could select the microflora.

PS991

COMPARISON BETWEEN MULTIPARAMETRIC FLOW CYTOMETRY AND RT-QPCR ASSAY IN EVALUATING MINIMAL RESIDUAL DISEASE BEFORE ALLOGENEIC STEM CELL TRANSPLANTATION IN NPM1 ACUTE MYELOID LEUKEMIA

C. Caprioli[1,*], F. Lussana[1], P. Stefanoni[1], C. Pavoni[1], O. Spinelli[1], K. Buklijas[1], A. Michelato[1], P. Zanghì[1], G. Borleri[1], A. Algarotti[1], C. Micò[1], A. Grassi[1], T. Intermesoli[1], A. Rambaldi[1,2]

[1]Hematology and Bone Marrow Transplant Unit, Ospedale Papa Giovanni XXIII, Bergamo, [2]Department of Oncology and Hematology, Università degli Studi di Milano, Milan, Italy

Background: Nucleophosmin (NPM1) is the most commonly mutated gene in acute myeloid leukemia (AML), occurring in 30% of cases. NPM1 transcript is also a stable marker when used to track minimal residual disease (MRD) by molecular analysis. Recent studies found an association between persistence/reoccurrence of NPM1 transcript and risk of relapse along with lower survival. Moreover, NPM1 persistence before allogeneic stem cell transplantation (alloHSCT) has been associated with a higher risk of relapse. However, other studies showed that similar conclusions could be drawn when pre-alloHSCT MRD is determined by multiparametric flow cytometry (MFC) regardless of molecular classification. To date there is no direct comparison that tested efficacy between pre-alloHSCT MRD by MFC and molecular analysis in predicting relapse risk in patients with NPM1 mutated AML.

Aims: To compare sensitivity and concordance of pre-alloHSCT MRD by MFC and molecular analysis and to evaluate the efficacy of combining the two methods in predicting leukemia free survival (LFS) and overall survival (OS).

Methods: Twenty-seven consecutive NPM1 AML patients who received alloHSCT in first or second complete hematologic remission between 2011 and 2017 were retrospectively analyzed. Pre-alloHSCT MRD determination by both MFC and molecular analysis on bone marrow aspirate was available for the whole cohort. Multiparametric flow cytometry MRD was performed using a leukemia-associated immunophenotype approach (8-color flow cytometry with a 8-antibody panel); the sensitivity level was 0.1% and MRD positivity was defined as any level of residual disease. Molecular analysis of MRD was performed using a mutation-specific RT-qPCR assay, with MRD levels expressed as percentage (ratio of the NPM1 copies to housekeeping gene ABL copies×100); the sensitivity level was 0.01% and MRD positivity was defined as any level above 0.01%. Combining the two methods, MRD was empirically divided into three levels: MRD^{high} (MRD detected by MFC or NPM1 ≥0.1%); MRD^{low} (MFC negative and NPM1 <0.1% but >0.01%); and $MRD^{negative}$ (MFC negative and NPM1 ≤0.01%). LFS and OS were estimated using the Kaplan-Meier method.

Results: At the time of alloHSCT, 23 patients were in first complete remission and 4 in second complete remission. The median age was 57 years (range 23-65). The proportion of patients achieving MRD negativity by molecular analysis was significantly lower than that of patients with MRD negativity by MFC (30% versus 74%, p<0.001). Sensitivity of molecular analysis was superior in comparison with MFC (90% versus 60%, p=0.0018). Concordance between the two methods was low (Cohen's kappa coefficient=0.13; p=0.15). No difference was observed in 3-year LFS and OS according to MRD negativity determined by molecular analysis and MFC, respectively. By combining the two methods, 15 patients had MRD^{high} (7 detected by MFC), 5 had MRD^{low}, and 7 had $MRD^{negative}$. Patients with MRD^{high} had a poor 3-year LFS as compared to patients with MRD^{low} and $MRD^{negative}$ (p=0.0078), while no significant difference was reported comparing MRD^{low} and $MRD^{negative}$ (p=0.3173) (Figure 1).

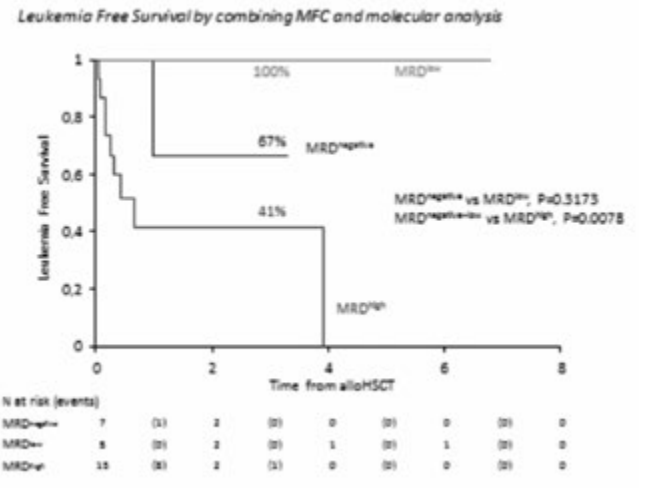

Figure 1.

Summary/Conclusion: Although molecular analysis resulted in a better sensitivity than MFC, pre-alloHSCT MRD negativity determined by molecular analysis and MFC showed similar 3-year LFS and OS. Achieving low-level or negative pre-alloHSCT MRD by combining MFC and molecular analysis is associated with an improved LFS compared to persistence of high levels.

Background: Allogeneic stem cell transplantation (HSCT) offers the greatest chance of cure for patients with acute myeloid leukemia (AML). Minimal residual disease status (MRD) before HSCT has been reported to predict relapse risk in patient transplanted in 1st complete remission (CR1). However, the role of pre-transplant MRD in AML patients undergoing HSCT beyond first CR has not been clearly established.

Aims: To analyze the role of pre-HSCT MRD in predicting post-transplant relapse risk in AML patients transplanted beyond 1st CR; to analyze whether MRD status at 1st CR influences the probability of achieving a subsequent MRD negative CR.

Methods: We retrospectively analyzed the outcome of 92 consecutive AML patients receiving allo-ASCT in 2nd or 3rd CR. MRD was evaluated on pre-HSCT marrow samples by multicolor flow cytometry (MFC) and WT1 expression. Pre-HSCT marrow samples were analyzed for MFC and WT1 expression for MRD evaluation. Median age at transplant was 45 years

(range 18-62). Disease status was CR2 in 63 (68%) and CR3 in 29 patients (32%). ELN risk at diagnosis was low in 28 (30%), intermediate (INT) in 44 (48%) and high in 20 (22%) patients. Sixty-six (71%) received myeloablative conditioning, whereas 26 patients (29%) received reduced intensity conditioning. Stem cell source was HLA-identical sibling in 18 (20%), haploidentical (HAPLO) in 24 (26%) and alternative donor in 50 (54%). Median follow-up was 64 months (95% CI 39.8 – 88.2 months). A positive MFC MRD was defined by the presence of at least $1x10^{-3}$ residual leukemic cells by four or eight (since 2011) color flow-cytometry. WT1 copy number/Abl copy number $250x10^4$ was used as cut-off value.

Results: Relapse occurred in 30 patients (33%). Three-year overall survival (OS) was 47.9% (median 19 months). The survival probability was significantly affected by donor source (better for HAPLO, p<0.05), ELN risk at diagnosis (better for ELN low risk, p<0.01), MRD status before HSCT measured with any method (p <0.01 for WT1-based MRD, p<0.03 for MFC based MRD) and was better for CR2 compared to CR3 patients (p<0.05). Pre-HSCT MRD negative patients showed a lower rate of relapse regardless of risk at diagnosis (2-years OS of 62.2% and 52.7% among MFC MRD negative patient with ELN risk low vs INT/high, Figure 1). In competitive risk analysis MRD evaluation with any method was a strong predictor of cumulative incidence (CI) of relapse (p<0.01 and p<0.03, respectively, for WT1 and MFC MRD). Multivariate analysis showed that donor source and MRD evaluation both significantly influenced CI of relapse (p <0.05 and <0.01, respectively). Interestingly, among 30 INT patients transplanted in 2nd or further CR, all 13 patients who were MRD negative after 1st induction, were able to obtain a 2nd MRD negative CR before HSCT. In this cohort, MRD negativity after induction was the strongest factor related to the probability of achieving a 2nd MRD negative CR.

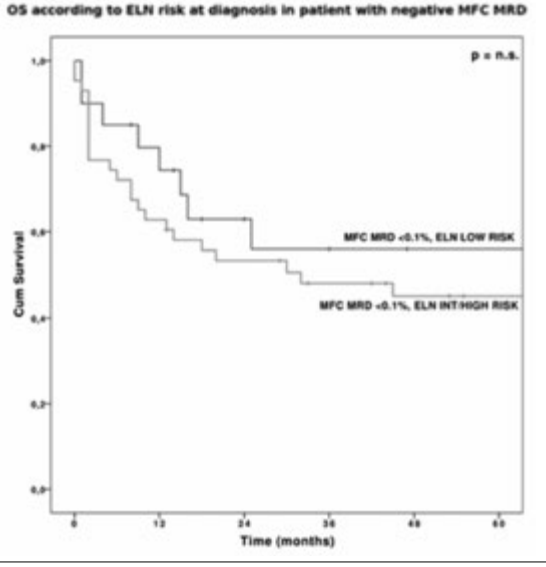

Figure 1.

Summary/Conclusion: Pre transplant MRD evaluation by both MFC and WT1 is a reliable predictor of relapse risk overcoming ELN risk assessment at diagnosis. Pre-HSCT MRD negative patients have a significantly lower risk of relapse. Furthermore, our result suggests that HAPLO donor source has a positive impact in reducing relapse rate in advanced AML patients. Our data show that all non-transplanted INT patients relapsing after the achievement of a 1st MRD negative were able to obtain a 2nd MRD negative CR. Postponing HSCT in INT patients with optimal response to frontline induction may be therefore a safe option.

THE CXCR4 INHIBITOR BL-8040 IN COMBINATION WITH CYTARABINE RESULTS IN A SIGNIFICANTLY EXTENDED OVERALL SURVIVAL OF RELAPSED/REFRACTORY AML PATIENTS

G. Borthakur[1,*], M. S. Tallman[2], Y. Ofran[3], J. Foran[4], G. Uy[5], J. Dipersio[5], A. Nagler[6], J. Rowe[7], M. M. Showel[8], J. K. Altman[9], A. Peled[10], M. Abraham[10], Y. Pereg[11], A. Vainstein[11], G. Oberkovitz[11], T.M. Lustig[11], S. Brawer[11], O. Bohana-Kashtan[11], J. E. Cortes[1], M. Andreef[1]

[1]MD Anderson Cancer Center, Houston, [2]Memorial Sloan Kettering Cancer Center, New York, United States, [3]Rambam Medical Center, Haifa, Israel, [4]Mayo Clinic, Jacksonville, [5]Washington University of St Louis, St Louis, United States, [6]Sheba Medical Center, Ramat Gan, [7]Shaarei Tzedek Medical Center, Jerusalem, Israel, [8]Johns Hopkins University, Baltimore, [9]Northwestern University, Chicago, United States, [10]The Hebrew University of Jerusalem, Jerusalem, [11]BioLineRx, Modiin, Israel

Background: CXCR4 plays a key role in the retention and survival of human acute myeloid leukemia (AML) blasts in the bone marrow (BM) microenvironment. Interaction of AML blasts with the leukemic microenvironment is considered an important mediator of resistance to chemotherapy, disease relapse and poor survival. Blockade of the CXCR4/CXCL12 pathway using the high-affinity CXCR4 antagonist BL-8040 interrupts this interaction, thereby mobilizing and increasing the sensitivity of leukemic blasts to chemotherapy as well as inducing a direct anti-leukemic effect.

Aims: To assess the safety and efficacy of BL-8040 combined with high-dose Cytarabine (HiDAC) in adult patients with relapsed/refractory (r/r) AML.

Methods: A Phase IIa study (NCT02073019) consisting of two cohorts: (i) dose-escalation (3+3 design, 6 escalating doses, range 0.5-2.0 mg/kg) and (ii) expansion at the selected dose of 1.5 mg/kg. Patients with r/r AML (salvage 1/2) were treated daily with BL-8040 monotherapy (SC) for two days followed by combined administration of BL-8040 and HiDAC (IV; 1.5g or 3.0 g/m^2/d,
based on age) for 5 days for 1-2 cycles. Efficacy endpoints included response rate (CR/CRi), overall survival (OS), duration of response (DOR) and event free survival (EFS).

Results: 42 patients, median age 61 (33-75) years were enrolled; 19 patients (45%) were refractory and 23 (55%) were relapsed. Overall, 26% (11/42) had secondary AML (from prior MDS), and 17% (7/42) were patients that relapsed after stem-cell transplantation. 81% (34/42) of patients had high-risk features that included primary refractory to one or two inductions or previous CR duration of less than 12 months. Twelve subjects (28.6%) were refractory to a single induction and seven were refractory to 2 or more inductions. Eight subjects relapsed after a complete response that lasted less than a year after diagnosis and primary induction and seven relapsed after a complete response for less than a year after salvage chemotherapy following first relapse. Median follow-up time was 213 days (1-958). BL-8040 in combination with HiDAC was safe and well tolerated. The CR/CRi rate for all dosing levels was 29% (12/42) and median OS (Kaplan-Meier estimate) was 9.1 months with 1-year and 2-year survival rates of 32.4% and 18.9%, respectively. In patients receiving the dose selected for expansion, 1.5 mg/kg (23 patients, 54.8%), the response rate (CR/CRi) was 39% (9/23) and median OS was 9.2 months with 1-year and 2-year survival rates of 31.6% and 21.1%, respectively. Median OS for responding (9/23 with CR/CRi) patients at the 1.5 mg/kg dose was 16.7 months, with 1- and 2-year survival rates of 50% and 37.5%, respectively. Median DOR for these patients was 10.1 months and EFS at 1 year and 2 years was 37.5% and 12.5%, respectively.

Summary/Conclusion: This study demonstrates that BL-8040 administered at a dose of 1.5 mg/kg in combination with HiDAC significantly improved overall survival of r/r AML patients compared with historical data[1] (overall survival of 6.1 months) for HiDAC alone. This supports continued clinical development of BL-8040 in frontline and early salvage AML patients.

CELL-FREE DNA MONITORING OF MINIMAL RESIDUAL DISEASE IN AML USING A TARGETED NGS GENE PANEL

Z. Xie[1,*], L. Chamberlain[1], A. Carson[1], V. McClain[1], O. Kiya[1], B. Patay[1], M. Blankfard[1], T. Stenzel[1], J. Miller[1,2]

[1]Invivoscribe Inc., [2]LabPMM LLC, San Diego, United States

Background: We have developed a sensitive NGS gene panel (MyMRD™), which identifies pathogenic variants in acute myeloid leukemia (AML) establishing remission status. This panel targets mutation hotspots in 23 genes associated with AML. It identifies driver mutations that cause relapse in >90% of all AML patients, as well as common drivers in other myeloid neoplasms (MPN) and myelodysplasic syndromes (MDS). We have leveraged data from literature that suggest cell-free DNA (cfDNA) isolated from blood plasma of cancer patients contains tumor-derived DNA fragments with a molecular profile similar to that of bone-marrow tumor cells, and that DNA obtained from plasma provided a more accurate assessment of disease burden than testing circulating leukocytes, and results correlated

with disease burden. Therefore we set out to investigate whether the MyMRD assay, originally developed for genomic DNA analysis, could be applied to cfDNA to assess mutations at a level comparable to testing of genomic DNA and developed the MyMRD cfDNA assay for characterization and residue disease monitoring of targeted variants.
Aims: To establish a sensitive, reliable, targeted NGS gene panel assay for cell-free DNA to detect and monitor at least one driver mutation in >90% of acute myeloid leukemias.
Methods: Cell-free DNA was extracted from fresh, frozen, and synthetic plasma using commercially available kits. To overcome the limitation of testing cfDNA, DNA fragments with size similar to cfDNA were generated for initial feasibility studies during assay development. Genomic DNA was fragmented by sonication and the DNA fragments were selected for size in the range of 50- 400bp (mean size ~160bp). Whole genome libraries, generated from cfDNA and DNA fragments, were hybridized with MyMRD probes. Enriched libraries were sequenced with the MiSeq®. Sequencing data was analyzed using proprietary Invivoscribe MyInformatics™ software.
Results: The linearity and limit of detection (LOD) of the MyMRD cfDNA assay were assessed using data obtained from DNA fragments generated from contrived cell lines with a range of variant allele frequencies (VAFs). The assay shows strong linearity (R^2=0.975 – 0.998) in the entire range of VAFs (0.1– 20%) tested. With DNA input of 25ng, the LOD was established to be 0.5% for targeted SNV sites, and 1% for targeted indel variant sites. When the assay was applied to plasma reference samples, mutations were successfully identified with expected VAFs. The cfDNA extracted from clinical samples, fresh or frozen plasmas, were also tested with the MyMRD cfDNA assay and quality data were generated.
Summary/Conclusion: This MyMRD gene panel is a sensitive, reliable assay that provides monitoring of residual disease using cfDNA. The assay is shown to detect clinically important driver variants and has excellent linearity and LOD for targeted variant sites. This assay can potentially replace invasive BM sampling and provide an alternative test for longitudinal genetic monitoring of patients receiving targeted therapy.

PS995

INTRA-PATIENT DOSE-ESCALATION STUDY OF CRENOLANIB MAINTENANCE THERAPY IN PATIENTS WITH FLT3 MUTANT AML WHO HAD UNDERGONE ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANT (ALLO-HSCT)

B. Oran[1,*], S. Ciurea[1], D. Marin[1], J. McCarty[1], Q. Bashir[1], S. Ahmed[1], A. Olson[1], U. Popat[1], Y. Nieto[1], P. Kebriaei[1], E. Shpall[1], T. Agrawal[2], R. Champlin[1]

[1]Department of Stem Cell Transplantation and Cellular Therapy, The University of Texas MD Anderson Cancer Center, Houston, [2]AROG Pharmaceuticals, Inc., Dallas, United States

Background: FLT3 inhibitors (like sorafenib and midostaurin) have been administered as maintenance therapy post allo-HSCT to reduce persistent relapse risks in FLT3-mutant AML patients. Recent studies suggest that inhibition of FLT3 can downregulate dendritic cell proliferation and increase cytotoxic $CD8^+$ T-cell function in allo-HSCT recipients thus increasing graft-versus-leukemia (GVL) effect (Lau *et al. J. Exp. Med.*, 2016). Some FLT3 inhibitors including crenolanib have shown increased IL-15 production resulting in elevated GVL activity, thus reducing the risk of post-transplant relapse (Mathew *et al. Nat. Med.*, 2018).
Only reduced doses of both sorafenib and midostaurin have been found to be tolerable in the post-HSCT setting. Crenolanib is a highly potent and selective FLT3-targeted TKI that has activity as a single-agent and combined with chemotherapy in patients with FLT3-ITD and/or FLT3-TKD mutations. Given the favorable safety profile of crenolanib at 100 mg TID (300 mg daily) and promising clinical benefits in AML patients, crenolanib has been used as maintenance therapy in the post-transplant setting. We here report the outcomes of safety and tolerability of crenolanib maintenance in FLT3 mutant AML patients with prior allo-HSCT (NCT02400255).
Aims: To assess the tolerability of crenolanib maintenance in the post allo-HSCT AML patients and evaluate the appropriate dose for such patient population.
Methods: A study of crenolanib maintenance therapy was performed in patients (age ≥18) with FLT3 mutant AML who had undergone HSCT. Initially, patients were treated with 80 mg TID (240 mg daily) which was subsequently changed to an intra-patient dose-escalation, in which patients received crenolanib starting at a dose of 60 mg BID for a month and then escalated to 80 mg BID and finally 80 mg TID as tolerated. Regular assessment of chemistry and hematologic laboratory values were performed to ensure safety of crenolanib in this patient population.
Results: 21 patients, who received a variety of prior treatments and graft sources, have been enrolled to date. 4 patients received an initial dose of 80 mg TID, but due to early tolerability issues dosing was changed to an intra-patient escalation, after which crenolanib was well tolerated at the initial dose of 60 mg BID as well as the next dose level of 80 mg BID. 16 patients have discontinued treatment: 7 due to patient choice, 5 due to disease progression and 4 due to investigator decision. Of 5 progressions, 4 were MRD positive prior to HSCT and 2 had received haplo transplant, with a median time to progression of 17 days (range: 7-29 days). Side effects were predominantly grade 1 and 2 with the most common (regardless of attribution) being nausea (62%), vomiting (38%), and diarrhea (33%). Of the 6 patients escalated to 80 mg TID, 4 tolerated multiple cycles. Currently, five patients remain on treatment and the median duration of survival follow-up is 433 days (Table 1).

Table 1.

Patient Characteristics	n = 21
Age, median (range)	54 (31-74)
FLT3 mutational status	
FLT3-ITD	16
FLT3-ITD+/NPM1+	8
FLT3-ITD+/NPM1-	5
FLT3-TKD	5
Disease status prior to HSCT	
CR	7
CRi	11
Residual disease	2
Unknown	1
Conditioning regimen	
Myeloablative	15
Reduced intensity	5
Unknown	1
Donor type	
Match-related donor	9
Match-unrelated donor	10
Haploidentical	2
Crenolanib start date post-HSCT, days, median (range)	80 (50-98)
Days on maintenance, median (range)	208 (4-699)

Summary/Conclusion: These interim results suggest that crenolanib can be safely given at a dose of 160 mg to 240 mg total daily in the post-HSCT setting. Two randomized phase III trials have been initiated to investigate the efficacy of crenolanib with chemotherapy vs chemotherapy alone in R/R FLT3 mutated AML as well as crenolanib vs midostaurin following chemotherapy in newly diagnosed FLT3 mutated AML (NCT03250338, EudraCT 2017-001600-29; NCT03258931). Based on these results, post HSCT crenolanib maintenance will be offered at 100 mg BID (200 mg daily) in both trials.

PS996

CONSOLIDATION THERAPY WITH PONATINIB IN COMBINATION WITH CYTARABINE IN PATIENTS FOR FLT3-ITD ACUTE MYELOID LEUKEMIA IN FIRST COMPLETE REMISSION

[1]Centre Hospitalier de Versailles, Le Chesnay, [2]INSERM U[1173]Université Versailles Saint-Quentin-en-Yvelines, Université Paris-Saclay, Paris Saclay, [3]French AML group, Paris, [4]Centre Hospitalier Haut-Lévêque, Pessac, [5]Hôpital Saint-Antoine, Paris, [6]Hôpital Larchet, Nice, [7]Hôpital Saint-Louis, Paris, [8]CHU de Dijon, Dijon, [9]CHU d'Angers, Angers, [10]Hôpital d'Instruction des Armées, Percy, [11]Centre Hospitalier Côte-de-Nacre, Caen, [12]CHU de Saint-Etienne, Saint-Etienne, [13]CHU d'Amiens, Amiens, [14]CH de Valenciennes, Valenciennes, [15]CHU de Nantes, Nantes, [16]Hôpital Huriez, Lille, [17]Hôpital Haut-Lévêque, Pessac, France

Background: Ponatinib is a third-generation tyrosine kinase inhibitor targeting the BCR-ABL tyrosine kinase domain. Despite low activity against FLT3 based on the IC50 value (FLT3 IC50: 12.6 nM), ponatinb has been reported to have significant activity against the MV4-11 cell line which harbors an FLT3-ITD activating mutation. Primary blasts from acute myeloid leukemia (AML) patients were also tested and ponatinib reduced their viability whereas no activity was shown on FLT3-ITD-negative blast cells.
Aims: We aim to combine ponatinib with cytarabine consolidations in FLT3-

ITD AML patients in first complete remission.
Methods: AML patients in first CR were eligible after signed informed consent if they had intermediate risk caryotype with FLT3-ITD allelic ratio >10%, normal pancreatic and hepatic functions, low cardiovascular risk, QTc > 470 ms and no CNS involvement. Patients aged 18-60y received high-dose ARA-C (HDAC, 3 g/m²/12h at D1, D3 and D5, 2 courses, cohort A) and patients aged over 60y received intermediate-dose ARA-C (IDAC, 1.5 g/m²/12h D1, D3 and D5, 3 courses, cohort B). Ponatinib was given continuously during the consolidation phases. Three dose levels of ponatinib were tested following a classical phase I – II dose escalation schedule (3-3-3) in each age group: 15 mg/d, 30 mg/d and 45 mg/d. Allogenic hematopoietic stem cell transplant was allowed for eligible patients. Primary end-point was dose limiting toxicity, secondary end-points were OS, RFS.
Results: Forty patients were included from April 2014 to October 2017, 24 in cohort A (median age 51.5y) and 16 in cohort B (median age 64y). Dose escalation of ponatinib in cohort A resulted in 1 dose limiting toxicity (DLT) (cardiac failure) at 45 mg/d. Thus, the recommended ponatinib daily dose was 30 mg/d for the remaining 13 patients and no further DLT was recorded. Nineteen patients received ponatinib during the second consolidation and 8 patients were allografted. Eight patients relapsed all during the first 15 months post inclusion. Kaplan-Meier (KM) estimate for OS at 12 and 24 months were 71.3% (95% CI: 44.1-86.9) and 59.4% (95% CI: 33.1-78.3) respectively. Median EFS was 23.8 months. KM estimate for EFS at 12 and 24 months were 51.7% (95% CI: 27-71.6) and 43% (95% CI: 18.8-65.3) respectively. Dose escalation of ponatinib in cohort B resulted in 2 DLTs at 30 mg/d (atrial fibrillation and pulmonary embolism). Thus, the recommended ponatinib daily dose was 15 mg/d for the remaining patients and only 1 delayed hematopoietic recovery was further observed. Twelve patients received ponatinib during the second consolidation and 2 patients were allografted. Five patients relapsed all during the first 9 months post inclusion. Median OS was 14.2 months. Kaplan-Meier (KM) estimate for OS at 12 and 24 months were 63% (95% CI: 32.3-82.8) and 36% (95% CI: 11.6-61.6) respectively. Median EFS was 14.2 months. KM estimate for EFS at 12 and 24 months were 52.5% (95% CI: 25.2-73.8) and 42% (95% CI: 17.4-68.3) respectively.
Summary/Conclusion: The combination of ponatinib and high or intermediate dose cytarabine is feasible and safe in patient with FLT3-ITD AML in first CR. The determined ponatinib daily dose is 30 mg/d in patients aged 18-60y and 15 mg/d for patients aged over 60y. Median overall survival was 21.7 months for all patients included in the study.

