Summary/Conclusion: Consistent with published data, no cases of primary HLH were identified in our adult cohort. HLH related to malignancy have an aggressive course associated with high mortality rates despite treatment. Thrombocytopenia, positive EBV DNA, and high triglyceride levels were independently associated with worse survival. Increased bilirubin, AST, and LDH are frequently found in adult HLH and presence of these features should precipitate a workup. Novel therapies and needed to improve outcomes in adult HLH.

PS1040

THE IMPACT OF DIFFERENT IMMUNOCHEMOTHERAPY REGIMENS ON SURVIVAL OUTCOMES IN^{131} NEWLY DIAGNOSED PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA

G. Tumian[1,*], O. Trofimova[1], N. Kokosadze[1], I. Zavodnova[1], M. Kichigina[1], D. Tupitsyna[2], P. Zeynalova[1]

[1]24Kashirskoy sh., [2]N.N. Blokhin National Cancer Research Center, Moscow, Russian Federation

Background: Primary mediastinal large B-cell lymphoma (PMBCL) is recognized as distinct clinicopathologic subtype of diffuse large B-cell lymphoma, predominantly affects young female and characterized mainly by the bulky tumor mass within the upper mediastinum with frequent development of pleuritis\pericarditis and syndrome of the vena cava superior. There is not standard of first line therapy, in particular, discussed the efficacy of more intensive chemotherapy regimens and feasibility of radiation therapy.
Aims: The purpose of our study is evaluated outcomes of PMBCL patients, treated with three different rituximab-chemotherapy regimens (R-CT) with and without radiotherapy (RT).
Methods: We performed a retrospective analysis of 131 patients (pts) with PMBCL since 2005-2017 treated in N.N. Blokhin National Cancer Research Center. The median age was 30 years (16-70), 58% were female, 66% had I/IIE stages, B-symptoms was present in 55% pts. Historically, pts received three different R-CT regimens: R-MACOP-B 55 pts (42%), R-CHOP 40 pts (30,5%), DA-R-EPOCH 36 pts (27,5%). Radiation therapy to the mediastinum received 99 (76%) pts.
Results: With median follow-up of 37 months, the estimated 3-year progression-free survival (PFS) was 78,6% [95% confidence interval (CI) 78,0-96,2] and overall survival (OS) was 88,3% (95% CI 83,8-97,7). The pts that were not responded to first-line treatment, had very poor prognosis (median OS 17 months). There were significant differences in PFS and OS depending on the three CT regimens – PFS were 78% vs 65% vs 91% respectively (p=0.002), OS were 88% vs 62% vs 97% respectively (p=0,003). If we exclude from analysis 40 pts treated with R-CHOP, the differences in PFS and OS between R-MACOP-B and R-DA-EPOCH groups were not obtained (P>0.1) with less radiation used after DA-R-EPOCH (44% vs. 29%).
Summary/Conclusion: Immunochemotherapy combined with local irradiation has become the standard of care PMBCL. There was a significant benefit of intensive chemotherapy regimens before the R-CHOP. The patients not responded to first-line treatment have very inferior outcome

Bleeding disorders (congenital and acquired)

PS1041

TREATMENT OF TRAUMATIC BLEEDS WITH RECOMBINANT FACTOR XIII-A2 IN PATIENTS WITH CONGENITAL FXIII-A SUBUNIT DEFICIENCY: RESULTS FROM THE MENTOR™6 STUDY

L. Hvitfeldt Poulsen[1,*], B. Kerlin[2], D. Nugent[3], S. Kearney[4], J. Klovaite[5], M. Carcao[6]

[1]Centre for Haemophilia and Thrombosis, Aarhus University Hospital, Aarhus, Denmark, [2]Ohio State University College of Medicine, Nationwide Children's Hospital, Columbus, Ohio, [3]UC Irvine Medical School, Children's Hospital of Orange County, Orange, CA, [4]CHCMN Hemophilia and Thrombosis Center, Children's Hospital and Clinics of Minnesota, Minneapolis, MN, United States, [5]Novo Nordisk A/S, Bagsværd, Denmark, [6]Division of Haematology/Oncology and Child Health Evaluative Sciences, Research Institute, Hospital for Sick Children, University of Toronto, Canada

Background: Recombinant factor XIII-A_2 (rFXIII-A_2) has been developed for prophylaxis in patients with congenital FXIII-A subunit (FXIII-A) deficiency. Phase 3 clinical trials showed that rFXIII-A_2 provided effective prophylaxis (35 IU/kg every four weeks) with a good safety profile in pediatric and adolescent/adult patients with severe (<0.05 IU/mL) congenital FXIII-A deficiency. rFXIII-A_2 prophylaxis also allowed for effective hemostasis during minor surgery without the need for additional FXIII treatment. However, the data for the effectiveness of rFXIII-A_2 to treat traumatic bleeds are limited due to the low bleeding rate on prophylaxis.
Aims: Evaluate the treatment of traumatic bleeds in patients receiving rFXIII-A_2 prophylaxis in a planned interim analysis.
Methods: mentor™6 is a prospective, multinational, non-interventional, postauthorization safety study. The interim analysis study period was from May 17, 2013 to May 17, 2017. Patients of all ages received rFXIII-A_2 prophylaxis. Hemostatic response for the treatment of bleeds was assessed by the investigator using a four-point scale (excellent, good/effective, moderate/partly effective, and none).
Results: A total of 30 patients (median [range] age 21 [2–68] years) were receiving prophylaxis with rFXIII-A_2. Three traumatic bleeds were treated with a single dose of rFXIII-A_2 in three patients. All traumatic bleeds were mild/moderate in severity and occurred after falls. Patient 1 (13 year-old female), 6 days after the last rFXIII-A_2 prophylaxis dose, suffered a head injury that resulted in headache/dizziness but no loss of consciousness. FXIII activity at the time of injury was not measured; rFXIII-A_2 was given as preventive treatment. Patient 2 (21-year-old male) suffered a joint bleed and hematoma after a fall on to his knee 10 days after the last rFXIII-A_2 prophylaxis dose. Ultrasound of the knee was performed and 60 ml blood was drained from the knee; re-bleeding occurred 30 min later. FXIII activity prior to rFXIII-A_2 treatment was 0.25 IU/ml, rising to 0.96 IU/ml 1 hour after rFXIII-A_2 treatment. Patient 3 (12-year-old female) suffered a knee bleed after a fall 24 days after the last rFXIII-A_2 prophylaxis dose. Three days after the trauma, the patient was examined by the Investigator and, based on clinical signs, a bleed in the knee joint was diagnosed, which required treatment. No imaging was performed. FXIII activity prior to rFXIII-A_2 treatment was 0.08 IU/ml. The patient received a single dose of rFXIII-A_2 for treatment of the bleed, which was also considered as the regular prophylaxis dose (the trauma occurred 3 days before the next scheduled visit). Two patients (Patients 1 and 2) were given a single additional dose of rFXIII-A_2 to treat the traumatic bleed. Patient 3 received rFXIII-A_2 treatment as the regular prophylaxis dose. Patients 1 and 3 reported excellent hemostatic outcome to treatment with rFXIII-A_2 while Patient 2 reported a good outcome. No adverse events related to the additional rFXIII-A_2 treatment were observed.
Summary/Conclusion: These data suggest a single dose of rFXIII-A_2 after trauma, during prophylaxis with rFXIII-A_2, provides sufficient hemostatic management of traumatic bleeds, with a favorable safety profile, in patients with congenital FXIII-A deficiency.

PS1042

BEVACIZUMAB SIGNIFICANTLY IMPROVES SEVERE EPISTAXIS IN HEREDITARY HEMORRHAGIC TELANGIECTASIA

S. Zupancic Salek[1,*], G. Poje [2], D. Pulanić[1], S. Bašić Kinda[1], A. Boban[1], M. Vodanović[1]

[1]Haematology, [2]ENT Clinic , University Hospital Zagreb, Croatia

Background: Rendu-Osler-Weber disease or hereditary hemorrhagic telangiectasia (HHT) is a rare genetic disorder that affects blood vessels. Patients have abnormal blood vessels clusters like AVMs or telangiectasias which often rupture and bleed. Epistaxis is the most often manifestation of HHT which results in severe anaemia, iron infusions, and blood transfusion. QoL is very poor in these patients.
Aims: Aim of the work is to show effective results of treatment with bevacizumab in two patients with severe and recurrent epistaxis in HHT.
Methods: Methods: Prospective report of two patients (man and woman) treated with bevacizumab due to HHT and severe epistaxis with long follow up.
Results: Results: Two patients (man 61 yrs and woman 70 yrs old) with long lasting HHT started treatment with intravenous bevacizumab due to severe, recurrent epistaxis refractory to standard treatment. The man failed all medical and interventional approaches to stop the bleeding including ENT laser cauterisation procedures, septodermoplasty, etc. They have been both RBC transfusion dependent and he man received about 79 transfusions before starting treatment with bevacizumab and she had about 20 RBC transfusions. The initial dosing of bevacizumab consisted of 4 cycles each administered two weeks apart for both patients. The next several doses of bevacizumab were a month apart. The man experienced one severe epistaxis during the monthly infusions of the drug so we continue the treatment every two weeks for the next 7 months. He continued without bleeding and without side effects. They both have not got any RBC transfusion at all since the introduction of bevacizumab in the treatment. She is six months on the therapy every two weeks with very minimal epistaxis from time to time. ESS questionnaire was used to assess the severity of nose bleeds at the beginning and after starting the bevacizumab treatment.
Summary/Conclusion: Conclusion: Treatment of HHT and severe epistaxis with bevacizumab resulted in excellent efficacy and safety. Both patients showed a dramatic change in transfusion requirement and significant difference in ESS. Intravenous bevacizumab should be the considered as a standard first-line treatment option for HHT patients with severe bleeding and transfusion dependent anemia.

PS1043

AN AUDIT OF THE USE OF PROTHROMBIN COMPLEX CONCENTRATION

S. Bonney[1,*], J. Schofield[2], P. Nee[3]

[1]Haematolgy and Blood Transfusion Laboratory, [2]Haematology, [3]Accident and Emergecny, St Helens and Knowsley Teaching Hosptials NHS Trust, St Helens, United Kingdom

Background: Prothrombin complex concentrate (PCC) is licensed for emergency reversal of anticoagulation in severe and life-threatening bleeding, intracranial haemorrhage and prior to emergency surgery. It is an expensive resource costing approximately Eur2000 per adult dose. There is evidence of inappropriate use of PCC leading to delays to treatment, inappropriate dosing and use of adjunctive vitamin K. Much product, delivered to clinical settings, is wasted and we reported previously an annual wastage of approximately Eur 15,000 per annum, amounting to a UK-wide financial loss of nearly Eur3 millions. Guidelines governing the use of PCC exist in order to ensure the rapid and appropriate use of the product.
Aims: The aim of the present audit was to determine the appropriateness of use of PCC in a UK teaching hospital setting against published standards (BCSH 2011)
Methods: An audit of the emergency use of PCC was undertaken in a UK teaching hospital in 2014/15. Patients prescribed PCC were identified from the Laboratory Information System. Patients were followed up using the hospital's electronic patient management system and the following parameter were recorded: patient demographics, indications for oral anticoagulation, reason for reversal, coagulation metrics, use of vitamin K, date and time that PCC was prescribed and given and 30-day outcome. The audit was repeated in 2016/17 after an educational programme directed at hospital doctors.
Results: There were 103 prescriptions for PCC in 2014/15 and 113 in 2016/17. The clinical settings are listed in Table 1. The indications for PCC are listed in Table 2 and the delays from issue to administration are presented in Table 3. Table 4 shows the number of prescribed units administered, returned and wasted during the two audit periods. Vitamin K pre-treatment is recommended for bleeding on warfarin. Thirteen patients in the first audit and ten in the second did not receive vitamin K.
Pre-treatment with vitamin K is unnecessary in patients on direct-acting oral anticoagulants (DOAC). Eleven patients in the first audit and 24 in the second audit were on DOAC. Of these, seven patients in the first audit and nine in the second audit received vitamin K inappropriately.
Two patients in the second audit received PCC inappropriately for bleeding associated with use of dabigatran; a specific antidote, idarucizumab, is available for this agent.

Table 1. Time between PCC issue and administration.

Time between PCC issue and administration	2014-2015	2016-2017
<1 hour	29	30
1-2	13	21
2-3	8	9
3-4	4	7
>4	6	4
No administration time	15	35

Table 2. Reason for request.

Reason for request	2014-2015	2016-2017
Intracranial bleed	44	41
GI bleed	35	30
AAA	0	3
Emergency surgery	10	26
Haematoma/ mucosal bleeding	12	2
Sepsis	0	1

Table 3. Location of request.

Location of request	2014-2015	2016-2017
Accident and Emergency	61	70
Medical Assessment /GP Assessment	10	15
Theatre	0	5
Medical wards	3	5
Surgical ward	19	13
Stroke ward	8	5
ITU	2	0

Table 4.

	Prescribed	Administered	Returned	Wasted
2015/16	103	75	4	141
2016/17	113	106	42	2
Total	223	181	44	143

Summary/Conclusion: The audit shows that PCC is being used with increasing frequency in the acute hospital setting in the UK, with the emergency department the major user. Adherence to published standards on the use of this agent is not optimal and there is substantial wastage. An educational programme, directed at clinical doctors, was effective at improving standards and wastage was reduced significantly.

PS1044

HAEMOSTATIC ABNORMALITIES OR DEFECTS IN GREEK PATIENTS WITH GAUCHER DISEASE

V. Komninaka[1,*], K. Repa[1], T. Marinakis[2], A. Pouliakis[3], D. Korakakis[4], T. Kati [5], D. Tsokanas[6], M. Politou[4]

[1]Thalassaemia Center, Laiko Hospital of Athens, Greece, [2]Haematology, Georgios Gennimatas Hospital, [3]2nd Department of Pathology, Attiko University Hospital, [4]Haematology Laboratory - Blood Bank, [5]Heamatology Laboratory - Blood Bank, Aretaieio Hospital, [6]Haematology Department, Georgios Gennimatas Hospital, Athens, Greece

Background: Gaucher disease (GD) is the most common of the lysosomal storage disorders. Glucocerebrosidase deficiency results accumulation of, glucocerebroside, in macrophages.40–50% of Gaucher disease patients (GDPs) present with bleeding symptoms which have been attributed to

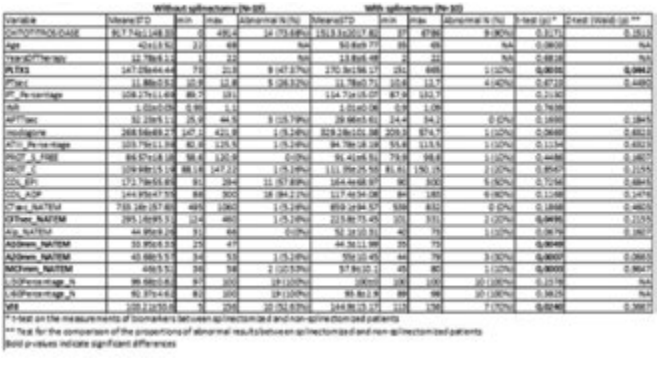
thrombocytopenia, clotting factor deficiencies and platelet disfunction. Enzyme replacement therapy (ERT) can reverse many of the systemic manifestations of (GD). However, little is known of the effects of ERT on the coagulation abnormalities and platelet function.

Aims: The aim of this study was to investigate parameters of coagulation as well as platelets function in (GDPs) in Greece and assess possible correlations with splenectomy and treatment

Methods: We studied 29 adult patients (14 males -15 females) with (GD), 27 with type I GD, and two patients with type III GD. 28 patients were under treatment with ERT. 10 of 29 patients had undergone splenectomy. All the patients were assessed with: Classic biochemistry and virilogy tests (HBV, HCV, HIV). Routine coagulation tests (PT, INR, aPTT) and fibrogen, D-Dimers, FVIII, vWF, Protein S, Protein C, ATIII, PAI (which were analysed with automatic coagulation analyser Sysmex Siemens). Platelets function (which was assessed with PFA-100 (COL, EPI, ADP). Global haemostatic potential (which was assessed with ROTEM® Tromboelastometry (NATEM) and the following parameters were recorded (CT, CFF, MCF, ML60 a-ANCKLE). Plasma chitotriosidase activity (CT) was also measured (as marker of disease activity) and ultrasound of the liver and spleen was performed, bleeding history and use of antiplatelets, NSAIDs history were recorded. The statistical analysis was performed by the SAS for Windows 9.4 software platform (SAS Institute Inc., NC, USA).

Results: All the patients presented normal hepatic biology. None of the patients took antiplatelets, NSAIDs. 10 of 29 patients had undergone splenectomy. 23 out of 29 patients had history of bleeding. 16 of 29 patients (55.2%) had abnormal PFA EPI. 22 of 29 patients (75.9%) had abnormal PFA ADP and 15 of 29 patients (51.7%) had both ADP and EPI abnormal but there was no difference between splenectomised and non splenectomised. The majority of the patients mentioned that there was improvement of the bleeding problems after splenectomy and treatment with ERT. 27 of 29 patients (93.1%) had normal values in routine clotting testing, fibrogen, protein S, protein C, AT III, with no significant differences between splenectomised and non splenectomised ones. Thromboelastometry parameters NATEM were within normal limits but patients with splenectomy had higher PLTS, p shorter CFT p, higher a angle p, higher MCF p and higher VIII p. The results of measurements are reported in Table 1. Chitotriosidase levels (as marker of disease activity) were elevated in both cohorts.

Table 1. Results of comparison between splenectomized and non-splenectomized patients.



Summary/Conclusion: Patients had normal rotem parameters while they had abnormal PFA 100 (COL_EPI, COL_ADP). Patients who have undergone splenectomy were more hypercoagulable in terms of Rotem parameters.Splenectomy does not seem to modify platelets activation.Patients bleeding diathesis has ameliorated after splenectomy and initiation of ERT, the patients after many years with ERT therapy, they still had abnormal platelet function tests. Platelet function tests should be performed on all Gaucher patients prior to surgical procedures, or with an unexplained bleeding disorder while thromboelastography does not seem to be able to detect such disfunctions limiting its value for prior to surgery assessments

PS1045

THALIDOMIDE USE IN HEREDITARY HEMORRHAGIC TELANGIECTASIA: A RETROSPECTIVE EVALUATION OF THE PATIENTS

M. Baysal[1,*], E. Umit[1], H.O. Kırkızlar[1], A.C. Özdöver[1], M. Demir[1]

[1]*Hematology, Trakya University Faculty of Medicine, Edirne, Turkey*

Background: Hereditary hemorrhagic telangiectasia (HHT) is a rare, autosomal dominant disorder characterized by telangiectasia and arteriovenous malformations (AVM) skin, mucosa and in internal organs such as liver and lungs. Its prevalence is estimated to be between 1/5000 and 1 / 10,000. Recurrent epistaxis due to nasal telangiectasia is the most common finding.HHT diagnosis is made clinically by Curaçao criteria. The presence of 3 of the 4 Curaçao criteria was enough for the diagnosis

Aims: Thalidomide is an immunmodulator drug commonly used in plasma cell disorders and especially in multiple myeloma. Angiogenesis and new vessel formation play a role in the pathophysiology of hereditary hemorrhagic telangiectasia It has been suggested that thalidomide may be effective in the treatment of HHT due to antiangiogenic effect.The efficacy of thalidomide is reported in small number of case series and phase two studies. Based on this knowledge we tried to present our experience and findings in this rare disorder

Methods: Data of six patients diagnosed with HHT according to the Curaçao criteria were recorded from their files in a retrospective manner. All patients were refractory to the local invasive procedures and cauterization.IBM SPSS V20 was used for statistical analysis. Descriptive analysis was used for all parameters.Patients were started to treat with thalidomide 50 mg daily. Thalidomide dose raised to the 100 mg according to the response.Epistaxis severity score which was interpreted and validated by Boag et.al. was used in the study. Besides these parameters and measurements; 36-Item Short Form Health Survey questionnaire (SF-36) was used for quality of life assessment before and after treatment.

Results: Six patients treated with thalidomide included in our study. Three patients were male and three were female. Mean age was 60.50±10,07 years (44-74). The mean ESS before treatment was 7,40±2,02 (4,31-9,66) and after treatment was 3,35±1,53 (0,92-4,94). One patient reported grade one dizziness and one patient reported grade one nausea which were resolved spontaneously. No other specific side effects were reported during treatment period. All SF-36 item scores were found to be increased after the treatment which may be regarded as improvement of quality of life with thalidomide treatment

Summary/Conclusion: HHT patients mostly suffer from epistaxis episodes. Epistaxis episodes brings a burden and reduces health related quality of life in HHT patients. Thus reducing bleeding symptoms and epistaxis episodes is an important goal and treatment evaluation tool. Hoag et. al. designed and validated. Epistaxis severity score (ESS) for HHT patients. ESS is an objective symptom assessment form for clinicians. Besides HTT patients frequently apply to emergency services with bleeding. Because of bleeding episodes, HHT patients are usually anemic and often transfused with erythrocyte suspensions or treated with iron supplements. Chronic nature of the disease may lead inability to search medical help for the symptoms of the patients. Thalidomide has promising results in HHT patients and there are many roads to go diagnosis and treatment of HTT and better edited, comprehensive studies are needed.

PS1046

DIAGNOSIS AND MANAGEMENT OF ACQUIRED VON WILLEBRAND DISEASE. A SINGLE CENTER EXPERIENCE

C. Santoro[1,*], A. Ferretti[1], E. Baldacci[1], R. Abbruzzese[1], A. Bruzzese[1], A. Serrao[1], F. Barone[1], R.A. Bochicchio[1], G. Maestrini[1], A. Chistolini[1], R. Foà[1], M.G. Mazzucconi[1]

[1]*Hematology, Department of Cellular Biotechnology and Hematology, Sapienza University, Rome, Italy*

Background: Acquired Von Willebrand syndrome (AVWS) is a rare acquired coagulopathy, often associated with an underlying disorder (lymphoproliferative, myeloproliferative, cardiovascular, neoplastic and autoimmune disorders). The diagnosis is not easy and relies on a negative familial and personal clinical hemorrhagic history and a late onset in life of bleeding symptoms, associated with a laboratory pattern for Von Willebrand Disease (VWD).

Aims: Aim of our study is to describe the experience in the diagnosis and management of AVWS patients (pts) at a single Italian hematologic center.

Methods: Between 2004-2017 we have diagnosed and managed 8 pts [5F, 3M; median age 62.4 years (50.4-81.6)] affected by AVWS. The diagnosis was made on the basis of clinical and laboratory features suggestive of AVWS. The screening for VWF:RCo inhibitor was made utilizing mixing studies.

Results: Reasons for diagnosis were: recent onset of bleeding symptoms in 5 pts, increased aPTT in 3. Five subjects received a diagnosis of AVWS type 2A, 1 of type 1 and 2 of type 3 [median VWF:Ag 15%, range 1.6-51% (n.v. blood group 0: 41-101%; non group 0: 50-130%); median VWF:RCo 5.65%, range <6.25-28% (n.v. blood group 0: 41-97%; non group 0: 52-124%); median FVIII:C 18.25%, range 2.1-53% (n.v. 58-130%)]. The pres-

ence of a VWF:RCo inhibitor was investigated in 4 pts: 3 were negative, 1 positive. All pts did not have a family or past personal history of bleeding disorders/symptoms. The spontaneous hemorrhagic events presented at diagnosis and during the follow-up were: GI and gum bleeding, muscle hematomas, ecchymoses, epistaxis. Moreover, 3 pts bled after dental extractions/procedures, although being prophylactically treated with VWF/FVIII concentrate. Desmopressin, tranexamic acid, VWF/FVIII concentrate and recombinant FVIII were used as prophylaxis or treatment of bleedings in all pts, with variable responses on clinical symptoms. Seven/8 cases showed a concomitant lymphoproliferative disorder: 1 gastric B-cell MALT lymphoma, 1 indolent B-cell lymphoma, 4 MGUS, 1 MGUS progressed to Waldenstrom's disease (WD). In one case, AVWS was idiopathic. The management of the lymphoproliferative disorders was as follows: the patient with gastric B cell MALT lymphoma was treated with rituximab, obtaining a complete remission (CR) of both the lymphoma and the AVWS. The patient with WD was treated first with R-CVP and then with Ibrutinib: she presents a stable lymphoproliferative disease and persistent AVWS. A watch and wait strategy was chosen for the patient with the indolent B-cell lymphoma. Strategies to manage AVWS in pts with a concomitant MGUS were: prednisone (PDN) + cyclophosphamide (CTX) and then high dose immunoglobulins (HDIg) in one patient, without obtaining a response to both therapies; infusion of HDIg in one other case with a transient CR of the VW disease laboratory parameters; no specific treatment in the other 2 MGUS cases. The idiopathic AVWS case was treated with PDN and obtained a CR of the VW disease laboratory parameters; he relapsed and was treated with CTX and PDN, obtaining a second CR.
Summary/Conclusion: AVWS is a rare syndrome, probably underdiagnosed because unrecognized. The rarity of the disease and the lack of specific assays are limiting factors. AVWS should be considered whenever a patient presents with a late onset in life of bleeding symptoms associated to laboratory characteristics compatible with VWD. It is mandatory to search for concomitant diseases.

PS1047

CONGENITAL FXIII DEFICIENCY IN PAKISTAN

M. Borhany[1,*], N. Fatima[2], M. Abid[2], T. Shamsi[2], V. Schroeder[3], H.-P. Kohler[3]

[1]Haematology and Blood Bank, [2]National Institute of Blood Disease and Bone Marrow Transplantation, Karachi, Pakistan, [3]Department for BioMedical Research,University of Bern, Bern, Switzerland

Background: Factor XIII (FXIII) deficiency is a rare bleeding disorder (RBD) with an incidence of about one in 1–2.5 million and its incidence is higher in populations with consanguineous marriages.
Aims: The aim of this study was to characterize patients and relatives from sixteen families with suspected FXIII deficiency from Pakistan and to identify the clinical characteristics and underlying mutations.
Methods: FXIII deficient patients, enrolled at National Institute of Blood diseases and Bone Marrow Transplantation were included in the study. The patients' medical histories were recorded in a questionnaire. As a first indicator of FXIII deficiency, a 5M urea clot solubility test was used. Plasma FXIII A- and B-subunit antigen levels were determined by ELISA. FXIII activity was measured with an incorporation assay. Sequencing of all exons and intron/exon boundaries of F13A was performed.
Results: We have analyzed 16 families in which 32 (female 18 and 14 males) were severe FXIII deficient with FXIII level <1%. 19 first-degree relatives with mean FXIII level 71.19±21.1 are asymptomatic. Each family had a history of consanguineous marriages except one. 50% had significant family history of bleeding. Age at first presentation ranged from birth to 18 years. In these patients; we identified 23 mutations which includes 19 missense mutations, 2 Splicing mutations and 2-nonsense mutations with 7 novel mutations. Main clinical manifestations were bleeding after injury (78%), umbilical cord bleeding (57%), intracranial bleed (43%), hematoma, bruises (39%), circumcision (35%), in female's abortions and menorrhagia (38%). Fresh frozen plasma / cryoprecipitate were used in the management of most patients and for weekly prophylaxis in 8 patients with grade III bleeding.
Summary/Conclusion: We have analyzed a cohort of 51 individuals from 16 families in which 32 were severe FXIII deficient (homozygous or compound heterozygous) and remaining were FXIII deficient carriers (heterozygous). We identified 23 mutations in these families leading to congenital FXIII deficiency. Diagnosis of FXIII deficiency should be made on time so that prophylaxis can be initiated immediately to prevent fatal bleeding and for genetic counseling.

PS1048

DISSEMINATED INTRAVASCULAR COAGULATION SCORING IN CHILDREN WITH ACUTE LEUKEMIA: IS THERE A SIMPLER AND ECONOMICAL ALTERNATIVE?

Y. El Chazli[1,*], H. Hassab[1], M. Salama[1], W. El Gendy[2]

[1]Pediatric Hematology/Oncology, Faculty of Medicine, Alexandria University, [2]Clinical and chemical pathology, Alexandria University, Alexandria, Egypt

Background: Coagulation abnormalities and disseminated intravascular coagulation (DIC) have been extensively studied in acute promyelocytic leukemia, but only a limited number of studies addressed this issue in children with other types of acute leukemia.
Aims: To detect coagulation abnormalities and DIC by using International Society on Thrombosis and Haemostasis (ISTH) scoring system in children with acute leukemia.
Methods: A diagnostic test accuracy study including children with acute leukemia (lymphoblastic and myeloid except the promyelocytic subtype) admitted to the Hematology-Oncology Unit at Alexandria University Children's Hospital, either at first diagnosis (before starting chemotherapy) or when presenting with systemic inflammatory response criteria (SIRS)/sepsis during chemotherapy. Patients were consecutively recruited between October 2016 and March 2017, after obtaining an informed consent. Prothrombin time (PT), D-dimer, fibrinogen, antithrombin III and protein C levels were assessed and the ISTH scoring system for overt and non-overt DIC was calculated. The patients were followed until disappearance of blasts from periphery or resolution of SIRS/sepsis.
Results: 25 patients were enrolled at first diagnosis, and 25 patients when presenting with SIRS/sepsis. Their median age was 47 months (range: 17 to 149 months). Forty-one patients had ALL and nine had AML. At baseline assessment, 32% of patients had a positive overt DIC score, with a score ranging from 0 to 7 and a median of 4, while 50% had a positive non-overt score (median of 4, range: -2 to 9). At baseline, the median platelet count, D-dimer, and protein C values were abnormal, while the median PT, fibrinogen and antithrombin III were within normal range; the same pattern was found when analyzing these parameters over the whole study period. A significantly higher percentage of patients had bleeding among the DIC positive group compared to DIC negative one (p=0.003), and the former group received significantly more transfusions (packed red cells, platelets, and plasma). By using receiver operating curve (ROC) analysis, platelet count, PT, D-dimer level, as well as fibrinogen level were found to be statistically significant discriminators of occurrence of overt DIC in children with acute leukemia. Interestingly, the PT diagnostic criterion using Youden index was 15 sec with a sensitivity of 47.62%, specificity of 82.22%, and ≤175 mg/dL for fibrinogen with a sensitivity of 67.21%, specificity of 71.21%. The platelet count & D-dimer were the best discriminators of overt DIC in newly diagnosed acute leukemia patients, while platelet count and protein C were best in patients with SIRS/sepsis. Looking at non-overt DIC score, there was a statistically significant moderate rate of specific agreement between non-overt DIC score calculated using major criteria only (the global coagulation tests and their trend) and non-overt DIC score using major and specific criteria (AT III and PC levels are added), with a Kappa of 0.436, p=0.000, and a high rate of negative agreement (83.2%).
Summary/Conclusion: These results indicate that using a lower cut-off for PT, a higher one for fibrinogen and adding more weight to a lower platelet count in the calculation of the overt DIC score might be indicated in children with acute leukemia. A revised non-overt DIC score using only the global coagulation tests and their trend over time would be a simpler and interesting alternative to the use of more expensive specific coagulation tests in resource-limited countries.

PS1049

EFFECT OF THROMBOELASTOGRAPHY DEFINED COAGULOPATHY IN TRAUMATIC BRAIN INJURY

D. De[1,*], D. Suvro Sankha[1], S. Das[2], S. Halder[2]

[1]Dept of Hematology, [2]the Mission Hospital, Kolkata India

Background: The presence of coagulopathy is common after severe trauma. It is associated with increased morbidities, increased transfusion requirement and mortality.
Aims: The aim of this study was to identify presence of coagulopathy in isolated traumatic brain injury, and its association with outcome.
Methods: This is a prospective observational study, with a cohort of patients admitted to neuro ICU with traumatic brain injury were evaluated. Conventional coagulation tests and Thomboelastography were done within first

24 hour of admission to identify coagulation status. The cohort is divided in 3 groups of hypercoaguable, normal, or hypocoaguable according to TEG report and the groups are compared. The SAPS II score and mortality rates were compared between the groups.
Results: Total 112 patients were included in the study during the period of December 2015 to November 2016. The overall mean age of the cohort was 58.65 years, and 80.4% were male. The overall mortality was 32.1%. by using TEG, about 44.64% patients showed hypercoaguability whereas hypocoaguable status was found in 4.46% patients. The mean age, sex ratio and other baseline parameters were comparable. The sensitivity of diagnosis of coagulopathy by conventional tests were 80.7%, but specificity was only 8.9%. Hypercoagulation status could not be picked up by conventional coagulation tests. However, the accuracy of diagnosing hypocoagulation status was 88.39% by conventional coagulation tests. The SAPS II score and mortality rates were comparable between hypercoaguable and normal hemostasis group (SAPS II score 43.66 and 42.46 respectively, p value >0.05, mortality rate were 32% and 28.1% respectively, p value >0.05) but hypocoaguable group showed significant higher SAPS II score and higher mortality compared to normal hemostasis (SAPS II score 60.0 and 42.46 respectively, p value 0.002, mortality rate were 80% and 28.1% respectively, p value 0.034) (Figure 1).

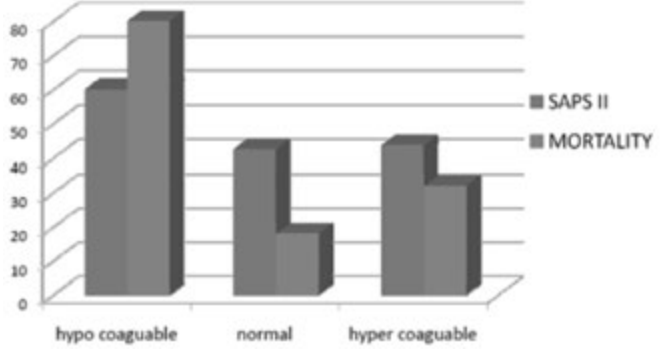


Figure 1.

Summary/Conclusion: Traumatic brain injury is often associated with coagulopathy. Thromboelastography is more reliable for diagnosing coagulopathy in these settings. The hypocoaguability is associated with higher SAPS II score and higher mortality rates.

ASSESSMENT AT DIAGNOSIS OF 200 PATIENTS WITH A PNH CLONE OR GPI-DEFICIENT CELLS ≥0.01% ENROLLED IN A NATION-WIDE MULTICENTRIC PROSPECTIVE OBSERVATIONAL STUDY

M. Le Garff-Tavernier[1,*], B. Drenou[2], A. Debliquis[2], R. Letestu[3], B. Chatelain[4], T. Boyer[5], J.-P. Vial[6], M. Peres[7], V. Harrivel[8], G. Socié[9], R. Peffault de Latour[9], O. Wagner-Ballon[10]

[1]Service d'Hématologie Biologique, APHP Groupe Hospitalier Pitié-Salpêtrière-Charles Foix, Paris, [2]Laboratoire d'Hématologie, Groupe Hospitalier de la Région Mulhouse Sud Alsace, Mulhouse, [3]Laboratoire d'Hématologie, APHP CHU Avicenne, Hôpitaux Universitaires de Seine-Saint-Denis, Bobigny, France, [4]Laboratoire d'Hématologie, CHU UCL Namur, Yvoir, Belgium, [5]Laboratoire d'Hématologie, CHU Lille, Lille, [6]Laboratoire d'Hématologie, CHU Bordeaux, Bordeaux, [7]Laboratoire d'Hématologie, CHU Toulouse, Toulouse, [8]Centre de Biologie Humaine - Laboratoire d'Hématologie, CHU Amiens Sud, Amiens, [9]Service d'Hématologie Clinique, APHP Hôpital universitaire Saint Louis, Paris, [10]Département d'hématologie et immunologie biologiques, APHP Hôpitaux universitaires Henri Mondor, Créteil, France

Background: The high frequency of minor PNH clones <1% highlights the use of high-resolution flow cytometry (FCM). Thus, the International Guidelines (Borowitz, 2010) were spread throughout French-speaking countries by a biological workshop, which allowed the detection of PNH cells with a 0.01% sensitivity in a multicenter approach. This diagnostic practice harmonization has been pursued through an inter-laboratory comparison program, involving more than 50 French-speaking centers since 2013 (Debliquis, 2015).
Aims: Our HPN^{AFC} group initiated a nation-wide multicenter prospective observational study on February 29th 2016, in order to collect all PNH cases ≥0.01% and notably to monitor the evolution of minor clones <1% during 5 years.
Methods: All patients with a PNH clone or GPI-deficient cells ≥0.01%, newly- or previously-diagnosed, detected from February 2016 until March 2021 in France are included in this Observatory, irrespective of age, provided that the center has validated a PNH FCM quality control. For each patient, the baseline assessment always corresponds to the initial PNH clone detection, even if it occurred before the Observatory opening. Thus, this strategy will allow the collection of all cases in the active French PNH file. Inclusions are made by the referent cytometrist of each center by filling in the e-CRF form available on the HPN^{AFC} website with clinical and biological data. This study was approved by the national research ethics board.
Results: As of January, 31th 2018, 40 cytometry laboratories have registered across France and 28 centers have submitted 265 inclusion points with a PNH clone or GPI-deficient cells ≥ 0.01%. All the cases have been reviewed by the 2 principal investigators, who carefully re-examined FCM data. This method enabled the validation of 200 cases, with 65 ongoing ones due to missing clinical or biological data. The patient median age at diagnosis was 46 years [10-87] with 14 pediatric cases (<18y) and a sex ratio of 0.90. Diagnoses were made between 1988 and 2018 with clinical information available in 93%. Out of these 186 patients, 28 (15%) had hemolytic anemia and more than half of them had aplastic anemia (n=119, 64%). Other clinical manifestations included 29 unexplained cytopenias (16%), 10 myelodysplastic syndromes (5%), 8 cases of hemoglobinuria (4%) and 6 rare cases of recurrent thrombosis (3%). Biological data showed a median hemoglobin value of 9.3 g/dL [4.1-16.5], 1.4 x10^9/L [0.1-11] neutrophils and 57 x10^9/L [1-360] platelets. The median clone size at diagnosis was 1.6% on neutrophils with a very wide range [0- 99.4], almost half of them being less than 1% and mainly composed of type III cells. The median clone size was slightly higher on monocytes (2.4% [0-99.6]) with a similar distribution of type III and type II cells. RBC analysis, performed for half of the patients, showed a majority of minor clones and no correlation was observed between PNH clone size on neutrophils and RBC. The median PNH clone size on neutrophils in case of aplastic anemia was 0.88%, yet some patients had very large clones ≥90%. Conversely, PNH clones from patients with hemolytic anemia were very large with a median size of 83.6%, but some patients had smaller clones of less than 20%.
Summary/Conclusion: Almost two years after its initiation, 200 confirmed patients have been yet enrolled in this National Observatory. A comprehensive follow-up of a foreseeable larger number of PNH clones (so far 115 out of the 200 already have at least 1 follow up point) will lead to better understand the minor PNH clone evolution.

PS1051

ASSOCIATION OF AUTOPHAGY-RELATED GENE 5 VARIANTS WITH ACQUIRED APLASTIC ANEMIA IN HAN-CHINESE POPULATION

Y. You[1,*], J. Huo[1]

[1]State Key Laboratory of Experimental Hematology, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Tianjin, China

Background: Acquired aplastic anemia (AA) is a life-threatening bone marrow failure syndrome characterized by hypocellular bone marrow and pancytopenia peripheral blood. It is beyond controversy that immune-mediated quantitative and qualitative defects of hematopoietic stem/progenitor cells (HSPCs) plays an vital role in the pathophysiology of acquired AA. While, Autophagy is closely related to T-cell pathophysiology and the destiny of HSPCs, and besides, autophagy-related gene 5 (ATG5) is a crucial autophagy gene and has emerged as a spotlight in a multitude of immune functions.
Aims: Considering the essential role of autophagy,we hypothesized that genetic variants in ATG5 might contribute to acquired AA.
Methods: Via the approach of Sequenom Massarray system we have studied six ATG5 polymorphisms in a Chinese cohort of 176 patients with acquired AA and compared with 157 healthy controls.
Results: We observed a lower risk of acquired AA in the recessive model of rs510432 and rs803360 polymorphisms (adjusted OR[95% CI]=0.467[0.236-0.924], p=0.029 for ATG5: rs 510432; adjusted OR[95% CI]=0.499[0.255-0.975], p=0.042 for ATG5: rs 803360). Further more, the decreased risk was even more pronounced among non-severe AA (NSAA) compared with health controls (adjusted OR[95% CI]=0.356[0.141-0.901], p=0.029 for ATG5: rs 510432; adjusted OR[95% CI]=0.348[0.138-0.878], p=0.025 for ATG5: rs 803360; adjusted OR[95% CI]=0.352[0.139-0.891], p=0.027 for ATG5: rs 473543). Moreover, rs573775 can strongly predict the disease evolution and recurrence in patients with acquired AA (Figure 1).

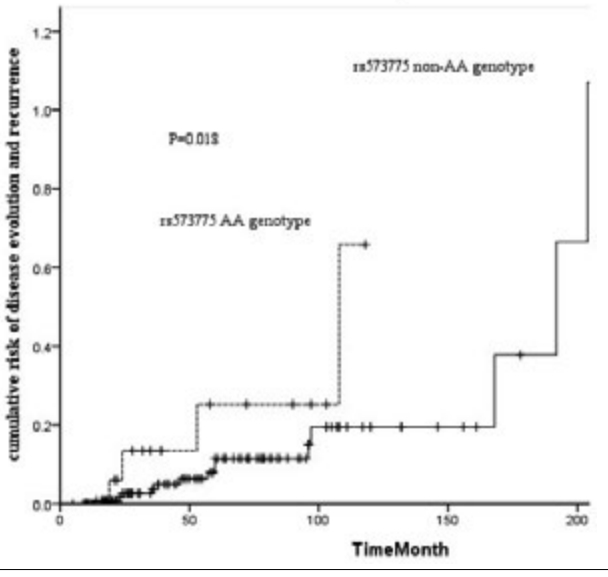

Figure 1.

Summary/Conclusion: Our results indicated that ATG5 variants are associated with acquired AA patients, which may facilitate further clarifying the autoimmune mechanisms and making the patients-tailored medical decisions.

PHASE IB STUDY OF THE CXCR4 ANTAGONIST BL8040 COMBINED WITH IMMUNOSUPPRESSIVE THERAPY IN PATIENTS WITH APLASTIC ANEMIA

T. Kadia[1,*], G. Borthakur[1], N. Jain[1], N. Pemmaraju[1], K. Takahashi[1], K. Dwyer[2], J. Khoury[3], A. Vainstein[4], C. Bivins[1], S. Dara[1], L. Xiao[5], F. Ravandi[1], G. Garcia-Manero[1], H. Kantarjian[1]

[1]Leukemia, [2]Stem Cell Transplant Research, [3]Hematopathology, MD Anderson Cancer Center, Houston, United States, [4]BiolineRx, Modi'in, Israel, [5]Biostatistics, MD Anderson Cancer Center, Houston, United States

Background: Aplastic anemia (AA) is a bone marrow (BM) failure syndrome characterized by a severe depletion of hematopoietic stem and progenitor cells (HSPCs) in the BM leading to cytopenias. Most cases of acquired AA are the result of destruction of the HSPCs by autoreactive cytotoxic T-cells. This is mediated through immunosuppressive cytokines as well as perforin/granzyme-mediated apoptosis, requiring close proximity in the microenvironment. CXCR4 expression on pathogenic T-cells in AA facilitate their homing to the BM (Arieta Kuksin Blood 2015). Blocking the CXCR4 signaling axis in pathogenic T-cells can disrupt their homing to the BM may improve responses when combined with immunosuppressive therapy (IST). BL8040 is a CXCR4 antagonist that also has effects in mobilizing and increasing the numbers of HSPCs.
Aims: We designed a pilot phase Ib study evaluating the feasibility, safety, and efficacy of BL8040 combined with IST for pts with AA or hypoplastic myelodysplastic syndrome (hMDS).
Methods: Pts ≥ 18 years, with adequate organ function, with a diagnosis of severe AA or hMDS, including those with relapsed (not refractory) AA were eligible. Pts were treated with BL8040 0.75 mg/kg SQ on D1-10, hATG 40 mg/kg/day (or 35 mg/kg/day for age ≥ 55 yrs) IV on D11-14, methylprednisone 1mg/kg/day IV daily on D11-14, followed by PO prednisone tapered off over 1 month, and cyclosporine (5 mg/kg) PO daily for up to 6 months. BL8040 (0.75 mg/kg) was continued on D1-5 of every month start with month 2. BM was performed at baseline, day 10, month 3 and month 6. Blood (PB) and BM samples were collected during treatment to explore the dynamics of immune cell and HSPC mobilization.
Results: Eight pts have been treated, with a median age of 70 years (range, 23-75). Three pts had no prior IST, 4 pts had relapsed AA, and 1 pt had hypoplastic MDS. Table 1 summarizes baseline characteristics. Six pts (75%) had diploid karyotype, while 2 had insufficient metaphases. At baseline 1 pt had mutations in TET2 and JAK2, and 1 pt had a DNMT3a mutation by next-generation sequencing. 4 pts have completed at least 5 months of therapy, 1 is too early in the treatment course, and 3 pts came off study early due to allergic reactions: 2 pts had grade 2 allergic reactions to the first doses of BL8040 and came off study, while 1 pt was noted to have an allergic reaction to the hATG skin test. Steroid premedication in subsequent pts mitigated BL8040-associated allergic reaction. 4 pts are evaluable for response with 2 CRs. Besides allergic reactions, the regimen was well tolerated. There were no grade ≥ 3 related AEs. Most common AEs possibly related to therapy were injection site pain, headaches, chills, and hot flashes. Quantification of T-cell subsets in the PB and BM by flow cytometry was available in 5 pts so far at 2-4 time points during therapy. On treatment, 3 pts had a notable relative increase in T-regulatory cells in the BM; there was a general trend for decrease in CD4+/CD45+ central memory T-cells, and increase in CD4+/CD45+ effector memory and CD4+/CD45+ TEMRA T-cells in the BM and PB; and there was a trend towards increased CD45+/CD8+ T-cells in the PB. In almost all cases, there was a significant decline in CXCR4 expression across T-cell subsets in BM and PB.

Table 1.

Characteristic	Median (range) or N [%]
Age	70 (23 - 75)
WBC [x10^9/L]	2.9 (1.4 – 6.9)
Platelets [x10^9/L]	20 (1 - 37)
Total Bilirubin	0.95 (0.5 – 3)
Creatinine	0.79 (0.74 – 0.97)
PNH Clone Detected	2 [25%]
T-cell Receptor Clonality	6 [75%]

Summary/Conclusion: Adding BL8040 to IST appears to be safe and feasible in patients with AA. Encouraging responses are seen with good tolerability. Preliminary analysis shows increasing BM T-regs and decreased CXCR4 expression after treatment. Complete profiling of the immune repertoire and HSPCs of pts will be summarized.

PS1053

CLINICAL EFFICACY OF THERAPIES FOR TRANSFUSION-DEPENDENT NON-SEVERE APLASTIC ANEMIA: A RETROSPECTIVE COHORT STUDY IN MULTIPLE HOSPITALS

S. Lin[1], Y. Yang[2], H. Yin[3], C. Huang[1], J. Chen[1], L. Wu[1], J. Shen[1], B. Ye[1], Z. Hu[1], Y. Shen[1], Z. Zheng[1], W. Shen[3], X. Wu[3], X. Lu[3], G. He[3,*], J. Li[3]

[1]Hematology, The First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou, [2]Hematology, The First Hospital of Jilin University, Changchun, [3]Hematology, The First Affiliated Hospital of Nanjing Medical University, Jiangsu Provincial People's Hospital in Nanjing, Key Laboratory of Hematology of Nanjing Medical University, Collaborative Innovation Center for Cancer Personalize, Nanjing, China

Background: Aplastic anemia (AA) is a bone marrow hypoplasia disease caused by multiple reasons. Its symptoms include failure of hematopoiesis and decrease in white blood cells, hemoglobin and platelets, with bleeding and infection at the same time. Based on the results of peripheral blood and bone marrow test, AA could be classified as severe AA (SAA) and non-severe AA (NSAA). Some patients with NSAA have a lower level of hemoglobin or platelets, and require regular blood transfusion, which have influenced their daily life. This condition was defined as transfusion-dependent NSAA (TD-NSAA). These patients' long-term transfusions and decreased immunity make them susceptible to different infections. In addition, the side-effects of drugs can also cause heavy burden to patients physically, psychologically, and economically. Without treatment, TD-NSAA can easily progress to SAA which have little response to drug therapies. Therefore, it is clinically important to study the early interventions for TD-NSAA.
Aims: This study aims to evaluate the clinical efficacy and prognosis of currently popular treatments for patients with transfusion-dependent non-severe aplastic anemia (TD-NSAA)
Methods: Medical records of patients with TD-NSAA were collected from three hospitals and divided into four groups based on their treatment. Treatment efficacy was evaluated at 6 months after treatment, with subgroup analysis based on patients' disease courses. Adverse events and 3-year survival status were also reviewed.
Results: A total of 175 patients' records were collected in this study. The analysis of treatment efficacy indicated that the most effective treatment was allo-HSCT with the response rate of 84.62%, which was followed by ATG + CsA (68.52%), CsA + androgen (26.92%), and androgen (0%), respectively. The subgroup analysis showed that for patients with less than 6-month disease courses, ATG + CsA treatment could achieve similar response rate as allo-HSCT (84.00%). Besides, ATG + CsA showed better efficacy than CsA + androgen in all stratified arms ($p<0.05$). Three-year event-free survival rates were higher in patients treated with ATG + CsA (83.3%) than with CsA + androgen (64.4%) ($p=0.013$) (Figure 1).

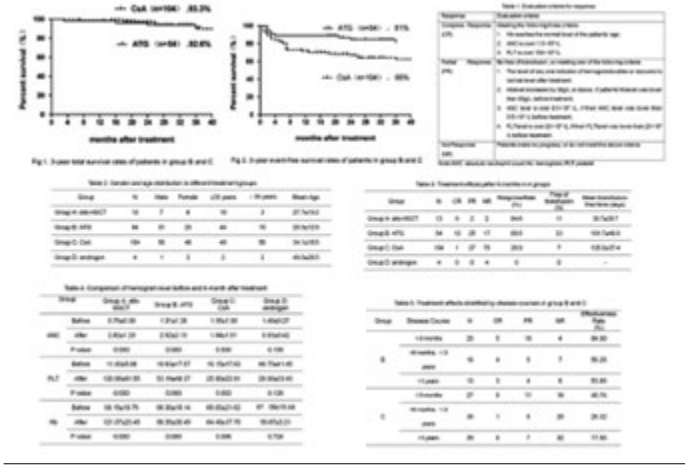

Figure 1.

Summary/Conclusion: In conclusion, TD-NSAA is clinically complicated, and its choice of treatment differs in considering the patients' age, disease courses, dependence on transfusion, socioeconomic status, and life expectation. At present, immunosuppression therapy has become the main choice of treatment. However, for patients with TD-NSAA for a long time, allo-HSCT may achieve better effect than combined ATG+CsA treatment. Allo-HSCT pre-treatment plan will be a new field to be explored for clinicians.

Background: Neutropenia is characterized by a reduced Absolute Neutrophil Count (ANC): it is defined as mild (ANC=1.0-1.5x10^9/L), moderate (ANC=0.5-1.0x10^9/L) and severe (ANC<0.5x10^9/L). Autoimmune Neutropenia of Infancy (AIN) is characterized by low risk of bacterial infection, tendency to spontaneously resolve and typically occurrence at ≤ 4-5 years of age; it is due to auto-antibodies, most frequently searched through GIFT in the patient sera, whose detection is often difficult (high frequency of false negatives). In case of negativity of the 1th test and with still a clinical picture consistent with AIN, the Italian guidelines recommend repeating the test up to 4 or more times and, if all tests are negative, no maturational arrest is assessed in bone marrow (BM) and neutropenia is clearly independent on drug exposure or infections, the patients will be defined as affected by "idiopathic neutropenia of infancy" (IN), even though the vast majority presumably present an AIN and the definitive diagnosis will be reached only "ex post," namely after the spontaneous recovery.
Aims: To describe the characteristics of the disease at presentation and the outcomes of IN patients and to compare them to children affected by AIN.
Methods: We analyzed the features of 78 IN patients enrolled in the Italian neutropenia registry over a 16-year time-span: they were compared to 311 children affected by AIN enrolled in the same period.
Results: Main characteristics of the study populations are shown in table I. Both the cohorts are the largest ever described. The main differences between AIN and IN (Table 1) are age at onset (later in IN) and length of disease (longer in IN). Earlier age at onset ($p=0.000031$), male sex ($p=0.00303$), absence of leucopenia ($p=0.00825$), higher number of lymphocytes ($p=0.0013$) and absence of monocytosis ($p=0.0142$) are associated with a significantly earlier recovery in the AIN group: a multivariate analysis by a Cox model showed that only age at onset and absence of monocytosis are independently significant ($p=0.00091$ and $p=0.00084$ respectively). In the IN group only age at onset was significant at bivariate analysis ($p=0.011$). None of the factors analyzed in the Cox model was statistically associated with a higher burden of infection.

Table 1.

	AIN	IN	p
Sex (Male%)	56.6%	50%	**0.029**
Age at onset (years, median)	0.8	1.4	**0.000066**
Neutropenia diagnosed by chance	32.6%	61.4%	**0.0000072**
ANC (median) at onset	0.44 x 10^9/L	0.42 x 10^9/L	0.78
Neutropenia (severe/moderate/mild)	55.8%/36.1%/8.8%	57.7%/30.8%/11.5%	0.49
Leucocytes (median) at onset	6.1 x 10^9/L	6.08 x 10^9/L	0.59
Leucopenia at onset	37.5%	40.3%	0.66
Monocytes (median) at onset	0.63 x 10^9/L	0.6 x 10^9/L	0.73
Monocytosis at onset	20.4%	29%	0.12
Lymphocytes (median) at onset	4.4 x 10^9/L	4.3 x 10^9/L	0.16
Severe infections	12.5%	11.5%	0.80
G-CSF "on demand" therapy	8.1%	7.1%	0.90
BM performed	32.6%	49.4%	**0.0061**
Recovery in patients with ≥ 5 years FUP	86.6%	85.4%	0.619
Analysis restricted to recovered patients			
Age at onset (years, median)	0.70	1.22	**0.0002017**
Age at recovery (year, median)	2.11	3.05	**0.00003534**
Median length of disease	1.19	1.60	**0.004062**
Patients with disease length ≤ 24 months	68.6%	58.1%	0.108
Patients recovered at less than 5 years of age	86.9%	76.8%	0.06222

Summary/Conclusion: Our report confirms that IN and AIN are similar, benign and self-limiting conditions but ages of appearance and remission were found to be later in IN and some factors affecting earlier recovery in AIN seems to be not relevant in IN.

PS1055

DYNAMICS OF CMV AND EBV LOADS AFTER IMMUNOSUPPRESSIVE TREATMENT WITH RABBIT ATG AND CYCLOSPORINE IN ADULT APLASTIC ANEMIA: A PROSPECTIVE OBSERVATIONAL STUDY

S.-S. Park[1,*], G.J. Min[1], Y.-W. Jeon[1], J.-H. Yoon[1], S.-E. Lee[1], B.-S. Cho[1], K.-S. Eom[1], Y.-J. Kim[1], S. Lee[1], H.-J. Kim[1], C.-K. Min[1], S.-G. Cho[1], D.-W. Kim[1], J. W. Lee[1]

[1]Division of Hematology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: When the cellular immune response is compromised in patients receiving immunosuppressive treatment (IST), both Cytomegalovirus (CMV) and Ebstein-Barr virus (EBV) can reactivate and cause clinical disease.
Aims: We aimed to identify the natural courses of CMV and EBV after IST with antithymocyte globulin (ATG) and cyclosporine A (CsA) for aplastic anemia (AA).
Methods: In this prospective study, CMV and EBV viral load of 99 adult patients with acquired AA who received rabbit ATG and CsA were analyzed. Each viral cohort was classified into two groups by the presence of viral load at the time of IST as follows: no CMV viral load at baseline (CMV-G1, n=98) and the presence of CMV at baseline (CMV-G2, n=1); No EBV viral load at baseline (EBV-G1, n=88) and the presence of EBV load at baseline (EBV-G2, n=11). Each viral data were collected at baseline, 1, 3, 6, and 12 months after ATG treatment.
Results: Median age and follow-up periods of cohort were 41 (18-75) years and 17.9 (1.1-71.2) months, respectively. In CMV-G1, CMV reactivation and CMV disease occurred in 41 (42.2%) and 4 (4.1%) patients, respectively. Dynamics of CMV-load tended to increase until 3 months, but were completely resolved at 6 and 12 months. Four (4.1%) patients developed CMV diseases after median 79 (45-138) days from ATG. One patient of CMV-G2 who presented 4.08 log of load at the time of IST had resolved state at 1 and 3 months without CMV treatment. Median CMV-load at the time of CMV disease was 5.61 (negative - 5.87) log. However, highest CMV load of 95 patients without CMV disease were not reached to 5.0 (negative-4.87) log. In EBV-G1, EBV reactivation and disease occurred in 54 (61.4%) and 1 patients (4.1%), respectively. EBV load peaked at 1 month and gradually decreased throughout 12 months, but remained until 12 months. Dynamics of EBV-G2 revealed fluctuated EBV-load without time point of a specific peak. None of EBV-G2 presented EBV disease during the follow-up periods. Individual median peak EBV-load was 4.48 (2.76-6.00) log. One patient with EBV associated lymphoproliferative disease (EBV-LD) showed EBV-loads of 7.06 and 5.52 log at 1 and 3 months, respectively. Median highest of EBV-load in 98 patients without EBV-LD was 2.99 (negative-6.72) log.
Summary/Conclusion: Reactivation of CMV and EBV was common after IST with rabbit ATG and CsA and showed different dynamics pattern. To predict the onset of each viral disease, it should be recommended to monitor CMV load for at least 3 months and EBV load for at least 1 month after IST, respectively. Cut-off for preemptive therapy might suggest 5 log of CMV-load and 7 log of EBV-load, respectively.

PS1056

PHASE 2 STUDY OF X4P-001: A TARGETED ORAL THERAPY FOR PATIENTS WITH WHIM SYNDROME

D. Dale[1,*], A.A. Bolyard[1], E. Dick[1], M. Kelley[1], V. Makaryan[1], R. Johnson[2], T. Ebrahim[2], S. Parasuraman[2]

[1]Medicine, University of Washington, Seattle, [2]X[4] Pharmaceuticals, Inc., Cambridge, United States

Background: WHIM syndrome (Warts, Hypogammaglobulinemia, Infections and Myelokathexis) is a rare immunodeficiency disorder caused by mutations in the CXCR4 chemokine receptor. Patients present with severe chronic neutropenia and lymphopenia due to aberrant retention of leukocytes in the bone marrow as a result of CXCR4 hyperactivation. There is no approved therapy for the treatment of patients with WHIM and current therapeutic options do not address the primary pathophysiology. X4P-001 is an oral, selective, small molecule, allosteric antagonist of CXCR4 signaling that is being evaluated as a targeted therapy for WHIM. It is hypothesized that X4P-001 will stimulate immune response by increasing neutrophil and lymphocyte mobilization from the bone marrow into the circulation and lead to improvement in various clinical symptoms of the disease.
Aims: We report preliminary results from Phase 2 of a Phase 2/3 study examining X4P-001 therapy in patients with WHIM syndrome. The primary study objectives are to evaluate safety and tolerability of X4P-001 in WHIM patients and determine the dose required to achieve a consistent increase in circulating neutrophils and lymphocytes for the Phase 3 portion of the study.
Methods: Patients have received increasing doses of X4P-001 from 50 to 300 mg once daily with monitoring of serial blood counts at weeks 5, 13, and 21. Intra-patient dose escalation decisions are based on 24-hour serial area-under-the-curve (AUC) measurements of absolute neutrophil counts (ANC) and absolute lymphocyte counts (ALC), with dose escalation proceeding if both measures fell below prespecified thresholds. Subsequent to the abstract data cutoff date, some patients were escalated to 400 mg/day, updated data will be presented.
Results: As of 22 January 2018, 6 patients (4 females, 2 males; 4 with R334X mutations, one each with E343X and S365X; age range 19 to 57 years) have been treated with X4P-001. The study entry screening WBC (mean±SEM) was 0.73×10^9/L±0.13, ANC was 0.11×10^9/L±0.03, and ALC was 0.54×10^9/L±0.13. All patients had low normal or mild mean baseline hypogammaglobulinemia: IgG 738±105, IgA 67±21, IgM 66±13. Five patients have escalated to 300 mg/day with total duration of exposure ranging from 86 to 348 days. One patient was discontinued soon after beginning X4P-001 due to grade 1 drug-related rash. All patients have demonstrated a dose-dependent increase in ANC and ALC from screening values, with ALC increasing in greater proportion than ANC. At the 300 mg dose level, the mean pre-dose WBC was 1.33×10^9/L±0.29, with peak levels of 3.45×10^9/L±0.69 (2.7-fold increase). The pre-dose ANC was 0.37×10^9/L±0.10, with peak levels of 0.72×10^9/L±0.18 (2.1-fold increase) and pre-dose ALC was 0.83×10^9/L±0.18, with peak levels of 2.6×10^9/L±0.56 (3.4-fold increase). No changes in immunoglobulin levels have been observed. In all dose levels tested, X4P-001 was well-tolerated with no serious adverse events (SAEs) reported. One patient developed cholecystitis requiring cholecystectomy in an out-patient setting; was maintained on X4P-001 and received G-CSF during the preoperative period without any reported AEs and recovered without sequelae.
Summary/Conclusion: Preliminary data from this ongoing study suggests treatment with X4P-001 in patients with WHIM syndrome is generally safe and well tolerated with no SAEs reported. Dose escalation continues, and updated safety and efficacy results will be presented.

PS1057

SCREENING FOR TELOMERE DISEASE IS IMPORTANT TO IMPROVE THE OUTCOME OF HSCT IN PEDIATRIC PATIENTS SUFFERING FROM SEVERE APLASTIC ANEMIA

I. Nederlof[1,*], D. Bresters[2], C. Lindemans[1], M. Bartels[1]

[1]Department of Pediatric Hematology and Stem Cell Transplantation, University Medical Centre Utrecht, Utrecht, [2]Willem-Alexander Children's Hospital, Department of Stem Cell Transplantation, Leiden University Medical Center, Leiden, Netherlands

Background: Telomeropathies comprise a complex spectrum of diseases

caused by shortened telomeres, resulting in bone marrow failure, and other organ disease, including lung fibrosis and liver cirrhosis. Patients with telomeropathies, of which dyskeratosis congenita (DC) is the best-known example, are at increased risk of hematopoietic stem cell transplantation (HSCT)-associated complications, predominantly significant organ damage following myeloablative conditioning regimen. In patients suffering from severe aplastic anemia (SAA), the preexistence of underlying inherited bone marrow failure syndromes (IBMFS), including Fanconi anemia (FA) and DC, should be considered. Screening for telomeropathies is of particular importance in young patients as the disorders encompass a wide spectrum and clinical presentation can therefore be subtle. Determining short telomere length in patients with SAA can strongly suggest an underlying telomeropathy. For these patients, adherence to specific HSCT protocols, e.g. adjusted treatment regimen and directed testing of potential sibling donors, could be indicated. A better understanding of the clinical presentation of telomeropathies is necessary to identify these patients before HSCT.
Aims: To identify clinical characteristics for patients with a telomeropathy and investigate outcome of allogeneic HSCT in these patients.
Methods: We investigated patients aged 0-18 years undergoing allogeneic HSCT at two paediatric HSCT departments between January 2009 and September 2017. All patients with SAA (n=29), refractory cytopenias of childhood (n=14) and a proven telomeropathy (n=8) were included. A telomeropathy was diagnosed based on short telomere length, characterized as a length below the first percentile corrected for age, in lymphocytes and granulocytes determined by FlowFISH. A retrospective analysis on clinical characteristics, chemical parameters, liver- or pulmonary disorder, complications and toxicity was performed for all patients (n=51) versus the subgroup with a proven telomeropathy (n=8). Mann-Whitney and Fisher's exact tests were used to analyze the differences between groups.
Results: Congenital physical anomalies were reported more frequently in the telomeropathy patients compared to all included HSCT patients ($p<0.05$). The subgroup with telomeropathies had significantly higher ASAT and ALAT ($p<0.01$) and gGT ($p<0.05$) compared to all patients. In line with this, previously reported liver dysfunction was more common in patients with a telomeropathy ($p<0.05$). Bilirubin, LDH levels, severity of thrombocytopenia or leukocytopenia were similar in both groups. As the lungs may also be affected in telomeropathies, we compared pre-SCT radiological abnormalities by HR-CT of the lungs, but found no difference. Post-HSCT, a higher occurrence of toxicity was reported in the telomeropathy patients compared to the entire group ($p<0.005$). Occurrence of acute graft versus host disease was not increased in patients with telomeropathies and mortality rates did not differ between groups. Increased use of adjusted conditioning regimens in the telomeropathy group might explain these similarities.
Summary/Conclusion: Significant overall HSCT-toxicity can be a consequence of underlying telomere disease. Therefore, in patients with congenital physical anomalies and abnormal liver enzymes prior to HSCT, an underlying telomeropathy should be considered. Moreover, since clinical symptoms in patients with telomeropathies can be subtle, routinely testing of telomere length can help to identify patients that have an increased risk for HSCT-associated complications.

PS1058

RESULTS OF HEMATOPOIETIC STEM CELLS TRANSPLANTATION IN CONGENITAL BONE MARROW FAILURE SYNDROMES: SINGLE CENTER EXPERIENCE WITH FOCUS ON TCR AB+/CD19+ DEPLETION

Z. Shekhovtsova[1,*], L. Shelikhova[1], D. Balashov[1], D. Shasheleva[1], M. Persianceva[1], A. Maschan[1], M. Maschan[1]

[1]Dmitry Rogachev Federal Research Centre Of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background: To date allogeneic hematopoietic stem cells transplantation (HSCT) still remains the only curative option for patients (pts) with congenital bone marrow failure (BMF).
Aims: Safe and effective measures to prevent graft-versus-host disease (GvHD) are needed to diminish the impact of transplant-related complications.
Methods: A total of 35 pediatric pts with congenital BMF (13 f/22 m, median age 9 years, range (0,9-16) underwent allogeneic HSCT between May 2012 and December 2017. The cohort included 17 pts with Fanconi anaemia (FA), 8 with dyskeratosis congenita (DC), 4 with congenital amegakaryocytic thrombocytopenia (Amega), 3 with Diamond-Blackfan anaemia (DBA) and 3 cases of undefined constitutional form of BMF. Twenty-four pts received grafts from HLA-matched unrelated volunteer: 22 - after TCR αβ+/CD19+ depletion (abTCD) of PBSC, 2 – bone marrow (BM) without graft processing; 8 - a graft from HAL-matched sibling: 6 – received BM, one pt – UCB and in one case PBSC after abTCD was used; and in 3 cases transplants were from haploidentical parents with abTCD. Thus the majority of pts received transplants after abTCD – 27 out of 35 pts. All pts were given a pretransplant conditioning regimen that differed according to the original disorder: FA – ATG, radiotherapy, fludarabin (Flu), busulfan 4mg/kg and cyclophosphamide (Cy); DC - ATG, radiotherapy, Flu and Cy; Amega - ATG, radiotherapy, treosulfan 42 mg/m^2, Flu and Cy; and for DBA – ATG, Flu and treosulfan 42 mg/m^2. For all pts it was first HSCT. The median dose of CD34+ cells in the graft was $10x10^6$/kg (range 1,3-29). Median dose of TcR αβ+ cells after depletion was $12x10^3$/kg (range 1-345).
Results: Median time of follow up for survivors was 2,7 years (range, 0,2 – 5,6), median time from diagnosis to HSCT was 1 year (range, 0,3-12). Primary engraftment of WBC and platelets was achieved in 34 pts, with median time 14 days (range, 8-36 and 8-229, respectively). One pt with FA after haplo HSCT with abTCD failed to engraft and died 3 months later due to fungal infection. One pt with DC 30 days after MUD HSCT with abTCD rejected the graft. Patient received second HSCT from another MUD with abTCD, engrafted but died 106 days later due to infection. CI of acute GvHD (aGvHD) grade ≥II at 100days after HSCT was 34% (95% CI: 22-54), there was one case of aGvHD grade III after MUD HSCT with abTCD, involving skin and gut and progression to cGvHD. According to the proportion there were more cases of aGvHD≥II grade after HSCT without abTCD - in 50% (4 out of 8 pts) vs 30% (8 out of 27 pts). CI of clinically relevant chronic GvHD 2 years after HSCT was 7% (95% CI: 2-26). OS 2 years after HSCT was 84% (95% CI: 71-97). Seven pts died. Two patients died as described above primary due to graft failure. Two patients with DC died 3 and 5 years after HSCT due to progression of non-haematological complications of the main disease. The rest 3 cases of mortality were due to mixed bacterial, fungal and viral infections during the first 6 months after HSCT with a prolonged immunosuppression therapy background.
Summary/Conclusion: Allogenic HSCT in the cohort of pts in the research we report is effective in the view of correction of bone marrow failure, but the problem of TRM still remain. Although observed number of patients was relatively small, according to the results of the study abTCD seems effective option to prevent severe GvHD, one of the main complications of allogenic HSCT.

PS1059

REACTIVATION OF HEPATITIS B VIRUS INFECTION IN APLASTIC ANEMIA PATIENTS RECEIVING IMMUNOSUPPRESSIVE THERAPY

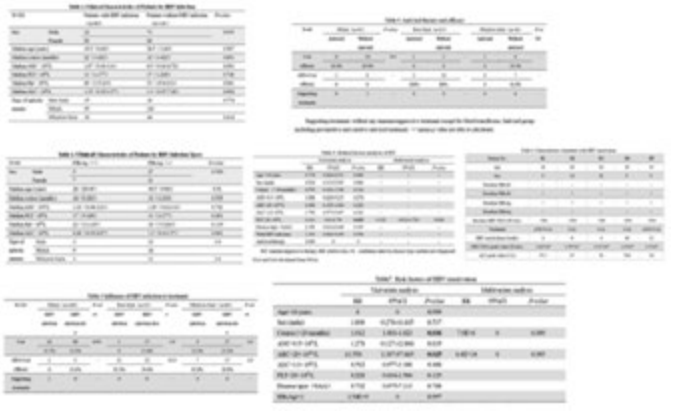
H. Yin[1], S. Wang[1], X. Lu[1], X. Wu[1], W. Shen[1], G. He[1,*], J. Li[1]

[1]Hematology, The First Affiliated Hospital of Nanjing Medical University, Jiangsu Provincial People's Hospital in Nanjing, Key Laboratory of Hematology of Nanjing Medical University, Collaborative Innovation Center for Cancer Personalize, Nanjing, China

Background: Aplastic anemia (AA) with hepatitis B virus (HBV) infection have already been reported in numerous studies, but the most focus was on clinical features rather than on virus reactivation, its assessment and prevention in immunosuppressive therapy (IST). Neither guidelines nor consensus from experts had recommendation for these issues [5, 6]. In this study, we analyzed HBV reactivation, prevention, treatment and IST results in aplastic anemia patients associated with HBV in our center over the past three years.
Aims: The aim of this study was to assess the therisk of hepatitis B virus (HBV) reactivation in hepatitis B surface antigen (HBsAg)-positive or negative, hepatitis B core antibody (HBcAb) -positive patients with aplastic anemia (AA) receiving immunosuppressive therapy of cyclosporin A (CsA) and/or anti-thymocyte globulin (ATG).
Methods: We analyzed clinical data of 60 AA patients with HBV infection out of 201 cases from our center during recent 3 years, laboratory test data such as levels of liver enzyme, HBV DNA, HBsAg, hepatitis B surface antibody (HBsAb), and HBcAb were also monitored. Entecavir ETV or lamivudine (LAM) therapy was initiated if HBV reactivation (defined as detectable HBV DNA) was encountered, or was used as antiviral prophylaxis regimen for some HBsAg-positive patients.
Results: Among 60 AA patients, 12 were chronically infected (HBsAg positive) and 48 were previously exposed (HBsAg negative/HBcAb positive). There was no difference in clinical features in AA patients with or without HBV infection, including gender, age, course of disease, as well as absolute neutrophil count, platelets and reticulocytes. The prevalence of non-severe AA (NSAA) progressed to severe AA (SAA) was similar in two groups *(35.6% vs 42.7%, p=1.0).* In the NSAA group, the response rate to CsA, response rate to ATG and CsA, and progression to SAA were similar in

patients with and without HBV infection (*35.7% vs 35.3%, p>0.05*; *42.8% vs 58.8%, p=1.0; 35.5% vs 42.7%, p=0.414)*. In the SAA group, the patients with or without HBV infection responded to ATG and CsA therapy similarly *(83.33% vs 59.0%, p=0.252)*. HBV reactivation was occurred in all 5 HBsAg positive patients without any antiviral therapy, while no HBV reactivation happened in other 7 patients received antiviral therapy. Disease course *(RR=1.012, p=0.036)* and absolute reticulocyte count *(RR=11.556, p=0.025)* were the risk factors for HBV reactivation by univariate analysis. Logistic regression indicated that HBsAg positivity without preventive therapy was the only strong factor for HBV reactivation (Tables).

Tables.



Summary/Conclusion: Antiviral prophylaxis is recommended for HBsAg-positive patients with AA who will receive IST because of high rate of HBV reactivation. HBV infection has no influence on the clinic course of AA, and antiviral therapy does not affect the efficacy of IST.

PS1060

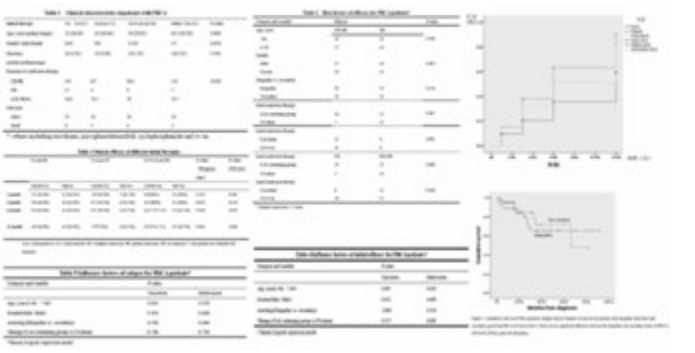
ADULT PATIENTS WITH ACQUIRED PURE RED CELL APLASIA: COMBINATION OF CYCLOSPORINE A AND CORTICOSTEROIDS PRODUCE BETTER CR

H. Yin[1], X. Wu[1], Y. Yang[2], W. Shen[1], G. He[1,*], J. Li[1]

[1]Hematology, The First Affiliated Hospital of Nanjing Medical University, Jiangsu Provincial People's Hospital in Nanjing, Key Laboratory of Hematology of Nanjing Medical University, Collaborative Innovation Center for Cancer Personalize, Nanjing, [2]Hematology, The First Hospital of Jilin University, Changchun, China

Background: Adult pure red cell aplasia (PRCA) is a syndrome characterized by a severe normocytic anemia, reticulocytopenia, and absence of erythroblasts from an otherwise normal bone marrow.
Aims: This article aims to evaluate whether the combination of cyclosporine A and corticosteroids produce better efficacy on PRCA than CsA alone or CS alone, and possible factors influencing it.
Methods: Clinical data of84 cases of PRCA were retrospectively analyzed from 2009 October.78 patients were evaluated in our two institutions (6 patients lost to follow-up).
Results: The remission induction therapy including CsA alone(n=17), CS alone(n=19), a simultaneous combination of CsA and CS (n=30), and other immunosuppressive agents (n=12), achieved remission in 13/17 (76.5%), 7/19 (36.8%), 21/30 (70%), 5/12 (41.7%) patients, respectively. The CR rate and the response rates of CsA-containing group (CsA alone and the combination of CS and CsA) was better than CS alone (51.1% *vs* 15.8%, p=*0.008*, 72.3% *vs* 36.8%, p=0.007). Combination of CS and CsA achieved better CR rate and response rate than CS alone (60% vs 15.8%, p=0.002, 70% *vs*36.8%, p=*0.022*). The response rate of CsA alone was better than CS alone (76.5% *vs* 36.8%, p=0.023*)*, While CsA alone did not show better CR rate than CS alone (35.3% vs 15.8%, p=0.255). Time of CsA-containing group to achieve remission was shorter than CS alone (p<0.05).
Summary/Conclusion: CS combined with CsA produced better CR than CS alone both in idiopathic and secondary PRCA. Combination of CS and CsA showed better CR rate and response rate than CS alone, and CsA-containing group produce remission faster than CS alone. It is recommended that CsA as the initial induction therapy for adult patients with acquired PRCA, and combination of CS and CsA could achieve better CR rate than CS alone.

Tables and Figures.



PS1061

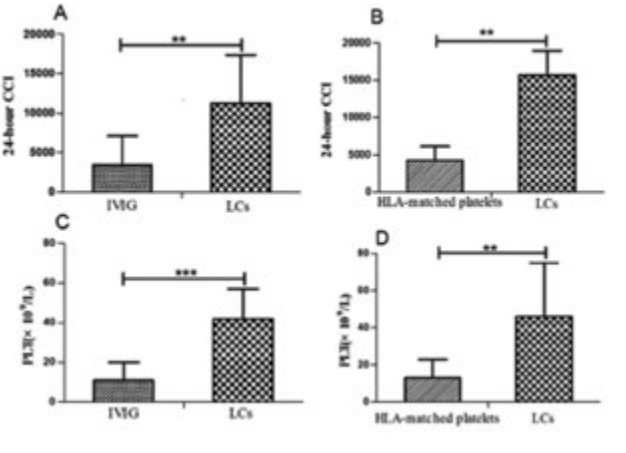
MANAGEMENT OF PATIENTS WITH SEVERE APLASTIC ANAEMIA WHO ARE REFRACTORY TO PLATELET TRANSFUSIONS USING LEUKOCYTE CONCENTRATES

J. Huo[1,*], Y. You[1]

[1]State Key Laboratory of Experimental Hematology, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Tianjin, China

Background: British guideline recommended that platelet counts should be maintained at greater than 30×10^9/L during antithymocyte globulin (ATG) administration for severe aplastic anemia (SAA) patients. While, 5 to 27% of patients developed platelet transfusion refractoriness (PTR) produced by repeated transfusions of platelet concentrates. Intravenous immunoglobulin (IVIG) and HLA-matched platelets were used to manage PTR. Unfortunately, 40 to 60% of patients failed to achieve satisfactory recovery of platelet counts. HLA alloimmunization played a major causative role in PTR. 47 to 62% of patients with AA who had transfusions at multiple times acquired anti-HLA antibodies. Given this, we probed a unique strategy, namely using leukocyte concentrates (LCs) followed by random platelets, to "crush" the problem of PTR in SAA patients during ATG administration. LCs contain a very high number of white blood cells which bear substantial HLA antigens on the surface. Infusion of LCs could adsorb the anti-HLA antibodies and save random platelets from the antibody-directed destruction.
Aims: We conducted this retrospective study to assess the safety and efficacy of LCs treatment in patients with SAA who developed PTR.
Methods: A cohort of 253 patients with SAA who received ATG at our institute between December 2008 and November 2016 was reviewed. Of these patients, 18 patients who developed the complication of PTR caused by HLA alloimmunization with or without HPA alloimmunization were included in this study. All the 18 patients were given LCs therapy to improve platelet recovery. Corrected count increment (CCI) and post-transfusion platelet counts were used as indicators of post-transfusion platelet response.

Figure 1.



Results: Eighteen of 253 (7.1%) patients developing PTR prior to ATG therapy were managed with LCs. The mean 24-hour CCIs after LC transfusions

were 13,346, which was significantly higher than that of random platelets infusions without LC transfusions (1,327, p 0.001). Compared with the 24-hour CCIs of IVIG or HLA-matched platelets, those of LCs were significantly improved (Figure 1A,B). Additionally, significant improvements of post-transfusion platelet counts were also found after LC transfusions compared with IVIG or HLA-matched platelet infusions (Figure 1 C,D). Notably, sufficient platelet counts (mean, 53×10^9/L) were obtained and ATG therapy were completed without any serious bleedings after LC transfusions. The hematological response rate to IST in 18 patients was 44.4% at 3 months and 61.1% at 6 months. The 3-yr OS was 68.8% (95% CI 25.9-44.6%).
Summary/Conclusion: LCs transfusion can bridge between PTR and ATG administration and escort the SAA patients during the period of ATG administration.

PS1062

IRON OVERLOAD AND MANAGEMENT IN PATIENTS WITH DIAMOND BLACKFAN ANEMIA

S. Unal[1,*], G. Soltanova[2], N. Akarsu[1], M. Cetin[1], F. Gumruk[1]

[1]Center for Fanconi Anemia and Inherited Bone Marrow Failure Syndromes, [2]Department of Pediatrics, Hacettepe University, Ankara, Turkey

Background: Diamond Blackfan anemia (DBA) is a rare genetic ribosomopathy charactherized with severe anemia related to low erythroid precursors in the bone marrow. The patients are prone to transfusional iron loading, in addition to iron loading related to paucity of erythroid precursors in the bone marrow which interrupts the iron turn-over.
Aims: In this study, we aimed to define the severity of iron loading among DBA patients. There is limited data on iron loading in DBA patients.
Methods: The patients were evaluated cross-sectionally with serum ferritin and cardiac and hepatic T2* MRI. All of the patients were evaluated with serum ferritin measurments and 13 were evaluated with cardiac and hepatic T2* MRI.
Results: A total of 45 patients with DBA were included. The median age of patiens at evaluation was 9 years (1-35) and female:male ratio was 1.5. The age of diagnosis of DBA was median 3 months-old (0-72). All of the patients were found to have transfusion history. At time of evaluation for iron laoding 17 (37.8%) were on transfusion programme, 15 (33.3%) were in remission, 11 (24.4%) were on steroid treatment and 2 (4.4%) were transplanted. Mean serum ferritin levels were found 1103.86±1558.17 ng/ml (19.8-6839). The patients were further grouped according to number of transfusions as ≤ 5, ≤ 10, > 10, ≥ 20 times and the serum ferritin leveles were measured as 154.13±198.54 ng/ml (19.8-461), 149.64±149.07 ng/ml (23-421), 616.97±565.84 ng/ml (31.7-1658) and 2306.06±1947.76 ng/ml (455-6839), respectively. The difference between these 4 groups were found statistically significant. Out of 13 patients who were evaluated with MRI, 4 (30.8%) had nor iron laoding, 8 (61.5%) had hepatic iron overload (moderate degree in 4, moderate to severe in 2 and severe in 2 patients), one (7.7%) had minimal degree of cardiac iron laoding. The median hepatic and cardiac T2* values were 8.7 ms (1.36-30) and 28.4 ms (12-41), respectively. Of the 8 patients who had hepatic iron loading, 5 (62.5%) wer on chronic transfusion programme, wheras 3 (37.5%) were steroid dependent. Sixteen (35.6%) of the patients were under chelation with deferasirox treatment.
Summary/Conclusion: There is limited data on the iron status of patients with DBA. Iron overloading not only has negative impact on organ functions, but also affects hematopoietic stem cell transplantation outcome. The iron loading differs in various disorders such as in thalassemia major both cardiac and hepatic iron laoding is an issue, whereas in patients with thalassemia intermedia or sickle cell disease, most of the iron accumulates in liver. In DBA patients both cardiac and hepatic iron loading is a concern, however hepatic iron laoding is more common. Besides the patients who are on steroid treatment are also prone to hepatic iron laoding. This might be related to paucity of the eryhtroid precursors in bone marrow that impairs iron turn-over; besides most of the patients who are on steroid treatment also have received at least one-year course of transfusion in infancy prior to steroid initiation. Patients with DBA should be screened for iron loading as early as possible and chelation treatment should be initiated to prevent the related morbidity and mortalities.

PS1063

HIGHER RATE OF DYSMORPHIC FEATURES IN PATIENTS WITH DIAMOND BLACKFAN ANEMIA

G. Soltanova[1], O. P. Simsek Kiper[2], S. Unal[2,*], F. Gumruk[2], E. Taskiran[2], B. Karaosmanoglu[2], N. Akarsu[2], M. Cetin[2]

[1]Department of Pediatrics, [2]Center for Fanconi Anemia and Inherited Bone Marrow Failure Syndromes, Hacettepe University, Ankara, Turkey

Background: Diamond Blackfan anemia (DBA) is the inherited form of pure red cell aplasia which is accompanied with several dysmorphic features and propensity to malignancies. Of the dysmorphic features the most common ones are craniofascial findings.
Aims: In this study, we aimed to define dysmorphic features in our DBA patients.
Methods: The patients were examined by an experienced dysmorphologist and echocaridography, abdominal ultrasonography, ENT and eye examinations were also performed.
Results: A total of 45 patients with DBA were included. The median age of patiens at evaluation was 9 years (1-35) and female:male ratio was 1.5. Of the patients 86.7% were found to have at least one dysmorphic finding and of these with dysmorphic features 33% were craniofascial (microcephaly, mikrognathia, prognathia, retrognathia, pointed chin, microstomia, hipertelorism, malar hypoplasia, mid-fascial hypoplasia, synorfia, deep-set eyes, lower/upper slenting palpebral fissures, epichantal folds, broad nasal bridge, prominent columella, short/long philtrum, round/course face, low hair line, low-set ears, anteverted helix, high-arched palate, cleft palate/lip, thin lip, broad/high/narrow forehead), 26% were skeletal (pes planus, cubitus valgus, genu valgum, narrow shoulder, short metacarpals, short limbs, syndactylia / clinodactylia / brachydactylia, proximal oriented, rudimentary or hypoplastic thumb, flattening of thenar eminence), 10% were cardiovascular (ASD, VSD, PFO, MVP, Fallot tetralogy, bicuspit/dysplastik aorta, tricuspid valve anomaly, pulmonary stenosis, dilated cardiomyopathy), 9% were related to neck (short, webbed), 9% were neuromotor, 3% were ophtalmological (strabismus, congenital cataract) 2% were genitourinary (hypospadias, bilateral renal pelvis dilatation) and 12% were various other findings (including skin, hair, nail findings, inguinal sacral dimple, pilonidal sinus). Although, not included as a dysmorphic finding, 41% of the patients were found to have short stature.
Summary/Conclusion: The rate of congenital malformations in patients with DBA have been reported previously as 50%. However, in our series of patients we have found a higher rate of dysmorphic features. This might be related to detailed examination of our patients by a dysmorphologist. The most common sysmorphic finding was craniofascial abnormalities compatible with the reported patients. These symorphic findings may be the only finding in a subgroup of patients who never develop anemia, however they are usually non-specific or subtle findings. However the presence of any of these findings in a family member of an index DBA patient might be a clue for a silent DBA case in that person, since incomplete penetrance is an issue in DBA.

OPTIMIZING MRD RESPONSE ASSESSMENT USING HIGH-SENSITIVITY PERIPHERAL BLOOD MONITORING DURING TREATMENT WITH IBRUTINIB COMBINED WITH OBINUTUZUMAB OR VENETOCLAX IN CLL

A. C. Rawstron[1,*], R.M. de Tute[1], N. Webster[2], D. Howard[3], K. Brock[4], S. Muñoz-Vicente[4], F. Yates[4], R. Bishop[4], T. Munir[1], P. Hillmen[2]

[1]St James's Institute of Oncology, Leeds Teaching Hospitals NHS Trust, [2]Leeds Institute of Cancer and Pathology, [3]CTRU, University of Leeds, Leeds, [4]Cancer Research UK Clinical Trials Unit, University of Birmingham, Birmingham, United Kingdom

Background: Minimal residual disease (MRD) in CLL is an independent predictor of outcome and an intermediate endpoint for licensure. Using MRD to guide treatment duration is under evaluation in several trials. However, different treatments vary in the extent of disease depletion in the peripheral blood (PB) compared to bone marrow (BM).
Aims: To assess MRD in PB vs. BM on ibrutinib (IBR) ±obinutuzumab (OBI) or venetoclax (VEN) & determine the duration/depth of PB MRD responses required to predict <0.01% BM MRD.
Methods: CLL cell percent of leucocytes (% MRD) was quantified using 8CLR ERIC-standard flow cytometry (detection limit 10-5/0.001%). PB (n=1481) & BM (n=478) samples were assessed in ADMIRE/ARCTIC (ISCRTN 42165735/16544962), IcICLLe (ISCRTN12695354) & CLARITY (ISCRTN13751862) trials.
Results: Rituximab (R) + fludaribine+cyclophosphamide (FC)±mitoxantrone (M) resulted in >0.88 log higher%MRD in BM compared to PB. There was no discernible compartment effect with IBR-monotherapy but no patients achieved <0.01% MRD. Patients receiving IBR+OBI or IBR+VEN showed higher BM than PB MRD levels (>0.36 and >0.44 log respectively) with a similar discrepancy rate at the IWCLL 0.01% threshold although most IBR+OBI discrepancies reflected >2 log higher BM vs. PB% MRD while all IBR+VEN discrepancies reflected <2 log difference. We next evaluated using PB MRD response to predict <0.01% BM MRD. No treatment-naïve (TN) patients (0/20) achieved <0.01% PB MRD with IBR-monotherapy; 3yr follow-up showed continuing PB CLL depletion in 10/14 evaluable patients but the rate of depletion from 24-36mth (median 0.27log, range -0.33 to 0.50) was markedly lower than the 1-12mth rate (median 1.5log, range 0.13 to 2.5). Relapsed/refractory (RR) patients (n=10) receiving OBI+IBR after >1yr prior IBR achieved <0.01% PB MRD in 7/8 evaluable patients of which 5/7 (50% of total) achieved <0.01% BM MRD; all 5/5 maintained <0.01% PB MRD for ≥6M prior to BM assessment. IBR-naïve RR patients (n=28) receiving IBR+OBI achieved <0.01% PB MRD in only 5/21 evaluable patients of which 3/5 achieved <0.01% BM MRD (11% of total). However, 2/5 subsequently became PB MRD-pos & overall 5/14 evaluable patients initially treated with IBR+OBI showed increasing PB% MRD 6-9mth after stopping OBI. In the CLARITY IBR+VEN trial, of 20 patients with >0.01% MRD at any time point 6mth prior to BM assessment, only 1/20 (5%) achieved <0.01% BM MRD. In contrast, of 12 patients with 6mth-sustained <0.01% PB MRD, 10/12 (83%) achieved <0.01% BM MRD of which all 10 had <0.001% PB MRD at the final assessment (Table 1).

Table 1.

Trial Name: timepoint/Rx for PB/BM assessment (n)	Median log difference	# discrepant at 0.01% MRD (%)	# with >2log difference (%)
ADMIRE/ARCTIC: 3mths post R-FCxM (n=272)	>0.88	59 (21.7%)	8 (2.9%)
IcICLLe: 1mth & 6mths of IBR (n=74)	0	none <0.01% MRD	0 (0%)
IcICLLe ext: 1mth & 9mths IBR+OBI (n=62)	>0.36	7 (11.3%)	6 (9.7%)
CLARITY: 8 or 14mths IBR+VEN (n=70)	>0.44	9 (12.9%)	0 (0%)

Summary/Conclusion: Ibrutinib monotherapy was associated with similar PB and BM MRD levels & long-term (3yr) monitoring was informative using PB only. A compartment effect was apparent during treatment with IBR+OBI & IBR+VEN and BM remains the optimal tissue for MRD response assessment. Sustaining a PB MRD response for 6mth, preferably using a 10-5/0.001% detection limit, can be used to predict a high probability of achieving undetectable BM MRD.

PS1065

DYNAMIC OF TELOMERIC PARAMETERS IN RELAPSING OR REFRACTORY (R/R) CHRONIC LYMPHOCYTIC LEUKEMIA (CLL), AN ANALYSIS OF THE FILO ICLL001 BOMP TRIAL

Background: In patients (pts) with CLL, telomeric parameters have prognostic impact. In a retrospective study, we found that *TP53*-disrupted pts show severe telomere dysfunction associated with high genomic instability and that downregulation of shelterin complex genes is an adverse prognostic factor in *TP53* wild-type (wt) patients (Guièze, 2016). Recently, germline mutations in shelterin genes were found in familial CLL (Speedy, 2016) and a poor prognostic impact of somatic *POT1* mutations (Ramsey, 2013) was reported in a front-line prospective study (Herling, 2016). A key and potentially early role of telomere dysfunction in disease progression is clearly suggested.
Aims: The aim of this study was to assess telomeric parameters and their evolution in R/R CLL patients treated in a prospective trial.
Methods: From a cohort of 74 R/R CLL pts included in the FILO phase II BOMP trial (NCT0161298) we identified 19 pts with available samples, with ≥70% tumor cell purity, at 2 successive time points (TP) to study the evolution of telomeric parameters. TP#1 was inclusion and TP#2 the subsequent CLL relapse after treatment (Bendamustine, Ofatumumab and high-dose Methyl-Prednisolone). The median time interval between the two TP was 17.5 months (mo) (range 4.9 - 37.8). The median follow-up was 33.9 mo (range 15.7 – 48.5). Prior to inclusion, 19 pts received 1 to 3 lines of treatment including FCR combination for all pts. Six pts had *17p* deletion by FISH and *TP53* mutation by Sanger and 13 pts had wt *TP53*. Telomere length (TL) was assessed by qPCR and expression of telomerase (*hTERT)* and shelterin complex (*TRF1, TRF2, TIN2, POT1, RAP1, TPP1, TIN2 spliced variant*) genes by qRT-PCR at TP#1 and TP#2.
Results: Between TP#1 and TP#2, TL decreased significantly (p=0.0006) and the expression of all shelterin genes was also considerably reduced: *TRF1* (2 fold-change, p<0.0001), *TRF2* (2.7 fold-change, p<0.0001), *POT1* (1.8 fold-change, p=0.0002), *RAP1* (2 fold-change, p=0.0009), *TPP1* (1.8 fold-change, p=0.0003), *TIN2* (2.3 fold-change, p=0.0004), *TIN2 spliced variant* (2.2 fold-change, p=0.002). In contrast, *hTERT* expression remained unchanged (p=0.64). Telomere shortening kinetics (TSK) in individual patients was variable. We calculated the relative telomere shortening per month expressed as percentage of the initial TL and identified 3 groups of patients with slow (<0.69%, n=4), intermediate (n=11) and rapid TSK (>4.24%, n=4). One patient slightly extended TL. At TP#1, the median rate of *hTERT, POT1* and *TIN2* were 24.5, 36.7 and 45.1 respectively. A significantly higher TSK was found in patients presenting low expression (using median level as cut-off) of *hTERT* (3.2% *vs* 0.7%, respectively, p=0.002), *POT1* (3.140% *vs* 0.9560%, p=0.0054) and *TIN2* (2.870% *vs* 1.199%, p=0.04).
Summary/Conclusion: We found that following immunochemotherapy, telomere length and shelterin complex gene expression in CLL patients show variable evolution over time which may preclude a next step of genomic instability. To address this point, telomere parameters at inclusion and relapse will be confronted to other biological data including cytogenetics, FISH and mutational pattern.

Background: The L265P somatic mutation in the Myeloid Differentiation Primary Response 88 (*MYD88*) gene is recurrent in chronic lymphocytic leukemia (CLL) but its role in CLL remains to be fully elucidated.
Aims: To understand the functional role of the MYD88 L265P mutation in CLL by examining gene expression profiles, clinical associations, and pathway inhibition.
Methods: Affymetrix U133 Plus 2.0 microarray data were analyzed using a published PAM-based approach. Since MYD88 L265P is associated with mutated *IGHV* (*IGHV*-M), which strongly influences gene expression in CLL, analysis was initially restricted to *IGHV*-M samples (n=10 MYD88 L265P, n=76 MYD88 WT). A composite gene signature score was derived from coefficient estimates of differentially expressed genes using a Cox model; this signature was then examined for associations with clinical outcome. RNA-Seq validation was performed using DESeq2 analysis. Cell TiterGlo was used to measure viability of CLL patient cells at baseline, upon CpG stimulation, and after drug treatment. Downstream pathway inhibition was examined using Western blot analysis.
Results: Microarray analysis identified 28 differentially expressed genes between *IGHV*-M MYD88 L265P and WT CLL. Gene Set Enrichment Analysis (GSEA) of these 28 genes in our RNA-Seq data demonstrated correlation with MYD88 L265P status ($q<0.05$). Analysis of a subset of the microarray samples by RNA-Seq identified 15 differentially expressed genes ($q<0.1$). Two of these genes, *CD9* and *RUNDC3B*, overlapped with the microarray analysis. Both genes showed higher expression in MYD88 L265P vs WT samples. Analysis for clinical association in a discovery cohort (n=150) showed that a higher 28-gene signature score predicted worse FFS ($p<0.0001$) and OS ($p<0.0001$). We then performed multivariable Cox regression analysis for FFS and OS, adjusting for established CLL risk factors. Since treatment status is highly correlated with *IGHV* and ZAP70 status, it was included with age and cytogenetics in a separate model for OS, and treated as a time-dependent variable. We found that a higher gene signature score predicted worse FFS ($p=0.003$) and OS ($p=0.0001$). To validate the 28-gene signature, we analyzed an independent cohort of CLL patients with available microarray data (n=87; n = 26 *IGHV*-UM, n=50 *IGHV*-M, n= 11 unknown *IGHV* status). The composite signature of the 28 genes again predicted worse FFS ($p<0.0001$) and OS ($p<0.001$). High *CD9* expression was associated with reduced failure-free survival (n=150, $p=0.007$); no clinical associations were found for *RUNDC3B*. To determine whether the MYD88 pathway can be therapeutically targeted in CLL, we sought to suppress MYD88 signaling by inhibiting its downstream effector, IRAK4, using ND-2158, a selective inhibitor of IRAK4 kinase activity (Nimbus Therapeutics). ND-2158 treatment led to a dose-dependent decrease in cell viability. CpG-stimulation sensitized *IGHV*-M MYD88 WT and L265P cells, but not *IGHV*-UM cells, to ND-2158 treatment ($p=0.001$ WT, $p=0.006$ L265P). Western blot analyses demonstrated that CpG stimulation led to a decrease in total IRAK1 and IkBa levels, which was inhibited by ND-2158 treatment in a dose-dependent manner ($p<0.0001$).
Summary/Conclusion: The MYD88 L265P mutation in CLL is associated with a 28-gene signature that predicted FFS and OS. Higher *CD9* expression was associated with MYD88 L265P and with reduced FFS. IRAK4 inhibition perturbs MYD88 pathway signaling, leading to CLL cell death.

Background: B cell receptor (BCR) signaling is pivotal to chronic lymphocytic leukemia (CLL) pathogenesis. The recent CLARITY-TAP clinical trial update at ASH 2017, investigating the role of ibrutinib in combination with venetoclax provided compelling evidence that this was a useful strategy for the treatment of CLL. However Bojarczuk *et al.* recently demonstrated that complete inhibition of BCR-induced Mcl-1 expression was only achieved with SYK inhibitors such as entospletinib, whereas ibrutinib and idelalisib only had partial effects at the same concentrations. In our own studies entospletinib and PRT062607 also provided greater inhibition of BCR signaling compared to idelalisib and ibrutinib. Herein we compared our dual SYK/JAK inhibitor (cerdulatinib) with SYK (entospletinib, PRT062607), BTK (ibrutinib) or PI3K (idelalisib) kinase inhibition in combination with the Bcl-2 (venetoclax) or Mcl-1 (S63845) inhibitors and assessed downstream signaling and tumor viability.
Aims: Evaluate which BCR kinase inhibitors optimally synergies with Bcl-2 family inhibitors and determine whether dual SYK/JAK inhibition provide any additional anti-tumor activity.
Methods: Primary CLL cases were treated with and without IL-4/CD40 in the presence or absence of ibrutinib, idelalisib, entospletinib, PRT062607 or cerdulatinib (all 1μM). Combination studies were performed with 10 or 100nM Venetoclax or 300 and 1000nM S63846. Cell viability was assessed by annexin V/PI using flow cytometry and changes in protein expression by immunoblotting.
Results: CLL cells were treated with IL-4/CD40L or the vehicle control and immunoblotting performed for Bcl-2 family protein expression. Basal Mcl-1, Bcl-X_L and Bim protein was expressed at relatively low levels compared to Bcl-2. However treatment with IL-4/CD40L induced a substantial and significant increase in Mcl-1 and Bcl-X_L compared to the vehicle control, whilst Bcl-2 and Bim expression remained relatively stable. CLL cells pretreated with ibrutinib, idelalisib, entospletinib, PRT062607 or cerdulatinib significantly reduced IL-4/CD40L induced Mcl-1 and Bcl-X_L expression, however in all cases cerdulatinib produced a more robust inhibition of these proteins compared to the other kinase inhibitors. Interestingly treatment with all BCR kinase inhibitors resulted in an increase in Bim expression at both the RNA and protein levels. However at equivalent drug concentrations Bim was induced to greater levels following cerdulatinib treatment compared to idelalisib and ibrutinib. Next we evaluated Bim co-localization with Bcl-2 and Mcl-1 proteins using immunoprecipitation. Bim co-localized largely with Bcl-2 and a lesser extent with Mcl-1 in all our CLL cases *in vitro*. Consequently these cells were primed for death, therefore we hypothesized that venetoclax and/or S63845 would synergise with the BCR kinase inhibitors. Indeed, venetoclax and S63845 synergised with all BCR kinase inhibitors to induced greater levels of CLL cell death by displacing Bim. However in all cases the SYK/JAK inhibitor cerdulatinib synergized to a greater extent with the Bcl-2 family inhibitors compared to BTK, PI3K and SYK inhibitors alone.
Summary/Conclusion: *In vitro* SYK inhibitors offer superior tumor cell killing compared to BTK and PI3K inhibitors in combination with Bcl-2 family inhibitors. However cell death is further augmented by co-inhibition of SYK and JAK and consequently requires further investigation in CLL and other B cell malignancies.

SELECTIVE CHK1 INHIBITOR MU380 EXHIBITS SINGLE-AGENT ACTIVITY AGAINST CHRONIC LYMPHOCYTIC LEUKEMIA CELLS WITH TP53 MUTATIONS

M. Boudny[1,*], J. Zemanova[1], P. Khirsariya[2], M. Borsky[1], J. Verner[1], J. Cerna[1], M. Mraz[1], A. Oltova[1], Z. Jaskova[1], M. Spunarova[1], V. Seda[1], Y. Brychtova[1], J. Mayer[1], K. Paruch[2], M. Trbusek[1]

[1]University Hospital Brno and Faculty of Medicine, Masaryk University, [2]Faculty of Science, Masaryk University, Brno, Czech Republic

Background: Significant therapeutic progress has been achieved in chronic lymphocytic leukemia (CLL) with development of small molecule inhibitors of the B-cell receptor (BCR) signaling and Bcl-2 protein. Majority of the published data concern BCR signaling inhibitor ibrutinib, and agree upon still inferior prognosis of patients with *TP53* defects; these patients constitute in the long term the most challenging group in CLL. Checkpoint kinase 1 (Chk1) is a protein operating in the intra-S and G_2/M cell cycle checkpoints and as such is essential for DNA replication. Various Chk1 inhibitors are tested for anti-cancer effects either alone or more frequently in combination with chemotherapy. Recently, we developed metabolically stable analog of a selective Chk1 inhibitor SCH900776 called MU380.
Aims: To analyze single-agent activity of our selective Chk1 inhibitor MU380 in (a) cell lines from lymphoid tumors, (b) dividing and non-dividing primary CLL cells, and (c) animal model.
Methods: Cell viability was measured by WST-1, apoptosis analyzed by western blot of PARP and caspase-3 proteins, and cell cycle determined by DNA content analysis. Pro-proliferative stimulation of primary CLL cells was done using co-culture with murine fibroblasts (CD32+), anti-CD40 antibody and IL-4. Genetic aberrations in CLL cells were assessed by FISH and NGS. In vivo effects were studied in mice strain NOD/SCID IL2Rγ-null with localized CLL tumors established by subcutaneous injection of MEC-1 cell line (5×10^6 cells). External measurement of tumors size and

volume was performed between days +14 and +29.
Results: After the 72 h treatment, MU380 reduced viability of all lymphoma (n=9) and leukemia (n=9) permanent cell lines (median IC_{50}=401 and 254 nM, respectively; P 0.001). CLL-derived cell lines were highly sensitive: IC_{50}=221 nM in *TP53*-wt OSU-CLL and 195 nM in *TP53*-mutated MEC-1. A pronounced cell accumulation in the S-phase (24 h) was followed by extensive apoptosis (at 48 h). Importantly, two cultures of healthy fibroblasts were substantially less affected (IC_{50}=3.7 and 8.1 μM). In primary CLL cells treated with the pro-proliferative stimuli (10 day co-culture), the 72 h treatment with MU380 reduced viability similarly in the *TP53*-mutated (n=7), *ATM*-mutated (n=3) and *ATM*-wt/*TP53*-wt (n=3) samples (all but one samples IC_{50} ~1 μM). Surprisingly, MU380 also reduced viability in the vast majority of non-stimulated CLL cultures (total n=96) with a low baseline Chk1 level. The effects were again similar among the tested genetic groups: median IC_{50}=0.34 μM in *TP53*-mutated samples (n=23), 0.38 μM in *ATM*-mutated samples (n=20), 0.35 μM in samples with sole 11q- (the other *ATM* allele intact) (n=17), and 0.41 μM in *ATM*-wt/*TP53*-wt samples (n=36). At the molecular level, MU380 triggered replication stress (γ-H2AX accumulation) and apoptosis, which was not, however, accompanied by the p53 protein accumulation (in p53-wt cells). Finally, MU380 significantly delayed growth of the localized *TP53*-mutated CLL tumors (subcutaneous MEC-1 injection) in mice. Seven doses of MU380 (each 20 mg/kg) were administered intraperitoneally (outside the tumor) between days +14 and +28 post-transplant. At day +29, the average tumor volume was 1072 mm^3 in the treated group vs. 1897 mm^3 in the control one (p=0.0015).
Summary/Conclusion: We present a remarkable single-agent anti-cancer activity of Chk1 inhibitor MU380 in CLL cells harboring *TP53* inactivation. Chk1 inhibition may represent novel therapeutic option for currently incurable *TP53*-mutated CLL.
Supported by projects MH CR AZV 15-33999A, FNBr 65269705 and MUNI/A/0968/2017.

San Martino-IST, Genoa, [9]Hematology Unit, Azienda Ospedaliera "Bianchi Melacrino Morelli", Reggio Calabria, [10]Department of Experimental and Clinical Medicine, University of Catanzaro Magna Graecia, Catanzaro, [11]Dipartmento di Medicine Sperimentale, University of Genoa, Genoa, Italy

Background: BCR stimulation of membrane-proximal kinases such as PI3Kδ is implicated in the survival and growth of CLL B-cells. Interactions of malignant cells, T cells and macrophages, particularly through the PD1 pathway, play a crucial role in the CLL TME and ultimately leads to T cell exhaustion. The PI3Kδ inhibitor (PI3K-I) idelalisib (CAL101) is approved for patients with relapsed CLL. PI3K signaling is also involved in T-cell activation thus specific PI3K-Is that favor tumor cell intrinsic activity sparing T-cell functionality are required, such agents in preclinical development are AMG-319 and IPI-145.
Aims: To examine the expression the PD1 receptor and its ligands; the role of the TME in controlling PD1 axis expression; and the role of the PI3K-Is on the PD1 axis in the TME.
Methods: Early-stage CLL patients (n=110) were prospectively enrolled at diagnosis. Gene expression (GE) was evaluated by qPCR assays (Thermofisher) and flow-cytometry (FC, BD-Biosciences) was used to evaluate protein expression. Activated autologous T-cells (AAT), obtained by *in vitro* exposure of patient T-cells with anti CD3/CD28 Dynabeads (Thermofisher) and IL2 in co-culture with CLL cells, was used as *in vitro* model for mimicking the CLL TME. Cultures were monitored until substantial clumping was observed, and then tested for PD1 axis expression by FC. In selected experiments CAL101 (1uM/5uM), AMG319 (1uM), and IPI145 (1uM) (all from Selleck Biochemicals) were added to cell cultures.
Results: Baseline protein expression of PD1 and ligands from B-CLL samples (n=110) indicated that circulating CD19+CD5+ showed similar levels of PD1 and PDL2, but limited PDL1 expression, while no significant differences in PD1 or its ligands were observed in the GE (n=27). Conversely, PD1 and its ligands evaluated by FC (n=106) revealed higher expression of CD3+PD1+ cells, which was significantly higher than that of malignant B-cells. CD4+ and CD8+ expressed comparable levels of PD1, whereas CD16+PD1+ expression was lower. Expression of PD1 and PDLs on CD19+CD5+ cells (n=40) showed no significant correlations with prognostic markers. FC analysis (n=32) of CLL cells after AAT coculture indicated higher percentage expression of PD1 axis members and PDLs with respect to baseline B-CLL cells also confirmed by qPCR GE (n=15). Conversely, T-cell subpopulations had higher number of CD3+, CD4+ and CD8+ cells bearing both PD1 and PDL1, while no substantial increment for CD3+, CD4+ or CD8+/PDL2+ cells following AAT co-culture was observed. Only PDL1 in CD16+ cells was also upregulated. AAT in presence of PI3K-Is (48h) showed, an overall reduction of PDL1+ and PDL2+ B-cells by CAL101 (n=9) and AMG (n=5), and more strongly by IPI-145 (n=5). Similarly, reduction in mRNA transcripts for PDL1 and PDL2 (n=7), although with a strong decrease of PD-1, IPI also significantly decreased mRNA for both ligands. PD1 expression on CLL cells, CD4+ and CD8+ subsets induced by AAT was inhibited by CAL101. AMG had similar effects as IPI on the number of CD4+ and CD8+ cells also expressing PD1 and PDL1, but not for PDL2 for both B- and T-cells. CD16 cells showed the greatest reduction in PD1 expression by CAL101 5uM, AMG and IPI, however co-expression of PDLs were also reduced.
Summary/Conclusion: TME-derived signals regulate PD1 and PDL1/PDL2 expression in both CLL- and AAT-cells. PI3K-Is, CAL101, AMG319, and IPI145 may play a role in controlling immunescape mechanisms via regulation of PD1 axis expression on neoplastic B- and T-cells in CLL.

Background: The programmed death receptor 1 (PD1) pathway is a general phenomenon involved in the neoplastic mechanism of immune escape. T cells from CLL patients exhibit defective immunity leading to T cell exhaustion. These functional defects coincide with higher PD1 expression on T cells. Antibodies blocking the PD1/PDLs axis are emerging for treatment of solid and hematological neoplasia. The applicability of these agents in CLL is promising.
Aims: To examine the 1) expression the PD1 receptor and its ligands on B-CLL and autologous T-cells; 2) role of the TME in controlling the expression of PD1 and its ligands; 3) role of the anti-PD1 inhibitor on the PD1 axis in the TME.
Methods: Baseline mRNA expression of PD1 and PDL1/2 in early-stage CLL patients, belonging to a prospective cohort (n=211, O-CLL1, clinicaltrial.govID:NCT00917540) was determined at diagnosis by GEP using the GeneChipVR Gene 1.0 STArray (Affymetrix) and was confirmed by QPCR. CLL clones derived from *ex vivo* exposure of autologous T-cells with anti-CD3/CD28 Dynabeads (Thermofisher) and IL2 (AAT) were used to mimic

the TME and model *in situ* T and B-cell interactions. Flow-cytometry (FC) was used to evaluate cellular phenotype (BD Biosciences). Cytokine levels were measured by FC (BD™Cytometric BeadArray, CBA). PEM was kindly provided by MERCK.
Results: CLL B-cells had higher mRNA transcripts of PD1 than PDL1 or PDL2m on GEP, which was confirmed by QRT-PCR performed in 20 samples of an independent cohort of 100 samples from B-CLL patients visiting our outpatient clinic. Baseline PD1/PDLs protein expression in these samples indicated that circulating CLL B-cells had similar levels of PD1 and PDL2, but limited PDL1 levels. Conversely, PD1 and its ligands in CD3+ cells showed higher expression of PD1, which was higher than that of malignant B-cells ($p<0.001$). CD4+ and CD8+ expressed comparable levels of PD1. CLL clones (n=15) exposed to TME stimuli by co-culture with autologous activated T-cells (AAT), monitored daily (range 2-7 days) for T-cell activation (identified as cell-clusters), showed a marked significant ($p<0.001$) up-regulation of PD1 ligand mRNA (PDL2>PDL1, 34.3±5.4-fold and 15.4±2.9-fold, respectively) in purified CD19+CD5+ compared to that of PD1 (4.7±0.9-fold). Similarly, cell surface protein expression (n=33) showed both ligands and PD1 were upregulated compared to baseline in B-cells with PDL2>>PDL1. T-cell subsets by FC detected stronger increase of CD3+, CD4+, and CD8+ cells bearing PDL1, and similar increment for either PD1 and PDL2+ in CD4+ or CD8+ cells following AAT co-cultures. In this context, PEM (0.37, 1.11, 3.3, 10.0 ug/mL) (n=8) did not influence the formation of AAT clusters on visual inspection nor PD1 /PDL1/2 protein and mRNA expression. PEM treatment (3.3-10 ug/mL) also failed affect IL-2, IFN-γ, or TNFα levels in supernatants, suggesting an attempt at reactivation of the T-mediated immune response was not possible in this strongly induced cellular context.
Summary/Conclusion: Our data suggest that TME-derived signals strongly induce gene and protein expression of PD1 and its ligands in both neoplastic B- and normal T-cells from CLL patients and PEM was unable to block PD1 axis protein and mRNA expression or cytokine secretion by T-cells in this context. Although, these unpromising results may be an artefact of the continuous superactivation of T-cells in our model, our data indicate that the presence of PEM failed to influence both the growth of CLL B-cells and the restoration of T-cell function. Drug combination studies are warranted.

DUAL MTOR KINASE INHIBITORS SYNERGIZE WITH IBRUTINIB TO INDUCE CLL APOPTOSIS, AND OVERCOME BCR- AND STROMAL-MEDIATED SURVIVAL ADVANTAGES CONFERRED IN THE MICROENVIRONMENT

M.W. Moles[1,*], E. Cosimo[1], H. Jorgensen[1], A. Michie[1]

[1]Paul O'Gorman Leukaemia Research Centre, University of Glasgow, Glasgow, United Kingdom

Background: Chronic lymphocytic leukemia (CLL) pathogenesis is inextricably linked to communication between CLL cells and non-malignant accessory cells of the tumor microenvironment (TME), conferring proliferative and pro-survival signals that mediate resistance to therapeutic agents and expansion of malignant clones. Therefore, inhibiting the signals orchestrating these events is key to disrupting disease progression, offering a potential cure for CLL. The Bruton's tyrosine kinase inhibitor, ibrutinib, has demonstrated excellent clinical activity in high-risk CLL patients through inhibition of B cell receptor-induced survival in the TME. However, resistance mutations in response to treatment have been demonstrated, underlining the importance of developing novel treatment strategies for this patient subgroup. The dual mTOR kinase inhibitor, AZD8055, selectively targets mTOR protein complexes, mTORC1 and mTORC2, which regulate essential cellular functions including cell growth, proliferation and survival. mTOR signalling is often deregulated in cancer, but little is known about its role in CLL pathogenesis. Interestingly, ibrutinib and AZD2014 (Vistusertib; a clinical analogue of AZD8055) synergize in diffuse large B cell lymphoma cell lines to enhance apoptosis.
Aims: We sought to examine whether combining ibrutinib with AZD8055/AZD2014 could represent a valid therapeutic approach for CLL under conditions mimicking the TME *in vitro*.
Methods: In the present study, we assessed the response of primary CLL cells to ibrutinib/AZD8055 treatment alone or in combination under culture conditions replicating TME signals: stromal cell cultures (NT-L); cultures mimicking T cell-CLL engagement (CD40L); and BCR ligation. We performed median-drug effect analysis to calculate combination indices (CI) to identify drug synergy between AZD2014 or AZD8055 and ibrutinib in CLL cells, and then established the impact of AZD8055 and/or ibrutinib on CLL cell viability under each TME condition. Finally, to delineate the molecular events underpinning the response to drug, substrate specificities of AZD8055 and/or ibrutinib downstream of mTORC1/2 were determined.
Results: The median drug-effect analysis revealed that both AZD2014 and AZD8055 synergize with ibrutinib ($CI < 1.0$) at clinically achievable doses in CLL cells. Treating BCR-ligated or NT-L-co-cultured CLL cells with AZD8055 or ibrutinib resulted in a significant reduction in cell viability, which was enhanced when combined. Although CLL cell proliferation was blocked, viability of CLL cells co-cultured on CD40L was not affected by AZD8055/ibrutinib alone or in combination. Analysis of drug selectivity for inhibition downstream of mTOR-mediated signalling revealed that AZD8055 reduced mTORC1 ($4EBP1^{T36/45}$, $S6^{S235/236}$) and mTORC2 (Akt^{S473}) activity in BCR-ligated or NT-L-co-cultured CLL cells and to a lesser extent on CD40L. Ibrutinib reduced phosphorylation of mTORC1/2 substrates in CLL cells upon BCR ligation, but to a lesser extent upon co-culture with NT-L or CD40L.
Summary/Conclusion: In conclusion, we report a synergistic interaction between ibrutinib and mTOR inhibitors in CLL cells, enabling enhanced apoptosis downstream of BCR- and stromal-signals. However, this could not be replicated in CD40L co-cultures. Analysis of drug selectivity downstream of mTORC1/2 suggests that AZD8055 inhibits molecular events required for cell proliferation. To this end, mTOR inhibitors may play a role in preventing CLL proliferation within the TME, and likely represents a promising therapy in combination.

Background: Casein kinase 1 (CK1) δ/ε is a key component of both canonical and non-canonical Wnt pathways, which were shown to drive chronic lymphocytic leukemia (CLL) by several mechanisms (Wang *et al.*, 2014, Kaucka *et al.*, 2013). Also other types of cancer, such as breast, prostate cancer or others were previously shown to depend on Wnt/CK1 activity and the pathway inhibition was suggested as a potential form of therapy. In recent study, we showed that CK1 inhibition can block processes involved in CLL progression *in vitro* as well as in vivo in the Eμ-TCL1 mouse model of CLL (Janovska *et al.*, 2018). Importantly, CK1 inhibition showed synergistic effects with ibrutinib treatment in blocking chemotaxis of CLL cells, a process important for CLL pathogenesis and showed to be beneficial also in vivo.
Aims: Our previous *in vitro* and *in vivo* data showed that inhibition of CK1 activity is a valid approach to block key processes of CLL progression. Until now, our studies were based on commercially available inhibitors. However, these may often show low selectivity and may not be suitable for therapy of patients. Current work has focused on development of more active and selective compounds, which could be used in future in clinical practice.
Methods: Rational design, synthesis of novel compounds targeting CK1δ/ε, followed by *in vitro* and *in vivo* characterization of the novel inhibitors focused on toxicity towards cancer and normal cells, inhibition of cell migration and activity *in vivo* in mice.
Results: Rational design approach was used to design and synthesize novel inhibitors targeting CK1 δ/ε kinase. A set of ~70 compounds was characterized using a standardized set of assays focused on activity of CK1 in cells and cytotoxicity. Primarily, the experiments were focused on CLL and MCL, and showed that the tested compounds have significant anti-cancer activity with low toxicity towards normal healthy cells. *in vitro* testing showed high selectivity of the tested compounds towards CK1 δ/ε isoforms and very high activity, with IC50 values in nanomolar range. Selected compounds were tested *in vivo* in mice and were well tolerated, reaching plasma concentration in range effectively inhibiting CK1 kinase. Activity against other types of cancer (B-cell lymphomas, prostate, breast, pancreatic cancer) was also tested and showed that the rationale of targeting CK1 δ/ε may be applicable in several types of malignancies.

Summary/Conclusion: We have developed a set of highly active and selective CK1 δ/ε inhibitors, which show activity against multiple types of malignancies – e.g. CLL, B-cell lymphomas, prostate, breast and pancreatic cancer. With focus on CLL, we showed that these inhibitors have significantly higher toxicity towards CLL cells than to normal healthy B cells and efficiently block processes involved in CLL pathogenesis. *In vivo* testing of these compounds confirms their ability to efficiently inhibit CK1 activity.

Background: *TP53* mutations can occur in up to 10% chronic lymphocytic leukemia (CLL) patients at diagnosis and 30-40% patients at relapse, being associated with short overall survival (OS), short progression free survival and chemotherapy resistance. However, the effects of *TP53* mutations in stable good prognostic CLLs have been less documented. Furthermore, the generation of *in vitro* models harboring the alterations detected by next-generation sequencing (NGS) in CLL patients would be useful to predict the response to treatments based on the patient mutational profile.
Aims: 1) To analyze the presence of *TP53* alterations by NGS and FISH in order to refine its impact in good prognosis del(13q) CLL cytogenetic subgroup. 2) To gain insight into the therapeutic implications of *TP53* inactivation in response to drugs currently used in CLL, generating *TP53*-mutated CLL cellular models by CRISPR/Cas9 technology.
Methods: The mutational status of *TP53* was analyzed by NGS in a cohort of 290 untreated CLLs, enriched for del(13q) cases (68.5%). In addition, the CRISPR/Cas9 system was used to generate *TP53* loss-of-function mutations in the CLL-derived HG3 cell line. Proliferation, apoptosis and cell cycle assays were performed to investigate the response of *TP53* wild-type (*TP53*wt) and *TP53*-mutated (*TP53*mut) cell lines to fludarabine and ibrutinib.
Results: 1) Mutations in *TP53* were observed in 7.2% of CLL patients. Overall, the frequency of alterations in this gene (either mutations or deletion) (*TP53*alt) was 8.3%. Within del(13q) subgroup, 7.6% (N=15) showed *TP53*alt. These patients presented significantly shorter OS than del(13q)-*TP53*wt cases (p=0.002). Additionally, 83.7% del(13q) patients harbored del(13q) as the sole cytogenetic aberration (del(13q)S) (N=164). Stratifying this CLL subgroup in terms of *TP53* mutational status, we observed that *TP53* mutations were associated with a reduced OS compared with del(13q)S-*TP53*wt patients (p=0.016). However, it is worth pointing out that a subset of patients (N=6) within del(13q)S-*TP53*mut group showed a high stable disease with no need of treatment and a similar OS compared to *TP53*wt cases (median not reached in both cases; p=0.575) . All of these cases carried *IGHV* mutated gene and their *TP53* mutations were predominantly subclonal. 2) Considering the NGS results, three HG3 cell lines (which harbors del(13q)) carrying different *TP53* frameshift mutations were generated using CRISPR/Cas9. Viability assays showed that HG3-*TP53*mut cell lines were more resistant to fludarabine than HG3-*TP53*wt cell lines (p<0.01). Annexin and cell cycle analyses revealed higher levels of apoptosis in HG3-*TP53*wt cells than in HG3-*TP53*mut cell lines (p<0.01) after 5 mM fludarabine exposure during 48 hours. By contrast, *TP53*mut cells responded to ibrutinib similarly as *TP53*wt cells, since no significant differences of viability were observed between HG3-*TP53*wt and HG3-*TP53*mut cells after ibrutinib treatment.
Summary/Conclusion: 1) *TP53* mutations detected by NGS allow us to better stratify the prognosis of del(13q) CLLs. 2) A subgroup of patients with del(13q)S-*TP53*mut-*IGHV*mut patients presents an stable disease despite the presence of *TP53* mutations. 3) CRISPR/Cas9 technology allow us to generate *in vitro* models with *TP53* mutations observed in patients in order to study the implications of these alterations in treatment response.

ENCYCLOPEDIA OF CLL SUBSETS: AN ONLINE KNOWLEDGEBASE FOR SUBSETS OF CLL CASES WITH STEREOTYPED B CELL RECEPTORS

T. Reigl[1,*], K. Stranska[1,2], V. Bystry[1], A. Krejci[1], A. Grioni[1], S. Pospisilova[1,2], K. Plevova[1,2], N. Darzentas[1,3]

[1]CEITEC - Central European Institute of Technology, Masaryk University, [2]University Hospital Brno, Brno, Czech Republic, [3]Department of Internal Medicine II, University Hospital Schleswig-Holstein, Kiel, Germany

Background: Chronic lymphocytic leukemia (CLL) is documented as a biologically and clinically heterogeneous disease with varying clinical outcome. A related and remarkable phenomenon in CLL is the presence of subsets of patients with highly similar, or stereotyped, B cell receptors (BcR) – or 'CLL subsets' herein, which have been reported to involve one in three cases. Importantly, 'major' subsets (with >=20 cases in the studied cohort), involving one in eight cases, also exhibit homogeneity regarding both clinical presentation and outcome. Recently, assignment of new CLL cases to major subsets was included in the updated ERIC recommendations for immunoglobulin gene sequence analysis in CLL.
Aims: To construct and make publicly available a unique online knowledgebase, the 'Encyclopedia of CLL Subsets', for the interactive overview and breakdown of major CLL subsets in the context of up-to-date published information about their biological and clinical interpretation. To link this resource to ARResT/AssignSubsets, the online tool for the assignment of new CLL cases to those subsets.
Methods: We employ web technologies and appropriate bioinformatic and statistical methods to manage, analyse, and present data and results – e.g. R / Shiny, HTML / CSS / Javascript.
Results: The Encyclopedia of CLL Subsets [bat.infspire.org/arrest/subsets] is based on the currently available 19 major CLL subsets. Interactive visualisations provide access to immunogenetic and clinical data from published studies, with tooltips and links to relevant publications (Figure 1A). Literature collected as directly or indirectly related to CLL subsets currently comprises more than 240 entries and is available in interactive tables with highlighted mentions of subsets and of other useful, e.g. medical and immunogenetic, keywords (Figure 1B). Instructions and disclaimers assist users to understand the implications of using the resource, especially for clinical purposes. Finally, ARResT/AssignSubsets, the aforementioned online tool for assignment of new cases to these subsets, is bi-directionally linked to the Encyclopedia – this facilitates the primary usage scenario, i.e. the interpretation of the assignment of new CLL cases to the major CLL subsets.

Figure 1.

Summary/Conclusion: BcR stereotypy in CLL has important biomedical and clinical implications. The Encyclopedia of CLL Subsets is a unique online knowledgebase on these homogeneous groups of CLL patients in an otherwise heterogeneous entity. Around it, bioinformatic solutions enable researchers and clinicians alike to tap into this reference resource to get insights, link their data robustly, and collaborate productively.
Supported by Ministry of Health of the Czech Republic, grant nr. 16-34272A. Acknowledging all underlying work, support, and advice from the IgCLL group, and all contributors and contributions to IMGT/CLL-DB. Computational resources were provided by the CESNET LM2015042 and the CERIT Scientific Cloud LM2015085, provided under the programme "Projects of Large Research, Development, and Innovations Infrastructures".

ANALYSIS OF LOCUS-SPECIFIC LINE-1 AND ALU ELEMENT DNA METHYLATION REVEALS NOVEL EARLY EPIGENETIC CHANGES IN CHRONIC LYMPHOCYTIC LEUKAEMIA

T. Barrow[1,*], N. Wong Doo[2,3], R. Milne[3], G. Giles[3], E. Willmore[4], G. Strathdee[4], H.-M. Byun[5]

[1]Faculty of Health Sciences and Wellbeing, University of Sunderland, Sunderland, United Kingdom, [2]Concord Hospital, University of Sydney, Sydney, [3]Cancer Epidemiology Centre & Intelligence Division, Cancer Council Victoria, Melbourne, Australia, [4]Northern Institute for Cancer Research, [5]Human Nutrition Research Centre, Institute of Cellular Medicine, Newcastle University, Newcastle, United Kingdom

Background: Retrotransposons, such as LINE-1 (L1) and *Alu* elements, comprise more than 25% of the human genome. Their ability to retrotranspose throughout the genome is normally suppressed by epigenetic mechanisms. However, this repression is frequently lost in solid tumours through internal and external stimuli, and consequently somatic retrotransposition can be an initiating event in carcinogenesis. The epigenome in chronic lymphocytic leukaemia (CLL) is shaped by the maturation stage of the cell of origin, and its evolution during disease progression is correlated with the acquisition of genetic abnormalities associated with poor patient prognosis. Early work has demonstrated that L1 and *Alu* hypomethylation are associated with the acquisition of 17p deletions in CLL, but to date there has been no comprehensive or locus-specific analysis of retrotransposon DNA methylation.
Aims: To develop an approach to enable locus-specific analysis of L1 and *Alu* subfamily DNA methylation using the Illumina Infinium 450K microarray platform (H450K) and apply this to study aberrant methylation of L1 and *Alu* elements in CLL.
Methods: H450K probes mapping to retrotransposons were identified using RepeatMasker. The probeset was applied to a publicly-available dataset from a study of 138 CLL patients and 13 healthy individuals available from the International Cancer Genome Consortium. Leading hits were further analysed in Gene Expression Omnibus (GEO) datasets from 1,169 healthy individuals, 764 acute lymphoblastic leukaemia (ALL) patients, 174 acute myeloid leukaemia (AML) patients, and 31 diffuse large B-cell and Burkitt's lymphoma patients, and also prospective samples from 82 future CLL cases (<18 years from diagnosis) and 82 age-matched controls within the Melbourne Collaborative Cohort Study.
Results: We identified 9,549 probes mapping to 117 L1 subfamilies, and 12,806 mapping to 37 *Alu* subfamilies. In normal B-cells from healthy individuals, DNA methylation at these sites was routinely high (mean β: 0.75), with greater variation observed in older subfamilies (L1M and *Alu*J) in comparison to the youngest (L1H/L1PA and *Alu*Y), especially at CpGs within 200 bases of TSS. We identified 10,782 CpG sites within L1 and *Alu* sequences that were differentially methylated between CLL patients and healthy individuals (P_{fdr}<0.05), of which 55 were hypomethylated in >90% of CLL patients but never in healthy individuals. Hypomethylation of *Alu* elements was associated with evolutionary age, with older subfamilies (*Alu*J) displaying greater changes than younger ones (*Alu*Y). Hypomethylation of 17 leading hits was highly confined to CLL, never observed in healthy individuals and infrequently in ALL, AML and lymphoma. In prospective samples, methylation at each of the 17 loci, located across the genome, was highly correlated within individual patients. In contrast to diagnosed CLL patients, hypomethylation at the loci was observed in only 9 future CLL cases (11%). Notably, however, this was more commonly observed in samples taken <7 years before diagnosis (7 of 24, 29%) than in those taken more than 7 years before diagnosis (2 of 58, 3%).
Summary/Conclusion: We have identified locus-specific hypomethylation events of L1 and *Alu* elements that are highly frequent and specific to CLL, and which are present prior to diagnosis for some patients. Further work is required to establish how these epigenetic changes correspond to modulation of global DNA methylation patterns in leukaemogenesis.

PS1077

ILT3/DELTEX-1/SHIP-1 AS A NOVEL INHIBITORY AXIS CONTROLLING B CELL RECEPTOR SIGNALING IN CHRONIC LYMPHOCYTIC LEUKEMIA

V. Zurli[1], G. Wimmer[1], F. Cattaneo[1], V. Candi[2], E. Cencini[2], A. Gozzetti[2], D. Raspadori[2], G. Campoccia[2], F. Sanseviero[1], M. Bocchia[2], C.T. Baldari[1], A. Kabanova[1,*]

[1]University of Siena, [2]University Hospital of Siena, Siena, Italy

Background: The high proportion of long term non-progressors among CLL patients suggests the existence of a regulatory network which restrains the proliferation of tumor B cells.
Aims: In this work we undertook to identify determinants composing such network, which could be fundamental for our understanding of mechanisms that control CLL development.
Methods: We used transcriptomics, signaling and imaging studies to characterize ILT3, the immunoglobulin-like transcript 3, as an inhibitory receptor ectopically expressed on CLL cells and endowed with important regulatory function.
Results: The ectopic expression of ILT3 in CLL was a distinctive feature of neoplastic B cells and hematopoietic stem cells, thus identifying ILT3 as a selective marker of malignancy in CLL and the first example of phenotypic continuity between mature CLL cells and their progenitors in the bone marrow. ILT3 expression was found to be driven by Deltex1, a suppressor of antigen receptor signaling in lymphocytes. Triggering of ILT3 inhibited the activation of Akt kinase upon B cell receptor (BCR) stimulation. This effect was achieved through the dynamic coalescence of ILT3, BCRs, and phosphatase SHIP-1 into inhibitory clusters at the cell surface. Finally, our findings showed that in CLL cells ILT3 was co-expressed with other genes that might have tumour suppressing function.
Summary/Conclusion: Collectively, our findings define the mechanism which promotes the ectopic expression of ILT3 in CLL cells and indicate that ILT3 may functionally contribute to a regulatory network controlling tumour progression by suppressing the Akt pathway. Moreover, we hypothesize that ILT3 could be not only the marker of CLL cells but rather a marker of a tumour-suppressing gene expression program characterizing CLL cells. An in-depth analysis of such program will be provide insights into the mechanisms underlying the frequently observed indolent nature of CLL.

DETIN: OVERCOMING TUMOR IN NORMAL CONTAMINATION

A. Taylor-Weiner[1,2,*], C. Stewart[1], T. Giordano[3], A. Macbeth[4], N. Lennon[4], E. Rheinbay[1], D.-A. Landau[5], C. Wu[6], G. Getz[17]

[1]Cancer Genomics, The Broad Institute, [2]Bioinformatics, Harvard University, Cambridge, [3]Department of Pathology, University of Michigan, Ann Arbor, [4]The Broad Institute, Cambridge, [5]Department of Medicine, Weill Cornell Medicine, New York, [6]Department of Medical Oncology, Dana-Farber Cancer Institute, [7]Department of Pathology, Mass General Hospital, Boston, United States

Background: A key step in sensitive and specific somatic mutation detection is comparison of the tumor sample to a matched germline control. Sensitivity to detect somatic variants is greatly reduced when the matched normal sample is contaminated with tumor cells. Procuring matched normal tissue for hematologic malignancies can be challenging. At times, the only available tissue may be contaminated with tumor cells. Tumor in normal (TiN) contamination can result from sampling techniques such as FACS sorting or skin tissue or saliva (that can be invaded by leukemic cells).
Aims: To overcome this limitation of somatic detection, we developed deTiN, a method that estimates TIN, and improves detection sensitivity when using a contaminated normal. We will demonstrate validation of deTiN's model as well as the effect of TiN contamination on genomic characterization of hematologic malignancies.
Methods: In order to experimentally validate deTiN, we performed an *in vitro* mixing experiment. We created 15 tumor and normal mixtures using a tumor (breast invasive ductal carcinoma, CRL-2321D) and a matched normal control (EBV-transformed lymphoblastoid, CRL-2362D) cell lines, with TiN ranging from 0.007 to 0.9. To examine the robustness and utility of deTiN in the analysis of hematological cancers, we applied deTiN to cohorts of CLL, AML and DLBCL patient derived sample pairs (N=1276).
Results: In the validation experiment, deTiN estimated the TiN mixture proportions with a mean absolute error of 0.019 (R^2=0.99, $p<10^{-4}$). TiN estimates were accurate across the full range of TiN values, including at the more common values of TiN<0.1 (mean absolute error = 0.005). We observed a significant decrease in mutation detection sensitivity when

using standard mutation calling protocols. Mutation detection sensitivity dropped below 50% for TiN values greater than 0.03. DeTiN was able to detect 96% of all known SSNVs using the ~0.03 contaminated normal compared to 52% without deTiN. Next we applied deTiN to cohorts of hematologic malignancies with matched normal tissues coming from a variety of sources including FACS sorted whole blood, saliva and skin biopsies. We detected varying levels of TiN across each of these sample collections. In CLL-normal sample pairs derived from patients (N=257), enrolled in a phase III clinical trial we found that TiN varied depending on patient disease status and control sample acquisition strategy. The mean fraction TiN observed in normals acquired by CD19- sorting was 0.028 (range= [0-0.17]). 78 of the 171 CD19- (46%) cases had TiN contamination greater than or equal to 0.02. In contrast, samples from patients who were MRD- exhibited no TiN contamination (mean=0;range=[0-0]). Finally, we show that deTiN is able to recover 20% more putative driver mutations in cohorts affected by TiN. deTiN recovered calls in both highly recurrent driver genes such as *SF3B1*, *ATM*, *TET2*, *ASXL1*, *JAK2* and *TP53*, as well as in significant genes mutated at lower frequencies such as *CHEK2*, *SAMHD1*, *XPO1*, *RUNX1*, and *FBXW7*. SSNVs and Indels identified by deTiN in these driver genes occurred in regions recurrently mutated in our cohort and in the COSMIC database, supporting their functional role in cancer.

Summary/Conclusion: We developed a novel method to detect TiN contamination and recover somatic events lost to this phenomenon. We validated the accuracy of deTiN's estimation of contamination using *in-vitro* mixing experiments and show that deTiN's model improves genomic characterization of hematologic malignancies.

PS1079

TRACKING THE MINOR CLONES IN OLIGOCLONAL CHRONIC LYMPHOCYTIC LEUKEMIA USING HIGH-THROUGHPUT IMMUNOPROFILING

Background: In CLL, multiple productive IGH gene rearrangements are detected in 2–5% of cases by conventional low-throughput methods, rising to a quarter of cases using next-generation sequencing (NGS). We have shown at the single cell level in these cases that each productive IGH gene rearrangement denotes a separate B-cell clone. Typically, a major clone coexists with one or more minor ones. Shifts in clonal ratios and prevailing of initially minor clones in the course of the disease were shown repeatedly. It is, therefore, desirable to monitor them, although discrepancies exist among various methods used for their detection.

Aims: To test the capability of NGS immunoprofiling methods to detect minor clones in oligoclonal CLL, with focus on cases showing discrepancies using various methods, and cases with considerable clonal shifts during disease course.

Methods: Overall, 21 samples from 14 patients (7 patients were monitored in several time-points) were submitted to NGS immunoprofiling with DNA and RNA as a starting material: DNA IG NGS was performed by applying multiplex primers to IGHV and IGHJ genes, 20 ng of DNA per sample was used for library preparation; raw NGS reads were analyzed using ARResT/Interrogate. For RNA IG NGS, protocol based on template switching approach and using unique molecular barcodes was used; raw NGS reads were analyzed using MIGEC and in-house bioinformatics pipelines. The results from both methods were compared to those obtained using bulk sample Sanger sequencing and SCA.

Results: Only complete IGH rearrangements were analyzed as those were obtained by all methods applied. Overall, 19 samples from 12 patients and 9 samples from 9 patients were analyzed by DNA and RNA IG NGS, respectively, with 7 samples submitted to both methods. Median filtered-in read count for DNA IG NGS was 5,610 (1,885–13,461), median molecule count for RNA IG NGS was 4,521 (1,670–21,975).

All 9 minor clones that were detected discrepantly by either Sanger sequencing or SCA were confirmed with NGS immunoprofiling in both DNA and RNA. While DNA IG NGS clonal ratios largely corresponded to SCA results, we detected dramatic differences in 3/7 cases using RNA IG NGS, likely related to uneven IG RNA expression among clones. In 4 cases studied longitudinally, a clone disappeared in time as detected by Sanger sequencing. Using DNA IG NGS, we confirmed the clone presence in the initial sample in all cases (clonal ratios 0.06, 5.8, 4.8, and 27%), while it was undetectable in subsequent samples (obtained after 1, 3, 4, and 7 years). In other 4 longitudinally studied cases, a new clone emerged over time. We confirmed this observation by DNA IG NGS in two cases (changes in clonal ratios from 3.3% to 76.0%, and from 0% to 6.9% in 7 and 1 year, respectively). In the remaining two cases, DNA IG NGS did not detect the clone in both initial and subsequent sample, likely due to a technical error. Using RNA IG NGS, we detected additional clonotypes on top of those expected in 3 cases; DNA IG NGS performed in two of them did not confirm their presence. On the other hand, all 3 new clonotypes recorded in 3 cases using DNA IG NGS were confirmed, either by their detection in two subsequent samples, or in one case by RNA IG NGS, although in negligible fraction.

Summary/Conclusion: Detection of minor clones in oligoclonal CLL is problematic and its efficiency varies with different approaches. Their significance is still unclear and should be investigated in more detail.

SINGLE CELL ABNORMALITIES ON CLASSIC G-BANDING ANALYSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA: A NEW DIAGNOSTIC AND BIOLOGICAL CHALLENGE?

A. Athanasiadou[1,*], M. Gkaitatzi[1], G. Papaioannou[1], M. Iskas[1], A. Xochelli[2], O. Asteriou[1], Z. Lazarou[1], N. Stavroyianni[1], A. Hadzidimitriou[2], A. Anagnostopoulos[1]

[1]Department of Hematology & BMT Unit, George Papanicolaou Hospital, [2]Institute of Applied Biosciences, CERTH, Thessaloniki, Greece

Background: Chromosomal abnormalities have a well accepted clinical and prognostic value in chronic lymphocytic leukemia (CLL). Occasionally, conventional G-banding cytogenetics in CLL can detect chromosomal aberrations that do not fulfill clonality criteria.

Aims: Here we aim to assess single cell abnormalities (sc-abs) whose significance, frequency and type have not yet been identified.

Methods: We studied 725 primary CLL samples subjected to G-banding analysis by two parallel cultures with the addition of either Phytohemagglutinin and Interleukin 2 (PHA/IL-2) or an immunostimulatory CpG-oligonucleotide DSP30 and IL-2 (CpG/IL-2).

Results: Overall, 1450 cultures were set up. Sc-abs were detected in 284/725 (39%) samples. One sc abnormal karyotype was detected in 141 samples, 2 in 70 samples, >2 in 73 samples (10%) and >4 in 29 samples. Of 284 samples with sc-ab, 219 had sc-abs in PHA/IL-2 and 113 in CpG/IL-2 cultures. More than 2 sc-ab were revealed in 46 in PHA/IL-2 and 12 in CpG/IL-2 cultures. Overall, 616 sc-ab were detected and of these 224 (36.3%) were present in samples with abnormal karyotype while the remaining 392 (63.6%) in samples with normal karyotype. Amongst 616 sc-ab samples, 167 (27.1%) had a complex karyotype and 449 (72.8%) a non-complex one. Out of 616 sc-abs, 326 (52.9%) were structural, 125 (20.3%) were numerical and 165 (26.8%) were both structural and numerical. All chromosomes participated in these sc-abs. Fifty sc-abs concerned evolution of a detected abnormal clone. Since two culture types were used and PHA/IL-2 cultures have been already reported to be related with sc-ab detection, we further studied the 73 samples containing >2 abnormalities. Distribution of the number of sc-abs across the samples was as follows: 3 sc-abs were detected in 34 samples, 4 in 10, 5 in 11, 6 in 9, 7 in 3, 8 in 1, 9 in 3 and 12 in 2. Forty-eight of these 73 samples had normal karyotype: amongst these 17 had ≥ 5 abnormalities. The remaining 25 samples had abnormal karyotype: 12 had ≥5 sc-abs (p=0.29). In these 73 samples, sc abnormalities were revealed in 65 samples by PHA/IL-2 culture and 43 by CpG/IL-2 culture. Sc-abs were detected only in 7 samples cultured with CpG/IL-2 and in 30 samples cultured with PHA/IL2. Forty-eight samples were checked for 13q deletion:17 and 6 samples had single and double del(13q), respectively. Sequence analysis for IGHV somatic hypermutation status was available in 65/73 cases: 39 were IG-unmutated and 26 were IG-mutated. Clinical data was available in 59/73 cases. Time from diagnosis to testing ranged between 0-174 months (median: 44); 17/59 samples were diagnostic, while 31/59 samples involved treatment naïve patients; of these 13 subsequently progressed.

Summary/Conclusion: Sc-abs seem to be a common finding in CLL patients regardless of treatment status probably suggesting genomic heterogeneity and instability. They are distributed across all chromosomes and are mainly structural. Clearly the issue of sc-abs should be systematically addressed in larger patient cohorts and the combination of PHA/IL2 and CpG/IL-2 cultures will help to acquire more comprehensive genetic data by revealing sc-abs that are more frequent in PHA/IL2 cultures.

PS1081

HIGHER RESPONSIVENESS OF CLL CELLS TO B-CELL RECEPTOR STIMULATION IS ASSOCIATED WITH REDUCED EXPRESSION OF INHIBITORY MOLECULES OF THE NF-κB PATHWAY

R.W. Meijers[1,*], A.F. Muggen[1], L.G. Leon[1], O.B. Corneth[2], R.W. Hendriks[2], J.J. van Dongen[1], A.W. Langerak[1]

[1]Department of Immunology, Laboratory Medical Immunology, [2]Department of Pulmonary Medicine, Erasmus MC, Rotterdam, Netherlands

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease based on both clinical (manifestation, disease course) and biological characteristics. We previously described (Muggen *et al*., Leukemia, 2015) that compared to normal B cells, human CLL cells have higher basal Ca^{2+} levels and respond poorly to B-cell receptor (BCR)-stimulation. In addition, we found differences in Ca^{2+} signaling among CLL cases, both in basal Ca^{2+} levels and levels upon B-cell receptor (BCR)-stimulation. Such differences in BCR responsiveness could reflect heterogeneity in CLL pathogenesis due to cell-intrinsic factors.
Aims: Here we aim to elucidate potential cell-intrinsic differences between CLL patients showing a good or a poor response upon BCR stimulation.
Methods: In peripheral blood CLL cells from 52 CLL patients the BCR responsiveness was determined *ex vivo* based on Ca^{2+} influx upon α-IgM stimulation. Phosphorylation levels of various signaling molecules downstream of the BCR, as well as the cell surface expression of markers associated with anergy and activation were assessed by flow cytometry. Transcription profiling of responsive CLL cases (n=6) and unresponsive CLL cases (n=6) was performed by RNA sequencing. RQ-PCR was used to validate transcriptional differences between these two CLL groups, as found by RNA sequencing.
Results: We observed that the increase in Ca^{2+} after α-IgM stimulation was accompanied by a higher phosphorylation of PLCγ2 and Akt molecules. Next to that, we found a significant positive correlation between the responsiveness to α-IgM and the expression levels of CD21, CD38, CD80, and CD27, which suggests that the α-IgM responsive CLL cells have a more activated cell signature. RNA sequencing revealed differences between the two groups of CLL patients, especially in the expression of NF-κB pathway genes. RQ-PCR validation of differentially expressed NF-κB pathway genes in an additional group of responsive and unresponsive CLL cases confirmed the significantly lower expression of the critical NF-κB inhibitors *NFKBIB* (p=0.021) and *NFKBIE* (p=0.009) genes in BCR-responsive CLL. Likewise, expression of the potential NF-κB inhibitors *NFKB1* (p=0.017) and *NFKB2* (p=0.009) was reduced in BCR-responsive CLL cases. Although no statistical differences were found in the expression of genes coding for the NF-κB subunits (*REL*, *RELA* and *RELB*), we did find strong correlations between the expression level of NF-κB inhibitors and the NF-κB subunits *REL and RELA*.
Summary/Conclusion: From our data we conclude that BCR-responsive CLL have a more activated cell surface phenotype and reduced expression of several components of the canonical NF-κB pathway that have been associated with inhibition of NF-κB signaling. These findings suggest that enhanced NF-κB activation may be critical for the responsive capacity of CLL cells to BCR stimulation, which would be in concordance with recent literature stating that progressive CLL cases display aberrant NF-κB signaling.

PS1082

COMPARISON OF CELLULAR AND CELL-FREE DNA FOR THE DETECTION AND MONITORING OF BTK MUTATED CLL CLONES IN PATIENTS WITH SUBSEQUENT THERAPY AFTER IBRUTINIB FAILURE

W. Schier[1,*], J. Christmann[2], H. Hannig[2], J. Krauter[1], A. Trummer[1]

[1]Hematology and Oncology, [2]Center for molecular diagnostics, Städtisches Klinikum Braunschweig, Braunschweig, Germany

Background: Ibrutinib is an orally available BTK inhibitor approved for the treatment in CLL patients. In patients with progression under ibrutinib, CLL clones with BTK and PLCG2 mutations, causing resistance towards ibrutinib, can be detected in up to 87 percent of cases. Only very few data are available regarding the monitoring of these resistant clones under subsequent therapies, e. g. venetoclax, and the sensitivity of cellular versus cell-free plasma DNA (cf-DNA) after reduction of peripheral lymphocyte counts.
Aims: To monitor BTK mutated CLL clones under the subsequent therapy with RT-PCR using DNA copy numbers and to compare the detection sensitivity of this method applying cellular or cf-DNA.
Methods: From July 2016 until February 2018, blood samples were taken simultaneously in EDTA and cf-DNA tubes from seven CLL patients at the time of progress under ibrutinib and at different time points thereafter during the subsequent therapy. DNA copy numbers were determined by using a modification of a published RT-PCR protocol with the aid of sequence specific primers for BTK C481S mutation or wildtype sequence and a fluorescence-labelled detection probe. Absolute copy number quantification was enabled by short control fragments (105nt) for mutated and wildtype DNA of which known amounts were included in a simultaneous RT-PCR reaction. Results are therefore given as a ratio of mutated to wildtype fragments (MUT/WT ratio). CLL samples without the BTK-C481S mutation (in Exon 14) were screened for BTK mutations in Exon 11, 15 and 16 as well as a PLCG2 mutation in Exon 19, 20 and 24 by Sanger sequencing.
Results: The seven patients received ibrutinib for a median of 26.4 (range: 16-33) months before progression. Mean follow-up after mutation analysis was 5.4 (range: 1-13.4) months. Three patients died under therapy with venetoclax, all due to Richter's transformation (RT). In five out of seven patients (71.4%), we were able to detect a mutation causing ibrutinib resistance: four showed a BTK-C481S mutation and one a PLCG2-G667E mutation, which has not been described so far and belongs to the SH2 domain. Within the four BTK mutated patients, three showed similar copy numbers and MUT/WT ratios for cellular and cf-DNA at time of progression, while in one, with a very low copy number, detection was only successful in cellular DNA. During the subsequent therapies (3x venetoclax, 1x R-CHOP for RT), MUT/WT ratios rapidly decreased but only one became undetectable. In 3 of 4 samples with a low copy number (<1000) using cellular DNA, cf-DNA showed no detectable mutation. So far, no increase of the MUT/WT ratio has been observed in the 4 patients remaining in clinical remission.
In the patient with the PLCG2-G667E mutation, ibrutinib was continued for further 5.7 months as progression was slow. Finally, the patient also had to be switched to venetoclax.
Summary/Conclusion: We were able to confirm the high incidence of BTK and PLCG2 mutations in CLL patients with progression under ibrutinib. In our setting, usage of cell-free DNA appears to be less sensitive compared to cellular DNA. Thus, for the monitoring of the BTK-C481S mutation during subsequent therapy, cellular DNA is still preferable, even when lymphocyte counts decline. Monitoring of ibrutinib resistant CLL clones during Venetoclax might be helpful in tailoring therapy in case of new progression.