PS997

PHASE 1/1B STUDY OF PEVONEDISTAT (PEV) AS A SINGLE AGENT OR COMBINED WITH AZACITIDINE (AZA) IN EAST ASIAN PATIENTS (PTS) WITH ACUTE MYELOID LEUKEMIA (AML) OR MYELODYSPLASTIC SYNDROME (MDS)

S.-J. Wu[1,*], J.-W. Cheong[2], Y. Onishi[3], H. Iida[4], Y. Kobayashi[5], H.-J. Kim[6], T.-J. Chiou[7], X. Zhou[8], H. Faessel[8], Y. Yuan[8], F. Sedarati[8], D. V. Faller[8], A. Kimura[9], H. Handa[10]

[1]National Taiwan University Hospital, Taipei, Taiwan, Republic of China, [2]Severence Hospital, Yonsei University Health System, Seoul, Korea, Republic Of, [3]National University, Corporation Tohoku University, Tohoku, [4]National Hospital Organization, Nagoya Medical Center, Nagoya, [5]International University of Health and Welfare, Mita Hospital, Tokyo, Japan, [6]Chonnam National University, Hwasun Hospital, Hwasun, Korea, Republic Of, [7]Taipei Veterans General Hospital, Taipei, Taiwan, Republic of China, [8]Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, United States, [9]Takeda Pharmaceutical Company Limited, Osaka, [10]Gunma University Hospital, Maebashi, Japan

Background: PEV, a first-in-class NEDD8-activating enzyme inhibitor, has demonstrated synergistic activity with AZA in preclinical AML models. The clinical safety and tolerability profile of PEV administered alone or in combination with AZA was shown in phase 1/1b studies of Western pts with AML/MDS.
Aims: The primary objectives of this phase 1/1b trial (NCT02782468) were to assess safety/tolerability and pharmacokinetics (PK) of PEV as a single agent (PEV arm) or combined with AZA (PEV+AZA arm) and to determine the recommended phase 2/3 dose (RP2/3D) of PEV in the PEV+AZA arm in East Asian pts with AML/MDS. Response evaluation was a secondary objective.
Methods: This 3+3 dose escalation and expansion study enrolled adult East Asian pts with WHO-defined AML or higher-risk MDS (IPSS-R very high/high/intermediate risk). Pts receiving PEV had relapsed/refractory (R/R) AML/MDS and pts receiving PEV+AZA had R/R or untreated disease and were unfit for intensive chemotherapy. In the PEV arm, pts received PEV 25 or 44 mg/m² IV on days 1, 3 and 5 (21 day cycle). Pts in the PEV+AZA arm received PEV 10 or 20 mg/m² IV on days 1, 3 and 5 + AZA 75 mg/m² IV or SC on days 1–5 and 8–9 (28 day cycle). Treatment was given until progressive disease or discontinuation for any reason. Informed consent was provided. PK samples were collected pre- and post-dose at various timepoints on days 1 and 5, and post-dose on days 2, 3, 6 and 7 of cycle 1. Best overall response was assessed by investigators according to International Working Group (IWG) criteria for AML or modified IWG criteria for MDS.
Results: As of 1-Nov-2017, 20 pts were enrolled in East Asian countries (safety population): 10 received single-agent PEV (25 mg/m², n=3; 44 mg/m², n=7) and 10 PEV+AZA (PEV 10 mg/m², n=3; PEV 20 mg/m², n=7); overall median treatment exposure was 3 (range: 1–19) cycles. Median age was 75 (range: 47–84) years in the PEV arm and 67 (range: 59–76) years in the PEV+AZA arm. In each arm, 9 pts (90%) were male, 4 (40%) had *de novo* AML, 4 (40%) had secondary AML (including 3 pts in the PEV arm and 2 pts in the PEV+AZA arm who had AML secondary to prior MDS) and 2 (20%) had *de novo* MDS. Most pts had received prior chemotherapy (13/16 AML and 3/4 MDS pts). There was 1 pt with dose-limiting toxicities in cycle 1 of grade 3 atrial fibrillation and grade 3 tumor lysis syndrome in the PEV 20 mg/m² +AZA arm. PEV RP2/3D in the PEV+AZA arm was 20 mg/m², identical to the RP2/3D determined for Western pts. All pts experienced grade ≥3 adverse events (AEs) (drug related in 4 PEV and 8 PEV+AZA pts). Nine (90%) PEV pts and 5 (50%) PEV+AZA pts had serious AEs, and 3 (30%) pts in each arm discontinued study due to AEs. Common any-grade AEs are shown in the Table 1. Three on-study deaths were reported (not treatment related): 1 PEV pt (AML) and 2 PEV+AZA pts (pneumonia; acute kidney injury). PEV PK were consistent with those observed in Western pts. In the PEV+AZA arm, all 5 evaluable AML pts (1 *de novo*, 1 relapsed/refractory, and 3 secondary AML) responded to treatment and 1 MDS pt had marrow CR. Responses were not observed in the PEV arm.

Increased AST	1 (33)	1 (14)	2 (20)	1 (33)	2 (29)	3 (30)	5 (25)
Dyspnea	0	2 (29)	2 (20)	1 (33)	2 (29)	3 (30)	5 (25)
Insomnia	1 (33)	3 (43)	4 (40)	0	1 (14)	1 (10)	5 (25)
Platelet count decreased	0	1 (14)	1 (10)	1 (33)	3 (43)	4 (40)	5 (25)

AE, adverse events; AST, aspartate aminotransferase; AZA, azacytidine; PEV, pevonedistat; pts, patients.

Summary/Conclusion: Single-agent PEV treatment in East Asian pts with AML/MDS appeared to be tolerable, with similar safety and PK profiles to those of Western pts. Addition of PEV to AZA did not result in additional toxicity and PEV RP2/3D was identical to that of Western pts. Substantial objective clinical responses were seen in East Asian pts with AML treated with PEV+AZA and were also consistent with those of Western pts with AML.

PS998

ANALYSIS OF PHASE I AND PILOT PHASE II DATA REVEAL 2,000 MG/M2 AS THE OPTIMAL DOSE OF CPI-613 IN COMBINATION WITH CYTARABINE AND MITOXANTRONE FOR ELDERLY PATIENTS WITH RELAPSED OR REFRACTORY AML

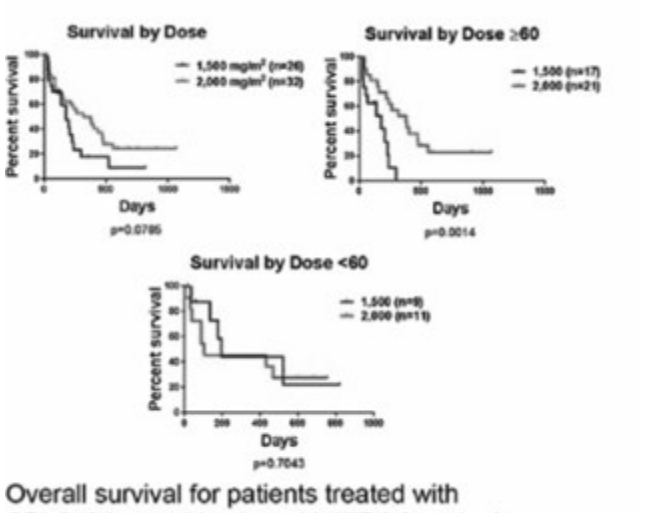
T. Pardee[1,2,*], S. Isom[3], K. Hu[2], L.W. Boteju[2], A.R. Boteju[2], R. Shorr[2], S. Luther[2], L. R. Ellis[1], D.S. Howard[1], R. Bhave[1], M. Manuel[1], S. Dralle[1], S. Lyerly[1], B.L. Powell[1]

[1]Internal Medicine, Section on Hematology and Oncology, Wake Forest Baptist Health, Winston-Salem, [2]Rafael Pharmaceuticals, Cranbury, [3]Department of Biostatistical Sciences, Wake Forest Baptist Health, Winston-Salem, United States

Background: CPI-613 is a first in class agent that inhibits pyruvate dehydrogenase and α-ketoglutarate dehydrogenase. In a phase I trial for relapsed AML patients CPI-613 combined with high dose cytarabine (HiDAC) and mitoxantrone was particularly effective in elderly patients.
Aims: To determine the optimal dose of CPI-613, demographics, response, survival and PK data for various dosing cohorts from the pooled dataset of phase I and II studies were analyzed.
Methods: All patients included in the analysis were treated with identical doses and schedules of HiDAC and Mitoxantrone as published. Only the doses of CPI-613 varied.
Results: The two largest cohorts of CPI-613 were 1,500 (n=26) and 2,000 mg/m^2 (n=32). Demographics for each group are shown. Response rates (CR+CRi) were similar in patients treated with 2,000 or 1,500 mg/m^2 at 47% vs 50% (Table 1). However, the median overall survival for patients treated with 2,000 was 11.4 vs 5.9 months with a p value of 0.0785 (Figure 1). To determine which age group contributed to this difference, data from patients ≥60 years of age was analyzed independently. In this group the response rate for patients treated with 2,000 was 57% vs 35% (Table 1). Survival was significantly increased for patients treated with 2,000 at 12.4 vs 5.7 months (Figure 1). In contrast, there was no significant difference in younger patients (<60 years, Figure 1). Additionally, 24% of older patients treated with 2,000 went on to receive an allogeneic stem cell transplant compared to none treated with 1,500. PK data showed the Cmax values on day 5 of dosing 1,500 and 2,000 mg/m^2 were approximately dose-proportional at 30.4 (SD±13.8) and 38.0 (SD± 26.1) mM, respectively.

Table 1. Demographics and Response.

Age	All	All	≥60 y/o	≥60 y/o
Dose of CPI-613 (mg/m^2)	2,000 (n=32)	1,500 (n=26)	2,000 (n=21)	1,500 (n=17)
Demographics				
Male	56% (18/32)	58% (15/26)	66% (14/21)	71% (12/17)
Median Age (range)	62.5 (21-76)	64.5 (28-79)	68 (60-75)	68 (60-79)
Line of Salvage (range)	1 (1-4)	1 (1-3)	1 (1-2)	1 (1-3)
Refractory to Initial Therapy	25% (8/32)	31% (8/26)	29% (6/21)	18% (3/17)
Duration of CR1 (months)	9	8	10	7.5
Cytogenetic Risk				
Poor	44% (14/32)	46% (12/26)	43% (9/21)	41% (7/17)
Intermediate	47% (15/32)	50% (13/26)	48% (10/21)	49% (10/17)
Good	9% (3/32)	0% (0/26)	9% (2/21)	0% (0/17)
Unknown	0% (0/32)	4% (1/26)	0% (0/21)	0% (0/17)
Outcomes:				
Median Survival (months)	11.4	5.9	12.4	5.7
Response (CR+CRi)	47% (15/32)	50% (13/26)	57% (12/21)	35% (6/17)
Went on to Transplant	25% (8/32)	12% (3/26)	24% (5/21)	0% (0/17)



Overall survival for patients treated with CPI-613 in combination with HiDAC and mitoxantrone.

Figure 1.

Summary/Conclusion: These data suggest that there was a dose response relationship for CPI-613 when given in combination with HiDAC and mitoxantrone for older patients with relapsed or refractory AML. The results obtained using a dose of 2,000 mg/m^2 are encouraging in this poor prognostic group.

PS999

CLADRIBINE ADDED TO STANDARD INDUCTION CHEMOTHERAPY FOR ACUTE MYELOID LEUKAEMIA, 4-YEAR EXPERIENCES FROM SLOVENIA

S. Anžej Doma[1,*], M. Škerget[1], S. Zver[1]

[1]*Hematology, University Medical Centre Ljubljana, Ljubljana Slovenia*

Background: Polish Adult Leukemia group demonstrated that addition of cladribine to standard daunorubicin + cytarabine induction chemotherapy for acute myeloid leukaemia (AML) increases remission rate and prolongs overall survival. In Slovenia we have been using this induction protocol since 2014 for all patients eligible for intensive chemotherapy aged 65 or less.
Aims: The study was performed to assess the efficacy and possible drawbacks of the daunorubicin+cytarabine+cladribine induction protocol; data on our patients' characteristics, remission induction rate, relapse rate and overall survival are presented.
Methods: We included all consecutive patients diagnosed with AML between April 2014 und February 2018, aged 65 or less, who were eligible for intensive chemotherapy according to ECOG performance status, echocardiography and spirometry. Exclusion criteria were severe organ impairment and acute promyelocytic leukaemia. The induction regimen consisted of daunorubicin 60 mg/m^2 on days 1,3 and 5, continuous infusion of cytarabine 200 mg/m^2 from day 1 to 7 and cladribine 5 mg/m2 in a 3-hour infusion on days 1 through 5. Consolidation treatment consisted of 2 or 3 courses of cytarabine and eligible patients with unfavorable characteristics (monosomal/complex kariotype, FLT3 ITD or KMT2A rearrangements, therapy-related AML) with a sibling or matched unrelated donor proceeded with alogenic bone marrow transplantation. The efficacy of induction treatment was assessed by bone marrow aspiration in the aplastic phase, preferably between days 7 and 10 after the last day of induction chemotherapy, and before the first consolidation therapy.
Results: 69 patients with AML (35 women, 34 men) were treated with daunorubicin+cytarabine+cladribine induction chemotherapy at our hematology department between April 2014 and February 2018. Median age was 55 years (range 20 to 65 years). 38/69 (55%) patients had unfavorable cytogenetics or therapy-related AML. 53/69 (77%) patients achieved remission after induction chemotherapy. With a median follow-up of 11 months (1-44 months), the probability of 1-year OS was 71%, and the median survival was not reached. 11 patients relapsed. There were no significant differences between patients with unfavorable characteristics versus the others. The most serious side effect, attributed to cladribine, was noncardiogenic pulmonary oedema, observed in 5/69 (7%) patients during the induction chemotherapy (Figure 1).

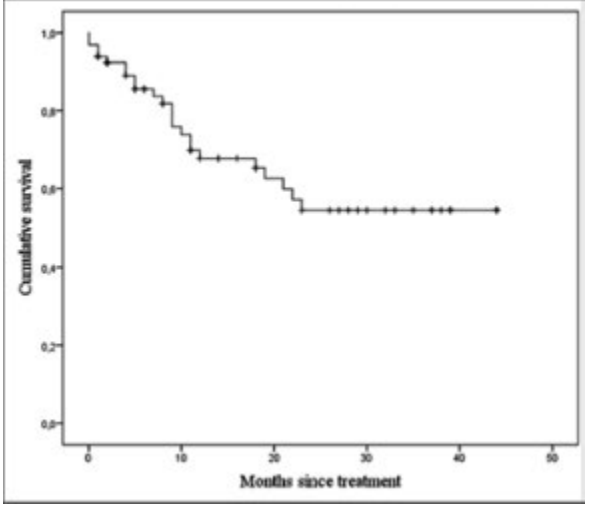


Figure 1.

Summary/Conclusion: Induction chemotherapy for AML, consisting of daunorubicin, cytarabine and cladribine results in a high remission rate (77%) and probability of 1- year OS of 71%. For predicting a long-term overall survival, further follow up is needed.

PS1000

DECITABINE AS SINGLE AGENT FOR TREATMENT OF NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (AML) IN ELDERLY PATIENTS: A RETROSPECTIVE, MULTICENTER REAL LIFE STUDY OF THE "RETE EMATOLOGICA PUGLIESE" (REP)

M. P. Loglisci[1,*], C. Buquicchio[2], P. Carluccio[3], G. Guaragna[4], G. Rossi[5], G. Greco[6], L. Aprile [7], G. Tarantini[2], G. Specchia[3], D. Pastore[4], N. Cascavilla[5], V. Pavone [6], P. Mazza[7], N. Di Renzo[1]

[1]Hematology, PO "V.Fazzi" , Lecce, [2]Hematology, PO "Mons. Dimiccoli", Barletta, [3]Hematology, AO Policlinico, Bari, [4]Hematology, PO "Di Summa", Brindisi, [5]Hematology, IRCCS "Casa Sollievo della Sofferenza", S.Giovanni Rotondo -FG, [6]Hematology, Ospedale Cardinale Panico, Tricase - Lecce, [7]Hematology, PO "G. Moscati", Taranto, Italy

Background: Standards of care for elderly AML patients unfit for intensive chemotherapy remain still to be defined. Decitabine, a DNA hypomethylating agent, has been recently approved for use in older adults with AML not eligible for standard chemotherapy and is now widely accented as standard treatment. However, its efficacy has not yet been assessed in a real life setting.
Aims: The aim of present study was to evaluate efficacy and toxicity of decitabine given as single agent in unselected previously untreated elderly patients with AML *de novo* or secondary/therapy-related to MDS.
Methods: One hundred and thirty-five patients with *de novo* (n=62) or secondary/therapy-related (n=73) AML were diagnosed between Sep 2013 and Jan 2018 in seven hematological departments of the "Rete Ematologica Pugliese". Patient was included in this study if 60 years or older, diagnosis of *de novo* or secondary/therapy-related AML and if treated with decitabine in a schedule of 20 mg/m^2 for five days every 4 weeks. Patients previously treated with HMA were not included. The median age was 76 years (range, 63 to 89 years) and 84 (62%) male. The median baseline BMblast percentage was 52% (range,10-90), median hemoglobin level 7.4 g/dL (range, 5.3-12.0), WBC count 12.8 mL (range, 0.8-248) and platelet count 47.000 mL (range, 2.000-380.000). Baseline karyotype analysis was performed in 90 (66%) of cases and based on cytogenetic risk group 12 cases (13%) were classified as favorable, 50 (55%) as intermediate and 28 (31%) as poor-risk. Molecular genetic profile was performed at diagnosis in 83 (61%) of cases and mutation of FLT3 or NPM1 was found in 12 (14%) and 10 (12%) of patients respectively. One-hundred and twenty patients (88%) presented comorbidity including previous myocardial infarction (6%), COPD (8%), atrial fibrillation (6%), hypertension with or without cardiomyopathy (25%) and positive serology for B or C viruses (24%). The median number of cycles delivered was 4 (range, 1-23).
Results: Seventy-five (55%) patients received a minimum of four cycles and were evaluated for response. According to AML response criteria the complete response rate was 20% (n=15) and partial response 38% (n=29) with an overall response (CR+PR) rate of 58%; in addition an hematologic improvements and stable disease was recorded in 6 (8%) and 2 (3%) of patients respectively. One hundred and two (75%) patients were admitted to the hospital to start treatment or for treatment related toxicity. The median duration of hospitalization was 15 days (range, 5-92 days). All patients experienced myelosuppression; the most commonly reported serious adverse events were febrile neutropenia (57%), grade 3-4 documented infection (9%), major bleeding (10%), atrial fibrillation (5%) and pleural effusion (2%). After a median follow-up of 10 months (95% CI, 6-14 months) the median overall survival in the intent to treat population was 7.0 months (95% CI, 6-8 months) from the start of decitabine treatment (Figure 1). At 12-months 31% (95% CI, 21-41%) of patients included in the analysis are alive.

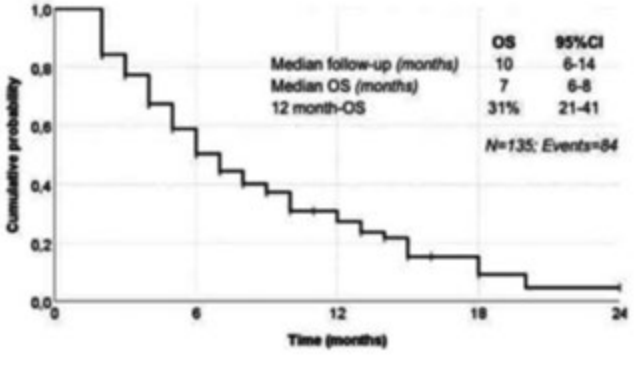

Figure 1.

Summary/Conclusion: The preliminary results of this retrospective, multicenter study of REP confirm, even in the real life setting, the reported ORR and OS rate of decitabine given as single agent for the treatment of elderly patients with AML ineligible for conventional chemotherapy.

PS1001

FLUDARABINE, HIGH DOSE CYTARABINE AND IDARUBICIN-BASED INDUCTION (FLAI) IS HIGHLY EFFECTIVE IN AML WITH MUTATED NPM1 WITH CONCOMITANT FLT3-ITD MUTATION IRRESPECTIVELY OF FLT3-ITD ALLELIC BURDEN

P. Minetto[1,*], A. Candoni[2], F. Guolo[1], M. Clavio[1], M. Miglino[1], N. Colombo[1], A. Kunkl[3], M. E. Zannier[2], M. V. Dubbini[2], D. Guardo[1], F. Ballerini[1], R. Fanin[2], R.M. Lemoli[1], M. Gobbi[1]

[1]Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, Policlinico San Martino, IRCCS per l'Oncologia, Genoa, [2]Division of Hematology and SCT, University of Udine, Udine, [3]Unit of Flow Cytometry, Department of Pathology, , Policlinico San Martino, IRCCS per l'Oncologia, Genoa, Italy

Background: The presence of FLT3 "internal tandem duplication" (FLT3-ITD) mutation is associated with poor prognosis in acute myeloid leukemia (AML). However, the concomitant presence of NPM1 mutation (NPM1-mut) mitigates the negative prognostic impact given by FLT3-ITD, which is also modulated by FLT3-ITD/wild type allelic ratio. NPM1 and FLT3 mutational status assessment is strongly recommended for risk stratification at diagnosis by the last ELN 2017 guidelines.
Aims: To investigate the efficacy of an intensive fludarabine, high dose cytarabine and Idarubicin based induction regimen (FLAI) as frontline treatment for fit, *de novo* AML patients according to NPM1 and FLT3-ITD mutational status.
Methods: One-hundred and one consecutive AML patients treated in two Hematology centers of Northern Italy were retrospectively included in this study: 21 carrying isolated FLT3-ITD, 22 concomitant FLT3-ITD and NPM1-mut and 58 isolated NPM-1 mut. Median age was 52 yrs (range: 17-68 years). All patients received FLAI induction (fludarabine 30 mg/sqm and ARA-C 2g/sqm on days 1 to 5 plus idarubicin 10 mg/sqm on days 1-3-5). Before 2017 patients with isolated FLT3-ITD mutation were scheduled to receive allogeneic bone marrow transplantation (BMT) in first complete remission. In most cases minimal residual disease has been evaluated on marrow samples using multicolor flow-cytometry (MFC) and NPM1 expression levels. Negative MFC-MRD was defined by the presence of less than 25 clustered leukemic cells/105 total events (threshold of 0.025% residual leukemic cells). NPM1 mutation (NPM1-A, B and D) was measured using Muta Quant Kit Ipsogen from Qiagen. FLT3-ITD allelic burden was available in 27/43 of FLT3-ITD patients.
Results: Two patients (2%) died of infections and two during the second induction course. Overall 60-days mortality was 4%. After two induction cycles, 87 patients achieved CR (87%). Thirty-three/101 (33%) CR patients underwent BMT in first CR. After a median follow up of 71 months, 3-year overall survival (OS) was 52.3% (median 65 months). OS duration was significantly longer in NPM1 mutated patients ($p < 0.05$) and in in patients achieving MRD-negative status after induction (both MFC and NPM1 based MRD) after induction ($p < 0.001$). Overall survival (OS) was comparable in patients with isolated NPM1 mutation and in those with concomitant NPM1/FLT3-ITD mutation (3-year OS 57.6% and 51.7%, respectively, p= n.s), regardless of FLT3-ITD allelic burden. Patients with isolated FLT3-ITD mutation had a significantly worse prognosis (3-year OS 38.7%, $p < 0.05$). Multivariate analysis showed that persistence of MRD (by any method, $p < 0.05$) was the strongest predictor of outcome. Interestingly, performing BMT in first CR did not impact OS both in univariate and multivariate analysis (Figure 1).

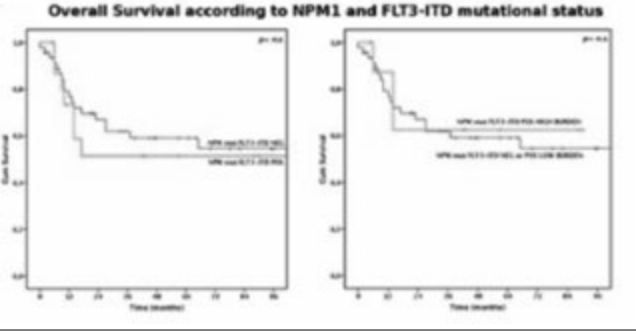

Figure 1.

Summary/Conclusion: Despite the potential bias due to the retrospective nature of the analysis, our data seem to indicate that FLAI displays a strong anti-leukemic efficacy in patients carrying NPM1 mutation irrespectively of FLT3-ITD mutational status. The synergism of fludarabine and cytarabine might increase the chemosensitivity of NPM1 mut leukemic cells, thus overcoming the negative impact of FLT3-ITD.