PS1083

NOVEL STRATEGIES OF TARGETING P53 RELATED VULNERABILITIES IN T-PLL CELLS

J. Von Jan[1,*], E. Andersson[2], A. Schrader[1], B. Yadav[2], P. Mayer[1], S. Mustjoki[2], M. Herling[1]

[1]Department I of Internal Medicine, Center for Integrated Oncology (CIO) Köln-Bonn, University of Cologne (UoC), Köln, Germany, [2]Helsinki University Hospital Comprehensive Cancer Center, Helsinki, Finland

Background: T-cell prolymphocytic leukemia (T-PLL) is a mature T-cell neoplasm commonly presenting at an aggressive phase associated with a marked chemotherapy resistance. Nucleosides and alkylators show very limited clinical activity. Although the monoclonal antibody alemtuzumab induces high response rates, virtually all patients relapse and the mostly elderly individuals are often not eligible for allogeneic stem cell transplantation. Overall, the treatment options for T-PLL are scarce and its general prognosis with average survival times of <3 yrs. remains poor. We could show that although genomic *TP53* aberrations in T-PLL are rare (8% in our series), T-PLL cells fail to generate a distal pP53 response upon y-irradiation. Based on the confirmed expression of *wildtype* p53 protein in T-PLL, we conclude that this master regulator of a (therapeutic) damage response is retained in its inactive state by regulatory factors, *i.e.* by its suppressor MDM2.
Aims: We plan to expand the portfolio of p53 reactivators and other non-genotoxic substances to study those and their most synergistic combinations in rigorous pre-clinical test systems, including our T-PLL mouse models.
Methods: - CellTiter-Low® Luminescent Cell Viability Assay
- FACS analysis (7AAD/AnnV Staining)
- Immunoblotting
Results: In an *ex vivo* drug screen (306 substances, n=39 cases) we established a high efficacy of p53 re-activating agents from the class of p53 de-repressing MDM2 Inhibitors, e.g. Nutlin-3 or Serdemetan with an average sDSS of 7 and 9, respectively. The DSS is a drug sensitivity score based on the measured integrative and robust dose-response area under the curve. The sDSSs as the selective DSSs presents the leukemia-specific responses, comparing DSS from patient samples to the median DSS of healthy donors. We then tested in more detail the potential of such p53 reactivators as possible novel therapeutic approaches. Idasanutlin, an MDM2 inhibitor in clin-

ical testing for AML, activated the repressed p53 in T-PLL cells as shown by pSer15p53 immunoblots. This effect was enhanced by combination with the alkylating agent Bendamustine or the HDAC inhibitor Panobinostat. The latter contributed to p53 reactivation by conferring a higher net-acetylation state. Flow cytometry based evaluations of the pro-apoptotic potential identified Idasanutlin and Panobionstat as most effective single substances (LD50s Idasanutlin / Panobinostat: 0.6 μM/0.15 μM) out of our selected panel. In a small *in vivo* pilot study, we confirm the efficacy of Idasanutlin against murine T-PLL (WBC vehicle ctrl. vs Idasanutlin, p=0,003). A second *ex vivo* screen designed for synergy detection (n=13 T-PLL cases) identified Idasanutlin and Panobionstat as highly effective single agents. In agreement with the marked pSer15p53 induction induced by this combination (above), both agents combined showed a significant over-additive effect (ZIP score: 5.65, measured with the zero interaction potency (ZIP) reference model).
Summary/Conclusion: Reconstitution of a lost TP53 response in T-PLL cekks seems highly synergistic in a combination with inhibited deacetylation. Combination of a clinical-grade TP53 derepressor and HDACi appears as an attractive rationale for a future clinical trial in T-PLL.

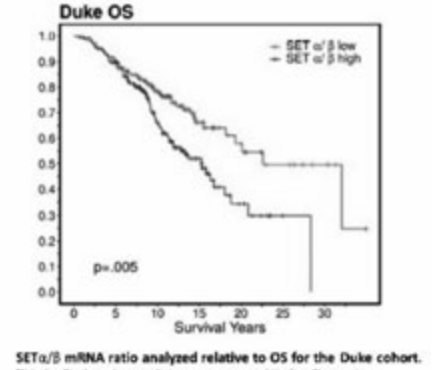
PS1084

HIGH SET ALPHA TO SET BETA ISOFORM EXPRESSION IS ASSOCIATED WITH INFERIOR OUTCOMES AND DISCRIMINATES FAVORABLE RISK IN TWO INDEPENDENT CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) COHORTS

D. Brander[1,*], A. Volkheimer[1], D. Christensen[1], L. Rassenti[2], T. Kipps[2], E. Guadalupe[1], Y. Chen[1], D. Zhang[3], X. Wang[3], K. Owzar[3], C. Davis[3], D. Friedman[1], J.B. Weinberg[1]

[1]Medicine, Duke University, Durham, [2]Medicine, UCSD, San Diego, [3]Duke University, Durham, United States

Background: SET oncoprotein, a physiological inhibitor of the most abundant serine-threonine phosphatase PP2A, has increased activity in malignancies. Investigators of SET have focused on total levels, without study of different SET isoforms. We previously demonstrated that the ratio of SET isoform (SETα and SETβ) protein levels by immunoblotting is significantly associated with overall survival (OS) and time to first treatment (TTFT) in CLL, and aimed to examine the importance of SET isoform mRNA expression by a novel assay in two large, independent cohorts.
Aims: 1. Examine the association of isoform expression of SET-α/β mRNA to clinical outcomes in two independent CLL patient cohorts
2. Test for interaction effect of SET-α/β mRNA ratio with established CLL risk biomarkers
Methods: We studied CLL patients at the Duke Univ/Durham VA (Duke) and the Univ California San Diego (UCSD) on IRB-approved protocols. Primers and probes for RT-qPCR were designed to amplify only the alpha or beta forms of SET. The SET α/β ratio was analyzed as a continuous variable for the primary analysis and as a binary variable (high *vs* low compared to the cohort median value; median SETα/β ratio=0.94 for Duke and 0.93 for UCSD) for visual display (Figure 1). Score test p-values and Wald test p-values were reported for univariate analysis and interaction analyses, respectively; Cox proportional hazard regression was used for the time to event analyses. Interactions of the dichotomous SET-α/β mRNA ratio with IGHV mutational status, FISH groupings (unfavorable FISH included any del17p, del11q, or 3 or more abnormalities), CD38 positivity and Rai staging were performed in the larger Duke cohort.



SETα/β mRNA ratio analyzed relative to OS for the Duke cohort. This is displayed as a dichotomous variable for illustrative purposes with the respective p-value. Duke patients with higher SET-α/β mRNA ratio as a continuous variable also had a significantly shorter OS.

Figure 1.

Results: The Duke combined population (n=307) was analyzed independently from the validation cohort of UCSD patients (n=166). The two cohorts were representative of other CLL populations, and there were no significant differences in median SET mRNA ratio or patient characteristics between cohorts. Duke patients with high SET-α/β mRNA ratio as continuous and dichotomous variable had significantly shorter TTFT [[HR 1.2 (1.2-1.3), p=0.001] and [HR 1.7 (1.3-2.3), p<0.001] for continuous and dichotomous, respectively]. As a dichotomous variable, Duke patients with high SET mRNA isoform ratio also had significantly shorter OS [HR 1.7 (1.2-2.5), p=0.005]. In the independent UCSD validation cohort, high SET-α/β mRNA ratio as a continuous and dichotomous variable was also significantly associated with shorter TTFT [[HR 1.3 (1.0-1.6), p=0.02] and [HR 1.8 (1.2-2.7), p=0.006 for continuous and dichotomous, respectively]. There was not a significant association of high SET mRNA ratio with shortened OS in the UCSD group; analysis for OS may have been limited due to a lower number of deaths at follow-up in this cohort. In Duke patients within the favorable risk mutated *IGHV (M-IGHV)* patients, those with high SET-α/β mRNA ratio had a shorter TTFT (significant interaction, p=.01). Similarly, in Duke patients with favorable FISH, high SET-α/β mRNA ratio predicted a shorter TTFT (significant interaction, p=.01).
Summary/Conclusion: SET-α/β mRNA isoform ratio expression modulates CLL aggressiveness and determines CLL outcomes of TTFT and OS in two large, independent CLL patient cohorts. High SET-α/β mRNA ratio adds valuable prognostic information and can discriminate within favorable risk groups those patients with poorer outcomes similar to the UM-*IGHV* and unfavorable FISH groups, respectively. SET is targetable, not just predictive, and could lead to new strategies in combination therapy.

PS1085

NOTCH1 MUTATIONS ARE AN INDEPENDENT PROGNOSTIC FACTOR IN IBRUTINIB- TREATED CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS

G. Del Poeta[1,*], M. Postorino[1], M.I. Del Principe[1], F. Pozzo[2], E. Santinelli[1], R. Bomben[2], L. Pupo[1], F. Buccisano[1], M.F. Rossi[2], L. Maurillo[1], A. Biagi[1], A. Venditti[1], W. Arcese[1], P. de Fabritiis[1], M. Cantonetti[1], S. Amadori[1], A. Zucchetto[2], V. Gattei[2]

[1]Hematology, University Tor Vergata, Rome, [2]Clinical and Experimental Hematology Unit, CRO IRCCS, Aviano (PN), Italy

Background: Ibrutinib, an oral, selective inhibitor of Bruton's tyrosyne kinase (BTK), demonstrated exceptional activity in patients with relapsed/refractory CLL as well as in untreated patients with genetic abnormalities which predict chemoresistance (i.e. *TP53* deletion or mutation). In fact, overall response rate (ORR), progression-free survival (PFS), overall survival (OS) were far superior in comparison with chemoimmunotherapy (Byrd, 2014). However, CD49d+ CLL were characterized by inferior PFS than CD49d- CLL with a significant lower reduction in organomegaly and lymph nodes size (Tissino, 2018). Even more, CD49d expression was strongly correlated with *NOTCH1* mutations (M) cases that significantly overexpressed the NF-kB pathway genes as compared to *NOTCH1* wild type (WT) CLL (Benedetti, 2017) and thus may confer poor response to ibrutinib in *NOTCH1* M CLL.
Aims: The primary aims of our research were: 1) to verify the correlations of *NOTCH1 M* with other biological and clinical prognosticators in patients treated with ibrutinib; 2) to evaluate the impact of *NOTCH1 M* on ORR, PFS and OS; 3) to confirm *NOTCH1 M* as an independent prognostic factor.
Methods: *NOTCH1 M* were investigated with ARMS PCR for c.75447545delCT or by Sanger sequencing of *NOTCH1* exon 34 and all cases were confirmed with next generation sequencing (NGS).
Results: Therefore, we evaluated the efficacy of ibrutinib, in a real-life contest, on 82 patients, median age 59 years (38-85), median number of previous regimens 2 (0-4; 13.4% previously untreated). Patients received 420 mg oral ibrutinib once daily until progression or occurrence of unacceptable side effects. Median follow up on ibrutinib was 13 months. ORR was 94% (complete response (CR): 20%, partial response (PR): 42%, PR with lymphocytosis (PR-L): 31%). The estimate 1-year PFS and OS were 79% and 83%, respectively. Twenty patients (24%) discontinued ibrutinib therapy due to progression (n=12), adverse events (n=6) or due to other reasons (n=2). Five out of 6 patients with Richter's syndrome (RS) had baseline del(17p)/*TP53* M (p=0.020). PFS was significantly better for patients in first/second lines vs later lines of therapy (p=0.033). Twenty-six patients were *NOTCH1 M* (32%). *NOTCH1 M* were significantly correlated with trisomy 12 (9/13; p=0.008), with CD49d >30% (24/26; p=0.0004) and with unmutated *IGHV* (23/26; p=0.020). With regard to clinical outcome, PR was significantly correlated with *NOTCH1 M* (p=0.008). Interestingly, lym-

phocyte counts were significantly lower in *NOTCH1* M patients both before and after ibrutinib therapy (p=0.0018 and p=0.019, respectively). On the other hand, burden disease was significantly higher in *NOTCH1* M patients both before and after ibrutinib therapy (p=0.025 and p=0.001, respectively). Significant shorter PFS was observed in *NOTCH1 M* patients (52% vs 87% at 24 months, p=0.0001; Figure 1). On the contrary, del(17)p/*TP53* M patients did not show significant worse PFS (p=0.097). Moreover, patients with *NOTCH1* M showed significant shorter OS (56% vs 80% at 24 months, p=0.018; Figure 1). In multivariate analysis of PFS and OS including del(17)p/*TP53*, *IGHV* status and age, only *NOTCH1 M* were confirmed as an independent prognostic factor (p=0.011 and p=0.009, respectively).

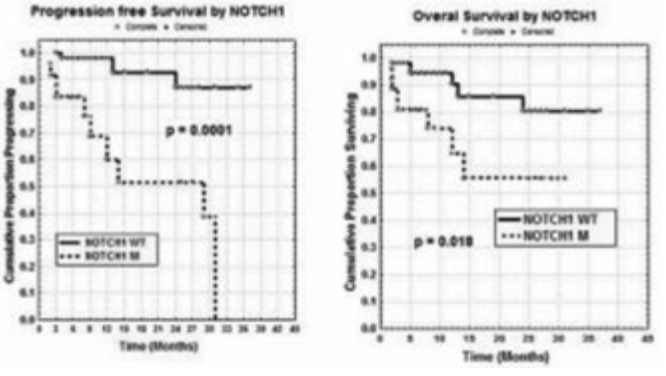


Figure 1.

Summary/Conclusion: Therefore, bcl-2 antagonists, such as venetoclax, working through a different pathway, could be combined with BTK inhibitors, in order to overcome resistance in some patients treated with ibrutinib, particularly within the CLL subset characterized by *NOTCH1 M.*

PS1086

INTEGRATED EXPRESSION PROFILING CHARACTERIZES BIOLOGICAL HETEROGENEITY IN REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA AND THE RISK OF RICHTER TRANSFORMATION

J. Bloehdorn[1,*], M. Sill[2], B.M.C. Jebaraj[1], K. Holzmann[1], A. Rouhi[1], F. Kuchenbauer[1], J. Bahlo[3], S. Robrecht[3], K. Fischer[3], B. Eichhorst[3], J. Edelmann[4], C. Schneider[1], L. Bullinger[5], M. Hallek[3], A. Benner[2], D. Mertens[1], H. Döhner[1], S. Stilgenbauer[1]

[1]Internal Medicine III, University Hospital Ulm, Ulm, [2]Division of Biostatistics, German Cancer Research Center (DKFZ), Heidelberg, [3]Department I of Internal Medicine and Center of Integrated Oncology Cologne Bonn, University Hospital Cologne, Cologne, Germany, [4]Barts Cancer Institute, Queen Mary University of London, London, United Kingdom, [5]Medical Clinic for Hematology, Oncology and Tumor Biology, Charite University Hospital, Berlin, Germany

Background: Impairment of TP53 is detected in up to 50% of refractory CLL cases and is associated with short survival after conventional chemoimmunotherapy. Resistance mechanisms also involve changes in microRNA expression, e.g. mir34a.
Aims: To investigate the transcriptional architecture of refractory CLL, we characterized a large multicenter treatment trial population by using combined mRNA and microRNA expression profiling.
Methods: The study was conducted on samples from refractory patients treated with alemtuzumab (CLL2H trial, multicenter, open-label, phase 2) and validated on treatment naïve samples (CLL8 trial, multicenter, open-label, phase 3). Profiling was performed on the Agilent Human microRNA Microarrays (miRBase Release v14) (n=58, refractory) and for the same refractory sample (n=51 with sufficient RNA available) or treatment naïve cases (n=337) with Affymetrix Human Exon 1.0 Arrays.
Results: Unsupervised clustering was used for class discovery on microRNA expression profiles and identified 3 independent clusters. Best response after alemtuzumab treatment with highest PR rate was observed for C1 (46%), while lowest PR rate was found in C3 (23%). Median progression-free survival (PFS) was 450 (C1) vs. 242 (C2) and 133 days (C3), median overall survival (OS) was 1319 (C1) vs. 629 (C2) and 466 days (C3). Inferior outcome in C2/C3 was not associated with genetic alterations. Richter transformation was observed for 11 of 58 cases (18.9%) of which 9 occurred in the C3 group, i.e. 30% of C3 cases transformed. Average time to transformation was 196 days (median: 96, range 0-824). Adverse prognostic impact of C3 classification was retained when cases with transformation were separated as single entity in the survival analysis. Investigating mRNA gene expression signatures using GSEA, we identified in C3 overexpression of genes coding for receptors or downstream effectors involved in transmembrane signaling, e.g. BCR components (BTK, CD79B, SYK), the TLR (TLR7, TLR10) and CD52. Genes overexpressed in C2 were functionally assigned to processes in the mitochondrial compartment and involved in the metabolism of hemoglobin (ALAS2, FECH, SLC25A39, BLVRB, HBG1, HBD, HBM, BCL2L1). Subsequent analysis on biologic features implies that C2 cases may be especially exposed to oxidative stress since corresponding transcriptional changes are involved in the antioxidative response and metabolic adaption including a deregulation of HIF1α. Using the cluster-defining genes identified in refractory CLL in a semi-supervised clustering of treatment naïve cases (n=337) from CLL8, showed identical expression patterns of clinical impact. With regard to respective clusters, OS was significantly different (p=0.04) with median OS in C1: not reached; C2: 77.6 months; C3: 86.4 months; Similar, PFS was different (p=0.01) with median PFS in C1: 59.1 months; C2: 36.1 months; C3: 35.9 months.
Summary/Conclusion: In conclusion, refractory CLL can be categorized in transcriptional subgroups with distinct biological features and predisposition to Richter transformation, independent of genetic variables. Being present both in refractory and untreated CLL, these signatures indicate the existence of biologic processes involved in the transformative process of CLL early in the disease course.

PS1087

DISTINCT DNA METHYLATION PROFILES IN DIFFERENT CYTOGENETIC SUBGROUPS OF CHRONIC LYMPHOCYTIC LEUKEMIA: THE INTRIGUING CASE OF TRISOMY 12

M. Tsagiopoulou[1,2,*], N. Papakonstantinou[1], M. Duran-Ferrer[3], V. Chapaprieta[3], T. Moysiadis[1], F. Psomopoulos[1], P. Kollia[2], E. Campo[3], K. Stamatopoulos[1], J.I. Martin-Subero[3]

[1]Institute of Applied Biosciences, Centre for Research and Technology Hellas (CERTH), Thessaloniki, Greece, [2]Department of Biology, National and Kapodistrian University of Athens, Athens, Greece, [3]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Universitat de Barcelona, Barcelona, Spain

Background: The pathogenesis of chronic lymphocytic leukemia (CLL) reflects an interaction between microenvironmental, genetics and epigenetics. CLLs show different cytogenetic alterations with clinical value, but it is unclear whether distinct CLL cytogenetic subgroups have different epigenetic landscapes.
Aims: We analyzed whether DNA methylation (DNAm) profiles can be linked to the pathophysiology of particular cytogenetic subgroups.
Methods: Using 450K methylation arrays, we investigated the poor prognosis del(11q) [n=29: 3 IG-mutated CLL (M-CLL)|26 IG-unmutated CLL (U-CLL)], the heterogeneous trisomy 12 [tris12, n=45: 17 M-CLL|28 U-CLL] and the favorable del(13q) [n=181: 131 M-CLL|50 U-CLL], as well as normal naïve (NBC, n=5) and memory (MBC, n=5) B cells. Moreover, methylation data were analyzed in the context of ChIP-seq data from MBC (Queiros *et al.*, Cancer Cell 2017) and expression arrays (69/250 CLLs).
Results: Principal Component Analysis (PCA) disclosed a distinct DNAm pattern for tris12 vs other cytogenetic subgroups, which was independent of IGHV gene somatic hypermutation status. We found 1760 CpGs contributing to the differences observed in the PCA; these findings were corroborated by hierarchical clustering analysis. We next performed differential methylation (DM) analysis (db=|0.4|, FDR<0.01) of each cytogenetic subgroup vs normal B cells. We observed 5409 DMCpGs in del(11q), 4497 in tris12 and 3412 in del(13q) cases, which frequently reflected a general CLL signature, as 2886 DMCpGs were shared in the three groups. The 685 hypomethylated CpGs unique to tris12, which were enriched in heterochromatin, enhancers, gene bodies and outside of CpG island (CGI), segregated tri12 cases from normal B cells and non-tris12 CLLs. The genes associated with these DMCpGs showed significant enrichment (FDR<0.001) in gene ontology (GO) terms, e.g. actin and kinase binding, glucuronosyltransferase activity, MHC protein binding. Additional DM analysis (db=|0.25|, FDR<0.05) of each cytogenetic subgroup vs all other CLLs revealed significant differences for tris12 vs non-tris12 (285 DMCpGs based on all CLLs, 646 DMCpGs based on U-CLL). In U-CLL, 523 hypo- and 123 hypermethylated CpGs were identified and targeted gene bodies outside CGIs. Hypermethylation was associated with polycomb-repressed regions and strong enhancers whereas hypomethylation was related to weak and strong enhancers. GO analysis showed that hypomethylated genes were enriched (FDR<0.001) in cytoskeletal protein, actin and kinase binding; and hypermethylated genes in transcription factor and histone deacetylase activity. DNA methylation correlated with gene expression (p<0.05) in only 3% of

the tris12-specific DMCpGs (compared to normal B cells and non-tris12 U-CLLs), in line with recent reports. Besides tris12, we also identified that del(11q) CLLs were also distinctive, albeit from a different perspective. In detail, as compared to normal B cells, this group had more DMCpGs than tris12 and del(13q) cases, although the signature was heterogeneous in different del(11q) cases. Comparing the epigenetic burden (EB, the number of DMCpGs per case) of each case vs MBC, del(11q) cases showed a higher burden than del(13q) (p=1.582e-06) and tris12 (p=0.0005) suggesting a more pronounced epigenetic evolution in these clinically agressive cases.
Summary/Conclusion: We highlight that tris12 CLLs have a distinct DNAm signature, further underscoring its unique biological background, and that del(11q) show a high EB which represents a potential predictive biomarker for CLL.

Landau[3], L. Bullinger[6], A. Benner[2], D.S. Neuberg[7], M. Hallek[5], C.J. Wu[3], D. Mertens[1], H. Döhner[1], S. Stilgenbauer[1]

[1]Internal Medicine III, University Hospital Ulm, Ulm, [2]Division of Biostatistics, German Cancer Research Center (DKFZ), Heidelberg, Germany, [3]Broad Institute , Harvard and MIT, Cambridge, United States, [4]Barts Cancer Institute, Queen Mary University of London, London, United Kingdom, [5]Department I of Internal Medicine and Center of Integrated Oncology Cologne Bonn, University Hospital Cologne, Cologne, [6]Medical Clinic for Hematology, Oncology and Tumor Biology, Charite University Hospital, Berlin, Germany, [7]Biostatistics and Computational Biology, Dana-Farber Cancer Institute, Boston, United States

Background: Cooperating pathogenic mechanism, other than alterations of TP53, ATM or NOTCH1 mutations, mediating the emergence of refractory disease, or decreased efficacy of chemoimmunotherapy, are incompletely understood in CLL. Research on genomic instability has frequently focused on functional loss of TP53 or ATM and subsequent downstream signaling with related impairment of DNA repair.
Aims: To elucidate other elements leading to genomic instability we used a multiplatform approach on specimen collected from patients registered on the CLL8 study (first-line, FC vs. FCR).
Methods: Data was generated for gene expression (n=337, Human Exon 1.0 ST arrays, Affymetrix), copy number aberrations (CNAs) (n=309, Human SNP Arrays 6.0, Affymetrix), mutation analyses combined with signature projections (n=171, whole exome sequencing, Illumina), telomere length (n=332) and protein data for confirmation in select cases (western blot n=11) using CD19 sorted samples. FISH, IGHV and TP53 mutation analysis were also available from trial enrolment.
Results: To explore tumor-heterogeneity we performed unsupervised clustering analysis using 2359 variably expressed genes (SD of > 0.5). Six distinct clusters (C1-C6) were identified that differed significantly in clinical and biologic characteristics. Variability (Fisher 's Exact Test) across all clusters was found for incidences of del(17p) (p<0.05), TP53 mutation (p<0.01), tri(12) (p<0.01), with enrichment of del(17p) and/or TP53 mutations in C2 (n=24/133, 18,5%), C3 (n=9/56, 16%) and tri(12) in C5 (n=8/11, 72.7%). With regard to mutation characteristics, TP53 frame shift mutations were enriched in C2, while splice site mutations were exclusively observed in C5. GSEA on hallmark gene sets highlighted DNA-repair amongst the processes specifically altered in C2 and C3. Notably, activation of DNA-damage response and repair was further confirmed by upregulation of TP53 and ATM mRNA (q<0.01), p53 and phospho-p53 in C2/C3. Further characteristics of genomic instability included increased telomere stress as indicated by significant variability of telomere length across clusters (p<0.01, Kruskal - Wallis rank sum test). Shortest telomeres were found in C2 cases (median 3.8 kb) with concurrent POT1 overexpression (q<0.01), indicating increased necessity of telomere protection. C2 and C3 showed the highest incidence of POT1 mutations (7.3%), which are reportedly associated with telomeric aberrations, chromosome breaks or fusions. Apart from POT1, distribution of driver mutations followed cluster specificity and showed a selective enrichment of alterations leading to genomic instability including e.g. CHEK2 or RPS15 in C2 and C3. When analyzing mutational signatures implicated in the pathogenic processes in cancer and documented in the COSMIC database, signatures for individual clusters indicated highest activation for signature 6 (defective MMR) and signature 9 (associated with the activity of AID during somatic hypermutation) in C2.
Summary/Conclusion: In conclusion, unsupervised clustering defined expression signatures that point to the pathogenic role of genomic instability in a considerable portion of patients with CLL in need of treatment. However, these signatures are not restricted to cases with TP53 impairment and rather integrate different biological mechanisms involved in genomic stability, such as alterations affecting telomere regulation and the proper execution of DNA-repair.

BIALLELIC INACTIVATION OF ATM AND BIRC3 IN DEL(11Q) CELLS DRIVES GENOMIC INSTABILITY AND TUMOR EXPANSION IN CRISPR/CAS9-GENERATED MODELS OF CHRONIC LYMPHOCYTIC LEUKEMIA

M. Quijada-Álamo[1,2,*], M. Hernández-Sánchez[1,2,3,4], J.L. Ordóñez[1,2], A.E. Rodríguez-Vicente[1,2], V. Alonso-Pérez[1,2], I. García-Tuñón[1,2], A.B. Herrero[1,2], R. Benito[1,2], J.L. García[1,2], M. Gruber[3,4,5,6], C.J. Wu[3,4], J.M. Hernández-Rivas[1,2]

[1]IBSAL, IBMCC, University of Salamanca, CSIC, Cancer Research Center, [2]Department of Hematology, University Hospital of Salamanca, Salamanca, Spain, [3]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, Massachusetts, [4]Broad Institute of Harvard and MIT, Cambridge, Massachusetts, United States, [5]CeMM Research Center for Molecular Medicine, [6]Department of Internal Medicine I, Division of Hematology and Hemostaseology, Medical University of Vienna, Vienna, Austria

Background: Chromosome 11q22.3 deletion (del(11q)) is one of the most common cytogenetic alterations in chronic lymphocytic leukemia (CLL) and usually involves both *ATM* and *BIRC3* genes. Concomitant mutations in *ATM* and/or *BIRC3* in the remaining allele have been associated with adverse prognosis in CLL. However, little is known about their functional impact as well as how multiple genetic alterations could synergistically act to drive tumor pathogenesis.
Aims: To assess the functional and clinical impact of del(11q) together with loss-of-function mutations in *ATM* and/or *BIRC3* through the analysis of isogenic CLL cell lines with del(11q), *ATM* and *BIRC3* mutations.
Methods: The CRISPR/Cas9 system was used to introduce del(11q), *ATM* and *BIRC3* mutations into CLL cell lines (HG3, MEC1). Proliferation, NF-kB2 activation, DNA damage response and *in vivo* xenograft studies were performed. In addition, the mutational status of untreated CLL patients (del(11q) N=27 and non-del(11q) N=174) was evaluated analyzing a panel of 42 CLL-related genes (including *ATM* and *BIRC3*) by NGS.
Results: By introducing two guide RNAs targeting 11q22.1 and 11q23.3 regions, an HG3-del(11q) cell line was generated. The presence of a monoallelic deletion was confirmed in 100% of the cells by FISH. Mutations in *ATM* and/or *BIRC3* were introduced in the remaining allele, generating HG3 del(11q) ATM^{KO}, del(11q) $BIRC3^{KO}$ and del(11q) $ATM^{KO}BIRC3^{KO}$ (three clones per condition). In parallel, single ATM^{KO} and $BIRC3^{KO}$ mutations, or the combination of both, were introduced in HG3 and MEC1 cells (three clones per condition). HG3-del(11q) clones presented cytoplasmic stabilization of NF-kB-inducing kinase (NIK), leading to NF-kB2 (p52) accumulation in the nucleus of CLL cells. In addition, biallelic inactivation of *BIRC3* in HG3-del(11q) cells resulted in higher p52 activation measured by ELISA assay, leading to a higher proliferation rate of HG3-del(11q) $BIRC3^{KO}$ clones compared to HG3-del(11q) $BIRC3^{WT}$ cells. Moreover, HG3-del(11q) ATM^{KO} cells displayed reduced p-H2AX levels and accumulation of unrepaired double strand breaks (DSB) after gamma-irradiation, as determined by immunofluorescence and neutral comet assays, exhibiting deficiencies in DSB repair. As expected, HG3-del(11q) $ATM^{KO}BIRC3^{KO}$ cells also presented NF-kB2 activation, enhanced proliferation and DNA damage accumulation, as a consequence of biallelic inactivation of *BIRC3* and *ATM*, respectively. These results were also confirmed in HG3 and MEC1 ATM^{KO} and $BIRC3^{KO}$ clones. *In vivo* subcutaneous xenograft models showed that HG3 $ATM^{KO}BIRC3^{KO}$ tumors presented proliferative advantage, higher p52 activation and greater genomic and mitotic instability than $HG3^{WT}$ tumors. In line with these results, NGS studies of CLL patients revealed that *BIRC3*-mutated patients showed shorter time to first treatment (TTFT) than $BIRC3^{WT}$ CLLs (p<0.001), whereas *ATM*-defective CLLs presented a higher number of mutations in CLL-related genes compared to ATM^{WT} cases (median 3 [1-6] *vs.* 1 [0-7]; p<0.001).
Summary/Conclusion: Del(11q) CLL cells with biallelic inactivation of *ATM* and *BIRC3* show enhanced proliferation through the activation of NF-kB2, and the accumulation of DNA damage contributing to genomic instability. These findings could be related with the shorter TTFT seen in *BIRC3*-mutated CLL patients and the high rates of genomic alterations observed in *ATM*-mutated CLLs. Thus, CRISPR/Cas9-generated models can be powerful tools to study the molecular mechanisms involved in the clinical impact of single and multiple CLL genetic alterations.

MASS CYTOMETRY REVEALED LEUKEMIC MICROENVIRONMENT COMPLEXITY: IMPLICATIONS FOR IMMUNOTHERAPY IN A MOUSE MODEL OF CHRONIC LYMPHOCYTIC LEUKEMIA

M. Wierz[1,*], S. Pierson[1], L. Guyonnet[2], A. Oudin[1], G. Berchem[1,3], B. Janji[1], C. Guérin[2], J. Paggetti[1], E. Moussay[1]

[1]Department of Oncology, [2]Department of Infection and Immunity, Luxembourg Institute for Health, [3]Centre Hospitalier de Luxembourg, Luxembourg, Luxembourg

Background: Chronic lymphocytic leukemia (CLL) is characterized by the accumulation of mature B lymphocytes in peripheral blood and primary lymphoid organs. The progression of CLL is highly dependent on complex interactions with immune cells and other non-malignant cells in the tumor microenvironment. Despite recent advances in CLL treatment, CLL remains an incurable disease.
Aims: We wanted to extensively characterize the immune cell populations in the murine CLL microenvironment to identify novel potential targets and consequently evaluate the efficacy of a dual antibody-based immunotherapy in CLL pre-clinical models.
Methods: We performed a mass cytometry analysis with a custom 35-marker panel to establish an extensive cartography of immune cell subsets populating the leukemic spleen of transgenic Eμ-TCL1 mice and of diseased C57BL/6 mice following adoptive transfer (AT-CLL). Following the identification of immune checkpoints, we injected antibodies against PD1 and LAG3 as dual therapy and monitored disease development by flow cytometry, blood cell count, and magnetic resonance imaging. The immune microenvironment was also analyzed after mice euthanasia.
Results: First, we observed that, compared to normal B cells, malignant CLL cells show a higher expression of immune checkpoints PD-L1 and LAG3 as well as several maturation and adhesion molecules such as CD44 and ICAM-1. Furthermore, PD-L1 expression on CLL cells was heterogeneous, a high expression being concomitant with a higher expression of maturation and adhesion molecules. Next, we identified a significant alteration in the immune cell composition in CLL reflecting strong immune suppression and dysfunctional anti-tumor immunity. More particularly, we noted an enrichment of CD8+ T cells displaying features of exhaustion such as the expression of the immune checkpoints PD1, LAG3 and TIM3 as well as an expansion of KLRG1+ CD69+ tumor-infiltrating Treg cells and Foxp3+ CD25low LAG3+ Treg cells, both showing enhanced suppressive capacities. In the myeloid compartment, we identified dysfunctional LAG3-expressing CD8+ dendritic cells and ICAM-1+ CLL-promoting patrolling monocytes as being more abundant in CLL.
As we observed a relevant upregulation of PD1 and LAG3 on the majority of immune cell populations, we tested a dual anti-PD1/anti-LAG3 immunotherapy in AT-CLL mice and transgenic Eμ-TCL1 mice. Indeed, dual PD1/LAG3 blockade efficiently limited CLL development in both murine models of CLL. More specifically, the percentage and number of CLL cells in blood and spleen significantly decreased in AT-CLL mice and an immuno-competent microenvironment was restored. In transgenic Eμ-TCL1 mice, PD1/LAG3 dual immunotherapy significantly reduced the spleen volume as determined by magnetic resonance imaging. Remarkably, the decrease in spleen volume strongly correlated with T cell phenotypes in peripheral blood before the beginning of the treatment.
Summary/Conclusion: In conclusion, we dissected and expanded the current knowledge of the phenotypic complexity of the CLL tumor microenvironment. We demonstrated that dual targeting of the immune checkpoints PD1 and LAG3 efficiently controlled CLL development in pre-clinical models and therefore could have potential benefits in CLL to restore a functional anti-tumor immunity.

CD20 IS A DIRECT REGULATOR OF B-CELL RECEPTOR SIGNALING IN THE MICROENVIRONMENT OF CHRONIC LYMPHOCYTIC LEUKEMIA

G. Pavlasova[1,2,*], V. Svobodova[1,2], M. Borský[2], J. Oppelt[13], J. Novotna[2], K. Cerna[1,2], K. Musilova[1,2], V. Seda[1,2], Y. Brychtova[2], M. Doubek[1,2], S. Pospisilova[1,2], J. Mayer[2], M. Mraz[1,2]

[1]Center of Molecular Medicine, CEITEC, Masaryk University, [2]Department of Internal Medicine - Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, [3]National Centre for Biomolecular Research, Faculty of Science, Masaryk University, Brno, Czech Republic

Background: The biological function of CD20 and the reasons for the impressive activity of anti-CD20 antibodies remain elusive. We have previously shown that CLL cells which have recently exited the lymph node microenvironment ($CXCR4^{dim}CD5^{bright}$ cells) express higher CD20 levels. This is due to its direct up-regulation by CXCR4/SDF1 axis (Pavlasova *et al.*, Blood, 2016).
Aims: We hypothesized that CD20 expression is of direct functional importance for B-cell receptor (BCR) signaling as CLL cells with high CD20 express also higher cell surface IgM levels and this was coupled with higher responsiveness to BCR-crosslinking ($p<0.0001$).
Methods: CLL cells were obtained from untreated CLL patients or patients undergoing FCR therapy and analyzed for BCR signaling capacity and rituximab effect.
Results: CD20 silencing using CD20 siRNA in B cells revealed that low levels of CD20 impair the phosphorylation of BCR/PI3K-associated molecules (LYN, SYK, ERK, GAB1) after BCR-crosslinking and BCR-induced calcium flux ($p<0.05$). This also impaired LYN kinase phosphorylation, which is the first kinase phosphorylated in response to BCR ligation. This suggests that CD20 up-regulation in the microenvironment is required for proper activity of BCR and that CD20 is very "intimately" connected with BCR. Interestingly, the CD20 effect on phosphorylation of BCR-associated kinases was not entirely dependent on its known calcium-channel function (Bubien *et al.*, JCB, 1993), as the effect of CD20 silencing was present also in calcium-free media. This suggests that CD20 has also other functions, such as a putative docking site for BCR-associated molecules. To investigate the relevance of CD20 in primary CLL cells *in vivo* we also analyzed proteins involved in BCR signaling pathway and cell activation in CXCR4/CD5 CLL subpopulations. The $CD20^{bright}CXCR4^{dim}CD5^{bright}$ subpopulation (represents cells that recently exited the lymph nodes) had higher levels of pAKT/pERK/pCD79a ($p<0.001$) and a gene expression signature enriched for genes involved in BCR and MAPK signaling, migration and actin cytoskeleton organization ($p<0.0001$). The overall activated status of $CD20^{bright}CXCR4^{dim}CD5^{bright}$ cells is also evidenced by enrichment in proliferative Ki67-positive cells ($p<0.0001$). We further hypothesized that the higher CD20 levels on $CXCR4^{dim}CD5^{bright}$ cells make them the primary target of rituximab, since certain rituximab-mediated effects depend on CD20 levels. Indeed, rituximab was *in vivo* ~10-fold more efficient in eliminating BCR signaling proficient $CD20^{bright}CXCR4^{dim}CD5^{bright}$ CLL cells than $CD20^{dim}CXCR4^{bright}CD5^{dim}$ cells in FCR treated patients (day 0 vs 1 and 3; $p<0.0001$).
Summary/Conclusion: Altogether, we described for the first time a direct role of CD20 in BCR signaling and its contribution to the aggressiveness of an intra-clonal CLL cell subpopulation. Additionally, we showed that this BCR signaling proficient $CD20^{bright}CXCR4^{dim}CD5^{bright}$ intra-clonal CLL cell subpopulation is preferentially eliminated by rituximab *in vivo*, which might partially account for the success of anti-CD20 antibodies.

ROLE OF MTORC1 IN NORMAL HAEMOPOIESIS AND LEUKAEMOGENESIS

N. Malik[1,2,*], K. Dunn[1], C. Estell[1], O. Sansom[2], A.M. Michie[1]

[1]Institute of Cancer Sciences, University of Glasgow, [2]Beatson Institute for Cancer Research, Glasgow, United Kingdom

Background: Mammalian target of rapamycin (mTOR) is a protein kinase that mediates phosphoinositide-3-kinase (PI3K)/Akt signalling. This pathway is involved in a plethora of cellular functions including protein and lipid synthesis, cell migration, and apoptosis. Our laboratory has shown that mTOR substrates are activated in samples isolated from chronic lymphocytic leukaemia (CLL) patients, and in our kinase dead PKCα mouse model (PKCαKR) which exhibits a CLL-like disease.
Aims: We proposed to delineate the role of mTOR complex 1 (mTORC1) using conditional knock out (cKO) mouse models to determine its role in normal haemopoiesis and to determine whether it plays a role in CLL initiation and/or development.
Methods: We exploit the cre-loxP system in murine models where the gene of interest (*raptor*) is excised either, in a time-controlled manner (*Mx1*) or at the haemopoietic stem cell stage (HSC, *Vav*) to assess molecular events through q-PCR, western blotting and cell viability assays. We also retrovirally (RV) transduce BM cells with either a PKCα-KR (CLL-like) or MIEV

construct for transplantation into host mice.
Results: Upon cKO of raptor (mTORC1; *Mx1-cre*$^{+}$*raptor*$^{fl/fl}$) in adult mice, we observe splenomegaly, a disruption in normal haemopoiesis, along with a significant reduction in the B cell lineage in the BM. A block in B cell lineage commitment was indicated by the significant increase in Lin^{-}Sca-1^{+}CD117^{+} (LSKs) in the spleen, and a decrease in proB cells in the BM.
While assessing the role of mTORC1 during early developmental stages in *vav*-cre^{+}*raptor*$^{fl/fl}$ mice, we established that the embryos do not survive due to a disruption in erythropoiesis. A significant decrease in Ter119^{+} cells was noted in E15 foetal livers (FL) in KO mice, with aberrations at megakaryocyte-erythrocyte progenitor (MEP) stage. Thus, we analysed the ability of mTOR inhibitors to block the differentiation of K562 cells towards red blood cells (RBCs) in galactose-rich cultures *in vitro*. Treatment of K562 cells in galactose-rich cultures with either mTORC1 inhibitor rapamycin or the pan-mTOR inhibitor AZD8055 significantly reduces key molecular events of RBC differentiation: generation of CD71^{+}GlyA^{+} cells; expression of *HBB (*β-globin) and *GATA2*, thereby establishing the importance of mTORC1 signalling/function in the promotion of RBC development. To address the role of raptor in CLL initiation/maintenance *in vitro*, we RV-transduced *Mx1*-cre^{-} or *Mx1*-cre^{+}*raptor*$^{fl/fl}$ BM (post cKO) with a PKCα-KR or MIEV construct. RV-transduction from *raptor* cKO mice with PKCα-KR failed to rescue the B cell lineage block or generate a CLL-like disease. To test mTORC1 requirement for maintenance of disease *in vivo*, *Mx1*-cre^{-} or *Mx1*-cre^{+}*raptor*$^{fl/fl}$ BM cells were RV-transduced with PKCα-KR-and transplanted into host mice. Once disease was established, as detected by blood sampling and analysis of GFP^{+}CD19^{+}CD5^{+} cells, mice were inoculated with polyI:C to induce cKO. Our results indicate that cKO of raptor with established CLL-like disease results in increase in survival time and decrease in disease load.
Summary/Conclusion: Taken together, our data supports the work of others demonstrating a block in B cell lineage commitment. Elevation in the MEP population observed in the *vav*-cre^{+}-*raptor*$^{fl/fl}$ mice leads to neonatal lethality due to a block in erythropoiesis. Importantly, our results suggest a critical role for mTORC1 in CLL initiation and maintenance *in vivo*. These studies will pave the way towards testing the efficacy of clinically-relevant mTOR inhibitors in blocking/reversing CLL in pre-clinical mouse models.

PS1093

FIRST-IN-CLASS ORAL TYROSINE KINASE INHIBITOR (KAN0439834) TARGETING ROR1 INDUCED SIGNIFICANT APOPTOSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

M. Hojjat-Farsangi[1,*], A. H. Daneshmanesh[1], F. Mozaffari[1], P. Kokhaei[1], L. Hansson[1], J. Vågberg[2], S. Byström[3], E. Olsson[3], C. Löfberg[3], C.C. Norström[3], J. Schultz[3], M. Norin[3], T. Olin[3], A. Österborg[1], A. Moshfegh[3], H. Mellstedt[1]

[1]Oncology-Pathology, Karolinska Institute, Stockholm, [2]Kancera AB, Solna, [3]Kancera AB, Stockholm, Sweden

Background: ROR1 is a transmembrane protein of the receptor tyrosine kinase (RTK) family expressed during embryogenesis, but repressed in adult tissues. In chronic lymphocytic leukemia (CLL), ROR1 is upregulated. Inhibition of ROR1 abrogated downstream kinase activities and induced apoptosis of CLL cells. KAN0439834, a small molecule inhibitor (ROR1-SMI) was synthesized with the aim to bind to the TK domain of ROR1 and inhibit phosphorylation.
Aims: In the present study we investigated the effects of KAN0439834, on survival of CLL cells, ROR1 dephosphorylation in CLL cells and signaling, and *in vivo* effects in NOD-SCID mice xenografted with human CLL cells.
Methods: MTT and Annexin V/PI assays were used to analyse cytotoxicity of KAN0439834. Fresh CLL cells were co-cultured with the stromal cell line HS-5 and incubated with KAN0439834 and apoptosis measured (Annexin V/PI). CLL cells were also cultured with KAN0439834 (50-250 nM) for 2 h and rWnt5a (25-50 μg/mL) was added. The cells were further incubated for 30 min before lysate preparation and cytotoxicity assayed after 24 h. Proximity ligation assay was used to investigate the effects of KAN0439834 on ROR1/LRP6 heterodimerization. Phosphorylated RTKs in CLL cells and the effects of KAN0439834 on phosphorylation of RTKs were analysed by the Human-Phospho-RTK Array and WB. Finally, in two mice experiments, fresh CLL cells were grafted into NOD-SCID mice and oral KAN0439834 treatment was started 7 days after transplantation and continued for 7 days in the first study and 14 days in the second study.
Results: KAN0439834 induced apoptosis of CLL cells (EC_{50}=250 nM) with a 60-fold selectivity for CLL cells compared to normal PBMC. KAN0439834 was significantly more effective than an anti-ROR1 mAb in inducing apoptosis of CLL cells. When CLL and HS-5 cells were co-cultured, HS-5 cells could prevent induction of apoptosis of CLL cells at low concentrations of KAN0439834, while at higher concentrations of KAN0439834 the presence of stromal cells had no effect. Wnt5a increased phosphorylation of ROR1. KAN0439834 dephosphorylated both ROR1 and SRC as well as inhibited Wnt5a-induced ROR1 phosphorylation in this system. KAN0439834 dephosphorylated ROR1, LRP6 and associated downstream signaling molecules as AKT, mTOR and CREB. Oral administration of KAN0439834 to NOD-SCID mice significantly inhibited growth of xenografted human CLL cells. Immunohistochemistry staining of spleens from the two studies showed a significant decrease of CLL cells in treated mice but not in controls.
Summary/Conclusion: KAN0439834 is the first generation of a novel class of ROR1-SMI developed by phenotypic screening using CLL cells. The small molecule was much more effective in inducing CLL apoptosis than the anti-ROR1 antibody. KAN0439834 inactivated various signaling pathways in the leukemic cells suggested to be associated with ROR1 signaling. The development of new anti-cancer drugs with other mechanisms of action than those clinically available when existing drugs fail is warranted to improve the prognosis of CLL. KAN0439834 may not only be potent in CLL but also in other ROR1 expressing tumors; such studies are in progress. Our results support the further development of ROR1 inhibitors as a new therapeutic principle.

Background: Currently, immunochemotherapy remains the standard of care in CLL for fit patients in first line. Clinical relevance of flow cytometry MRD at a 0.01% threshold has been widely demonstrated.
Aims: In this work, we assessed the prognostic value of high sensitivity MRD in a large cohort of Fludarabine Endoxan Rituximab (FCR) treated CLL patients within three FILO first line clinical trials.
Methods: We collected data from 859 patients randomized in 3 trials: FMP2007 (FCRx6 vsFCCampathx6), LLC2007SA (4FC+6R +/- R maintenance) and FMP2010 (FCRx6 vs high dose R FCx6). Only patients who received FCR based without maintenance were considered for this study (n=574). MRD was evaluated with high sensitivity flow cytometry techniques using 6 and 8 color panels through a paucicentric network. These procedures resulted in >1-Log improvement in sensitivity as compared to 4-color tests, allowing the detection of positive MRD down to 0.001%.
Results: Validated follow-up data were available for 540/574 patients with a median follow-up of 49,5 months. MRD was tested 3 months after the last FCR course in blood and bone marrow (BM). Completeness of data was good since results were available for 401 and 339 patients respectively with paired results in 329 patients. Cases with insufficient sensitivity (>10^{-4}) were excluded. When MRD was detectable in blood, it was positive in BM in 100% cases. In cases with undetectable blood MRD (und-MRD) residual disease was still detectable in BM in 64/197 patients (32.5%). We then studied the impact of MRD status on PFS using both blood and BM MRD. First, we applied the conventional threshold of 0.01% and as expected we observed that positive MRD was predictive of PFS. Then we considered separately patients who showed low level MRD positivity (<0.01%) from the patients with und-MRD. We observed that positive blood MRD, whether >0.01% or <0.01% (considered as negative with the conventional threshold) was associated with shorter PFS (Figure 1). When considering BM, the 0.01% threshold remained for prediction of adverse outcome. We considered the impact of sensitive MRD status on clinical response (CR+CRivs.PR+nPR). As expected und-MRD/CR group had the longest PFS (72.2 mo) whereas MRD+/PR group had the shortest PFS (35.5 mo). In the 2 other groups with discordant status (MRD+/CR and und-MRD/PR) the prognostic value of MRD appeared prevalent on that of clinical response. Finally, we correlated MRD and IGHV mutational status and examined the impact on outcome. In MRD+/Unmutated IGVH group we observed the shortest PFS (5-yPFS: 16%) while the longest PFS was noted in und-MRD/Mutated IGHV group (5-yPFS: 71%). The evolution of this latter group was not significantly different from that of the MRD+/Mutated IGHV group (5-yPFS: 60%, p=0.22). Interestingly, Unmutated IGHV patients reaching und-MRD had a similar PFS to that of patients with Mutated IGHV genes (5-yPFS: 60% and 71% respectively, p=0.34).

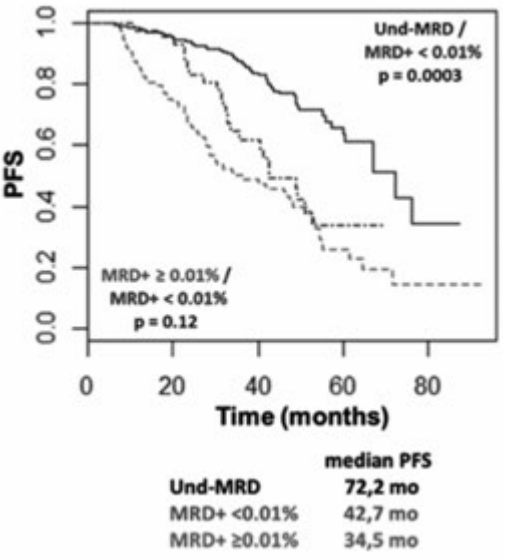

Figure 1.

Summary/Conclusion: In conclusion, this study shows the applicability and the usefulness of high-sensitivity MRD testing in a multicenter network. We show the respective value of blood and bone marrow sensitive MRD assessment, and the impact of MRD status on PFS, clinical response and IGHV mutational status. The prognostic importance of blood sensitive MRD suggests that it could be used as a routine tool and reduce the need for bone marrow assessment for MRD driven therapeutic strategies.

PS1095

EVALUATION OF THE INCIDENCE, RISK FACTORS, AND MANAGEMENT OF HYPERTENSION IN PATIENTS RECEIVING IBRUTINIB FOR HEMATOLOGIC MALIGNANCIES

T. Dickerson[1], T. Wiczer[1], A. Waller[1], J. Philippon[1], A. Guha[2], K. Rogers[1], J. Woyach[1], J. Byrd[1], D. Addison[2], F. Awan[1,*]

[1]The Ohio State University Comprehensive Cancer Center, [2]The Ohio State University, Columbus, United States

Background: The approval of Ibrutinib (IB) for various hematologic malignancies has significantly improved disease control rates, progression free, and overall survival. However, targeting of multiple kinases may result in a number of adverse effects and complications that can lead to discontinuation of the drug. New or worsening hypertension (HTN) has been reported in 10-29% of patients receiving IB on clinical trials. Recent observational data suggests that this rate may be as high as 40% in clinical practice and resistant to treatment with multiple agents. Management of patients who develop HTN on IB has not previously been well described. Additionally, the relationship between IB-associated HTN and cardiovascular complications is not known.
Aims: The aim of this study was to characterize the development of HTN in patients treated with IB; describe the management and complications of IB-associated HTN, and define risk factors for the development of HTN while on therapy.
Methods: In order to describe the incidence, management, complications, and risk factors for the development of HTN in patients treated with IB, a retrospective single-center cohort study was conducted of adult patients who started IB for hematologic malignancies over a 6 year period after obtaining appropriate IRB approval. HTN was defined as systolic blood pressure of at least 130 mmHg on 2 separate visits within 3 months. Severity of new or worsened HTN was defined according to the Common Terminology Criteria for Adverse Events (CTCAE) and was causality assessed using the Naranjo Scale. A composite cardiovascular event endpoint (MACE) that included incident myocardial infarction, unstable angina, heart failure, stroke, or need for percutaneous coronary intervention while excluding atrial fibrillation was assessed.
Results: Five hundred and sixty-two (562) patients treated with IB were identified. A majority of patients had CLL (73%) and were male (70%). Sixty-one percent had preexisting HTN at the time of starting IB therapy with 35% requiring at least one medication. With a median follow up of

>3 years, 26% of the patients developed new HTN. In patients who had preexisting HTN, 84% had worsening of their condition, which was defined as a worsening of the CTCAE grade of HTN in 93%, while 56% of these patients required a change in therapy. MACE occurred in 7% of patients and atrial fibrillation in 13% of patients. Incidence of HTN and comparative assessment of risk factors for HTN are being made using a competing risks regression model and survival analysis to evaluate the association between HTN and IB and will be reported in detail at the meeting.
Summary/Conclusion: In our retrospective study, patients receiving IB had a substantial increase in the incidence or severity of HTN. Assessment of pre-existing risk factors, close monitoring, and a team approach are required for optimal management of this complication.

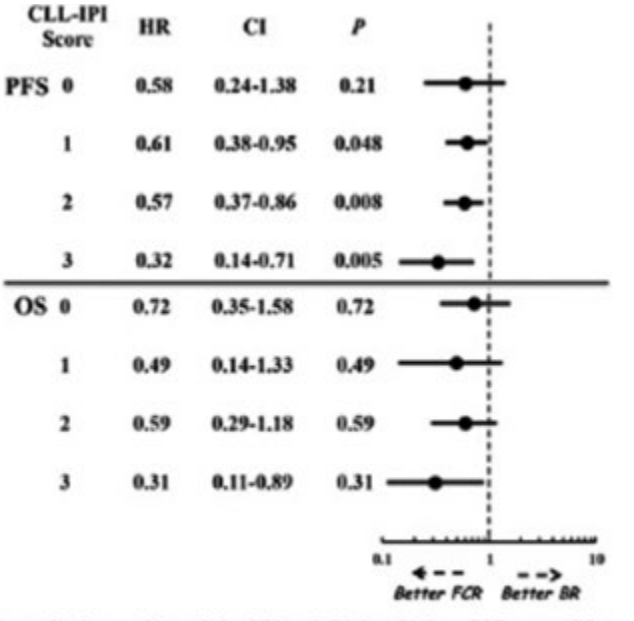
Background: An earlier international collaborative effort collected data from 3500 chronic lymphocytic leukemia (CLL) patients to develop a comprehensive tool for predicting overall survival (OS) based on the CLL-IPI (international prognostic index for CLL patients). This score, built on *TP53* deletion and/or mutation, *IGHV* mutational status, b2-microglobulin, clinical stage and age, represents a simple "globally applicable" model available in the daily clinical practice and able to improve risk stratification for all CLL patients.
Aims: The aim of our study was to evaluate the prediction power of the CLL-IPI on OS, assessed at the time of first treatment, in a cohort of CLL patients who received chemo-immunotherapy as first-line therapy. We also investigated whether CLL-IPI could predict progression free survival (PFS). Finally, we assessed the impact of this tool in a specific cohort of fludarabine-cyclophosphamide-rituximab (FCR) or bendamustine-rituximab (BR) treated cases.
Methods: This study included CLL patients who received a first-line treatment with chemo-immunotherapy [FCR, BR, pentostatin-cyclophosphamide-rituximab (PCR) and pentostatin-cyclophosphamide-ofatumumab (PCO)] and with data available for CLL-IPI at the time of progression. OS was estimated for low-, intermediate, high- and very high-risk patients. Additionally, risk-specific PFS was assessed. Methods included Kaplan-Meier curve, log-rank test and Cox regression analyses. The prognostic accuracy of predictive model was assessed by the C-index.
Results: A total of 845 CLL patients were included in this analysis. The majority of patients were Binet stage B and C (77.9%). The median age was 63 years (range 25-86) and 566 cases (67%) were male. Four hundred and two cases received the FCR schedule, 252 BR, 142 PCR and 49 PCO. After a median follow-up of 3.7 years (range, 3 months-15.7 years), 157 patients have died and 402 have experienced an event (death or progression). According to the CLL-IPI, 183 patients (21.7%) were classified as low-risk, 337 (39.9%) as intermediate-risk, 276 (32.7%) as high-risk and 49 (5.8%) as very high-risk. Stratification of patients according to the CLL-IPI predicted significant differences in terms of OS after first-line treatment. Low-risk patients had a 3-year OS probability of 96.6% (HR=1), intermediate-risk of 92.8% (HR=3.73,p<0.0001), high-risk of 81.4% (HR=7.35,p<0.0001) and very high-risk of 64.7% (HR=17.3,p<0.0001). The C-index was 0.69 (p<0.001) for predicting OS. PFS also differed between CLL-IPI risk groups. The 3-year PFS probability was 82.6% (HR=1) for low-risk, 63.6% (HR=2.27;p<0.0001) for intermediate-risk, 53.9% (HR=2.87,p<0.0001) for high-risk, and 32.8% (HR=5.01,p<0.0001) for very high-risk. The C-index for PFS was 0.61 (p<0.001). Comparing patients who received FCR to those who received BR, a significantly higher percentage of elderly cases and patients with a high-risk CLL-IPI score were evident in the BR group. A significant PFS benefit for FCR relative to BR was maintained across CLL-IPI intermediate, high- and very high-risk groups, while no significant difference was observed in the low-risk group (Figure 1). In contrast, an OS benefit for FCR relative to BR was only observed in the very-high risk group (Figure 1).



Cox univariate analyses of the PFS and OS benefit from FCR versus BR treatment as first-line therapy according to CLL-IPI score. Hazard ratios (HR) lower than indicates a lower risk of progression or survival for FCR-treated patients. The I bars represent 95% confidence intervals (CI).

Figure 1.

Summary/Conclusion: This is the first validation study of the CLL-IPI, assessed at the time of first treatment, in patients who received a variety of chemo-immunotherapy approaches. Results confirm the ability of the CLL-IPI to stratify patients' outcome in terms of both OS and PFS. Moreover, the CLL-IPI may help to select patients towards FCR or BR treatment.

Background: In chronic lymphocytic leukemia (CLL), spontaneous regression (SR) is a rare but possible event.
Aims: To identify the clinico-biological features of CLL patients (pts) experiencing a SR, ERIC (European Research Initiative on CLL) group has set up an international registry to collect and to analyze such cases from both the clinical and biologic standpoints.
Methods: Inclusion criteria are: (i) CLL diagnosis as per 2008 IWCLL criteria (i.e. clonal lymphocyte (Ly) count at diagnosis ≥5×10^9/L with a typical immunophenotype); (ii) subsequent spontaneous Ly count normalization to less than 5×10^9/L, persisting for ≥12 months; (iii) disappearance of disease-related signs/symptoms (i.e. splenomegaly or lymphadenopathy) if previously present; (iv) no prior therapy.

Table 1.

Clinical and biologic characteristics at diagnosis of 27 CLL patients with SR	
Sex	11 M (41%) / 16 F (59%)
Median age (range)	76.5 years (58-94)
Stage (Binet/Rai)	21 A/0 (78%); 2 A/I (7.4%); 1 A/II (3.6%); 3 B/II
Mean lymphocyte count (x10^9/L)	14.3 (5.6-51.9)
Beta 2-microglobulin (normal)	18/22 (81.8%)
LDH (normal)	21/22 (95.4%)
CD38 (<30%)	22/22 (100%)
CD49d (<30%)	8/11 (72.7%)
ZAP70 (<20%)	15/19 (78.9%)
FISH	
del 13q	10/24 (41.7%)
Normal	10/24 (41.7%)
Trisomy 12	3/24 (12.5%)
del 17p	1/24 (4.1%)
TP53 WT	13/13 (100%)
Mutated *IGHV*	24/25 (96%)
IGHV gene	1 VH1-2; 1 VH1-46
	1 VH3-7; 2 VH3-15; 1 VH3-21; 3 VH3-23; 3 VH3-30
	1 VH4-4; 1 VH4-31; 4 VH4-34; 2 VH4-59; 2 VH4-61
Events concurrent with SR	1 viral respiratory infections; 1 pneumonia
	1 intracerebral hemorrhage; 1 cerebral stroke
	1 pelvis fracture
	1 chronic hepatitis C with thrombocytopenia
	1 rheumatoid arthritis
	1 Richter syndrome
	3 concomitant neoplasia

Results: Of 32 registered pts from 2012 to 2018, 26 fulfilling the inclusion criteria and 1 outlier (see below) have been included: 14 cases were from Italy, 11 from Spain and 2 from Sweden (Table 1). The estimated frequency of SR was 0.33-1% of the total cases followed at each center. The median time from diagnosis to SR was 9 years (range, 1.4-25), the median follow-up was 12 years (3-27). The duration of SR was 48 months (12-151). The mean Ly count at diagnosis was 14.3×10^9/L (5.6-51.9). The mean Ly peak was 24.7×10^9/L (8.3-107). At SR, the mean Ly count was 3.4×10^9/L (1.3-5.6) and at the last observation, it was 3.4×10^9/L (1.3-5.6), with 0.9×10^9/L CLL cells (0-5.5) in 12 cases evaluated by flow cytometry, all staged A/0. No patient underwent treatment, except outlier pt #27. In 11/27 cases (41%), concurrently with the onset of SR, important clinical events were recorded (Table 1). No correlation with concomitant medication was observed. Two pts had a distinctive history: 1) Pt #26, 60 years old, female (mutated VH4-31, del13q). In 2013, diagnosis of stage A/I CLL, Ly 37.3×10^9/L. Nineteen months later, a Ly peak of 91.2×10^9/L was recorded. In 2015 she was restaged to A/0 and experienced a progressive decrease in her Ly count (39.6×10^9/L, 10.1×10^9/L, 5.6×10^9/L at the last observation in 2017). 2) Pt #13, 68 years old, male (mutated VH3-21, +12). In 2008, diagnosis of stage B/II CLL, Ly 51.9×10^9/L. Five months later, in 2009 a peak at 76.0×10^9/L was recorded; in 2011, the pt experienced several mild viral upper respiratory infections and CLL underwent SR that turn out to be complete in November 2011 and persists up to the last follow-up (Ly 1.9×10^9/L in April 2017), with stage A disease. Outlier pt #27 was the only who received treatment: 60 years old, male (mutated VH3-15, del13q), in 2009 was diagnosed with stage A/I CLL, Ly 14×10^9/L. In 2013, he received FCR for 6 cycles for disease progression (Ly 107×10^9/L) obtaining a PR but 18 months later he developed Richter's syndrome (DLBCL clonally unrelated to CLL) with the concomitant disappearance of the CLL clone from the peripheral blood and bone marrow, that has lasted up to August 2017 (Ly 2.2×10^9/L, CLL 0.037×10^9/L).
Summary/Conclusion: SR is a possibility, albeit infrequent, in the natural history of CLL, of which clinicians should be aware. In our large series, SR occurred preferably in pts in early clinical stage, low Ly count, negative CD38, favorable FISH, *TP53* WT, mutated *IGHV*, a preferential usage of the VH4-34, VH3-30 and 3-23 genes; SR was also observed in cases with trisomy 12. In most cases, SR was observed after a long observation period, usually in concurrence with infections or the appearance of second cancers, and were long-lasting, even in the presence of a persistent small clone of circulating leukemic cells.

PS1098

A PROGNOSTIC TOOL FOR THE IDENTIFICATION OF EARLY STAGE CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS AT IMMINENT RISK OF PROGRESSION

Background: Binet A CLL, that nowadays includes most of newly diagnosed cases, is usually managed with watch and wait. Binet A CLL has a considerable heterogeneous course. Some patients live for decades without therapy, while others require therapy within months from diagnosis. While current scoring systems anticipate overall survival among unselected CLL (i.e. MDACC, CLL-IPI, Barcelona-Brno scores), their performance in discriminating imminent risk of progression among Binet A patients is limited or unexplored.
Aims: Development of a model for prediction of treatment free survival (TFS) in Binet A CLL.
Methods: This is a multicentre, international, retrospective, observational study in which already existing and coded health-related personal data were further used. The adjusted association between exposure variables and TFS was estimated by Cox regression. Cox regression included exposure variables showing univariate association with TFS with Bonferroni corrected significant level <0.1. Backward elimination using likelihood ratio statistics with selection criterion p <.05 was used to derive the final model. An equally weighted combination of covariates was considered adequate if all pairwise ratios of regression coefficients ranged between 1:2 and 2:1. Discrimination capacity of the model was assessed through c-index.
Results: The study included a monoistitutional training cohort comprising 408 consecutive Binet A CLL patients initially managed with watch and wait, and followed for a median of 7 years. According to the CLL-IPI, 55% of patients scored low-risk, 37% intermediate-risk, 14% high-risk, and 4% very-high risk; according to the MDACC model, 32% scored low-risk, 67% intermediate-risk, and 1% high-risk; according to the Barcelona-Brno model, 67% scored low-risk, 27% intermediate-risk and 6% high-risk. Five independent predictors of TFS were identified: baseline lymphocyte count >15 G/L (HR 2.6), palpable lymph nodes (HR 2.3), palpable spleen (HR 2.7), unmutated IGHV genes (HR 2.7) and trisomy 12 (HR 2.4). Using weighted grading, a prognostic index was derived separating 4 different groups: low- (score 0), intermediate- (score 1), high- (score 2) and very high-risk (score 3-4) with significantly different probability of imminent need of therapy (2.8%, 6.9%, 24.6%, and 42.9% at 2 years for the low to very high-risk group, respectively) (Figure 1A). The ability of the model in discriminating treatment need (c-index 0.77) improved compared to the CLL-IPI (c-index 0.69), Barcelona-Brno score (c-index 0.66), and MDACC

score (c-index 0.61). The model was confirmed and the 4 risk groups were reproduced in a validation series comprising 287 Binet A CLL patients initially managed with watch and wait within the O-CLL1 (NCT00917540) prospective study (median follow-up 7 years; cumulative probability of treatment at 2 years: 0%, 10.4%, 17.0%, and 38.6% for the low to very high-risk group, respectively, c-index: 0.67) (Figure 1 B).

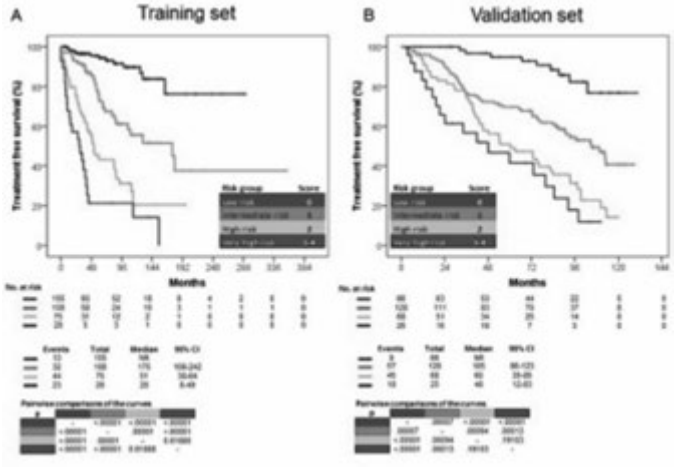

Figure 1.

Summary/Conclusion: The resulting "Binet A model" combines routine clinical and genetic variables into an easily applicable prognostic score for personalized estimate of the probability of imminent progression in early stage CLL. The Binet A model can help: i) design of clinical trials testing whether therapy initiation at an earlier stage than at manifestation of organ complications is beneficial for very high-risk patients; ii) precise prognostic counselling of patients regarding the implications of their disease.

PS1099

SURVIVAL CONTINUES TO INCREASE IN CHRONIC LYMPHOCYTIC LEUKEMIA: A POPULATION-BASED ANALYSIS AMONG 19,131 PATIENTS DIAGNOSED IN THE NETHERLANDS BETWEEN 1989 AND 2015

L. Van Der Straten[1,2,*], M.-D. Levin[2], O. Visser[3], E.F. Posthuma[4,5], J.K. Doorduijn[6], A.P. Kater[7], A.G. Dinmohamed[1,6,8]

[1]Research, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [2]Internal Medicine, Albert Schweitzer Hospital, Dordrecht, [3]Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [4]Internal Medicine, Reinier The Graaf Hospital, Delft, [5]Hematology, Leiden University Medical Center, Leiden, [6]Hematology, Erasmus MC Cancer Institute , Rotterdam, [7]Hematology, Academic Medical Center, Amsterdam, [8]Public Health, Erasmus University Medical Center, Rotterdam, Netherlands

Background: The treatment landscape in chronic lymphocytic leukemia (CLL) rapidly evolved since the last decade with improvements in supportive care and the advent of anti-CD20 agents, kinase inhibitors, and anti-apoptotic agents. At present, it is largely unknown how these advances impacted survival of CLL patients at the population level.
Aims: The aim of this nationwide, population-study was to assess trends in short-term and long-term excess mortality (EM) among CLL patients diagnosed during a 27-year period in the Netherlands.
Methods: We selected all 19,131 CLL patients diagnosed between 1989-2015 (median age 69 years; range 21-101 years; 61% males; 14% with a prior malignancy) from the nationwide Netherlands Cancer Registry with follow-up through December 31, 2016. Patients were categorized into 4 periods (1989-1995, 1996-2002, 2003-2008, and 2009-2015) and 4 age groups (18-59, 60-69, 70-79, and ≥80). Age-standardized incidence rates (ASRs) were calculated per 100,000 person-years and standardized according to the European standard population. Relative survival (RS) was calculated as a measure of disease-specific survival. Multivariable evaluation of RS was performed using Poisson regression with adjustment for period of diagnosis, sex, age at diagnosis and a prior malignancy before CLL diagnosis. A $p<0.05$ indicates statistical significance.
Results: The annual ASR of CLL initially increased gradually since 1989; however, the overall incidence pattern subsequently stabilized at around 4.0 to 4.5 as from 2003. The overall ASR was consistently higher among males than females throughout the entire study period (5.0 *vs.* 2.6 in 1989-2015). Patients across the 4 age groups experienced continued EM as compared to the general population during all periods studies (Figure 1). Nevertheless, RS improved with each period for all 4 age groups. More specifically, 5-year RS (95% confidence intervals) was 80% (77%>83%), 71% (68%>75%), 64% (61%>68%), and 52% (46%>59%) in 1989-1995 for the 4 age groups, as compared with 94% (92%>96%), 90% (88%>92%), 84% (81%>87%), and 75% (69%>82%) in 2009-2015 ($p<0.001$ for all comparisons). Furthermore, 10-year RS was 58% (54%>62%), 51% (47%>55%), 42% (38%>47%), and 32% (23%>43%) in 1989-1995, as compared with 79% (76%>81%), 69% (65%>72%), 62% (58%>66%), and 43% (34%>53%) in 2003-2008 ($p<0.001$ for all comparisons). The multivariable analysis confirmed an improvement of survival over time, with an EM ratio (EMR) of 2.04 ($p<0.001$) in 1989-1995, 1.45 ($p<0.001$) in 1996-2002, and 0.65 ($p<0.001$) in 2009-2015, as compared with 2003-2008. Furthermore, females had lower EM, as compared to males (EMR, 0.66; $p<0.001$), whereas patients with a prior malignancy had higher EM, as compared with patients without a prior malignancy (EMR, 1.80; $p<0.001$). Subgroup analyses confirmed the consistency of the abovementioned associations across the 4 age groups, with the exception that females and males age ≥80 had comparable EM (EMR, 0.99; p=0.906).

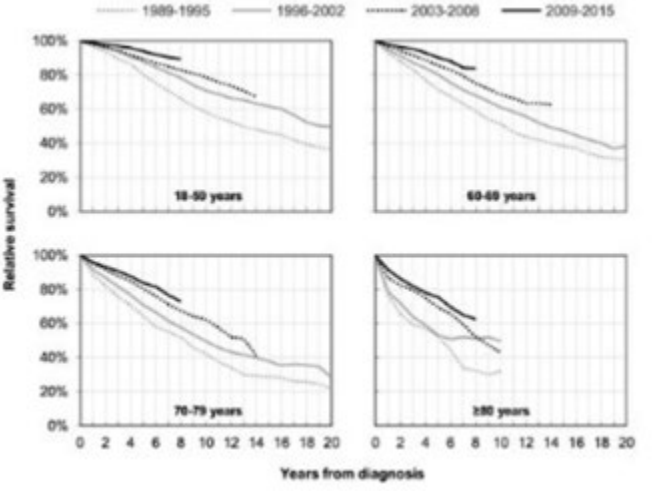

Figure 1.

Summary/Conclusion: In this large, nationwide, population-based study, 5- and 10-year RS improved over time among CLL patients across all age groups. Advances in supportive care, ameliorated management, and the advent of novel agents might have accounted for the improvement. Earlier detection of CLL might also have artificially increased survival estimates. However, this would have only marginally biased our results, as the overall ASR remained comparatively stable since 2003. As kinase inhibitors and anti-apoptotic agents have been introduced recently for routine use, EM will hopefully improve even more in the next decade.

PS1100

PROGNOSTICATION AND FIRST-LINE TREATMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA: A CONTEMPORARY, NATIONWIDE, POPULATION-BASED ANALYSIS AMONG 1,677 PATIENTS DIAGNOSED IN THE NETHERLANDS

L. Van Der Straten[1,2,*], M.-D. Levin[2], O. Visser[3], E. F. Posthuma[4,5], J.K. Doorduijn[6], A.P. Kater[7], A.G. Dinmohamed[1,6,8]

[1]Research, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [2]Internal Medicine, Albert Schweitzer Hospital, Dordrecht, [3]Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [4]Internal Medicine, Reinier The Graaf Hospital, Delft, [5]Hematology, Leiden University Medical Center, Leiden, [6]Hematology, Erasmus MC Cancer Institute, Rotterdam, [7]Hematology, Academic Medical Center, Amsterdam, [8]Public Health, Erasmus University Medical Center, Rotterdam, Netherlands

Background: The natural history of chronic lymphocytic leukemia (CLL) is heterogeneous. Therefore, accurate prognostication is pivotal to predict outcome and plan risk-adapted therapy. At present, it is virtually unknown how prognostic tests and first-line treatment are applied among CLL patients at the population level.
Aims: The aim of this nationwide, population-study was to assess how prog-

nostic tests and first-line treatment were utilized among CLL patients diagnosed in a contemporary era in the Netherlands.
Methods: We selected all CLL patients diagnosed between 2014-2015 from the nationwide Netherlands Cancer Registry (NCR) with follow-up for survival until December 31, 2016. Information on cytogenetic (ie, karyotyping and/or FISH) and molecular testing, Rai stage, and first-line treatment started within one year after diagnosis is available in the NCR as from 2014 onward. Multivariable logistic regression (MLR) analysis was used to assess factors associated with cytogenetic testing and first-line treatment, adjusted for covariates presented in the Figure. One-year relative survival (RS) was calculated as a measure of early excess mortality (EEM). p<0.05 indicates statistical significance.
Results: A total of 1,667 CLL patients (median age 69 years; 63% males) was included in the study. Patient characteristics are presented in Table 1. The Rai stage was undeterminable in 139 (8%) patients because at least one of the parameters that compose the Rai stage was missing. Cytogenetic and molecular testing were performed in 435 (26%) and 106 (6%) of patients, respectively. Del(17p) and *TP53* mutations were detected in 12 of 435 (3%) and 6 of 106 (6%) patients, respectively. First-line therapy was started in 347 (21%) patients. R-Chl (36%; median age 77; interquartile range [IQR] 72-81) and FCR (30%; median age 61; IQR 56-65) were the most commonly applied therapies. Following MLR analysis, age per 10-year increase and female sex were associated with unperformed cytogenetics, whereas cytogenetic testing was more likely performed among patients diagnosed in academic centers, patients with Rai stage ≥1, and patients who started first-line treatment (Table 2). Now turning to variables associated with the start of first-line treatment (Table 3). Comorbidity per one condition increase and Rai stage 0-1 were factors associated with a lower odds to start first-line treatment. Conversely, patients with Rai stage 3-4 and patients in whom cytogenetic and molecular testing were performed were more likely to start with first-line therapy (Table 3). One-year RS (95% confidence intervals) was 100% (98%>101%), 99% (95%>101%), 97% (93%>100%), 87% (80%>92%), and 85% (76%>91%) for patients with Rai stage 0, 1, 2, 3, and 4, respectively.

Cytogenetic testing performed	2.70	1.94 - 3.76	<0.001
Molecular testing performed	2.44	1.42 - 4.21	0.001

Summary/Conclusion: This is the first population-based study showing how prognostic procedures and first-line treatment are utilized among CLL patients diagnosed in a contemporary era. Congruent with clinical practice guidelines, most, but not all, CLL patients with advanced disease and who started with first-line therapy underwent (cyto)genetic testing. A novel, although expected finding was that patients with Rai stage 0-2 do not experience EEM, whereas patients with Rai stage 3-4 experience considerable EEM, as compared with the general population. To date, no study has presented such outcomes corrected for the life expectancy in the general population. Collectively, population-based registries are useful instruments to assess guideline adherence and the prognostic value of staging systems at the population level.

"IMMUNO-FLOW-FISH": HIGH THROUGHPUT FLUORESCENCE IN SITU HYBRIDISATION OF PHENOTYPED CHRONIC LYMPHOCYTIC LEUKAEMIA BY IMAGING FLOW CYTOMETRY FOR CLINICAL APPLICATION

W. Erber[1,2,*], H. Hui[3], K. Fuller[2,3]

[1]Faculty of Health and Medical Sciences, University of Western Australia, Crawley, [2]Translational Cancer Pathology Laboratory, PathWest Laboratory Medicine, Nedlands, [3]School of Biomedical Sciences, University of Western Australia, Crawley, Australia

Background: Imaging flow cytometry is emerging as a diagnostic tool for the assessment of leukaemia. It has the functionality of standard flow cytometry and generates high-resolution digital images of each cell and fluorescence signals with quantifiable numerical data. We have developed an automated high-throughput method for performing FISH on phenotyped whole cells and analysed by imaging flow cytometry.
Aims: Our aim was to investigate the capability and sensitivity of this "immuno-flowFISH" method to detect trisomy 12 and del(17p) in phenotyped chronic lymphocytic leukaemia (CLL) cells.
Methods: Blood from 55 *de novo* and treated CLL patients with lymphocyte counts ranging from 3.6-210 x10^9/L was collected into EDTA anticoagulant. After red cell lysis, cells were incubated with CD3, CD5 and CD19 antibodies conjugated to fluorochromes (BV480, AF647, BB515, V500c). Following fixation, cell membranes were permeabilised and double-stranded DNA denatured (73-74°C for 5 mins). FISH probes to chromosomes 12 (CEP12) or 17 (CEP17) and 17p12 (Spectrum Orange, Spectrum Green or Orange Red fluorochromes) were added and hybridised for 24-30 hours at 37°C. Nuclei were stained with SYTOX AADvanced. Data for up to 50,000 cells was collected on the Amnis ImageStream®^{X} Mark II imaging flow cytometer. Digital images (x60) and quantitative data (IDEAS software) were used to assess FISH signals overlying the SYTOX-stained nuclei of CD5/CD19-positive CLL cells for each probe. The number and percent FISH-positive CLL cells was determined. The ratio of FISH spot counts for CD5/CD19-positive CLL cells to CD3/CD5-positive T cells (FISH "mean spot ratio") was calculated. FISH results were compared with pre-treatment traditional FISH.
Results: A total of 10,000-50,000 cells (mean = 20,000 per case) was analysed per CLL case. Of the 55 CLL cases, there were 13 with trisomy 12 (+12) and 5 with del(17p) in the CD5/CD19-positive CLL cells. The FISH abnormalities were seen on the digital images and confirmed by quantitative mean channel fluorescence intensity of the probes. The CD3/CD5-positive T cells in all cases had diploid signals for each probe in all cells. In the +12 cases, 3 FISH spots for CEP12 were detected in 0.1-46.0% of the CLL cells (26-9,111 cells); the FISH "mean spot ratio" for CEP12 ranged from 1.09-1.36. There were 5 cases with del(17p) in the CLL cells; these all had normal diploid spots for the control CEP17 probe. The number of CLL cells with del(17p) ranged from 3.5-22.8% (363-3,382 cells) and the FISH "mean spot ratio" 0.86-0.96. The remaining 42/55 cases had normal 2-spot patterns for CEP12, 17p12 and CEP17 in CLL and T-cells. All CLL FISH results were concordant with pre-treatment FISH results.
Summary/Conclusion: Immuno-flowFISH is a powerful and highly sensitive automated high throughput method capable of detecting FISH abnormalities in intact phenotyped CLL cells. By analyzing CLL with 3 antibodies and probes, and a minimum of 10,000 cells per case, we have significantly increased both the sensitivity and specificity over traditional FISH (100-200 times more cells and restricted to the CLL population). Immuno-flowFISH is an exciting new automated method that significantly improves the accuracy and limit of detection of chromosomal abnormalities in CLL. This method is capable of detecting low-level abnormalities that are clinically significant in therapeutic decision-making and for disease monitoring.

PS1102

EXPRESSION OF ANTIGENS INVOLVED IN THE FORMATION OF AN IMMUNOLOGICAL SYNAPSE IN CHRONIC LYMPHOCYTIC LEUKEMIA

D. Badmazhapova[1,*], I. Galtseva[2], E. Zvonkov[1], Y. Davydova[2], N. Kapranov[2], E. Parovichnikova[2], V. Savchenko[2]

[1]Department of lymphoma chemotherapy, [2]National Research Center for Hematology, Moscow, Russian Federation

Background: The pathogenesis of Chronic lymphocytic leukemia (CLL) is very complex. Recently it was found that CLL cells are able to form immunological synapses with microenvironment cells, directly and indirectly affecting their function. Therefore, it became clear that the pathogenesis of

CLL includes not only inhibition of apoptosis but also the ability of CLL cells to cause T-lymphocyte anergy, thereby avoiding immune surveillance.
Aims: to study the expression of FAS, CD80 and CD86, PD-1, PD-L1 on CLL cells, and also to evaluate the main subpopulations of T-cells (naïve (CD95-CD28+), memory (CD95+CD28+), effector cells (CD95+CD28-)).
Methods: The study included 46 CLL patients: 16 patients were in progression of the disease after chemotherapy and 30 patients had newly diagnosed with CLL (primary). Primary CLL patients were categorized according to Binet stages. Stage A was established in 14 patients, B - 10, C - 6. The control group included 29 healthy donors. Peripheral blood samples were analysed on a 6-color flow cytometer BD FACS Canto II (BD Biosciences, USA). The panel of monoclonal antibodies included antibodies against: CD19 PE (SJ25C1), CD5 PerCP-Cy5.5 (L17F12), CD4 APC-Cy7 (SK3), CD8 PerCP (SK1), CD3 APC (SK7), CD279 (PD-1) FITC (MIH4), CD274 (PD-L1) PE-Cy7 (MIH1), CD80 FITC (L307.4), CD86 APC (2331), CD95 (FAS) PE-Cy7 (DX2), CD28 PE (CD28.2), CD25 FITC (2A3), CD45 APC-Cy7 (2D1) from BD Biosciences.
Results: In CLL patients, the% CD80+, CD86+, FAS+ B-cells were significantly lower than in donors. In primary CLL the% CD80+ B-cells was higher than in CLL progression. That means, CLL cells do not form a second co-stimulatory signal with T cells and promote their anergy. Low expression of FAS on CLL cells provides protection of FAS-mediated apoptosis. The data is presented in Table 1. Among primary CLL patients% CD80+ and CD86+ B-cells was lower in advanced stages of the disease (CD80: A – 5.94±1.61%, B – 3.49±1.95%, C – 0.43±1.67%; CD86: A – 8.95±2.49%, B – 4.04±3.11%, C – 1.45±0.75%, p<0.05). Probably, in advanced stages CLL the formation of the immune synapse is much more altered than in low grades CLL. PD-L1+ B-cells was lower in CLL patients than in donors.% PD-1+ B-cells was higher in CLL progression than in donors and primary CLL.% In primary CLL,% PD-L1+ B-cells was higher in stage A (A-10.02±5.75, B-0.25±0.03, C-2.05±1.32, p<0.05). Thus, in non-advanced stages CLL cells are resembling healthy B-cells. % PD-1+ T-helpers was higher in CLL patients than in donors, and in primary CLL it was higher in advanced stages (B vs C, 14.43±2.51 vs 27.43±4.75, p=0.046). This increase means that T-cells gain the "exhausted" phenotype.% PD-L1+ T-cells in CLL was lower than in donors.% naive T-cells were lower,% effector cells and% memory cells were higher in patients compared to donors.

Table 1.

Parameters, %	Primary CLL	CLL progression	Donors
B-cells			
CD19+CD80+	4.02±1.04	1.15±0.43**	16.89±1.55*
CD19+CD86+	5.81±1.62	2.46±0.66	9.77±2.32*
CD19+FAS+	6.14±1.21	11.34±2.60**	16.59±1.99*
CD19+PD-1+	12.31±2.64	19.57±3.75	1.27±0.23*
CD19+PD-L1+	5.17±2.78	4.14±2.99	35.76±3.13*
T-cells			
CD4+PD-1+	19.8±2.21	30.05±3.90**	10.78±0.93*
CD8+PD-1+	18.14±2.30	15.35±2.39	16.89±1.36
CD4+PD-L1+	0.93±0.15	0.59±0.12	1.21±0.16***
CD8+PD-L1+	0.43±0.08	0.25±0.05	1.09±0.26*
Naive CD4+	30.93±3.74	5.35±1.90**	40.20±3.83***
CD4+ memory	59.47±3.53	78.76±4.54**	54.36±3.27***
CD4+ effectors	9.32±2.17	15.75±4.68	5.24±1.85
Naive CD8+	16.92±3.39	3.76±1.61**	34.39±3.90*
CD8+ memory	26.75±2.49	33.74±4.60	27.97±2.03
CD8+ effectors	9.32±2.17	15.75±4.68	5.24±1.85*
* - differences between donors and both CLL, ** - differences between both CLL, *** - differences between donors and progression CLL			

Summary/Conclusion: Decline of CD80+ and CD86+ B-cells in CLL can cause ineffectiveness of an immunological synapse between CLL cells and T-cells, which leads to anergy of T-cells. Low expression of FAS allows CLL cells to avoid FAS-mediated apoptosis. A shift in the T-cell subpopulations toward memory cells and effectors, high PD-1 expression on T-cells, impairs antitumor immunity and, possibly, supports CLL progression.

PS1103

IDENTIFICATION OF NEWLY DIAGNOSED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA AT HIGH RISK OF INFECTION OR TREATMENT THROUGH MACHINE LEARNING ALGORITHMS

Background: For patients with Chronic Lymphocytic Leukemia (CLL), infections are a significant cause of morbidity and mortality despite improved supportive care. More than 30% of fatalities in CLL list infections as primary or contributory cause of death. Based on a prognostic index like CLL-IPI, patients at high risk of short treatment free survival can be identified. However, identification of patients at high risk of infection prior to treatment is warranted to allow for preemptive and prophylactic measures for those patients.
Aims: We set out to predict risk of early infection or treatment for patients newly diagnosed with CLL based on known prognostic factors and laboratory results. We systematically assessed the performance of various machine learning algorithms for this task.
Methods: By means of the nationwide Danish CLL registry, the Danish Microbiology Database, the Persimune data warehouse and health registries, data for 2772 CLL patients were assembled. The study was approved by the Danish Health Authorities and Data Protection Agency. The event of a blood culture was used as a proxy for severe infection, regardless of the result. Data on treatment for CLL and survival were registry based. Standard hematology and biochemistry results from general practitioners and hospitals, in addition to microbiology, cytogenetics, and IGHV mutational status, were included for the period 12 months prior to diagnosis until 3 months post diagnosis. We trained models to predict a composite outcome defined as either the development of an infection or starting CLL treatment within two years. Model development and data analysis were initiated during a one week international workshop with performance assessments of different approaches including simple linear-models, ensemble tree-based methods and deep learning approaches. Models were trained on a random split 80% of the data set and tested for generalizability on the remaining 20% test set. The here reported model, which performed best on the test set, was an extreme gradient boosting model using a combined set of features designed to capture information on the distribution of laboratory events and "Bag-of-Words" features akin to those used in early natural language processing models.

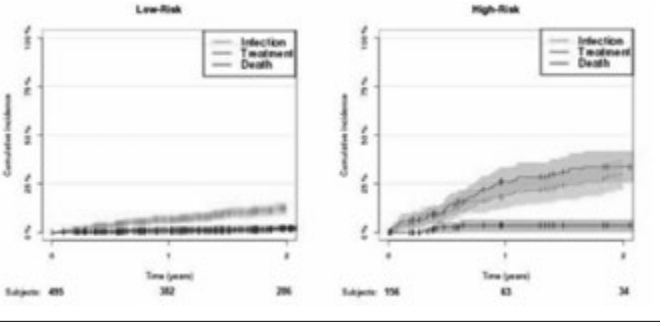

Figure 1.

Results: Within two years, 31% of newly diagnosed CLL patients had an event of severe infection or treatment, which our model could predict with a positive predictive value (PPV) of 70% and a true positive rate (TPR) of 58%. When restricting the analysis to the subset with full CLL-IPI variables available (cytogenetics, IGHV mutational status, beta2microglobuline, clinical stage and age), a PPV of 75% and a TPR of 58% was achieved. Thus, our model was capable of accounting for missing values with only a slight reduction in PPV. On the same subset, the CLL-IPI Index (score 0-3 vs. 4-10) achieved a PPV of 61% and a TPR of 28%. As seen from the cumulative incidence plots of infection, treatment and death (only first event counting), both infection and treatment events are predicted for the high risk population, which constituted 24% of the full population (Figure 1).
Summary/Conclusion: By applying machine learning models on baseline characteristics and laboratory values, previous prognostic approaches in

CLL were improved. We identified a sub-population (24%) of patients with a 70% risk of infection or CLL treatment within two years of diagnosis. A randomized, preemptive trial with targeted therapy for this patient population is being planned, by which we aim to change the natural history of immune dysfunction in CLL for this patient population.

PS1104

HEALTH-RELATED QUALITY OF LIFE (HRQOL) IN RELATION TO RESPONSE TO FIRSTLINE THERAPY AND SUBSEQUENT TREATMENTS – A METAANALYSIS OF HRQOL MEASURED IN PHASE III TRIALS OF THE GERMAN CLL STUDY GROUP

N. Kutsch[1,*], V. Goede[1], S. Robrecht[1], F. Kelma[1], J. Bahlo[1], K. Fischer[1], A.-M. Fink[1], R. Schlag[2], E. Lange[3], R. Weide[4], M. Dreyling[5], U. Jäger[6], S. Stilgenbauer[7], H. Döhner[7], M. Kneba[8], M. Ritgen[8], C.-M. Wendtner[9], M. Hallek[1], B. Eichhorst[1]

[1]Department I of Internal Medicine and Center of Integrated Oncology Cologne Bonn, University Hospital of Cologne, Cologne, [2]Onkologische Gemeinschaftspraxis Würzburg, Würzburg, [3]Evangelisches Krankenhaus Hamm, Hamm, [4]Praxisklinik für Hämatologie und Onkologie Koblenz, Koblenz, [5]Department of Internal Medicine III, Ludwig-Maximilians-Universität Munich, Munich, Germany, [6]Vienna General Hospital, Vienna, Austria, [7]Department of Internal Medicine III, University Hospital of Ulm, Ulm, [8]Department of Medicine II, University of Schleswig-Holstein, Kiel, [9]Department of Hematology, Oncology, Immunology, Infectious Diseases and Tropical Medicine, Klinikum Schwabing, Munich, Germany

Background: Treatment of advanced CLL with chemoimmunotherapy (CIT) has improved outcome with regards to progression-free survival and overall survival significantly. Besides these endpoints health-related quality of life (HRQOL) becomes increasingly relevant for physicians and patients (pts). The German CLL study group (GCLLSG) has performed a metaanalysis on HRQOL of pts receiving different chemotherapies (CT) and CIT within three phase III trials.
Aims: To evaluate HRQOL in relation to response to firstline therapy and subsequent treatments.
Methods: Data of 2159 pts from the CLL 8 (817 pts), CLL10 (561 pts) and CLL11 (781 pts) study protocol of the GCLLSG were pooled. In the CLL8 and CLL10 study, the questionnaires (ques) were sent to all patients at baseline and after 3, 6 or 8 and 12 months and then yearly as follow up (FU). In the CLL11 study, ques were sent out at screening, twice during therapy, at end of therapy and then every 3 months until 3 years, and later every 6 months until 5 years. The first three months of treatment are referred to treatment phase (TP) I, treatment beyond the first three months to TP II. HRQOL was evaluated using the EORTC C30 questionnaire. All scales were calculated according to the standard procedure as given by the EORTC-QLQ-C30 manual.
Results: 2065 pts receiving treatment filled out at least one ques. These pts were treated with the following frontline CT and CIT: 374 FC, 663 FCR, 268 BR, 116 Chlorambucil (Clb), 322 R-Clb and 322 G-Clb. 1334 pts filled out ques at baseline, 1139 pts in TP I and 575 pts in TP II. In the first 12 months of FU, 1773 pts filled out ques, while at later FU after 60 months only 291 pts completed ques. Comparing baseline global health status (GH) of responders versus non-responders, responders had a higher GH score than non-responders (mean 62.2 vs. 58.2, p= 0.028). Responders also had a higher GH than non-responders at FU until month 12 (mean 68.2 vs. 61.4, p<0.001). Similarly, physical functioning (PF) in responders was better at baseline (79.8 vs. 75.4, p=0.004) and in FU until month 12 (81.3 vs. 76.1, p<0.001). In contrast to that, role functioning (RF) and social functioning were worse in responders in TP I (73.9 vs. 79.6, p=0.017; 78.5 vs. 85.3, p=0.001). Responders had higher fatigue symptoms than non-responders in TP II only (mean 41.1 vs. 29.3, p=0.017), but not in TP I (mean 36.0 vs.31.9, p=0.060). Furthermore, a subgroup analysis of HRQOL according to progression after frontline treatment was performed. In patients with progression but without subsequent treatment (N=188) GH, PF, RF and fatigue were significantly impaired after progression occurred (before vs. after progression: GH: mean 69.5 vs. 65.9, p= 0.018; PF: 82.2 vs. 78.8, p=0.001; RF: 77.3 vs. 73.4, p= 0.029; fatigue: 30.1 vs. 33.1, p=0.025). In patients with progression and subsequent therapy (N=92) all HRQOL items were impaired after start of relapse therapy (Figure 1). Subsequent therapies consisted of CT in 20 pts and CIT in 68 pts with the exception of 2 stem cell transplants, 1 unknown treatment and 1 patient presumably receiving ibrutinib.
Summary/Conclusion: This meta-analysis shows that HRQOL in CLL pts is correlated to treatment interventions including outcome of therapy. HRQOL was impaired in pts with progression after frontline without immediate therapy, but was more profoundly negatively affected in all functioning and symptom scales when subsequent therapy was administered. The question remains if new oral inhibitors achieve a better tolerance and therefore an improved HRQOL.

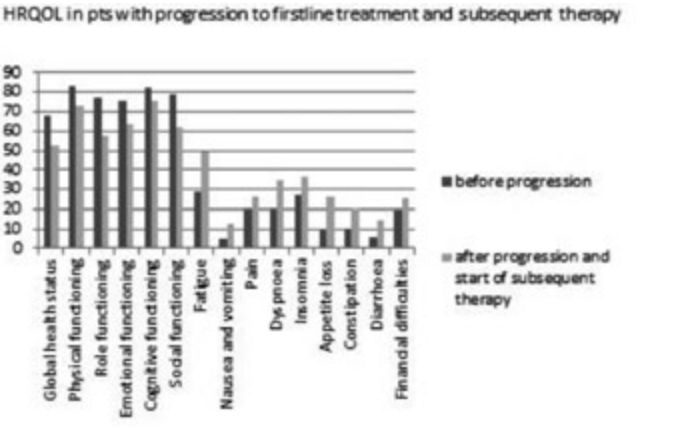

Figure 1.

PS1105

T-LARGE GRANULAR LYMPHOCYTIC (T-LGL) LEUKEMIA: A LONG-TERM STUDY ON 51 PATIENTS-COULD WE CONFINE THE USE OF THE TERM "LEUKEMIA"?

X. Yiakoumis[1,*], E. Koulieris[1], C. Kalpadakis[2], S. Sachanas[1], M. Moschogiannis[1], P. Tsirkinidis[1], E. Kyritsi[3], M. Angelopoulou[3], T. Vassilakopoulos[3], F. Kontopidou[4], P. Korkolopoulou[5], D. Rontogianni[6], H. Papadaki[2], G. Pangalis[1]

[1]Haematology, Athens Medical Center-Psychikon branch, Athens, [2]Haematology, University Hospital, University of Crete, Heraclion, [3]Haematology, University of Athens, Laikon General Hospital, [4]Second Department of Internal Medicine, University of Athens, "Hippocrateio" General Hospital, [5]Pathology, University of Athens, [6]Anatomic Pathology, Evangelismos General Hospital, Athens, Greece

Background: T-LGL leukemia is a clonal lymphoproliferative disorder with abnormal blood parameters and/or recurrent infections, as well as immunophenotypic confirmation of a clonal CD3+/CD8+/CD57+population, usually but not necessarily > $0.5x10^9$/L. The above criteria, through usage of sensitive techniques, help to identify even more frequently patients with clonal T-cell disorders, who seem to have a relatively heterogeneous clinical and prognostic features and their optimal long-term management is not defined.
Aims: To report a series of patients (pts) diagnosed with T-LGL leukemia, according to established criteria and to address the question regarding the universal use of the term "leukemia" for these patients.
Methods: Our pts were identified on the basis of an abnormal leucocyte number or differential, as having a T-LGL expansion by morphology and were further studied. hey underwent a complete clinical, laboratory, radiologic, and immunological screening, combined with a blood immunophenotype, a T-cell receptor clonality assay by PCR (TCR), as well as a bone marrow trephine biopsy, whenever possible, and then followed on a regular basis or treated accordingly.
Results: 51 pts (30 female) were included. 30 presented with a reverse differential, 13 with neutropenia ($0.4\text{-}1.5x10^9$/L, median 1.2) and 8 with lymphocytosis ($4.0\text{-}10.2x10^9$/L, median 5.6). Only 2 reported a concurrent autoimmune disease (1 rheumatoid arthritis and 1 systemic lupus erythematosus) and none mentioned serious/recurrent infections. Median age was 55 years (15-80) and median follow up from diagnosis 34 months (6-178). 20% have been followed for >5 years (60 months) and 10% > 10 years. Most pts reported the presence of the disorder for more than 3 years before diagnosis (range 0-21 years). All had a blood smear indicative of T-LGL lymphocytosis by morphology and underwent a blood immunophenotype which pointed out a T-LGL expansion with a median absolute number of CD8+/CD57+ of $0.545x10^9$/L (0.02-4.9). 44 were also found to have a clonal TCR by PCR while 7 were TCR (-). 31 underwent bone marrow core biopsy. 21/31 had a bone marrow infiltration (12-25%) and 10/31 had only reactive bone marrow findings. All patients with T-LGL absolute number >1.0 10^9/L (8/51) had a significant infiltration of bone marrow; the same was also observed in 6 pts with T-LGL <$0.5x10^9$/l; median T-LGL count in pts with bone marrow infiltration was $0.72x10^9$/L (0.02-4.95) (Table 1). Only 2 received supportive treatment (erythropoietin) due to symptomatic anemia, with good response and both remain asymptomatic

after 37 and 45 months respectively. All patients were alive, with no disease progression at last follow up. No evolution to frank leukemia, requiring additional studies or therapeutic management was observed in our series.

Table 1. Characteristics of T-LGL patients.

Number of pts	51
Male/female	21/30
Median age	55 (15-80)
Clinical presentation -Reverse differential -Neutropenia -Lymphocytosis -Anemia -Autoimmune diseases	 30 (59%) 13 (25%) 8 (16%) 2 (4%) 2 (4%)
Median T-LGL count	0.545 x 10^9/l (0.02-4.9)
TCR +/-	44/7
Bone marrow infiltration	21/31 (68%)
Median T-LGL count in pts with bone marrow infiltration	0.72 x 10^9/l (0.02-4.95)
Median follow-up duration	34mo (6-178)

Summary/Conclusion: We present a series of patients with clonal T-LGL lymphoproliferation who, with current use of international criteria, should bare the diagnosis of T-LGL leukemia. The prognosis was excellent for the entire series. The presence of serious symptoms and/or progression of the disease should be necessary for the diagnosis of and any therapeutic intervention for T-LGL leukemia. In their absence, the terminology of "monoclonal T-large granular cell lymphocytosis" could be more appropriate.

PS1106

FLOW CYTOMETRY AND PCR-BASED T-CELL CLONALITY TESTING FOR DISCRIMINATING BETWEEN REACTIVE AND NEOPLASTIC PROLIFERATION OF LARGE GRANULAR LYMPHOCYTES

N. Chernova[1,*], Y. Sidorova[2], E. Zakharko[3], N. Ryzhikova[2], E. Rybkina[3], V. Dvirnyk[3], A. Sudarikov[2], E. Zvonkov[1]

[1]Department Chemotherapy of Lymphomas, [2]Department of Molecular Hematology, [3]Clinical diagnostic laboratory, National Research Center for Hematology, Moscow, Russian Federation

Background: Large granular lymphocytes (LGL) lymphocytosis can be associated with viral infections, autoimmune disorders, chronic lymphoproliferative disorder of NK-cells (CLPD-NK) and T-cell large granular lymphocytic leukemia (T-LGL). Differential diagnosis between reactive and neoplastic LGL proliferation could be a challenge.
Aims: To evaluate the importance of morphological, immunophenotypic (flow cytometry) and molecular genetic (PCR-based T-cell clonality) studies in differential diagnosis for LGL proliferation.
Methods: 67 patients with increased peripheral blood LGL counts were enrolled in the study. Male/female ratio was 19/48; a median age was 53 (22–79) years. Morphology, immunophenotype by flow cytometry and PCR-detection of T-cell clonality (TCRG (Vγ-Jγ) and TCRB (Dβ-Jβ and Vβ-Jβ)) were performed in all cases.
Results: All patients were divided into 3 groups according to their diagnosis: CLPD-NK (n = 8), T-LGL (n = 42), reactive LGL lymphocytosis (n = 17). CLPD-NK was established based on LGL morphology, CD3-CD4-CD8+/-CD16+CD56+/- immunophenotype and germline configure uration of TCR genes. The heterogeneity of CD7 expression was identified in 2 of 8 cases. Persistent increase (> 6 mouths) in peripheral blood LGL counts was noted in 42 patients with T-LGL. 30 cases were TCRαβ-positive and 12 cases were TCRγδ-positive. Immunophenotypic variants of 30 TCRαβ-positive cases were: CD3+CD4-CD8+CD16-CD56- in 13, CD3+CD4-CD8+CD16+/-CD56+/- in 9, CD3+CD4+CD8-CD16+/-CD56+/- in 4, CD3+CD4+CD8+CD16+/-CD56+/- in 4. TCRγδ-positive cases were characterized by CD3+CD4- immunophenotype and variable expression of CD8, CD16 and CD56. CD3+CD4-CD8- variant of T-LGL was determined in 5 patients. The relative and absolute LGL counts were different depending on immunophenotypic variant of T-LGL. The heterogenic expression of at least one of CD2, CD5 and CD7 was noted for 85% of cases. TCRG (Vγ-Jγ) and/or TCRB (Vβ-Jβ, Dβ-Jβ) genes were clonally rearranged in 41 (97.6%) of 42 cases. Clonal rearrangements of δ-chain TCR genes only were observed in one TCRγδ-positive case of T-LGL.
Persistent increase (< 6 mouths) in peripheral blood LGL counts was observed in 17 cases of reactive lymphocytosis. Immunophenotype of LGL was CD3+CD4-CD8+CD16-CD56- in 11 of 17 cases, CD3+CD4-CD8+CD16+/-CD56+/- – in 6. The heterogenic expression of at least one of T-cell markers was observed in 47,1% of cases. Interestingly, LGL number exceeded 2x10^9/l twice in 5 of 17 cases. Notably, reactive LGL lymphocytosis was detected in 7 patients with other tumors of haematopoietic and lymphoid tissues: extranodal NK/T cell lymphoma, nasal type – in 1 case, T-cell/histiocyte-rich large B-cell lymphoma – in 1, myelodysplastic syndrome – in 5. Clonal rearrangements of TCRG (Vγ-Jγ) and incomplete TCRB (Dβ-Jβ) genes were determined in 3 and 1 cases respectively. TCRB (Vβ-Jβ) genes were not clonally rearranged in any case. The results of T-cell clonality testing are summarized in the Table 1.

Table 1.

Parameter	TCRG (Vγ-Jγ)	TCRB (Dβ-Jβ)	TCRB (Vβ-Jβ)	TCRB (Dβ-Jβ and/or Vβ-Jβ)
CLPD-NK, n=8	0	0	0	0
T-LGL, n=42	36 (85,7%)	22 (52,4%)	33 (78,6%)	37 (88,1%)
TCRαβ-positive T-LGL, n=30	25 (83,3%)	17 (56,7%)	29 (96,7%)	30 (100%)
TCRγδ-positive T-LGL, n=12	11 (91,7%)	5 (41,7%)	4 (33,3%)	7 (58,3%)
Reactive LGL lymphocytosis, n=17	3 (17,6%)	1 (5,9%)	0	1 (5,9%)

Summary/Conclusion: Discriminating between reactive LGL lymphocytosis and T-cell large granular lymphocytic leukemia still could be a challenge. Morphology, immunophenotype, relative and absolute LGL counts and the heterogenic expression of T-cell markers do not distinguish between neoplastic and reactive processes. Clonal TCRG (Vγ-Jγ) and TCRB (Dβ-Jβ) gene rearrangements were observed in reactive LGL lymphocytes and T-LGL. The complete rearrangements of TCRB (Vβ-Jβ) genes were specific for the tumor process and were not detected in either case of reactive lymphocytosis.

PS1107

A US BASED SURVEY: THE EXPERIENCES AND PERSPECTIVES OF 1147 CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS

B. Koffman[1,*], B. Dennison[2], K. Kennard[3], R. Furman[4], J. Byrd[5], J. Pagel[6], M. S. Davids[7], C. Nabhan[8], N. Kay[9], D. Brander[10], T. Siddiqi[11], B. Hill[12], J. Pinilla-Ibarz[13], B. Cheson[14], S. T. Rosen[15], W.G. Wierda[16], D.M. Stephens[17], F.T. Awan[18], M.Y. Choi[19], A. R. Mato[20], A.R. Mato[21]

[1]CLL Society Inc., Claremont, [2]CLL Society Inc., Pompton Lakes, [3]University of Pennsylvania, Abramson Cancer Center, Philadelphia, [4]Weill Cornell Medicine, New York City, [5]Ohio State University, Columbus, [6]Swedish Cancer Institute, Seattle, [7]Dana-Farber Cancer Institute, Boston, [8]Cardinal Health, Dublin, [9]Mayo Clinic, Rochester, [10]Duke University School of Medicine, Durham, [11]City of Hope National Medical, Duarte, [12]Cleveland Clinic Foundation, Cleveland, [13]H. Lee Moffitt Cancer Center and Research Institute, Tampa, [14]Georgetown University Hospital, Lombardi Comprehensive Cancer Center, Washington DC, [15]City of Hope Medical Center, Duarte, [16]MD Anderson Cancer Center, Houston, [17]University of Utah, Huntsman Cancer Institute, Salt Lake City, [18]The Ohio State University Comprehensive Cancer Center, Columbus, [19]Moores Cancer Center University of California San Diego, San Diego, [20]Memorial Sloan Kettering Cancer Center, New York City, United States, [21]CLL Program, Leukemia Service, Section of Hematological Malignancies, Memorial Sloan Kettering Cancer Center, New York City, United States

Background: The CLL literature focuses largely on the objective aspects of diagnosis (dx), active observation (AO), prognosis and management. While health care providers (HCPs) try to effectively educate and reassure patients, the literature on patients' subjective experience through the continuum of care is limited.
Aims: To better describe the patient experience from time of dx, through AO, prognostic testing and clinical trial consideration so as to identify unmet educational and psychological needs.
Methods: We utilized an online or paper 64 question survey directed to CLL patients to capture more information on their experience with CLL. The survey was IRB-approved and took place between October-December 2017. All analyses are descriptive in nature.

Results: 1147 patients from 48 American states completed the survey. Median age was 65 (range 28-86), 46% male, 96% Caucasian. 88% of patients cited conversations with their doctor as the most frequent educational format overall, followed by online sources (CLL specific 67%; general blood cancer 55%) and print materials (52%). Following education, 66% of patients reported a good understanding of sources of information on CLL, 64% of disease characteristics and 62% of therapy indications. 98% reported looking for more information themselves citing CLL-specific websites (90%), online CLL patient blogs or forums (69%) and general blood cancer websites (64%) as the main sources. At dx, 67% of patients reported receiving education by their HCP, however at disease progression, only 23% of patients report education from their HCPs. Effects of treatment and clinical trial opportunities were discussed by 43% and 35% respectively. At dx, 48% were told they had the "good" cancer, yet when AO was recommended, patients reported a mixed picture of anxiety (56%), relief (52%) and confusion (31%). During AO patients reported fatigue (51%), enlarged nodes (47%), anxiety (39%), depression (21%), and night sweats (21%). Also during AO, 653 patients (66%) utilized herbals and other non-traditional interventions for CLL management (Table 1). 34% and 16% of patients respectively reported that discussing prognostic indicators increased their anxiety and confusion. Only 1/3 of patients were offered clinical trial participation and those patients that declined participation or would have declined if asked stated their reasons as preference for a "proven" treatment (38%), distance from the trial site (29%), fear (20%), and frequent imaging (20%).

Table 1.

During AO	% used
Green tea or derivatives	60
Vitamin D	56
Prayer	36
Exercise	30
Curcumin	27
Other herbs/supplements	26

Summary/Conclusion: To our knowledge, this is the largest survey of CLL patients. Much can be learned by detailed surveying of CLL patients throughout their disease course, including previously unrecognized suboptimal interactions between CLL patients and their HCPs. AO is an emotional and active time. Prognostic testing is stressful for many patients. 1/3 of patients recall no HCP education at dx and re-education is infrequent. When patients decline clinical trials, it is due to preference for a "proven therapy", fear, distance and frequent imaging. Understanding how patients experience their disease is critical to improve communication between patients and their HCPs, which may ultimately advance CLL outcomes.

PS1108

CHRONIC LYMPHOCYTIC LEUKEMIA IN ICELAND: A NATION-WIDE EPIDEMIOLOGY STUDY FROM 2003 TO 2016

H. H. Thorvaldsson[1,*], B. Vidarsson[1,2], S.V. Sveinsdottir[1,2], A.M. Halldorsdottir[13]

[1]Faculty of Medicine, University of Iceland, [2]Department of Hematology, [3]Blood Bank, Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland

Background: Chronic lymphocytic leukemia (CLL) is the most common leukemia in Western countries. Small lymphocytic lymphoma (SLL) is considered the same disease by the World Health Organization (WHO). CLL/SLL has not been extensively studied in Iceland with regards to epidemiology or outcome.
Aims: To assess the epidemiology, treatment and survival of CLL/SLL patients in Iceland.
Methods: This nation-wide study includes CLL/SLL patients diagnosed in Iceland during the years 2003-2016. Registries of patients with a CLL diagnosis were obtained from the Icelandic Cancer Registry, Landspitali National University Hospital and the Medical Center in Mjodd. Medical records were reviewed for information on symptoms, diagnosis and treatment. Survival data and causes of death were obtained from national registries. Time of data capture was March 2017.
Results: During the study period 213 patients were diagnosed with CLL/SLL in Iceland. The crude incidence rate was 4.8/100,000 person years (PY) and the WHO age standardized incidence rate was 3.4/100,000 PY. Symptoms were present at diagnosis in 98 (48.8%) patients (data available in 201 cases), but many patients (51.2%) were initially diagnosed due to incidental findings. The most common symptoms were palpably enlarged lymph nodes (n=51, 25.4%) and fatigue (n=48, 23.9%), while B-symptoms were present in 45 (22.4%). Of 77 (36.2%) patients that received chemotherapy, less than half (n=31, 40.3%) were treated within 5 years from diagnosis. The most frequently used first-line treatment was fludarabine, cyclophosphamide and rituximab (n=30, 39.0%). Both higher Rai stage ($p<0.01$) and the presence of symptoms at diagnosis ($p<0.01$) were significantly associated with shorter time to treat in univariate analysis. A total of 73 (34.3%) patients died during the study period. Five-year survival was 70% and median overall survival was 9.6 years. CLL/SLL was registered as the main cause of death in 31 (42.4%) cases, more frequently in patients that received chemotherapy ($p<0.01$). Higher lymphocyte counts and age at diagnosis, as well as earlier need for blood transfusion, were significantly related to poor survival in multivariate analysis.
Summary/Conclusion: The incidence rate of CLL/SLL in Iceland is similar to the incidence in other Western countries. Many patients were initially diagnosed with CLL/SLL after routine blood tests for other conditions. Most patients (85.4%) had not yet received any chemotherapy 5 years after diagnosis and the median overall survival was almost 10 years. The majority of patients died of other causes than CLL/SLL. Higher Rai stage at diagnosis predicted shorter time to treatment which is in accordance with the literature. However higher Rai stage was not significantly associated with shorter survival although there was a trend towards shorter survival for patients with Rai stage 3/4 compared to other Rai stages. That may be due to the small number of patients included, as well as the relatively short follow-up time.

Chronic myeloid leukemia – Biology & Translational Research

PS1109

ENRICHMENT OF ASXL1 PATHOGENIC VARIANTS AMONG PRIMARY REFRACTORY CML PATIENTS

K. Ayoola Gustafsson[1,*], U. Olsson-Strömberg[2], L. Arngården[2], M. Hermanson[3], P. Baliakas[1], L. Cavelier[4]

[1]Immunology,Genetics and Pathology, Science for Life Laboratory, Uppsala University, [2]Department of Medical Science, Division of Hematology, Uppsala University, [3]Immunology,Genetics and Pathology, Uppsala University Hospital, [4]Clinical Genomics, SciLife Laboratory, Uppsala, Sweden

Background: Little is known about the actual mechanism of resistance in patients with chronic myeloid leukemia (CML) with primary resistance to first and second-generation tyrosine kinase inhibitors (TKI), especially in the absence of mutations in the *ABL1* kinase domain and/or additional cytogenetic abnormalities. Preliminary evidence suggests that pathogenic variants in epigenetic regulator genes may be enriched among CML patients with suboptimal response. However, the studies published so far have included patients with various types of responses to TKI treatment, while in the great majority the presence of mutations within the *ABL1* kinase domain was evaluated with Sanger sequencing which does not allow the detection of small clones.
Aims: To evaluate whether pathogenic variants in genes are enriched at the time of diagnosis in primary refractory CML patients negative for mutations in the *ABL1* kinase domain evaluated with next generation sequencing.
Methods: The patient cohort consisted of 20 CML patients in chronic phase (male/female: 10/10, median age: 52) and primary failure, defined as the presence of >1% *BCR-ABL1* p210 IS (international standard) after one year of TKI treatment, excluding non-compliance. All patients were analyzed with (i) PacBio long-range sequencing, with a threshold of 1% for sensitive detection of *ABL1* kinase domain resistance mutations at the time of treatment failure, according to ELN guidelines and; (ii) NGS sequencing at the time of diagnosis using the TruSight myeloid panel (Illumina) with a threshold of 5%. The panel includes 54 genes recurrently mutated in myeloid malignancies. Longitudinal samples with a median follow-up of 21 months were available in 7 patients. The control group comprised 10 age and sex-matched CML patients with major molecular response within 6-12 months with first-line TKI therapy. Cytogenetic data was available for all patients.
Results: : 12 of 20 patients (60%) had a pathogenic truncating variant in *ASXL1* (n=7, 35%, median VAF=23%), *DNMT3A* (n=2, median VAF=51%), *IKZF1* (n=2, median VAF=9%), *GATA2* (n=1), *TP53* (n=1) or *NRAS* (n=1). All 12 patients carried only the t(9;22) translocation at diagnosis and did not acquire additional cytogenic abnormalities during the disease progression. Londitudinal samples of 3/7 patients with truncating *ASXL1* mutations and a median follow-up of 18 months, showed stable *ASXL1* VAF in parallel to *BCR-ABL1* level and no additional pathogenic variants. Interestingly, 5/7 patients carrying pathogenic variants in *ASXL1* were treated with third generation TKI, but showed no response and were eventually transplanted. Three of these patients with available clinical data remain in MMR after transplantation with a median follow up of 9 months. Within the 8 patients with no mutations in the TruSight myeloid panel, 3 developed clonal evolution with major route abnormalities (+8=2, der20=1), while 2/5 of the remaining patients carried variants of unknown significance (VUS) according to the ACMG criteria in the *CUX1* gene (median VAF=45%). No pathogenic variants or VUS were detected in the control group.
Summary/Conclusion: Detection of additional molecular abnormalities at the time of diagnosis especially in the *ASXL1* gene among patients with CML in chronic phase may be associated with primary resistance to the TKI treatment. Alternative therapeutic approaches should be considered for these patients.

PS1110

THE PIVOTAL ROLE OF INSULIN-LIKE GROWTH FACTOR PATHWAY AS A THERAPEUTIC TARGET IN ABL TYROSINE KINASE INHIBITOR RESISTANT LEUKEMIA CELLS

S. Okabe[1,*], T. Tauchi[1], Y. Tanaka[1], K. Ohyashiki[1]

[1]Department of Hematology, Tokio Medical University, Tokyo, Japan

Background: ABL tyrosine kinase inhibitors (TKIs) such as imatinib have demonstrated the potency against Philadelphia chromosome (Ph)-positive leukemia patients, however, some patients are still resistance to ABL TKIs. It has already reported that ABL kinase domain mutations have been implicated in the pathogenesis of ABL TKI resistance, however, mechanisms of intrinsic resistance without point mutation of ABL kinase domain are not fully understood.
Aims: Insulin-like growth factor (IGF) cause intracellular signaling that ultimately results in cellular growth and proliferation. Because IGF signaling pathways have crucial functions in hematological malignancies and solid tumors, IGF pathways may regulate ABL TKI sensitivity and drug resistant.
Methods: We established ABL TKI-resistant *in vitro* cell line models. The total expression profiles of four ABL TKI-resistant cell lines (K562 imatinib-R, K562 nilotinib-R, K562 dasatinib-R, K562 ponatinib-R) were examined using the Agilent Human Gene Expression Microarrays.
Results: We first investigated the relationship of IGF signaling pathways and ABL TKI sensitivity by microarray gene expression data from the online Gene Expression Omnibus (GEO). IGF is tightly regulated by six related IGF-binding proteins (IGFBPs). One of IGFBP, IGFBP5 is related to imatinib sensitivity and resistant in chronic myeloid leukemia (CML) patients from the public microarray datasets of GSE14671. We also found that gene expression of IGF2 and IGFBP5 were increased after imatinib treatment in CML patients (GSE12211). We next examined ABL TKI resistant cell lines (K562 imatinib-R, K562 nilotinib-R, K562 dasatinib-R, K562 ponatinib-R) in this study. BCR-ABL expression levels were not increased in ABL TKI resistant K562 cells compared to parental K562. We could not detect the BCR-ABL point mutation in ABL TKI resistant cells. Although cellular growth was reduced in ABL TKI resistant cells compared to parental cell line K562, these cells were highly resistant to ABL TKIs (K562 imatinib-R: imatinib 2 μM, nilotinib-R: nilotinib 2μM, dasatinib-R: dasatinib 100nM, ponatinib-R: ponatinib 50nM). Using the DNA microarray approach, we investigated gene expression profiles in cultured ABL TKI resistant K562 cells. We found gene expression of insulin-like growth factor 1 (IGF1) receptor (IGF1R) was increased ABL TKI resistant K562 cells. IGF1R gene amplification was confirmed by RT-PCR analysis. IGF1R is a transmembrane receptor implicated in the regulation of cell metabolism, growth, and survival. IGF signaling pathway may be a cause of resistance to ABL TKIs, we examined the IGF1R inhibitor in ABL TKI resistant cells. One of IGF1R inhibitor, linsitinib was not effective on parental K562 cells. In contrast, linsitinib inhibited ABL TKI resistant cells in a dose dependent manner. Combined treatment of ABL TKI resistant cells with imatinib and linsitinib caused more cytotoxicity than each drug alone. Caspase 3/7 activity and cellular cytotoxicity was also increased. We next blocked IGF1R function by small interfering RNA (siRNA). SiRNA transfected cells were reduced cellular proliferation. We also found drug sensitivity of the cells to the imatinib was increased compared to mock-transfected cells. Apoptotic cells and caspase 3/7 activity were increased after imatinib treatment in siRNA transfected cells.
Summary/Conclusion: The IGF signaling pathway is involved in ABL TKI sensitivity and drug resistant in CML cells. We also provide the promising clinical relevance as a candidate drug for treatment of ABL TKI resistant leukemia patients.

Background: A subset of patients diagnosed with Chronic Myeloid Leukemia (CML) is at elevated risk of progression to CML blastic phase (CML-BP) due to primary or acquired resistance to treatment with tyrosine kinase inhibitors (TKI-res). While leukemic clones harboring BCR-ABL1 kinase domain mutations are responsible for majority of clinical resistance cases, predicting TKI response is still challenging.
Aims: We and others previously reported an incidence of somatic mutations

in myeloid-associated genes in CML patients progressing to CML-BP. Here, we aimed to assess prevalence of those mutations in a group of 23 patients with TKI-res (as confirmed by loss of molecular and/or cytogenetic response according to ELN criteria) and compare this group with our previously reported cohort of 36 CML patients, who reached major molecular response (MMR) within 6 months from the start of treatment and remained in MMR for at least 4 years.

Methods: We applied next-generation sequencing (Roche SeqCap EZ, Illumina HiSeq) to determine mutational status of ~1000 cancer-associated genes. We also analyzed disturbances in variant allele frequencies (VAF) of common SNPs along with coverage analysis to detect any major chromosomal aberrations.

Results: The most common detected genetic alterations in TKI-res patients were *ASXL1* truncating mutations (7/23 patients, 30,4%) and *BCR-ABL1* kinase domain mutations (5/23, 21,7%). In 3 patients (13%) we observed co-existence of *ASXL1* and *BCR-ABL1* mutations. All of *ASXL1*/*BCR-ABL1* mutations had VAFs ranging from 12 to 52%, suggesting that they were harbored by dominant clones, except for one patient (Res6) who had three different *ASXL1* mutations, two of which were subclonal (Table 1). We noted a significantly higher frequency of *ASXL1* mutations in TKI-res patients than in our cohort of MMR patients (7/23 vs 2/36, p=0.0213; Fisher exact test). We did not observe any additional chromosomal aberrations in any of the patients.

Table 1. BCR-ABL1 and ASXL1 mutations in patients from TKIres and MMR cohorts.

Patient	Mutation		VAF [%]	
	BCR-ABL1	ASXL1	BCR-ABL1	ASXL1
Res1	Gln252His	-	52.6	-
Res2	Ile418Val	Tyr591_Gln592fs	31.3	34.1
Res3	Met244Val	-	20.0	-
Res4	Thr315Ile	Ala640fs	19.0	12.2
Res5	Thr315Ile	Gly643_Gly644fs	28.5	31.2
Res6	-	Arg693*/Asp943_Leu944fs/Tyr591*	-	37.7/5.94/4.54
Res7	-	Glu797*	-	41.0
Res8	-	His630fs	-	40.4
Res9	-	Lys686fs	-	43.0
MMR1	-	Gly643_Gly644fs	-	21.6
MMR2	-	Gly643_Gly644fs	-	36.4

Summary/Conclusion: According to several reports, *ASXL1* is one of the most commonly mutated genes in CML besides *BCR/ABL1* itself. Our data indicates that inactivating mutations in *ASXL1* may precede clinical resistance or emerge with the TKI-resistant clone. This emphasizes the potential biological importance of somatic mutations in epigenetic regulators such as *ASXL1* in the resistance to TKI. Further studies in terms of patient cohorts extension as well as verification of detected mutations in diagnostic samples are warranted.

PS1112

THE UNCOVERING OF A BCR-ABL1 TYROSINE KINASE-INDEPENDENT SIGNATURE REVEALS NEW POTENTIAL THERAPEUTIC TARGETS IN CHRONIC MYELOID LEUKAEMIA STEM CELLS

E. Gomez-Castaneda[1,*], C. Munje[1], R. Hyde[1], F. Pellicano[1], D. Vetrie[2], H. Wheadon[1], M. Copland[1], T. Holyoake[1], L. Hopcroft[1], S. Rogers[3], H. Jørgensen[1]

[1]Paul O'Gorman Leukaemia Research Centre, [2]Wolfson Wohl Translational Cancer Research Centre, [3]School of Computer Science, University of Glasgow, Glasgow, United Kingdom

Background: Although the introduction of tyrosine kinase inhibitors (TKI) into clinical practice at the beginning of the century greatly increased life expectancy of patients with chronic myeloid leukaemia (CML), the majority of CML patients are not cured, and a small population of leukemia stem cells (LSCs) persist despite treatment and may reinitiate the disease upon treatment withdrawal. Thus, most patients require life-long therapy, meaning a higher risk of treatment side effects and the prolonged psychological burden of living with leukemia. It has already been demonstrated that CML LSCs are not addicted to BCR-ABL1 tyrosine kinase (TK) and that they survive under suppression of the kinase.

Aims: To uncover BCR-ABL1 TK independent mechanisms in CML LSCs and target these to eradicate CML LSCs.

Methods: Public microarray datasets were analysed with *limma/Bioconductor* to detect differential gene expression between CML LSCs and normal hematopoietic stem cells (HSC; GSE47927 and E-MTAB-2581) and to detect genes not affected by TKI treatment (E-MTAB-2594). Validation of gene expression was performed in CD34$^+$ cells from 5 CML patients and 2 healthy donors. For this, CML CD34$^+$ cells were cultivated in serum free media without growth factors for 7 days±5μM imatinib. Targeting of the BCR-ABL1 TK independent genes was performed by treating CD34$^+$ CML and normal cells with different concentrations of gemtuzumab-ozogamicin (GO) or cyclosporine A (CsA)±2 μM imatinib in serum free media with physiological growth factors (SCF, G-CSF, GM-CSF, IL6, LIF and MIPα). The effect of treatment was measured by cell counts; annexin V-DAPI, Ki-67-DRAQ7, and γH2AX staining; and colony forming cell (CFC) assay. IC_{50} were calculated using *drc* package for R.

Results: Microarray analyses revealed 527 consistently de-regulated genes in CML and 5,706 genes not affected by TKI treatment. The comparison of both lists revealed a 60 gene signature that is differentially expressed in CML LSC (as compared with normal HSC) and not affected by TKI treatment of CML CD34$^+$ cells. Of the 60, 4 genes (*CD33, CHST2, PPIF, ERG*) were validated in a set of independent patients and controls by qPCR. *CD33*, a myeloid cell surface marker, and *PPIF*, a key member of the mitochondria permeability transition pore that is an important regulator of both apoptosis and necrosis, were found to be upregulated in CML. Both can be targeted by clinical grade compounds GO and CsA, respectively. These drugs proved effective at targeting CML CD34$^+$ cells *in vitro*. GO had an IC_{50} of 136ng/mL, which is 19 times lower than the control after 72h of treatment and about 7 times lower than the FDA-approved dose for AML (≈1000 ng/mL). CFC counts were reduced by 95% after 72h 100 ng/mL GO + 2 μM imatinib in CML compared with 78% in normal controls, mirroring the apoptosis staining by flow cytometry (83% and 71% reduction in viability, respectively). Preliminary results shows that the IC_{50} of CsA was 4 μM when treating CML CD34$^+$ cells, 2-fold lower than in the healthy controls.

Summary/Conclusion: CML LSCs have de-regulated gene expression that is not corrected by TKI treatment, further supporting the hypothesis that CML LSCs have TKI-independent pathways contributing to TKI persistence. We have shown that targeting these proteins leads to a decrease in the number of CML CD34$^+$ cells and in the number of CFC. Taken together, our work confirms the existence of the BCR-ABL1 TK independent signature in CML LSCs and represents an avenue for novel therapy in CML.

PS1113

OPTIMAL TIME POINT FOR BCR-ABL1 KD MUTATION ANALYSIS IN CML PATIENTS; BASED ON 2013 ELN GUIDELINE

Y. R. Do[1,*], H.-L. Yoo[2], S.-H. Kim[2], S.-Y. Choi[2], M.-Y. Lee[2], H.-Y. Song[2], K.-H. Kang[2], K.-M. Ki[2], J.-H. Suh[2], S.-Y. Yang[2], S. Oh[3], S. H. Kim[4], D.Y. Zang[5], S.-E. Lee[6], D.-W. Kim[7]

[1]HematoOncology, Medicine, Keimyung University, Dongsan Medical Center, Daegu, [2]Leukemia Research Institute, [3]HematoOncology, Medicine, Sungkyunkwan University, Kangbuk Samsung Hospital, Seoul, [4]HematoOncology, Medicine, Dong-A University Hospital, Busan, [5]HematoOncology, Medicine, Hallym University Hospital, [6]HematoOncology, Medicine, [7]Department of Hematology, Seoul St. Mary's Hospital, The Catholic University , Seoul, Korea, Republic Of

Background: BCR-ABL1 kinase domain (KD) mutations are closely related to tyrosine kinase inhibitor (TKI) resistance in chronic myeloid leukemia (CML). Although mutation analysis has been suggested in CML patients with treatment failure, there is no standard guideline according to landmark responses at specific timepoints of European LeukemiaNet (ELN) recommendation.

Aims: To determine appropriate timepoints for mutation analysis, the frequency and type of BCR-ABL1 kinase domain mutation were analyzed using Sanger sequencing and were assessed by achieving landmark responses at specific timepoints.

Methods: From 605 newly diagnosed chronic phases CML patients, 961 peripheral blood samples were analyzed for BCR-ABL1 KD mutation and all of patients were treated with frontline imatinib for at least 3 months. The patients with atypical transcripts were excluded. Hematologic, cytogenetic, and molecular responses on 3, 6, and 12 months were also assessed by ELN criteria. To determine appropriate timepoint for mutation analysis, the frequency and type of BCR-ABL1 KD mutation were analyzed using Sanger sequencing and were assessed by achieving landmark responses at specific timepoints

Results: Of the 605 patients, BCR-ABL1 KD mutations were detected in 28 patients (4.6%) and a total of 33 mutations were detected. Of the 33 mutations, 23 mutations (69.7%) were highly resistant mutations of T315I and P-loop. In cytogenetic response criteria, the mutation frequencies of optimal, warning and failure group were 0.7% (5/671 samples), 1.8% (2/110 samples) and 16.0% (17/106 samples) respectively and were 0.7% (3/425 samples), 3.6% (13/359 samples) and 7.6% (13/172 samples) respectively in molecular response criteria. Under 18 different response criteria of

ELN recommendation, there was a higher incidence of mutations among patients with 12 month-cytogenetic treatment failure (21.8%; 12/55 patients), 3 month-cytogenetic treatment failure (20.0%; 3/15 patients) and 12 month-molecular treatment failure (9.3%; 10/107 patients). Interestingly, mutations were also detected in 5 optimal cytogenetic responders (2/280 patients at 6 month-criteria and 3/241 patients at 12 month-criteria; 1 G250E, 2 Y253H, 1 V280M and 1 M351T)

Summary/Conclusion: We conclude that some patients with treatment failure, especially with cytogenetic criteria, should be warranted for mutation analysis. In addition, the majority of patients with warning criteria may be enough only with a close monitoring without routine mutation analysis. However, as a few patients with optimal response had mutation, mutation analysis should not be totally excluded.

PS1114

CLONAL SELECTION DETERMINES RESULTANT DOMINANCE OF TYROSINE KINASE INHIBITOR-RESISTANT CELLS IN CHRONIC MYELOID LEUKAEMIA

B. Leow[1,2,*], L. Eadie[1,2], I. Pagani[1,2], D. Yeung[1,2], T. Hughes[1,2], D. White[1,2]

[1]Cancer Theme, South Australian Health and Medical Research Institute, [2]Health Sciences, University of Adelaide, Adelaide, Australia

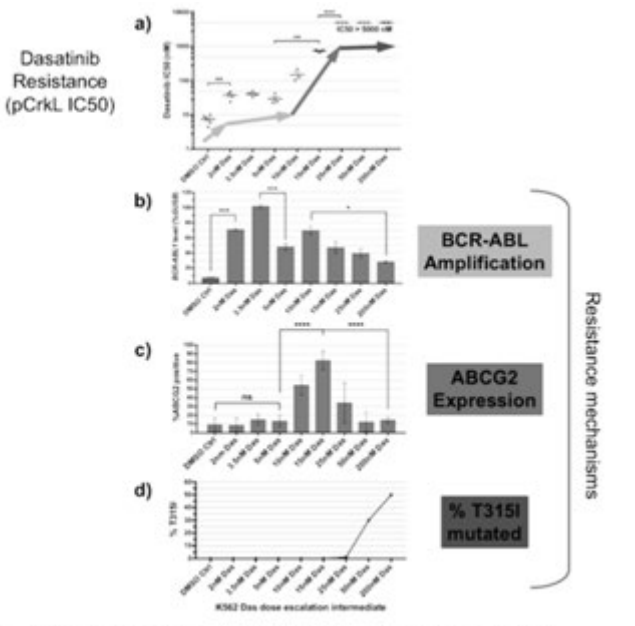
Background: Emergence of resistance to therapeutic drugs is detrimental to treatment effectiveness in CML. Modelling the clonal dynamics of accrued drug resistance can aid the design of therapeutic strategies. Excessive myeloproliferation is driven by the constitutively active tyrosine kinase, BCR-ABL, and has been treated effectively using tyrosine kinase inhibitor (TKI) therapy. However, TKI resistance is an issue in a significant subset of patients, whose prognosis remains poor. Mechanisms of TKI resistance include: the overexpression of BCR-ABL; perturbed TKI influx/efflux transporter activity; single nucleotide mutations in BCR-ABL which preclude TKI binding, and loss of dependence on BCR-ABL kinase activity. Several studies have observed a temporal order to the emergence of resistance mechanisms, with shifts in clonal architecture altering therapy sensitivity. Here, a model of natural selection describes accrual of drug resistance, informing the fitness and resultant clonal dominance of leukaemic cells during TKI treatment, as well as upon treatment withdrawal.

Aims: To determine the effect of various TKI resistance mechanisms on the survival of a BCR-ABL+ leukaemic cell population, over the course of increasing TKI exposure and treatment withdrawal. To examine TKI cross-resistance and find novel treatment strategies to target TKI resistant cells.

Methods: A dasatinib (Das) resistant K562 cell line was established by culture in increasing concentrations of Das over 11 months. Intermediate samples harvested over Das dose escalation were examined. Sensitivity of cell viability and BCR-ABL activity to gradient Das was determined by AnnV/7-AAD co-stain, and phospho-CrkL IC50. TKI resistance mechanisms were explored by transcriptome RNAseq, interrogating gene expression, structural rearrangement and nucleotide variant analysis. Results were validated by PCR, Sanger sequencing, flow cytometry (ABC membrane transporters ABCB1/ABCG2), and western blotting analysis (BCR-ABL and CrkL IC50 in the presence of ABCG2 inhibitor, Ko143). To determine the effect of resistance mechanisms on selection and clonal architecture, Das resistant cells were cultured for prolonged periods +/- Das, recording the effects on CrkL IC50 and continued expression of resistance mechanisms.

Results: Resistance to clinical doses of Das was attained during dose escalation, evidenced by increased Das IC50 and decreased Das induced cell death (Figure 1a, $p<0.01$). qPCR results implicated perturbed BCR-ABL signalling (Figure 1b), and expression of efflux pump, ABCG2 (Figure 1c), transiently overexpressed during acquired drug resistance. This finding was validated with functional studies: flow cytometry demonstrated increased membrane expression of ABCG2 ($p<0.001$), and inhibition of ABCG2 function using the small molecule inhibitor, Ko143, sensitised these cells to TKI-induced cell death. Additionally, variant analysis of resistant K562 lines identified the BCR-ABL kinase domain mutation, T315I, which completely abrogated Das binding (Figure 1d). Importantly, these resistance mechanisms also contributed to a significant decrease in sensitivity to the 3rd generation inhibitor, ponatinib, used for TKI-refractory disease. Withdrawal of TKI in culture resulted in lowered IC50, re-sensitising leukaemic cells to treatment.

Summary/Conclusion: In a therapy resistant context, flux in clonal cell populations leads to shifts in sensitivity to TKI therapy. Our model, recapitulating several relevant resistance mechanisms, enables an accurate description of the dynamics of drug resistance in future research.



Resistance to dasatinib in K562 cell line increases following dose escalation in dasatinib, via multiple, temporally overlapping resistance mechanisms.

Figure 1.

WT1 ANALYSIS IN CHRONIC MYELOID LEUKEMIA (CML) PATIENTS

S. Coluzzi[1,*], T. Introcaso[1], F. Perutelli[2], S. P. Pascale[1], O. Villani[3], F. Guerrini[2], G. Bianchino[3], A. Matturro[1], I. Attolico[1], D. Vertone[1], N. Filardi[1], A. Amendola[1], R. Nuccorini[1], G. Pietrantuono[3], S. Galimberti[2], M. Pizzuti[1]

[1]U. O. di Ematologia, Azienda Ospedaliera Regionale San Carlo, Potenza, [2]Dipartimento di medicina clinica e sperimentale, Università di Pisa, Pisa, [3]IRCCS Crob, Rionero in Vulture (Pz), Italy

Background: Diagnosis and monitoring of CML patients is based on bcr/abl evaluation by RQ-PCR. ELN guidelines show that bcr/abl superior to 10% after 6 months of therapy and bcr/abl superior to 1% after 12 months of therapy are defined as failure of therapy. Different clinical parameters are used to predict patients' prognosis at onset in the three most commonly used score indexes. No other useful tools have been identified. WT1 gene is over expressed at onset in several diseases including 80% of Acute Myeloid Leukaemia cases (AML): gene's levels decrease during disease remission and are low in healthy people. WT1 is over expressed also in case of AML relapse. Few data are available on WT1 expression in CML patients.

Aims: The aim was to investigate the role of WT1 in CML outcome and prognosis.

Methods: We evaluated 58 patients with CML referred to our centres between 2009 and 2018. RT-PCR and RQ PCR on RNA were performed to quantify bcr/abl and WT1 in the peripheral blood of all patients at onset and after 3, 6, 9, 12 months of therapy and after (median follow up 39 months, range: 9-106). The type of transcript was p210 b2a2 in 10 pts, p210 b3a2 in 30, both in 4 pts, 14 were not analyzed. Sokal risk was low in 24 pts, intermediate in 19, high in 14, not evaluable in 1 patient. 34 patients received Imatinib, 7 Dasatinib and 17 Nilotinib as first line therapy.

Results: ROC analysis defIned a cut-off value of 156 (WT1/Abl*10e4) usefull to discriminate at onset patients who will have failure on ELN criteria basis from patients without failure (sensibility 69%, specificity 76%).
21/58 of patients (36%) had high levels of WT1 (WT1-H) at onset. Sokal risk was high in 8, intermediate in 6, low in 7. 37/58 of patients (64%) had low levels of WT1 (WT1-L): Sokal risk was high in 6, intermediate in 13, low in 17, not evaluable in 1. We observe that sokal risk is independent of WT1. 16/21 WT1-H patients were evaluable for bcr/abl at three months of therapy: 3 had bcr/abl > 10%, 7 between 1 and 10% and 6 lower than 1%. 32/37 WT1-L patients were evaluable at three months: 4 had bcr/abl > 10%, 9 between 1 and 10%, 19 lower than 1%. At sixth month the differences between the two cohorts seems more clear: 7/19 (36%) of WT1-H and only 6/31 (19%) of WT1-L patients showed bcr/abl levels>1%. Moreover, the outcome of the two groups seems different. During follow up, 11/21 (52%) WT1-H patients had a failure on ELN criteria basis, and needed to change

therapy with second line drug; 7 of them used Imatinib as first line therapy. 5/37 (13%) WT1-L patients had a failure and changed therapy. The EFS, intended as survival of patient until failure on ELN criteria basis, is rappresented in the Figure 1. Patient actual status is also different in the two groups. 14/21 (66%) WT1-H patients are in MR3 or better, 7/21 (33%) in MR2 or worse (among these 2 patients died). 29/37 (78%) WT1-L patients are in MR3 or better, 8 (22%) in MR2 or worse (1 patient died).

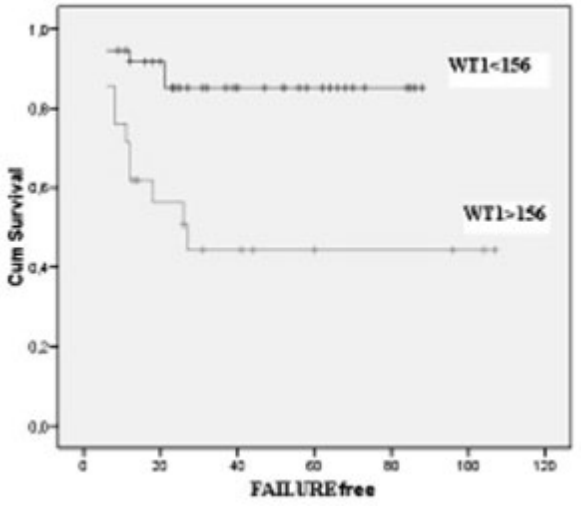

Figure 1.

Summary/Conclusion: In our study cohort, WT1-H patients seem to have a worse outcome than WT1-L, in terms of failure free survival and molecular response: 52% of WT1-H patients vs 13% of WT1-L patients had failure and needed to change therapy. So, WT1 could be a prognostic marker at onset. We suppose that WT1-H effect could be neutralized by correct use of second generation TKI. However, we need to study a larger number of patients to confirm this hypothesis.

PS1116

DIGITAL DROPLET PCR MAY BETTER IDENTIFY CANDIDATES FOR TREATMENT DISCONTINUATION IN CHRONIC MYELOID LEUKEMIA REGARDLESS OF MEDIAN TREATMENT DURATION

G. Colafigure Ii[1,*], M. Breccia[1], D. Diverio[1], M. Molica[1], M.G. Loglisci[1], A. Guarini[2], R. Foà[1]

[1]Department of Cellular Biotechnologies and Hematology, [2]Molecular Medicine, Hematology, Sapienza University, Rome, Rome, Italy

Background: Discontinuation of tyrosine kinase inhibitors (TKIs) in patients with chronic myeloid leukemia achieving a deep molecular response (DMR) would be an innovative cost-effective strategy in order to reduce long-term toxicity. Several studies have reported that about 40% of patients maintain the response after therapy discontinuation and reach a treatment free-remission. BCR-ABL1 transcript quantification is usually performed by RQ-PCR, but the lower limit of detection (LOD) or quantification (LOQ) may be insufficient to manage CML patients candidates for discontinuation. Digital droplet PCR (ddPCR) is a highly accurate molecular approach that could prove advantageous for the quantification of the BCR-ABL1 fusion transcript copy number.
Aims: To evaluate the feasibility of ddPCR evaluation in CML patients who have reached a DMR, in order to verify the advantage in terms of LOD and LOQ, to validate the test and to propose the quantification of residual transcript amounts as an alternative test prior to discontinuation.
Methods: We tested RNA samples from 50 patients who were in undetectable MR4.5 according to IS previously evaluated by RQ-PCR. The ddPCR assay was carried out in triplicate using the Biorad-QX100 platform. To test the BCR-ABL1 fusion transcript and ABL control gene, we used the same primers and probes used in the standard RQ-PCR reaction. Each reaction mixture was partitioned into approximately 20,000 droplets and then amplified. Cycled droplets were read in the QX200 droplet-reader and analysis of the ddPCR data was performed using the QuantaSoft analysis software. The threshold was manually set using the FAM channel and expressed as the absolute number of BCR-ABL1 copies. Samples yielding a minimum of 1 positive droplet scored as positive.
Results: We analyzed 50 patients in undetectable MR4.5 by RQ-PCR after a median time of treatment of 8.9 years [1.4-14.4]. There were 25 males and 25 females, median age was 63.4 years [37.5-85.5]. Forty-one patients had been treated with imatinib, while 9 patients had received second generation TKIs. In 29 (58%) patients, ddPCR confirmed the negativity of the samples, whereas in 21 (42%) a positivity was detected in at least 1 droplet with a median of 0.52 [0.22-2] BCR-ABL1 copies. We did not identify significant differences in baseline clinical features between ddPCR-positive and ddPCR-negative patients. No differences were revealed according to Sokal risk or in the type of TKI used as first-line treatment to reach a DMR between the two groups. Ten and 8 patients had been previously exposed to IFN-α in the ddPCR-positive and ddPCR-negative groups, respectively. The duration of stable DMR was 2.7 years [0.4-3] and 3.3 years [1.5-4.3] in ddPCR-positive and ddPCR-negative patients, respectively (p=ns). The median duration of treatment was 7.2 years in the ddPCR-positive group versus 9.6 years in the ddPCR-negative group (p=ns).
Summary/Conclusion: Our results suggest that ddPCR could be superior in terms of quantification of low levels of residual disease without the need of a calibration curve, as compared to classic RQ-PCR, in the same clinical conditions. In our cohort, considering any ddPCR positivity we could detect 42% of patients with a likely presence of minimal residual disease, suggesting that this tool increases the likelihood of identifying patients who could (or not) attempt TKI discontinuation within patients with an undetectable MR4.5, independently of the median time of treatment and of a stable DMR.

FREQUENCY OF TYPICAL AND ATYPICAL FUSION TRANSCRIPTS IN PATIENTS WITH BCR-ABL1-POSITIVE LEUKEMIAS – A SINGLE INSTITUTION STUDY

G. Balatzenko[1,*], M. Guenova[2], K. Ignatova[3], S. Ivanova[4], J. Stoyanova[3], A. Lilova[3], V. Stoeva[3], Y. Petrov[3], E. Hadjiev[5], G. Tsvetkova[6], B. Spassov[3]

[1]Laboratory of Cytogenetics and Molecular Biology, National Specialised Hospital for Active Treatment of Hematological Diseases, [2]Laboratory of Hematopathology and Immunology, [3]Department of Clinical Hematology, [4]Laboratory of Cytogenetics and Molecular Biology, National Specialized Hospital for Active Treatment of Hematological Diseases, [5]Clinic of Hematology, Medical University Sofia, Faculty of Medicine, Department of Internal Diseases, UMHAT Alexandrovska, [6]Clinic of Hematology, Medical University Sofia, Faculty of Medicine, Department of Internal Diseases, UMHAT Alexandrovska, Sofia, Bulgaria

Background: At molecular level, Philadelphia (Ph)-chromosome results in a heterogeneous group of different *BCR-ABL1* fusion genes. The identification of the type of *BCR-ABL1* mRNA is highly recommended because: (i) some of these transcripts could be missed by the routinely used reverse-transcription polymerase chain reaction (RT-PCR) techniques; (ii) the conventional reagents and protocols used for molecular monitoring might yield false negative results; and (iii) clinical features, course of disease and response to treatment might be different depending on the type of transcripts.
Aims: To determine the incidence of typical and atypical transcripts in a large cohort of patients with *BCR-ABL1* leukemias.
Methods: Between 1998 and 2018, 950 patients (pts) were found to be *BCR-ABL1*-positive, as follows: 845 with chronic myeloid leukemia (CML) [402 females/443 males, mean age 51.8±17.1 years, including 25 (3.0%) children and 820 (97%) adults]; 87 with acute lymphoblastic leukemia (ALL) [39 females/48 males; mean age 39.4±23.1 years; 16 children (18.4%) and 71 (81.6%) adults]; 5 adults with acute biphenotypic leukemias (ABL) [2 females /3 males; mean age 43.5±11.5 years); 15 adults with AML [8 females/7 males; mean age 54.7±11.9 years]. *BCR-ABL1* (both p210 and p190) at diagnosis was determined by qualitative RT-PCR using BIOMED-1 protocol.
Results: In CML, typical p210 *BCR-ABL1* transcripts were found in 827 (97.9%) pts, including 460 (55.6%) b3a2, 340 (40.2%) b2a2 and 27 b3a2/b2a2 (3.2%). In 36 of these pts (4.4%), in addition to the p210 *BCR-ABL1* mRNA, e1a2 transcripts were found, most commonly in cases diagnosed in advanced stages of CML. In the remaining 18 (2.1%) cases, atypical *BCR-ABL1* transcripts were found, including e1a2 (n=9); e6a2 (n=3); e19a2 (n=2); b2a3 (n=2), b3a3 (n=1) and 1 case with transcripts amplified by m-BCR primer, not further specified. Besides, in one another case, despite of the presence of typical b2a2 transcripts at the diagnosis, a qualitative RT-PCR monitoring using 2 different commercially available kits for manual and automated testing showed false negative results suggesting the presence of additional rearrangements within the fusion gene. Among 12 pts with atypical transcripts treated with tyrosine kinase inhibitors, 8 (66.7%) fail to respond to therapy, while among the remaining 4 pts with molecular response, *BCR-ABL1* negativity was documented in 2 cases (16.7%) with

b3a2 and b2a2 transcripts, respectively. In ALL, p190 and p210 transcripts were detected respectively in 53 (60.2%) and 34 cases (38.6%)[i.e. 18 b2a2 and 16 b3a2; in 3 cases with co-expression of e1a2]. Atypical e1a3 (1.1%) was observed on one case. Pts with P190 transcripts were significantly younger compared to P210-positive pts – 36.6±21.8 years vs. 47.4±21.3 years (p=0.039). In ABL, 3 pts were positive for e1a2, 1 for b3a2 and 1 for b2a2. In AML, 7 pts were positive for p190 (e1a2) and 8 pts for p210 (6 b2a2; 2 b3a2, with co-expression of e1a2 in one of them).

Summary/Conclusion: Our study further confirms the extreme heterogeneity of *BCR-ABL1* positive leukemia patients, as detected by qualitative RT-PCR. In CML, atypical *BCR-ABL1* rearrangements, although rare, account for 2.1%, and raise several practical issues concerning their monitoring and frequently non-optimal response to the applied therapy.

PATIENT-SPECIFIC BCR-ABL1 GENOMIC FUSION ANALYSIS OF MINIMAL RESIDUAL DISEASE OF CML PATIENTS ELIGIBLE FOR TKI STOPPING SIGNIFICANTLY OUTPERFORMED MRNA DETECTION EITHER BY QPCR OR DIGITAL PCR

K. Machova Polakova[1,*], H. Zizkova[1], E. Motlova[1], P. Pecherkova[1], J. Zuna[2], L. Hovorkova[2], O. Zimmermannova[2], T. Jurcek[3], K. Vlcanova[1], H. Klamova[1], N.C. Cross[4,5], A. Hochhaus[6], T. Ernst[6]

[1]Institute of Hematology and Blood Transfusion, [2]CLIP, Dept. of Paediatric Haematology and Oncology, Second Faculty of Medicine, Charles University and University Hospital Motol, Prague, [3]Center of Molecular Biology and Gene Therapy, Internal Hematology and Oncology Clinic, Faculty Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Czech Republic, [4]Wessex Regional Genetics Laboratory, Salisbury NHS Foundation Trust, Salisbury, [5]Faculty of Medicine, University of Southampton, Southampton, United Kingdom, [6]Abteilung Hämatologie/Onkologie, Klinik für Innere Medizin II, University of Jena, Jena, Germany

Background: Data from clinical studies on stopping tyrosine kinase inhibitor (TKI) treatment of eligible patients with chronic myeloid leukemia (CML) show that a TKI cessation treatment protocol is safe under strict conditions and 40-60% of patients may sustain treatment free remission. The critical issue of the protocol is the sensitive and precise monitoring of deep molecular response (DMR)/minimal residual disease (MRD). The ELN recommended the use of standardized qPCR of Major BCR-ABL1 transcripts for MRD assessment; a limitation of qPCR is accurate detection and quantification of rare targets. Published data indicates that digital PCR may enable more sensitive and accurate assessment of DMR. Furthermore, DNA assays detecting patient specific BCR-ABL1 genomic fusions may uncover the presence of residual CML cells in cases with undetectable BCR-ABL1 transcripts.
Aims: To assess differences of MRD detection of BCR-ABL1 by 4 approaches in CML patients who responded to TKI treatment with sustained DMR.
Methods: BCR-ABL1 DNA fusions were identified in 78 CML patients. TKI was stopped in 14/78 patients within the EURO-SKI study. So far, DNA specific assays for quantification by qPCR and droplet digital PCR (ddPCR) have been optimized for 42 patients. DNA and RNA were extracted from the same number of leukocytes per sample of peripheral blood (PB) from regularly scheduled monitoring in practice or EURO-SKI study. Bone marrow (BM) was collected at the time of sustained DMR in 7 patients to follow differences in MRD detection between BM and PB. For each approach applied, mRNA qPCR (1), DNA qPCR (2), mRNA ddPCR (3) and DNA ddPCR (4), we established stringent quality requirements to exclude poor quality samples from evaluations (Table 1). So far, we analyzed 829 paired PB samples with BCR-ABL1 transcripts at levels <0.1% BCR-ABL IS from 42 patients by (1) and (2) and 423 paired PB samples of 22 patients by (3) and (4). Two-proportion z-test was applied to compare the level of sensitivity.

Table 1. Condition for data evaluation.

Assay	Negative (score 3)	Positive unquantifiable (score 2)	Positive quantifiable (score 1)	Sensitivity
(1) *mRNA qPCR	Negative triplicates or averaged copies less than LoD	Averaged copies within the range LoD-LoQ	Averaged number of copies equal or higher than LoQ	At least 24000 copies of control gene GUSB ensuring sensitivity MR[4]
(2) mRNA ddPCR	Negative quadruplicates or averaged copies less than LoD	Averaged copies within the range LoD-LoQ	Averaged number of copies equal or higher than LoQ	
(3) **DNA qPCR	Negative triplicates or more than 4 Ct higher than the highest Ct of the individual calibration curve	Up to 4 Ct higher than the highest Ct of the individual calibration curve	Averaged Ct of triplicates within a quantification range specified by individual calibration curve	At least 20000 copies of control gene ALB (reflecting 10000 cells) ensuring sensitivity 10^{-4}
(4) DNA ddPCR	Negative quadruplicates (no copy detected in negative controls of 6 healthy donors)***	NA	Averaged copy number (no copy detected in negative controls of 6 healthy donors)***	

* Conditions differ from the evaluation of deep MR recommended by ELN (Cross et al. Leukemia 2016) to ensure reliable comparison with qPCR DNA analysis, which is patient specific.
** Conditions were applied as was previously described in Hovorkova et al. Blood 2017.
*** All droplets observed after ddPCR DNA analysis of patient-specific assays were negative when 6 healthy donors were analyzed.
Abbreviations: LoD = Limit of Detection; LoQ = Limit of Quantification; ALB = albumin (ALB is recommended control gene for analysis of patient specific Ig/TCR rearrangement; standardized primers and probes were applied from EURO-MRD consortia)

Results: DNA analysis showed better score for BCR-ABL1 detection and quantification by qPCR (for scoring see Table 1) in 338/829 (41%) paired samples (PS) compared to mRNA, while BCR-ABL1 at mRNA level was better in 42 (5%) cases (p<0.0001). When we adjusted the level of sensitivity for mRNA and DNA analysis of PS, we found, that at level $MR^{4-4.5}$ or 10^{-4}

(n=484), respectively, DNA analysis was more sensitive in 163 (34%) PS, while the mRNA BCR-ABL1 was more sensitive in 27 (6%) PS (p<0.0001). At level MR^5 and 10^{-5} (n=43), respectively, DNA was more sensitive in 14 (33%) PS and less sensitive than mRNA in 2 (5%) PS (p=0.0023). DNA analysis was more sensitive by ddPCR in 194/423 PS (46%), while mRNA was better in 6 PS (1.4%) (p<0.0001). DdPCR increased sensitivity of mRNA compared to qPCR in 96/614 PS (16%). We did not observe any differences in BCR-ABL1 detection between PB and BM using all 4 approaches in 7 patients with sustained DMR. In one patient BCR-ABL1 was positive by (3) and (4) in PB but not in BM. When we analyzed whole extracted DNA from BM by (4) we detected 2.2 BCR-ABL1 copies in $20x10^6$ copies of ALB.
Summary/Conclusion: BCR-ABL1 DNA-based approaches were more precise and sensitive than mRNA analyses in significant number of patient samples of peripheral blood. Whether this difference will be reflected also in better outcome prediction within TKI stopping protocols remains to be addressed in subsequent long-term analysis.

TREATMENT-FREE REMISSION AFTER SECOND-STOP OF IMATINIB THERAPY IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE

S. Oh[1,*], S.-E. Lee[2], S.-Y. Choi[3], S.-H. Kim[2], S.-H. Kim[4], D.Y. Zang[5], Y.R. Do[6], J.-Y. Kwak[7], J.-A. Kim[8], D.-W. Kim[9]

[1]Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University, [2]Hematology, Seoul St. Mary's Hospital, The Catholic University of Korea, [3]Hematology, Seoul St. Mary Hospital,The Catholic University of Korea, Seoul, [4]Internal Medicine, Dong-A University College of Medicine, Pusan, [5]Internal Medicine, Hallym University College of Medicine, Anyang, [6]Hematology-Oncology, Keimyung University Hospital, Daegu, [7]Hematology, Chonbuk National University Hospital, Jeonju, [8]Hematology, St. Vincent Hospital, Suwon, [9]Hematology, Seoul St. Mary Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Based on the accumulated results from clinical trials during the last 10 years, it is known that about 50% of chronic phase chronic myeloid leukemia (CP CML) patients with sustained deep molecular responses after enough tyrosine kinase inhibitors (TKIs) therapy may successfully stop their TKI therapy. Consequently, treatment-free remission (TFR) has been a new therapeutic goal. However, for the patients who relapsed after imatinib (IM) discontinuation, the questions on the best type of TKI for reintroducing and possibility of a second TKI discontinuation attempt are not clear.
Aims: We analyzed data from patients who regained durable deep molecular response after IM resumption for relapse and stopped IM therapy again in the Korean multicenter prospective study (Korean Imatinib Discontinuation Study; KID Study).
Methods: CP CML patients who were treated with IM for more than 3 years and had undetectable levels of BCR-ABL1 transcripts determined by quantitative reverse transcriptase polymerase chain reaction (PCR) for at least 2 years were eligible for KID study and in cases of MMR loss after 2 consecutive assessments, IM treatment was re-introduced. After IM resumption for MMR loss, the molecular response was evaluated every month until MMR was re-achieved and every 3 months thereafter. The second stop was permitted in the patients who were in second UMRD for at least 2 years.
Results: Among patients who lost MMR in 2 consecutive analyses and resumed IM in the KID study, 17 patients (9 men and 8 women) with a median age of 45 years (range, 18-63 years) entered into a second IM discontinuation after sustaining a second UMRD for a median of 25.9 months (range, 23.9-37.1 months). After a median follow-up of 17.1 months (range, 0.7-50.9 months) after second IM discontinuation, 13/17 patients (76%) and 11/17 patients (65%) lost UMRD and MMR, respectively. Among two patients who lost UMRD but not MMR, one patient showed fluctuation of *BCR-ABL1* transcript under the level of 0.1% on IS for 19.5 months and another patient have shown gradually increasing BCR-ABL1 transcripts under the level of 0.1%. Eleven patients who experienced second relapse (MMR loss) after a median 2.8 months (range, 1.8-30.7 months). All the patients who lost MMR were retreated with IM for a median of 14.6 months (range, 6.6-37.6 months); eleven patients re-achieved MMR at a median of 2.8 months (range, 1.0-10.2 months) and eight patients re-achieved UMRD at 7.4 months (range, 1.8-19.5 months). When we compared the molecular kinetics after the first and second IM discontinuation, there were no differences; median time to relapse was 3.7 months vs. 2.8 months after first and second IM discontinuation, respectively, and median time to re-achieved UMRD was 7.4 months vs. 7.4 months after first and second IM resumption, respectively.
Summary/Conclusion: Our data demonstrated that a second attempt might be possible and the median time to MMR loss after second discontinuation was similar to those of the first discontinuation. But the molecular kinetics after second IM resumption needs longer follow-up with more patients. Further studies on the predictors to select patients for a trial of second TFR and novel strategies such as intermittent therapy will be warranted.

Background: Imatinib generics were introduced into Poland in 2014. An analysis of efficacy and safety after one-year therapy with imatinib generics of a large patient cohort (726) suffering from chronic myeloid leukemia in the chronic phase has suggested that they are not inferior to branded imatinib in terms of clinical efficacy and tolerability without any increased switching rate between imatinib generics and 2GTKI.
Aims: To evaluate the efficacy and safety of imatinib generics in the same cohort of patients after two years of therapy.
Methods: We report on 394 patients prospectively observed for two years within the Polish Adult Leukemia Group (PALG) Imatinib Generics Registry who completed a 24-month observation (all patients with available RQ-PCR results at the 24th month). The cohort consisted of previously untreated patients who started therapy with the imatinib generic, and patients switched to the generic from branded imatinib in 2014. All patients have been treated with at least two generics and a majority received three or more. All patients observed within the registry have been analyzed for: the frequency of molecular monitoring with RQ-PCR, the rate of sustained, improved and worsened molecular response, the rate of CCyR, MMR, MR4, and MR4,5 loss and for the switching rate between imatinib generics and 2GTKI during the first and the second year of therapy. The hematologic (3rd or 4th grade), and non-hematologic adverse events (all grades according to CTCAE criteria) in the first and second year of therapy were recorded .
Results: Four, three, two and one RQ-PCR tests were respectively performed in 53%, 25%, 16% and 6% of patients during the first year and in 64%, 9%, 12% and 15% of patients during the second year of observation. The molecular response under therapy with generics was respectively sustained, improved and worsened in 69.7%, 22.6%, and 7.7% of patients at 12 months and in 67.6%, 22.1% and 10% of patients at 24 months of therapy.During the first and the second year of therapy, MMR was respectively lost in 1.8% and 2.3%, CCyR in 1.5% and 0.8%, MR4.5 in 3.8% and 6.1% of patients. One patient lost MMR, CCyR and CHR at the 24th month of therapy. During the first and second year of observation, 4.5% and 3% of patients were respectively switched to 2GTKI, 3.8% and 1.3% for intolerance (non-hematologic toxicity only) and 0.8% and 1% for resistance during the first and second year. Hematologic toxicity (grade 3 or 4) during the first and second year was respectively observed in 2 and 3 patients, whereas non-hematologic toxicity (all grades)occurred in 17 patients during first year and in 36 patients during the second year of treatment.
Summary/Conclusion: This report on "real life" the effectiveness and safety of imatinib generics in a big cohort of CML patients after two years of observation suggests that they seem to be not less effective as Glivec in treating patients with CML CP; the responses being stable and safety profile is acceptable, without any increased switching rate between the 1st and 2GTKI during the first and second year of observation.

PS1121

MAINTENANCE THERAPY WITH DASATINIB ADMINISTRATED EVERY OTHER DAY IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

Background: Dasatinib is a second-generation tyrosine kinase inhibitor (TKI) approved in first and subsequent lines for the treatment of patients (pts) with chronic phase-chronic myeloid leukemia (CP-CML). The standard dosing regimen is once daily resulting in a [C]max associated with a transient inhibition of BCR-ABL kinase activity. In order to optimize tolerability, we proposed a maintenance therapy with dasatinib once every 48h in CP-CML pts in deep molecular response (MR4; BCR-ABL^{IS}≤0.01%).
Aims: We first conducted a retrospective analysis on real-life CML pts allocated to maintenance therapy and then proposed a prospective maintenance study as part of the OPTIM dasatinib trial (EudraCT 2008-006854-17). The primary objective was to assess survival in maintenance without loss of MMR (BCR-ABL^{IS}>0.1%).
Methods: Kaplan-Meier estimates for maintenance without loss of MMR were calculated between two groups of pts in the retrospective cohort (pts in MR4 or pts matching the Euroski eligibility criteria (duration of TKIs ≥3y and duration of MR4≥1y). Pts with duration of TKIs ≥3y and duration of MR4≥1y were eligible for inclusion in the prospective maintenance study.
Results: Fifty-two CP-CML pts were eligible for the retrospective cohort, after one or two lines of therapy. Thirty-six pts were included in the prospective maintenance study after front line dasatinib. Median age at diagnosis was 47.8y (range 18.9-78) and 48% pts were male. Median duration of dasatinib in the retrospective cohort and in the prospective study was 40.5 months (range 6.2-116) and 47.7 months (range 32.7-88.4) respectively. Median daily dose before maintenance was 50 mg (range 40-100) and 100 mg (range 40-100) in both retrospective and prospective cohorts respectively. At baseline, 46% of the pts matched the Euroski criteria in the retrospective cohort.

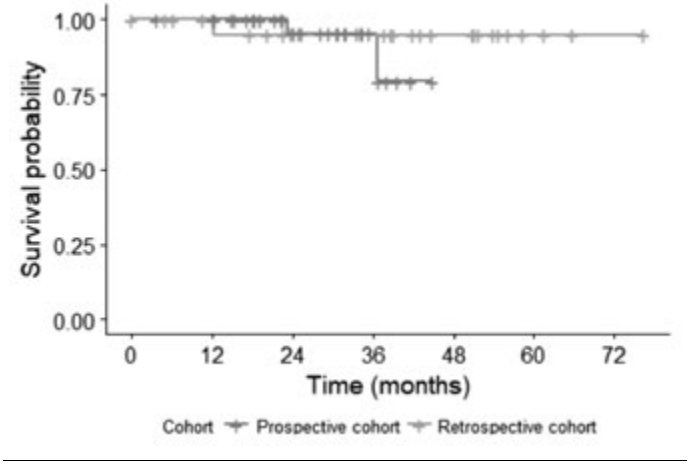

Figure 1. Survival in maintenance without MMR loss.

Median follow-up was 28.2 months and 30.7 months in both retrospective and prospective cohorts respectively. Kaplan-Meier estimate of survival without MMR loss in the retrospective cohort was 95.7% (95% CI, 89.9-100) at 12 months and 88.5% (95% CI, 79.4-98.6) at 24 months. We then focused on pts with duration of TKIs≥3y and duration of MR4≥1y. Only one patient lost MMR at 12.2 months. Survival in maintenance without MMR loss was 95% (95% CI, 85-100) at 12 and 24 months. As a comparison, 5 pts lost MMR if only MR4 was achieved at maintenance start. We then analyzed survival in maintenance without loss of MMR in the prospective study. Only 2 pts lost MMR after 23.3 and 36.6 months and maintenance without MMR loss was 100% at 12 months, 95.4% (95% CI, 71.8-99.2) at 24 months. These two pts regained a deep molecular response with dasatinib once daily without occurrence of BCR-ABL tyrosine kinase domain mutation. Focusing on pts included in the prospective study, 5 pts lost MR4 during maintenance at 3.3, 7.7, 8.9, 23.3 and 27.6 months including 2 pts who spontaneously regained MR4 during maintenance continuation and the 2 pts who lost MMR later. Tolerability was excellent with no withdrawal syndrome and no pleural effusion during maintenance. (Figure 1).
Summary/Conclusion: A maintenance therapy with dasatinib once every 48 hours after achievement of a deep molecular response is feasible. Pts with duration of TKIs≥3y and duration of MR4≥1y experienced very high rates of survival in maintenance without loss of MMR (>95%) and without dasatinib related toxicities. Our results suggest that maintenance with dasatinib is an attractive option for pts in sustained deep molecular response.

Background: The third generation tyrosine kinase inhibitor ponatinib is effective as salvage treatment for chronic phase (CP) Ph+ chronic myeloid leukemia (CML) patients resistant or intolerant to prior TKIs. Considering the demonstrated impact of ponatinib dose on the incidence of cardiovascular adverse events, a dose reduction to 15 mg daily is recommended in CP after the achievement of treatment milestones. Lower than 45 mg ponatinib dose strategies are currently under investigation in prospective clinical trials. There is a strong interest on independent data describing the efficacy and the safety of 15 mg daily ponatinib.
Aims: Describe and assess the efficacy and toxicity of low doses of ponatinib in CML-CP resistant or intolerant to previous TKIs.
Methods: A retrospective analysis of consecutive, CML-CP patients treated with ponatinib 15 mg as starting or de-escalated dose has been performed. No pre-specified criteria to switch to ponatinib or to reduce the dose were indicated.
Results: 62 patients are included, 53% males. Median age at ponatinib start was 57 (28-87) years. The median time from CML diagnosis to ponatinib treatment was 53.2 months (4.8-230). ABL1 mutations were detected in 29.3% patients (being 41% of them positive for the T315I mutation). Roughly half of the patients (45%) received ponatinib as 4th or 5th line of treatment. Ponatinib was started at 45, 30 and 15 mg, in 24, 13 and 25 patients, respectively. Resistance to prior TKIs was the reason for switch in all patients treated with higher than 15 mg dose, while 12/25 patients starting with 15 mg were purely intolerant or intolerant and resistant. The median treatment duration at any dose was 21.2 months, with 45/62 (72%) patients exposed to ponatinib for more than 12 months. Overall, 68% of patients improved response status. In patients treated with 45 or 30 mg the CCyR, MR3 and MR4/MR4.5 rates were 76%, 55% and 32% respectively. Responses were achieved after a median of 3.5, 4.3 and 6.7 months, respec-

tively. Dose reduction to 15 mg was decided after a median time of 10 months, mostly due to adverse events (73%) and less frequently, to prevent toxicity and/or following response attainment (27%). Median duration of treatment was 32.4 months, with a discontinuation rate of 5/37 (1 cerebrovascular accident, 2 severe hematologic toxicities, two cases of resistance/progression). Two deaths were registered (both in the 45 mg group), one after blast crisis and one for a fatal cardiovascular event. Focusing the 25 patients started with ponatinib 15 mg, median duration of treatment was 15 months (4.3-58.1). CCyR was obtained in 55% of patients lacking CCyR and MR3 in 50% without MMR with a median time of 3.8 and 3.4 months, respectively. During follow-up, MR3 or deeper responses were maintained or improved in 80% of cases, while 7 patients lost their best acquired response (4 MR4/4.5 to MR3, 1 MR3 to MR2, 1 CCyR to PHR and 1 progression to accelerated phase). Three patients of this group discontinued the treatment (1 coronary vasospasm-induced acute coronary syndrome, 2 muscle skeletal pain). After a median follow-up of 21 months, 35/54 (65%) patients on ponatinib mantain a MR3 or deeper response; 48 (89%) are taking 15 mg or lower.

Summary/Conclusion: This analysis confirms the efficacy of de-escalated ponatinib dose in CML patients resistant to prior TKIs, with acceptable toxicity profile. Promising data on 15 mg as a starting dose in selected patients (intolerant or with low level resistance) warrant further investigation in larger prospective trials.

PS1123

THE EUTOS LONG-TERM SURVIVAL SCORE PREDICTS RESPONSE AND SURVIVAL OF ELDERLY CHRONIC MYELOID LEUKEMIA PATIENTS BETTER THAN SOKAL SCORE

Seràgnoli", University of Bologna, Bologna, Italy

Background: The EUTOS long-term survival (ELTS) score, based on a large cohort of chronic myeloid leukemia (CML) patients treated frontline with imatinib (IM), has been developed to discriminate the probability of dying of disease progression, but many clinicians still use the traditional Sokal score. Few comparisons between the two scores are available and the clinical usefulness of ELTS score has not been clearly demonstrated yet.

Aims: To compare the prognostic value of ELTS and Sokal scores in a cohort of CML patients treated in early chronic phase with tyrosine kinase inhibitors (TKIs) as first-line therapy. Given the different weight that the variable "age" has in the two score formulations, we hypothesized a different predictive value in specific age groups, so we compared the ELTS and Sokal scores in patients < 30 years, 30-64 years and > 65 years old.

Methods: Nine hundred and four adult patients were included, 559 treated with IM and 345 treated with nilotinib-based regimens (NIL). The patients were enrolled in six multicenter studies (NCT00481052, NCT00769327, NCT01535391, NCT00514488, NCT00510926, observational trial CML/023) conducted by the GIMEMA CML WP. The intention-to-treat population of each study was analyzed. Definitions: progression, transformation according to ELN criteria; leukemia related death (LRD): death after progression.

Results: Median age, 52 years (range 18-86); age distribution, 8% patients < 30 years old and 22% of patients ≥ 65 years old. The median follow-up was 6 years (range: 2-9 years). The patient distribution according to the different scoring systems was as follows: 57% low, 30% intermediate and 13% high ELTS score, 40% low, 39% intermediate and 21% high Sokal score, respectively. The risk distribution was comparable in patients treated with IM or NIL. Approximately 2/3 of patients with low (64%), intermediate (64%) or high (71%) ELTS score had the same risk classification according to the Sokal score. The concordance between the two scores, in particular for low and high risk category, was even better in patients < 30 (87% and 80%, respectively) or 30-64 years old (71% and 88% respectively); in contrast, in elderly patients only 8% of low ELTS patients had a low Sokal score, and only 48% of high ELTS score had a high Sokal score. Overall, both scores were able to predict significantly different probabilities of MR3, MR4, overall survival (OS) and LRD, but in elderly patients (≥ 65 years) only the ELTS score was able to predict the achievement of MR3 (99%, 87% and 75% in low, intermediate and high risk patients, respectively; p=0.001) and MR4 (82%, 61% and 50% in low, intermediate and high ELTS score patients, respectively; p=0.005). Interestingly, both scores predicted the OS, while only the ELTS score predicted a significantly different LRD probability (cumulative incidence 2%, 6% and 14% in low, intermediate and high risk patients, respectively; p=0.05). The results were similar considering patients ≥ 60 years old.

Summary/Conclusion: The risk distribution according to the ELTS and Sokal score and the concordance between the 2 scores was different in specific age groups (< 30, 30-64, ≥ 65 years old). In elderly CML patients treated with IM or NIL as frontline therapy the prognostic predictive ability of ELTS score resulted superior to the Sokal score.

Background: Cardiovascular adverse events (CV-AE) represent emerging complications in chronic myeloid leukemia (CML) patients treated with second-generation tyrosine kinase inhibitors (2ndGTKIs). Current recommendations highlight the importance of a careful evaluation of CV risk factors but the role of a primary prophylaxis with aspirin is still a matter of debate.

Aims: We therefore analyzed a large real-life cohort of Italian CML patients

treated with a 2ndGTKIs as first or subsequent line of treatment. The primary objective was to evaluate the incidence of CV-AE and the association with the Systematic Coronary Risk Evaluation (SCORE) assessment and other baseline risk factors. Secondary objective were to evaluate the role of primary or secondary prophylaxis in preventing CV atherothrombotic events and to report the management of CV-AE complications in the clinical practice.

Methods: We evaluated 506 adult CML patients (mean age 52, range 18-87) who were treated with nilotinib (286) or dasatinib (220) as first or subsequent lines of treatment between January 2012 and December 2015. CV diseases (CVD) and risk factors, primary and secondary prophylaxis, and management of CV-AE were assessed at baseline and during treatment.

Results: Anamnesis for CVD was positive in 181 (35.8%) patients. The 60-month cumulative CV-AE incidence was 21.7%. Patients treated with nilotinib or dasatinib showed a CV-AE incidence of 24.7% and 16.4%, respectively (p=NS). A positive history for CVD (p=0.001) and a 2ndGTKI line of treatment >1 (p=0.002) were significantly associated to a higher incidence of CV-AE. Patients with both 2 risk factors (CML-CV high risk score) showed a CV-AE incidence significantly higher (45.9% vs 16.3% and 18.7%, p<0.001) (Figure 1). The atherothrombotic AE incidence was 13.1%. No significant difference in atherothrombotic AE incidence was found in patients who underwent aspirin primary prophylaxis before starting 2ndGTKIs. Considering only patients with age>60 years and CML-CV high risk score, atherothrombotic AE incidence was significantly lower in those treated with aspirin (0% vs 58.2%; p=0.01).

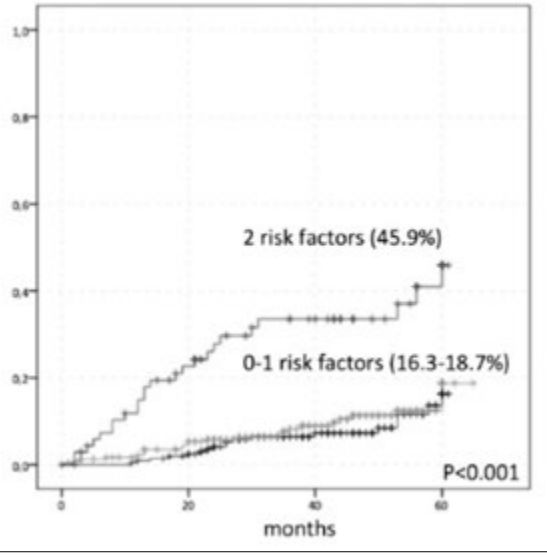

Figure 1.

Summary/Conclusion: This study confirmed the increased risk of CV-AE in CML patients treated with 2ndGTKIs in the real-life, particularly in those patients with positive anamnesis for CVD and 2ndGTKI line of treatment >1. Our findings emphasize the need of personalized prevention strategies based on CV risk factors; ideally, management and treatment of these patients should be performed in close collaboration with cardio-oncologists, angiologists and vascular surgeons. We suggest that patients with age >60 years and CV diseases undergoing a 2ndGTKI line treatment >1 are likely to be the best candidates to aspirin. Data on efficacy of primary prophylaxis in CV-CML high risk patients should be confirmed in prospective randomised trials.

PS1125

ULTRA-SENSITIVE DETECTION OF TYROSINE KINASE INHIBITOR RESISTANT MUTATIONS IN CHRONIC MYELOID LEUKEMIA PATIENTS USING MISEQ ILLUMINA NEXT GENERATION SEQUENCING PLATFORM

M. Romzova[1,*], D. Smitalova[1], N. Tom[1], T. Jurcek[2], J. Mayer[1,2], Z. Racil[1,2]

[1]Department of Molecular Medicine, Central European Institute of Technology, Masaryk University, [2]Department of Internal Medicine, Haematology and Oncology, University Hospital Brno, Masaryk University, Brno, Czech Republic

Background: The discovery of tyrosine kinase inhibitors (TKI) brought a revolution in the management of chronic myeloid leukemia (CML), increasing survival and life-quality of patients. However, a resistance caused by mutations in kinase domain (KD) of *BCR-ABL1* may occur, which can result in therapy failure. Although KD mutations screening is routinely done by Sanger sequencing (SS), its major disadvantage is detection limit above 20% VAF. Recently, numerous studies investigated next generation sequencing (NGS) of KD region, showing enhanced sensitivity below 15% and thus earlier mutation detection. These studies used a nested or semi-nested PCR for KD region amplification. Such approach is however hindered by possible errors introduced during reverse transcription (RT) and 2-round amplification steps (nested PCR), restricting the mutation detection limit to 1% and above. Majority of these studies used Roche platform for KD sequencing, and only one study employed Illumina platform, despite it is nowadays the most widely accessible sequencing platform.

Aims: Our aim was to develop a simple and efficient Illumina-based one-round PCR amplification protocol, which would reduce PCR-mediated errors and increase sensitivity of KD mutation detection ≤1%, with still acceptable specificity.

Methods: New Illumina-based NGS protocol for KD sequencing was established and tested on the set of 34 retrospective samples from 13 CML patients who developed TKI resistant mutations. We tested 15 follow-up (FUP) samples at the time of SS mutation detection, 11 FUP samples collected 1-18 month before SS mutation detection, 8 diagnostic samples and 6 healthy controls. High fidelity enzymes were used for RT and PCR amplification. The performance of protocol was assessed in comparison to routinely used SS. The bioinformatics (BI) pipeline was designed with respect to biological input (cDNA) and required very high sensitivity, allowing detection of insertions/deletions and single nucleotide variants with frequency down to 0.1%.

Results: No mutations were detected in *ABL1* KD of healthy controls, showing that employment of high-fidelity RT and PCR enzymes and BI filtering led to decreased background noise. NGS detected mutations in 15/15 (100%) FUP samples previously positive for mutation by SS (R^2_{VAF} =0.96). Further, NGS detected mutations in 7/11 (63%) SS negative FUP samples, collected before SS mutation detection and in 1/8 (12.5%) SS negative diagnostic samples (T315I mutation at 0.5% VAF). Together 8 different mutations were detected by SS multiple times (≥20% VAF), while NGS detected 15 different mutations multiple times, of which 19 times with ≥20% VAF, and 26 times at the level 0.1 – 11% VAF (Table 1). With exception of R307W and E450Q, all other mutations detected by NGS were previously described to be associated with TKI sensitivity. The mutation most frequently detected prior identification by SS was T315I (5 pts, 1-8 months earlier). Moreover, 3 other mutations were detected at earlier time point (3 pts; 12 – 20 months earlier).

Table 1.

	Diagnosis				Earlier in follow-up				At the time of Sanger sequencing detection			
Patient	SS	NGS >20%	NGS <20%	Month	SS	NGS >20%	NGS <20%	Month	SS	NGS >20%	NGS <2
1	0	0	0	M3	0	0	M351T 1.6% R307W 2.2%	M21	M351T 100%	M351T 91%	E450Q 5

9				M28	0	T315I 20%	0	M35 M40	T315I 20% T315I 42%	T315I 32 % T315I 50%	0 F467S 1
10				M5	0	0	T315I 1.6% F317L 0.4%	M6	T315I 95%	T315I 87 %	0
11	0	0	0					M18	F359I 100%	F359I 99 %	0
12	0	0	T315I 0.5%					M6	T315I 100%	T315I 99 %	Y253H 1
13				M206	0	0	T315I 1.4% F317L 4% F359V 6.4% G250E 1% M351T 0.7%	M214	T315I 18%	T315I 18%	V299L 0 F317L 3 F359V 0 G250E 0
								M234	T315I 65% V299L 35%	T315I 64% V299L 31%	F317L 0

Summary/Conclusion: Overall, we have confirmed that results from NGS analysis, using Illumina-based one-round PCR amplification protocol, highly correlated with SS when mutations with >20% VAF were analyzed. Due to high sensitivity (together with high specificity) Illumina-based NGS analysis was able to detect mutations in 24% more samples than SS and proved to be suitable for earlier detection of TKI resistant mutations at very low frequencies (≥0.1%).

Supported by Ministry of Health of the Czech Republic, grant NR.17-30397A.

PEG-INTERFERON ALPHA 2B CAN IMPROVE MOLECULAR RECURRENCES IN THE TREATMENT-FREE REMISSION; A PILOT STUDY WITH 18-MONTH FOLLOW-UP

M. Ayala[1,*], D. Moreno-Lorenzana[2], E. J. Cordova[3], X. Aquino[4], A. Chavez-Gonzalez[2]

[1]Hematology & BMT Unit, Specialties Hospital, Nacional Medical Center "La Raza", [2]Oncology Research Unit, Oncology Hospital, National Medical Center, Mexican Institute for Social Security, [3]Immunogenomics and Metabolics Disease Laboratory, Instituto Nacional de Medicina Genómica, SS , [4]Grupo Consulmed, Mexico

Background: In 2010, Mahon *et al.* reported the results of the STIM study in 100 patients with stable undetectable molecular response (uMR) for at least 2 years. Finding 6 months of relapses in 58% and year in 61% of patients, most of the losses of the uMR occur in the first 6 months of the suspension of the TKI. An update of the results at 65 months, found no relapse after 2 years of suspension.
Aims: Decrease molecular recurrence (MolRel) rate in patients with CML-CP in stable uRM with TKI suspension and maintenance for 6 months with P-IFNα2b.
Methods: A prospective, longitudinal, descriptive, single-cohort, open pilot study was conducted to evaluate the effectiveness of maintenance for 6 months with P-IFNα2b in reducing the rate of MolRel in patients with CML-CP in stable uRM. Treatment was initiated after elective discontinuation of TKI will receive 100 mg of P-IFNα2b subcutaneous weekly for 6 months. They will then suspend all treatment. MolRel surveillance will be initiated simultaneously with the TKI suspension, with peripheral blood simple taken for baseline quantitative q-PCR measurement and quarterly until 6 months of surveillance from the TKI suspension of or have molecular relapse. An analysis of lymphocyte subpopulations was performed by baseline flow cytometry and quarterly up to 6 months of suspended P-IFNα2b, as well as a blood analysis of basal and half-yearly microRNAs during the two years of suspension. In patients in whom molecular relapse is documented, TKI will be restarted at the dose prescribed prior to discontinuation of treatment.
Results: Thirty-one patients (16 male and 15 female) were included, with a median age at diagnosis of 44.5 years (25-77), the risks of Sokal to diagnosis were; high 20%, intermediate 23%, low 27%, N/A 30%. Twenty-four patients were suspended from imatinib, 6 of dasatinib, and one with nilotinib and the median time uRM was 49 (28-102). Twenty-seven patients completed 6 months of TKI discontinuation remaining at uRM 85%, the majority of MolRel occurred within 12 months of discontinuation; the molecular recurrence-free survival (MRFS) rate was 85%, 67% and 58% at 6, 12 and 24 months respectively. Patients who lost MMR (5/dasatinib and 8/imatinib) re-started the same TKI and all have now recovered MMR. The Adverse Events presented were grade 1-2 for myalgias 72% (17/55), headache 64% (30/34), hyperpigmentation 58% (41/17), asthenia 41% (17/24), adynamia 38%(14/24), arthralgias 35% (14/21), nausea 14/0%, alopecia 10/0%, fever 7/0%, diarrhea 3/0%, media time from TKI suspension is 19 (range 16-23) months (Figure 1).

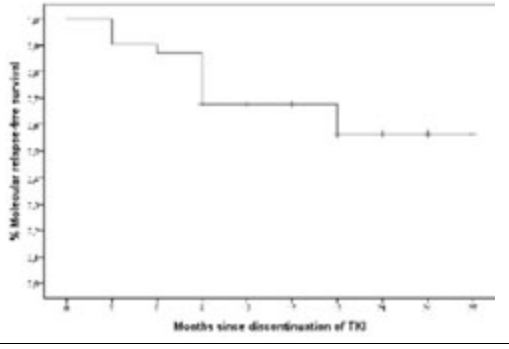

Figure 1. Molecular relapse-free survival.

Summary/Conclusion: Although these results are preliminary (since a sample of 50 patients is expected to be included), the trend suggests that P-IFNα2b may be useful as maintenance after TKI suspension to decrease the rate of molecular relapse at 6 months of the suspension of the TKI. It is expected to determine the involvement of the immunological behavior of lymphocyte subpopulations in the maintenance of uMR, using P-IFNα2b after TKI suspension, which will be reported later to complete the year of TKI suspension. To our knowledge this is the first prospective study in Latin America that reports this therapeutic strategy of TFR.

Background: Bosutinib has a distinct adverse event (AE) profile vs other tyrosine kinase inhibitors (TKIs) used to treat Philadelphia chromosome–positive (Ph+) leukemia.
Aims: Cross-intolerance between bosutinib and prior TKI therapy was evaluated after ≥4 years of follow-up of a phase 1/2 study (NCT00261846).
Methods: Patients with chronic phase (CP) chronic myeloid leukemia (CML; n=403) or accelerated/blast phase CML or Ph+ acute lymphoblastic leukemia (ADV; n=167) previously treated with imatinib±dasatinib and/or nilotinib received bosutinib (starting dose 500 mg QD) in a phase 1/2 study. Cross-intolerance (AEs leading to discontinuation of both prior TKI and bosutinib) and AEs causing prior TKI intolerance and recurring as grade 3/4 AEs with bosutinib were assessed.
Results: In imatinib-intolerant and dasatinib-intolerant patients, respectively, 18% and 24% in the CP CML group and 18% and 5% in the ADV group had cross-intolerance with bosutinib, which was most commonly due to hematologic AEs (Table 1). Cross-intolerance in imatinib-intolerant patients with CP CML due to AEs common with imatinib was low (rash 6%; diarrhea 10%; edema/fluid retention 0; myalgia 0); cross-intolerance due to pleural effusion was low in dasatinib-intolerant patients with CP CML (13%) and dasatinib-intolerant ADV patients (0). No deaths occurred due to cross-intolerance.

Table 1.

Cause of intolerance*	n	Bosutinib discontinuation due to same AE n (%)	Same grade 3/4 AE with bosutinib n (%)
CP CML – imatinib intolerance			
Any AE	120†	21 (18)	39 (33)
Thrombocytopenia	27	7 (26)	17 (63)
Neutropenia	21	2 (10)	7 (33)
Rash	18	1 (6)	2 (11)
Anemia	14	0	6 (43)
Edema	12	0	0
Diarrhea	10	1 (10)	3 (30)
Hematologic toxicity	7	4 (57)	5 (71)
Vomiting	7	1 (14)	1 (14)
Fatigue	7	1 (14)	0
Nausea	6	0	0
Fluid retention	5	0	0
Myalgia	5	0	0
CP CML – dasatinib intolerance			
Any AE	50	12 (24)	18 (36)
Pleural effusion	16	2 (13)	3 (19)
Thrombocytopenia	8	4 (50)	8 (100)
Pancytopenia	6	0	0
ADV – imatinib intolerance			
Any AE	22†	4 (18)	8 (36)
Thrombocytopenia	7	4 (57)	6 (86)
ADV – dasatinib intolerance			
Any AE	21†	1 (5)	10 (48)
Pleural effusion	7	0	2 (29)
Thrombocytopenia	5	1 (20)	5 (100)

* Causes in ≥5 patients shown; † Patients with known causes shown

Summary/Conclusion: Cross-intolerance with bosutinib was low and largely due to hematologic AEs, supporting bosutinib use in patients with Ph+ leukemia intolerant to prior TKIs, including those with intolerance due to rash or diarrhea.

Background: Chronic Myeloid Leukemia (CML) is a disease characterized by the presence of a BCR-ABL rearrangement, whose outcome, very poor until a few years ago, was totally changed by the advent of Tyrosine Kinase Inhibitors (TKI) therapy. Most of information about the clinical characteristics of the CML patients are based on data derived from clinical trials, that often exclude patients not fitting with strict inclusion criteria. In routine clinical practice may be important to know the characteristics of the entire CML patients' population and this is better reflected by registries studies including all consecutive patients.
Aims: To provide a robust and updated information on the clinical, hematologic characteristics and treatment response in non-selected Italian patients with chronic myeloid leukemia (CML) in each phase of the disease.
Methods: We retrospectively and prospectively recorder in a web-based database clinical, hematological, cytogenetic and biological information about all new diagnosis of CML patients referred to Hematology Centers of the GIMEMA Study Group from January 2012 to December 2017
Results: The study covered 1330 patients newly diagnosed with CML between January 2012 and December 2017 in 66 Italian centers. Median age at diagnosis was 59 years (range 17-71) and 59.7% were males. At diagnosis, 1075 (98.8%) patients were in chronic phase, 10 (1%) patients in accelerate phase and 3 (0.3%) in blastic crisis. Among 936 patients, 175 (13%), 421 (32%), 340 (25%) were high, intermediate and low risk by Sokal; 93 (7%), 480 (36%), 362 (27%) by EURO; 335 (25%), 77 (6%), 918 (69%) by EUTOS; 119 (9%), 246 (18%), 246 (18%) and 590 (44%) by ELTS, respectively. The median follow-up was 24.6 months and 26 patients died. At the cytogenetic analysis, among 533 patients there were: 443 (83,1%) without additional cytogenetic aberrations (ACA), 62 (11,6%) with major route and 28 (5,6%) with minor route ACA respectively. BCR-ABL transcripts among 1056 patients were: *b2a2* in 341 (32.3%), *b3a2* in 582 (55.1%), b2a2+b3a2 in 95 (9%), *e1a2* in 21 (2%), e19a2 in 3 (0.3%) *b3a2+e1a2* in 14 (1.3%) patients respectively. ECOG performance status was 0, 1, or ≥ 2 in 663 (52.3%), 227 (17.9%) and 53 (4.2%) cases respectively. According to co-morbidity, the Charlson comorbidity index was 0, 1, 2 or > 3 in 1013 (79%), 110 (8,6%), 75 (6%) and 71 (6%) patients respectively. Among 574 cases cardiovascular, lung, metabolic and oncologic diseases were observed in 423 (73%), 55 (9.6%), 112 (19.5%) and 73 (13%) patients respectively. Among 1143 cases 576 (50.4%) and 567 (49.6%) patients were treated in first-line with imatinib (IMA) and with II generation TKI respectively. One hundred fourty-two cases were pretreated with hydroxyurea
Summary/Conclusion: Our preliminary results of this observational epidemiologic study suggest that collection of clinical data of CML patients treated out of strictly clinical trials represent an essential tool for long/term treatment, able to observe setting strategies based on the clinical characteristics, the degree of response obtained and the toxicity related to the therapy in overall CML population. We are planning to analyze all these tools in order to observe the response according to ELN guidelines, toxicity and feasibility of treatment sequence in a cohort of patients treated in real-life. In conclusion, is needful to continue recruiting patients due to obtain a greater representativeness

Background: Several studies have been reported to show about a half of CML patients who have continuously achieved adequate molecular response to BCR/ABL tyrosine kinase inhibitor (TKI) can achieve therapy-free remission (TFR). In Japan the real time quantitative polymerase chain reaction (PQ-PCR) of BCR/ABL had not been applicable to insurance until April 2015; the TFR has not been well investigated in Japanese clinical setting.
Aims: We conducted a multicenter phase II trial to test the safety and efficacy of discontinuing imatinib after at least 2 years of MR4.0-equivalent (UMIN Clinical Trials Registry UMIN000012472).
Methods: The patients who kept MR4.0 or MR4.0-equivalent (nested reverse transcriptase-polymerase chain reaction (RT-PCR) assay negative or a highly sensitive transcription-mediated amplification (TMA) method assay negative) for at least two years and confirmed MR4.0 at the beginning of the study were enrolled. Molecular recurrence was defined as loss of MR4.0 on 2 successive tests or loss of MR3.0 once. Recurrent patients were immediately treated with dasatinib or other TKIs including imatinib. In this study, rate of recurrence was assessed for patients with at least 12 months of follow up.
Results: Patients were enrolled at 25 participating institutions from January 2014 to May 2015. Among 110 enrolled patients, 99 patients (male 65, female 34, median age 62years) were evaluable. Median time from diagnosis to end of imatinib was 103(29-287) months, imatinib therapy duration 100(28-160) months and preceding MR4.0 or MR4.0 equivalent period 55(24-133) months. Recurrence-free survival rate was 68.6% at 12 months with Kaplan-Meier method. TFR rates of the patients whose time from diagnosis to the end of imatinib was longer than 103 months were significantly better than TFR rates of patients with shorter sick periods by univariate

analysis (p=0.0449).
Summary/Conclusion: This phase 2 study was contrived to be feasible in Japanese clinical setting. The outcome is comparable to other TFR studies.

PS1130

THE TARGET UK STUDY: AN EVALUATION OF TYROSINE KINASE INHIBITOR RESPONSE MONITORING PATTERNS AND REAL-WORLD MOLECULAR RESPONSE RATES IN UK PATIENTS WITH CHRONIC MYELOID LEUKAEMIA

D. Milojkovic[1], R. Clark[2], P. Neelakantan[3], J. Ryan[4], S. Collington[4], N.C. Cross[5], A. Mead[6,*]

[1]Imperial College Healthcare NHS Trust, London, [2]The Royal Liverpool and Broadgreen University Hospitals NHS Trust, Liverpool, [3]Royal Berkshire NHS Foundation Trust, Reading, [4]Novartis Pharmaceuticals UK Limited, Camberley, [5]University of Southampton, Southampton, [6]Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

Background: Speed and depth of response to tyrosine kinase inhibitor (TKI) treatment are key predictors of patient outcomes in chronic myeloid leukaemia (CML), as reviewed in the latest European evidence-based recommendations for CML management (European LeukemiaNet [ELN] 2013; Baccarani *et al*., 2013). ELN2013 defines molecular responses as "optimal", "warning" and "failure" at specific milestones to guide TKI therapy switch. An early molecular response (EMR; BCR-ABL1IS <10%) at 3 months(m), BCR-ABL1IS <1% at 6m, and major molecular response (MMR; BCR-ABL1IS ≤0.1%) by 12m are key optimal responses to first line (1L) treatment. Furthermore, achievement of sustained deep molecular response (DMR; BCR-ABL1IS ≤0.01%) may give an advantage for successful treatment-free remission (Mahon FX ASH-educational, 2017). Real-world evidence on TKI management and outcomes is however currently lacking in the UK.
Aims: This study aims to evaluate TKI pathways, monitoring patterns and real-world response rates in UK patients with CML against ELN2013 to inform future clinical practice.
Methods: In a retrospective observational study at 21 UK centres; data on Pt characteristics, TKI choice, and molecular responses were collected by medical record review in 257 adult Pts (≥18 years) with chronic phase CML. Eligible Pts were first prescribed a TKI from January 2013 with ≥6m follow-up.

Table 1. Summary of molecular response.*

Molecular response	Overall responses* (n=257)		1st TKI† (n=257)		Switched to 2nd TKI ‡ (n=104)			
	Imatinib as 1L TKI (N=203)	2G TKI as 1L TKI (N=54)	Imatinib (N=203)	2G TKI (N=54)	2G TKI (N=62) ‡	Switched to 2nd TKI for intolerance/ other (N=42) ‡	Switched to 2nd TKI for resistance (N=62) ‡	All switched Pts (N=104) ‡
Available follow-up Median (range) months	26.1 (5.9 - 56.8)	24.9 (6.3 - 56.8)	14.4 (0.3- 56.0)	18.5 (0.5 - 55.3)	15.2 (1.1 - 51.4)	16.1 (2.4 - 49.6)	17.2 (1.1 - 51.4)	16.6 (1.1 - 51.4)
EMR at 3 months (+/- 1 month) in Pts with a BCR-ABL1 at 3m + [n(%)]	88/163 (54%)	29/41 (71%)	87/146 (60%)	28/37 (76%)	49/56 (88%)	25/26 (96%)	33/39 (85%)	58/65 (89%)
MMR (BCR-ABL1 ≤0.1%) by 12 month (+/- 1) in Pts with ≥13m follow-up ¶ [n(%)]	66/169 (39%)	27/47 (57%)	54/116 (47%)	24/35 (69%)	27/46 (59%)	15/22 (68%)	16/32 (50%)	31/54 (57%)
MMR at any time (BCR-ABL1 ≤0.1%) in Pts with ≥13m follow-up † [n(%)]	126/169 (75%)	39/47 (83%)	78/116 (67%)	32/35 (91%)	30/46 (65%)	16/22 (73%)	19/32 (59%)	35/54 (65%)
DMR at any time (BCR-ABL1 ≤0.01%) in Pts with ≥13m follow-up+ [n(%)]	78/169 (46%)	31/47 (66%)	50/116 (43%)	26/35 (74%)	20/46 (43%)	12/22 (55%)	10/32 (31%)	22/54 (41%)

*Where BCR-ABL1IS results were unavailable, comparison with ELN milestones (3/6/12m; with +/-1m window) was made using converted BCR-ABL1(ABL1% results.
† Overall response follow-up for all Pts =months from 1st TKI to data collection/death, 2G TKI, n=50 nilotinib, n=4 dasatinib. ‡ The 1L response follow up = months from 1st TKI to switch to 2nd TKI or data collection/death. ‡For Pts switching to 2nd TKI, follow-up= months from start of 2nd TKI to data collection/death (note outcomes include n=59 who received > 2 TKIs as a result of further TKI switch). ¶ EMR=Early Molecular Response. Patient had "optimal" response if BCR-ABL1 IS ≤10% at 3m (+/- 1m) post TKI start-date. Denominator shows number of Pts who had at least 4m follow-up and an RQPCR at 3m (+/- 1m) after starting that TKI line. +Denominator is number of Pts with at least 13m available follow-up from start of TKI line. Response could be achieved at any time (any line).‡ n=64 nilotinib, n=17 dasatinib, n=10 bosutinib, n=1 ponatinib. (n=12 imatinib 2L not included here). ‡ switched for intolerance (n=30)/switched for another reason (n=13)‡ n=53 on imatinib 1L; n=8 on 2G TKI 1L. ‡ n=64 nilotinib, n=17 dasatinib, n=10 bosutinib, n=1 ponatinib, n=12 imatinib.

Results: Median follow-up was 26m (range 6-57) and median age at start of 1st TKI was 53 years (144 [56%] Pts were male). Imatinib was used 1L in 203/257 Pts and a 2nd generation TKI (2G TKI) in 54/257 (n=50 nilotinib, n=4 dasatinib). In Pts with ≥13m follow-up post 1st TKI, 187/216 (87%) had ≥3 BCR-ABL1 RQ-PCR tests within 13m (208/216 [96%] had ≥1); 174/216 (81%) had a test at 3m, 151/216 (70%) at 6m, and 138/216 (64%) at 12m. In 2013, 2/14 centres used a lab reporting on the international scale versus 17/21 centres in 2017 (Table 1 summarises molecular responses).
During follow-up, 104/257 (40%) Pts switched TKI at least once, including 84/203 (41%) on 1L imatinib; documented reasons were resistance (61/104), intolerance (30/104) and other reasons (13/104). An ELN warning, >1 warning, or failure response was observed prior to switch in 22/104, 6/104 and 31/104 Pts respectively; 21/104 had a kinase domain mutation screen prior to switch. In the Pts switching to 2L following an ELN failure response, an optimal response of MMR was subsequently observed in 14/31 (7/14 with DMR), while 13 Pts remained on 1L following an ELN failure response (3/13 achieved MMR; 0/13 DMR).
Summary/Conclusion: Findings in this real-world UK cohort suggest a higher proportion of Pts treated with 2G TKI (1L or 2L) achieve optimal ELN responses than with imatinib. The observed proportion achieving an optimal response was greater in Pts who switched TKI following an ELN "failure" response than those who remained on 1L therapy, supporting the use of ELN2013 recommendations to guide TKI management. Results also highlight MMR and DMR can be achieved in real world practice even in Pts switching TKI following an ELN failure, warning, or documented resistance. However, the findings also demonstrate ELN2013 recommendations are not universally implemented in UK practice; the timing of PCR monitoring, the performance of mutational analysis, and management of Pts with an ELN warning/failure response frequently deviated from ELN recommendations highlighting areas for improvement for optimal patient management in the UK. Further follow-up is planned to investigate longer-term outcomes in this real-world cohort.

Enzymopathies, membranopathies and other anemias

PS1131

THE OCCURRENCE AND SURVIVAL OF COLD AGGLUTININ DISEASE IN DENMARK

L.C. Bylsma[1], A.G. Ording[2], T. Frøslev[2], F. Mehnert[2], J.P. Fryzek[1,2], J. Morales Arias[3], A. Röth[4], H.T. Sørensen[2], S. Berentsen[5,*]

[1]EpidStat Institute, Ann Arbor, MI, United States, [2]Department of Clinical Epidemiology, Aarhus University, Aarhus, Denmark, [3]Bioverativ, Boston, MA, United States, [4]Department of Haematology, University Hospital, University of Duisburg-Essen, Duisburg, Germany, [5]Department of Research and Innovation, Haugesund Hospital, Haugesund, Norway

Background: Cold agglutinin disease (CAD) is a rare subtype of complement-mediated autoimmune hemolytic anemia. CAD incidence, prevalence, and survival are poorly understood. CAD patients previously have been reported to be at increased risk of thromboembolic events (TE) compared to the general population. A better understanding of the basic epidemiology of this rare disease is needed.
Aims: Danish national population and medical registries were used to calculate the incidence and prevalence of CAD in Denmark, to characterize the CAD patient population, and to examine incidence of TE and survival with a matched comparison cohort from the general population.
Methods: CAD patients diagnosed during 1999-2013 were identified from the Danish National Patient Registry, using the first hospitalization with the ICD-10 discharge code D59.1A. The Registry covers all Danish hospitals. The Danish Civil Registry System was used to match each CAD patient on age, gender, and region of residence to 10 comparison cohort members from the general population who were alive at the time of the patient's diagnosis. Study participants were followed from the patient's diagnosis date through 2013. Incidence rate ratios for TE were calculated from a stratified Cox regression and survival was calculated using the Kaplan-Meier method. Both were adjusted for Charlson Comorbidity Index scores, which encompass cancer, heart disease, diabetes, and other comorbidities.
Results: In 2013, the prevalence of CAD was 1.26 per 100,000 persons in Denmark and the incidence rate was 0.18 per 100,000 person-years. We identified 72 CAD patients and 720 matched general population comparators. Median age at diagnosis was 68.5 years and 58% of the cohort was female. The probability of mortality at 1, 3, and 5 years from diagnosis was greater in the CAD patients when compared to the matched general population cohort. The Charlson comorbidity score-adjusted hazard ratio for mortality among CAD patients was 1.84 (95% CI: 1.10 – 3.06). The hazard ratios for patients with Charlson comorbidity scores 1-2 and 3+ were also increased for CAD patients when compared to the non-CAD cohort. The incidence rate of TE was 52.1 per 1000 person-years in CAD patients compared with 27 per 1000 person-years in the matched comparison cohort. The incidence rate ratio was 2.28 (95% CI: 1.20-4.34) in the crude analysis and became 1.43 (95% CI: 0.71-2.90) when we adjusted for Charlson Comorbidity Score. However, when stratified by Charlson comorbidity score (1-2 and ≥3), both models showed an increased incidence of TE in CAD patients (Charlson score 1-2 aIRR=2.22, 95% CI:1.32-3.72; Charlson score 3+ aIRR=3.43, 95% CI: 1.64-7.15). At 1 year, the cumulative incidence of TE was 4.6% in the CAD cohort and 0.9% in the matched comparisons; at 3 years, 8.4% and 4.8%, and at 5 years, 15.6% and 10.0%, respectively (Figure 1).

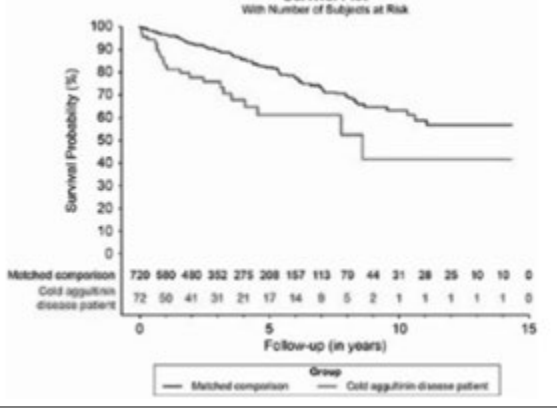

Figure 1. Kaplan-Meier survival curves for patients with cold agglutin disease and general population comparisons. Denmark. 1999-2013.

Summary/Conclusion: This population-based cohort study is the first to compare survival among CAD patients with survival in the general population. An increased rate of mortality and TE was observed among CAD patients, starting within the first year from diagnosis. These results indicate that CAD is a more severe disease than previously thought. Further studies should explore the potential of earlier instituted therapy in reducing mortality and risk of complications.

PS1132

DENSITY, HETEROGENEITY AND DEFORMABILITY OF RED CELLS AS MARKERS OF CLINICAL SEVERITY IN HEREDITARY SPHEROCYTOSIS

R. Huisjes[1], A. Makhro[2], E. Llaudet-Planas[3], L. Hertz[4], P. Petkova-Kirova[4], L.P. Verhagen[1], S. Pignatelli[1], M.A. Rab[1], R. M. Schiffelers[1], E. Seiler[2], W.W. van Solinge[1], J.L. Vives Corrons[3], M. Mañú-Pereira del[3], L. Kaestner[4,5], A. Bogdanova[2], R. van Wijk[1,*]

[1]Department for Clinical Chemistry and Haematology, University Medical Center Utrecht, Utrecht, Netherlands, [2]Red Blood Cell Research Group, Institute of Veterinary Physiology, Vetsuisse Faculty and the Zurich Center for Integrative Human Physiology (ZIHP), University of Zurich, Zurich, Switzerland, [3]Red Blood Cell defects and Hematopoietic disorders unit, Josep Carreras Leukaemia Research Institute, Barcelona, Spain, [4]Research Centre for Molecular Imaging and Screening, Saarland University, Homburg, [5]Experimental Physics, Saarland University, Saarbrücken, Germany

Background: Hereditary spherocytosis (HS) originates from defective anchoring of the cytoskeletal network to the transmembrane protein complexes of the red blood cell (RBC). Most frequently HS is caused by mutations in the membrane proteins ankyrin (*ANK1)*, band 3 (*SLC4A1)*, α-spectrin (*SPTA1)* and β-spectrin (*SPTB*). In HS, RBCs are characterized by membrane instability and consequent reduced RBC deformability. Clinically, a large heterogeneity in disease severity is observed among patients. Predictors of clinical severity in HS are however currently lacking.
Aims: To address the large heterogeneity in disease-severity in HS, we explored the correlation between the genotype and specific RBC properties with clinical severity.
Methods: Blood samples from 22 well characterized HS patients were collected after informed consent. Patients were categorized according to their disease severity (mild/moderate/severe, Bolton-Maggs *et al.*, Br. J. Haematol 2012). RBC indices were determined by routine hemocytometry, EMA-binding was determined by flow cytometry and the osmotic fragility test was determined according to standard methods. RBC deformability and hydration status was measured by osmotic gradient ektacytometry on the Lorrca (Mechatronics, the Zwaag, NL). RBC density was further determined by Percoll density gradient separation, intracellular potassium levels and capillary-based measurements of MCV and MCHC. RBC vesiculation was measured using the CytoFLEX flow cytometer after staining of plasma with mouse anti-human CD235a-APC. In addition, we used reticulocyte counts, phosphatidylserine exposure, CD71 abundance, and HbA1c as markers of RBC turnover and clearance.
Results: We found that a more severe clinical picture was statistically overrepresented in patients with genetic defects in ankyrin *(ANK1)* and β-spectrin (*SPTB)*. Further detailed analysis of HS RBCs showed that RBCs from patients with moderate/severe HS have a lower maximum deformability (EI_{max}) and a higher concentration of circulating RBC vesicles when compared to patients with mild HS. In addition, we found that a lower mean RBC density is associated with lower hemoglobin levels in blood. Furthermore, moderate/severe HS is accompanied with increased RBC turn-over and increased clearance as reflected by increased reticulocyte count, increased CD71 and decreased HbA1c and abnormally high intercellular heterogeneity (increased RDW and more cell fractions on the Percoll density gradient).

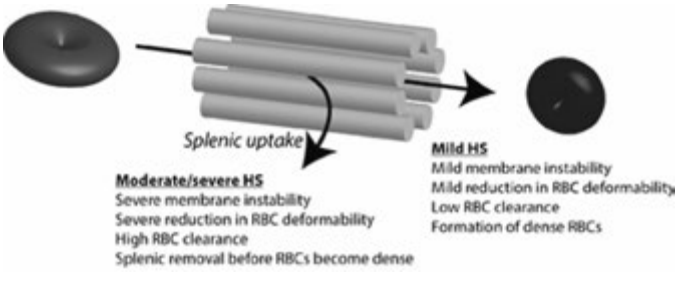

Figure 1.

Summary/Conclusion: In this study we show that disease severity in HS can not be solely attributed to the genotype. We found that RBCs patients with moderate/severe HS show a more prominent decrease in RBC deformability and show low RBC density when compared with patients with mild HS. We hypothesize that the severe RBC membrane instability in these patients facilitate early removal of these RBCs from the circulation by the spleen before their density increases (Figure 1). In contrast, in mild HS a less pronounced reduction in deformability is expected to result in prolonged RBC life-span and, hence, cells are subjected to progressive loss of membrane. RBCs from patients with mild HS thus become more dense before they are taken up by the spleen. Based on our findings, we conclude that RBC membrane loss, heterogeneity and cellular density are strong markers of clinical severity in HS.

PS1133

GAU-PED STUDY: UPDATE ON RESULTS AND LONG-TERM OUTCOME OF PATIENTS WITH GAUCHER DISEASE DIAGNOSED THROUGH A PAEDIATRIC ALGORITHM

W. Morello[1,*], M. Filocamo[2], M. Stroppiano[2], M. Di Rocco[3], N. Tovaglieri[4], G. Russo[5], F. Menni[6], G. Vergine[7], R. Burnelli[8], A. Pession[1]

[1]Pediatric Oncology and Hematology, Sant'Orsola-Malpighi University Hospital, Bologna, [2]Centro di Diagnostica Genetica e Biochimica delle Malattie Metaboliche Gaslini Hospital, [3]Pediatrics, Unit of Rare Diseases - Gaslini Hospital, Genoa, [4]Pediatrics, Niguarda Hospital, Milano, [55]Pediatric Hematology and Oncology Unit, Azienda Policlinico-Vittorio Emanuele Università di Catania, Catania, [6]Pediatrics, Fondazione IRCCS Ca Granda, Milano, [7]Pediatrcis, Azienda Ospedaliera di Rimini, Rimini, [8]Pediatrics, Ospedale di Ferrara, Ferrata, Italy

Background: Gaucher disease (GD) is an autosomal recessive lysosomal storage disease related to the deficient activity of beta-glucocerebrosidase (GBA). Typical features are spleno-hepatomegaly, thrombocytopenia, anemia, growth retardation, bone involvement, gammopathies, increased risk of malignancies and, in some patients, neurological manifestations. Symptoms are non-specific and the diagnosis can be delayed for years or missed. Enzyme replacement therapy (ERT) with recombinant GBA is safe and effective in preventing and reversing many clinical manifestations. However, if the diagnosis is delayed, major complications can be permanent.
Aims: We designed the GAU-PED study to evaluate the prevalence of GD among children referred to the haematology paediatric units and selected according a proposed diagnostic algorithm (*Di Rocco et al., Ped Blood & Cancer 2014*). Here, we report an update on results 30 months after the study start, focusing on the long-term outcome of identified GD patients.
Methods: The GAU-PED study, partially funded by Sanofi Genzyme, involves 53 centers of AIEOP Study Group, the Italian clinical research consortium in paediatric hematology. Patients (1-18 years old) referred for spleno-w/wo hepatomegaly and cytopenia (thrombocytopenia and/or anaemia), where other causes of splenomegaly were excluded, are tested for GBA activity on Dried Blood Spots (DBS). Patients whose GBA activity are below normal on DBS are recalled to confirm GBA deficiency using the gold standard assay. For every tested patient, clinical information are collected. The identified GD patients are followed-up.

Table 1.

Clinical characteristics of the 6 patients with Gaucher disease, identified during the first 30 months of enrolment (N/A, not applicable)

	CT_01	MN_01	GE_01	MP_01	FE_01	RN_01

Results: During the first 30 months 74 DBS have been collected from 22 centers. DBS values under 5 pmol/punch^{-1}/h^{-1} were found in 25/74 patients (34%). These patients have been recalled for the conventional enzymatic test. The diagnosis of GD has been confirmed in 6/25 (24%) DBS + patients. In all 6 patients the genetic analysis was consistent with GD. Overall, in the tested population, the prevalence of GD is 8.1% (95% CI, 3.34 - 17.4%) equal to 6/74 enrolled patients. The clinical characteristics of GD patients are summarized in Table 1. Three patients were females and 3 males. The mean age at diagnosis was 9 years (2 - 14 years). Mean time from clinical presentation to diagnosis was 50 months (6-120 months), while the mean time from enrolment to diagnosis was 5 months (3 - 6 months). ERT was started in all GD patients (60 U/kg every 2 weeks). Follow-up data are available for 5/6 patients, since the last patient has just been identified. After a median time from the beginning of ERT of 19 months (6-22 months), cytopenia improved in 4/4 pts, one patient had isolated splenomegaly. 5/5 patients showed a reduction of hepato-splenomegaly, with normalization in 1/5. 1/2 pts with growth delay showed an improvement of growth parameters. No patients had adverse events related to the ERT.
Summary/Conclusion: Our preliminary results support GD screening in a selected population of children with splenomegaly and/or cytopenia, at increased risk for the disease. The proposed algorithm is useful to increase awareness of GD among pediatric hematologists and to shorten the time to diagnosis. Even after a short follow-up, ERT has been able to reverse clinical manifestations and prevent major complications in the identified GD patients. Taking in consideration the long life expectancy of pediatric GD patients, the early diagnosis will have a strong impact on health and quality of life.

LONG-TERM TREATMENT RESPONSE BASED ON SEVERITY OF GAUCHER DISEASE TYPE 1 AT BASELINE IN TREATMENT-NAÏVE ADULT PATIENTS AFTER 8 YEARS OF TREATMENT WITH ORAL ELIGLUSTAT

E. Lukina[1,*], N. Watman[2], M. Dragosky[3], H. Lau[4], E. Avila Arreguin[5], H. Rosenbaum[6], M. Foster[7], S. Gaemers[7], M.J. Peterschmitt[7]

[1]Orphan diseases, National Research Center for Hematology, Moscow, Russian Federation, [2]Hospital Ramos Mejia, [3]IMAI-Research, Buenos Aires, Argentina, [4]New York University School of Medicine, New York, United States, [5]Instituto Mexicano del Seguro Social Hospital de Especialidades, Col. La Raza, Mexico, [6]Rambam Medical Center, Haifa, Israel, [7]Sanofi Genzyme, Cambridge, United States

Background: Gaucher disease type 1 (GD1) is caused by deficient lysosomal enzyme acid β-glucosidase activity, leading to accumulation of glucosylceramide, primarily in macrophages (Gaucher cells). Thrombocytopenia, anemia, hepatosplenomegaly, and skeletal disease are common presenting symptoms. Hematologists frequently diagnose and manage GD1. Eliglustat, an oral substrate reduction therapy, reduces glucosylceramide accumulation by partially inhibiting glucosylceramide synthase and is approved as first-line treatment for adults with GD1 with poor, intermediate, or extensive CYP2D6-metabolizer phenotypes (>90% of patients).
Aims: We report 8-year results of a Phase 2 trial of oral eliglustat (NCT00358150, Sanofi Genzyme) in previously untreated GD1 adults by baseline disease severity (N=26).
Methods: Among the 19 patients who completed the trial, 8-year changes in hematologic and visceral outcomes were evaluated for those with and without moderate/severe baseline disease, defined as platelets <60 x10^9/L (n=8), hemoglobin <10 g/dL for women and <11 g/dL for men (n=7), spleen volume >15 multiples of normal (MN) (n=6), and liver volume >1.25 MN (n=15). We also report individual achievement of long-term Gaucher therapeutic goals (Pastores. *Semin Hematol* 2004), and individual changes in lumbar spine T-score categories.
Results: Trial withdrawals were due to pregnancy (n=3), unrelated adverse events (n=2), related adverse event (n=1), and administrative reasons (n=1). Final mean values for platelets, hemoglobin, spleen, and liver were similar for patients with and without severe baseline disease. All groups attained values within established long-term Gaucher therapeutic goals. Mean platelet counts (x10^9/L) increased by 164% (from 50 to 128) for patients with platelet counts <60 and by 75% (from 83 to 140) for patients with baseline platelet counts ≥60, with an overall increase of 113% (from 69 to 135) for all patients. Mean hemoglobin values in g/dL increased by 3.5

(from 9.6 to 13.1) among patients with moderate to severe baseline anemia and by 1.4 (from 12.3 to 13.7) in patients with no or mild anemia, with an overall increase of 2.2 (from 11.3 to 13.5). Mean spleen volume in MN for patients with severe splenomegaly decreased by 80% (from 26.8 to 5.7) and by 63% (from 12.2 to 4.5) for patents with baseline spleen volume ≤15, with an overall decrease of 69% (from 16.8 to 4.9). Mean liver volumes in MN for patients with baseline liver volume >1.25 decreased by 37% (from 1.81 to 1.12) and by 22% (from 1.08 to 0.85) for patients with baseline liver volumes ≤1.25, with an overall decrease of 34% (from 1.65 to 1.06). Individually, all patients met ≥3 of 4 therapeutic goals after 8 years of eliglustat; all patients showed clinical stability or improvement in all parameters. Baseline lumbar spine T-scores were normal in 5 patients, osteopenic in 8 patients, and osteoporotic in 6 patients. After 7–8 years, T-score categories remained normal or improved in 16 patients and were unchanged in 3 patients, 2 of whom were postmenopausal women. Overall, mean total lumbar spine T-score moved from the osteopenic to the normal range. Eliglustat was well-tolerated; 98% of adverse events were mild or moderate, and 94% were considered unrelated to treatment.

Summary/Conclusion: Treatment-naïve GD1 patients, many with severe baseline disease, experienced clinically meaningful and sustained improvements after 8 years of eliglustat by both aggregate and individual measures. The largest margins of improvement were seen among patients with the most severe baseline disease.

PS1136

COMBINED EMA-BINDING TEST AND OSMOTIC GRADIANT EKTACYTOMETRY SIGNIFICANTLY IMPROVE THE LABORATORY DIAGNOSIS OF HEREDITARY SPHEROCYTOSIS

A. Glenthøj[1,*], J. Petersen[1], A. Nardo-Marino[1], H. Birgens[1]

[1]Department of Hematology, Herlev University Hospital, Herlev, Denmark

Background: Hereditary spherocytosis (HS) is the most common genetic erythrocyte membrane disorder. The laboratory diagnosis of HS has traditionally been based on either osmotic fragility testing (OFT) or flowcytometric measurement of eosin-5-maleimide (EMA) binding to band 3 of the erythrocyte membrane. Osmotic gradiant ektacytometry analyses the erythrocyte deformability as a function of changing osmotic environment under constant shear stress. The test has only recently become widely available for clinical laboratory diagnosis of erythrocyte membrane disorders.
In this study, we combined the EMA-binding test with osmotic gradiant ektacytometry, comparing the results to a comprehensive NGS membranopathy panel.
Aims: To provide a more accurate and cost-effective approach to the laboratory diagnosis of HS and other erythrocyte membrane disorders.
Methods: We included a total of 52 consecutive patients (0 to 86 years old), all referred to our laboratory on the suspicion of a hereditary erythrocyte membrane disorder. In addition to a modified EMA-binding test using commercial rainbow beads as reference, we performed osmotic gradiant ektacytometry using the osmoscan module of the Laser-assisted Optical Rotational Deformability Cell Analyser (LoRRca MaxSis, RR Mechatronics, The Netherlands), as well as a comprehensive NGS membranopathy panel (including a-spectrin, b-spectrin, ankyrin, band 3, protein 4.1, and protein 4.2).
Results: 26 patients had pathogenic or likely pathogenic mutations in a cytoskeleton protein. Individually, osmotic gradiant ektacytometry was highly sensitive in identifying patients with pathogenic mutations and provided an overall accuracy of 0.83 (95% CI: 0.70-0.92), while EMA-binding test delivered a similar accuracy of 0.87 (95% CI: 0.74-0.94). Combination of EMA-binding test and ektacytometry (depicted in Figure 1) was sensitive to all pathogenic mutations and provided an excellent accuracy of 0.92 (95% CI: 0.81-0.98).

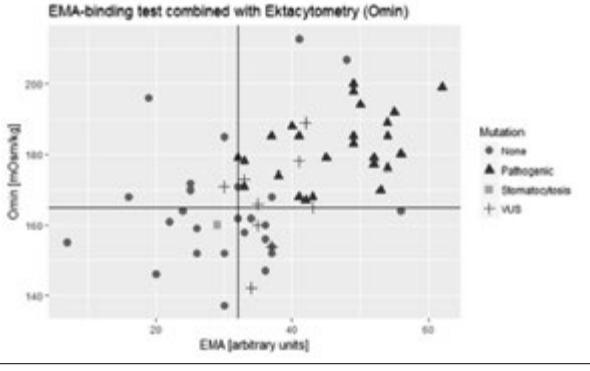

Figure 1.

Summary/Conclusion: Combination of osmotic gradiant ektacytometry and EMA-binding test provided superior precision in diagnostic workup of HS and related disorders.

PREVALENCE AND PREDICTORS OF LIVER FIBROSIS EVALUATED BY VIBRATION CONTROLLED TRANSIENT ELASTOGRAPHY (FIBROSCAN®) IN ADULT PATIENTS WITH TYPE 1 GAUCHER DISEASE

F. Nascimbeni[1], E. Cassinerio[2], A. Dalla Salda[1], I. Motta[2], S. Bursi[1], S. Donatiello[3], V. Spina[3], M.D. Cappellini[2,4,*], F. Carubbi[1]

[1]Division of Internal Medicine and Metabolism, Regional Referral Centre for Lysosomal Storage Diseases, OCSAE, AOU Modena, University of Modena and Reggio Emilia, Modena, [2]Department of Medicine and Medical Specialities, Rare Disease Center, Ca' Granda Foundation IRCCS Ospedale Maggiore Policlinico, University of Milan, Milan, Italy, Milan, [3]Radiology Division, Radiology Division, OCSAE , AOU Modena, Modena, [4]Department of Clinical Sciences and Community Health, Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy, Milan, Italy

Background: Gaucher disease (GD), a rare lysosomal storage disorder, results from glucocerebrosidase (GBA) deficiency, which leads to glycosphingolipids accumulation in macrophages. Liver involvement in GD may range from hepatomegaly to cirrhosis, portal hypertension and hepatocellular carcinoma. Since the risk for liver-related complications is mainly driven by fibrosis, its assessment represents an important step in identifying patients at risk for manifestations of advanced liver disease. However, liver fibrosis has rarely been evaluated in previously published cohorts of GD patients. Vibration controlled transient elastography (VCTE) could be a useful tool for non-invasively screening GD patients for the presence of liver fibrosis.
Aims: We aimed at: 1) assessing the prevalence of significant liver fibrosis by measuring liver stiffness (LS) by VCTE (Fibroscan®) in a cohort of adult patients with type 1 GD; 2) identifying the predictors of LS and significant fibrosis among GD-related variables, enzyme replacement therapy (ERT) and metabolic features.
Methods: 37 adult patients with type 1 GD from two Italian referral centers (Modena and Milan) underwent assessment of GD severity (including Disease Severity scoring system (DS3) and Severity Scoring Index (SSI)), evaluation of metabolic features and VCTE for measuring LS. Significant fibrosis was defined as LS ≥7 kPa.
Results: 21 patients (57%) were males, median age was 46 [18-78] years. 33 (89%) carried at least one GBA N370S mutation. GD severity was mainly mild according to DS3 (1.1 [0-6.7]) and SSI (5 [1-16]). 10 patients (27%) were splenectomized. All but 2 patients were on ERT; median ERT length was 98 [0-294] months. 15 patients (41%) were overweight, 14 (38%) had arterial hypertension and 6 (16%) the metabolic syndrome (MetS). Median LS was 4.6 [3-15.1] kPa and 7 patients (19%) had significant fibrosis. LS was significantly correlated with scores (DS3: rho=0.499, p=0.002; SSI: rho=0.385, p=0.019) and biomarkers (ACE: rho=0.516, p=0.020; HDL cholesterol: rho=-0.423, p=0.009) of GD severity. LS was significantly higher in splenectomized patients (6.7 [3.3-11.3] vs. 4.4 [3-15.1] kPa, p=0.021) and in GD patients who had received ERT for less than 24 months (7.5 [4.4-15.1] vs. 4.3 [3.0-11.3] kPa, p=0.002). Consistently, patients with significant fibrosis presented statistically significant higher values of DS3 and SSI, higher levels of ACE and lower levels of HDL cholesterol, and were more often splenectomized than those without significant fibrosis. Length of ERT was significantly lower in GD patients with significant fibrosis than in those without. In the subgroup of 29 patients who were on stable ERT for at least 24 months, further to splenectomy status (p=0.009), moderate-marked GD according to DS3 (p=0.004) and SSI (p<0.001), non-N370S genotypes (p<0.001), also diastolic blood pressure (rho=0.424, p=0.022), BMI (rho=0.419, p=0.024) and the number of MetS components (rho=0.417, p=0.025) emerged as factors significantly associated with LS and/or significant fibrosis.
Summary/Conclusion: Significant liver fibrosis is present in a non-negligible proportion of adult type 1 GD patients. Splenectomy status, GD severity and GBA non-N370S genotypes were major GD-related predictors of liver fibrosis. Length of ERT was inversely correlated with liver disease in GD patients, suggesting a beneficial effect of ERT on liver fibrosis. However, GD patients on stable ERT should be monitored for metabolic complications, since MetS features may enhance liver disease progression despite optimal GD control.

PS1138

PREVALENCE AND CLINICAL SIGNIFICANCE OF SMALL PNH CLONES IN PATIENTS WITH PRIMARY AUTOIMMUNE HEMOLYTIC ANEMIA

B. Fattizzo[1,*], A. Zaninoni[2], R. Pasquale[1], L. Cro[3], A. Dunlop[4], A. Cortelezzi[5], A. Kulasekararaj[4], W. Barcellini[6]

[1]Hematology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico and University of Milan, [2]Hematology, [3]Cytofluorimetric Service, Central Laboratory, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico of Milan, Milan, Italy, [4]Hematology, King's College Hospital, London, United Kingdom, [5]Hematology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico and University of Milan, [6]Hematology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico of Milan, Milan, Italy

Background: Autoimmune hemolytic anemia (AIHA) is caused by autoantibodies directed against autologous erythrocytes, diagnosed by the direct antiglobulin test (DAT), and classified as warm (IgG+ or IgG and C+), cold (C+), mixed (IgG+high titer C+), and atypical (DAT-, IgM warm, and IgA+). Recently, autoimmunity against marrow precursors, increased presence of fibrosis/dyserythropoiesis, and possible evolution to bone marrow failure (BMF) have been reported and correlated with poor outcome. PNH clone is a typical finding in up to 20-40% of patients with BMF and MDS, and its presence correlates with favorable prognosis and predicts response to immunesuppression.
Aims: To evaluate the prevalence of PNH clones in patients with primary AIHA, and assess its prognostic/predictive significance.
Methods: AIHA patients followed at two tertiary hematology centers in UK and Italy were followed-up from December 2007 until February 2018. The PNH clone was assessed at the time of AIHA diagnosis by FLAER flow-cytometry technique. Clinical characteristics, including therapy lines and marrow features, were also collected. Continuous and categorical variables were assessed by Student's t-test and chi-square or Fisher test, respectively. Kaplan Meyer method was used to evaluate and compare relapse free survival (RFS) and overall survival (OS).

*p≤0.05

Results: Table 1 shows clinical and morphologic characteristics of the 35 patients enrolled, altogether and divided according to PNH clone positivity. Twelve patients (34%) showed a positive clone, with a median size of 0.2% on granulocytes (range 0.1-16%). Considering AIHA type, 2 atypical forms (DAT negative) were PNH+, warm AIHA mainly PNH-, and cold and mixed forms equally distributed. PNH+ cases were more anemic, although not significantly, and displayed higher hemolytic pattern compared to PNH- ones, both considering absolute LDH levels and categorization (92% of cases versus 47% showing LDH levels above 1.5x ULN). As expected, Hb levels positively correlated with bone marrow responsiveness index (r=0.40, p=0.008) and negatively with LDH levels (r=-0.31, p=0.03). Considering marrow characteristics, PNH+ patients showed lower prevalence of hypercellularity (28 vs 43%), MF-1 fibrosis (57 vs 71%, p=0.07), dyserythropoiesis (14 vs 57%, p=0.01), and displayed a smaller lymphoid infiltrate (p=0.05), compared to PNH- ones. Lymphoid infiltrate was CD3+ in 1 PNH+ patient, CD20+ in 2 PNH- cases, and mixed in all the others. Regarding therapy, PNH+ and PNH- cases received 1st and 2nd lines (steroids, rituximab, immunesuppressors and splenectomy) with equal rate. However, the former less frequently required a 3rd treatment course (8% versus 35%, p=0.09) and displayed a significantly higher response to rituximab therapy (100% vs 70%, p=0.04). AIHA related complications occurred in 18 cases, with thrombosis observed more commonly in PNH+ patients (25% vs 13%), acute renal failure in PNH- only (21%), and infections equally in both groups (17 and 21%). Finally, 7 patients died during the observation period, mostly because of infections (N=5). The small number of events precluded any statistical analysis.
Summary/Conclusion: Here we firstly report the prevalence of a small PNH clone in about 30% of primary AIHA patients. PNH+ cases show an increased hemolytic pattern and a better response to first and second therapy lines, suggesting a prevalent autoimmune habitus.

PS1139

COMBINATION TREATMENT OF RITUXIMAB, CYCLOPHOSPHAMIDE, AND DEXAMETHASONE FOR WARM AUTOIMMUNE HEMOLYTIC ANEMIA

C. Piatek[1,*], H. Bocian[2], C. O'Connell[1], I. Weitz[1], H. Liebman[1]

[1]Hematology, [2]Medicine, University of Southern California, Los Angeles, United States

Background: Warm autoimmune hemolytic anemia (WAIHA) is an uncommon disorder of autoantibody-mediated destruction of red blood cells. Because of limited clinical trials, the management of WAIHA is largely based on expert opinion. The standard first and second line therapies are corticosteroids and rituximab, respectively. Although both have high initial response rates, low long-term response rates are often reported. Splenectomy may also be pursued as secondary line therapy; however, response rates are low in patients with secondary WAIHA. The combined regimen of rituximab, cyclophosphamide and dexamethasone (RCD) has been reported to be highly effective in the treatment of AIHA with chronic lymphocytic leukemia (CLL) in the upfront and relapsed setting.
Aims: To evaluate the efficacy of RCD therapy in patients with primary and secondary WAIHA without CLL.
Methods: Between 2009 and 2017, patients with primary and secondary WAIHA without CLL were treated with RCD at Los Angeles County-University of Southern California (LAC-USC) Medical Center and USC Norris Cancer Center. RCD was administered as follows: rituximab 375 mg/m2 IV day (D) 1, cyclophosphamide 750 mg/m^2 IV D1 or 2, and dexamethasone 12 mg orally or IV D1-7. Treatment cycles were repeated at 3-to-4-week intervals at the discretion of the treating physician. Maintenance therapy was defined as immunosuppressive therapy continued or started at the discretion of the treating physician ≤6 weeks after completion of RCD in the patients who achieved a PR or CR. The primary objective was to evaluate the efficacy of RCD therapy in terms of overall response (OR), combining CR and PR. A CR was defined as hemoglobin (Hb) ≥ 12 g/dL without transfusion. A PR was defined as Hb 10-11.9 g/dL or ≥ 2 g/dL increase in Hb without transfusion. Additional objectives were to evaluate the number of cycles until best response and the duration of a sustained response (SR). For patients not receiving maintenance therapy, a SR was defined as Hb ≥ 10 g/dL in the absence of any treatment. For patients receiving maintenance therapy, a SR was defined as Hb ≥ 10 g/dL in the absence of any treatment changes. The duration of SR was calculated from the date of last RCD cycle to the date that the patient no longer met the criteria for SR or date of last follow-up if the patient remained in a SR.
Results: 23 patients with WAIHA were treated with RCD (9 with primary WAIHA and 14 with secondary WAIHA) for a median number of 4 cycles (range 2-6). RCD was given for relapsed/refractory disease in 16 patients. The median pre-treatment Hb was 9.2 g/dL (4.3-12.2). The median best Hb achieved with RCD was 12.5 g/dL (10.6-15.1) with a median Hb

increase of 4.2 g/dL (0.4-9.8). The OR was 96% (16 with CR, 6 with PR) with a median number of 2 cycles given until best Hb response. Among the patients who achieved a CR, 11 had secondary WAIHA and 12 had received prior treatment. Among those who achieved a PR, 3 had secondary WAIHA and 2 had received prior treatment. 11 patients received maintenance immunosuppression (prednisone, azathioprine, mycophenolate, sirolimus, and cyclosporine) after completing RCD with a median duration of response of 6 months with responses ongoing in 7 patients. For the 12 patients not on maintenance immunosuppression, the median duration of response was 8 months with responses ongoing in 4 patients.
Summary/Conclusion: RCD had a high OR in the upfront and relapsed/refractory treatment of primary and secondary WAIHA with an acceptable toxicity profile.

PS1140

THE ESTABLISHMENT OF SD RAT MODEL AND HISTOPATHOLOGICAL STUDY OF IMMUNE HEMOLYTIC DISEASE INDUCED BY ANTIBODY

S. Yan[1,*], L. Li[1], Z. Li[1]

[1]Shanghai Jiao Tong University Affiliated Sixth People's Hospital, shanghai, China

Background: At present, the animal model of immune hemolytic preparation mainly in two ways, respectively for Playfair –MarshallClarke's autoimmune hemolytic anemia mouse model in 1973 and spontaneous immune hemolytic disease in NZB mice, The former model establishes need a longer period of preparation, with low success rate , the latter model is also expensive in price and not easy to get. Therefore, both of the two animal models were not widely used. In addition, subcutaneous injection of phenylhydrazine or other chemical agents can also establish the animal model of hemolytic anemia, but its further research is limited in Pathogenesis and pathological process and drug efficacy study of many immune factors inducing the clinical hemolytic disease.
Aims: To establish an immune hemolytic SD rat model, to provide an experimental platform for its pathogenesis, pathological process and the evaluation of drug effect.
Methods: The red blood cells of SD rats were isolated and intraperitoneally injected into balb/c mice to induce the production of anti SD rat red blood cell antibody serum.Twenty SD rats were randomly divided into two groups. The model group:were injected with 0.1 ml antiserum via tail vein ;the control group: were injected with 0.1 ml saline via tail vein.The clinical symptoms, hemolysis related indexes and histopathological changes of the main organs were observed in both two groups after injection.
Results: After the injection of antiserum,the model group of SD rat developed shortness of breath, fatigue and weakness, weakened ability of ingestion and water intake, skin and mucosal jaundice and hemoglobin urine visible to the naked eyes.Four days after the injection, the weight of SD rats in the model group was significantly lower than that in the control group ($p<0.01$), and the coefficients of liver and spleen increased significantly ($p<0.01$); The levels of blood WBC, MCV, MCH, DBIL, DBIL/TBIL and FHb all increased significantly, and RBC, Hb, HCT, MCHC and PLT levels decreased significantly, which were all statistically significant compared with the control group ($p<0.01$). In the model group of SD rat, hemolytic pathological changes were observed in liver, spleen, kidney, lung and small intestine, and erythroid proliferation was observed in bone marrow smears.
Summary/Conclusion: The SD rat model of immune hemolytic disease can be successfully established by using balb/c mouse anti-SD rat erythrocyte antibody serum, and the pathological changes of liver, spleen, kidney, intestine, bone marrow and other important organs can be observed.It has the characteristics of a high success rate, good repeatability and low preparation cost. Therefore, the establishment of the model is helpful to further study the pathogenesis of immune hemolytic disease and the efficacy of drugs, which have important clinical significance.

PS1141

ALPS AND GAUCHER DISEASE. A CLINICAL AND IMMUNOLOGICAL OVERLAP

M. Miano[1,*], E. Palmisani[1], F. Fioredda[1], P. Terranova[2], E. Cappelli[2], T. Lanza[2], R. Maggiore[1], A. Pezzulla[1], C. Dufour[1], C. Micalizzi[1], A. Beccaria[1], A. Madeo[1], M. Di Rocco[1]

[1]Haematology Unit, [2]Haematology Lab Unit, IRCCS Istituto Giannina Gaslini, Genova, Italy

Background: Gaucher Disease (GD) is anautosomal recessive lysosomal disorder secondary to a mutation in the GBA1 gene that causes a defective function of the catabolic enzyme β-glucocerebrosidase (GBA). The impaired function of this enzyme leadsto a progressive accumulation of its substrate-glucocerebroside (GC) -in various organs in particular in mononuclear phagocite system. Bone infiltration, hepatosplenomegaly and cytopenia represent the most common features of the disease. Since clinical manifestation can be subdolous, in some cases, phenotype can overlap with Autoimmune Lymphoproliferative Sindrome. Nonetheless, GD patients also show hyper-inflammatory features-secondary to machrophages engorgement and actviation-and animmune-dysregulation involving B , T and NK cells. However, few data are available on specific immunity pattern in these patients.
Aims: to evaluate immune-phenotype and other ALPS parameters in a cohort of patients with GD
Methods: We evaluated the test of apoptosis and the immunophenotypic and serological features usually typical of ALPS patients (Double Negative T-cells, TCR alfa/beta B220, B-memory cells, T-regs/HLA-DR ratio, IL-10, IL-18,) in a cohort of patients with GD followed-up at Istituto Giannina Gaslini.
Results: 35 patients (28 in treatment, 5 not) were studied. DNTs and TCR alfa/beta B220+ resulted to be >1.5% of T-lymphocytes and > 60% in 6/32 (19%) and in 7/32 (22%), respectively. B-memory cells and T-regs/HLA-DR ratio were <15% and <1 in 11/32 patients (34%). 3/32 evaluable (9%) had all these parameters concomitantly alterated. 4/19 (21%) evaluable patients were resistant to apoposis. IL-18 was pathological in 26/29 (89%) patients All patients had normal levels of IL-10 and sFAS.
Summary/Conclusion: This study shows that some patients with GD may present an immune-dysregulation pattern that can overlap with ALPS features. Therefore, the differential diagnosis of GD should be taken into consideration by clinicians during diagnostic work-up of patients with an ALPS-like phenotype

PS1142

ORGAN INVOLVEMENT IN RARE HEREDITARY HEMOLYTIC ANEMIA

S. Van Straaten[1,2,*], J. Verhoeven[1,2], S. Hagens[1,2], R. Schutgens[2], W. van Solinge[1], R. van Wijk[1], E. J. van Beers[2]

[1]Laboratory of Clinical Chemistry & Haematology, [2]Van Creveldkliniek, University Medical Center Utrecht, Utrecht, Netherlands

Background: In sickle cell anemia and β-thalassemia the occurrence of disease related organ damage is a well-known important determinant of morbidity and prognosis. However, for other forms of rare hereditary hemolytic anemia, not much is known about disease-related organ involvement, especially for non-transfusion dependent patients.
Aims: The goal of this study is to analyze occurrence and severity of organ involvement in several rare forms of hereditary hemolytic anemia.
Methods: This is a cross sectional, observational study on 97 patients with rare hereditary hemolytic anemia. It encompasses (early markers of future) organ damage, markers of altered organ function (e.g. endocrine changes) and other non-hematological symptoms known to influence morbidity and prognosis in chronically ill patients (e.g. inflammation). After informed consent patients were divided into four disease categories: sickle cell disease (SCD), other hemoglobin disorders (e.g. β-thalassemia), red cell enzyme disorders (e.g. pyruvate kinase deficiency) and red cell membrane disorders (e.g. hereditary spherocytosis). Data was collected through chart review. Clinical parameters of organ involvement were scored according to diagnosis by the treating physician. (Bio)marker based organ involvement was scored according to international standards. When the medical history of a patient was not available, parameters were regarded as missing. Only patients with more than 12 scorings items available were included in the analysis.
Results: At inclusion patients had a median age of 40 years (range 18-84) and a median Hb of 11,3 g/dL (range 6,4-16,4). 47% was female. Of the 90 patients with more than 12 scorings items available, 80 (88%) showed a form of organ involvement. Most reported organ involvement was liver iron overload (LIC>3 mg/g DW) as reported in 43/55 (78%) of patients. Most importantly, organ involvement was not limited to transfusion dependent patients: 29/34 (85%) patients who had never received a red cell transfusion did show some form of organ involvement. These patients did not have a significantly different median Hb or reticulocyte count compared to never transfused patients without organ involvement (SCD patients were excluded from this analysis) (Table 1).
Summary/Conclusion: This study shows that organ involvement is not limited to patients with SCD or β-thalassemia, but also occurs in other forms of hereditary hemolytic anemia. Importantly, organ involvement also occurs in patients who never received blood transfusion(s). This study also shows that often parameters indicative of organ involvement were not measured or not mentioned in patients' file. This indicates that screening for organ involvement does not structurally occur in patients with hereditary hemolytic anemia. The development of

better screening guidelines is therefore important to identify organ involvement in patients with hereditary hemolytic anemia at an early stage.

SUCCESSFUL TREATMENT OF MEGALOBLASTIC ANEMIA WITH BONE MARROW MYELODYSPLASIA IN LESCH-NYHAN SYNDROME

M. Machaczka[1,2,*], G. Kleinotiene[3], M. Klimkowska[4]

[1]Medical Faculty, University of Rzeszow, Rzeszow, Poland, [2]Hematology Center Karolinska, Karolinska University Hospital Huddinge, Stockholm, Sweden, [3]Cente of Hematology and Oncology, Children's Hospital, Affiliate of Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania, [4]Department of Clinical Pathology and Cytology, Karolinska University Hospital Huddinge, Stockholm, Sweden

Background: Lesch-Nyhan syndrome (LNS) is a very rare (incidence 1-9 patients/1 million people), inherited disease of purine metabolism. Deficient activity of enzyme hypoxanthine-guanine phosphoribosyltransferase (HPRT) causes dysfunction of nervous system and kidneys. LNS is the most severe form of HPRT deficiency, with deeply decreased or complete lack of HPRT activity. Children with LNS usually present no symptoms at birth but 3-6 months later a delay in psychomotor development is revealed. Patients develop hyperuricemia, impaired kidney function, articular and nervous system symptoms, including cognitive impairment and behavioral problems such as self-mutilation. Megaloblastic anemia may also occur, which is not a constant feature of LNS but develops only in some patients. Anemia is cobalamin (vitamin B12) and folic acid (FA) resistant, however, it is believed that increased consumption of these vitamins occurs in LNS patients.

Aims: We present a case of a young man with LNS who developed severe megaloblastic anemia which has been successfully treated with adenine.

Methods: A 25-year-old man with LNS developed megaloblastic anemia (Hb 96 g/L, MCV 121 fL) refractory to 3 months' treatment with vitamin B12 and FA. Other lab values showed: WBC 6.3×10^9/L (ref.: 3.5–8.8), PLT 139×10^9/L (ref.: 145–348), cobalamin 560 pmol/L (ref.: 150–650), folic acid >1200 nmol/L (ref.: 330–870), S-methylmalonate 0,26 µmol/L (ref.: <0,4), P-homocysteine 6,1 µmol/L (ref.: 5–15). Bone marrow (BM) examination revealed a slightly reduced BM cellularity (hypocellular) with 1% of blasts, 5% of promyelocytes/promonocytes, and distinct maturation abnormalities in all hematopoietic cell lines, with pictures of multilineage dysplasia resembling a myelodysplastic syndrome (Figure 1 - BM smear: myeloid cell with ring-shaped nucleus, erythroid precursors with multiple or irregular nuclei, stippling).

Results: Thanks to pharmaceutical company Apoteket AB, capsules with adenine (formerly called as a vitamin B4) 300 mg per capsule were prepared for the patient and administered t.i.d. (900 mg/day). Oral adenine treatment rapidly cured the patient's megaloblastic anemia within one month (Hb concentration increased to 132 g/L and MCV decreased to 95 fL). Moreover, BM examination performed 6 months after onset of adenine therapy showed significantly improved cytomorphology of hematopoietic cells, primarily concerning erythropoiesis. Other hematopoietic cell lines still showed dysplastic features but to a significantly lesser extent. Megaloblastic anemia has been permanently cured in the patient thanks to long-term oral adenine administration. No adverse reactions have been observed. The effect of adenine treatment remains stable for 7 years now.

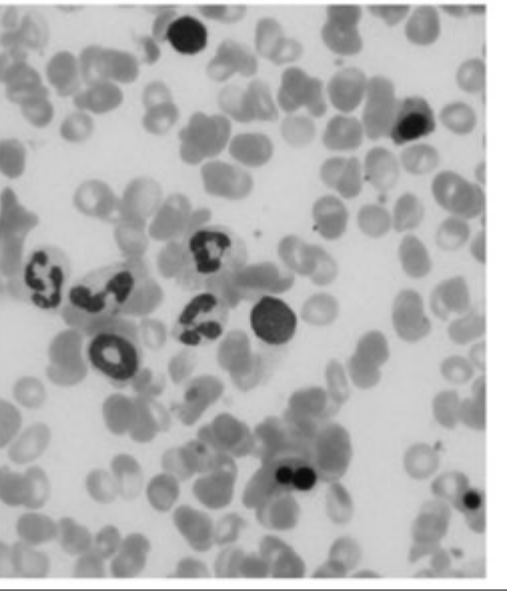

Figure 1.

Summary/Conclusion: Long-term oral administration of adenine, previously known as vitamin B4, has a potential to cure megaloblastic anemia in patients with LNS. Moreover, adenine significantly improves multilineage dysplasia in BM underlying the diagnosis of megaloblastic anemia. Protracted therapy with adenine is well tolerated, with no adverse events in the described patient under 7 years of treatment.

CORD BLOOD DERIVED GAMMA-DELTA T CELLS CAN BE EXPONENTIALLY EXPANDED *IN VITRO* TO INDUCE POTENT CYTOTOXICITY AGAINST HUMAN ACUTE MYELOID LEUKEMIA CELLS

A. Cheung[1,2,*], K. W. Tan[3], D. Guo[1], A. Lau[3], X. Fan[3], Z.Y. Poon[1], Y.C. Linn[1], W. Hwang[1], S. Li[2], Y.T. Goh[1]

[1]Haematology, Singapore General Hospital, [2]Cancer and Stem Cell Biology, Duke-NUS Medical School, [3]Clinical Translational Research, Singapore General Hospital, Singapore, Singapore

Background: Despite the unsurpassed efficacy of standard chemotherapy for acute myeloid leukemia (AML) patients in the past decades, the overall survival (OS) remains dismal due to the high rate of disease relapse and treatment intolerance. There is thus an urging need for more effective treatment alternatives.
Aims: Early seminal studies had observed strong association of an increased number of donor derived γδ T cells (specifically the Vδ1+ subtype) in AML patients receiving allogeneic hematopoietic stem cell transplant (HSCT) with improved OS. As such, we hypothesize that these allogeneic γδ T cells may exhibit potent leukemia specific cytotoxicity and serve as an effective treatment for AML.
Methods: Given the rapid availability and widespread use of cord blood (CB) as an alternative for allogeneic HSCT, we had explored the potential of expanding CB derived γδ T cells *in vitro*. In our cohort of CB, 0.17±0.04% of mononuclear cells are γδ T cells. Contrary to adult mobilized peripheral blood, majority of the CB derived γδ T cells are of $V\delta1^+$ and $V\delta1^-\delta2^-$ subtype (93.6±2.4%). Importantly, our data showed that in keeping with the neonatal origin of CB, γδ T cells in CB display a predominately central memory (T_{cm}) and naïve (T_n) phenotype, making these cells favorable for extensive *in vitro* expansion. Using our in-house optimized *in vitro* expansion protocol, we were able to achieve up to 10^5-fold expansion of the starting γδ T cells over a period of 21 days.
Results: The expanded γδ T cells exhibit potent *in vitro* cytotoxicity against a range of human AML cell lines in a dose dependent manner, yet display minimal cytotoxicity against $CD34^+$ cells isolated from allogeneic CB samples. Notably, we found that NK receptors (NKR) such as NKG2D, NKp30 and NKp46, were minimally expressed (<10%) in the expanded γδ T cells. Consistent with this, when specific TCRγδ and NKR receptor-blocking antibodies were added to the mixture of γδ T cells and AML cell line in standard ^{51}Cr-release assays, no significant decrease in γδ T cell cytotoxicity were observed. These data suggest that the expanded γδ T cell cytotoxicity is likely to be mediated via TCRγδ and NKR independent signaling pathways. Intravenous infusion of the expanded γδ T cells into NOD/SCID/IL2R$\gamma^{-/-}$ (NSG) mice that had been xenografted with primary AML patient sample led to the detection of these cells across major hematopoietic tissues including the bone marrow (BM), spleen and liver, as well as in the circulation. Moreover, the homing potential of the infused γδ T cells significantly correlated with the amount of AML cells present in the tissues, demonstrating that these cells are chemotactic towards primary AML cells *in vivo*. Such *in vivo* γδ T cell treatment resulted in significant reduction of BM leukemic burden compared to untreated control. More importantly, BM cells from γδ T cells-treated mice had a significantly reduced ability to regenerate leukemia upon secondary transplantation, strongly suggesting that the infused γδ T cells also targets the primitive leukemia initiating cells.
Summary/Conclusion: In summary, our data demonstrates that *in vitro* expanded CB derived γδ T cells show potent AML-specific cytotoxicity both *in vitro* and *in vivo*, making it a promising alternative cell source for immunotherapy. Further investigations to enhance the mechanistic understanding would be needed to seed for future clinical translation.

PS1145

ENHANCED BONE MARROW HOMING OF NATURAL KILLER CELLS FOLLOWING MRNA TRANSFECTION WITH GAIN-OF-FUNCTION CXCR4

E. Levy[1,2,*], R. Reger[1], R. Childs*[1], M. Carlsten*[1,3]

[1]Hematology, National Institutes of Health, Bethesda MD, [2]Molecular Medicine, George Washington University, Washington DC, United States, [3]Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden

Background: Natural killer (NK) cells have proven to be powerful effectors against hematological tumor targets in pre-clinical studies. In subsets of patients with hematological malignancies, NK cell infusions can induce remission. However, the therapeutic potential of intravenously (IV) transferred NK cells has thus far been limited, perhaps in part the consequence of their suboptimal bone marrow (BM) homing capacity. As most hematological malignancies arise and reside in BM compartments, developing an NK cell product that has an improved ability to home to the BM may lead to improved clinical response. As hematopoietic stem cells (HSCs) are known to engraft in BM compartments via CXCR4/SDF-1a signaling, we explored the potential of NK cells genetically engineered to express a naturally occurring gain-of-function CXCR4 (CXCR4-R334X) receptor to enhance their BM homing capacity.
Aims: The aim of this study was to generate a modified NK cell product with improved BM homing capacity compared to unmodified NK cells.
Methods: Human NK cells were isolated from healthy donor buffy coats and expanded for 14 days with irradiated EBV-LCL feeder cells in IL-2 containing media. Electroporation of NK cells with mRNA coding for either the wild-type CXCR4 (CXCR4-WT) or the gain-of-function CXCR4-R334X receptor, was performed using the cGMP-compliant MaxCyte GT instrument. NK cell chemotaxis towards SDF-1a (0, 25, 50, 100, 200 ng/mL) was assessed *in vitro* 8 hours post transfection using transwell migration assays (n=10 donors). *In vivo* homing studies were conducted in NSG mice receiving either $10x10^6$ control NK cells, $10x10^6$ CXCR4-R334X NK cells, or as a BM homing control, $1x10^6$ plerixafor-mobilized CD34+ HSCs (n=9-10 animals per group). Blood, BM (femur), liver, lung, and spleen were harvested 24 hours post IV infusion and recovered cells were analyzed with flow cytometry.
Results: CXCR4-R334X transfected NK cells exhibited more prominent migration *in vitro* to SDF-1a at 25 and 50 ng/mL compared to control NK cells ($p<0.001$ for both concentrations). Overall, NK cell CXCR4 surface expression positively correlated with *in vitro* migration towards SDF-1a ($r=0.64$, $p=0.0002$). Consistent with the *in vitro* findings, significantly less circulating CXCR4-R334X transfected NK cells were found in blood of NSG mice ($t=3.45$, 95%CI=-0.1383 to -0.02828, $p<0.01$) and more CXCR4-R334X NK cells were found in the BM ($t=5.017$, 95%CI=0.002348 to 0.005756, $p=0.0001$) compared to control NK cells. The recovery of HSCs in BM compartments was significantly higher than that of non-transfected and transfected NK cells ($t=15.5$ and 14.2 respectively, and $p<0.0001$ for both). These findings demonstrate that low baseline homing of NK cells to the BM can be significantly improved by genetically modifying NK cells to express CXCR4-R334X (Figure 1).

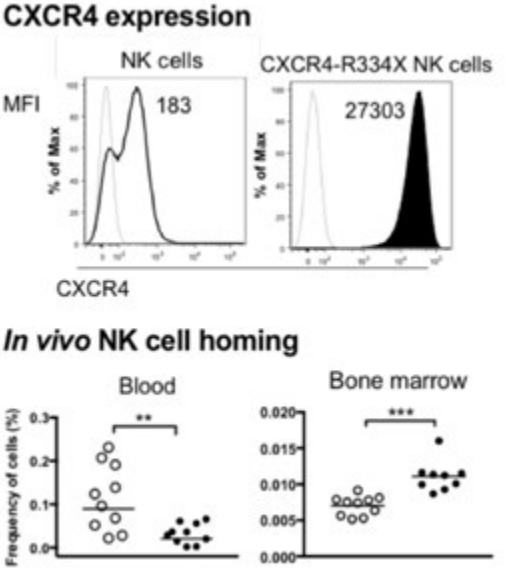

Figure 1.

Summary/Conclusion: This proof-of-concept study demonstrates that NK cell homing to BM compartments can be significantly enhanced as a result of transfection with CXCR4-R334X-coding mRNA. These data suggest CXCR4-R334X-expressing NK cells might be a more effective NK cell product than unmodified NK cells for the treatment of patients with BM-residing hematological malignancies. Efforts to modify ex vivo expanded NK cells to overexpress CXCR4 and other receptor/receptor ligands to establish BM homing capacity comparable to CD34+ HSCs are ongoing.

PS1146

INTERLEUKIN-15-CULTURED DENDRITIC CELLS ENHANCE ANTI-TUMOR GAMMA DELTA T CELL FUNCTIONS THROUGH IL-15 SECRETION

H. Van Acker[1,*], S. Anguille[2,3], H. De Reu[1], Z. Berneman[1,2,3], E. Smits[1,3,4], V. Van Tendeloo[1]

[1]Laboratory of Experimental Hematology, University of Antwerp, Antwerp, [2]Division of Hematology, [3]Center for Cell Therapy & Regenerative Medicine, Antwerp University Hospital, Edegem, [4]Center for Oncological Research (CORE), University of Antwerp, Antwerp, Belgium

Background: Dendritic cell (DC) vaccination can be an effective post-remission therapy for acute myeloid leukemia (AML). We recently showed that WT1 mRNA-electroporated conventional interleukin (IL)-4 DCs prevent or delay relapse in 43% of AML patients in remission after chemotherapy (Anguille *et al.* Blood 2017). Yet, these current IL-4 DC vaccines do not encompass the ideal stimulatory triggers for innate gamma delta (γδ) T cell anti-tumor activity. Promoting type 1 cytotoxic γδ T cells in patients with AML is, however, most interesting, considering these unconventional T cells are primed for rapid function and exert meaningful control over AML. Indeed, a recent meta-analysis of gene expression data from over 18000 cancers, including hematological malignancies, identified the presence of γδ T cells to be the most significant factor associated with favorable prognosis (Gentles *et al.* Nature Medicine 2015). We have recently shown that our IL-15 DCs are capable of recruiting various cytotoxic effector cells including γδ T cells suggesting the possibility of interaction (Van Acker *et al.* Oncotarget 2017).
Aims: In the current study, we characterized the IL-15 DC-mediated γδ T cell activation on both the phenotypic and functional level and investigated the potential mechanisms involved.
Methods: Human monocyte-derived DCs were generated according to our rapid DC culture protocol involving IL-15 for DC differentiation and a Toll-like receptor agonist for DC maturation. These IL-15 DCs were tested in terms of their capacity to boost type 1 cytotoxic γδ T cells.
Results: In this work we demonstrate that IL-15 DCs have the capacity to enhance the anti-tumoral functions of γδ T cells. IL-15 DCs of healthy donors and of AML patients in remission induce the upregulation of cytotoxicity-associated and co-stimulatory molecules on the γδ T cell surface, but not of co-inhibitory molecules, incite γδ T cell proliferation and stimulate their interferon-γ production in the presence of blood cancer cells and phosphoantigens. Moreover, the innate cytotoxic capacity of γδ T cells is significantly enhanced upon interaction with IL-15 DCs, both towards leukemic cell lines and allogeneic primary AML blasts. Finally, we address soluble IL-15 secreted by IL-15 DCs as the main mechanism behind the IL-15 DC-mediated γδ T cell activation.
Summary/Conclusion: These results indicate that the application of IL-15-secreting DC subsets could render DC-based anti-cancer vaccines more effective through, among others, the involvement of γδ T cells in the anti-leukemic immune response.

PS1147

SYNERGISTIC ANTITUMORAL EFFICACY OF A NOVEL REPLICATIVE ADENOVIRUS SG611-PDCD5 AND DAUNORUBICIN IN HUMAN LEUKEMIC CELLS

Y.-L. Zhou[1,*], Q.-M. Yao[1], J. Zhou[1], Y. Chang[1], J.-L. Li[1], Y.-Z. Wang[1], Q.-J. Qian[2], H.-P. Wu[2], L.-F. Li[2], Y.-H. Chen[1], Y.-R. Liu[1], X.-J. Huang[1], G.-R. Ruan[#1]

[1]Peking University People's Hospital, Beijing, [2]Laboratory of Viral and Gene Therapy, Eastern Hepatobiliary Surgical Hospital, Second Military Medical University, Shanghai, China

Background: Daunorubicin is a traditional chemotherapeutic agent and plays a pivotal role in leukemia therapy. However, the dose-related toxicity, especially cardiotoxicity, caused by daunorubicin limits its clinical use and remains a considerable challenge for clinicians. The apoptosis-regulating gene *PDCD5*, is downregulated in various tumors including leukemias, might provide a potential target for the diagnosis and treatment of leukemia.
Aims: The purpose of this study was to construct a triple-regulated oncolytic adenovirus carrying *PDCD5* gene expression cassette(SG611-PDCD5) and to explore the combined antitumor efficacy of SG611-PDCD5 in combination with low dose daunorubicin on leukemia cell lines and nude mouse xenograft models.
Methods: A variety of leukemic cell lines were cultured according to the providers instructions. The insertion and orientation of all recombined plasmids were confirmed by restriction enzyme digestion and polymerase chain reaction. The tumor-selective replication of the constructed conditionally replicating SG611-PDCD5 and its antitumor efficacy in combination with daunorubicin were characterized in several leukemic cell lines *in vitro* and in nude mouse xenograft model of K562 cells *in vivo*. Cell viability was detected by using Cell Counting Kit-8. Cell Apoptosis was detected in whole living cells using flow cytometry and in paraffin-embedded tumor tissues using the TUNEL kit.
Results: The triple-regulated CRAd carrying the *PDCD5* gene expression cassette, SG611-PDCD5 and the nude mouse xenograft models of K562 cells were successfully constructed. In SG611-PDCD5, the *E1a* gene with 24 nucleotides deleted from the CR2 region was controlled by the human telomerase reverse transcriptase (hTERT) promoter, *E1b* gene expression was directed by the hypoxia response element (HRE), and the *PDCD5* gene was controlled by the cytomegalovirus promoter. SG611-PDCD5 in combination with low-dose daunorubicin demonstrated more potent anti-proliferative and pro-apoptotic effects in leukemic cells in a dose-dependent manner *in vitro*. In xenograft nude mice models, tumor sizes in the control, daunorubicin, SG611-PDCD5, and combined treatment groups on day 10 were 170.1±47.8, 111.9±81.1, 60.7±12.3, 33.2±17.5 mm^3, respectively. TUNEL assay showed significantly more apoptotic cells in the SG611-PDCD5 plus daunorubicin group than in the SG611-PDCD5 or daunorubicin groups (25, 12.5, and 7.8 apoptotic cells/field, respectively; $p<0.05$). (Figure 1).

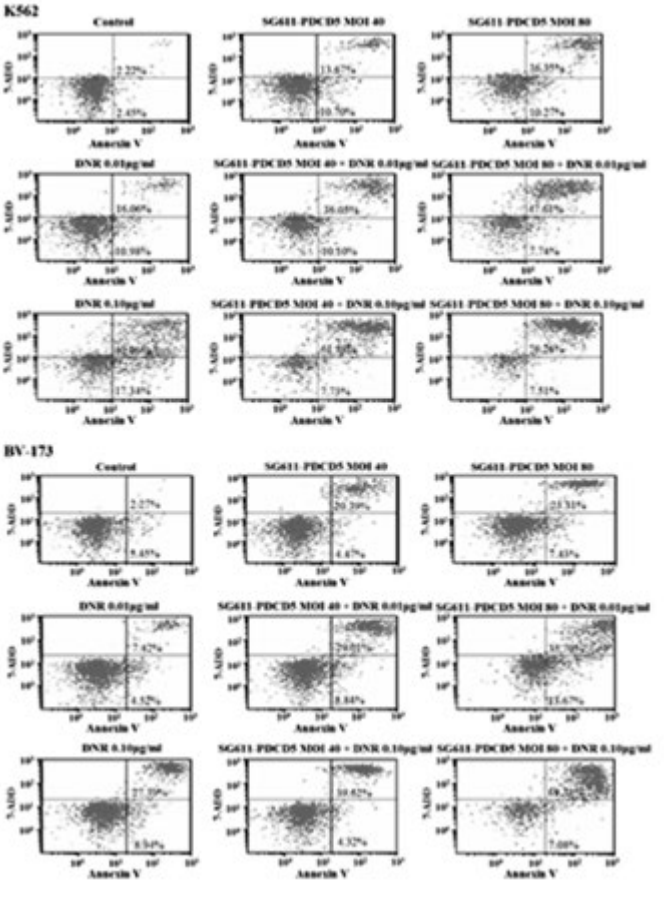

Figure 1. Apoptosis of K562 and BV-173 cells treated with SG611-PDCD5 followed by daunorubicin treatment. SG611-PDCD5 and low-dose daunorubicin synergistically showed pro-apoptosis effects that were significantly more potent than those of SG611-PDCD5 or daunorubicin alone.

Summary/Conclusion: Our findings suggested that combined treatment with SG611-PDCD5 and daunorubicin may be a promising strategy for enhancing chemosensitivity and thus lowering the dose-related toxicity of daunorubicin in leukemia therapy.

PS1148

NOVEL RNA CONSTRUCT INCREASES PERFORIN AND GRANZYME B IN NATURAL KILLER AND CYTOTOXIC T CELLS

A. Wagner[1,*], M. Chrobok[1,2], A. Hussain Baloch[1], C. Dahlberg[1], H. Nahi[1,3], H.-G. Ljunggren[1], E. Alici[1,2,3]

[1]Dept. of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden, [2]NSU Cell Therapy Institute, Nova Southeastern University, Fort Lauderdale, Florida, United States, [3]Haematology Centre, Karolinska University Hospital, Stockholm, Sweden

Background: Stimulation and activation of the cytosolic RNA recognition receptors RIG-I and MDA-5 are very attractive to boost the immune response of activated lymphocytes. Activation will stimulate the synthesis of a broad range of antiviral effector molecules, cytokines and chemokines that have a crucial role for priming, expansion and polarization of immune cells.
Aims: In this study, we aimed to identify optimal inducers of perforin and granzyme B production in cytotoxic lymphocytes.
Methods: We used NK cell and T cell *in vitro* response assays, measured granule content of Granzymes and Perforin, tested the compound in a mouse model for *in vivo* activity.
Results: Initially, we tested the hypothesis of RIG-I induction leading to better perforin and granzyme B expression by using previously published RIG-I agonists. While we can observe an increase in type I interferon secretion, we could not detect a significant increase in either of the cytotoxic granule components. In contrast, when we screened novel, much shorter and structurally different RNA constructs, a significant increase in expression of perforin and granzyme B could be detected in NK cells and T cells.
Introduction of the best construct to NK cells using transfection or extracellular vesicle-mediated delivery resulted in a rapid increase of both molecules, which could be further boosted by IL-2. To our knowledge, this is the first report of an RNA construct leading to such a drastic difference in the proteomic profile of cytotoxic lymphocytes. We administered the RNA construct to a syngeneic immunocompetent multiple myeloma (MM) mouse model in which activated NK cells are critical for MM rejection in a dose-dependent manner. When administered for a brief period shortly after establishment of minimal residual disease, the construct resulted in a significant delay in tumor development and increased survival compared to published RIG-I agonists. We have not observed any off-target effects or severe adverse events. Further studies are needed to elucidate the best platform and method of delivery for optimal anti-tumor activity.
Summary/Conclusion: Our novel RNA construct leads to an increase in cytotoxic granule content in Natural Killer and Cytotoxic T cells, and increased killing activity *in vitro*. When used *in vivo*, in a mouse model for multiple myeloma, the compound delayed tumor growth and increased survival of tumor-bearing mice.

THE REDUCTION OF GRAFT-VERSUS-HOST DISEASE AND TRANSFUSIONAL NEEDS AFTER THE APPLICATION OF MESENCHYMAL STEM CELL THERAPY FOLLOWING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

E. Molnar[1], A. Barta[2], A. Batai[2], Z. Csukly[2], L. Gopcsa[2], G. Tatai[2], L. Lengyel[2], T. Masszi[3], G. Mikala[2], M. Paksi[2], M. Réti[2], E. Torbagyi[2], H. Andrikovics[4,*], H. Bönig[5], P. Bader[5], P. Remenyi[2]

[1]Department of Serology, Hungarian National Blood Transfusion Service, [2]Department of Hematology and HSCT , Central Hospital of Sothern Pest, [33]rd Department Of Internal Medicine, Semmelweis University, [4]Laboratory of Molecular Diagnostics, Central Hospital of Sothern Pest, Budapest, Hungary, [5]Division for Stem Cell Transplantation and Immunology, University Hospital Frankfurt/Main, Frankfurt, Germany

Background: Steroid refractory *graft*-versus-host disease (GvHD) is a serious complication of allogeneic hematopoietic stem cell transplantation (HSCT). *More experience accumulates in* the immunomodulatory effect of mesenchymal stem cell (MSC) infusion in numerous *immunopathological* disorders – such as GvHD – and signals. *MSCs have a HLA-restrictive and non-immunogenic nature.*
Aims: *We have evaluated the efficacy of MSC transfusions in cases of GvHD refractory to conventional immunosuppressive treatment.*
Methods: *Patients with steroid-resistant GvHD* were treated with the licensed MSC product *(derived from bone marrow,* "MSC-FFM" /Kuci *et al.* Haematologica 2016/ submitted on a named-patient basis) *4 times per case weekly at a dose of 1 million cells/kg. This is a novel MSC product originating from 8 volunteer donors generated in the University of Frankfurt am Main, Germany. Clinical response was assessed 28 days after administering the first dose. Complete remission was defined as the complete disappearance of symptoms. Partial remission was assessed by the significant relief of symptoms and by the general improvement of the patient's condition. We have evaluated the red blood cell and platelet concentrate needs of the patients before and after the treatment.*
Results: Our 12 patients had received a total of 13 cycles of MSC-treatment (4 doses per cycle). The median age was 47 (19-56) years with a male/female ratio of 1:2. Distribution of the underlying malignancies (n): acute myeloid leukemia: 6; acute lymphoblastic leukemia: 2; myelofibrosis: 1; myelodysplastic syndrome: 1; multiple myeloma: 1; T-cell lymphoma: 1. Nine patients had undergone allogeneic HSCT with matched unrelated donors, the other three had stem cells derived from HLA-identic relatives. The first episode of GvHD after HSCT was observed on the median 63rd (7-455) day. The involved organs were skin (2), gut (4), skin and gut combined (7) and lung in 3 cases. We applied an average of 3 lines of treatment (it varies from 1-5 lines) before we started MSC treatment. The median time of MSC's first infusion was 274 (114-1981) days after stem cell transplantation (HSCT) and 165 (19-1974) days after the first episode of GvHD. Four of the 13 cycles of MSC-treatment led to complete remission (30.8%) and 7 resulted in partial remission (53.8%). All of the patients GvHD NIH stage score was 3 before MSC infusions, and it decreased to a median of 1 after treatment. The overall survival on the 180th day after the first GvHD was 75%. After the MSC treatment the need of red blood cell concentrate were reduced from an average of 12.83 to 8.92 (30.5% reduction) and the platelet concentrate need from an average of 107.17 to 50.75 (52.6% reduction). The average Corrected Count Increment indicating the effectivity of the platelet concentrates administered increased from 0.173 before MSC treatment to 0.511.
Summary/Conclusion: *According to our observation MSC-therapy with the novel and unique MSC product MSC-FFM is an effective treatment for GvHD in the majority of the observed cases with 83% overall cumulative response rate. The reduction of the transfusional needs of after the MSC treatment also shows promising results. The application of third-party MSCs offers a promising alternative in the therapy of GvHD and other GvHD-associated complications after HSCT. Further research is required to warrant the optimal start and dosage of the MSC treatment, along with the issue of long-term safety.*

PS1150

IMMUNOGENICITY OF TISAGENLECLEUCEL IN RELAPSED/REFRACTORY (R/R) B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL) AND DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) PATIENTS

Background: Tisagenlecleucel, a chimeric antigen receptor (CAR) T-cell therapy, contains a murine single chain variable fragment (mCAR19) binding domain. Humoral immunity to anti-mCAR19 had no impact on safety or efficacy in pediatric r/r B-ALL patients (Mueller ASH 2017); immunogenicity in r/r DLBCL has not been studied.
Aims: Tisagenlecleucel immunogenicity was measured in r/r B-ALL (ELIANA [NCT02435849, n=75]; ENSIGN [NCT02228096, n=29]) and r/r DLBCL (JULIET [NCT02445248, n=99]) ≤12 months after infusion.
Methods: Cellular immunity was measured in PBMCs and tested for mCAR19 peptide-activated T cell responses by stimulated intracellular interferon-gamma production. Anti-mCAR19 antibodies (Ig) were measured by flow cytometry at baseline and after treatment. Treatment-induced Ig was defined as the ratio of postbaseline Ig levels to baseline. The impact of preexisting and treatment-induced Ig and T-cell activation on cellular kinetics, efficacy and safety were determined.

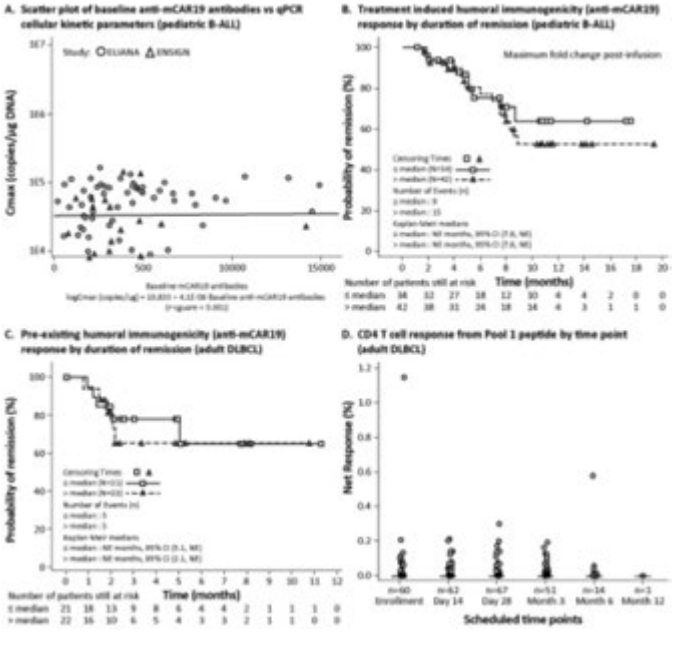

Figure 1.

Results: 84.6% of r/r B-ALL and 91.4% of r/r DLBCL patients had preexisting anti-mCAR19 antibodies. Treatment-induced rises in anti-mCAR19 antibodies occurred in 34.6% of r/r B-ALL and 5% of r/r DLBCL patients. No relationship was found between tisagenlecleucel expansion ($AUC_{0\text{-}28d}$) and preexisting humoral responses in r/r B-ALL (r^2=0.002) or r/r DLBCL (r^2=0.008), or treatment-induced humoral responses in r/r B-ALL (r^2=0.006). Results for C_{max} were similar (Figure 1 A, pediatric B-ALL). Treatment induced humoral responses did not impact expansion, persistence or duration of response (Figure 1 B, pediatric B-ALL) of CARs in B-ALL, but sample size prevented correlation analysis in DLBCL as only 5% of patients had treatment-induced Ig. Preexisting humoral immunity did not appear to impact transgene persistence, duration of response (Figure 1 C, DLBCL), event-free survival or safety in either indication. T-cell responses were consistent over time with net responses <1% at baseline and postinfusion for the majority of patients. T-cell responses did not appear to impact transgene expansion or persistence or patient outcomes (Figure 1 D, DLBCL).
Summary/Conclusion: Preexisting/treatment-induced humoral and antigen-specific cellular immunity did not impact tisagenlecleucel expansion, persistence, efficacy or safety.

Background: Analyses supporting a safe and efficacious dose for chimeric antigen receptor (CAR) therapies are not well defined and vary across CAR-T programs.
Aims: These analyses present key considerations to support tisagenlecleucel dose range in relapsed/refractory (r/r) pediatric and young adult acute lymphoblastic leukemia (B-ALL) and adult diffuse large B cell lymphoma (DLBCL) indications.
Methods: Data from pivotal phase II studies in B-ALL patients (pts) (ELIANA [NCT02435849, n=75]; ENSIGN [NCT02228096, n=29]) and DLBCL pts (JULIET [NCT02445248, n=99]) were used to investigate dose related impact on efficacy, safety, and exposure.

Table 1. Summary of dose-related analyses.

Endpoints	Analysis	Pediatric ALL (N=104)	Adult DLBCL (N=99)
Product attributes	Scatter plots/ regression	No impact	
Exposure		No impact	
Response	Logistic regression	For Day 28 response: Slight positive trend at lower end, while the probability plateaus for doses higher than 1.5×10^6 per kg for pts ≤ 50 kg and 1.0×10^6 cells for pts > 50 kg.	No impact on Month 3 response
		*OR: 1.56 (95% CI: 1.000, 2.424)	OR: 1.03 (95% CI: 0.624, 1.685)
	Quartile analysis	Similar response rate across dose quartiles	
CRS	Logistic regression	No impact (any G or G 3/4 CRS); slight positive trend (grade 4 CRS) for wt adjusted dose	Increased probability of CRS (G 3/4 or any G)
		*OR: 0.79 (95% CI: 0.327, 1.911)	†OR: 2.79 (95% CI: 1.394, 5.567)
Neurologic events (NE)		No impact	
		*OR (for G ≥2 NE): 1.12 (95% CI: 0.736, 1.700)	†OR: 0.99 (95% CI: 0.544, 1.801)

OR: Odds ratio for 2-fold increase in dose.
*for total dose; †any grade safety endpoint.

Results: Unlike conventional drugs, the dose in T cell therapy is a result of various factors: pt characteristics, manufacturing attributes, indication. Final product attributes (transduction efficiency,%T cells, cell viability, total cell count), exposure (maximal *in vivo* expansion), efficacy (Day 28 response in B-ALL, and Month 3 response in DLBCL), and safety endpoints (cytokine release syndrome, CRS; and neurological events) were evaluated against dose. The aforementioned final product attributes did not relate to the dose or *in vivo* expansion thus providing the clinical support for the product attributes specifications. Dose and exposure were independent. Clinically meaningful responses were observed across the dose range. The dose quartile analysis demonstrated similar response rate across all the quartiles in both the indications. Increased probability of any grade (G) or G 3/4 CRS was associated with increase in dose in DLBCL; no impact was observed in B-ALL.CRS is manageable with the CRS management algorithm. No impact of dose on neurological events was observed for both indications. Results are presented in Table 1. The proposed dose range, as CAR positive viable T cells, were based on totality of these analyses considering the benefit-risk ratio (B-ALL: body weight (wt) ≤50 kg, $0.2\text{-}5.0\times10^6$/kg, for >50 kg, $0.1\text{-}2.5\times10^8$; DLBCL: $0.6\text{-}6.0\times10^8$).
Summary/Conclusion: Product attributes, efficacy, safety, and exposure of CAR T, as key parameters supported the recommended dose range. These analyses serve as a recommendation for the dose-related relationships that needs to be investigated for justification of the proposed dose range for CAR therapies.

PS1152

MTL-CEBPA, A SMALL ACTIVATING RNA FOR INTRAVENOUS ADMINISTRATION TO ENHANCE C/EBPA EXPRESSION IN PATIENTS WITH LIVER CANCER SHOWS POTENTIAL USE IN NEUTROPENIA

V. Reebye[1], C. P. Tan[2,*], P. Andrikakou[1], J. Vasara[1], J. Voutila[2], R. Habib[2], D. Blakey[2], J. Rossi[3], N. Habib[1]

[1]Department of Surgery and Cancer, Imperial College London, [2]MiNA Therapeutics, London, United Kingdom, [3]Department of Molecular and Cellular Biology, Beckman Research Institute of City of Hope, Duarte, California, United States

Background: C/EBPα (CCAAT/enhancer-binding protein alpha) is a transcription factor and master regulator of cell differentiation, and cell cycle regulation. It plays an important role in a range of biological processes including lung development, hepatocyte function and maturation of blood cells in the myeloid lineage. We have developed MTL-CEBPA, a small activating RNA formulated inside liposomal nanoparticles for intravenous delivery to the liver. MTL-CEBPA induced activation of C/EBPα reverses liver diseases and improves liver function in preclinical diseased models. Patients currently being treated with MTL-CEBPA for advanced hepatocellular carcinoma (HCC) have shown a significant upregulation of C/EBPα expression in circulating white blood cells (WBCs). Consistent with this increase, total WBC and neutrophil counts also significantly increased dose dependently within 24 hours of MTL-CEBPA administration.
Aims: We evaluated whether, in addition to its benefits on liver disease, MTL-CEBPA could impact the bone marrow and lead to enhanced cells of the myeloid lineage particularly neutrophils to provide a rationale for its use in neutropenic patients.
Methods: Patients with advanced HCC and with acceptable hematologic liver and renal function were enrolled for a standard 3+3 dose escalation study (Clinical trial: NCT02716012). MTL-CEBPA was administered as a 1hour IV infusion on Day 1, 8 and 15 of a 28 day cycle. Correlative analysis of the blood was carried out to measure C/EBPα levels in PBMCs and haematological changes to WBC and neutrophil counts.
Results: Patients receiving a single dose of 28mg/m^2 MTL-CEBPA showed a significant increase of C/EBPα expression in the WBC by 1.4 fold. A dose escalation to 48 mg/m^2, 70 mg/m^2 and 90 mg/m^2 of MTL-CEBPA showed 2.2 fold, 1.8 fold and 2.4 fold increase in C/EBPα expression, respectively. Although C/EBPα expression in the WBCs appeared to have reached a saturation point in these patients, an increasing WBC count and neutrophil count correlated to each treatment points and at each dose increase. WBC and neutrophil counts increased by 40-50% within 24 hours of MTL-CEBPA infusion at a dose of 28 mg/m^2. Values returned back to the basal levels 24hours later but maintained this increase following each infusion at day 8 and 15. At subsequent dose increases of 48; 70 and 90mg/m^2, WBC counts increased by 50-60%; 60-80% and 90-100% above baseline values, respectively for each infusion at days 1, 8 and 15. In all instances, the values returned back to the basal range within 48hours of MTL-CEBPA treatment.
Summary/Conclusion: The data reported here demonstrates that MTL-CEBPA has a specific effect on the bone marrow by causing responsive changes in PBMCs, particularly in neutrophils. Since C/EBPα is a key transcription factor in maturation and differentiation of blood cells, we are the first to propose a clinically safe mode of increasing expression of C/EBPα in the bone marrow and PBMCs. Since MTL-CEBPA is already in a Phase 1 human trial for liver cancer the data presented here suggests this saRNA therapy may have utility in additional settings such as neutropenia.

PS1153

SIGNIFICANT ARI-0001 (A3B1:CD8:4-1BB:CD3Z CAR19) CELL EXPANSION IN A PATIENT WITH REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA THROUGH PRE-LYMPHOAPHERESIS IBRUTINIB ADMINISTRATION

V. Ortiz-Maldonado[1,*], M. Caballero-Baños[2], A. Bataller[1], A. Oliver[1], A. Rivero[1], T. Baumann[1], B. Marzal[2], M. Castella[2], A. Boronat[2], J. Cid[1], M. Diaz-Beya[1], J. Esteve[1], J. Yague[2], A. Urbano[1], M. Juan[2], J. Delgado[1]

[1]Hematology, [2]Immunology, Hospital Clínic Barcelona, Barcelona, Spain

Background: Patients with chronic lymphocytic leukemia (CLL) who do not respond or show refractoriness to available treatment options face a grim prognosis. Recently, several chimeric antigen receptor constructs targeting CD19 (CAR19), such as tisagenlecleucel, have been developed and showed promising results in patients with CD19+ B-cell malignancies including CLL. However, whilst excellent complete response rates (CRR) around 80% have been documented in acute lymphoblastic leukemia, much less impressive rates, around 20-35%, have been observed in CLL. This lower CRR may be secondary to the characteristic T cell dysfunction of CLL patients. Some studies have shown that ibrutinib not only has a direct antitumor effect but also reverses such T-cell dysfunctionality, thus optimizing CAR19 efficacy. Indeed, there is currently a clinical trial evaluating the role of ibrutinib in patients with CLL receiving tisagenlecleucel.
Aims: To report a case of exceptional ARI-0001 proliferation in a patient with CLL who received ibrutinib pre-apheresis.
Methods: A 53-year-old female diagnosed with CLL was referred to us after treatment with fludarabine, cyclophosphamide and rituximab, rituximab plus bendamustine, ibrutinib, idelalisib, obinutuzumab and venetoclax. The patient was either refractory or intolerant to all these agents. She was enrolled in the CART19-BE-01 clinical trial (clinicaltrials.gov NCT03144583) on the administration of ARI-0001 (A3B1:CD8:4-1BB:CD3z CART19) cells in patients with relapsed/refractory CD19+ B-cell malignancies. At screening, her bone marrow showed 29% of CLL cells and a CT scan revealed extensive lymphadenopathy in the neck, axillae and abdomen. Ibrutinib (420 mg/day) was restarted for two weeks before lymphoapheresis and then stopped. ARI-0001 production was accomplished using the CliniMACS Prodigy System (Miltenyi). A dose of $1x10^6$ ARI-0001 cells /kg was infused after lymphodepletion with fludarabine (90 mg/m^2) and cyclophosphamide (900 mg/m^2). ARI-0001 proliferation, CLL response and B-cell aplasia was later assessed by means of flow cytometry.
Results: A total of 2.8 x10^9 PBMCs were collected from the patient, with a CD4 / CD8 composition of 8.8% and 10.1%, respectively (19.7% CD3+). After aliquoting the apheresis product, a cell count of 100 x10^6 CD4/CD8 + cells was introduced to the CliniMACS Prodigy System. After 10 days of expansion, a total count of 350 x10^6 mononuclear cells was achieved (97.2% CD3+). The CD4 / CD8 composition of the final cell product was 69.5% and 29.2%, respectively, with a T cell transfection percentage of 23.3% (ARI-0001 cells). ARI-0001 cells were administered to the patient without complications. She soonly developed a transient grade I cytokine release syndrome (fever) that resolved with antipyretics plus antibiotics. No neurologic symptoms were observed. ARI-0001 cell expansion peaked at day +28, with 30% of total lymphocytes being ARI-0001 cells at that time (844 x10^9/L absolute ARI-0001 cell count). The patient achieved a CR with a negative MRD (<0.01%) measured in the marrow at week 4, with B cell aplasia and ARI-0001 cells detected in peripheral blood at last follow-up (month 3). Complete hematological recovery was seen at day +70, with no further complications.
Summary/Conclusion: This case of significant ARI-0001 cell proliferation is consistent with what has been observed with tisagenlecleucel and other emerging pre-clinical data. Preliminary data may suggest that ibrutinib, even when given in a short period of time (2 weeks), could improve ARI-0001 performance in this disease.

HIGH BASELINE FERRITIN IS ASSOCIATED WITH GRADE 2 CRS REQUIRING TOCILIZUMAB OR GRADE ≥ 3 CRS IN RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS TREATED WITH BB2121 ANTI-BCMA CAR T CELLS

J. Berdeja[1,*], Y. Lin[2], J. N. Kochenderfer[3], N. Raje[4], N. Munshi[5], D. Siegel[6], M. Liedtke[7], D. Madduri[8], J. Rosenblatt[9], M. Maus[4], A. Turka[10], L. P. Lam[10],

K. Hege[11], T. Campbell[11], M. Massaro[10], F. Petrocca[10], S. Jagannath[8]

[1]Sarah Cannon Research Institute and Tennessee Oncology, Nashville, [2]Mayo Clinic, Rochester, [3]Experimental Transplantation and Immunology Branch, National Cancer Institute/National Institutes of Health, Bethesda, [4]Massachusetts General Hospital Cancer Center, [5]Dana-Farber Cancer Institute, Boston, [6]Hackensack University Medical Center, Hackensack, [7]Stanford University Medical Center, Palo Alto, [8]Mount Sinai Medical Center, New York, [9]Beth Israel Deaconess Medical Center, Boston, [10]Bluebird Bio Inc., Cambridge, [11]Celgene Corporation, San Francisco, United States

Background: Cytokine release syndrome (CRS) is the most common risk associated with chimeric antigen receptor (CAR) T cell therapies. Identification of predictors of severe CRS may enable earlier, more aggressive treatment of patients at high risk.
Aims: To report key parameters associated with grade 2 CRS requiring tocilizumab or grade 3 CRS (tCRS) in an ongoing phase I trial of anti-BCMA CAR T cell therapy bb2121 in relapsed/refractory multiple myeloma [CRB-401, NCT02658929].
Methods: Patients who received active doses in Part A (150 [6], 450 [9], or 800 [3] × 10^6 CAR T cells) were included. Standard criteria for grading CAR T-associated CRS were used (Lee 2015).
Results: Four of 18 (22%) patients developed tCRS, all within 30 days of bb2121 infusion. Pre-treatment serum ferritin > 1500 µg/L was seen in 5 patients (min, max: 1516, 4653 µg/L); 4 developed tCRS. None of 13 patients with ferritin ≤ 1500 (min, max: 17, 381 µg/L) experienced tCRS. Serial ferritin levels were measured in 11 evaluable patients; ferritin further increased 1-2 days prior to tCRS in 3 of 3 evaluable tCRS patients, but not in 7 of 8 (87.5%) evaluable patients with CRS not requiring tocilizumab (non-tCRS; median peak, 9902 vs 324 mg/L). Baseline C-reactive protein (CRP) and IL-6 levels were not associated with tCRS; both increased 1-2 days prior to tCRS and non-tCRS (median peak CRP, 163 vs 68 mg/L; median peak IL-6, 413 vs 17 pg/mL). Extensive bone marrow involvement (> 50% plasma cells) was seen in 3 of 4 tCRS patients. All 4 tCRS patients had CAR T cell expansion after infusion (peak vector copies min, max: 361,474, 959,041 copies/µg gDNA), but comparable expansion was observed in 8 of 12 evaluable non-tCRS patients. All 4 tCRS patients received ≥ 450×10^6 CAR T cells. The fifth patient with baseline ferritin >1500 µg/L had extramedullary disease with no bone marrow involvement and received 800×10^6 CAR T cells, but only developed grade 1 CRS. We found no association between tCRS and age, gender, number of prior lines of therapy, bridging therapy, immunoglobulin subtype, or high-risk cytogenetics.
Summary/Conclusion: The overall frequency of tCRS in this study was relatively low and associated with high baseline ferritin. High bone marrow involvement and CAR T cell dose may contribute to the risk.

PS1155

THE COMBINATION OF CD19/BCMA-DIRECTED CART CELLS INDUCED THERAPEUTIC RESPONSE AND REVERSIBLE COMPARTMENTAL CYTOKINE RELEASE SYNDROME CONFINED TO CEREBRAL REGION IN A PATIENT WITH CNS MULTIPLE MYELOMA

C. Li[1,*], J. Chen[1], Y. Zhang[1], J. Zhou[1], J. Zhang[1], D. Yang[1], P. Wang[1], C. Zhang[2], C. Fu[1], D. Wu[1]

[1]The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, [2]UniCar Therapy Ltd., Shanghai, China

Background: Patients with CNS diseases have increased risks of cerebral CRS after CAR-T therapy, but the machanism has been yet determined. Whether CAR-T cells could cross BBB and induce CRS directly is contraversial.
Aims: To provide an innovation to investigate the machanism of cerebral CRS after CAR-T treatment.
Methods: We report a case of a 56-year-old male diagnosed with multiple myeloma (κ-chain) with CNS involvement who received a combination of CD19/BCMA-directed CART and achieved response and reversible compartmental cytokine release syndrome confined to the cerebral region. The patient was first diagnosed with MM in 2014 and received induction treatment followed by ASCT. In January 2016 and June 2017 he experienced relapse twice, and in the second relapse involved the CNS (confirmed by MRI as shown in Figure 1A). The salvage therapy consisted of DECP regimen and pomalidomide but the CNS symptoms progressed along with both-side hemiparesis and incontinence sequentially. Intrathecal chemotherapy agents and daratumumab were given but had no response indicating a refractory disease. In November 2017, he was admitted in our hospital and was enrolled in our clinical trial of CAR-T therapy (NCT03196414). Autologous anti-CD19 and anti-BCMA CAR-T cells were manufactured and infused in consecutive three days with no preconditioning regimen. On Day 3 of the infusion, the patient developed CART-related toxicities including febrile, hypotension and hypoxia accompanied by escalations of cytokine levels indicating a grade 2 CRS. On Day 5, he developed somnolence and mental obtundation, and the neurological symptoms worsened gradually in the next 4 days. On Day 9 the patient developed pupil asymmetry. Methylprednisolone was then administered. Imaging showed decreased size of intracranial lesion while emerging demyelinating lesions. A dramatic increase of IL-6 was detected in CSF (peak value 6091.2 pg/ml) rather than in peripheral blood (peak value 240.5 pg/ml), while CAR-T cells existed both in CSF and peripheral blood (18,000 versus 251,000 cells/ml CSF) , indicating a compartmental CRS confined to the cerebral region.
Results: IL-6 level in CFS and peripheral blood significantly dropped (Figure 1B), and all CRS-related toxicities including CNS symptoms ameliorated gradually in 3 weeks. MRI performed on Day 46 revealed that the intracranial disease was stable though the demyelinating lesions remained (Figure 1C), and IL-6 level in CFS decreased to about 400 pg/ml with most CRS symptoms relieved.

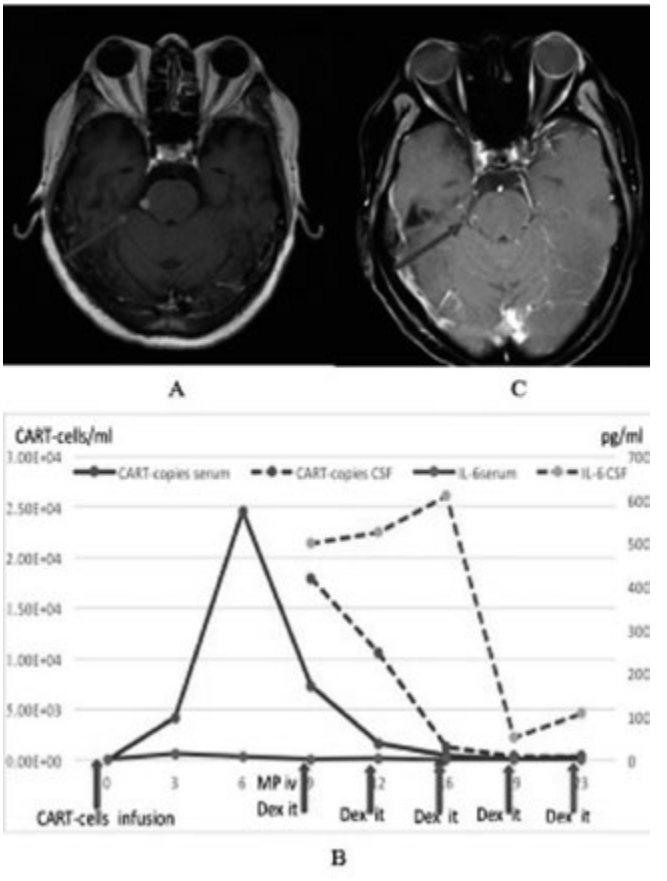

Figure 1.

Summary/Conclusion: This is the first description of a compartmental CRS confined to the cerebral region in a patient with CNS multiple myeloma which was then successfully reversed by appropriate medical interventions. The huge cytokine concentration gradient between peripheral blood and CSF in this case suggests the ability of CAR-T cells to cross the blood–brain barrier and induce cytokine increase and related toxicities in cerebral region. This case suggested that CART therapy is capable to treat diseases in CNS system with possibly severe but reversible CRS adverse events.