PS1002

CLINICAL CHARACTERISTICS AND PROGNOSIS OF 34 CASES OF ACUTE MYELOID LEUKEMIA WITH FLT3 INTERNAL TANDEM DUPLICATION AND MLL GENE REARRANGEMENT

J. Zhou[1], X. Zhang[1], Y. Zhao[1], J. Yang[1], J. Zhang[1], X. Cao[1], Y. Lu[1], D. Liu[1], F. Lv[1], J. Ouyang[1,*], P. Lu[1], D. Lu[1]

[1]Hematology, Hebei Yanda Ludaopei Hospital, Langfang Shanghe city Hebei Province, China

Background: The internal tandem duplication (ITD) of the juxtamembrane region of the FLT3 receptor tyrosine kinase gene and MLL gene rearrangement have been described in acute myeloid leukemia (AML) patients. These alterations have been associated with a poor prognosis. The data about the AML patients with both FLT3-ITD and MLL gene abnormalities is scarce. In our study, we retrospectively analysis of clinical features and prognosis in 34 AML patients with both FLT3-ITD and MLL gene abnormalities.
Aims: To analyze the clinical characteristics and prognosis of 34 cases of AML with FLT3 internal tandem duplication(FLT3-ITD) and MLL gene rearrangement.
Methods: The clinical data of 34 AML patients with FLT3-ITD and MLL gene rearrangement was compared and analyzed for the therapeutic efficacy, influencing factors when treated with chemotherapy, chemotherapy combined with targeted therapy or allogenic hematopoietic stem cell transplantation (allo-HSCT).
Results: Of the thirty-four cases with median age 41 (4-71), 63.6% presented with white blood cells (WBC) greater than 30×10^9/L , 39.4% greater than 50×10^9/L respectively on admission. M5 (35.3%) made up the highest proportion. The cytogenetic abnormality reached 63.64%, of which the complex cytogenetic abnormality accounted for 12.12%. Eleven patients (32.35%) had both FLT3-ITD and MLL gene abnormalities. In addition to FLT3 and MLL abnormalities, 23 patients (67.65%) had one or more other gene abnormalities (multiple gene abnormalities). Of the 34 cases, 29.4% patients went into complete remission (CR) after two courses of chemotherapy. 20.6% (7 patients) went into CR after 3 or more courses of chemotherapy. The rate of early recurrence in the CR of this group of patients was 52.9%. Patients with WBC> 50×10^9/L, cytogenetic abnormalities and multiple gene abnormalities had a lower remission rate (5.43% -19.04%) after two courses of chemotherapy. The CR rate for the patients with more than three gene abnormalities was 0.00%. The total 2-year overall survival (OS) in the 34 patients was 28.8% (95% CI 13.5% -46%) and the disease-free survival (DFS) was 27.1% (95% CI 12.5% -44%). Of the 18 patients treated with chemotherapy alone or chemotherapy combined with targeted therapy, 17 cases died within 2 years and 1 lost follow-up after giving up treatment. For the 16 patients received allo-HSCT, the three-year OS was 43.4% (95% CI 13.7% to 70.4%) and DFS 42.7% (95% CI 13.4% to 69.7%).
Summary/Conclusion: AML patients with FLT3-ITD and MLL gene rearrangement often presented with M5, accompanied by hyperleukocytosis, cytogenetic or multiple gene abnormalities. Those patients were observed to have low response rate and high early recurrence when treated with chemotherapy without allo-HSCT. Patients had multiple gene abnormalities may be an important poor prognostic factor. Allo-HSCT is an effective treatment which could significantly improve the prognosis and survival of AML patients with FLT3-ITD and MLL gene abnormalities.

PS1003

PROGNOSTIC RELEVANCE OF FLT3, NPM1, DNMT3A, IDH1/2 GENE MUTATIONS IN ACUTE MYELOID LEUKEMIA PATIENTS

E. Motyko[1,*], I. Martynkevich[1], O. Blau[2], L. Polushkina[1], L. Martynenko[1], M. Bakai[1], N. Cybakova[1], I. Ruzhenkova[1], E. Kleina[1], N. Pavlenko[1], A. Radzhabova[1], C. Baldus[2], I. Blau[2], S. Voloshin[1], A. Chechetkin[1]

[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Saint-Petersburg, Russian Federation, [2]Charité University School of Medicine, Berlin, Germany

Background: Acute myeloid leukemia (AML) is a heterogeneous disease characterized by differentiation arrest and uncontrolled clonal proliferation of immature hematopoietic precursors. The prognosis of AML is variable, partly based on clinical features (patient age, medical comorbidities, performance status) and also on underlying genetic characteristics (cytogenetic and molecular aberrations). The development of new classification strategy is an important step in understanding the molecular complexity of AML and also leads to new targeted therapy.
Aims: To analyze the prognostic effect of typical mutations in AML patients.
Methods: The study included 620 AML patients, treated in Saint-Petersburg and Berlin. Cytogenetic analysis was performed using standard GTG-method. Screening of mutations in genes *FLT3, NPM1, DNMT3A, IDH1/2* was realized by PCR, DNA fragment analysis and sequencing.
Results: Mutations were found in 343/620 (55.3%) AML patients and were more often detected in patients with normal karyotype (NK) (220/328 (67.1%)) (p=0.001). Single gene mutations were revealed in 199/343 (58.0%) patients. The presence of *FLT3*-ITD mutation was associated with adverse overall survival (OS) and relapse-free survival (RFS): 11.3 and 15.8 months (*FLT3*-ITD-), p=0.005; 10.0 and 13.3 months (*FLT3*-ITD +), p=0.009, respectively. Increased *FLT3*-ITD allelic ratio (≥0.5) correlated with low OS (p=0.028). Patients with single *NPM1* mutation reached significantly better OS and RFS compared to other patients (27.4 and 13.9 months, p=0.040, 19.3 and 12.0 months, p=0.049, respectively). The negative influence of *DNMT3A* gene mutations on OS was not significant: 12.0 (*DNMT3A*+) and 15.0 (*DNMT3A*-) months (p=0.112). The presence of *IDH1*+ mutation (R132) correlated with better OS (p=0.092), whereas polymorphism rs11554137 in *IDH1* gene - with worsening of outcome in the group of patients with NK (p=0.186). In 144 patients various combinations of 2 to 5 mutations were detected. It was found that mutations in *FLT3* (*FLT3*-ITD), *NPM1, DNMT3A* and *IDH2* genes were significantly more often detected in combination with other mutations, than alone (p=0.001). The most frequent combinations were: *NPM1+/FLT3*-ITD+ (20.8%), *NPM1+/FLT3*-ITD+/*DNMT3A*+ (8.3%) and *FLT3*-ITD+/*DNMT3A*+ (8.3%). Patients with single mutation had significantly longer OS compared with patients with 2 mutations (18.1 and 12.2 months, p=0.003). For patients with *NPM1*+ the most unfavorable OS was found in the presence of *FLT3*-ITD (27.4 and 9.2 months, p=0.019), and a combination of *FLT3*-ITD+/*DNMT3A*+ (27.4 and 14.6 months, p=0.141). Patients with *DNMT3A*+ tended to have lower OS in the presence of *FLT3*-ITD mutation (17.3 and 7.1 months, p=0.074).
Summary/Conclusion: Mutations in analyzed genes are frequent in intermediate risk group of AML patients. They significantly affect the prognosis. Our data support the importance of the type of mutation, its allele ratio and the presence of additional mutations. The presence of 2 mutations significantly reduces OS compared to patients with one mutation. The worst prognosis was found in patients with following mutations combinations: *NPM1+/FLT3-ITD+, NPM1+/FLT3*-ITD*+/DNMT3A+, DNMT3A+/FLT3-ITD+*. Complex analysis of genetic aberrations in AML patients provides the most accurate prognosis prediction and planning of targeted therapy.

PS1004

IMPACT OF BCL2 AND ABCG2 OVEREXPRESSION IN ACUTE MYELOID LEUKEMIA

M. Tiribelli[1,*], M. Cavallin[1], S. Di Giusto[1], E. Toffoletti[1], D. Lazzarotto[1], R. Fanin[1], D. Damiani[1]

[1]Division of Hematology and BMT, Azienda Sanitaria Universitaria Integrata di Udine, Udine, Italy

Background: ABCG2, the last discovered member of ABC transporter family, is frequently overexpressed in acute myeloid leukemia (AML). A high expression at diagnosis has been associated with increased AML relapse after conventional chemotherapy and after stem cell transplantation. In the last years the ABCG2 substrate spectrum has greatly increased, including so called "target drugs" directed against molecular markers of hematologic malignancies but often with non-univocal effects. Among these drugs interacting with ABCG2 there are also Bcl2 inhibitors, recently approved for lymphoproliferative disorders but under active investigation also in AML, where their use appears rationale due to the negative role of Bcl2 overexpression. Data on cell lines suggest that at least venetoclax could be an ABCG2 inhibitor, so potentially sensitizing cell to chemotherapeutics.
Aims: To evaluate the incidence of concomitant ABCG2 and Bcl2 overexpression in AML, to assess their impact on response to therapy and to possibly identify subsets of patients with the highest drug sensitivity.
Methods: ABCG2 and Bcl2 expression was evaluated by flow cytometry in 290 adult patients with non-promyelocytic AML. Logistic regression was employed to assess their association with other clinical and biological features and with response rate. Leukemia free survival (LFS) and overall survival (OS) in the different subgroups were compared by log-rank test.

Results: ABCG2 overexpression was found in 116/290 patient (40%) and Bcl2 was overexpressed in 190/290 (65%) patients. Eighty-one patients (28%) were double positive (DP), 65 (22%) were double negative (DN) and 144/290 (50%) expressed either ABCG2 or Bcl2. WBC count ad diagnosis was higher in DP patients (mean $52\pm78\times10^9$/L vs $30\pm35\times10^9$/L in other groups; p=0.04) and DN patients were younger (mean age 52±11 years vs 62±14 years in other groups; p=0.02). No patient with favorable karyotype was observed among DP cases compared to 16 patients in other groups (0% vs 18%; p=0.003). CD34-negativity was significantly more common in DN patients (32/56, 57% vs 92/224, 41%; p=0.03). No difference was observed in CD56 expression, frequency of Flt3-ITD mutation and NPM1 mutation. No difference in OS was observed according to Bcl2 and/or ABCG2 expression. Considering disease relapse, Bcl2 expression "per se" did not affect LFS in ABCG2 negative cases but have a negative impact in ABCG2 positive patients. So, we can identify 3 groups with significantly different LFS: 3-years LFS was 25% (95%CI: 9-40) in ABCG2+/Bcl2+ patients, compared to 46% (95%CI: 24-68) in ABCG2+/Bcl2- patients and 61% (95%CI: 48-74) in ABCG2- patients, irrespectively of Bcl2 (p=0.008) (Figure 1).

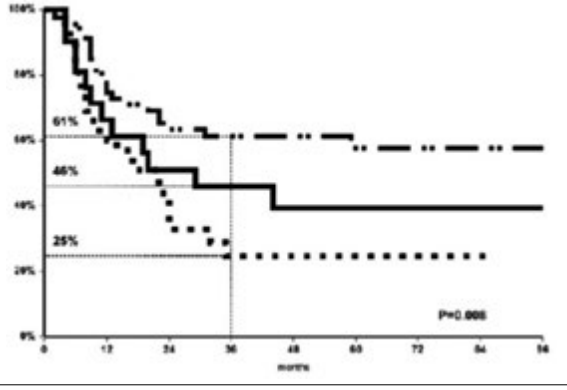

Figure 1. Leukemia free survival.

Summary/Conclusion: The effect of ABCG2 and Bcl2 concomitant overexpression in AML has never been described. Our data suggest an additive negative impact of Bcl2 overexpression in ABCG2 patients. Further *in vitro* data are needed to investigate the effect of Bcl2 inhibitors on ABCG2 efflux activity, to prove the hypothesized sensitizing action of Bcl2 inhibitors and to identify patients who may maximally benefit from combination therapy to reduce the risk of AML recurrence.

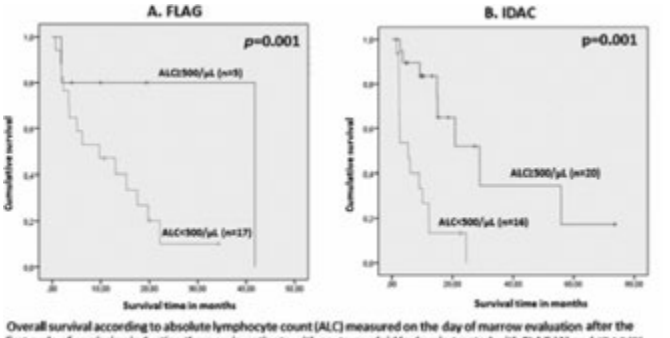
PS1005

ABSOLUTE LYMPHOCYTE COUNT RECOVERY AFTER INDUCTION REMISSION THERAPY IS A STRONG PREDICTOR OF OVERALL SURVIVAL IN ADULT ACUTE MYELOID LEUKAEMIA

J. Infante[1,*], H. Martins[1], S. Valle[1], G. Esteves[1], J. Raposo[1]

[1]Serviço de Hematologia e Transplantação de Medula Óssea, Centro Hospitalar Lisboa Norte - Hospital de Santa Maria, Lisboa, Portugal

Background: Acute Myeloid Leukaemia (AML) carries a dismal prognosis, with an estimated 5-year overall survival (OS) of 30%. Achievement of a complete response (CR) after remission induction therapy (IT) is an independent prognostic marker for OS in AML. Response criteria include evaluation of the peripheral blood for neutrophil and platelet recovery only, with no defined significance for lymphocyte recovery.
It has been proposed that an adequate absolute lymphocyte count (ALC) after IT may reflect a deeper marrow leukaemia cell burden reduction with restoration of hematopoietic function, and that these lymphocytes may exert an antileukemic effect and prevent serious infections. Whether lymphocyte recovery after IT has an impact on prognosis is unclear, and few studies have focused on the subject.
Aims: To determine the impact of ALC recovery after a first cycle of IT on OS in adults with newly diagnosed AML.
Methods: Between 2012 and 2017, 64 patients with previously untreated acute myeloid (non-promyelocytic) leukaemia received IT at our center – 36 received IDAC (idarubicin 12 mg/m^2×3 days plus cytarabine 100 mg/m^2×7 days) and 18 received FLAG (fludarabine 30 mg/m^2×5 days plus cytarabine 2 g/m^2×5 days). Patients who died during aplasia were excluded (n=10). Baseline patient characteristics and performance status, cytogenetic risk, type of treatment, response to treatment and the ALC on the day of morphologic marrow evaluation (between days 21-30 after first cycle of IT) were collected. All patients were followed until death or until the end of the observation period on February 22nd 2018.
In each treatment group, patients were separated according to the ALC: less than 500/µL (n=14 with FLAG, n=16 with IDAC) and 500/µL or more (n=4 with FLAG, n=20 with IDAC). Survival analysis with Kaplan-Meier curves was performed for each group and multivariate survival analysis using Cox's regression model was performed.
Results: Median age of this population was 62 years (range, 17-79). CR and CR with incomplete hematologic recovery rates were 36% and 19% in the IDAC group, and 28% and 17% in the FLAG group, respectively.
On univariate analysis, an ALC<500 cells/µL was significantly associated only with an ECOG performance status of 1 (p=0.01) versus 0 in the IDAC-treated group; there was no association with response to induction nor cytogenetic risk groups. Median follow-up time was 22.55 months. Overall, median survival was 15.32 months for FLAG-treated patients and 12.20 months for IDAC-treated patients (p=0.839). IDAC-treated patients had a median survival of 28.99 months if N>500/µL and 5.33 months if <500/µL. FLAG-treated patients had a median survival of 41.82 months if N>500/µL and 12.99 months if <500/µL (Figure 1). Difference between survival curves was statistically significant (log-rank test p<0.001), before and after adjusting for treatment protocol. After adjusting for high-risk cytogenetics, treatment protocol and achievement of a CR/CRi using a Cox Regression model, the only independent predictor of death was an ALC<500/µL after IT (HR 7.45, 95% CI 2.00-27.83).



Overall survival according to absolute lymphocyte count (ALC) measured on the day of marrow evaluation after the first cycle of remission induction therapy, in patients with acute myeloid leukemia treated with FLAG (A) and IDAC (B).

Figure 1.

Summary/Conclusion: An ALC<500/µL after the first cycle of IT independently predicts an inferior OS, independently of treatment with IDAC or FLAG. Adjusting for validated predictors of reduced survival in the literature, the ALC was still the only parameter to predict OS. These results suggest that the ALC after IT, a widely available and inexpensive parameter, could be useful in establishing prognosis early in the course of treatment of AML.

PS1006

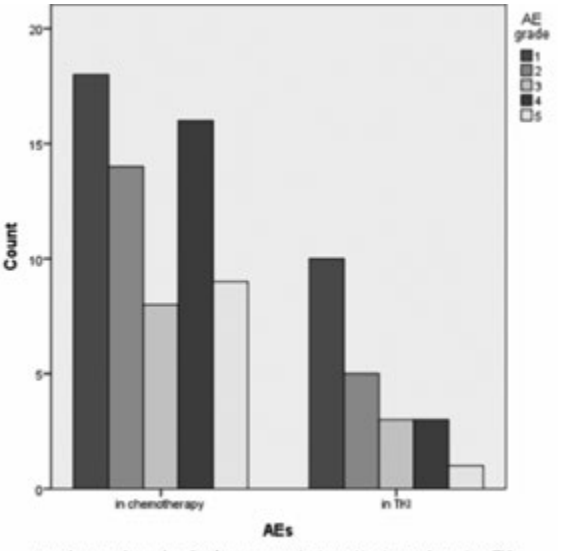
TYROSINE KINASE INHIBITORS (TKI) IN RELAPSED/REFRACTORY (RR) PATIENTS WITH FLT3-ITD POSITIVE ACUTE MYELOID LEUKEMIA (AML) CONFER BETTER SURVIVAL THAN CHEMOTHERAPY, DUE TO A BETTER SAFETY PROFILE

G. Marconi[1,*], S. De Polo[1], E. Ottaviani[1], S. Paolini[1], M.T. Bochicchio[1], J. Nanni[1], L. Bertamini[1], M. C. Abbenante[1], C. Sartor[1], S. Parisi[1], A. Talami[1], M. Olivi[1], S. Ragaini[1], M. Raffini[1], C. Baldazzi[1], N. Testoni[1], M. Cavo[1], A. Curti[1], G. Martinelli[1,2], C. Papayannidis[1]

[1]Istituto di Ematologia e Oncologia Medica "Lorenzo e Ariosto Seràgnoli", bologna, [2]Istituto Scientifico Romagnolo Per Lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy

Background: Approximately 20-30% of AML patients harbor internal tandem duplication (ITD) of FLT3 gene. FLT-ITD mutations are associated with a poor prognosis, due to a high relapse rate. Several drugs have been developed to inhibit FLT3. However, R/R FLT3-ITD AML patients still represent an unmet clinical need.
Aims: Since no prospective randomized studies comparing the role of chemotherapy and TKIs in R/R FLT3 ITD AML patients have been conducted, our aim is to assess outcome, safety and duration of hospitalizations in two retrospective groups of patients, referred to or diagnosed at our Institution, and treated with TKIs or chemotherapy, respectively.
Methods: We retrospectively collected and analyzed clinical and biological data of 58 consecutive FLT3-ITD AML patients, treated at our Institution

from 2004 to 2017 with chemotherapy (3+7 like regimens; 3+7 like regimens with the addition of a third agent; fludarabine based regimens) and/or single agent TKIs (Sorafenib, Ponatinib, Quizartinib, Gilteritinib, Midostaurin). All the patients underwent any kind of therapy after informed consent was signed.



number and grade of adverse events in patients undergoing TKI compared with patients treated with chemotherapy (p=.049).

Figure 1.

Results: We compared patients who received at least once in their life, as salvage treatment, a TKI inhibitor ("TKI" group; N=36) with patients that were treated exclusively with conventional cytotoxic ("conventional group"; N=22). The median age of the entire population was 59 years (range 17-74); there were no significant differences in patient age, white blood cells count, platelet count and ELN risk at diagnosis between the two groups. Fifty-one out of 58 patients (86%) relapsed after (N=22; 36%) or were refractory (N=29; 50%) to the first course of induction chemotherapy. Second-line therapy included salvage chemotherapy (N=32/51, 63%), a TKI as single agent (N=12/51, 23%) or best supportive therapy (N=14%, 7/51). Forty-one patients experienced a 2nd relapse, or were persistently refractory, and of these 18 received a single agent TKI as salvage treatment. Six patients received a TKI in 3rd or further relapse.Standard chemotherapy compared with TKIs did not show an increased efficacy in terms of CR (25% vs 16.7%), and it was not a better bridge-to-transplant option. However, among R/R patients, we observed an advantage in terms of OS for patients of the "TKI" group compared with "conventional" group (median OS from R/R of 10 months [95% CI, 5.89-14.12] and 4 months [95% CI, 3.12- 4.90], respectively; p= .017). Finally, as far as toxicity is concerned, patients in "TKI" group experienced a lower number of AEs during treatment with TKIs (1.63 mean AEs in each TKI line vs 3.03 mean AEs in each chemotherapy line, excluding stem cell transplant; p< .001; grade III-IV 6/23 and grade V 2/23 with TKI; grade III-IV 24/66 and grade V 12/66 with chemotherapy). Furthermore, AEs during TKI therapy were less severe if compared with AEs during chemotherapy (Figure 1, p= .049). We also noted a trend toward less day spent in hospital per month by patients during TKI treatment, compared to patients treated with standard chemotherapy (including post chemotherapy remission period): 10.5 days and 16.7 days in the two groups, respectively.

Summary/Conclusion: Our study, even if in a retrospective set, reports a survival advantage of TKI in R/R FLT3 ITD AML patients, compared with conventional approaches. Such an advantage is due to the lower number and grade of AEs of "TKI" group. For their safety profile, TKIs are probably a better option to bridge patients to transplant, thanks to a lower risk of toxicity. *Supported by: ELN, AIL, AIRC, FP7 NGS-PTL project; GM and SDP equally contributed*

ADDITION OF BORTEZOMIB TO AML-LIKE TREATMENT FOLLOWED BY NMA ALLO-SCT IN PATIENTS WITH BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM

E. Reuben Tolley[1,*], E. Clasen-Linde[2], H. Sengeløv[1], L. Smidstrup Friis[1], I. M. Schjødt[1], P. Kampmann[1]

[1]Dept. of Hematology, [2]Dept. of Pathology, Rigshospitalet, Copenhagen O, Denmark

Background: Blastic plasmacytoid dndritic cell neoplasm (BPDCN) is an aggressive, rare hematopoietic malignancy derived from CD4+ CD56+ precursors of plasmacytoid dendritic cells. The skin is the most common site (64-100%) but involvement of the bone marrow and peripheral blood (60-90%) and lymph nodes (40-60%) is frequent. The BPDCN immunohistophenotype is characterized by the co-expression of CD4, (CD43, CD45RA,) and CD56 and associated antigens CD123, CD303 (BDCA2), TCLA1, CD2AP, SPIB, MT1 as well as negativity in regard to specific myeloid, T- and B-cell markers. Genetic profiling finds complex karyotypes with 2/3 of the patients but no specific chromosomal aberrations. Gene expression however shows noticeable alterations including aberrant activation of the NF-kappaB pathway. The prognosis is poor with a median survival of 10.0-19.8 months. Transplant-eligible patients are treated with typically standardized ALL or AML-regimes followed by allogenic stem cell transplantation (allo-SCT) in first CR. The majority of patients show a clinical response to treatment, but approximately 1/3 of the patients relapse despite allo-SCT. There is no consensus regarding standard treatment. Novel treatment options have suggested targeting of the nuclear factor-kappa B pathway and recent murine studies have shown that treatment with Bortezomib significantly increased the animals' survival.
Aims: In this article we present three cases of BPDCN with different clinical presentations. In all cases treatment with standardized AML-regimes was combined with off-label use of Bortezomib + Dexamethasone in an adapted Multiple Myeloma dosing schedule before undergoing non-myeloablative allogeneic hematopoietic stem cell transplantations (NMA allo-SCT).
Methods: Patient 1 had primarily received standard AML-regime treatment, but relapsed in CNS. The relapse brought in remission with triple-IT and Bortezomib before undergoing NMA allo-SCT. Patient 2 was given AML induction therapy combined with Bortezomib + Dexamethasone and prophylactic Triple IT treatment. This was repeated after reinduction and consolidation with Cytosar before undergoing NMA allo-SCT. Patient 3 received AML induction combined with Bortezomib + Dexamethasone and Triple It. Patient 3 relapsed and was brought into remission with one serie FLAG-Mitox followed by one serie NOPHO high risk Block A regime before NMA allo-SCT.
Results: All three patients are in CR 3, 2,5 and 2 years after NMA allo-SCT respectively and thus still alive past the time of median survival for BPDCN reported in literature. (Table 1).

Table 1.

Patient	Age	Sex	Location	Immunophenotype	Treatment	Relapse	Complications
Pt 1	60	M	Lymph nodes/ Bone marrow	Pos: CD 4+, CD 56+ Neg: myeloid, B and T-cell markers Not tested: CD123, CD303 (BDCA2), TCLA1, CD2AP, SPIB, MT1	1. DA 3+10 2. DA 3+8 3. Consolidation, multiple triple IT, Bortezomib+ Dexamethasone 4. NMA Allo-SCT	Yes, before Allo-SCT. CNS involvement. Remission on Triple IT and Bortezomib	Pre transplant: Parasthesis bilat in lower extremities Post transplant: Skin: GvH stadium II, complete remission
Pt 2	64	F	Skin	Pos: CD 4+, CD 56+, CD 123+ Neg: Myeloid, B- and T-cell markers Not tested: CD303 (BDCA2), TCLA1, CD2AP, SPIB, MT1	1. DA 3+10, Prophylactic Triple IT, Bortezomib + Dexamethasone 2. DA3+8 Prophylactic Triple IT, Bortezomib+ Dexamethasone 3. Consolidation, Prophylactic Triple IT, Bortezomib + Dexamethasone 4. Consolidation, Prophylactic Triple IT 5. NMA Allo-SCT	No	Pre transplant: Parasthesis of lower extremities Post transplant: Cronic oral GvH and skin GvH with sclerodermia
Pt 3	64	F	Bone marrow	Pos: CD 4+, CD 56+, CD 123+ Neg: Myeloid, B- and T-cell markers Not tested: CD303 (BDCA2), TCLA1, CD2AP, SPIB, MT1	1. DA 3+10, Prophylactic Triple IT, Bortezomib + Dexamethasone 2. DA3+8 Prophylactic Triple IT, Bortezomib+ Dexamethasone 3. FLAG-Mitox 4. NOPHO block A 5. NMA Allo-SCT	Yes, before Allo-SCT. BM. 1 curis of FLAG-Mitox and 1 curis of NOPHO block A CR before ITC	Post transplant: Skin: Chronic GvH

Summary/Conclusion: We conclude that addition of Bortezomib + Dexamethasone to AML-Like induction and consolidating regimens followed by Non-Myeloablative Allogeneic Hematopoietic Stem Cell Transplant is feasible with acceptable peripheral neuropathic toxicity.