PS1156

INITIAL EXPERIENCE IN US COMMERCIAL MANUFACTURING OF TISAGENLECLEUCEL, A CHIMERIC ANTIGEN RECEPTOR (CAR)-T CELL THERAPY FOR PEDIATRIC RELAPSED/REFRACTORY B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA

B. Majors[1,*], T. Spencer[2], S. Ericson[2], V. Romanov[2]

[1]Novartis Pharmaceuticals Corporation, Morris Plains, [2]Novartis Pharmaceuticals

Corporation, US Clinical Development and Medical Affairs, East Hanover, United States

Background: Tisagenlecleucel, a CD19-directed genetically modified autologous T cell immunotherapy, is approved for the treatment of patients up to 25 years of age with B-cell precursor acute lymphoblastic leukemia (B-ALL) that is refractory or in second or later relapse. The processing technology for tisagenlecleucel was transferred from an academic production facility to an industry-owned facility following current Good Manufacturing Practice for optimization, validation, and scale-up for use in global clinical trials and commercial manufacturing.
Aims: To present initial data on manufacturing process time and success for commercially manufactured tisagenlecleucel used to treat pediatric and young adult patients with relapsed/refractory B-ALL following approval by the United States Food and Drug Administration on Aug 30, 2017.
Methods: Key steps and timing targets for the commercial manufacturing process are shown (Figure 1). Leukapheresed mononuclear cells from patients are cryopreserved and shipped to a centralized manufacturing facility. The core manufacturing process consists of enrichment of T cells, activation *ex vivo*, transduction with a lentiviral vector containing the anti-CD19 CAR transgene, cellular expansion, formulation, and cryopreservation. The manufactured products then undergo extensive testing to assess product quality and safety. Once all quality release requirements are satisfied, the products are shipped to the treatment facilities for administration to patients.
Results: Of the initial37 sequential commercial patient orders placed for tisagenlecleucel that have been processed to completion and successfully supplied with final commercial tisagenlecleucel products, the median throughput time from receipt of leukapheresis material to return of manufactured product to treatment site was 23 days (range, 21–37 days). Consistent product quality was demonstrated by extensive testing. Rigorous sterility testing in the tisagenlecleucel manufacturing process is part of an overall sterility assurance strategy to ensure tisagenlecleucel is free of potential contaminants. Although cryopreservation of collected leukapheresis material prior to shipment for central manufacturing results in additional manufacturing time, it also has several advantages over shipping fresh leukapheresis material including timing flexibility for leukapheresis and shipping, no negative effects on cell function, enrichment of lymphocytes, and reliable and consistent manufacturing.

Figure 1.

Summary/Conclusion: There is an acute medical need of pediatric and young adult patients with relapsed/refractory B-ALL to receive tisagenlecleucel as promptly as possible. Continuous improvements in the tisagenlecleucel manufacturing process have resulted in the development and execution of high quality and safety standards. The current process, based on 37 initial commercial patients, highlights a median 23-day time period from receipt of leukapheresed material to return of manufactured tisagenlecleucel to the clinical site (including shipping time) with all 37 sequential patients receiving the final product.

PS1157

ALLOGENEIC NK CELLS AND THEIR USE IN CLINICAL TRIALS

L. Bielik[1,*], P. Lesny[1], J. Rychla[1], I. Kastankova[1], P. Otahal[1]

[1]Dept. of Immunoterapy, Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: New trend in hematological malignancy therapies are haploidentical NK (natural killer) cells expanded *in vitro* in presence of growth and stimulation cytokines. These cells belong in the category of advanced therapy medicinal products (ATMP) and must be manufactured within the Good Manufacturing Practice (GMP) Quality Management System.
Aims: We aim for the production of clinically applicable NK cells for the experimental treatment of acute myeloid leukemia (AML) patients in our laboratoeries.
Methods: Patient apheresis was used as our starting material for production, from which 10^9 mononuclear cells were used further in process. Patient was not stimulated with growth factors prior to the apheresis. After immunomagnetic depletion of non-NK cells with commercially available kit (CD2, CD335), the NK cells were further stimulated with interleukins IL-2 and IL-15 during the 14 days expansion.
Results: After immunomagnetic depletion $79\pm23x10^6$ cells (8±2%) was acquired, from which 83±2% of cells were with NK phenotype ($CD45^+$, $CD16/CD56^+$, $CD3^-$). During the 14 days expansion we achieved a total yield of $1,1\pm0,2x10^9$ cells, comprised of 78±6% cells with NK phenotype. The NK cells had from the beginning of expansion high expression of perforin and the expression of activation marker CD69 rose from less than 5% to more than 80% of all cells in the suspension during the expansion. Furthermore, they were submitted to *in vitro* testing, in which they were highly cytotoxic against the K562 tumour cell line.
Summary/Conclusion: Produced amount of NK cells was in accord with the demand of clinicians, who planned to use the effective dose of 10^7 cells/kg of body mass. As a suitable primary packaging for expected treatment was chosen prefilled 50ml injection containing $20\pm2x10^6$ cells/ml. Production process was fully validated and we acquired authorization for production and subsequent clinical trial on AML within allogeneic hematopoietic transplantation from haploidentical donor after sequential preparation protocol from national regulatory authority.

PS1158

IMMUNO-T, A MOTION COMIC EDUCATING PATIENTS AND CAREGIVERS ON HOW IMMUNOTHERAPY WORKS

T. Kerre[1,2,*], C. Charakhani Nia[3], S. Calis[4], Y. Bertrand[4], L. Achten[5], J. Soetens[6], B. Casteels[7], D. Flamez[8,9], B. Bollaert[10]

[1]Cancer Research Institute Gent, Ghent University and Ghent University Hospital, [2]Hematology, Ghent University Hospital, [3]Hematology, UZ Gent, [4]Holofarm, [5]Telma, [6]Cancer Center, Ghent University Hopsital, [7]Cancer Center, Ghent University Hospital, [8]Cancer Research Institute Gent, [9]IOF Consortium, Ghent University, [10]WahWah vzw, Gent, Belgium

Background: The introduction of immunotherapy has been a major breakthrough in the treatment of cancer. In the general public and the average patient populations, the overall knowledge of the immune system and its role in cancer is very limited. Moreover, explaining the immune system and how immunotherapy works to patients and their caregivers, is challenging because of the extreme complexity.
Serious games and virtual aids have only been scarcely used for cancer patients or patients in general. However, the limited amount of literature evinces the benefit patients and caregivers experience when these services are employed.
Aims: We now have developed Immuno-T: a motion comic, explaining the genesis of cancer and the working mechanisms of three types of immunotherapy. A motion comic combines a digital comic with animation, sound effects, voice-over and/or a musical score. The aim was to develop a tool in order to inform patients and their caregivers on the complex subject of immunotherapy, create a feeling of hope, and increase adherence to the therapy with improved outcomes.
Methods: The scenario, story board and basic character design were developed by a hematologist and executed by game developers, and further refined in small focus groups consisting of hematologists-oncologists, psychologists, study coordinators, medical students, nurses and communication managers, into the first version. This version was evaluated by 40 people of different backgrounds, including a small number of patients, and further adapted into the final version.
Results: Immuno-T explains three types of immunotherapy in an engaging, easy-to-understand way. The majority of the evaluators (94.9%) considered the motion comic a good tool to explain immunotherapy to patients, in addition to the physician consultation. Almost 40% of the evaluators felt hopeful after watching the motion comic, 30% experienced other positive emotions (happy, well-informed, strengthened).
Summary/Conclusion: Although motion comics carry important advantages (a clear and graphic presentation of complex information and a more engaging way of delivering information), they have only rarely been used in healthcare settings. Immuno-T, while still evolving and growing, is ready to be rolled out in real hospital settings. We are currently preparing a clinical trial to evaluate the effectiveness of information transmission using Immuno-T: does it lead to better understanding of the given treatment? Increasing patients' knowledge of disease and treatment has a proven impact on hope, strength and empowerment, and on adherence to the treatment.

Hematopoiesis, stem cells and microenvironment

PERTURBATION OF FETAL LIVER STROMAL CELL FUNCTION BY TRISOMY 21 PROMOTES INCREASED ERYTHRO-MEGAKARYOPOIESIS BY FETAL HSPC

N. Elliott[1,*], D. O'Connor[2], A. Roy[1], E.-M. Labbett[3], S. O'Byrne[1], S. Rice[4], N. Fordham[4], B. Liu[1], G. Cowan[2], A. Karadimitris[2], P. Vyas[4], I. Roberts[1]

[1]Paediatrics, University of Oxford, Weatherall Institute of Molecular Medicine, Oxford, [2]Centre for Haematology, Imperial College London, London, [3]University of Oxford, [4]MRC Molecular Haematology Unit, University of Oxford, Weatherall Institute of Molecular Medicine, Oxford, United Kingdom

Background: Children with Down syndrome (DS; trisomy 21- T21) have an increased risk of leukemia in early childhood. The reasons for this are unclear. We previously showed that T21 itself perturbs fetal liver (FL) hemopoiesis with increased erythro-megakaryopoiesis the most prominent finding. Although this is still evident in neonates, erythroid/megakaryocyte (MK) abnormalities largely resolve by age 12m. This, and the natural history of DS myeloid leukemia, which presents before or just after birth with liver involvement and spontaneously resolves in >80% of cases before 3m of age, implicates the FL microenvironment in T21-associated perturbation of hemopoiesis and myeloid leukemogenesis.
Aims: To investigate the impact of T21 on FL stromal cell function.
Methods: We performed transcriptomic (microarray, qRT-PCR), proteomic (mass spectrometry, ELISA) and functional analysis of T21 (n=3-7) and normal (n=3-9) disomic FL mesenchymal stromal cells (MSC), including their ability to support T21 and normal FL hemopoietic stem/progenitor cells (HSPC).
Results: While the morphological and immunophenotypic characteristics of T21 and normal FL MSC appeared identical, T21 MSC grew more slowly (doubling 3.0 vs 1.7 days; p=0.0044). Consistent with T21 effects on MSC function, co-culture of normal FL Lin-CD34+ cells on T21 or normal FL MSC showed markedly increased erythroid (5-fold) and MK (2-fold) output, recapitulating the T21 HSPC phenotype. Similarly, T21 HSPC had increased erythroid/MK output when co-cultured with T21 vs normal FL MSC although overall erythroid/MK output was greater from T21 HSPC consistent with both HSPC-intrinsic as well as microenvironment-induced effects of T21. Conditioned medium (CM) from T21 FL MSC stimulated erythroid/MK output from normal and T21 HSPC supporting a role for secreted proteins. To investigate the molecular basis for these effects, we first used microarray analysis to compare gene expression of T21 and normal FL MSC. Of 627 differentially expressed (DE) genes, most were overexpressed by T21 vs normal FL MSC; however, known cytokine genes were not increased in T21 MSC and neither *EPO* nor *TPO*, the principal erythroid and MK cytokine genes, were detectable. Although 28 of the top 50 DE genes were on Hsa21, none were known growth factors or predicted to encode secreted proteins. By contrast, of 25 DE upregulated genes of FC >2, 7 encoded secreted proteins of which only *IGFBP1*, previously implicated in increased erythropoiesis in primary myeloproliferative disorders, had known hemopoietic activity. Increased *IGFBP1* was confirmed by qPCR and IGFBP1 was present at high concentrations in T21 MSC CM but undetectable in normal FL MSC CM by ELISA. Addition of IGFBP1 directly to normal/T21 HSPC or MSC:HSPC co-cultures partially, but not completely, restored erythroid/MK output to that of T21 MSC:HSPC co-cultures. Proteomic analysis of normal and T21 supernatants to identify additional factors showed DE of ~40 secreted proteins including several with hemopoietic activity and 8 encoded by Hsa21 genes.
Summary/Conclusion: T21-mediated perturbation of gene expression in FL MSC fundamentally alters their secretome and function, promoting increased MK/erythropoiesis of FL HSPC.

PS1160

PROTEIN KINASE CK2 AS A NEW PLAYER IN GATA-1 REGULATION DURING ERYTHROPOIESIS

L. Quotti Tubi[1,2,*], S. Canovas Nunes[1,2], E. Mandato[1,2], S. Manni[1,2], M. Carrino[1,2], F. Piazza[1,2]

[1]Department of Medicine, Hematology and Clinical Immunology Branch, University of Padova, [2]Venetian Institute of Molecular Medicine, Padova, Italy

Background: Protein kinase CK2 is a Ser-Thr kinase usually represented as a holoenzyme, composed of two catalytic (α) and two regulatory (β) subunits, although these components can also work independently. CK2 promotes cell survival and proliferation and it is involved in hematological malignancies. Despite CK2 regulates key signaling pathways for hematopoiesis, its role in blood cell development is still unexplored. To fill this gap, we have generated a conditional knockout (KO) mouse model for CK2β in all the hematopoietic compartments (Vav1-CRE CK2β flox). CK2β KO resulted to be lethal, thus the analysis was done *in utero*. CK2 loss caused a depletion of all hematopoietic lineages, markedly of the erythroid population; moreover, CK2β KO led to down-modulation of some proteins downstream the Epo-receptor in particular of GATA-1 transcription factor.
Aims: Here, we wanted to understand at the molecular level, how CK2β could drive erythroid differentiation. We hypothesized a functional relationship between GATA-1 and CK2β. To demonstrate it, an *in vitro* model of erythroid differentiation was used based on G1E-ER mouse proerythroblast cell line that presents an inducible form of GATA-1 activated through β-estradiol.
Methods: G1E-ER cells were exposed to b-estradiol with or without CK2 inactivation with either inhibitor CX-4945 or siRNA against CK2β; Bortezomib was add to determine GATA-1 turnover. Through flow cytometry analysis we assessed erythroid differentiation, after staining with anti c-KIT, TER119 and CD71 antibodies, and we studied cell cycle, upon fixing and staining cells with propidium iodide. mRNA expression levels were evaluated by RT-PCR. WB was used to determine protein amount, immunofluorescence to investigate GATA-1 and CK2β cell localization.
Results: CK2 inhibition/silencing, in the presence of β-estradiol-induced differentiation, caused a reduction of differentiated TER119$^+$ cells and a down-regulation of CD71 expression; moreover, CK2 blockade prevented cell cycle arrest in G0/G1 phase, that is required for the onset of cell differentiation. Molecularly, we observed a down-modulation of STAT5, AKT and GATA-1 protein levels and an impairment of GATA-1 transcriptional activity. Nuclear GATA-1 resulted lowered and differently distributed. Treatment with Bortezomib restored GATA-1 levels. As CK2 influences HSP70, HSP90 and CDC37 ability to stabilize client proteins, including GATA1, we considered a possible indirect role of CK2 in GATA-1 protein turnover control. Indeed, we observed a decrease in these chaperone expression, upon CK2 inactivation, which could account for GATA1 instability. However, GATA-1 and CK2β also colocalized in the nucleus in presence of the β-estradiol suggesting a possible direct mechanism in CK2-mediated control of this transcription factor.
Summary/Conclusion: CK2β is essential for erythroid maturation, regulating STAT5, AKT and GATA-1. CK2β subunit could regulate these factors in two possible ways: an indirect mechanism, through the control of chaperones; a direct mechanism, through physical interaction. Further research will clarify the mechanism(s).

PS1161

TRANSCRIPTION FACTORS REGULATE DNA METHYLATION DYNAMICS IN HEMATOPOIETIC DEVELOPMENT

T. Suzuki[1,2,*], S. Maeda[2], E. Furuhata[2], Y. Shimizu[2], M. Kishima[2], H. Nishimura[2], H. Suzuki[2]

[1]Graduate School of Medical Life Science, Yokohama City University, [2]Center for Life Science Technologies, RIKEN, Yokohama, Japan

Background: DNA methylation of CpG dinucleotides at gene regulatory regions is a fundamental epigenetic modification for gene silencing. During the hematopoietic development, DNA methylation acts as a safeguard to prevent the expression of unnecessary genes, while regulatory regions of master transcription factors (TFs) must be demethylated before or during the differentiation. Thus, the dynamics of DNA methylation have to be strictly regulated to give rise to blood cells. However, while enzymatic mechanisms of DNA methylation and demethylation are well characterized, little is known about how DNA methylation dynamics are spatiotemporally regulated in hematopoietic development.
Aims: Here, we present that RUNX1 is capable of regulating DNA demethylation at the binsing site-directed manner.
Methods: ectopic expressin of RUNX1 followed by DNA methylome analysis, transcription factor binding motif enrichment analysis, co-immunoprecipitation analysis, and ChIP-seq.
Results: We have found that ectopic expressin of RUNX1 induces binding site-directed DNA demethylation. Coimmunoprecipitation and ChIP-seq analyses have showed that RUNX1 mediates DNA demethylation by recuiting DNA demethylation enzymes such as TET. Furthermore, comparing DNA methylome data of human iPS cells, hematopoietic progenotuore cells, and terminally differentiated blood cells, we have found that not only RUNX1 but also some hematopoietic TFs may be involved in the regulation of DNA methylation dynamics. Finally, methylome data and toranscriptome

data suggest that DNA demethylation is not represents the gene activation but rather the poised status for it.
Summary/Conclusion: Thus, our findings indicate a possibility that TF-mediated bindingsite-directed DNA methylation regulation plays an important role in hematopoietic development and functions.

PS1162

CANONICAL NOTCH SIGNALING IS DISPENSIBLE FOR ADULT STEADY-STATE AND STRESS MYELO-ERYTHROPOIESIS

[1]Haematopoietic Stem Cell Biology Laboratory, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom, [2]Clinical Hematology Department, University Hospital Center of Coimbra, coimbra, Portugal, [3]Department of Medicine, Huddinge, Center for Hematology and Regenerative Medicine, Karolinska Institutet, [4]Department of Cell and Molecular Biology, Karolinska Institute, Stockholm, Sweden, [5]Computational Biology Research Group, [6]MRC Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom, [7]sten.jacobsen@imm.ox.ac.uk, Stockholm, Sweden

Background: Canonical signaling through all Notch receptors converges on the Csl transcription factor recombination signal binding protein for immunoglobulin kappa J region (Rbpj). Canonical Notch signaling has been shown to be dispensable for hematopoietic stem cell (HSC) homeostasis in adult bone marrow (aBM). However, other studies have implicated an important role of canonical Notch signaling in regulation of myelopoiesis, erythropoiesis and megakaryopoiesis in aBM. However, these studies might also have targeted other pathways.
Aims: Investigate the role of canonical Notch signaling in steady-state and stress myelo-erythropoiesis through deletion of *Rbpj* in aBM.
Methods: *Rbpj*$^{fl/fl}$ mice were crossed with *Mx1-Cre* or *Vav-Cre* mice to effectively delete *Rbpj* in adult HSC/progenitor cells. HSCs and erythroid (E), megakaryocyte (Mk) and granulocyte-macrophage (GM) progenitors were enumerated and characterized phenotypically (by FACS), molecularly, and through functional Mk/E and GM *in vitro* colony forming assays, in steady state aBM as well as following transplantation and erythropoietic stress.
Results: FACS analysis of distinct stages of myelo-erythropoiesis revealed no defects, at any progenitor stage, in aBM of *Rbpj*-deficient mice. In addition, the number of GM, Mk and E colonies generated from unfractionated aBM cells as well as circulating platelets and red blood cells (RBC) counts were unaffected. No deficiencies were observed in the replenishment of HSCs and any stages of E as well as GM and Mk progenitors in mice competitively transplanted with *Rbpj*-deficient as compared to control WT BM cells. The transcript levels of genes encoding key Mk/E regulators were also unaffected in *Rbpj*-deficient Mk/E progenitors. Likewise, low expression of key Notch target genes detected in Mk/E progenitors in aBM was independent of canonical Notch signaling. We also assessed the impact of *Rbpj*-deficiency on mature circulating RBCs and the reactive regeneration of E progenitors after PHZ-induced haemolytic anemia. The reduction in RBC numbers was not aggravated by Rbpj-deficiency and E progenitors devoid of *Rbpj* were not affected in their ability to rapidly expand in response to PHZ-induced anemia, neither in BM nor spleen. In the previous study implicating a role of canonical Notch signaling in megakaryopoiesis, a dominant negative (dn) version of Mastermind-like protein 1 (MAML1) was used to block Notch signaling. While dnMAML1 has been demonstrated to block canonical Notch signaling, it has been less clear whether it may also affect other signaling pathways related to MAML1, such as MEF2C or p53. To address possible Rbpj-independent transcriptional alterations mediated by dnMAML1, we transfected *Rbpj*$^{-/-}$ embryonic stem (ES) with dnMAML1 and performed a gene expression array. Of a total of 13020 transcripts detected (CPM>1), only one gene (*Hsph1*) could be found to be significantly (but marginally) deregulated in *Rbpj*$^{-/-}$ dnMAML1 ES cells.
Summary/Conclusion: By specifically addressing canonical Notch signaling through deletion of Rbpj in aBM, we show that this pathway is dispensable for development and maintenance of Mk/E progenitors in steady-state and regenerative aBM. Moreover, the robust reactive erythropoiesis seen in response to PHZ-induced anemia occured independently of canonical Notch signaling. The explanation for the discrepancy between our findings and those based on other approaches to inhibit Notch signaling remains unclear, and we failed to obtain experimental support for Notch-independent effects of dnMAML1.

PS1163

ENHANCING BONE MARROW TREPHINE BIOPSY ANALYZES: DEFINING PEDIATRIC LYMPHOID SUBPOPULATION REFEERENCE RANGES BY AUTOMATED ENUMERATION

J. Malherbe[1,2,*], J. Liang[2,3], K. Fuller[2,4], B. Mirzai[2,4], T. Carter[4,5], C. Cole[1,2,4,5], W. Erber[1,2,4]

[1]School of Medicine, [2]School of Biomedical Sciences, Univeristy of Western Australia, Crawley, [3]Department of Haematology, Sir Charles Gairdner Hospital, [4]Path-West Laboratory Medicine, Nedlands, [5]Department of Haematology & Oncology, Princess Margaret Hospital, Subiaco, Australia

Background: Bone marrow examination involves the morphological assessment of aspirated material and the trephine (BMT) biopsy specimen. This includes cellularity, cytological detail and quantitative analyzes of cell populations of interest (*e.g.* percent composition). For aspirates, accurate quantitation is aided by flow cytometry. In contrast, manual "eye-ball" estimation of hematoxylin and eosin or immunophenotyped cells is performed for the BMT biopsy; this represents an estimate only and lacks reproducibility. Aspirate references tend to be applied to the BMT estimate. This is not valid as the aspirate data is skewed by peripheral blood contamination and hinders accurate diagnostic reporting. Accurate reference ranges for the number of cells in the bone marrow (uncontaminated by blood) are required and are presently not available.
Aims: We aimed to establish the number of lymphoid progenitor cells, T- and B-lymphocytes and plasma cells in normal BMT biopsies of infants, children and adolescents by performing combined immunophenotyping and automated digital enumeration. From this, we aimed to establish normal age-specific reference ranges for routine clinical application.
Methods: Archival, formalin-fixed, morphologically normal BMT biopsy specimens (N=238) were obtained from pediatric patients aged one month to 17 years of age. Cases were immunohistochemically stained to identify lymphoid progenitors (TdT), T-lymphocytes (CD3), B-lymphocytes (CD20) and plasma cells (CD138). Tissue Image Analysis enumeration software (Leica, Ireland) was used, with modifications, for the automated digital enumeration of these populations. Geometric mean (GM) values were generated for specific age groups and age-defined reference ranges (RR) were determined for each antigen using normalized data.
Results: A mean of 17,458 cells were analyzed per biopsy (range: 8,224-34,097 cells). Infants <2 years old showed high numbers of lymphoid progenitors (GM=3.5%, RR: 1.0-12.6%) and B-lymphocytes (GM=7.4%, RR: 0.25-22.8%) in comparison to older children. In contrast, T-cell numbers were low (GM=2.2%, RR: 0.37-12.8%) while plasma cells were virtually absent from the marrow (GM=0.08%, RR: 0.008-0.80%). With increasing age (*i.e.* 2-17 years), lymphoid progenitors declined to reach a steady state (GM range: 1.6-2.4%). B-cell numbers continued to decrease (2-5 years: GM=5.0%, RR: 0.48-13.4% versus 15-17 years: GM=2.7%, RR: 0.87-8.5%) while T-lymphocytes peaked during the age group of 6-9 years (GM=5.6%, RR: 1.9-16.6%). Following infancy, plasma cells significantly increased and remained constant, but still accounted for <1.0% of the total marrow population (GM range: 0.25-0.47%).
Summary/Conclusion: We have established normal pediatric reference ranges for lymphoid progenitor cells, B- and T-lymphoid cells and plasma cells using a novel, automated enumeration platform. The data is accurate and reproducible. Infant marrows are characterized by having high numbers of immature lymphoid precursors and B-lymphocytes. With increasing age, the marrow shifts towards a more mature profile with increased numbers of T-cells and plasma cells. These findings are in keeping with flow cytometry data. This demonstrates that automated digital enumeration of immunostained cells in BMT biopsies is valid and highly applicable to routine haematopathology practice. Moreover, this automated method overcomes laborious and inaccurate manual estimation of cell number.

PS1164

ROLE OF SPHINGOLIPID SIGNALING IN HEMATOPOIETIC STEM AND PROGENITOR CELL MOBILIZATION

E. Naser[1], J. R. Goethert[2], M. Hanoun[2], A. Carpinteiro[1,2,*]

[1]Department of Molecular Biology, University of Essen, [2]Department of Hematology, University Hospital of Essen, Essen, Germany

Background: Hematopoietic stem cell mobilisation is a prerequisite for high dose chemotherapy, which is a module common in the treatment of several hematopoietic and some oncological malignancies. In about 20% of the attempts stem cell mobilisation turns out to be diffcult or to be insufficient. Therefore, approaches to improve hematopoietic stem cell mobilisation are

a valuable aim.
Aims: The aim of this study is to investigate the role of sphingolipid signaling in hematopoietic stem and progenitor cell HSPC mobilization and improve the outcome of standard clinical mobilizing agents G-CSF and AMD3100 by targeting enzymes in the sphingolipid pathway.
Methods: C57BL/6 acid sphingomyelinase-knockout (Asm-/-) mice, transgenic mice overexpressing acid ceramidase (CAG-Asah1 tg), and control wild-type littermates (wt) were injected s.c. with rhG-CSF 250μg/kg/d for 5 days. On day 5, peripheral blood (PB), spleen and bone marrow were collected. PB was analyzed phenotypically, functionally *in vitro* (CFU-C) assay and *in vivo*. Wild-type mice were treated with Amitriptyline, an inhibitor of Asm. Amitriptyline was applied in the drinking water beginning 2 weeks before and during treatment with rhG-CSF.
Results: CAG-Asah1 tg but not Asm-/- mice showed significantly increased numbers of the lineage- Sca-1+ c-kit+ (LSK) population and CFU-C/mL PB compared with their wt littermates. PB from G-CSF-treated donors was transplanted into lethally irradiated CD45.1 mice. Recipients transplanted with PB from CAG-Asah1 tg but not Asm-/- donors showed significantly increased CD45.2 donor-derived PB chimerism compared with recipients transplanted with PB from CAG-Asah1 wt littermates. Amitriptyline synergizes with G-CSF and significantly increases LSK cells, CFU-C/mL PB and CD45.2 chimerism but, at least partially, via mechanisms independent of Asm inhibition.
Summary/Conclusion: Overexpression of acid ceramidase enhances G-CSF mediated HSPC mobilization via yet not defined mechanisms. Amitriptyline enhances G-CSF mobilization. Outlook: Utilization of Asm-/- model and pharmacological inhibition of Asm with Amitriptyline to enhance the rapid AMD3100-mediated HSPC mobilization.

PS1165

TELOMERASE TRANSCRIPTS FLOATING IN CANCER-DERIVED EXOSOMES REPROGRAM THE MICRORNA TRANSCRIPTOME PROFILE OF THE RECIPIENT CELLS

D. Likonen[1,*], E. Beery[1], P. Raanani[2], M. Lahav[1], U. Rozovski[2], O. Uziel[1]

[1]FMRC, Rabin Medical Center and Tel Aviv University, Petah-Tikva, Israel, [2]Hematological Institute, FMRC, Rabin Medical Center and Tel Aviv University, Petah-Tikva, Israel

Background: Previously, we showed that hTERT transcripts are exported in exosomes to various types of cancer derived cells. These transcripts, formed almost exclusively in neoplastic cells are subsequently taken up by non-neoplastic cells and alter their phenotype. How neoplastic cells modify recipient cells is currently unknown, but since hTERT has been shown to regulate microRNA expression, we hypothesized that hTERT(+) exosomes alter the microRNA profile of recipient cells.
Aims: 1) Verify that hTERT(+) exosomes are taken up by fibroblasts. 2) Determine whether exposure to hTERT(+) exosomes alter the microRNA profile recipient cells. 3) Determine whether the phenotype observed in recipient cells is driven by reprograming of the microRNA transcriptome.
Methods: We grew cells derived from T-cell leukemia cell line (Jurkat cells) in exosome free medium and isolated the exosomes after 72 hours by serial ultracentrifugation. Subsequently we verified that Jurkat cells shed exosomes at large quantities by NanoSight tracking device. We then stained the exosomes with FM-134, exposed foreskin derived fibroblasts to these exosomes and used flow cytometry to determine the time of maximal exosomal uptake. In addition we verified the uptake of the hTERT transcripts via exosomes by RT-PCR. We then extracted the RNA from recipient cells using RNeasy and performed high throughput analysis of the microRNA transcriptome (Rosetta Genomics, Rehovot Israel). We transfected the fibroblasts with a microRNA mimic harboring the sequence of microRNA 342 and studied proliferation (by the SRB method) and cells cycle rate (by PI) in the treated cells.
Results: As we previously showed Jurkat-cell derived exosomes, carry the hTERT transcripts. These exosomes were taken up by fibroblast in a time and dose dependent manner. By microarray we detected seven microRNAs that were more than 2 folds upregulated and two microRNAs that were more than 2 folds downregulated after exosomal exposure. The overexpression of these microRNAs was verified by RT-PCR. Furthermore, after transfection of naïve fibroblasts with miR342, we observed a marked increase in proliferation rate and significant decrease in apoptotic rates, recapitulating the phenotype of fibroblasts following exposure to hTERT(+) exosomes.
Summary/Conclusion: Our current study shows that hTERT(+) exosomes alter the microRNA transcription profile of recipient fibroblasts and that these changes contribute to the oncogenic phenotype of non-transformed fibroblasts.

PS1166

ALTERATIONS IN STROMAL PRECURSOR CELLS IN THE BONE MARROW OF PATIENTS WITH LEUKEMIA IN THE ONSET OF THE DISEASE AND AFTER TREATMENT

N. Petinati[1,*], I. Shipounova [1], N. Sats[1], A. Bigildeev[1], N. Drize[1], L. Kuzmina[1], E. Parovichnikova[1], V. Savchenko[1]

[1]National Research Center For Hematology, Moscow, Russian Federation

Background: Tumor cells and chemotherapy damage bone marrow (BM) stroma in patients with leukemia. Stromal precursor cells (multipotent mesenchymal stromal cells /MSC/ and colony forming unit fibroblasts /CFU-F/) take part in regulation and maintenance of hematopoiesis. The alterations in their characteristics can explain the changes in the hematopoietic system of patients.
Aims: The aim of the study was to compare the changes in MSC and CFU-F from the BM of patients with leukemia at the onset of the disease and at different stages of treatment.
Methods: The study included 33 AML, 20 ALL, 19 CML patients. In all patients, BM was taken at the time of diagnosis, in AML and ALL patients, BM was collected 37, 100 and 180 days after diagnosis, in patients with CML 125 and 225 days after initiation of treatment. From the BM, MSCs were isolated by the standard method and the concentration of CFU-F was determined. The relative expression level (REL) of various genes in CFU-F and MSCs was determined by real-time PCR. Control samples from the BM of healthy donors were selected for each group of patients according to age.

Table 1.

Leukemia stromal precursor cells characteristics compared to donors, fold

Diagnosis		AML		ALL		CML	
Time point		debut	therapy	debut	therapy	debut	therapy
CFU-F	Concentration per 10^9 BM cells	0.52±0.02	0.97±0.07	0.28±0.02	0.85±0.07	0.73±0.05	0.78±0.07

Results: The Table 1 shows the ratio of values MSCs and CFU-F characteristics of patients to donors. Concentration of CFU-F in BM of patients with acute leukemia is reduced several times in comparison with donors, and in ALL stronger than in AML. In patients CFU-F the REL of genes responsible for bone, fat and cartilage differentiation is increased both in the onset of the disease and at all stages of treatment. An exception is the REL of the *SPP1* gene associated with terminal bone differentiation, which is markedly reduced and becomes less than that of donors during treatment.
The total cell production of MSCs at the onset of the disease is not significantly different from donors in patients with AML, decreases in ALL and increases with CML. With the treatment, it significantly increases in patients with acute leukemia and continues to be elevated in patients with CML. In all patients, the time to P0, which characterizes the concentration of progenitor cells, is increased in comparison with donors, indicating that the number of MSCs decreases in the stromal microenvironment of leukemia patients. Unlike CFU-F, the differentiation potential in patients MSCs is lowered already in the debut, and then decreases further as decay. Adhesion molecules are increased at the onset of the disease and are greatly reduced with treatment. The REL of proinflammatory cytokines is increased at the onset of the disease and slowly normalize with treatment, with the exception of *IL6*, whose expression

remains elevated tenfold for all leukemia's. The most dramatic changes are associated with the expression of SDF1 and VEGF. The REL of their expression decreased very much as patients were treated.
Summary/Conclusion: The data obtained indicates that the recovery of the quantitative characteristics of stromal precursor cells occurs in the treatment; however, the qualitative characteristics suffer even more from the effects of therapy and are not restored in the observation periods. The function of hematopoiesis maintaining is disturbed in patients with leukemia at all stages of therapy.

LYMPHOPENIA AND RISK OF INFECTIONS AND INFECTION-RELATED DEATH IN DENMARK, 2003-2013: A PROSPECTIVE COHORT STUDY OF 98,344 INDIVIDUALS FROM THE GENERAL POPULATION

M. Warny[1,*], S. E. Bojesen[2,3], H. Birgens[1], J. Helby[2,3,4], B. Nordestgaard[2,3]

[1]Hematology, [2]Clinical Biochemistry, [3]Copenhagen General Population Study, Herlev and Gentofte Hospital, Copenhagen University Hospital, Denmark, Copenhagen, [4]Hematology, Zealand University Hospital, Roskilde, Denmark

Background: Neutropenia increases the risk of infections, but it is unknown if this also applies to lymphopenia.
Aims: To test the hypotheses that lymphopenia is associated with high risk of infections and infection-related death.
Methods: The study is an observational cohort study including 98,344 individuals from the Copenhagen General Population Study. The participants had 8,401 infections, and 1,042 infection-related deaths over a median of 6 years of follow-up. No participants were lost to follow-up. We measured lymphocyte count, and collected information on hospitalization due to any infection, specific infections, and registration of infection-related death.
Results: Individuals with lymphopenia ($<1.1\times10^9$/L) compared to those with lymphocytes in the reference range ($1.1–3.7\times10^9$/L) had hazard ratios of 1.42 (95% confidence interval 1.28-1.56) for any infection, 1.31 (1.13-1.51) for pneumonia, 1.44 (1.16-1.80) for skin infection, 1.26 (1.02-1.56) for urinary tract infection, 1.50 (1.20-1.87) for sepsis, 1.42 (1.04-1.94) for diarrhoeal disease, 2.08 (1.12-3.84) for endocarditis, and 2.18 (1.16-4.09) for other infections. The corresponding hazard ratio for infection-related death was 1.68 (1.36-2.08). Analyses were adjusted for age, sex, smoking status, cumulative smoking, alcohol intake, body mass index, plasma C-reactive protein, blood neutrophil count, recent infection, Charlson comorbidity index, medication use, and immunodeficiency/hematologic disease. The findings were robust in all stratified analyses and also only including events more than 2 years after date of examination.
Summary/Conclusion: Lymphopenia was associated with an increased risk of hospitalization with infections and an increased risk of infection-related death in the general population.

HEMATOPOIETIC EFFECTS OF A COMPOUND: SXN AGAINST MYELOSUPPRESSION

L. Ding[1,*], F. Zhou[1], Y. Jin[1], Y. Liu[2], H. Liu[3], B. Wu[1]

[1]Department of Hematology, [2]Department of Clinical Oncology, Zhongnan Hospital of Wuhan University, Wuhan, [3]Department of Hematology, Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Background: Shengxuening (SXN), a compound extracted from silkworm excrement, is second grade national new traditional Chinese medicine. The main components of SXN are chlorophyll derivatives and sodium iron chlorophyllin(SIC). SIC, a water-soluble chlorophyll ferrous derivative, which has a quasi structure to heme, just the magnesium in the porphyrin ring has been replaced by iron, can be used as an iron fortificant and promote hematopoiesis.
Aims: The present study aimed to evaluate the efficacy and safety of SXN treatment for iron deficiency anemia(IDA) patients, investigating the hematopoietic effects of SXN on radiation induced myelosuppressed mice, exploring the underlying mechanisms.
Methods: Participants of Phase IV clinical trial were 2001 patients with IDA, randomly divided into three groups. Blood was tested before and after treatment. The mice were irradiated to induce myelosuppressed model. SXN was administered by gavage. The numbers of peripheral blood were counted and body weight, spleen indices were measured. The histology of femur was examined by hematoxylin and eosin staining. The levels of thrombopoietin (TPO), erythropoietin (EPO) and granulocyte-macrophage colony stimulating factor (GM-CSF) in serum were measured by ELISA. Hemopoiesis genes in liver was detected by quantitative real-time PCR array.
Results: The total effective rate in SXN treated group reached 84.8%, significantly increasing levels of RBC, HGB, reticulocyte counts, MCV, MCH, MCHC, SI, SF, reducing levels of TIBC. The incidence rate of AEs was 4.07%. In myelosuppressed model, SXN significantly increased the numbers of peripheral blood cells and improve the bone marrow morphology. The decreases of body weight and spleen indices can be reversed by SXN. Furthermore, SXN could increase the levels of EPO and GM-CSF in serum and enhance the expression of Blnk, Stat3 in liver.
Summary/Conclusion: SXN was proved to be safe and effective in IDA patient population, and confirmed to promote the recovery of hemopoietic function in myelosuppressed model, which attributed to improving bone marrow hematopoiesis; increasing the secretion of hematopoietic growth factors; stimulating the expression of hemopoiesis genes.

PI3P MODULATES MEGAKARYOCYTE MATURATION AND PROPLATELET PRODUCTION *IN VITRO*

I. Bertović[1,*], R. Kurelić[1], M. Krauss[2], V. Haucke[2], A. Jurak Begonja[1]

[1]Department of biotechnology, University of Rijeka, Rijeka, Croatia, [2]Department Molecular Pharmacology and Cell Biology , Leibniz Institut for molecular pharmacology, Berlin, Germany

Background: Phosphoinositides (PIs) are short-lived membrane phospholipids that mediate crucial cellular functions inlcluding signalling, gating of ion channels, cytoskeleton regulation and motility. Phosphatidylinositol 3-monophosphate (PI3P), mainly produced by Vps34 kinase, is confined to endosomal compartment where it regulates intracellular membrane trafficking. We hypothesized that traffic of endolysosomal membranes regulated by PI3P could contribute to platelet formation. Platelets are produced within bone marrow from precursor cells, megakaryocytes (MK). MKs generate prolonged cytoplasmic protrusions called proplatelets that extend through the vascular sinusoids and release platelets into the bloodstream.
Aims: The aim of our study was to determine the role of PI3P and endolysosomal trafficking in megakaryocyte maturation and proplatelet formation.
Methods: We analyzed localization of PI3P, early (EE; EEA1) and late endosomes/lysosomes (LE/Lys; Rab7, LAMP1) by confocal microscopy using recombinant PI3P-binding probe (GFP-2xFYVE) in immature and mature primary mouse megakaryocytes (MKs). We found that in immature MKs, PI3P was confined to large vesicles, mostly colocalizing with EE, while in mature MKs PI3P resembled discrete vesicles localized to both EE and LE/Lys. Moreover, while in immature MKs PI3P and LE/Lys were mostly scattered or perinuclear, in mature MKs they translocated to the cell periphery. In mature MKs, PI3P (GFP-2xFYVE probe or expressed PX) colocalized with GPIbβ, or CD61 (MK plasma membrane markers). Also, PI3P partially colocalized with both $PI(4,5)P_2$ and LAMP1 at the same sites, and inhibition of PI3P production (PI3KCIII inhibitor) decreased LAMP1 localization on the plasma membrane. Importantly, PI3KCIII inhibitor significantly reduced the size of MKs when applied at earlier stages
Results: Overexpression of PI3P binding domains YFP-PX and GFP-2xFYVE, but not the expression of YFP/ GFP, diminished production of proplatelets, final stages of MK development, suggesting that they act as dominant-negative inhibitors. These results were further confirmed by inhibition of PI3P production (PI3KCIII inhibitor, overexpression of MTM1), or by inhibiting endosomal maturation to LE/Lys (concanamycin). Furthermore, overexpression of LE small GTPase Rab7 increased proplatelet formation from MKs.
Summary/Conclusion: Altogether, these results suggest that PI3P-positive LE/Lys contribute to membrane growth and proplatelet formation from MKs.

PS1170

IMPACT OF SPLENECTOMY ON CD34+ BLOOD COUNT

V. Savchenko[1], I. Galtseva[1,*], S. Kulikov[1], E. Parovichnikova[1], K. Danishyan[1], N. Kapranov[1], Y. Davydova[1], H. Julhakyan[1], A. Melikian[1], K. Sabirov[1], E. Mikhaylova[1], N. Tsvetaeva[1]

[1]National Research Center for Hematology, Moscow, Russian Federation

Background: Splenectomy may be carried out in the treatment of various hematological diseases such as idiopathic thrombocytopenic purpura (ITP), autoimmune hemolytic anemia (AIHA), lymphomas, primary myelofibrosis (PMF) etc. Spleen participates in the processes of blood cell recirculation,

so investigation of hematopoietic progenitor cells prior and after splenectomy is of great interest. The influence of splenectomy on the amount of CD34+ cells is unknown.
Aims: The aim of the study is to determine the alterations in the amount of CD34+ cells in peripheral blood of patients after splenectomy.
Methods: The study included 90 patients (23 males and 67 females, median age was 55 years) diagnosed with 20 different hematological and non-hematological diseases. Patients were divided into 4 groups: group I (AA, MDS, PNH), group IIa (Lymphomas, CML) and group IIb (AIHA, ITP), group III (PMF) and group IV (non-hematological diseases). The number of CD34+ cells was determined in peripheral blood prior to splenectomy and at day 1, 3, 5, 7 and 14 of post operational period. CD34+ count was determined by flow cytometry according to ISHAGE protocol. For measurement of absolute number of CD34+ cells we determined the absolute number of white blood cells (WBC). We analyze 379 samples of peripheral blood (PB): 90 prior splenectomy and 81, 68, 65, 67 and 20 on 1, 3, 5, 7 and 14 days after operation, respectively. Data is presented as mean±SEM. Wilcoxon criterion was used for paired comparisons (due to non-normal distribution of data) and $p<0.05$ was suggested as significant.
Results: The 3.1 times increase of WBC was shown immediately after splenectomy on +1 day ($p<0.0001$) which was followed by consisted 1,6-times decrease on +7d compared to WBC prior operation ($p=0.0003$).
CD34+ cells (%) in PB slightly decreased on +1d after splenectomy and was 0.9-times lower than initial ($p<0.0001$). This decrease was followed by consisted increase of CD34+ cells (%) up to 3-times in 2 weeks ($p=0.049$). PMF patients had higher CD34+ cells (%) than patients with other diseases before splenectomy. We observed significant decrease in CD34+% after splenectomy in PMF patients (2-times decrease on +1d and 9-times decrease on +3d, $p=0.0159$), but this decrease was followed by continuous increase on later dates. PMF patients had significantly higher CD34+ cells (%) in PB than other patients at any time point after operation.
Absolute number of CD34+ cells in all groups increased 2.6-times on +3d post operation ($p=0.002$), 3.4 ($p=0.0009$) and 3.7 ($p=0.0001$) times on +5d and +7d, respectively. Absolute number of CD34+ cells in peripheral blood samples varied significantly between patients with different diseases. PMF patients had higher absolute count of CD34+ cells before splenectomy and its decrease was observed on +3d after splenectomy. But absolute CD34+ count had increased on later date in PMF and was significantly higher than in patients with other diseases (Table 1).

Table 1.

Groups	n	prior	+1d	+3d	+5d	+7d	+14d
WBC, x10^3/ml							
Group I (AA, MDS, PNH)	12	2.80±0.42	4.92±1.03	4.28±1.24	2.76±0.32	3.66±0.34	3.62±0.36
Group IIa (Lymphomas, CML)	30	20.33±4.6	22.75±5.63	19.25±4.32	17.35±4.21	12.64±2.1	20.33±4.6
Group IIb (AIHA, ITP)	37	8.96±0.97	17.51±2.76	14.28±2.14	12.69±1.23	10.77±0.92	9.13±0.85
Group III (PMF)	5	9.18±2.2	22.74±6.48	17.25±5.51	14.13±3.94	15.77±3.66	17.41±1.85
Group IV (Non-hematological diseases)	6	4.18±1.47	11.63±1.70	12.90±3.16	9.48±1.94	9.08±2.46	6.85±3.36
Total	90	7.78±0.91	16.45±2.00	15.62±2.39	13.63±1.92	12.52±1.99	9.58±1.80
CD34, x10^3/ml							
Group I (AA, MDS, PNH)	12	0.41±0.34	0.56±0.45	1.54±1.26	0.09±0.05	0.11±0.05	0.09±0.05
Group IIa (Lymphomas, CML)	30	2.58±1.02	4.03±2.31	5.29±2.63	5.23±2.23	5.7±1.79	4.01±1.35
Group IIb (AIHA, ITP)	37	2.69±0.57	2.27±0.42	3.97±0.93	3.2±0.65	3.12±0.49	3.11±0.3
Group III (PMF)	5	125.43±39.29	184.70±62.27	33.66±7.82	52.19±6.89	118.24±47.27	113.30±23.49
Group IV (Non-hematological diseases)	6	0.22±0.07	0.77±0.48	0.91±0.40	3.04±1.61	2.59±1.66	1.22±0.86
Total	90	9.14±3.77	13.73±6.22	5.59±1.42	6.54±1.78	11.69±5.13	13.5±7.86

Summary/Conclusion: Alteration in CD34+ cells count after splenectomy is the evidence of great impact of spleen on functional activity of hematopoietic system. Constant increase of CD34+ cells in PMF could be explained by diminishing of hematopoiesis in bone marrow due to fibrosis and sporadic decrease on +3d reflects the extraction of spleen. PMF patients had the highest percentage and count of CD34+ cells in PB before and after splenectomy.

[1]Department of Haematology and Bone Morrow Transplantation, [2]1st Department of Internal Medicine, [3]1st Propaedeutic Department of Internal Medicine, Laikon General Hospital, National and Kapodistrian University of Athens, [4]Department of Haematology, Athens Medical Center, Psychikon Branch, Athens, Greece

Background: Despite significant improvements in the outcome of HL, VLRs (≥5 years after initial CT±RT) do occur. Data on VLRs after standard CT±RT are very limited, including our initial report and the recent large observational GHSG study with a 20-year follow-up (4935 patients; estimated 45% after BEACOPP). However, the incidence, risk factors and outcome of VLRs in HL require further evaluation, especially after ABVD-like CT. Very prolonged follow-up time is also of paramount importance.
Aims: To examine the incidence and prognostic factors for the development as well as the outcome of VLRs in patients with HL, who remain in first complete remission (CR1) for ≥5 years from treatment initiation.
Methods: Retrospective study of 931 adult patients, diagnosed with HL and remained in CR1 for ≥5 years after treatment initiation (maximum follow-up exceeding 35 years). Anthracycline-based chemotherapy was administered in 89% of patients [mainly A(E)BVD], whereas 11% received MOPP. Survival analysis was performed using competing-risk regression models.
Results: VLRs occurred in 52/931 patients (2/52 relapsed as composite lymphoma) and the most delayed relapse occurred after 35 years. The distribution and cumulative incidence (CI) of VLRs are presented in Table 1. CI rose linearly over time after 5 years and the annual incidence rate was roughly estimated at 0.40% per person-year. After treatment with ABVD CT±RT, the CI of VLR at 20 and 30 years, was estimated at 7.2% and 9.7% respectively. In multivariate analysis, independent protective prognostic factors were nodular sclerosing (NS) histology [hazard ratio (HR)=0.41, $p=0.007$], anthracycline-based (ABVD-type) CT±RT vs MOPP-type (HR=0.49, $p=0.04$) and CT+RT vs CT (HR=0.43, $p=0.03$). Among 830 patients treated with anthracycline-based CT, independent protective prognostic factor was the NS histology (HR=0.33, $p=0.006$); age ≤45 years was of borderline significance (HR=0.57, $p=0.14$). Most patients did not undergo autologous stem cell transplantation. The 5-year and 10-year overall survival after relapse was 67% and 46% respectively. Analysis of treatment and prognostic factors for the outcome of VLRs will be the subject of another study.

Table 1.

Patient subgroups	Patients/ Relapses	Cumulative incidence of relapse at n-years					Annual incidence (%)
		10y	15y	20y	25y	30y	
Total patients	931/52	3.4%	6.0%	8.2%	9.4%	11.1%	0.40
ABVD or equivalent	830/36	2.8%	5.3%	7.2%	8.4%	9.7%	0.32
MOPP or equivalent	101/16	8.0%	11.2%	14.1%	15.9%	17.7%	0.67
Nodular sclerosis	608/20	2.2%	2.8%	5.2%	5.2%	8.5%	0.23
Other histological subtypes	323/32	5.5%	11.5%	13.5%	16.3%	16.3%	0.71
Time	**Patients/ Relapses**	**Follow-up**					**Total**
		5-10y	**10-15y**	**15-20y**	**20-25y**	**25-35y**	
Relapses (#)	931/52	28	13	6	2	3	**52**

Summary/Conclusion: This study is the 2nd largest one aiming to determine the incidence of VLRs in HL, providing the longest follow-up and reporting on the prognostic factors for their development. We confirm the linear pattern of VLR up to 20 years after ABVD-like CT±RT, but we also highlight

that VLRs can occur up to at least 35 years after initial CT±RT. VLRs were more common after MOPP than after ABVD. Patients with non-NS histology had an increased risk of VLRs with mixed cellularity being the most adverse, pointing out to a potentially different biology among different histologic subtypes. The 10-year overall survival after VRLs was not satisfactory with conventional salvage therapy. These conclusions have clinical and biological significance and obvious implications for patient counseling.

PS1172

BRENTUXIMAB VEDOTIN WITH CHEMOTHERAPY FOR STAGE III OR IV HODGKIN LYMPHOMA: IMPACT OF CYCLE 2 PET RESULT ON MODIFIED PROGRESSION-FREE SURVIVAL

Background: The ECHELON-1 trial demonstrated improved outcomes for patients with advanced Hodgkin lymphoma (HL) who received frontline A+AVD (brentuximab vedotin, doxorubicin, vinblastine, dacarbazine) vs ABVD (doxorubicin, bleomycin, vinblastine, dacarbazine), with 2-year modified progression-free survival (mPFS) rates of 82% and 77%, respectively.
Aims: In this *post-hoc* analysis, we examine the mPFS outcomes and clinical characteristics by Cycle 2 positron-emission tomography (PET2) status, per independent review facility (IRF).
Methods: Patients were randomized 1:1 to A+AVD or ABVD on Days 1 and 15 for up to six 28-day cycles. PET scans were conducted at the end of Cycle 2 and end of treatment. PET2 results guided an optional switch to alternative therapy at the treating physician's discretion for patients with a Deauville score of 5. A switch to alternative therapy was not considered an event. The primary endpoint, mPFS, was defined as time to progression, death, or absence of a complete response with subsequent anticancer therapy, per IRF.

Table 1. Summary of mPFS by PET2 Status.

	2-year mPFS (per IRF), %			
	A+AVD	ABVD	HR	P-value
Overall	82.1	77.2	0.77	0.035
95% CI	78.8–85.0	73.7–80.4	0.603–0.983	
N	664	670		
PET2–	85.2	80.9	0.774	0.070
95% CI	81.9–88.0	77.3–84.0	0.586–1.022	
N	588	577		
PET2+	57.5	42.0	0.609	0.089
95% CI	41.0–70.9	28.6–54.8	0.341–1.088	
N	47	58		

Results: PET2 negativity rates (Deauville ≤3) were 89% (588/664 patients) in the A+AVD arm and 86% (577/670) with ABVD. Baseline characteristics were well-balanced across arms, with no significant differences in PET2– vs PET2+ patients in either arm. PET2 positivity rates (Deauville ≥4) were 7% (47/644) in the A+AVD arm and 9% (58/670) with ABVD; in total, 5 patients with a Deauville score of 5 switched to alternative frontline therapy. Subgroup analyses showed a favorable treatment effect for both subgroups in favor of A+AVD (Table 1), with 2-year mPFS (PET2– vs PET2+) of 85.2 vs 57.5% in the A+AVD arm, and 80.9 vs 42.0% in the ABVD arm. In both arms, outcomes for PET2+ patients were poor compared with PET– patients, consistent with findings from other studies.
Summary/Conclusion: Overall, ECHELON-1 demonstrated a treatment effect in favor of A+AVD over ABVD. This post-hoc analysis showed a similar treatment effect on mPFS consistently in favor of A+AVD regardless of PET2 status.

PS1173

NIVOLUMAB TREATMENT DISCONTINUATION IN RELAPSED OR REFRACTORY HODGKIN LYMPHOMA: PAVLOV FIRST SAINT PETERSBURG STATE MEDICAL UNIVERSITY EXPERIENCE

L. Fedorova[1,*], K. Lepik[1], N. Mikhailova[1], E. Kondakova[1], A. Kozlov[1], Y. Zalyalov[1], E. Borzenkova[1], V. Baykov[1], L. Stelmakh[1], L. Tsvetkova[1], B.V. Afanasyev[1]

[1]Raisa Gorbacheva Memorial Institute of Children Oncology Hematology and Transplantation, Pavlov First Saint Petersburg State Medical University, Saint Petersburg, Russian Federation

Background: Nivolumab has demonstrated high response rate and sustained remission in patients with relapsed or refractory Hodgkin lymphoma. However, information about the optimal duration of therapy with nivolumab after achieving the complete response (CR) and the duration of response after discontinuation of nivolumab therapy is lacking.
Aims: To assess the duration of remissions in patients with CR to nivolumab monotherapy after treatment discontinuation.
Methods: 19 adult patients (4 male/15 females, median age 31 years) with relapsed/refractory Hodgkin lymphoma who were treated with nivolumab (3 mg/kg every 2 weeks) and achieved CR were included in this analysis. During therapy, the response was assessed by positron-emission tomography/computed tomography (PET/CT) using LYRIC criteria every 6 cycles. Treatment was stopped because of toxicity or named patient program was closed. After nivolumab therapy had been stopped patients received no other treatment and disease was assessed every 3 months by PET/CT. Median follow-up time since cessation of therapy was 11,1 months.
Results: Before the nivolumab therapy initiation 11 (57,9%) patients had stage 4 disease, 12 (63,2%) patients had B-symptoms. 14 out of 19 patients had previously refractory disease (73,7%), 1 (5,3%) patient had early relapse. The median number of previous therapies was 5 (3-10). High dose chemotherapy with autologous stem cell transplantation (ASCT) was performed in 8 (42,1%), 7 (36,8%) patients received brentuximab vedotin (BV). The median number of nivolumab cycles was 20 (13-30). The median number of cycles before CR achievement was 6 (6-18). The median duration of therapy after achievement of CR was 6,9 months. At the time of analysis, all patients were alive and 17 (89,5%) out of 19 patients are free of relapse. Two patients relapsed after 6,4 months and 5,2 months after therapy discontinuation. In these patients the CR were achieved after 12 and 6 cycles and nivolumab monotherapy was continued for 20 and 25 cycles respectively. After disease relapse the first patient was retreated with nivolumab-containing regimen with achievement of CR and the second patient is also going to be retreated with nivolumab.
Summary/Conclusion: Our analysis demonstrate that in patients with complete response during nivolumab monotherapy, the sustained remissions without additional therapy is possible after cessation of nivolumab treatment but optimal time for discontinuation of therapy is still unknown. Future patients monitoring is planned with retreatment with nivolumab in case of relapse of the disease.

PS1174

BENDAMUSTINE IN COMBINATION WITH NIVOLUMAB IN PATIENTS WITH RELAPSED OR REFRACTORY HODGKIN LYMPHOMA AFTER FAILURE OR SUBOPTIMAL RESPONSES TO NIVOLUMAB THERAPY

K. Lepik[1,*], L. Tsvetkova[1], A. Kozlov[1], E. Kondakova[1], Y. Zalyalov[1], E. Borzenkova[1], V. Baykov[1], N. Mikhailova[1], B. Afanasyev[1]

[1]Research Institute of Pediatric Oncology, Hematology and Transplantology them. By R.M. Gorbachev, St. Petersburg, Russian Federation

Background: Immune checkpoints inhibitors therapy is associated with the high response rate in patients with relapsed and refractory Hodgkin's lymphoma (r/r HL) even after ASCT and brentuximab vedotin (BV). However, a fraction of patients fails to achieve an objective response or have disease progression with clinical manifestation after objective response achievement.

The lymphodepletion and tumor microenvironment shift induced by chemotherapeutic agents are considered as a perspective approach that may enhance the effect of immune checkpoint blockade. Bendamustine (benda) is a bifunctional alkylating agent, which is effective as monotherapy or in combination with BV in patients with r/r HL.
Aims: This report summarizes the preliminary results of First I. P. Pavlov State Medical University of St. Petersburg in the treatment of patients with r/r HL using nivolumab (nivo) in combination with bendamustine after the failure of initial nivolumab monotherapy.
Methods: The analysis included 30 (20 m/10 f) patients. Pts received 90 mg/m^2 benda on D1-2 and 3 mg/kg nivo on Day 1,14 of the 28-day cycle up to 3 cycles. After completion of the Cycle 3 the response evaluation was performed by total body PET-CT scan and assessed by investigators using LYRIC criteria. The adverse events profile was evaluated and scored according to NCI CTCAE v.4.03
Results: The median age was 30 years (21-60). The median number of prior therapy lines was 6 (range 3-11). All patients received nivolumab treatment with a median number of infusions - 18 (8-27). The reason for combined treatment initiation was disease progression in 20 (67%), and indeterminate response in 10 (33%) patients during nivolumab monotherapy according to LYRIC criteria. Prior to nivo-benda combination therapy, 20 (66%) pts had received benda containing regimens earlier during the course of the disease, 14 (46%) had received BV, and 6 (20%) had received nivo-BV combination. At the time of analysis median follow up was 9 months (3-15). Safety analysis showed that 27 (90)% of the pts had drug-related adverse events (AEs) of any grade. Grade 3-4 AEs was noted in 6 (23%) of treated patients. Fatigue (80%), nausea (73%) and pyrexia (37%) were the most common AEs. Grade 3-4 AE's included 4 cases of pneumonia, 1 uveitis, 1 colitis, 1 severe infusion reaction. One patient has discontinued treatment prematurely due consent withdrawal. All patients were evaluated for the response to treatment. The objective response was observed in 26 (86%) patients, a complete metabolic response was observed in 16 (52%) patients. One patient has disease stabilization, one disease progression and 2 have indeterminate response according to LYRIC criteria. Of patients achieved CR, 10 (63%) have received and failed the bendamustine containing regimen earlier, and 9 (56%) have received and failed brentuximab vedotin treatment. Allogeneic transplant was performed in 4 patients. At the median of 9 months, 29 (97%) of patients were alive, and 22 (73%) were free of disease progression. One patient died due to haploidentical transplantation complications.
Summary/Conclusion: Our results suggest that although an elevated incidence of AEs has been observed, toxicities with this regimen appear to be manageable and the combination of benda and nivo may be an effective salvage therapy in patients with r/r HL. Achievement of complete responses in patients that have failed either benda and nivo treatment with the combination of this drugs may suggest a synergistic effect. To draw more solid conclusions it is necessary to expand cohort of patients and increase the duration of follow-up.

PS1175

NIVOLUMAB RESTORES SENSITIVITY TO CHEMOTHERAPY IN CHEMOREFRACTORY CLASSICAL HODGKIN LYMPHOMA PATIENTS

C. Carlo-Stella[1,*], L. Castagna[1], M. Magagnoli[1], L. Morello[1], R. Mazza[1], F. Ricci[1], S. Viviani[2], S. Pileri[3], P. Corradini[4], A. Santoro[1]

[1]Hematology, Humanitas Clinical and Research Center, Rozzano, [2]Hematology, Fondazione IRCCS Istituto Nazionale Tumori, [3]Hematolymphopathology Unit, European Institute of Oncology, [4]Chair of Hematology, University of Milano, Milano, Italy

Background: Classical Hodgkin lymphoma (cHL) patients who relapse after autologous stem cell transplantation (Auto-SCT) and/or brentuximab vedotin (BV) experience unprecedented objective response rates (ORR) when treated with the anti-programmed death-1 (anti-PD-1) antibodies Nivolumab or Pembrolizumab. However, after an initial complete remission (CR) or partial remission (PR) in response to Nivolumab, a substantial proportion of patients will ultimately progress/relapse and have limited treatment options.
Aims: In order to investigate whether chemotherapy might represent a treatment option in this clinical setting, we retrospectively analyzed a series of relapsed/refractory cHL patients who received chemotherapy after experiencing progressive disease (PD) during Nivolumab therapy.
Methods: We analyzed 16 relapsed/refractory cHL patients who received Nivolumab in the context of the CA209-205 phase 2 trial and the CA209-254 Expanded Access Program. After an initial response, all these patients stopped Nivolumab due to progressive disease and were addressed to a variety of chemotherapy regimens. Response to chemotherapy and immunotherapy was assessed according to the Lugano Classification (JCO, 2014) and subsequent LYRIC modifications (Blood, 2016).
Results: The median age of study patients was 30 years (range, 19-57), 60% had Ann Arbor III/IV stage, 33% B-symptoms, 13% bulky disease, and 53% extranodal disease. Prior to Nivolumab therapy, they received a median of 4 (range, 3-6) chemotherapy regimens, 60% had primary chemorefractory disease, and 80% were refractory to last chemotherapy regimen. The best ORR to Nivolumab included CR (n =2), PR (n =9), SD (n =4), PD (n =1). After a median of 26 (range, 10-55) Nivolumab infusions, all patients experienced PD, defined according to LYRIC. In 8 patients, PD was histologically confirmed. Nivolumab was then stopped and the patients were addressed to a variety of chemotherapy regimens [BEGEV (n =5), BEACOPP (n =4), Bendamustine (n =1), BV (n =1), Auto-SCT (n =3), Gemcitabine (n =1), HD-VP-16 (n =1)]. After a median of 4 (range, 1-6) chemotherapy cycles, patients experienced CR (n =11), PR (n =4), and PD (n =1). Interestingly, in some patients, an objective response was achieved using regimens to whom they had resulted refractory prior to Nivolumab. No unexpected toxicity was observed during chemotherapy administration. Fourteen of 16 patients were addressed to Allo-SCT while in CR (n =10) or in PR (n =4), one patient in CR refused allo-SCT and remains in follow-up, and a patient in PD is still alive under Brentuximab Vedotin. At a median follow-up of 12 months (range, 1 – 31) after allo-SCT, 14 patients are alive in CR and 2 died (PD, interstitial pneumonia).
Summary/Conclusion: This retrospective analysis suggests that the great majority of patients who experience PD upon Nivolumab may be effectively rescued with chemotherapy. Notwithstanding their primary or acquired chemorefractoriness, cHL patients may achieve CR or PR using chemotherapy regimens to whom they were refractory prior to Nivolumab, suggesting that Nivolumab may restore chemosensitivity.

PS1176

EARLY DETECTION OF RECURRENCE IN HIGH-RISK HODGKIN LYMPHOMA IN FIRST COMPLETE REMISSION IMPROVES OUTCOME

N. Pugliese[1,*], M. Picardi[1], S. Luigia[1], R. Della Pepa[1], C. Giordano[1], F. Cacace[1], P. Zeppa[1], C. Salvatore[2], F. Pane[3]

[1]University of Naples Federico II, Naples, [2]University of Molise, Campobasso, [3]University Medical School, Salerno, Salerno, Italy

Background: Despite the high complete response (CR) rate to first-line therapy, approximately one-third of patients with advanced-stage Hodgkin lymphoma (HL) eventually relapses. Many relapses (30–50%) are clinically asymptomatic, without any physical and/or laboratory signs. For patients at high-risk of relapse, a close monitoring, based on imaging procedures is justified if an early detection of recurrence would allow a timely administration of salvage therapy and a survival improvement.
Aims: The primary objective of our study was to compare the event free survival (EFS) in three different surveillance cohorts, defined as the time period from the onset of first relapse after induction therapy up to the date of an event or the last follow-up visit after ASCT. Refractoriness to salvage therapy, second relapse or death from any cause were considered events. Secondary endpoints were: (i) the occurrence of relapse without clinical/lab findings in the whole imaging cohort and the relative EFS; (ii) the rate of complete response (CR) after salvage therapy in each group; (iii) clinical characteristic at first relapse as follow.
Methods: We analyzed in this study two cohorts of patients who were under follow-up after therapy for high-risk HL and had disease recurrence. Patients had received one of the following surveillance programs in use at our Institution between June 2004 and December 2016: i) follow-up based on the systematic use of either PET/CT (PET/CT cohort) or ii) ultrasonography (US) plus chest radiography (US/CXR cohort), as integrated part of the conventional follow-up strategy. The two study groups of HL patients were compared to the historical cohort of high-risk HL who received the conventional follow-up program including symptom assessment, blood tests and physical examination (Cilinical/Lab Cohort). All relapsed patients received a salvage therapy (DHAP or IGEV), followed by ASCT.
Results: After a median 33-months (range, 4–108 months), 123 patients experienced relapse. Of those, 43 patients had received the traditional follow-up (Clinical/Lab cohort), while the subsequent 80 were randomly assigned to the PET/CT and the US/CXR follow-up. The EFS after rescue therapy of the two study cohorts was much longer than that of patients who received the traditional Clinical/Lab surveillance (68% and 71% in the PET/CT cohort and UX/CXR cohort, respectively, vs 37.2%; p=0.004 Figure 1). This difference were mainly due to the earlier diagnosis of recurrence in patients with clinical and/or biochemistry markers negative. Indeed, the 2-years EFS was 75.1% in the 51 patients with not silent relapses while

42.2% in the 72 patients with silent relapse (p<0.0001). Furthermore, the CR rate after salvage therapy were higher in the PET/CT cohort (27/40, 67.5%) and US/CXR cohort (28/40, 70%), compared with the Clinical/Lab cohort (18/43, 41.9%), p=0.015. Lastly, advanced stages and bulky disease were more frequent within the Clinical/Lab cohort (67.4%/65.1%) than in the PET/CT (45%/22.5%) and US/CXR cohorts (40%/25%), p=0.028. No difference was found regarding the extranodal involvement and the involvement of three or more nodal areas.

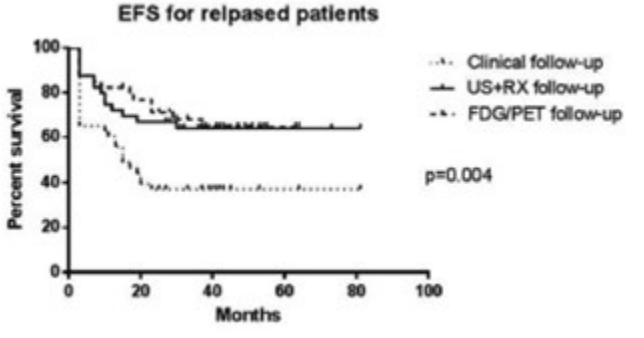

Figure 1.

Summary/Conclusion: Our data provided evidence that an imaging based follow-up strategy, independently if it was based on FDG PET/CT or US/CXR, ameliorated EFS for advanced stage HL patients in first relapse, by allowing us to detect HL recurrence at an earlier stage. We suggested that US plus CXR is a valuable adjunct to conventional follow-up in patients with high risk HL, to be preferred from FDG PET/CT, due to its low-cost and safety.

PS1177

THE RISK OF LUNG CANCER IN HODGKIN LYMPHOMA SURVIVORS; A US POPULATION-BASED STUDY

M.M. Moussa[1,*], A. Saad[2], M. Atia[2], M. Al-Husseini[2], S. Janoudi[3], L. Namous[3]

[1]Internal Medicine, Hematology and BMT unit, [2]Internal Medicine, Ain Shams University, [3]Internal Medicine, cairo university, Cairo, Egypt

Background: The advancements in treatment regiments of Hodgkin lymphoma (HL) have made it a curable disease, with a five-year survival of more than 80%. However, HL survivors are still at higher risk of morbidity and mortality compared to the general population. Second primary malignancies are a major issue with HL survivors, lung cancer is considered one of the most common and serious cancer to occur in this population.
Aims: We aim to estimate the risk of developing lung cancer in HL survivors.
Methods: We used the Surveillance Epidemiology and End Results 'SEER' program of the National Cancer Institute 'NCI' in the United States, to obtain data of HL patients. We selected all patients diagnosed with HL between 1973 and 2014. An event was defined as a diagnosis of a second primary lung cancer after a six-month latency period following HL diagnosis, and we followed patients to observe who experienced the event. We then calculated the Observed/Expected (O/E) ratio, and the excess risk per 10,000 person-years, to estimate the change of risk following the diagnosis when compared to the general US population.
Results: Our study included 26,589 HL patients, of which 594 patients were diagnosed with a second primary lung cancer. The risk of developing a primary lung cancer increased significantly after a diagnosis with HL with an O/E of 2.92 and an excess risk of 11.38 per 10,000. The highest increase in O/E was after 10 years or more following HL diagnosis (3.54), with 377 patients, and an excess risk of 16.83 per 10,000. When calculated according to sex, O/E of both males and females increased significantly; 2.82, and 3.10 respectively. Most patients who developed a second primary lung cancer were in the age groups of 20-44, and 44-65 (253 and 237 patients respectively), with a relatively less number of patients younger than 20 or older than 65. The number of patients younger than 20 who developed lung cancer was 19. However, this group's risk of primary lung cancer increased significantly with an O/E of 7.80. When we analyzed cases according to lymphoma's subtype, all subtypes were associated with an increase in the risk, with most cases having a nodular-sclerosis subtype before the subsequent primary lung cancer. The highest increase in lung cancer risk was following the mixed cellularity subtype with an O/E of 3.28.
Summary/Conclusion: The risk of lung cancer is higher in HL survivors than the general population. This increase in risk may be due to the interaction between different factors related to the cancer itself, radiation exposure, and unhealthy lifestyles. A strict screening program may help detect these cancers earlier, and therefore may decrease associated mortality. Further studies on survival of HL survivors with second primary lung cancers are needed.

PS1178

RELEVANCE OF PRE AND POST TRANSPLANT PET AND HASENCLEVER INDEX IN PATIENTS UNDERGOING AUTOLOGOUS TRANSPLANT FOR HODGKIN LYMPHOMA

S. Turkar[1,*], A. Gokarn[1], L. Nayak[1], S. Punatar[1], A. Bonda[1], L. Mathew[1], S. Kannan[1], B. Bagal[1], N. Khattry[1]

[1]Medical Oncology, Tata Memorial Hospital, Mumbai, India

Background: Autologous stem cell transplantation (ASCT) is the treatment of choice for patients with relapsed and refractory Hodgkin lymphoma (HL). PET response and Hasenclever index (HI) for patients with advanced-stage HL are considered to have prognostic significance in upfront setting. This retrospective analysis was done to evaluate the relevance of various prognostic factors including PET response at predefined time points and HI in patients with relapsed and refractory HL undergoing autologous stem cell transplant.
Aims: To evaluate prognostic factors including pre and post-transplant PET-CT and Hasenclever index in patients undergoing autologous transplant for Hodgkin lymphoma
Methods: All consecutive patients between 1st November 2007- 31st December 2015 who underwent autologous transplant for primary progressive, chemotherapy sensitive relapse or relapsed-refractory HL were included. PET-CT was performed in all patients after 2-3 cycles of salvage chemotherapy. Response assessment post salvage therapy was performed according to Cheson's criteria. PET-CT was done on day 100, day 360 post-transplant and then yearly for next 4 years. Prognostic factors evaluated for overall survival (OS) and relapse-free survival (RFS) included time between diagnosis – transplant; time between CR1 - first relapse; baseline, presalvage and pretransplant serum albumin, LDH and B2 microglobulin; PET status - pretransplant, at day 100 and day 360; remission status at time of transplant; HI at baseline and at relapse; stage at diagnosis and at relapse.
Probabilities of OS and RFS were estimated using the Kaplan–Meier method. Log-rank test and Cox regression analysis were used for univariate and multivariate analysis respectively.
Results: Consecutive 97 HL patients with median age at transplant of 22 years (range: 5-64) were included in the analysis. The median time from complete remission (CR) to first relapse and time from diagnosis to transplant were 1.2 years (range - 0-18years) and 2.56 years (range: 0.3-22 years) respectively. The median number of lines of chemotherapy pretransplant was 2 (range 2-4). At the time of transplant, 66 patients (68%) were in complete remission (CR), 28 patients(29%) in partial remission (PR) and 3 patients (3%) had the refractory state. Median follow up of the whole cohort was 4 years. The OS and PFS at 5 years was 67% and 60% for the whole cohort respectively. Five year OS according to PET status pretransplant (PET negative - 81% vs PET positive - 46%; p=0.001), day 100 (PET negative - 84% vs PET positive - 57%; p=0.033), day 360 (PET negative - 100% vs PET positive- 66%; p=0.007) showed significantly better OS with PET negativity. Five year RFS according to PET status pretransplant (PET negative – 71% vs PET positive - 46%; p<0.001), day 100 (PET negative – 77% vs PET positive - 60%; p=0.027), day 360 (PET negative - 82% vs PET positive- 56%; p=0.001) showed significantly better RFS with PET negativity. Similarly 5 year OS and RFS for patients with stage III and IV disease at relapse with HI ≥ 4 (OS- HI<4 – 71% vs HI ≥ 4 – 38%; p=0.033: RFS- HI<4 – 56% vs HI ≥ 4- 42%; p=0.02) had inferior outcomes. Multivariate analysis of HI at pre-salvage, PET status at pre-transplant, day 100 and at day 360 showed HI to be an independent prognostic marker for overall survival.
Summary/Conclusion: Hasenclever Index at the time of salvage therapy is the most important prognostic factor in our cohort.PET status is also an important prognostic factor with patients showing PET negativity at pre-transplant, day 100 and day 360 have better survival.

PS1179

A REAL WORLD STUDY OF CLINICAL CHARACTERISTICS AND TREATMENT OUTCOME OF HODGKIN LYMPHOMA IN MALAYSIA: A SINGLE CENTER EXPERIENCE IN A RESOURCE LIMITED SETTING

T.S. Leong[1,*], S.L. Hon[1], K.W. Ho[1], S.M. Tan[1], T.C. Ong[1], J.T.C. Tan[1], P.K. Liew[1], N.S. Lau[1], S.S. Abdul Kadir[1], V. Selvaratnam[1], J. Sathar[1]

[1]Department of Hematology, Ampang Hospital, Selangor, Malaysia

Background: Hodgkin's lymphoma (HL) is a rare hematological malignancy of the lymphatic system. It is one of the most curable cancers, with overall survival (OS) of approximately 80-90%. Demographic, treatment and survival outcome data for HL is scarce in the developing world, especially in the Southeast Asian region. Furthermore, a lot of the outcome data were extracted from large scale, phase III studies. Hence, it is still uncertain whether these results are reproducible in clinical practice.
Aims: This is the first 'real world' study from Malaysia, aiming to assess clinical characteristics, treatment and how it might affects survival outcomes in terms of overall survival (OS) and progression free survival (PFS) of HL patients in the context of resource limited setting in the developing world.
Methods: This is a 12-year -retrospective analysis of adult patients diagnosed with HL between 2006 to 2017 in Ampang Hospital, Malaysia. Ampang Hospital is the national hematology referral center with bone marrow transplant facility in Malaysia.
Results: There were 541 patients with a male to female ratio of 1.2 : 1. The median age of patients were 26 years old (range 12-86). They mostly consists of Malay (73.6%), followed by Indian (13.7%) and Chinese (11.5%). Most of the HL were of nodular sclerosing (n= 279, 51.6%) and mixed cellularity (n= 116, 21.4%) subtype. More than half (78.9%) of them had B symptoms at presentation. ABVD was the most common first line treatment (81%, n= 438) followed by escBEACOPP (9.1%, n=49). Approximately 23.7% of the patients have radiotherapy. One hundred and eighty two patients (33.6%) received salvage chemotherapy such as ICE (n= 152), DHAP (n=55) and gemcitabine (n=41). Twenty four percent of patients (n= 135) undergone bone marrow transplant (auto =122, allo= 13). There were 18 patients who were treated with brentuximab. More than half of the patients achieved complete remission (CR, n=298, 55.1%) while 18.5% achieved partial response (PR). The overall response rate (ORR) was 73.6%. Sixty six patients (12.2%) has progressive disease while seventy five patients (13.9%) has relapsed disease. With median follow up of 40 months, the 5 year overall survival (OS) and 5 year progression free survival (PFS) was 78.6% and 66.8% respectively. In multivariable analysis, only complete remission after first line treatment was of independent prognostic significance for both OS (p=0.001) and PFS (p= 0.002). In the subgroup analysis of the transplanted patient (n= 135), the overall survival at 5 years was 78.4%. Disease status at ASCT was also the best predictor of transplant outcome. Patients in CR before transplant had significantly better 5-years OS (86%, p <0.001) and PFS (82.4%, p<0.001).
Summary/Conclusion: In our cohort, the incidence peaked between 16 and 29 (n=346, 64), unlike the bimodal age distribution seen in Western countries. Patients at our center have a delayed presentation with advanced disease (n=459, 84.8%) and IPS score 3 or more (n=274, 59.7%).Default/refuse treatment rate was relatively high (n=54, 10%). . These are among the few reasons our cohort shows a comparatively lower OS and PFS compared to our global counterparts. Despite the emergence of expensive novel agent such as brentuximab and PD1 inhibitors, bone marrow transplant remained the choice of treatment for relapsed refractory HL in resource limited setting as it produces satisfactory OS. A properly designed registry involving all the centers in Malaysia with more patients and longer follow-up are still needed to examine the long-term survival of patients with HL in Malaysia.

PS1180

PROGNOSTIC VALUE OF FDG-PET QUANTITATIVE ASSESSMENT OF TUMOR REDUCTION BY ΔSUVMAX, ΔTMTV AND ΔTLG IN HODGKIN LYMPHOMA PATIENTS TREATED WITH AUTOLOGOUS HEMATOPOIEIC STEM CELL TRANSPLANTATION

P. Perlaza[1,*], V. Ortiz-Maldonado[2], S. Rodríguez[3], G. Gutiérrez[2], N. Sanchez[1], X. Setoain[1], C. Martinez[2]

[1]Deparment of Nuclear Medicine, [2]Deparment of Haematology, [3]Deparment of Radiology, Hospital Clinic, Barcelona, Spain

Background: Disease status of relapsed/refractory Hodgkin lymphoma (HL) after salvage therapy and previous to autologous hematopoietic stem cell transplantation (AHSCT) is a well-recognized prognostic factor. Although positron emission tomography using ^{18}F-fluordeoxyglucose (FDG-PET) is a standard assessment tool in HL, qualitative assessment is object of significant inter-observer variability. FDG-PET quantitative parameters, such as maximum standardized uptake value (SUVmax), total metabolic tumor volume (TMTV) and total lesion glycolysis (TLG), may be more reproducible and accurate to assess response and predict outcome of HL patients after AHSCT.
Aims: To determine the prognostic value of the SUVmax, TMTV and TLG index reduction in relapse/refractory HL patients treated with salvage chemotherapy and AHSCT.
Methods: We retrospectively analyzed 100 FDG-PET of 50 patients with relapse/refractory HL (from 2005 to 2015). FDG-PET was performed pre-salvage therapy (PET0) and pre-ASCT (PET-ASCT). SUVmax, TMTV and TLG reduction between PET0 and PET-ASCT (ΔSUVmax; ΔTMTV; ΔTLG, respectively) was computed. TMTV was measured with a semiautomatic method using 41% SUVmax threshold. Quantitative parameters were measured using MIM® Version 6.7. ROC analysis determined the cut-off to define good response (complete response, CR, plus partial response, PR) vs. bad response (disease progression) for survival outcomes. Kaplan-Meier estimation was used to analyze overall survival (OS) and progression free survival (PFS).
Results: In the analysis of OS, patients with a ΔSUVmax >43.7% (Area Under the Curve, AUC, 0.68), ΔTMTV >73.5% (AUC 0.75) and ΔTLG >82.7% (AUC 0.77) were considered good responders. The number of patients good responders according to SUVmax, TMTV and TLG index reduction, were 39 (78%), 27 (54%), and 32 (64%), respectively. The 5-year OS in the group of good responders vs. bad responders calculated with ΔSUVmax was 96% vs. 44% (p<0.001), with ΔTMTV 100% vs. 71% (p=0.012), and with ΔTLG 100% vs. 60% (p=0.001). In the analysis of PFS, patients with a ΔSUVmax >67.6% (AUC 0.68), ΔTMTV >18.2% (0.75) and ΔTLG >88.5% (0.77) were considered good responders. The number of patients good responders according to SUVmax, TMTV and TLG index reduction, were 24 (48%), 41 (82%), and 26 (52%), respectively. The 5-year PFS in the group for good responders vs. bad responders calculated with ΔSUVmax was 86% vs. 51% (p 0.008), with ΔTMTV 97% vs. 74% (p <0.001), and with ΔTLG 87% vs. 47% (p 0.002).
Summary/Conclusion: Our results suggest that in patients with relapsed/refractory HL, tumor reduction after salvage therapy and prior to AHSCT assessed by ΔSUVmax, ΔTMTV, and ΔTLG, is a good predictor for survival outcomes after transplant. Thus, patients with reductions higher than 86.1% of SUVmax, 18.2% of TMTV, or 88.5% of TLG have an excellent prognosis with PFS at 5-year over 85%. These results deserve confirmation in a large series of patients.

DIFFERENTIAL DIAGNOSIS OF ENLARGED LYMPH NODE USING ULTRASOUND ELASTOSONOGRAPHY

N. Pugliese[1,*], S. Luigia[1], F. Cacace[1], R. Della Pepa[1], E. Vigliar[1], C. Giordano[1], D. De Novellis[1], D. Nappi[1], C. Frieri[1], F. Pane[1], M. Picardi[1]

[1]University of Naples Federico II, Naples, Italy

Background: In patients with suspected neoplastic diseases, lymph-node (LN) ultrasonography (US) with Doppler evaluation of hilar arterial vascularization, proved to be a powerful non-invasive tool to investigate lymphadenopathies. However, differential diagnosis could be difficult in some situations. The recent introduction of US elastography (ES) to measure tissue stiffness has increased the capability of conventional US for the early diagnosis of breast and thyroid cancer. In particular, quantitative ES, especially with strain ratio (SR) index, improves diagnostic accuracy for malignancy.
Aims: This prospective study aims to evaluate the diagnostic efficacy of real time ES in differentiating benign from malignant lymphadenopathies.
Methods: We evaluated enlarged LNs of 141 patients with suspect diagnosis of lymphoma using Power Doppler US scan followed by ES. The following LN features were considered for malignancy diagnosis: (a) long axis greater than or equal to 1.5 cm, (b) round shape, (c) hilus absent, (d) hypoechoic parenchyma, and (e) hypervascularization, (ie, neoangiogenesis with high resistive index value [≥ 0.6]). In all patients, we measured LN stiffness using a four points scale and the muscle-to-LN SR. The cutoff point of SR was calculated using the ROC curve analysis. After combined US+ES examination, each lymph node has undergone histological examination.
Results: The pathologic evaluation of lymph node biopsies provides the following diagnosis: 47 benign hyperplasia, 30 Hodgkin Lymphoma (HL), 25 DLBCL, 10 SLL/CLL, 12 follicular lymphomas, 4 acute lymphoblastic leukemia, 3 T-cell lymphomas, 2 marginal zone lymphoma, 2 mantle cell lymphoma and 6 metastatic carcinomas. There was a significant difference in median SR between benign (1.0; range 0.3-3.1) and malignant LN (1.87 range 0.57-3.86), p<0.0001. Among the numerous cutoff values tested, the

SR cutoff value of 1.41 enabled the best distinction between malignant and benign LN, with 92.1% specificity and 72.3% sensitivity. The AUC of the ROC curve was 88% (p<0.0001).
The overall diagnostic efficacy for malignancy of the Power Doppler US followed by ES indicated 97.4% specificity and 77.7% sensitivity, when considering HL.
Summary/Conclusion: ES is a simple, fast and non-invasive diagnostic method that may be a useful aid to US in the assessment of lymphadenopathies in patients suspected of having lymphoma. The high specificity of this test in all lymphomas subtypes could help to avoid unnecessary LN biopsy in patients with non-malignant lymphadenopathies. In the subset of HL it revealed higher sensitivity.

Background: Approximately 30% of patients (pts) with advanced-stage classical Hodgkin Lymphoma (cHL) have refractory disease or relapse after frontline treatment with doxorubicin, bleomycin, vinblastine, and dacarbazine (ABVD). Brentuximab vedotin is a CD30 directed antibody-drug conjugate approved for cHL after failure of autologous stem cell transplantation (ASCT) or ≥2 prior chemotherapy regimens and as consolidation post ASCT for increased risk cHL.
Aims: To compare effects of frontline brentuximab vedotin plus doxorubicin, vinblastine, and dacarbazine (A+AVD) vs frontline ABVD in pts with advanced cHL.
Methods: In this phase 3, unblinded, open-label, multicenter study, 1334 pts with Stage III (36%) or IV (64%) cHL were randomized 1:1 to receive intravenous A+AVD or ABVD on Days 1 and 15 for up to six 28-day cycles. Pts with a PET scan Deauville score of 5 after Cycle 2 could switch to alternative therapy at the treating physician's discretion. Towards end of enrolment, newly randomized pts receiving A+AVD were recommended G-CSF primary prophylaxis due to high incidence of febrile neutropenia (FN) vs ABVD. Primary endpoint was modified progression-free survival (mPFS; defined as time to progression, death, or evidence of incomplete response followed by subsequent anticancer therapy) per independent review facility (IRF) assessment. Overall survival (OS) was key secondary endpoint.
Results: Primary endpoint, mPFS per IRF, was met (hazard ratio [HR] 0.77 [95% CI 0.60–0.98]; p=0.04), with 117 and 146 events in A+AVD and ABVD arms, respectively (Figure 1), and was consistent with mPFS per investigator (INV) (HR 0.72 [95% CI 0.57–0.91]; p=0.006). Causes of mPFS events per IRF were progression (90 vs 102), death (18 vs 22), or receipt of additional anticancer therapy for incomplete response (9 vs 22) after A+AVD or ABVD, respectively. The 2-year mPFS per IRF was 82.1% (95% CI 78.8–85.0) with A+AVD vs 77.2% (95% CI 73.7–80.4) with ABVD, and per INV was 81.0% [95% CI 77.6–83.9) with A+AVD vs 74.4% [95% CI 70.7–77.7] with ABVD. There were 28 and 39 deaths in A+AVD and ABVD arms, respectively (interim OS HR 0.73 [95% CI 0.45–1.18]; p=0.20). Safety profiles were consistent with known toxicities of the single agents. Neutropenia was reported in 58% and 45% and FN in 19% and 8% of A+AVD and ABVD pts, respectively. Discontinuations due to neutropenia or FN were ≤1% in both arms. Grade ≥3 infections were more common with A+AVD (18%) than ABVD (10%). In A+AVD pts, G-CSF primary prophylaxis (n=83) reduced FN from 21% to 11% and Grade ≥3 infections and infestations from 18% to 11%. Peripheral neuropathy (PN) occurred in 67% of A+AVD pts and 43% of ABVD pts (Grade ≥3: 11% A+AVD [1 pt with Grade 4] vs 2% ABVD); 67% of pts experiencing PN in the A+AVD arm had resolution or improvement of PN at last follow-up. Pulmonary toxicity was more frequent and severe with ABVD (Grade ≥3: 3% ABVD vs <1% A+AVD). Of on-study deaths, 7/9 in the A+AVD arm were associated with neutropenia; these deaths occurred in pts who had not received G-CSF primary prophylaxis. Of 13 on-study deaths in the ABVD arm, 11 were due to, or associated with, pulmonary toxicity.

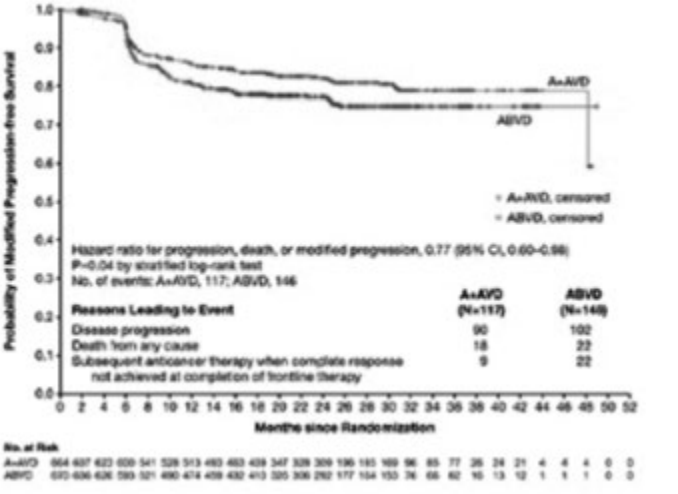

Figure 1.

Summary/Conclusion: Compared with ABVD, frontline A+AVD improved outcomes for pts with advanced cHL, including a 23% risk reduction in progression, death, or need for additional anticancer therapy. This supports the possible use of A+AVD as a new frontline option for pts with advanced-stage cHL.

Athens, Greece

Background: A positive PET/Computed Tomography (PET/CT) after 2 cycles of ABVD (interim PET - iPET) has a strong adverse prognostic significance in patients with advanced HL.
Aims: The aim of this study was the description of treatment strategies according to iPET results in everyday practice and the evaluation of the outcome according to iPET and other potential prognostic factors in a multicenter setting in Athens, Greece
Methods: Retrospective analysis of 135 patients (134/135 ≤60 years old) with advanced HL according to GHSG (stages III/IV or IIB with mediastinal bulky disease and/or extranodal disease), who received ABVD treatment and underwent iPET. iPET was evaluated according to Deauville 5-point scale and was considered as positive in cases with scores 4 or 5 (residual uptake >liver). In case of iPET positivity, further treatment strategy (intensification to BEACOPP or not) was at the treating physician's discretion. However, consistent strategies were followed within the same Department, with 3/6 departments applying the intensification strategy and 1 continuing with ABVD. Two centers had the intention to intensify treatment but this was not done, due to lack of iPET(+) cases. Radiotherapy (RT) was administered at physician's discretion
Results: The median age was 32 years (15-73), 59% were males, 78% had nodular sclerosis, 11% had mixed cellularity and 4% nodular lymphocyte predominant histology, 42%, 43% and 16% had stage IV, III and II respectively and 66% of patients had B-symptoms. The median IPS was 3 (range: 0-6, ≥3 in 51%). Based on initial PET/CT, 54% of patients had stage IV. Overall, compared to published studies, the patient population described had more adverse characteristics. iPET was negative in 99 patients (73%) and positive in 36 (27%). Overall, the 5-year progression free survival (PFS) was 77%. In particular PFS was 87% in iPET(-) and 46% in iPET(+) patients (p<0.0001), despite that 58% of the latter received BEACOPP. *PET-2 (+) patients:* Out of 36 patients with PET-2(+), 21 received BEACOPP (19 escalated and 2 baseline), whereas 15 continued with ABVD. The 5-year PFS was 57% and 32% respectively (p=0.10). It was 61% vs 33% (p=0.16) for Deauville scores 4 and 5 respectively (68% vs 40%, p=0.31 for those who received BEACOPP and 53% vs 0%, p=0.003 for those who continued on ABVD). *PET2(-) patients:* According to conventional staging there was no difference in 5-year PFS between stages II-IIII or IV (90% and 83% respectively, p=0.46). However, when PET/CT was used for staging, there was a trend to inferior outcome for stage IV (5-year PFS 94% vs 80%, p=0.11).
Summary/Conclusion: This study confirms the prognostic significance of iPET in advanced HL, in spite of treatment escalation in many iPET(+) patients. Treatment intensification to BEACOPPesc in cases of iPET(+) seems to offer satisfactory disease control in real life. More research is need to identify prognostic factors for the outcome of iPET(-) patients.

Indolent Non–Hodgkin lymphoma – Clinical

PS1184

THE IMPACT OF CXCR4 MUTATION SUBTYPES IN THE RESPONSE AND PROGRESSION-FREE SURVIVAL OF PATIENTS WITH WALDENSTROM MACROGLOBULINEMIA TREATED WITH IBRUTINIB

J. Castillo[1,*], J. Gustine[1], K. Meid[1], T. Dubeau[1], L. Xu[1], G. Yang[1], Z. Hunter[1], S. Treon[1]

[1]Dana-Farber Cancer Institute, Boston, United States

Background: Ibrutinib is the only approved drug for the treatment of symptomatic Waldenstrom macroglobulinemia (WM), with a major response rate of 70% and a median progression-free survival (PFS) that has not yet been reached at 4 years of follow-up. Over 40 variants of CXCR4 mutations have been described in WM, and have been associated with lower response rates and shorter PFS in patients treated with ibrutinib.
Aims: To investigate the impact of CXCR4 mutation subtypes in clinical presentation, response and PFS in WM patients treated with ibrutinib.
Methods: We identified patients seen at our institution between May 2012 and December 2017 who met clinicopathological criteria for WM and received ibrutinib therapy. CXCR4 mutations were detected using Sanger sequencing. CXCR4 mutations were divided in 3 groups: wild-type (WT), frameshift (FS) and nonsense (NS). Response was defined based on IWWM6 criteria. PFS was defined as the time between ibrutinib initiation and disease progression or death from any cause. PFS curves were estimated using the Kaplan-Meier method, and compared using the log-rank test. p<0.05 was considered statistically significant.

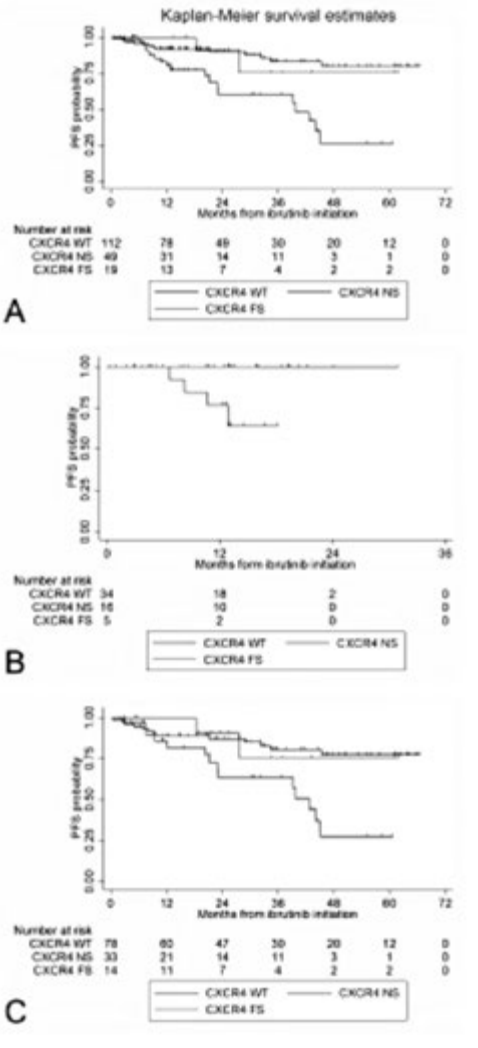

Figure 1.

Results: A total of 180 patients were included. The $MYD88^{L265P}$ mutation was detected in all patients. CXCR4 mutations were detected in 68 patients (38%), of which 49 (27%) had $CXCR4^{NS}$ and 19 (11%) had $CXCR4^{FS}$ mutations. Patients with $CXCR4^{NS}$ and $CXCR4^{FS}$ were more likely to have platelets ≤100 k/ul (17%, 32% and 5%, respectively; p=0.002), were more likely to have serum IgM >7,000 mg/dl (12%, 11% and 3%, respectively; p=0.04), were more likely to initiate therapy due to symptomatic hyperviscosity (27%, 21% and 9%, respectively; p=0.01), and were less likely to present with extramedullary disease (2%, 0% and 16%, respectively; p=0.008) than $CXCR4^{WT}$ patients. Patients with $CXCR4^{NS}$ had lower rate of major response than $CXCR4^{FS}$ and $CXCR4^{WT}$ patients (55%, 79% and 85%, respectively; p<0.001). When compared with $CXCR4^{WT}$ patients, $CXCR4^{NS}$ patients had lower odds of major response (OR 0.25, 95% CI 0.12-0.53; p<0.001) but major response rate was no different in $CXCR4^{FS}$ patients (OR 0.77, 95% CI 0.23-2.56; p=0.67). The median follow-up time is 23 months (95% CI 20-30 months), and 39 patients (18%) have progressed. The median PFS in $CXCR4^{NS}$ patients was 40 months (95% CI 21-45 months) and was not reached in $CXCR4^{FS}$ and $CXCR4^{WT}$ patients (log-rank p<0.001; Figure 1A). The 5-year PFS rate was lower for $CXCR4^{NS}$ patients (60%, 95% CI 40-76%) than for $CXCR4^{FS}$ (91%, 95% CI 51-99%) and $CXCR4^{WT}$ patients (90%, 95% CI 82-95%). In previously treated patients, the median follow-up time was 35 months (95% CI 31-41 months). The median PFS in $CXCR4^{NS}$ patients was 43 months (95% CI 23-NR) and was not reached in $CXCR4^{FS}$ and $CXCR4^{WT}$ patients (log-rank p=0.01; Figure 1B). The 3-year PFS rate was lower for $CXCR4^{NS}$ patients (64%, 95% CI 41-79%) than for $CXCR4^{FS}$ (76%, 95% CI 30-94%) and $CXCR4^{WT}$ patients (81%, 95% CI 68-89%). In previously untreated patients, the median follow-up time was 13 months (95% CI 12-16 months). The median PFS in $CXCR4^{NS}$ patients was not reached in any group, and the 1-year PFS rate was lower for $CXCR4^{NS}$ patients (77%, 95% CI 44-92%) than for $CXCR4^{FS}$ and $CXCR4^{WT}$ patients, in whom no progressions were seen (log-rank p=0.01; Figure 1C).

Summary/Conclusion: When treated with ibrutinib, WM patients with $CXCR4^{NS}$ were more likely to present with low platelets, high serum IgM level, were less likely to have extramedullary disease, and had lower major response rates and shorter PFS than $CXCR4^{FS}$ patients.

PS1185

IBRUTINIB SHOWS PROLONGED PROGRESSION-FREE SURVIVAL IN SYMPTOMATIC, PREVIOUSLY TREATED PATIENTS WITH MYD88 MUTATED WALDENSTROM'S MACROGLOBULINEMIA: LONG-TERM FOLLOW-UP OF PIVOTAL TRIAL (NCT01614821)

S. Treon[1,*], K. Meid[1], J. Gustine[1], T. Dubeau[1], M. L. Palomba[2], R. Advani[3], J. Castillo[1]

[1]Dana Farber Cancer Institute, Boston, [2]Memorial Sloan Kettering Cancer Center, New York, [3]Stanford University Medical Center, Palo Alto, United States

Background: Activating mutations in MYD88 mutations are present in ≥ 95% of WM patients and trigger malignant cell survival through activation of BTK and HCK, both targeted by ibrutinib. CXCR4 mutations are found in 30-40% of WM patients and confer *in vitro* resistance to ibrutinib.

Aims: We examined ibrutinib in previously treated WM patients based on the above findings (Treon *et al.* NEJM 2015), that provided support for the first ever FDA and EMA drug approval in WM. Herein, we provide a long-term follow-up of this study.

Methods: 63 symptomatic WM patients who received at least one prior therapy were enrolled. The median prior therapies were 2 (range 1-9), and 40% of patients were refractory to previous therapy. MYD88 and CXCR4 genotyping was performed for 63 and 62 patients, respectively. Ibrutinib was initiated at 420 mg/day, and dose de-escalation for toxicity permitted. Median time on ibrutinib was 47 (range 0.5-64 months).

Results: At best response, median bone marrow involvement declined from 60% to 20% (p<0.0001), and the median hemoglobin level rose from 10.5 to 14.2 g/dL (p<0.0001). The impact of MYD88 and CXCR4 mutation status on responses, and time to at least minor and major response attainment were as in Table 1. For patients with $MYD88^{Mut}CXCR4^{WT}$, the median PFS was not reached (5-year PFS was 73%; 95% CI 55-85%). For patients with $MYD88^{Mut}CXCR4^{Mut}$, the median PFS was 42 months (5-year PFS 46%; 95% CI 23-67%), and for those with $MYD88^{WT}$ disease it was 5 months (Log-rank p<0.001) The 5-year overall survival for all patients was 87%, and 93% and 80% for $MYD88^{Mut}CXCR4^{WT}$ and $MYD88^{Mut}CXCR4^{Mut}$ patients, respectively (Log-rank p=0.41). Adverse events (Grade ≥2) in ≥5% of patients during active follow-up were: neutropenia (22%); thrombocytopenia (14%), pneumonia (9%); GERD (8%); hypertension (8%); anemia (6%); and skin infection (5%). Seven patients (11%) had atrial arrhythmia, and 6 continued ibrutinib following medical management. Four patients came off protocol therapy for atrial fibrillation (n=1); infection unrelated to drug therapy (n=1), procedure related hematoma (n=1), and thrombocytopenia (n=1). Two others had disease transformation, both with prior nucleoside analogue exposure. One heavily pre-treated patient with pre-ibrutinib 5q- cytogenetics developed AML while a major responder on ibrutinib for WM.

Table 1.

	All Patients (n=63)	$MYD88^{MUT}$ $CXCR^{WT}$ (n=36)	$MYD88^{MUT}$ $CXCR4^{Mut}$ (n=22)	$MYD88^{WT}$ $CXCR4^{WT}$ (n=4)	P-value
Overall Responses (%)	90.4	100	86.4	50.0	<0.001
Major Responses (%)	77.7	97.2	63.6	0	<0.001
VGPR (%)	27.0	44.4	9.1	0	<0.001
Median Time to Minor Response or better (months)	1.0 (range 1.0-22.5)	1.0 (range 1.0-15)	1.0 (range 1.0-22.5)	1.0	0.10

Summary/Conclusion: The findings confirm that ibrutinib is highly active and produces long-term responses in symptomatic patients with relapsed and refractory WM. Prolonged ibrutinib therapy is associated with improvements in categorical responses, including attainment of VGPR. Response activity, time to major response, and PFS are impacted by MYD88 and CXCR4 mutation status in this patient population.

PS1186

IMPROVED DEPTH OF RESPONSE WITH INCREASED FOLLOW-UP FOR PATIENTS (PTS) WITH WALDENSTRÖM MACROGLOBULINEMIA (WM) TREATED WITH BRUTON'S TYROSINE KINASE (BTK) INHIBITOR ZANUBRUTINIB

Ltd., Beijing, China, [15]Beigene (Beijing) Co. Ltd., Emeryville, CA, United States, [16]Royal Melbourne Hospital, Parkville, Victoria, [17]Monash University, Clayton, Victoria, Australia

Background: Zanubrutinib (zanu) is a potent, specific and irreversible oral BTK inhibitor. In Phase 1 testing, we have demonstrated that high plasma concentrations can be safely achieved, resulting in complete and sustained BTK inhibition in blood and lymph nodes. Early clinical data from an ongoing Phase 1 trial has shown single-agent zanu to be safe and efficacious for the treatment of pts with chronic lymphocytic leukemia (Seymour 2017), WM (Trotman 2017), and other non-Hodgkin lymphomas (Tam 2017).

Aims: Report updated safety and efficacy data from WM pts with a median follow-up of >1 year in this Phase 1 trial.

Methods: This is an open-label, multi-center, dose-finding Phase I study of zanu in pts with B-cell malignancies, with indication-specific expansion cohorts: reported here are data from 67 WM pts enrolled as of 3 Nov 2017. Pts received doses of zanu ranging from 40 mg once daily to the final RP2D of 160 mg twice daily until disease progression (PD) or unacceptable toxicity. Pts were assessed by IgM monthly with full assessment of extramedullary disease every 3 months.

Results: 67 pts with WM were enrolled and evaluable for safety; 51 pts were evaluable for efficacy, excluding those with <12 weeks follow-up (n=13) or IgM <5 g/L at baseline (n=3). The 67 pts included 21 treatment-native (TN) and 46 relapsed/refractory (R/R; 1-8 prior therapies) and median follow-up 15.5 months (range, 0.1-37.6). The most frequent AEs (≥15%,

all Gr 1-2 but 1) were petechia/purpura/contusion (37%), upper respiratory tract infection (34%), constipation (18%) and diarrhea (18%). Gr 3-4 AEs included anemia (8%), headache (2%), and diarrhea (2%). Serious AEs (SAEs) were seen in 22 pts (33%) with 5 individual pts (8%) considered related to zanu; febrile neutropenia, colitis, atrial fibrillation, hemothorax (spontaneous), and headache. There was 1 fatal event from worsening pre-existing bronchiectasis in a pt with VGPR. Atrial fibrillation/flutter was experienced by 4 pts (6%), all Gr 1-2, and major hemorrhage seen in 2 pts (3%). Discontinuation of zanu due to adverse events was seen in 3 pts (5%): the previously mentioned fatal bronchiectasis, prostate adenocarcinoma, and gastric adenocarcinoma. Two pts (3%) discontinued study treatment due to PD as assessed by investigator, 1 pt remains on treatment post PD. The objective response rate was 92% (47/51), with a major response rate of 80% (41/51); rate of VGPR increased with increasing follow-up (Table 1). Median time to response was 88 days (range, 77-279). Of 22/51 (43%) efficacy evaluable pts with hemoglobin <10 g/dL at baseline, the median increased from 8.7 g/dL (range, 6.3-9.8) to 13.8 g/dL (range, 7.7-15.8). For all efficacy evaluable pts, median IgM decreased from 32.5 g/L (range, 5.3-88.5) at baseline to 4.9 g/L (range, 0.1-57). For the 21/51 pts with baseline extramedullary disease, median of maximum post-baseline SPD decrease was 46% (range, 18-81%). Median PFS has not been reached; 91% progression-free at 1 year (Figure 1).

Table 1. Efficacy per investigator assessment.

Best Response, n (%)	Best Overall Response (n=51)	Response Over Time for Pts Reaching 1 Year Follow-Up		
		Up to Week 12 (n=39)	Up to Week 24 (n=39)	Up to 1 year (n=39)
VGPR	22 (43.1)	3 (7.7)	6 (15.4)	14 (35.9)
PR	19 (37.3)	23 (59.0)	23 (59.0)	17 (43.6)
MR	6 (11.8)	10 (25.6)	8 (20.5)	6 (15.4)
SD	4 (7.8)	3 (7.7)	2 (5.1)	2 (5.1)

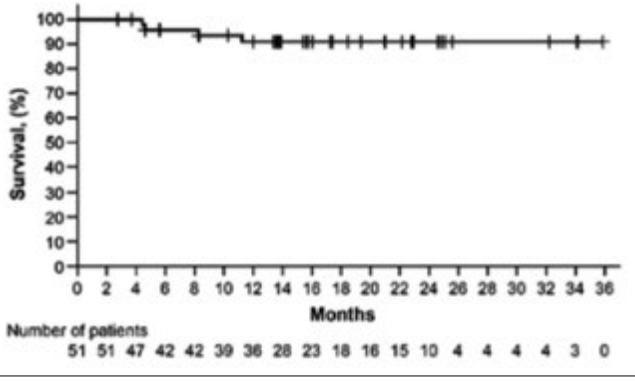

Figure 1. Progression-free survival, efficacy analysis set.

Summary/Conclusion: Zanu is generally well tolerated and highly active in WM with VGPR rates improving over time. A Phase 3 study comparing zanu with ibrutinib in WM is ongoing.

PS1187

CHARACTERIZATION OF MALT LYMPHOMA WITH T(11;18): LONG-TERM FOLLOW-UP

K. Toyoda[1,*], A. Miyagi Maeshima[2], J. Nomoto[1], T. Suzuki[1], S. Yuda[1], N. Yamauchi[1], H. Taniguchi[2], S. Makita[1], S. Fukuhara[1], W. Munakata[1], D. Maruyama[1], K. Tobinai[1], Y. Kobayashi[13]

[1]Department of Hematology, [2]Department of Pathology and Clinical Laboratory, National Cancer Center Hospital, [3]Department of Hematology, International University of Health and Welfare, Mita Hospital, Tokyo, Japan

Background: Translocation (11;18)(q21;q21) is one of the most common chromosomal abnormalities found in mucosa-associated lymphoid tissue (MALT) lymphoma, resulting in API2/MALT1 gene fusion which can activate both the canonical and non-canonical NF-κB pathway. It is well known that MALT lymphoma with t(11;18) shows a tendency to disseminate and be resistant to *Helicobacter pylori* eradication. However, the prognostic features including recurrence and histologic transformation (HT) are largely obscure.

Aims: To evaluate the impact of t(11;18) on MALT lymphoma, focusing on recurrence, survival and HT.

Methods: We conducted a single-institute retrospective analysis of 464 patients with newly diagnosed MALT lymphoma between 1997 and 2014. Among them, those who were screened for the translocation by FISH and/or RT-PCR were extracted. Whenever either serum IgM or IgG level was elevated, we examined *MYD88* gene status to rule out Waldenström macroglobulinemia using allele-specific PCR and Sanger sequencing. After adding information on t(11;18) to the archive data, all patients were categorized as positive, negative, and "not-tested" group. We first compared positive and negative group. Then, to explore a potential selection bias, the positive and negative groups were combined as a "tested" group and compared with the "not-tested" group. The comparisons were made regarding clinical characteristics as follows: sex, age, IPI, MALT-IPI, Ann Arbor Stage, number of extranodal lesion, primary site of lesion, monoclonal gammopathy, HT and initial therapy. To verify the impact of t(11;18) on MALT lymphoma circumspectly, we performed analyses of survival and cumulative incidence of HT only in patients who were tested for t(11;18) and were treated at our institute.

Results: There were 106 patients examined for t(11;18), consisting of 26 (25%) of the positive group and 80 (75%) of the negative group. In the positive group, 11 (42%) patients showed advanced stage III or IV, and primary sites were as follows: multiple (n = 10), lung (n = 6), stomach (n = 6), intestine (n = 2), orbit (n = 1) and salivary gland (n = 1). In addition, patients with t(11;18) had more extranodal lesions, compared to those without t(11;18) (≥2; positive *v* negative, 39% *v* 16% Fisher's exact test, p=0.027). Confirming previous studies reporting that MALT lymphoma with t(11;18) possessed characteristics of disseminated disease and refractoriness to *H. pylori* eradication, we also found that this entity had more frequent monoclonal gammopathy (31% *v* 8%; Fisher's exact test, p=0.008), especially of IgM subtype, some of which developed class switch from IgM.

The median follow-up period was 120 months. The positive group had a significantly shortened progression-free survival (PFS at 10 years; 26% *v* 57%; log-rank test, p=0.004). Additionally, this prognostic feature was present both in the localized and the disseminated disease presentation. The multivariate Cox regression analysis also demonstrated that the presence of t(11;18) significantly influences PFS (p=0.033). However, these findings did not translate into overall survival (OS at 10 years; 87% *v* 92%; log-rank test, p=0.58) or the incidence of HT (4% *v* 8%; Gray test, p=0.497).

Summary/Conclusion: MALT lymphoma with t(11;18) could be characterized by high incidence of monoclonal gammopathy, especially of the IgM subtype, a significantly higher recurrence rate, but with favorable overall outcome. Among the heterogeneities of MALT lymphoma with predictable benign prognosis, it is noteworthy to identify this distinct entity carrying API2/MALT1.

PS1188

CLONAL B-CELL LYMPHOCYTOSIS OF MARGINAL ZONE ORIGIN (CBL-MZ): DESCRIPTION OF MAIN DISEASE FEATURES, CLINICAL COURSE AND OUTCOME IN A SERIES OF 98 CASES

C. Kalpadakis[1,*], G. Pangalis[2], E. Konstantinou[3], T. Vassilakopoulos[3], V. Telonis[3], S. Sachanas[2], P. Tsirkinidis[2], M. Moschogiannis[2], X. Yiakoumis[2], M. Siakantaris[4], P. Psylaki[1], M. Roumelioti[5], D. Rontogiannis[9], H. Papadaki[1], P. Panagiotidis[5], M. Angelopoulou[3]

[1]Department of Hematology, Department of Hematology, University Hospital, University of Crete, Heraklion, Crete, Greece, Heraklion, Crete, [2]Department of Haematology, Athens Medical Center – Psychiko Branch, Athens, Greece, Athens Medical Center, [3]Department of Hematology, [4]Department of Pathology, [51]st Department of Propedeutics, [6]Immunology Laboratory, University of Athens, Laikon General Hospital, [7]Department of Pathology, University of Athens, [8]Second Department of Internal Medicine, University of Athens, "Hippocrateio" General Hospital, [9]Department of Anatomic Pathology, Evangelismos General Hospital, Athens, Greece

Background: CBL-MZ has been recently recognized as a provisional entity with still many unresolved issues.

Aims: To describe disease characteristics and investigate possible prognostic factors for outcome in a large series of CBL-MZ cases with long follow-up.

Methods: CBL-MZ cases were selected based on the presence of circulating CD5-clonal B-cells with MZ features, without B-symptoms, no evidence of disease localization other than bone marrow (BM) and no cytopenias.

Results: 98 patients were analyzed. The median age was 70 years (range,33-90) without sex predilection. Reasons for referral were incidental finding of lymphocytosis (77%) or paraproteinemia (13%) or inverted differential

(10%). The median number of absolute lymphocyte counts (ALCs) and circulating CBL were 6780/μL (1000-150.000) and 3447/μl (185-145.000), respectively. Elevated LDH and paraproteinemia were found in 10% and 38%, respectively. All but one cases presented BM infiltration (median 30%) by small cells with an intrasinusoidal pattern in 1/3 of the cases. Immunophenotyping revealed positivity for CD23, CD11c and CD38 in 31%, 43% and 11% of the cases, respectively. MYD-88 was positive in 9/84 (11%). The presence of paraprotein was significantly associated with MYD-88 positivity (p<0.0001), lower ALCs (p=0.002) and CBL (p=0.001) counts, higher frequency of CD38 expression (p=0.03) and lymphoplasmacytic differentiation in the BM (p=0.001). The degree of BM infiltration was associated with the level of ALCs (p=0.003). At a median follow-up time of 42.3 months, 30 pts progressed but only 10 required treatment. Progression included: worsening lymphocytosis in 17%, cytopenias (4%), splenomegaly (5%), nodal MZL (1%) and increase in paraprotein levels in 3%. Treatment was delivered due to cytopenias in 7 cases, symptomatic paraprotein in 1 and bulky splenomegaly in 2.7 deaths have been recorded, one disease related. The median OS has not been reached; 5-year time to treatment (TTT) was 91%, and the median time to progression (TTP) 95.6 months. By univariate analysis ALC ≥median (6780/μL), p=0.014, CD38+, p=0.006 and elevated LDH, p<0.0001 were significantly associated with TTP. All three factors remained significant by multivariate analysis with a relative risk (RR) of 3.6, 9.0 and 12.9 for ALC, CD38 and LDH, respectively. Based on these parameters, we constructed a prognostic model for TTP that can stratify patients into 3 risk groups: low-risk - 0 risk factors; intermediate - ALC≥median; high-risk – any of the 2 remaining risk factors or ≥2 factors. Median TTP was 159, 96 and 49 months, for the low-, intermediate and high-risk groups, respectively (p<0.0001) Figure 1]. This model was prognostic of TTT, as well, though at a lower level of significance (p=0.03).

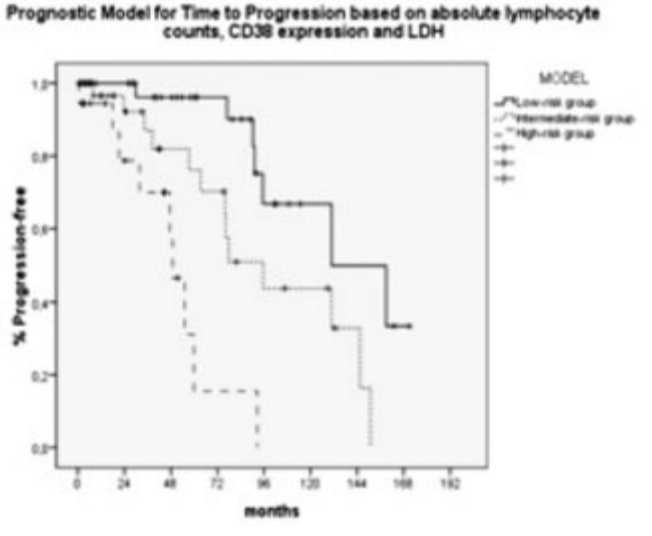

Figure 1.

Summary/Conclusion: CBL-MZ tends to remain stable in the majority of the cases. Progressive disease requiring treatment occurs rarely and it is usually associated with worsening cytopenias. Progression to SMZL was evident in 5%. A prognostic model for TTP using 3 factors was developed: ALCs, LDH and CD38 expression, requiring further validation.

PS1189

OVERALL SURVIVAL OF MANTLE CELL LYMPHOMA (MCL) PATIENTS HAS BEEN SIGNIFICANTLY IMPROVED DURING THE TIME, MAINLY DUE TO THE RITUXIMAB MAINTENANCE IN ELDERLY POPULATION, REAL WORLD DATA

M. Trneny[1,*], D. Salek[2], V. Campr[3], D. Belada[4], K. Steinerova[5], H. Mocikova[6], V. Prochazka[7], J. Duras[8], J. Pirnos[9], K. Kopeckova[10], A. Janikova[2], R. Pytlik[11], P. Blahovcova[12], P. Klener[13]

[1]1st Dept of Medicine, [1]st Faculty of Medicine, Charles University & General University Hospital Prague, 1st Faculty of Medicine, Charles University & General University Hospital Prague, Prague, [2]Dept. of Internal Medicine, Hematology and Oncology, University Hospital Brno, Brno, [3]Dept of Pathology, University Hospital Motol, Prague, [4]4th Department of Internal Medicine - Hematology, University Hospital, Hradec Kralove, [5]Dept. of Hematology/Oncology, University Hospital, Plzen, [6]Dept. of Clin. Hematology, 3rd Medical Faculty, Faculty Hospital Kralovske Vinohrady, Prague, [7]Department of Haemato-Oncology, University Hospital, Olomouc, [8]Department of Haematooncology, University Hospital, Ostrava, [9]Dept of Oncology, Hospital C. Budejovice, Ceske Budejovice, [10]Dept of Oncology, Faculty Hospital Motol, [11]Cell Therapy Department, Institute of Hematology and Blood Transfusion, [12]Czech Lymphoma Study Group, General University Hospital, [13]1st Dept of Medicine, 1st Faculty of Medicine, Charles University & General University Hospital Prague, Prague, Czech Republic

Background: The outcome of MCL patients improved during the time. The main contributors are implementation of HDT with ASCT, high dose Ara-C and rituximab, as part of induction as well as maintenance (RM).
Aims: There is however not clear which one contributes most, or if any has impact on the OS improvement of the whole group of MCL patients. To answer these questions, we have decided to perform analysis of MCL pts diagnosed in 2 period 1999-2005 (1999gr) and 2009-2015 (2009gr)
Methods: This analysis was part of NiHiL project (GovTrial No: NCT03199066), focused on prospective collection of diagnostic, epidemiologic and therapeutic data of NHL pts. All patients signed the informed consent. The eligibility criteria were: all consecutively diagnosed pts with confirmed MCL, availability of clinical characteristics- MIPI, therapy, follow-up. There were 232 pts in 1999gr (dg in 1999-2005) and 596 in 2009gr (dg in 2009-2015), altogether 828 pts. Pearson's Chi-square Test was used for group comparison, log rank test for survival analysis.
Results: The characteristics were comparable between 1999gr and 2009gr,except slightly higher median age in 2009gr (67vs 65y,p<0.001), lower proportion of low MIPI (16.6% vs 26.2%) and higher of high MIPI (50.3% vs 42.1%) in 2009gr vs 1999gr (p<0.01). Median follow-up 12.9y in 1999gr and 4.1y in 2009 gr meant signif. improvement- PFS med. 3.4y vs 1.9y (HR 0.68, CI 95% 0.53-0.77,p<0.0001) and OS median 6.4y vs 4.1y (HR 0.81,CI 95% 0.64-0.95 p<0.01).Pts ≤65y in 2009gr (n 258) have signif. improved PFS with median 7.6 vs 3.6 (HR 0.57, CI 95% 0.39-0.70, p<0.0001), but only trend to better OS with median not reached vs 8.4 (HR 0.81, CI 95% 0.66-1.06,p 0.16) compared to 1999gr (n 120). In contrary pts ≥66y in 2009gr have signif. improved PFS with median 2.3y vs 1.3y and HR 0.66. (CI 95% 0.48-0.80,p<0.0004) as well as OS with median 3.6y vs 2.3y and HR 0.71(CI95% 0.51-0.86,p<0.004). The differences in treatment strategies in 2009gr vs 1999gr consisted of signif. increase R use in induction Tx (93.3% vs 52.6%,p<0.0001),use of HD Ara-C (52.7% vs 29.7%,p< 0.0001),ASCT (25.2% vs 9.5%,p<0.0001),and RM in responded pts (59.0% vs 12.3% p<0.0001). The RM approach was centre based (range between 31.3% and 76.2% pts).We can distinguish 2 RM centre subgroups in 2009gr: RM maintenance policy centres (RM+) with 68.5% (66.4%>76.2%) pts on RM and no RM policy centres (RM-) with 34.6% (31.3%>38.7%) pts with RM. Other parameters were not different between RM+ and RM- centres (RM induction was slightly higher in RM+ 94.9% vs 90.7%,p 0.047).OS improvement was observed only in RM+ centres with HR 0.74(CI95%, 0.52-0.91, p<0.02) for all pts, HR 0.76 (CI95%, 0.44-1.14, p 0.189) for pts ≤65y and HR 0.63 (CI95%, 0.39-0.79, p<0.003) for pts ≥66y. No OS improvement was in RM- centres between 2009gr vs 1999gr,HR 0.91 (CI95%, 0.66-1.20, p ns) for all pts, HR 0.88 (CI95%, 0.53-1.36, p ns) for pts ≤65y and HR 0.82 (CI95%,0.54-1.88, p ns) for pts ≥66y.
Summary/Conclusion: Significant OS benefit was observed in MCL patients diagnosed in 2009-2015 compared to pts diagnosed 10years earlier with relative death risk reduction by 19%. This finding was based mainly on improvement in elderly population ≥66y with 29% death risk decrease. It was observed only in those centres who have adopted rituximab maintenance as a standard of care. Rituximab maintenance (together with R induction) seems to be the most important factors in OS improvement.
Supported by grant: AZV 16-31092A, Progres Q28 UK.

PS1190

IBRUTINIB FOR THE TREATMENT OF BING-NEEL SYNDROME

J. Castillo[1,*], G. Itchaki[1], J. Paludo[2], S. Ansell[2], L. Palomba[3], S. Treon[1]

[1]Dana-Farber Cancer Institute, Boston, [2]Mayo Clinic, Rochester, [3]Memorial Sloan Kettering Cancer Center, New York, United States

Background: The oral BTK inhibitor ibrutinib is the only approved therapy for patients with symptomatic Waldenstrom macroglobulinemia (WM). Bing-Neel syndrome (BNS) is a rare complication of WM, in which WM cells gain access to the central nervous system (CNS) causing neurological deficits. Treatment options in patients with BNS are limited to agents with CNS penetration. Ibrutinib can penetrate into the CNS, but data on its efficacy in BNS is lacking.

Aims: To evalauate the efficacy of ibrutinib in patients with BNS.
Methods: We carried a retrospective study evaluating the efficacy of ibrutinib in patients with BNS. The diagnosis of BNS was established in patients with a clinicopathological diagnosis of WM by radiological and/or cytological evidence of CNS involvement by WM, and response was assessed based on recently published criteria. Ibrutinib was given orally at doses of 420-560 mg PO once daily until disease progression or intolerable toxicity.
Results: We present data on 11 patients with BNS treated with ibrutinib. The median age at diagnosis of WM was 60 years (range 48-73). 6 were men. The median lines of therapy for WM prior to BNS diagnosis was 2 (range 0-7). 4 patients (36%) were untreated for WM at the time of BNS diagnosis. Previous WM therapies included, alkylators (n=11), anti-CD20 antibodies (n=11), nucleoside analogues (n=4), proteasome inhibitors (n=2), immunomodulators (n=2), and autologous transplant (n=1). The median age at BNS diagnosis was 65 years (range 49-78). The median time from WM to BNS diagnosis was 6.6 years (range 0.1-15). In 2 patients, the diagnosis of BNS was made within 6 months of WM diagnosis. The median number of BNS lines prior to ibrutinib was 1 (range 0-4). Previous BNS therapies included high-dose methotrexate (n=5), intrathecal chemotherapy (n=2), bendamustine (n=1) and radiation therapy (n=2). In 5 patients, ibrutinib was the first line of treatment for BNS. The most common symptoms at BNS presentation were motor deficits (n=7), sensory deficits (n=5), cognitive deficits (n=4) and seizures (n=3). MRI findings included leptomeningeal enhancement (n=6) and brain masses (n=4). Cerebrospinal fluid (CSF) cytology showed presence of abnormal cells in 7 patients. CSF flow cytometry confirmed the presence of clonal CD19+ in all patients with abnormal CSF cytology. Biopsies were performed in 3 patients and confirmed presence of WM cells. 1 patient had normal MRI but had abnormal CSF cytology and flow cytometry. Tissue was not obtained in 1 patient but MRI showed leptomeningeal enhancement. The median serum IgM prior to ibrutinib initiation was 1218 mg/dl (range 616-3330 mg/dl), and the median hemoglobin level was 11.8 g/dl (9.2-13.5 g/dl). 7 patients received ibrutinib 560 mg PO once daily, and 4 received ibrutinib 420 mg PO once daily. At best response, median serum IgM and hemoglobin levels were 384 mg/dl (222-3330 mg/dl) and 13.3 g/dl (range 9.2-15 g/dl). MRI findings improved in 7 of 8 patients with available data and were stable in 1. CSF studies cleared in 2 patients and were stable in 2 patients. Symptoms improved in 8 of 9 patients with available data. To date, 4 patients have stopped ibrutinib for BNS, 2 progressed and received methotrexate-temozolomide and fludarabine-rituximab, 1 patient did not tolerate ibrutinib 560 mg and received bendamustine-rituximab, and 1 patient died of BNS progression. The 1-year and 2-year PFS rate were 69% (95% CI 30-89%) and 57% (22%>81%). The 2-year OS rate was 90% (95% CI 47-99%).
Summary/Conclusion: Ibrutinib is a safe and effective treatment option for patients with BNS.

PS1191

IBRUTINIB MONOTHERAPY IN SYMPTOMATIC, TREATMENT-NAIVE PATIENTS WITH WALDENSTROM'S MACROGLOBULINEMIA

S. Treon[1,*], J. Gustine[1], K. Meid[1], T. Dubeau[1], N. Raje[2], A. Yee[2], E. O'Donnell[2], J. Castillo[1]

[1]Dana Farber Cancer Institute, [2]Massachusetts General Hospital, Boston, United States

Background: Ibrutinib is active in previously-treated Waldenstrom's Macroglobulinemia (WM). MYD88 and CXCR4 mutations impact ibrutinib response. We report on the first prospective study of ibrutinib monotherapy in symptomatic, untreated WM patients, and impact of CXCR4 mutation status on outcome.
Aims: To evaluate ibrutinib monotherapy in symptomatic, treatment-naive WM patients. Primary study endpoint was assessment of overall and major response rates. Secondary endpoints included assessment of safety, and impact of MYD88 and CXCR4 tumor mutation status on response outcome.
Methods: Ibrutinib (420 mg) was administered daily until progression or unacceptable toxicity. Dose reduction was permitted for toxicity. All patient tumors were genotyped for MYD88 and CXCR4.
Results: 30 WM patients received ibrutinib. All carried MYD88 mutation, and 14 (47%) CXCR4 mutation. Following ibrutinib, median serum IgM levels declined from 4,370 to 1,513 mg/dL; bone marrow involvement declined from 65% to 20%; and hemoglobin rose from 10.3 to 13.9 g/dL ($p<0.0001$ for all comparisons). Overall (≥ minor) and major (≥ partial) responses for all patients were 100% and 83%, respectively. Major (94% vs. 71%) and very good partial (31 vs. 7%) responses were higher, and time to major responses more rapid (1.8 vs. 7.3 months; $p=0.01$) in wild-type versus mutated CXCR4 patients, respectively. With a median follow-up of 14.6 months, two patients (both CXCR4 mutated) progressed. The 18-month estimated progression-free survival for all patients is 92% (95% CI 73-98%). All patients are alive. Grade 2/3 treatment-related toxicities in >5% of patients included arthralgia (7%), bruising (7%), neutropenia (7%), URTI (7%), UTI (7%), atrial fibrillation (10%), and hypertension (13%). There was no grade 4, or unexpected toxicities.
Summary/Conclusion: Ibrutinib is highly active, produces durable responses, and is safe as primary therapy in symptomatic WM patients. CXCR4 mutation status impacts responses to ibrutinib.

CLINICAL OUTCOME OF PATIENTS WITH LOCALIZED PRIMARY OCULAR ADNEXAL MUCOSA-ASSOCIATED LYMPHOID TISSUE (MALT) LYMPHOMA (OAL): LONG-TERM FOLLOW-UP RESULTS FROM A SINGLE-INSTITUTION OBSERVATIONAL STUDY

R. Nakai[1,*], D. Maruyama[1], A. Miyagi Maeshima[2], K. Tajima[1], Y. Ito[1], S. Hatta[1], S. Yuda[1], T. Suzuki[1], S. Makita[1], S. Fukuhara[1], W. Munakata[1], T. Suzuki[1], J. Itami[3], S. Suzuki[4], H. Taniguchi[2], Y. Kobayashi[1], K. Tobinai[1], K. Izutsu[1]

[1]Hematology, [2]Pathology, [3]Radiology, [4]Ophthalmology, National Cancer Center Hospital, Tokyo, Japan

Background: As the incidence of non-gastric MALT lymphoma, such as that derived from ocular adnexa, is relatively rare, several clinical questions, including optimal treatment strategy, especially the validity of watchful waiting (WW), incidence of systemic relapse, histologic transformation (HT) and survival, remain unclear. Although radiotherapy (RT) is regarded as the standard treatment for localized OAL, RT-related complications, such as dry eyes and cataracts, are not completely avoidable. We previously reported that WW may be an acceptable approach for OAL patients (pts) [Ann Oncol. 2006; 17: 135.]. Here, we conducted up-dated analysis for evaluating the clinical outcome of localized OAL pts in the recent era.
Aims: The objective of this study was to clarify the clinical outcomes of pts with localized OAL. Furthermore, we compared these outcomes with those of pts treated with WW or RT.
Methods: We retrospectively analyzed pts who were initially diagnosed with localized OAL and managed at our institution between 1997 and 2015. Time to progression was defined as the time from diagnosis to first progression regardless of the initial approach. Freedom from requiring systemic therapy was defined as the time from diagnosis to receiving systemic chemotherapy.

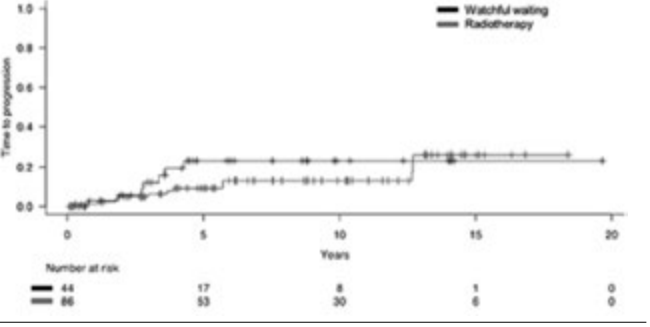

Figure 1.

Results: The subjects in this analysis were 130 localized OAL pts. The median age was 57 years (range 14-89), with 63 males (48%) and 67 females (52%). All 130 pts had stage I disease, consisting of 107 unilateral (82%) and 23 bilateral (18%) legions. The most frequently involved site was the conjunctiva (50%). Forty-four pts were initially managed with WW (WW group) and 86 pts received immediate RT (RT group) at the physician's discretion. During the median follow-up duration of 7.5 years (range 0.1-20), no patients died due to lymphoma progression or any other cause. Among the 44 pts in the WW group, 7 pts had lymphoma progression at their primary site (6 pts) or HT at a distant lymph node (1 pt). Thirty-seven pts (84%) in the WW group did not require any treatment during the follow-up period. In the RT group, all 86 pts achieved complete response after RT, but 12 pts relapsed at the opposite ocular adnexa (4 pts), other extranodal sites (3 pts), distant lymph nodes (3 pts), at the primary site within the radiation field (1 pt) or HT at submandibular gland (1 pt). Notably, 2 relapses at an extranodal site (pleura or stomach) were observed more than 15 years after RT. The time to progression estimated by the cumulative incidence at

5 and 10 years in both groups (WW vs RT) was 23% (95% CI 6-37%) and 9% (95% CI 2-16%), and 23% (95% CI 6-37%) and 13% (95% CI 5-21%), respectively, with no significant difference between the 2 groups (p=0.377) (Figure 1). Freedom from requiring systemic therapy at 10 years were 94% (95%CI 85-100%) in WW group and 96% (95%CI 91-100%) in RT group, respectively. There were no significant differences between the 2 groups (p=0.529). Regarding RT-related complications, 27 pts (31%) and 49 pts (57%) developed dry eyes and cataracts, respectively. Furthermore, nearly 30% of pts who developed cataracts after RT needed surgical intervention.

Summary/Conclusion: This updated observational analysis suggested that the WW strategy is an acceptable treatment option for selected pts with localized OAL because 84% of WW pts remained untreated at a median of 7.9 years, and there was no significant difference in time to progression, time to systemic therapy, incidence of systemic relapse, HT or survival between the WW and RT groups.

PS1193

CD5-NEGATIVE MANTLE CELL LYMPHOMA: A DIAGNOSTIC CHALLENGE IN LEUKEMIC NON-NODAL CASES EXCLUSIVELY DIAGNOSED IN PERIPHERAL BLOOD

S. Montesdeoca[1,*], X. Calvo[1], L. Arenillas[1], A. Puiggros[1], M. Salido[1], A. Salar[2], B. Sánchez-González[2], L. Colomo[3], N. Papaleo[3], R. Navarro[1], B. Costan[1], L. Florensa[1], B. Espinet[1], A. Ferrer[1]

[1]Laboratoris de Citologia Hematològica i Citogenètica, servei de Patologia. GRETNHE- Institut Hospital del Mar d'Investigacions Mèdiques (IMIM), [2]Servei d'Hematologia, [3]Servei de Patologia. GRETNHE- Institut Hospital del Mar d'Investigacions Mèdiques (IMIM), Hospital del Mar, Barcelona, Spain

Background: Mantle cell lymphoma (MCL) is an aggressive mature B-cell neoplasm. Indolent variants, including leukemic non-nodal MCL (nnMCL), are now well recognized. One of the most characteristic features of MCL is the expression of CD5. Approximately 5-10% of cases are CD5 negative but precise data on this issue are scarce. Recent studies suggest that CD5 expression may be less common in leukemic nnMCL than in classic MCL (cMCL). Since the lack of expression of CD5 can hinder the diagnosis of MCL, it is important to contribute with useful data delineating this particular subset, specially in leukemic non-nodal cases, to avoid misdiagnosis with other diseases such as the recently recognized clonal B-cell lymphocytosis of marginal zone origin (CBL-MZ).

Aims: To determine the incidence of CD5-negative cases in a series of MCL patients diagnosed in a single institution, with special emphasis on cases diagnosed exclusively in peripheral blood (PB), and to analyze additional phenotypic features that could be useful to differentiate CD5-negative MCL from CBL-MZ.

Methods: 53 patients diagnosed with MCL according to the WHO classification between 1997 and 2017 (median age 68 years, range 42-88; 60% male; 44 cMCL, 9 clinically indolent leukemic nnMCL) were selected on the basis of PB flow cytometry (FC) availability. The diagnosis of MCL was first established in lymph node (24), spleen (3), tonsil (4), salivary gland (1), colon (1) and PB/bone marrow (BM) (20). All cases displayed the t(11;14)(q13;q32) by cytogenetics or FISH. Cyclin D1 expression was detected on histologic sections in all cases. FC analysis was performed according standard procedures. The expression of pan-B cell markers, CD5, CD10, CD11c, CD23, CD25, CD38, CD43, CD49d, CD200, kappa and lambda was assessed in most cases. Positivity was considered when at least 20% of cells expressed a single marker.

Results: CD5 expression was observed in 38/53 MCL patients (72%) by FC or immunohistochemistry (IHC). CD5 expression could be assessed by FC in PB and IHC on tissue samples (including BM) in 43/53 patients. In 7 cases, results were discordant (FC+/IHC-, 3 cases; FC-/IHC+, 4 cases). Overall, 9/44 (20%) cMCL and 6/9 (66%) clinically indolent leukemic nnMCL were CD5 negative. PB involvement by FC at diagnosis was detected in 48/53 (90%). Among cases with PB involvement, 15/48 (31%) corresponded to CD5-negative MCL by FC: 9/15 (60%) were cMCL and 6/15 (40%) leukemic nnMCL. All non-leukemic cases expressed CD5 in tissue samples. Regarding the immunophenotypical features of 20 MCL diagnosed exclusively in PB/BM, 10/20 (50%) were CD5 negative. None of these CD5-negative cases expressed CD43, all but one were CD11c negative, 1/10 expressed CD23, and 2/8 cases were CD25 positive.

Summary/Conclusion: In our series, lack of CD5 expression was observed with higher incidence (28%) than previously recognized. Of note, 40% of CD5-negative cases corresponded to leukemic nnMCL. Moreover, lack of CD5 was observed in 50% of cases diagnosed exclusively in PB/BM samples. To avoid MCL underdiagnosis and misdiagnosis with CBL-MZ, a high degree of suspicion is necessary in the diagnosis workup of the disease. Therefore, histologic and cytogenetic studies must be mandatory in all mature B-cell neoplasms with a non-specific phenotype. Additional immunophenotypical data can be potentially useful in the distinction of these entities, being especially helpful the absence of CD11c expression in MCL.

Buyanova, [6]24Kashirskoy sh., Hematologic Moscow City Center at the State Clinical Hospital named by S. Botkin., [7]24Kashirskoy sh., National Research Medical University named by N.I. Pirogov, Moscow, Russian Federation

Background: The association between hepatitis C virus (HCV) and B-cell non-Hodgkin lymphomas (NHL) is now widely accepted, as a result of evidence from epidemiological and therapeutic studies carried out in the last decades. Among B-cell NHL indolent subtypes, HCV has been consistently associated with marginal-zone lymphomas (MZL). A large number of studies demonstrated that front-line antiviral therapy (AT) with interferon (IFN) and ribavirin is able to induce high response rate in HCV-associated indolent B-cell lymphomas.

Aims: The purpose of our study is evaluated clinical feature and outcomes of MZL patients with and without association HCV infection.

Methods: We performed a retrospective analysis of 56 pts with MZL (Group 1) and 27 pts with HCV+ MZL (Group 2) since 2005-2017 treated in N.N. Blokhin National Cancer Research Center. Median follow-up was 48 months and 52 months. There were statistically significant differences in the clinical manifestations of the MZL in patients in the Group1 and Group2 (p<0,05): the median age was 58 and 43 years, 21% and 59% were male, 41% vs 74% had IV stages. There were also differences in the distribution of MZL subtypes (p=0,05): Nodal 14% vs 7%, Extranodal 54% vs 30%, Splenic 14% vs 30%, Disseminated 18% vs 33% respectively of HCV-neg and HCV+MZL. Front-line systemic therapy for MZL without HCV was received 47 of 56 pts (84%): Rituximab monotherapy (13%), R-CHOP\CVP (53%), RB (25%), R-Chl (9%). All 27 pts with HCV+MZL as first-line has IFN-based AT.

Results: The overall response rate (ORR) and duration of response were comparable in the Group1 and Group2. ORR were 87% vs 83% (p=ns), the estimated 3-year progression-free survival (PFS) were 72% vs 67% respectively (p=0.6). In univariate analysis, there was a higher risk of not-response\relapse in HCV+MZL pts with low Hb and albumin levers and spleen involvement. In contrast, the favorable prognostic factors in this group were extranodal disease and serum mixed cryoglobulinemia (OR, 0.1;95% CI).

Summary/Conclusion: Antiviral therapy is a preferential first-line option in patients with HCV-associated marginal zone lymphoma. HCV+MZL patients on IFN-based AT without additional complications have the comparable high response rates and long-term progression-free survival, as patients with MZL on systemic antitumor therapy. Very preliminary data about the use of the new direct-acting antiviral agents (DAAs) suggest a similar activity in HCV+ NHL, but this data needs future investigation.

PS1195

STUDY OF THE DISSEMINATION PATTERNS AND CLONAL RELATIONSHIP IN DIFFERENT SITES IN MULTI-SITED MALT LYMPHOMAS. A SINGLE CENTRE ANALYSIS

M. Condom[1,*], D. Fernandez[2], F. Climent[2], M. Varela[3], J. Hernández Gañán[4], S. Mercadal[1], E. González-Barca[1], I. Carro[1], M. Oliva[1], M. Pané[2], C. Aguilera[1], A. Sureda[1], E. Domingo-Domènech[1]

[1]Hematology, Hospital Duran i Reynals, Institut Català d'Oncologia, [2]Pathology, Hospital Universitari de Bellvitge, [3]Pathology, Hospital Universitari de Bellvitge. Institut Català d'Oncologia, [4]Radiology, Hospital Universitari de Bellvitge, Barcelona, Spain

Background: Extranodal mucosa-associated lymphoid tissue (MALT) lymphomas account for 7-8% of all non Hodgkin lymphomas, being the stomach the most frequent location. It is a multiorganic disease in approximately 50% of extragastric MALT lymphomas, and 25% of gastric ones. In clinical practice, it is often assumed that simultaneous and subsequent lymphoid neoplasms in the same patient come all from one common origin, and so they are clonally related. However, the evidence supporting this fact in MALT lymphomas is scarce. To date, there is very few literature published about the clonal relationship of MALT lymphomas with multiorganic involvement.
Aims: To study clonality in multi-sited MALT lymphomas.
Methods: We reviewed all the cases of MALT lymphoma diagnosed at a single centre between 2009 and 2017. We selected the cases with multi-sited disease, including those with multifocal disease (multiple involvements within one organ, e.g. both side ocular lesions) and those with multiorganic disease, and we excluded those with exclusive skin involvement. Demographic and clinical data regarding different locations and treatment response were collected. Clonality was detected by polymerase chain reaction (PCR) for immunoglobulin heavy chain (IGH) FR3 and FR2 primers and for immunoglobulin kappa chain (IGK) at the locations with available specimens.
Results: Eighty patients were diagnosed with MALT lymphoma during the study period. 27 (34%) of those had a multi-sited disease. Thirteen patients were males and 14 females, with a median age of 60 years (range 38-84). In 19 patients the multi-sited involvement was synchronous and in 8 it was sequential. The most frequently involved primary locations were lung (9 specimens from 5 different patients) followed by stomach (7 specimens from 6 patients) and orbit (5 specimens from 3 patients). The most frequent dissemination patterns were: from primary site to lymph nodes (n=8), to the bone marrow (n=6), and bilateral involvement of paired organs (3 patients with bilateral lung involvement, 2 patients with dissemination within the gastrointestinal tract). Twenty-three patients received systemic treatment, 2 radiotherapy alone and 1 surgery alone. Clonality was analysed in 34 specimens from 20 different patients. In 9 patients it was detected in two or more of the specimens available. Regarding those nine patients, four had different clones in the different sites analysed. Two of these 4 had synchronous multi-sited involvement and in the other 2 cases it was sequential. Specific data regarding the patients' characteristics and the involved locations are depicted in Table 1.

Table 1. Clinical characteristics of the patients, involved locations and clonality.

Patient	Sex	Age at diagnosis	Primary location/s and clone	Treatment and cycles	Relapse	Secondary location/s and clone	Follow-up (time in months and status)
A	F	62	Endometrium (A) Stomach (A) Bone marrow (B)	R-FxS	No		20, ACR
B	M	55	Stomach (A) Loco-regional lymph node (B)	R-FxS	No		6, OT
C	F	68	Parotid gland (A)	RT	Yes	Right lung (D)	87, ACR
D	F	63	Salivary gland (A) Left breast (A)	R-FxS	No		24, ACR
E	F	58	Left parotid gland (A) Right breast (A)	RxA	No		23, ACR
F	F	70	Salivary gland/ Loco-regional lymph node (A)	RxA	Yes	Loco-regional lymph node (A)	27, AWD
G	M	40	Stomach (A) Right lung (A)				76, ACR
H	F	44	Left breast (A) Bone marrow* Left lung (A) Stomach (A)	R-BxS	No		70, AWDL
I	M	38	Duodenum (A) Esophagus (A)	R-FxS	Yes	Duodenum (B)	9, OT

*No biopsy. †Clonality non evaluable. R-F: Rituximab-Fludarabine; RT: Radiotherapy; R: Rituximab; R-Bendamustin; (A): same clone, (B): different clones; ACR: Alive, complete response, OT: ongoing treatment, AWD: Alive, with disease, AWDL: Alive, with high grade B lymphoma

Summary/Conclusion: MALT lymphoma was a multi-sited disease in 34% of our cases. Of the 9 cases in which clonality could be compared, almost half of them presented different clones, irrespective of having a synchronous or sequential multi-sited involvement. This is the largest series that compares clonality in multi-sited MALT lymphomas.

GENETIC POLYMORPHISMS OF DC-SIGN AND L-FICOLIN ARE ASSOCIATED WITH INFECTIOUS COMPLICATIONS AFTER INDUCTION CHEMOTHERAPY: A VALIDATION STUDY IN PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA

U. Schnetzke[1,*], C. Röllig[2], M. Fischer[1], H. Altmann[2], F. Stölzel[2], N. Alakel[2], G. Ehninger[2], M. Bornhäuser[2], A. Hochhaus[1], S. Scholl[1]

[1]Klinik für Innere Medizin II, Abteilung für Hämatologie und Internistische Onkologie, Universitätsklinikum Jena, Jena, [2]Medizinische Klinik I, Universitätsklinikum der Technischen Universität Dresden, Dresden, Germany

Background: Infectious events including invasive fungal disease (IFD) remain a significant cause of morbidity and mortality in neutropenic patients with acute myeloid leukemia (AML). Several studies propose a contribution of single nucleotide polymorphisms (SNPs) of the innate immune system to the individual risk of infections but the majority of those association studies are not validated in an independent cohort.
Aims: We sought to replicate the impact of 11 candidate SNPs in 6 genes (TLR2, TLR4, Dectin-1, DC-SIGN, PTX3, L-Ficolin). All SNPs were associated with infectious events such as sepsis, pneumonia or IFD in our own study cohort or as published by other groups.
Methods: Our initial cohort included 186 AML patients, all of them treated at Jena University Hospital using single induction chemotherapy according to the OSHO protocol. In contrast, our independent validation cohort consists of 138 adult patients with newly diagnosed AML who underwent "3 plus 7" induction chemotherapy at the Dresden University Hospital (SAL study group). Genotyping of TLR2, TLR4, Dectin-1, DC-SIGN, PTX3 and L-Ficolin SNPs was performed by TaqMan assay. Multiple logistic regression analyses were applied to evaluate the association between the polymorphisms and the occurrence of infectious events.
Results: We were able to validate the association between the DC-SIGN SNP rs4804800 and the development of sepsis (OR: 2.58; 95% CI: 1.1 – 6.2, p=0.042). A statistical trend for this SNP was seen for pneumonia including IFD. We could also replicate a trend towards a higher risk for developing pneumonia including IFD for patients carrying either the L-Ficolin SNP rs17549193 or rs17514136. Within the validation cohort two SNPs in the PTX3 (rs1840680) and Dectin-1 gene (rs16910526), respectively, were associated with the development of IFD: rs1840680: OR 7.4, (95% CI: 1.7 – 33.3, p=0.002) and rs16910526 OR 2.8, (95% CI: 1.2 – 7.0, p=0.027).
Summary/Conclusion: To our best knowledge, this study represents the first validation study of candidate genes that have been associated with infectious events in AML patients following induction chemotherapy. We are able to confirm an association between SNPs of DC-SIGN or L-Ficolin and the development of sepsis and pneumonia in AML patients.
The different impact of PTX3 (rs1840680) and Dectin-1 (rs16910526) polymorphisms on the occurrence of IFD in the validation cohort underlines the impact of case numbers but might at least in part also be due to slight differences between the induction regimens and the following duration of neutropenia.