PS1008

BLAST TRANSFORMATION IN MYELODYSPLASTIC AND MYELOPROLIFERATIVE NEOPLASMS - SIMILARITIES AND DIFFERENCES - A REVIEW OF 100 CASES

M. Jagurinoski[1,*], M. Stoychov[1], Y. Petrov[1], V. Madzarova[1], S. Angelova[1], G. Balatzenko[1], B. Spassov[1], M. Guenova[1]

[1]Specialized Hospital for Active Therapy of Hematological Diseases, Sofia, Bulgaria

Background: Myelodysplastic syndromes (MDS) and myeloproliferative neoplasms (MPN), i.e. chronic myeloid leukemia (CML) and Ph(-)MPNs, are clonal disorders of hematopoiesis characterized by high rates of genetic alterations and an increasing predisposition to transform to acute leukemia (AL).
Aims: To compare the main features of pts with blast transformation (BT) of MDS or MPN with *de novo* acute myeloid leukemia with myelodysplasia-related changes (AML-MDS), and to assess survival after BT.
Methods: Our study includes 100 pts, 60 men/40 women: BT of Ph(-)MPNs (n=20), CML (n=18),MDS (n=30), AML-MDS (n=32). Demographic, morphological, phenotypic, cytogenetic and survival data were evaluated.
Results: The comparative analysis did not show significant differences in gender and age within disease entities, except for the younger age in CML (p=0.005). There was no difference in Hb levels (mean 82.9±18.8 g/l) and blast% (mean45.3±20.6), while BT in Ph(-)MPNs and CML was characterized by signficantly higher mean PLT counts and the mean WBC count was higher in CML. Morphologically, as opposed to AML-MDS (96.8%) and MDS (96.4%), dysplasia in ≥ 2 lineages was found in only 33.3% and 44.4% of CML and MPN, respectively (p=0.000). The blast cell phenotype was generally myeloid, except 4 CML lymphoid blast crises(BC). On average, 67.4% of all groups (incl. all myeloid CML BC) had aberrant co-expression of 1-4 lymphoid-associated markers, most commonly CD7, CD19, CD56, CD22. The genetic profile demonstrated significant differences as well. Higher incidence of abnormal karyotypes was found in AML-MDS compared to BT of MDS and CML aside of Ph' chromosome (p=0.042). Chromosomal aberrations were found in 80% with Ph(-)MPNs, however the number of successful karyotypes was low. The molecular pattern also differed within the groups. The incidence of *FLT3-ITD* was higher in AL after MDS compared to AML-MDS and MPN, while *EVI1* overexpression was found at the time of BT in a high proportion of CML and Ph(-)MPN. No significant difference was observed in regard to *NPM1* mutations. The mean time to BT was signficantly shorter in MDS (12.5±23.0 mo) compared to MPN (32.4±34.5 mo) and CML (34.1±25.2 mo) (p=0.033) and the mean overall survival after the BT was poorer in MDS and MPN compared to CML BC and *de novo* AML-MDS (Table 1).
Summary/Conclusion: The main clinical and laboratory characteristics of AL occurring *de novo* or based on a BT of a previous MDS or MPN highlights both similarities and certain differences in the biology and clinical course and may require a different therapeutic approach in future. However, the outcome of pts with BT after MDS or MPN is poor and attempts should concentrate on early identification of pts at risk for disease progression.

Table 1.

Variables	Ph(-) MPN	CML	MDS	De novo AML-MDS	P
Age years (mean, SD)	64.8±10.5	49.2±14.1	61.2±16.9	62.8±13.9	0.005
WBC x10⁹/L (mean, SD)	63.9±61.9	227.3±426.3	25.8±42.7	16.1±33.3	0.002

QUALITY OF LIFE IN ACUTE LEUKEMIA PATIENTS WITH COMORBID ISCHEMIC HEART DISEASE

T. Lymanets[1,*], I. Skrypnyk[1], G. Maslova[1], I. Gusachenko[2]

[1]Chair of Internal Medicine #1, Ukrainian Medical Stomatological Academy, [2]Hematology Department, Poltava Regional Clinical Hospital n.a.M.V. Sklifosovsky, Poltava, Ukraine

Background: Due to significant advances in the treatment of oncohematological patients their survival rates, life expectancy and progression-free period have been greatly improved. The study of quality of life (QoL) parameters in patients with acute leukemia during the induction chemotherapy (ICT) has aquired special interest. Patients with comorbid ischemic heart disease (IHD) are at extremely high risk of anthracycline cardiotoxicity development that may significantly reduce their QoL.
Aims: To assess quality of life before and after induction chemotherapy in acute leukemia patients with comorbid ischemic heart disease depending on prescribed cardioprotective therapy.
Methods: The study involved 66 patients with newly diagnosed acute leukemia (acute lymphoblastic leukemia - 7, acute myeloblastic leukemia - 59 patients) and comorbid IHD, treated with ICT at Hematology Department, Poltava Regional Clinical Hospital n.a.M.V. Sklifosovsky, Ukraine. The cohort consisted of 34 (51.5%) males and 32 (48.5%) females, age of 54-72 years, ECOG I-II. The duration of IHD ranged from 3 to 15 years. QoL of patients was assessed using a questionnaire SF-36 V2 counting the physical and mental components of health before treatment and after ICT before remission consolidation. The study was approved by the local ethical committee and all patients gave a written consent before they were included in the study. Patients were divided into two groups: I (n=36)-patients treated with ICT; II (n=30)-patients, whom during the ICT L-arginine was prescribed.
Results: At baseline, all patients had significantly lower QoL, both physical and mental components of health, compared with healthy respondents (Table 1). The newly diagnosed acute leukemia in combination with currently existing IHD had a great influence on different aspects of subjective well-being. At follow-up, we noticed a significant improvement of physical functioning, vitality, general and mental health in patients of group I; and role physical, vitality, bodily pain and role emotional QoL parameters' improvement in patients of group II. The average physical status indicators in patients of groups I and II did not significantly change. At the same time, the mental status of patients improved: in group I in 1.3 times (37.3±2.82 vs 28.3±2.37 before ICT, p<0.05), in group II – in 1.4 times (37.6±3.46 vs 27.5±3.04 before ICT; p<0.05). Differences between groups were not statistically significant on all scales. However, in comparison with the data of practically healthy individuals, QoL of patients with acute leukemia after ICT remained significantly lower.

Table 1.

Quality of life in patients with acute leukemia and comorbid ischemic heart disease

PCS (physical component summary)	57.5±1.26	36.4±2.34*	40.8±2.60*	37.9±2.45*	42.5±2.65*
MCS (mental component summary)	51.6±3.29	28.3±2.37*	37.3±2.82*√	27.5±3.04*	37.6±3.46*√

Note: significant differences, p<0.05: *– between indicators of healthy persons and in the group; √ – between indicators before and after induction chemotherapy.

Summary/Conclusion: The QoL assessment in patients with acute leukemia and ischemic heart disease during induction chemotherapy is an important component of oncological patient's management, which allows to individualize the approach to each patient in the presence of this type of comorbidity. Psychological and supportive therapy during induction chemotherapy could improve QoL of these patients.

Aggressive Non-Hodgkin lymphoma – Clinical

Background: The global trial JULIET (NCT02445248) is evaluating the efficacy and safety of tisagenlecleucel in adult patients (pts) with R/R DLBCL. Tisagenlecleucel is an autologous chimeric antigen receptor (CAR)–expressing T-cell therapy targeting CD19+ cells.
Aims: To explore the potential correlation of tisagenlecleucel efficacy with CD19 and immune checkpoint protein expression in pre-infusion biopsies of patients with DLBCL.
Methods: Exploratory analyses were conducted in archival formalin-fixed, paraffin-embedded tumor tissue samples collected months prior to infusion. 92 patients were evaluated for efficacy as of September 6, 2017; 81 had baseline biopsy results included in this analysis. Of these samples, the majority were collected within 1-year pre-infusion (8 from 1-3 months, 26 from 3-6 months, and 25 from 6 months to 1 year). Quantitative immunofluorescence and image analyses by AQUA Technology were used to evaluate relative levels of CD19, presence of total PD-L1+ cells, and frequency of T cells and non–T cells positive for immune checkpoint molecules (PD-1, LAG3, TIM3). PD-1/PD-L1 interaction scores, defined as the proportion of PD-1–positive cells colocalized with PD-L1–positive cells, were also derived. Results were assessed in the context of response to tisagenlecleucel to investigate a potential relationship between tissue biomarkers and efficacy.
Results: Response to tisagenlecleucel was observed in pts whose tumor samples showed unequivocal CD19-positive expression (best overall response rate [ORR], 49% [95% CI, 34%-64%]) and pts with low/negative CD19 expression (best ORR, 52% [95% CI, 31%-73%]). No apparent differences were observed among the best overall response (BOR) groups (CR, PR, SD, PD, unknown) in median or mean levels of the percentages of PD-L1+, PD-1+, LAG3+, or TIM3+ cells. Similarly, no apparent differences were observed between BOR groups in median and mean levels of: proportions of PD-1+, LAG3+, and TIM3+ T cells and PD-1/PD-L1 interaction scores.
Despite no apparent differences, some markers showed higher expression in a small subset of patients in whom tisagenlecleucel had reduced efficacy. The 5 patients with the highest PD-1/PD-L1 interaction score did not respond to tisagenlecleucel or relapsed by month 3. Likewise, the 10 patients with the highest proportion of LAG3+ T cells did not respond to tisagenlecleucel or relapsed by months 3-6 (by objective response criteria or according to clinical criteria). Furthermore, of 8 pts with the highest percentage (> 30%) of PD-1+ cells (in areas selected based on high PD-L1 expression), only 2 responded to tisagenlecleucel, and 1 progressed at month 3. Interestingly, the majority of PD-1+ cells in these 8 patients were not T cells, as the percentage of T cells was much lower than the percentage of PD-1+ cells. Additional analysis correlating tissue biomarkers with efficacy will be presented.
Summary/Conclusion: These preliminary exploratory biomarker data indicate similar response rates across all CD19 expression levels. Furthermore, a small subset of pts with the highest levels of PD-1/PD-L1 interaction score, PD-1+ cells, and high proportion of LAG3+ T cells (among T cells present) seem to not respond to tisagenlecleucel or have early relapse. These preliminary observations require further investigation but nonetheless raise the possibility that patients with a high PD-1/PD-L1 interaction score, a high proportion of PD-1+ cells, and/or a high proportion of LAG3+ cells present among T cells, may experience reduced tisagenlecleucel efficacy.

PS1011

ACALABRUTINIB IN COMBINATION WITH THE PI3Kδ INHIBITOR ACP-319 IN PATIENTS WITH RELAPSED/REFRACTORY B-CELL MALIGNANCIES

P. M. Barr[1,*], S.D. Smith[2], M. Roschewski[3], S.M. O'Brien[4], J. Sharman[5], J.M. Melear[6], A. Hamdy[7], R. Izumi[7], J.G. Slatter[7], N. Chernyukhin[7], E. Bibikova[7], M. Yin[7], T. Chen[7], S. E. Spurgeon[8]

[1]Wilmont Cancer Institute, University of Rochester Medical Center, Rochester, [2]University of Washington/Fred Hutchinson Cancer Research Center, Seattle, [3]National Cancer Institute, Bethesda, [4]Chao Family Comprehensive Cancer Center, University of California-Irvine, Irvine, [5]Willamette Valley Cancer Institute and Research Center, US Oncology Research, Springfield, [6]Texas Oncology, Austin, [7]Acerta Pharma, Redwood City, [8]Center for Hematologic Malignancies/Knight Cancer Institute, Oregon Health and Sciences University, Portland, United States

Background: Bruton tyrosine kinase (BTK) is a clinically validated target in B-cell malignancies. Acalabrutinib is a selective, covalent inhibitor of BTK. Preclinical studies show synergy with combined BTK and PI3K inhibition in B-cell lymphoma (Griner *PNAS* 2014).
Aims: Acalabrutinib was evaluated in combination with the PI3Kδ inhibitor ACP-319 in patients with relapsed/refractory B-cell malignancies.
Methods: Patients with relapsed/refractory B-cell malignancies, ≥1 prior therapy and ECOG PS ≤2 received oral acalabrutinib 100 mg bid and ACP-319 in escalating doses (25/50/100 mg bid [n=6 per dose]; Part 1) or 50 mg bid (expansion cohort; Part 2) until progressive disease or unacceptable toxicity. The primary endpoint was safety (including dose-limiting toxicity [DLT] in Part 1). Secondary endpoints were pharmacokinetics/pharmacodynamics, overall response rate (ORR), duration of response (DOR) and progression-free survival (PFS).
Results: Eighteen patients were enrolled in Part 1: 8 had chronic lymphocytic leukemia/small lymphocytic leukemia (CLL/SLL), 3 had follicular lymphoma, 3 had mantle cell lymphoma, 3 had diffuse large B-cell lymphoma (DLBCL) and 1 had Waldenstrom macroglobulinemia. Part 1 patients had a median age of 65 y (range 48-77); all had ECOG PS ≤1. One patient had a DLT in the ACP-319 50-mg group (maculopapular rash) and 2 had DLTs in the 100-mg group (maculopapular rash; febrile neutropenia, diarrhea and pneumonitis). The maximum tolerated dose was defined as ACP-319 50 mg bid with acalabrutinib 100 mg bid. Patients with CLL/SLL were switched to acalabrutinib monotherapy in 2016 due to reduced benefit:risk ratio with added ACP-319. Herein, 25 patients with DLBCL (Part 1, n=3; Part 2, n=22) were analyzed; by immunohistochemistry (Hans algorithm), 9 had germinal center B-cell (GCB) and 16 had non-GCB DLBCL. Median age was 70 y (range 55-90) and the median number of prior therapies was 2 (range 1-5). The most common adverse events (AEs; ≥40% of patients) were increased AST/ALT (48%/52% [Grade ≥3, 28%/20%]), diarrhea (52% [12%]), fatigue (40% [0%]) and rash (40% [12%]). Twenty-two patients discontinued (5 discontinued acalabrutinib and 7 discontinued ACP-319 due to AEs); no deaths were due to AEs. ORR is shown in the Table 1. ACP-319 exposure was dose proportional with higher/variable exposure to an inactive metabolite. Acalabrutinib exposure was slightly higher at ACP-319 100 (vs 25/50) mg bid. Median BTK occupancy at trough was 95%; p-AKT inhibition was ACP-319 dose dependent.

Table 1.

	DLBCL	
	GCB n=9	Non-GCB n=16
ORR (≥ PR), n (%)	0	10 (63)
95% CI	–	35, 85
Complete response	0	4 (25)
Partial response (PR)	0	6 (38)
Median, months		
Time on study (range)	2.4 (0.8, 10.4)	4.0 (0.8, 29.7)
DOR (95% CI)	–	NR (1.8, NR) range, 0.03* – 18.4*
PFS (95% CI)	1.8 (1.7, 10.4)	5.5(1.6, NR)

*Censored. NR, not reached.

Summary/Conclusion: The combination of acalabrutinib + ACP-319 was tolerable with manageable AEs; response rate was high in patients with non-GCB DLBCL.

PS1012

TIME TO RELAPSE OF MANTLE CELL LYMPHOMA AFTER INTENSIVE HIGH DOSE CYTARABINE CONTAINING REGIMENS DEFINES PATIENTS RISK FOR DEATH: AN ANALYSIS FROM CENTERS OF THE FONDAZIONE ITALIANA LINFOMI

Background: Most patients with mantle cell lymphoma (MCL) respond to initial therapy, but inevitably experience relapse or progression of disease (POD) despite the use of very effective initial chemoimmunotherapy including high-dose cytarabine (HDAraC).
Aims: The goal of this analysis was to characterize the outcomes in patients with MCL following POD and to identify if time to progression may define a subgrouop of patients at high risk of death.
Methods: We retrospectively analyzed data from 188 patients with MCL that were refractory or had first relapse after induction regimens including rituximab and HDAraC followed by high-dose chemotherapy and autologous stem cell transplant, if appropriate. These 188 patients were retrieved from 418 patients with MCL treated upfront with intensive regimens that were consecutively recruited from 26 centers of the Fondazione Italiana Linfomi between 2007 and 2016. Primary outcome was the overall survival from time of POD (OS-2).
Results: Based on a linear regression model showing the relationship between risk of death (Log relative hazard) and time to first relapse or progression in 188 patients with MCL (Figure 1A), two groups were defined: patients with early POD 2 years or less after diagnosis (n=90, 48%) and those with late POD (n=98, 52%). Overall, OS-2 was 34 months (range 25-42), with early POD being the most powerful adverse factor (12 months versus not reached in the later POD group, p<0.0001, hazard ratio, 3.90; 95% CI, 2.16 to 7.06; Figure 1B). This significant impact on survival was independent of other known prognostic variable, and maintained after adjusting for MCL International Prognostic Index, tumor kinetics, morphological variant, presence of B-symptoms, different induction regimens, or allogeneic stem cell transplantation. Median overall survival from time of initial diagnosis (OS-1) was 76 months (range 64-88), 27 months in the early POD group and 127 months in remaining patients. Forty-one patients (22%) underwent allogeneic stem cell transplant (AlloSCT) during study follow-up. A significantly effect modification of AlloSCT according to POD time was detected (interaction test P .012), with early POD patients that benefited most of the procedure.

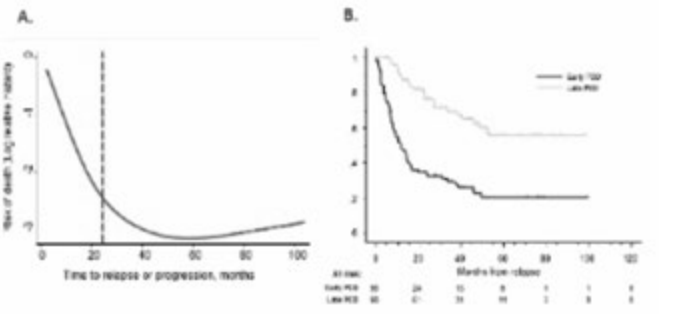

Figure 1.

Summary/Conclusion: In patients with MCL who received upfront HDAraC containing regimens, POD within 2 years after diagnosis was associated with poor survival and should be validated as a standard endpoint of chemoimmunotherapy trials of untreated MCL. Contrarily, late POD patients had an unexpectedly long life expectancy in the modern treatment era.

Lee Moffitt Cancer Center & Research Institute, Tampa, United States

Background: Patients (pts) with diffuse large B-cell lymphoma (DLBCL) unresponsive to standard therapies have limited curative options (Crump *et al.*, *Blood* 2017). Novel therapeutics are being developed based on the improved understanding of the biology of DLBCL. CC-122 is a cereblon-modulating agent that promotes degradation of the hematopoietic transcription factors Aiolos and Ikaros (Hagner *et al.*, *Blood* 2015). CC-122 has shown promising activity in combination with obinutuzumab or rituximab in relapsed or refractory DLBCL and follicular lymphoma (FL) (Michot *et al.*, ASH 2017; Ribrag *et al.*, ASH 2017).
Aims: To report updated results of the safety and efficacy of CC-122 in combination with rituximab in chemo-refractory DLBCL pts from Arm D (expansion phase) of the CC-122-DLBCL-001 study.
Methods: CC-122-DLBCL-001 is a phase Ib dose escalation/expansion study of CC-122, CC-223, and CC-292 given orally as doublets and triplets in combination with rituximab in chemo-refractory pts (NCT02031419; Ribrag *et al.*, ASH 2016). Chemo-refractory DLBCL is defined as: duration of stable disease ≤ 12 months, progressive disease as the best response to the last chemotherapy containing regimen, or disease progression or recurrence ≤ 12 months of prior autologous SCT. In the dose-escalation phase (3+3), pts received CC-122 at 1, 2, 3, or 4 mg orally daily (QD) or 5 days per week (5/7d), with a fixed dose of intravenous rituximab 375 mg/m^2 once every 28 days. The dose expansion cohort received 3 mg CC-122 QD 5/7 d as a formulated capsule plus rituximab. The primary endpoints were to determine safety, NTD, MTD, and RP2D. Secondary endpoints included PK, PD, and preliminary efficacy assessments. Gene expression profiling identified the cell-of-origin subset of DLBCL. A novel gene expression classifier was developed from a public DLBCL dataset and applied using NanoString profiling on tumor samples to assess enrichment for CC-122 respon-

ders (Risueño *et al.*, ASH 2017).
Results: As of January 10, 2018, a total of 27 DLBCL pts were enrolled in Arm D expansion. The median age was 63 years (range, 33-84), 20 (74%) were male, 22 (81%) had stage III/IV disease. The median number of prior systemic anticancer therapies was 3 (range, 2-6). One pt had a DLT due to grade 4 neutropenia during cycle 1. Two pts (7%) had at least one dose reduction (4% due to AEs) and 14 pts (52%) had at least one dose interruption (44% due to AEs). The most common AEs (all grades) were neutropenia (48%), fatigue, and peripheral edema (30% each). Grade 3/4 AEs were neutropenia (44%), fatigue and decreased neutrophil count (11% each), and anemia, abdominal pain, and pain in extremity (7% each). Nine pts (33%) had SAEs, including infections and vascular disorders (7% each). The objective response rate (ORR) was 41% with a complete response (CR) rate of 22%. The median duration of response (mDOR) was not yet reached. Median treatment duration was 2.0 months (range, 0-15, Q1 1.5, Q3 8.9). Subgroup efficacy analyses are shown in Table 1. Gene expression classifier positive pts had a CR rate of 50% and 6-mos PFS rate of 50% compared with 13% CR rate and 16% 6-mos PFS rate in gene expression classifier negative pts.

Table 1.

Subgroup Efficacy Analyses in Arm D (CC-122 + R) (n = 27)

DLBCL Type	n	ORR n (%) (95% CI)	CR n (%) (95% CI)	6-mo PFS rate % (95% CI)
All	27	11 (41) (22-61)	6 (22) (9-42)	32 (15-50)
DLBCL NOS	19	9 (47) (24-71)	5 (26) (9-51)	35 (15-56)
DLBCL NOS COO				
ABC	2	1 (50) (1-99)	1 (50) (1-99)	50 (1-91)
GCB	9	5 (56) (21-86)	3 (33) (8-70)	33 (8-62)
Unclassified	3	1 (33) (1-91)	0 (0) (0-71)	NR (NR-NR)
DLBCL NOS Gene Classifier				
Gene classifier +	6	3 (50) (12-88)	3 (50) (12-88)	50 (11-80)
Gene classifier -	8	4 (50) (16-84)	1 (13) (0-53)	16 (1-49)
Gene expression unknown*	5	2 (40) (5-85)	1 (20) (1-72)	40 (5-75)

Data cutoff was January 10, 2018.
ABC, activated B-cell; CI, confidence interval; COO, cell-of-origin; CR, complete response; GCB, germinal center B-cell; PFS, progression-free survival; NOS, not otherwise specified; NR, not reached; ORR, overall response rate
*Patients defined as classifier unknown were due to failure to meet pathology requirements for gene classifier evaluation.

Summary/Conclusion: In pts with chemo-refractory DLBCL, CC-122 combined with rituximab demonstrated manageable toxicities, with a low incidence of severe AEs. This combination showed favorable clinical activity and may represent an important treatment option in a difficult to treat pt population. Notably, gene expression classifier positive pts had encouraging clinical activity.

PS1014

EXTRACELLULAR CIRCULATING DNA IN DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS: BIOLOGICAL CORRELATES AND PROGNOSTIC IMPACT

D. Dujmovic[1,*], S. Bašić Kinda[1], P. Rončević[1], A. Samardžić[1], I. Radman[1], V. Škaro[2], G. Lauc[2], K. Dubravčić[3], I. Aurer[1]

[1]Hematology, UHC Zagreb, [2]Molecular biology, PMF Zagreb, [3]Molecular biology, UHC Zagreb, Zagreb, Croatia

Background: Extracellular circulating DNA (cfDNA) can be found in small quantities in plasma of healthy persons, but higher concentrations are found in various disorders including malignant and autoimmune diseases, myocardial infarction, trauma, inflammation and complications of pregnancy. In patients with tumors, cfDNA is of tumor origin. Although it has been studied extensively in solid cancers, there is a dearth of information on cfDNA in hematologic neoplasia.
Aims: The goal of this study was to determine the concentration of cfDNA in patients with lymphoma, its relation to demographic, biologic and clinical patient and tumor characteristics and to investigate its potential role as a marker of disease activity, prognosis or response to treatment.
Methods: The study was performed in 47 patients with diffuse B-large cell lymphoma from 2010-2013 lymphoma treated according to standard guidelines (Figure 1). cfDNA concentration was determined using quantitative real-time PCR before and at the end of treatment.
Results: In DLBCL patients cfDNA concentration is somewhat higher than in healthy persons (median 24.6 ng/ml vs. 12.1 ng/ml), range from 0.45 ng/ml – 1675 ng/ml. In all patients cfDNA concentration correlated with unfavorable prognostic characteristics: age, LDH, beta-2 microglobulin, disease stage and IPI but not with Ki-67, gender or presence of extranodal disease. Correlation with beta-2 microglobulin was strongest. The conctration of cfDNA had no impact on survival(both OS and PFS). (Figure 1). In multivariate analysis, cfDNA concentration was not an independent prognostic factor. In the vast majority of patients cfDNA concentrations at the end of treatment were lower than at the beginning but neither the absolute nor relative decline correlated with treatment outcomes.

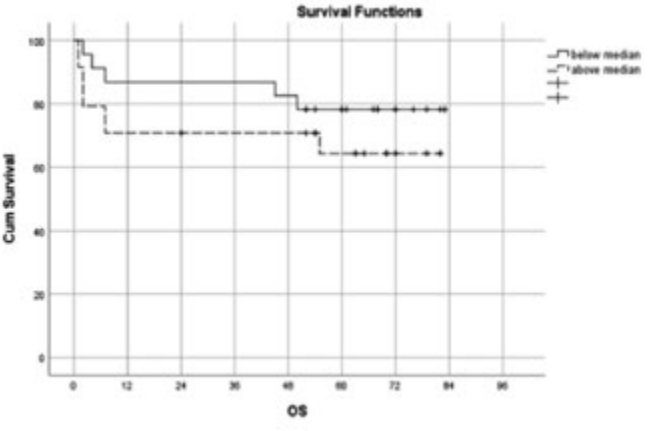

Figure 1.

Summary/Conclusion: In patients with diffuse large cell lymphoma, cfDNA concentration prior to treatment start correlates with negative prognostic factors, dominantly with those related to the total tumor mass. However, measuring cfDNA does not add independent clinically meaningful information and seems to be neither of diagnostic nor of prognostic value.