ONE-YEAR SURVIVAL AMONG PATIENTS WITH HEMATOLOGICAL DISEASE ADMITTED TO THE INTENSIVE CARE UNIT: A NATIONWIDE COHORT STUDY

P. Asdahl[1,2,*], S. Christensen[3], A. Kjaersgaard[4], C.F. Christiansen[4], P. Kamper[1]

[1]Hematology, Aarhus University Hospital, Aarhus, [2]Hematology, Regional Hospital West Denmark, Holstebro, [3]Intensive Care, [4]Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark

Background: Improved supportive care for critically ill patients has increased survival among patients with hematological diseases. Slowly, the reluctance to admit critically ill patients with hematological diseases to the intensive care unit is eroding. However, data on outcome after admission to the intensive care unit in comparison to non-hematological patients are limited and inconsistent.
Aims: The aim of the current study was to assess survival after admission to the intensive care unit among hematological patients treated according to contemporary treatment regimens in comparison to non-hematological patients.
Methods: This cohort study included all intensive care unit admissions from 2005 to 2015 registered in the Danish Intensive Care Database combined with information on hematological diagnoses from the Danish National Hematology Database. Information on survival was collected from the Civil Registration System. All data included was nationwide and population-based. Patients were followed until one year after admission to the intensive care unit. Survival was estimated using Kaplan-Meier survival function and compared using Cox proportional hazard regression with age, sex, Charlson co-morbidity index (CCI), and admission type as covariates.
Results: During follow-up 2,820 patients with hematological disease and 153,408 without hematological disease was admitted to an intensive care unit. Of the hematological patients, the majority had lymphoma (43%), myeloma (21%), or acute leukemia (16%). 30-day survival was 55% among hematological patients and 74% among non-hematological patients. One-year survival was 33% and 64%, respectively. Hematological patients had increased mortality across all age-categories, however, the relative rate was higher among younger individuals (Hazard ratio: <60 years: 2.6 (95% Confidence interval: 2.3–2.9); ≥60 years: 1.5 (1.4–1.6)). Similarly, hematological patients had increased mortality across all levels of co-morbidity (Hazard ratio: CCI 0: 2.8 (2.5–3.1); CCI 1–3: 1.7 (1.6–1.8); CCI >3: 1.3 (1.1–1.4).
Summary/Conclusion: Patients with hematological disease treated according to contemporary treatment regimens has poorer survival rates than non-hematological patients after admission to the intensive care unit. The differences in survival was most pronounced among younger individuals without co-morbidity.

PS1199

INTESTINAL COLONIZATION BY MULTIDRUG-RESISTANT GRAM-NEGATIVE PATHOGENS IN HEMATOLOGICAL PATIENTS: REAPPRAISAL OF SELECTIVE ORAL DECONTAMINATION

I. Stoma[1,*], I. Iskrov[2], A. Uss[3], N. Milanovich[4], I. Karpov[1], I. Lendina[5]

[1]Department of Infectious Diseases, Belarusian state medical university, [2]Department of cell transplants, [3]Republican center for hematology and bone marrow transplantation, [4]Department of Bone Marrow Transplantation, [5]Department of Hematology №[3], City clinical hospital №[9], Minsk, Belarus

Background: Intestinal colonization by MDR/XDR gram-negative bacteria leads to an increased risk of subsequent bloodstream infections in patients receiving chemotherapy as a treatment for hematologic malignancies. There is a lack of data on efficacy and safety of selective decontamination strategies in hematologic patients with neutropenia, especially in the setting of high-prevalence of MDR/XDR Gram-negative microorganisms.
Aims: The objective of this study was to evaluate the efficacy of oral colistin as an agent for selective decontamination of the intestinal carriage of MDR/XDR Gram-negative bacteria in patients with hematological malignancies.
Methods: In a tertiary national clinical and research hematology center adult patients with intestinal colonization by MDR/XDR Gram-negative bacteria were included in a randomized controlled trial (RCT) during a period of November 2016 to October 2017. Patients were treated with oral colistin for 14 days or observed while receiving treatment for the primary hematological diseases. The primary outcome was MDR/XDR intestinal decolonization on day 21 post-treatment assessed by an intention-to-treat analysis. Secondary outcomes included safety of treatment and changes in MICs of isolated microorganisms.
Results: In the primary outcome analysis on day 21 post-treatment 13 of 31 patients (41.9%) have shown a decolonization effect in treatment group and 12 of 31 (38.7%) in the control group, without any statistical difference. Although, a short-time positive microbiological effect of selective oral decontamination in the conducted study (61.3% vs 32.3%; OR 3.32; 95% CI 1.17–9.44; p=0.0241) was demonstrated on the last day of colistin treatment (day 14). The incidence of BSI (as shown on Figure 1) in decontamination group was lower in the first 30 days after the intervention (3.2% vs 12.9%), but overall in the 90-day observation period it did not show any advantages comparing to control group (log-rank test; p=0.4721). No serious adverse effects or increase in resistance to colistin was observed during the study.

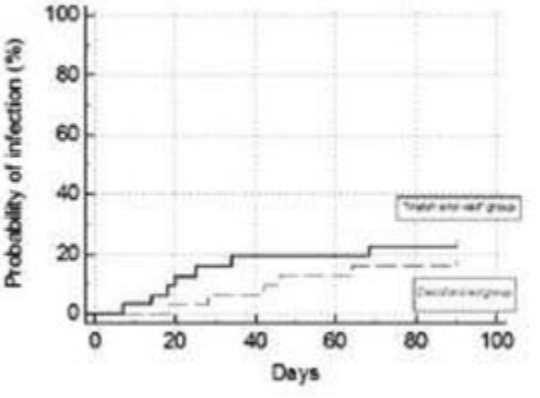

Figure 1.

Summary/Conclusion: This study suggests that in hematological patients with neutropenia the strategy of selective intestinal decontamination by colistin may be beneficial to decrease the rate of MDR/XDR Gram-negative intestinal colonization and the risk of bloodstream infections only in the short-term period, having no long-term sustainable effects.

PS1200

PREVALENCE AND RISK FACTORS OF RESISTANT GRAM-NEGATIVE BACILLI COLONIZATION AND INFECTION IN HOSPITALIZED HAEMATOLOGICAL PATIENTS

A. P. Gonzalez-Rodriguez[1,*], A.M. Fernandez-Verdugo[2], A.J. González-Huerta[1], P. Palomo[1], A. Alonso Cabrero[3], A. Sole[1], C. Valdes-Arias[1], T. Bernal[1], S. Gonzalez-Muñiz[1]

[1]Hematology- Stem cell transplantation Unit, [2]Microbiology, Hospital Universitario Central de Asturias, [3]Department of Medicine, University of Oviedo, Oviedo, Spain

Background: Hematological patients are frequently severely immunocompromised and there is a significant increased risk of mortality due to infection related with gram negative bacterial resistance (MRGN). Bacterial microflora of these patients changes from natural primary to secondary with higher proportion of mulirresistant bacteria.
Aims: To evaluate the prevalence and risk factors of MRGN colonization and infection among those colonized in hospitalized hematological patients.
Methods: Routine surveillance cultures and active screening (throat and rectal in parallel) in our hospital to know prevalence of MRGN colonization -extended spectrum **beta-lactamase** (ESBL) producing *Klebsiella pneumoniae (KB)*, multirresistant *Acinetobacter Baumanii* (MRAB) and multirresistant *Pseudomonas aeruginosa* (MRPA)- to indentificate risk factors for colonization and infection among those colonized. We collected samples in 130 hospitalized patients in Hematology Unit of Hospital Universitario Central de Asturias between 1st March 2016 and 30st October 2017. Main reason for admission was acute leukemia or myelodysplastic syndrome (n=74) followed by stem cell transplantation (12 allogeneic and 10 autologous).
Results: We screened 1843 samples: 306 rectal and 70 throats were positive for MRD. Sixty patients (46,2%) were colonized with a MRGN: 53 KB (6 KB and carbapenemasa) 8 MRPA and 6 MRAB. Seven of these were multiple MRGN carriers. Forty-two patients developed MRGN infection (32,3%): 26 KB, 4 MRPA and 3 MRAB (surveillance samples in 11,5% KB, 25% MRPA and 66,6% MRAB surveillance samples were negative). Risk factors for colonization and infection are showed in Table 1. Colonized patients

had increased risk for infection (80,95% vs 35,22%) and admission in intensive care unit (p< 0,001). High disease risk and poor performance status were risk factors for infection but not for colonization.

Table 1. Risk factors for colonization and infection.

	Infection Yes (42)	Infection No (88)	p	Colonization Yes(60)	Colonization No (70)	p
Days of hospitalization	35	27	0,01	35	24	<0.001
Prior quinolones prophylaxis	26 (61,9%)	67(76,1%)	ns	22 (36,7%)	15 (21,4%)	0.042
Prior exposure to beta lactam antibiotics	24 (57,1%)	25 (28,4%)	0,02	32 (53,3%)	17 (24,3%)	0,001
Recent hospitalization	10 (23,8%)	10 (11,5%)	ns	15 (25%)	5 (7,2%)	0,005
Prior mucositis	24 (57,1%)	16 (18,2%)	<0,001	29 (48,3%)	11 (15,7%)	<0,001
Catheter venous central	39 (92,8%)	49 (55,7%)	<0,001	51(85%)	37 (52,5%)	<0,001
Catheter urinary	10(23,8%)	12(14%)	ns	15(25,4%)	7(10,1%)	0,02
Disease Risk index high	22 (52,%)	28 (31,8%)	0,020	25(41,7%)	25 (35,7%)	ns
ECOG ≥ 2	28 (66,6%)	37 (42,0%)	0,007	34(56,7%)	31 (44,3%)	ns
Previous neutropenia febrile	15 (35,7%)	6 (6,9%)	<0,001	15(25%)	6(8,7%)	0,011

Summary/Conclusion: Rate of MRGN colonization is very high in our hospitalized patients and was associated with significant higher frequency of subsequent infection. Detection of carriers and the knowledge of local epidemiology can be useful to decide antibiotic therapy. In high risk hospitalized patients is mandatory the development of a screening programme for MDR strains associated by guidelines of contact isolation and antibacterial use. There is a growing problem of antimicrobial resistance among pathogens isolated in hematological patients and the paucity of new antibacterial drugs should limit use of drugs where there is no other alternative and to develop strategies to decrease these infections.

PS1201

PEDIATRIC INTENSIVE CARE ADMISSIONS IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

M. Rompola[1,*], S. Rogosic[2], E. Kane[3], E. Roman[3], S. Kinsey[1]

[1]Leeds Institute of Cancer and Pathology, University of Leeds, [2]Pediatric Hematology, Leeds Children's Hospital, Leeds, [3]Epidemiology and Cancer Statistics Group, University of York, York, United Kingdom

Background: The outcomes for children with acute lymphoblastic leukemia (ALL) are steadily improving, with cure rates of over 93%. However, treatment-related mortality is still significant; infection being the leading cause of morbidity and mortality in these immunocompromised patients. Children with ALL who suffer from disease or treatment complications may require escalation of care to the pediatric intensive care unit (PICU).
Aims: To identify the main reasons for children with ALL to be admitted to PICU and review the impact on morbidity and mortality.
Methods: Using the PICANet national database, we reviewed the PICU admissions and chemotherapy records of patients diagnosed with ALL under the age of 16 years in Leeds Children's Hospital over a 13 year period (June 2004- May 2017), regardless of trial participation.
Results: Over the 13 year study period, approximately 450 under 16s were treated for ALL in the study centre, and 67 (15%) of these had at least one PICU admission (84 admissions in total). Fifty-three patients had one PICU admission and fourteen had more than one; over half of second admissions occurring within a month of the previous PICU discharge. Infection was associated with 61 (73%) PICU admissions. The most common causes for admission were sepsis (22/84), respiratory infection (16/84), and respiratory failure (13/84). The mean length of stay for patients with infection was 8.9 days compared to 3.9 days in patients without an infection. Complete treatment information was available for fifty-eight patients. Of these, nine patients had relapsed disease (11 admissions), three were infants (10 admissions), two had Philadelphia positive ALL (3 admissions), and two had had a haematopoietic stem cell transplantation (3 admissions). In the remaining forty-two patients, there were 49 PICU admissions: 27/49 in induction, 4/49 in consolidation, 7/49 in delayed intensification, and 11/49 in maintenance. Of the total 84 admissions, 49 admissions required ventilation, 73% of which were due to infection. In 45 of the admissions the patient required inotropic support; 80% of these admissions were secondary to infection. Twenty of the patients who died were ventilated, eleven of which were on inotropic support. There were twenty-two deaths within the first 30 days from discharge from PICU. Seven of those deaths were in patients with relapsed disease. Patients who died in PICU had shorter admissions with a mean duration of 5 days. The mortality rate for patients in PICU was 16 per 100 person-days at risk. Crude mortality rate ratio in patients at induction versus other phases was 3.5 p=0.05. The mortality rate was higher in those who were ventilated, however, only inotrope requirement reached statistical significance: crude rate ratio 3.5 p=0.03, increased to 4.6 p=0.02 controlling for ventilation status.
Summary/Conclusion: Most admissions to PICU in this cohort of patients occurred during induction, however, a significant number of admissions happened in maintenance treatment with 3 deaths in 11 PICU admissions during this phase. Children with ALL who are admitted to PICU have poor outcomes; nearly 1 in 3 children died. Patients with relapsed ALL are at particularly high risk of mortality in PICU (7/9). Overall, infection was the main underlying reason for the requirement of intensive care in children with ALL.

PS1202

OUTCOME OF HIGH RISK FEBRILE NEUTROPENIC PATIENTS WITH GUT COLONIZATION WITH CARBAPENEM RESISTANT ENTEROBACTERIACEAE(CRE) IN SURVEILLANCE CULTURES "

S. Lunkad[1,*], M. Mahapatra[1], T. Seth[1], S. Mahapatra[2], M. Aggarwal[1], R. Dhawan[1], R. Haldar[1], A. Kumar[2], R. Saxena[1], H.P. Pati[1], S. Tyagi[1]

[1]Hematology, [2]Microbiology, AIIMS, New Delhi, India

Background: Febrile neutropenia particularly with carbapenam resistant bacteria(CRE) is a leading cause of induction mortality in acute leukemia. Various studies reveal correlation between positive cultures and colonization with multiresistant bacteria. But does having CRE colonization would always result in a resistant blood stream infection and would this adversely affect the outcome of these patients is not known.
Aims: Primary Objectives: To study the mortality rate in those having CRE vs Non- CRE in surveillance culture. **Secondary Objectives:** To compare the duration of febrile period, antibiotic use and interruptions of chemotherapy in both CRE vs Non CRE groups.
Methods: It was a prospective observational study. Institute Ethics clearance was taken. Perianal surveillance cultures were taken on admission to hospital after taking an informed consent. Cultures were processed as per CDC guidelines and CRE was identified. These patients were divided in to two groups: CRE and Non CRE. These patients were followed prospectively during their induction course and above mentioned parameters were recorded
Results: A total of 100 patients were screened. 96 patients were included as 2 did not give consent, 2 were lost to follow up. 56 were CRE and 40 Non CRE. Their demographic data is as below in Table 1 and results in Table 2 Mortality in the CRE group was higher upto 42% and the difference in two groups was statistically significant. The duration of fever, use of antibiotics, interruptions of chemotherapy were also higher in CRE group but none reached statistically significant value.

Table 1. Demographic finding of the patients.

Parameters		CRE	Non CRE
Number		56	40
Median Age		28	28
Sex	Male	45	23
	Female	12	18
Disease	AML	27	18
	ALL	27	21
	MPAL	2	1

Table 2. Results of the study are as below.

Parameters	CRE	Non CRE	P Value
Organism most common in CRE screening	E. Coli (62%)	E. Coli (80%)	0.20
Death	24(42%)	8(20%)	0.019
Not received chemotherapy due to sepsis	8(14%)	2(5%)	0.14
Chemotherapy interruptions due to sepsis	18(32%)	6(15%)	0.57
Median duration of antibiotics	24 days	23 days	0.58
Median duration of fever	6 days	4 days	0.05

Summary/Conclusion: CRE colonization was seen in 58% of patients in our study. Preinduction screening of CRE colonization is an important tool as it is one of the important predictors of induction chemotherapy mortality.

PS1203

COLONIZATION WITH MULTIDRUG-RESISTANT BACTERIA (MDRB) IS ASSOCIATED WITH COMPLICATIONS AND POOR OUTCOME AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT)

A. Busca[1,*], R. Passera[2], C.M. Dellacasa[1], S. Manetta[3], G. Iovino[3], F.G. De Rosa[4], S. Corcione[4], L. Brunello[3], S. Aydin[3], L. Giaccone[1], R. Cavallo[5], B. Bruno[1]

[1]Transplant Unit, [2]Nuclear Medicine, [3]Hematology, [4]Infectious Diseases, [5]Microbiology, OU Città della Salute e della Scienza di Torino, Italy

Background: Composition of intestinal microbiota may influence early complications of allogeneic HSCT, including bacterial infections and acute GVHD.
Aims: To assess the impact of colonization with MDRB prior to HSCT on the outcomes of HSCT.
Methods: In the present study, rectal swabs were prospectively collected upon admission to the hospital and routinely repeated on a weekly basis from 157 patients with hematologic disorders who received HSCT between January 2013 and January 2018.
Results: Overall, 84 patients received HSCT from matched unrelated donors, 45 patients from a matched sibling donor and 28 from an haploidentical donor. The MDRB included extended-spectrum beta-lactamase (ESBL)-producing enterobacteriaceae and carbapenem-resistant enterobacteriaceae (CRE). Antimicrobial prophylaxis with fluoroquinolones (FQ) was administered to all patients until September 2016. Overall, 18 patients (12%) were colonized with MDRB at the time of HSCT; seven additional patients became colonized with MDRB during the post-transplant course. A significantly higher incidence of gram negative (GN) bacteremia occurred in patients colonized with MDRB at the time of HSCT: 9 out of 18 patients (50%) developed GN bacteremia, and in 7 cases (78%) the infection was due to MDRB (n=2 ESBL-producing *K. pneumoniae*; n=2 ESBL-producing *E. coli*; n=3 carbapenem-resistant *K. pneumoniae*); no gram positive (GP) bacteremia has been reported in this group of patients. By contrast, among the 139 patients who were not colonized upon admission to the transplant unit, 20 patients (14%) developed a GN bacteremia (p=0.01) and 9 of these (45%) were due to MDRB; 26 patients developed a GP bacteremia and 3 patients developed polymicrobial infections. Overall, 76 of 144 evaluable patients received FQ as antibacterial prophylaxis, and none of these was colonized with MDRB at the time of HSCT; by contrast, among the 68 patients who did not receive FQ, 13 were colonized with MDRB. The median duration of neutropenia was not statistically different between the colonized (13 days; range 11-22) and the noncolonized group (15 days; range 9-30). The incidence of grades II-IV acute GVHD showed a tendency to be higher in the colonized group than in the noncolonized group (56% vs 38%), however, the difference was not significant (p=0.182). Four of the 25 patients (16%) with pre- and post-HSCT MDRB colonization, died of sepsis or septic shock as compared to 5 of the 132 patients (4%) in the noncolonized group (p=0.37).
Summary/Conclusion: Our preliminary results suggest that patients colonized with MDRB are more susceptible to life-threatening infections and this may impact the overall outcome of HSCT recipients. Investigation regarding colonization with alert pathogens may have practical implications for the selection of prophylactic and infection-driven antibiotic strategies that may improve the outcomes of HSCT recipients.

PS1204

ANTIBIOTICS CAN SAFELY BE DISCONTINUED IN NEUTROPENIC HEMATOLOGY PATIENTS: A PROSPECTIVE COHORT

Z. Van De Wyngaert[1,*], C. Berthon[1,2], H. Debarri[1], C. Bories[1], S. Bonnet[1], M. Nudel[1], B. Carpentier[1], C. Legrand[1], S. Barbieux[1], P. Chauvet[1], A. Simonnet[1], A. Willaume[1], J.-B. Bossard[1], L. Renaud[1], K. Wattebled[1], G. Escure[1], N. Branche[1], I. Arib[1], M. Titecat[3], B. Quesnel[1,24], S. Alfandari[5]

[1]Maladies du Sang, CHU Lille, [2]INSERM UMR-S 1172 Institut pour la recherche sur le Cancer de Lille, [3]Service de bactériologie, Centre de biologie-pathologie, CHU de Lille, [4]Faculté de médecine, Université Lille, Lille, [5]Service de réanimation et maladies infectieuses, CH Dron, Tourcoing, France

Background: Antibiotics for febrile neutropenia in acute myeloid leukemia patients, undergoing intensive chemotherapy, are usually maintained until absolute neutrophil count >500/mm^3, because of the risk of uncontrolled sepsis in this vulnerable population. This can lead to unnecessarily prolonged antimicrobial therapy.
Aims: Based on recent European recommendations (ECIL-4), we modified our management strategy and introduced antibiotics discontinuation among patients receiving intensive chemotherapy, and treated for a first episode of febrile neutropenia.
Methods: The policy change concerned adult patients, newly diagnosed with AML, receiving intensive chemotherapy and presenting with a non-severe episode of febrile neutropenia, including fever of unknown origin, primary bacteremia and focal infections. Antimicrobial therapy was discontinued after ≥7 days of intravenous treatment, in hemodynamically stable patients, after resolution of clinical symptoms and ≥5 days of apyrexia, regardless of the absolute neutrophil count or the predicted duration of neutropenia.
Results: Antibiotics were stopped in 49 neutropenic patients. Median age was 51 years, 28 patients (57%) received induction and 21 (43%) consolidation chemotherapy. 32 patients (65%) were asymptomatic, 35 cases (71%) were undocumented. Median neutropenia length was 26 days [IQR 24–31]. Antibiotics were started at day 9 [5.75–14.25], and given for 10 days [7–16], most patients received piperacillin-tazobactam (n=23, 47%) or cefepime (n=13, 27%). After antibiotics discontinuation, 10 patients (20%) experienced fever recurrence, within a median 5.5 days [3–7.5]. None of these febrile episodes were severe. 39 patients (80%) remained afebrile, with neutrophil recovery occurring within 5 days [2–8.5]. Overall, 287 antibiotics days were spared; this represents 49% of all days with antibiotics. No patient had died at day 30 from intervention; 6 died during late follow-up, 2 from GVHD and 4 from relapsed or refractory leukemia.
Summary/Conclusion: Discontinuing antibiotics in neutropenic acute myeloid leukemia patients treated for a first episode of febrile neutropenia is safe, and results in significant antibiotic sparing.

PS1205

RISK OF INFECTIOUS COMPLICATIONS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA IN THE ERA OF NOVEL THERAPIES: A RETROSPECTIVE SINGLE INSTITUTION EXPERIENCE

F. Autore[1,*], I. Innocenti[1], F. Morelli[1], F. Sorà[1], A. Corbingi[1], D. Soldati[1], L. Fianchi[1], M. Criscuolo[1], L. Pagano[1], S. Sica[1], L. Laurenti[1]

[1]Università Cattolica del Sacro Cuore, Fondazione Policlinico Universitario A. Gemelli, Rome, Italy

Background: Recently, the development of novel therapeutic agents in the treatment of chronic lymphocytic leukemia (CLL) tends to decrease the rate of infections in spite of standard immuno-chemotherapy regimens. Ibrutinib and Idelalisib show a different profile due to the association of Idelalisib to monoclonal antibody. The few data about the infectious complications during the use of Obinutuzumab with Chlorambucil derive from German CLL Group.
Aims: The aim of this study is to evaluate incidence and type of infection in CLL patients treated with Ibrutinib, Idelalisib plus Rituximb and Obinutuzumab.
Methods: We present the retrospective analysis of CLL patients treated at our institution from 2015 to 2018. In the study 54 patients were evaluated: 37 patients treated with Ibrutinib, 9 patients treated with Idelalisib plus Rituximab and 8 patients treated with Obinutuzumab.
Results: We recorded 45 episodes of infections, of which 27 occurred in 12 patients treated with Ibrutinib, 15 in 6 patients treated with Idelalisib and 3 episodes of infections in 1 patient treated with Obinutuzumab. All the patients who presented infectious complications started these drugs as second or following line of treatment, except 1 patient who started Ibrutinib and 1 patient who was treated with Obinutuzumab as first line. The rate of infections was 0.73 episodes/patient for Ibrutinib and 1.66 episodes/patient for Idelalisib; each patient with infection showed a median of 2.25 and 2.5 episodes for Ibrutinib and Idelalisib, respectively. Only 1 patient treated with Obinutuzumab had 3 infectious events. In the group of Ibrutinib the most common infections were the respiratory tract infections (44%, 12 events out of 27), followed by urinary tract infections (22%, 6 events). In the group of Idelalisib 6 infections (40%) were viral (EBV or CMV) reactivations and 5 (33%) were respiratory tract infections. The patients treated with Obinutuzumab showed 2 bacterial urinary infections and 1 viral reactivation. Also the pathogens implicated in the infections were different between Ibrutinib and Idelalisib group: in the first 52% were bacterial, 26% fungal and 22% viral, on the contrary in the second group 20% were bacterial, 13% fungal and 67% viral (Table 1). The majority of the infections were grade I or II and no deaths due to infection were registered.

Table 1. Type of infection and pathogens in CLL patients.

	Infections with Ibrutinib (27 episodes)	Infections with Idelalisib plus Rituximab (15 episodes)	Infections with Obinutuzumab (3 episodes)
Respiratory tract infections	13 (8 bacterial, 5 fungal)	5 (2 viral, 2 fungal, 1 bacterial)	-
Urinary tract infections	6 (4 bacterial, 2 viral)	2 (1 bacterial, 1 viral)	2 (2 bacterial)
Blood infections or reactivactions	5 (3 viral, 1 bacterial, 1 fungal)	6 (6 viral)	-
Others	3	2	1

Summary/Conclusion: BCR signaling pathway inhibitors and new monoclonal antibodies showed a good safety profile even if the risk of infection in CLL patients remained high even with the use of less immunosuppressive therapies. We confirmed the higher prevalence of bacterial infections in patients treated with Ibrutinib and the higher prevalence of viral infections in patients treated with Idelalisib. A good safety profile is more evident in patients treated with these drugs as first line of treatment. In the future a multicenter study could collect data on infectious events in CLL patients treated with BCR signaling pathway inhibitors and new monoclonal antibodies exploring the risk factors due to clinical features of the patients, drugs and concomitant medications and prophylaxis, pathogens.

PS1206

EMERGING MICROBIAL RESISTANCE IN FEBRILE NEUTROPENIA- IS IT HIGH TIME TO EVALUATE QUALITY CONTROL MEASURES?

N. Anwar[1,*], N. Fatima[2], J. Hassan[1], M. Borhany[1], T. Shamsi[1]

[1]Hematology, [2]Research and Development, National Institute of Blood Disease and Bone Marrow Transplantation, Karachi, Pakistan

Background: Bacterial infections are one of the most common causes of morbidity and mortality among patients of febrile neutropenia. A considerable antimicrobial resistance has been observed in the susceptibility of the causative microorganism with the passage of time which poses a serious threat to public health especially in neutropenia setting.
Aims: A prospective study to observe the trend of infection by culture and susceptibility in patients of febrile neutropenia with back ground aim to review and re assess institutional policies and quality control measures for better surveillance in the treatment paradigm of hematological malignancies.
Methods: The study was conducted at National institute of blood diseases and bone marrow transplantation from January 2017 to December 2017. This study was approved by Institutional review board. Informed consent was taken by the patients enrolled in the study presenting with absolute neutrophil count (ANC) of less than 500/ml.
Results: A total of 403 bacterial isolates were obtained from 242 patients suffering from hematological disorders. Out of total, 25% were gram positive and 75% were gram negative. Staphylococcus aureus was the most common isolated gram positive organism i.e. 55%, followed by enterococcus species (36%). However, *E. coli* was the most common gram negative organism i.e. 40%, followed by Pseudomonas aeruginosa and klebsiella (28% and 27% respectively). The resistance patterns of various organisms were noted. Methicillin resistance was very high among staphylococcus aureus whereas vancomycin resistance was high among enterococcus species. There was higher level of resistance observed among isolates of the E. coli, pseudomononas and klebsiella to penicillin i.e. 57%, 40%, and 36% respectively and higher sensitivity to colistin i.e. 55%, 24% and 37% respectively. Isolates of staphylococcus aureus were resistant to penicillin (35%) and sensitive to fosfomycin(15%). Similar trend was observed in enterococcus. Resistance to piperacillin- tazobactam and meropenem was found in 32% and 29% of the isolates of all organisms respectively. E. coli, proteus and pseudomonas were found to be more prevalent in urine C/S, whereas staphylococcus aureus and salmonella were predominantly noted in blood C/S. High frequency of klebsiella and beta hemolytic streptococcus was found in throat C/S. However streptococcus epidermidis was frequently observed in pus as well as in blood C/S and it was found statistically significant (p value 0.000).
Summary/Conclusion: The study reveals an emergent need to reevaluate institutional policies and quality management. The emerging resistance could be hospital environmental related, bug resistance or lack of quality control. Further studies in future are needed in this aspect.

PS1207

THERAPEUTIC ADMINISTRATION OF IGM-ENRICHED IMMUNOGLOBULINS IMPROVES SURVIVAL IN HEMATOLOGICAL CANCER PATIENTS WITH SEVERE NEUTROPENIC SEPSIS

A. Forcina[1,*], A.M. Mazzone[2], F. Lorentino[1], G. Palazzo[2], F. Ciceri[1,3], G. Pisapia[2]

[1]Hematology and Bone Marrow Transplant Unit, IRCCS San Raffaele Scientific Institute, Milan, [2]Hematology and Bone Marrow Transplant Unit, San Giuseppe Moscati Hospital, Taranto, [3]University Vita-Salute, Milan, Italy

Background: Severe bacterial infections (SBI) occurring in neutropenic hematological cancer patients represent a major cause of mortality. Four-months overall survival (OS) in hematopoietic stem cell transplantation (HSCT) recipients developing Carbapemen-resistant *Klebsiella pneumoniae* (CR-Kp) or *Pseudomonas aeruginosa* (PA) SBI is particularly dismal, being as low as 40% (Girmenia *et al.*, Clin Infec Dis 2017).
Aims: The aim of the study was to explore infection-related mortality (IRM) and overall survival in consecutive neutropenic patients developing SBI, treated with IgM-enriched immunoglobulins (IgM-IGIV) in combination to antimicrobial therapy.
Methods: A total of 35 adult patients suffering from hematological malignancies and developing SBI according to standard criteria were retrospectively evaluated from April 2014 to February 2018. Sixteen out of 35 (48.5%) patients received autologous HSCT (auto-HSCT), 10/35 (28.5%) allogeneic HSCT (allo-HSCT) and 9/35 (22.8%) chemotherapy alone (CT). All patients were treated with IgM-IGIV 5 ml/kg/day for 3 consecutive days as adjunctive therapy to antimicrobial agents. Kaplan-Meier curves were used to estimate OS. Disease recurrence, graft-versus-host-disease and death from any other cause were competing risks for IRM. Univariate comparisons of survival curves were made using the Log-rank test, while the Gray's test was used for univariate comparisons of cumulative incidence functions
Results: Median time from SBI to IgM-IGIV administration was 2 days (range 0-8). Median follow-up after SBI was 186 days (range 1-938). The majority of patients was diagnosed with acute leukemia (54.2%), had active disease at onset on infection (65.7%) and was beyond first-line disease-specific treatment (64.2%). All patients had grade IV neutropenia. A microbiologically documented SBI was reported in 31/35 cases and sustained by Gram-negative bacteria in 20/35 (62.5%, 13 by CR-Kp, 4 by *Escherichia coli*, 2 by PA, 1 *Acinetobacter baumanii*) and by Gram-positive bacteria in 10/35 (31%). Three patients had polymicrobial infection, in one case with concomitant *Candida glabrata* bacteremia. In 4 patients, no isolates could be documented. Overall, 14-days crude mortality was 11.4% and only 13.3% in the case of SBI sustained by CR-Kp and PA. Despite first-line antimicrobial therapy was inadequate in 85.8% of cases, only 5/35 (14.2%) patients progressed to septic shock when IgM-IGIV were used. Four-months OS after transplant was not significantly different between auto- and allo-HSCT recipients (93.3% vs 71.4% p=0.16) and was of 70% overall after the BSI onset, being of 93.3% for auto-, 58.3% for allo-HSCT and 25% for patients receiving CT alone (p<0.001). According to etiology, 4-months OS was 77.1% when BSI were sustained by Gram-positive, 64.9% by Gram-negative and 75% in case of no isolates. Interestingly, 4-months OS in case of CR-Kp and PA SBI (n=15) was up to 70% (100% for auto-HSCT, 75% for allo-HSCT and 33% for CT patients, p=0.07), significantly higher compared to historical published data. Cumulative incidence of IRM in HSCT recipients was 0% at 4 months and of 5.4% at 1 year.
Summary/Conclusion: The addition of IgM-IGIV to antimicrobial targeted therapy in neutropenic cancer patients developing SBI may synergize with standard treatment to ameliorate survival and reduce infection-mortality, particularly when the infection is sustained by multidrug-resistant Gram-negative bacteria such as CR-Kp. This experience warrants further investigation in a prospective study in hematological patients.

PS1208

TETANUS, DIPHTHERIA AND POLIO IMMUNITY AFTER CHEMOTHERAPY AND RITUXIMAB IN PATIENTS WITH LEUKEMIA AND LYMPHOMA

S. Einarsdottir[1,*], P. Ljungman[2], T. Bergstrom[3], M. Brune[1]

[1]Department of Medicine, Section of Hematology, Sahlgrenska University hospital, Gothenburg, [2]Department of Cellular Therapy and Allogeneic Stem Cell Transplantation, Karolinska University hospital, Stockholm, [3]Department of Clinical Microbiology, Sahlgrenska University hospital, Gothenburg, Sweden

Background: After chemotherapy, children with acute lymphocytic leukemia lose immunity and need revaccination against tetanus, diphtheria and haemophilus influenza typ B (T Ek, Pediatr Blood Cancer, 2005).
Aims: In this study we aimed to assess immunity and possible need for revaccination in adult patients (pts) after conventional treatment (not BMT) for leukemia and lymphoma.
Methods: At a median of 17 (6-60) months after last chemotherapy 103 pts, age 59 (19-86) yrs, with acute leukemia (n=27) or high-grade lymphoma (n=76) were included. Of lymphoma pts, 47 (62%) had received rituximab as part of standard treatment. Pre-treatment sera were available in 69 cases enabling comparisons of immunity *pre*- versus *post*-treatment in individual pts. Healthy, age- and sex matched controls were available for 44 pts.
Tetanus antibodies were quantified using ELISA technique and antibody-levels ≥0,01 IU/ml were considered protective. Diphtheria antibodies were analyzed using neutralization test (n=73) and by ELISA (n=34), in both tests values ≥0,01 IU/ml were considered protective. Antibodies against poliovirus serotype -1 and -3 were assessed by a neutralizing test where a microneutralisation titer ≥2 was considered protective.
Results: *Diphtheria*: Post treatment antibody levels (IgG per IU/mL) were lower than pre-treatment levels (p=0.03) and controls (p=0.0005). Rituximab treatment did not have any impact on the *pre*- versus *post* comparison (p=0.35). Antibody levels were not correlated with gender or myeloid/lymphoid disease (p=1.0), but inversely correlated with age (p=0.02). There was no correlation between immunity (Ab-levels) and time since last chemo (p=0,18). *Tetanus*: Post treatment antibody-levels (IgG per IU/mL) were lower than pre-treatment levels (n=68; p=0.02), and pts were after treatment to a greater extent "not-immune" compared to "immune" (p=0.02). However, there was no difference in Ab-levels between pts and healthy controls (p=0.52). Tetanus immunity was similar in the myeloid and lymphoid groups (n=102; p=0.3). In the lymphoid group, there was a trend to a higher rate of "not-immune" versus "immune" in pts after previous rituximab treatment: 12/48 vs 3/31; p=0.07). Antibody levels were inversely correlated with age (p=0.02). There was no correlation between immunity (Ab-levels) and time since last chemo (p=0,4). *Polio:* No differences in antibody levels were seen between myeloid and lymphoid pts (p=0.18). Polio serotype 1 post-treatment Ab-levels were similar to pre-treatment levels (p=0.42,) and to levels in healthy controls (p=0.3). However, for serotype 3, post-treatment levels were lower than pre-treatment levels (p=0.006), but there was no difference in the comparison between patients and healthy controls (p=0.7). There was no impact of previous rituximab treatment in any polio serotype on the rates of "not-immune" vs "immune" (p=0.7).
Summary/Conclusion: We found that many leukemia and lymphoma patients lacked immunity to diphtheria (35%), tetanus (18%) or polio serotypes 1 or 3 (26%). There was a significant decrease in antibody-levels for both diphtheria and tetanus comparing samples at diagnosis with post-treatment samples. Rituximab treatment was associated with a trend in reduced immunity to diphtheria. There was no tendency of immune reconstitution after long-time follow-up.
We conclude that after standard chemotherapy, patients treated for leukemia and lymphoma with intensive chemotherapy may have an impaired humoral immunity to diphtheria, tetanus and polio. Measurement of antibody-levels and revaccination should be considered.

PS1209

THE DIAGNOSTIC UTILITY AND SENSITIVITY OF THE XPERT® MTB/RIF ASSAY IN DIAGNOSING MYCOBACTERIUM TUBERCULOSIS IN BONE MARROW ASPIRATE SPECIMENS

N. Subramony[1,*], L. Scott[1], J. Vaughan[1]

[1]Molecular Medicine and Haematology, National Health Laboratory Services/University of the Witwatersrand, Johannesburg, South Africa

Background: In South Africa, the World Health Organisation estimated 454 000 new cases of *Mycobacterium tuberculosis (M.tb)* infection (MTB) in 2015. Disseminated tuberculosis arises from the haematogenous spread and seeding of the bacilli in extrapulmonary sites. The gold standard for the detection of MTB in bone marrow is TB culture which has an average turnaround time of 6 weeks. Histological examinations of trephine biopsies to diagnose MTB also have a time delay owing mainly to the 5-7 day processing period prior to microscopic examination. Adding to the diagnostic delay is the non-specific nature of granulomatous inflammation which is the hallmark of MTB involvement of the bone marrow. A Ziehl-Neelson stain (which highlights acid-fast bacilli) is therefore mandatory to confirm the diagnosis but can take up to 3 days for processing and evaluation. Owing to this delay in diagnosis, many patients are lost to follow up or remain untreated whilst results are awaited, thus encouraging the spread of undiagnosed TB.
Aims: The Xpert® MTB/RIF (Cepheid, Sunnyvale, CA) is the molecular test used in the South African national TB program as the initial diagnostic test for pulmonary TB. This study investigates the optimisation and performance of the Xpert® MTB/RIF on bone marrow aspirate specimens (BMA), a first since the introduction of the assay in the diagnosis of extrapulmonary TB.
Methods: BMA received for immunophenotypic analysis as part of the investigation into disseminated MTB or in the evaluation of cytopenias in immunocompromised patients were used. Processing BMA on the Xpert® MTB/RIF was optimised to ensure bone marrow in EDTA and heparin did not inhibit the PCR reaction. Inactivated *M.tb* was spiked into the clinical bone marrow specimen and distilled water (as a control). A volume of 500mcl and an incubation time of 15 minutes with sample reagent were investigated as the processing protocol.
Results: 135 BMA specimens had sufficient residual volume for Xpert® MTB/RIF testing however 22 specimens (16.3%) were not included in the final statistical analysis as an adequate trephine biopsy and/or TB culture was not available. Xpert® MTB/RIF testing was not affected by BMA material in the presence of heparin or EDTA, but the overall detection of MTB in BMA was low compared to histology and culture. Sensitivity of the Xpert® MTB/RIF compared to histology and culture was 8.7% (95% confidence interval (CI): 1.07-28.04%) and sensitivity compared to histology only was 11.1% (95% CI: 1.38-34.7%). Specificity of the Xpert® MTB/RIF was 98.9% (95% CI: 93.9-99.7%).
Summary/Conclusion: Although the Xpert® MTB/RIF generates a faster result than histology and TB culture and is less expensive than culture and drug susceptibility testing, the low sensitivity of the Xpert® MTB/RIF precludes its use for the diagnosis of MTB in bone marrow aspirate specimens and warrants alternative/additional testing to optimise the assay.

PS1210

CLINICAL AND MICROBIOLOGICAL PROFILE OF BLOODSTREAM INFECTIONS IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES AND FEBRILE NEUTROPENIA

G. Mendez[1], C. Niveyro[1], H. Bernard[2*], S. Villamandos[1], J. Fernandez[1], P. Villalba Apestegui[1]

[1]Infectious Diseases, [2]hematology Department, Hospital Escuela de Agudos Dr Ramon Madariaga, Posadas, Argentina

Background: Patients with hematologic malignancies (HM) are at a high risk of infectious complications, and bacterial bloodstream infections (BSI) represent the most severe among these. The reported prevalence of BSI among HM patients ranges from 11% to 38%, and the crude mortality rate reaches up to 40%. Antimicrobial treatment depends on the local prevalence of pathogens causing infection and their antibiotic susceptibility, which may change over the time.
Aims: The aim of this study was to evaluate the clinical and epidemiologic characteristics and mortality rates of BSI that occurred in a large tertiary care university hospital.
Methods: A total of 244 patients with HM with 497 neutropenic episodes followed between june 2010 and august 2017 at Madariaga's Hospital in Misiones Argentina, were retrospectively reviewed. The microorganism isolation was performed using BACTEC 9240 with classical identification and antibiogram disk by diffusion. All statistical analysis were perfomed with Minitab 16 program.
Results: Throughout the study period, 497 febrile neutropenic episodes ocurred in 244 patients. The median age at the fever onset was 37 y (range 14-79 y) and 295 (59%) episodes ocurred in males. The predominant underlying diagnoses were acute leukemia (lymphoblastic and myeloid) *n*= 356 (71%), lymphoma *n*= 83 (16%) other diagnosis *n*= 58 (11%). One hundred and eleven (22%) patients had relapse of disease. Bloodstream infection: in 155 episodes (31%) 1 or more bacterial pathogens was detected in blood cultures. Gram-negative bacteria was detected in 82 of these episodes (58%), whereas in 58 (41%) only Gram-positive bacteria were found. Klebsiella pneu-

moniae and Escherichia coli were the most common GNB (21% and 31%), whereas the most common GPB were CoNS and *Staphylococcus aureus* (11% and 16%). Fifteen (10%) cases of polymicrobial bacteremia were recovered. In the group of BSI patients previous stay in hospital in the last 30 days (p 0.01), neutropenia >7 days (p 0.44), previous chemotherapy (p 0.01) and mortality (p 0.0001) were risk factors for the development of BSI (Table 1).

Table 1.

Data	No BSI Total (n=342)	BSI Total (n=155)
Age (years) Media Mediana	37 32	37 35
Sex Male	194 (56%)	101 (65%)
Type of tumor Acute leukemia Lymphoma	232 (67%) 65 (19%)	124 (80%) 18 (11%)
Relapse of disease Yes	272 (79%)	114 (73%)
Hospitalization 30 days Yes	197 (57%)	107 (69%) ***p 0.01***
ATB 30 days Si	103 (30%)	60 (38%)
Chemtherapy Yes	279 (81%)	138 (89%) ***p 0.01***
Central catheter Yes No	106 (30%) 236 (69%)	44 (28%) 111 (71%)
Neutropenia >7d Yes	247 (72%)	117 (75%) ***p 0.44***
Dead	13	***23 p 0.0001***

Summary/Conclusion: Appropriate empiric antibiotic treatment is an essential tool for managing infections in HM particularly during the neutropenic phases. Antibiotic choice should be based on the knowledge of epidemiological scenario, which is constantly changing because of the antibiotic pressure, causing the emergence of new and worrisome resistant strains. The frequency of severe complications including death was also significantly higher in bacteraemic patients (14%) compared to non-bacteraemic patients (3%).

PS1211

ROLE OF GRANULOCYTE TRANSFUSIONS IN COMBATING LIFE-THREATENING INFECTIONS IN PATIENTS WITH SEVERE NEUTROPENIA IN INDIA

S. Nityanand[1,*], A. Garg[1], A. Gupta[1], A. Mishra[1], M. Singh[1], S. Kumar[1]

[1]Hematology, SGPGIMS, Lucknow, Lucknow, India

Background: Bacterial and fungal infections still remain an important cause of mortality in patients with hematological malignancies and in recipients of hematopoietic stem cell transplants (HSCT) in developing countries like India. One of the most important contributing factors to this is the increase in the prevalence of multi- drug resistant organisms (MDROs) in the last decade. Granulocyte transfusions (GTX) from healthy donors may lead to early clearance of index infection and thus prevent mortality.
Aims: To evaluate the efficacy of GTX in combating life-threatening infections and preventing mortality in patients of hematological disorders/recipients of HSCT with severe neutropenia.
Methods: A prospective, observational analysis of patients with different hematological disorders/recipients of HSCT, who received GTX from January 2014 to December 2017, was carried out. All patients had an ANC < 0.5×10^9 /L and a life threatening sepsis defined by presence of hemodynamic instability/ impending septic shock/ continuous high fever despite the use of the highest line of antimicrobials. The primary outcome measures were resolution of the index infection and overall survival (OS) at 30 days. The secondary outcome measures were the frequency and nature of adverse reactions to GTX. Granulocytes were collected from blood group matched healthy donors who were mobilized with G-CSF (@10mcg/kg SC) and dexamethasone (8 mg IV), 12 hours prior to collection. Granulocytes were collected using Spectra Optia system. The target granulocyte collection was of 50×10^9 granulocytes/L.
Results: A total of 143 granulocyte collections were done for 66 infectious episodes (IEs) in 60 patients. The median age of the patients was 21yrs (interquartile range (IQR) 16-45yrs). MDROs were observed in 47/66 IEs (71.2%) and fungal infections were seen in 9/66 IEs (13.6%). For each IE, a median of 57.7×10^9 granulocytes/L (IQR- 47-68.4×10^9/L) were collected. Resolution of index infection after GTX was seen in 45/66 IEs (68.2%), and the 30 day OS was 67.7%. OS was significantly higher in patients who received GTX within 7 days of neutropenic sepsis in comparison to those who received after 7 days (81.8% vs 54.5%, p=0.01) (Figure 1). The mean durations of fever and neutropenia were shorter in patients who received early GTX within 7 days of the IE as compared to those who received after 7 days (8 days vs 19 days, p=0.001 and 20 days vs 32 days, p= 0.02, respectively). Patients with MDROs who received early GTX therapy had a better OS as compared to those who received late GTX (75.3% vs 56.4%, p= 0.02). Though the post GTX 6 hour increment in the TLC and ANC values were higher in the group which received a GTX dose > 50×10^9 granulocytes per IE in comparison to those who received ≤ 50×10^9, but the OS in the two groups was comparable (71.7% vs. 60%, p= 0.36). GTX were well tolerated and only 6 patients developed mild features of transfusion related acute lung injury (TRALI) which were managed conservatively, and 1 patient demonstrated hypocalcemic tetany.

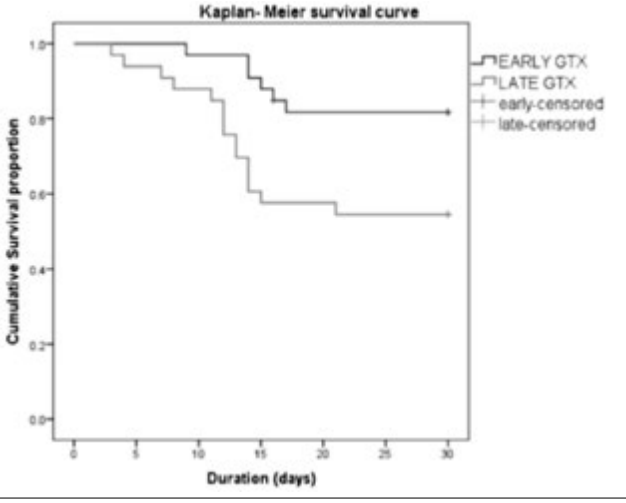

Figure 1.

Summary/Conclusion: GTX are an important modality of therapy in combating life threatening infections and preventing mortality in patients with severe neutropenia. Early institution of GTX before 7 days of neutropenic sepsis is associated with a lower mortality in comparison to when given after 7 days. GTX are well tolerated with no significant side effects. GTX may be of particular relevance in countries like India, where the incidence of infections is very high in neutropenic patients and there is an increasing emergence of MDROs.

PS1212

VACCINATION IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES OR SOLID TUMORS – GUIDELINE OF THE INFECTIOUS DISEASES WORKING PARTY (AGIHO) OF THE GERMAN SOCIETY FOR HEMATOLOGY AND MEDICAL ONCOLOGY (DGHO)

S. Mellinghoff[1,*], B. Liss[1], O. Cornely[1], C. Rieger[2]

[1]University Hospital of Cologne, Cologne, [2]Medizinische Klinik und Poliklinik III, Klinikum der Universität München, Munich, Germany

Background: Infections are a significant cause of morbidity and mortality in patients with haematological and solid organ malignancies. Prevention of infection by vaccination is hence an important aspect of clinical care of cancer patients. Immunocompromising effects of the underlying disease as well as specifics of antineoplastic therapies need to be considered when devising vaccination strategies.
Aims: To give evidence-based recommendations on vaccination in patients with haematologic and solid organ malignancies.
Methods: The AGIHO has reviewed currently available data to provide guidance on vaccination of cancer patients. It gives practical advice for clinicians in hematology and oncology.

Results: Examples are the recommendations on pneumococcal and influenza vaccination.
Summary/Conclusion: Even if there have been a variety of studies on the topic of vaccination of cancer patients in recent years, more information on vaccination strategies in cancer patients (e.g. with new immunomodulatory treatments) are warranted. In addition, coverage of vaccination is lacking in the general population as well as in patients at risk, in particular hematological and oncologic patients. Detailed information and clear recommendations by physicians have a high impact on acceptance of vaccination, while the main reasons for denial of vaccination are concerns about interaction with the malignant disease and potential side-effects. Increased awareness among physicians is of great importance to effectively improve vaccination in patients with malignant disease. To eliminate misperception and improve vaccination coverage in the population of cancer patients, educational programs for patients and for physicians focusing on safety and efficacy of vaccine are warranted.

PS1213

CHARACTERISTICS OF HEMATOLOGICAL PATIENTS WITH BLOOD CULTURES PROVEN SEPSIS – EXPERIENCE OF ONE CENTER

K. Misura Jakobac[1,*], N. Gredelj Simec[1], V. Zatezalo[1], I. Butic[2], A. Hanzek[3], D. Radic Kristo[1,4], S. Ostojic Kolonic[1,3]

[1]Department of Hematology, Merkur University Hospital, [2]Department of clinical microbiology and hospital infection, Clinic for Infectious Diseases "Dr. Fran Mihaljevic", [3]School of Medicine, University of Zagreb, Zagreb, [4]School of Medicine, University of Osijek, Osijek, Croatia

Background: Hematological patients are at higher risk for infections and their subsequent complications. Febrile neutropenia and sepsis are the main causes of non-selective mortality in patients with malignant hematological diseases. For adequate treatment, it is necessary to know the characteristics of the disease and the local microbiological situation. Patients with febrile neutropenia should be approached in accordance with the guidelines for management of sepsis with the aim of preventing the development of septic shock and possible death.
Aims: To determine the risk factors for sepsis development in hematological patients, the type of cause and the outcome of the treatment.
Methods: The available clinical, laboratory and microbiological data of hematological patients treated for sepsis at the Clinic for Internal Diseases, KB Merkur, were collected and analyzed from January 2013. until April 2017.
Results: We analyzed 239 patients and 319 episodes of fever with positive blood cultures. Of these, 38.55% patiens had acute leukemia, 31.32% had non Hodgkin's lymphoma, 15.26% had multiple myeloma and 6.014% patients had Hodgkin's lymphom. Other 8.835% of all patients were treated for some other diagnoses (amyloidosis, myeloproliferative neoplasm, myelodisplastic syndrom, aplastic anemia, Langerhans cell histiocytosis). 14% patients had undergone *autologous peripheral stem-cell transplantation.* A total of 80.8% of the patients had an active disease while having sepsis. Neutropenic were 70.5% of the patients. The most common cause of neutropenia was intensive chemotherapy (52.5%). Other causes of neutropenia were: lower intensity chemotherapy (19.2%), bone marrow transplantation (18.5%) or untreated hematological disease (9.8%). The average duration of neutropenia was 12.4 days (median 9). The average duration of the fever was 5.71 days (median 5) for not transplanted patients and 4.29 days (median 6) for transplanted patients. More than half of the patients (59.8%) had a central venous route (CVK) at the moment of febrile illness. A total of 36 different agents were isolated, out of which 53% were gram negative. The most commonly isolated agents were *E. coli* (17.1%), *K. pneumoniae* (16.2%), coagulase negative staphylococci (14.1%) and P. aeruginosa (8.6%). There was no statistically significant difference in the frequency of gram positive or negative pathogens between patients who had CVK and those who did not. Total mortality was 29%. Most of the deaths (84.5%) had prolonged neutropenia due to intensive chemotherapy. In 60% of the cases, the cause of death was gram negative sepsis. Among the patients with active disease who died in sepsis the most common diagnosis were acute myeloid leukemia (34.9%) and non Hodgkin's lymphoma (30.2%). We found a statistically significant correlation between the mortality rate and the couse of neutropenia (p=0.002). Also, statistically significant correlation was found between the mortality rate and disease activity in patients with sepsis (p=0.001). No statistically significant association of mortality with the type of causative agent or with the presence of CVK was found.
Summary/Conclusion: The analysis of our data showed a high mortality rate in hematological patients with sepsis, depending on the type and activity of the underlying disease which confirms the importance of an early and aggressive treatment of each infection in immunocompromised patients.

PS1214

CHARACTERISTICS AND OUTCOME OF POLYMICROBIAL BLOODSTREAM INFECTIONS (P-BSI) IN PATIENTS WITH HEMATOLOGICAL CANCER

M.E. Zannier[1,*], M.V. Dubbini[1], A. Candoni[1], C. Filì[1], D. Lazzarotto[1], N. Rabassi[1], C. Scarparo[2], A. Sartor[2], R. Fanin[1]

[1]Hematology, [2]microbiology, ASUIUD Udine Italy, udine, Italy

Background: Polymicrobial bloodstream infections (p-BSI) may complicate the course of hematological diseases. They may negatively impact on patients' survival, although they do not represent a frequent event.
Aims: Aim of our study was to characterize polymicrobial bloodstream infections occuring in patients with hematological cancer.
Methods: We analyze clinical characteristics and outcome of 109 p-BSI occurring in patients with hematologic diseases over a 9-year period (2008-2017).
Results: P-BSI were 25% (109/432) of total BSI observed at our center during the whole period of observation. Their incidence was 12.1 cases per year vs 37,5 cases per year of not-polymicrobial BSI. The most common underlying hematological disease was Acute Myeloid Leukemia (AML) (57%) and the median age at onset of p-BSI was 60 yrs (range 19-79). 51/109 (47%) patients had a refractory/relapsed underlying hematological disease, while 33% were in complete remission and 19% in first induction. The majority of cases had severe neutropenia (87%) and carried a central venous catheter (96%). In 58/109 (53%) cases there was another contemporary site of infection, including catheter-related BSI (24%), pneumonia (24%), abdominal infection (enteritis, cholangitis) (24%) followed by skin and soft tissue infection (16%). The most common bacterial association was Gram-negative plus Gram-positive bacteria (56%). The most common isolates were coagulase–neg *Staphylococcus* spp, *Enterococcus* spp, *E. Coli* and *P. aeruginosa*. Susceptibility and antibiotic treatment have been recorded. The resolution rate of p-BSI was 81%. The mortality p-BSI related was 16%. 25/109 (22%) p-BSI were complicated by acute renal failure, septic shock or acute heart failure. Septic shock occurred in 17% cases and the septic shock related mortality was 63%. Multidrug Resistant (MDR) bacteria were 10% of bacteria isolates. The mortality was significantly higher in MDR p-BSI (35% vs 12%), in patients with a contemporary other site of infection (24% vs 8%) and in patients with an active (not-complete remission) hematological disease (25% vs 0%) ($p<0.05$).
Summary/Conclusion: This observational study confirms that p-BSI is a rare infectious complication in hematological patients; it is more frequent during a severe neutropenia and in AML. The mortality p-BSI related is lower than 20% but if septic shock occurs the related-mortality is high (63%). A significantly higher mortality was also documented in p-BSI due to MDR bacteria and in those patients with active hematological disease.

PS1215

IS ANTIMICROBIAL PROPHYLAXIS NECESSARY FOR LYMPHOMA PATIENTS? A SINGLE CENTRE, REAL-LIFE EXPERIENCE

A. Yildiz[1,*], H. B. Afacan Öztürk[1], M. Albayrak[1], Ç. Pala Öztürk[1], O. Şahin[1], S. Maral[1], H. Okutan[2]

[1]Hematology, University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, [2]Hematology, Lösante's Children and Adult Hospital, Ankara, Turkey

Background: Prophylaxis is strongly recommended in patients with hematological malignancy who are usually at higher risk for infection and neutropenic fever. It is still unclear whether or not there is a definite need for antimicrobial prophylaxis in intermediate-risk hematology patients such as those with lymphoma.
Aims: To assess the benefit of antimicrobial prophylaxis in lymphoma patients who were treated in our centre.
Methods: A retrospective analysis was made of patients admitted from January 2009 to December 2017 to the Hematology Department of Diskapi Yildirim Beyazit Training and Research Hospital, a tertiary referral hospital in Ankara, Turkey. The study included patients who were diagnosed with any type of lymphoma and given chemotherapy. Routine antimicrobial prophylaxis was administered to 127 lymphoma patients, and not to 65 lymphoma patients. These two groups were compared in respect of the incidence of total infection episodes (IE), febrile neutropenia (FN) episodes, and non-neutropenic clinically documented infection (CDI) episodes.
Results: For all patients with lymphoma and subtypes of NHL or HL, no significant difference was determined between the groups in respect of the total incidence of IE, FN and nonneutropenic CDI both during the first line

chemotherapy and throughout the total follow-up period (p>0.05). Patients with prophylaxis had a higher incidence of IE, which was treated with parenteral antibiotics both during the first line chemotherapy and throughout the total follow-up period (p<0.05) (Table 1).

Table 1. The comparison of patients with or without prophylaxis according to the incidence of infection types.

	Patients with prophylaxis (n:127)	Patients without prophylaxis (n:65)	RR	p
Events occuring in total follow-up period		No. of patients (%)		
Total infection episodes	38 (29.9%)	20 (30.8%)	0.972 (0.619-1.527)	0.904
FN episodes	21 (16.5%)	7 (10.8%)	1.535 (0.689-3.422)	0.284
Nonneutropenic CDI episodes	19 (15.0%)	12 (18.5%)	0.810 (0.420-1.565)	0.533
Events occuring during first line chemotherapy		No. of patients (%)		
Total infection episodes	37 (29.1%)	20 (30.8%)	0.947 (0.601-1.492)	0.814
FN episodes	21 (16.5%)	8 (12.3%)	1.344 (0.630-2.866)	0.439
Nonneutropenic CDI episodes	18 (14.2%)	12 (18.5%)	0.768 (0.394-1.495)	0.439

IE: Infection episodes, FN: Febrile neutropenia, CDI: Clinically documented infection, RR: Relative risk.

Summary/Conclusion: Antimicrobial prophylaxis was seen to have no effect on the total incidence of IE and FN. Therefore, the routine use of antimicrobial prophylaxis should not be recommended for patients with lymphoma.

PS1216

CASTLEMAN DISEASE WITH THE EXPERIENCE OVER 17 YEARS

F. D. Atilla[1], N. Soyer[2], M. Tombuloglu[1], F. Vural[2], F. Sahin[2], M. Tobu[2], D. Demir[3], N. Ozsan[3], M. Hekimgil[3], G. Saydam[1,*]

[1]Hematology, [2]EGE University, Izmir, Turkey, [3]Pathology, EGE University, Izmir, Turkey

Background: Castleman disease (CD) is a non-clonal lymphoproliferative disorder as a common cause of non-neoplastic lymphadenopathy. CD encompasses several distinct clinicopathological disorders at the intersection of haematology, immunology, oncology, rheumatology and virology that share a spectrum of histopathological features. An international collaborative working group has reached consensus definitions and classification, defining diagnostic criteria for CD which enables to clinicians reaching the proper diagnose.
Aims: The aim of this study is to review our CD patients from a single centre according to newly established diagnostic criterias.
Methods: All patients with a biopsy proven histopathological characteristics of CD diagnosed at Ege University Hospital between 2000-2017 years were reviewed for analysis. Clinical and laboratory datas were collected retrospectively. The patients were divided into two main groups based on the anatomical distribution of the disease: Unicentric CD (UCD) and multicentric CD (MCD). Also MCD were divided into two groups: HHV8 positive MCD and idiopathic MCD.
Results: A total of 64 patients were reviewed. Among the study group; 34 patients were excluded because two were diagnosed with synchronous Hodgkin lymphoma, one was diagnosed with POEMS, and the rest were unable to access all data. Detailed clinical and laboratory datas were summarized in Table 1. The mean age at diagnosis of 30 patients with adequate data was 48.8 (26-82). After histopathological evaluation, majority had hyaline vascular type (n=19), followed by mixed type (n=8) and plasma cell type (n=3). There were 16 patients in UCH group, none of them had HHV-8 and HIV positivity. After a median follow up of 54 months, the estimated 2-year OS was 87.7% [95% confidence interval (CI): 72.1–103.3]. There were 7 patients in the HHV-8+MCH group and two of them had Kaposi sarcoma. All of whom received chemotherapy and/or immunotherapy treatments. Clinical manifestations in the HHV-8+MCH group were; fever, splenomegaly, skin lesions, acute renal failure, oedema, effusion, respiratory symptoms, CRP/ferritin and LDH elevation. After a median follow up of 38.2 months, the estimated 2-year OS was 46% [95% confidence interval (CI): 17.1–74.9]. There are 7 patients in the iMCH group with HHV-8 negative and the clinical findings are very similar to the HHV-8+MCH group. Two-year overall survival in iMCH group was higher than HHV-8+MCH with 82.7% [95% confidence interval (CI): 58.6–106.8].

Table 1. CD Patient characteristics.

	UCD			MCD		
	Total	Single lesion	Single station	Total	HHV-8+MCD	iMCD

Deaths	2	-	2	3	2	1

Summary/Conclusion: CH is a very rare lymphoproliferative disease which should be kept in mind in the differential diagnosis with asymptomatic and localized lymphadenopathies or widespread lymphadenopathies with severe systemic symptoms. Future studies should be multicentred and collaborative in order to evaluate significant numbers of patients and to establish up to date and effective treatment protocols for this rare but potentially life-threatening disorder.

Iron metabolism, deficiency and overload

EFFECTIVENESS OF DIFFERENT IRON ORAL FORMULATION IN IRON DEFICIENCY ANEMIA DUE TO GASTROINTESTINAL BLEEDING: MULTICENTRIC RANDOMIZED STUDY

G. Giordano[1,*], D. Berardi[2], A. Parente[3], D. Castaldi[3], M.A. Cinotti[3], F. Vedruccio[3], V. Susca[4], L. Petrella[4], G. Berardi[5], M. Magri[6], G. Niro[6], R. Gigli[6]

[1]Medicine, Regional Hospital "A. Cardarelli", Campobasso, [2]Medicine, University la Sapienza, Rome, [3]Medicine, General Medicine, [4]Medicine, University of Molise, [5]Family Medicine, General Medicine, [6]Laboratory Medicine, Regional Hospital "A. Cardarelli", Campobasso, Italy

Background: Ther'are several different oral iron formulation with different mechanisms of uptake known or supposed (DMT1 for iron sulphate, microencapsulated iron and sunactive iron, transcellular and lymphatic way for sucrosomial iron, heme and peptones carrier for heminic chelated bisglycinated iron, peptones carrier for chelated bisglycinated iron).
Aims: Data regarding absorbtion and effectiveness for each kind of iron are lacking. Aim of this study is to see if ther'is some difference regarding effectiveness and tolerability among different oral iron formulation.
Methods: This study is a multicentric randomized study. 300 patients with iron deficiency anemia in gastrointestinal bleeding were randomized 1:1:1:1:1:1 to receive iron sulphate (65 mg of elemental iron oid), microencapsulated iron, sunactive iron, sucrosomial iron, heminic chelated bisglycinated iron (30 mg of elemental iron tid), chelated bisglycinated iron (15 mg of elemental iron tid). Patients charachteristics were similar in all six groups. Hemoglobin trend and side effects were recorded in general patients population and in C reactive protein (CRP) high level patients. Median Hb value at start of treatment was 8.2 g/dl. In group of patients with high CRP median Hb value was 7.8 g/dl. Median follow-up was 4.5 months (R 3-6).
Results: The Hb increase rate in the first two weeks of treatment is the same in the group of sucrosomial, chelated bisglycinated and heminic bisglycinated iron, but from the third to the sixth week Hb increase rate is higher in sucrosomial iron group. In this group from the sixth to the twelfth week the Hb increase rate is still higher, but shows a slight decrease. In all group Hb level achieves a plateau phase after three months and ferritin level starts to increase. At three monts higher levels of hemoglobin are present in sucrosomial iron (13.2 g/dl), heminic chelated bisglycinated iron (11.7 g/dl), chelated bisglycinated iron (11.3 g/dl). In group of patients with high CRP level (>30 ng/ml) the Hb increase is higher in sucrosomial iron group from the tenth week, is continuous until the sixth month (Hb 12.5 g/dl) and is linked to a marked decrease of CRP (5 ng/ml). All type and grade of side effects are higher in ferrous sulphate group (15/50) and in sunactive iron group (6/60)
Summary/Conclusion: Among different oral iron formulation in iron deficiency anemia sucrosomial iron shows a faster activity, an higher efficacy more evident in patients with high CRP value linked to a marked CRP level decrease after three month of treatment

PS1218

RENAL FUNCTION IN TRANSFUSION-DEPENDENT B-THALASSEMIA PATIENTS: A DECADE OF FOLLOW-UP AND COMPARISON BETWEEN CHELATION REGIMES

O. Tanous[1], Y. Azulai[2], T. Dujovny[3], N. Swartz[4], R. Colodner[2], A. Koren[5], C. Levin[3,*]

[1]Ward A, [2]Yetzhak Rabin 20, [3]Pediatric Hematology Unit, [4]Hematology Laboratory, [5]Hematology Unit, Emek Medical Center, Afula, Israel

Background: Glomerular and tubular dysfunctions in β-thalassemia major (β-TM) patients (pts) have been attributed to iron overload, chronic anemia and iron-chelation therapy (ICT) toxicity.
Aims: We studied glomerular and tubular function in β-TM pts treated with 2 different ICT regimes.
Methods: We studied 36 β-TM pts (18 females and 18 males). Mean age was 20.92±9.7 (range 5–45) years. 26 pts received deferasirox (DFX) for a mean period of 59 months; this was the first ICT for 6 of them; 10 pts were treated with deferoxamine (DFO) or DFO + deferiprone (DFP) (4 and 6 pts, respectively; hereafter DFO+/-DFP group). Clinical data were collected from pts' files.We evaluated serum urea, creatinine (sCr) and electrolytes, and estimated glomerular filtration rate (eGFR); fractional excretion of sodium (feNa), Urinary N-acetyl-β-D-glucosaminidase (uNAG) was also measured as a marker of tubular injury.
Results: eGFR was normal in all patients (mean 104.6±19 mL/min per 1.73 m^2); in the DFX group, eGFR was slightly lower than in the DFO+/-DFP group (100.9±17.09 vs. 114.0±22.31 mL/min per 1.73 m^2; p=0.0676). Increased uNAG was found in 9 pts (25%) – 30% in the DFX group vs. 10% in the DFO+/-DFP group, and was significantly higher in the DFX group (mean 10.4±6.1 vs. 5.3±2.7 IU/L, p=0.012). A moderate negative correlation was found between uNAG levels and mean serum ferritin for the prior 10 years (r = -0.35, p=0.03). In the DFO+/-DFP group, a strong positive correlation was found between uNAG levels and the amount of iron transfused over the prior 10 years (r = 0.7647, p=0.021); this correlation was not found in DFX pts. A moderate negative correlation was found for urinary Ca/Cr ratio with 10-year mean serum ferritin level and with 10-year amount of transfused iron (r = -0.35, p=0.34; r = -0.4, p=0.014, respectively). These correlations were stronger in the DFO+/-DFP group. Renal function had been previously evaluated in 20 pts treated with DFO (Smolkin *et al.*, 2008) and those results were compared with the current values. The eGFR significantly declined in pts switched to DFX (mean eGFR in first study 113.5±26 vs. 100.1±17 mL/min per 1.73 m^2, p=0.0093) but not in pts who continued DFO+/-DFP. A significant increase in sCr compared to the previous study was found in pts who switched to DFX (mean 0.51±0.9 vs. 0.67±0.1 mg/dl, p=0.0008), but not in pts who continued treatment with DFO+/-DFP. The same observation was made regarding urine Ca/Cr (mean 0.08±0.11 vs. 0.176±0.12, p=0.001).
Summary/Conclusion: A high prevalence of renal tubular abnormalities was observed in our pediatric and adult β-TM pts, particularly in the DFX group. The marker of tubular injury – uNAG – was negatively associated with mean 10-year serum ferritin, suggesting ICT's involvement in tubular injury. Moreover, uNAG was associated with transfusional iron burden in the DFO+/-DFP group, but not in the DFX group, proposing a mechanism other than iron overload for the pathogenesis of tubular injury in DFX-treated pts. Finally, glomerular function remained within the normal range in all pts; however a significant decline in glomerular function compared to a decade earlier was observed only in the pts currently treated with DFX. Strict follow-up of renal function in β-TM pts, especially children, is warranted.

PS1219

GENETIC STUDIES REVEAL NEW MUTATIONS IN THE CP GENE IN ACERULOPLASMINEMIA PATIENTS

Background: Aceruloplasminemia is a rare autosomal recessive genetic disease characterized by mild refractory anaemia, diabetes, retinopathy, liver disease and progressive neurological symptoms due to iron accumulation in brain, liver and retina. This disease is caused by mutations in *CP* gene that produce a strong reduction or absence of ceruloplasmin ferroxidase activity, leading to an impairment of iron metabolism. Up to date, around 60 families have been described worldwide, most of them in Japan. Prompt diagnosis and therapy are crucial to prevent neurological complications of the disease since, once established, they are usually irreversible.
Aims: The aim of our international collaborative study is to increase molecular and clinical knowledge of this rare disorder of iron metabolism.
Methods: We collected patients with an established diagnosis of aceruloplasminemia from multiple referral Centers. Patients were from several countries and had different origins (but none of them was from Japan). We sequenced the entire coding, intron-exon boundaries and 5' and 3' regulatory

regions of the *CP* gene by Sanger sequencing and next generation sequencing (NGS). The frequency of each variant and its possible pathogenetic role was evaluated by bioinformatical tools. In silico modeling provided a functional explanation of the pathogenic variants.
Results: In this study, we describe 11 families affected by aceruloplasminemia, and 13 mutations (12 of them being novel) in the *CP* gene. Functional characterization of a recurrent pathological splicing mutation was performed, along with computational modelling of missense mutations.
Summary/Conclusion: This series, the largest so far including non-Japanese patients, adds to the molecular and clinical heterogeneity of aceruloplasminemia, a disease expected to be increasingly diagnosed in the Next-Generation Sequencing era.

PS1220

DIAGNOSIS OF HEREDITARY HAEMATOLOGICAL DISEASES USING NEXT GENERATION SEQUENCING PANELS

Background: Next Generation Sequencing (NGS) gene panels are currently used for clinical diagnosis of many hereditary diseases.
Aims: The objective of this work is the development and commercialization of gene panels for the diagnosis of hereditary haematological diseases.
Methods: All patients studied signed informed consent for genetic studies and for research. DNA extraction was done using FlexiGene DNA kit (Quiagen). Library preparation was done using a customized HaloPlex™ Target Enrichment System (Agilent), and was sequenced in Illumina platform. Data analysis was done using software SureCall software (Agilent) and subsequent processing with proprietary algorithms. The variants found as pathogenic or probably pathogenic are confirmed by Sanger sequencing.
Results: NGS gene panels have been developed for the diagnosis of inherited haematological diseases (v15). The panels were validated by including 27 cases with known mutations by Sanger methodology. In 26 of the 27 cases analyzed (96.3%) the mutation/s previously described was detected, in one case the mutation was present in a not covered region; subsequent re-design of the panel solved this problem.
Several cases will be exposed where a satisfactory diagnosis has been reached for different diseases. In particular, we will discuss a paediatric case of hypoferritinemia, 2 cases of Hemochromatosis (young and adult case), 2 cases of enzymopathies, one case of congenital dyserythropoietic anemia due to a mutation in KLF1 and a case of congenital sideroblastic anaemia with mutations in the YARS2 gene with a mild clinical presentation that has allowed the re-evaluation of the clinical symptoms in this type of patients.
Summary/Conclusion: The implementation of the new sequencing methodology in clinical practice for the diagnosis of hereditary haematological diseases allows the inclusion of the study of multiple genes and a rapid and effective diagnosis of these cases. In addition, the analysis of several cases has allowed us to extend the genetic diagnosis with research studies.

PS1221

HEMATOPOIETIC IMPROVEMENT AFTER DEFERASIROX TREATMENT IN A CHILD WITH APLASTIC ANEMIA

G. Ersoy[1,*], C. Bayram[1], B. Koç[1], E.P. Uysalol[1], A. Ayçiçek[1], N.N. Ozdemir[1]

[1]Pediatric Hematology Oncology, Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey

Background: Aplastic anemia (AA) is a rare, life threatening disorder characterized by pancytopenia and hypocellular bone marrow in the absence of an abnormal infiltrate or marrow fibrosis. Bone marrow transplantation (BMT) if a human leukocyte antigen (HLA)-matched sibling donor is available or immunosupressive therapy (IST) for patients without an HLA-matched siblig donor are the recommended first-line treatments options for acquired severe AA.
Aims: Here we present a 7 5/12 year old male with acquired AA who lack an HLA-matched sibling donor, and failed IST but achieved a hematopoietic trilinear complete response and transfusion independence after deferasirox (DFX) treatment.
Methods: -
Results: A Syrian refugee presented with bleeding gums and bruises two years ago. His past medical history revealed that he had been diagnosed with severe AA 9 months ago, and was not responsive to IST at another center. Physical examination revealed multiple echimosis and petechia with no additional findings. Laboratory tests revealed pancytopenia and reticulocytes 0.5%. Bone marrow aspiration and biopsy was consistent with aplastic anemia, without blasts. Viral serology was negative, immunoglobulins were normal and DEB test for Fanconi anemia was normal. On follow-up, over a 6-month period, the patient received platelet transfusion every week due to oral mucosal bleeding, and required erythrocyte transfusion every 4 weeks. A second attemp of IST was recommended howeever the family rejected. At 5th month of follow-up, his ferritin level was 1487 ng/mL, and he was started on DFX treatment at a dose of 25 mg/kg/day. The patient achieved transfusion independence at the 6th month of DFX therapy, and complete hematopoietic recovery at the 22th month of DFX therapy with a ferritin level of 490 ng/mL. His last blood count is completely normal.
Summary/Conclusion: Deferasirox chelation therapy has been shown to inhibit nuclear factor-κB in patients with MDS, ALL and in leukemic cell lines, which is the current proposed mechanism for the improved erythropoiesis observed in such patients. Our case unexpectedly achieved total transfusion independence and hematopoietic complete improvement after DFX treatment and is presented to highlight the possible impact of DFX on hematopoietic recovery in patients with AA. Further prospective, controlled studies are mandatory for clinical use.

PS1222

TREATMENT WITH FERRIC CARBOXYMALTOSE FOR SEVERE IRON DEFICIENCY ANEMIA IN STABLE NOT ACTIVELY BLEEDING PATIENTS IN THE EMERGENCY DEPARTMENT

I. Motta[1,2,*], M. Migone De Amicis[1], A. Marcon[3], O. Milani[2], M. Porzio[2], A.M. Rusconi[2], A.M. Brambilla[2], N. Montano[2,3], M.D. Cappellini[13]

[1]Department of Internal Medicine, [2]Emergency Department, Fondazione IRCCS Cà Granda Policlinico, [3]Dipartimento di Scienze Cliniche e di Comunità, Università degli Studi di Milano, Milan, Italy

Background: Anemia affects a third of the world population and half of the cases are due to iron deficiency (ID). The current AABB red blood cell (RBC) transfusion guidelines recommend a restrictive strategy, with hemoglobin (Hb) thresholds <7 g/dL in hospitalized stable patients (pts) and <8g/dL in pts with cardiovascular disease. Despite these guidelines, variation in clinical practice exists. Moderate and severe anemia is a frequent cause of hospitalization; however data about the prevalence in the emergency department (ED) are scarce. Besides severity, the time of onset is crucial. Acute anemia may present with hemodynamic instability and requires prompt treatment including transfusion. Conversely, when anemia develops chronically, compensatory mechanisms arise and pts are often paucisymptomatic. No data are available about the management of stable pts who present to the ED with severe iron deficiency anemia (IDA). The AABB Choosing Wisely Campaign recommends not transfusing RBC for IDA without hemodynamic instability; however the management of these pts depends on physician experience. As a consequence, in many cases pts are transfused and then discharged from the ED. IDA treatment, beside the diagnostic work-up, is based on iron supplementation and oral iron is the gold standard. However, in presence of low levels of Hb, IV iron is more effective, bypassing intestinal absorption, and produces a faster increase in Hb. In the past the use of IV iron has been limited by hypersensitivity reactions. A new IV iron formulation, ferric carboxymaltose (FCM), allows the administration of high dose of iron with low immunogenic potential.
Aims: Aim of this study is to retrospectively analyze data from hemodynamically stable, not actively bleeding pts aged<60 years, who presented to the ED of Fondazione IRCCS Cà Granda Policlinico in Milan (Italy) in 2017 and 2018 with severe (<8 g/dL) IDA due to suspected or known source of chronic loss or malabsorption, and have been treated with FCM in the

ED and discharged afterwards.
Methods: Iron status (serum iron, transferrin, ferritin) performed within the last 3 months was accepted, while pts without iron status were tested in the ED. Once treated, pts were discharged and evaluated in a hematology out-patient clinic at T1 (after 10.1±3.7 days) and T2 (median 43, range 21-122 days). We collected hematological data from the ED (T0), T1 and T2.
Results: We treated 16 pts (14F/2M). Mean Hb value at T0 was 6.2±0.8 g/dL. Mean serum ferritin was 3.1±2.1 ng/ml, transferrin saturation 2.6±0.8%. 4/16 (25%) were transfused because symptomatic. 3 pts received 1 unit and 1 patient 2 units of RBC. The mean Hb after transfusions was 6.6±1.1 g/dL. 13/16 have been treated with 1000 mg of FCM and 3 with 500 mg. The net increase of Hb at T1 (excluding transfusions) was 2.6±1.1 g/dL with a robust reticulocytosis in most of the pts (mean 161785±95998, median 127000, range 67000-371000/mm^3). The net increase at T2 was 4.9±1.8 g/dL, with mean Hb 11.8±1.3 g/dL. Consistently MCV increased from 62.6 (T0) to 80.6±8.3 fl (T2). The cause was hemorrhoids in the 2 men, malabsorption in 1 woman and menstrual losses in 13/16. No adverse events have been observed.
Summary/Conclusion: Administration of FCM in the ED resulted to be safe and effective in stable not actively bleeding pts with severe IDA. All the pts have been discharged after treatment. Thus, we prevented inappropriate transfusions, reducing related risks, saving units for pts who need them and reducing costs of treatment. Further studies are needed to produce robust evidence for non-hospitalized pts with severe IDA.

PS1223

IRON DEFICIENCY ANAEMIA – ZINC PROTOPORPHYRIN, A SIMPLE, FAST, INEXPENSIVE DIAGNOSTIC METHOD

L. Relvas[1], J. Silva Gomes[1,*], T. Nascimento[1], A. Oliveira[1], E. Cunha[1], J. Pereira[1], C. Bento[1], T. Magalhães Maia[1], M.L. Ribeiro[1]

[1]Clinical Haematology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Iron deficiency is the most common cause of anaemia worldwide. The ferritin level is the most reliable diagnostic test, however, in the presence of chronic inflammatory conditions, it can be difficult to interpret. The final reaction in haem biosynthesis is the incorporation of iron in a protoporphyrin ring. In the absence of iron, zinc is incorporated, leading to the formation of zinc protoporphyrin (ZPP). ZPP is quantifiable by fluorimetry in peripheral blood samples stored in EDTA or in capillary blood samples, making it a useful, fast and inexpensive method for the diagnosis of iron deficiency anaemia (IDA).
Aims: To determine a cut-off of ZPP measurement for the diagnosis of iron deficiency and to validate the use of this technique in a Haematology Laboratory.
Methods: The authors prospectively and anonymously analysed paediatric and adult blood samples with anaemia. Two groups were defined according to the following inclusion criteria: IDA group: anaemia, as defined by World Health Organisation (WHO) criteria by age and gender, ferritin <20 ng/mL and erythrocyte sedimentation rate (ESR) <22 mm/h; Control group: no anaemia according to WHO criteria, ferritin 20-120 ng/mL and ESR <22 mm/h. ZPP was measured by haematofluorimetry of EDTA samples (AVIV Biomedical).
Results: A total of 132 samples were included: 97 in the IDA group and 35 in the control group. IDA group: 74% female, median age 32.3 yo (2-79); 26% male, median age 26.4 yo (1-78); average haemoglobin (Hb) 10.5 g/dL (SD 1.29); average ferritin 8.3 ng/mL (SD 4.4); average ZPP 215.4 μmol/mol (SD 111.6); average ESR 17.7 mm/h (SD 8.1). Control group: 62.9% female, median age 40 yo (1-79); 37.1% male, median age 17 yo (2-69); average Hb 13.5 (SD 1.2); average ferritin 111.7 ng/mL (SD 117); average ZPP 77 μmol/mol (SD 21.3); average ESR 12.3 mm/h (SD 5.1). ROC curve analysis led to the definition of a ZPP cut-off of ≥ 98 μmol/mol for the diagnosis of iron deficiency, with a sensitivity of 90.8% and specificity of 86.67% when compared with the control group.
Summary/Conclusion: The results of this study allowed the authors to securely establish a cut-off of 98 μmol/mol of ZPP for the diagnosis of iron deficiency, with good sensitivity and specificity values. This diagnostic test does not require blood collection in a specific tube, is reliable when using capillary blood samples and may prove itself an excellent technique for the diagnosis of iron deficiency in paediatric populations and in the screening of blood donors. This test may also be an asset for the diagnosis of IDA in underdeveloped countries since it is fast, accurate, inexpensive and doesn't require elaborate machinery.

PS1224

STUDY OF A MEDICO-ECONOMIC ADVANTAGE IN USING NEW PARAMETERS OF CBC-DIFF-RETIC IN THE EARLY DETECTION OF IRON DEFICIENCY FOR DIALYSIS PATIENTS**

E. Sukhacheva[1,*], M. Hoffmann[2], D. Loze[3], G. Brochard[4]

[1]Beckman Coulter Eurocenter, Nyon, Switzerland, [2]Nephrology and dialysis department, Private Hospital La Louviere, [3]Cerballiance Haut de France Laboratory - La Digue, Lille, [4]Beckman Coulter France, Villepinte, France

Background: Cerballiance Haut de France laboratory is a part of Cerba-Healthcare Group which has an important place in specialized biology in France. The laboratory located in Lille analyses more than 2000 blood samples daily, including samples from the clinic La Louviere specialized for dialysis patients. Dialysis patients are monitored monthly for iron deficiency, beyond the standard of care, in order to quickly detect iron deficiency and to minimize Erythropoietin (EPO) dosing, providing less toxicity and economic advantages for the center. The method must follow the Kidney Disease Outcomes Quality Initiative (KDOQI) recommendations which includes iron, transferrin saturation and ferritin. The global recommendations and laboratory technologies are currently evolving, there are new parameters considered for the evaluation of iron deficiency whose application remains to be demonstrated. Low Hemoglobin Density (@LHD%), Red cell Size Factor (@RSF) and Microcytic Anemia Factor (@MAF) which are research use only parameters provided by Beckman Coulter DxH800 as part of routine CBC-DIFF and Reticulocytes count which are currently performed for patient monitoring.
Aims: We aimed to investigate if these parameters could potentially substitute the recommended parameters and present a medico-economic advantage by limiting the injection of expensive factors stimulating erythropoiesis and thereby also limiting the clinical risk to the patient.
Methods: The laboratory retrospectively studied 248 patients from the dialysis center of La Louviere. Normal ranges for @LHD%, @RSF and @MAF were defined using 318 normal patients. The recommended markers (@LHD%, @RSF and @MAF) were compared to: iron, transferrin, transferrin saturation and ferritin, in the group of patients with inflammation (defined as CRP>10mg/dL) and group without inflammation (defined as CRp<10mg/dL). At the next step among patients without inflammation, we identified responders and non-responders based on the dosage and frequency of EPO administration. All parameters were compared between groups of responders and non-responders. Finally we tried to define cut-offs for new parameters which can potentially be used to follow-up patients' treatment**.
Results: Normal ranges were analyzed for @LHD, @MAF and @RSF, which were used to interpret the results of different groups of dialyzed patients. The data demonstrated that these markers vary significantly for patients with or without inflammation: the group with inflammation has higher@ LHD, lower @MAF and lower @RSF values. @LHD demonstrated the best correlation with transferrin saturation. Among patients without inflammation non-responders have higher @RSF values and higher @LHD values than responders. In our cohort of patients, a criteria @LHD>15% and @MAF>10 seems to be acceptable to follow-up the treatment without risk of missing clinically important iron deficiency**.
Summary/Conclusion: In daily practice, the data suggests that @LHD and @MAF has potential in allowing for an early detection of iron deficiency, similar to transferrin saturation**. The monitoring of dialysis patients could be done with reduced cost, performing only CBC-DIFF-Retic and limiting the rhythm of transferrin saturation testing**.
@For research use only. Not for use in diagnostic procedures
***Clinical utility requires validation through a controlled clinical trial*

PS1225

ACERULOPLASMINAEMIA - THE EXTREMELY RARE ALSO EXISTS

J. Silva Gomes[1,*], A. Azevedo[1], T. Nascimento[1], D. Viegas[1], A. Roque[1], L. Relvas[1], J. Pereira[1], E. Cunha[1], A. Oliveira[1], C. Bento[1], T. Magalhães Maia[1], M.L. Ribeiro[1]

[1]Clinical Haematology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Hereditary aceruloplasminaemia (HA) is a rare, autosomal recessive condition, characterized by iron overload affecting the liver, pancreas and brain, caused by mutations in the ceruloplasmin gene (*CP*), leading to an absence of the enzyme ceruloplasmin ferroxidase. Anaemia (usually normocytic or microcytic), associated with hyperferritinaemia and low transferrin saturation (TS), along with non-doseable serum ceruloplasmin and low serum copper are findings which may lead to a suspicion of HA. Some patients may develop symptoms associated with tissue iron overload, including diabetes mellitus and neurodegenerative symptoms. The incidence of

HA in western countries is unknown.
Aims: To report the first case of HA with a confirmed molecular diagnosis in a reference centre, diagnosed in the context of asymptomatic anaemia and hyperferritinaemia.
Methods: Patient Description: 38 year-old caucasian female, referred to Haematology consultation for normocytic normochromic anaemia known for at least several years. The patient complained of tiredness and mood changes, for which she had already been referred to Psychiatry consultations.
Results: Initial workup confirmed normocytic normochromic anaemia (Hb 10.8 g/dL) with normal reticulocyte count, as well as hyperferritinaemia (ferritin 825 ng/mL, TS <15%), with normal liver enzymes. During follow-up: ferritin levels progressively increased to a maximum of 1124 ng/mL, anaemia was stable and asymptomatic, TS <10% and liver enzymes were normal. *HFE* mutations associated with haemochromatosis were excluded. Liver iron overload was confirmed by magnetic resonance imaging (MRI), with hepatic iron levels of 270 µmol/g (N<36 µmol/g) and liver iron concentration (LIC) of 15.1 mg/g. Because of a positive result for anti-mitochondrial antibodies, liver biopsy was performed by recommendation of Hepatology, which excluded primary hepatic conditions, but revealed grade 4 haemosiderosis (scale of 0-4), with no fibrosis or copper deposits. A study of copper metabolism was performed which revealed non-doseable ceruloplasmin and low serum copper as well as decreased copper urinary excretion. Cerebral MRI revealed signs of iron overload in the basal ganglia, thalamus, cerebral cortex and cerebellar cortex. Sequencing of the *CP* gene revealed homozygosity for point mutation c.885C>G (p.His295Gln), a pathological variant not previously described in literature.
Summary/Conclusion: Although it is a very rare disease, the diagnosis of HA is particularly relevant because iron overload, when untreated, can lead to irreversible organ damage, including in the central nervous system. A high level of suspicion for HA is fundamental to achieve a diagnosis, and a few diagnostic clues may be useful: history of anaemia with hyperferritinaemia, low TS and confirmed organ iron overload, with or without accompanying neurodegenerative symptoms or mood disorders. In cases of hyperferritinaemia with low TS, when chronic illness has been excluded, a study of copper metabolism should be performed.

PS1226

IT TAKES A LOT OF IRON TO AVOID TRANSFUSION

M. Al-Obaidi[1,*], M. Chituku[1], C. Jardiel[1], R. Ingrey[2], A. Babb[1], N. Wiles[1]

[1]Haematology, [2]Medicine, West Middlesex Univesity Hospital, London, United Kingdom

Background: There is ample evidence of unnecessary transfusion in iron deficiency anaemia both in the literature and in our institute. In a concerted effort to optimise the safe and appropriate use of allogeneic red cell transfusion we established a weekly nurse led anaemia clinic with capacity to treat four to five patients weekly, and to which primary and secondary care physicians could refer patients for assessment, investigations and correction of iron deficiency with parenteral iron.
Aims: To assess effectiveness of the anaemia clinic in correcting iron deficiency and preventing transfusion.
Methods: Results for all patients seen in the clinic from January 2016 to December 2017 were analysed, blood parameters prior to and 8 weeks after iron infusions were reviewed, and any transfusions prior to or during the two year period were logged.
Results: One hundred and ninety two new patients were seen in clinic, 18 were not iron deficient. Of the remaining 173 patients, 40 were referred or treated repeatedly in the two years. Patient demographics and results are presented in Table 1. Females outnumbered males by 2.9:1 (138:36), and were younger (median age 50 years compared to 71 years). The commonest cause of iron deficiency was menorrhagia; other common aetiology themes included low iron diet, iron mal-absorption due to proton pump inhibitors, metformin and bariatric surgery. As well as possible gastrointestinal bleeding due to inflammatory bowel disease or malignancy or exposure to anticoagulant or antiplatelet agents. Most patients (87%) received iron infusion, at a dose calculated using the Ganzoni equation (using ideal weight where appropriate). Of those treated with intravenous iron the majority received total dose infusion of iron isomaltose Monofer® with a median dose of 800mg (500-1800), sixteen patients received iron sucrose Venofer® in divided doses (when only small dose needed, history of asthma (2), inflammatory arthritis (6), pregnancy (1) or reaction to single dose infusions (6) in the past). An additional three patients developed mild to moderate reaction such that the iron product was changed. Overall the treatment was effective with a median rise of 14g/L in haemoglobin, and similar overall improvement in ferritin and iron saturation; however a large proportion of patients required more than one iron infusion over the two year period; 44% of patients still had a haemoglobin <120 g/L on repeat blood testing. The rate of transfusion was low with only 12 patients receiving blood over the two years. Two patients required treatment on a regular (weekly / monthly) regimen due to the need for iron sucrose Venofer® divided doses and on-going epistaxis in one patient with hereditary haemorrhagic telangiectasia and gastrointestinal bleeding in a patient with large bowel angiodysplasia, these patients required a total of 17200mg and 5400 mg of Venofer® respectively, and 10% of clinic slots, they also received nine of the 37 units of blood transfused.

Table 1.

Patient demographics treatment and results		
Gender (female / male)	138/36	
Age	54 (18-91)	
Factors contributing to iron deficiency		
Menorrhagia	63 (45%)	
Proton pump inhibitor	54 (31%)	
Metformin	26 (15%)	
Bariatric surgery	8 (4.6%)	
Low iron diet	37 (21%)	
Antiplatelet / Anticoagulant	45 (26%	
Inflammatory / malignant bowel disease	6 (3.4%)	
Treatment		
Oral iron	23	
Monofer*	134 (89%)	
Venofer	16 (10%)	
Number of infusions over 24 months		
1	112	
2	21	
3 to 5	13	
>20	2	
Patients requiring transfusions	12(7%)	
Response to treatment	Prior to infusion	Following infusion
Mean Haemoglobin	104	118
Mean Ferritin	19	61
Mean Iron saturation	10%	36%

Summary/Conclusion: The dedicated iron deficiency clinic was well received by patients, primary and secondary care providers, and was able to correct iron deficiency in large numbers of patients. However, reducing the use of allogeneic blood transfusion in patients with on-going blood loss was only partially achieved by frequent hospital visits and very high doses of intravenous iron.

Ragusa, Ragusa, [6]Presidio Ospedaliero "San Francesco" ASL Nuoro, Nuoro, [7]Presidio Ospedaliero Orientale "M. Giannuzzi", Manduria (TA), [8]Ospedale "Sant'Eugenio", Roma, [9]Azienda Ospedaliero-Universitaria Ospedali Riuniti "Umberto I-Lancisi-Salesi", Ancona, [10]Ospedale "Sandro Pertini", Roma, Italy

Background: The MIOT (Myocardial Iron Overload in Thalassemia) project is a multicentric study aimed to validate the T2* Magnetic Resonance Imaging (MRI) technique as non invasive approach for the cardiac and hepatic iron overload assessment in patients with hemoglobinopathies and to correlate the T2* values with other clinical-instrumental parameters. More recently, the E-MIOT (Extension-MIOT) project has been approved, with the aim of adding the assessment of the pancreatic iron
Aims: More recently, the E-MIOT (Extension-MIOT) project has been approved, with the aim of adding the assessment of the pancreatic iron.
Methods: We report the baseline MRI findings at the end of the first year of recruitment in the E-MIOT study, outlying the differences among different emoglobinopathies.
Results: First, we selected all transfusion-dependent (TD) patients: 7 with sickle-cell disease-SCD or thalasso-drepanocytosis (42.9% F, 32.47±17.93 years), 16 with thalassemia intermedia-TI (56.3% F, 36.66±13.72 years), and 232 with thalassemia major-TM (55.6% F, 36.95±9.83 years). Sex, mean age, serum ferritin levels, MRI liver iron concentration (LIC) values,

and global heart T2* values were comparable among the three groups of patients. Pancreatic T2* values were significantly lower in TM patients versus both SCD and TI patients.
Second, we focused our analysis on all TI patients, divided in two subgroups: transfusion dependent and no-TD. Global pancreas T2* values and the number of patients with pancreatic iron (T2*<26 ms) were comparable between the two groups (see Table 1).

Table 1.

	TI-noTD (N=16)	TI-TD (N=16)	p
Sex (% of F)	33.3	56.3	0.300
Age (years)	42.78 ± 13.34	36.66 ± 13.72	0.427
Ferritin (ng/ml)	452 ± 251	750 ± 583	0.336
MRI LIC (mg/g dw)	5.37 ± 6.68	5.72 ± 8.58	0.270
MRI LIC < 3 mg/g dw, N (%)	9 (50)	5 (31.3)	0.268
Global heart T2* (ms)	43.94 ± 4.69	35.79 ± 9.58	0.008
Global heart T2*<20 ms, N(%)	0	1 (6.3)	0.471
Global pancreas T2* (ms)	26.57 ± 10.46	21.89 ± 13.37	0.317
Global pancreas T2*<26 ms, N(%)	8 (44.4)	9 (56.3)	0.492

Summary/Conclusion: SCD and TI TD patients have lower pancreatic iron loading than chronically-transfused TM patients. Much of this disparity can be explained by the larger transfusional burdens and durations observed in TM patients (years of regular transfusions: 34.18±10.75 in TM, 22.27±18.53 in SCD and 28.33±15.30 in TI, p=0.023). However, TI-TD and TI-noTD patients had comparable pancreatic T2* values. So, innate differences in iron handling and elimination among different diseases also could contribute to the differences in pancreatic iron loading.

PS1228

CHR AND%HYPO: BETTER METHODS FOR ASSESSING FUNCTIONAL IRON DEFICIENCY IN CHRONIC KIDNEY DISEASE?

L. Smith[1,*], F. Buckley[2], K. Gelly[2]

[1]*Hematological Malignancy Diagnostic Service (HMDS), NHS Lothian, Edinburgh,* [2]*Department of Hematology, NHS Tayside, Dundee, United Kingdom*

Background: Renal anemia is multifactorial but is associated with functional iron deficiency (FID). Serum ferritin alone is not a useful marker in identifying patients with FID, nor predicting response to iron replacement in patients with chronic kidney disease (CKD). The KDIGO guidelines 2012, which contain recommendations for assessment of iron status and prediction of response to iron therapy in CKD, were superseded by the NICE guidelines in 2015. The new guidelines recommended a shift from using% transferrin saturation (%TFsat) and ferritin in combination, to using either% hypochromic red cells (%HYPO) or reticulocyte hemoglobin concentration (CHr). Whilst analyzers are capable of generating these parameters, there are no existing external quality assessment (EQA) schemes available for them.
Aims: We aimed to assess whether: 1. The Siemens Advia 2120 generated reliable and accurate%HYPO and CHr results; 2. These parameters appear to be adequately predictive for FID in CKD patients on regular hemodialysis; and 3. There would be tangible cost implications in terms of testing and treating FID.
Methods: Samples were analyzed on one day, on a freshly calibrated and dedicated analyzer, within 4 hours. Data were captured for Hb,%TFsat, ferritin,%HYPO and CHr. Details of IV iron treatment were noted per patient. These results were applied to both existing and updated guidelines to determine the corresponding recommended treatment.
Results: Samples were collected from 37 patients on regular hemodialysis ('CKD group'), 3 patients with iron deficiency and 14 non-anemic non-iron deficient individuals. 18 patients in the CKD group were already on regular IV iron supplementation. Applying the NICE guidelines 2015 to the CKD group to identify patients who would benefit from iron supplementation: 8 patients were identified according to%TFsat and ferritin; 23 patients according to%HYPO and no patients according to CHr. Amongst the CKD group, withdrawal of iron supplementation was recommended in 7, 4 and 12 patients according to the above parameters respectively. CHr did appear to be predictive for iron deficiency in non-CKD patients, although this group was very small.
Summary/Conclusion: No clear trend was seen to suggest that%HYPO was more predictive for FID in CKD patients than%TFsat and ferritin.%HYPO did not reliably offer benefit over%TFsat and ferritin and could not be applied to delayed samples or patients with thalassemia. CHr was a particularly poor marker of FID in CKD patients on regular hemodialysis. It would also significantly increase the cost of iron status monitoring. It was not possible to draw conclusions regarding the interpretation of these assays in the context of IV iron therapy. On the basis of these results and in conjunction with our local Renal Department, we have chosen not to report%HYPO or CHr in our lab. We recommend that labs perform similar analyses locally prior to reporting these parameters. Development of EQA schemes will be necessary to maximize the utility of these results where a lab chooses to report them.

Myelodysplastic syndromes – Biology & Translational Research

PS1229

BONE MARROW FAILURE AND PREDISPOSITION TO LEUKEMIA IN GATA2 HAPLOINSUFFICIENT MICE

J. Weiss[1,*], I. Schmitt[1], C. Molnár[1,2,3], N. Fischer[1], M. Wlodarski[1], C. Niemeyer[1], M. Erlacher[1]

[1]Pediatric Oncology/Hematology, University Hospital Freiburg, [2]Faculty of Biology, [3]Spemann Graduate School of Biology and Medicine, University of Freiburg, Freiburg, Germany

Background: The transcription factor GATA2 is indispensable for the generation and maintenance of hematopoietic stem cells (HSCs). Heterozygous *GATA2* germline mutations have been associated with several clinical symptoms e.g. lymphedema, deficiencies of monocytes, B and/or NK cells. Strikingly, up to 75% of affected individuals develop myelodysplastic syndromes (MDS) with a risk of further progression to acute myeloid leukemia (AML).
Aims: Although GATA2 is considered to be a major predisposition factor for MDS, the underlying mechanisms leading to malignant transformation are largely unknown. The aim of this study is therefore to understand, how *GATA2* haploinsufficiency causes MDS/AML. Since murine HSCs lacking both *Gata2* alleles are not viable, we propose that *Gata2*$^{+/-}$ HSCs are able to live, but exhaust faster, live shorter and therefore lead to bone marrow failure. In such a situation, preleukemic cells would have the opportunity to emerge and proliferate, which would ultimately result in MDS and AML.
Methods: To verify this hypothesis, we put murine *Gata2*$^{+/-}$ stem and progenitor cells (=HSPCs) under different kind of stress conditions and analyzed them for signs of exhaustion and susceptibility to develop bone marrow failure. We performed competitive and serial transplantations and analyzed the HSPC compartment of aged *Gata2*$^{+/-}$ mice
Results: Analysis of competitively transplanted recipient mice showed that significantly fewer cells derived from *Gata2*$^{+/-}$ HSPCs than from WT HSPCs suggesting that *Gata2*$^{+/-}$ HSPCs were less competitive and less efficient than WT HSPCs. To further assess the reconstitution potential of *Gata2*$^{+/-}$ HSPCs under stress conditions, we performed serial transplantations. Decreased cell counts in spleen and lymph nodes after 1st and 2nd passages indicated an accelerated exhaustion of *Gata2*$^{+/-}$ HSPCs. Analysis of the HSPC pool of aged *Gata2*$^{+/-}$ mice revealed a reduced number of long-term HSCs and multipotent progenitors. When we performed a single transplantation of HSPCs and monitored recipient mice over time, we observed that 50% of them died within 6 months after transplantation. At time of death, recipient mice showed a strongly reduced bone marrow cellularity with complete lack of mature myeloid cells, disturbed B-cell differentiation and elevated T-cell counts in bone marrow and spleen. Histochemical analysis confirmed the presence of bone marrow failure. In addition, leukemic infiltrations were found in the spleens of some of the recipient mice. Predisposition to leukemia was also observed, when *Gata2*$^{+/-}$ mice were treated with the mutagen ENU. Both WT and *Gata2*$^{+/-}$ mice developed immature T-cell leukemia but *Gata2*$^{+/-}$ mice died significantly earlier than WT mice.
Summary/Conclusion: Our results demonstrate that *Gata2*$^{+/-}$ HSPCs are less competitive, exhaust faster and have a reduced lifespan compared to WT HSPCs. As a consequence, *Gata2*$^{+/-}$ mice are more prone to develop bone marrow follow and leukemia. Next, we will identify which second hits contributed to leukemogenesis in *Gata2*$^{+/-}$ mice. This will reveal cooperating pathways and give new insights into the oncogenic role of GATA2 in the hematopoietic compartment.

PS1230

GROWING IMPORTANCE OF FLOW CYTOMETRY (FCM) IN THE DIAGNOSTICS OF MYELODYSPLASTIC SYNDROMES: SENSITIVITY AND SPECIFICITY OF THE UP-TO-DATE SCORING SYSTEMS UNDER SPECIAL CONSIDERATION OF THE NEW IFSCORE

U. Oelschlaegel[1,*], L. Oelschlaeger[1], B. Mohr[1], K. Sockel[1], M. Bornhäuser[1], U. Platzbecker[1]

[1]Medical Clinic and Policlinic I, MK1-L06, University Hospital of Tu Dresden, Dresden, Germany

Background: Following the harmonization efforts of the international MDS-flow working group of the ELN, the value of flow cytometry (FCM) as one recommended part in MDS diagnostics is growing. Currently, different scores were applied, evaluating abnormal maturation pattern as expression of dyspoiesis in various hematopoietic cell lineages.
Aims: Aim of the recent study was to compare the different FCM scores concerning sensitivity and specificity referring to cytomorphology as standard diagnostic procedure.
Methods: 1076 FCM measurements were performed in bone marrow of 769 patients with MDS or cytopenias suspected for MDS. Additionally, 96 patients with AML, 45 with MPN, as well as 50 age matched hip surgery patients were utilized as controls. For measurement and analysis the FACS-CantoII cytometer including DiVa software was used, performing an 8-color panel and measuring 200,000 events per sample. The following FCM-scores were compared: FCSS (granulopoiesis/monopoiesis), Ogata-score (blasts), ELN-red-score and Mathis-score (both erythropoiesis), and the new iFScore (granulo-, mono-, erythropoiesis, and blasts).
Results: The sensitivity of the new iFS-score, evaluating granulo- ,mono-, erythropoiesis and blasts, is comparable with FCSS and much higher than that of Ogata- and the red-scores (81%, 82%, 59%, 31%, 40%). Of note, assigning the patients according to the WHO2016 classification a sensitivity of 63% was achieved even for the MDS-SLD subgroup (MDS-MLD=69%; del(5q)-syndrome=89%; EB1/2>90%; CMML=96%). Considering only patients with MDS-SLD or MLD with normal karyotype and without ring sideroblasts the sensitivity comprised 68% and 65%, respectively. Considering the very low cytogenetic risk and very low IPSS-R group sensitivity was even slightly better. Regarding specificity the new iFScore was also comparably high as the other scores with 98% (100%, 100%, 98%, 92%) in controls. In non-clonal cytopenias the new iFS showed a specificity of 81% compared to FCSS with 53% and to the only one cell lineage considering Ogata- and red-scores (95%, 96%, 89%). Considering sensitivity and specificity together the new iFScore seems to give the best results. Interestingly, despite inappropriate bone marrow aspirations (w/o spiculae) in 22 patients the new iFScore resulted in "consistent with MDS" in 72% of these cases. Finally, even being in cytogenetic CR 29% of the investigated MDS patients showed an iFScore consistent with MDS, having a borderline significant impact on overall survival (p=0.075).
Summary/Conclusion: Currently available and used FCM scores showed differences in sensitivity and specificity, with the new iFScore being the most comprehensive approach in MDS diagnostics by FCM evaluating granuo-, mono-, erythropoiesis and blasts. Especially in low risk MDS and cases with inappropriate bone marrow aspiration FCM can clearly contribute to MDS diagnostics. The value of FCM response monitoring with a special focus on evaluating the deepness of response remains to be studied further.

EXPLORING THE LONG NON-CODING RNA TRANSCRIPTOME IN JUVENILE MYELOMONOCYTIC LEUKEMIA

M. Hofmans[1,*], T. Lammens[1], H. H. Helsmoortel[2], S. Bresolin[3], H. Cavé[4], C. Flotho[5], H. Hasle[6], M. M. van den Heuvel-Eibrink[7], C. Niemeyer[5], J. Stary[8], N. Van Roy[2], P. Van Vlierberghe[2], J. Philippé[9], B. De Moerloose[1]

[1]Department of Pediatric Hematology-Oncology and Stem Cell Transplantation, [2]Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium, [3]Department of Women and Child Health, University of Padova, Padua, Italy, [4]Department of Genetics, University Hospital of Robert Debré and Paris-Diderot University, Paris, France, [5]Division of Pediatric Hematology and Oncology, Department of Pediatrics and Adolescent Medicine, University of Freiburg, Freiburg, Germany, [6]Department of Pediatrics, Aarhus University Hospital Skejby, Aarhus, Denmark, [7]Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands, [8]Department of Pediatric Hematology/ Oncology, Charles University and University Hospital Motol, Prague, Czech Republic, [9]Department of Clinical Chemistry, Microbiology and Immunology, Ghent University, Ghent, Belgium

Background: Juvenile myelomonocytic leukemia (JMML) is a rare and aggressive myelodysplastic/myeloproliferative disorder of early childhood. Hematopoietic stem cell transplantation results in long-term overall survival (OS) of only 50-60% and is fraught with frequent relapse and toxicity. Consequently, there is need to develop novel treatments. Recent work from our group identified *LIN28B* as key player in JMML. Moreover, we have illustrated that *LIN28B* overexpression deregulated expression of the long non-coding RNA (lncRNA) H19, the first lncRNA discovered in JMML biology. LncRNAs are a recently discovered class of RNAs, with a minimum length of 200 nucleotides, which play a crucial role in oncogenesis.
Aims: The major aim of this work was to document the lncRNA landscape in JMML patients and associate lncRNA expression with cytogenetic, mutational and clinical characteristics.
Methods: We studied a publically available RNA dataset (GEO number GSE71449) comprising of microarrays from a cohort of 44 JMML patients and 7 healthy age-matched controls. In total 23728 lncRNA probes (corresponding to 17845 unique lncRNAs) were identified. Differential gene

expression analysis between JMML patients and controls was performed with the samr package (R BioConductor).
Results: A total of 300 differentially expressed lncRNAs were identified (15 upregulated in JMML and 285 downregulated; Figure 1). Guilt-by-association analysis through pre-ranked gene set enrichment analysis discovered various gene sets (anti-)correlated with the top five up- and downregulated lncRNAs, and related to myeloid cell development, dendritic cell maturation, neutrophil function and different AML phenotypes. Furthermore, distinct lncRNA expression profiles could be attributed to specific patient characteristics. I.e., lncRNAs downregulated in patients with elevated HbF for age were anti-correlated with genes involved in HbF regulation. Moreover, the majority of these lncRNAs were also upregulated in patients with monosomy 7, confirming the inverse relation between monosomy 7 and elevated HbF. Sixty-one lncRNAs were differentially expressed between patients with and without *LIN28B* overexpression of which 60 were upregulated in *LIN28B* overexpression. Interestingly, both MEG3 and MEG8 were upregulated and are known to be involved in regulation of pluripotence and fetal development. Next, we hypothesized that lncRNA expression might influence clinical outcome. Multivariable cox-regression analysis with age, HbF, karyotype and molecular status identified 7 lncRNAs highly associated with OS ($p<0.001$). Interestingly, these lncRNAs did not associate with known prognostic characteristics and no common (anti-)correlated gene sets could be identified. A lncRNA score, derived as a linear combination of the expression of the significant lncRNAs, was used to dichotomize patients. Patients with a high lncRNA score had a significantly lower OS and EFS after HSCT (log rank test; $p<0.001$). Together, this suggested that lncRNAs might be of prognostic significance in JMML. However, studies in independent patient cohorts are necessary to validate the prognostic value of lncRNA expression in JMML.

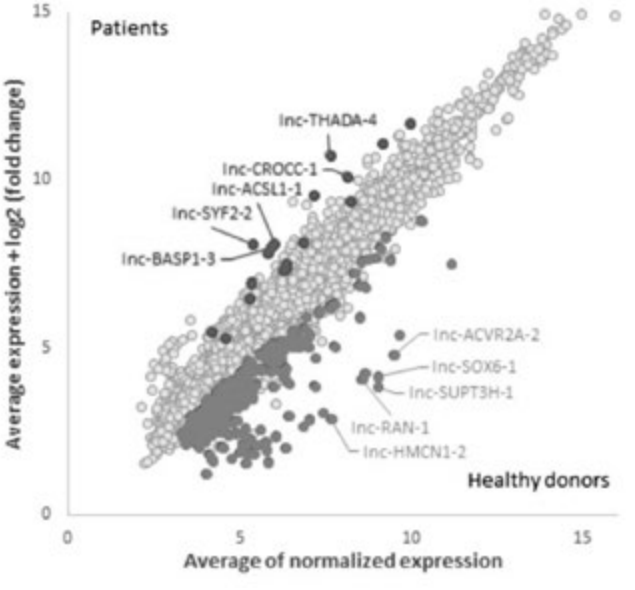

Figure 1.

Summary/Conclusion: We documented for the first time the lncRNA landscape in 44 JMML patients and identified deregulated lncRNAs associated with key processes in JMML pathogenesis and the biology of specific JMML subgroups. Follow-up studies are needed to confirm the prognostic value of lncRNAs. Altogether, this study paves the way for further functional research on the role of lncRNAs in JMML and their therapeutic application.

PS1232

A MIR-150 / TET3 PATHWAY REGULATES THE GENERATION OF MOUSE AND HUMAN NON-CLASSICAL MONOCYTE SUBSET

D. Selimoglu-Buet[1,*], J. Riviere[1], H. Ghamlouch[1], L. Bencheikh[1], M. Morabito[1], M. Diop[2], G. Meurice[2], M. Breckler[2], A. Chauveau[1], C. Debord[1], R. Itzykson[1], N. Chapuis[3], C. Willekens[1], O. Wagner-Ballon[4], O. Bernard[1], N. Droin[1], E. Solary[1]

[1]U1170 INSERM, [2]INSERM US23, CNRS UMS 3655, Gustave Roussy Institute, Villejuif, [3]Departement d Immuno-Hematologie, Institut Cochin, Paris, [4]Biological hematology and immunology department, Hôpital Henri-Mondor, Créteil, France

Background: Monocytes are heterogeneous leucocytes comprising two main subsets in mice and three in humans. The expression of CD14 and CD16 distinguishes $CD14^+/CD16^-$ classical from $CD14^+/CD16^+$ intermediate and $CD14^{low}/CD16^+$ nonclassical human monocytes. In mice, Ly6C expression distinguishes classical monocytes ($LY6C^{high}$) and nonclassical monocytes ($Ly6C^{low}$). A consensus model supports that nonclassical monocyte subset may derive from classical monocyte differentiation. Proportion of each subset is tightly controlled but the molecular mechanisms that regulate monocyte subset differentiation remain poorly understood.
Aims: Monocyte subset repartition can be deregulated in human diseases such as chronic myelomonocytic leukemia (CMML) in which the fraction of nonclassical monocytes typically decreases in the favour of classical monocytes. CMML samples were used as a starting model to identify some of the molecular mechanisms involved in the generation of nonclassical monocytes.
Methods: A microarray screen of miRNA expression was performed in peripheral blood monocytes of 33 CMML and 5 healthy donor blood samples and RT-PCR validation was performed in monocytes from a cohort of 139 CMML patients and 24 controls. We then combine analysis of knockout mouse models, CRISPR-CAS9 deletions, ChIP-Seq analyses, bisulfite sequencing and miRNA pulldown to explore the mechanisms by which the disease-associated deregulation of a specific miRNA leads to an abnormal generation of monocytes subsets in both mice and humans.
Results: The down-regulated expression of miR-150 is a characteristic feature of CMML monocytes. This down-regulation is explained by hypermethylation of a myeloid lineage specific promoter in *MIR150* gene, which is corrected in patients who respond to demethylating drugs and recapitulate a normal repartition of monocyte subsets. *miR150*$^{-/-}$ mice demonstrate an increase in $Ly6C^{high}$ monocyte fraction at the expense of $Ly6C^{low}$ monocytes. The number of myeloid progenitors is normal in *miR150*$^{-/-}$ mice and the remaining $Ly6C^{low}$ monocytes do not demonstrate an increased sensitivity to apoptosis. This abnormal repartition of monocyte populations in *miR150*$^{-/-}$ mice is a cell-autonomous phenotype that is rescued by re-expression of miR150 in bone marrow cells of *miR150*$^{-/-}$ mice before engraftment. Competitive reconstitution experiments combining WT and *miR150*$^{-/-}$ cells do not identify any significant fitness advantage to *miR150*$^{-/-}$ cells, but *miR150*$^{-/-}$ cells develop reduced numbers of $Ly6C^{low}$ monocytes than WT donors. In human cells, depletion or overexpression of miR-150 in $CD34^+$ cells alters the repartition of $CD14^+/CD16^-$ and $CD14^+/CD16^+$ cells generated in culture. In mice and humans, the expression of miR-150 is also lower in classical monocytes compared to nonclassical subsets. Pulldown experiments pointed to Ten-Eleven-Translocation-3 (TET3) mRNA as a miR-150 target in classical monocytes, with *Tet3*$^{-/-}$ mice generating an increased number of nonclassical monocytes.
Summary/Conclusion: Our results demonstrate that a miR-150 / TET3 pathway, which is conserved in mice and humans and is epigenetically deregulated in CMML cells, is involved in the generation of nonclassical monocyte subsets.

PS1233

IMPACT OF RED BLOOD CELL TRANSFUSION RATE, ADJUSTED BY THERAPEUTIC INTERVENTIONS, ON PROGRESSION-FREE SURVIVAL IN LOWER RISK MDS PATIENTS WITHIN THE EUROPEAN LEUKEMIANET MDS REGISTRY

tologie, CHU Brabois Vandoeuvre, Nancy, [18]Service de Medecine Interne, CHU Toulouse, Toulouse, France, [19]Haematology, Aberdeen Royal Infirmary, Aberdeen, [20]St. James's Institute of Oncology, Leeds Teaching Hospitals, Leeds, United Kingdom, [21]Tumor Immunology, Radboudumc, Nijmegen, Netherlands

Background: Progression-free survival (PFS) of lower-risk (LR) MDS patients treated with red blood cell transfusions (transfusions) is usually reduced, but whether this effect is caused by the actual transfusion itself remains debatable. The EUMDS Registry contains data on 2,192 newly diagnosed LR-MDS patients from 16 European countries and Israel, collected at diagnosis and at 6 months intervals.
Aims: The aim of this analysis is to assess the effect of transfusion rate on PFS.
Methods: The cumulative dose received at the end of each interval was divided by the time since the start of the first RBCT to give an overall dose density in that period. Dose density rises over time when transfusion rate increases over time, but declines when a patient becomes RBCT independent after treatment. PFS was adjusted by relevant confounders, including age, gender, self-reported patient condition (proxied by EQ-5D index), and number of cytopenias at diagnosis, using Cox regression with time-varying covariates.
Results: We analysed a cohort of 1,273 patients with all relevant data available. Within this group 669 patients received transfusions after registration. Univariate analysis of the 669 transfused patients showed a strong association of age ($p<4\times10^{-4}$) with PFS. The EQ-5D index, baseline MDS diagnosis, bone marrow percentage and number of cytopenias were all associated with PFS in univariate regression. The dose density was associated with PFS ($p<1\times10^{-4}$) with a significant non-linear component ($p<1\times10^{-4}$). The following variables were entered into multivariate regression analysis: transfusion dose density, diagnostic age, number of transfusions received before diagnosis, EQ-5D index, bone marrow blast percentage and cytogenetic category. All variables entered in the regression retained statistical significance. The functional form of the dose density effect (p=0.009) is shown in Figure 1A. The dose density had an increasing effect until a dose density of about one unit/month. Thereafter, the effect leveled off. Treatment with ESAs, lenalidomide and iron chelators may improve erythropoiesis and reduce the need for RBCT, resulting in a gradual decrease of the subsequent RBCT dose densities in intervals during the response period. Patients, treated with ESA, lenalidomide, or iron chelators, showed a decrease of transfusion density in 22%, 53% and 40% of the patients, respectively. The observed patterns of dose density trajectories suggest that receipt of ESA, lenalidomide and iron chelation modulate the dose density and therefore, we included these variables as confounding variables in the regression model. This analysis showed that the impact of the dose density remained similar to the previous analyses, but in contrast the dose density effect continues to increase beyond 1 unit per month after correction for the three interventions (Figure 1B).

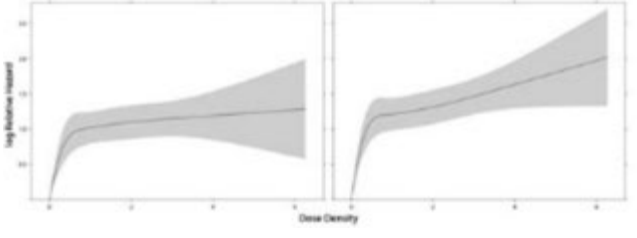

Figure 1.

Summary/Conclusion: The multivariate regression models showed that administration of transfusions is associated with decreased PFS when compared to non-transfused patients. The negative effect of transfusions on PFS already occurs at low transfusion densities below 1 unit per month. This indicates that the transfusion dependency, even at relatively low rate, may be considered as an indicator of poor prognosis.

PS1234

EXPRESSION PATTERN OF LONG-NONCODING RNAS ALTERS IN DIFFERENT FORMS OF MYELODYSPLASTIC SYNDROMES

K. Szikszai[1,*], Z. Krejcik[1], A. Hrustincova[1], M. Belickova[1], J. Cermak[2], A. Jonasova[3], M. Dostalova Merkerova[1]

[1]Department of Genomics, [2]Outpatient Department, Institute of Hematology and Blood Transfusion, [3]Faculty Hospital, Prague, Czech Republic

Background: Long non-coding RNAs (lncRNAs) regulate hematopoietic lineage differentiation at almost every stage and their abnormal expression contributes to various hematopoietic disorders. They may become useful molecular markers contributing to the detection of disease progression and increase of patients' survival. However, the information about influence of lncRNA expression on pathogenesis of myelodysplastic syndromes (MDS) is limited.
Aims: Genome-wide screening of lncRNA levels was employed to compare expression profiles between various subtypes and risk groups of MDS patients with the aim to find lncRNAs potentially relevant for MDS.
Methods: Microarray profiling (22,001 lncRNA transcripts and 17,535 protein-coding mRNAs) was performed on CD34+ bone marrow cells in a cohort of 54 patients with various subtypes of MDS, 14 patients with acute myeloid leukemia with myelodysplasia-related changes (AML-MRC) and 9 healthy donors. Reverse-transcription quantitative-PCR (RT-qPCR) was applied to validate the microarray results by quantification of expression level of selected individual lncRNAs in an independent cohort (106 samples).
Results: The most altered lncRNAs (adj. p<.05) in MDS patients across all the disease subtypes included e.g., H19, MEG3, DLX6-AS1, and PRKAR2A-AS1 (up-regulated compared to controls) and PRR7-AS1, MEF2C-AS1, TTN-AS1, and U3 (down-regulated). Interestingly, H19 lncRNA regulates early hematopoiesis and MEG3 was one of the first lncRNAs associated with MDS. Expression profiles of the patients with lower-risk subtypes (MDS-SLD, MDS-MLD, MDS with del(5q)) were more similar to the profiles of healthy controls, whereas those of the patients with higher-risk diagnoses (MDS-EB1/2) rather resembled to the profiles of AML-MRC. Concerning cytogenetic abnormalities, patients with del(5q) showed specific lncRNA profile with down-regulation of EPB41L4A-AS1, CTB-118N6, and MEF2C-AS1 that are located in 5q locus. Stratification of expression profiles according to IPSS-R confirmed significantly different levels of many lncRNAs between very low/low and very high/high risk categories, pointing out to the lncRNAs whose expression changes are related to the disease prognosis. The lncRNAs with decreased levels in very high/high patient group (compared to very low/low risk categories) were e.g., TCL6, LEF1-AS1, PCED1B-AS1, and CXADRP3. The opposite trend (increased in very high/high compared to very low/low patients) showed e.g., RBPMS-AS1, BAIAP2-AS1, and MCM3AP-AS41. Some of these lncRNAs have already been linked to hematopoiesis. For example, TCL6 has been previously reported as a potential player in T-cell leukemia and may be involved in leukemogenesis, and LEF1, protein-coding gene related to lncRNA LEF1-AS1, plays a critical role in hematopoietic cell differentiation.
Summary/Conclusion: The results of the present study identified a number of differentially expressed lncRNAs, providing one of the first insights into the involvement of lncRNAs in MDS. However, further characterization of those lncRNAs would contribute to better understanding of lncRNAs action in MDS pathogenesis. Besides, the work demonstrates a potential of non-coding RNAs to become, after additional experimental investigation, prognostic markers in myelodysplasia in future.
Supported by grants No. 17-31398A and 16-33617A, and by the project for conceptual development of research organization No. 00023736 (all from the Ministry of Health of the Czech Republic).

Osp. San Giovanni-Addolorata , Rome, Italy, [13]Weill Cornell Medical College, New York, United States, [14]Università Cattolica del Sacro Cuore - Policlinico A. Gemelli, Rome, [15]University of Milan, ASST Papa Giovanni XXIII, Bergamo, Italy

Background: TP53 mutations occurs in about 10% of patients with myelodysplastic syndromes (MDS), increasing up to 30-40% in those pts with therapy-related MDS. TP53 mutations frequently are loss of function and cause a stabilization of mutant p53 proteins, leading to their increased

accumulation at cellular level (detectable by immunohistochemistry). However, p53 hyperexpression in cancer can also be observed in the presence of wild-type TP53 genes

Aims: In this study we evaluated the prevalence and clinical implications of p53 dysfunction in a large MDS cohort

Methods: This is an observational retrospective analysis of 3 different groups of MDS pts: receiving best supportive care (BSC, n=495), hypomethylating agents (HMAs, n=198) or allogeneic transplantation (HSCT, n=305).Hystopathological analysis in order to evaluate p53 expression was done with a DO-1 antibody stain (Santa Cruz Biotechnology, Santa Cruz, CA). TP53 mutation status was carried out through massive parallel sequencing panel (JCO 2016;30:3627-3637). Recursive partitioning analysis (NEJM 2017;376:536-47) was used to generate a hierarchical model for overall survival integrating clinical and genetic characteristics

Results: Hyperexpression of p53 was defined with a 2% or more of positive cells (p53++/dark brown, nuclear staining).Bone marrow biopsy were reviewed by expert pathologists with a concordance >95% (p<.001) for recognition of percentage of p53++ cells.Globally TP53 mutations were detected in 11% of pts, these pts had a paucity of other gene mutations; TP53 mutations were infrequent in pts with splicing mutations vs pts with wt splicing factor genes (p=.002). Known poor prognostic factors, such as int-2/high and poor/very poor cytogenetic risk were associated to TP53 mutations (p=.02 and p<.001 respectively). Pts with TP53 mutation had a shorter survival than wt pts (15 vs 66 months, p<.001), data has been confirmed within a multivariable model. Mutations of TP53 were stable over time in serial samples showing no disappearance and no late appearance. A reduction in mutant clone correlated with response to HMAs and HSCT, however clones increased in non-responders and persisted at disease relapse. Pts with high p53 expression (17% of all) had a same survival independently by the presence or absence of TP53 mutations. (15 vs 17 months, p=ns). Than we focused on the MDS with p53 dysfunction category,which includes pts with TP53 mutations and/or p53 hyperexpression.Through the recursive partitioning analysis we compared clinical and genomic variables. In pts receiving BSC, p53 dysfunction had a bad prognostic impact on disease progression and survival (p=0.001)(Figure 1A). In pts treated with HMAs, p53 dysfunction was predictive for a lower efficacy of the treatment(CR 21% vs 25%; p=.038) and higher% of relapse (p=.01). Eventually pts treated with HSCT with the p53 dysfunction had a higher risk of relapse after transplant when compared with pts without p53 disfunction. (p=0.002) (Figure 1B).

Figure 1.

Summary/Conclusion: MDS with p53 dysfunction is a well defined clinical category characterized by poor prognosis due to high risk of disease evolution and low probability of response to disease modifying treatments. Hystopathological and molecular assessments which can define p53 status should be widely adopted for a better prognostic definition of MDS pts.

PS1236

A FLOW-CYTOMETRY SCORING SYSTEM OF ABNORMAL GRANULOCYTES AND MONOCYTES MATURATION PROFILES FOR DIAGNOSIS OF MYELODYSPLASTIC SYNDROMES

S. Barreau[1], A. Green[1], O. Kosmider[1], L. Willems[2], V. Bardet[3], M. Fontenay[1], N. Chapuis[1,*]

Background: Diagnosis of myelodysplastic syndromes (MDS) mainly relies, on evaluation of dysplasia, quantification of blast cells and detection of cytogenetic abnormalities. Multiparametric flow cytometry (MFC) was recently reported to be a helpful additional tool for MDS diagnosis. However, the number of phenotypic abnormalities recommended to be analyzed is high and their quantification is difficult. Simplified approaches were developed and clearly demonstrated their utility but also showed a relative low sensibility possibly due to the restricted number of phenotypic abnormalities analyzed.

Aims: We aimed at developing a simple useful MFC tool based on the evaluation of granulocyte and monocyte maturation profiles in order to allow reproducible MDS diagnosis with high specificity and sensitivity.

Methods: We apply a 1-tube panel strategy allowing detection of abnormal expression of CD11b, CD56, CD10, CD13, CD14, CD33, CD34, CD64, CD16 and CD45 on both granulocytes and monocytes and the calculation of Ogata score (Navios, Beckman Coulter). We tested 283 samples including 20 control samples for the creation of a reference database. For each case, granulocytes and monocytes maturation profiles were compared to the reference maturation database (Infinicyt, Cytognos). The addition of the standard deviations (SD) outside the normalized database maturation (2 SD) for each stage of maturation (5 and 3 for granulocytes and monocytes respectively) for all tested parameters defined the Diff-Score.

		Ogata Score >2	Diff Score >17.2	Both
Learning Cohort				
Specificity (%)		93.4 (n=61)	92.1 (n=63)	85.2 (n=61)
Sensitivity (%)	All	52.6 (n=97)	60.6 (n=99)	73.2 (n=97)
	MDS-Low	37.1 (n=62)	46.0 (n=63)	61.3 (n=62)
	MDS-High	81.5 (n=27)	92.9 (n=28)	96.3 (n=27)
	MDS/MPN	75 (n=8)	62.5 (n=8)	87.5 (n=8)
Validation Cohort				
Specificity (%)		87.9 (n=33)	97 (n=33)	84.8 (n=33)
Sensitivity (%)	All	50 (n=52)	69.2 (n=52)	80.8 (n=52)
	MDS-Low	28.6 (n=35)	60 (n=35)	71.4 (n=35)
	MDS-High	90.9 (n=11)	81.8 (n=11)	100 (n=11)
	MDS/MPN	100 (n=6)	100 (n=6)	100 (n=6)

Figure 1.

Results: Among 178 consecutive patients referred for MDS suspicion, 99 patients were classified with proven MDS by morphological analysis of bone marrow and/or by cytogenetic analysis (MDS-SLD n=1; MDS-RS-SLD n=3; MDS 5q- n=6; MDS-MLD n=41; MDS-RS-MLD n=12; MDS-EB-1 n=19; MDS-EB-2 n=9; CMML-0/1 n=6 and CMML-2 n=2), 16 patients with ICUS and 63 patients with non-hematologic causes of cytopenia. We observed significantly more differences of both monocyte and granulocyte maturation profiles compared to the normal reference database in patients with MDS than in patients without MDS (p<0.0001). A similar result was observed after the comparison of cumulative differences detected in both granulocyte and monocyte maturation profiles (p<0.0001) for all types of MDS. A ROC analysis was performed to test the capacity of Diff-score to diagnose MDS. The area under the ROC curve (AUC) was 0.781 (95% CI, 0.711-0.850). A cutoff value of 17,2 SD outside the threshold (2 SD) established on the normalized reference database was calculated with a specificity of 94.9% and a sensitivity of 60.6% (46%, 92.9% and 62.5% for MDS-low (MDS

without excess blasts), MDS-high (MDS-EB-1/2) and MDS/MPN respectively). Interestingly, combination with the Ogata Score allowed MDS diagnosis with a specificity of 85.2% and a sensitivity of 73.2% (61.3%, 96.3% and 87.5% for MDS-low, MDS-high and MDS/MPN respectively). These results were validated in a second independent cohort of patients with MDS (n=52; with 35 MDS-low, 11 MDS-high and 6 MDS/MPN) or with non-clonal cytopenia(s) (n=33) with specificity and sensitivity values of the "Diff Score of 17.2 SD outside the threshold" criterion of 97% and 69.2%, respectively. Again, combination with the Ogata Score increased the sensitivity to 80.8% and to 71.4% for MDS-low samples (Figure 1).
Summary/Conclusion: We report here a simple useful MFC tool based on evaluation of granulocyte and monocyte maturation profiles which in combination to the Ogata-score allows reproducible MDS diagnosis with better sensitivity and higher specificity than the Ogata score alone.

PS1237

ALTERED CARBONYLATION PATTERN IN MYELODISPLASTIC SYNDROMES

A. Rodríguez García[1,*], M. Linares[1], K. Quiroz[1], T. Cedena[1], A. Arenas[1], M.L. Morales[1], R. Ayala[1], J.M. Bautista[1], J. Martínez López[1]

**ARG and ML authors have contributed equally.*

Background: Myelodysplastic syndrome (MDS) is an aging associated clonal hematopoietic disorder characterized by a bone marrow failure in which immature blood cells do not mature properly. Oxidative stress seems to play a role in its pathogenesis. Interestingly, high ROS levels have been observed in MDS, which has been correlated with a diminished survival. However, the oxidation of proteins is of particular concern since it leads to aggregation, unfolding, or conformational changes that may confer a loss of structural or functional activity.
Aims: As an altered proteome has also been described during MDS, in this study we have analyzed the pattern of oxidized protein associated to MDS through detection of protein carbonylation. Moreover, we analyzed whether MDS patients could be beneficed by Deferasirox as antioxidant therapy.
Methods: Protein carbonylation was analyzed in bone marrow (n=14; 8 MDS and 6 controls) by immunohistochemistry after derivatization of carbonyl compounds with 2,4-dinitrophenylhydrazine (DNPH) and specific antibody detection of the 2,4-dinitrophenyl hydrazones. Protein carbonylation was also studied in expanded erythroblasts during *in vitro* erythropoiesis (n=9; 5 MDS and 4 controls) by 1-D and 2-D immunoproteomics. p21 mRNA levels were analysed by qRT-PCR.

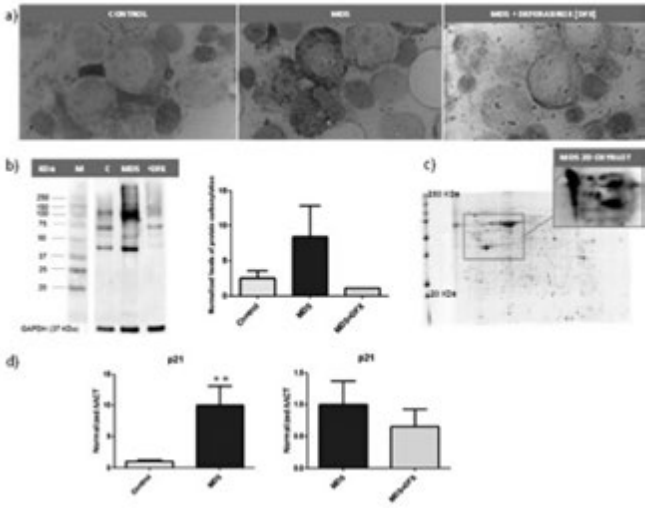

Figure 1.

Results: Immunohistochemistry assays showed a higher level of carbonylation in MDS samples (Figure 1a). We observed carbonylation in the cytoplasm of myeloid cells, whereas erythroid cells remained negative in both, patients and controls. Interestingly, MDS patients treated with Deferasirox presented lower levels than non-treated patients. Further, to assess carbonylation in the erythroid precursors, we analyzed the pattern of carbonylated proteins in expanded erythroblasts. Again, a higher level was observed in MDS vs. control group, which was reverted after Deferasirox treatment (Figure 1b). Most carbonylated proteins ranged in a size between 40-250 KDa. A highly carbonylated 40 KDa band was detected in all analyzed SMD samples. As seen in the 2D immunoblots, these differences in carbonylation were caused by a limited number of proteins or aggregates, rather than to a large spectrum of proteins (Figure 1c). Finally, as oxidative stress signaling pathways could regulate the cell cycle by p53, we analyzed the expression of p21, a p53 target during stress response. Upregulation of p21 was significantly observed in MDS samples. Remarkably, this effect was reverted upon Deferasirox treatment (Figure 1d).
Summary/Conclusion: An altered protein carbonylation pattern of myeloid and erythroid lineages was observed in MDS patients. This boosted oxidative cellular environment seems to activate signaling pathways involving p21. Deferaxirox treatment partially reverted these oxidative lesions at cellular level.

PS1238

EXPRESSION LEVEL OF SPECIFIC MIRNAS BEFORE AZACITIDINE THERAPY INITIATION MAY PREDICT FUTURE EFFICACY OF THE TREATMENT IN MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIA

M. Dostalova Merkerova[1,*], Z. Krejcik[1], A. Hrustincova[1], K. Szikszai[1], A. Jonasova[2], J. Cermak[3], M. Belickova[1]

[1]Department of Genomics, Institute of Hematology and Blood Transfusion, [2]Faculty Hospital, [3]Outpatient Department, Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: Azacitidine (AZA) is a hypomethylating agent that can improve the clinical outcome in approx. 50% of patients with myelodysplasia, and the prediction of AZA responsiveness is important for the therapy management.
Aims: We searched for specific microRNA (miRNA) profiles associated with AZA treatment in patients with higher-risk myelodysplastic syndromes (MDS) or acute myeloid leukemia with myelodysplasia-related changes (AML-MRC) with the aim to identify potential molecular markers of the response.
Methods: Microarray profiling (Human miRNA Microarrays, Agilent Technologies) was performed on CD34+ bone marrow cells in a discovery cohort (28 samples from 12 patients at baseline and during AZA therapy and four healthy donors) to preselect miRNAs with altered expression between responders and non-responders. To validate the microarray results and find clinically significant molecules, reverse-transcription quantitative-PCR (RT-qPCR) was applied to measure expression levels of individual preselected miRNAs in a validation cohort (50 samples from 27 patients at baseline and during AZA therapy and 11 controls).
Results: At baseline, the miRNA profiles stratified patients according to their future response status. The complete responders showed the most distinct miRNA expression pattern, whereas the patients with partial response had miRNA profiles that were more similar to those of the non-responders. Expression analyses of particular miRNAs between responders and non-responders found that the overall response rate was significantly higher in the patients with upregulated miR-17-3p and downregulated miR-100-5p and miR-133b at baseline. Importantly, the high level of miR-100-5p at baseline was associated with shorter overall survival (HR = 4.066, p=.008). To determine the miRNAs involved in AZA response, we compared miRNA expression of responders after AZA treatment with paired pretreatment samples and observed significant deregulation (p=.05) of 30 miRNAs (including decreased levels of miR-10b-5p, miR-15a-5p/b-5p, miR-24-3p, miR-148b-3p, and miR-199a-3p and increased levels of miR-1202 or miR-1260a), while the level of these miRNAs remained unchanged in the non-responders.
Summary/Conclusion: Our study demonstrates that responders and non-responders have distinct miRNA expression patterns before and during AZA therapy and that the level of specific miRNAs before therapy initiation may predict the future efficacy of AZA treatment.
Supported by grants No. 17-31398A and 16-33617A, and by the project for conceptual development of research organization No. 00023736 (all from the Ministry of Health of the Czech Republic).

MULTICENTRIC VALIDATION OF THE "MONOCYTE ASSAY" FOR CHRONIC MYELOMONOCYTIC LEUKEMIA DIAGNOSIS BY FLOW CYTOMETRY

S. Tarfi-Bekkour[1], V. Harrivel[2], F. Dumezy[3], J. Guy[4], M. Roussel[5], A. Mimoun[6], P. Fenaux[7], N. Chapuis[8], E. Solary[9], D. Selimoglu-Buet[9], O. Wagner-Ballon[1,*]

[1]Département d'Hématologie et Immunologie biologiques, APHP Hôpitaux universitaires Henri Mondor, Créteil, [2]Centre de Biologie Humaine - Laboratoire d'Hématologie, CHU Amiens Sud, Amiens, [3]Laboratoire d'hématologie, Centre Hospitalier Régional Universitaire de Lille, Lille, [4]Laboratoire d'hématologie, Centre Hospitalo-universitaire Dijon, Dijon, [5]Laboratoire Hématologie, Centre Hospitalo-universitaire de Rennes, Rennes, [6]Laboratoire d'hématologie, Centre Hospitalier de la Côte Basque, Bayonne, [7]Service d'Hématologie clinique, Hôpital Universitaire Saint-Louis, [8]Laboratoire Hématologie, Hôpital Universitaire Cochin, Paris, [9]INSERM U1170, Institut Gustave Roussy, Villejuif, France

Background: Accumulation of classical monocytes (cMO) $CD14^{++}CD16^{-}$ ≥94% of total peripheral blood monocytes analyzed by flow cytometry (FCM) was demonstrated to be a specific and sensitive tool that distinguishes chronic myelomonocytic leukemia (CMML) from reactive monocytosis (Selimoglu-Buet, 2015). The 94% threshold was further validated in two independent studies (Talati, 2017; Patnaik, 2017) and is increasingly used as a diagnosis marker of CMML.
Aims: Since this "monocyte assay" has been largely adopted by French diagnosis laboratories, we evaluated its performance in a multicentric evaluation.
Methods: A short survey was sent by personalized emails between July and September 2016 to 48 French laboratories performing routinely FCM diagnosis of myeloid neoplasms. Afterwards, a few selected centers were asked to send their raw data files as well as the corresponding cMO percentage evaluation in order to perform a double centralized blind analysis. Biological and clinical data were also provided when available.
Results: We obtained a comprehensive reply to the survey with a 100% rate of response. Thirty of 48 centers (63%) use routinely the "monocyte assay": apart from the three centers that participated to the initial study and keep using it, 27 centers spontaneously implemented it, most often following the initial publication and/or a meeting presentation. All the surveyed cytometrists consider the "monocyte assay" useful for CMML diagnosis.
In a second step, five centers (named A to E) provided 329 FCM raw data files with the corresponding cMO percentage. All these files were reanalyzed in a blind fashion by two different operators (skilled and trainee). These congruent centralized analyses compared to the cMO percentage determined by the centers showed an excellent correlation (r=0.93; p<0.0001, Figure 1A) without any major bias. As the cut-off value of 94% cMO is the most relevant parameter in the "monocyte assay", we compared the patients with cMO≥94% by centralized analysis (i.e. suspected of being diagnosed as CMML) and found an excellent agreement between both analyses (matching for 110 analyses/ 115 (95.7%), Figure 1B). Conversely, of the 214 patients with a fraction of cMO<94% by the centralized analysis, 201 (93.5%) displayed cMO<94% in the original center. In most of the 18 divergent cases, the difficulty in drawing cMO gate was related to an insufficient number of cMO analyzed. Hence, we decided to exclude all the files showing cMO event number below 10,000 (Figure 1C), thereby improving the correlation (r=0.94) and the agreement for the 245 remaining files (total matching files: 95%).

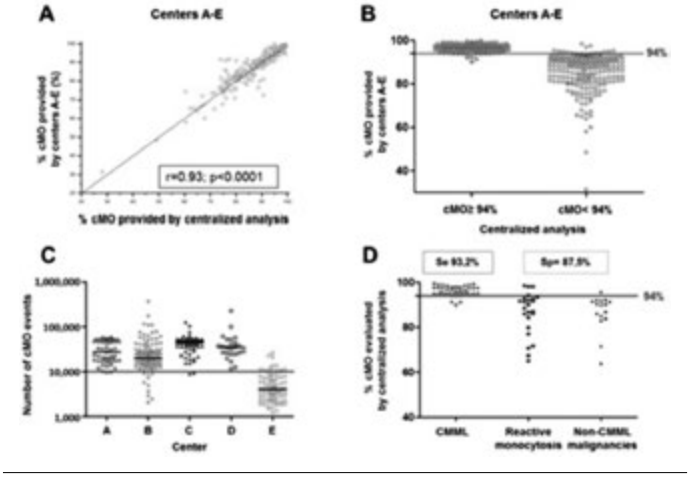

Figure 1.

Among these latter files, we collected clinical data for 84 patients for whom an overt diagnosis was made, namely 46 CMML, 24 reactive monocytosis and 14 non-CMML malignancies. cMO accumulation ≥94% determined by centralized analysis was observed in 43 of the 46 CMML (Figure 1D), indicating a sensitivity of 93.5% in accordance with previous results. A specificity of 86.8% was calculated as 5 of the 38 "non-CMML" patients displayed cMO<94% determined by centralized analysis. Interestingly, using these data we established a new Receiver Operator Curve (ROC) and obtained yet again a 94% cut-off value.
Summary/Conclusion: This study demonstrates a strong adhesion of the French laboratories to the "monocyte assay" for CMML diagnosis set-up in 2015, with 30 user centers so far. We observed a low variability of the cMO percentage quantification between centers and validated the published 94% cut-off value with a 93.5% sensitivity and a 86.8% specificity. Besides, we propose conclusion models for result reporting.

PS1240

CHARACTERIZATION AND DIFFERENTIAL EFFECTS OF MESENCHYMAL STROMAL CELL-DERIVED EXTRACELLULAR VESICLES IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES

M. Wobus[1,*], A. Mies[1], U. Oelschlägel[1], C. Kahlert[2], F. Stölzel[1], M. Bornhäuser[1], U. Platzbecker[1]

[1]Hematology/Oncology, [2]Department of Gastrointestinal, Thoracic and Vascular Surgery, Medical Faculty, University Hospital TU Dresden, Dresden, Germany

Background: Beyond the genetically altered hematopoietic compartment, the pathogenesis of myelodysplastic syndromes (MDS) relies on a defective bone marrow niche, a highly specialized microenvironment ensuring stem cell self-renewal and differentiation during hematopoiesis. Within this niche, intercellular communication e.g. between hematopoietic stem and progenitor cells (HSPCs) and mesenchymal stromal cells (MSCs), is facilitated either by direct cell-cell contact or by soluble factors. Recently, non-contact communication processes were described on the basis of secretion of extracellular vesicles (EVs) that were able to modify functional properties of recipient cells by the transfer of bioactive molecules including RNAs and proteins. However, detailed mechanisms and the relevance for MDS pathogenesis as well as EV's potential as diagnostic and/or therapeutic targets remain to be defined.
Aims: Here, we investigated distinct characteristics of MDS MSC-derived EVs and their impact on HSPC phenotype and function.
Methods: MSCs were isolated from bone marrow of MDS patients (n=10) and age-adjusted healthy donors (HD, n=10)). After FCS-depleted culture for 48h, EVs were purified by using the Total Exosomes Isolation Kit (Thermo Fisher Scientific). Concentration and size of the EV population were analyzed with a ZetaView instrument (Particle Metrix GmbH) with multi-parameter nanoparticle tracking analyses (NTA) as well as transmission electron microscopy (TEM). Moreover, EVs were characterized by flow cytometry and Western blot. The functional impact of incorporated EVs on HSPCs derived from HD was evaluated by colony (CFU) and differentiation assays, proliferation and survival assays, phenotyping as well as trans-well migration experiments.
Results: NTA and TEM revealed a heterogeneous morphology of the EV populations with an average size of 148 nm for HD MSC-derived EVs and 156 nm for MDS MSC-derived EVs. EV concentration was higher in HD than in MDS samples (5.9E+08 vs. 2.1E+08 particles/ml). All EV preparations expressed typical exosomal markers including CD9, CD63 and CD81. Flow cytometry analysis of isolated EVs and their corresponding MSCs revealed that EVs expressed common MSC markers such as CD90 (MDS only), CD105 and CD146 (HD + MDS).
Next, we demonstrated the incorporation of Vybrant DiI-labeled EVs from both HD and MDS MSCs into CD34+ HSPCs by confocal imaging. The uptake of EVs had no influence on HSPC proliferation and survival. However, the *in vitro* differentiation of HSPCs was modulated in the presence of EVs. Of note, the presence of MDS MSC-derived vesicles resulted in increased numbers of CFU-G (81±15 with MDS EVs vs. 15.5±4.5 without EVs), CFU-M (79.5±16.5 vs. 26±10) and CFU-GM (51.5±9.5 vs. 18.5±4.5). The priming into the myeloid lineage of HSPCs by MDS EVs showed an increased expression of CD69 and CD11b as well as down-regulation of HLA-DR after granulocytic/monocytic differentiation in the presence of EVs. One possible underlying mechanism could be the transfer of miRNA-29a, which was detected at significant higher levels in HSPCs after incubation with MDS EVs. Moreover, we observed a higher migratory capacity towards a SDF-1 gradient of HSPCs which were pre-incubated with MDS EVs in comparison to HD EVs (33.3% vs. 12.2%) which was associated with higher CXCR4 expression levels.
Summary/Conclusion: In summary, we describe new mechanisms for the

intercellular communication between MSCs and HSPCs in the MDS microenvironment. The specific modulation of EVs from MDS patients offers new therapeutic and/or prognostic targets.

PS1241

MYELODISPLASTIC SYNDROMES: MECHANISMS INVOLVED IN THE TRANSFORMATION TO ACUTE MYELOID LEUKEMIA (AML)

F. Hernández Mohedo[1,*], P. Montes Ramos[2], M. Bernal Sánchez[2], P. Jiménez Gámiz[2], M. Corzo Corbera[2], A. R. González Ramirez[3], M. Jurado Chacón[1], F. Ruiz-Cabello Osuna[2]

[1]UGC Hematología Y Hemoterapia, [2]Análisis Clínicos e Inmunología, Hospital Universitario Virgen de Las Nieves, [3]Fundación de Investigación Biosanitaria Alejandro Otero (Fibao), Granada

Background: Myelodysplastic Syndromes (MDS) are a heterogeneous group of clonal neoplasms with variable risk of progression to Acute Myeloid Leukemia (AML) (1). Recently, several authors indicated that the progression may be mediated by a selective growth of a leukemic clone influenced by the mutational status. In this line, Next Generation Sequencing (NGS) studies have identified recurrent somatic mutations where mutations in high molecular risk (HMR) genes (*TP53, ETV6, ASXL1, RUNX1, EZH2*) have a relevant impact on survival and risk of progression to AML (2,3). However, independently of these factors, clinical evidence supports the existence of a dysregulation of the immune system (4).
Aims: To study both the mutational status and the role of the tumor microenvironment in the progression of the Myelodysplastic Syndrome
Methods: The study of the tumor microenvironment was carried out in 56 patients with primary MDS according to WHO-2008: RARS (n=2), RCMD (n=21), RCUD (n=2), Isolated 5q (n=7), RAEB-1,-2 (n=13), U.MDS (n=2) and LMA secondary to MDS (sAML) (n=9), using multiparametric flow-cytometry. 40 peripheral blood samples were used as controls. The mutational study was divided into: early state, pre-leukemic state (RAEB-1,-2) and sAML. Samples were sequenced by NGS techniques using a panel of 54 genes associated with myeloid neoplasms (TruSight, Illumina) and the MiSeq platform (Illumina, San Diego).
Results: In relation to the tumor microenvironment, we observed a significant increase of NK cells with $CD56^{-}CD16^{bright}$ ($p<0.01$) and $CD56^{bright}$ phenotypes ($p<0.01$) in patients with MDS compared to controls. In AML patients, we observed a decrease in the latter NK cell subset ($p<0.05$) together with a reduced cytotoxic effector NK cell numbers ($CD56^{dim}$ $CD16^{bright}$) ($p<0.01$) as compared to controls. Based on the expression of activating receptors on CD56+ NK cells, we observed a significant decrease of NKG2D both in patients with MDS ($p<0.05$) and AML ($p<0.01$) when compared to controls. We also observed that the increase of the NKG2D expression correlates with the low risk of progression according to IPSS/IPSS-R score ($p<0.01$). In contrast, the NKp46 and CD161 receptors were normally expressed in the MDS group, but not in patients with AML, where the expression of the CD161 receptor was significantly decreased ($p<0.01$). On the other hand, we detected higher numbers of granulocytic-myeloid derived suppressor cells (Gr-MDSC) in patients with MDS ($p<0.001$) and AML ($p<0.001$), with the increase in the monocytic-MDSC (Mo-MDSCs) in the latter group ($p<0.05$). In addition, we observed an increase in MDSC cells (Gr- and Mo-MDSCs) in patients with a high risk of progression according to the IPSS and IPSS-R score ($p<0.001$). Regarding the mutational profile, we observed that the percentage of patients with mutations in HMR genes was higher in the RAEB group (n=8, 53%) than in the early MDS group (n=9, 25.7%). In the latter, however, we detected a higher percentage of patients with mutations in NO-HMR (n=17, 47%), mainly related to DNA methylation and the RNA splicing compared to RAEB group (n=3; 20%). In addition, the variant allele frequency (VAF) in HMR genes was more than 40% in 6 of 8 patients in the RAEB group, whereas in the early stage group the VAF was less than 30% in 6 of 10 patients. Finally, AML group presented ≥3 mutated genes compared to the MDS group ($p<0.05$).
Summary/Conclusion: Both immune escape and acquired genetic changes can satisfactorily explain the progression of MDS

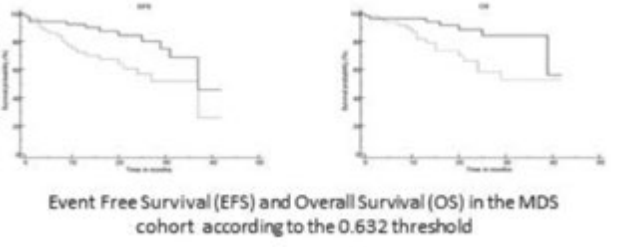
PS1242

COMPLETE BLOOD COUNT- BASED SCORE FOR THE DIAGNOSIS AND PROGNOSIS OF MYELODYSPLASTIC SYNDROMES IN CYTOPENIC PATIENTS

R. Boutault[11], P. Peterlin[2], M. Boubaya[3], K. Sockel[4], C. Godon[1], O. Theisen[1], Y. Le Bris[1], F. Kroschinsky[4], M. C. Béné[1], U. Platzbecker[4], M. Eveillard[1,*]

[1]Hematology Biology, [2]Hematology Clinic, CHU Nantes, Nantes, [3]Statistical Department, CHU Avicennes, Bobigny, France, [4]Hematology Clinic, Medizinische Klinik und Poliklinik I, Dresden, Germany

Background: A prospective study was performed in order to investigate whether suspected myelodysplastic syndromes (MDS) could be detected on a complete blood count (CBC) using the recently developed XN-10® analyzer (Sysmex, Kobe, Japan).
Aims: The principal objective of the study was to discriminate MDS patients from a cohort of 399 cytopenic controls by developing a scoring system. The secondary objective was to explore whether this new score, at diagnosis, had a value to predict disease evolution.
Methods: The study enrolled 109 untreated patients over 50 years old (61 men/48 women, median age 78) for whom a diagnosis of MDS was concluded based on CBC, bone marrow (BM) smears examination and karyotype. CBC included both quantitative parameters (hemoglobin [Hb] level, Mean Corpuscular Volume [MCV], reticulocytes, platelets, absolute neutrophil counts [ANC]) and positioning and dispersion parameters including Ne-WX, a new parameter which characterizes the dispersion of neutrophils. According to WHO criteria, patients were diagnosed with MDS-EB (n=33), MDS-MLD-RS (n=35), MDS-SLD-RS (n=25), MDS-SLD (n=12) without RS and MDS with isolated del(5q)(n=4). A diagnosis of MDS was excluded from the control cohort by BM examination, clinical features and biochemical data.
Results: Each WHO-MDS subgroup was significantly different from controls for MCV, ANC, platelets and Ne-WX ($p<0,0001$). Within MDS-SLD, platelet counts were similar to those of controls, yet significantly higher than for MDS-EB ($p=0.004$) or MDS-MLD ($p=0,029$). No other parameter discriminated between MDS subgroups.
Multiparametric analysis highlighted three parameters significantly different between the MDS and cytopenic control cohorts: median MCV (100.3±10.5fL; $p<0.0001$), median ANC (2.41±2.50x10^9/L; $p<0.001$) and median Ne-WX (384±70; $p<0.0001$). The latter, by itself, allowed to suspect MDS with a sensitivity of 71% and a specificity of 86%. Logistic regression and multivariate analysis were used to define a multiparametric screening MDS-CBC score with the combination of the three parameters. This score allowed to detect MDS with 86% sensitivity and 88% specificity at a threshold of 0.2. Moreover, high score values (>0.632) at diagnosis significantly correlated with decreased survival in MDS patients. The median EFS was 37 months in both high and low MDS-CBC score groups, while at 24 months the EFS was significantly higher for low scores at 84.6±5 vs 57.1±8 ($p=0.02$) Two year OS was significantly different at 88.5±5 months for low MDS-CBC scores vs 58.5±9 for high MDS-CBC scores ($p=0.008$; Figure 1). The 15 false-negative MDS patients were all IPSS low risk and five of them reached a positive score during follow-up. MDS could be excluded in 89% of cytopenic controls. False positive patients had one or several of the MDS-CBC score altered for other reasons (i.e. liver disease, vitamin deficiency, immunosuppressive treatment). A validation cohort tested in another center confirmed the power of the MDS-CBC score.



Event Free Survival (EFS) and Overall Survival (OS) in the MDS cohort according to the 0.632 threshold

Figure 1.

Summary/Conclusion: Overall, this study demonstrates that a simple CBC allows to screen for MDS using a multiparameter score including the newly available parameter Ne-WX. Blood smear examination should be performed in case of a positive score, in patients older than 50 with cytopenia, taking into account the clinical context. This score may improve the efficiency of laboratory practice and could be a valuable help in early screening, diagnosis and management of this hematological disease.

PS1243

AUTOPHAGY IN MYELODYSPLASTIC SYNDROMES: THE ROLE OF HIF-1A/REDD1 MOLECULAR PATHWAY

I. Stergiou[1,*], K. Kambas[1], S. Giannouli[2], D. Aglaia[3], K. Ritis[4], A. Tzioufas[1], M. Voulgarelis[1]

[1]Department of Pathophysiology, School of Medicine, [2]2nd Department of Internal Medicine, National and Kapodistrian University of Athens, [3]Immunology and histocompatibility departement, Laiko General Hospital, Athens, [4]Department of internal Medicine, Democritus University of Thrace, Alexandroupolis, Greece

Background: Hypoxia is a prominent feature of the bone marrow (BM) microenvironment influencing both normal and malignant hemopoiesis. It has been proposed that differential Hypoxia Inducible Factor 1α (HIF-1α) protein expression and programming finely regulate normal haemopoiesis by promoting both quiescence and survival of hemopoietic stem cells (HSCs) within hypoxic BM endosteal niche, as well as proliferation and differentiation of hemopoietic progenitor cells (HPCs) in less hypoxic BM vascular niche. DNA damage response 1 gene (REDD1) is a direct transcriptional target of HIF-1α linking hypoxia to energy regulation and autophagy. Evidence suggests that metabolism and autophagy are developmentally programmed and essential for effective haemopoiesis. A severely altered topobiology of the BM niche in myelodysplastic syndromes (MDS) is indicated by the presence of abnormal localization of immature precursors (ALIP), which is characterized by HPCs displacement towards the more hypoxic intertrabecular space. This abnormal localization could lead to aberrations of the HIF-1α/REDD1 axis and programming of HSPCs, thus compromising haemopoiesis in the context of MDS.
Aims: To study the implication of HIF-1α/REDD1/autophagy axis in differentiation/maturation defects of haematopoietic BM cells of MDS patients.
Methods: BM aspiration samples were collected from 15 newly diagnosed previously untreated MDS patients and 7 age matched controls with non-malignant hematologic disorder. We included patients with all MDS subtypes (9 MDS with multilineage dysplasia, 1 MDS with unilineage dysplasia, 2 RAEB I, 2 RAEB II, 1 MDS dep5q) excluding patients with MDS-RARS subtype. CD34 and myeloid lineage cells were collected with the use of magnetic beads and ficoll bilayer protocol respectively. BM cell populations were determined by FACS analysis using standard gating strategies. HIF1a and REDD1, gene expression was quantified with qRT-PCR and protein expression with FACS analysis. Determination of autophagy was performed using immunofluorescence and immunoblotting for LC3B, with concurrent definition of cell populations with CD34 and MPO staining.
Results: We demonstrated significant *REDD1* overexpression in mRNA level both in CD34 (p=0,005) and myeloid cells (p<0,0001) from MDS patients compared to controls, using qRT-PCR. Expectedly, no difference in *HIF1A* expression in mRNA was observed in these cells. However, both HIF-1α and REDD1 protein expression were significantly higher in MDS patients compared to controls (CD34: p<0,05 for HIF-1α, p<0,01 for REDD1 / myeloid cells: p<0,05 for HIF-1α, p<0,05 for REDD1), as assessed by flow cytometry. Higher REDD1 protein expression was shown in patients with high grade dysplasia as assessed by the Ogata classification system. Moreover, HIF-1α and REDD1 protein coexpression in these cells verified HIF-1α/REDD1 signaling. Finally, increased autophagy was present in CD34 and myeloid cells from MDS patients compared to controls by immunofluorescence study for LC3B with concurrent staining for CD34 and MPO (Figure 1).

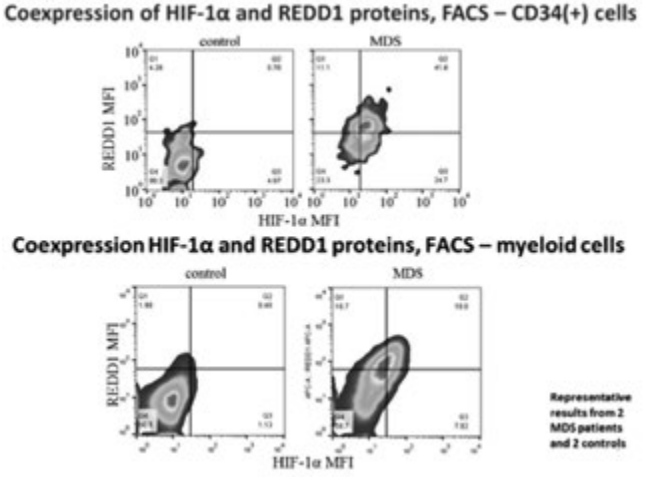


Figure 1.

Summary/Conclusion: Our current results prove activation of the HIF-1α/REDD1 pathway both in CD34 and myeloid cells from patients with MDS compared to controls, leading to increased autophagy in these cell populations. This pathway may lead to dysregulation of differentiation potential for the myeloid cells, unraveling dysregulated autophagy as a new pathogenetic mechanism for the MDS. The exact type of autophagy remains to be clarified.

Myelodysplastic syndromes – Clinical

Background: Upregulation of programmed death ligand-1 (PD-L1) has been observed in patients with myelodysplastic syndrome (MDS). PD-L1 expression on myeloblasts has been associated with MDS transformation to acute myeloid leukemia (AML) and with reduced antileukemic effect of CD8+ cytotoxic T lymphocytes in AML. Anti–PD-L1 antibodies, such as durvalumab, block the interaction of PD-L1 with programmed death-1 (PD-1) and CD80, which reduces the suppressive effects of PD-1 on immune cells. This trial evaluated durvalumab in patients with MDS with disease progression after treatment with hypomethylating agents (HMAs); it began as a durvalumab monotherapy study (described here) and was expanded to include combinations with tremelimumab with/without azacitidine.
Aims: This study evaluated the safety of durvalumab in patients with MDS. Efficacy and pharmacokinetic (PK) end points were also evaluated.
Methods: Adults with pathologically confirmed MDS who were immunotherapy-naive and previously treated with HMAs (with no response, relapse, or inability to tolerate) were included; all patients provided written informed consent. Patients received durvalumab 10 mg/kg intravenously every 2 weeks. Safety evaluations included dose-limiting toxicities (DLTs) and adverse events (AEs). Response was defined by the International Working Group 2006 MDS response criteria. Serum concentrations of durvalumab were evaluated to determine drug exposure and PK parameters.
Results: Forty patients were treated (median age, 73 years [48-96]; 29 men, 11 women; 18 low/intermediate-1 risk; 22 intermediate-2/high risk). Median duration of follow-up was 10.8 months (range 1.2–41.2). All patients had ≥1 AE; 26 (65%) had durvalumab-related AEs; 12 (30%) had grade ≥3 durvalumab-related AEs. The most common treatment-related AEs were diarrhea (n=6; 15%), fatigue (n=6; 15%), increased aspartate aminotransferase (AST) (n=4, 10%) and increased alanine aminotransferase (ALT) (n=4, 10%). The most common grade 3 or greater treatment-related AEs were decreased platelet count (n=2, 5%), pleural effusion (n=2, 5%), and pneumonitis (n=2, 5%). The best overall response was marrow complete remission (mCR) in 7 patients (18%) all of whom had >5% baseline blasts (including 4 in the intermediate-2/high-risk group who had blast decreases from 10% to 5%, 6.8% to 1.8%, 10% to 4%, and 11% to 3%). There were no complete (CR) or partial responses (PR); 8 patients (20%) achieved stable disease (SD; 3 in the low/intermediate-1 risk group; 5 in the intermediate-2/high-risk group). Disease control (CR/PR, mCR and SD) rates were 33% in the low/intermediate-1 risk group and 41% in the intermediate-2/high-risk group. Median overall survival was 23.8 months for the low/intermediate-1 risk group and 8.0 months for the intermediate-2/high-risk group. Median time on treatment was 8.7 months (range 1.2–29.2); 45% discontinued treatment due to progressive disease and 15% had 1 or more related AE leading to treatment discontinuation (1 each of systemic immune activation, increased ALT, increased AST, increased transaminases, nephritis, pleural effusion, pneumonitis, maculo-papular rash). Durvalumab PK results will be presented.
Summary/Conclusion: Durvalumab demonstrated a safety profile consistent with other PD-1/PD-L1 targeting agents with minimal clinical activity in patients with MDS previously treated with HMAs. Based on these results and preclinical studies the trial was expanded to include treatment combi-

nations with tremelimumab with/without azacitidine; this portion of the study is currently ongoing.

PS1245

SINGLE AGENT TALACOTUZUMAB IN ELDERLY HIGH-RISK MDS OR AML PATIENTS FAILING HYPOMETHYLATING AGENTS – RESULTS OF THE SAMBA STUDY BY THE EMSCO NETWORK

U. Platzbecker[1,*], K. Götze[2], J. Krönke[3], U. Oelschlägel[1], F. Schulze[1], K. Sockel[1], J. M. Middeke[1], F. Chermat[4], S. Gloaguen[5], M. Puttrich[6], C. Weigt[6], K. Jersemann[6], P. Fenaux[7], R. Schlenk[8], A. Giagounidis[9], L. Adès[7]

[1]Department of Medicine I, University Hospital Dresden, Dresden, [2]Department of Medicine III, Klinikum rechts der Isar, TUM, Munich, [3]Department of Internal Medicine III, University Hospital Ulm, Ulm, Germany, [4]Groupe Francophone des Myélodysplasies, Paris, France, [5]EMSCO, [6]GWT-TUD GmbH, Dresden, Germany, [7]Service d'Hématologie seniors, Hôpital Saint-Louis, Paris, France, [8]Nationales Centrum für Tumorerkrankungen (NCT), Heidelberg, [9]Dept. for Oncology, Hematology and Palliative Care, Marien Hospital Düsseldorf, Düsseldorf, Germany

Background: AML and MDS patients failing hypomethylating agents (HMA) based therapies have a dismal prognosis highlighting an unmet medical need for these patients. CD123 (Interleukin-3 receptor alpha chain [IL3RA]) is overexpressed in MDS and AML progenitors and seems to be a promising target for immunotherapy. Talacotuzumab (TAL, JNJ-56022473) is an IgG1 monoclonal antibody targeting CD123 preferentially via antibody-dependent cellular cytotoxicity (ADCC). In addition the antibody inhibits IL-3 signaling to impede proliferation of leukemic progenitor cells.
Aims: The SAMBA trial of the German and French MDS study groups within the EMSCO network assessed the safety and efficacy of single agent TAL treatment in patients with higher-risk MDS or AML failing first line treatment with HMAs.
Methods: TAL was given i.v. at a dose of 9 mg/kg once every two weeks (14d ± 2d) for a total of 6 infusions and could be continued in responding patients. The study was accompanied by an immune monitoring via flow-cytometric analysis to investigate the dispersion of T- and NK cells in blood (PB) and bone marrow (BM) at the time of screening and during therapy in comparison with healthy, age matched controls. Of special importance were NK cells, as they are activated by high-affinity binding by the Fc-region of TAL inducing ADCC at targeted cells.

Table 1. Patient characteristics within the SAMBA trial.

Patient characteristics	n = 24
Age (years), median (IQR)	77 (71-90)
Women, n (%)	7 (29)
AML, n (%)	19 (79)
MDS, n (%)	5 (21)
Cytogenetics	
Normal karyotype, n (%)	12 (50)
Aberrant karyotype, n (%)	12 (50)
Complex aberrant (≥3), n (%)	5 (21)
ELN2017 AML risk classification (n=19)	
fav, n (%)	2 (10)
int1/2, n (%)	8 (42.5)
adv, n (%)	9 (47.5)
MDS, n (%)	5 (9)
Haematological parameters at screening	
WBC in /nl, median (range)	2.51 (0.37-12.64)
Hemoglobin in g/dl, median (range)	9.25 (8.05-11.7)
PLT in /nl, median (range)	28 (4-1018)
Neutrophils in /nl, median (range)	0.59 (0.0-5.59)
Lymphocytes in /nl, median (range)	0.80 (0.024-4)
marrow blasts %, median (range)	27 (7-89)
Years from diagnosis to treatment start, median (range)	1.76 (0.61-7.82)
Therapy outcome	
Days on treatment, median (range)	56 (1-282)
Dosage IMP in mg median (range)	653.5 (59-828)
Applied cycles median (range)	3 (0-17)

Results: A total of 24 AML/MDS patients having failed HMA with a median age of 77 years were included (Table 1). Therapy resulted in grade 3/4 infusion related side effects (pneumonia, n=1; infusion-related reaction, n=3; septic shock, n=1) in 4 patients, which led to early study discontinuation. Most frequent severe adverse events observed were infections (38%), cytopenias (9%), cardiac and gastrointestinal (7.5%, each) as well as nervous systems disorders (7.5%) in this older HMA-refractory MDS/AML population. Fourteen patients were assessed for response after 4 infusions and 8 after 6 infusions, respectively. Overall, 5 responders were identified; four AML patients with a marrow partial remission and one with a marrow complete remission; none of the responding patients achieved formal hematological improvement. Duration of response in these patients was short (median 1 month, range 1-6). Three patients are still on treatment based on subjective benefit in two of them despite losing objective response and one MDS patient with disease stabilization. Median survival for the entire cohort of patients is 4.8 months (95%>CI, 2.7–8.7). Prior to therapy, patients already displayed a disturbed immune profile compared to healthy controls. In fact, patients had significantly less mature NK-cells (75% CD56 dim NK-cells in patients vs. 87.9% in controls; $p<0.01$) including a higher expression of inhibiting (NK-KIR) and less activating (NKG2D and DNAM1) NK-cell receptors ($p<0.01$).
Summary/Conclusion: Even though ADCC-mediated targeting of CD123 seems to be a promising treatment option, patients with advanced MDS/AML displayed significant alterations in their immune cell repertoire which may have contributed to the moderate clinical benefit with single agent TAL treatment.

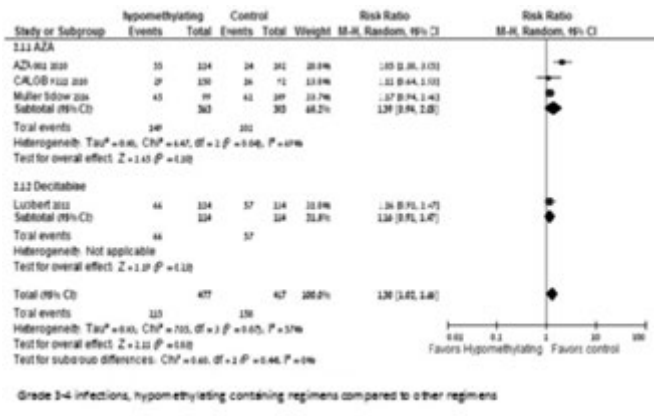
PS1246

HYPOMETHYLATING AGENTS ASSOCIATED INFECTIONS - SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

L. Shargian-Alon[1,2,*], R. Gurion[1,2], P. Raanani[1,2], D. Yahav[2,3], A. Gafter-Gvili[2,4]

[1]Hematology, Rabin Medical Center, Petah Tikva, [2]Sackler School of Medicine, Tel-Aviv, [3]Infectious disease unit, [4]Medicine A, Rabin Medical Center, Petah Tikva, Israel

Background: Hypomethylating agents (HMA) are considered the standard of care for elderly patients with higher-risk myelodysplastic syndrome (MDS), who are not candidates for allogeneic stem cell transplantation, due to survival benefit. HMA are also considered as an emerging treatment option for acute myeloid leukemia (AML) patients who are not eligible for intensive chemotherapy. Although HMA are regarded as safe and are usually administrated in the outpatient setting, infectious complications remain a main concern. Data in the literature regarding the effects of HMA on the risk of infection seem to be poorly documented and heterogeneous.
Aims: To assess the risk of infectious complications among MDS and AML patients treated with HMA.
Methods: We conducted a systematic review and meta analysis of all randomized controlled trials (RCTs) comparing HMA containing regimens (alone or combined with other chemotherapeutic agents) to any other regimen administered to patients with MDS or AML.
A comprehensive search encompassing *the Cochrane Library*, MEDLINE, conference proceedings, and databases of ongoing trials was conducted until February 2018. Two reviewers appraised the quality of trials and extracted data. Primary outcome was grade 3 to 4 infections; Secondary outcomes included: febrile neutropenia, fever of unknown origin (FUO), neutropenia grade 3-4, infection related mortality and all-cause mortality. Relative risks (RRs) with 95% confidence intervals (CIs) were estimated and pooled. A fixed effect model was used to pool data unless there was significant heterogeneity, in which case a random effects model was used.
Results: We identified 9 trials published between the years 2002 to 2016 and randomizing 2184 patients that fulfilled the inclusion criteria and reported relevant outcomes. Three trials included patients with MDS, four trials included AML patients and two included both. The HMA arm consisted of azacitidine in five trials and decitabine in four trials. Six trials evaluated patients in the first line setting, and HMA was given as a standalone treatment. The control arm consisted of best supportive care (BSC) in three trials. In additional three trials control arm consisted of either BSC, low dose cytarabine or intensive chemotherapy. HMA were associated with an increase in grade 3-4 infections, compared to the comparator [RR 1.30 (95% CI 1.02-1.66), Figure 1]. This was true for the whole cohort and for the subgroup of patients older than 60 years [RR 1.19 (95% CI 1.01-1.39)]. In addition, there was an increase in the rate of FUO events and neutropenia [RR 1.48 (95% CI 1.15-1.92) and RR 1.48 (95% CI 1.22-1.78), respectively]. There was no difference in fatal infections [RR 1.44, 95% CI 0.72 to 2.89]. Yet, treatment with HMA reduced all-cause mortality [RR 0.74, 95% CI 0.66-0.88].



Grade 3-4 infections, hypomethylating containing regimens compared to other regimens

Figure 1.

Summary/Conclusion: Treatment with HMA was associated with an increase in grade 3-4 infections rate. Although there was no difference in infection related mortality, all-cause mortality at 6 months was significantly lower among patients treated with HMA. Thus, the overall survival advantage of HMA is achieved despite the higher toxicity profile of these drugs, and probably due to a better effect on disease control.

PS1247

RESPONSE TO HYPOMETHYLATING AGENTS IMPROVES LONG-TERM OUTCOMES FOR LOWER-RISK PATIENTS WITH MYELODYSPLASTIC SYNDROME IN CASE-MATCHED COHORTS

[1]Hematology/Oncology, Kyungpook National University Hospital, Daegu, [2]Hematology/Oncology, Chonnam National University Hwasun Hospital, Chonnam, [3]Hematology/Oncology, Busan National University Hospital, [4]Hematology/Oncology, Inje University Busan Baik Hospital, Busan, [5]Hematology/Oncology, Chunnam National University Hospital, Chonnam, [6]Hematology/Oncology, Chungnam National University Hospital, Chungnam, [7]Hematology/Oncology, Kosin University College of Medicine, Busan, [8]Hematology/Oncology, Gyeongsang National University Hospital, Jinju, [9]Hematology/Oncology, Ulsan University Hospital, Ulsan, [10]Hematology/Oncology, Daegu Catholic University Hospital, Daegu, Korea, Republic Of

Background: Hypomethylating agents (HMAs) are also used to treat patient with lower-risk myelodysplastic syndrome (LR-MDS) relapsing after best supportive care (BSC). However, little is known about the predictive factors using HMAs and the survival benefit of HMAs for LR-MDS.
Aims: This study evaluated the factors affecting the use of HMAs and compared the long-term outcomes after matching baseline clinical factors between BSC and HMA groups
Methods: The data of 353 patients diagnosed with International Prognostic Scoring System (IPSS) lower risk (low and intermediate-1) between Oct 1992 and Jul 2013 were retrospectively analyzed. HMAs were given continuously until progression. The response was assessed using the International Working Group response criteria for MDS. The cumulative incidence of HMA treatment was analyzed using Gray's test considering non-relapse death as competing event.
Results: HMAs were administered in 243 patients, while 110 patients were treated with BSC. Among 243 patients treated with HMAs, azacitidine and decitabine were administered in 191 patients (78.6%) and 52 (21.4%), respectively. HMAs were administered median 5 cycles (range 1-26 cycles) and overall response was achieved in 104 patients (42.8%) including 30 complete response (12.4%), 15 partial response (6.2%), and 59 hematologic improvement (24.3%). The cumulative incidence of HMA treatment was significantly lower in very low risk groups by revised IPSS (IPSS-R) or WHO prognostic scoring system (WPSS), and category 1 by Low Risk Prognostic Scoring System (LR-PSS). Factors using HMA treatment were intermediate or poor cytogenetic risk (OR 0.53, p=0.001), intermediate/high risk group by WPSS (OR 1.55, p=0.001), and category 3 by LR-PSS (OR 1.95, p<0.001) in multivariate analysis. The 3-year overall survival (OS) rate in 243 patients was 69.1±6.5%, 47.4±6.1%, and 46.3±4.7% in BSC group, HMA responder, and HMA non-responder, respectively (p=0.023). Among 162 case-matched cohorts, 3-year OS rate was comparable between BSC group (67.1±7.4%) and HMA responder (58.1±10.8%), while that of HMA non-responder was low (32.2±7.2%, p<0.001). In the IPSS lower risk patients, following factors adversely affected OS in the multivariate analysis: age (HR 1.03, p=0.001), ECOG performance status ≥ 2 (HR 2.65, p<0.001), higher risk group by IPSS-R (HR 2.69, p<0.001) or WPSS (HR 1.63, p=0.022), and HMA non-responder (HR 3.79, p=0.001). In the case-matched cohorts, age (HR 1.03, p=0.018), ECOG performance status ≥ 2 (HR 2.47, p=0.024), low platelet < 50×10^3/L (HR 2.30, p=0.009), higher risk group by IPSS-R (HR3.10, p<0.001), and HMA non-responder (HR 3.01, p=0.001) were associated with inferior OS rate.
Summary/Conclusion: Our study demonstrated that the higher risk groups by WPSS or LR-PSS among IPSS lower risk patients showed an increased risk of using HMAs. Although long-term outcomes for the patients treated with HMAs shows an inferior OS rate, the OS rate of HMA responders among case-matched cohorts showed an improved OS rate similar to BSC group.

PS1248

A SYSTEMATIC REVIEW PROVIDES LIMITED CLINICAL EVIDENCE FOR ADDITIONAL EFFICACY OF G-CSF + ESA COMPARED TO FULL-DOSE ESA ALONE IN THE TREATMENT OF ANEMIA IN PATIENTS WITH LOW-RISK MDS

L. Affentranger[1,*], J. Bohlius[2], N. Bonadies[1]

[1]Department of Haematology and Central Haematology Laboratory, Inselspital, Bern University Hospital, University of Bern, [2]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland

Background: Myelodysplastic syndromes (MDS) are a group of heterogeneous hematopoietic stem cell disorders characterized by dysplasia and peripheral cytopenia with a propensity to evolve towards acute myeloid leukemia (AML). The treatment of patients with low-risk MDS includes the administration of hematopoietic growth factors like erythropoiesis stimulating agents (ESA) eventually in combination with granulocyte colony stimulating factor (G-CSF). However, the evidence on the additional effect of G-CSF on erythropoiesis remains controversial.
Aims: The aim of this systematic review was to identify the level of evidence for treatment of anemia with the combination of G-CSF and ESA in low-risk MDS patients.

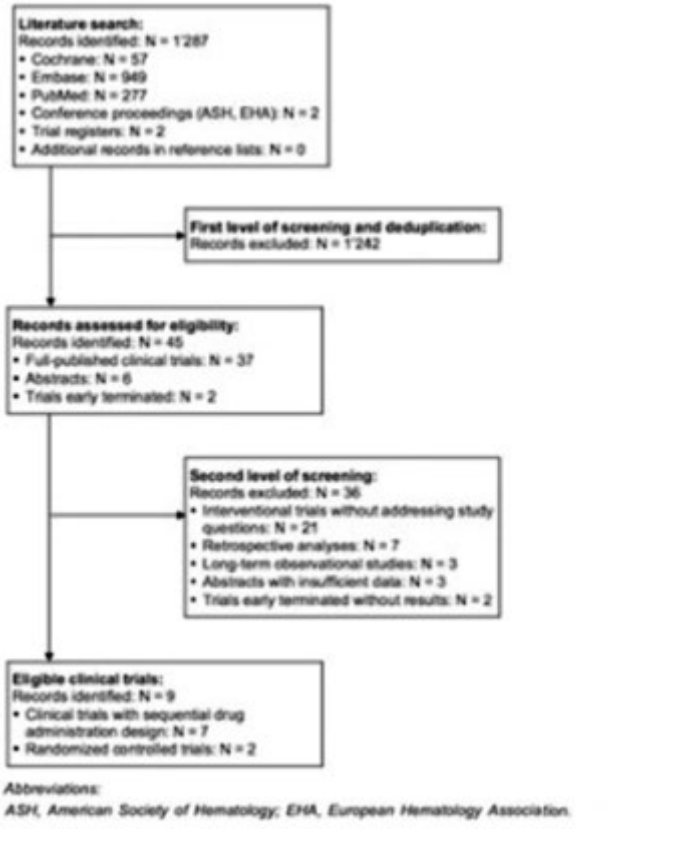

Figure 1. Flow chart of the systematic literature search and the study selection process.

Methods: We performed a systematic literature review by examining the

Cochrane Library, *Embase* and *PubMed* databases and checked additionally ongoing trials as well as conference abstracts (Figure 1). Randomized controlled trials (RCTs) investigating ESA + G-CSF versus ESA alone as well as prospective trials investigating sequential administration of ESA + G-CSF after ESA alone were considered. The primary endpoint of interest was erythroid response according to the *International Working Group* (IWG) criteria and secondary endpoints included duration of response, quality of life (QoL), progression and safety.
Results: We could identify nine eligible publications. Only two small RCTs showed erythroid response rates (ERR) ranging from 65-73% in patients receiving ESA + G-CSF compared to 33-40% in patients treated with standard doses of ESA only (up to 40'000 IU recombinant human erythropoietin (rhEPO) per week). In seven studies with a sequential drug administration design, ERR ranged from 13-71% after treatment with standard- or full-dose ESA (60'000-80'000 IU rhEPO per week) alone and from 39-74% after the combination therapy with G-CSF. Thus overall ERR increased by 0-42% after the administration of combination therapy in these non-randomized clinical trials. In all publications, secondary endpoints were not evaluable due to missing data.
Summary/Conclusion: Two small RCTs showed a clinical efficacy for the addition of G-CSF to standard-dose ESA in low-risk MDS patients. However, evidence for the addition of G-CSF to full-dose ESA is only available from non-randomized clinical trials with sequential drug administration design. We conclude that the number of clinical trials is low, the sizes of study populations small and the study designs not fully appropriate to provide undisputable evidence that G-CSF+ESA provides additional efficacy compared to full-dose ESA alone in the treatment of anemia in low-risk MDS patients. Evidence from properly designed RCTs on the efficacy of G-CSF added to full-dose ESA as well as information on duration of response, QoL, progression and safety are currently lacking and desirable for the future.

PS1249

LOW RISK MDS WITHOUT RING SIDEROBLASTS. CLINICAL AND BIOLOGICAL CHARACTERIZATION FROM THE SPANISH GROUP OF MDS

Background: Low risk myelodysplastic syndromes (LR-MDS) are a heterogeneous group of patients poorly characterized. The subgroup of patients with ring sideroblasts (RS) shows a homogeneous clinical and genetic profile and novel therapeutic approaches had been recently incorporated (Luspatercept). Nevertheless, in non-RS patients the clinical-biological characteristics and outcome are heterogeneous. Accurate clinical and biological knowledge of this large group of patients is mandatory to improve the therapeutic approaches in the near future.
Aims: Our Aim was to analyze baseline characteristics of clinical and biological parameters involved in overall survival (OS) among LR-MDS patients without RS.
Methods: We performed a multicenter research from the Spanish MDS registry. Data from 2215 (low and int risk according to IPSS and very low, low and Int risk according to R-IPSS) LR-MDS patients without RS were retrospectively analyzed. Funding PI17/01741; GRS 1349/A/16; GRS 1179/A/15; and CM17/00171.
Results: Median age at diagnosis was 73.5 years (p25 – p75 67-81) and 59% of patients were male. MDS was secondary in 7,8%. According to WHO2008 classification: 55.9% were RCUD/RCMD, 7,3% 5q- syndrome, 2% RAEB, 19.7% MDS/MPS and 0.8% unclassifiable MDS + other subtypes, 13.4% of patients are under morphological review. At presentation, median and range (p25-p75) of Hemoglobin, neutrophils and platelets at diagnosis was 10.6 g/dL (9.3-12.1), 2,35x10^9/L (1,4-3,97) and 151x10^9/L (92-235), respectively. Only 4.2% of patients presented peripheral blasts at diagnosis. Regarding bone marrow (BM) blast, a median of 1.6% was detected (p25-p75 0,5-3,0). Bone marrow cellularity was hypercellular in 50.6% of patients. Median ferritine level was 180ng/mL (p25-p75 76-382). According IPSS 64,7% and 35,3% of patients were low and intermediate-1 risk respectively. In addition, most of the patients were in the low risk R-IPSS (89,2% very low/low) and only 10,8% of patients were intermediate R-IPSS risk. Among 1943 patients with data available and with a median follow up of 32 months, median overall survival was 5,7 years (p25-p75 2,5-11,4). Regarding OS, older age at diagnosis(p<0.001), male gender (p<0.001), secondary MDS (p=0.024), hypercellular BM (p<0.001), Hb <10g/dL (p<0.001), Plt<100x10^9/L (p=0.002), the presence of PB blasts (<0.001), >5% of BM blasts (p=0.009), ferritine level >1000 mg/dL (p=0.015), int IPSS(<0.001), int R-IPSS (<0.001), poor cytogenetics by IPSS (<0.001) and poor and very poor cytogenetics according to R-IPSS (0.012) adversely impact on survival in this subset of patients. Nevertheless, in the multivariate analysis (Table 1), only male gender, secondary MDS, Hypercellular BM, Hb<10g/dL, Plt<100x10^9/L and PB Blast retained statistical significance.

Table 1.

	Sig.	HR	95,0% CI	
			Inf.	Sup.
Male gender	**0,000**	**1,971**	**1,645**	**2,361**
Secondary MDS	**0,017**	**1,489**	**1,073**	**2,066**
Hypercellular BM	**0,027**	**1,215**	**1,023**	**1,444**
Hb<10g/dL	**0,000**	**1,691**	**1,346**	**2,126**
Plts<100x10^9/L	**0,045**	**1,508**	**1,009**	**2,253**
PB Blast>2%	**0,000**	**2,823**	**1,874**	**4,254**
Ferritine level (>1000ng/mL)	0,46	1,138	0,807	1,605
BM Blast>5%	0,985	1,002	0,794	1,265
IPSS_Category	0,178	1,143	0,941	1,387
IPSSr_Category	0,26	1,09	0,938	1,267

Summary/Conclusion: Clinical and biological characteristics of LR-MDS patients without RS are necessary in order to improve our knowledge in this subset of patients. A better understanding could help us to personalize therapeutic options in this heterogeneous subset of patients.

PS1250

SEROTONIN RECEPTOR TYPE 1B CONSTITUTES A THERAPEUTIC TARGET FOR MDS AND CMML

A. Banus Mulet[1,2,*], A. Etxabe[1,2], J.M. Cornet Masana[3,4], M.C. Lara Castillo[1], M.A. Torrente Marchante[5], J. Esteve[1,4,5,6], R.M. Risueño[1]

[1]Institut de Recerca Contra la Leucèmia Josep Carreras, [2]Faculty of Pharmacy, Barcelona university, Barcelona, [3]Institut Germans Trias i Pujol, Badalona, [4]Faculty of Medicine, Barcelona university, [5]Department of Hematology, Hospital Clínic , [6]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain

Background: Myelodysplastic syndromes (MDS) and chronic myelomonocytic leukemia (CMML) are chronic myeloid clonal neoplasms. To date, the only potentially curative therapy for these disorders remains allogeneic hematopoietic progenitor cell transplantation (HCT), although patient eligibility is limited due to high morbimortality associated with this procedure coupled with advanced age of most patients. Moreover, HCT is followed by a high relapse incidence. Thus, new therapeutic approaches are urgently

needed. Previously, dopamine receptors (DRs) and serotonin receptors type 1 (HTR1s) were identified as a cancer stem cell therapeutic target in acute myeloid leukemia (AML). Here we interrogated the function of DRs and HTR1s in MDS and CMML.

Aims: Our main goal was to determine the function of DRs and HTR1s in the survival of both MDS and CMML cells. By studying the expression of these receptors and evaluating the effect of specific antagonist at different levels. The expression of HTR1s and DRs was interrogated in MDS (n=72) and CMML (n=19) primary samples by flow cytometry using specific surface antibodies for DRs and HTRs simultaneously with the live-dead discriminator dye 7AAD and an anti-human CD45 antibody for blast identification. The cytotoxicity induced by specific antagonists was also assessed by flow cytometry. Clonogenic assays were performed in CMML primary samples cells after 18-hour treatment with antagonists followed by 14-day culture in complete Methocult medium.

Methods: The expression of HTR1s and DRs was interrogated in MDS (n=72) and CMML (n=19) primary samples by flow cytometry using specific surface antibodies for DRs and HTRs simultaneously with the live-dead discriminator dye 7AAD and an anti-human CD45 antibody for blast identification. The cytotoxicity induced by specific antagonists was also assessed by flow cytometry. Clonogenic assays were performed in CMML primary samples cells after 18-hour treatment with antagonists followed by 14-day culture in complete Methocult medium.

Results: HTR1s and DRs were differentially expressed in MDS and CMML (>3 and >4 fold of change, respectively) in patient bone marrow samples compared to healthy donors. Moreover, treatment with HTR1B antagonists significantly reduced cell viability in primary samples from both MDS and CMML. In addition, HTR1B antagonists showed a significant effect in clonogenicity capability of CMML cells. Moreover, HTR1B antagonist showed a synergistic cytotoxic effect with currently approved hypomethylating agents.

Summary/Conclusion: These results suggest that HTR1B might constitute a novel therapeutic target for MDS and CMML. Due to its druggability, the clinical development of new regimens based on HTR1B antagonists is promising.

PS1251

INTENSIVE CHEMOTHERAPY (IC) IS MORE EFFECTIVE THAN HYPOMETHYLATING AGENTS (HMA) FOR THE TREATMENT OF YOUNGER PATIENTS WITH MYELODYSPLASTIC SYNDROME (MDS) AND ELEVATED BONE MARROW BLASTS

P. Strati[1,*], G. Garcia-Manero[1], T. Kadia[1], G. Borthakur[1], M. Konopleva[1], N. Daver[1], C. DiNardo[1], N. Short[1], M. Yilmaz[1], K. Naqvi[1], S. Pierce[1], J. Cortes[1], H. Kantarjian[1], F. Ravandi[1]

[1]MD Anderson Cancer Center, Houston, United States

Background: Younger patients with high risk MDS are commonly treated with IC or enrolled in clinical trials investigating IC. The AZA-001 trial has shown a survival advantage for patients with high-risk MDS treated with HMA as compared to IC. However, this study was conducted mainly in an older population.

Aims: We retrospectively analyzed the characteristics and outcomes of patients with MDS or MDS/myeloproliferative neoplasms (MPN), younger than 60 years of age, with ≥ 10% bone marrow blasts who received frontline treatment with HMA or anthracycline-cytarabine-based IC at our institution between 10/1993 and 12/2017.

Methods: IC was defined as a regimen including both anthracyclines and > 1 g/m^2/daily of cytarabine. Response categories were assessed using the modified International Working Group (IWG) criteria. Response duration (RD) was defined as time from achievement of response until progression or relapse. Patients who did not progress or relapse were censored at the date of death or last follow-up.

Results: One-hundred and six patients were included in the study, 57 treated with HMA and 49 with IC. Patients treated with IC were significantly younger (45 vs 55 years, p=0.03), had a higher percentage of bone marrow blasts (15% vs 13%, p<0.001), and were less likely to have unfavorable cytogenetics (27% vs 46%, p=0.05), a gene mutation (31% vs 60%, p=0.003) or a diagnosis of MDS/MPN (2% vs 21%, p=0.003). Use of IC was associated with shorter time to response (1 months vs 2 months, p<0.001) and higher overall response rate (ORR)(82% vs 60%, p=0.02). On univariate analysis (UA) age younger than 50 (p=0.03) and use of IC (p=0.02) were associated with ORR, but on multivariate analysis (MVA) only use of IC maintained its association (OR 4.3, 95% CI 2-9.1; p<0.001). Forty-seven (96%) patients treated with IC and 56 (98%) treated with HMA discontinued treatment (p=0.60), after a median time of 4 and 5 months, respectively (p=0.74). Patients receiving HMA tended to discontinue treatment as a consequence of progression (58% vs 39%, p=0.07), whereas rates of discontinuation secondary to early death (4% vs 10%, p=0.25) or toxicity (2% vs 8%, p=0.18) were comparable; 31% of patients on HMA and 33% on IC proceeded to stem cell transplant (SCT). After a median follow-up of 15 months (range, 1-178 months), 38 (51%) out of 74 patients lost their response, and median response duration (RD) was 19 months (range, 1-166 months). Factors associated with longer RD on UA were lack of unfavorable cytogenetics (p=0.04), consolidation with SCT in first remission (p=0.009) and use of IC (26 months vs 11 months, p=0.03) (Figure 1); on MVA, use of IC maintained its association (HR 2.9, 95% CI 1.4-5.8, p=0.03). Eight (8%) patients transformed to acute myeloid leukemia during frontline treatment, 7 (12%) on HMA and 1 (2%) on IC (p=0.07). At most recent follow-up, 65 (61%) patients died, median overall survival was 21 months (range, 1-178 months) and was significantly longer for patients treated with IC (43 months vs 15 months; p=0.05) (Figure 1).

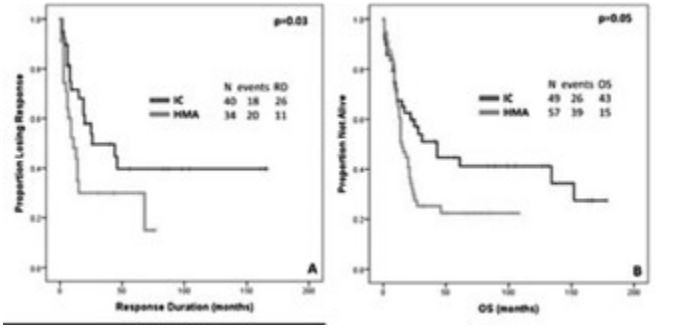

Figure 1.

Summary/Conclusion: IC is more effective than HMA for younger patients with MDS and bone marrow blasts ≥ 10%, irrespective of other baseline characteristics. Strategies combining targeted agents with either HMA or IC should be investigated, to determine whether this advantage will be maintained.

PS1252

FETAL HEMOGLOBIN INDUCTION DURING DECITABINE TREATMENT OF ELDERLY MDS/AML PATIENTS: A POTENTIAL DYNAMIC BIOMARKER FOR OUTCOME

J. Stomper[1,*], G. Ihorst[2], S. Suciu[3], P. Sander[1], H. Becker[1], P. Wijermans[4], E. Bissé[5], R. Claus[6], M. Lübbert[1]

[1]Department of Hematology, Oncology, and Stem-Cell Transplantation, [2]Clinical Trials Unit, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany, [3]EORTC Headquarters, Brussels, Belgium, [4]Department of Hematology, Haga Hospital, The Hague, Netherlands, [5]Institute for Clinical Chemistry and Laboratory Medicine, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, [6]Department of Internal Medicine, Medical Center Augsburg, Augsburg, Germany

Background: Hematologic responses to DNA-hypomethylating agents (HMA) in MDS/AML are often delayed and not attained by all patients. Fetal hemoglobin (HbF) is among the potential novel outcome predictors for epigenetic treatments, being induced *in vitro* and *in vivo* by HMAs and HDAC inhibitors (Press *et al*., Leuk. Lymph. 2017); recently, we could demonstrate that HbF elevation already prior to decitabine (DAC) treatment was associated with superior outcome of MDS/AML patients (Lübbert *et al*., Br. J. Haematol. 2017).

Aims: We now asked whether early HbF induction during DAC treatment also had predictive value. Additionally, we sought to investigate the potential of DAC for *in vitro* induction of erythroid differentiation and HbF expression.

Methods: 16 MDS and 37 AML patients enrolled on two clinical trials, the 06011 EORTC-GMDSSG phase III trial of higher-risk MDS, and the 00331 phase II trial of older, non-fit AML patients, received DAC (15 mg/m^2 TID×3 days / 42 day cycle). After 4 courses, AML patients attaining CR, PR, or an antileukemic effect continued with DAC maintenance treatment at 20 mg/m^2. HbF levels were measured in peripheral blood erythrocytes by HPLC before treatment and sequentially, i.e. after the end of each treatment course. HbF > 1.0% was considered induced. *In vitro* effects of DAC were investigated in two myeloid leukemia cell line models with bilineage differentiation potential (K562, HEL).

Results: Compared to the median pre-treatment HbF of 0.8%, we observed overall induction to 1.1% after course 2 (the first on-treatment time point

with robust HbF induction), and, in patients achieving CR or PR as best overall response, a median HbF of 1.9% at this time point compared to 0.8% in patients not attaining CR/PR (p=0.015). Correlation analyses revealed an association between% HbF after DAC course 2 and responses of the different hematopoietic lineages after course 4. For platelet counts, Spearman's correlation coefficient r_s was 0.49 (p=0.01); for neutrophils, r_s=0.35 (p=0.08); for Hb, r_s=0.36 (p=0.08); for% bone marrow blasts, r_s=-0.48 (p=0.03). In addition, HbF induction after 2 courses was associated with early platelet-doubling (p=0.006). In MDS patients, induced HbF after course 2 was associated with longer median overall survival compared to non-induced HbF: 22.9 vs. 7.3 months (hazard ratio [HR] 0.21 [95% CI 0.05 – 0.87], p=0.03), progression-free survival was 7.7 vs. 2.4 months (HR 0.32 [95% CI 0.10 – 1.10], p=0.07), AML-free survival was 13.1 vs. 7.6 months (HR 0.42 [95% CI 0.13 – 1.38], p=0.15). For AML patients, median OS from end of course 2 was 20.0 vs. 10.4 months (HR 0.61 [95% CI 0.21 – 1.75], p=0.35), PFS was not determined. Linear regression analyses, in conjunction with FISH analyses, strongly suggested that HbF induction observed after 4 treatment courses occurred preferentially in the emerging non-clonal erythroid cells. *In vitro* DAC treatment of K562 and HEL cells resulted in induction of an erythroid (but not megakaryocytic) differentiation program, of gamma globin expression, and of HbF tetramer formation.

Summary/Conclusion: HbF induction during DAC treatment was successfully modelled in myeloid cell lines, was associated with early platelet doubling, was predictive for subsequent objective responses and, in MDS patients, for longer survival. Thus HbF may provide a dynamic biomarker during HMA therapy of MDS/AML. This is addressed prospectively within the EORTC trial AML21 ("inDACtion vs. induction", NCT0217287).

PS1253

CLINICAL IMPACT ON THE THERAPEUTIC STRATEGY ADAPTED TO THE MUTATIONAL PROFILE IN PATIENTS WITH MYELODYSPLASTIC SYNDROME ASSOCIATED WITH DEL(5Q)

C. Alarcón-Payer[1,*], F. Hernández Mohedo[2], A. Jiménez Morales[1], M. Bernal Sánchez[3], Z. Mesa Morales[2], J. Badiola González[2], F. Ruiz Cabello[3], A. Romero Aguilar[2], M. Jurado Chacón[2]

[1]Servicio de Farmacia, Hospital Universitario Virgen de las Nieves, [2]UGC Intercentro Hematología y Hemoterapia, Hospitales HUVN-PTS, [3]Servicio de Análisis Clínicos e Inmunología, Hospital Universitario Virgen de las Nieves, Granada, Spain

Background: According to OMS-2016, myelodysplastic syndrome (MDS) associated with del(5q) is manifested by a transfusion-dependent progressive bone marrow failure, with Lenalidomide acting as the intended drug to treat this syndrome. Recent attention has received the mutational profile analysis using massive parallel sequencing also called as new generation sequencing (NGS) to predict lenalidomide response in function of the presence or absence of a high-risk mutational profile.

Aims: To analyze the clinical impact of the directed risk-stratification therapy and to evaluate the clinical benefit associated to the discontinuation of the Lenalidomide treatment due to side effects or intolerance.

Methods: Three-year prospective observational study on 69 cases of MDS, 17 of them with del(5q). Mutational profile analysis using a NGS prior to Lenalidomide treatment decision-making, with TP53 mutation as ultra-high risk profile for discouraging its use. Treatment discontinuation was studied in those candidates with side effects or intolerance. The variables considered in this study were: beginning of treatment, Lenalidomide mean dose, ending of treatment and beginning of discontinuation, side effects, time after discontinuation, evaluation of the drug withdrawal response according to IWG-MDS (Chenson *et al.* 2006), and cost savings.

Results: 69 MDS cases were analyzed by NGS (58% male and 42% female). According to the myeloid panel, the mutational profile was classified as: high-risk (3,6%), low-risk (12,7%), intermediate risk (10,9%), very high-risk (4,2%) and very low-risk (24,6%). 17 cases were detected as MDS associated to del(5q) (24,6%) and 17,6% of them showed positive TP53 mutation and were treated with hypomethylating agents instead of Lenalidomide meanwhile 11,7% of them showed DNMT3A, ASXL1, SF3B1 and TET2 mutations. 64,7% of the cases were treated with Lenalidomide, the treatment were discontinued in 54,5% of them due to side effects and the dose reduced in 18% due to intolerance. The reported side effects were: Grade 4 neutropenia, rhabdomyolysis, erythematous reactions and haemolytic crisis. 100% of patients in which Lenalidomide was discontinued due to side effects, maintained complete haematological and cytogenetic response, reaching a mean monitoring time of 12 months since the withdrawal of Lenalidomide. The cost saving associated to the discontinuation of Lenalidomide 10mg was 48.000 euros per patient per year.

Summary/Conclusion: The use of NGS allows selecting the mutational profile of each patient, resulting in a change in the therapeutic decision-making, the selection of more cost-effective drugs and a directed and personalized treatment. Discontinuation of Lenalidomide, due to side effects or intolerance, involves a clinical benefit to those patients who maintain a complete haematological response after interruption of the treatment.

PS1254

CHRONIC MYELOMONOCYTIC LEUKEMIA TREATED WITH 5-AZACYTIDINE. RESULTS FROM THE HELLENIC 5-AZACYTIDINE REGISTRY

Background: Chronic myelomonocytic leukemia (CMML) has been classified as a myelodysplastic syndrome/myeloproliferative neoplasm since 2002. Treating CMML remains challenging, partly due to the lack of large CMML-specific clinical trials. Supportive treatment is usually offered to lower-risk patients while hypomethylating agents (HMA) have been approved for higher-risk patients, but their effectiveness and safety have not been thoroughly studied. Approval studies for the use of HMAs in MDS included only a few patients with CMML, and very few and small-sized phase I/II CMML-specific studies with HMAs are available, showing overall response rates varying from 35% to 69% and overall survival (OS) from 12 to 37 months. Moreover, the literature lacks real-world data on the use of HMAs in patients with CMML.

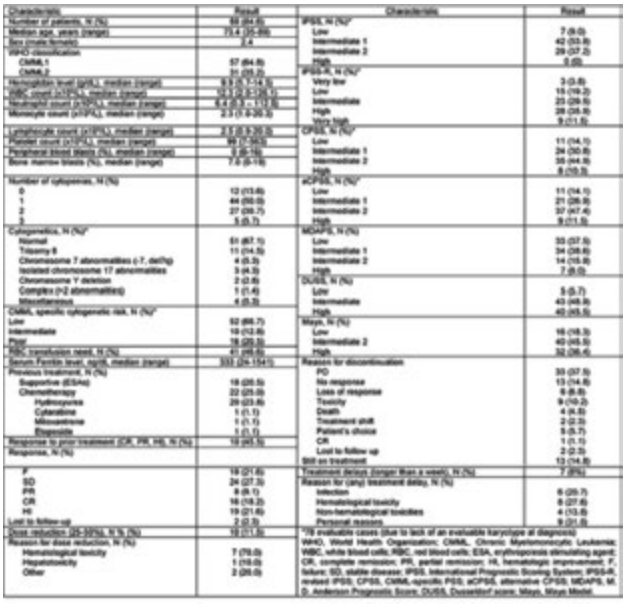
Aims: To provide real-world data on treatment response and survival in a cohort of patients with CMML treated with 5-azacytidine (5AZA) and to evaluate the implementation of the currently available risk stratification systems to our population.

Methods: We retrospectively recorded the characteristics of patients with CMML treated with 5AZA through the Hellenic 5-azacytidine registry. The International Prognostic Scoring System (IPSS), the revised IPSS (IPSS-R), the CMML-specific PSS (CPSS), the alternative CPSS (aCPSS), the M. D. Anderson Prognostic Score (MDAPS), the Dusseldorf score for CMML (DUSS), and the Mayo Model were used for risk stratification. 5AZA was administered as monotherapy subcutaneously at 75 mg/m^2/day for 7 days every 28 days. Responses were assessed per the modified 2006 International Working Group response criteria for MDS. Complete remission (CR), partial remission (PR), and hematological improvement (HI) were defined as response and stable disease (SD) or failure (F) as no response. IBM SPSS statistics, v23.0 (IBM Corporation, N. Castle, NY, USA) was used for statistical analysis.

Results: The baseline demographic and hematologic characteristics of 88 patients with CMML are listed in Table 1. Sixty-six (75%) patients were treatment-naïve, the rest being previously treated mostly with hydroxyurea with a variable response. The median number of 5AZA cycles was 8 (1-40), and most patients experienced no treatment delays. Infections, hematological and non-hematological toxicity were the major causes of treatment delays and dose reductions. Response to 5AZA is shown in Table 1. The overall response rate was 48.9%. The median duration of response was 12.1 months (95% CI, 9.0-15.2). Response did not differ between patients with CMML1 and CMML2 (X^2, p=0.82).

The median OS was 29.7 months and the median survival after 5AZA failure was 4.5 months. CMML2, anemia (<10 g/dL), circulating blasts, high serum ferritin level and thrombocytopenia were correlated to lower OS, but circulating blasts and ferritin level were the only factors retaining their statistical significance in multivariate analysis (HR, 3.47, p=0.014 and 2.84, p=0.022 respectively). All risk stratification systems could predict OS, but DUSS and aCPSS were better implemented to our group of patients.

Table 1. Patient characteristics and results.



Summary/Conclusion: Patients with CMML are underrepresented in large clinical trials on HMAs in MDS. Several CMML-specific prognostic models have been developed but none has been universally adopted. Our study supports the use of 5AZA in patients with CMML providing real-world data in the largest – to our knowledge – cohort of patients homogeneously treated with 5AZA, since response rates were rather high (48.9%).

PS1255

OUTCOME OF PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND STABLE DISEASE DURING TREATMENT WITH AZACITIDINE: A REPORT FROM GRUPPO ROMANO MIELODISPLASIE (GROM) AND RETE EMATOLOGICA LOMBARDA (REL)

Background: Treatment with azacitidine (AZA) in MDS may improve overall survival (OS) even in patients who do not necessarily achieve complete or partial remission (CR or PR), raising the question whether bone marrow (BM) response should be considered the only therapeutic goal. In this regard, it is therefore not clear whether patients who achieve stable disease (SD) after 4-6 cycles of therapy should stop or continue the treatment.
Aims: We retrospectively evaluated the outcome of 100 high risk MDS patients with SD according to International Working Group (IWG) 2006 criteria, after 4 cycles of therapy.
Methods: Patients from the two Italian regional networks GROM and REL were included. Patients were diagnosed with MDS according to 2008 WHO criteria: 65% had Refractory anemia with excess blasts-2 (RAEB-2), 21% Refractory anemia with excess blasts-1 (RAEB-1), 9% Refractory cytopenia with multilineage dysplasia (RCMD), 2% Refractory anemia with ring sideroblasts (RARS), 3% Refractory cytopenia with unilineage dysplasia (RCUD). Median age was 70 years (range 33-85), 59% were male. Median follow up was 36 months (range 6-217) and 40% of patients progressed in acute myeloid leukemia. Karyotype was evaluable in 97 patients and, according to the revised International Prognostic Scoring System (IPSS-R) cytogenetic scoring system, 58% had good risk, 16% intermediate-risk, 12.5% poor risk and 13.5% very poor risk karyotype, corresponding to higher-risk disease by IPSS-R (9.5% intermediate, 51.5% high, and 39% very high risk). AZA was administered at the conventional dose of 75 mg/m^2 daily for 7 days per month. The median number of cycles delivered was 11 (range 4-78). After 4 cycles of therapy, 16 patients did not continue treatment for medical decision or patient's wishes.
Results: Thirty-one (37%) out of 84 patients who continued AZA treatment, improved response (IR) after a median number of 8 cycles (range 5-13). IR were: 6 CR, 1 marrow CR (mCR), 8 PR and 16 hematological improvement (HI). IR rate was significantly higher in patients who continued treatment after 4 cycles and received 10 or more cycles of therapy (p=0.002 and 0.001, respectively). Evolution in AML was significantly more frequent in patients in SD compared with those who obtained IR (82.5% vs 17.5% respectively, p=0.02). Median OS was 19.7 months. In univariate analysis, patients who received more than 10 cycles of AZA, those who went on treatment with AZA after 4 cycles and those who achieved IR had significantly longer OS duration (p=0.00002 Figure 1, 0.02 and p=0.005, respectively). In multivariate analysis 10 or more cycles of AZA and IR were significantly associated with prolonged OS (p<0.0001 and 0.05, respectively).

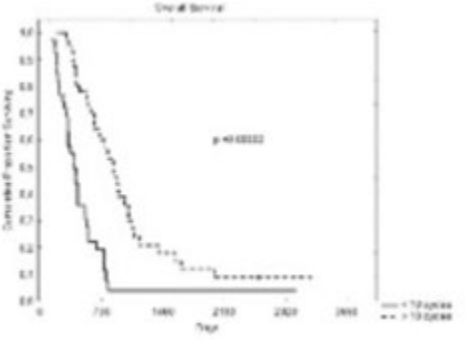

Figure 1.

Summary/Conclusion: In conclusion: 1) a substantial fraction of patients (37%) classified as SD after 4 cycles of AZA will improve response with additional treatment; 2) patients keeping on treatment with AZA (≥ 10 cycles) and patients who achieve a IR had a longer survival. Our analysis suggests that, in the absence of therapeutic alternatives, patients in SD should continue treatment with AZA until disease progression or unacceptable toxicity.

Background: Older patients with a severe disease are always a dilemma for physicians. A more detailed screening of candidates for hypomethylating

treatment by using predictive factors may maximize clinical success and minimize the exposure of inappropriate patients to excessive toxicity.
Aims: To evaluate overall survival and clinical predictive factors in an older high risk (HR) MDS and CMML cohort under HMA treatment as well as identify patients more likely to reach response in the real world.
Methods: This retrospective and multinational study was focused on older patients (>65 years old) with HR (IPSS-R>3.5 or CPSS>1). The population was selected from a Latin-American Ad-Hoc database of 340 patients who received hypomethylating agents (HMAs) between Jan-2007 and Jan-2018. OS was evaluated as from HMA initiation, either censoring or not, other treatments such as chemotherapy, other HMA or HSCT, up to time to death or last follow-up. Kaplan Meier, Log-rank test and Cox-regression were applied to evaluate survival. Chi2/Fisher Exact test and logistic regression were used to analyze categorical variables regarding response. Predictive factors included age, gender, comorbidities by Charlson Comorbidity Index (CCI), physical performance (ECOG), transfusion dependence, different cut-offs for hemoglobin level, platelet and neutrophil counts, BM and PB blasts, and karyotype.
Results: We evaluated 138 patients (MDS 92 [67%], CMML 32 [23%], sMDS 8 [6%], and oligoblastic AML 6 [4%]) with median follow-up of 12.4 months and median number of HMA cycles of 7 (range 1-37). Median age was 75 (range 66-89) with a male predominance of 57%, 34% CCI≥3, 23% ECOG ≥2 and 66% were transfusion dependent before treatment. Predictive factors of shorter OS at treatment initiation included CCI≥3 (p=0.041), HR karyotypes (p=0.002), Hb gender-adjusted (M<9/F<8 g/dL, p=0.009), platelet count ≤30,000/µL (p=0.010) with a borderline significant of transfusion dependency (p=0.076) with similar results to last follow-up. After Cox's regression analyses, high risk karyotypes (HR3.0, 95%IC 1.6-5.7, p<0.001) sustained its impact with a statistical tendency of Hb gender-adjusted (HR1.6, 95%IC 0.9-2.8, p=0.081) and platelet count <30,000/µL (HR1.7, 95%IC 1.0-2.9, p=0.067). When patients were evaluated to last follow-up, previous transfusion dependency (HR2.1, p=0.009) and blast in PB (HR1.8, p=0.026) were also relevant. A total of 119 patients were evaluated for response to treatment with an overall response rate of 61% (CR/mCR/PR: 34%, HI: 15%, SD: 12%) during a median follow-up period of 12.8 months. Non-responders, 22 (47%) received an optimum treatment (>4=DAC or >6=AZA cycles), showed a dismal outcome with a median OS of 7.6 m (vs responders: 25.9 months, p<0.001). Not achieving response was related to ECOG≥2 (34% vs17%, p=0.026), Hb level <10g/dL (87% vs 69% p=0.020), platelets count <30000/µL (47% vs 27%, p=0.021), presence of PB blast (35% vs16%, p=0.029), with a statistical tendency for CCI≥3 (40% vs 25%, p=0.084) and other Hb cut-offs. The logistic regression analyses confirmed the importance of ECOG≥2 (OR 4.3, p=0.009), platelets count <30,000/µL (OR2.6, p=0.049) and presence of PB blast (OR3.4, p=0.031) as the main parameter associated with treatment failure.
Summary/Conclusion: In our cohort, short OS was mainly influenced by high-risk karyotype and, failure to achieve response was significantly associated with a PS≥2, platelets count <30,000/µL and presence of PB blast. These results identified predictive factors that might be useful to tailor treatment.

PS1257

IRON SUPPORT ENHANCES ERYTHROPOIETIN EFFECTIVENESS IN REFRACTORY ANEMIA WITH HIGH RETICULOCYTE COUNT, TRANSFERRIN SATURATION BELOW 30% AND HIGH LEVEL OF ERYPTOSIS

G. Giordano[1,*], A. Parente[2], D. Berardi[3], D. Castaldi[2], M.A. Cinotti[2], F. Vedruccio[2], V. Susca[4], L. Petrella[4], G. Berardi[5], M. Magri[6], G. Niro[6], R. Gigli[6]

Background: Eryptosis (erythrocyte apoptosis) is an enhanced phenomenon in myelodysplastic syndromes(MDS) positively related to reticulocyte count and triggered by iron deficiency. Iron support is not recommended in MDS,also at low risk, in which iron chelation is a pivot of treatment
Aims: Aim of this study is to see if iron support enhances erythropoietin effectiveness in refractory anemia with high reticulocyte count, transferrin saturation below 30%, regardless of ferritin level
Methods: Between july 2015 and december 2018, 40 patients affected by refractory anemia with IPSS low-risk were studied. Median follow-up was 16 months (R12-28). Patients were randomized 1:1 to receive in group A (with corrected reticulocyte count <2.5%, transferrin saturation >30%) sucrosomial iron 30 mg 2 tablets orally/day +erythropoietin 40000 IU sc/t.i.w + calcium levofolinate 7.5 mg/day orally + Vitamin B12: 400 mg/day orally. In group B (with corrected reticulocyte count >2.5%, transferrin saturation <30%)patient received sucrosomial iron 30 mg 2 tablets orally/day + alpha erythropoietin 40000 IU sc/t.i.w. + calcium levofolinate 7.5 mg/day orally + Vitamin B12: 400 mg/day orally. In group A median age was 75 years (R70-81), M/F: 8/12. In group B median age was 72 years (R68-77), M/F: 10/10. Caryotype was normal in group A and B patients. Median level of haemoglobin was 9.5 g/dl in group A (R9-10) and 8.9 g/dl (R8.5-10) in group B. Median ferritin level was 900 ng/ml in group A (R890-1100) and 800 ng/ml g/dl (R750-950) in group B. Eryptosis was measured with cytosolic Ca2+, utilizing Fluo3 fluorescence, after cells staining with the Fluo-3 AM dye (Biotium, Hayward, USA). Levels of eryptosis at start of treatment were higher in group B.
Results: Group A patients increased Hb level of 1 g/dl after a median time of 6weeks (R4-7), 11 g/dl after 3 month. Group B patients increased Hb level of 1 g/dl after a median time of 4weeks (R3-5), 12g/dl after 3 month. Median ferritin level was 1100 ng/ml in group A (R950-1300) and 850 ng/ml (R800-900) in group B. After treatment levels of eryptosis were higher in group A.
Summary/Conclusion: Iron support enhances erythropoietin effectiveness in refractory anemia with high reticulocyte count, transferrin saturation below 30% probably reducing level of eryptosis involved in ineffective erythropoiesis.

[1]HIGA Dr Diego Paroissien, [2]Sanatorio Sagrado Corazón, [3]Hospital Durand, [4]Hospital Italiano , [5]Hospital Nacional Posadas, Buenos Aires, Argentina, [6]Hospital San José, Bogotá, Colombia, [7]Hospital de Clínicas, Buenos Aires, [8]Clínica La Pequeña Familia, Junín, [9]HR Dr Ramón Carrillo , Santiago del Estero, [10]Sanatorio Municipal Julio Méndez, [11]IIHEMA/Academia Nacional de Medicina, [12]Hospital Universitario Austral, [13]Hospital Tornú, Buenos Aires, Argentina, [14]Hospital Einstein, Sao Paulo, Brazil, [15]Hospital Italiano de La Plata, La Plata, Argentina

Background: Hypomethylating agents (HMA) are the first line option for high-risk patient and lower-risk patient with transfusion dependence, or, during the follow-up according to worsening clinical features. Thrombocytopenia is a frequent finding in myelodysplastic syndromes (MDS) during the course of the disease and, recently, severe thrombocytopenia (<30,000/µL) has been proposed as an independent adverse prognostic factor for survival.
Aims: To examine the influence of severe thrombocytopenia <30,000/µL in the outcome and response to HMA therapy in a MDS cohort from Latin-America (LA).
Methods: We identified 215 eligible MDS patients (excluding CMML, secondary MDS and AML) from a multicentric retrospective LA database of 340 patients who were treated between January-07/January-18. Statistical analysis included Kaplan-Meier survival analysis, Cox proportional hazard and Logistic regression.
Results: The median age of patients was 71 years (range 20-89) being 74.9% >60 years old and 54% were males. At treatment initiation, 79.0% showed hemoglobin <10g/dL, 32.7% platelet counts <30,000/µL, 14.7% poor karyotypes and 67.4% at IPSS-R>3.5. Among the low-risk group, 75.7% patients were resistant to erythropoietin and a remaining 8.6% were transfusion dependent. Regarding HMA therapy, 92.1% patients received AZA and 7.9% DAC, with a median number of cycles of 7 (1-58) during a median period of 8.1 months (m). The median overall survival (OS) of the cohort was 21.9m, after cessation 6.1m and since last treatment 4.0m. The rate of AML transformation was 29.8% and 52.6% died. In this sub-analysis, we investigate the prognostic parameters that were useful to predict outcome from treatment to last follow up. Cox regression analysis revealed that male sex (HR 2.0, 95% CI 1.3-3.1, p=0.002), poor karyotypes (HR 1.7, 95% CI

1.0-2.9, p=0.044), lower hemoglobin level (ref. ≥10g/dL, <10g/dL-≥8g/dL, HR 2.6, 95% CI 1.4-5.1, p=0.003; <8g/dL, HR 2.4, 95% CI 1.3-4.6, p=0.006), platelet count <30.000/µL (HR 3.2, 95% CI 2.1-5.0, p<0.001) and older than 60 years (HR 1.8, 95% CI 1.1-3.0, p=0.022) were independently associated with a reduced OS. All this parameters sustained their independency when other treatments were censored (chemotherapy, other HMA or HSCT). A total of 176 patients were evaluated for response to treatment with an overall response rate of 67% (CR/mCR/PR: 30.7%, HI: 20.4%, SD: 15.7%) evaluated at optimum treatment (6-AZA/4-DAC). The median survival in responders was 30.0 months compared with 7.9 months in non responders (p<0.001), with a median follow-up period of 12.4 months. The outcome of patients with SD was similar to those with CR/mCR/HI (p=0.760). Among those parameters that were predictive for survival, failure to achieve response (Logistic regression) was associated with lower hemoglobin level (ref.≥10g/dL, <10g/dL-≥8g/dL, OR 5.6, 95% CI 1.5-21.1, p=0.011; <8 g/dL OR 5.9 95% CI 1.6-21.9, p=0.008) and platelet count <30,000/µL (OR 2.9, 95% CI 1.4-6.0, p=0.005).

Moreover, a severe thrombocytopenia <30,000/µL adversely impacts on the OS of responders (15.1 months vs 39.0 months, HR 3.8, 95% CI 2.1-6.7, p<0.001, Figure 1).

Summary/Conclusion: Our results highlight the adverse impact of the severe thrombocytopenia <30,000/µL on the outcome of patients under HMA influencing the response rate and the survival, even in responders.

TLR4 SIGNALING DRIVES MESENCHYMAL STEM CELLS (MSC) COMMITMENT TO PROMOTE TUMOR MICROENVIRONMENT TRANSFORMATION IN MULTIPLE MYELOMA

C. Giallongo[1,*], D. Tibullo[1], G. Camiolo[1], N. L. Parrinello[2], P. La Cava[2], A. Romano[2], F. Puglisi[2], E. Martino[2], G. Sapienza[2], C. Conticello[2], G.A. Palumbo[2], F. Di Raimondo[2]

[1]Division of Hematology, [2]University of Catania, Catania, Italy

Background: MSC, through a complex crosstalk with neighboring cells/factors, can inhibit many effector functions of immune cells, thereby promoting an immunosuppressive state in the tumor microenvironment that allows tumor cells to overcome the immune surveillance.
Aims: Since it has been demonstrated a connection between the stimulation of specific Toll-like receptors (TLR) and MSC activation status, including two distinct phenotypes defined MSC1 (TLR4-dependent) or MSC2 (TLR3-dependent), we hypothesized that MSC derived from Multple Myeloma patients (MM-MSC) could be activated to better 'serve' the cancer cells.
Methods: Healthy Peripheral blood mononucleated cells (PBMC) were cultured with healthy controls (HC-), MGUS-, SMM- or MM-MSC. After 6 days, educated neutrophils (ed-N) were isolated using magnetic microbeads. Immunocompetent adult Zebrafish was used as *in vivo* model for myeloma cells engraftment.
Results: Only SMM- and MM-MSC induced a neutrophils N2 phenotype able to promote suppressive effects on T cell proliferation ($p<0.001$) and to exert a pro-angiogenic activity ($p<0.05$). No N2 activation was observed in neutrophils co-cultured with HC- or MGUS-MSC, demonstrating that tumor-associated MSC were functionally different from HC-MSC. By adding Bortezomib, Lenalidomide or Pomalidomide during co-culture, ed-N lost the pro-angiogenic activity but not the immunosuppressive ability.Using specific agonists for TLR4 (LPS) or TLR3 (poly(I:C)), we observed that healthy MSC acquired the same immunological alteration of SMM- and MM-MSC after a pre-treatment with LPS. Moreover, wester blotting analysis confirmed the activation of TLR4/MyD88 pathway in MM-MSC but not in HC-MSC.To examine if myeloma plasma cells (PC) play a role in MSC polarization, before performing co-cultures with PBMC, we pre-treated HC-MSC with MM cell lines. Plasmacell pre-treatment drove healthy MSC to activate neutrophils in immunosuppressive and pro-angiogenic cells. Therefore, we investigated if PC activated TLR4 pathway in healthy MSC and we found that co-culture with PC induced IRF3 nuclear translocation, indicating the involvement of a TLR4-MyD88-independent pathway in MSC commitment. Next, we explored the effects of the "activated" status of MM-MSC investigating their pro-tumor role *in vivo*. Six days after implanting a mixtures of fluorescently labeled MM cells plus HC- or MM-MSC, zebrafish co-injected with PC and MM-MSC showed enhanced tumor colonization and growth (calculated as tumor volume and fluorescence intensity) compared with animals injected with PC and HC-MSC (control) ($p<0.05$). Flow cytometry detection of hCD138+ cells confirmed less MM cells in zebrafish injected with PC and HC-MSC ($p<0.001$). Therefore, we analyzed the expression of the master regulator transcription factors for Th1/Th2 (tbx21 and gata3) and Th1- and Th2-type cytokines to better assess *in vivo* the involvement of the immune escape mechanisms promoted by co-injection of PC with MM-MSC. As compared to control animals, gata3, IL-4 and IL-13 were significantly up-regulated in zebrafish injected with PC plus MM-MSC, revealing that MM-MSC and PC mixture promoted a Th2 responce. To investigate TLR4 role, we used TAK-242 to inhibit the signaling in MM-MSC before injection in zebrafish. Animals co-injected with PC and MM-MSC pre-treated with TAK-242 showed 48% less tumor engraftment compared to zebrafish injected with PC and MM-MSC.
Summary/Conclusion: TLR4 signaling plays a pivotal role in MSC commitment towards an inflammatory phenotype which is associated with a tumor permissive microenvironment.

Background: High-throughput sequencing studies have rendered seminal knowledge in monoclonal gammopathies such as multiple myeloma (MM) and Waldenström's macroglobulinemia (WM). Unfortunately, the low incidence of AL amyloidosis and its typically low tumor burden, often masked by a polyclonal plasma cell (PC) background, account for the limited information on its tumor cell biology. Thus, it remains unknown if AL amyloidosis harbors a unifying mutation as occurs in WM or if, in its absence, there are recurrent mutations and if these overlap with those observed in MM.
Aims: To perform whole exome sequencing (WES) in a series of patients with AL amyloidosis and to compare mutational profiles in AL amyloidosis vs MM.
Methods: A total of 28 patients with confirmed diagnosis of AL were included. WES was performed in 56 paired samples of FACSorted bone marrow tumor plasma cells and peripheral blood mononucleated cells. Each tumor sample was captured in triplicate using Agilent's SureSelect Human All Exon V6 + UTR kit and sequenced on the Illumina NextSeq 500 platform. Data was analyzed with Strelka software to discard germinal mutations, ANNOVAR for functional annotation, and a data reduction strategy to identify candidate variants. The mutational signature was analyzed with DeconstructSigs software. We used the MMRF CoMMpass dataset (895 patients) to compare the mutational landscape of MM vs AL amyloidosis. We also determined immunoglobulin gene rearrangements in AL amyloidosis by next generation sequencing.
Results: The mean depth coverage for control and tumor samples was 64x and 186x, respectively. A total of 1983 somatic SNV and 133 INDEL were identified, with an average of 71 (20-281) SNV and 5 (0-25) INDEL per patient. When compared to MM (average of 66 SNV and 2,5 INDEL), patients with AL showed similar mutational load. None of the most frequently mutated genes in MM (i.e. *KRAS, NRAS, FAM46C, BRAF, TP53, DIS3, PRDM1, SP140, RGR1, TRAF3, ATM, CCND1, HISTH1E, LTB, IRF4, FGFR3, RB1, ACTG1, CYLD, MAX, ATR*) were recurrently mutated in patients with AL. The only genes commonly mutated in AL amyloidosis and MM were MUC16 (recurrence of 17% and 8%, respectively) and IGLL5 (recurrence of 17% each). Overall, the most frequently mutated genes in this series were IGLL5, MUC16 and DHFR2 (recurrence of 17% each). Most patients with AL harbored between 1 and 8 mutational signatures (Alexandrov, Nature 2013), implying that multiple mutational processes are operative. The most frequent mutational signatures were 1 (spontaneous deamination of methylated cytosines that to C>T transition at CpG sites), 3 (failure of DNA double-strand break-repair by homologous recombination) and 9 (T>G transversions at ApTpN and TpTpN trinucleotides), present in 96%, 54% and 46% of patients, respectively. Regarding the immunoglobulin gene repertoire, we noted that 26% of patients with AL amyloidosis harbored more than one clone; this extent in clonal heterogeneity being similar to that found in MM (23%). The most frequent IGH gene involved was *IGHV3-30* in both AL (recurrence of 10%) and MM (recurrence of 12%).
Summary/Conclusion: This is the first WES study performed in a series of patients with AL. We demonstrated the lack of a common driver mutation in this disease and unveiled that recurrently mutated genes in AL amyloidosis do not overlap with those observed in MM. Overall, these results may have significant impact in our understanding of the pathogenesis of AL amyloidosis and its differential diagnosis vs other monoclonal gammopathies.

BI-ALLELIC LOSS OF FAM46C BY CRISPR/CAS9 SYSTEM ENHANCES MYELOMA CELL GROWTH

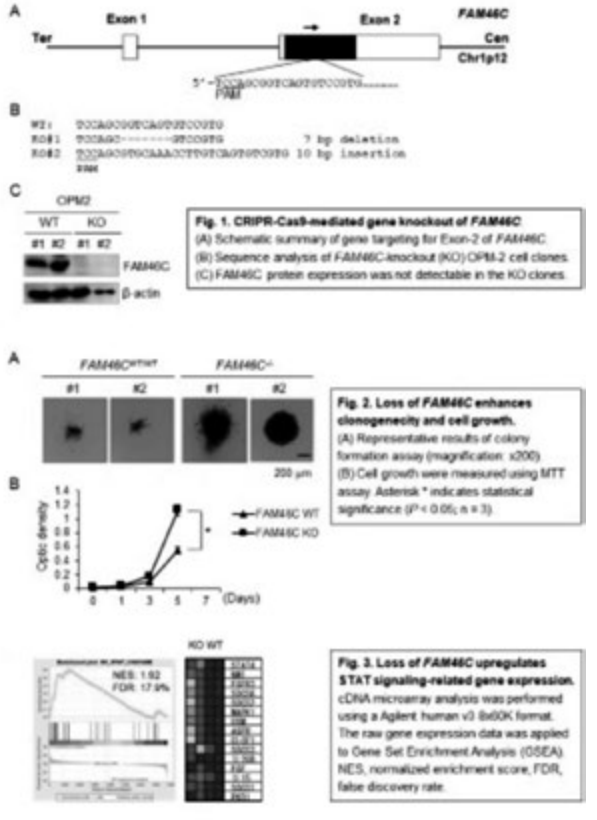
J. Kanasugi[1,*], I. Hanamura[1], A. Ota[2], S. Karnan[2], S. Mizuno[1], K. Uchino[1], S. Suzuki[3], Y. Hosokawa[2], A. Takami[1]

[1]Division of Hematology, Department of Internal Medicine, [2]Department of Biochem-

istry, [3]Department of Tumor Immunology, Aichi Medical University, Nagakute, Japan

Background: Multiple myeloma is a plasma cell malignancy which develops by acquiring a series of genomic alterations. Translocations involving the immunoglobulin loci are related with myelomagenesis. The sequential acquisition of additional genetic aberrations such as del(1p), del(17p) and 1q21 gain lead to the progression and drug resistance. Del(1p) is detected in around 20% of newly diagnosed myeloma. *FAM46C* is a candidate tumor suppressor gene at chromosome 1p12 and has been reported to be associated with a non-canonical poly (A) polymerase. However, pathogenic role of FAM46C in myeloma cells has not been well characterized.
Aims: The aim of this work was to elucidate the *FAM46C* gene function associated with myeloma cell growth and drug resistance *in vitro* and *in vivo* using CRISPR/Cas9 system.
Methods: We generated transfectants disrupting *FAM46C* using a CRISPR/Cas9 system with the human myeloma cell line OPM2 and explored its biological characteristics. A plasmid purchased from Addgene, containing *EGFP*, *Cas9* and a 20bp single guide RNA sequence for *FAM46C exon14* (Figure 1A) was constructed. After transfection using Nucleofection™, and GFP sorting, we performed single cell cloning, and then screened for *FAM46C* expression by western blotting. We obtained 2 clones with bi-allelic loss of *FAM46C* as determined by genomic sequencing (Figure 1B and 1C). Using these clones, cell proliferation, clonogenicity and drug sensitivity were examined by MTT and colony formation assay. OPM2 and OPM2 with bi-allelic disruption of *FAM46C* were xenografted into immunodeficient SCID mice (n=6, each), and the tumor sizes were measured twice a week. The gene expression changes by *FAM46C* disruption were analyzed by cDNA array analysis (Whole Human Genome 4×44k Oligomicroarray Chip, Agilent Technologies). A gene set enrichment analysis (GSEA) was performed to investigate a specific set of genes associated with FAM46C disruption.
Results: The *FAM46C* KO cells showed the higher cell proliferation compared with parent cells both *in vitro* (Figure 2) and *in vivo*. The sensitivity to lenalidomide and pomalidomide was similar between *FAM46C* KO and parent cells by MTT assay. GSEA revealed that loss of *FAM46C* upregulated expression of genes related with STAT signaling (Figure 3).

Figures 1, 2, 3.



Summary/Conclusion: The findings indicate that bi-allelic loss of *FAM46C* enhances myeloma cell proliferation but did not affect the sensitivity to IMiDs. This suggests that bi-allelic loss of *FAM46C* may be associated with disease progression. The growth advantage was due to upregulation of STAT signaling. Our genome-editing approach using CRISPR/Cas9 system is useful for exploration of a molecular pathology and therapeutic implication for oncogenic gene mutations in myeloma.

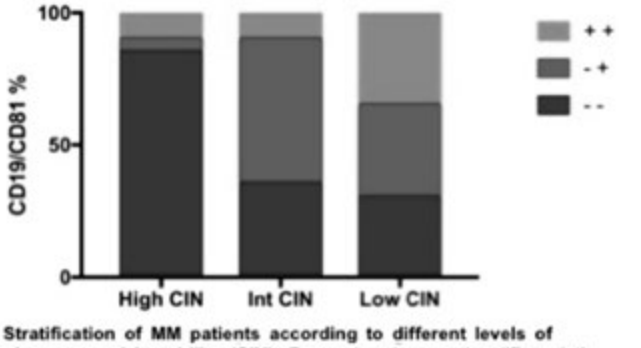
PS1263

A HIGH LEVEL OF GENOMIC COMPLEXITY CORRELATES WITH ADVANCED PLASMA CELL DIFFERENTIATION STAGES IN NEWLY DIAGNOSED MM PATIENTS

M. Martello[1,*], R. Termini[1], B. Santacroce[1], E. Borsi[1], V. Solli[1], C. Benni[1], A. Poletti[1], L. Pantani[1], B. A. Zannetti[1], S. Rocchi[1], E. Zamagni[1], P. Tacchetti[1], F. Ulbar[1], M. Arpinati[1], G. Chirumbolo[1], N. Testoni[1], G. Martinelli[2], M. Cavo[1], C. Terragna[1]

[1]DIMES-Department of Experimental Diagnostic and Specialty Medicine, L. e A. Seràgnoli, bologna, [2]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) Srl, IRCCS, Meldola, Italy

Background: Chromosomal instability (CIN) is a driving force of myelomagenesis: the continuous modification of plasma cell (PC) genomes favours the acquisition of progressively more DNA alterations, clonal evolution and heterogeneity, thereby promoting tumour development. Similarly, the pliancy of Multiple Myeloma (MM) plasma cells differentiation status acts as adaptive strategy to exogenous stress (e.g. in response to therapy). However, the genomic background that supports any diverse plasma cell differentiation phenotype has not yet been inferred.
Aims: To correlate the genomic background with the phenotypic plasticity of MM clone(s) at diagnosis, in order to stratify patients (pts) according to both the level of CIN and their PC differentiation stages, and ultimately to evaluate the impact of this stratification on the disease outcome.
Methods: A total of 78 newly diagnosed pts were included in the present study. Most pts (68/78) received a PI-based treatment as a front-line therapy. In each patient, both the BM CD138+/CD38+ PC and CD19+ B cell compartments were characterized by 6-color multiparametric flow citometry analysis, combining CD138-PE, CD38-PE-Cy7, CD20-APC, CD19-APC-Cy7, CD27-FITC, CD45-FITC, CD28-APC, CD44-FITC, CD54-APC, CD81-PerCP-Cy5.5, CD56-APC and SHH-PE, as a functional marker of Hedgehog pathway activation (Miltenyi Biotech). Whole copy number abnormalities (CNAs) characterization of CD138+ purified BM PCs was carried out by SNP array hybridization with Cytoscan HD array (Affymetrix).
Results: According to the detected CIN, as described both by total CNAs and portion of genome changed (GC), three major subgroups were identified: the first one, including 21 pts with high CIN (medium tot. CNAs = 550,% GC ≥ 25%); the second one including 25 pts with a intermediate CIN (medium tot. CNAs = 315,% GC = 10-25%) and the third one including 18 pts with low CIN (medium tot. CNAs = 105,% GC ≤ 10%). As expected, in pts with high CIN, more than a quarter of unstable genome was due to the hyperdiploidy; however, they were also characterized by a higher prevalence of high-risk features. Indeed, 1p deletion (*FAF1*), 16q deletion (*WWOX*, *FANCA*) and 17p deletion (*TP53*) were the most recurrent abnormalities, and almost exclusively associated to high CIN pts (p<.05). A detailed immunophenotypic analysis of the three subgroups of pts showed that high CIN background mainly characterized mature PCs (17/21 = 81%) (Figure 1), as described by: a) a significant deregulation of both CD19 and CD81 markers; b) a higher expression of CD28 and CD44, which usually characterized advanced disease stages; c) a reduced expression of CD20, CD27 and CD45, commonly associated to preceding PC differentiation stages (p<.05).



Stratification of MM patients according to different levels of chromosomal instability (CIN). For each subgroup the differentiation stages distribution of the is indicated: CD19-/CD81- (blue), CD19-/CD81+ (red) and CD19+/CD81+ (green).

Figure 1.

Finally, the presence of more mature PCs with high CIN characterizes pts carrying baseline clinical features associated to bad prognosis (e.g. n. PET lesions, k/l ratio, ISS III, β2-microglobulin; p<.05). In addition, these pts tend to obtain high quality response rates (≥CR) to PI induction therapy.
Summary/Conclusion: A high level of genomic complexity correlates with an advanced PCs differentiation stages in newly diagnosed MM patients, and this is lastly associated with a prevalence of bad prognosis features. Chromosomal instability, together with cellular phenotypic pliancy, represents an important, yet poorly defined, mechanism by which MM clone(s) accelerate their own evolution and survival. *Acknowledgements: AIRC IG2014, Fondazione Berlucchi.*

MOLECULAR SEGMENTATION OF MULTIPLE MYELOMA BY INTEGRATIVE MULTI-OMICS ANALYSIS

M. Ortiz Estevez[1,*], M. Samur[2], F. Towfic[3], K. Mavrommatis[4], E. Flynt[5], B.A. Walker[6], M. Trotter[1], G. Morgan[6], N. Munshi[2], A. Thakurta[5]

[1]Reasearch Analytics, CITRE, Celgene Institute Translational Research Europe, Sevilla, Spain, [2]Dana-Farber Cancer Institute, Harvard Medical School, Boston, [3]Reasearch Analytics, Celgene Corporation, Summit, [4]Reasearch Analytics, Celgene Corporation, San Francisco, [5]Translational Development, Celgene Corporation, Summit, [6]Myeloma Institute, University of Arkansas for Medical Sciences, Little Rock, United States

Background: There is currently no comprehensive classification of newly diagnosed Multiple Myeloma (ndMM) tumor biology that integrates heterogeneous molecular information including gene expression (GEP), mutation (SNV), copy number alteration (CNA), and structural variant (SV) profiling. A robust classification of ndMM at this level of resolution would yield the potential to improve diagnosis, prognosis and treatment of patients with MM by describing the etymology of the disease.
Aims: As part of the Multiple Myeloma Genome Project (MGP) collaborative initiative, we aimed to develop an integrative molecular segmentation strategy with the overall goal to provide actionable insights into the heterogeneity of ndMM biology.
Methods: In order to investigate molecular segments of ndMM, we assembled a high quality clinical (ISS, Age, Sex) and uniformly processed genomics dataset and defined progression-free survival (PFS) and overall survival (OS) across all studies involved. To overcome FISH and cytogenetic data variability between studies, we re-derived 18 common structural variants including del17p, t(4;14), t(6;14), t(11;14), t(14;16) and t(14;20) using whole genome and whole exome sequencing data to ensure high confidence calls across all studies. SNVs were aggregated into pathways to improve interpretability and assign functionality to their effect. Two multi-omics integrative clustering methods were run multiple times with number of clusters ranging from K= 2 to 20 and patient resampling: 1-Cluster of Clusters (CoCA) and 2-iClusterPlus. The number of clusters was selected based on feature and sample resampling and convergence of the Bayesian Information Criterion (BIC) and Normalized Mutual Information (NMI). Consensus matrices generated by iClusterPlus and CoCA were compared using BIC and NMI to select more robust patient segmentation.
Results: We discovered that copy-number, gene expression, and SVs account for highest proportion of variance across segments when compared to single nucleotide variants (as defined by contribution to overall variability in Joint and individual variation explained (JIVE), coherence of clusters in iClusterPlus and CoCA).
Multi-dimensional unsupervised analysis identified 12 stable patient segments (no cluster contained less than 5% of samples) including patient tumors enriched in t(4;14) and t(11;14) and various subsets of del17p patients stratified by CNA and distinct mRNA expression patterns. The highest risk group (11% of samples, C8), as measured by PFS and OS, is defined by a combination of biomarkers including del13q/14q/17p and amp1q and a down-regulation of related gene expression profiles; while the lowest risk group (5% of samples, C2) is significantly associated with low mutation rate. (Figure 1).
Summary/Conclusion: This is the first analysis of a large dataset in ndMM to perform an unsupervised biomarker analysis to stratify patients into 12 segments based primarily on SVs, CNAs and mRNA differences across tumors. The segments are driven by features such as SVs involving 14q, CNAs (del17p, del13q, amp1q), and specific GE profiles. In contrast, SNVs contributed less to the variance across MM segments. This finding suggests that wider DNA alterations and potentially related transcriptomic changes drives the MM segments. To understand the biological consequences of alterations, genomic and transcriptomic pathway analysis are being performed. These analyses will likely reveal underlying biological drivers of the disease, lead to potential new targets and foster mechanism-based approaches for MM therapeutics development in specific molecular segments.

[1]Translational and Personalized Medicine, Institute for Molecular Medicine Finland(FIMM), HiLIFE, University of Helsinki, Helsinki, [2]Helsinki Institute for Information Technology (HIIT), Aalto University, Espoo, Finland, [3]Dept. of Experimental and Health Sciences, University Pompeu Fabra, Barcelona, Spain, [4]Department of Hematology, Helsinki University Hospital and Comprehensive Cancer Center, Helsinki, [5]Department of Medicine, Kuopio University Hospital, Kuopio, [6]Hematology Research Unit, University of Helsinki, Helsinki, Finland

Background: Multiple myeloma (MM) displays enormous genetic complexity and heterogeneity, which may ascribe to diversity in response observed in patients sharing identical prognostic markers or disease stage. Precision medicine holds the promise of selectively and efficiently eradicating malignant cells by targeting the mechanisms driving their key phenotype. However, the success critically relies on relevant biomarkers that can be used to identify responding patients.
Aims: To decipher complex pharmacogenomics interactions, we comprehensively assessed *ex vivo* responses of 100 MM samples to 142 drugs and compared to matching genomic, transcriptomic and clinical profiles of the patients. Utilizing a unique data resource, we aimed to i) stratify myeloma patients based on their *ex vivo* drug response, ii) understand drug response and resistance mechanisms, ii) identify molecular indicators of response, and iii) evaluate drug repositioning possibilities
Methods: 100 bone marrow (BM) aspirates were collected from 32 newly diagnosed and 51 relapsed myeloma patients. CD138+ cells were isolated and tested against a 142 oncology compounds. DNA and RNA were sequenced for 98 and 78 samples, respectively. Pairwise and multivariate statistical approaches were applied to provide integrative analyses on the datasets.
Results: Based on overall drug response profiles, the patients clustered into four drug sensitivity subgroups (Group-I-IV). A higher mutation load in patients was associated with higher *ex vivo* sensitivity to signal transduction inhibitors (PI3K-AKT-mTOR, HDAC and CDK inhibitors) and associated with poor survival. 14% of the samples exhibited a resistant phenotype and showed elevated expression multidrug resistance genes *ABCB1* (*MDR1*) and *ABCC3* (*MRP3*). Integrative analysis allowed assimilation of multiple datasets and revealed putative molecular signatures associated to individual

drugs. For example, a hyperdiploid karyotype was associated to *ex vivo* response to glucocorticoids and bromodomain inhibitors. *CCND1* and *BMI1* expression correlated with sensitivity to BCL2 inhibitor venetoclax. MEK inhibitor response was detected in 55% of samples with *NRAS*, *KRAS*, *NF1*, and *BRAF* mutations. 20% of the patient samples harbored mutations in genes involved in DNA damage repair signaling, namely *ATM*, *ATR*, *MSH* and *TP73*, in a mutually exclusive pattern. Patients with these mutations had a high relapse rate, poor overall survival (HR=3.2,95%CI 1.1-9.02), and displayed acquired sensitivity to PI3K-mTOR and HDAC inhibitors in longitudinal samples. Sensitivity to midostaurin (median IC50, 211 nM), identical to FLT3 mutated AML, was detected in 43% of relapsed patient specimens enriched for mutations to *TP53*, *NRAS* and *FAM46C*.
Summary/Conclusion: We identified molecular subgroups of myeloma patients with distinct drug response profiles, which are driven by underlying molecular alterations. Acquisition of DNA damage repair signaling alterations conferred poor prognosis and corresponded to PI3K-mTOR and HDAC inhibitor sensitivity. Integrative analyses leveraging on a multi-omics dataset uncovered biomarkers, which could facilitate identification of responding patients to individual drugs. We identified drug candidates that could potentially be repurposed to treat myeloma patients. Our study provides a valuable resource and framework to identify novel pharmacogenomics interactions and facilitate precision therapies, especially for relapsed/refractory myeloma patients.

PS1266

ADAR1-MEDIATED-NEIL1 EDITING IS OF BIOLOGICAL SIGNIFICANCE IN MULTIPLE MYELOMA

P.J. Teoh[1,*], O. An[1], T.-H. Chung[1], H. Yang[1], W.J. Chng[1,2,3,4]

[1]Cancer Science Institute of Singapore, [2]National University Cancer Institute, [3]Medicine, National University of Singapore, [4]Haematology-Oncology, National University Health System, Singapore, Singapore

Background: The physiological and biological roles of RNA editing have been actively studied in recent years and emerging evidence revealed a close association between an aberrant ADAR1-mediated-A-to-I editing and tumorigenesis in various cancer types. As compared to solid tumors, this topic has not been comprehensively studied in hematological malignancies, and only until recently that a deregulated A-to-I editing was critically reported in multiple myeloma (MM), whereby, *GLI1* (Hedgehog signaling gene) editing was of prognostic significance in MM patients. As RNA editing is a pervasive mechanism constituting 85% of human transcriptome, we hypothesize that an aberrant editing can occur in other genes in MM.
Aims: We aim to delineate other biologically important genes that are abnormally edited. Although ADAR1 can promiscuously edit mRNA, the occurence at the coding sequences (CDS) can potentially modify the protein structure and function, thus, our focus was on the genes that are hyperedited at the CDS.
Methods: To study the A-to-I editing, we performed whole transcriptome sequencing of the normal and malignant plasma cells obtained from healthy volunteers and MM patients, respectively. We also analysed the publicly available RNA-sequencing dataset from MMRF (CoMMpass). For the identification of ADAR1-specific-editing events, we performed ADAR1 knockdown and overexpression on human myeloma cell lines (HMCLs) and genes showing non-synonymous editing were selected for further validation. Site-directed mutagenesis was done to generate stable HMCL overexpressing the edited variant of the candidate gene. We performed functional assays on these cells to look at its phenotype comparatively to cells overexpressing the WT gene.
Results: There was a global increase of exonic editing events along the disease progression route, underscoring its potential biological importance. Based on the list of differentially edited genes on ADAR1-knockdown and -overexpressed HMCLs and a thorough literature search, we selected NEIL1 (DNA base-excision repair gene) editing (A726G, Lys242Arg) for downstream analyses. RNA-immunoprecipitation and Sanger sequencing confirmed NEIL1 as a direct ADAR1 target. Analysis of the CoMMpass dataset revealed that NEIL1 editing was ubiquitious, whereby, 69% of the patients had A726G editing, of which the highest number of events was found in the relapsed patients. Importantly, the recoded NEIL1 exhibited gain-of-function properties and an inefficient oxidative damage repair capability. Although unrepaired DNA damage is known to lead to apoptosis, we observed that the recoded NEIL1 ironically caused increased resistance to melphalan. NEIL1-edited cells displayed an enrichment of double stranded DNA breaks (DSB) proteins (p53, p-H2Ax, p-CHK1, Ku80), implying that they could be more sensitive to DSB-inducing drugs. Indeed, treatment of the cells with etoposide (DSB inducer) alone and in combination with melphalan confers a higher cellular inhibition to NEIL1-edited cells than to the NEIL1-WT cells.
Summary/Conclusion: A defective DNA damage repair can predispose the genome to increased random mutagenesis, thus, it is plausible that an aberrant NEIL1 mRNA (A726G) and its protein product (Lys242Arg) may be one of the mechanisms by which RNA editing affects the genome integrity and how it wires the MM cells into acquiring undesirable mutations to further trigger disease pathogenesis. For the first time, our study collectively shows that ADAR1-mediated-NEIL1-editing is biologically and functionally relevant in MM and should be further explored as a potential predictive biomarker.

PS1267

DETECTION OF MYD88 AND CXCR4 MUTATIONS IN CELL-FREE DNA OF PATIENTS WITH IGM MONOCLONAL GAMMOPATHIES

T. Bagratuni[1,*], I. Ntanasis-Stathopoulos[1], M. Gavriatopoulou[1], N. Mavrianou-Koutsoukou[1], C. Liacos[1], D. Patseas[1], N. Kanellias[1], M. Migkou[1], D. Ziogas[1], E. Eleutherakis-Papaiakovou[1], M. Roussou[1], D. Fotiou[1], E. Terpos[1], K. Efstathios[1], M. Dimopoulos[1]

[1]National And Kapodistrian University Of Athens, Athens, Greece

Background: Mutational characterization of Waldenström's macroglobulinemia (WM) currently relies on DNA from CD19-selected cells derived from bone marrow (BM) aspirates, which is an invasive technique, associated with significant patient discomfort. Liquid biopsy is being integrated into cancer diagnostics with profound therapeutic implications. Peripheral blood cell-free tumour DNA (cfDNA), also known as liquid biopsy, has been recently shown to be a powerful non-invasive molecular biomarker in monitoring tumor status in several cancers.
Aims: In this study, we aimed to characterize the mutational status of WM/IgM MGUS patients by using peripheral blood plasma-derived cfDNA and using matched tumor DNA (tDNA) from BM-CD19$^+$ selected cells, in order to determine whether cfDNA, can be used as an additional diagnostic tool in identifying the mutational profile of WM.
Methods: A total of 68 consecutive patients with IgM monoclonal gammopathies and 10 controls were included in this study. Peripheral blood (10-12mL) was collected in EDTA tubes and DNA was extracted using the MagMax cell free DNA isolation kit. BM aspirates were collected at the same time with peripheral blood, and were processed for CD19 enrichment, using CD19 magnetic beads, followed by DNA extraction. tDNA and cfDNA samples were analyzed for the MYD88 L265P and for CXCR4 mutations. The presence of L265P mutation was initially assessed by Allele-Specific PCR and then confirmed with direct sequencing. The presence of CXCR4 mutations was assessed with direct sequencing.
Results: Among the 68 patients, 54 patients had both tDNA and cfDNA informative samples. $MYD88^{L265P}$ mutation was detected in 40 out of 54 patients (74%) in both tDNA and cfDNA; in 4 out of 54 (7%) the mutation was seen in tDNA but not in cfDNA and 10 out of 54 (19%) patients harbored the $MYD88^{WT}$ genotype both in tDNA and cfDNA. Thus, the overall concordance between tDNA and cfDNA for *MYD88* genotype was 93% (50 out of 54 patients). Among patients with IgM MGUS, WM in remission and sWM /NDWM/relapsed (RR) WM, the concordance rates were 100% (3 out of 3 patients), 96% (25 out 26 patients) and 88% (22 out of 25 patients), respectively. The assessment of *CXCR4* mutations in both tDNA and cfDNA was feasible in 47 out of 68 patients(69%). In seven patients (7 out of 47, 19%), mutations were detected in both paired samples. *CXCR4* mutations by either cfDNA or tDNA were present in 2 out of 5 MGUS (40%) patients, 7 out of 35 (20%) patients with disease in remission and in 5 out of 26 (19%) patients with sWM/NDWM/RRWM. The pathogenic mutation *S338X* was present in one patient with sWM and one with NDWM. The *F29L*, *P27T*, *P31T* and *I53L* mutations were also found 2-4% of patients. In 3 out of 47 patients the *E343D, H228Q* and *L50X* truncating mutations were detected in tDNA but not in cfDNA. Overall, the concordance rate between tDNA and cfDNA was 92% (43 out of 47 patients).
Summary/Conclusion: In conclusion, PB cfDNA is a useful, minimally invasive, cost-effective tool for the detection of *MYD88* and *CXCR4* mutations in patients with IgM monoclonal gammopathies avoiding unnecessary BM assessment.

PS1268

NEXT-GENERATION SEQUENCING ALTERNATIVES FOR THE DETECTION AND QUANTIFICATION OF MINIMAL RESIDUAL DISEASE IN MULTIPLE MYELOMA PATIENTS

[1]Departamento de Hematología, Hospital Universitario de Salamanca (HUSAL), IBSAL, IBMCC (USAL-CSIC), CIBERONC, Salamanca, [2]Departamento de Hematología, Hospital [12] de Octubre, CIBERONC, Madrid, [3]Clínica Universidad de Navarra, Centro de Investigación Médica Aplicada (CIMA), IDISNA, CIBERONC, Pamplona, [4]Hospital Clinic, Barcelona, [5]ICO Hospital Germans Trias i Pujol, Badalona, Barcelona, Spain, [6]Invivoscribe Technologies, Inc, San Diego, United States, [7]Departamento de Hematología, Hospital Universitario de Canarias, Santa Cruz de Tenerife, [8]Departamento de Hematología, Hospital Clínico San Carlos, Madrid, Spain

Background: Minimal residual disease (MRD) has emerged as a key parameter in the evaluation of multiple myeloma (MM) response to therapy. Next-generation sequencing (NGS) detection of the IGH clonal rearrangement has demonstrated some advantages over allele-specific oligonucleotide PCR (ASO-PCR) to detect low MRD levels in MM. However, only the LymphoSight® strategy, (Sequenta, San Francisco, CA) has demonstrated utility in clinical practice; accordingly, such strategy is the only one accepted by the International Myeloma Working Group (IMWG) criteria (Kumar *et al.*, Lancet Oncol 2016). Hence, additional commercial or academic efforts to evaluate MRD by NGS in MM would be very welcome.
Aims: Here, we have evaluated the LymphoTrack® commercial kit (Invivoscribe, San Diego, CA) to validate its potential applicability and usefulness in the MRD detection of MM. Results were compared with those obtained with Multiparametric Flow Cytometry (MFC).
Methods: 244 bone marrow samples from a cohort of 122 patients were evaluated at two different time-points: diagnosis and follow-up after response achievement (median, 3 months after transplant, or at the end of the induction treatment). All patients had been enrolled in clinical trials from the Spanish MM group: GEM2005menos65 (n=24), GEM2010 (n=17) and GEM2012 (n=81). We first tried to identify tumor clonal VDJH rearrangements in diagnostic samples through the amplification of IGH-FR1/FR2 regions followed by conventional Sanger sequencing. NGS analysis of the diagnostic sample was also performed in 81 cases. We then assessed MRD levels in follow-up samples using the LymphoTrack® NGS assay. More than 650 ng DNA (>10^5 cells) per reaction were used to warrant a sensitivity of 10^{-5} or better. 1 uL spike-in DNA corresponding to 100 clonal cells was added to the reaction to allow the absolute quantification of tumor plasma cells. Amplicons were then sequenced in a MiSeq® platform (Illumina, San Diego, CA), processed using the LymphoTrack® software, and results were compared with those obtained by MFC.
Results: Myeloma-specific clonal rearrangements and CDR3 regions were obtained in 121/122 patients (99.2%). Therefore, we tested MRD in their corresponding follow-up samples. Two samples (1.6%) were excluded from the final MRD analysis due to low read counts in the post-therapy sample. Of the remaining 119 cases, 66 were MRD positive and 53 were MRD negative by sequencing. A high correlation between MFC and NGS MRD results was observed (R=0.943) although we found 24 discordant cases: 9 cases were negative by MFC but positive by NGS, and 15 cases were positive by MFC but negative by NGS. Time to Tumor Progression (TTP) was significantly longer in the MRD negative than in the MRD positive subsets by NGS, providing a projected 40-month Time to Tumor Progression of 94.4% vs. 65.4%, respectively (p=0.001). This was translated into a better Overall Survival (OS) for patients with a negative MRD, who had a 40-month projected OS of 97.8% compared with 71% for patients with a positive MRD (p=0.01) (Figure 1A and 1B).

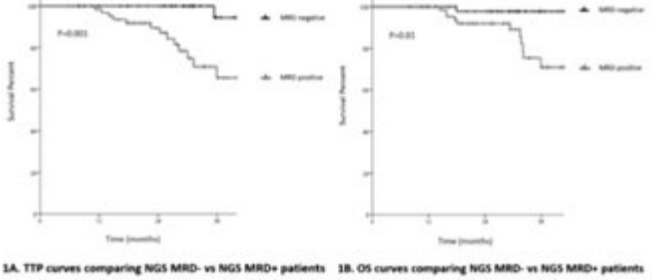

Figure 1.

Summary/Conclusion: LymphoTrack® applicability was very high (98.8%), like that reported for MFC and other NGS approaches. There was a high correlation between MRD levels by NGS and MFC, with an excellent capacity to predict the outcome. These results reinforce the usefulness of the MRD assessment by NGS for patient risk stratification in MM and provides a new approach easily available for most laboratories.

Background: Multiple Myeloma (MM) cells rearrange iron trafficking proteins to promote iron retention and favor proliferation. However, iron balance is essential even in cancer cells. We have previously demonstrated that iron excess delays disease development in MM pre-clinical models and that the proteasome inhibitor bortezomib (BTZ) interferes with the cell defensive response against iron excess, maximizing iron toxicity and oxidative damage within MM cells. Accordingly, high iron dose increases BTZ efficacy *in vivo* (Bordini *et al.* Leukemia 2017). Searching for the mechanisms of iron toxicity we reasoned that, since MM cells stem from non-malignant professional secretory precursors, iron excess might interfere with proteasome and autophagy degradation pathways. In addition iron may affect also the microenvironment: it has been reported that iron loaded tumor associated macrophages (TAM) shift from pro-survival to pro-inflammatory phenotype that negatively affects tumor expansion in implanted mammary tumors and in liver and lung metastasis models.
Aims: To demonstrate that iron supplementation increases the efficacy of proteasome inhibitors-based protocols in transgenic Vk*MYC MM murine model and to analyze the molecular mechanisms underlying iron toxicity with the final aim of providing novel, even iron-independent, targetable pathways in MM.
Methods: Vk*MYC mice were treated with three consecutive cycles of BTZ, melphalan and prednisone (VMP regimen). In every cycle, a pool of mice was additionally treated with iron dextran (100 mg/Kg). Treatment efficacy was determined by serum monoclonal component reduction. To analyze protein homeostasis, we assayed poly-ubiquitinated (poly-Ub) proteins level and of the autophagic marker LC3 in MM cell lines treated with increasing concentration of Ferric Ammonium Citrate (FAC), either alone or in combination with BTZ. To evaluate macrophage polarization, bone marrow derived macrophages (BMDM) were cultured 72h in medium conditioned by MM cell lines and supplemented or not with FAC.
Results: At the end of the first VMP cycle mice treated with iron (VMP-Iron) showed stronger disease reduction than VMP-Saline mice (p <0,01). Subsequent VMP-Iron cycles successfully controlled the disease while VMP-Saline mice became refractory. No alteration of liver and kidney function was observed in VMP-Iron mice at the end of treatment. Within tumor tissue, iron accumulated preferentially in bone marrow macrophages. *in vitro*, we observed a dose dependent accumulation of poly-Ub proteins after iron exposure, suggesting that iron burden might impair proteasome functionality. Addition of iron further increased poly-Ub proteins levels upon BTZ. Moreover, BTZ increased LC3 levels and consumption rate, suggesting increased autophagic flux as compensatory mechanism after proteasome inhibition. Iron addition to BTZ reduced LC3 consumption, suggesting a decrease of autophagic response and a mechanism of reversing BTZ resistance. As for macrophage polarization, BMDM exposed to medium conditioned by MM cells rearranged iron proteins expression toward the iron recycling phenotype as observed in M2-like polarization. Addition of FAC stimulated TNF-alpha expression, suggesting a switch to M1-like phenotype associated to anti-tumor activity.
Summary/Conclusion: High iron dose negatively affects MM cells proliferation by interfering with multiple cellular pathways and tumor microenvironment. Since iron increases VMP regimen efficacy, our data suggest that iron administration might impact on MM therapy.

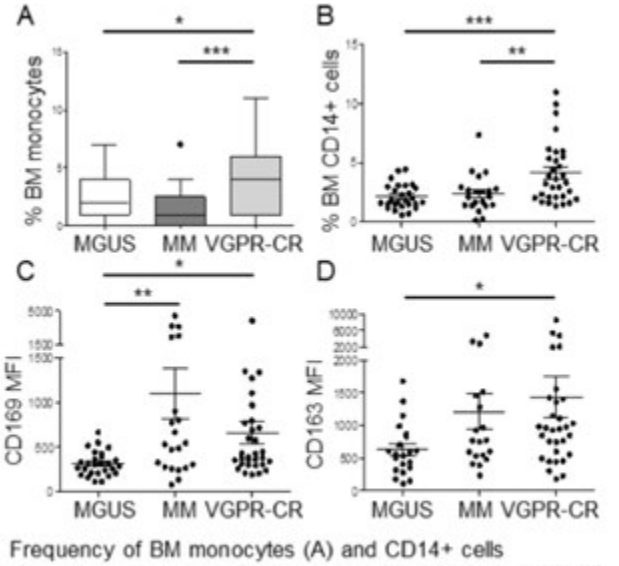
BONE MARROW MACROPHAGES IN PATIENTS WITH MULTIPLE MYELOMA IN COMPLETE REMISSION RETAIN PRO-TUMOR M2 PHENOTYPE

E. Lozano[1,*], T. Diaz[1], M.-P. Mena[1], M.T. Cibeira[1], I. Isola[1], L. Rosinol[1], J. Blade[1], C. Fernandez de Larrea[1]

[1]Amyloidosis and Myeloma Unit. Hematology Department, Hospital Clinic-IDIBAPS, Barcelona, Spain

Background: Macrophages may play pro-tumor or anti-tumor roles depending on the hematological malignancy and the stage of the disease. In this sense, immune regulation control proliferation of aberrant plasma cells (PCs) in the asymptomatic monoclonal gammopathy of undetermined sig-

nificance (MGUS) that precedes multiple myeloma (MM) and in patients with MM in sustained complete remission (CR) after treatment. Thus, a better understanding of the roles of macrophages at different stages of MM pathogenesis may provide new opportunities for therapeutic intervention.
Aims: The aim of this study was to investigate macrophage contribution to immune regulation in MGUS, symptomatic MM and patients with MM who have achieved CR or very good partial response (VGPR).
Methods: Frequency of monocyte-macrophage in bone marrow (BM) was analyzed by May-Grünwald-Giemsa staining of BM smears. We quantified BM CD45+CD3-CD4^{med}CD14+ cells and expression of CD169 (also known as Siglec1) and the M2-associated marker CD163 by 8-color flow cytometry. Concentrations of soluble CD169 and CD163 in BM plasma were measured by ELISA.
Results: Statistical analysis of frequency of BM monocyte-macrophages comparing MGUS (n=33), symptomatic MM (n=45) and MM in VGPR/CR (n=59) showed a significant increase of monocyte-macrophages in VGPR/CR status versus MM (ANOVA test ***p<0.0001) (Figure 1A). However, more than 4% of BM monocytes in patients with CR (n=67) was associated with a trend toward shorter PFS (2.5 vs. 4.9 years, p=0.092). To better understand the role of macrophages in patients in VGPR/CR, we next quantified frequency and changes in macrophage phenotype by flow cytometry. Indeed, we found that patients with MM in VGPR/CR (n=31) showed significantly higher frequency of CD14+ cells compared to patients with symptomatic MM (n=21) and MGUS (n=27) (ANOVA test ***p=0.0003) (Figure 1B). Moreover, expression of CD169 was significantly higher in symptomatic MM and VGPR/CR compared to MGUS (ANOVA test **p=0.0051), without differences between MM and VGPR/CR. Similarly, expression of the M2-associated marker CD163 was higher in MM and patients in VGPR/CR compared to MGUS (ANOVA test *p=0.03) (Figure 1 C-D) indicating no significant differences in macrophage phenotype in VGPR-CR compared to symptomatic MM.
Since CD169 and scavenger receptor CD163 can be found as soluble form after shedding, we next quantified their levels in BM plasma. No significant differences were found in sCD169 and sCD163 between MGUS (n=16) and symptomatic MM (n=31). We then measured sCD169 and sCD163 in paired samples from patients with active MM and in CR after treatment (n=14). Values of sCD169 were significantly increased in CR (Mean±SEM 3.214 ng/mL±0.422) compared to the previous corresponding values when active MM (0.8571±0.231; paired t test ***p=0.0001). Moreover, levels of sCD163 were also higher in CR (573.2 ng/mL±58.65) compared to active MM (388.4±37.24, paired t test **p=0.0085).



Frequency of BM monocytes (A) and CD14+ cells (B) by flow cytometry. Expression of CD169 (C) and CD163 (D) in BM CD14+ cells. *p<0.05, **p<0.01, ***p<0.001.

Figure 1.

Summary/Conclusion: The frequency of macrophages in BM from patients with MM in VGPR/CR is increased compared to patients with symptomatic MM. However, the high expression of M2-marker CD163 both soluble and on cell surface suggests that BM macrophages from patients with MM in VGPR/CR may retain the pro-tumor M2-phenotype found in patients with active myeloma. M2-macrophages may collaborate to support malignant cell survival in symptomatic MM and during relapses, suggesting that targeting macrophage could offer new opportunities of therapeutic approach in myeloma.

PTC-028 DEMONSTRATES POTENT PRE-CLINICAL ACTIVITY AND PROVIDES A NOVEL OPPORTUNITY TO MODULATE BMI1 IN MULTIPLE MYELOMA

A. Bolomsky[1], J. Muller[2], K. Stangelberger[1], R. Heusschen[2], M. Weetall[3], A. Branstrom[3], N. Zojer[1], J. Caers[2], H. Ludwig[1,*]

[1]Wilhelminen Cancer Research Institute, Vienna, Austria, [2]Laboratory of Hematology, University of Liège, Liège, Belgium, [3]PTC Therapeutics Inc., South Plainfield, NJ, United States

Background: The polycomb group protein BMI1 was linked to the pathogenesis of MM more than a decade ago, and represents a prominent intrinsic driver of MM with close associations to high-risk genes such as MYC and FOXM1. However, similar to other promising drug targets in MM biology (e.g. IRF4), direct modulation of these factors is impeded by the lack of clinically effective inhibitors.
Aims: In the current study, we explored the anti-myeloma efficacy of PTC-028, the first in class BMI1 protein modulator and confirmed its applicability to target a so far not drug-able key molecule in MM.
Methods: The anti-MM efficacy of PTC-028 (kindly provided by PTC Therapeutics Inc.) was studied *in vitro* using human MM cell lines (HMCLs) and primary MM cells. Candidate gene expression levels were analyzed by quantitative PCR (qPCR), Western Blot and/or flow cytometry (FC). Mechanistic studies were conducted via FC, phospho-specific ELISAs and immunoblot experiments. Confirmatory studies are employed using lentiviral transduction of BMI1 overexpression or knockout plasmids, respectively.
Results: PTC-028 induced a rapid decrease of BMI1 protein levels and demonstrated potent anti-MM activity in all primary MM cells and HMCLs tested (median IC50: 39 nM, range: 11-102 nM). Anti-myeloma activity persisted in the presence of bone marrow stromal cells and in proteasome inhibitor (PI) resistant HMCLs. Importantly, median IC50 values were significantly reduced compared to a transcriptional repressor of BMI1 - PTC-209 (median IC50 39 vs. 680 nM, p<0.05). We also observed a significant correlation between PTC-028 IC50 values and the reduction of BMI1 protein levels in HMCLs (R=0.86, p=0.01), suggesting that alterations of BMI1 levels could serve as predictive marker for treatment efficacy.
Mechanistic analyses demonstrated an accumulation of MM cells in the G2/M phase of the cell cycle as well as the induction of apoptosis accompanied by the presence of cleaved caspases 8 and 9, cleaved PARP, and depolarization of the mitochondrial membrane potential. Time course experiments with U266 and KMS-12-BM cells revealed rapid induction of G2/M cell cycle arrest (evident 6h post treatment) in line with an accumulation of CDK1 and Cyclin B1 at the protein level. This was followed by a significant reduction of MCL1 protein levels during mitotic arrest. Further validation of these results was obtained by qPCR analysis demonstrating upregulation of mitosis associated genes (*CCNB1, AURKA, BIRC5*) and downregulation of *MCL1* 6h and 24h post treatment.
BMI1 was reported to interact with several signaling axes important for the survival of MM. We therefore examined the impact of PTC-028 on MYC, AKT, ERK, and GSK3b activity. These analyses demonstrated a significant reduction of MYC and AKT activity 24h post treatment, while ERK and GSK3b activation remained unaffected. In addition, MYC protein expression was found to be downregulated together with FOXM1 expression suggesting that PTC-028 might provide a novel strategy to target a so far not drug-able high-risk network.
Summary/Conclusion: This study demonstrates potent *in vitro* activity of the first in class BMI1 modulator PTC-028 in a panel of HMCLs, primary MM cells, and PI-resistant HMCLs. Moreover, our data point to significant impact on a currently not targetable high-risk network consisting of BMI1, MYC and FOXM1. Based on these potent *in vitro* results further pre-clinical evaluation of PTC-028 in murine models of MM is in progress.

tology Section, Università degli Studi di Catania, CATANIA, [2]Age and disease related Unit, Fondazione Centro San Raffaele, Milano, [3]Laboratory of Pre-Clinical and Translational Research, Reference Cancer Center of Basilicata, IRCCS CROB, Rionero in Vulture, [4]Università degli Studi di Catania, CATANIA, [5]Fondazione Centro San Raffaele, Milano, Italy

Background: Multiple myeloma (MM) originates from a clone of transformed plasma cells (PCs) that establish vicious interactions with the multicellular bone marrow (BM) environment. Disease progression depends on the ability of malignant PCs to subvert such environment to reshape host immunity and support tumor growth.
Aims: To evaluate how environmental signals, such as arginine deprivation, can modulate p62 and IRF4 in MM.
Methods: Little being known on metabolic changes during MM progression, we first deployed a comprehensive metabolic analysis at different stages of disease. We adopted ultra-high performance liquid and gas chromatography followed by mass spectrometry (UHPLC/GC-MS) on an independent series of 167 samples of BM and peripheral plasma collected *ad hoc* from 125 individuals, and age-matched healthy volunteers (n=29). Upon exclusion of drug metabolites and xenobiotic compounds, 284 endogenous metabolites were processed by PCA (unsupervised) and OPLS-DA (supervised) multivariate analyses to identify myeloma-associated metabolites. Next, we explored the expression levels of key metabolic genes in a large series of highly purified BM PC samples from healthy donors (n=4) and patients with MM (n=129), primary PC leukemia (pPCL, n=24), and secondary PC leukemia (sPCL, n=12) from a proprietary dataset (GSE66293).
Results: Metabolomics revealed the presence of robust metabolic differences in the progression from MGUS to MM, sustained by reduced amount of lysolipids and selected amino acids. In particular, we found MM progression to correlate with shortage of arginine, a well-established tolerogenic signal. These findings were validated by HPLC and ELISA in an independent cohort confirming the association of arginine deprivation with progression from MGUS through MM. Moreover, enolase-1 (ENO-1), phosphoglycerate kinase 1 (PGK-1), and dihydrolipoamide dehydrogenase (DLD) were increased upon progression, suggesting that branched chain amino acids, alpha-ketoglutarate, and glycine cleavage products are used in MM to sustain NADH availability and energy production. Using arginine deprivation and pharmacological inhibitors of glucose metabolism (2-deoxyglucose) and GCN2 signalling (ISRIB) we collected evidence that MM cells generally deploy TCA and oxidative phosphorylation, with glucose catabolism as a major source of ATP. Next, we sought to determine whether the adaptation to amino acid depletion through autophagy altered cellular glucose dependence in three MM cell lines chosen for their cytogenetic alterations: U266 (t 11;14); H929 (t 4;14) and MM.1s (t 14;16). Progressive arginine deprivation (1 μM-10 nM) did not affect proliferation *in vitro*, even in low-glucose media. However, long-term arginine deprivation, or treatment with human recombinant arginase-1 (which reduced extra-cellular arginine availability within 12 hours of exposure), altered the cellular dependence on mitochondrial ATP generation via oxidative phosphorylation, increased glutamine anaplerosis, and induced increased expression of p62 and IRF4 in a time-dependent manner. In primary MGUS and MM samples, we identified $CD11b^+CD33^+CD15^+CD14^-HLA\text{-}DR^-$ myeloid cells as the chief source of Arg-1, which was not expressed by T-cells, $CD11b^+CD33^+CD15^-CD14^+HLA\text{-}DR^-$ myeloid cells or PCs.
Summary/Conclusion: Our study implicates arginine shortage, likely accounted for by increased Arg-1 in myeloid cells, in MM progression. Reduced arginine availability in the BM may promote a large-scale metabolic adaptation of MM to the microenvironment, sustaining tumor growth and offering new potential targets for synthetic lethality.

PS1273

DEMETHYLATION SENSITISES T(4;14) MULTIPLE MYELOMA TO RAS-MAPK PATHWAY INHIBITION

J. Hocking[1,2,*], A. Spencer[1,2], S. Mithraprabhu[2], T. Khong[2]

[1]Malignant Haematology and Stem Cell Transplant, Alfred Hospital, [2]Australian Centre for Blood Disease, Monash University, Melbourne, Australia

Background: The t(4;14) translocation is present in 15% of multiple myelomas. It juxtaposes the MMSET/FGFR3 locus on chromosome 4 with the IgH gene on chromosome 14 resulting in dysregulation of both MMSET and FGFR3. It defines a high risk subset of multiple myeloma with worse outcomes and shortened overall survival. FGFR3 is a receptor tyrosine kinase that inputs via the RAS-MAPK, and is considered mutually exclusive with activating mutations of RAS (RAS^M). MMSET is a histone methylator and thought to act predominantly through epigenetic modification.
Aims: We investigated the impact of trametinib (MEK inhibitor) with and without azacitidine (AZA) pre-treatment (hypomethylating agent) on human myeloma cell lines (HMCLs) harbouring t(4;14) or neither t(4;14) nor RAS^M (WT). We aimed to identify mechanisms of action of AZA treatment that may sensitise HMCLs to MEK inhibtion.
Finally we evaluated the combination of AZA and trametinib in our murine xenograft model to determine effects on disease kinetics and survival.
Methods: Three t(4;14) HMCLs with FGFR3 overexpression (19-500 fold overexpression by RT-PCR c/w WT HMCLs) and 2 WT HMCLs were pre-treated with AZA (200nM) daily for 7 days followed by trametinib (10nM, 100 nM, 1 μM) for 72 hours. Proliferation, cell viability and cell cycle were evaluated by propidium iodide based flow cytometry. RNA was isolated pre- and post-AZA treatment for RNA sequencing using the HiSeq2500 platform to identify gene epxression changes that may impact on MEK inhibitor sensitivity. A second set of HMCLs harbouring the t(4;14) was tested to validate the initial results. Mechanistic studies were undertaken to evaluate the effects on histone methylation (targets of MMSET). The effects on known targets of AZA - DNMT3a and DNMT3b were also evaluated. DNMT3b siRNA knockdown was undertaken in one t(4;14) HMCL. Murine xenograft studies of a t(4;14) and WT were performed to evaluate the combination of azacitidine and trametinib *in vivo*.
Results: Neither the AZA (200 nM) pre-treatment alone nor single agent trametinib resulted in any significant effect on either group of HMCLs in all outcomes measured. Conversely trametinib exposure following AZA pre-treatment resulted in a significant reduction in proliferation ($p<0.002$) in all t(4;14) HMCLs at all doses. The most profound reduction in proliferation of 55-92% ($p<0.002$) was seen at 1 μM. Similarly following trametinib (1 μM) a relative increase of 25-55% of cells in the pre-apoptotic phase of the cell cycle was observed in 2 of 3 t(4;14) HMCLs. These results were recapitulated in the validation set of t(4;14) HMCLs. Interestingly, no significant changes in all outcomes measured were observered in the WT HMCLs despite pre-treatment with AZA. We found that t(4;14) HMCLs overexpress DNMT3b compared with WT HMCLs ($p<0.0001$). Whilst no difference was observed in expression of DNMT3a. No consistent change or effect was observed on the histone methylation marks at H3K27 or H3K36. Finally, in our murine xenograft pre-treatment with AZA then trametinib resulted in slower disease growth kinetics and an increase in overall survival in mice with t(4;14) treated with the combination compared with either single agent and in all outcomes compared with WT.
Summary/Conclusion: The combination of AZA and trametinib is effective against high risk t(4;14) MM representing a potential novel targeted therapeutic approach that warrants further investigation.

PS1274

CD96 (TACTILE) NEGATIVELY REGULATES THE CYTOTOXIC FUNCTIONS OF NATURAL KILLER CELLS AGAINST MULTIPLE MYELOMA

T. Duggan[1], S. Sarkar[1,2], S. Chauhan[1,2], J. Daly[1], M. O'Dwyer[1,2,*]

[1]Apoptosis Research Centre, National University of Ireland, [2]Onkimmune Ltd., Galway, Ireland

Background: Cellular immunotherapeutic approaches, including Natural Killer (NK) cell therapy, have recently shown very promising results in the treatment of blood cancers, including Multiple Myeloma (MM). CD96 (TACTILE) is a newly identified inhibitory checkpoint receptor expressed on the surface of NK cells. Ligand binding studies have shown that CD96 competes with CD226 (DNAM-1), a co-activating receptor on the surface of NK cells. This competitive interaction between CD96 and CD226 for binding to tumour bound CD155 could influence the cytotoxic activity of NK cells. Although the precise role of CD96 in regulating NK cells is not clearly understood, recent studies have shown that blocking CD96 with a monoclonal antibody can reduce tumour cell metastasis in murine models of solid tumours. In contrast, blocking CD96 receptors on human NK cells *in vitro* have shown conflicting results, with CD96 acting as an activating or inhibitory receptor depending on the tumour subtype.
Aims: In this study, our aim was to explore for the first time the immunomodulatory functioning of CD96 in mediating human NK cell cytotoxicity against MM.
Methods: CD155 expression was determined on a panel of cell lines MM1S, RPMI-8226, JJN3, H929, and U266. CD96 surface expression of KHYG1 NK cell line was knocked-down by nucleofection with either scrambled control (SC) siRNA or CD96 siRNA (GE, cat: L-020045-02) using AMAXA Nucleofector II. 72 hours post-nucleofection, the cells were analysed for surface CD96 expression and subsequently co-cultured with MM cell lines. Functional assays were performed with MM cell lines at E:T ratios of 0.125:1, 0.25:1, 0.5:1, 1:1. 2:1 and 4:1.NK cell-induced cytotoxicity was measured by FACS-based methods. KHYG1 NK cells were cultured either

at normoxia (21% O_2) or hypoxia (1% O_2) for 72 hours to determine CD96 expression.
Results: Immunophenotyping revealed that MM cell lines have a broad spectrum cell surface expression of CD155, the ligand for CD96, and therefore we classified them as CD155-*high* (JJN3), CD155-*mod* (U266, MM1S, RPMI-8226), and CD155-*low* (H929). Thereafter cytotoxicity assays were performed against a panel of MM cell lines (JJN3, U266, and H929) with control SC siRNA KHYG1 or CD96 siRNA KHYG1. CD96 siRNA KHYG1 was significantly more cytotoxic towards the moderately expressing CD155 cell line U266 at E:T 1:1, 2:1, and 4:1 as compared to SC siRNA KHYG1. Furthermore, this increase in cytotoxicity was also observed against the CD155-*high* cell line JJN3 at E:T 0.5:1 and 4:1. Interestingly, no significant increase in cytotoxicity was observed for the CD155-*low* cell line H929, suggesting the presence of the CD155 ligand on the tumour cell surface is necessary for CD96 mediated impairment of NK cell cytotoxic function. Furthermore, CD96 expression was significantly up-regulated under hypoxia as compared to normoxic culture conditions.
Summary/Conclusion: This study demonstrates the immunosuppressive function of the CD96 receptor during human NK cell-mediated cytotoxicity against MM *in vitro*. The contribution of this inhibitory signalling could be of paramount significance considering its upregulation under hypoxia. The enhanced cytotoxicity observed upon knockdown of CD96 could be of further therapeutic benefit during treatment with Bortezomib, as this is known to upregulate DNAM-1 ligands (CD155). Finally, we propose that siRNA based targeting of CD96 using clinical grade electroporation systems (e.g. MaxCyte GT) on therapeutically administered NK cells could significantly improve the clinical efficacy of contemporary NK cell-based treatments.

PS1275

GLUTAMINE-DEPENDENCE TARGETING BY ASPARAGINASE SIGNIFICANTLY INCREASES ANTI-MM ACTIVITY OF PROTEASOME INHIBITION

P. Minetto[1,*], D. Soncini[1], A. Cagnetta[1], F. Guolo[1], V. Retali[1], S. Ruberti[1], G. Rivoli[1], N. Bisso[1], N. Di Felice[1], M. Miglino[1], L. Canepa[1], M. Gobbi[1], R.M. Lemoli[1], M. Cea[1]

[1]Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, Policlinico San Martino, IRCCS per l'Oncologia, Genoa, Italy

Background: Human tumors exhibit high dependence on Glutamine (Gln) for their metabolic processes and macromolecule synthesis, condition that has been defined as "Gln-addiction". The role of such vulnerability has been recently investigated also in Multiple Myeloma (MM) cells, with Gln uptake exploited as novel therapeutic target. Indeed, MM cells by exhibiting significant lack of Gln synthetase become highly sensitive to Gln depletion as reported with L-asparaginase (ASNase), a bacteric enzyme that by degradating circulating asparagine and glutamine leads to intracellular aminoacids depletion.
Aims: Based on these data, here we explored the anti-MM activity of *Erwinia chrysantemi*-derived L. Asparaginase (ASNase; 10-folder higher glutaminase activity than its native formulation) in combination with carfilzomib (KAR).
Methods: The IC_{50} value of both E. chrysantemi ASNase and KAR was evaluated in a panel of HMCL carrying a different genetic background. Next, we found that low doses of KAR enhances significantly the anti-MM activity of ASNase. The effect of such combination was also tested in presence of IL6 and IGF-1, which mimics BMSCs milieu. Cell death analysis was measured with Annexin V/Propidium Iodide (AV/PI) staining followed by flow-cytometric analysis. The efficacy of co-treatment was confirmed by treating freshly isolated CD138 positive cells obtained from newly diagnosed MM patients (NDMM). Finally, western blot analysis was employed to fully elucidate mechanisms causing the observed synergism.
Results: ASNase treatment showed potent cytotoxic activity in all HMCL lines tested with an IC_{50} value ranging from 0,03 U/mL to 0.3 U/mL. High sensitivity was also observed on primary MM cells obtained from NDMM (IC_{50} =0.3 U/mL). Importantly, anti-MM activity of ASNase was further increased by adding low doses of the irreversible proteasome inhibitor KAR with a Combination Index value less than 1 in almost all tested drug-concentrations. Similar data were observed in tumors cells obtained from NDMM patients. Of note, the combination ASNase plus KAR resulted more potent than single agent treatment also in culture condition of Gln deprivation, suggesting that ASNase toxicity is not only related to its ASN-ase glutaminase activity. IL6 or IGF-1 addition did not reduce anti-MM activity of ASNase plus KAR, indicating that BMSCs microenvironment does not reduce its activity. A time and dose-dependent activity of co-treatment was also observed, with higher efficacy measured at 48 h compared with 24h of drugs exposure. Caspase-3 and PARP cleavage was observed in co-treated cells and the addition of the pan-caspase inhibitor Z-VAD-FMK reverted the cytotoxic effects of the combination revealing the role of apoptosis in observed synergism. Authophagic features, including LC3II cleavage, were observed in tumor cells treated with ASNase; the addition of authophagy inhibitor 3-Methyladenine was not able to revert the cytotoxic effect of the combination.
Summary/Conclusion: Gln dependence represents an attractive therapeutic target to be exploited in plasma cells disorders. Our preliminary data show that *E. chrysantemy* derived asparaginase exerts a potent anti-MM activity by affecting neoplastic cells metabolism. This activity is further increased by the addition of the irreversible proteasome inhibitor carfilzomib mainly through an apoptotic-mediated mechanism while autophagy plays a cytoprotective role in L-asp-treated plasmacells.

PS1276

MITOCHONDRIAL ACTIVITY PLAYS A CRITICAL ROLE IN MULTIPLE MYELOMA RESISTANCE

A. Ortiz[1,*], Y. Ruiz-Heredia[2], M. L. Morales[2], C. Barcenas[2], R. M. García-Martin[2], V. Garrido[2], I. Baquero[2], R. Alonso[2], J. Martínez-López[2], M. Linares[1], M. Gallardo[1]

[1]CNIO, [2]Hospital 12 de octubre, Madrid, Spain
**MG and ML contribute equally to this manuscript*

Background: Mitochondria control crucial biological pathways such as proliferation, apoptosis and cell growth. Some studies evaluated the role of mitochondria in cancer, demonstrating its relation to cancer formation and growth. However, the implication of mitochondrial activity in the pathogenesis of Multiple Myeloma (MM) stills remains unknown and only a few studies connect the mitochondria status and MM.
Aims: We have studied the impact of mitochondrial genes, protein expression, and activity in MM progression and treatment resistance. Furthermore, we have studied the potential exploitation of mitochondrial activity as a functional target in the MM therapy.
Methods: We have performed gene expression studies by RT-PCR of known factors that regulate and are involved in the mitochondrial function such as: c-Myc, transcription factor A mitochondrial (TFAM), elongation factor thermo unstable (EF-Tu), nuclear respiratory factor 1 (NRF1) and hnRNPK. We have studied a total of 34 cDNA sample patients (12 MGUS, 15 MM at Diagnosis, 7 MM at relapse). In order to validate gene expression results, we developed an immunohistochemistry (IHC) assay of COX II, representative protein of mitochondrial burden. We evaluate a total of 49 patients (9 MGUS, 20 MM at Diagnosis, 20 MM at relapse). Next we analyzed the mitochondrial activity with the study of COX2 histoenzymatic reaction in 15 patients (2 MGUS, 9 MM at Diagnosis and 4 MM at relapse). Finally, we have tested the effect in plasma cells of Metformin and Tigecycline, two drugs that were demonstrated to inhibit the mitochondrial activity, in monotherapy and in combination with Bortezomib over four MM cell lines (JJN3, L363, NCI-H929 and NCI-H929 R20). Besides, we analyze the mitochondrial DNA (mtDNA) burden in these cell lines. Our further studies include *in vivo* validation in NSG mice models of results obtained *in vitro*.

Figure 1.

Results: We have observed a significant overexpression of genes C-Myc, TFAM, EF-Tu, and a higher expression trend of hnRNPK in MM relapsed patients compared with MGUS and newly diagnose MM groups (p-value *<0.05; p-value **<0.001) (Figure 1A). Moreover, IHC reveals overexpression of mitochondrial COXII protein in newly diagnose MM and relapsed

groups compared with MGUS (Figure 1B). By a functional assay we have demonstrated that gene and protein overexpression drives to an increase of activity, comparing MGUS and MM at diagnosis versus MM at relapse (p-value ***<0.0001) (Figure 1C). We confirmed the correlation between higher mitochondrial burden and resistance to bortezomib in JJN3 and L363, and NCI-H929 and its resistant, NCI-H929 R20 (p-value*<0.05) (Figure 1D). *In vitro* drug assays showed a synergistic effect of tigecycline with bortezomib, suggesting that could be used as a potential therapy in combination for MM patients.
Summary/Conclusion: Mitochondrial machinery plays a critical role in the development, progression and resistance of MM patients. Mitochondrial protein components that generates the activity could be prospective targets for MM treatment. Tigecycline demonstrates synergistic effect with Bortezomib suggesting potential use as novel drug combination therapy in MM patients.

ELOTUZUMAB PROMOTES SELF-ENGAGEMENT OF SLAMF7 BETWEEN NATURAL KILLER AND MULTIPLE MYELOMA CELLS TO ENHANCE CYTOTOXICITY

T. Pazina[1], A.M. James[2], A. Jhatakia[3], R.F. Graziano[3], N.A. Bezman[3], M. D. Robbins[3,*], A.D. Cohen[4], K. S. Campbell[1]

[1]Fox Chase Cancer Center, [2]American Association for Cancer Research, Philadelphia, [3]Bristol-Myers Squibb, Princeton, [4]University of Pennsylvania, Philadelphia, United States

Background: Elotuzumab is an immunoglobulin G1 monoclonal antibody targeting signaling lymphocytic activation molecule family member 7 (SLAMF7), which is highly expressed on multiple myeloma (MM) cells, natural killer (NK) cells, and, to varying degrees, other immune cells. Preclinical reports show that elotuzumab promotes potent NK cell–mediated antibody-dependent cellular cytotoxicity via Fc interaction with FcgRIIIA (CD16), resulting in killing of SLAMF7+ MM cells, which is further enhanced in combination with lenalidomide. Previous preclinical studies also suggest that elotuzumab can enhance NK cell activity via a costimulation mechanism independent of CD16 binding. In patients with relapsed/refractory MM, elotuzumab combined with lenalidomide and low-dose dexamethasone improves progression-free survival.
Aims: To characterize how elotuzumab affects interactions between NK and MM cells to enhance NK cell–mediated cytotoxicity.
Methods: We generated 2 MM cell lines (MM.1R and RPMI8226) modified to express low or high levels of SLAMF7, as well as the SKOV3 ovarian adenocarcinoma cell line transduced to express SLAMF7. CRISPR/Cas9 technology was used to generate a SLAMF7-deficient human NK-92 cell line. Variants of this SLAMF7-deficient line and an NK-92 line expressing high levels of SLAMF7 that expressed or lacked CD16 were also generated. Cytotoxicity was measured with CytoTox 96® (Promega) and xCELLigence® real-time cell analysis (ACEA Biosciences) platforms. A human SLAMF7 extracellular/T-cell receptor [TCR]-zeta intracellular fusion construct was transfected into a 3A9 mouse T-cell line and used as a reporter of SLAMF7 engagement by measuring interleukin-2 production using an enzyme-linked immunosorbent assay.
Results: Consistent with previous reports, addition of elotuzumab strongly enhanced cytotoxicity of CD16-expressing SLAMF7+ NK-92 cells against SLAMF7+ MM and SKOV3 cells. Elotuzumab also substantially boosted cytotoxicity by CD16-deficient SLAMF7+ parental NK-92 cells toward SLAMF7+ RPMI8226 and SKOV3 cells. Knockout of SLAMF7 on parental NK-92 cells, however, abrogated elotuzumab-mediated cytotoxicity toward SLAMF7+ SKOV3 targets. Additionally, by using a SLAMF7/TCR-zeta–expressing reporter cell line and plate-bound recombinant SLAMF7, we found that elotuzumab promoted reporter activity, suggesting it may facilitate or enhance SLAMF7–SLAMF7 interactions. Interestingly, other anti-SLAMF7 antibodies were ineffective in stimulating reporter activity.
Summary/Conclusion: We conclude that elotuzumab has an additional function as an NK cell–activating antibody. SLAMF7 naturally engages with itself in homotypic interactions. Elotuzumab uniquely promoted NK cell–mediated cytotoxicity in a CD16-independent manner, but only if both NK and target cells expressed SLAMF7. This suggests that elotuzumab can facilitate or enhance SLAMF7–SLAMF7 interactions between NK cells and MM targets. As elotuzumab is clinically used in combination with lenalidomide, additional studies are needed to understand the impact of combination treatment on elotuzumab-mediated SLAMF7–SLAMF7 interactions. Based on these preclinical observations, SLAMF7 expression on NK cells warrants further investigation as a potential biomarker for elotuzumab efficacy.

CARFILZOMIB-INDUCED CARDIOTOXICITY: MOLECULAR MECHANISMS AND THE EMERGING ROLE OF METFORMIN AS A PROPHYLACTIC THERAPY

G. Kremastiotis[1], P. Efentakis[1], A. Varela[2], C. H. Davos[2], E.-D. Papanagnou[3], I. P. Trougakos[3], E. Kastritis[4], Z. Kanaki[2], E. Iliodromitis[5], A. Klinakis[2], M.A. Dimopoulos[4], I. Andreadou[1], E. Terpos[4,*]

[1]Laboratory of Pharmacology, Faculty of Pharmacy, National and Kapodistrian University of Athens, [2]Biomedical Research Foundation Academy of Athens, [3]Department of Cell Biology and Biophysics, Faculty of Biology, National and Kapodistrian University of Athens, [4]Department of Clinical Therapeutics, [5]Second Department of Cardiology, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

Background: Carfilzomib (Cfz) is an irreversible proteasome inhibitor, which is used for the treatment of relapsed/refractory multiple myeloma (RRMM). In phase III trials, Cfz has been associated with higher cardiotoxicity and heart failure rates compared to the control treatment. Due to the severity of these adverse events and the lacking data regarding the induced cardiotoxicity, there is an imperative need for the elucidation and abrogation of the underlying mechanisms of Cfz-induced cardiotoxicity.
Aims: The aim of this study was to investigate the molecular mechanisms of Cfz-induced cardiotoxicity and to evaluate possible cardioprotective effects of concomitant medications based on our initial results.
Methods: Protocol 1: Male C57BL/6 mice, were randomized into: Control (/S 0.9%, n=7) and Cfz group (n=8). Based on the results showing below we also developed a second protocol using metformin (met); Protocol 2: Male C57BL/6 mice were randomized into: Control (/S 0.9%, n=8); Cfz (n=8) and Cfz+Met (n=10). Cfz (8 mg/kg ip) was administered every 48 hours in both protocols and Met (140 mg/kg po) every 24 hours for 6 days. Fastening glucose levels were monitored. At baseline and at the end of treatments mice underwent echocardiographic assessment. Animals were sacrificed and blood and myocardial tissue samples were obtained for the analysis of proteasome peptidases activity, protein phosphatase 2A (PP2A) activity and molecular signaling mechanisms. Protein kinase Akt, along with its downstream NO synthases; endothelial (eNOS) and inducible (iNOS), were identified as targets of possible endothelial dysfunction and inflammation. Moreover, the transcription factor FOXO1, downstream target of Akt and AMPKα, was identified in order to investigate possible changes in the expression of apoptotic factors. Finally, AMPKα was identified since – besides phosphorylating eNOS and FOXO1 – it functions as a regulator of autophagy.
Results: Administration of Cfz resulted in significant reduction of the chymotrypsin-like (CT-L) proteasome activity in myocardial tissue and peripheral blood mononuclear cells of Cfz-treated mice vs controls (p<0.01). Protocol 1: Reduction in fractional shortening (FS%) was observed in the Cfz group vs Control at Day 6 (39.87±0.47% vs 42.05±0.64% respectively, p<0.05). Cfz increased PP2A activity vs Control (p<0.05), without altering PP2A expression. A decrease in pAkt/tAkt (p<0.05), peNOS/teNOS (p<0.05), pAMPKα/tAMPKα (p<0.001) and an increase in the expression of iNOS (p<0.01) was observed in the Cfz group vs Control. Protocol 2: Met did not reduce fastening glucose levels at day 6 in Cfz+Met compared to Control and Cfz groups. Echocardiographic assessment at day 6 revealed that Met reversed Cfz-induced reduction in the FS% in Cfz+Met vs Cfz group (43.4±0.5% vs 41.5±0.4% respectively, p<0.05). AMPKα phosphorylation was significantly increased in the same group compared to Cfz group (p<0.01).
Summary/Conclusion: The present study demonstrates that Cfz induces cardiac dysfunction via increasing PP2A activity, leading to decreased phosphorylation of Akt, eNOS and AMPKα. The disturbance of Akt/AMPKα/eNOS axis and the increase of iNOS, suggests that Cfz might intervene with oxidative stress, apoptosis and myocardial energetic pathways. Thus, Cfz-induced increase in PP2A activity seems to be essential in the mechanism of cardiotoxicity. Met restored AMPKα phosphorylation and reversed Cfz-induced contractile dysfunction, emerging to be a potent pharmacological intervention for the management of Cfz-induced cardiotoxicity.