PS1015

ACALABRUTINIB MONOTHERAPY IN PATIENTS WITH RELAPSED/REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) IN THE PHASE 1B ACE-LY-002 STUDY

M.J.S. Dyer[1,*], S. de Vos[2], J. Ruan[3], C. Flowers[4], K. Maddocks[5], S. Rule[6], A. Hamdy[7], R. Izumi[7], J.G. Slatter[7], J. Cheung[7], M.M. Frigault[7], H. Wei[7], S. Mourya[7], N. Hunder[7], N.H. Fowler[8]

[1]The Ernest and Helen Scott Haematological Research Institute, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom, [2]UCLA, Division of Hematology/Oncology, David Geffen School of Medicine, Los Angeles, [3]Joan and Sanford I. Weill Medical College of Cornell University, New York, [4]Emory University School of Medicine, Atlanta, [5]The Ohio State University Comprehensive Cancer Center, Columbus, United States, [6]Derriford Hospital, Plymouth, United Kingdom, [7]Acerta Pharma, Redwood City, [8]The University of Texas MD Anderson Cancer Center, Houston, United States

Background: DLBCL is an aggressive non-Hodgkin lymphoma, with poor prognosis in relapsed/refractory patients. Current therapy for relapsed/refractory DLBCL typically yields low overall response rates (ORRs) and short remissions. Acalabrutinib is a highly selective, potent, covalent Bruton tyrosine kinase inhibitor with minimal off-target activity.
Aims: To evaluate acalabrutinib as monotherapy in patients with relapsed/refractory *de novo* DLBCL in the Phase 1b ACE-LY-002 study.
Methods: Eligible patients aged ≥18 y, with Eastern Cooperative Oncology Group performance status (ECOG PS) ≤2 and confirmed relapsed/refractory non-germinal center (GCB) type DLBCL (assessed by local immunohistochemistry) were enrolled. Patients received oral acalabrutinib 100 mg bid until progressive disease (PD) or unacceptable toxicity. The primary endpoint

was safety; secondary endpoints included pharmacokinetics and pharmacodynamics as well as investigator-assessed ORR (according to Lugano criteria), duration of response (DOR) and progression-free survival (PFS).
Results: In total, 21 patients were enrolled. To their most recent therapy, 11 patients were relapsed (partial response or better [≥PR] followed by PD) and 10 were refractory (no response or stable disease). Median age was 64 y (range 32-84); 86% had ECOG PS ≤1; 57% had extranodal disease; 81% had Ann Arbor stage III/IV. Median number of prior therapies was 3 (range 1-5). Median time on study was 3.9 months (range 0.8-22.5), with 1 patient continuing therapy. PD (81%) was the most common reason for treatment discontinuation. Two patients discontinued treatment due to adverse events (AEs) that were considered unrelated to treatment. Pharmacokinetic parameters were similar to previous studies, with rapid absorption and clearance; median steady-state BTK target occupancy was 97% - 99% (n=5). ORR (≥PR) for all patients was 24% (5/21; 19% complete response [CR]). NanoString subtyping conducted on 15 patients revealed 5 GCB, 9 activated B-cell (ABC), and 1 unclassified DLBCL. Characteristics of the 5 responders are listed in the Table 1. Common AEs (any grade) were diarrhea (43%), fatigue (43%), anemia (29%), cough (29%) and dizziness (29%); common Grade 3/4 AEs were anemia (24%), fatigue (10%) and abdominal pain (10%). Three patients had Grade 5 AEs (respiratory failure, meningeal progression and sepsis); none were drug related. No atrial fibrillation, hypertension, tumor lysis syndrome or Grade ≥3 bleeding AEs occurred.

Table 1.

Patient	Subtype by Nanostring	Relapsed/ refractory	Prior therapies, #	Best response	DOR, mo	PFS, mo
1	ABC	Refractory	3	CR	0.7*	2.6*
2	ABC	Relapsed	2	CR	13.7*	15.5*
3	ABC	Relapsed	2	PR	1.8	3.7
4 (ongoing)	GCB	Refractory	3	CR	15.9*	20.3*
5	Missing	Relapsed	4	CR	1.9	3.8

*Censored.

Summary/Conclusion: Acalabrutinib monotherapy was tolerable and had activity with durable remission in difficult-to-treat DLBCL patients including refractory patients.

PS1016

LENALIDOMIDE PLUS BENDAMUSTINE-RITUXIMAB DOES NOT OVERCOME THE ADVERSE IMPACT OF TP53 MUTATIONS IN MANTLE CELL LYMPHOMA

C.W. Eskelund[1,2,*], A. Albertsson-Lindblad[3], A. Kolstad[4], A. Laurell[5], R. Räty[6], L.B. Pedersen[2], C. Geisler[2], M. Jerkeman[3], K. Grønbæk[1,2]

[1]Biotech Research and Innovation Centre, [2]Rigshospitalet, Copenhagen, Denmark, [3]Skåne Universtity Hospital, Lund, Sweden, [4]Oslo University Hospital, Oslo, Norway, [5]Uppsala University Hospital, Uppsala, Sweden, [6]Helsinki Universty Hospital, Helsinki, Finland

Background: Despite the general improvement in the outcomes for patients with mantle cell lymphoma (MCL), recent studies have demonstrated that *TP53* mutations still designate approximately 10% of patients to a very high-risk sub-group in need of novel treatment strategies. Lenalidomide has shown high response rates in MCL in combination with rituximab, and preliminary experiences from chronic lymphocytic leukemia show promising effects in high-risk patients, including cases with *TP53* aberrations.
Aims: Thus, in this study we aimed at exploring the additive effect of lenalidomide to chemo-immunotherapy in *TP53* mutated patients.
Methods: The study cohort consisted of 50 elderly (or younger and frail) patients from the previously published frontline trial, MCL4 "Lena-Berit" (Albertsson-Lindblad, Blood, 2016), and of these pre-treatment DNA was available for 46 patients. The regimen consisted of an induction phase of bendamustin, rituximab and lenalidomide for 24 weeks, followed by lenalidomide maintenance for another 32 weeks. Pre-treatment bone marrow (BM, n=39) or peripheral blood (PB, n=7) DNA samples were analysed for the common deletions (chr17p13 (*TP53*) and chr9p21 (*CDKN2A*)) by droplet digital PCR (ddPCR) and point mutations and smaller deletions/insertions (indels) by targeted DNA sequencing on the Ion Torrent platform as previously described (Eskelund, Blood, 2017).
Results: After a median FU of 45 months, median overall (OS) and progression-free (PFS) survival were 69 months and 42 months, respectively. A drawback to the regimen was the large number of adverse events, especially infections and secondary malignancies. To date, 9 secondary malignancies have been reported (not including non-invasive skin cancers).
Most common mutations were *ATM* (34%), *KMT2D* (18%) and *TP53* (14%), and deletions of *TP53* and *CDKN2A* were detected in 20% and 22%, respectively. *TP53* (n=6) mutations were associated with significantly shorter median OS (25 months (95% CI: 6.6-43.4) versus 69 months (95% CI: 67.0-70.7), p<0.0001), PFS (10 months (95% CI: 0-22.9) versus 42 months (95% CI: 21.8-62.2), p=0.001) and time to relapse/progression (10 months (95% CI: 0-22.9) versus 58 months (95% CI: 35.7-80.3), p<0.0001) (Figure 1), and none of *TP53*-mutated patients achieved MRD negativity in both BM and PB at any time during treatment. Cases with deletions of both *TP53* and *CDKN2A* showed a trend towards inferior outcomes; however this was not significant.

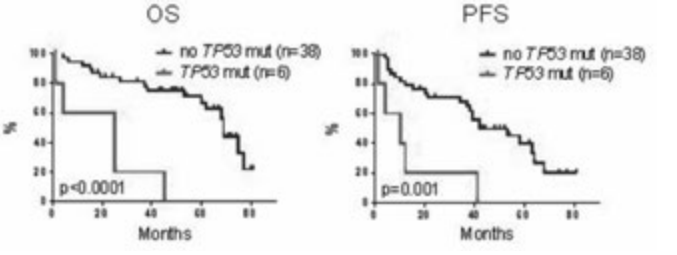

Figure 1.

Summary/Conclusion: Our results confirm the poor prognostic impact of *TP53* mutations in MCL, despite the addition of lenalidomide to rituximab-bendamustine. Trials evaluating novel agents in relation to *TP53* status are highly warranted to improve outcome in these MCL patients.

PS1017

OUTCOME OF PATIENTS WITH RELAPSED/REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) NOT ELIGIBLE FOR AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT)

Background: Relapsed/refractory DLBCL has poor prognosis, especially when patients cannot be salvaged by high dose therapy with SCT (age, comorbidities). There is no standard of treatment for these patients, therefore, the optimal combination of drugs, as well as intensity of next-line therapy have to be solved.
Aims: To describe the outcome of patients in Czech Lymphoma Study Group (CLSG) database who were refractory to or relapsed after R-CHOP treatment and found ineligible for SCT.
Methods: This analysis was a part of the NiHiL project (GovTrial No: NCT03199066). Patients with DLBCL progressing on or after treatment with R-CHOP (including reduced intensity R-CHOP or R-miniCHOP) between 2006 and 2016 who did not receive transplantation were identified. Primary progression was defined as progression ≤ 3 months, early relapse as progression 3-12 months, and late relapse > 12 months after completion of R-CHOP. Intensive second-line therapy was defined as a salvage regimen with ≥3 cytotoxic drugs, including high-dose dexamethasone. Palliative second-line treatment was defined as a regimen with ≤ 2 cytotoxic drugs. Categorical data were compared by chi-square tests, numerical data with Mann-Whitney U tests, survival curves were constructed according to Kaplan-Meier method and compared by log-rank test.
Results: Of 355 R/R DLBCL patients, 55 (15%) received autologous SCT and 1 (0.3%) allogeneic SCT. Median age of 299 patients, who were not transplanted, was 71 years (32-91). 48% of them were males, 64% had clinical stage III-IV, 65% had elevated LDH, 41% had ECOG performance status ≥ 2 and 62% had secondary IPI 3-5. There were 37% primary progressions, 30% early and 33% late relapses, with no significant differences in characteristics among these three subgroups. 41% of patients received

intensive salvage treatment at relapse, 130 patients (44%) palliative treatment and 47 patients (16%) best supportive care only. 52% of patients received rituximab (Rx). Median PFS for the whole group was 4.7 and median OS 8 months, with significant survival differences among primary progressions, early and late relapses (OS 4.3 v. 8.3 v. 14.5 months, p=0.0007, PFS 3.2 v. 5.0 v. 9.2 months, p=0.0001). Survival differences were not statistically significant among age subgroups ≤60, 61-70 and >70 years (OS 14.1 v. 6.7 v. 8.6 months, p=0.13, PFS 4.1 v. 4.1 v. 6.2 months, p=0.50). When patients receiving best supportive care only were excluded, there were no significant differences between intensive and palliative second-line treatment subgroups (OS 9 v. 8.4 months, p=0.7927, PFS 5 v. 5 months, p=0.6245). When patients receiving only best supportive care were excluded, Rx improved only PFS (5.5 v. 3.2 months, p=0.04) but not OS (10.9 v. 4.9 months, p=0.07) compared to treatment without Rx.

Summary/Conclusion: In our registry-based population of R/R DLBCL patients, 85% did not receive SCT, and their prognosis was dismal. Intensive second-line treatment did not bring survival benefit in transplant ineligible patients. Addition of rituximab to second-line therapy significantly improved their progression-free but not overall survival.

WOMEN WITH DIFFUSE LARGE B CELL LYMPHOMA BENEFIT MORE FROM RITUXIMAB-CONTAINING CHEMOTHERAPY

H.-H. Huang[1,*], F.-Y. Hsiao[2,3,4], L.-J. Chen[1], H.-M. Chen[5], B.-S. Ko[1]

[1]Division of Hematology, Department of Internal Medicine, National Taiwan University Hospital, [2]Graduate Institute of Clinical Pharmacy, [3]School of Pharmacy, [4]Department of Pharmacy, [5]Health Data Research Center, National Taiwan University, Taipei City, Taiwan, Republic of China

Background: Diffuse large B cell lymphoma (DLBCL) is the most common non-Hodgkin lymphoma. The treatment response and overall survival improved after incorporating rituximab with chemotherapies. Yet, available evidence as to whether women and men may benefit similarly from rituximab have not been adequately addressed, particularly in the real-world setting.

Aims: To examine gender differences in the clinical outcomes of rituximab in DLBCL patients using the Taiwan Cancer Registry Database and National Health Insurance Research Database.

Methods: All DLBCL patients aged 20 years and older during 2009 to 2013 were identified (n=4490; women=2048). Cox proportional hazard models were used to compare the results.

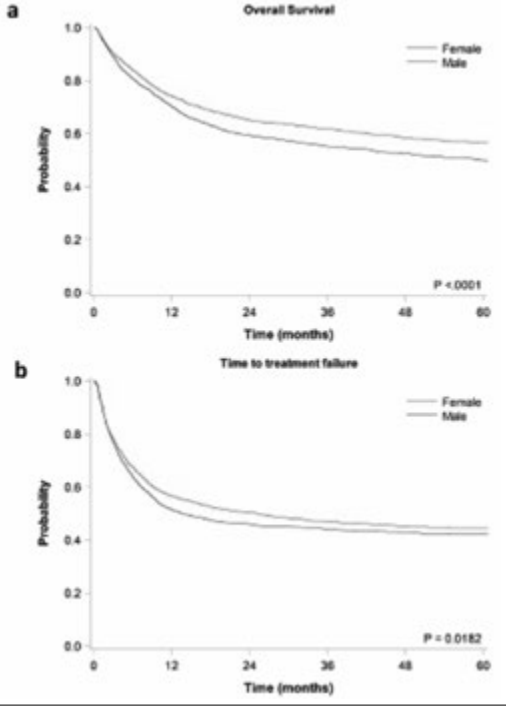

Figure 1.

Results: The baseline characteristics were similar between women and men with DLBCL, except that women had lower Charlson Comorbidity scores (CCS), and that fewer women underwent R-CHOP. In the survival analysis, women had better overall survival (OS) and longer time to treatment failure (TTF). The multivariate analysis of OS showed that the female gender remained to be an independent favorable prognostic factor regardless of Ann Arbor stages, age, treatments, CCS, and practice settings. In the subgroup analysis, the female advantage was only significant in the patients receiving rituximab-CHOP chemotherapy instead of in those receiving other rituximab-containing or non-rituximab therapies. This advantage diminished when rituximab dose was higher. (Figure 1).

Summary/Conclusion: From our population-based study, women demonstrated more survival benefits from the use of rituximab-containing induction chemotherapies for DLBCL.

Background: Double-hit lymphomas (DHL) are high-risk, non-Hodgkin B-cell lymphomas with dismal prognosis. The definition of DHL based on MYC, BCL2 and BCL6 abnormalities by FISH analysis is debated, as well as the optimal treatment strategy.

Aims: This multicentric, retrospective study aimed to characterize the clinical landscape of DHL in Italy, describing the current diagnostic paradigms and the preferred therapeutic choices.

Methods: Patients (pts) with ewly diagnosed diffuse large B-cell lymphoma (DLBCL) or "unclassifiable" aggressive B-cell lymphoma (BCLU) with at least one FISH alteration on either MYC, BCL2 or BCL6 loci were included. The main endpoints were clinical response rate, progression-free survival (PFS) and overall survival (OS).

Results: A total of 124 MYC aberrant pts (2010-2016) with DLBCL [42 BCLU and 82 DLBCL NOS] were screened by FISH among 30 Institutions of the Fondazione Italiana Linfomi. 109 pts resulted MYC translocated by FISH analysis. Of these pts, 83/109 (76%) were also studied for BCL2 and 58/109 (53%) for BCL6. Thus, out of the 109 MYC translocated pts, 60/109 (55%) were classified as DHL [41/60 (68%) MYC/BCL2, 19/60 (32%) MYC/BCL6] and 5/109 (4%) as "triple hit" lymphoma [(THL) - MYC/BCL2/BCL6]. 18/109 (17%) pts showed only a single translocation on MYC (S-MYC). The other 26/109 (24%) resulted not clearly classifiable (studied by FISH for MYC only). Thus, further analysis was focused on the series of 83 S-MYC/DHL/THL pts. Median age was 62 years, (19-84), 50 males. Thirty-one (37%) showed ECOG-PS≥2, 64 (77%) stage >2, 44 (53%)

>1 extranodal site, 59 (71%) elevated LDH and 48 (58%) bulky disease (> 6 cm). Therefore, 30 pts (36%) had intermediate and 53 (64%) had high IPI risk group. Fifty pts (69%) were defined as GCB according to the Hans algorithm. The most common upfront treatments were intensive regimens (R-hyperCVAD/MA, BFM, CODOX-M/IVAC or front line HSCT, n=37), median age 62, followed by R-CHOP (n=31), median age 61, and DA-EPOCH-R (n=11), median age 64. Four patients received palliative regimens. The median follow up of survivors was 27.7 months. The CR rate was 57% in the overall series and 42% in DHL/THL group. The 2 years PFS and OS of the overall series were 55% (95% CI 43-65) and 59% (95% CI 47-69), respectively; in the DHL/THL group the 2 years PFS and OS were 50% (95% CI 36-61) and 56% (96% CI 42-67), respectively. According to received treatment, the 2 years PFS of the overall series was 65% (95% CI 47-78) in pts who received intensive treatments, 48% (95% CI 29-65) in pts who received R-CHOP, and 40% (95% CI 11-68) in pts who received DA-EPOCH-R (p=0.05). This trend was confirmed in the DHL/THL group, with a 2 years PFS of 66% (95% CI 45-80) vs 42% (95% CI 22-61), vs 28% (95% CI 4-59), respectively (p=0.02), (Figure 1). B-symptoms (p=0.04), ECOG PS≥2 (p=0.005), bone marrow invasion (p=0.02), elevated LDH (p=.0.03) and high risk IPI (p=0.03) were associated to shorter PFS in univariate analysis, while only ECOG PS≥2 was independent predictor of PFS in multivariate analysis (p=0.01).

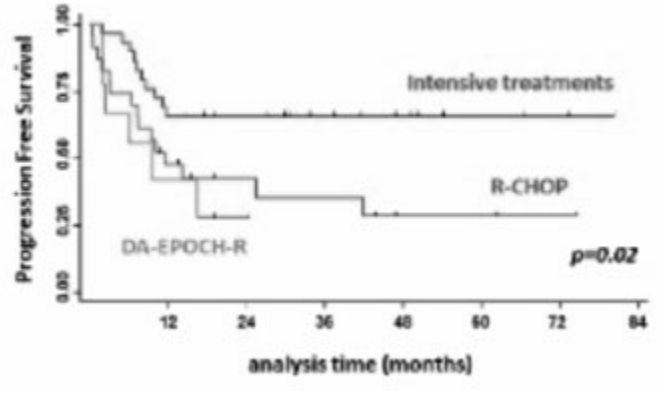

Figure 1. PFS in 65 DHL/THL pts according to received treatment.

Summary/Conclusion: This is the first, multicenter, retrospective study collecting DHL cases in Italy. Despite a fully annotated FISH profile is not always available in all centers, our preliminary data confirms that R-CHOP is no more the standard for these high-risk pts and suggest that intensified treatments might induce a PFS advantage. An extension of the series is needed to strengthen the data.

On behalf of the Fondazione Italiana Linfomi Postgraduate Master course.

PS1020

RITUXIMAB, BENDAMUSTINE AND CYTARABINE (R-BAC) IN PATIENTS WITH RELAPSED-REFRACTORY AGGRESSIVE B- CELL LYMPHOMA

M. C. Tisi[1,*], R. Paolini[2], F. Piazza[3], C. Tecchio[4], E. Ravelli[5], B. Famengo[6], E. S. D'Amore[6], G. Carli[1], O. Perbellini[1], M. Ruggeri[1], C. Visco[1]

[1]Cell Therapy and Hematology, San Bortolo Hospital, Vicenza, [2]Oncohematology, Santa Maria della Misericordia Hospital, Rovigo, [3]Hematology and Clinical Immunology Unit, Department of Medicine, University of Padua, Padova, [4]Medicine, Section of Hematology and Bone Marrow Transplant Unit, University of Verona, Verona, [5]Hematology, Valduce Hospital, Como, [6]Department of Pathology, San Bortolo Hospital, Vicenza, Italy

Background: Relapsed or refractory (R/R) aggressive lymphomas (i.e. diffuse large B-cell lymphoma -DLBCL-) have poor outcome, especially if not candidate to autologous stem cell transplant (ASCT). In this setting no standard therapy exists. Among salvage regimens that may be used, the combination of rituximab and bendamustine was associated to promising overall response rates (OR, 32-63%), but progression-free survival (PFS) was in the range of 3 to 8 months.

Aims: In this multicenter pilot study we evaluated the safety and efficacy of rituximab, bendamustine and cytarabine (R–BAC), as salvage treatment in R/R aggressive B-cell lymphomas not eligible to ASCT.

Methods: The study enrolled previously treated, histologically confirmed DLBCL, either de-novo or transformed from low grade B-cell lymphoma (t-DLBCL), and primary mediastinal B-cell lymphoma (PMBL), treated with the R-BAC regimen between November 2012 and September 2017 in four Centers. The R-BAC consisted of rituximab (R, 375 mg/m^2 intravenously [IV], day1), bendamustine (B, 70 mg/m^2 IV, days 2 and 3), and cytarabine (500 mg/m^2, IV on days 2 to 4) every 21/28 days, up to 6 cycles. The primary end-point was the complete remission rate (CR). Secondary end-points included OR, PFS, overall survival (OS), duration of response (DOR), and safety. Response was assessed according to IWG 2007 criteria.

Results: Thirty two patients (20 DLBCL, 11 t-DLBCL, 1 PMBL), aged 21-84 years (median 68), were enrolled and treated. All patients had received anthracycline containing induction therapy (R-CHOP or R-CHOP-like), six (19%) had previous ASCT, and median number of previous treatment was 2 (range 1-4). Median time from initial lymphoma diagnosis to enrollment was 22 months (4-120). Overall, 47% had relapsed disease, and 53% had refractory disease, with 35% of patients being refractory both to R-CHOP and R-DHAP (double refractory).

Patients received a median of 4 cycles of R-BAC (2-6). Overall, OR was 66%, and CR was 38%. Tumor shrinkage was observed in 78% of patients (25/32), as shown in the Waterfall plot in Figure 1A. Among different histologies, OR was 75% in DLBCL (CR 45%), and 55% in t-DLBCL (CR 27%). The only patient with PMBC had a transient promising response that was then classified as stable disease. The median PFS and OS were 13.9 months, and 17.3 months, respectively (Figure 1B). Median duration of response was 16 months. Treatment was well tolerated, with main toxicity being hematological, as expected. Treatment was discontinued before cycle 4 in 15 patients (47%), due to toxicity/adverse events in two patients, progressive disease in nine patients, and other reasons in four patients. Twenty patients (63%) had to delay or reduce treatment dose at least once along cycles, however, delays lasted < 14 days. Refractory disease (p=0.03), shorter time since prior anti-lymphoma treatment (p=0.007) and non-GCB cell-of-origin (p=0.01) were the only variables associated to a significantly inferior PFS in univariate analysis.

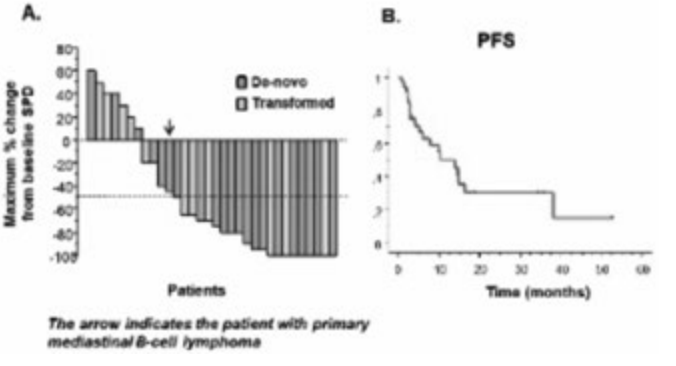

Figure 1.

Summary/Conclusion: R-BAC had promising activity with an acceptable toxicity profile in this small pilot trial on heavily pretreated R/R aggressive lymphomas. Our results suggest that R-BAC should be further investigated in this setting.

PS1021

A PROPENSITY SCORE ANALYSIS SHOWS THAT RITUXIMAB DOSE-ADJUSTED EPOCH IMPROVES PROGRESSION-FREE SURVIVAL OF YOUNG PATIENTS AFFECTED BY DOUBLE EXPRESSOR DIFFUSE LARGE B -CELL LYMPHOMAS

A. Guidetti[1,*], A. Dodero[1], A. Tucci[2], M. Novo[3], L. Devizzi[1], L. Farina[1], G. Pruneri[4], F. Barretta[5], R. Miceli[5], V. Monti[4], G. Dagrada[4], M. Pennisi[1], M. Dichio[1], A. Mussetti[1], C. Carniti[1], G. Rossi[2], P. Corradini[1]

[1]Hematology , Fondazione IRCCS Istituto Nazionale dei Tumori Milano , Milano, [2]Hematology , Azienda Ospedaliera Spedali Civili Brescia, Brescia, [3]Hematology, Azienda Ospedaliero Universitaria Citta' della Salute e della Scienza di Torino, Torino, [4]Pathology, [5]Department of Clinical Epidemiology and Trial Organization, Fondazione IRCCS Istituto Nazionale dei Tumori Milano , Milano, Italy

Background: A large portion of diffuse large B-cell lymphomas (DLBCL), ranging from 20% to 40%, has the double expression of MYC and BCL2 proteins (DEL). A subset of these patients have also Double Hit or Triple Lymphomas (DHL/THL) with concurrent chromosomal rearrangements involving the MYC and BCL2 and/or BCL6 genes. These lymphomas have poor outcome following standard R-CHOP chemotherapy. The optimal

induction regimen for DEL and DHL/THL has not been established yet. Preliminary data suggested a high complete response rate following Dose Adjusted EPOCH plus Rituximab (R-DAEPOCH).
Aims: The purpose of this study was to retrospectively compare survival outcome of DEL and DH/TH DEL pts treated with RDAEPOCH or RCHOP. A propensity score analysis (PS) was used to identify a control RCHOP group matched 1:1 by age, stage and IPI.
Methods: Eligible patients (n=121) had biopsy proven diagnosis of *de novo* DEL and were treated between January 2010 and December 2017. DEL were defined by immunohistochemical analysis with MYC expression ≥40% and BCL2 ≥ 50% of tumor cells. Fluorescence in situ hybridization (FISH) analysis for MYC, BCL2 and BCL6 was performed in all cases. Assignement of tumors to germinal center B-cell like (GCB) DLBCL or non GCB was done according to Hans algorithm. Fifty-eight pts were consecutively treated with R-DAEPOCH (RDA cohort) and their outcome was compared with a cohort of 63 patients treated with R-CHOP. Assignement to different treatment was based on istitutional practice at three Italian Hematological Divisions.
Results: After a median follow-up of survivors of 20 months (range, 6-100), estimated 3 years PFS and OS was 66% (95%CI:48%>79%) and 69% (95%CI: 35%>87%) in RDA cohort and 49% (95%CI: 36%>61%) and 62%(95%CI: 48%>73%) in R-CHOP cohort, respectively. Toxic deaths were observed in both groups (n=1 RDA, n=2 R-CHOP). Propensity score matching identified 45 pts pairs: median age was 56 (range, 28-78) and 63 (range, 33-84), stage III/IV were 37 (82%) and 39 (87%) and IPI 3-5 were 25 (56%) and 21 (47%), non-GCB pts were and 22 (49%) and 27 (60%), DH/TH pts were 9 (20%) and 1 (2%), in R-DA and R-CHOP group respectively. Considering the 90 pts (45 pairs), no statistically significant difference in 3-years PFS (66% versus 44%, p=0.102) and OS (65% versus 60%, p=0.149) were found in pts treated with RDA and R-CHOP, respectively. Younger patients (≤65 years) (n=59) had a significant advantage from the treatment with RDA in terms of PFS (p= 0.00873) and a trend for OS (88% versus 56%, p=0.05). Of note, the estimated 3-years OS was 73% and 58% in the pts who receive RDAEPOCH with DEL or DEL and DHL/THL, respectively.
Summary/Conclusion: RDAEPOCH is an active and safe regimen for DEL. In comparison to R-CHOP, we reported a significative advantage in term of PFS in patients aged below 65 yrs. This result is probably related to the better dose escalation achieved in the young population. Randomized trials are needed to confirm these results.

PS1022

GENETIC EVIDENCE IMPLYING THE COMMON PRECURSOR CELLS FOR PRIMARY AND EXTRA-CENTRAL NERVOUS SYSTEM RELAPSED TUMORS IN PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA

K. Hattori[1,*], M. Sakata-Yanagimoto[1], T. Nanmoku[2], Y. Suehara[2], R. Matsuoka[2], M. Noguchi[2], Y. Yokoyama[2], T. Kato[2], N. Kurita[2], H. Nishikii[2], N. Obara[2], S. Takano[2], E. Ishikawa[2], A. Matsumura[2], M. Muratani[2], Y. Hasegawa[2], S. Chiba[2]

[1]Hematology, [2]University of Tsukuba, Tsukuba, Japan

Background: Primary central nervous system lymphoma (PCNSL) is a rare form of diffuse large B cell lymphoma that arises within the brain or the eyes. Recent exome sequencing studies have revealed that the L265P *MYD88* mutation is highly prevalent in patients with PCNSL (38-85.4%). This mutation, but not other mutations found in PCNSL tumors, was previously reported to be detected in peripheral blood mononuclear cells (PBMNCs). This finding may imply the presence of clonal expansion of B cells harboring the L265P *MYD88* mutation at outside the central nervous system (CNS) compartment.
Aims: We explored this possibility by examining paired primary PCNSL and extra-CNS relapse tumors, and bone marrow mononuclear cells (BMMNCs).
Methods: Targeted sequencing was performed for 39 genes in 5 pairs of primary intra-CNS and relapsed extra-CNS tumors using the Lymphopanel (Dubois, Clin Cancer Res 2016) and our in-house panel (Hattori, Br J Haematol 2017).Whole exome sequencing (WES) was also performed on 1 pair of primary and relapsed tumors and BMMNCs.
Results: The mean coverages using these panels were 1310×(range, 379 to 3099) and 1563×(range, 1084 to 1990), respectively. Targeted sequencing in 5 primary intra-CNS tumors and relapsed extra-CNS tumors identified 60 and 68 gene mutations, respectively. The mean coverage in WES was 81.1×(range, 64.9 to 99.1). WES in primary and relapsed tumors identified 45 and 10 mutations, respectively. By combining the results from targeted sequencing and WES, recurrent mutations were found in *MYD88* (4/5, 80%), *CD79B* (4/5, 80%), *PIM1* (3/5, 60%), *KMT2D* (3/5, 60%), *GNA13* (2/5, 40%), *CARD11* (2/5, 40%), and *PRDM1* (2/5, 20%) in either or both of the primary intra-CNS and relapsed extra-CNS tumors. The shared genetic alterations was present in all the 5 pairs. Especially, the *MYD88* mutations, L265P in 3, and P258L in 1, were shared by the 4 paired tumors. On the other hand, somatic mutations in other genes, such as *GNA13*, *CREBBP*, *BTG2*, and *TNFAIP3* were specific to either primary or relapsed tumors.IgH rearrangement status of paired tumors was examined to determine the clonal evolution from common precursor cells (CPCs). Because of the limitation of the quality of DNAs, the procedure was successful only in one paired tumors. The intra- and the extra-CNS tumors of this patient showed the monoclonal bands. Direct sequencing of the clonal bands confirmed that both tumors shared the same VDJ sequences. These data suggest that intra-CNS and extra-CNS tumors may originate from CPCs having the identical VDJ usage.In order to confirm the presence of pre-lymphoma cells with the L265P *MYD88* mutations, tumor-free BMMNCs or PBMNCs from patients whose tumors had this mutation were also studied. This mutation was detected with droplet digital PCR assay in 10 out of 24 tumor-free BMMNCs or PBMNCs, most of which were stemming from patients without extra-CNS relapse.
Summary/Conclusion: In this study, the analysis of 5 PCNSL patients who relapsed at extra-CNS sites suggest a branched pattern evolution from the *MYD88*-mutated CPCs to either primary PCNSL or relapsed extra-CNS tumors, supporting the concept of CPCs. Additionally, from the result of the analysis for the BMMNCs of CNS lesion-only patients, the possibility of the presence of pre-lymphoma cells in the extra-CNS compartment was also raised. Based on the result of these combinational analyses, it should be reasonable to consider that the pre-lymphoma cells outside of CNS can develop into primary intra-CNS tumors and occasionally into relapsed extra-CNS tumors.

PS1023

REAL-TIME CELL-OF-ORIGIN SUBTYPE IDENTIFICATION BY GENE EXPRESSION PROFILING IN PATIENTS WITH ABC-TYPE DLBCL IN THE PHASE III TRIAL OF LENALIDOMIDE + R-CHOP (R2-CHOP) VS PLACEBO + R-CHOP (ROBUST)

A. Chiappella[1,*], U. Vitolo[1], T. E. Witzig[2], D. W. Scott[3], M. Spina[4], R.D. Gascoyne[3], L. Zhang[5], J. Russo[5], J. Kang[5], J. Zhang[5], Y. Xu[5], G.S. Nowakowski[2]

[1]Division of Hematology, Città della Salute e della Scienza Hospital and University, Torino, Italy, [2]Division of Hematology, Mayo Clinic, Rochester, United States, [3]Centre for Lymphoid Cancer, British Columbia Cancer, Vancouver, Canada, [4]Division of Medical Oncology A, National Cancer Institute, Aviano, Italy, [5]Celgene Corporation, Summit, United States

Background: Activated B-cell-like (ABC) diffuse large B-cell lymphoma (DLBCL) is a subtype associated with inferior outcomes. Gene expression profiling (GEP) is the gold standard in identification of ABC-type DLBCL. In previously reported phase II studies, the combination of lenalidomide + R-CHOP (R^2-CHOP) provided efficacy based on cell-of-origin (COO) in patients with DLBCL (Vitolo, *Lancet Oncol* 2014; Nowakowski, *J Clin Oncol* 2015).
Aims: The goal of this analysis was to investigate the feasibility of performing real-time COO assessments using GEP in a large, global, randomized study.
Methods: ROBUST is a global, multicenter, randomized, double-blind, phase III study comparing R^2-CHOP vs placebo + R-CHOP in patients with previously untreated ABC-type CD20+ DLBCL (NCT02285062). ROBUST methods were previously described, and patients provided informed consent (Nowakowski, *Fut Oncol* 2016). Formalin-fixed paraffin-embedded excisional/surgical or core needle biopsy samples (Storhoff, *Blood* 2015) were analyzed by central pathology using the NanoString Lymphoma Subtyping Test (LST; Wallden, *JCO* 2015), based on the Lymph2Cx GEP assay (Scott, *Blood* 2014). Turnaround time was defined as the number of days between receipt of the central pathology sample and results being provided to the study site.
Results: 2093 patients were screened from January 21, 2015 to August 3, 2017; 570 patients were enrolled in ROBUST. Samples were analyzed in three central pathology labs in China, USA and the UK. Of 2110 submitted samples (including 1 or more sample per patient), 1798 were successfully tested; 312 (15%) samples could not be processed for technical reasons (incorrect/insufficient slides or blocks, or low tissue RNA concentration and/or purity). Mean turnaround time was 2.4 days. Among successfully tested samples, COO was 788 (44%) ABC and 1010 (56%) non-ABC. The ABC-type DLBCL rate according to geographic region of origin was 60% (241/404) from China/Japan/South Korea/Taiwan; 40% (441/1105) from

Russia/Europe/Middle East; and 37% (106/289) from North America/Australia/New Zealand.
Summary/Conclusion: In the phase III ROBUST study, real-time COO assessment from multiple global regions was feasible with a short turnaround time, which minimizes the delay in patients receiving treatment. The proportion of patients with ABC-type DLBCL was similar to previous reports in the literature. Our findings impact the size estimation and design of future studies utilizing COO as a biomarker in newly diagnosed DLBCL, which provides a significant advance in precision medicine for patients with DLBCL.

PS1024

EXCELLENT OUTCOMES OF OLDER PATIENTS WITH PCNSL USING R-MPV/ARA-C IMMUNOCHEMOTHERAPY WITHOUT WHOLE BRAIN RADIOTHERAPY (WBRT)

M. Tatarczuch[1,2,*], E. Paul[34], M. Gilbertson[2], G. Gregory[25], A. Bazargan[6], H. Quach[4], R. Filshie[4], M. Ku[4], C. Tam[4], S. Opat[27]

[1]Medicine, Monash University, [2]Haematology, Monash Health, [3]Medicine, University of Melbourne, [4]Haematology, St. Vincent's Hospital, [5]School of Clinical Sciences at Monash Health, Monash University, Melbourne, [6]Haematology, St. Vincent's Haematology, Melbourn, [7]School of Clinical Sciences at Monash Health, Monash University, Monash, Australia

Background: Primary CNS lymphoma (PCNSL) is a rare and poor-prognostic disease. While randomised studies including IELSG32 have confirmed chemoimmunotherapy regimens containing methotrexate, cytarabine and rituximab as standard of care, the role of ASCT or WBRT consolidative strategies are associated with significant toxicities and questionable benefit. Furthermore, many PCNSL patients are precluded from ASCT or WBRT due to age and co-morbidities.
Aims: This study seeks to assess outcomes of R-MPV/Ara-C chemotherapy in older (≥60yo) PCNSL patients.
Methods: Patients presenting with PCNSL (WHO Criteria: 2008) and treated with curative intent using R-MPV/Ara-C (Morris PG *et al.* J Clin Oncol. 2013;31(31):3971-9) were identified at 2 university hospitals: Monash Health (November 2009-December 2016) and St. Vincent's Hospital (June 2003-October 2012). Patients were separated according to age (i.e >60 vs ≤60yo). Risk-stratification was as per IELSG criteria. In the >60yo cohort, consolidative WBRT was omitted for patients in complete remission (CR) as per institutional practices. Only cases with biopsy-proven PCNSL and adequate information (i.e. baseline characteristics, treatment and outcome) were included. Outcome analysis was restricted to the rituximab cohort. Overall survival (OS) and progression free survival (PFS) were modelled by Cox regression. The Mann-Whitney and Fischer's exact test were used to calculate p-values for continuous and discrete variables, respectively.
Results: 44 patients were identified, 38 received R-MPV/ARA-C as per protocol (excluded: received other chemotherapy regimens: 6). Of these, 27 (71%) were >60yo (median: 67.5, range 38-86, p<0.0001) and 74% were intermediate-risk as per IELSG criteria (p>0.999). Therapy was well tolerated; 78% of older patients completed MTX therapy (vs 100%, p= 0.154), but with more frequent dose-attenuation (48% vs 9%, p: 0.003). WBRT was rarely used in the older cohort (11% vs 91%, p <0.0001). Despite this, older patients had excellent response rates (OR 89% vs 100%, p:0.54), 5-year PFS (65% vs 81%, p=0.54], and OS (65% vs 81%, p=0.56) [Figure 1]. There were 8 deaths, 6 of which were >60yo (median age: 70yo [57-83]). Neurotoxicity was reported in 5 (19%) patients, 3 of whom received WBRT, and contributed to the death of 1 patient.

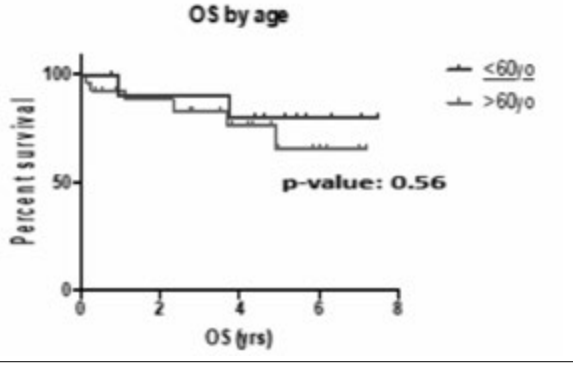

Figure 1.

Summary/Conclusion: Older patients treated with R-MPV/Ara-C without WBRT have excellent outcomes. Age and comorbidity should not exclude patients from receiving potentially curative immunochemotherapy.

PS1025

FIRST REPORT ON A SUCCESSFUL SCREENING PROGRAM FOR MYC REARRANGEMENTS AND A PROSPECTIVE CLINICAL TRIAL BASED ON MYC REARRANGEMENT IN NEWLY DIAGNOSED DLBCL PATIENTS IN THE NETHERLANDS

M. Chamuleau[1,*], M. Nijland[2], N. Lamers[3], N. Hijmering[4], K. Bakunina[3], J. Zijlstra[1], O. Visser[5], J. Vos[6], H. Berenschot[7], R. Boersma[8], M.J. Kersten[9], D. de Jong[4]

[1]Department of Hematology, VU University Medical Center, Amsterdam, [2]University Medical Center Groningen, Groningen, [3]HOVON Data Center, Rotterdam, [4]Department of Pathology, VU University Medical Center, Amsterdam, [5]Isala Clinics, Zwolle, [6]St Antonius Hospital, Nieuwegein, [7]Albert Schweitzer Hospital, Dordrecht, [8]Amphia Hospital, Breda, [9]Department of Hematology, Academic Medical Center, Amsterdam, Netherlands

Background: Patients with B-cell lymphoma that harbor a *MYC* rearrangement (Diffuse Large B-cell Lymphoma (DLBCL) or B-cell lymphoma with features intermediate between DLBCL and Burkitt lymphoma (BCL-U)) have a dismal prognosis following standard first-line treatment. Intensifying chemotherapy prolongs disease free survival when compared to R-CHOP. However, relapses often occur and overall survival has not been improved, hence justifying trials with MYC targeting drugs. Lenalidomide has demonstrated to down-regulate MYC and its target genes in *MYC* rearranged B-cells. Although lenalidomide seems mainly effective in ABC subtype DLBCL, the ability of MYC downregulation provides a rationale for lenalidomide administration in *MYC* rearranged lymphoma, that are usually of the GCB subtype.
Aims: To set up a *MYC* FISH screening program for all newly diagnosed DLBCL patients which allows patients with a *MYC* rearrangement to be included in a prospective interventional clinical trial to improve their prognosis.

Table 1. Clinical characteristcs of the total 32 eligible patients in the HOVON 130 study.

	N (%)

I-II	13 (16)
III	12 (15)
IV	57 (69)

Methods: A screening program for all newly diagnosed DLBCL patients in which performing *MYC* FISH is advocated (HOVON 900) has been set

up. Patients with a proven *MYC* rearrangement were subsequently included in a clinical trial *(HOVON 130: A phase II non randomized study evaluating the effect of the addition of lenalidomide to R-CHOP for patients with newly diagnosed MYC positive DLBCL and BCL-U)*. During the screening period administration of one cycle of R-CHOP21 is allowed. After being diagnosed with a *MYC* rearrangement, lenalidomide 15 mg on day 1-14 of R-CHOP21 is added. Patients receive 6 cycles of R-CHOP21 plus lenalidomide plus an additional 2 cycles of rituximab monotherapy. Intrathecal prophylaxis is given to all patients. Primary endpoint of the study is centrally reviewed end-of-treatment complete metabolic remission rate on ^{18}F-FDG PET-CT scan.

Results: Screening database (HOVON 900): Between Aug 2015 and Feb 2018, 816 newly diagnosed DLBCL patients have been registered. Median age at diagnosis was 67 years (18 to 88 years). *MYC* FISH analysis was successful in 73% of patients. Logistics showed that within 2-3 weeks *MYC* FISH results were available. Clinical trial (HOVON 130): 85 patients with a *MYC* rearrangement were included. After central pathology review, 3 patients were declared ineligible. Additional FISH analysis on *BCL2* and *BCL6* rearrangements revealed that 33% were *MYC* single hit, 55% were double hit (*MYC* and *BCL2* or *BCL6*) and 12% were triple hit (*MYC* and *BCL2* and *BCL6*) (analysis of 69 patients, to be completed). Clinical baseline characteristics of the 82 eligible patients are shown in Table 1. A planned interim analysis (after 27 patients finished treatment) showed grade 2 toxicity in 41%, grade 3 in 33% and grade 4 in 15% of patients. Most common toxicities were polyneuropathy (44%), infections (33%) and gastrointestinal disorders (30%). 16 severe adverse events were reported (all hospitalizations due to infections). The DSMB concluded that no safety issues prohibit continuation of the trial. Efficacy results are blinded until the last patient finished treatment (expected Q3 2018). Updated demographic results will be available in June 2018.

Summary/Conclusion: A successful screening program for *MYC* rearrangements in the Netherlands enables newly diagnosed DLBCL patients with a proven *MYC* rearrangement to switch to a prospective biomarker-based clinical trial that evaluates the addition of lenalidomide to standard R-CHOP, demonstrating feasibility of this program.

PS1026

A NOVEL IMMUNOHISTOCHEMICAL PROGNOSTIC SCORE BASED ON MYC, BCL2 AND BCL6 EXPRESSION IN DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL): RETROSPECTIVE ANALYSIS OF *DE NOVO* DLBCL TREATED WITH RITUXIMAB-CHOP

M. Novo[1,*], A. Castellino[1], C. Ciochetto[1], F. vittone[2], B. Botto[1], F. Cavallo[3], A. Chiappella[1], A. Evangelista[4], P. Ghione[3], M. Nicolosi[1], E. Santambrogio[1], M. S. Scalzo[2], G. Ciccone[4], R. Chiarle[5], D. Novero[2], A. Zamò[2], U. Vitolo[1]

[1]S.C. Hematology, [2]Patology Unit, AOU Città della Salute e della Scienza, Torino, Italy, [3]S.C. Hematology, Università degli Studi di Torino, Torino, Italy, [4]Unit of Clinical Epidemiology, AOU Città della Salute e della Scienza, Torino, Italy, Torino, Italy, [5]Patology Unit, Boston Children's Hospital and Harvard Medical School, Boston, United States

Background: The dismal prognosis of Double-Hit Lymphoma (DHL) is well known, whereas the prognostic impact of *MYC*, *BCL2* and *BCL6* expression is still contradictory.

Aims: The aim of the study was to assess the prognostic role of *MYC*, *BCL2*, and *BCL6* expression in a retrospective cohort of de-novo DLBCL, treated with R-CHOP between January 2003 and December 2013.

Methods: *BCL2*, *BCL6* and *MYC* expression were evaluated by Immunohistochemistry (IHC) using Tissue Micro Arrays (TMA) technique; cases were deemed positive for *MYC*, *BCL2* or *BCL6* if >40%, >40% or >25% of cells stained positive, respectively. Fluorescent in situ hybridization (FISH) analysis for *MYC* and *BCL2* were analyzed with dual color break apart probes on TMA samples. Survival analysis of Progression Free Survival (PFS) and Overall Survival (OS) were performed using Kaplan-Meier method and compared amongst groups with log-rank and Cox model. In a pilot series on 56 patients, *MYC* and *BCL2* overexpression and *BCL6* lack of expression showed prognostic relevance in a Cox multivariate regression model adjusted for IPI and age with PFS as endpoint; established that these 3 variables contributed with different risk (Hazard Ratio 2.23 for *MYC*+, 2.29 for *BCL2*+ and 1.67 for *BCL6*-), an IHC sum additive score of 0-5 was calculated assigning an individual risk of 2 points for *MYC* or *BCL2* positivity and 1 point for *BCL6* negativity stratifying patients in 3 risk groups; Low-[0-1 point] (no *BCL2* or *MYC* overexpression, with or without *BCL6* lack expression), Intermediate-[2 points] (*MYC* or *BCL2* single overexpression) and High-risk [≥3 points] (*MYC*+/*BCL6*-, *BCL2*+/*BCL6*-, *MYC*+/*BCL2*+, *MYC*+/*BCL2*+/*BCL6*-).

Results: Of 297 DLBCL included into the study, 265 were evaluable for survival analysis; median age was 65 years (range 20-90); 152 were evaluable by IHC and 100 by both IHC and FISH. No bias selections were observed within the two groups. Among 100 patients investigated by FISH, 8 DHL cases were recorded (8%); with a median follow up of 60 months, 5-year PFS was 66% in DLBCL and 25% in DHL [HR 3.05 (95% CI: 1.26-7.36, p 0.013)] and 5-year OS was 80% and 25% respectively [HR 3.63 (95% CI:1.48- 8.91 p 0.005)]. Excluding the 8 DHL patients, the remaining 144 patients with complete IHC data were distributed as follows based on IHC score: low risk 12 (8%), intermediate risk 59 (41%) and high risk 73 (51%). 5-year PFS rates were significantly different across the three groups: 91% vs 68% vs 48% (p=0.014) respectively (HR per unit increase 1.63 (95% CI: 1.14 -2.55) p 0.032), (Figure 1).

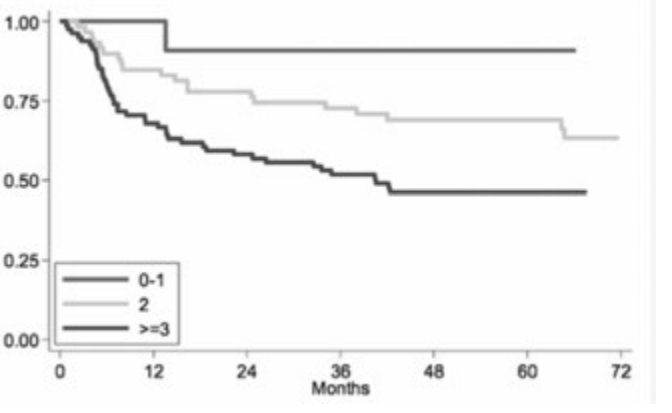

Figure 1. IHC score 5y-PFS on 144 patients (DHL excluded).

Summary/Conclusion: Our data showed that in a large cohort of DLBCL homogeneously treated with R-CHOP, excluding DHL cases, our simple and reproducible score based on *MYC*, *BCL2* and *BCL6* IHC expression had a prognostic value and was able to identify three groups at different outcome. This score is useful to select patients at poorer prognosis even if not DHL, that may take advantage of a more intensive chemotherapy regimen or combination of novel drugs.

PS1027

ASSESSMENT OF BONE MARROW INFILTRATION AND MINIMAL RESIDUAL DISEASE BY MULTIDIMENSIONAL FLOW CYTOMETRY IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

M. Baile[1,*], S. Barrena[2], J. Sancho[3], C. Grande[4], R. Fernández[5], A. Batlle[6], M. Peñarrubia[7], F. Peñalver[8], J. Hernández-Rivas[9], J. Guinea[10], J. Pérez[1], M. Vidriales[1], A. Martín[1]

[1]Hematology, Hospital Universitario de Salamanca/IBSAL, [2]Citometry, Cancer Research Center and University of Salamanca (IBMCC-USAL-CISC, SALAMANCA, [3]Hematology, Hospital Germans Trias i Pujol / ICO-IJC, Barcelona, [4]Hospital Universitario [12] de Octubre, Madrid, [5]Hematology, Hospital de Cabueñas, Gijón, [6]Hematology, Hospital Universitario Marqués de Valdecilla, Santander, [7]Hematology, Hospital Clínico de Valladolid, Valladolid, [8]Hematology, Hospital Universitario Fundanción de Alcorcón, [9]Hematology, Hospital Infanta Leonor, Madrid, [10]Hematology, Hospital Universitario de Araba, Vitoria, Spain

Background: Multidimensional flow cytometry (MFC) has not yet shown a high clinical value in patients with diffuse large B-cell lymphoma (DLBCL), probably due to the phenotypic heterogeneity of these lymphomas. In the present study, we have evaluated bone marrow (BM) infiltration of in patients with DLBCL using MFC.

Aims: 1) evaluating its prognostic impact compared to other techniques such as histology or PET; 2) determine the specific phenotypic pattern of the tumor cell of each patient for subsequent follow-up of minimal residual disease (MRD) after treatment.

Methods: We centrally evaluated BM samples from patients included in the multicenter randomized phase 2 clinical trial GEL-R-COMP-2013 (EudraCT: 2013-001065-17), that compares R-CHOP versus R-COMP in patients with newly diagnosed DLBCL or follicular lymphoma (FL) grade 3b. High resolution (8 colors) and high sensitivity (more than 1 million cells analyzed) direct immunofluorescence techniques were used, following the protocols defined by EuroFlow (Leukemia 2012, 26: 1908-1975). In order to further characterize the tumor population, an automatic analysis was

carried out in addition to the manual analysis, using the Compass III tool, available in the Infinicyt analysis software (Cytognos, S.L.).
Results: From a total of 91 patients included in the clinical trial, 56 participated in the present study (50 DLBCL and 6 FL grade 3b). The median age was 75.5 years (61-86) and the R-IPI was: 0 in 11% of patients, 1-2 in 32% and 3-5 in 57%. BM infiltration was detected by MFC in 20 out of 56 (36%) patients at diagnosis and 0 out of 13 at post-treatment evaluation. In 10 patients, infiltration was <1% of total BM cellularity. Regarding the phenotypic characterization, concordant BM infiltration by DLBCL was detected in only 5 cases. In contrast, discordant infiltration was detected in 15 (27%) patients, with a very heterogeneous phenotype: 4 low grade FL, 2 chronic lymphocytic leukemia, 5 marginal zone lymphoma and 4 small cell lymphoma with non-specific phenotype. Preliminary analysis of the prognostic impact of BM infiltration by MFC is shown in Table 1. The presence of concordant BM infiltration was associated with lower response rates and worse event-free survival, although the differences were not statistically significant, possibly due to the low number of cases. On the other hand, discordant BM infiltration had no significant prognostic influence.