PS1279

JAGGED1/2 INHIBITION PROMOTES TUMOR CELLS RESPONSE TO BORTEZOMIB IN A ZEBRAFISH MODEL OF MULTIPLE MYELOMA

M. Colombo[1,*], M. Mazzola[2], R. Colella[1], S. Garavelli[1], M. T. Palano[1], D. Giannandrea[1], N. Platonova[1], A. Neri[3], A. Pistocchi[2], R. Chiaramonte[1]

[1]Health Sciences, [2]Medical Biotechnology and Translational Medicine, [3]Oncology

and Hemato-oncology, Università degli Studi di Milano, Milano, Italy

Background: Multiple myeloma (MM) is the second most frequently diagnosed hematological malignancy and today is still incurable, mainly due to the development of drug resistance that causes relapse and contributes to the fatal outcome of this disease. MM cells accumulate in the bone marrow (BM) and establish complex interactions with the surrounding normal cells, forcing them to assume a pro-tumor behavior. In this process, a key role is played by the two Notch ligands Jagged1 and 2, whose dysregulated expression causes an aberrant activation of the Notch pathway both in MM cells and in the BM niche cells.
Aims: We aimed to validate the effect of Jagged1/2 silencing on MM cells resistance to the standard-of-care drug Bortezomib by: i) *in vitro*, on co-culture of MM cell lines and BM stromal cells (BNSC); ii) *ex vivo*, on co-culture of primary cells from MM patients and BMSC; iii) *in vivo*, using a zebrafish xenograft model of MM that allows a rapid and reliable screening of MM cells response to chemotherapics.
Methods: Jagged1/2 expression was inhibited transiently in MM cell lines using specific siRNAs and constitutively in primary MM cells using a lentiviral vector that encodes specific shRNAs. Cells were cultured alone or co-cultured with BMSC and treated with 8nM Bortezomib. Apoptosis was evaluated by Annexin V staining and flow cytometry. For *in vivo* experiments cells were stained with the CM-Dil vital dye, resuspended in PBS + 3% polyvinyl pyrrolidone and injected in the yolk area of 2dpf (days post fertilization) zebrafish embryos. Injected embryos were treated with 10μM Bortezomib or DMSO for 48h. MM cells growth in zebrafish was evaluated by fluorescence microscopy and tumor area were calculated using ImageJ and normalized on tumor volume at the time of injection.
Results: Jagged1/2 blockade reduces MM cells ability to induce Notch activation in BMSC, causing a decrease in their capacity to sustain MM resistance to Bortezomib. Results obtained *in vitro* on MM cells lines were further validated on co-culture of primary CD138+ cells and BMSC from newly diagnosed MM patients. The analysis performed on xenotransplanted embryos showed that the treatment with 10μM Bortezomib caused a decrease of about the 50% in tumor growth in comparison to DMSO-treated controls, with no effect on embryos viability. Jagged1/2 knockdown alone has a comparable effect to Bortezomib, while the combination of Bortezomib and Jagged1/2 inhibition results in a stronger decrease in tumor growth of about the 75% in comparison to the vehicle-controls.
Summary/Conclusion: Our findings demonstrate that Jagged1/2 inhibition represents a suitable strategy to promote MM response to the standard of care drug Bortezomib, contrasting BM-induced drug resistance.

PS1280

TGFB INHIBITION IN COMBINATION WITH CHEMOTHERAPY REPAIRS EXISTING LYTIC BONE LESIONS IN A NOVEL PLATEAU PHASE MODEL OF MULTIPLE MYELOMA

A. Chantry[1,*], G. Alanna[1], D. Jenny[1], E. Holly[1], J. Paton-Hough[1], S. John[1], L. Michelle[1]

[1]Oncology and Metabolism, University of Sheffield, Sheffield, United Kingdom

Background: Multiple myeloma (MM) causes a destructive bone disease in >85% of patients and current therapies do little to repair existing bone damage. We previously identified that combined bone anabolic and anti-resorptive therapy repairs osteolytic lesions in mice with high tumour load. In patients, if bone repair agents were given, they would be administered in combination with chemotherapy.
Aims: This study aimed to determine if bone recovers after chemotherapy and if this is enhanced by bone anabolic therapy.
Methods: Human U266-GFP-luc MM cells were i.v. injected into NSG mice (n=5-7/group). After tumour and lytic bone lesion development, mice were administered first-line chemotherapeutics (bortezomib±lenalidomide)±a bone anabolic (SD208; transforming growth factor β receptor 1 inhibitor) or vehicles for 2 weeks. Tumour and bone lesions were monitored *in vivo* by bioluminescence imaging (BLI), serum paraprotein ELISAs and μCT. Flow cytometry, histomorphometry, μCT, TRAP and P1NP ELISAs and QPCR were performed for endpoint analyses.
Results: Chemotherapy significantly reduced total body tumour burden and paraprotein, and increased survival. Combined chemotherapy was more effective than either given alone, reducing tumour to levels undetectable by BLI and paraprotein. However, flow cytometry revealed low tumour levels of 100MM cells/10^6 bone marrow cells. Lytic bone lesions developed ~8 weeks after tumour inoculation. Vehicle treated mice exhibited progressive bone lesion development and virtually no trabecular bone at endpoint. Lesions in mice administered bortezomib±lenalidomide were unchanged after 1 week but began to repair after 2 weeks, with significantly reduced TRAP+ osteoclasts and increased osteoblasts, indicating recovery of bone. Mice treated with chemotherapy + anabolic SD-208 exhibited enhanced repair of bone lesions, with partial repair of perforating cortical lesions on all tibial surfaces within 1 week and complete repair of lesions within 2 weeks. SD-208 also significantly increased trabecular bone volume after 2 weeks.
Summary/Conclusion: This study identified SD-208 enhances MM bone lesion repair when combined with first-line chemotherapeutics. Future studies combining SD-208 and chemotherapy with anti-resorptive therapy will identify optimum treatment regimens for translation of bone anabolic therapy into MM clinical trials.

MULTIPLE MYELOMA: SINGLE PLARFORM ABSOLUTE COUNT OF CIRCULATING PLASMA CELLS AT DIAGNOSIS CORRELATE WITH POOR PROGNOSIS PARAMETERS

V. E. Muccio[1,*], M. Gilestro[2], E. Saraci[1], S. Spada[1], M. Ruggeri[1], S. Caltagirone[1], D. Oddolo[1], M. Cavo[3], V. Pavone[3], S. Ronconi[3], D. Vincelli[3], A.M. Cafro[3], C. Cellini[3], C. Musolino[3], S. Molica[3], A. Bernardini[1], F. Gay[1], P. Musto[3], M. Boccadoro[1], P. Omedé[2]

[1]Myeloma Unit, Division of Hematology, University of Torino, [2]Myeloma Unit, Division of Hematology, Città della Salute e della Scienza di Torino, Torino, [3]Italian Multiple Myeloma Network, GIMEMA, Italy, Italy

Background: Risk stratification of newly diagnosed multiple myeloma (NDMM) patients is based on clinical and laboratory parameters. In previous studies, circulating plasma cells (CPC) showed a significant correlation with more aggressive disease: CPC were detected by flow cytometry after separation by ficoll gradient, which can reduce the recovery of plasma cells, or by acquiring a defined total number of events, and the absolute CPC number was obtained using an automated hematology analyzer.
Aims: This is the first study to perform a single platform absolute count of CPC. We compared CPC with patients' baseline characteristics.
Methods: We collected 413 peripheral blood (PB) samples of NDMM patients enrolled in the UNITO-MM-01/FORTE. For the single platform tube, the antibody combination CD38PC7/CD138PC5.5/CD45KO/CD56PE/CD19PB was mixed with 100 μL of EDTA PB dispensed with reverse pipetting, added with 500 μL of lysing solution. After 15 min, 100μL of flow count were dispensed with reverse pipetting and acquired with Navios flow cytometer. In order to reduce the acquisition of cellular debris, a "live gate" was set on CD45/CD38 dot plot and all the events CD38 and CD45 negative were excluded. The CPC clonality was confirmed, in a second tube, by the determination of kappa and lambda light chains of intracytoplasmic immunoglobulins.
Results: CPC were detected in 390 of 413 samples (94.4%): median values were 0.03% (range 0%>51%), 2.37/mm^3 (range 0/mm^3-6272/mm^3), number of absolute CPC was 58 (range 0-441000); cellular events acquired 190000 (range 4428-1300000). Statistically significant higher values of CPC were found in samples from patients with poor prognosis features: Hb <10 g/dL, ISS stage III, R-ISS stage III, Albumin <3.5 g/dL, b2-microglobulin >5.4 mg/dL, LDH >upper limit, PC in biopsy ≥60%, presence of del13, ECOG 3 (all with a p value <0.001); ampl1, High Fonseca cytogenetic risk, High Morgan cytogenetic risk all with a p value <0.05.
A linear correlation was found between CPC and hemoglobin (r=-0.46 p<0.001), bone marrow aspirate plasma cells (r=0.36 p<0.001), plasma cells in biopsy (r=0.38 p<0.001), b2-microglobulin (r=0.25 p<0.001). CPC absolute values were sorted in quartiles (0/mm^3-0.86/mm^3, 0.86/mm^3-2.37/mm^3, 2.37/mm^3-11.2/mm^3, 11.2/mm^3-6272/mm^3) and associated with poor prognosis features. Significant differences expressed by Cramer's V >0.2 were observed between CPC and hemoglobin (V= 0.41 p<0.001), ISS (V= 0.26 p<0.001), R-ISS (V= 0.24 p<0.001), ≥60% of plasma cells in biopsy (V= 0.23 p<0.001), bone marrow aspirate plasma cells sorted in quartiles (V= 0.21 p<0.001), LDH upper the high limit (V= 0.24 p<0.001), del13q14 (V= 0.21 p=0.002), 1q gain (V=0.21 p=0.001).
Summary/Conclusion: The single platform cytometric method quantified CPC in 94.4% of PB samples from NDMM patients. Higher CPC number significantly correlated with poor clinical and laboratory features, confirming that CPC are an indicator of more aggressive disease, as showed by other studies. This method allows a high recovery of CPC, needs a small amount of PB sample, is a fast procedure, does not need cell separation, and is accurate. Moreover, it can be performed in all patients and can be particularly useful when cytogenetic score cannot be defined.

PS1282

MULTIPLE MYELOMA PATHOGENESIS: THE ROLE OF JUNB IN BONE MARROW ANGIOGENESIS

S. Malvestiti[1,*], F. Fan[1], H. M. Bashari[1], E. Morelli[2], A. Seckinger[3], D. Hose[3], H. Goldschmidt[3], I. Zoernig[1], L. Bakiri[4], M. Sattler[5], S. Vallet[1,6], M. Pecherstorfer[6], E.F. Wagner[4], P. Tassone[2], D. Jaeger[1], K. Podar[1,6]

[1]Medical Oncology, National Center for Tumor Diseases, University of Heidelberg, Heidelberg, Germany, [2]University "Magna Graecia" of Catanzaro, Catanzaro, Italy, [3]Section Multiple Myeloma, Department of Internal Medicine V, National Center for Tumor Diseases, University of Heidelberg, Heidelberg, Germany, [4]Genes Development and Disease Group, Spanish National Cancer Research Centre (CNIO), Madrid, Spain, [5]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, United States, [6]Department of Internal Medicine II, University Hospital Krems, Karl Landsteiner University of Health Science, Krems, Austria

Background: Angiogenesis is a hallmark of cancer. It importantly affects disease progression in multiple myeloma (MM) patients and correlates with adverse prognosis. Particularly, a significant rise in vascular density (VD) in the bone marrow (BM) is fundamental for the progression of MGUS to clinical manifest MM. The increase in vascularization is induced by oncogene-mediated expression of various angiogenic growth factors, most prominently VEGF. Over the past years, members of the AP-1 family of transcription factors (TFs) have been proposed as new potential therapeutic targets. Our previous work demonstrated a pivotal role for the AP-1 family member JunB in MM cell proliferation, survival and drug resistance (Fan *et al.*, 2017). However, whether JunB also affects MM BM angiogenesis still needs to be elucidated.
Aims: The present study aims to clarify the role of JunB in BM angiogenesis both *in vitro* and *in vivo*. One major objective is to evaluate whether production and secretion of angiogenic factors in MM cells within the BM microenvironment is JunB-dependent. Moreover, this project wants to assess the functional interrelation of JunB, IL-6 and other cytokines and growth factors. Further topics that have been addressed are the functional effect of genetic JunB downregulation and overexpression on BM angiogenesis and the specific role of JunB in BM angiogenesis in *in vivo* models of human MM in the BM microenvironment.
Methods: Expression patterns of JunB and angiogenic factors were evaluated in 2 independent Oncomine data sets. Co-cultures (CoCs) consisting of bone marrow stromal cells (BMSC) or osteoblasts (OB) and TetR-shJunB/MM.1S cells were performed in the presence and absence of doxycycline to investigate whether JunB knockdown interferes with paracrine induction of angiogenic factors and BM angiogenesis. Effects were assessed with RTqPCR, ELISA and *in vitro* angiogenesis assays. Obtained results were verified using JunB-ER/MM1.s cells, in which JunB activity is induced by 4-OHT. Data obtained in MM1.s models were confirmed using IL-6-mediated JunB stimulation or traditional JunB knockdown in other MM cell lines (e.g. MR20, RPMI8226, U266). Effects were assessed with RTqPCR. The functional role of JunB on BM angiogenesis was studied *in vivo* using MM xenograft mouse model. NSG mice were inoculated with TetR-SCR/MM.1S or TetR-shJunB/MM.1S and fed with doxycycline. IHC was then performed on tumor samples for Ki-67, anti-CD31 and anti-JunB.
Results: Similar to JunB Oncomine analysis revealed significant induction of VEGF, VEGFB, IGF-1 and PlGF expression progressing from healthy donors to MGUS and MM. We investigated next whether BMSC- and OB-induced production and secretion of angiogenic factors in MM is mediated via JunB. Knockdown of BMSC-mediated JunB upregulation in TetR-shJunB/MM.1S cells significantly reduces expression of VEGF, VEGFB, IGF-1 and PlGF. Subsequently, conditioned media obtained from doxycycline-treated BMSC: and OB:TetR-shJunB/MM.1S CoCs significantly inhibited angiogenesis. Conversely, 4-OHT-mediated induction of JunB activity potently enhanced the expression and secretion of angiogenic factors and angiogenesis. Data were confirmed in other MM cell lines (MR20, RPMI8226, U266). Furthermore, JunB inhibition in *in vivo* models induced a significant reduction in growth and VD in tumors formed by Tet-shJUNB/MM.1S versus control.
Summary/Conclusion: In conclusion, our findings show for the first time a pivotal role of JunB in MM bone marrow angiogenesis and thereby strongly support this transcription factor as a novel promising therapeutic target in MM treatment.

TARGETED LIPOSOMAL MULTI-DRUG DELIVERY TO TUMOR-ASSOCIATED ENDOTHELIUM AS A NOVEL STRATEGY TO REVERSE MICROENVIRONMENT-INDUCED DRUG RESISTANCE IN MULTIPLE MYELOMA

C. Federico[1,*], B. Muz[1], F. Azab[1], P. de la Puente[1], J. Sun[1], K. Alhallak[1], J. King[2], V. Kapoor[1], A. Roccaro[3], D. Thotala[1], D. E. Hallahan[1], S. Achilefu[4], R. Vij[2], A.K. Azab[1]

[1]Department of Radiation Oncology, [2]Department of Medicine, Washington University in St. Louis School of Medicine, Saint Louis, United States, [3]Clinical Research Development and Phase I Unit, ASST Spedali Civili di Brescia, Brescia, Italy, [4]Department of Radiology, Washington University in St. Louis School of Medicine, Saint Louis, United States

Background: The bone marrow microenvironment (BMME) induces drug-resistance in multiple myeloma (MM). We have previously shown that the inhibition of CXCR4 signaling attenuates the interaction between MM cells and BMME, re-sensitizing MM cells to bortezomib (BTZ). Moreover, we found that inhibition of ROCK kinase blocked the interaction of MM with the BMME. Therefore, we propose to inhibit ROCK kinase as a novel strategy to sensitize MM cells to BTZ. However, the limitations of this strategy are: the kinetic synchronization of the delivery of both drugs and the specific delivery to the MM-BMME for limiting side effects. We found that the MM-associated endothelium significantly expresses high levels of P-selectin, which provides an opportunity for selective delivery to the BMME-associated MM.
Aims: To reverse BMME-induced BTZ resistance we developed P-selectin targeted liposomes towards MM-associated endothelium by decorating their surface with P-selectin glycoprotein ligand 1 (PSGL-1), the physiological ligand of P-selectin. To ensure synchronized delivery, liposomes were loaded with BTZ and ROCK inhibitor (ROCKI). Based on their solubility, BTZ and ROCKI were encapsulated in the lipid membrane and in the aqueous core, respectively.
Methods: We assessed the expression of P-selectin in endothelial cells (ECs) by flow cytometry analysis. Liposomes were prepared by thin layer evaporation method, followed by extrusion. Coupling of PSGL-1 to the liposomes was performed by carbodiimide chemistry. Liposomes were characterized by dynamic light scattering analysis and the entrapment efficiency (EE) of both drugs was quantified by HPLC analysis. The binding of PSGL-1-targeted liposomes to P-selectin was assessed by Biacore assay. Moreover, the *in vitro* binding to ECs and to ECs in the BM from MM-bearing mice was investigated by flow cytometry analysis. The effect of free or liposomal-ROCKI on migration and adhesion *in vitro* was tested by trans-endothelial migration assay and fluorescence spectroscopy. Cytotoxicity, proliferation, cell cycle, apoptosis and cytoskeletal signaling of the drugs in free or liposomal forms were evaluated by MTT and western blot. The effect of free or liposomal drugs on tumor progression *in vivo* was tested by live imaging.
Results: Expression of P-selectin in ECs isolated from MM patients was higher than healthy donors (3-fold), from MM-bearing mice compared to naïve mice (7-fold), and in MM-activated ECs compared to naïve ECs *in vitro* (7-fold). PSGL-1-targeted liposomes showed specific binding to immobilized P-selectin and to MM-activated ECs *in vitro* and *in vivo*. Loading of the liposomes with BTZ and/or ROCKI did not affect the structure and the physical parameters of the liposomes. The EE of the drugs was around 54% and 66%, respectively. MM cell adhesion to ECs, trans-endothelial migration and SRC, cofilin and FAK signaling were decreased by liposomal-ROCKI compared to free drug. Liposomal-BTZ induced significant reduction of cell viability, MAPK, PI3K, and cell cycle signaling; and induced pro-apoptotic signaling in MM cells compared to free BTZ. The combination of both drugs in the liposomal form reversed the BMME-induced resistance to BTZ *in vitro*, and induced a remarkable decrease in tumor growth, improved overall survival, and reduction of side effects compared to the free drugs.
Summary/Conclusion: Our data indicate that the synchronized and PSGL-1-targeted liposomal delivery of BTZ and ROCKI reversed the BMME-induced resistance and sensitized the MM tumors to BTZ better than the free non-synchronized non-targeted drugs, *in vitro* and *in vivo*.

WNT/B-CATENIN AND HEDGEHOG INHIBITORS AS THERAPEUTIC APPROACHES IN B-CELL NEOPLASMS

C. Ferreira[1], J. Jorge[2,3], R. Alves[2,3], A.C. Gonçalves[2,3], A.B. Sarmento Ribeiro[2,3,4,5,*]

[1]Chemistry Department, University of Aveiro, Aveiro, [2]Laboratory of Oncobiology and Hematology and University Clinic of Hematology, Faculty of Medicine, University of Coimbra (FMUC), [3]Coimbra Institute for Clinical and Biomedical Research (iCBR) - Group of Environment Genetics and Oncobiology (CIMAGO), FMUC, [4]Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra (CHUC), [5]Center for Neuroscience and Cell Biology (CNC), University of Coimbra, Coimbra, Portugal

Background: B-cell neoplasms are a heterogeneous group of diseases that

include B-cell lymphomas and plasma cell disorders. Multiple myeloma (MM) is a malignant neoplasm originated by the proliferation of monoclonal plasma cells that remains incurable. Diffuse large B-cell lymphoma (DLBCL) is an aggressive lymphoma, with a fast growing that is rapidly fatal if untreated. Inappropriate activation of conserved embryonic signaling pathways critical for stem cell self-renewal and differentiation in hematopoiesis, such as WNT/β-catenin and Hedgehog (Hh), has been implicated in a number of cancers. Deregulation of components involved in WNT/β-catenin signaling had been implicated in a wide spectrum of diseases including B-cell neoplasms. The key mediator of WNT signaling, β-catenin, serves several cellular functions and its inhibition showed successful results in some cancers. On the other hand, abnormal Hh signaling triggered by mutations in Hh pathway, and paracrine or autocrine activation by Hh ligands, may induce cancer development or progression. Hedgehog pathway inhibitors have shown clinical benefit and have been approved to treat patients with advanced basal cell carcinoma.

Aims: The main goal of this study was to evaluate the therapeutic potential of WNT/β-catenin and Hedgehog inhibitors, respectively IWR-1 and vismodegib, alone and in combination in *in vitro* models of MM and DLBCL.

Methods: The therapeutic potential of IWR-1 and vismodegib, in monotherapy and in therapeutic combination, was evaluated in two *in vitro* models of MM and DLBC, the H929 and FARAGE cell lines, respectively. The metabolic activity was evaluated by resazurin assay and cell death by optical microscopy (May-Grunwald staining) and flow cytometry (FC; Annexin V/7-AAD double staining). Cell cycle analysis was evaluated by FC, using a PI/RNase solution. Proteins related to apoptosis (BAX, BCL2, caspases) and some molecules related to WNT and Hh signaling pathways [β-catenin and phosphorylated (p-)ERK] were quantified by FC. The results were statistically analyzed by uni- and multivariate tests, considering a level of significance of 95% ($p<0.05$).

Results: The results showed that IWR-1 and vismodegib reduced metabolic activity in a time-, dose- and cell type-dependent manner. H929 cells were more sensitive to IWR-1 (IC_{50} 40μM) than FARAGE cells (IC_{50} 75 μM), while FARAGE cells were more sensitive to vismodegib (IC_{50} 57 μM) compared to H929 (IC_{50} 70 μM). The reduction of metabolic activity was more pronounced in the combination regimens as well as in fractional administration of drugs compared to single-dose regimens, especially in MM cells. DLBCL cells were more sensitive to therapeutic combinations than MM cells. IWR-1 and vismodegib induced cell death mainly by apoptosis, associated with increased activated-caspases, and an anti-proliferative effect with cell cycle arrest in G_0/G_1 phase. In addition, both drugs induced a decrease in β-catenin and p-ERK expression levels, more pronounced in MM cells (H929).

Summary/Conclusion: The results suggest that MM cells are more sensitive to single inhibitor regimes and LDGCB cells to combination regimes. However, both drugs, IWR-1 and vismodegib, may represent potential therapeutic approaches in these lymphoid neoplasms.

MULTIPLE MYELOMA INDUCES CHANGES IN BONE MARROW ADIPOCYTES *IN VITRO* AND *IN VIVO*

M. Reagan[1,*], C. Falank[1], M. Farrell[1], M. McDonald[2], P. Croucher[2], H. Fairfield[1]

[1]Center for Molecular Medicine, Maine Medical Center Research Institute, Scarborough, United States, [2]Bone Biology Division, Garvan Institute of Medical Research, Sydney, Australia

Background: Multiple myeloma (MM) is a hematological malignancy that is characterized by clonal proliferation of transformed plasma cells within the bone marrow (BM) and severe bone disease. Although MM cells are initially sensitive to many therapies, patients eventually relapse with refractory disease. Because MM cells show a dependency on the BM microenvironment for survival and proliferation, and BM adipocytes (BMAs) demonstrate a unique, endocrine signaling capacity and lipid composition, it is likely that there is cross-talk between MM cells and BMAs that leads to tumor support.

Aims: We aim to identify the direct effect of MM cells on mature BMAs and on BMA progenitors in the early stages of adipogenesis. These data could be revolutionary for our understanding of MM.

Methods: Herein, we explored the direct effects of MM cells on adipocytes before and after adipogenic differentiation using microarrays, cytokine arrays, qRT-PCR, Oil Red O lipid staining, and seahorse metabolic analyses. 3T3-L1 pre-adipocytes or primary mouse or human BM-MSCs were differentiated into adipocytes and co-cultured with MM cell lines (MM.1S, MM.1R, 5TGM1, and OPM2). To investigate the effect of MM cells on MSC adipogenic differentiation capacity, pre-adipocytes were grown to confluency and then myeloma cells were added for a 3-day exposure period prior to adipogenic differentiation. Direct and indirect (MM conditioned media (CM) and transwell cultures) effects of MM cells on MSC adipogenesis were assessed. We also developed a novel, tissue-engineered (TE) 3-D *in vitro* MAT model, as published[1], and used this for co-cultures with MM cells. BMA changes were also analyzed with histology in the MM1S Scid-Beige and the 5TGM1 C57BL/*KaLwRij* mouse models.

Results: The influence of MM cells on BMAs before or after differentiation was readily observed in multiple assays. Indirect co-culture of 3T3-L1 adipocytes with MM cells significantly reduced both adipogenic transcription factors (*Pparγ* and *Cebpα*) as well as mature adipocyte markers (*Adipoq*). This effect was also observed in BM-MSCs differentiated into adipocytes from mouse (*Pparγ and Adipoq*) and human donors (*PPARγ* and *FABP4*), suggesting a common mechanism of MM-induced inhibition between peripheral adipocytes and BMAs. Lipids were also reduced in 3T3-L1 adipocytes in direct co-culture with MM.1S cells for 7-14 days. Co-culture with MM cells reduced the expression of genes involved in lipogenesis and fatty acid oxidation, including *Srebf1*, *Cpt1*, and *Fasn,* in many adipocyte cell types, suggesting a suppression of adipogenic function as well as phenotype. Importantly, similar delipidation was also observed in TE-MAT co-cultures with myeloma cells. *In vivo,* MM decreased BM adiposity in the MM1S/SCID-Beige and 5TGM1/KaLwRij models (Figure 1).

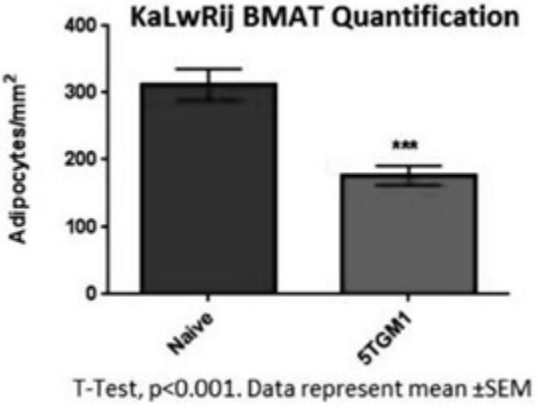

Figure 1.

Summary/Conclusion: These results indicate an adverse effect of MM cells on adipocytes and illuminate the BMA as a new member of the complex BM milieu in which the myeloma cells thrive. MM-induced reductions in BM adiposity may contribute to the skeletal changes induced by MM, i.e. suppressed bone formation and increased osteoclast activation. Our data support the need for further research into the roles of BMAT in MM pathogenesis, osteolysis and chemoresistance.

PROTEIN KINASE CK1 ALPHA MODULATES PROSURVIVAL AUTOPHAGY IN MULTIPLE MYELOMA

M. Carrino[1,2,*], S. Manni[1,2], L. Quotti Tubi[1,2], S. Canovas Nunes[1,2], K. Gianesin[1,2], G. Barilà[1,2], L. Trentin[1,2], R. Zambello[1,2], G. Semenzato[1,2], F. Piazza[1,2]

[1]Department of Medicine, Hematology and Clinical Immunology Branch, University of Padova, Padova, Italy, University of Padova, Padova, Italy, [2]Venetian Institute of Molecular Mediicine, Padova, Italy

Background: Multiple Myeloma (MM) is a tumor of antibody-secreting plasma cells (PCs) that accumulate in the bone marrow. As MM cells massively produce and secrete immunoglobulins, they are prone to endoplasmic reticulum stress, therefore the ubiquitin-proteasome system, the unfolded protein response and the autophagic pathway cooperate in order to avoid proteotoxicity. Autophagy is a fundamental process for both normal and malignant PCs and its impairment results in loss of PC differentiation and MM cell death. Recently, CK1α, a kinase critical for MM cell survival, was

described as a novel regulator of the autophagic pathway in RAS-driven cancers. CK1α, by phosphorylating S318/321 of the proautophagic transcription factor FOXO3a, promotes its nuclear exclusion, leading to a reduction in autophagic genes transcription.
Aims: In this study, we aimed at investigating the role of CK1α in the modulation of prosurvival autophagy in MM cells.
Methods: We inhibited CK1α with the chemical D4476 and we silenced CK1α through RNA interference (electroporation of ds CK1α siRNA or expression of an IPTG inducible CK1α shRNA). We generated MM cell clones stably expressing the mCherry-eGFP-LC3B fusion protein, which allows monitoring the autophagic flux, since double fluorescent (yellow) autophagosome become mCherry-only fluorescent (red) after their fusion with the lysosome due to an acidic pH dependent quenching of eGFP fluorescence. The effects of CK1α inactivation on autophagy related proteins were investigated by WB and qRT-PCR. The localization of FOXO3a was evaluated by nuclear proteins extraction and WB. Subcellular localization of LC3B and LAMP-2 was evaluated by immunofluorescence.
Results: In mCherry-eGFP-LC3B MM clones, upon treatment with D4476, yellow vesicles accumulated suggesting an impairment in the autophagic flux. In order to understand if autophagosomes were able to fuse with lysosomes, we stained autophagic vesicles and lysosomes respectively with an anti-LC3B and an anti-LAMP-2 antibody finding that autolysosomes were formed in D4476-treated cells, indicating that an alteration of the lysosomal pH was probably responsible of the impairment of the autophagic flux. D4476 treatment reduced FOXO3a phosphorylations, which accumulated in the nucleus, allowing the transcription of autophagic genes. Differently, upon CK1α silencing, the autophagic flux was induced as judged by the accumulation of red vesicles in mCherry-eGFP-LC3B MM clones. However, pFOXO3a S318/321 levels did not change and the transcription factor did not accumulate in the nucleus. As a consequence, the increase in transcription of autophagy-related genes was not observed.
Summary/Conclusion: We demonstrated that in MM cells the chemical inhibition or the silencing of CK1α induced apoptosis, however the two modalities of CK1α inactivation affected differently the autophagic pathway. A possible explanation is that D4476 causes accumulation of ineffective autophagic vesicles provoking an engulfment of the autophagic/lysosomal machinery that culminates in cell death. Differently, upon CK1α silencing, the autophagic flux is correctly triggered, however a genetic program backing up the autophagic flux is not activated. In this latter case, it is possible that proteins important in the autophagic machinery are progressively depleted and autophagy breaks down with the occurrence of cell death. Taken together our results suggest that CK1α supports MM cells survival also by modulating the prosurvival autophagic pathway.

Background: A comprehensive analysis of metabolites (metabolomics) in biofluids is a promising new strategy for liquid biopsy, as well as for biomarker analyses to predict the response to or adverse events of specific treatments. With respect to the metabolic pathways in multiple myeloma (MM) cells, only a few studies have applied metabolomics for the analysis of MM cells or serum/plasma samples from the patients to elucidate MM pathogenesis or the mechanisms underlying the transformation of MM cells. In addition, no metabolomic profile has been characterized for the response to or adverse events of MM treatments.
Aims: In this study, we performed a lipid metabolomics analysis of sera from patients with MM who received bortezomib (BTZ) plus low-dose dexamethasone (Bd) therapy to identify predictive markers for response to Bd therapy and the severity of BTZ-induced peripheral neuropathy (BiPN).
Methods: Sixty serum samples were collected prior to Bd therapy and subjected to lipid metabolomics analysis. Levels of phospholipids, sphingolipids, and neutral lipids and polyunsaturated fatty acids (FAs) and their oxidation products were measured using UPLC-TOFMS and UPLC/MS/MS, respectively. We then evaluated whether the levels of specific lipid metabolites were associated with the response to Bd therapy and the grade of peripheral neuropathy.
Results: Approximately 2000 ion peaks of phospholipids or triglycerides (PT) and 50 FAs were detected from the metabolomics analysis of 60 serum samples. In the 54 Bd samples evaluable of the response to Bd therapy, the levels of 46 PTs and 2 FAs were identified to be associated with the response. Among these, the levels of 2 FAs (TXB_2 and 12-HHT) were highly correlated with the response to Bd therapy: low levels of these 2 FAs were observed in poor responders, i.e. SD or PD patients. These 2 FAs were regulated by the same enzyme, thromboxane A synthase, which is anchored at the endoplasmic reticulum membrane, and are involved in platelet aggregation, vasoconstriction, and the progression and metastasis of several tumors.
Next, we evaluated the association of the lipid metabolites with the grade of peripheral neuropathy by lipid metabolomics analysis of all 60 serum samples; 5 PTs and 11 FAs were identified as markers of grade 2 or a higher degree of BiPN. Of the 5 PTs, a higher level of one lysophosphatidylcholine (LPC) species, which is considered as a factor promoting neuropathic pain, was observed in patients with grade 2 or higher peripheral neuropathy, suggesting an association between serum LPC and the severity of BiPN. In addition, two FAs, 14,15-DiHETE and 19,20-DiHDoPE, were present at higher levels in patients with grade 2 or higher peripheral neuropathy. These two FAs belong to the -3 FA group and have been reported to inhibit the activity of natural killer (NK) cells. The association between reduced NK cell activity and the severity of BiPN is currently under investigation (Figure 1).

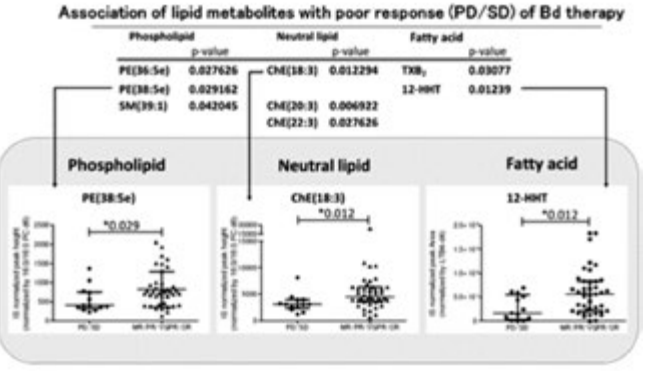

Figure 1.

Summary/Conclusion: Using serum lipid metabolomics, we have demonstrated for the first time that the specific lipid metabolite levels in the serum are associated with the response to Bd therapy and the severity of BiPN in patients with MM. These metabolites may serve as candidate biomarkers for predicting the efficacy of BTZ treatment against MM.

CIRCULATING SOLUBLE UROKINASE-TYPE PLASMINOGEN ACTIVATOR RECEPTOR LEVELS REFLECTS RENAL FUNCTION IN NEWLY DIAGNOSED PATIENTS WITH MULTIPLE MYELOMA WHO ARE TREATED WITH BORTEZOMIB-BASED THERAPY

E. Terpos[1,*], G.-P. Papassotiriou[1], E. Kastritis[1], A. Margeli[2], N. Kanellias[1], E. Eleutherakis-Papaiakovou[1], M. Migkou[1], I. Ntanasis-Stathopoulos[1], M. Gavriatopoulou[1], E. Psimenou[1], I. Papassotiriou[2], M.A. Dimopoulos[1]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, [2]Department of Clinical Biochemistry, "Aghia Sophia" Children's Hospital, Athens, Greece

Background: Renal impairment (RI) is a common complication of multiple myeloma (MM). Soluble urokinase-type plasminogen activator receptor (suPAR) is the circulating form of a glycosyl-phosphatidylinositol-anchored three domain membrane protein that has been implicated in the pathogenesis of kidney disease of different etiology (Hayek *et al.* N Engl J Med 2015;373:1916).
Aims: The aim of this study was to investigate a possible link between suPAR circulating levels and RI in newly diagnosed patients with symptomatic MM (NDMM) before and after frontline therapy with bortezomib-based regimens.

Methods: We studied 47 NDMM patients (26M/20F, median age 69.5 years) before the administration of any kind of therapy and after best response to bortezomib-based therapy. Thirty (64%) patients had IgG MM, 7 (15%) IgA and 10 (21%) had light-chain only MM; 13 (28%) patients had ISS-1, 19 (40%) ISS-2 and 15 (31%) had ISS-3 MM. Twenty-seven (57%) patients had eGFR <60 ml/min/1.73m^2, 23 (49%) had eGFR <50 ml/min/1.73m^2 and 10 (21%) had eGFR <30 ml/min/1.73m^2; no patient was on dialysis. suPAR was measured in the serum of all patients and of 24 healthy individuals of similar age, gender and body index (controls), using an immunoenzymatic assay (ViroGates, Denmark) along with a series of other markers of renal function (Cystatin-C), renal injury (Neutrophil Gelatinase-Associated Lipocalin, NGAL), inflammation (hs-CRP and IL-6) and cardiac function (hs-Troponin-T and NT-proBNP). eGFR values were calculated based on CKD-EPI/Cystatin-C equation (Inker *et al.* N Engl J Med 2012;367:20).
Results: suPAR levels were elevated in MM patients at diagnosis compared to controls (mean±SD, range: 4.1±2.2 pg/mL (1.4-13.0 pg/mL) vs. 1.8±0.3 pg/mL (1.1-2.6 pg/mL), p<0.001). Similarly, all other markers of cardio-renal dysfunction and inflammation were elevated in MM patients compared to controls (p<0.01 for all comparisons). suPAR levels strongly correlated with disease stage (ISS-1: 2.4±1.2 pg/mL; ISS-2: 3.6±1.8 pg/mL and ISS-3: 5.1±2.2 pg/mL; p-ANOVA <0.001). After bortezomib-based frontline therapy (VCD=32, VTD=7, VMp=7, VD=1), 9 (19%) patients achieved a CR, 11 (23%) vgPR and 19 (40%) PR. Of 23 patients with eGFR <50 ml/min/1.73m^2, 18 (78%) showed at least minor renal response to bortezomib-based frontline treatment, according to IMWG criteria. However, at patients' best response no significant changes of suPAR (4.4±2.7 pg/mL) levels were observed (p=0.31). On the other hand, suPAR levels both at diagnosis and at best response strongly correlated with eGFR values (r=-0.700, p<0.001 and r=-0.890, p<0.001, respectively) and NGAL levels (r=0.657, p<0.001 and r=0.586, p<0.001, respectively). suPAR levels at diagnosis and at best response also correlated positively with log(IL-6) and log(hs-CRP) values (p<0.001) and markers of cardiac function hs-Troponin-T and NT-proBNP (p<0.001).
Summary/Conclusion: We conclude that suPAR levels are associated with renal function in MM both at diagnosis and at best response to bortezomib-based frontline therapy. Although suPAR correlates with disease stage, confirming previous observations (Rigolin *et al.* Br J Haematol 2003;120:953), responders to anti-myeloma therapy continued to have elevated circulating suPAR, possibly reflecting persistent kidney damage, despite their renal response. Furthermore, suPAR correlated with the degree of inflammation and heart dysfunction in these patients. Further studies are needed to explore whether changes in suPAR may reflect increased risk for renal failure and/or progression in MM patients.

Nocivelli", [4]Hematology, [5]Clinical Chemistry Laboratory, Diagnostic Department; CREA Laboratory, ASST Spedali Civili di Brescia, Brescia, [6]Dept of Food and Drug, University of Parma Medical School, Parma, Italy

Background: Bone marrow (BM) angiogenesis plays a crucial role in several hematologic malignancies, including both myeloid neoplasms and lymphoproliferative disorders. Nevertheless, the contribution of angiogenesis in patients with lymphoplasmacytic lymphoma/Waldenstrom's Macroglobulinemia (WM) and how it might be targeted for potential therapeutical intervention has not been described.
Aims: 1) To dissect the role of angiogenesis in supporting WM pathogenesis; 2) To investigate the anti-WM activity of a novel anti-pan-FGF molecule.
Methods: Publically available mRNA profiling datasets of primary bone marrow (BM)-derived CD19 WM cells were used (i.e. GSE6691; GSE9656). The Gene Set Enrichment Analysis (GSEA) computational method was adopted (FDR<0.25; p<0.05). Co-culture proliferation and adhesion assays were performed using available WM (BCWM.1; MWCL1; WMWSU), IgM secreting cell lines (MEC1), and primary WM bone marrow (BM)-derived mesenchymal stromal cells (MSCs). Cell viability of primary CD19 positive-selected BM WM cells and peripheral blood-derived mononuclear cells (PBMC) was assessed by MTS assay. Modulation of signaling pathways was studied at protein level using western blot analysis. A pan-FGF trap NSC12 molecule was identified by a virtual screening of a NCI small molecule library: it acts a trap able to block the FGF2/FGFR interaction. NSC12 was tested in order to define its potential anti-WM activity *in vitro*.
Results: GSE6691 gene expression dataset was used to investigate the most differentially expressed mRNA in WM cells as compared to their normal cellular counterpart: the top two pathways (ranked based on the normalized enrichment score and p-value) were related to "TNF-alpha signaling via NF-kB" and "angiogenesis". It has been already reported on the constitutive activation of NF-kB in WM; and therefore selected the "angiogenesis cascade" for further investigation (FDR 0.10; P 0.03). FGFR-1 was one of the most up-regulated genes in WM cells. We therefore looked at FGF- and FGFR-related mRNAs, using an independent GEP data set (GSE9656); and found FGFR-1, FGF-2, -12, -17 and -18 to be significantly enriched in WM cells as compared to their normal cellular counterpart (p<0.05). We next sought to determine the functional sequelae induced by the NSC12-mediated FGF2/FGFR blockade on WM cells. NSC12 exerted a direct anti-WM activity against all the cell lines tested (IC50: 3mM; p<0.05). Importantly, NCS12-induced cytotoxicity was demonstrated using WM patients' BM-derived CD19+ cells. NSC12 selectively targeted the FGF/FGFR axis, as demonstrated by inhibition of phospho(p)-FGFR1, as well as of downstream targets such as p-FSR2, p-JAK2, p-STAT3, and p-ERK. Of note, NSC12 inhibited WM cell proliferation even in a co-culture system with primary WM BM-MSCs. BM-MSC-induced up-regulation of p-FGFR1, p-STAT3, p-AKT was inhibited in WM cells exposed to increasing NCS12 doses, thus suggesting the activity of the compound even in the presence of the supportive BM milieu. We further confirmed NSC12-dependent induction of pro-apoptotic pathways, as shown at protein level by enhanced caspase-3- and PARP-cleavage. Notably, NSC12 did not induce cytotoxicity against healthy donor-PBMC.
Summary/Conclusion: These findings provide novel insights into the pathogenesis of WM, describing the up-regulation of the FGF/FGFR axis in WM cells, thus providing the preclinical rational for targeting FGF in this disease. Consistently, the novel pan-FGF trap NSC12 demonstrated an anti-WM activity, through both a direct and an indirect effect against WM cells and the WM cell/BM interaction, respectively.

EVALUATION OF THE ACTIVITY OF IMIDS IN MM PROLIFERATING CELLS

J. Ballesteros[1,*], B. Puła[2,3], R. Pawel[3,4], A. Walter-Croneck[3,5], A. Druzd-Sitek[3,6], D. Dytfeld[3,7], J. Martínez López[8], P. Hernández[1], J. Gorrochategui[1], J.L. Rojas[1], D. Primo[1], K. Jamroziak[2,3]

[1]Vivia Biotech, Tres Cantos, Madrid, Spain, [2]Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, [3]Polish Myeloma Consortium, Poznan, [4]Department of Hematology, Medical University of Lodz, Copernicus Memorial Hospital, Lodz, [5]Department of Haematooncology and Bone Marrow Transplantation, Medical University of Lublin, Lublin, [6]Department of Lymphoid Malignancies, Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, [7]Department of Hematology and Bone Marrow Transplantation, University of Medical Sciences in Poznan, Poznan, Poland, [8]Hospital Universitario 12 de Octubre, Madrid, Spain

Background: Treatment of multiple myeloma (MM) has evolved from non-specific chemotherapeutic agents to novel targeted therapy. Among these new treatment approaches, the immunomodulatory drugs (IMiDs) represent a good therapeutic option for many MM patients. Several mechanism of action has been proposed to explain the direct and indirect effect of IMiDs, such as antiangiogenic, proapoptotic, antiproliferative and immunomodulatory. Although there are 3 IMID drugs approved (Thalidomide, Lenalidomide, Pomalidomide), *in vitro* assays to capture the IMiDs activities are still in development. Precision medicine tests evaluating these drugs could represent a valuable tool to assess the subgroup of patients who could benefit from these treatments.
Aims: The goal of this study is to design an ex vivo model with the PharmaFlow technology, that allows to simultaneously measure cytotoxic activity and cell cycle arrest, to identify the antiproliferative effect of IMiDs agents, such as lenalidomide (LEN), in plasma cells (PC) from whole bone marrow MM samples, as a putative secondary reflect of IMiDs activity, that could predict the clinical response ex vivo.
Methods: Bone marrow samples from 16 MM patients were sent to Vivia from Polish Myeloma Consortium (PMC) and Spanish hospitals within 24h after extraction. Whole sample were incubated for 96h in well plates containing 8 concentrations of LEN. To induce plasma cell proliferation, PC were resuspended in IMDM medium supplemented with 20% autologous plasma. The number of proliferating and non proliferating live leukemic cells was determined using the CFDA dye, and the PC population and viability was determined labeling with monoclonal antibodies and Annexin V. Dose response curves of LEN for proliferating and non proliferating live

pathological cells were measured, and pharmacological responses were calculated using pharmacokinetic population models.
Results: A clear difference in the sensitivity of proliferating vs. non-proliferating MM cell subsets was observed. LEN was more active towards proliferative live tumor cells, with a median maximum effect (Emax) of 74% vs 49% and a 2 fold more sensitive potency (EC50) of 0.05 mM vs. 0.1 mM, concentrations achievable clinically. This effect was probably due to a cell cycle arrest (Figure 1, left panel). Interestingly, there is a great heterogeneity in the potency and effect (panel right, Figure 1) in all samples, pointing the possibility of patient selection for LEN treatment. In addition, the efficacy was incomplete in many patients (median Emax of proliferating live tumor cells equal to 49) leaving a significant number of proliferating cells, still even at the higher drug concentrations, that suggest the use of additional targets.

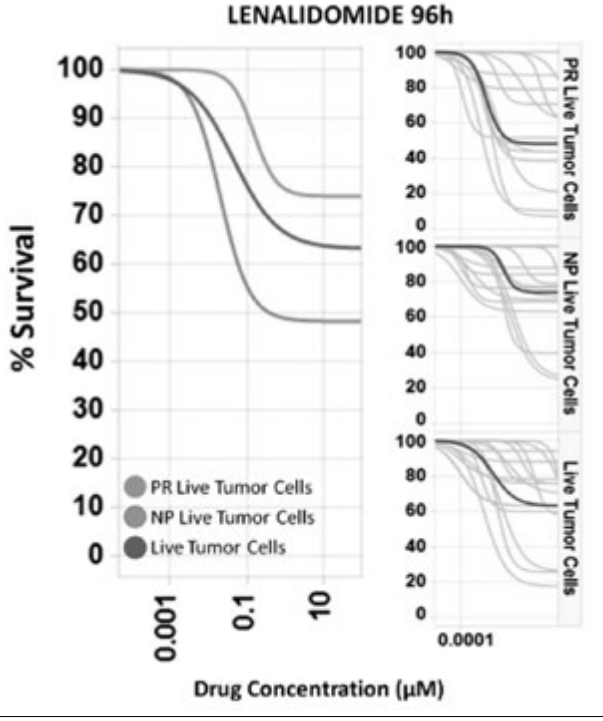

Figure 1.

Summary/Conclusion: We report a novel *ex vivo* assay incorporating autologous serum that enables the measurement of the effects of IMiDs on MM patients and thereby, a more accurately simulation of the *in vivo* conditions. This innovative assay offers better opportunities for *ex vivo* pharmacology in particular for the IMiDs, drugs with antiproliferative properties. The interpatient variability in the pharmacological profile for the LEN, if clinically validated, could help guiding a personalized treatment selection for IMiDs.

[1]Haematology, University Hospital Southampton NHS Foundation Trust, Southampton, [2]Clinical Trials Research Unit, University of Leeds, Leeds, United Kingdom, [3]Myeloma Institute, University of Arkansas for Medical Sciences, Little Rock, United States, [4]The Institute of Cancer Research, [5]The Royal Marsden Hospital, London, [6]Heart of England Foundation Trust, Birmingham, [7]Leicester Royal Infirmary, Leicester, [8]Centre for Clinical Haematology, Nottingham University Hospital, Nottingham, [9]University Hospital of North Midlands, Stoke-on-Trent, [10]Kent and Canterbury NHS Trust, Canterbury, [11]Leeds Institute of Cancer and Pathology, University of Leeds, Leeds, [12]Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, [13]St James' University Hospital, Leeds, [14]Department of Haematology, Newcastle University, Newcastle upon Tyne, United Kingdom

Background: We previously reported in the Myeloma XI trial the improvement in PFS with lenalidomide maintenance versus observation of 38.9 versus 20.0 months. Vorinostat is an HDAC inhibitor that has shown improved PFS combined with bortezomib compared with bortezomib alone in relapsed myeloma.
Aims: We will present results of the Myeloma XI study in which patients were randomised between lenalidomide alone or lenalidomide and vorinostat maintenance.
Methods: The phase III NCRI Myeloma XI study recruited newly diagnosed myeloma patients from over 100 centers across the UK. Following protocol amendment between September 2011 and June 2013, patients were randomised in a 1:1:1 ratio comparing maintenance lenalidomide (len: 10 mg, days 1-21/28), lenalidomide plus vorinostat (len-vori: 10 mg, days 1-21/28 and 300 mg, days 1-7 and 15-21) and observation (obs) until disease progression, stratifying for induction treatments and response prior to therapy. There was an intensive pathway for transplant eligible (TE) and non-intensive pathway for transplant non eligible (TNE) patients. Primary analysis combined these pathways. The study was powered for both PFS and OS, with these being co-primary endpoints. 614 patients (395 TE, 219 TNE) were randomised, median age 66 years, between len (307) and len-vori (307). Groups were well balanced between arms.
Results: In the overall intention to treat (ITT) population, participants randomised to len received a median of 28 cycles (range 1, 60) compared with a median of 17 cycles (range 1, 63) in the len-vori group. In the TE population participants received a median of 30 cycles (range 1, 60) of len and 21 cycles (range 1, 63) of len-vori. In the TNE population participants received a median of 23 cycles (range 1, 56) of len and 13 cycles (range 1, 54) of len-vori. Overall 8.8% of participants discontinued within the first 3 cycles of maintenance in the len group compared with 22.1% in the len-vori group. 171 participants (55.7%) in the len group had dose modifications and 241 (78.5%) in the len-vori group. In the len-vori group, 197 (64.2%) had dose modification of lenalidomide and 230 (74.9%) had dose modification of vorinostat. Of those that stopped therapy, 114 (37.1%) in the len group stopped due to disease progression and 29 (9.4%) because of toxicity whereas 103 (33.6%) stopped for disease progression and 68 (22.1%) because of toxicity in the len-vori group. At a median follow up of 41 months, there were 151 PFS events (49.2%) in the len group and 168 PFS events (54.7%) in the len-vori group. PFS was not significantly different between the len group, PFS 40.2 months [95% CI 35.2, 52.6] and the len-vori group, PFS 33.1 months (95% CI 28.7, 40.6), p-value 0.1457. The hazard ratio for len-vori was 1.18 (95% CI 0.94, 1.47) indicating no PFS benefit of len-vori maintenance over len alone. There were 76 deaths (24.8%) in the len group and 75 deaths (24.4%) in the len-vori group. OS was not significantly prolonged in the len-vori group, 60.7 months, compared with not reached in the len group, p-value 0.7499 and hazard ratio 0.95 [95% CI 0.69, 1.31]. Full subgroup analysis will be presented during the meeting including of the factors influencing prolonged duration of maintenance with len-vori.
Summary/Conclusion: Addition of vorinostat to lenalidomide maintenance does not improve outcomes compared with lenalidomide alone in newly diagnosed myeloma yet despite earlier discontinuation and greater dose reductions outcomes of the combination remain favourable compared to observation alone.

PS1292

POMALIDOMIDE + LOW-DOSE DEXAMETHASONE + DARATUMUMAB IN PATIENTS WITH RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA AFTER LENALIDOMIDE-BASED TREATMENT FAILURE

Bar[13], D. Quick[14], B. Anz[15], G. Fonseca[16], D. Reece[17], F. Zafar[18], W. Chung[18], N.J. Bahlis[19]

[1]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, [2]David Geffen School of Medicine at University of California, Los Angeles, [3]Cleveland Clinic, Cleveland , United States, [4]McGill University Health Centre, Montreal, Canada, [5]Sarah Cannon Research Institute, Nashville, [6]The University of Kansas Cancer Center, Fairway, [7]Colorado Blood Cancer Institute, Denver, United States, [8]Vancouver General Hospital, Vancouver , Canada, [9]University of California, Los Angeles Medical Center, Los Angeles, [10]Penn State Hershey Cancer Institute, Hershey, [11]Veterans Affairs New Jersey Health Care System, East Orange, United States, [12]Fundación de Investigación, San Juan, Puerto Rico, [13]Stamford Hospital, Stamford, [14]Joe Arrington Cancer Research and Treatment Center, Lubbock, [15]Tennessee Oncology, Chattanooga, [16]Florida Cancer Specialists, St. Petersburg, United States, [17]Princess Margaret Cancer Centre, Toronto, Canada, [18]Celgene Corporation, Summit, United States, [19]University of Calgary, Calgary, Canada

Background: MM-014 (NCT01946477) was designed to assess outcomes with pomalidomide (POM)-based treatment in patients with lenalidomide (LEN) treatment failure immediately before study entry. POM + low-dose dexamethasone (LoDEX) + daratumumab (DARA) was approved in the United States for use in patients with multiple myeloma (MM) who have received ≥ 2 prior therapies, including LEN and a proteasome inhibitor. However, data on the use of this triplet regimen in earlier lines of therapy and immediately after LEN-based treatment are limited. Cohort B of the MM-014 trial is investigating POM + LoDEX + DARA in this setting.
Aims: To present efficacy and safety analyses of cohort B of the MM-014 trial in which POM + LoDEX + DARA was given as second-line or greater treatment in patients with relapsed and/or refractory MM (RRMM).
Methods: Patients with RRMM who had received 1 or 2 prior lines of treatment, had a LEN-based treatment immediately before the study, and had progressive disease (PD) were eligible. In 28-day cycles, patients received POM 4 mg/day orally on days 1 to 21 + LoDEX 40 mg/day (20 mg/day if aged > 75 years) on days 1, 8, 15, and 22 + DARA 16 mg/kg intravenously on the LoDEX dosing days of cycles 1 and 2, then days 1 and 15 of cycles 3 to 6, then day 1 of cycles 7 onward. Thromboprophylaxis was mandatory. The primary objective was overall response rate (ORR) by modified International Myeloma Working Group criteria. All patients provided informed consent.

Table 1. Efficacy and safety.

Outcomes, %	N = 46
Efficacy	
ORR	71.7
CR	4.3
VGPR	21.7
PR	45.7
Minimal response	6.5
Clinical benefit (CR + VGPR + PR + MR)	78.3
SD	8.7
PD	6.5
1-year PFS	76.9
Safety	
Grade 3/4 TEAEs (occurring in ≥ 10% of patients)	
Neutropenia	71.7
Thrombocytopenia	23.9
Anemia	17.4
Infection	28.3

CR, complete response; MR, minimal response; PFS, progression-free survival; ORR, overall response rate; PD, progressive disease; PR, partial response; SD, stable disease; TEAE, treatment-emergent adverse event; VGPR, very good partial response.

Results: The intention-to-treat population (ITT) included 46 patients. The median follow-up was 7.8 months; 13 patients discontinued treatment because of PD (n = 7), adverse events (n = 2), or other reasons (n = 4). Patients were refractory to (n = 36 [78%]) or had relapsed after (n = 10 [22%]) LEN-based treatment. The median duration of prior LEN-based treatment was 23.6 months, and 20 patients (43%) received LEN 25 mg/day as their last LEN-based treatment. Efficacy outcomes in the ITT population and grade 3/4 treatment-emergent adverse events in the safety population (n = 46; defined as all patients who received ≥ 1 dose of study drug) are shown in Table 1. The ORR was 76.7% in the efficacy-evaluable population (n = 43; defined as all patients who received ≥ 1 dose of study drug and had ≥1 post-baseline assessment for response), 72.2% in LEN-refractory patients, and 75.0% in patients who received LEN 25 mg/day as their last LEN-based treatment. Clinical benefit (defined as complete response, very good partial response, partial response, or minimal response) was achieved in 78.3% of patients, and the 1-year progression-free survival rate was 76.9%. At baseline, 10 patients (21.7%) had grade ≥ 2 neutropenia. Grade 3/4 pulmonary embolism and peripheral neuropathy occurred in 1 patient each. Any-grade infusion-related reactions occurred in 13 patients. The primary reasons for dose interruptions were neutropenia (POM and DARA) and infusion-related reactions (DARA only).
Summary/Conclusion: These results indicate that POM + LoDEX + DARA is an effective and tolerable regimen when sequenced in earlier lines of therapy in patients with RRMM and in whom first- or second-line therapy with a LEN-based treatment failed.

PS1293

DOUBLET VS TRIPLET LENALIDOMIDE-CONTAINING REGIMENS FOLLOWED BY MAINTENANCE: SUBGROUP ANALYSIS BY FRAILTY STATUS AFTER A MEDIAN FOLLOW-UP OF 5 YEARS (EMN01 PHASE III STUDY)

S. Bringhen[1,*], N. Giuliani[2], A. Rambaldi[2], F. Bonello[1], S. Ballanti[2], P. Tosi[2], A. Belotti[2], F. Ciambelli[2], S. Caltagirone[1], S. Ronconi[2], A.M. Cafro[2], C. Cangialosi[2], D. Vincelli[2], C. Cellini[2], F. Morabito[2], M. Girotto[2], M. Grasso[2], A. Palumbo[3], R. Hajek[4], M. Boccadoro[1], A. Larocca[1]

[1]Myeloma Unit, Division of Hematology, University of Torino, A.O.U. Città della Salute e della Scienza di Torino, Torino, [2]Italian Multiple Myeloma Network, GIMEMA, [3]University of Torino, A.O.U. Città della Salute e della Scienza di Torino - Currently Takeda Pharmaceuticals Co., Torino, Italy, [4]Department of Hematooncology, University hospital Ostrava, Ostrava, Czech Republic

Background: The frailty status was associated with an increased risk of death, progression, non-hematologic adverse events (AEs) and treatment discontinuation. The "one size fits all" is no longer a suitable approach, and many recommendations suggested that fit patients (pts) may benefit from triplet regimens, while intermediate and frail pts may benefit from doublet regimens. There are no data from prospective trials supporting these recommendations.
Aims: To evaluate the impact of patient frailty status on outcome of different lenalidomide-containing regimes.
Methods: 662 pts with newly diagnosed MM were randomized to receive 9 28-day cycles of Rd (lenalidomide 25 mg/day for 21 days; dexamethasone 40 mg on days 1,8,15,22 in pts 65-75 years old, 20 mg in those >75 years), MPR (melphalan orally 0.18 mg/Kg for 4 days in pts 65-75 years old and 0.13 mg/Kg in those >75 years; prednisone 1.5 mg/Kg for 4 days; lenalidomide 10 mg/day for 21 days) or CPR (cyclophosphamide orally 50 mg/day for 21 days in pts 65-75 years old and 50 mg every other day in those >75 years; prednisone 25 mg every other day; lenalidomide 25 mg/day for 21 days). After induction, pts were randomized to receive maintenance with R alone (lenalidomide 10 mg/day for 21 days) or RP (lenalidomide 10 mg/day for 21 days; prednisone 25 mg every other day), until disease progression. At diagnosis, a geriatric assessment had been performed to assess cognitive and physical status, and comorbidities with Katz's Activity of Daily Living (ADL), Lawton's Instrumental Activity of Daily Living (IADL) and Charlson comorbidity index (CCI).
Results: 217 pts in Rd, 217 in MPR and 220 in CPR arms were evaluable. According to the IMWG frailty score, 284 (43%) pts were fit, 205 (31%) intermediate and 165 (25%) frail. After a median follow-up of 5.5 years, MPR significantly prolonged PFS from 18 months to 22 months compared to CPR (HR 0.78, p=0.02) and Rd (HR 0.83, p=0.09). This difference was evident only in fit pts (5-year PFS: 37% vs 17%, HR 0.70, p=0.03), no difference was observed in intermediate and frail pts. Median OS was 66 months in MPR pts, 67 in CPR pts and 62 in Rd pts. In fit pts a survival benefit was evident: MPR and CPR prolonged OS compared to Rd (83 months vs 50 months; HR 0.69, p=0.09). Hematologic toxicity was the most frequent toxicity and was mainly related to MPR, regardless of frailty status. As expected, the occurrence of AEs and the risk of discontinuation due to AEs increased with the worsening of fitness status. At the end of induction, 402 pts were eligible for maintenance, 204 with R and 198 with RP. 192 (48%) pts were fit, 121 (30%) intermediate and 89 (22%) frail. After a median duration of maintenance of 22.0 months, PFS from start of maintenance was 22.2 months with RP vs 17.6 months with R (HR 0.80, p=0.07). This difference was significant only in fit pts (median PFS 24 vs 18 months, HR 0.70, p=0.03), no difference was seen in intermediate and frail pts. No difference in OS was observed. The occurrence of AEs and the risk of discontinuation due to AEs increased with the worsening of fitness status. (Table 1).

Table 1.

	FIT			INTERMEDIATE			FRAIL		
Arm	PFS Median	OS 5 yrs	Disc. for AEs	PFS Median	OS 5 yrs	Disc. for AEs	PFS Median	OS 5 yrs	Disc. for AEs
MPR	25.6	62%	23 (26)	20	53%	24 (30)	21.5	33%	19 (39)
CPR	21.7	58%	18 (18)	20.9	63%	19 (28)	13.8	39%	20 (38)
Rd	20.5	46%	17 (18)	16.6	67%	14 (25)	15.8	44%	15 (24)

Summary/Conclusion: This subgroup analysis showed for the first time that fit pts benefit from triplet full-dose regimens, while intermediate and frail pts benefit from a gentler doublet regimen. The higher incidence of hematologic AEs with MPR should be considered. In the future, the triplet regimen containing proteasome inhibitors and lenalidomide could be the best option in fit pts. All pts, even frail ones, benefit from continuous treatment with lenalidomide.

PS1294

POMALIDOMIDE, CYCLOPHOSPHAMIDE AND DEXAMETHASONE IN CASE OF SUBOPTIMAL RESPONSE TO POMALIDOMIDE AND DEXAMETHASONE IN RELAPSED AND REFRACTORY MULTIPLE MYELOMA: RESULTS OF THE GMMG-PERSPECTIVE TRIAL

K. Weisel[1,*], H. Salwender[2], C. Scheid[3], M. Zago[1], B. Besemer[1], M. Haenel[4], J. Duerig[5], M. Munder[6], H.-W. Lindemann[7], A. Seckinger[8], C. Kunz[9], A. Benner[9], D. Hose[8], A. Jauch[8], L. Kanz[1], H. Goldschmidt[8]

[1]University Hospital of Tuebingen, Tuebingen, [2]Asklepios Clinic, Hamburg, [3]University of Cologne, Cologne, [4]Clinic of Chemnitz, Chemnitz, [5]University of Essen, Essen, [6]University of Mainz, Mainz, [7]Catholic Hospital Hagen, Hagen, [8]University of Heidelberg, [9]German Cancer Research Center, Heidelberg, Germany

Background: Pomalidomide (POM) + dexamethasone (Dex) is a standard treatment in relapsed and refractory multiple myeloma (RRMM) resulting in an overall response rate (ORR) of approximately 30% and a median progression-free survival of 4.0 months (San Miguel *et al.*, Lancet Oncol 2013). Patients responding to POM + Dex show extended progression-free (PFS) and overall survival (OS) (Moreau *et al.*, Leuk Lymphoma 2016). Cyclophosphamide (CY) is an alkylating agent showing anti-myeloma activity with potential synergistic effects to immunomodulating agents (IMiDs) as POM and lenalidomide.
Aims: The GMMG-PERSPECTIVE trial (Eudra-CT No. 2013 003678 29) is a phase II multicenter investigator initiated trial in RRMM patients investigating efficacy when CY is added to POM + Dex standard treatment in case of primary progression or less than partial remission (PR) after 3 treatment cycles of POM + Dex. The primary objective of the trial is to demonstrate that the objective response rate (ORR) exceeds 30%, key secondary endpoints are PFS, time to next treatment (TTNT), OS and safety.
Methods: 60 patients with RRMM after at least 2 prior treatment lines including bortezomib and lenalidomide and not responding to the last prior regimen were included. All patients were included in safety analyses. 59 patients were eligible for the intention-to-treat (ITT) analysis of primary and secondary endpoints. Patients received standard dose of POM + Dex (POM 4 mg day 1-21, Dex 40 mg day 1, 8, 15, 22 of a 28-day cycle, Dex 20 mg weekly in patients > 75 years). In case of no PR after 3 cycles and/or disease progression (PD) during cycle 1-3, CY in a dose of 500 mg/m² intravenously day 1 and 15 per cycle was added. Patients were treated until PD or unacceptable toxicity. ORR as primary endpoint was evaluated after a median follow-up of 20.1 months. After a median follow-up of 32.8 months PFS, PFS from start of CY, OS, TTNT as secondary endpoints and safety data were reported.
Results: 60 patients were included into the trial. Median age was 67.0 (range 47-81) years, median number of prior treatment lines was 3 (2-5). 45% of evaluable patients had cytogenetic high-risk disease. ORR (≥ PR) was 39% (not significant with a lower 95% confidence bound of 29.2%). PR was reached in 14 (23.7%), very good partial remission (VGPR) in 7 (11.9%) and complete remission (CR) in 2 (3.4%) patients. 36/59 patients received CY after a median time of 2.9 months (1.1-4.4 months). At the time of addition of CY 16 patients had PD, 15 stable disease (SD) and 5 showed minimal response (MR). 13/36 patients with addition of CY to POM + Dex achieved a response: 8 PR (22.2%), 3 VGPR (8.3%), 2 CR (5.6%). Median PFS of the ITT population was 6.4 months. Median PFS from start of CY was 4.8 months. Median TTNT was 11.0 months. Median OS was 18.3 months. Main hematologic toxicities ≥ grade 3 were neutropenia in 26 (43.3%), anemia in 16 (26.7%), leukopenia in 15 (25.0%) and thrombocytopenia in 9 (15.0%) patients. Main non-hematologic toxicities ≥ grade 3 were pneumonia in 10 (16.7%) patients. All other toxicities ≥ grade 3 were ≤ 5%.
Summary/Conclusion: In RRMM patients, addition of CY to standard POM + Dex treatment is able to overcome lack of response or primary resistance to POM + Dex in a marked proportion of patients. PFS, TTNT and OS of the IIT compares favorably with published data for POM + Dex alone. With a favorable toxicity profile of the triple combination, primary addition of CY to POM + Dex should be considered in future to further optimize efficacy and durability of responses in POM + Dex standard treatment.

PS1295

SKY92 RISK STRATIFICATION AT RELAPSE PROVIDES ADDITIONAL PROGNOSTIC INFORMATION FOR STANDARD-RISK MULTIPLE MYELOMA PATIENTS

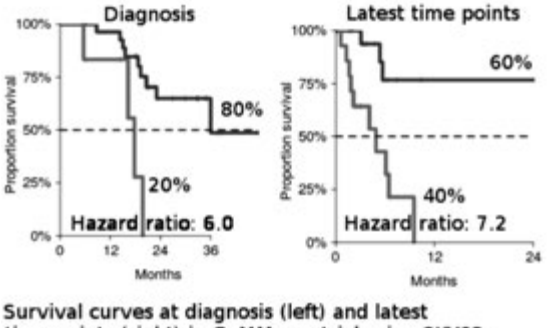
R. Kuiper[1,2,*], E. H. van Beers[3], M. H. van Vliet[2]

[1]Department of Hematology, Erasmus MC Cancer Institute, [2]Department of Bioinformatics, [3]Department of Oncogenomics, SkylineDx, Rotterdam, Netherlands

Background: Multiple myeloma (MM) is a plasma cell cancer with a disease course of recurrent relapses, resulting in a 5 yr median overall survival (OS). Gene expression (GEP) classifiers, such as SKY92, are able to differentiate high-risk (HR) and standard-risk (SR) patients at diagnosis and relapse. The SKY92 has been validated in several independent cohorts, identifying on average 18% of patients as HR. Although those cohorts differed in treatment, age of the patients and disease stage, the classifier was prognostic in all of them. However, it is unknown how the SKY92 risk classification evolves as the disease progresses.
Aims: In this study, we present the first longitudinal analysis of SKY92 by comparing classifications of samples obtained at diagnosis and relapse of the same patient.

Table 1. SKY92 risk stratification matrix in CoMMpass and TTx for newly diagnosed MM vs. relapse.

TTx					CoMMpass				
		Relapse					Latest time point		
		SR	HR	Total			SR	HR	Total
NDMM	SR	100(69%)	23(19%)	**88%**	NDMM	SR	20(57%)	8(23%)	**80%**
	HR	4 (3%)	13(9%)	**12%**		HR	1 (3%)	6(17%)	**20%**
	Total	**72%**	**28%**			Total	**60%**	**40%**	



Survival curves at diagnosis (left) and latest time points (right) in CoMMpass trial using SKY92. High-risk in red, standard-risk in blue.

Figure 1.

Methods: Two publically available MM patient data sets were used: the Multiple Myeloma Research Foundation (MMRF) CoMMpass trial (NCT145429) and the University of Arkansas for Medical Sciences (UAMS) total therapy cohorts (TTx). In the TTx cohort, microarray RNA expression data from tumor cells were determined at both diagnosis and relapse in 146

patients. OS was measured from diagnosis but not from relapse. The CoMMpass is a longitudinal study in 1000 NDMM patients, receiving treatment containing a proteasome inhibitor, IMiD or both. For 632 patients RNA-Seq was performed at diagnosis. A subset of 35 patients were sequenced at a later time point as well and had OS available as of both time points. RNA-Seq data was analyzed using the converted SKY92 classifier for that platform (SKY92r). In brief, 87 of 92 probesets of the microarray method were mapped to the RNA-Seq data; the original microarray classifier was corrected for this composition, and the classifier was then used on RNA-Seq data. For the TTx studies, microarray data is available, and SKY92 was calculated according to the algorithms routinely used in our lab for microarrays. For clarity we indicate the use of both classifiers below as SKY92.

Results: In the TTx cohorts, 12% of patients were HR at diagnosis, increasing to 28% at relapse (McNemar test $p=4.7x10^{-5}$; Table 1). In the CoMMpass cohort, 20% HR was seen at diagnosis increasing to 40% at the latest time point ($p=0.046$); all patients classified as HR at the late time point died within 1 yr from that time point (Figure 1). For 22% and 26% of patients in the TTx and CoMMpass, respectively, risk status changed, of which 19% and 23% transformed to higher risk. This suggests that in MM risk evolution, HR patients predominantly remain HR while SR patients mostly progress toward HR.

Summary/Conclusion: We observed the SKY92 risk classification for the first time in a longitudinal analysis. Reclassification at relapse provides additional prognostic insight, mostly for patients initially classified as SR at diagnosis

PS1296

CARFILZOMIB, CYCLOPHOSPHAMIDE, AND DEXAMETHASONE IN TRANSPLANT ELIGIBLE NEWLY DIAGNOSED MULTIPLE MYELOMA: PRELIMINARY RESULT OF SGHMM1 TRIAL, HIGH-RISK COHORT (NCT02217163)

Y. Chen[1], S. Gopalakrishnan[2], M. Ooi[3], N. Grigoropoulos[1], Y.S. Lee[1], C. Phipps[1], Y.T. Goh[1], W. J. Chng[3], W. Hwang[1], C. Nagarajan[1,*]

[1]Haematology, Singapore General Hospital, Singapore, Singapore, [2]Haematology, Health Sciences North, Sudbury, Ontario, Canada, [3]Haematology, National University Hospital, Singapore, Singapore

Background: Outcomes for high-risk MM patients is generally poor and could be improved through attainment of deeper responses. Carfilzomib is a second generation proteasome inhibitor with the ability to attain deep responses. Its efficacy and safety in the upfront setting for transplant-eligible high-risk MM patients is explored in this study.

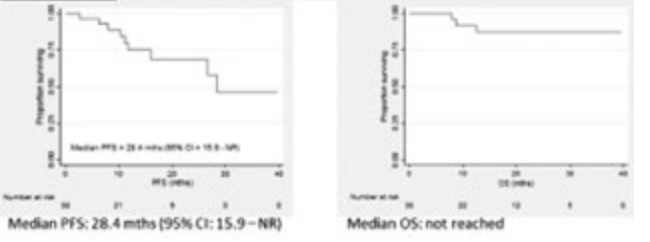
Aims: The primary objective was to assess the progression free survival (PFS) in autologous stem cell transplant (ASCT) - eligible, high-risk, newly diagnosed MM (NDMM) patients treated with the combination of Carfilzomib, Cyclophosphamide, and Dexamethasone (KCd). The secondary objective was to determine the overall survival and to assess minimal residual disease (MRD) status by multi parameter flow cytometry (MPFC) which was used to decide whether patients will receive maintenance Carfilzomib or not.

Methods: This IRB approved, open-label, Phase II study was conducted at 2 transplant centers in Singapore. Patients under 70yrs of age with high-risk NDMM (defined as any of: ISS 3, del17p, t(4;14), t(14;16)or 1q21amp) who were eligible for ASCT were enrolled. Eligible patients received six 28-day induction cycles of KCd - Carfilzomib 20/56 mg/m^2 (D1,2,8,9,15,16), Cyclophosphamide (flat dose) 500mg per week (D1,8,15,22), Dexamethasone 20 mg (D1,2,8,9,15,16). Following a safety review the dose escalation for Carfilzomib was capped at 36 mg/m^2 after 6 patients were recruited. After induction, patients had high dose Melphalan (200 mg/m^2) with stem cell rescue and consolidation with 2 cycles of KCd after three months as per above dose schedule. After consolidation, subjects who had at least a VGPR underwent disease assessment and MRD analysis by MPFC. Patients who achieved MRD negativity (MRD-) were managed expectantly whereas patients who were MRD positive (MRD+) received maintenance (Carfilzomib 36 mg/m^2 on D1,8,15 every 28 days) for 2 years or till disease progression.

Results: Median age of the patients was 63.0 years and 51.7% were Male. As of 31 December 2017, 32 patients were screened and 30 patients went on to receive KCd (2 patients were ineligible). 19 patients had completed ASCT at time of analysis, 6 patients were withdrawn from the study during induction (5 due to toxicity and 1 patient withdrew consent). With a median follow-up of 19.8 months, the median PFS was 28.4months (95% CI = 15.9 - not reached). Overall responses are shown in Table 1. Amongst the 13 patients who had completed consolidation and had MRD assessment done, 7 were MRD+ and went on to receive maintenance whilst 6 were MRD- and received no maintenance. Grade 3/4 haematologic treatment emergent adverse events (TEAEs) were seen in 9 (30%) patients: anaemia (16.7%), neutropenia (16.7%) and thrombocytopenia (13.3%). Other common TEAE were LRTI/pneumonia (23.3%), diarrhoea (10%) and acute kidney injury (13.3%). These are consistent with other reported studies with the same triplet combination. There were 6 TEAEs that lead to treatment discontinuation (3 thrombotic microangiopathies, 1 NSTEMI, 1 pulmonary oedema and 1 CMV retinitis).

Table 1.

	Post-induction (N=30) n (%)	Post-ASCT (N=25) n (%)	Post-consolidation (N=21) n (%)
MRD-	N.A.	N.A.	6 (28.6)
≥CR	10 (33.3)	11 (44.0)	12 (57.1)
≥VGPR	19 (63.3)	18 (72.0)	15 (71.4)
ORR (≥ PR)	26 (86.7)	21 (84.0)	17 (81.0)



Median PFS: 28.4 mths (95% CI: 15.9 – NR) Median OS: not reached

Summary/Conclusion: Carfilzomib, cyclophosphamide and dexamethasone (KCd) is an effective and generally well tolerated combination. Deep responses including MRD negativity are achievable with this triplet combination even in high-risk MM patients. Preliminary results from this ongoing study, support continued investigation of KCd, as a more economical alternative first-line treatment regimen (for example as compared to VRD) in high risk NDMM. Updated data based on longer follow-up and QOL data will be presented subsequently.

PS1297

WEEKLY CARFILZOMIB, LENALIDOMIDE, AND DEXAMETHASONE (KRD) IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA (RRMM): A PHASE 1B STUDY

N. Biran[1,*], D. Siegel[1], J.G. Berdeja[2], N. Raje[3], R.F. Cornell[4], M. Alsina[5], T. Kovacsovics[6], B. Fang[7], A. Kimball[7], O. Landgren[8]

[1]John Theurer Cancer Center at Hackensack University Medical Center, Hackensack, [2]Sarah Cannon Research Institute, Nashville, [3]Massachusetts General Hospital Cancer Center, Boston, [4]Vanderbilt University Medical Center, Nashville, [5]Moffit Cancer Center, Tampa, [6]Huntsman Cancer Institute, Salt Lake City, [7]Amgen Inc., Thousand Oaks, [8]Memorial Sloan Kettering Cancer Center, New York, United States

Background: KRd is approved for treatment of RRMM patients (pts). Under the approved KRd regimen, carfilzomib is given twice weekly (20/27 mg/m^2; 10-min IV infusion).

Aims: Here we present updated results from a dose-finding study assessing weekly KRd.

Methods: This study consisted of a dose-evaluation component and a dose-expansion component in both RRMM and newly diagnosed MM. Results for RRMM pts are presented here. Two dose levels were evaluated: carfilzomib 56 mg/m^2 and carfilzomib 70 mg/m^2. All pts received carfilzomib (30-min IV infusion on days [D] 1, 8, and 15; 20 mg/m^2 on C1D1), lenalidomide 25 mg (D1–21), and dexamethasone 40 mg (D1, 8, 15, and 22) on a 28-day cycle (dexamethasone was not given on D22 for cycles 9+). Pts in the expansion arm received the selected KRd regimen on the same schedule used for dose evaluation. Response was assessed by investigators.

Results: Twenty-two RRMM pts were enrolled in the dose-evaluation part and received study drug (56 mg/m^2, n=10; 70 mg/m^2, n=12). The maximum tolerated dose of carfilzomib was not reached; the 70 mg/m^2 dose was selected for dose expansion and 34 additional RRMM pts received this dose. Results are presented for pts who received carfilzomib 56 mg/m^2 during dose evaluation (n=10; median 2 prior regimens [range 1-3]) and for pts who received carfilzomib 70 mg/m^2 during dose evaluation or expansion (n=46; median 1 prior regimen [range 1-5]). Median (mean) average carfilzomib dose was 53.2 (52.8) mg/m^2 in the 56 mg/m^2 group and 62.4 (61.3) mg/m^2 in the 70 mg/m^2 group. Pt incidence of grade ≥3 adverse events was 70.0% (56 mg/m^2) and 71.7% (70 mg/m^2). Pt incidence of carfilzomib discontinuation due to adverse events was 20.0% (56 mg/m^2) and 17.4% (70 mg/m^2). There were three total deaths in the 70 mg/m^2 group (one each due

to cardiac arrest, cardiac disorder, and progressive disease). Overall response rates were 90.0% (56 mg/m^2) and 89.1% (70 mg/m^2); 20.0% (56 mg/m^2) and 30.4% (70 mg/m^2) of pts achieved a complete response (CR) or stringent CR.

Summary/Conclusion: Once weekly KRd was effective and had manageable toxicity in pts with RRMM. As a weekly carfilzomib dosing regimen could offer pts greater convenience, these results support further clinical evaluation.

PS1298

EXTENDED 5-Y FOLLOW-UP OF PHASE 3 ELOQUENT-2 STUDY: ELOTUZUMAB PLUS LENALIDOMIDE/DEXAMETHASONE VS LENALIDOMIDE/DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

Background: Elotuzumab, an immunostimulatory monoclonal antibody targeting SLAMF7, has a dual mechanism of action, directly activating natural killer cells and tagging myeloma cells for death via antibody-dependent cell-mediated cytotoxicity. In the phase 3 ELOQUENT-2 study (NCT01239797) of elotuzumab plus lenalidomide/dexamethasone (ELd) in patients (pts) with relapsed/refractory multiple myeloma (RRMM), ELd showed a 30% reduction in the risk of disease progression or death vs lenalidomide/dexamethasone (Ld) alone at 2-y follow-up (FU); this was sustained at 3-y (27%) and 4-y (29%) FU. ELd also demonstrated a favorable trend in overall survival ahead of the final analysis planned at 427 deaths.
Aims: To evaluate the progression-free survival (PFS) and safety of ELd at 5 y, a milestone timepoint in cancer survival analyses.
Methods: Pts with RRMM and 1–3 prior lines of therapy were randomized 1:1 to receive ELd or Ld in 28-d cycles until disease progression, unacceptable toxicity, or withdrawal of consent. Coprimary endpoints were PFS and overall response rate (ORR) as assessed by independent review committee. Safety was an exploratory endpoint. All pts provided written informed consent.
Results: Of 646 pts, 321 were randomized to ELd and 325 to Ld. At database lock (Nov 29, 2017), 13% (ELd) vs 7% (Ld) of pts remained on treatment; disease progression (ELd 55% vs Ld 56%) was the most common reason for treatment discontinuation. At 5-y FU (minimum 60 mo), ELd demonstrated a relative improvement of 50% in PFS compared with Ld (18% vs 12%) and a 27% reduction in risk of progression or death vs Ld (hazard ratio [HR] 0.73; 95% CI 0.60, 0.87; Figure 1). Pts with very good partial response or better (ELd 36% vs Ld 30%) had the greatest reduction in risk of progression/death (HR 0.63; 95% CI 0.44, 0.89). Median (95% CI) PFS was 19 (17, 22) mo with ELd and 15 (12, 17) mo with Ld. ORR was higher with ELd vs Ld (79% vs 66%), and median duration of response was also longer (22 vs 17 mo) with ELd. All-cause grade 3–4 adverse events (AEs; ELd vs Ld) included blood and lymphatic system disorders (46% vs 46%), infections (35% vs 27%), vascular diseases (11% vs 8%), second primary malignancies (SPMs; 10% vs 6%), and cardiac disorders (5% vs 8%). The most common treatment-related grade 3–4 AEs were blood and lymphatic system disorders (35% vs 38%) and infections (16% vs 11%). Rates of all-cause, any-grade infections (84% vs 75%) and SPMs (17% vs 11%) were higher with ELd than Ld, which may reflect longer median duration of treatment (17 vs 12 mo for each individual agent in the ELd vs Ld regimens). Fewer deaths occurred in the ELd than the Ld arm (193 vs 208). Of all treated patients, most deaths (ELd vs Ld) were due to disease progression (39% vs 42%) or infection (8% vs 5%).

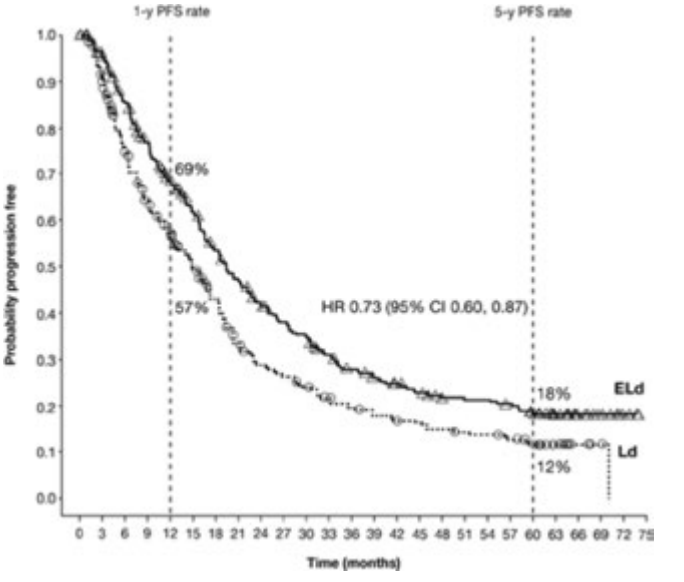

Figure 1.

Summary/Conclusion: At the milestone timepoint of 5 y, elotuzumab in combination with Ld showed durable, clinically relevant improvement in PFS and a 27% sustained reduction in the risk of progression/death vs Ld. Safety was consistent with previous findings, with minimal incremental AEs with ELd vs Ld despite longer exposure. ELd continues to show long-term treatment benefits, with the longest median FU of an immuno-oncology agent in MM.

PS1299

LENALIDOMIDE-PREDNISONE VS LENALIDOMIDE ALONE MAINTENANCE IN NEWLY DIAGNOSED MULTIPLE MYELOMA: INDIVIDUAL PATIENT DATA META-ANALYSIS OF 2 RANDOMIZED PHASE III TRIALS

F. Gay[1,*], L. De Paoli[2], A. Larocca[1], C. Musolino[2], M. Genuardi[1], V. Montefusco[2], S. Spada[1], R. Centurioni[2], E. Aitini[2], A. Malfitano[1], G. Latte[2], G. De Sabbata[2], F. De Santis[1], N. Pescosta[2], P. Musto[2], G. Benevolo[2], T. Guglielmelli[2], N. Cascavilla[2], F. Patriarca[2], C. Conticello[2], R. Hajek[3], A. Spencer[4], M. Boccadoro[1]

[1]Myeloma Unit, Division of Hematology, University of Torino, A.O.U. Città della Salute e della Scienza di Torino, Torino, [2]Italian Multiple Myeloma Network, GIMEMA, Italy, [3]Department of Hematooncology, University hospital Ostrava, Ostrava, Czech Republic, [4]Alfred Health - Monash University, Melbourne, Australia

Background: Lenalidomide maintenance is approved in newly diagnosed multiple myeloma (NDMM) patients (pts) who received high-dose therapy (HDT) and autologous stem cell transplant (ASCT).
Aims: The primary aim was to compare progression-free survival (PFS), time to next therapy (TTNT), PFS2 and overall survival (OS) of NDMM pts randomized to lenalidomide-prednisone (RP) vs lenalidomide alone (R) maintenance. The secondary aim was to identify the main predictors of long term endpoints (PFS2 and OS) in pts receiving lenalidomide-based maintenance.
Methods: Data of 2 phase III multicenter randomized trials (EMN441 and EMN01) enrolling NDMM pts were pooled together. Pts received lenalidomide-based upfront treatment (EMN441 - transplant eligible pts: lenalidomide-dexamethasone [Rd] induction followed by 2 courses of HDT-ASCT or 6 cycles of cyclophosphamide-dexamethasone-lenalidomide; EMN01 - transplant ineligible pts: 9 cycles of Rd or melphalan-prednisone-lenalidomide or cyclophosphamide-prednisone-lenalidomide); after lenalidomide-based upfront treatment pts were randomized to maintenance with R alone (10 mg day 1-21 every 28) or plus prednisone (RP) (EMN441: 50 mg every other day [eod]; EMN01: 25 mg eod) until progression (PD)/tolerated. Data cut-off was October, 2017.
Results: 1051 pts were enrolled; 625 were eligible for maintenance: 315 received RP and 310 R. Median follow-up was 5 years. Median age was 69 vs 70 years in RP and R, respectively; 24% vs 21% of pts in RP and R had Revised-International Staging System (R-ISS) stage I, 69% vs 73% stage II

and 7% vs 6% stage III. Median duration of maintenance was 27 months (m) in RP and 22 m in R. At data cut-off, 78% vs 77% of pts discontinued RP and R; main reasons were PD (68% vs 75% in RP and R) and adverse events (15% in each groups). A trend towards improved PFS was seen with RP vs R (median 25 vs 19 m; HR 0.85, p=0.08). Median TTNT was 35 m with RP vs 30 m with R (HR 0.96, p=0.66), resulting in about a 10 m improvement from median PFS in both groups. There were no significant differences in PFS2 (median 57 vs 49 m; HR 0.99, p=0.947) and OS (5-year 60% vs 65%, HR 1.26, p=0.10) between the 2 arms. In multivariate cox regression analysis, the main baseline independent predictors of PFS in this lenalidomide-treated population were R-ISS Stage (I vs II: HR 0.52, p<0.001; I vs III: HR 0.40, p<0.001) and achievement of sCR/CR before maintenance (sCR/CR vs VGPR/PR: HR 0.67, p=0.04); R-ISS Stage was the main predictor of TTNT (I vs II: HR 0.48; p<0.001; I vs III: 0.34, p<0.001), PFS2 (I vs II: HR 0.38, p<0.001; I vs III: HR 0.26, p<0.001) and OS (I vs II: HR 0.39, p<0.001; I vs III: HR 0.23, p<0.001). In multivariate cox-regression analysis, the main independent factor predicting a longer time from first PD to start of second-line therapy was duration of maintenance (13-24 vs ≤12 m: HR 0.66 p<0.001; >24 vs ≤12: HR 0.30, p<0.001). Duration of maintenance had a similar impact on second PFS (13-24 vs ≤12 m: HR 0.73 p=0.002; >24 vs ≤12 m: HR 0.30, p<0.001) and on OS from relapse (13-24 vs ≤12 m: HR 0.64 p=0.008; >24 vs ≤12 m: HR 0.20, p<0.001).

Summary/Conclusion: Despite a moderate PFS benefit with RP vs R, the lack of PFS2 and OS advantage confirmed R alone as the standard maintenance. The 10-m median improvement from PFS to TTNT, plus the positive impact of prolonged duration of maintenance on time from first PD to start of second-line therapy, as well as its impact on second-PFS and OS from relapse, suggest no significant chemo-resistance with prolonged therapy and support lenalidomide use until PD.

Background: Therapeutic advances in the past 15 years have resulted in significantly improved outcomes for MM patients (pts). However, in worldwide routine clinical practice, there is no standard of therapy in the management of newly diagnosed or relapsed/refractory MM (NDMM/RRMM). Outcomes reported in real-world clinical practice versus controlled clinical trials show markedly shorter treatment durations, progression-free and overall survival. Understanding the global availability and effectiveness of treatment regimens is critical.

Aims: INSIGHT MM (NCT02761187), the largest global, prospective, observational MM study to date, aims to understand disease and pt characteristics at presentation and relapse, treatment and clinical outcomes, and the association of treatment with tolerability, effectiveness, quality of life, and healthcare resource utilization. This pre-specified first interim analysis focused on global and regional treatment patterns.

Methods: More than 4000 adult pts with NDMM or RRMM (1–3 prior therapies) will be enrolled from 15 countries in Europe (EU), the United States (US), Asia and Latin America (LA). Pts will be followed prospectively for ≥5 yrs.

Results: At data cut-off, 1000 (535 NDMM, 465 RRMM) pts had been enrolled in 13 countries. RRMM pts had received a median of 2 prior therapies. Overall, 476 (48%) pts were from EU (8 countries), 337 (34%) from the US, 94 (9%) from Taiwan, 93 (9%) from LA (3 countries); 77% White/Caucasian, 11% Asian, 8% Black/African American. Median age was 63 (range 32–89) and 67 (36–94) yrs for NDMM and RRMM pts, respectively; 68 (13%) and 91 (20%) were aged >75 yrs (19%/15%/11%/10% in EU/US/Taiwan/LA). 35% and 38% of NDMM and RRMM pts, respectively, had Charlson Comorbidity Index scores ≥1. 36% and 45% of RRMM pts had received prior SCT in 1st line and any line of therapy, respectively. Overall, 60% were treated at academic centers (96%/83%/29%/24% in Taiwan/EU/US/LA); 85% were treated outside of clinical trials. 29% were diagnosed unexpectedly during blood tests/radiological exams; other common reasons for pts seeking care were bone pain (34%), weakness/fatigue/anemia (13%), and kidney problems (6%); this breakdown was similar in academic and community centers. In RRMM pts, time to relapse decreased with each subsequent line of therapy (median times to relapse during 1st/2nd/3rd line therapy were 23.4/16.6/10.3 months). At start of treatment, 31% (NDMM) and 63% (RRMM) of physicians selected a treat-to-progression regimen. The most commonly administered regimens are shown in the Table 1. For NDMM pts triplet regimens dominated over doublets/monotherapy (41% vs 15%); bortezomib was most commonly used (65%). For RRMM doublets/monotherapy were more common than triplets (32% vs 14%); lenalidomide-based therapy was preferred at relapse (40%). 50% of pts who received a proteasome inhibitor (PI) at 1st line, received a PI-based regimen again at 2nd line; 32% of pts who received an immunomodulatory drug at 1st line received an immunomodulatory drug at 2nd line. Efficacy data are awaited.

Table 1.

Most common regimens for NDMM patients overall and by region/countries					
Rank	Overall (13 countries) N=535	Europe (8 countries) n=243	United States n=175	Taiwan n=71	Latin America (3 countries) n=46
1	VCD 89 (17%)	VCD 60 (25%)	VRD 68 (39%)	Td 28 (39%)	VCD 18 (39%)
2	VRD 79 (15%)	VTD 36 (15%)	Vd 21 (12%)	VTD 12 (17%)	CTD 6 (13%)
3	VTD 49 (9%)	Rd 20 (8%)	Rd 18 (10%)	VCD-T 10 (14%)	VMP 3 (7%)
Most common regimens for RRMM patients, overall and by region/countries					
Rank	Overall N=452	Europe n=227	United States n=157	Taiwan n=23	Latin America n=45
1	Rd 90 (20%)	Rd 49 (22%)	Rd 23 (15%)	Rd 13 (57%)	VTd 7 (16%)
2	Kd 35 (8%)	IRd 21 (9%)	Kd 14 (9%)		VCd, Vd-other, Rd Each n=5 (11%)
3	IRd 26 (6%)	Kd 18 (8%)	Vd 12 (8%)		Kd 3 (7%)

C, cyclophosphamide; d, dexamethasone; D, daratumumab; I, ixazomib; K, carfilzomib; M, melphalan; P, prednisone; R, lenalidomide; T, thalidomide; V, bortezomib.

Summary/Conclusion: There is no global treatment standard in NDMM/RRMM; marked regional differences exist, potentially due to differences in drug/trial availability and treatment patterns at academic vs community centers. Our data confirm PIs and immunomodulatory drugs as backbones of MM therapy, with bortezomib- and lenalidomide-based treatment dominating the NDMM and RRMM settings, respectively. New-generation agents, plus drugs with new mechanisms of action, are used less frequently and mostly in later lines of therapy.

PS1301

TREATMENT AND SURVIVAL OF PATIENTS WITH PRIMARY PLASMA CELL LEUKEMIA: A NATIONWIDE POPULATION-BASED STUDY AMONG 179 PATIENTS DIAGNOSED IN THE NETHERLANDS FROM 1989 TO 2015

M. Brink[1,*], O. Visser[2], S. Zweegman[3], P. Sonneveld[4], A. Broijl[4], N. van de Donk[3], A. Dinmohamed[1,4,5]

[1]Research, [2]Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [3]Hematology, VU University Medical Center, Amsterdam, [4]Hematology, Erasmus MC Cancer Institute, [5]Public Health, Erasmus University Medical Center, Rot-

terdam, Netherlands

Background: Primary plasma cell leukemia (pPCL) is a very rare plasma cell dyscrasia with a very poor outcome. At present, there is a paucity of data on the outcome of pPCL, as prospective intervention studies in pPCL are very scare. Population-based studies can provide valuable information complementary to prospective intervention studies to assess treatment strategies and outcome in patients at the population level.
Aims: The aim of this nationwide, population-based study was to assess trends in primary therapy and survival among pPCL patients diagnosed during a 27-year period in the Netherlands.
Methods: We selected all pPCL patients diagnosed between 1989-2015 from the nationwide Netherlands Cancer Registry. Patients were categorized into three periods (1989-2000, 2001-2007, and 2008-2015) and two age groups (≤65 *v* ≥66 years). The periods were chosen based on the implementation of autologous stem cell transplantation (ASCT) and novel agents for multiple myeloma (MM) in the Netherlands. Data on primary therapy – i.e. no therapy and anti-pPCL therapy with or without a SCT – were available for individual patients. The primary end point was overall survival (OS), defined as the date from pPCL diagnosis to all-cause death. Patients alive were censored at February 1, 2017. Multivariable evaluation of OS was performed using Cox regression. p<0.05 indicates statistical significance.
Results: Our analytical cohort included 179 pPCL patients (median age, 65 years; age range, 34-91 years; 53% males; 79% diagnosed in non-academic centers; 8% with a prior malignancy). Patient characteristics were comparable across the three study periods. Overall, the application of anti-PCL therapy (including SCT) increased modestly from 88 to 92% among patients aged ≤65 (p=0.640) and from 67 to 71% among patients aged ≥66 (p=0.047) between 1989-2000 and 2008-2015, respectively. As for no therapy, the corresponding proportions were 12 and 8% among patients aged ≤65 and 33 and 29% among patients aged ≥66, respectively. What was noteworthy was that the application of SCT increased from 23 to 59% among patients aged ≤65 (p=0.004) and from 0 to 12% among patients aged ≥66 (p=0.084) between 1989-2000 and 2008-2015, respectively. During follow-up, 155 (87%) patients died. The median OS increased from 12.2 to 28.4 months for patients aged ≤65 (p=0.012; Figure 1A) and from 2.0 to 5.3 months for patients aged ≥66 (p=0.044; Figure 1B) between 1989-2000 and 2008-2015, respectively. Overall, when adjusted for the covariates listed in Table 1, the multivariable Cox model demonstrated an improvement of survival over time and an adverse effect of older age. However, when information on treatment was added to that model, the wider use of therapy explained the improved survival over time.

Table 1. Results of the multivariable Cox regression.

Covariate	Model without primary therapy HR[a]	95% CI	p[b]	Model adjusted for primary therapy HR[a]	95% CI	p[b]
Period of diagnosis						
1989-2000	1.26	0.83-1.91	0.279	1.41	0.92-2.17	0.113
2001-2007	1			1		
2008-2015	0.61	0.41-0.90	0.013	1.04	0.68-1.58	0.856
Female sex	1.05	0.76-1.45	0.753	0.92	0.67-1.28	0.628
Age ≥66 years at diagnosis	2.02	1.45-2.81	<0.001	1.24	0.87-1.78	0.235
Diagnosis in academic center	0.82	0.55-1.22	0.328	0.97	0.65-1.45	0.868
Previous malignancy	1.38	0.79-2.43	0.256	1.22	0.70-2.14	0.483
Primary therapy						
No therapy				2.64	1.78-3.93	<0.001
Anti-pPCL therapy without SCT				1		
Anti-pPCL therapy with SCT				0.34	0.20-0.57	<0.001

Abbreviations: HR, hazard ratio; CI, confidence interval; pPCL, primary plasma cell leukemia; SCT, stem cell transplantation.
[a]All covariates are simultaneously adjusted.
[b]P-values are compared with the reference category.

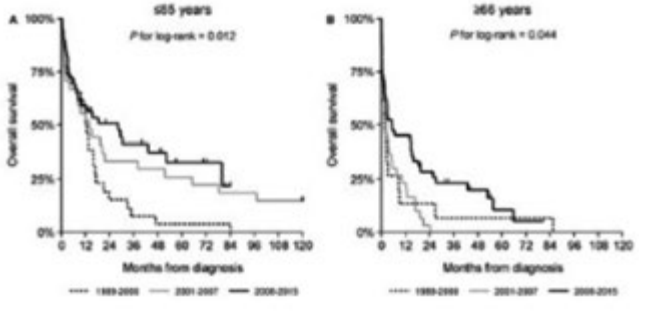

Figure 1.

Summary/Conclusion: In this nationwide, population-based study, we demonstrated that survival in pPCL improved over time. The improvement is largely explained by the wider application of SCT over time, especially among patients aged ≤65, and the introduction of novel agents. Collectively, the therapeutic advances achieved in MM seem to gradually translate into benefits for pPCL patients. Nevertheless, outcome remains disappointingly poor among patients aged ≥66. Therefore, prospective intervention studies in pPCL are imperative to further improve outcome.

PS1302

NEUTROPHIL GELATINASE-ASSOCIATED LIPOCALIN AS A BIOMARKER IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA AND RENAL IMPAIRMENT: DATA FROM A PHASE II TRIAL OF POMALIDOMIDE PLUS DEXAMETHASONE

K. Weisel[1,*], M. A. Dimopoulos[2], F. Bridoux[3], N.W. Van de Donk[4], K. Ramasamy[5], E. Kueenburg[6], A. Di Micco[6], B. Rosettani[6], P. Bacon[6], P. Sonneveld[7]

[1]University Hospital of Tubingen, Tubingen, Germany, [2]National and Kapodistrian University of Athens, Athens, Greece, [3]Department of Nephrology and National Referral Center for AL Amyloidosis, CHU, Poitiers, France, [4]Department of Hematology, VU University Medical Center, Amsterdam, Netherlands, [5]Department of Hematology, Oxford University Hospitals NHS Foundation Trust, Oxford, [6] NIHR BRC Blood Theme, United Kingdom, [6]Celgene International, Boudry, Switzerland, [7]Erasmus MC Institute, Rotterdam, Netherlands

Background: Renal impairment (RI) is a common comorbidity in patients (pts) with multiple myeloma (MM) and is present in 20 to 30% of pts with newly diagnosed MM; approximately 10% require hemodialysis. Urine neutrophil gelatinase-associated lipocalin (NGAL), a protein that is released from injured nephron epithelia, has been studied as a biomarker of RI and MM disease burden. Pomalidomide (POM) is approved by the US Food and Drug Administration and European Medicines Agency for use in pts with RI, including those with severe RI on hemodialysis. A phase 2 trial investigated the safety and efficacy of POM plus low-dose dexamethasone (LoDEX) in pts with relapsed or refractory MM (RRMM) and moderate or severe RI, including those on hemodialysis. Additional markers, such as NGAL, were assessed for further understanding of their role in a population of pts with RRMM and RI.
Aims: To demonstrate the potential of NGAL as a prognostic biomarker in pts with RRMM and RI treated with POM + LoDEX.
Methods: Pts with RRMM and RI were enrolled in 3 cohorts: moderate RI (estimated glomerular filtration rate [eGFR] 30 to < 45 mL/min/1.73 m^2), severe RI (eGFR < 30 mL/min/1.73 m^2), and severe RI requiring hemodialysis. Pts provided informed consent. Urine samples were collected at baseline and sent to a central facility for NGAL analysis. Median NGAL across cohorts was 58.5 µg/L (range, 1.0-4096.0 µg/L). This median was used to delineate between low (baseline NGAL ≤ 58.5 µg/L) and high (baseline NGAL > 58.5 µg/L) NGAL levels.

Table 1.

Response	Low NGAL (n = 37)	High NGAL (n = 36)
Overall renal response rate	12 (32.4)	5 (13.9)
Renal CR	5 (13.5)	0
Renal PR	1 (2.7)	1 (2.8)
Renal MR	6 (16.2)	4 (11.1)
Stable	23 (62.2)	26 (72.2)
Worsening	2 (5.4)	3 (8.3)
Overall clinical response rate[a]	20 (54.1)	15 (41.7)
Overall response rate[b]	15 (40.5)	11 (30.6)
CR	0	0
VGPR	6 (16.2)	4 (11.1)
PR	9 (24.3)	7 (19.4)
MR	5 (13.5)	4 (11.1)
SD	15 (40.5)	15 (41.7)
PD	1 (2.7)	4 (11.1)
NE	1 (2.7)	2 (5.6)

[a] ≥ MR. [b] ≥ PR.
CR, complete response; MR, minimal response; NE, not evaluable; NGAL, neutrophil gelatinase-associated lipocalin; PD, progressive disease; PR, partial response; SD, stable disease; VGPR, very good partial response.

Key words: Pomalidomide, relapsed/refractory multiple myeloma, neutrophil gelatinase-associated lipocalin, renal impairment

Results: This analysis included 73 pts with urine NGAL measurements at baseline: 37 had low NGAL and 36 had high NGAL. Median age was similar between pts with low vs high NGAL (72.0 vs 71.0 yrs). In the low-NGAL group, 64.9% of pts were male vs 55.6% in the high-NGAL group. The median duration of MM was 48.2 mos in the low-NGAL group vs

43.2 mos in the high-NGAL group, and the median duration of RI was 35.7 vs 26.9 mos, respectively. Fewer pts in the low-NGAL group than in the high-NGAL group had an ECOG performance status of 2 (13.5% vs 27.8%) or had ISS stage III disease (78.4% vs 97.2%). Median percentage of plasma cells in the bone marrow aspirate at baseline was similar between the groups (20.0% vs 22.0%, respectively). Among 55 pts with cytogenetic data (low NGAL, 25; high NGAL, 30), fewer pts with low NGAL had del17p (8.0% vs 16.7%). At baseline, median involved serum κ free light chain (FLC) levels were 1446.50 mg/L and 3580.0 mg/L in the low-NGAL and high-NGAL groups, respectively, and λ FLC levels were 2365.0 mg/L and 2630.0 mg/L, respectively. Baseline median eGFR was 35.0 mL/min/1.73 m2 in pts with low NGAL and 17.5 mL/min/1.73 m^2 in pts with high NGAL. Treatment duration with POM + LoDEX was longer in pts with low NGAL than in pts with high NGAL (median, 31.0 vs 18.8 wks); these pts also had more cycles of treatment (median, 7.0 vs 4.5, respectively). The overall renal response rate was higher in the low-NGAL group (32.4% vs 13.9%, respectively; Table 1), as was ORR (40.5% vs 30.6%, respectively).

Summary/Conclusion: Low urine NGAL levels at baseline were associated with better response to POM + LoDEX treatment, as reflected in the higher ORR and overall renal response rate vs pts with high urine NGAL levels. Further, pts with low NGAL had longer times from diagnoses of MM and RI to study inclusion, while pts with high NGAL had worse renal function and more advanced disease at baseline. These findings suggest that higher NGAL may be related to more aggressive disease. NGAL may be a promising prognostic biomarker in pts with RRMM and RI.

PS1303

REAL WORLD CLINICAL IMPLICATIONS OF THE LIMITATIONS ASSOCIATED WITH THE REVISED INTERNATIONAL STAGING SYSTEM: UNSELECTED PATIENTS WITH MULTIPLE MYELOMA TREATED WITH NOVEL AGENTS IN AGEING SOCIETY

Y. Abe[1,*], K. Narita[1], H. Kobayashi[1], A. Kitadate[1], M. Takeuchi[1], K. Matsue[1]

[1]Division of Hematology/Oncology, Department of Internal Medicine, Kameda Medical Center, Kamogawa, Japan

Background: The Revised International Staging System (R-ISS) was developed in 2015 for more accurate prognostication by combining widely used International Staging System (ISS) with high-risk cytogenetic abnormalities (CA) [t(4;14), t(14;16) and del(17p)] as well as elevated serum lactate dehydrogenase. However, both the original and validation studies of R-ISS included relatively young patients with a median age of approximately 65 years, and more than half of the patients included in these studies were treated without bortezomib.

Aims: We aimed to investigate the superiority of R-ISS to ISS in a real world setting of an ageing society, by determining the usefulness of both R-ISS and ISS in patients with multiple myeloma (MM) treated with novel agents.

Methods: Data for 245 consecutive patients with newly diagnosed MM who were treated with chemotherapy between January 2006 and October 2017 at our institution were retrospectively analyzed. Diagnosis and treatment response were evaluated per IMWG criteria. We included patients who only received novel agents (bortezomib and/or lenalidomide).

Results: In contrast to previous studies, the median age of all 245 patients included in our study was 73.3 years, and bortezomib was used in most of the patients (96.7%). The number of patients categorized as ISS stage I, II, and III were 50 (20.4%), 66 (26.9%) and 129 (52.7%) with a median age of 69.9, 74.7 and 74.4 years, respectively. The number of patients categorized as R-ISS stage I, II, and III were 33 (14.3%), 140 (60.9%) and 57 (24.8%) with a median age of 70.3, 74.5 and 70.3 years, respectively. There was a significant difference in age between R-ISS stage II and III patients; The R-ISS stage II patients were significantly older than the R-ISS stage III patients (p=0.014). There was no significant difference in overall survival (OS) between R-ISS stage II and III patients (median OS, 73.2 and 52.1 months, respectively; p=0.192); however, a significant difference in OS was detected between ISS stage II and III patients (p=0.048) (Figure 1). Patients who were recategorized from ISS stage III to R-ISS stage II were significantly older than those who were recategorized from ISS stage III to R-ISS stage III (median age, 76.5 and 70.3 years, respectively); however, no significant difference in OS was detected between these patients. Patients with t(4;14) or t(14;16) were significantly younger than those without (median age, 74.0 and 69.3 years, respectively; p=0.012). Accordingly, there was no significant difference in OS regardless of harboring any of the high-risk CA (median OS, 60.3 and 86.4 months, respectively; p=0.572). Furthermore, patients with t(4;14) had rather favorable OS than those without, although the difference was not statistically significant (median OS, not reached and 58.3 months, respectively; p=0.096).

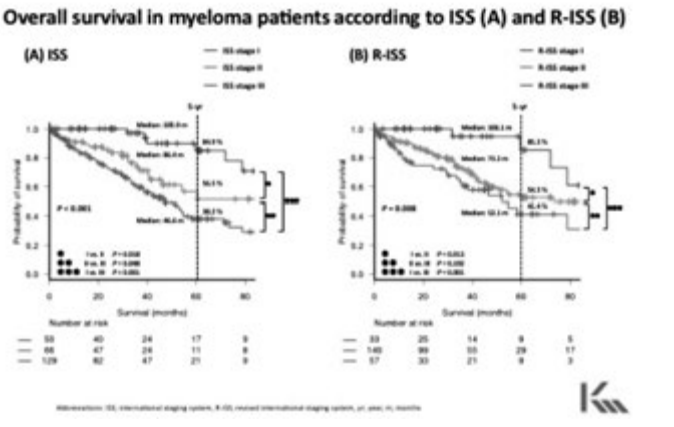

Figure 1.

Summary/Conclusion: To our knowledge, this is the first report on the limitations associated with R-ISS over ISS when used in patients with MM with a wide age-range who are treated with bortezomib-containing regimens in an ageing society. This limitation may be attributed to adopting t(4;14) as a high-risk CA for R-ISS classification. This potential limitation should be widely considered in risk stratification for MM patients because many developed countries including Western countries will successively enter the period of super-ageing society, like Japan.

PS1304

EVALUATION OF MINIMAL RESIDUAL DISEASE USING NEXT GENERATION FLOW CYTOMETRY IN PATIENTS WITH LIGHT CHAIN (AL) AMYLOIDOSIS

E. Kastritis[1], I. Kostopoulos[2,*], E. Terpos[1], D. Fotiou[1], M. Gavriatopoulou[1], N. Kanellias[1], D. C. Ziogas[1], M. Roussou[1], M. Migkou[1], E. Eleutherakis-Papaiakovou[1], O. Tsitsilonis[2], M.A. Dimopoulos[1]

[1]Department of Clinical Therapeutics, [2]Department of Biology, National and Kapodistrian University of Athens, Athens, Greece

Background: Complete hematologic response (hemCR) is associated with better survival and organ function improvement in patients with AL amyloidosis. Hematologic relapses occur even in pateinst with a hemCR and organ function may continue to deteriorate due to small residual clones that may lead to disease recurrence or may produce very small amounts of toxic light chains, which go undetectable by conventional techniques. Next generation flow cytometry (NGF) is a very sensitive method to evaluate the presence of minimal residual disease (MRD) and is a standard method for the assessment of MRD in patients with myeloma.

Aims: The aim of the current study was to evaluate feasibility and applicability of MRD by NGF in patients with AL at complete hematologic response.

Methods: We evaluated MRD in 24 patients with AL amyloidosis in sustained hemCR. MRD was assessed in BM samples according to the Euroflow guidelines, using two independent 8-color panels, both containing CD19-PC7, CD27-BV510, CD38-FITC, CD45-PerCPCy5.5, CD56-PE, CD138-BV421, and additionally CD117-APC and CD81-APCC750 only in the surface tube or CyIgκ-APC and CyIgλ-APCC750 only in the intracytoplasmic tube. A median number of 5 million events (range $3.9x10^6$-$6.1x10^6$) were acquired for each tube in a BD FACSCantoII cytometer and data analysis was conducted with Infinicyt software, that allowed merging of the two panels based on the 6 backbone markers, offering a median sensitivity level of $2.3x10^{-6}$ (range $2x10^{-6}$-$3.1x10^{-6}$).

Results: The median age at diagnosis was 59 years (range 42-75), 75% had λ-light chain, 90% had renal, 15% liver and 35% had cardiac involvement; 40% were Mayo stage-1, 50% stage-2 and 10% stage-3. At diagnosis median dFLC was 94 mg/L (range 17-879) and 15% had negative serum and urine immunofixation. Median clonal plasma cell infiltration was 8%. Primary treatment was bortezomib-based in 88% and MDex in 11%, while 33% had received ASCT. At the time of MRD testing, 50% of the patients had achieved a renal response, 4/7 (57%) patients with cardiac involvement had a cardiac response, and 1/3 (33%) a liver response. Ten (42%) patients were MRD negative (MRD^{neg}) and 14 (58%) were positive (MRD^{pos}). Notably, 6/14 (43%) MRD^{pos} cases had very low residual tumor load at levels $<3x10^{-5}$. Median time from CR to MRD testing was 36 months (39 vs 35 months for MRD^{pos} vs MRD^{neg} patients). MRD was positive in 3/4 patients with negative baseline serum and urine immunofixation and in 2/3

patients with baseline dFLC<40 mgL. Responses of at least one involved organ were documented in 70% of patients and in particular in 70% of MRD^{pos} patients vs 67% of MRD^{neg}. Among cardiac responders (n=4), 3 were MRD^{neg}. Renal responses occurred in 67% of MRD^{pos} and 75% of MRD^{neg} patients. MRD^{neg} patients had more often response in more than one organ (in all a cardiac and a renal response) while among MRD^{pos} patients all had responses to a single organ. We found no significant differences in baseline characteristics (age, dFLC, BM infiltration, NTproBNP, Mayo stage) among MRD^{neg} and MRD^{pos} patients. Among patients who received ASCT, 2/8 (25%) were MRD^{neg} vs. 6/12 (50%) that were MRD^{neg} among patients who did not have ASCT.

Summary/Conclusion: Among patients with AL amyloidosis in sustained hemCR, assessed with high sensitivity NGF 42% were MRD^{neg} and 58% were MRD^{pos}. This finding may have implications in the management of patients with AL who achieve a hemCR, especially among those who fail to achieve an organ response and may also have implication for their management, in an era of expanding treatment options.

PS1305

EARLY LIGHT CHAIN KINETICS AND DEPTH/DURATION OF HEMATOLOGIC RESPONSES TO DARATUMUMAB IN PREVIOUSLY TREATED LIGHT CHAIN AMYLOIDOSIS

G. Kaufman[1,*], S. Schrier[1], R. Witteles[2], P. Ulloa[1], M. Lugtu[1], S.A. Arai[3], M. O'Shaughnessy[4], R. Lafayette[4], M. Liedtke[1]

[1]Hematology, [2]Cardiology, [3]Blood and Marrow Transplantation, [4]Nephrology, Stanford University, Palo Alto, United States

Background: Daratumumab (dara) can produce rapid and deep ≥VGPR in pts with previously treated light chain amyloidosis (AL). However, around 1/3 of pts experience non-response (NR) or plateau at partial response (PR). Furthermore, little is known about hematologic response duration. Biomarkers correlating with depth and duration of response would be clinically useful, as have been identified for myeloma (Moritz B. ASH 2017 abs 4355).
Aims: To evaluate the relationship between early changes in disease specific light chains and long term response and clinical outcomes of AL pts treated with dara.
Methods: We retrospectively studied 44 pts with biopsy proven AL, previously treated, who subsequently received dara (with dexamethasone) at our institution between 1/2016 and 2/2018. Dara was given intravenously at a dose of 16 mg/kg weekly for 8 weeks, then biweekly for 16 weeks, and monthly thereafter. We evaluated differential free light chain (dFLC = involved–uninvolved serum light chain) changes at one month into therapy (d28), in relation to heme depth of response per consensus criteria and time to next therapy (TNT) defined as time to addition of, or change to alternative plasma cell directed agents, or death due to any cause. The Wilcoxon each pair method was used to compare change in dFLC at d28 with depth of response achieved to dara. Proportional hazards models were constructed to analyze the impact of early dFLC changes with TNT.
Results: Forty-four pts received a median 2 prior lines of therapy (1-6), including bortezomib or carfilzomib in 43 (97.8%), and lenalidomide or pomalidomide in 24 (55%). Median follow up from dara initiation was 9 months (1-24). Prior to dara, median dFLC was 4.9 mg/dL (0.4-46.7). For all pts, median d28 reduction in dFLC was 71% and maximal median reduction in dFLC during dara was 87%. Of 8 NR pts, the median d28 reduction in dFLC was 13%, of 7 pts achieving a maximum PR the median d28 dFLC reduction was 63% (p<0.01 vs NR), whereas for the 29 pts with VGPR or CR the median d28 reduction in dFLC was 81% (p<0.0001 vs NR, p=0.04 vs PR). Of 12 pts achieving less than 50% reduction in dFLC at d28, only 4 (33%) went on to achieve ≥PR. Failure to achieve at least 50% reduction in dFLC at d28 was associated with a significantly increased risk of being a dara non-responder (RR 3.67, CI 1.7-7.1, p<0.001). Median TNT was not reached for the cohort and at 9 months 70% of pts had not met criteria for TNT failure (Figure 1). Failure to achieve ≥50% reduction in dFLC at d28 was associated with shorter TNT (HR 4.28, CI 1.2-13.7, p=0.02). Of importance, median number of dara infusions after d28 was 6 in the group achieving less than 50% reduction in d28 dFLC, and 12 in the group achieving >50% reduction in d28 dFLC. Among the deep responding subgroup of 29 pts with ≥VGPR, there was no relationship between early TNT failure and d28 dFLC reduction (HR 1.005, CI 0.95-1.08, p=0.86) though the number of events was low (n=4) and 25/29 pts had not met TNT failure at last follow up.
Summary/Conclusion: In pts with pretreated AL receiving dara, responses stratify after the first treatment cycle, and change in dFLC by d28 was significantly associated with longer term treatment response. Pts achieving <50% dFLC reduction at d28 were unlikely to experience a deep heme response with further dara monotherapy. For the subgroup of deep dara responders (≥VGPR), d28 dFLC reduction did not correlate with TNT though number of events was low and longer follow up is needed.

PS1306

EFFICACY AND TOLERABILITY OF DARATUMUMAB AFTER ALLOGENEIC TRANSPLANTATION FOR HEAVILY TREATED MULTIPLE MYELOMA

A. P. Gonzalez-Rodriguez[1,*], L. Lopez Corral[2], A. Bermudez[3], T. Zudaire Ripa[4], P. Santos Diaz[5], A.J. Gonzalez-Huerta[1], P. Palomo[1], M.V. Mateos[2], S. Gonzalez-Muñiz[1]

[1]Hematology- Stem cell transplantation Unit, Hospital Universitario Central de Asturias, Oviedo, [2]Hematology, Hospital Universitario de Salamanca, Salamanca, [3]Hematology, Hospital Universitario Marques de Valdecilla, Santander, [4]Hematology, Complejo Hospitalario de Navarra, Pamplona, [5]Hematology, Complejo Hospitalario Universitario de Pontevedra, Pontevedra, Spain

Background: Allogenic stem cell transplantation (allo-STC) in multiple myeloma (MM) in Europe has increased in the last decades and although it is not a curative approach, the allo-SCT contributes to prolong the overall survival (OS) mainly because of the responses so far reported with novel agents after allo, through the enhancement of the graft versus myeloma. Daratumumab targets CD38 on the plasma cells resulting into a direct antitumor activity but also reduces local immune suppression within the bone marrow microenvironment, facilitating the expansion of positive immune effector cells, contributing to the antimyeloma response.
Aims: In spite of its efficacy, there are not many data about its efficacy and safety of Daratumumab in patients that had been previously received allo-SCT especially because this population was not allowed to be included in the trials and most All-SCT relapsed and we must decide the next treatment.
Methods: In this multi-center retrospective analysis, we collected and analyzed efficacy and safety data of patients receiving Daratumumab for relapsed MM following allo-SCT.
Results: Eleven patients were included (males, n=9) and the median age was 57 years (range 34-66). Eight out of 11presented with high risk features (2 plasma cell leukemia, and 6 genetic features of high risk) and 3 with early relapsed (≤ 12 months after allo-SCT). Patients were heavily pretreated and received a median of 6 prior lines (4-10). Fifty four percent were bortezomib-refractory and 81% lenalidomide-refractory. The median time from allo-STC to first dose of Daratumumab was 25 moths (7-96). Median number of Daratumumab infusions was 13 (range 4-26). Ten patients were evaluable for response and 5 (50%) achieved at least partial response (1 complete response, 1 very good partial response, 3 partial response). Three additional patients achieved stable disease so daratumumab single agent did control the disease in 80% of the patients.
Safety profile was acceptable, only two patient had infusion related reaction during the first infusion (grade 1). GVHD reactivation was only reported in a patient with prior history of acute GVHD but daratumumab did no trigger a flare for cGVHD. Four patients developped infections during treatment (pseudomona, enterobacter, CMV, influenza B). Four deaths have been

so far reported, 3 due to progression and one due to CMV infection. There are 4 patients that are ongoing receiving daratumumab. The median of PFS was 11months and median overall survival not reached at a median of follow-up of 9 moths.

Summary/Conclusion: In conclusion, we confirmed the efficacy of Daratumumab in the setting of MM relapsing after Allo-SCT in heavily treated patients with overall response of 50% and disease control rate of 80%. This encouraging efficacy is associated with a safety profile consistent with other daratumumab studies and no new safety signal. All these findings would need to be confirmed in large trials but Daratumumab can be used after allo-SCT without risk of GVHD reactivation.

PS1307

CHARACTERISTICS, TREATMENT PATTERNS, AND SURVIVAL OUTCOMES OF PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM) IN NORTH AMERICA AND EUROPE: FINDINGS FROM THE PREAMBLE STUDY

R. Vij[1,*], C. Chen[2], C. Davis[2], H. Kim[3], B. Durie[4], G. Cook[5], H. Goldschmidt[6]

[1]Washington University School of Medicine, St Louis, [2]Bristol-Myers Squibb, Princeton, [3]PAREXEL, Billerica, [4]Cedars-Sinai Medical Center, Los Angeles, United States, [5]University of Leeds, Leeds, United Kingdom, [6]Heidelberg University Hospital, Heidelberg, Germany

Background: With improved treatment strategies and access to therapies that have novel mechanisms of action (MoAs), prolonging survival for patients (pts) with MM has become a realistic goal. Proteasome inhibitors (PIs), immunomodulatory drugs (IMiDs), and PI+IMiD combinations have become the standard of care in MM. In addition, the monoclonal antibodies (mAbs) elotuzumab and daratumumab are a relatively new class of approved agents. Despite increasing treatment options, access to therapies may vary between North America (NA) and Europe, thereby affecting outcomes.

Aims: To evaluate the impact of regional treatment differences on outcomes in RRMM.

Methods: Pts aged ≥18 y with RRMM from NA (US and Canada) and Europe (France, Germany, Italy, and the UK) were identified from PREAMBLE (NCT01838512), an ongoing, prospective, observational study. Pts had ≥1 prior therapy, and began treatment with a PI, IMiD, PI+IMiD combination, or new agent (those with newer MoAs, such as mAbs, histone deacetylase inhibitors, and novel combinations) ≤90 d before or 30 d after informed consent. Data were collected at every healthcare visit for 3 y or until the end of follow-up (FU). Baseline characteristics and length of FU were assessed using descriptive analysis. Statistical comparisons were made using *t* tests, Mann–Whitney *U* tests (continuous variables), and chi-square tests (categorical variables); 2-sided p-values were obtained. Overall survival (OS) was analyzed using Kaplan–Meier (K-M) and multivariate Cox regression (adjusted from covariates selected using stepwise regression) techniques.

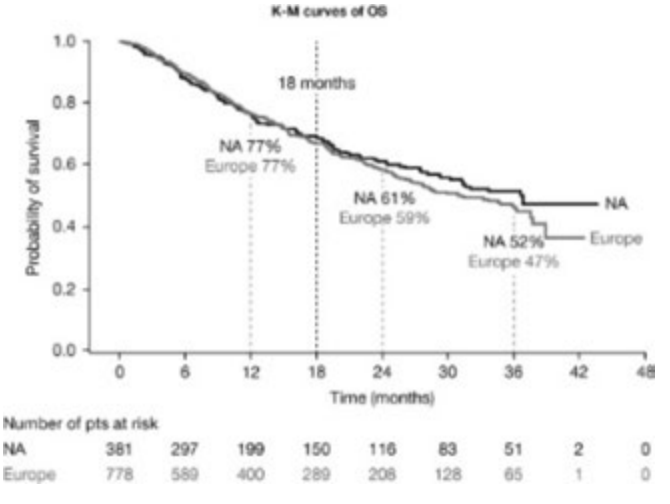

Figure 1.

Results: At database lock (Nov 30, 2017), 381 pts in NA and 778 pts in Europe were identified. In total, 58% of pts in NA and 48% of pts in Europe withdrew from the study due to death or other reasons; most deaths were due to disease progression (NA, 68%; Europe, 67%). Median (range) FU was 13 (7–27) mo and 12 (6–25) mo for pts in NA and Europe, respectively. Pts in NA vs Europe were younger at enrollment (median 66 y vs 70 y; p<0.0001), but more likely to have comorbidities (94% vs 80%; p<0.0001), including vascular (63% vs 42%), metabolic and nutritional (46% vs 27%), and musculoskeletal/connective tissue (42% vs 22%) disorders. Prior to enrollment, a greater proportion of pts in NA than Europe received ≥2 therapies (62% vs 52%; p=0.004), PI+IMiDs (29% vs 16%; p<0.0001), and new agents (3% vs 1%; p=0.0390). After enrollment, a greater proportion of pts in NA vs Europe received PIs (56% vs 46%), PI+IMIDs (29% vs 9%), and new agents (21% vs 5%; p<0.001 for all). Median (95% CI) OS was 37 (29, not estimable) mo in NA and 31 (27, 38) mo in Europe. In a multivariate analysis, risk of death was 17% lower in pts in NA vs Europe (hazard ratio [95% CI]: 0.83 [0.66, 1.04]; p=0.110). A significant separation of OS K-M curves in favor of NA was seen from 18 mo onward (p=0.0402), but not across the entire FU period (Figure 1).

Summary/Conclusion: Real-world data suggest that pts with RRMM in NA had greater access to newer agents and PI+IMiD combination regimens than pts in Europe. Survival analysis identified a potential but non-significant reduction in the risk of death for pts in NA vs Europe. OS was significantly higher from 18 mo onward for pts in NA vs Europe, which may be partly due to possible benefits from newer agents often reserved for later lines of therapy. Further analysis is warranted.

Writing support: L Yee, Caudex, funded by BMS.

PS1308

COMPLETE RESPONSE AND INDUCTION TREATMENT DOES NOT AFFECT SURVIVAL IN MYELOMA PATIENTS RELAPSING WITHIN 18 MONTHS FOLLOWING UP-FRONT HDM-ASCT. A POPULATION-BASED STUDY FROM 1994 TO 2015

A. Vangsted[1,*], S.N. Clemmensen[1], K. Dimoupolous[1], U.C. Frølund[2], C. Helleberg[3], N.F. Andersen[4], N. Abildgaard[5], P. Gimsing[1], H. Gregersen[6], T.W. Klausen[3]

[1]Department of Hematology,, Rigshospitalet, Copenhagen University, Denmark, Copenhagen, [2]Department of Hematology,, Department of Hematology, Roskilde Hospital, Roskilde, [3]Department of Hematology,, Herlev University Hospital, Copenhagen, [4]Department of Hematology, Aarhus University Hospital, Aarhus, [5]Department of Hematology,, Odense University Hospital, Odense, [6]Department of Hematology,, Aalborg University Hospital, Aalborg, Denmark

Background: Despite the introduction of proteasome inhibitors (PI) as induction treatment preceding high-dose melphalan an autologous hematopoietic stem cell transplantation (HDM-ASCT) for patients with multiple myeloma (MM), a subgroup of these patients experiences early relapsed myeloma (ER) leading to poor overall survival (OS).

Aims: To analyze if there is a difference in OS for MM patients achieving greater-than or equal to complete remission (CR) compared to patients achieving less than or equal to partial remission (PR) among newly diagnosed MM patients with ER within 18 months after up-front HDM-ASCT.

Methods: We analyzed the importance of achieving at least CR in a population-based cohort of 929 patients uniformly treated with HDM-ASCT. Patients treated in the high-dose trials conducted by the Nordic Myeloma Study Group (NMSG no. 5/94, 7/98 and 11/00) between 1994 and 2004 and patients registered prospectively in the Danish National Multiple Myeloma Registry between 2005 and 2015 were included. The median follow-up for OS was 63.0 months (43.6-91.8 months). Induction treatment was vincristine, adriamycin, and dexamethasone; cyclophosphamide and dexamethasone; bortezomib and dexamethasone with and without cyclophosphamide.

Results: Among patients experiencing ER, 32.3% achieved ≥ CR and 67.7% achieved PR, compared to patients with a later relapse where ≥ CR was seen in 45.3% and PR in 54.7% (p=0.0002). In patients with an ER, the fraction of patients with ≥ CR was higher (38.5%) for patients treated with a bortezomib-based induction as compared to other regimens (28.8%). There was no difference in the fraction of patients with an ER achieving ≥CR or PR in relation to bortezomib-based treatment and other treatments (OR: 1.8; CI 1.1-2.8) versus (OR: 1.7; CI: 1.1-2.4) (p=0.84), respectively. Furthermore, the fraction of patients achieving ≥CR did not differ in relation to the calendar period 1994-2004 (OR: 1.6; CI: 0.8-3.1) and 2005-2013 (OR: 1.8; CI: 1.3-2.5)(p=0.73). Interestingly, for patients with an ER, achieving ≥ CR did not result in better OS after HDT-ASCT or OS after their first relapse post-HDT-ASCT (Figure 1).

Summary/Conclusion: This population-based study shows, that among patients with an ER within 18 months, achievement of CR does not translate into improved OS irrespectively of the inclusion of PI in induction

treatment. Whether these patients have a unique resistant disease or still are MRD (minimal residual disease) positive after HDM-ASCT remains to be analyzed.

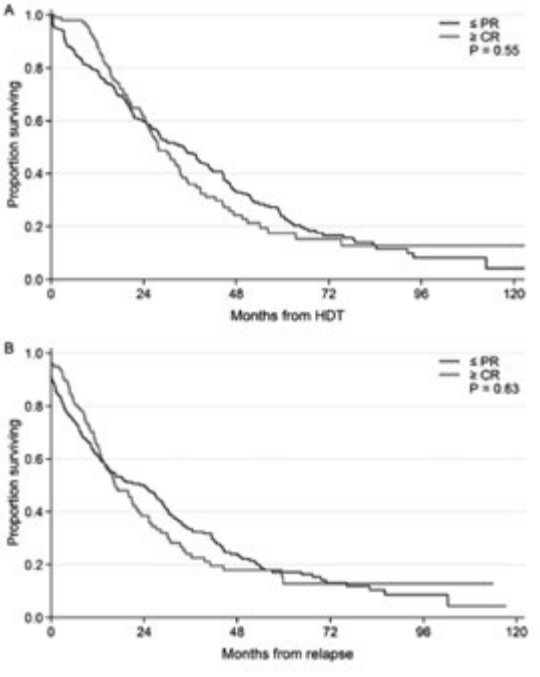

Figure 1. Overall survival for patients with an ER within 18 months depending on response after HDM-ASCT (≥ CR or ≤ PR).The upper panel shows OS after HDT-ASCT and the lower panel shows OS after first relapse after HDM-ASCT. The red line is patients achieving ≥ CR; the blue line is patients achieving ≤ partial remission (PR).

PS1309

OVERALL SURVIVAL OF PATIENTS POST-TRANSPLANT: STUDY RESULTS FROM TWO PHASE 3 TRIALS ASPIRE AND ENDEAVOR

H. Goldschmidt[1,*], M.-V. Mateos[2], D. Siegel[3], R. Abonour[4], H. Ludwig[5], M. Obreja[6], K.S. Iskander[6], P. Hari[7]

[1]University Hospital Heidelberg, Heidelberg, Germany, [2]Hematology Service, University Hospital Salamanca, Salamanca, Spain, [3]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, [4]Indiana Cancer Pavilion, Indianapolis, United States, [5]Department of Medicine, Wilhelminen Cancer Research Institute, Wilhelminenspital, Vienna, Austria, [6]Amgen Inc., Thousand Oaks, [7]Medical College of Wisconsin, Milwaukee, United States

Background: In the phase 3 ASPIRE (carfilzomib-lenalidomide-dexamethasone [KRd] vs lenalidomide-dexamethasone [Rd]) and ENDEAVOR trials (carfilzomib-dexamethasone [Kd56] vs bortezomib-dexamethasone [Vd]), carfilzomib-based regimens demonstrated superior overall survival (OS) vs standard therapies in relapsed/refractory multiple myeloma (RRMM).
Aims: In this subgroup ad-hoc analysis of ASPIRE and ENDEAVOR, OS was evaluated based on prior autologous stem cell transplant (ASCT) status.
Methods: OS was summarized using the Kaplan-Meier method.
Results: Of the patients with prior ASCT in ASPIRE (n=446) and ENDEAVOR (n=538), baseline patient and disease characteristics were generally balanced between treatment groups. In ASPIRE, patients with prior ASCT treated with KRd had an 11.4 month improvement in median OS and, for those with first relapse after ASCT, an 18.6 month improvement in median OS (57 months vs 39 months; HR=0.71 [0.48, 1.0]). In ENDEAVOR, a consistent OS benefit was observed for Kd56 vs Vd across ASCT subgroups; the benefit was more evident in the no prior transplant groups. In the updated safety analysis, adverse events were comparable between patients with and without prior ASCT and consistent with previous reports (Hari *et al.*, *Leukemia* 2017) Table 1.
Summary/Conclusion: These results suggest carfilzomib-based regimens led to clinically meaningful improvements in survival for patients who had received prior ASCT. For patients who were treated at first relapse, more differences were observed for KRd vs Rd after ASCT and Kd56 vs Vd for transplant-ineligible patients.

Table 1.

	ASPIRE[1]				ENDEAVOR[2]			
	Prior ASCT		No Prior ASCT		Prior ASCT		No Prior ASCT

DURABLE PROGRESSION-FREE SURVIVAL BENEFIT IN EARLY RESPONDERS TO ELOTUZUMAB PLUS LENALIDOMIDE AND DEXAMETHASONE FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA: ANALYSIS OF 4-YEAR DATA FROM ELOQUENT-2

C. Scheid[1,*], C. Röllig[2], K. Weisel[3], H.-J. Salwender[4], M. Gramatzki[5], K. Edmaier-Schröger[6], O. Sy[7], H. Goldschmidt[8]

[1]University Clinic Cologne, Cologne, [2]University Clinic Dresden, Dresden, [3]University Clinic Tübingen, Tübingen, [4]Asklepios Klinik Hamburg, Hamburg, [5]University Clinic Schleswig-Holstein, Kiel, [6]Bristol-Myers Squibb, Munich, Germany, [7]Bristol-Myers Squibb, Princeton, United States, [8]University Clinic Heidelberg, Heidelberg, Germany

Background: Despite therapeutic advances, most patients with multiple myeloma (MM) ultimately experience relapse. In the phase 3 randomized ELOQUENT-2 study (NCT01239797) of elotuzumab combined with lenalidomide and dexamethasone (ELd) vs Ld for relapsed/refractory (RR) MM, overall response rate (ORR) was 79% vs 66% and median duration of response (DOR) was 21 vs 17 months at 4-year follow-up. Durable benefits in progression-free survival (PFS) vs Ld were reported, with a 29% reduction in the risk of progression/death and an overall survival (OS) benefit with ELd in the 4-year analysis (Dimopoulos MA *et al.* EHA 2017 [Oral S456]; final OS analysis planned at 427 events). MM is typically more aggressive with each relapse, and survival shorter with each failed therapy, presenting a challenge for clinicians treating RRMM (Dimopoulos MA *et al. Nat Rev Clin Oncol* 2015;12:42–54). Clinical decisions are often made in a timeframe of ~3 months after initiation of treatment, and responses to ELd typically begin early; in ELOQUENT-2, median time to first response (TTR) was 2 months and median time to best response was 3 months.
Aims: To analyze PFS in patients achieving early responses (within 3 months of treatment initiation) to either ELd or Ld, with an extended 4-year follow-up of ELOQUENT-2.
Methods: In ELOQUENT-2, patients ≥18 years of age with RRMM and 1–3 prior lines of therapy were randomized 1:1 to either ELd or Ld, after informed consent. Coprimary endpoints were PFS and ORR; DOR and TTR were exploratory endpoints. In this landmark analysis, PFS was analyzed by TTR for patients who achieved ≥partial response (PR) or ≥very good PR (VGPR).
Results: At database lock (Oct 18, 2016), 321 patients had been randomized to ELd and 325 to Ld; minimum follow-up was 48 months. Baseline characteristics were similar between arms; median age (ELd vs Ld) was 67 vs 66 years, 21% (both arms) had stage III disease, 52% vs 57% had prior stem cell transplantation, 35% (both arms) had refractory disease, and median time from diagnosis was 3.5 years (both arms). Patients with TTR (≥PR) of <3 months (ELd vs Ld: 210 [65%] vs 172 [53%]) showed a durable PFS benefit, with a 27% reduction in the risk of progression/death sustained throughout treatment (hazard ratio [HR] 0.73 [95% CI 0.58, 0.91]; p=0.0062) and median (95% CI) PFS for ELd vs Ld of 23.1 (20.3, 28.1) vs

18.5 (15.7, 20.4) months. Similarly, patients who achieved ≥PR and who achieved ≥VGPR within 3 months (ELd vs Ld: 102 [32%] vs 82 [25%]) showed a 39% reduction in the risk of progression/death (HR 0.61 [95% CI 0.43, 0.87]; p=0.0065) and median (95% CI) PFS for ELd vs Ld of 33.4 (30.3, 51.2) vs 23.4 (20.4, 29.5) months (Figure 1).

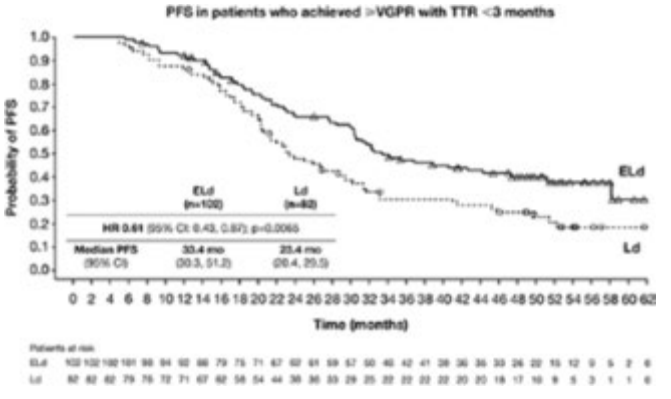

Figure 1.

Summary/Conclusion: 65% of patients achieved ≥PR to ELd within 3 months, compared with 53% of patients who received Ld. Treatment with ELd was associated with a 27% and 39% reduction in the risk of progression/death in patients with ≥PR and ≥VGPR, respectively, within 3 months, throughout an extended 4-year follow-up. These data suggest that patients with an early response to ELd may derive particular benefit from continued ELd treatment. Results of this analysis using response within 3 months may aid timely clinical decision-making in the increasingly complex treatment landscape of RRMM.

PS1311

SERIAL SERUM FREE LIGHT CHAIN ASSAY CAN REDUCE THE NEED FOR 24-HOUR URINE PROTEIN ASSESSMENT FOR RESPONSE ASSESSMENT IN MULTIPLE MYELOMA

M. Tschautscher[1,*], V. Rajkumar[2], A. Dispenzieri[2], M. Lacy[2], M. Gertz[2], F. Buadi[2], D. Dingli[2], L. Hwa[2], A. Fonder[2], M. Hobbs[2], S. Hayman[2], S. Zeldenrust[2], J. Lust[2], S. Russell[3], N. Leung[4], P. Kapoor[2], R. Go[2], Y. Lin[2], W. Gonsalves[2], T. Kourelis[2], R. Warsame[2], R. Kyle[2], S. Kumar[2]

[1]Internal Medicine, [2]Hematology, [3]Molecular Medicine, [4]Nephrology and Hypertension, Mayo Clinic, Rochester, United States

Background: According to current IMWG guidelines, detection of myeloma progression (PD) through disease surveillance relies on serial 24-hr urinary M protein levels in patients without measurable serum, but with detectable urine M protein. Only in those patients without measurable serum *and* urine M protein can the criteria involving difference in free light chain (dFLC) levels be used to monitor for and confirm PD.
Aims: Since serial 24-hr urine collections are bothersome and time consuming for our patients, we examined whether serial dFLC levels could be used as a surrogate for serial 24-hr urine protein measurements in monitoring for PD in patients with baseline measurable urine M protein.
Methods: A retrospective cohort study was conducted on all patients diagnosed with MM between 2003 and 2015. Only patients who had evidence of both confirmed (at least two consecutive measurements) and unconfirmed (<2 measurements) PD (defined by ≥25% increase in urinary protein and a minimum of 200mg protein over a 24-hr period) and sFLC measured at PD were included for the analysis. First, dFLC levels were recorded as absolute and percentage increases. Then, the quantity of patients who met dFLC thresholds of >10 mg/dL and ≥25% increase from the nadir was determined.
Results: A total of 811 24-hr urine protein collections were available for analysis of which 122 patients were identified for our study who developed PD (confirmed or unconfirmed) using 24-hr urine M protein, and had serial dFLC levels available for analysis at PD. At PD, the median percentage increase in dFLC was 110% with an interquartile range (IQR): 55-312. The median absolute increase in dFLC at PD was 74 mg/dL with an IQR: 34-168. Among our first population, 89% of patients had dFLC>25%, 94% had dFLC>10mg/dL from the nadir, and 98% met at least one of these two criteria. In our second population consisting of patients with baseline sFLC defined as a dFLC>10 mg/dL at diagnosis (n=118), 89% had dFLC>25%, 97% had dFLC>10 mg/dL increase from the nadir, and 98% met either of these two criteria. Finally, in our third population consisting of patients who met criteria for confirmed PD (≥2 urine protein assessments), 35/36 patients had >10mg/dL increase in dFLC at PD.
Summary/Conclusion: Taken together, we conclude that serial dFLC assessments can be performed in place of serial 24-hour urine protein assessments during myeloma surveillance to monitor for PD. Specifically, once these patients have an increase in dFLC of >10 mg/dL from the nadir, a 24-hour urine collection can then be assessed for M protein to evaluate for and confirm PD as described in the most current IMWG criteria, likely leading to better patient compliance, ease of testing, and reduced financial burden.

PS1312

NOVEL THERAPIES DIFFERENTIALLY IMPACT POLYCLONAL IMMUNOGLOBULIN RECOVERY IN MYELOMA PATIENTS: A LONGITUDINAL STUDY

M. Michallet[1,*], C. Chapuis-Cellier[2], C. Lombard[3], M. Sobh[1], T. Dejoie[4], H. Caillon[4], M. Attal[5], P. Moreau[6], H. Avet-Loiseau[7]

[1]Department of Haematology, Centre de Lutte contre le Cancer Leon Berard de Lyon, [2]Immunological Laboratory, Centre Hospitalier Universitaire Lyon Sud, [3]Immunological Laboratory, Centre Hospitalier Lyon Sud, Lyon, [4]Biochemistry Laboratory, Centre Hospitalier Universitaire de Nantes, Nantes, [5]Institut Universitaire du Cancer de Toulouse-Oncopole, Toulouse, [6]Department of Haematology, Centre Hospitalier Universitaire de Nantes, Nantes, [7]Unite de Genomique du Myelome, Institut Universitaire du Cancer de Toulouse-Oncopole, Toulouse, France

Background: The majority of myeloma patients present with suppressed levels of polyclonal immunoglobulins. Reconstitution to normal concentrations provides insight into the patient's immune status; however, studies in the era of novel agents are scarce and have mostly focused on single timepoints, limiting our understanding of the kinetics and significance of immunoglobulin recovery after treatment.
Aims: We studied the pattern and clinical impact of polyclonal immunoglobulin suppression in consecutive samples from patients treated with novel agents±ASCT.
Methods: We included 509 newly diagnosed patients (393 IgG, 116 IgA) from the IFM2009 trial treated with VRD±ASCT. Median follow-up was 36(2-57) months. Sera were analysed for heavy+light chain (HLC) levels using Hevylite® (The Binding Site Group Ltd, UK) at 16 consecutive timepoints spanning nearly 3 years from diagnosis. Median number of patients at each time-point was 364(224-509). HLC-pair suppression was defined as an abnormal HLC ratio and uninvolved HLC (uHLC) levels below the lower limit of normal (IgGκ<3.84, IgGλ<1.91, IgAκ<0.57 and IgAλ<0.44 g/L); and severe HLC-pair suppression as uHLC levels >50% below normal. Responses were determined by IMWG criteria. Minimal residual disease (MRD) was determined by 7-colour flow cytometry.
Results: 475/509(93%) patients presented with HLC-pair suppression. Treatment positively impacted immunoglobulin recovery; however prevalence of uHLC suppression remained significantly higher in non-transplant patients at all time-points. By the end of treatment, 12% transplant and 17% non-transplant patients remained suppressed; this percentage was sustained in the transplant arm for the following (out-of-treatment) year, but increased to 28% in the non-transplant group (p=0.003) (Figure 1).

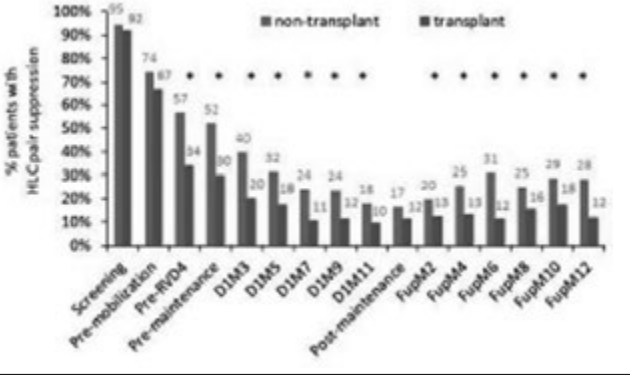

Figure 1.

Treatment also positively influenced levels of polyclonal immunoglobulin recovery. At diagnosis, uHLC levels were suppressed by a median 86% below normal. Severity of suppression gradually attenuated after transplant and throughout consolidation, reaching a plateau during maintenance after

which uHLC levels remained suppressed by about 20-30%. By contrast, consolidation in non-transplant patients did not prompt polyclonal immunoglobulin recovery; and post-maintenance uHLC levels remained moderately more suppressed (30-40% below normal) compared to the transplant arm. Similar results were obtained separately in IgG and IgA patients, although prevalence of suppression was significantly higher in the former throughout monitoring. HLC-pair suppression negatively impacted PFS during follow-up; and in multivariate analysis, severe suppression post-consolidation associated with shorter PFS in IgA patients (hazard ratio: 3.4; p=0.010). Conversely, normalisation of uHLC prior to consolidation therapy in all patients associated with higher odds of achieving ≥VGPR (odds ratio (OR): 11.6), ≥CR (OR: 3.7), and MRD negativity (OR: 2.5) post-consolidation (p≤0.001).

Summary/Conclusion: Long-term HLC-pair suppression is a relatively common occurrence in the era of novel agents; and associates with poorer outcomes. Stem cell transplantation and lenalidomide maintenance can mitigate partly the negative impact of immunoglobulin suppression through better reconstitution of humoral responses, which may result in more efficient disease control and improve clinical outcomes. Early recovery of uHLC levels alongside standard monitoring of the M-protein might provide relevant information about treatment efficacy and response outcomes.

PS1313

REAL-WORLD OUTCOMES IN TRANSPLANT INELIGIBLE NDMM PATIENTS: RESULTS FROM A LARGE UK COHORT

F. Djebbari[1,*], F. Sharpley[1], S. Fourali[1], G. Vallance[1], S. McLain-Smith[2], J. Kothari[1], K. Ramasamy[1]

[1]Haematology, Oxford Cancer and Haematology Centre, Oxford, [2]Data Analysis, Ph Associates, Marlow, United Kingdom

Background: Fixed duration therapy (FDT) is the UK standard of care for transplant-ineligible (TNE) newly diagnosed multiple myeloma (NDMM). Treatment objective is disease control whilst maintaining QoL, which translates into improved survival. QoL is often reported to be better during treatment free intervals (TFI).

Aims: We performed a retrospective analysis in TNE NDMM patients to evaluate the influence of age and choice of upfront therapy on clinical outcomes. We quantified treatment free interval (TFI).

Methods: 292 TNE NDMM patients treated between 2009-2017 within Thames Valley Cancer Network (UK) were eligible for inclusion. Data was collected from the chemotherapy database and patient records. Primary outcome was OS and the secondary outcomes were PFS, TTNT, TFI and response rates for the total cohort. Subgroup analyses were performed based on first line treatment: thalidomide-based (THAL) vs. proteasome inhibitor-based (PI), and age at presentation: ≤75 years vs. >75 years. Differences between subgroups were tested using an unstratified log-rank test. Medians and Cox hazard ratios (HR), with 95% confidence intervals (CIs) were calculated and survival estimates are presented.