Table 1.

Prognostic factor	n	CR (%)	p	OR (%)	p	EFS (%)	p	OS (%)	p
Bone Marrow infiltration by MFC	5	20		60		20		70	
- Concordant	15	67		100		50		64	
- Discordant	36	67	0,1	83	0,8	52	0,1	72	0,6
- Not infiltrated									
R-IPI									
- 0	6	**83**		**100**		67		**83**	
- 1-2	17	**88**		**100**		60		**100**	
- 3-5	30	**47**	**0,008**	**73**	**0,0016**	41	0,06	**50**	**0,03**

CR: Complete Response; OR: Overall Response; EFS: Event Free Survival; OS: Overall Survival.

Summary/Conclusion: High resolution MFC allowed the detection of small clonal populations in BM in a very high proportion of patients with newly diagnosed DLBCL. In most cases, infiltration was discordant with tumor histology and, apparently, had no prognostic relevance. The treatment administered was very effective in eradicating these populations, since MRD was not detected in any of the cases. We plan to correlate MFC findings with those of histology and PET, also centrally reviewed, as well as to perform molecular studies on tumor and BM samples to assess their clonal relationship.

PS1028

ON THE APPLICABILITY OF RHOA GLY17VAL POINT MUTATION TESTING FOR A DIFFERENTIAL DIAGNOSIS OF ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA

Y. Sidorova[1,*], N. Chernova [1], M. Sinitsyna[1], T. Moiseeva[1], L. Al-Radi[1], M. Aleksenko[1], O. Glinshchikova[1], S. Smirnova[1], N. Ryzhikova[1], E. Nikulina[1], E. Zakharko[1], E. Rybkina[1], V. Dvirnyk[1], A. Kovrigina[1], E. Zvonkov[1], A. Sudarikov[1]

[1]National Research Center for Hematology, Moscow, Russia, Moscow, Russian Federation

Background: Angioimmunoblastic T-cell lymphoma (AITL) is a T-cell lymphoma, characterized by abundant polymorphocellular infiltrate of lymph nodes with the small number of tumor CD4+ T-cells. Despite the use of various diagnostic methods, including immunohistochemistry and PCR-based clonality testing, AITL could often be misdiagnosed as reactive processes and other lymphomas, including Hodgkin's lymphoma and diffuse large B-cell lymphoma (DLBCL). Recently discovered point somatic RHOA Gly17Val mutation is present in 53-71% of angioimmunoblastic T-cell lymphomas, still it is not completely clear if this marker specific for AITL exclusively. Data on the presence of this point mutation in Hodgkin's lymphoma or DLBCL are limited.
Aims: To define if RHOA Gly17Val is a specific marker for angioimmunoblastic T-cell lymphoma.
Methods: The study included 62 patients diagnosed with AITL, established on the basis of WHO criteria. The ratio m/f - 37/25, the median age was 62 years (29-87). The control group included patients with Hodgkin's lymphoma <35 years old (n 35), ≥35 years old (n 25), DLBCL (n 15), reactive lymphadenitis (n 14), and other indolent B-cell lymphomas (n 20). Gly17Val mutation was analyzed in lymph nodes by quantitative allele-specific (qAS) TaqMan Real-Time PCR assay.
Results: RHOA Gly17Val mutation was detected in 53% of patients with AITL (32 of 62). Study of this mutation in the control group of patients with Hodgkin's lymphoma, DLBCL, reactive lymphadenitis, indolent B-cell lymphomas (n 109) showed a negative result, except for 5 patients (Figure 1). In two patients, males, 38 and 65 yo, with Hodgkin's lymphoma cell selection approach have shown that the CD4+ peripheral blood population contains cells with RHOA Gly17Val mutation. Flow cytometry of blood revealed a population of $CD3_{dim}$ CD5+ CD4+ CD10+/- CD279+ (2.251% of lymphocytes and 0.295% of all events) in one patient and CD3+ CD4+ CD10+ CD279- (0.2% of lymphocytes and 0.04% of all events) in another indicating AITL to exist as second tumor in these cases. In addition, clonal rearrangements of TCRG and TCRB in the lymph nodes were detected in these two patients. In the third case diagnosed as DLBCL (female, 63 yo) we revealed a small number of cells (0.24%) with an RHOA mutation in the lymph node sample, with no clonal rearrangements of TCRG, TCRB. Now the patient is in remission and under observation. In the fourth patient (female, 50 yo), DLBCL developed 7 months after the diagnosis of AITL. In the first and the second biopsies of lymph nodes, there is practically the same number of cells with a RHOA mutation - 1.5% and 2%, as well as the same clone of cells with clonal rearrangement of IgH, which indicates the initial presence of composite lymphoma in this patient. In patient # 5 diagnosed as reactive lymphadenitis in 2008 (female, 58 y.o.) cells with the RHOA Gly17Val mutation were detected in the lymph node at the amount of 1.5%. In the biopsy of the lymph node in 2017, 29% of the cells with the RHOA Gly17Val mutation were detected. The T-cell receptor clonal rearrangements coincided in both lymph nodes, so it can be an argument that this case of reactive lymphadenitis was the onset of AITL. Thus, in 4 out of 5 cases positive for RHOA Gly17Val point mutation, the presence of AITL as the primary or second tumor was demonstrated.

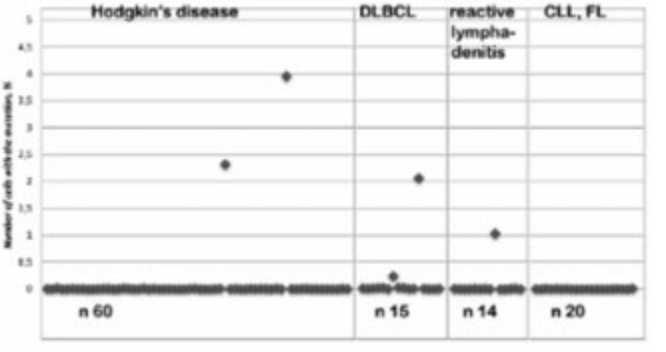

Figure 1.

Summary/Conclusion: Somatic RHOA Gly17Val point mutation is a specific marker of AITL in differential diagnosis with Hodgkin's lymphoma, reactive lymphadenitis and DLBCL and should be used as a screening method in a group of patients older than 35 years.

PS1029

THE ADDITION OF ROMIDEPSIN TO CHOEP FOLLOWED BY HIGH-DOSE CHEMOTHERAPY AND TRANSPLANTATION IS FEASIBLE IN UNTREATED PERIPHERAL T-CELL LYMPHOMAS: RESULTS OF PHASE IB FIL-PTCL13

Background: Peripheral T-cell lymphoma (PTCL) is a heterogeneous disease at dismal prognosis. The addition of etoposide to cyclophosphamide-doxorubicin-vincristine regimen (CHOEP) followed by a consolidation with autologous stem cell transplantation (autoSCT) can be considered a standard strategy in young patients with chemo-sensitive disease. However, 25-30% of patients are not eligible to transplant due to primary refractoriness or early progression. Romidepsin is a histone deacetylase inhibitor, a non-cross resistant agent that showed antitumor activity in PTCL and a manageable toxicity profile in combination with chemotherapy. On these bases, we designed the FIL-PTCL13 phase Ib/II study (NCT02223208). Herein, we report the phase I part of the study.
Aims: Aims of FIL-PTCL13 were to define the maximum tolerated dose (MTD) of romidepsin (Ro) when administered in combination with CHOEP in the treatment of PTCL patients' candidate to stem cell transplant, and to evaluate safety and efficacy of this combination.
Methods: Inclusion criteria were: stage II-IV patients aged 18-65, with newly diagnosis of PTCL not otherwise specified, angioimmunoblastic, ALK negative. Treatment scheme was: an induction with 6 courses of CHOEP every 21 days combined with Ro at the allocated dose, at day 1 and 8 of each cycle (Ro-CHOEP); responsive patients continued the program with one course of cisplatin, citarabine, desamethasone (DHAP) followed by stem cell harvest. Patients in complete remission after Ro-CHOEP proceeded to autoSCT; patients in partial remission and with an available donor, were sent to upfront alloSCT. Romidepsin dose allocation for sequential cohorts of 3 patients at each dose was defined according to the Continual Reassessment Method (O'Quigley and Zohar, 2006). The MTD of Ro was defined as the dose that achieves a dose-limiting toxicity (DLT) in 33% of patients reported during the first 2 courses of Ro-CHOEP. Four dose levels were tested, namely 8, 10, 12 and 14 mg/ms. According to expert opinions, the first administered dose was 12 mg/ms. Toxicities were classified according to the NCI Common Terminology Criteria for Adverse Events, version 4.0.
Results: From September 2014 to July 2017, 21 patients were enrolled into the phase I. Clinical characteristics were: median age 57 years (IQR 53;61); IPI risk ≥ 3 8 (38%); bone marrow involvement 6 (29%); stage III-IV 18 (86%). As for the protocol, the first 3 patients were treated with Ro at 12 mg/ms, and no DLTs were observed; the subsequent 6 cohorts were treated with Ro at 14 mg/ms. Nine DLTs were reported in 7 patients: 3 events of grade (g)3 mucositis and one event of g3 maculopapular rash, g3 fatigue, g3 fever, g3 respiratory failure, g3 typhlitis and g4 neutropenic fever, respectively. The observed toxicity was 35.2% (95% Credibility Interval: 17.1%>56.5%) and prompted to define 14 mg/ms the recommended dose of Ro in addition to CHOEP. No unexpected toxicities and no toxic deaths were reported into the phase I part of the trial. The addition of Ro during induction did not impact the harvest, with a median of 4.3×10 (IQR 3.4-5.71) peripheral blood CD34-positive cells/Kg collected. On September 2017, the phase II of the trial was opened. All enrolled patients included into phase I part completed the study and preliminary efficacy analyses are ongoing.
Summary/Conclusion: The phase Ib FIL-PTCL13 part of the study defined Romidepsin 14 mg/ms on day 1 and day 8 as the MTD, when administered in combination to CHOEP as induction in untreated T-cell lymphoma patients candidate to stem cell transplant.

PS1030

A PHASE I, MULTICENTER, OPEN-LABEL DOSE-ESCALATION STUDY OF CC-122, A NOVEL CEREBLON-MODULATING AGENT, IN ADULT JAPANESE PATIENTS WITH ADVANCED NON-HODGKIN LYMPHOMA OR SOLID TUMOR

K. Yamamoto[1,*], T. Chou[2], T. Doi[3], Y. Terui[4], H. Kato[1], T. Hirose[2], S. Seo[5], Y. Ogaki[6], H. Fujimoto[6], T. Ohtsu[6], K. Hatake[7]

[1]Department of Hematology and Cell Therapy, Aichi Cancer Center Hospital, Nagoya, [2]Department of Hematology Oncology, Niigata Cancer Center Hospital, Niigata, [3]Department of Experimental Therapeutics, National Cancer Center Hospital East, Chiba, [4]Department of Hematology Oncology, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, [5]Department of Hematology and Oncology, National Cancer Center Hospital East, Chiba, [6]Celgene K. K., Tokyo, [7]Department of Hematology, International University of Health and Welfare, Mita, Tokyo, Japan

Background: Treatment for relapsed/refractory non-Hodgkin lymphoma (R/R NHL) continues to be a challenge, with many patients (pts) relapsing despite the availability of new treatment options. CC-122 is a novel cereblon-modulating agent that degrades the hematopoietic transcription factors Ikaros and Aiolos. CC-122 exerts antiproliferative, antiangiogenic, and immunomodulatory effects in solid and hematologic malignancies (Hagner *Blood* 2015; Gandhi *Clin Lymphoma, Myeloma & Leukemia* 2013; Carpio ASH 2017).
Aims: The current phase I CC-122-ST-002 study evaluates the safety and efficacy of CC-122 in Japanese pts with advanced NHL or solid tumors (NCT02509039).
Methods: Pts age ≥ 20 years, with ECOG PS 0-2, and documented diagnosis of advanced solid tumors (cohort 1 only) or NHL (all cohorts) were eligible for the study, including those who had progressed on or were ineligible for standard anticancer therapy. Pts received oral CC-122 active ingredient in capsule (AIC) 2.0 mg/day (cohort 1, n=3), 3.0 mg/day (cohort 2, n=3), 4.0 mg/day (cohort 3, n=3), or 3 mg/day of formulated capsules (FC) (cohort 4, n=6). All cohorts received CC-122 on 5 consecutive days of 7 days per week in a 3+3 design until progression, unacceptable toxicity, or pt/physician withdrawal. The primary endpoints were to assess safety (per NCI CTCAE v4.03) and to determine dose-limiting toxicity (DLT), maximum tolerated dose (MTD) or recommended phase II dose (RP2D), and pharmacokinetics (PK) of CC-122.
Results: As of data cut-off of 30 Mar 2017, 15 pts, 14 with NHL (5 DLBCL, 5 FL, 4 peripheral T-cell lymphoma) and 1 with a solid tumor (esophageal carcinoma) participated in the study. The median age was 64 years (range, 48-78), and 9 (60%) were male. The median number of prior systemic anticancer therapies was 3 (range, 1-10). Pts received CC-122 for a median of 29 weeks (range, 4-82). DLTs were reported in 1 pt (cohort 4) and included grade 1 facial edema, grade 1 pharyngeal edema, and grade 1 tumor flare reaction. Grade ≥ 3 adverse events (AEs) occurred in 11/15 pts (73%). The most frequently reported grade ≥ 3 AEs were neutrophil count decreased (5/15, [33%]), and lymphocyte count decreased (3/15, [20%]). Three pts experienced serious AEs (SAE); 1 SAE of pulmonary eosinophilia was suspected to be related to CC-122. The most common AEs (≥ 30%) were maculo-papular rash (53%), lymphocyte count decreased (47%), constipation (40%), neutrophil count decreased (40%), upper respiratory tract infection (40%), platelet count decreased (33%), and white blood cell count decreased (33%). No AEs led to discontinuation of CC-122. Seven pts discontinued treatment due to progressive disease. Two pts died within 30 days of the last dose of CC-122, both due to progressive disease. ORR for efficacy-evaluable NHL pts (n=13) was 54%, with 31% complete response. The best response for the single solid tumor pt in the study was progressive disease. Median time to response was 6.3 weeks (range, 5.9-22.0). Median DOR was not reached. Median progression-free survival was 46.1 weeks (95% CI, 13.9-NR). At steady state, PK showed that the 4 mg AIC cohort had the highest exposure followed by the 3 mg FC, 2 mg AIC and 3 mg AIC cohorts (Figure 1).

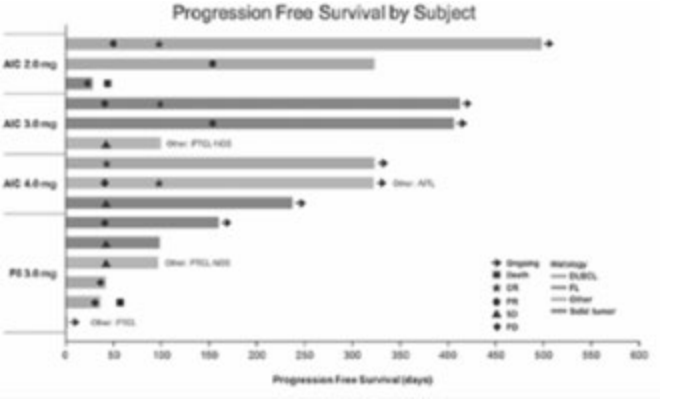

Figure 1.

Summary/Conclusion: The safety and PK results observed in this study are consistent with the known profile of CC-122 and the 3.0-mg dose using FC was considered safe and tolerable. Overall, the CC-122-ST-002 study showed preliminary efficacy with CC-122 in Japanese patients with previously treated NHL.

PS1031

GLOBAL LONGITUDINAL STRAIN (2D-GLS) IN LYMPHOMA PATIENTS TREATED WITH CHEMOTHERAPY +/- MEDIASTINAL RADIOTHERAPY: EARLY SUBCLINICAL CARDIOTOXICITY IN THE CARDIOCARE PROSPECTIVE OBSERVATIONAL STUDY

B. Botto[1,*], M. Levis[2], L. Orsucci[1], V. De Luca[3], S. Bartoncini[2], M. Giorgi[4], A. Chiappella[1], S. Ferrero[5], A. Fava[4], F. Cavallo[5], D. Caracciolo[5], S. Vicentini[4], A. Gastino[3], G. Furfaro[2], M. Nicolosi[1], P. Pregno[1], G. Priolo[1], A.R. Filippi[3], U. Ricardi[3], U. Vitolo[1]

[1]Department of Hematology, [2]Department of Radiation Oncology, A.O.U. Città della Salute e della Scienza, [3]Department of Oncology, Radiation Oncology, University of Torino, [4]Department of Cardiology, A.O.U. Città della Salute e della Scienza, [5]Department of Hematology, University of Torino, Torino, Italy

Background: Treatments-related cardiotoxicity is a critical issue in long term lymphoma survivors, particularly at young age, and its early identification is important to prevent clinically relevant cardiac events. Complete echocardiographic assessment including 2-dimension global longitudinal strain (2D-GLS), seems to be an effective tools in detecting preclinical systolic changes to the cardiac funtion even when the ejection fraction is preserved.
Aims: The aim of CARDIOCARE study is to investigate early detection of subclinical chemo and radiation-induced changes in left ventricular function using 2D-GLS
Methods: CARDIOCARE is an ongoing monocentric prospective observational study, approved by the ethic committee of our hospital (approval number: CS/370); the planned accrual will finally include 100 patients, of which 50 treated with chemotherapy alone (CT-alone) and 50 treated with combined modality treatment (CMT) including chemotherapy + mediastinal radiotherapy. Patients aged 18-70, affected with either Hodgkin or diffuse large B-cell (DLBCL) or primary mediastinal lymphomas (PML) were eligible. Patients received a complete echocardiographic assessment including 2D-GLS at baseline, after chemotherapy, after radiotherapy (if planned), and 3 months after end of treatment. Paired samples T test correlations were applied to evaluate GLS changes at each time-point. The cumulative dose of anthracycline and the adsorbed radiation dose of whole heart and cardiac substructures (coronaries, chambers and valves) were assessed for each patient. All patients signed an informed consent before the enrollment.
Results: Fifty-two patients (24 in CT-alone group and 28 in CMT group), out of 65 enrolled to date, completed the observational program and were included into this analysis. No patients experienced a significant reduction of the left ventricular (LV) ejection fraction during the entire treatment period. Median dose of anthracycline was 500 mg in CT arm vs 400 mg in CMT arm. A marginal reduction of 2D-GLS was seen after chemotherapy for patients in CT-alone arm ($GLS_{baseline}$: -19.24 vs $GLS_{post\text{-}CT}$: -18.42, p =0.06), but not for patients in CMT arm ($GLS_{baseline}$: -20.08 vs $GLS_{post\text{-}RT}$: -20.05, p=0.94). In the whole series a marginal reduction of GLS after CT was observed also for patients with Age >40 ($GLS_{baseline}$: -19.34 vs $GLS_{post\text{-}CT}$ -17.93 p =0.056) and receiving >4 cycles ($GLS_{baseline}$: -19.55 vs $GLS_{post\text{-}CT}$: -18.68 p =0.055). After mediastinal RT, a significant reduction of 2D-GLS was found in patients receiving: *A) maximum dose* to interventricular septum >10 Gy ($GLS_{baseline}$: -20.10 vs $GLS_{post\text{-}RT}$: -18.67 p =0.006), to lateral wall of the LV >8 Gy ($GLS_{baseline}$: -20.31vs $GLS_{post\text{-}RT}$: -18.53 p=0.002) and to whole LV >11 Gy ($GLS_{baseline}$: -20.37 vs $GLS_{post\text{-}RT}$: -19.1, p=0.002); *B) mean dose* to whole heart >4.5 Gy ($GLS_{baseline}$: -20.9 vs $GLS_{post\text{-}RT}$: -18.39, p=0.007) and mean dose ≥2 to interventricular septum ($GLS_{baseline}$: -20.21 vs $GLS_{post\text{-}RT}$: -18.45, p=0.01), to lateral wall of the LV ($GLS_{baseline}$: -18.84 vs $GLS_{post\text{-}RT}$: -18.84,p= 0.02) and to whole LV ($GLS_{baseline}$: - 20.17vs $GLS_{post\text{-}RT}$: - 18.58,p=0.006).
Summary/Conclusion: 2D-GLS seems a promising tool to detect early cardiotoxicity in lymphoma patients. Preliminary results suggest a correlation of both anthracyclines and radiation dose with preclinical heart damage. The completion of CARDIOCARE study, and a future correlation with clinical events are needed to support and strengthen these preliminary assumptions.

PS1032

CLINICAL FEATURES, TREATMENT AND PROGNOSTIC FACTORS FOR EXTRANODAL NATURAL KILLER/T-CELL LYMPHOMA, NASAL TYPE, IN THE SPANISH POPULATION. A STUDY FROM THE SPANISH GROUP GELTAMO

Background: Extranodal natural killer (NK)/T-cell lymphoma, nasal type (ENKTL-NT) is a rare disease associated with Epstein-Barr virus (EBV) and is much more common in Asia and Latin America than in western countries. Data on disease presentation and outcome from European cases are very limited.
Aims: To analyze the clinical characteristics at diagnosis, treatment and outcome of a large retrospective series of Spanish patients diagnosed with ENKTL-NT.
Methods: Fifty-six patients with ENKTL-NT diagnosed from 2000 to 2016 were identified in 16 academic centers in Spain. Clinical data were collected retrospectively. Survival curves were estimated by the Kaplan-Meier method and compared using the Log-Rank test. Variables included in the univariate analysis were: race, gender, age, previous sinusitis, nasal localization, Ann Arbor stage, ≥2 extranodal sites, ECOG, B-symptoms, LDH, beta2-microglobulin, albumin and C-reactive protein. Multivariate analyses were performed by Cox proportional hazard regression model.
Results: Clinical characteristics at presentation: median age 51 yr (limits 23-89), Caucasian 42, previous history of chronic sinusitis 13 (23%), localized nasal involvement 27 (49%), Ann Arbor I/II 31/53 (57%), B symptoms 16/55 (29%), ≥2 extranodal sites 20/53 (38%), ECOG 0-1 36/50 (72%), elevated LDH 21/49 (43%), elevated beta2-microglobuline 13/31 (42%), elevated C-reactive protein 14/24 (58%), low albumin 17/30 (57%). Fifty-two patients received active treatment, 24 (46%) with chemotherapy (CT), 25 (48%) with CT+radiotherapy (RT), 3 with RT. Median RT dose was 50 Gy. CT with high doses of L-asparaginase (SMILE / Sandwich) was used in 18 (36%), CHOP/CHOP-like in 25 (50%) and intensive regimens ICE/PROMACE in 5 (10%). Nine patients proceed to a stem-cell transplant after CT in first line (8 auto/1 allo). Response rate was evaluable in 48 patients [by PET/TC in 21 (44%)]: CR 25 (52%), PR 6 (13%), progression 17 (35%). With a median follow-up of 37 months for alive patients, median OS and PFS were 14.3 months (95% CI 8.9-19.6). Causes of death: progression 25 (71%), toxicity 7 (20%), secondary neoplasms 3 (9%). In the univariate analysis, the following variables grant worse prognosis: age≥60 yrs, extra-nasal localization, Ann Arbor III-IV, B symptoms, ECOG 2-4, elevated LDH, elevated beta2-mycroglobulin, low albumin level. In the multivariate analysis (including all the previous variables except albumin and beta2-microglobulin due to the high number of missing data), B symptoms (OR 2.9, 95% CI 1.3-6.6, p=0.009) and Ann Arbor III-IV (OR 2.4 95% CI 1.1-5.3, p=0.03) were significantly related with worse OS. There was a trend to a better outcome in patients treated with high dose L-asparaginase (p=0.09) (Figure 1).

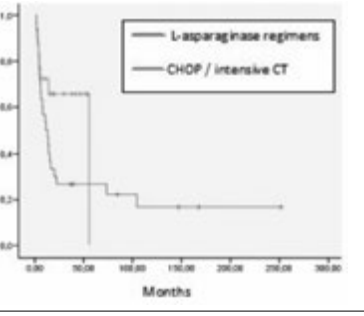

Figure 1. Overall Survival of ENKTL-NT patients according to initial theraphy.

Summary/Conclusion: In this European population mostly Caucasian, ENKTL-NT is diagnosed with a median age of around 50 yrs, and one fourth of the patients had a previous history of sinusitis. These patients have a very poor survival, being the main cause of death lymphoma progression. B symptoms and advanced stage disease at diagnosis are independent factors associated to worse outcome. The use of high dose of L-asparaginase seems to improve the outcome of these patients, although longer follow-up is needed.

PS1033

ARE OUTCOMES IMPROVING IN POST TRANSPLANT LYMPHOPROLIFERATIVE DISORDER? A RETROSPECTIVE ANALYSIS OF THE LAST 10 YEARS

N. Denny[1,*], J. Norman[1], M. Morton[2], S. Burns[1]

[1]Department of Haematology, [2]Department of Renal Medicine, Manchester University Foundation Trust, Manchester, United Kingdom

Background: Post transplant lymphoproliferative disorder (PTLD) is a spectrum of lymphoid and plasmacytic proliferations diagnosed in the context of previous solid organ (SOT) or haemopoietic stem cell transplantation (HSCT). The incidence varies between 1-20% depending on the transplanted organ. Many are driven by EBV infection. Understanding of PTLD is limited due to its heterogeneity and rarity. Our centre performs over 200 kidney and simultaneous kidney pancreas (SPK) transplants per year.
Aims: To review the local management of PTLD over the previous 10 years and to contribute to the understanding of this disorder.
Methods: Data was collected for all new PTLD patients diagnosed between 01/01/2007 and 31/12/2017 at Manchester Royal Infirmary. Patient notes were reviewed and the following details were collected; patient demographics, transplant details, type of PTLD (WHO 2016 classification), staging including organs involved, PS, EBV status, management and outcome. Statistics were performed using XLSTAT.
Results: 59 patients were diagnosed with a PTLD and 8 were excluded as the diagnosis was incorrect or they were treated at an external hospital. 51 patients were included in the final analysis with a mean age 47 years and 72.5% were male. 49 received a renal transplant and 2 SPK. 41 patients had 1 transplant, 9 had 2 transplants and 1 had 3 transplants. Mean age at time of transplant was 38 years old. Median time to PTLD diagnosis was 86 months. 43% of patients presented with GI symptoms, 27% with ENT symptoms and 10% with constitutional symptoms alone. Histology and site of disease are shown in Table 1; 66% of cases were extranodal and 61% were monomorphic. 70% of patients were EBV PCR positive in peripheral blood at diagnosis and a similar proportion of tissue specimens were EBV positive. Polymorphic PTLD occurred significantly earlier post transplant than monomorphic PTLD (p=0.04) and was strongly associated with positive EBV PCR. 37 patients had a R-IPI score 2 or less, 11 a R-IPI score of 3 or more and 3 primary CNS disease. Logistic regression analysis found a high R-IPI score/primary CNS disease to be significantly associated with death (p=0.004). Median time from diagnosis to starting treatment was 30 days and median follow up was 32 months. All patients had reduction in immunosuppression; in 10 this was the sole treatment, 26 received chemotherapy (81% RCHOP) and 7 received Rituximab. 2 out of 3 patients with CNS PTLD underwent surgical resection and WBRT as their primary treatment. There were 15 deaths during the 10 year period; 6 patients received no treatment/failed to complete treatment, 3 had primary CNS lymphoma and 6 completed treatment. Kaplan Meier analysis showed a 2 year OS of 75%. 44 patients completed treatment; 39 achieved CR, 2 had refractory disease and 3 had unknown response. Of the 39 patients achieving CR; 10 patients relapsed and 1 was lost to follow up. Kaplan Meier analysis showed a 2 year PFS of 80%.

Table 1.

Histology of PTLD	Number of patients (n=51)
Early IM like	2
Early plasmacytic	2
Polymorphic	13
Monomorphic	31
Hodgkin's	2
T-cell anaplastic	1

Site of disease	Number of patients (n=51)
Nodes	17
Extranodal	34
GI	13
Multiple	10
Liver	3
Oral	3
CNS	3
Adrenal	1
BM	1

Summary/Conclusion: In conclusion, our study shows that the majority of patients with PTLD present with extranodal disease and a significant proportion have a moderate to high R-IPI score. Nevertheless, with collaborative haematology/renal approach, controlled reduction in immunosuppression and Rituximab based chemotherapy, a 2 year OS of 75% can be achieved. Unfortunately, a significant minority of patients succumb at presentation or early in their treatment course highlighting the need to develop robust tools for monitoring SOT patients and early diagnosis of PTLD patients.

PS1034

PHASE II STUDY WITH OBINUTUZUMAB-DHAP IN RELAPSED/REFRACTORY DLBCL PATIENTS BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION: A STUDY FROM THE FONDAZIONE ITALIANA LINFOMI (GIOTTO STUDY)

L. Rigacci[1,*], B. Puccini[1], C. Visco[2], R. Battistini[3], L. Arcaini[4], M. Gotti[5], M. C. Tisi[2], L. Mannelli[1], M. Mian[6], M. Martelli[7], L. Flenghi[8], S. Pozzi[9], F. Palombi[10], A. Pascarella[11], A. Evangelista[12], C. Peracchio[13]

[1]Haematology, AOU Careggi, Firenze, [2]Cell Therapy and Hematology, San Bortolo Hospital, Vicenza, [3]Hematology, AO San Camillo Forlanini, Roma, [4]Molecular Medicine and Hematology Division , University of Pavia and IRCCS Policlinico S Matteo, [5] Hematology Division, IRCCS Policlinico S Matteo, Pavia, [6]Hematology-CBMT and Internal Medicine V, Hematology and Oncology, Hospital of Bolzano and Medical University of Innsbruck, Bolzano, [7]Hematology, University La Sapienza, Roma, [8]Hematology, Azienda Ospedaliera, Perugia, [9]Hematology, Medicina Diagnostica Clinica, Modena, [10]Hematology, IFO Regina Elena, Roma, [11]Hematology, Ospedale dell'Angelo, Venezia-Mestre, [12]Epidemiology , Unit of Clinical Epidemiology and CPO Piemonte, Torino, [13]Clinical Trial, Fondazione Italiana Linfomi, Alessandria, Italy

Background: Salvage immune-chemotherapy followed by autologous stem cell transplantation (ASCT) is the standard second line treatment for relapsed and refractory Diffuse Large B Cell Lymphoma (DLBCL). The initial exposure to Rituximab may increase the difficulty of salvaging patients who fail first line therapy, particularly refractory patients had poor clinical outcomes.
Aims: The aim of this phase II study (GIOTTO study, Eudract: 2013-004014-17) was to evaluate the efficacy and safety of the new anti-CD20 antibody (Obinutuzumab) in association with DHAP as induction therapy followed by high dose chemotherapy BEAM or FEAM with ASCT in patients with relapsed/refractory DLBCL.
Methods: The primary objective was to assess whether the treatment achieves an absolute increase of the complete remission (CR) proportion of at least 20% (hypothesizing from 30% to 50%) with respect to the standard treatment with an acceptable extra-hematological toxicity grade 3-4 of 0.25 (unacceptable extra-hematological toxicity=0.40). The CR rate was evaluated by PET scan after four cycles of GA101-DHAP before ASCT according to Cheson criteria from 2007. According to a Briant & Day design an interim analysis was necessary after the enrollment of 29 patients. To continue the study, at interim analysis at least 10 patients were required to obtain a CR while non-haematological toxicities of grade>=3 did not have to occur in more than 19 patients.
Results: From June 2014 to June 2017, 29 patients were enrolled; according to clinical characteristics 17 patients were refractory to first line therapy and 12 were relapsed. Five patients progressed or stopped due to an adverse event after the first GA101-DHAP cycle, 24 patients reached the intermediate evaluation and 9 were withdrawn from the study for the following reasons: 7 for progressive disease, 1 for physician decision and 1 for other reason. Fifthteen patients performed pre-ASCT evaluation, and 7 of them did not perform ASCT: 6 for progressive disease and 1 for adverse event. Finally eight patients underwent ASCT of whom 7 patients were in complete remission and 1 had stable disease. Overall, before ASCT, 6 patients obtained a CR (6/29=21%), 4 a partial remission, 1 stable disease and 13 progressive disease. Of note, 4 out 6 CR (4/17=24%) were obtained in refractory subset and 2 out 6 CR in relapsed subset (2/12=17%). Non-hematological toxicity grade >=3 was reported in 9 patients. Hematological toxicities were those usually reported with DHAP chemotherapy. In this first stage analysis the number of complete response pre-ASCT, 6 out 29 patients (21%), was lower than the level set for continuing the study (10 out 29 patients). The number of patients with non-haematological toxicities with grade>=3 during experimental therapy (9 out 29, 31%) was within the limits of the study design.
Summary/Conclusion: The results of the interim analysis, did not allow to reopen patients' accrual because we did not achieved 10 CR. Patients will be followed in the next years. Even if the study couldn't be completed after this interim analysis, the addition of Obinutuzumab to DHAP, led to a promising response rate in refractory patients (4 CR/17) moreover it was well tolerated and safe in this group of patients.

PS1035

COMPARISON OF R-CHOP, R-CVP, CHOP, AND CVP FOR PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA IN TAIWAN: A POPULATION-BASED STUDY, 2009-2013

H.-H. Huang[1,*], F.-Y. Hsiao[2,3,4], L.-J. Chen[1], H.-M. Chen[5], B.-S. Ko[1]

[1]Division of Hematology, Department of Internal Medicine, National Taiwan University Hospital, [2]Graduate Institute of Clinical Pharmacy, [3]School of Pharmacy, [4]Department of Pharmacy, [5]Health Data Research Center, National Taiwan University, Taipei City, Taiwan, Republic of China

Background: Diffuse large B cell lymphoma (DLBCL) is the most common type of non-Hodgkin lymphoma, and majority of the patients are older than 60 years. CHOP is the standard regimen for DLBCL patients, and additional rituximab improves the treatment responses and overall survival. However, elder DLBCL patients receive less anthracycline or omit it because of comorbidities, especially cardiac diseases.
Aims: To examine the clinical benefit of rituximab and anthracycline in different age groups of DLBCL patients, we used the Taiwan Cancer Registry Database (TCRD) and National Health Insurance Research Database (NHIRD) in our study.
Methods: We identified 4834 DLBCL patients with aged 20 years and older and known Ann Arbor stages from TCRD. According to the data from NHIRD, we excluded the patients receiving other chemotherapies or without any chemotherapy. 3989 DLBCL patients were included for further studies. 2859 DLBCL patients received R-CHOP, 750 received R-CVP, 252 received CHOP, and 128 received CVP.
Results: Compared to the anthracycline-containing groups (R-CHOP and CHOP groups), the median ages were older, the male-to-female ratio was lower, the Charlson comorbidity index was lower in the non-anthracycline groups (R-CVP and CVP groups). This observation showed that the clinicians tended to avoid anthracycline if the patients had older ages or more comorbidities. The overall survival (OS) and the time-to-treatment failure (TTF) were better if DLBCL patients received anthracycline (Figure 1 A and B; p value < 0.0001), and were dramatically improved with additional rituximab (Figure 1 A and B; p value < 0.0001). Multivariate analysis of OS and TTF demonstrated that the type of frontline chemotherapies (R-CHOP, R-CVP, CHOP, or CVP) was an independent prognostic factor. In the subgroup analysis, DLBCL patients were still benefit from the use of rituximab and anthracycline no matter in any gender (male, Figure1 C; female, Figure 1 D) or age groups (20-59 years, Figure 1 E; older than 60 years, Figure 1 F).

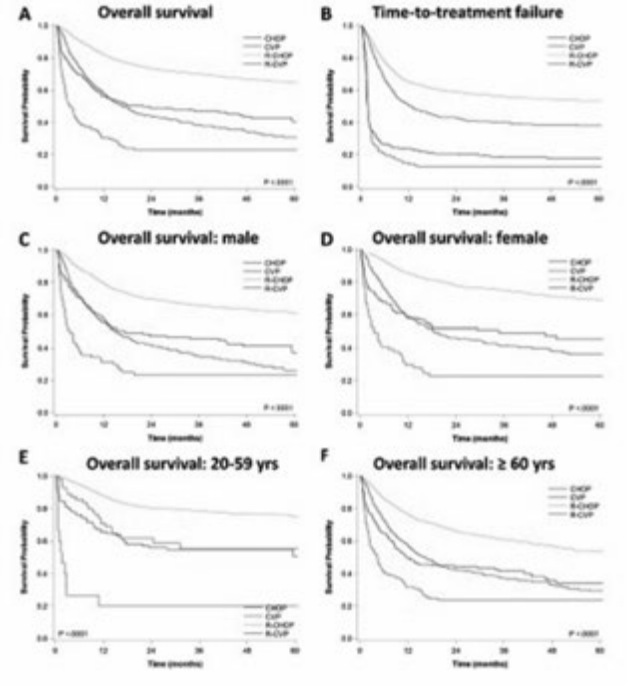

Figure 1.

Summary/Conclusion: From our population-based study, we illustrated that clinical benefit of rituximab and anthracycline in the patients with DLBCL. In the patients older than 60 years, additional anthracycline also improved their clinical outcomes.

PS1036

HIGH INCIDENCE OF CARDIOMYOPATHY IN PATIENTS RECEIVING CHOEP14 - POSSIBLE SYNERGISTIC CARDIOTOXICITY OF DOSE-DENSE DOXORUBICIN AND ETOPOSIDE

I. Zekanovic[1], S. Basic-Kinda[2], I. Radman[2], I. Hude[2], D. Dujmovic[3], I. Ilic[4], M. Kralik[5], M. Dobrenic[36], I. Aurer[2,3,*]

[1]Department of Internal Medicine, General Hospital Zadar, Zadar, [2]Division of Hematology, Department of Internal Medicine, University Hospital Centre Zagreb, [3]Medical School, University of Zagreb, [4]Deparment of Pathology and Cytology, [5]Department of Radiology, [6]Department of Nuclear Medicine, University Hospital Centre Zagreb, Zagreb, Croatia

Background: (R)CHOEP14 is a very effective front-line treatment of high-risk aggressive lymphomas. We observed an unusually high frequency of cardiotoxicity in patients treated with this regimen.
Aims: This study was performed to describe and analyze the frequency and risk factors for development of cardiac side-effects during and after (R)CHOEP treatment.
Methods: We retrospectively analyzed charts of all our patients treated with CHOEP14 or R-CHOEP14.
Results: Seventy-six patients were treated with 6-8 cycles of CHOEP14; 63, having B-lymphomas, in combination with rituximab and 13, having T-lymphomas, without it. Median age was 43, range 18 to 66 years; 46 were male and 30 female. All were fit prior to development of lymphoma and none had a history of cardiac disease. After a median follow-up of 29 months, 12 patients (16%) developed symptomatic cardiomyopathy with reduced systolic function, four during treatment and eight 3-60 (median 16) months after end of treatment. Five of the events were CTCAE grade 2, and 7 grade 3-5; one patient died of cardiac arrest. The incidence of cardiomyopathy did not correlate with age, sex, lymphoma type, hematological toxicity, mediastinal irradiation or use of salvage chemotherapy. Interestingly, 2 of the 12 patients with cardiotoxicity developed secondary tumors in comparison to only 1 of 66 without it.
Summary/Conclusion: The frequency of cardiomyopathy in our patients treated with (R)CHOEP was significantly higher than in patients of similar age receiving (R)CHOP, and even more so than in those receiving eBEACOPP or DA-(R)-EPOCH. The course of the cardiomyopathies was different than usually seen in doxorubicin-induced acute heart failure and they occurred earlier than usual for late-onset doxorubicin-induced heart failure. This indicates that the cardiotoxic effects of high peak concentrations of doxorubicin, due either to topoisomerase IIβ inhibition or to its intercalating action, are potentiated by additional topoisomerase IIβ inhibition by etoposide. Additional studies are needed to clarify involved molecular mechanisms which might be similar to those causing secondary cancers.

Background: Diffuse large B-cell lymphoma (DLBCL) sometimes involves extranodal lesion. The most common used prognostic score in patients with DLBCL is the revised international prognostic index (R-IPI) score. The score defines the more than two extranodal lesions of involvement is worse prognostic factor. However, R-IPI score doesn't consider the site of extranodal involvement.
Aims: This study was aimed at investigating the site of extranodal involvement associates with prognosis in patients with DLBCL.
Methods: We retrospectively analyzed the patients diagnosed DLBCL and treated with R-CHOP in our hospital from January 2005 to January 2017. We evaluated the 21 extranodal lesion by PET-CT, MRI or CT image. We categorized the extranodal to 18 classifications (the stomach or duodenum, bone, colon, muscle, skin, paranasal sinus, breast, lung, liver, thyroid, tongue or gingiva, eyes, testis, adrenal gland, kidney, uterus or ovary, pancreas, and the central nervous system). We analyzed overall survival (OS) and progression free survival (PFS).
Results: A total of 636 patients with DLBCL was collected data. Median follow-up time is 53 months and the 4-years OS is 80.7% (Median OS is not reached). All patients of complete remission rate is 92.3% after last R-

CHOP chemotherapy or radiation therapy. The 422 of 636 patients (66.4%) had extranodal lesion involvement. And the 297 of 422 patients (70.4%) had only one site of extranodal involvement. The extranodal site was the stomach or duodenum in 112 patients (25.2%), bone in 104 (23.0), colon in 49 (11.0%), muscle in 42 (9.5%) , skin in 41 (9.2%), paranasal sinus in 41 (9.2%),breast in 37 (8.3%), lung in 28 (6.3%), liver in 27 (6.1%), thyroid in 25 (5.6%), tongue or gingiva in 23 (5.2%), eyes in 20 (4.5%), testis in 16 (3.6%), adrenal gland in 11 (2.5%), pancreas in 10 (2.3%), kidney in 7 (1.6%), uterus or ovary in 6 (1.4%), the central nervous system (CNS) in 6 (1.4%). In the result of univariate analysis, muscle (p<0.01), skin (p<0.01), lung (p<0.01), liver (p<0.01), adrenal grand (p<0.01), pancreas (p<0.01), kidney (p<0.01) or CNS (p<0.01) of involvement is worse 4-years OS. However, in multivariate analysis result worse prognosis of OS in patients with liver (p=0.039), pancreas (p<0.01), lung (p<0.01) or skin (p<0.01) of involvement. Furthermore, we evaluated 4-years PFS. In the result of univariate analysis, bone (p=0.012), muscle (p<0.01), skin (p<0.01), lung (p<0.01), liver (p<0.01), adrenal grand (p<0.01), pancreas (p<0.01), uterus or ovary (p=0.021), kidney (p=0.045) or CNS (p<0.01) of involvement is worse 4-years PFS. In multivariate analysis result, bone, muscle, skin, lung, liver, adrenal grand, pancreas, uterus, ovary, kidney or CNS of involvement is also worse (p<0.01). The more than two extranodal lesions involvement is worse prognosis than 0 or 1 extranodal. (Four-years OS is 85.3% vs 62.4%, p<0.01. Four-years PFS is 77.7% vs 53.7%, p<0.01) (Table 1).

Table 1.

Site of involvement	Number(%)	4 years OS Rate	4 years OS Univariate analysis	4 years OS Multivariate analysis
stomach or duodenum	112 (25.2%)	75.6%	P=0.1	-
bone	104 (23.0%)	72.5%	p=0.073	-
Colon	49 (11.0%)	74.3%	P=0.768	-
Muscle	42 (9.5%)	61.1%	p<0.01	P=0.447
Skin	41 (9.2%)	57.8%	p<0.01	p<0.01
Paranasal sinus	41 (9.2%)	89.7%	P=0.761	-
Breat	37 (8.3%)	76.4%	P=0.786	-
Lung	28 (6.3%)	46.6%	p<0.01	p<0.01
Liver	27 (6.1%)	56.1%	p<0.01	P=0.039
Thyroid	25 (5.6%)	82.9%	P=0.539	-
Tongue or gingiva	23 (5.2%)	90.6%	P=0.089	-
Eye	20 (4.5%)	82.2%	P=0.583	-
Testis	16 (3.6%)	87.5%	P=0.902	-
Adrenal gland	11 (2.5%)	39.8%	p<0.01	P=0.132
Pancreas	10 (2.3%)	36.0%	p<0.01	p<0.01
Kidney	7 (1.6%)	42.9%	p<0.01	P=0.785
Uterus or ovary	6 (1.4%)	66.7%	P=0.358	-
Central nervous system	6 (1.4%)	33.3%	p<0.01	P=0.121

Summary/Conclusion: The patients with extranodal involvement DLBCL is not only the number of the lesion but also the site of extranodal involvement important.

LIPOSOMAL DOXORUBICIN IN AGGRESSIVE B CELL LYMPHOMA SHOWS SIMILAR EFFICACY TO THE CONVENTIONAL FORMULATION: LONG TERM RESULTS FROM A RETROSPECTIVE COHORT STUDY

A. García-Noblejas[1,*], J. Cannata-Ortiz[1], E. Acuña[1], J. Loscertales[1], A. Alegre[1], R. Arranz[1]

[1]Hematology, Hospital La Princesa, Madrid, Spain

Background: Anthracyclines play a key role in the treatment of Diffuse Large B cell Lymphoma (DLBCL). Now that long term disease control can be achieved there is a raising concern about cardiotoxicity, mainly in the elderly population with associated morbidities. Liposomal doxorubicin (LD) has proven to be efficacious and less cardiotoxic in breast cancer through phase III studies. In DLBCL we are waiting the results of controlled trials.
Aims: To analyze the efficacy and toxicity of LD (Myocet^{R}) in DLBCL patients with cardiovascular risks (CVR), in comparison with a cohort who received the conventional formulation during the same time period.
Methods: This is a retrospective cohort study in patients with *de novo*DLBCL consecutively treated with immunochemotherapy from March 2006 to June 2012, with conventional doxorubicin (CD) or LD. Criteria to indicate LD were any of the following: left ventricular ejection fraction (LVEF) < 50%, CVR factors or prior cardiopathy. Selection of a 3.5 vs 1 ratio (treated with CD vs LD) was used to increase statistic power. We studied response rates, progression free survival (PFS) and overall survival (OS). Toxicity was evaluated with CTCAE v.4.0. Statistical package used was SPSS v15.0.
Results: 78 patients (pts) were retrieved: 61 pts in the control arm (group A) and 17 in the study arm (group B). Characteristics are shown in Table 1. Older age, LVEF < 50%, cardiopathy history and hypertension were significantly higher in group B but the other characteristics were balanced between both groups. Efficacy: 69 pts were evaluable for response and 9 were not as they received less than 3 cycles (4 due to infection /sepsis, 3 due to stomach/bowel perforation, 1 due to worsening of cardiopathy and 1 lost to follow-up). We observed similar OR (82% in group A and 83% in group B) and CR rates (70% in group A and 83% in group B). Median follow for surviving pts was up of 7.25 years (0.16 yrs – 11.2 yrs), 7.35 years in group A and 5.5 in group B. Considering all the patients, OS and PFS at 10 years in group A were 60% ±SD 9% and 46% ±SD 9%, respectively and 73% ±SD 11% and 50% ±SD 13%, respectively in group B without significant differences between both arms. Toxicity: grade 3-4 neutropenic events were in group A 17% vs 2% in group B (p=0.02), and febrile neutropenia in group A was 13% vs 5% (5%) in group B (p=0.033). Peg- GSF was systematically used in group B. During treatment, 1 patient (2%) in the control group presented atrial fibrillation and in the Myocet^{R} group 3 (18%) patients with previous cardiomyopathy had cardiac events (2 atrial fibrillation, 1 congestive heart failure). During follow-up, 11 patients had new cardiac events, 9 in group A and 2 in group B. Twenty three (29%) pts died: 12 due to lymphoma, 4 due to grade 5 infection during treatment, 3 due to infection while in CR after treatment, 1 due to allo-SCT after secondary AML, 2 due to stroke and 1 due to non filiated cardiac tamponade.

Table 1.

Characteristics	Group A N= 61	Group B N= 17	p
Age (range)	70 (41-88)	78 (59-89)	0.001
Male / female	21/40	9/8	0.165
ECOG >2	4 (7%)	2 (11%)	0.617
Ann Arbor III-IV	43 (70%)	10 (56%)	0.389
B symptoms	38 (63%)	8 (44%)	0.179
Comorbidities			
HBP	24 (39%)	13 (76%)	0.007
DM	3 (5%)	2 (12%)	0.308
Dyslipemia	11 (18%)	5 (29%)	0.304
Smoking	15 (25%)	2 (12%)	0.257
Cardiopathy			0.001
Atrial fibrillation	6 (10%)	3 (18%)	
Ischemic	-	3 (18%)	
cardiopathy	-	1 (6%)	
Other			
LVEF <50%	2 (4%)	5 (31%)	0.001

Summary/Conclusion: In this study, the association use of LD to inmunochemotherapy in fragile patients showed similar efficacy as conventional doxorubicin, without increased toxicity.

CLINICAL CHARACTERISTICS AND PROGNOSTIC FACTORS OF HEMOPHAGOCYTIC SYNDROME IN ADULT PATIENTS: A RETROSPECTIVE SINGLE-CENTER STUDY FROM SINGAPORE

S.-Y. Ong[1,*], S. Y. Tan[2], Y. Chen[2], C. Nagarajan[2], N. Grigoropoulos[2], Y.S. Lee[2]

[1]Singapore General Hospital, [2]Singapore General Hospital, Singapore, Singapore

Background: Hemophagocytic lymphohistiocytosis (HLH) is a life-threatening syndrome of excess immune activation. Acquired HLH has a different epidemiology in Asia.
Aims: Our retrospective study aims to review the clinical characteristics and outcomes of HLH in our tertiary institution to identify strategies to improve outcomes.
Methods: A retrospective review of bone marrow aspirate reports between 1 January 2007 and 31 December 2016 was performed to identify cases with presence of haemophagocytes on aspirate smears. Patients were included if they have HLH based on the HLH-2004 criteria. Analysis of parameters of potential prognostic significance included age ≥60, sex, race (Chinese vs Malay), etiology (NK/T lymphoma vs others), haematological parameters (hemoglobin (Hb) ≤9 g/dL, absolute neutrophil count (ANC) ≤ $0.5x10^9$/L, platelet ≤$40x10^9$/L), LDH ≥1500 U/L, bilirubin ≥100 µmol/L, AST ≥500 U/L, and Epstein-Barr Virus (EBV) titre above detectable range. Survival probabilities were calculated using the Kaplan–Meier estimator, with log-rank analysis used to compare between different groups. Univariate and multivariate analyses were performed to identify variables prognostic for survival. Forward stepwise variable selection at a 0.2 significance level was used to identify covariates to

build the multivariate model. All analyses were performed using Stata (Statacorp, College Station, TX, USA).
Results: 49 patients (33 male, 16 female) fulfilled the diagnostic criteria of HLH. The median age was 53 (range 17 - 78) years old. The median haematological parameters were Hb 8.3 (3.7-13.7) g/dL, ANC 1.16 (0 – 22)×10^9/L, and platelet 55 (3-129)×10^9/L. The underlying diagnosis was NK/T-lymphoproliferative disease (LPD) (n=32), B-LPD (n=8), infections (n=5) and others including autoimmune diseases, non-haematological malignancies, and acute myeloid leukemia (n=5). 82% of patients were not alive at analysis, and major causes of death include severe lactic acidosis, multi-organ failure syndrome, coagulopathy and bleeding, infection, and disease relapse. The median survival of those who died was 35 days (95% CI 17-68 days). In univariate analysis, older age ≥ 60, NK/T LPD, LDH ≥1500 U/L, bilirubin ≥ 100 µmol/L, ANC < 0.5x 10^9/L, triglyceride ≥ 5 mmol/L, platelet < 40x10^9/L, and presence of EBV DNA above detectable range (≥ 3.3 log) were associated with poor survival and included in the multivariate model. However, patient's sex, racial group, presence of splenomegaly, and laboratory values including Hb, AST, fibrinogen, and ferritin were not associated with survival (all p>0.2). In multivariate analysis, low platelet < 40 x10^9/L (HR 2.4, 95% CI 1.02-5.70, p=0.046), presence of EBV (HR 2.8, 95% CI 1.20-6.89, p=0.018), and high triglyceride ≥ 5 mmol (HR 5.90, 95% CI 1.98-17.01, p=0.001) were independently associated with poorer survival.