Results: At start of first line therapy, median age was 75.1 years (IQR: 69 to 81), ≤75: n=144, >75: n=148, male 57%, female 43%, and ISS stage (I: 18%, II: 16%, III: 48%, unknown: 18%), serum creatinine ≥ 140micromol/L was recorded in 28% of patients. Upfront therapy was THAL: 61%, PI: 22%, alkylator-based: 10%, lenalidomide-based: 7%. Treatment was a triplet regimen (70%) and doublet (30%). Patient numbers within treatment subgroups were: THAL: n=178, PI: n=64. Median follow-up for the total cohort was 22.5 months (IQR 11.2 to 41.1). Median length of upfront FDT was 4.6 months (IQR: 2.5-5.7). Overall response rate (ORR) for first-line therapy in all patients was 66%, with responses categorised as CR: 21%, VGPR: 16%, PR: 30%, SD: 18%, PD: 8% and unknown 7%. Both gender distribution and therapy proportions (doublet, triplet) were comparable across the 2 age groups: ≤75 (56% M, 44% F, doublet 31%, triplet 69%), >75 (57% M, 43% F, doublet 29%, triplet 71%), and treatment groups: THAL group (54% M, 46% F), PI group (53% M, 47% F). ORR between subgroups was as follows: (THAL: 73% vs. PI: 72%) and (≤75: 70% vs. >75: 63%). Patients aged ≤75 showed a statistically significant improvement in OS and PFS compared to those >75: OS (49.0 vs. 22.4 months, p<0.0001, HR: 2.08, 95% CI: 1.53-2.83), PFS (9.7 vs. 8.0 months, p<0.01, HR: 1.47, 95% CI: 1.13-1.89). Survival rates at 1 year and 2 years between ≤75 and >75 were (80.4% vs. 75.9%) and (64.8% vs. 46.2%) respectively. Differences in OS and PFS were not statistically significant between the THAL and PI subgroups: OS (32.6 vs. 30.2 months, p=0.644, HR 1.09, 95% CI: 0.75-1.58), PFS (9.2 vs. 8.4 months, p=0.155, HR 1.25, 95% CI: 0.92-1.70). Difference in TTNT was not statistically significant between subgroups. The longest TFI during FDT was following first-line therapy with a median of 6.9 months (IQR: 1.4-16.9, n=190), reducing to 1.8 and 0.6 after 2nd and 3rd lines (Figure 1).

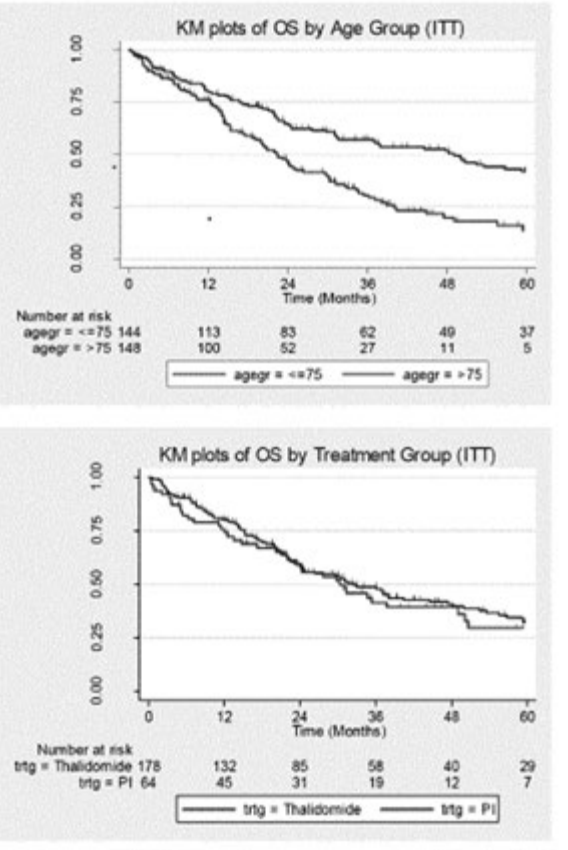

Figure 1.

Summary/Conclusion: This large real-world data study showed significantly improved OS and PFS for patients aged ≤75 compared to those >75 years, whilst choice of therapy (THAL or PI) had limited impact, when evaluated as individual factors. Clinically meaningful TFI was only recorded after first line FDT. This data suggests that a continuous therapeutic approach with manageable toxicities may be more appropriate in TNE myeloma patients.

PS1314

BONE MARROW PLASMA CELL INFILTRATION IN LIGHT-CHAIN AMYLOIDOSIS: IMPACT ON ORGAN INVOLVEMENT AND OUTCOME

L. G. Rodríguez-Lobato[1,*], N. Tovar[1], M. T. Cibeira[1], L. Magnano[2], I. Isola[1], L. Rosiñol[1], J. Bladé[1], C. Fernández de Larrea[1]

[1]Hematology, [2]Hematopathology Unit, Hospital Clínic, Barcelona, Spain

Background: Prognosis of immunoglobulin light-chain (AL) amyloidosis depends mainly on the presence of cardiac involvement and the disease burden. A higher bone marrow plasma cell (BMPC) burden has been suggested as an adverse prognostic factor.

Aims: The aim of our study was to analyze the correlation between the BMPC infiltration, clinical features and outcomes in patients with AL amyloidosis at a single institution.

Methods: We reviewed the clinical records of patients with AL amyloidosis diagnosed from January 2006 to April 2016. Seventy-nine patients (42F/37M; median age at diagnosis 65) were the final study population. Initial baseline demographics, clinical and laboratory data, treatment and follow-up were collected. Median follow-up for alive patients was 45 months. BMPC were identified by optic microscopic revision of May-Grünwald–Giemsa–stained BM smears processed according to standard procedures. All 79 patients had BM samples with adequate cellularity and BMPC infiltration was evaluated by senior cytologists. A second independent revision was performed. The concordance between the results obtained by both group of cytologists was excellent (R=0.949; p<0.001).

Results: Median BMPC infiltration at diagnosis was 11% (interquartile range 7-18). Eighteen patients (23%) presented more than 20% BMPC infiltration. BMPC infiltration significantly correlated with the serum free light-chain difference (R=0.551; p<0.001). Patients with more than 10%

BMPCs had more frequent cardiac involvement (86% *vs.* 63%; p=0.015), more stage III or IV of the revised Mayo risk stratification system (61% *vs.* 29%; p=0.01), a trend towards a higher early mortality (27% *vs.* 11%; p=0.08) and a significantly shorter progression-free survival (PFS) (median of 18 *vs.* 48 months, p=0.02) and overall survival (OS) (median of 33 months *vs.* not reached; p=0.046) (Figure 1A and 1B). Interestingly, those patients with lower BMPC infiltration were associated with kidney involvement (86% *vs.* 48%; p=0.001). Two multivariate Cox proportional hazards models were built. The first one included the 2004 Mayo Clinic staging system, BMPC infiltration and the dFLC; and the second included the revised Mayo risk stratification system and BMPC infiltration. In both analysis BMPC infiltration > 10% retained its independent prognostic value for worse PFS (HR=1.86; 95% CI, 1.013-3.73; p=0.049 and HR=2.26; 95% CI, 1.048-4.866; p=0.038, respectively) but not in OS. The use of new drugs (bortezomib or lenalidomide) seemed to overcome the negative prognostic impact of a higher BMPC infiltration (3-year PFS of 47% in ≤ 10% BMPC *vs.* 35% in > 10% BMPC; p=0.29 and 3-year OS of 62% in ≤10% BMPC *vs.* 57% in > 10% BMPC; p=0.58) (Figure 1C and 1D).

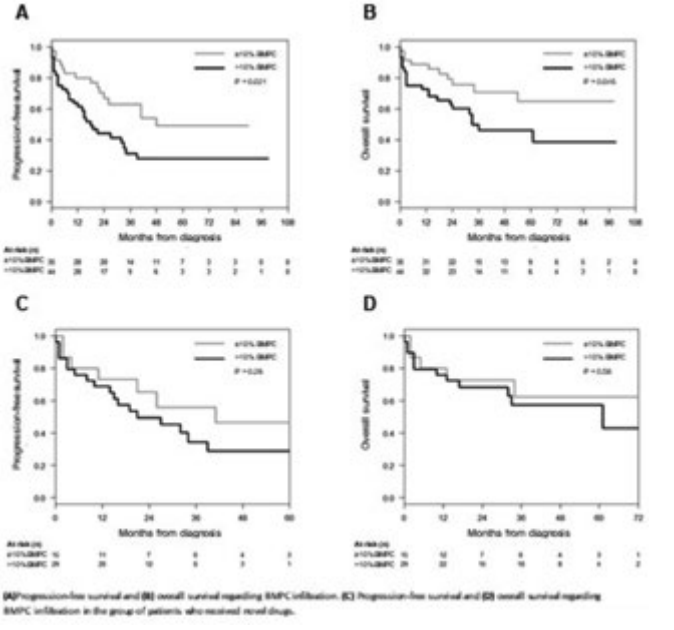

Figure 1.

Summary/Conclusion: Higher BMPC infiltration in patients with AL amyloidosis was associated with increased systemic organ damage, particularly cardiac involvement, but this fact was not related to the development of myeloma features.

PS1315

TREATMENT OF IGM-ASSOCIATED SYSTEMIC AL AMYLOIDOSIS WITH RITUXIMAB-BENDAMUSTINE

R. Manwani[1,*], D. Foard[1], S. Mahmood[1], S. Sachchithanantham[1], T. Lane[1], F. Sharpley[1], C. Quarta[1], T. Rezk[1], A. Martinez De Azcona Naharro[1], H. Lachmann[1], J. Gillmore[1], M. Fontana[1], C. Whelan[1], P. Hawkins[1], A. Wechalekar[1]

[1]National Amyloidosis Centre, University College London, London, United Kingdom

Background: Systemic AL amyloidosis is characterised by fibrillary deposition of misfolded immunoglobulin light chains within viscera. IgM-associated AL amyloidosis (IgM AL) is rare, accounting for 5-7% of patients with AL. There is a paucity of data on optimal therapy in IgM AL and outcomes are poor, with very few complete responses. Bendamustine, which has features of both an alkylating agent and purine analog, is increasingly used alongside rituximab in the treatment of non-Hodgkin's lymphoma. There have been no studies to date focusing on the use of bendamustine-rituximab (BR) in upfront or relapsed/refractory IgM AL.
Aims: To assess efficacy of BR in treatment-naïve and relapsed/refractory IgM AL. Primary outcome variables: haematological and organ response; overall survival (OS); progression free survival (PFS, progression defined as time to next treatment or death).
Methods: 27 patients with AL treated with BR from October 2011-June 2017 were included; 22 received BR as first-line treatment and 5 as second-line. 25 had a serum IgM M-protein. Of the remaining two, one had a serum IgG M-protein and the other had both a lambda and IgG M-protein; both were treated with BR first-line and both had bone marrow infiltration with lymphoplasmacytic lymphoma (LPL).
Results: Median age was 70 years (range 56-86). The number of patients with Mayo Stage I, II and III was: 9 (33%), 12 (45%) and 6 (22%). The number of patients with cardiac, renal, liver, peripheral nerve, autonomic, soft tissue and lymph node involvement was: 9 (33%), 17 (63%), 6 (22%), 6 (22%), 4 (15%), 2 (7%) and 13 (48%). Median NT-proBNP was 978ng/L (42-5708ng/L). Median M-protein was 11.5g/L (1-30g/L); 19 had a serum free light chain excess (12 lambda, 7 kappa) and median dFLC was 59.8mg/L (2.2-856mg/L). 21 patients had available bone marrow data: 3 normal, 1 plasma cell infiltrate, 14 LPL and 3 NHL not specifically classified. Five were treated second-line with BR for refractory disease, previous therapy included bortezomib-cyclophosphamide-dexamethasone (2 patients); rituximab-bortezomib-dexamethasone (1 patient); rituximab-cyclophosphamide-vincristine-prednisolone (1 patient); rituximab-cyclophosphamide-dexamethasone (1 patient); median number of previous cycles was 6 (4-8). Patients received a median of 5 cycles of BR (1-8).
Haematological responses on an ITT basis (by AL criteria) were: complete response (CR) 3 (11%), very good partial response (VGPR) 10 (37%), partial response (PR) 3 (11%), non-response (NR) 11 (41%, including 6 deaths). In the first-line group, haematological responses were: CR 3 (14%), VGPR 7 (32%), PR 3 (14%) and NR 9 (40%, including 4 deaths). In the second-line group, 3 (60%) achieved VGPR and 2 were non-responders (including 1 death). 11% of patients with cardiac involvement achieved a cardiac response and 18% patients achieved a renal response by amyloidosis consensus criteria. Median follow up was 18 months (range 3-55). In patients treated with BR first-line, median OS was not reached and median PFS was 34 months. In the second-line group, median OS was not reached and median PFS was 17 months.
Summary/Conclusion: The treatment approach in IgM AL has been heterogenous due to scant data and poor haematological responses historically. Data from this small retrospective study demonstrate an excellent overall response rate (ITT) of 59% in patients treated with BR, much higher than previously reported in this cohort, with a higher proportion achieving VGPR or better. This study suggests that first-line BR may be the treatment of choice for IgM AL if these findings are confirmed in a larger series.

Background: Evidence on the impact of high-risk cytogenetics, such as del(17p), in newly diagnosed multiple myeloma (NDMM) patients with extramedullary disease (EMD) after transplantation is limited.
Aims: We aimed to analyze the impact of cytogenetics on outcome after single-, tandem-autologous (tandem-auto) and autologous/reduced-intensity allogeneic (auto-allo) transplantation in NDMM with EMD.
Methods: Within the EBMT registry, we identified 488 patients (59% male, 41% female) with available data on extramedullary involvement and cytogenetics at diagnosis who received first-line single-auto (n = 373), tandem-auto (n = 84) or auto-allo (n = 31) between 2003 and 2015. Extramedullary involvement was defined as manifestations resulting from bone lesions (paraskeletal, n = 376) or hematogenous spread into different organs (n = 85), or both (n = 27). High-risk cytogenetics were defined as presence of at

least one of the following abnormalities by using FISH: del(17p) (n = 70), t(4;14) (n = 83), t(14;16) (n = 10), t(14;20) (n = 6), and abn(1) (n = 25); and was thus detected in 40% of the patients. The remaining patients had normal cytogenetics (n = 250) or other (n = 44), including other translocations or deletions, hyper- or hypodiploidy.
Patients receiving auto-allo were younger (median, 49 years) vs. single-auto (60 years) and tandem-auto (60 years; p<0.001). Before transplant, complete remission was achieved by 24% (single-auto), 13% (tandem-auto) and 19% (auto-allo; p=0.08). Median follow-up was 49.3 months.
Results: In univariate analysis, high-risk cytogenetics showed significant lower PFS and OS of 28.4% (19.6-37.2) and 48.2% (40.0-56.4) vs. 48.5% (41.4-54.8) and 78.0% (72.5-83.5; p<0.001, respectively). Evaluating outcome according to del(17p) and t(4;14) vs. normal cytogenetics showed worse PFS and OS of each abnormality (p<0.001, respectively). Progression-free survival appeared to be better after tandem-auto and auto-allo with 51.5% (39.3-63.7; p=0.06) and 60.7% (32.7-88.7; p=0.14) versus 38.3% (32.0-44.6) for single-auto while OS was significantly better for tandem-auto with 77.8% (68.4-87.2) vs. single-auto showing 62.1% (56.2-68.0; p=0.04), and not significant for auto-allo (81.1%, 66.0-96.2) vs. single-auto (p=0.17). In patients with EMD and high-risk cytogenetics overall, tandem-auto resulted in a significantly improved PFS and OS (p=0.02 and p=0.001) in comparison to single-auto while auto-allo showed significantly improved OS vs. single-auto (p=0.05). In a subgroup analysis, tandem-auto overcame poor prognosis of high-risk vs. normal or other cytogenetics in the univariate (PFS at four years: 50.4% vs. 53.6%, p=0.49; OS: 80.8% vs. 80.4% p=0.92) as well as in the multivariate analysis in terms of PFS (hazard ratio, 1.17; p=0.70) and OS (hazard ratio, 0.92; p=0.90). Regarding del(17p) and t(4;14), single-auto did not influence onset poor prognosis when compared with normal cytogenetics (p<0.001, respectively) while tandem-auto improved outcome of each of the present abnormalities resulting in similar 4-year survival vs. normal cytogenetics (p=0.83 and p=0.89).
Summary/Conclusion: High-risk cytogenetics are seen in nearly 40% of NDMM patients with EMD significantly influences PFS and OS. In comparison to single autografting, tandem-auto improves survival and overcomes poor prognosis of high-risk cytogenetics, especially in patients presenting with del(17p) and t(4;14).

VENETOCLAX MONOTHERAPY AND COMBINED WITH DEXAMETHASONE AS TARGETED THERAPY FOR RELAPSED/REFRACTORY T(11;14) MULTIPLE MYELOMA

J. Kaufman[1,*], C. Gasparetto[2], J. Mikhael[3,4], P. Moreau[5], C. Touzeau[5], R. Vij[6], T. Facon[7], B. Pegourie[8], L. Benboubker[9], L. Boise[1], W. J. Hong[10], Y. Jiang[10], S. Alzate[11], M. Dunbar[11], J. Pesko[11], K. Friese[11], J. Ross[11], P. Maciag[11], S. Kumar[12]

Background: The BCL-2 inhibitor venetoclax (Ven) induces cell death in multiple myeloma (MM) cell lines and primary samples, particularly those with t(11;14). Based on data indicating that dexamethasone (Dex) enhances BCL-2 expression and priming to sensitize the MM cell to Ven, Ven + Dex may provide a novel targeted combination in patients (pts) with t(11;14) MM.
Aims: To report safety, efficacy, exploratory biomarkers, and pharmacokinetics evaluated for Ven monotherapy and Ven + Dex for pts with relapsed/refractory (R/R) t(11;14) MM.
Methods: In the ongoing phase 1, open label study, pts received Ven once daily as monotherapy (n=30; 300, 600, 900, 1200 mg) or Ven 800mg + Dex 40mg (n=20). Responses were assessed by investigators using IMWG criteria. Minimal residual disease (MRD) was assessed at time of suspected complete response (CR) by next-generation sequencing in a subset of pts with available bone marrow specimens. *BCL2:BCL2L1* gene expression in bone marrow plasma cells in baseline samples were determined by quantitative real-time PCR. Results are based on a 1Dec2017 data cut.
Results: For 50 pts enrolled with t(11;14), pts had a median of 4 prior therapies (range: 1–10), with 88% prior bortezomib (68% refractory), 90% prior lenalidomide (80% refractory), and 76% prior autologous stem cell transplant. In addition to t(11;14), 6 (12%) pts had 17p deletion. Exposure to Ven was highly variable, with similar mean trough values with 800mg Ven in combination therapy and 1200mg Ven monotherapy.
Median time on study for pts with t(11;14) was similar for Ven monotherapy vs Ven + Dex (8 [range: .4–36] vs 9 [range: .1–15] months, respectively). 35 pts discontinued, with 32 related to disease progression. The most common any-grade AEs in pts with t(11;14) were diarrhea (36%), nausea (36%), neutropenia (30%), decreased white blood cell count (26%), thrombocytopenia (24%), hypophosphatemia (24%), hypokalemia (24%), upper respiratory tract infection (24%), fatigue (22%), and cough (22%). Common grade 3/4 AEs in these pts were neutropenia (22%), and thrombocytopenia (16%), and decreased lymphocyte count (16%). The most common serious AEs included pneumonia and sepsis (6% each). 2 pts had grade 3 laboratory tumor lysis syndrome that resolved with temporary interruption of Ven. No pts with t(11;14) had dose-limiting toxicities. The overall response rate (ORR) for pts with t(11;14) MM was 50% (25/50; 30% had ≥very good partial response [VGPR]). For Ven monotherapy, ORR was 40% (12/30; 27% had ≥VGPR). On Ven + Dex, ORR was 65% (13/20; 35% had ≥VGPR). ORR were consistent across subgroups within each treatment approach (Ven monotherapy vs Ven + Dex; see Table 1). Of 5 pts evaluated (2 CR, 3 VGPR), MRD negativity (10^{-4}) was observed in 2 pts (1 had CR with 1200mg Ven monotherapy and 1 had VGPR with Ven + Dex). As previously reported, response to Ven monotherapy was associated with a higher *BCL2:BCL2L1* gene expression ratio and improved ORR (high vs low ratio: 89% vs 27%). For 17 pts with evaluable bone marrow who received Ven + Dex, there was no observed difference in *BCL2:BCL2L1* expression in this small group of pts with ≥partial response (median 2^{-DDCt}: 0.067; n=12) vs those who did not achieve a response (median 2^{-DDCt}: 0.017; n=5).

Table 1.

	Ven n=30	Ven + Dex n=20
Months on study, median (range)	7.7 (.4 – 36.4)	9.3 (.07 – 14.5)
Overall response rate, n (%)	12 (40)	13 (65)
Stringent complete response	1 (3)	0
Complete response	3 (10)	0
Very good partial response	4 (13)	7 (35)
Partial response	4 (13)	6 (30)
Median (range) time to progression, months	8.3 (3.9, 11.5)	12.5 (3.6, -)
Overall response rates by subgroups, number of pts with response/total number of pts per subgroup by treatment group (%)		
No. prior therapies		
1 – 3	3/9 (33)	7/11 (64)
≥4	9/21 (43)	6/9 (67)
Refractory to last therapy	8/19 (42)	10/17 (59)
Bortezomib refractory	8/22 (36)	9/12 (75)
Lenalidomide refractory	8/23 (35)	11/17 (65)

Summary/Conclusion: Ven monotherapy and Ven + Dex had tolerable and comparable safety profiles in these heavily pre-treated pts. With ORR of 40% with Ven monotherapy and 65% with Ven + Dex, these results confirm the efficacy of Ven in pts with t(11;14) MM and support ongoing study of Ven + Dex.

Hospital, Heidelberg, Germany, [7]Univ. College London and the Royal Free London NHS Foundation Trust, London, United Kingdom, [8]Janssen Research & Development, LLC, Spring House, PA, [9]Janssen Research &

Development, LLC, Raritan, NJ, [10]Division of Hematology/Oncology, John C. Davis Myeloma and Amyloid Program, Tufts Medical Center, Boston, MA, United States

Background: Systemic AL amyloidosis is characterized by deposition of insoluble amyloid fibrils, which are derived from immunoglobulin light chains produced by clonal CD38+ plasma cells, into tissues and organs.
Aims: We present the safety run-in findings of DARA SC + CyBorD in patients with newly diagnosed AL amyloidosis in ANDROMEDA (NCT03201965).
Methods: Eligible patients had ≥1 involved organ, Eastern Cooperative Oncology Group (ECOG) score ≤2, absolute neutrophil count ≥1.0×10^9/L; hemoglobin ≥8.0 g/dL; platelet count ≥50×10^9/L; estimated glomerular filtration rate ≥20 mL/min/1.73m^2, and NT-ProBNP ≤8,500 ng/L. In the safety run-in, patients received a concentrated co-formulation of DARA (1,800 mg in 15 mL) and recombinant human hyaluronidase enzyme (rHuPH20; 30,000 U) in a single, pre-mixed vial, given by manual SC injection qw in Cycles 1-2, q2w in Cycles 3-6, and q4w thereafter ≤2 y. Cyclophosphamide 300 mg/m^2 PO or IV and bortezomib 1.3 mg/m^2 SC were given on Days 1, 8, 15, 22 of each 28-day cycle for ≤6 cycles and dexamethasone 40 mg was given qw. Dosing was staggered ≥48 hours between patients to assess infusion related reactions (IRRs). Safety was evaluated after ≥10 patients received ≥1 treatment cycle.
Results: Patients (n = 15) had a median age of 63 (range 35-77) years and a median of 58 (range 15-157) days from diagnosis. Patients had a median of 1 (range 1-3) involved organ, with kidney involvement affecting 67% of patients, cardiac involvement in 33% of patients, and ≥2 organ involvement in 40% of patients. At baseline, 33%, 60%, and 7% of patients were grouped into Mayo Clinic cardiac stage I, II, and IIIa, respectively, and 93% of patients had an ECOG score of ≤1. Among the 14 patients with available data, baseline creatinine clearance was ≥60 mL/minute in 78.6% of patients and <60 mL/minute in 21.4% of patients. Patients received a median of 2 (range 1-4) treatment cycles and a median of 5 (range 1-10) DARA injections. At the cutoff, the most common (>2 patients) treatment emergent adverse events (TEAEs) were nausea (53%), diarrhea (40%), fatigue (33%), injection site erythema (27%), and constipation, headache, anemia, rash, and cough (20% each). Dyspnea and peripheral edema were reported in 1 patient (7%) and 2 patients (13%), respectively. One grade 3/4 TEAE (hypertension; unrelated to treatment) and no serious TEAEs occurred. IRRs occurred in 1 (6.7%) patients (all grade 1). Additional data will be presented at the meeting.
Summary/Conclusion: DARA-CyBorD is tolerable in patients with AL amyloidosis, with a low IRR rate and no new safety signals. The limited incidence of dyspnea and peripheral edema indicate a low risk for volume overload.

PS1319

DISEASE ASSESSMENT BY PET-CT PLUS FLOW CYTOMETRY IN MULTIPLE MYELOMA IDENTIFIES PATIENTS WITH DIFFERENT SURVIVAL OUTCOMES

R. Alonso Fernández[1,*], M.T. Cedena[1], R. Ríos[2], J.M. Moraleda[3], V. Cabañas[3], M.J. Moreno[3], J. López-Jiménez[4], A. Sanz[4], F. Martín[4], A. Valeri[1], A. Jiménez[1], A. Gómez-Grande[1], J.J. Lahuerta[1], J. Martínez-López[1]

[1]Hematology Department, Hospital Universitario 12 de Octubre, Madrid, [2]Hematology Department, Hospital Universitario Virgen de las Nieves, Granada, [3]Hematology Department, Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, [4]Hematology Department, Hospital Universitario Ramón y Cajal, Madrid, Spain

Background: The prognostic value of Minimal Residual Disease (MRD) assessed by NGS or flow cytometry (FCM) in Multiple Myeloma (MM) has been confirmed in different works. In this way, currently, achieving MRD- is considered a surrogate marker for survival and could be a primary endpoint with clinical relevance. Recently, it has been identified the effect on survival related to persistence of active tumor burden in PET-CT after treatment. However, the available information about complementarity of both techniques and prognosis in discordant cases (MRD-/PET+ or MRD+/PET) is limited.
Aims: To improve knowledge in the prognostic value of combined PET-CT and FCM in disease assessment
Methods: We have performed an observational study collecting retrospective information from 148 MM patients treated between 2008 and 2018 in 4 Spanish hospitals. The main selection criterion was to perform FCM in bone marrow and PET-CT jointly in order to assess response at different points in the same line of treatment, regardless of treatment regimen used. We obtain data about clinical and biological parameters at baseline and response assessment by FCM and PET-CT at the beginning and on-treatment period or during follow-up. Statistical analysis was realized with SPSS 21.0 version (SPSS, Inc., Armonk, NY).
Results: Our study was performed in 148 patients with a median age of 61 years-old (68,2% ≤65 years-old) and 1-5 lines of treatment (74,3% of patients were at first line). By using diferent treatment regimes, 72,3% of patients achieved Complete Response (CR), with median Progresion-Free Survival (PFS) of 54 months and median Overall Survival (OS) not reached (NR). 73% of the patients assessed by PET-CT were PET-; meanwhile 56,1% became MRD- by FCM. By combining both techniques in response assessment to treatment (available data in 122 patients), 55,4% of patients were MRD-/PET-, 26,4% were MRD+/PET-, 10,7% were MRD-/PET+ and 7,4% were MRD+/PET+ (67, 32, 13 and 9 patients, respectively). Given the absence of significant differences in survival results and the reduced sample size of patients with PET+, we consider MRD-/PET+ and MRD+/PET+ together for the analysis. In terms of PFS we detected a significant difference (p<0,001) between patients who became MRD-/PET-, with a median PFS NR, and MRD+/PET- patients (median PFS 45 months); both have significant prolonged PFS than PET+ patients (median PFS 28 months). These differences in PFS were similar when the analysis was performed separately un patients who received a transplant or those who achieved CR at first line. In the same way, we observed significant difference in terms of OS between MRD-/PET- and MRD+/PET- patients (both median OS NR) versus PET+ patients (median PFS 64 months) (Figure 1). When the analysis employed techniques to remove guarantee-time bias (conditional landmark analysis) the effect of MRD-/PET- on PFS and OS continued to be observed. In multivariant analysis, only MRD by FCM (HR 2,14, CI95% 1,12-4,10;p=0,021) and PET+ (HR 4,15, CI95% 2,02-8,55; p<0,001) were independently associated with higher risk of progression or death.

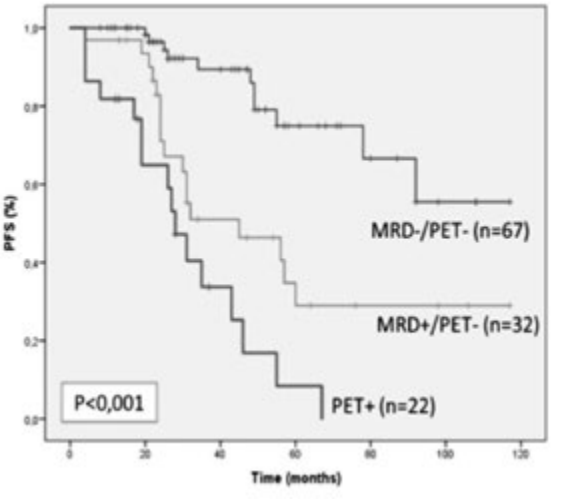

Figure 1.

Summary/Conclusion: Patients with persistent positive PET-CT, regardless of MRD status, have significant worse prognosis; meanwhile those who become both MRD and PET-CT negative, show longer PFS and OS. Both techniques are complementary and jointly provide information with prognostic relevance.

PS1320

PREDICTORS OF HEMATOLOGIC AND ORGAN RESPONSE IN AL AMYLOIDOSIS

G. Palladini[1,*], P. Milani[1], M. Basset[1], A. Foli[1], R. Mussinelli[1], P. Stefano[2], G. Merlini[1]

[1]Department of Molecular Medicine, University of Pavia, Pavia, Italy, [2]Department of Internal Medicine, University of Pavia, Pavia, Italy, Amyloidosis Research and Treatment Center, Foundation IRCCS Policlinico San Matteo, Pavia, Italy, Pavia, Italy

Background: Response to therapy favorably impacts prognosis of patients with AL amyloidosis, but cannot be predicted at the time of diagnosis.
Aims: We explored the baseline variables that predict response to upfront therapy in newly diagnosed AL amyloidosis patients.
Methods: The prospectively maintained database of the Pavia Amyloidosis Center was systematically searched for patients surviving until the first assessment of response (3 months after diagnosis). Baseline variables were

tested by logistic regression for their ability to predict hematologic, cardiac or renal response and best cutoffs were identified by ROC analysis.
Results: A total of 782 consecutive patients diagnosed between 2004 and 2015 were included. Overt multiple myeloma was excluded. Median age was 64 years (IQR 56-70 years) and 447 patients (57%) were males. Involved organs were heart (79%), kidney (69%), soft tissues (18%), liver (12%), and peripheral nervous system (11%). Cardiac stage was: I, 20%; II, 49%; IIIa, 18%; IIIb, 13%. Renal stage was: I, 48%; II, 39%; III, 13%. Upfront therapy was melphalan/dexamethasone (MDex) in 37% of patients, cyclophosphamide/ bortezomib/dexamethasone (CyBorD) in 27%, BMDex in 13%, immune modulatory drugs-based in 9%, BDex in 4%, treatment for IgM-AL amyloidosis in 3%, ASCT in 2%, other in 5%. Overall hematologic response rate was 68% [complete response (CR) 15%, very good partial response (VGPR) 39%], and cardiac (CardResp) and renal (RenResp) responses were achieved in 26% and 32% of evaluable patients, respectively. At multivariate analysis, baseline variables predicting achievement of CR/VGPR were difference between involved and uninvolved free light chain (dFLC) <130 mg/L (OR 3.70, p<0.001), BMPC<13%, (OR 1.54, p=0.043) and exposure to B (OR 2.00, p=0.001). Rate of CR/VGPR was 70%, 36%, and 23% with MDex, and 81%, 60%, and 42% with BMDex or CyBorD in patients with 0, 1, and 2 predictors, respectively. The only baseline variable associated with achievement of CardResp was female sex (OR 1.92, p=0.001). Interestingly, cardiac stage did not predict CardResp that was 21% in males and 35% in females (p=0.001). Females were more likely to obtain CardResp (OR 1.75, p=0.009) also in a multivariable analysis including achievement of CR/VGPR (OR 4.55, p<0.001). RenResp was significantly more likely in patients with baseline proteinuria <5 g/24h (40% vs 24%, p<0.001) and in those with dFLC >130 mg/L (39% vs 25%, p<0.001), and was reached in 47%, 30%, and 20% of subjects with 0, 1, and 2 risk factors, respectively. At multivariate analysis proteinuria <5 g/24h (OR 2.22, p<0.001) and dFLC >130 mg/L (OR 2.24, p<0.001) remained independent predictors of RenResp also when achievement of CR/VGPR (OR 2.20, p<0.001) was included in the model.
Summary/Conclusion: In patients surviving until the first response assessment, CR/VGPR is predicted by low baseline clonal burden and use of bortezomib. Reversibility of cardiac dysfunction is more likely in females, independently of cardiac stage and hematologic response. Investigation of sex-related factors in recovering of amyloid cardiomyopathy is warranted. The cutoff of 5 g/24h used in staging also identifies reversibility of renal damage. Renal damage associated with higher baseline dFLC (but not BMPC) was more amenable of rapid recovery after FLC reducing chemotherapy. This warrants further investigation of the role of FLC in the pathogenesis of kidney involvement.

Background: Ixazomib is an effective oral proteasome inhibitor with a favorable toxicity profile. Recent studies showed significant activity in combination with lenalidomide-dexamethasone in RRMM pts. and in combination with thalidomide-dexamethasone in NDMM.
Aims: To evaluate the activity and tolerability of ixazomib-thalidomide-dexamethasone (IxaThalDex) in pts. with RRMM.
Methods: Patients with RRMM after ≥1 prior line of therapy (TX) meeting the following criteria were eligible: Measurable disease, ECOG PS ≤2, ANC ≥1000/µL, platelet count ≥50.000µL, GFR ≥15mL/min. TX regimen: Ixazomib (4mg, d 1, 8 and 15), thalidomide (100mg/d), and dexamethasone (40mg once/week); in pts aged ≥75 years: thalidomide (50mg/d) and dexamethasone (20mg); 8 cycles induction TX, followed by 12 cycle of ixazomib maintenance therapy (1 year). Primary objective: PFS, secondary objectives: ORR, OS, impact of cytogenetic risk and of renal impairment, safety and myeloma frailty status and QoL.
Results: 94 planned pts have been enrolled, 4 pts. did not meet the inclusion criteria and were excluded. 90 pts comprised the ITT group: age (median): 67, (44-84) years, ISS stage I: 37, II 30, III: 22, not known: 1, median number of prior TX lines: 1 (range: 1-8). 13 pts discontinued TX before completion of 2 cycles (7 progressions, 2 deaths due to myeloma). 38 pts. have already started ixazomib maintenance TX after completion of 8 cycles of induction TX; 7 pts. have not yet completed induction TX. Median FU is 11 mos., and median number of cycles is 6 (range 0-8). PR or better was achieved in 47 pts of 77 pts (61%), nCR: 7 pts (9%), VGPR: 11 (14%), PR: 29 (38%), MR: 5 (7%); clinical benefit rate (CBR) of 68%. FISH data are available in 63 of the 77 pts. ≥PR was seen in 16/26 (62%) pts with *t (4; 14)* and/or *t (14; 16)* and/or *del17p* and in 22/37 (60%) with standard risk cytogenetics. Response rates were similar in the 8 pts. classified as unfit or frail (7/8 vs 40/69, p=0.1399). Similarly, response rates did not differ between the 27 (35%) pts. with GFR <60 ml/min and those with higher levels (62.9% vs 60%, p=1.00). Median PFS at the time of reporting is 9.3 mos. (95% CI 6.9 – 11.5) in the ITT group (Figure 1). PFS was similar in pts. with and without high-risk cytogenetics (9.3 and 9.0 mos., p=0.8209, Figure 2). PFS tended to be higher, though not significantly (18.0 mos. *vs.* not reached, p=0.2942) in the non-fit/frail pts.; likewise PFS did not differ between pts. with GFR ≤60 ml/min or higher (8.3 vs 9.3 mos., p=0.2785). Median OS has not been reached (Figure 1) and was similar between cytogenetic high- and standard-risk pts. No significant difference in OS was observed between those with GFR ≤ 60 ml/min or higher (18.0 mos. *vs.* not reached, p=0.0709). Neutropenia was noted in 41%, (22% grade 2, and 3% grade 3). Leucopenia was seen in 56%, (29% grade 2, and 5% grade 3). 91% had anemia (26% grade 2, and 17% grade 3). The most frequent non-hematological toxicity was fatigue observed in 32% of pts. Infections were noted in 53% (17% grade 3). Polyneuropathy was seen in 18% (15 grade 1 or 2% grade 3).

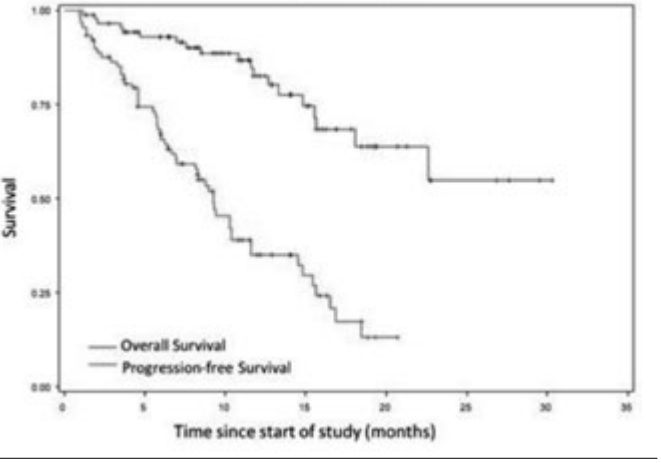

Figure 1. PFS ans OS IxaThalDex in RRMM.

Summary/Conclusion: The all oral IxaThalDex regimen showed an ORR of 61% with no difference in pts with/without high-risk cytogenetics, a CBR of 68%, and a PFS of 9.3 mos. in pts with RRMM. The regimen was well tolerated and was associated with a low incidence of mainly grade ≤2 PNP, which required dose reduction in one patient only. Response rates improved with continuation of therapy and treatment was associated with an increase in health related QoL.

PS1322

SELINEXOR COMBINED WITH LOW DOSE BORTEZOMIB AND DEXAMETHASONE (SVD) INDUCES A HIGH RESPONSE RATE IN PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA (MM)

N. Bahlis[1,*], H. Sutherland[2], D. White[3], M. Sebag[4], S. Lentzsch[5], R. Kotb[6], C. Venner[7], C. Gasparetto[8], G. Schiller[9], R. LeBlanc[10], W. Bensinger[11], B. Lipe[12], A. Del Col[13], M. Kauffman[14], S. Shacham[14], J. Jeha[14], J.-R. Saint-Martin[14], J. Shah[14], C. Chen[15]

Background: Selinexor is a first-in-class Selective Inhibitor of Nuclear Export (SINE) compound that binds and inactivates Exportin 1 (XPO1). Twice weekly (BIW) bortezomib (bort) in combination with dexamethasone (Vd) is an established therapy in relapsed and refractory multiple myeloma (RRMM). While the activity of bort BIW in combination with other agents is efficacious, prolonged use is limited due to peripheral neuropathy (PN, 50-60%) as well as acquired resistance to bort. New dosing regimes with improved tolerability and the ability to overcome resistance are needed. Preclinical studies have shown that selinexor, in combination with bort, can restore sensitivity of bort-resistant MM, in murine MM xenografts.
Aims: This Ph 1b/2 (NCT02343042), dose escalation study was designed to determine the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) for the safety, tolerability and efficacy of the combination of selinexor, bort and low dose dex (SVd) in patients (pts) with RRMM.
Methods: The study enrolled pts with RRMM after ≥ 1 prior therapy. Pts with prior exposure or refractory to proteasome inhibitors (PI) were included, provided they were not refractory to bort as a last therapy. Selinexor was dosed escalated in once-weekly (QW, 80; 100 mg) or twice-weekly (BIW, 60; 80 mg) regimens. Bort (1.3 mg/m^2 sc) was administered QW or BIW. Dex was given orally 40 mg per week.
Results: As of Feb 27th, 2018, 42 pts were enrolled; 22 pts in the dose escalation and 20 pts in the expansion (RP2D) cohort. Median age was 64 years; 23 M 19 F, median of 3 (range, 1 – 11) prior trement regimens. The MTD was not reached. Three pts in the BIW bort cohort were dose reduced to QW bort after Cycle 1. Common treatment related grade 1/2 adverse events (AEs) included: anorexia (57%), nausea (57%), fatigue (45%), and diarrhea (36%). Grade 3/4 AEs included: thrombocytopenia (45%), neutropenia (24%) and anemia (12%). Importantly, PN across all pts was limited to 6 patients (14%) (G1 4pts, G2 2 pts) of which 5 had prior bort exposure. Based on tolerability and efficacy, the RP2D of SVd is selinexor 100 mg, bort 1.3 mg/m^2 and dex 40 mg, all QW (40% less bort and 25% less dex compared to the standard, approved BIW schedule of Vd). Median PFS in PI relapsed or naïve pts is >13 months. Median PFS in PI refractory pts is 6.4 months. The median duration of response is ~12 months. Response rates can be seen in Table 1.

Table 1. SVd Best Response in PI non-Refractory & PI-Refractory Patients.

Category	N	ORR (%)	CBR (%)	CR (%)	VGPR (%)	PR* (%)	MR (%)	SD (%)	PD (%)
PI Relapsed or Naïve	19	16 (84%)	16 (95%)	2 (11%)	5 (26%)	9 (47%)	2 (11%)	1 (5%)	–
PI Refractory	21	9 (43%)	14 (67%)	1 (5%)	4 (19%)	4 (19%)	5 (24%)	6 (29%)	1 (5%)
PI Relapsed or Naïve, ≤ 3 Prior Treatments	18	15 (83%)	16 (89%)	2 (11%)	6 (33%)	7 (39%)	1 (6%)	2 (11%)	–

*1 PR unconfirmed

Summary/Conclusion: Selinexor in combination with weekly bort and dex is well tolerated and highly active in RRMM. The high ORR with SVd is achieved with 40% less bort and 25% less dex and no overt major organ toxicities. Furthermore, in pts with PI refractory MM, the ORR of 43% and CBR of 67% which support preclinical findings that selinexor re-sensitizes and overcomes resistance to PIs. This data supports the ongoing Ph 3 BOSTON study examining SVd vs Vd.

PS1323

THE MAJORITY OF NEWLY DIAGNOSED MYELOMA PATIENTS DO NOT FULFIL THE INCLUSION CRITERIA IN CLINICAL PHASE III TRIALS

T. W. Klausen[1,*], H. Gregersen[2], N. Abildgaard[3], N.F. Andersen[4], U.C. Frølund[5], P. Gimsing[6], C. Helleberg[1], K. F. Iversen[7], P.T. Pedersen[8], R.S. Pedersen[9], A.J. Vangsted[6]

[1]Department of Hematology, Herlev Hospital, Herlev, [2]Department of Hematology, Aalborg University Hospital, Aalborg, [3]Department of Hematology, Odense University Hospital, Odense, [4]Department of Hematology, Aarhus University Hospital, Aarhus, [5]Department of Hematology, Roskilde Hospital, Roskilde, [6]Department of Hematology, Rigshospitalet, University of Copenhagen, Copenhagen, [7]Department of Hematology, Vejle Hospital, Vejle, [8]Department of Hematology, Esbjerg Hospital, Esbjerg, [9]Department of Hematology, Regional Hospital West Jutland, Holstebro, Denmark

Background: Randomized phase III trials on multiple myeloma (MM) have strict patient inclusion and exclusion criteria and currently it is unknown how many patients with MM that are represented in these clinical trials.
Aims: To analyze the fraction of a population based cohort of newly diagnosed younger and older myeloma patients that fulfil the in- and exclusion criteria in clinical trials and to analyze the overall survival (OS) according to these criteria.
Methods: Four clinical trials for elderly (Hovon 87 trial; VISTA trial; FIRST trial and the SWOG S0777 trial) and younger patients (STaMINA trial; IFM2013-04 trial; IFM DFCI 2009, and the EMN02 trial) were selected. Twelve predefined in - and exclusion criteria, found in 3 out of 4 trials in each age group, were selected. The three inclusion criteria were: CRAB, measurable disease, plasma cells in bone marrow (PLC) ≥ 10% and the nine exclusion criteria were: Kidney failure, WHO performance status (PS) > 2, amyloidosis, acute myocardial infarction (AMI) within last 6 months, human immunodeficiency virus (HIV), hepatitis B or C, cancer within 5 years (excluding stage 0-1 cervical cancer, some skin cancers), severe comorbidity (congestive heart failure, dementia, severe diabetes, moderate or severe lever disease, hemiplegia). The patients were separated into two cohorts, those that were eligible for protocol inclusion (IC) and those that were not (non-IC). The IC cohort and non-IC cohort were compared using the Kaplan-Meier statistics and Cox proportional hazard models with OS as outcome. The Danish Multiple Myeloma Registry (DMMR) was used to include patients with treatment demanding MM. The Danish National Patient Registry (DNPR) was used for collection of co-morbidity data.
Results: 2189 patients, 1425 patients 65 years and 764 patients ≤ 65 years were registered in the DMMR. In the elderly cohort 522 (36.6%) fulfilled IC whereas 903 (63.4%) were non-IC. The most common reason for non-IC was kidney failure (26.1%) followed by severe comorbidity (18.5%) and PS > 2 (16.4%). Patients in the non-IC cohort had significantly worse OS compared to the IC cohort, median OS 21.3 mo. versus 44.0 mo., HR =1.7 (95% CI: 1.5-1.9), p<0.0001 (Figure 1A). In the younger cohort 345 (45.2%) fulfilled IC whereas 419 (54.8%) were non-IC. The most common reason for non-IC was kidney failure (22.2%) followed by PS > 2 (14.8%) and PLC < 10% (13.1%). Patients in the non-IC cohort had shorter OS compared to the IC cohort (median OS was 65.5 mo. versus 78.4 mo., HR 1.3 (95% CI: 1.0-1.5), p=0.021) (Figure 1B).

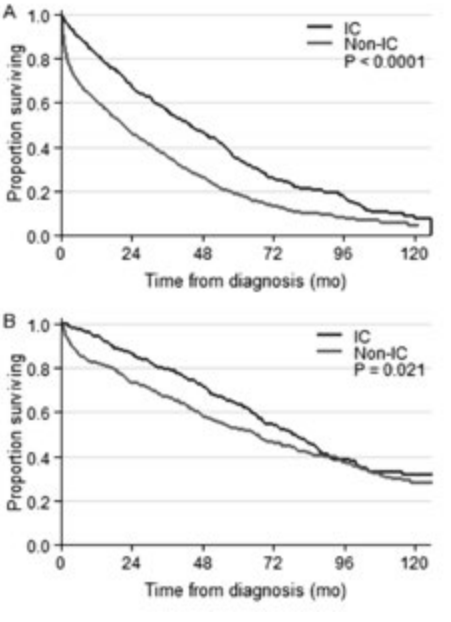

Figure 1. Figure shows OS IC vs non-IC for A) the >65 years cohort and B) the ≤65 years cohort. The blue line shows patients that fulfil the inclusion criteria the red line shows patients that do not.

Summary/Conclusion: The majority (63.4%) of elderly MM patients in a population cohort is not eligible for inclusion in most clinical trials. Elderly patients not eligible for inclusion in clinical trials have worse OS than those who are. For patients ≤ 65 years, 54.8% did not fulfill the inclusion criteria and these patients also have significantly shorter OS. These observations

affect the application of data from clinical trials to the real life MM population.

PS1324

COMPARISON OF LYMPHOTRACK® MISEQ® ASSAYS AND FLOW CYTOMETRY FOR CLONALITY AND MINIMUM RESIDUAL DISEASE ASSESSMENT IN MULTIPLE MYELOMA

Y. Huang[1,*], J. Panganiban[1], A. Jacobsen[1], M. Kaminsky[1], K. Hutt[1], J. Heilman[1], F. W. Martinez[1], M. Blankfard[1], T. Stenzel [1], A. Medina[2], C. Jiménez[2], R. García-Sanz [2], J. E. Miller[1]

[1]Invivoscribe, San Diego, United States, [2]Hospital Universitario de Salamanca-IBSAL, Salamanca, Spain

Background: Multiple myeloma (MM), characterized by presence of excess plasma cells (PCs) in bone morrow (BM), accounts for about 10% of all hematological malignancies. Multiparameter flow cytometry (MFC) is a standard tool used to detect and monitor MM in patients. Since PCR-based NGS methods can identify clonal rearrangements within the immunoglobulin (*Ig*) loci, international organizations such as NCCN, IMWG and ESMO have recently included NGS as a recommended tool for MRD assessment in MM. Recently we developed NGS-based LymphoTrack® Assays and bioinformatics software to detect and track clonal rearrangements within the *Ig* genes in B-cells. The *IGH* FR1, *IGH* FR2, *IGH* FR3 and *IGK* assays detect and track clonal rearrangements in B-cell malignancies. Here we compare the performance of LymphoTrack® MiSeq® Assays and MFC by testing 101 anonymized, paired diagnostic and MRD MM specimens.
Aims: To assess performance of LymphoTrack® MiSeq® assays in detecting and tracking clonotypes in MM samples.
Methods: 101 paired BM samples from MM patients were tested in this study. The MFC methods utilize 8-color direct immunofluorescence technique. Genomic DNA from the same collected specimens were extracted, anonymized and blinded prior to testing with the LymphoTrack® *IGH* and *IGK* MiSeq assays. Libraries were pooled and sequenced on a single MiSeq run. LymphoTrack Software was used to sort data by target and index. Diagnostic specimens were tested using all LymphoTrack® MiSeq B-cell assays to identify a MM-specific clonotype, which was tracked using a single assay in subsequent samples.
Results: Out of 101 diagnostic specimens, 84 (83%), 80 (79%), 63 (62%) and 87 (86%) samples were detected as clonal positive by *IGH* FR1, FR2, FR3 and *IGK*, respectively. When combining all 4 targets, 100% (101/101) clonal positivity was achieved.
Using LymphoTrack® MRD Software to identify clonotype sequence identified in diagnostic samples, we performed MRD assessment on 84 samples that tested positive using *IGH* FR1. 41 (49%) were positive, 42 (50%) were negative, and 1 (1%) was not evaluable, due to insufficient reads. MRD results by MFC on the same 84 patients showed 40 (48%) positive, 36 (43%) negative, and 8 (9%) not evaluable samples. Excluding samples with DNA less than 700 ng (~100,000 cell equivalents), concordance between these two methods was 85.4%. Three samples were detected by MCF but not by NGS while four samples were detected by NGS but not by MCF.
Summary/Conclusion: LymphoTrack assays detected clonotype sequences in 100% of MM diagnostic samples and achieved 85.4% agreement with MFC in detecting MRD. This suggests LymphoTrack assays are a useful tool in identifying and tracking disease status in MM samples. Unlike MFC, the LymphoTrack assays and accompanying bioinformatics software can be submitted for approval to regulatory authorities worldwide.

PS1325

QUALITY OF HEMATOLOGIC RESPONSE BUT NOT DEPTH OF NT-PROBNP RESPONSE IMPROVES SURVIVAL OF PATIENTS WITH AL AMYLOIDOSIS WHO ACHIEVE CARDIAC RESPONSE

P. Milani[1,*], M. Basset[1], A. Foli[1], R. Mussinelli[1], P. Stefano[2], G. Merlini[1], G. Palladini[1]

[1]Department of Molecular Medicine, University of Pavia, Pavia, Italy, [2]Department of Internal Medicine, University of Pavia, Pavia, Italy, Amyloidosis Research and Treatment Center, Foundation IRCCS Policlinico San Matteo, Pavia, Italy, Pavia, Italy

Background: Markers of clonal and organ disease allow accurate assessment of response to therapy in AL amyloidosis. However, while hematologic response is graded, cardiac response is defined as present or absent, and it is unclear whether the depth of NT-proBNP reduction further improves outcomes.
Aims: We evaluated the impact of depth of NT-proBNP reduction at the time of hematologic response in AL amyloidosis.
Methods: The prospectively maintained database of the Pavia Amyloidosis Research and Treatment Center was systematically searched for patients who obtained cardiac response after frontline therapy, defined as a >30% and >300 ng/L of NT-proBNP decrease compared to baseline. Cardiac response was assessed at the time of best hematologic response. Survival was calculated from the time of achievement of best hematologic response to the time of death or last contact. Cutoffs of NT-proBNP absolute values and percent reduction best predicting survival were searched by ROC analysis based on death at 1 year.
Results: A total of 130 patients evaluable for cardiac response (baseline NT-proBNP >650 ng/L) who achieved NT-proBNP response were included. Other organs involved were kidney (68%), soft tissue (24%), and liver (16%), peripheral nervous system (15%), and more than 2 organs were involved in 87% of patients. The median follow-up of living patients was 49 months [interquartile range (IQR): 36-78 months] and 105 patients (42%) died. The median time to achievement of cardiac response was 7.8 (IQR: 5.5-10.3 months). The median maximal reduction in NT-proBNP from baseline was 55.8% (IQR: 46-70%). The ROC analyses failed to identify cutoffs of NT-proBNP reduction able to significantly discriminate the outcome. Thus, patients were grouped according to tertiles and quartiles of NT-proBNP percent reductions. However, there was no significant difference in patient survival between subgroups. The best cutoff predicting survival from best response was an absolute concentration of NT-proBNP after therapy below 2100 ng/L (median survival 86 vs. 57 months, p=0.047). However, when the analysis was limited to patients who had a baseline value of NT-proBNP >3000 ng/L (required to be classified as responders with a post treatment value of 2100 ng/L), no difference in survival was observed, indicating that the impact on survival of the absolute NT-proBNP value actually reflects pre-treatment severity of cardiac dysfunction. A normalization of NT-proBNP was observed only in 9 (7%) of patients and it was not associated with a significant improvement in survival compared to other responders. Obtaining a complete response and/or very good partial response was associated with a significantly better survival from response (median survival 45 vs. 86 months, p=0.016).
Summary/Conclusion: Among cardiac responders, the depth of reduction of NT-proBNP at the time of best hematologic response does not add additional prognostic information. Even in this group of patients, severity of cardiac involvement at diagnosis retains its prognostic impact also in cardiac responders. Moreover, the achievement of a profound hematologic response identifies cardiac responders with a significantly longer survival. Thus, once cardiac response is reached, the decision on whether to discontinue treatment should be based on the depth of hematologic response aiming at VGPR or better.

PS1326

SUSTAINED MRD NEGATIVITY AT 12 MONTHS POST-ASCT PREDICTS OUTCOMES FOR MYELOMA PATIENTS: A REAL WORLD STUDY

M. Austin[1,*], C. Pawlyn[1,2], H. Woods[1], R. Morilla[1], M. Potter[1], M. Ethell[1], R. Saso[1], M. Kaiser[1,2], K. Boyd[1]

[1]Haematology, The Royal Marsden NHS Trust, [2]Myeloma group, The Institute of Cancer Research, London, United Kingdom

Background: Minimal residual disease (MRD) negativity by multiparameter flow cytometry (MFC) at 3 months post autologous stem cell transplantation (ASCT) in newly diagnosed multiple myeloma (MM) is recognised as an independent predictor of progression free survival (PFS) and overall survival (OS) in clinical trials. Additional analysis of MRD at 1-year post-ASCT, is less well established. There is also little available data on the use of MRD in the relapse setting, especially in the context of second ASCT, or from real-world clinical practice.
Aims: This study was performed to characterise the prognostic benefit of multiple time point MRD monitoring by MFC and the impact of sustained MRD negativity on outcomes after first and second ASCT in a real-world dataset.
Methods: We retrospectively analysed data for 232 consecutive MM patients who underwent ASCT between January 2012 and December 2014 at the Royal Marsden Hospital. Flow cytometry was performed at 3 and 12 months post-ASCT in the regional Haematological Malignancy Diagnostic Services Laboratory. Limit of detection was 0.01%. Baseline variable and outcome data were analysed using Kaplan-Meier survival curves and the Log-rank test using R. PFS and OS were measured from the date of ASCT using IMWG criteria.
Results: Of the 232 transplants, 188 were after first induction (ASCT1) and 44 as a second transplant after second-line or later therapy (ASCT2). Medi-

an age was 61.4 years (range 23-72). Pre-ASCT induction therapy was with IMiD (57%), proteasome inhibitor (PI, 16%) or combined IMiD+PI therapy (25%) in most cases. 81% of patients underwent a bone marrow evaluation at 3 months post ASCT and 55% at both 3 and 12 months.
56.9% of patients (n=86) were MRD- at 3 months post ASCT. Logarithmic reduction in MRD at 3 months correlated with PFS but not OS across 3 logs from <0.01% to <1% (p<0.001).
50.5% of patients (n=53) were MRD- at 12 months post ASCT. MRD- at 12 months post ASCT1 was associated with a significantly improved median PFS (55.2 vs 26.8 months p=0.007) (Figure 1a) and OS at 3 years (96% vs 92%; p=0.022). Logarithmic reduction in MRD at 1 year correlated with PFS across 5 logs from <0.01% to >10% (Figure 1b).
Longest median PFS was seen in those patients who had sustained MRD- or who deepened response from MRD+ to MRD- from 3 to 12 months. Those patients with MRD+ at both time points and those who went from MRD- at 3 months to MRD+ at 12 months had the shortest median PFS.
Post-ASCT2 at 12 months MRD- was associated with a trend to longer median PFS (32.6 vs 13.0 months, p=0.266). The longest median PFS was found in the group who remained MRD- from 3 to 12 months and the shortest in those who went from MRD- to MRD+ across these time points.

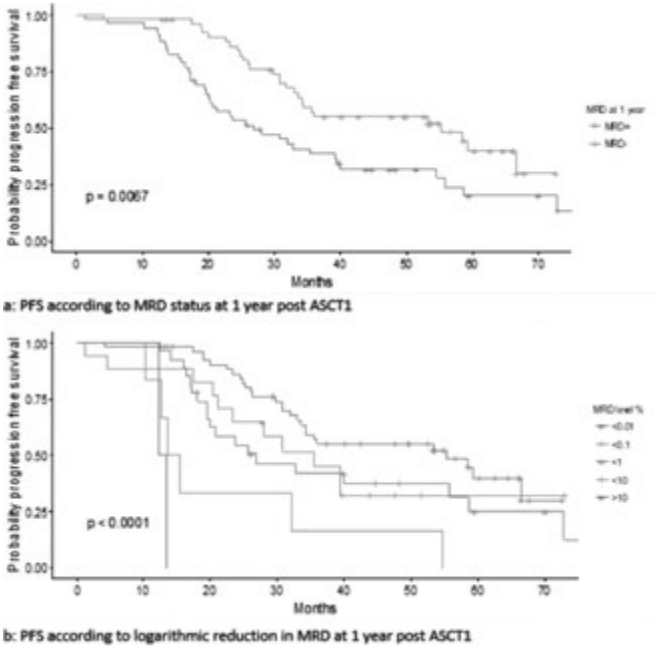

Figure 1.

Summary/Conclusion: In our real-world study, sustained MRD negativity was associated with improved survival outcomes following ASCT in both newly diagnosed MM patients and those undergoing a second transplant. Our findings support the utility of multiple time point MRD assessment in routine clinical practice and treatment strategies aiming to achieve sustained MRD- at these time points.

PS1327

MULTIPLE MYELOMA IN PATIENTS UNDER 40 YEARS OLD: A RETROSPECTIVE ANALYSIS FROM THE INTERGOUPE FRANCOPHONE DU MYELOME (IFM)

[1]Hematology, CHU Amiens, Amiens, [2]Hematology, CHU Toulouse, Toulouse, [3]Hematology, CHU Bordeaux, Bordeaux, [4]Hematology, CHU Nançy, Nançy, [5]Hematology, CHU Nantes, Nantes, France, [6]Hematology, CHU Dinant-Godinne, Namur, Belgium, [7]Hematology, CHU Grenoble, Grenoble, [8]Hematology, CHU Dijon, Dijon, [9]Hematology, CHU Rouen, Rouen, [10]Hematology, Hôpital Avicenne, Bobigny, [11]Hematology, CHU Besançon, Besançon, [12]Hematology, Institut Paoli-Calmettes, Marseille, [13]Hematology, CHRU Lille, Lille, [14]Hematology, Hôpital Saint-Antoine, Paris, [15]Hematology, CHU Poitiers, Poitiers, [16]Hematology, Hôpital Saint-Louis, Paris, France

Background: Median age at diagnosis for multiple myeloma patients is approximately 68 years, and only 2% of them are less than 40 years old. It has been suggested that younger patients may present with different disease features and worse outcomes, but few data are available in the era of novel therapies.
Aims: Our primary objective was to describe this specific population. Secondary objectives comprised outcomes and predictive factors for survival.
Methods: We report here a multicenter retrospective study of 185 patients aged up to 40 years old, diagnosed in 37 IFM centers between 01/01/2000 and 31/12/2015. The demographics, baseline biological, cytogenetic and clinical features plus frontline therapies were analyzed using descriptive statistics. Survival outcomes (progression-free (PFS) and overall (OS) survivals) were estimated using Kaplan-Meier method.
Results: Data completion rate was 90% in patient charts and baseline characteristics are summarized in Table 1. Sex ratio M/F was 1.8. Median age was 37.6 (range 18.6-40.9) and 9% (n=16) were <31 years-old. 9 patients (5%) had primary plasma cell leukemia (pPCL) and 1 had Randall disease. Solitary Plasmacytoma was present in 3 patients (2%) at diagnosis and 9 had smoldering myeloma (SMM). Half of patients display abnormal cytogenetics. Symptomatic MM patients received induction therapy with proteasome inhibitors (PI, 73%), IMIDs (58%), or both in 53%. Overall, 88,5% of patients underwent transplant with high dose melphalan + autograft (ASCT), frontline or at time of relapse. Furthermore, 34 patients received a double intensification, and 42 underwent allogeneic transplant. Frontline response rates were good with 71% of patient in VGPR or better. Median follow-up was 5.9 years (range 0.0-16.8). None of SMM patients progressed to overt MM. Considering symptomatic MM patients, median PFS was 3.2 years (IC95:2.2-4.2). Within the whole cohort, 5- and 10-y OS were 80.5% and 61.9% respectively. Considering only symptomatic MM (excluding pPCL and SMM), 5- and 10-y OS were 81.5% and 61.3% respectively. Allogeneic transplant significantly decreased OS (5-y OS = 66.8% vs 86.2%, p<0.001), as 50% of patients died after allograft. Post-allograft median OS was 3.9 years (IC95:1.5-6.2). Age, cytopenia, renal failure, hypercalcemia and ISS score did not impact response to induction therapy. Date of diagnosis and treatment with PI or IMID did not influence OS, but higher ISS score significantly decreases OS (5-y OS =87.8%, 79.1%, 60.1% for ISS1, 2, 3 respectively, p=0.018). Strikingly, high-risk (HR) cytogenetics was associated with better response to induction therapy (VGPR/RC =87.8% in HR vs 66.7%, p=0.01) contrasting to worse OS (5-y OS =55.7% in HR vs 89.3%, p<0.001).

Table 1. Demographic and biological characteristics of the population.

Total population, n (%)	185 (100)
- Diagnosis < year 2006	44 (23.8)
- Diagnosis 2006-2010	51 (27.6)
- Diagnosis > 2010	90 (48.6)
Gender, n (%)	
- Male / Female	119 (64.3) / 66 (35.7)
Age, years median (±SD ;min;max)	37.6 (±4.1 ;18.6 ;40.9)
Type of disease, n (%)	
- symptomatic MM	162 (87.6)
- pPCL	9 (4.9)
- SMM	10 (5.4)
- Solitary plasmacytoma	3 (1.6)
- Randall disease	1 (0.5)
Calcemia , n (%)	
- ≥ 3mmol/l	13 (7.7)
- < 3 mmol/l	156 (92.3)
- ND/NA	16/0
Serum Creatinine, µmol/l median (±SD ;min;max)	81.6 (±173.7 ;43 ;1293)
Creatinine clearance. ml/mn (MDRD)	
- ≥ 60	143 (88.1)
- <60	29 (16.9)
- ND	13
ISS score 1 / 2 / 3, n (%)	89 (52) / 47 (27.5) / 35 (20.5)
- ND	14
Cytopenia, n (%)	
- Anemia / ND	59 (34.1) / 12
- Thrombopenia / ND	7 (4.1) / 13
- Neutropenia / ND	9 (5.6) / 25
Bone lesions / ND, n (%)	127 (74.7) / 15
Cytogenetics / ND, n (%)	168 (90.8) / 17
- Abnormal cytogenetics	91 (54.2)
- High-Risk (HR), including*:	48 (28.6)
del17p / t(4 ;14) / t(14 ;16) / +1q / Hypodiploidy	16 / 16 / 0 / 16 /16
*some patients display multiple abnormabilities	

Summary/Conclusion: This retrospective analysis showed that MM patients under 40 years are a heterogeneous population, in which some known prognostic factors such as ISS and HR cytogenetics remain discriminatory. Despite long survivors, survival outcome remains poor, particularly in case of HR cytogenetics. Importantly, we did not find any OS improvement for patients recently diagnosed and treated with novel agents. More aggressive

treatment strategies are required to improve survival in this young patient population.

Background: Measurement of MRD has become an important tool to assess deep response to treatment in many clinical myeloma trials. Molecular techniques have been shown to have a higher sensitivity for MRD assessment compared to standard flow cytometry (FCM). However, molecular MRD quantification in MM using allele specific IG-PCR has a number of disadvantages, including failure of marker identification due to highly hypermutated IG loci and complex design of patient-specific PCR assays. Amplicon-based IG NGS has the potential to overcome such limitations and serve as a meaningful alternative to FCM-based MRD assessment.
Aims: Our aim was to evaluate the applicability of comprehensive IG amplicon NGS to detect molecular MRD markers and to compare the results of IG NGS during follow-up with those of multicolour FCM.
Methods: NGS-based marker screening was performed in pre-treatment bone marrow (BM) samples of 103 patients of the DSMM XIV phase 3 trial. Sequencing libraries were prepared using a 2-step PCR with multiplexed primer sets for IGH V-D-J (FR1, FR2 and FR3), IGH D-J, and IGK V-J and KDE loci. For MRD detection, 1-step library preparation using the same primer sets was employed. MRD was measured by NGS in 500ng BM DNA of 53 follow-up samples. The final MRD values were normalized using the IG sequences of cell-lines, which were added as spike-ins to the patient DNA in known copy numbers. The analysis of NGS MRD-negative samples was extended by NGS analysis of additional 500ng DNA. The libraries were sequenced on the Illumina MiSeq with a median coverage of 396,074 reads/sample. Raw NGS data were analysed with ARResT/Interrogate. The NGS MRD results were compared to the MRD values obtained by FCM. The flow approach consists of an optimized 2-tube 8-colour antibody panel and a bulk-lysis procedure for acquisition of 10^7 cells/sample according to the NGF EuroFlow MM MRD protocol. In the cases with discordances between NGS MRD and FCM MRD, a digital PCR (ddPCR) approach is in progress to confirm NGS MRD positivity.

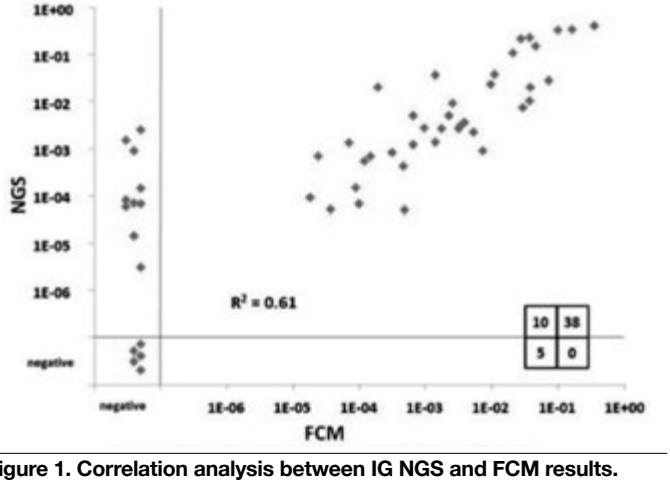

Figure 1. Correlation analysis between IG NGS and FCM results.

Results: Employing NGS-based methodology at least one clonal marker was detected in 98 of 103 patients (95%), 79/103 (77%) patients had two or more. Complete IGH rearrangements were present in 82 (80%), incomplete IGH rearrangements in 55 (53%), and IGK rearrangements in 61 (59%) patients. We detected on average 2.6 clonal markers per patient (range 0-7). From the 53 follow-up samples analysed, 48 (91%) were MRD positive using NGS. A correlation analysis between NGS and FCM is shown in Figure 1: NGS MRD data were concordant to FCM-based MRD results in 43 samples (81%) with 38 (72%) samples being MRD positive by both methods and 5 (9%) being double negative. The remaining 10 samples (19%) were only positive by NGS, of which only 2 had NGS MRD values above 0.1% (1E-03) - both positivities were confirmed by ddPCR.
Summary/Conclusion: NGS is a valuable tool for IG marker identification and MRD detection in MM, reaching at least similar sensitivities compared to standardized next generation flow (NGF). Clonal IG markers were successfully identified in >95% of patients. Still, prospective comparative analysis of unselected cases has to be performed to verify the clinical impact of NGS compared to NGF for sensitive and robust MRD assessment.

Background: Selinexor is a first-in-class Selective Inhibitor of Nuclear Export (SINE) compound that binds and inactivates Exportin 1 (XPO1). Selinexor, as a single agent, or in combination with PIs or IMiDs, has shown anti-MM activity in patients (pts) with relapsed or refractory multiple myeloma (RRMM). Daratumumab, an anti-CD38 monoclonal antibody, is approved for the treatment of RRMM. In CD138(+) myeloma cells, from newly diagnosed MM patients, were sensitized to the combination of selinexor and daratumumab as compared to single agent selinexor (p=0.005) or Dara (p=0.004).
Aims: This Ph 1b (NCT02343042), dose escalation study was designed to determine the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) for the safety, tolerability and efficacy of the combination of selinexor, daratumumab, and low dose dex (SDd) in pts with RRMM.
Methods: Pts were eligible if they had RRMM and had received ≥ 3 prior therapies, including a PI and IMiD. Selinexor was independently dosed escalated in 2 concurrent cohorts: once-weekly (QW, at 100 mg) or twice-weekly (BIW, at 60 mg) regimens. Daratumumab (16 mg/kg IV) was administered QW and dexamethasone (dex) was given orally 40 mg QW or 20 mg BIW.
Results: As of Feb 27th 2018, 13 pts (7 males / 6 females) have been enrolled. Three pts have been enrolled into the 60 mg BIW and 10 pts in the 100 mg QW cohorts. Pts have a median age of 67 years and a median of 4 (range, 2 – 10) prior treatment regimens. Adverse events include: fatigue (9 pts), thrombocytopenia (8 pts), neutropenia (7 pts), and nausea (5 pts). Two DLT's were reported in the 60 mg BIW cohort: G3 thrombocytopenia and G2 fatigue requiring dose reduction in selinexor to 100 mg QW. In the 100 mg QW cohort, 6 pts enrolled, 5 evaluable, with no DLTs; enrollment in this cohort is ongoing. A total of 10 pts were evaluable for response. In 8 dara-naïve pts, the ORR was 88% (4 VGPR, 3 PR, 1 PD), two PRs unconfirmed, and responses usually occurred within 1 cycle of treament. In the 2 pts with daratumumab refractory MM, there was one PD and one SD. Based on tolerability and efficacy, the RP2D of SDd is selinexor 100 mg, daratumumab 16 mg/kg and dex 40 mg, administered QW.
Summary/Conclusion: Selinexor 100 mg QW, can be combined safely with standard dose/schedule daratumumab and dex. The preliminary activiy with an ORR of 88% in RRMM patients who are dara naïve is promising. Enrollment is ongoing and updated data from the full phase 1 will be presented.

A REAL WORLD RETROSPECTIVE ANALYSIS OF EXTRAMEDULLARY DISEASE FROM BALKAN MYELOMA STUDY GROUP AND BARCELONA UNIVERSITY: CLINICAL FEATURES AND OUTCOME

M. Beksac[1,*], N. Kanellias[2], L. Rosinol[3], G. S. Cengiz[1], G. Ozet[4], V. Goranova[5], D. Coriu[6], J. Bila[7], H. Ozsan[8], L.I. Balic[9], A. Ivanaj[10], E. Kastritis[2], J. Blade[11], M. Dimopoulos[2]

[1]Hematology, Ankara University, Ankara, Turkey, [2]Hematology, National and Kapodistrian University of Athens Alexandra Hospital, Athens, Greece, [3]University of Barcelona, Department of Hematology, Barcelona, Spain, [4]Hematology, Numune Hospital, Ankara, Turkey, [5]Hematology, University of Pulovdiv, Pulovdiv, Bulgaria, [6]Hematology, Fundeni Clinical Institute, Bucharest, Romania, [7]Hematology, University of Belgrade, Belgrade, Serbia, [8]Hematology, Dokuz Eylül University, Izmir, Turkey, [9]Hematology, University of Sarajevo , Sarajevo , Bosnia and Herzegovina, [10]Hematology, University of Tirana, Tirana, Albania, [11]Hematology, University of Barcelona, Barcelona, Spain

Background: Extramedullary disease (EMD), defined as a clonal plasmacytic infiltration at anatomic sites distant from the bone marrow or adjacent soft tissue, appear to account for 6-7.5% of the total myeloma population at diagnosis and tend to increase at relapse with an unfavorable prognosis (Blade, Usmani).
Aims: Here, following an international collaborative effort, we are reporting the clinical features and outcome of myeloma patients with EMD or paraosseous (PO) involvement.
Methods: This multicenter retrospective study conducted in 16 centers from 11 countries included 206 adult patients diagnosed with EMD between January 2010 and November 2017. The diagnosis of EMD was rendered in accordance with the International Myeloma Working Group Guidelines. Eligibility criteria included EMD at any time following the initial diagnosis of Multiple Myeloma (MM) excluding plasma cell leukemia or solitary plasmacytoma. Those patients with pathological or radiological evidence of neoplastic plasma cells in the soft tissues adjacent to axial skeleton were deemed to have PO involvement of locally-advanced myeloma, but not EMD. Outcome was determined as response to treatment, progression free survival (PFS) and overall survival (OS) in months by Kaplan-Meier analysis using SPSS (IBM SPSS Statistics 21; IBM Corp., Chicago, IL) statistical tool kit. We also compared the PFS and OS between the paraosseous and EMD cohorts.

Table 1. Baseline characteristics of the patients.

Caracteristic (n=195)		Results	
Age, years, Median (range)		62 (34-87)	
ISS stage (at myeloma diagnosis)			
Stage I, n (%)		66 (33.8%)	
Stage II, n (%)		58 (29.7%)	
Stage III, n (%)		65 (33.3%)	
Number of FISH abnormalities			
No abnormalities, n (%)		50 (49.2%)	
1 abnormality, n (%)		28 (27.4%)	
2 abnormalities, n (%)		12 (11.7%)	
≥3 abnormalities, n (%)		12 (11.7%)	
Del17p, n (%)		10 (9.8%)	
Del13q, n (%)		20 (19.6%)	
t(4;14), n (%)		8 (7.8%)	
t(14;16), n (%)		2 (2%)	
t(11;14), n (%)		4 (4%)	
Anatomical locations of EMD			
Soft tissue(muscle/skin) , n (%)		51 (26.2%)	
Lymph nodes, n (%)		20 (10.3%)	
Chest, n (%)		19 (9.3%)	
Liver, n (%)		17 (8.7%)	
Central nervous system, n (%)		14 (7.2%)	
Oropharynx, n (%)		8 (4.1%)	
Lung, n (%)		6 (3.1%)	
Abdominal, n (%)		6 (3.1%)	
Testis, n (%)		4 (2.1%)	
Others, n (%)		5 (2.6%)	
Initial therapy for EMD			
Systemic chemo with radiotherapy, n (%)		55 (28.2%)	
PI, n (%)		104 (55%)	
IMIDs, n (%)		53 (27.3%)	
Only radiotherapy, n (%)		9 (4.8%)	
Monoclonal antibodies (CD38,CS1), n (%)		8 (4.2%)	
Lines of therapy (Myeloma+EMD)			
1-2 lines, n (%)		75 (56.4%)	
>2 lines, n (%)		58 (43.7%)	
Autologous stem cell transplantation, n (%)		76 (39%)	
CR diagnosis	EMD, % (n)	18.3%(15/82)	p=n.s
	PO, % (n)	28.1%(9/32)	
CR relapse	EMD, % (n)	2.9 % (20/69)	p=0.001
	PO, % (n)	41.7% (5/12)	
PFS diagnosis	EMD, Mean±SD	52.2±5.3	p=n.s
	PO, Mean±SD	75.9±11.4	
PFS relapse	EMD, Mean±SD	21.3±5.0	p=n.s
	PO, Mean±SD	20.8±4.2	
OS diagnosis	EMD, Mean±SD	55.7±6.2	p=0.02
	PO, Mean±SD	108.7±13.0	
OS relapse	EMD, Mean±SD	37.9±7.9	p=0.03
	PO, Mean±SD	30.1±4.7	

Results: A total of 195 patients met the predetermined criteria for inclusion. Baseline characteristics of the patients are summarized in Table 1. The median age at diagnosis of EMD was 62 years (range 34-87 years). Out of 114 patients at diagnosis EMD/PO were 82/32 and of the 81 patients at relapse 69/12 respectively. The median time from MM diagnosis to the development of EMD in the relapse/progression group was 28.4 months (range 1-157 months). Imaging approach for EMD was CT (n:109), PET-CT (n:48) or MRI (n:30). The most common locations for EMD at the time of diagnosis of MM were the soft tissues ie muscle and/or skin (26.2%) and lymph nodes (10.3%). FISH analyses prior to the diagnosis of EMD were available for 102 patients (52.3%). The entire group received a median number of two lines of treatment following the diagnosis of EMD/MM. Although response was higher for PO vs EMD at relapse, PFS was similar (Table 1). At the time of this report, 101 patients (52.3%) have died. The estimated median OS from time of diagnosis was 2.2 years (EMD) and 6.3 (PO) years (p=0.001). For both PO and EMD, outcomes DFS and OS were better when detected at diagnosis vs relapse (p=0.000). In addition, PO disease had a better outcome(OS) compared to EMD at diagnosis (p=0.02) and relapse (p=0.032). We could not find an association between ISS.
Summary/Conclusion: EMD is an uncommon, but by no means rare, manifestation of MM. This cohort of 195 patients represents a large group of patients with EMD demonstrating CR as a reachable but not sustainable target for both PO and EMD. EMD at relapse, but not at diagnosis, is the worst group with the poorest response and survival.

AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) IN AL AMYLOIDOSIS: SURVIVAL IMPROVEMENT IN DIFFERENT RISK CATEGORIES IN A SINGLE CENTER EXPERIENCE

A. Belotti[1,*], R. Ribolla[2], C. Crippa[2], V. Orlando[2], M. D'Adda[3], A. Re[2], C. Cattaneo[2], G. Rossi[2]

[1]Hematology Division, Spedali Civili di Brescia, [2]Hematology Division, Brescia, Italy, [3]Hematology Division, Hematology Division, Brescia, Italy

Background: Treatment of AL amyloidosis (ALA) is based on anti-myeloma therapy but there is no standard and the outcome of high risk patients still remains poor: autologous stem cell transplantation (ASCT) is recommended for patients with low organ damage, whereas in intermediate and high risk patients concerns about treatment-related toxicity limit this approach. Moreover, ALA may occur in association with symptomatic (active) multiple myeloma and the concomitant high risk ALA features that can be observed require caution when transplant stategy is considered.
Aims: Aims: we analysed the outcome of patients with ALA treated at our center according to their disease risk category. Furthermore, we analysed the outcome according to the use of ASCT as part of first line treatment strategy.
Methods: Of 66 patients newly diagnosed between Jan 1999 to december 2017 (median age 63 years), 24 (36%) underwent first line ASCT, upfront (6) or following induction chemotherapy (18). The 42 patients (63%) who didn't receive ASCT (control group) were treated with CyBorD regimen (24), melphalan-dexamethasone (9), VMDex (6), VD (1) or lenalidomide-dexamethasone (2). Risk groups were identified as follows: cTnI >0.1ng/ml and/or ECOG PS ≥3: high risk; age ≤65 years with normal cTnI levels, ECOG PS <3 and eGFR > 50ml/min: low risk. Intermediate risk patients were defined if not meeting criteria for high or low risk. Haematological and organ response were analyzed; Log-rank (Mantel-Cox) test applied to the Kaplan-Meyer method was used to estimate overall survival (OS) and event free survival (EFS: time to 2nd line therapy or death). Multivariate analysis was performed using Cox proportional hazard models to compare the influence of risk categories and treatment strategy on outcome.
Results: median follow up was 2.7 years. Patient characteristics are shown in Table 1. Overall response rate (ORR) and complete remission (CR) were not significantly different between the two groups: 82% and 45% in the ASCT group and 74% and 26% in the control group, respectively. Organ response (OR) rate was significantly higher in the ASCT group (82% vs 38%, p 0.0009). Toxicity was manageable in both groups, with day 100 post-ASCT mortality rate of 4.5%. Superior EFS was observed in low risk patients compared to high risk patients (median 8.9 vs 2.58 years, p 0.01; HR 0.36, 95% CI 0.17-0.79), whereas no difference was observed between low and intermediate risk patients. Superior OS was observed as well in low risk patients compared to high risk patients (median not reached vs 2.72 years, p 0.04; HR 0.37, 95% CI 0.13-0.99), with no difference if com-

pared with intermediate risk patients. Patients receiving ASCT as part of first line treatment strategy significantly improved both EFS (median 8.0 vs 2.2 years, p 0.001; HR 0.49, 95% CI 0.26-0.89) and OS (median not reached vs 2.73 years, p 0.0007; HR 0.23, 95% CI 0.10-0.52), compared to patients in the control group. Considering intermediate/high risk categories and transplant strategy in a multivariate analysis, ASCT independently affected EFS (p 0.04; HR 1.97, 95% IC 1.03-3.77) and OS (p 0.004, HR 6.19, 95% CI 1.81-21.73).

Table 1. Patients characteristics.

	Overall (N: 66) N, %	ASCT group (N: 24, 36%)	Control Group (N: 42, 63%)	P value	Concomitant Multiple Myeloma (N, %)
Median age (range)	63 (43-86)	58 (43-72)	66 (47-86)	0.001	
Risk category					
Low	14 (23%)	9 (36%)	7 (17%)	NS	11 (16%)
Intermediate	22 (33%)	6 (28%)	14 (33%)	NS	13 (20%)
high	29 (44%)	9 (36%)	21 (50%)	NS	19 (29%)
Concomitant Multiple Myeloma	43 (65%)	18 (75%)	25 (60%)	NS	

Summary/Conclusion: Conclusion: with the limit of a small case series we provide evidence of a significant OR and survival benefit with the inclusion of ASCT in first line treatment strategy, even in the intermediate and high risk group, thus reflecting the importance of an accurate re-assessment of the patient for ASCT eligibility after induction therapy and achievement of haematological response

PS1332

COMPARABLE OUTCOMES USING PROPYLENE GLYCOL-FREE MELPHALAN FOR AUTOLOGOUS STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA

K. Miller[1,*], H. Sidiqi[1], M. Gertz[1], F. Buadi[1], S. Hayman[1], M. Lacy[1], A. Dispenzieri[1], D. Dingli[1], P. Kapoor[1], W. Gonsalves[1], T. Kourelis[1], W. Hogan[1], S. Kumar[1]

[1]Division of Hematology, Mayo Clinic, Rochester, United States

Background: A propylene glycol-free version of melphalan (PG-free MEL; Evomela™) was recently approved by the United States Food and Drug Administration as a conditioning regimen for autologous stem cell transplantation (ASCT) in patients with multiple myeloma. PG-free MEL incorporates a modified cyclodextrin, making it more stable and soluble than propylene glycol-solubilized melphalan (PG-solubilized MEL; Alkeran™) (Koltun *et al.*, 2010). As such, there is speculation that PG-free MEL may be less toxic than its PG-solubilized counterpart.
For example, it was noted that patients treated with PG-free MEL had a relatively low incidence of severe oral mucositis in the study which lead to its approval (Hari *et al.*, 2015). However, this was a single-arm, Phase IIb trial; hence, it is unclear if ASCT outcomes differ significantly between patients treated with either PG-free or PG-solubilized MEL in clinical practice.
Aims: In pursuit of this, we compared the clinical course of multiple myeloma patients who underwent ASCT before and after an institutional switch to PG-free MEL.
Methods: After institutional review board approval, we conducted a retrospective chart review of 416 patients who underwent ASCT for the treatment of multiple myeloma at Mayo Clinic Rochester from October 15, 2015 to October 27, 2017. The switch from PG-solubilized MEL (Alkeran™; GlaxoSmithKline, Research Triangle Park, NC, USA) to PG-free MEL (Evomela™; Spectrum Pharmaceuticals, Inc., Irvine, CA, USA) occurred on October 10, 2016. Thus, 200 patients in our study received PG-solubilized MEL; 216 received PG-free MEL. The Mann-Whitney *U* test and Fisher's Exact test were used to compared continuous and categorical variables, respectively. Oral mucositis was graded according to the World Health Organization (WHO) criteria. The presence of oral ulcers, or severe pain resulting in a significant limitation in oral intake was graded as ≥2. Moreover, patients with severe esophagitis that significantly limited oral intake were graded as ≥2. Statistical analysis was completed using JMP 13 (SAS Institute Inc., Cary, NC, USA).
Results: Patients conditioned with PG-free and PG-solubilized MEL were balanced in terms of age, sex, time to ASCT, serum creatinine, disease status, and melphalan dose (Table 1a).
After ASCT, there were no significant differences between patients treated with either PG-free or PG-solubilized MEL in terms of hospitalization, neutropenic fever, WHO Grade ≥2 oral mucositis/esophagitis, narcotic usage, IV fluid utilization, IV granisetron requirement, transfusions, and time to engraftment (Table 1b). Moreover, there were no significant differences in Day +100 hematologic responses between the two groups.

Table 1.

Baseline characteristics and ASCT outcomes for patients conditioned with PG-free MEL (Evomela™) and PG-solubilized MEL (Alkeran™).

1a. Baseline Characteristics	PG-free MEL (Evomela™) n=216	PG-solubilized MEL (Alkeran™) n=200	*P*-value
Age at ASCT (years), median (range)	62 (31-75)	61 (29-77)	0.76
Male, n (%)	132 (61%)	116 (58%)	0.55
Months to ASCT from diagnosis, median (IQR)	6 (5-10)	6 (5-9)	0.92
Serum Creatinine prior to ASCT (mg/dL), median (IQR)	1 (0.8-1.2)	1 (0.8-1.2)	0.51
Disease status prior to ASCT, n (%)			0.31
Stable or Progressive Disease	21 (10%)	26 (13%)	
PR	72 (33%)	77 (39%)	
VGPR	83 (38%)	61 (31%)	
CR	17 (8%)	11 (6%)	
sCR	23 (11%)	25 (13%)

200 mg/m^2	161 (75%)	164 (82%)	
140 mg/m^2	27 (13%)	22 (11%)	
Other (e.g. w/ carfilzomib or bortezomib, BEAM)	28 (13%)	14 (7%)	
1b. ASCT Outcomes	**PG-free MEL (Evomela™)**	**PG-solubilized MEL (Alkeran™)**	***P*-value**
Days to ASCT dismissal visit (from Day 0), median (IQR)	20 (18-21)	20 (18-22)	0.79
Hospitalization during ASCT, n (%)	92 (43%)	78 (39%)	0.49
Number of nights in hospital, median (IQR)	6 (3-10)	6 (3-9)	0.67
Neutropenic Fever, n (%)	133 (62%)	126 (63%)	0.84
w/ Bacteremia	38 (29%)	37 (29%)	0.80
Oral/Esophageal Mucositis (WHO Grade ≥2), n (%)	52 (24%)	40 (20%)	0.35
Narcotic requirement during ASCT, n (%)	153 (71%)	144 (72%)	0.30
Oral narcotics (tramadol, oxycodone, etc.)	108 (50%)	90 (45%)	
Fentanyl (patch)	22 (10%)	33 (17%)	
Fentanyl, Dilaudid, or Morphine IV	23 (11%)	21 (11%)	
IV Fluid requirement (liters), median (IQR)	7 (3-12)	8 (3-11)	0.45
Granisetron IV requirement (# of days on therapy after Day 0), median (IQR)	10 (3-13)	9 (1-13)	0.48
Granisetron IV cumulative dose (mg), median (IQR)	12.5 (3-20)	11 (1-18)	0.36
RBC transfusion requirement (# of units), median (IQR)	0 (0-1)	0 (0-1)	0.79
Time to ANC engraftment (>0.5 x 10^9/L) (days), median (IQR)	16 (14-17)	15 (14-17)	0.74
Platelet transfusion requirement (# of units), median (IQR)	1 (1-2)	1 (1-2)	0.45
Time to platelet engraftment (>20 x 10^9/L) (days), median (IQR)	16 (16-17)	16 (15-18)	0.77
Hematologic response at Day +100, n (%)			0.73
Stable or Progressive Disease	4 (2)	2 (1)	
PR	58 (27)	65 (33)	
VGPR	72 (33)	62 (31)	
CR	36 (17)	33 (17)	
sCR	46 (21)	38 (19)	
Day +100 All-Cause Mortality, n (%)	1 (1)	1 (1)	1.0

Summary/Conclusion: ASCT outcomes for patients conditioned with either PG-free or PG-solubilized MEL were comparable, including for the incidence of WHO Grade ≥2 oral mucositis/esophagitis (24% *vs.* 20%, respectively, p=0.35). Further studies should investigate if using PG-free MEL alters other ASCT outcomes or impacts survival in multiple myeloma.

Background: Daratumumab (DARA) has been approved for patients with relapsed and refractory myeloma multiple (RRMM) that have received ≥3 prior lines of therapy including proteasome inhibitor (PI) and an immunomodulatory (IMID) agent. It is not necessary to adjust the dosage of DARA in patients with creatinine clearance 30-60 mL/min, there are no published data available in patients requiring dialysis.
Aims: The objective of this retrospective, multicenter, open-label study is to report the safety and efficacy of DARA in patients with RRMM with end-

stage renal failure requiring dialysis.
Methods: This study included patients ≥18 years, documented progression of MM following the most recent therapy including a PI and an IMiD, ECOG 0-2, absence of chronic obstructive pulmonary disease, and no prior exposure to anti-CD38. Patients received DARA at the standard dose (16 mg/kg/IV/weekly/8 weeks, then every 2 weeks/16 weeks, and then every 4 weeks) until disease progression or unacceptable toxicity. Premedications with antihistamines, montelukast, antipyretics and corticosteroids and post-infusion medications with corticosteroids were administered. Data on efficacy and adverse events (AEs) including grade 3-4 AEs and infusion related reactions (IRRs) were collected.
Results: The study, including 12 Spanish centers is ongoing and we report here the preliminary results of the first 12 patients included from January 2017 to February, 2018. There were 8 male and 4 female with a median age of 62 years (51-71) and with a median time from diagnosis to initiation of DARA of 2.24 years (0.47 – 13.78). MM was BJ in 6 patients, IgG type in 3, IgA type in 2, and IgD in 1 patient. According to the ISS, 2 patients were in stage I, 1 patient was in stage II, and the remaining 9 patients were in stage III. The median number of prior lines was 3 (2 -6); 58% of patients received ≥3 prior lines. All patients were double refractory to both a PI and IMiD, 3 patients were also refractory to carfilzomib. Four patients had received previous stem-cell transplant (3 autologous and 1 allogeneic). Five out of the 12 patients had high-risk cytogenetics (Table 1). In 11 patients, end stage renal failure was myeloma-related (4 patients with acute renal injury at time of diagnosis), while the remaining patient was already on dialysis at time of diagnosis MM. The median time on dialysis at study entry was 2 months (range, 0.36 - 91). The median (range) number of cycles of DARA administered was 6 (1-15). The ORR and the clinical benefit rate (SD or better) was 50% (2 VGPR, 2 PR, and 2 SD). With a median follow-up of 12 months (range 7 - 15), no patient has become dialysis independent, 6 patients have died, 4 patients due to disease progression, 1 patient due to toxicity, and 1 patient due to non-myeloma related causes (bowel perforation). The remaining 6 patients are still alive with ongoing DARA treatment. No patient discontinued treatment due to AEs. Grade 1-2 IRRs were only during the first cycle (5 patients). Anemia (n=4, 50% grade ≤2), thrombocytopenia (n=4, 25% grade ≤2), and neutropenia (n=3, 33% grade ≤2).

Table 1. Baseline characteristics.

Age, years	
Median (range)	62 (51-71)

t(14;16)	1
add(1q)	3
Median time from diagnosis to initiation of DARA, years (range)	2.24 (0.47-13.78)
Median time on dialysis at beginning DARA, months (range)	2 (0.36-91)
No. of cycles of DARA, median (range)	6 (1-15)
Response	
ORR (≥PR)	6
VGPR	2
PR	2
SD	2
PD	4
NA	2
AEs, N, (alls, grade ≤2)	
Anemia	4 (2)
Thrombocytopenia	4 (1)
Neutropenia	3 (1)
IRRs, N, (alls, grade ≤2)	5 (5)

ECOG: Eastern Cooperative Oncology Group; ASCT: autologous stem cell transplantation; DARA: daratumumab; AEs: Adverse Events; ORR: overall response rate; CR: complete response; VGPR: very good partial response; PR: partial response; SD: stable disease; PD: progressive disease; NA: not evaluable; IRRs: infusion-related reactions; DARA: daratumumab.

Summary/Conclusion: Although still preliminary, our data suggest that DARA monotherapy is an efficacious and safe therapeutic option for patients with RRMM and end-stage renal failure including dialysis. AE profile seems to be similar to that previously observed in patients with normal or moderately impaired renal function.

PS1334

OPTIMISING TREATMENT FOR HIGH-RISK MYELOMA IN A STRATIFIED MULTI-CENTRE TRIAL: EXPERIENCE FROM MUKNINE OPTIMUM STUDY

V. Shah[1,2], S. Hinsley[3], A. Sherborne[1], S. Ellis[1], A. Price[1], J. Kendall[1], D. Johnson[1], R. Owen[4], M. Drayson[5], L. Flanagan[3], D. Sherratt[3], W. Gregory[3], G. Jackson[6], G. Pratt[7], G. Cook[8], S. Brown[3], M. Jenner[9], M. Kaiser[1,2,*]

[1]The Institute of Cancer Research, [2]The Royal Marsden Hospital, London, [3]Leeds Institute of Clinical Trials Research, Leeds University, [4]St James University Hospital, Leeds, [5]University of Birmingham, Birmingham, [6]Newcastle University, Newcastle, [7]University Hospitals Birmingham NHS Foundation Trust, Birmingham, [8]Leeds Institute of Cancer and Pathology, University of Leeds, Leeds, Leeds, [9]University Hospital Southampton, Southampton, United Kingdom

Background: Outcomes for newly diagnosed myeloma (NDMM) patients with high risk molecular tumor features remain unsatisfactory.
Aims: Insights from trials in relapsed myeloma and tumor evolutionary studies suggest that multi-targeted combination therapies could improve outcomes through eradication of rapidly evolving tumor sub-clones. We report here an update on one of the first multi-centre clinical trials for high risk NDMM, Myeloma UK (MUK) nine: OPTIMUM (NCT03188172).
Methods: MUKnine OPTIMUM investigates the five-drug combination Daratumumab, Cyclophosphamide, Bortezomib, Lenalidomide, Dexamethasone (DCVRd) followed by high dose melphalan + ASCT augmented by Bortezomib, intensified consolidation (DVR) and maintenance (DR) in high risk NDMM. Challenges inherent to high risk sub-group trials were addressed in line with recommendations for trials in rare cancers (Bogaerts, Eur J Canc 2015). Outcomes for DCVRd are compared using a Bayesian strategy against molecularly matched near-concurrent high risk NDMM treated on the Myeloma XI trial. Precise molecular definition of high risk is key and based on evidence from independent Myeloma IX and Myeloma XI trials demonstrating the specific association of presence of 2 or more ('double-hit') high-risk genetic lesions (Adverse translocations; del(1p32); gain(1q21); del(17p)) AND/OR a SKY92 High Risk GEP Profile with adverse PFS and OS. Molecular risk screening is performed in a central laboratory using a combination of molecular genetic (MRC Holland) and gene expression (SkylineDx) assays. Primary endpoint of MUKnine is a 25% improvement in PFS over to the molecularly matched comparator high risk group from Myeloma XI. Central longitudinal flow-based MRD (10^{-5}) is assessed for early surrogate PFS endpoint assessment and monitoring of disease dynamics. Up to 620 newly diagnosed patients will be molecularly screened and up to 105 patients with high risk status will receive OPTIMUM DCVRd therapy. Patient reported outcomes and clinical outcomes for non-high risk patients form part of the analysis.
Results: OPTIMUM opened to recruitment in October 2017 and at the time of abstract submission 41 patients have been registered for central molecular risk profiling. For 37 patients screening results were successfully generated, 4 samples failed due insufficient bone marrow myeloma cell content. Turnaround time for central screening results was on average 17 days (range 6-33 days), shorter than the protocol-defined maximum of 56 days. If clinically indicated, patients received up to two cycles of local standard induction therapy, e.g. VTD, whilst central screening was performed. Tumour cells from 18 patients were found to carry molecular high risk features as defined above, 7 were high risk by 'double-hit' genetics and SKY92, 3 by 'double-hit' only and 8 by SKY92 only. This overlapping but non-identical identification of high risk by genetic and GEP profiling prospectively confirms findings from MRC Myeloma IX and NCRI Myeloma XI and supports combined molecular testing, in particular for molecularly stratified trials. At the time of abstract submission, ten high risk patients had been registered for DCVRd therapy. Updated screening and recruitment results will be presented at the meeting.
Summary/Conclusion: We provide a first update on central molecular screening feasibility for stratification in the multi-centre UKMRA MUKnine OPTIMUM trial investigating five-drug combination therapy in high risk NDMM.

PS1335

ASYMPTOMATIC HEART INVOLVEMENT IN AL AMYLOIDOSIS

M. Basset[1,*], P. Milani[1], A. Foli[1], R. Mussinelli[1], P. Stefano[2], G. Palladini[1], G. Merlini[1]

[1]Department of Molecular Medicine, University of Pavia, Pavia, Italy, [2]Department of Internal Medicine, University of Pavia, Pavia, Italy, Amyloidosis Research and Treatment Center, Foundation IRCCS Policlinico San Matteo, Pavia, Italy, Pavia, Italy

Background: Late recognition of advanced cardiac dysfunction is still responsible for a high proportion early deaths in AL amyloidosis. However, NT-proBNP allows early recognition of cardiac amyloidosis before it manifests clinically.
Aims: In the present study we describe the clinical presentation and outcome of patients with asymptomatic cardiac AL amyloidosis.
Methods: The prospectively maintained database of the Amyloidosis Research and Treatment Center was searched for patients with cardiac amyloidosis, defined as mean left ventricular wall (mLVW) thickness >12 mm or NT-proBNP >332 ng/L in the absence of other causes, who did not present symptoms or signs of heart involvement. Baseline variables were tested by Cox univariate and multivariate analysis and best cutoffs were identified by ROC analysis.
Results: A total of 155 consecutive patients diagnosed between 2004 and 2015 were included in the study. Fifteen subjects had isolated cardiac involvement and were diagnosed because elevated NT-proBNP was detected during screening for MGUS. In 140 patients (90%) AL amyloidosis was suspected because of clinical manifestation of involvement of organs other than the heart, namely kidney in 78% of subjects, liver in 15%, soft tissues in 14%, and peripheral and autonomic nervous system in 11% and 7% of patients, respectively. Median age was 65 years and 57% of patients were males. Cardiac stage was II in all patients, representing 33% of the stage II patients diagnosed at our center in the study timeframe. Median mLVW thickness was 12.6 mm (range 9-17 mm) and median ejection fraction was 60 (range 52-71%). Median NT-proBNP was 1102 ng/L (range 349-6770 ng/L). Renal stage was I in 34% of subjects, II in 38%, and III in 28%. Upfront therapy was cyclophosphamide/bortezomib(B)/dexamethasone (CyBorD) in 33%, melphalan/dexamethasone (MDex) in 29% of patients, BMDex in 11%, B/dexamethasone in 6%, treatment for IgM-AL amyloidosis in 6%, immune modulatory drugs-based in 5%, autologous stem cell transplant in 2%, other in 9%. Overall hematologic response rate was 65% [complete response (CR) 15%, very good partial response (VGPR) 39%], and cardiac and renal responses were achieved in 28% and 29% of patients with measurable organ involvement, respectively. After a median follow-up of living patients of 36 months, median survival was 57 months, which was significantly longer than that (15 months) of 639 patients with symptomatic heart involvement diagnosed in the same timeframe (p<0.001). The baseline variables associated with survival were age, NT-proBNP, bone marrow plasma cell infiltrate (BMPC), and difference between involved and uninvolved free light chain (dFLC). The multivariate model best predicting survival included age >75 years [hazard ratio (HR) 3.38, p=0.001], NT-proBNP >850 ng/L (HR 2.29, p=0.011), and BMPC >10% (HR 2.15, p=0.026). Only 7 patients (4%) presented with all the 3 risk factors, and they all died a cardiac death after a median of 8 months. The median survival of patients with 0, 1, and 2 risk factors was not reached, 56, and 45 months, respectively.
Summary/Conclusion: Patients with AL amyloidosis diagnosed at an asymptomatic stage have a significantly better outcome than those who present with heart failure. However, advanced age, relatively high NT-proBNP concentration and plasma cell burden identify a minority of subjects who are still at high risk of early death.

PS1336

RANDOMIZED CLINICAL TRIAL (RCT) REPRESENTATIVENESS & OUTCOMES IN RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM) REAL WORLD (RW) PATIENTS: COMPARISON OF ASPIRE, TOURMALINE-MM1, POLLUX, & ELOQUENT RCTS

A. Chari[1,*], D. Romanus[2], E. Farrelly[3], H. Huang[2], M. Blazer[3], A. Raju[3], S. Noga[2], P. Richardson[4]

[1]Icahn School of Medicine at Mount Sinai, New York, [2]Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, [3]Xcenda, LLC, Palm Harbor, [4]Dana Farber Cancer Institute, Boston, United States

Background: Only 3% of patients (pts) participate in oncology trials in the United States (US).[1] Strict eligibility criteria and high enrolment ex-US limit the generalizability of trial results and applicability of the benefit/risk treatment profile to RW pts.[2]
Aims: To estimate the proportion of US RW pts who are representative of eligibility criteria in recently completed trials of triplet lenalidomide/dexamethasone (Rd)-based regimens in RRMM and to compare the baseline characteristics and overall survival (OS) between RCT-eligible and RCT-ineligible pts within each trial group.
Methods: RRMM pts were followed retrospectively in a large US electronic health record (EHR) database.[3] Included were pts initiating treatments consistent with either the experimental or control regimen in 2nd-4th line of therapy (LOT) based on 4 RCTs: 2 proteasome inhibitor-based (PI) (ASPIRE; TOURMALINE-MM1) and 2 monoclonal antibody-based (mAb) triplet regimens with an Rd backbone (POLLUX; ELOQUENT). RW pts were categorized into "RCT-**elig**" vs "RCT-**inelig**" based on whether eligibility criteria for each of the 4 trials in RRMM were met vs not. Unadjusted Cox PH models were performed to estimate OS from start of the index regimen to death between RCT-**elig** vs RCT-**inelig** pts in each trial group. Observations were censored at time of loss to follow up/end of study period (6/2017).
Results: Applying the individual trial criteria, 25% (ASPIRE), 35% (TOURMALINE), 41% (ELOQUENT), and 47% (POLLUX) US RW pts met the eligibility criteria. In addition to exclusion criteria related to prior treatment history of/refractory status to an immunomodulatory drug (21% [ELOQUENT], 8% [other trials] of RCT-**inelig** pts), the most common reasons for ineligibility across trial groups were: low creatinine clearance (27% [ASPIRE]; 9% [other trials]) and other cancer diagnoses (12% [all trials]). Refractory status to a PI as an exclusion criterion in the PI-based trials applied to 54% of ASPIRE & TOURMALINE RCT-**inelig** pts. Less than 1% of pts were RCT-**inelig** using the POLLUX & ELOQUENT mAb-based trial criterion of prior exposure to a mAb. Clinically relevant recent cardiovascular comorbidities accounted for 12% (ASPIRE), 9.2% (TOURMALINE), 9.0% (ELOQUENT), and 5.9% (POLLUX) RCT-**inelig** pts. RW pts who were RCT-**elig** were generally significantly younger, treated in earlier LOT, more likely to have a history of stem-cell transplant, had a lower comorbidity burden. A lower proportion also had known ISS III disease vs RCT-**inelig** pts (Table). Except in the ELOQUENT group, the 3-year OS was significantly higher among RCT-**elig** v RCT-**inelig** pts but the difference in OS varied across trial groups: 77% v 57% (ASPIRE, p<0.001), 75% v 60% (TOURMALINE, p<0.001), 70% v 63% (POLLUX, p<0.01) and 67% v 65% (ELOQUENT, p=0.16) (Table 1).

Table 1.

Variable	ASPIRE N=822			TOURMALINE MM1 N=656			POLLUX N=813			ELOQUENT N=823

REFERENCES: 1) Institute of Medicine (US). https://www.ncbi.nlm.nih.gov/books/NBK83089/; 2) Kim ES et al. JCO Oct 2, 2017 (online). 3. Optum's de-identified EHR dataset (2007-2017) 4. Usmani S et al. Oncologist 2016; 21: 1-7

Summary/Conclusion: 53-75% of RW US pts do not meet eligibility criteria of recently completed trials of novel-triplet regimens in RRMM in large part due to refractoriness to lenalidomide and also PIs, for the PI containing studies. Importantly, OS between RCT-**elig** vs RCT-**inelig** pts varied based on trial eligibility characteristics. A limitation of the data is that treatment refractory disease was defined using a proxy[4] and may overestimate the true proportion of ineligible pts. Future work will evaluate the impact of individual eligibility criteria on OS.

PHARMACOKINETIC EVALUATION OF TEST DOSE PREDICTIONS OF HIGH DOSE MELPHALAN EXPOSURE IN PATIENTS WITH MULTIPLE MYELOMA

J. Trotman[1,2,*], P. Shaw[34], C. Tiley[5,6], S. Ramanathan[7], A. Grigg[8,9], P. Presgrave[10,11], E. Newman[1], J. Estell[1,2], S.-J. Ho[7], S. Larsen[12], C. Nath[3,4]

[1]Concord Repatriation General Hospital, Concord, [2]University of Sydney, Sydney, [3]The Children's Hospital at Westmead, Westmead, [4]University of Sydney, Camperdown, [5]Gosford Hospital, Gosford, [6]University of Newcastle, Newcastle, [7]St George Hospital, Kogarah, [8]Austin Hospital, Heidelberg, [9]Univeristy of Melbourne, Melbourne, [10]Wollongong Hospital, Woollongong, [11]University of Wollongong, Wollongong, [12]Royal Prince Alfred Hospital, Camperdown, Australia

Background: High-dose melphalan (HDM) and autologous transplantation (ASCT) is used to treat multiple myeloma (MM). We have previously shown that the standard dose of 200 mg/m^2 results in a 5 fold variation in melphalan exposure, with area under the concentration versus time curve (AUC) ranging from 5 to 25 mg/L.h in 114 patients (pts). AUC above the median (12.8 mg/L.h) was associated with improved OS (8.5y vs. 5.4 y, HR 0.4, p<0.001).[1]

Aims: The aim of this pilot study was to evaluate the feasibility and accuracy of test dose pharmacokinetic (PK) predictions of subsequent high dose melphalan exposure in patients with MM.

Methods: Thirty-five pts (age range: 44 to 71y, median 60y) were recruited from 6 hospitals located up to 860km from the PK laboratory. A test dose of melphalan (20mg/m^2) was administered 1-3 days prior to the remaining 180 mg/m^2. Melphalan was infused over 30-36 min for the test dose and from 15-45 min for the subsequent dose. Blood was collected at: 5,15,30,40,75 and 150 min after completion of the infusions. Plasma melphalan concentrations were measured by HPLC-UV detection. Test dose AUC was calculated using the trapezoidal rule and used to predict the AUC for the subsequent dose, assuming linear PK. Percentage deviation of actual-from-predicted AUC was calculated as% deviation = (actual AUC – predicted AUC) / predicted AUC*100. Predicted vs actual AUC were compared using the paired Wilcoxin Rank Sign Test. Linear regression was used to test whether age, gender, renal function or body weight were associated with% deviation of actual versus predicted AUC.

Results: All sites promptly delivered all samples to the PK lab. Figure 1 shows predicted and actual melphalan AUC values listed consecutively with the first pt at each institution marked with an asterisk. Median (range) for test dose AUC was 1.32(0.98-2.03) mg/L.h. For the subsequent dose, the median predicted AUC was significantly (p<0.001) higher than the actual AUC; 11.9 (8.8–18.6) mg/L.h versus 11.0(6.3-16.0) mg/L.h. The% deviation of actual from predicted values was median (range) -10.7%, (-44% to 11%), with predictions being within±15% for 24 pts (69%). The median% deviation for the first pt in each centre (n=6) was -22; for subsequent pts (n=29) it was -9.5%, (p=0.2) and of these, 22 (76%) had full dose AUC values within±15%. Age, height ,weight and renal function did not significantly impact on the predictions. Total melphalan exposure was median 12.2 (7.6 – 17.8) mg/L.h; in 18(of 35) pts it was below 12.8 mg/L.h, the value previously associated with inferior OS.[1]

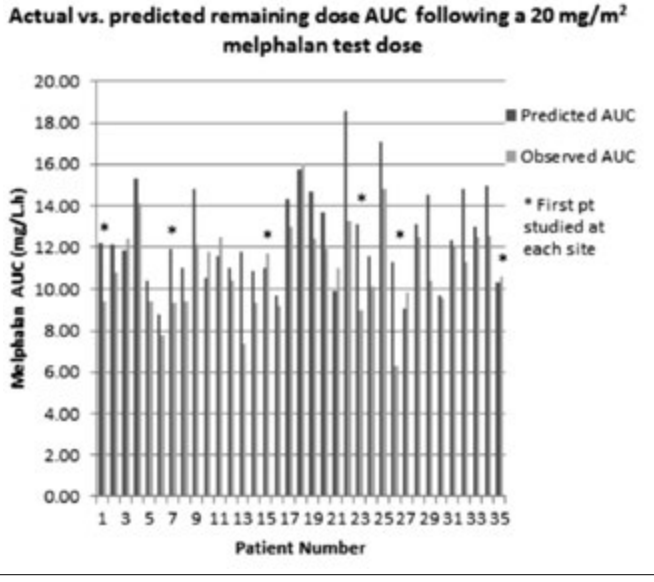

Figure 1.

Summary/Conclusion: Test-dose PK predictions of melphalan exposure were feasible and accurate to within ±15% for 69% of pts. The predictive value increased with experience possibly reflecting improved consistency in blood sampling. Further improvements might be obtained by standardizing HDM preparation and administration times, since melphalan solution is unstable, and there may have been different rates of degradation of the test and subsequent doses. The common over-prediction of the full dose AUC could lead to potential below-target dosing; conversely no patient had an actual AUC more than 11% of predicted. Investigation of infusion stability at different melphalan concentrations is underway. PK directed dosing of HDM to achieve a desirable AUC has the potential to provide more consistent melphalan exposure than the current BSA-based approach but further work to define the desirable AUC and the optimal adjustment strategy based on initial PK is needed.

PS1338

A PHASE II STUDY OF SELINEXOR(KPT-330) COMBINED WITH BORTEZOMIB AND DEXAMETHASONE (SVD) FOR INDUCTION AND CONSOLIDATION FOR PATIENTS WITH PROGRESSIVE OR REFRACTORY MULTIPLE MYELOMA: THE SELVEDEX TRIAL

A. Broijl[1,*], E. Asselbergs[1], M. Minnema[2], S. Lonergan[1], B. van der Holt[3], N. van de Donk[4], S. Zweegman[4], P. Sonneveld[1]

[1]Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, [2]Department of Hematology, UMC Utrecht Cancer Center , Utrecht, [3]HOVON Data Center, Erasmus MC Cancer Institute, Rotterdam, [4]Department of Hematology, VU Medical Center, Amsterdam, Netherlands

Background: Selinexor is an oral selective exportin-1 (XPO-1) inhibitor that forces nuclear retention and activation of many tumor suppressor proteins (TSPs) and IkB and is active as monotherapy and combined with dexamethasone in multiple myeloma (MM). Addition of proteasome inhibitors to selinexor increases levels and activity of TSPs/IkB leading to synergistic MM cell death.

Aims: A dose escalating phase I/II study was performed in patients with progressive and/or refractory MM, evaluating feasibility (phase I) and efficacy (phase II) of selinexor at 3 dose levels combined with twice weekly (BIW) bortezomib and dexamethasone (SVd).

Methods: The maximum tolerated dose (MTD) and recommended dose level (RDL) were determined using a 3+3 dose escalation scheme. Patients could be included if they had received at least one prior anti-myeloma regimen, and were not refractory to bortezomib. Selinexor on days 1,8,15,22, bortezomib 1.3 mg/m^2 subcutaneously on days 1,4,8,11, dexamethasone 40 mg on days 1,8,15,22 in a 28-days schedule.

Results: Seven patients were treated at the first selinexor dose level of 45 mg/m^2. The median number of prior treatments was 3 (range 2-7). Three patients were lenalidomide refractory during their last treatment. Two patients were deemed ineligible after inclusion, one patient had a transformation to plasma cell leukemia, one was bortezomib refractory. Two out of 5 eligible patients completed treatment as planned. Only one patient completed selinexor at the preplanned dose of 45 mg/m^2. Reasons for discontinuation were excessive toxicity(n=1), progressive disease(1), other reasons not specified(1). Two patients experienced a DLT, one grade 4 thrombocytopenia with epistaxis, one patient had an ischemic cerebrovascular event. Adverse events (AE) CTC grade 3-4 were observed in all treated patients (Table 1). The study continued with a lower dose level of selinexor of 30 mg/m^2 with adjustment of bortezomib frequency to once weekly on days 4 and 11. The median number of prior treatments was 3 (range 1-7). Three patients were lenalidomide refractory. Two out of 6 patients who started treatment completed treatment as planned. Reasons for discontinuation were neuropathy grade 4(1), pneumonia(1), progressive disease(3). Six patients were treated of whom 4 patients experienced a DLT: hyponatremia grade 3(2), polyneuropathy grade 3(1), syncope grade 3(1).The study was stopped prematurely due to unacceptable toxicity observed in the 2 different dosing schedules of SVd. In the 45mg/m^2 group 4 out of 5 (80%) patients achieved ≥PR, including 2 VGPR, and 1 sCR. Median follow-up (FU) was 27 months (range 0.6-31.5). Median PFS was 17 months, OS at 1 and 2 years was 100% and 75%, respectively. Four out of 6 (67%) patients in the 30 mg/m^2 group achieved ≥PR, including 1 VGPR; no CRs were seen. Median FU was 10.1 months (range 0.6-17.9). Median PFS was 10 months, 1 year OS was 75%.

Table 1. Adverse events CTC grade 3-4.

Adverse events CTC grade 3,4	Selinexor 45 mg/m2 (n=5)		Selinexor 30 mg/m2 (n=6)	
	Grade 3 (n)	Grade 4 (n)	Grade 3 (n)	Grade 4 (n)
Any	2	3	2	4

Gastrointestinal disorders:				
Diarrhea	1			
General disorders and administration site conditions:				
Fatigue	1			

Summary/Conclusion: We found that both 30 and 45mg/m^2 of selinexor in combination with either twice or once weekly bortezomib resulted in unacceptable toxicity. However, in those patients in whom the regimen was feasible we observed remarkable ORR, PFS and OS in this pretreated, predominantly lenalidomide-refractory MM population. This is consistent with results recently presented for once weekly SVd regimens. This regimen, which also showed high ORR and PFS, is currently being evaluated in the international Phase 3 randomized BOSTON study of SVd vs Vd (NCT 03110562).

PS1339

LONG-TERM OUTCOMES OF ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

Q. Bashir[1,*], K. Chamoun[1], F. H. Cheema[2], B. Oran[1], S. Ciurea[1], Y. Nieto[1], C. Hosing[1], U. R. Popat[1], P. Kebriaei[1], S. Ahmed[1], A. Olson[1], G. Al-Atrash[1], R. Mehta[1], R.Z. Orlowski[3], E.E. Manasanch[3], H.C. Lee[3], K. Patel[3], E. Shpall[1], R.E. Champlin[1], M.H. Qazilbash[1]

[1]Stem Cell Transplantation, UTMD Anderson Cancer Center, [2]Cardiovascular Research, Baylor College of Medicine, [3]Lymphoma/Myeloma, UTMD Anderson Cancer Center, Houston, United States

Background: Multiple myeloma (MM) is considered an incurable malignancy, however allogeneic hematopoietic cell transplantation (allo-HCT) can result in long-term survival in select group of patients. Long-term follow-up is needed to establish the realistic benefits of allo-HCT in myeloma patients.
Aims: To characterize the long-term outcomes of allo-HCT in patients with newly diagnosed MM>
Methods: We retrospectively analyzed all consecutive patients with newly diagnosed MM who received allo-HCT at our center between January 1994 and December 2016.
Results: Thirty-seven patients were identified. The median age was 54.6 (range= 32.4 – 68.1) years and 54.1% were male. The international staging system (ISS) stage was I, II, III and unknown in 35%, 24%, 22%, and 19% of patients, respectively. High-risk cytogenetics (IMWG definition) was identified in 19.4% of patients. Seventy-three percent had received a prior autologous HCT. A total of 24.3% received myeloablative conditioning (MAC) while 75.7% received reduced intensity (RIC) or non-myeloablative (NMA) conditioning. The graft source was match unrelated (MUD) in 16% and matched sibling donor (MRD) in 84% of patients. Prior to allo-HCT, 1 patient was in complete remission (CR), 49% were in near CR or in very good partial remission (VGPR), and 49% were in partial remission (PR). Median time from diagnosis to allo-HCT was 8.8 months. Twenty-seven percent of patients received maintenance therapy after allo-HCT. The median time to neutrophil and platelet engraftment was 12 (ANC ≥500/mL) and 13 (platelet count ≥20K/mL) days, respectively. The cumulative incidence (CI) of non-relapse mortality (NRM) was 3% at day-100 and 17% at 1-year. There was no difference in NRM between MAC or NMA conditioning. The stringent CR+CR rate was 56% (20/36) after allo-HCT. Overall response rate (PR or better) was 97%. The incidence of grade I-IV acute graft-versus host disease (GVHD) was 35%, while chronic GVHD was seen in 62%. The median follow-up in surviving patients was 123.8 months (range: 15.6-213.5). The 3, 5, and 10-year actuarial progression-free survival (PFS) were 51%, 39.1%, and 29.3%, respectively (Figure 1A). The 3, 5, and 10-year actuarial overall (OS) were 72.7%, 57.5%, and 47.9%, respectively (Figure 1B). In multivariate Cox proportional-hazards model, high-risk cytogenetics (p=0.009, Hazards Ratio (HR): 22.5, 95% CI: 2.2-236.2) independently predicted PFS whereas graft source from matched sibling donor (p=0.03, HR: 0.14, 95% CI: 0.02 – 0.85) was identified as an independent predictor for OS. At the last follow up, 51% (n=19) of patients were alive in the entire cohort, 35% (n=13) of which survived for longer than 10-years from transplant. Twenty-two percent (n=8) of patients remained alive and in remission for more than 10 years from transplant, the longest ongoing remission being 17.7 years.

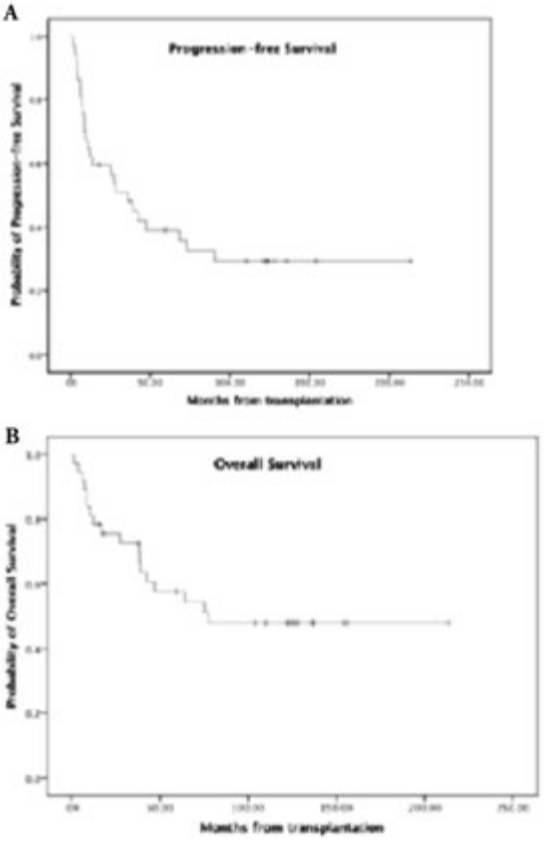

Figure 1.

Summary/Conclusion: Allo-HCT is an effective therapy for patients with MM, which can produce durable long-term remission in a significant number of patients when performed early in disease course.

THE SCREENING OF PROTEINS SIGNATURES WITH SIGNALING PATHWAY IN POLYCYTHEMIA VERA AND INHIBITION OF PIM ENHANCES JAK2 INHIBITOR SENSITIVITY

W. Hui[1,*], F. Ye[2], W. Zhang[1], S. Wan[1], L. Su[1]

[1]Xuan Wu Hospital, Capital Medical University, beijing, China, [2]Mount Sinai School of Medicine, new york, United States

Background: The *JAK2-V617F* mutation is observed in nearly all cases of polycythemia vera (PV) and aberrant JAK2 signaling plays an etiological role. However, JAK2 inhibitors are unable to induce molecular complete remission in patients with PV, effective therapies remain needed. Targeting JAK2 downstream pathways is potential as a therapeutic approach.
Aims: This study aim to screen signaling pathway proteins in PV and explore potential therapeutic targeting.
Methods: Protein pathway array was performed to analyze the expression levels of signaling pathway proteins in peripheral blood neutrophils from 35 PV patients with *JAK2V617F* mutation and furthermore to identify the significant pathways affected by these differential expression of the proteins using Ingenuity Pathways Analysis(IPA). We hypothesized that apoptosis signaling may offer a therapeutic target for PV, apoptosis-related proteins were quantified by western blotting in an additional 38 patients with PV. Further studies using the HEL cell line, a MPN model cells which harboring the *JAKV617F* mutation, transfected with *PIM1* siRNA and treated with the JAK2 inhibitor ruxolitinib, signaling pathways and downstream effectors were characterized by Western blotting, quantitative PCR. We utilized PIM inhibitor, SGI-1776, and determined its effect on HEL cells as well as primary PV patient cells alone and in combination with ruxolitinib. The cell survival rates and the apoptosis were detected by CCK-8 and flow cytometry.
Results: There were 20 proteins were found to be dysregulated in PV patients compared with those in healthy controls ($p<0.05$). Among them, 9 proteins were up-regulated, while 11 proteins were down-regulated. These dysregulated proteins were involved in 10 major signaling pathways including apoptosis pathway. Among apoptosis-related proteins, expression of BCL-xL was correlated with the expression of PIM1 and BAD in PV patients. Furthermore, *PIM1* knockout inhibited expression of BCL-xL and BAD. Additionally, inhibition of PIM leads to an increased apoptosis and decreased cell proliferation via arrest at G1 phase in HEL cells. These data suggested PIM/BCL-xL/BAD plays an important role in promoting cell survival of PV. Furthermore, inhibition of JAK2 resulted in decreased *PIM1* mRNA expression. We found that JAK2 inhibition induces apoptosis by regulation of the PIM/ BCL-xL/BAD. PIM inhibitor synergistically enhanced JAK2 inhibitor-induced apoptosis in both HEL cells and primary cells from PV patients. In addition, SGI-1776/ruxolitinib combination therapy synergistically suppressed erythropoietin independent erythroid colony formation of primary PV cells.
Summary/Conclusion: In summary, our study demonstrated a broad dysregulation of signaling proteins and pathways including PIM/ BCL-xL/BAD in PV, and targeting PIMs may increase the efficacy of JAK2 inhibitors therapy.

Background: The prognosis of Essential Thrombocythemia (ET) is related to an increased risk of thrombosis and to a long-term risk of hematological evolution (myelofibrotic and leukemic transformation). Different prognosis scoring systems based on clinical and biological parameters including driver mutations have been proposed in the last few years. Additional mutations have been demonstrated as important prognostic factor in myelofibrosis but little is known in ET.
Aims: We aim to evaluate the prognostic input of additional mutations in ET in terms of survival, thrombosis and hematological transformation.
Methods: The cohort consisted in 190 ET patients diagnosed between January 2000 and December 2016. Diagnosis was based on WHO2008 criteria and the median follow-up was 6.4 years. In addition to driver mutations testing (*JAK2*V617F, *CALR* exon 9 and *MPL*W515) all coding exons of 16 genes (*ASXL1*, *EZH2*, *TP53*, *SF3B1*, *SRSF2*, *TET2*, *IDH1*, *IDH2*, *DNMT3A*, *CBL*, *NRAS*, *JAK2*, *MPL*, *SH2B3*, *IKZF1*, *KRAS*) were sequenced by NGS (TSCA and MiSeq 2x250pb, Illumina). Mutations were called with an in-house pipeline. Only exonic nonsynonymous mutations were retained and putative somatic mutations were obtained by removal of known polymorphisms. Comparisons were performed using Fisher exact test, or Student t-test or Mann-Whitney test, as appropriate. Survival curves were obtained with the Kaplan-Meier method and Cox proportional hazard regression models were performed.
Results: In our cohort, driver mutations were distributed as 116 (61%) *JAK2*V617F, 27 (14%) *CALR,* 4 (2%) *MPL*W515 and 43 (23%) triple negative. At least one additional mutation was found in 44% of the patients in the entire cohort and in 35% of the triple negative ET. No additional mutation was found in 60 *JAK2* mutated cases, 17 *CALR* cases and 28 triple negative cases. The most frequently mutated genes were *TET2* (14%), *DNMT3A* (12%) and *ASXL1* (6%). *DNMT3A, TET2, ASXL1* and *SRSF2* mutations were associated to an older age (respectively p=0.022, p=0.0066, p=0.04 and p=0.0087), while *JAK2* mutations (other than V617F) and *TET2* mutations were associated to lower leukocytes counts (respectively p=0.0014 and p=0.042). During the follow-up 16 deaths, 18 thrombosis and 11 hematological evolutions were observed. In our cohort, among classical prognostic scores (ELN, IPSET-survival and IPSET-thrombosis) the ELN scoring system was the most effective to predict survival. In univariate analysis, the presence of at least one additional mutation (p=0.012) and the number of additional mutation (p=0.019) were associated with an adverse prognosis in term of survival. In multivariate analysis including sex, ELN classification, driver mutations and additional mutation, both ELN (HR:9.6 (High risk/Low risk), p=0.029) and the presence of at least one additional mutation (HR:3.5 (Yes/No), p=0.022) were associated to a risk of death. Hematological transformation was associated with male sex (p=0.0047) and splice mutations in univariate analysis but only sex (HR:5.9 (Male/Female), p=0.029) in multivariate analysis. Only cardiovascular risk was associated with thrombosis events in univariate (p=0.013) and multivariate (HR:3.2 (Yes/No), p=0.016) analysis.
Summary/Conclusion: In our study, screening for additional mutations by NGS in ET improved the prognostic evaluation of ELN classification in term of survival. Larger studies are needed for recommending a systematic molecular screening in ET.

PS1342

THE ROLE OF THE THROMBOPOIETIN RECEPTOR (MPL) IN MYELOPROLIFERATIVE NEOPLASMS

K. Behrens[1,2,*], E.M. Viney[2], T.A. Willson[2], J.J. Babon[1,2], N.A. Nicola[1,2], W. S. Alexander[2,3]

[1]Department of Medical Biology, University of Melbourne, [2]Walter and Eliza Hall Institute, [3]University of Melbourne, Parkville, Australia

Background: Constitutive activation of the Jak/Stat signalling pathway is a hallmark of Myeloproliferative Neoplasms (MPN), with 60-90% of patients carrying the activating JAK2 mutation, $JAK2^{V617F}$. The second most frequently mutated gene is *Calreticulin* (CALR). Mutant CALR binds and activates the thrombopoietin (Tpo) receptor (Mpl), likewise inducing constitutive JAK2 activation. Several studies suggest expression of a type I cytokine receptor is essential for $JAK2^{V617F}$- and $CALR^{mut}$-mediated transformation, but the precise contribution of such receptors is unresolved.
Aims: Here we investigate the functional role of Mpl in $JAK2^{V617F}$ and $CALR^{del52}$ activity.
Methods: Mpl mutants lacking various functional domains were tested for their capacity to support either $JAK2^{V617F}$- or $CALR^{del52}$-mediated factor independence in BaF/3 cells.
Results: Similar to the wildtype (wt) receptor, a Mpl truncation mutant retaining the JAK2-interaction domain, but lacking the C-terminus, typically associated with Stat5 binding, supported $JAK2^{V617F}$-induced transformation. Interestingly, Stat5-phosphorylation was maintained. In contrast, deletion of the entire cytoplasmic receptor domain abrogated Stat5 phosphorylation and factor-independent proliferation. In contrast, in $CALR^{del52}$-expressing

BaF/3 cells, loss of a single Mpl residue, Tyrosine 599, required for Shc binding and MAKP activation, prevented factor-independent proliferation. Furthermore, pharmacological inhibition of MAPK abolished factor-independent growth of Mpl-wt CALR^{del52} cells. In factor-independent Mpl-wt CALR^{del52} cells, Tpo stimulation augmented proliferation. Stat5 phosphorylation was not observed unless Tpo was added.
Summary/Conclusion: While JAK2^{V617F} and CALR^{del52} both require Mpl to induce transformation, the cellular pathways activated downstream of the receptor differ. JAK2^{V617F} transformation is associated with Stat5 activation, although the C-terminus of the receptor, usually linked with Stat5 phosphorylation, appears dispensable. Thus, other mechanisms of Stat5 activation may exist. In contrast, CALR^{del52}-mediated transformation is dependent on Mpl-induced MAPK-signalling and can be augmented by Tpo-mediated Stat5 signalling.

PS1343

BOARDING ON THE SECRETARY PATHWAY IS REQUIRED FOR THE ONCOGENIC PROPERTY OF MUTANT CALRETICULIN

M. Araki[1,*], N. Masubuchi[2], E. Hayashi[2], Y. Yang[2], M. Imai[2], Y. Kihara[2], Y. Mizukami[2], Y. Hironaka[2], Y. Edahiro[2], A. Ohsaka[1], N. Komatsu[2]

[1]Blood Transfusion and Stem Cell Regulation, [2]Hematology, Juntendo University Graduate School of Medicine, Tokyo, Japan

Background: Recurrent somatic mutations on *calreticulin (CALR)* gene that encodes a molecular chaperone have been identified in a subset of patients with myeloproliferative neoplasms (MPNs). Studies have shown that mutant CALR interacts and constitutively activates thrombopoietin receptor MPL, which promotes the development of MPN. However, the underlying molecular mechanism of the interaction between mutant CALR and MPL was poorly understood.
Aims: We aimed to elucidate how mutant CALR interacts with MPL for the oncogenic activation in the cells.
Methods: To understand the regulatory mechanism for the interaction between mutant CALR and MPL, subcellular localization of those proteins were determined by confocal microscopic imaging in a human megakaryocytic cell line UT-7/TPO where mutant CALR exhibited the oncogenic property by activating endogenously expressed MPL. To examine the significance of subcellular localization on its oncogenic capacity, mutant CALR harboring alterations on the signal peptide sequence were expressed and examined for subcellular localization, capacity to interact with MPL, and capacity to induce factor-independent growth. To investigate the glycan-binding capacity of mutant CALR plays a role for the interaction with MPL, mutant CALR harboring mutations on glycan-binding site was expressed and examined for subcellular localization, capacity to interact with MPL, and capacity to induce factor-independent growth.
Results: Although wild-type CALR predominantly localized in endoplasmic reticulum, mutant CALR was accumulated in Golgi apparatus with MPL in UT-7/TPO cells. Deletion of signal peptide sequence from mutant CALR resulted in a loss of localization to Golgi apparatus. The mislocalized mutant CALR exhibited significantly reduced capacity to interact with MPL and no capacity to induce factor-independent growth in UT-7/TPO cells. Replacing the signal peptide sequence of mutant CALR with ones from unrelated proteins sustained the localization in Golgi apparatus, and the MPL-binding and oncogenic capacity. Mutant CALR lacking glycan-binding capacity exhibited the Golgi localization but failed to interact with MPL and to induce factor-independent growth in UT-7/TPO cells.
Summary/Conclusion: We have demonstrated that the signal peptide sequence was required for mutant CALR to localize in Golgi apparatus and to induce factor-independent growth. Consistent to previous studies, we have shown that the glycan-binding capacity of mutant CALR was required for the MPL-binding and oncogenic activation of MPL. Taken together, we proposed a model in which mutant CALR engages with MPL in the secretary pathway by recognizing N-glycosylation of MPL, which eventually induces constitutive activation of MPL.

PS1344

PHARMACOLOGICAL INHIBITION OF IGF1R/IRS TARGETING STAT3/STAT5 SIGNALING HAS ANTI-NEOPLASTIC EFFECTS IN JAK2 V617F MYELOPROLIFERATIVE NEOPLASMS

J.C. Fernandes[1,*], J.A. Machado-Neto[1], B.A. Fenerich[1], J.L. Coelho-Silva[1], A.P.N.R. Alves[1], P.S. Scheucher[1], L.L. Figueiredo-Pontes[1], E.M. Rego[1], F. Traina[1]

[1]Internal Medicine, University of São Paulo at Ribeirão Preto Medical School, Ribeirão Preto, Brazil

Background: The lack of efficiency in inducing complete remission in most patients with myeloproliferative neoplasms (MPN) treated with the JAK1/2 selective inhibitor, ruxolitinib, indicates the need to identify new therapies. IGF1 upregulation induced myeloid transformation and the multi-targeted tyrosine kinase inhibitor NVP-AEW541 notable reverted the malignant phenotype in a Jak2V617F conditional knock-in mouse model. IRS2 silencing inhibited STAT5 phosphorylation, increased apoptosis and potentiated the effects of ruxolitinib in JAK2V617F cell lines. The IGF1R/IR selective inhibitor Linsitinib (OSI-906) has anti-tumors effects *in vitro*, and clinical trials are ongoing. However, the best pharmacological strategy to target IGF1R/IRS and the molecular consequences of specific inhibitors remains undetermined.
Aims: We aimed to investigate and to compare the effects of three IGF1R/IRS pharmacological inhibitors, NT157, OSI-906 and NVP-AEW541, in Ba/F3 cells expressing wild-type (WT) and V617F mutant JAK2 and mononuclear cells from Jak2V617F and WT knockin-induced MPN mice.
Methods: Cells were cultured in the presence or not of IL-3-rich Wehi-3B-conditioned medium and the effects of inhibitors on cell viability (MTT), apoptosis (annexin V/PI and caspase 3 cleavage), proliferation (Ki-67) and protein expression (Western blot) were evaluated. Ba/F3 cells were treated with NT157, OSI-906 and NVP-AEW541 for 24, 48 and 72 hours. Bone marrow mononuclear cells from mice were treated with the inhibitors for 72 hours and cell viability was evaluated. Statistical analysis were performed by ANOVA.
Results: In Ba/F3 JAK2V617F, NT157 (≥0.4 μM), for 48 and 72 hours, significantly reduced cell viability, cell proliferation and induced apoptosis (all $p<0.05$). NT157 reduced protein expression/activation of IRS1/2, STAT3, STAT5 and P70S6K, increased ERK1/2 phosphorylation and cleaved caspase 3. OSI-906 reduced cell viability, cell proliferation, and induced apoptosis only at higher dose (40 μM) (all $p<0.05$). OSI-906 reduced protein expression/activation of IRS1/2, IGF1R, AKT1/2/3 and P70S6K, increased ERK1/2 phosphorylation and cleaved caspase 3, but did not modulated STAT5. NVP-AEW541 treatment reduced cell viability and increased apoptosis at doses ≥2 μM upon all treatment duration (all $p<0.05$) and reduced protein expression/activation of IRS1/2, IGF1R, AKT1/2/3 and STAT5, but did not modulate ERK1/2 and STAT3. In Ba/F3 JAK2WT, all inhibitors were able to prevent IL-3 dependent growth factor-induced survival, indicating that these pharmacological inhibitors potentially act in key proteins involved IL-3 signaling. In mononuclear cells from WT and Jak2V617F knockin-induced MPN mice, the three inhibitors had similar effects to those observed in cell lines. NT157 reduced cell viability at 6.4μM and OSI-906 only at higher dose (≥20 μM); while NVP-AEW541 had the best effect, reducing cell viability upon doses ≥6 μM.
Summary/Conclusion: NT157 presented anti-neoplastic effects in low doses and was able to inhibit STAT3 and STAT5. OSI-906 exerts its anti-leukemic effects only at higher doses, and did not inhibited STAT5. NVP-AEW541 demonstrated anti-leukemic effects upon all doses and time tested, probably due to its effect not only on IGF1R, but also on KIT and FLT3 signaling, as previously demonstrated (Chapuis *et al.* Haematologica, 2010). The results highlight NT157 as a potent IGF1R/IRS and STAT3/STAT5 inhibitor with anti-tumor effects in JAK2V617F MPN models.

PS1345

IN VIVO INHIBITION OF JAKS IN MYELOFIBROSIS IMPROVES MONOCYTES DIFFERENTIATION AND REACTIVATES PRO-INFLAMMATORY RESPONSE IN INFECTION-STIMULATED MONOCYTES

M. Barone[1], M. Romano[2], D. Sollazzo[1], D. Forte[3], E. Ottaviani[1], G. Auteri[1], N. Vianelli[1], M. Cavo[1], F. Palandri[1], L. Catani[1,*]

[1]Experimental, Diagnostic and Specialty Medicine, University of Bologna, Institute of Hematology "L. e A. Seragnoli", Bologna, Italy, [2]School of Immunology & Microbial Sciences, King's College London, Guy's Hospital, London, [3]Wellcome Trust-Medical Research Council Cambridge Stem Cell Institute and Department of Haematology, University of Cambridge, Bologna, United Kingdom

Background: Myelofibrosis (MF) is a clonal disorder of the hemopoietic stem cells characterized by hyperactivation of the JAK-STAT pathway and chronic inflammation. Ruxolitinib (RUX), a JAK1/2 inhibitor, exerts also immunosuppressive/anti-inflammatory activity, resulting in increased infectious risk in RUX-treated MF patients (pts). Among the cells targeted by RUX, monocytes (Mo) might be highly affected due to the importance of the JAK-STAT signalling pathway in their differentiation/function. However, the effects of RUX toward this cell remain to be clarified.
Aims: To study whether and to what extent RUX affects the ex vivo/*in vitro*

functional behaviour of circulating Mo in MF pts.
Methods: Peripheral blood (PB) was collected from 12 *JAK2*^{V617F} mutated MF pts before and after 6 months of RUX therapy and from 10 age/sex-matched healthy donors (HD). Pts were int-2 and high IPSS risk. Total Mo and subsets (Classical- CD14++/CD16-, Intermediate- CD14+/CD16+, Non-Classical-Mo CD14-/CD16++) were characterized by flow cytometry (chemokine receptors (R): CCR2, CX3CR1, CCR5; functional markers: CD86, HLA-DR, Interleukin (IL)-10R) in mononuclear cells (PBMCs). After *in vitro* stimulation of PBMCs with lipopolysaccarides (LPS), the Interleukin (IL)-1β/-6, and Tumor Necrosis Factor (TNF)-α producing Mo were measured by intracellular flow cytometry analysis. IL-10 plasma levels were measured by ELISA.
Results: We firstly observed a dysregulation of MF-Mo differentiation. During physiological maturation from Classical- to Intermediate- and Non-Classical-Mo, CCR2 is downregulated and CX3CR1 is upregulated. By contrast, in MF pts, the Intermediate- and Non-Classical-Mo maintain a high expression of CCR2 (Figure 1A) and do not upregulate CX3CR1 in Non-Classical-Mo (Figure 1B). After 6 months of therapy, RUX significantly reduced the mean percentage of CCR2+ cells (Figure 1A) and increases the intensity of CX3CR1 expression in Non-Classic-Mo (Figure 1B). In addition, RUX normalized the intensity of the motility-related CCR5 expression in all Mo-subsets (data not shown). Given the importance of IL-10 pathway in the negative feedback control of inflammatory cytokines production, we then analysed IL-10R expression in MF Mo. At baseline, the mean percentage of IL-10R+ cells was significantly increased in MF-Mo, especially Classical and Non-Classical-Mo; RUX significantly decreased the mean percentages of IL-10R+ cells in Total and Non-Classical-Mo (Figure 1C). Additionally, the increased IL-10 plasma level at baseline was not significantly modified by RUX (data not shown). Following *in vitro* LPS stimulation, total-MF-Mo at baseline showed dramatically decreased mean percentage of IL-1β, IL-6 and TNF-α producing cells. Surprisingly, RUX counteracted the LPS-mediated effects increasing and normalizing the proportion of inflammatory cytokines-producing cells in all Mo-subsets (Figure 1D, E, F). Of note, analysing baseline and RUX-treated cells, we detected an inverse correlation between the percentages of IL10R+ cells and LPS-stimulated inflammatory cytokines-producing cells ($r \leq -0.7$; $p \leq 0.04$; expressed as% IL10R/% cytokines LPS-stimulated producing cells ratio; Figure 1 G,H,I).

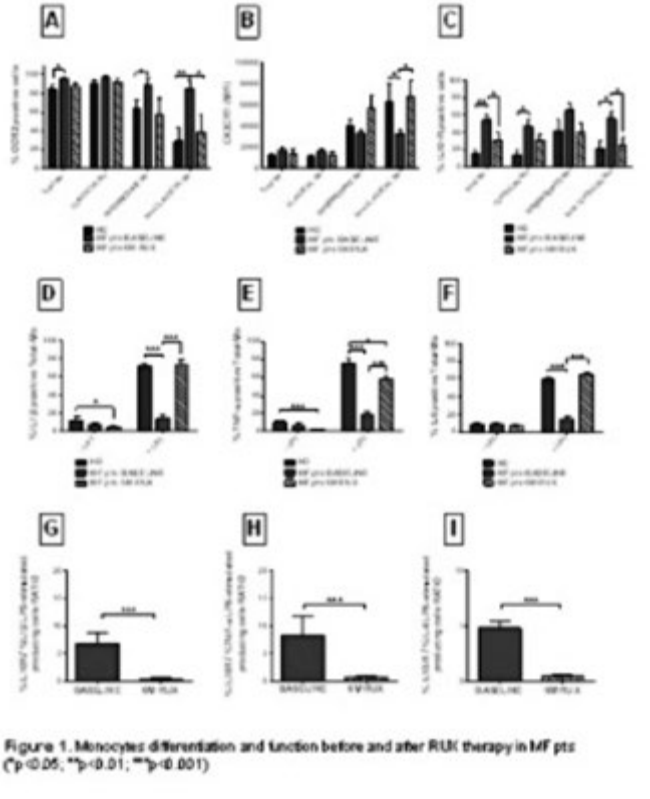

Figure 1. Monocytes differentiation and function before and after RUX therapy in MF pts (*p<0.05; **p<0.01; ***p<0.001)

Figure 1.

Summary/Conclusion: Here we demonstrated that, at variance with natural killer and T cells, which were described to be reduced in number/function by RUX in previous studies, RUX ameliorates *ex vivo* Mo differentiation/function in MF. This finding further refines the effects of RUX on MF immune system and suggests that RUX activity is cell type-dependent. A larger cohort of pts is now under evaluation to confirm these data.

PS1346

POLO-LIKE KINASE-1, AURORA KINASE A AND WEE1: NEW THERAPEUTIC TARGETS IN SYSTEMIC MASTOCYTOSIS

M. Mancini[1,*], C. Monaldi[2], S. De Santis[2], C. Papayannidis[2], M. Rondoni[3], M.C. Abbenante[2], L. Bavaro[2], M. Martelli[2], R. Zanotti[4], L. Pagano[5], M. Cavo[2], P. Valent[6], G. Martinelli[7], S. Soverini[2]

Seràgnoli", [2]Department of Experimental Diagnostic and Specialty Medicine - DIMES, Istituto di Ematologia Seràgnoli-DIMES, Bologna, [3]Azienda USL della Romagna, Ravenna, [4]Azienda Ospedaliera di Verona, Verona, [5]Fondazione Policlinico Universitario A. Gemelli , Roma, Italy, [6]Department of Hematology, Internal Medicine I, Medical University of Vienna, Vienna, Austria, [7]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (I.R.S.T.) , Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (I.R.S.T.), Meldola, Italy

Background: Systemic mastocytosis (SM) is due to the pathologic accumulation of neoplastic mast cells in one or more extracutaneous organ(s). Advanced forms of SM are associated with poor prognosis. Although midostaurin, a multikinase inhibitor active against both wild type and D816V-mutated KIT, improves organ damage and symptoms, there is still a need for new targeted agents for patients (pts) who relapse or have resistant disease. It is well known that Aurora-A overexpression promotes tumorigenesis, but the role of Aurora-A in the development of cancer has not been fully investigated. Recent studies indicate that Aurora-A may confer cancer cell chemo-resistance through dysregulation of cell cycle progression and DNA damage response. Direct evidences from literatures suggest that Aurora-A inhibits p53, but enhances Plk1, CDC25, CDK1, and cyclin B1 to promote cell cycle progression. Other studies indicate that Aurora-A suppresses RAD51, poly(ADP ribose) polymerase (PARP), and gamma-H2AX to dysregulate DNA damage response.
Aims: In this study we aimed to investigate the role of Aurora-A and Plk 1 in genomic instability and aggressiveness of advanced SM and if they may represent promising therapeutic targets.
Methods: Experiments were conducted in the HMC-1 MC leukemia cell line and in primary neoplastic MCs obtained from 7 SM patients (indolent SM, n=3; aggressive SM, n=3 and MC leukemia, n=1). Protein expression and activation was assessed by Western Blotting. Apoptotic cell death and cell cycle distribution were evaluated by flow cytometry after annexin V and propidium iodide staining, respectively. Drug cytotoxicity in *in vitro* experiments was evaluated by clonogenic assays.
Results: HMC-1 cells as well as primary neoplastic MCs displayed hyperphosphorylated AKA and Plk1. Danusertib (AKA inhibitor) and Volasertib (Plk1 inhibitor) inhibited growth and induced apoptotic cell death in HMC-1.1 (IC50=649nM and 443nM, respectively) and -1.2 cells (IC50=892nM and 808nM, respectively). The growth-inhibitory effects of Danusertib and Volasertib were found to be associated with mitotic arrest and activation of apoptosis. Cell cycle arrest was associated with increased levels of phospho (p)-Chk1 and p-Chk2, p-cyclin B1, p-cdc2 and p-Wee1. Apoptosis was demonstrated by an increase of annexin-V-positive cells and by the detection of the cleaved forms of caspase-3, -8, -9, and PARP. Wee1 inhibition by AZD1775 (500 nM) after 24h treatment with Danusertib or Volasertib (100nM), when cells were arrested in G2 phase and Wee1 was overexpressed and hyper-activated, resulted in a percentage of apoptotic cells significantly higher than that obtained from concomitant treatment with Danusertib or Volasertib (100nM) + AZD1775 (500 nM) for 48h. Moreover, both drug combinations induced a significant increase of the DNA double-strand break marker γH2AX and RAD51, suggesting that Wee1 inhibition promotes mitosis and propagates genomic instability. Finally, Danusertib and Volasertib were found to synergize with AZD1775 in inhibiting HMC-1 clonogenic potential and in inducing apoptotic cell death. Volasertib or Danusertib±MK1775 did not induce apoptosis in normal cultured cells.
Summary/Conclusion: Plk1 and AKA, alone or together with Wee1, are attractive therapeutic targets in neoplastic MCs. Repurposing Plk1 or AKA±Wee1 inhibitors in advanced clinical development for other indications is a therapeutic strategy worth to be explored in an attempt to improve the outcome of patients with advanced SM.

PS1347

NLR AS SURROGATE OF MYELOID IMMUNE SUPPRESSION CAN PREDICT EARLY SPLENIC RESPONSE TO RUXOLITINIB IN MYELOFIBROSIS

A. Bonanno[1,*], A. Romano[1], S. Stella[1], P. La Cava[1], N.L. Parrinello[1], C. Giallongo[1], D. Tibullo[1], E. Lambusta[1], M.S. Pennisi[1], F. Di Raimondo[1], G. Palumbo[1]

[1]Università degli Studi di Catania, Catania, Italy

Background: Myelofibrosis (MF), include primary myelofibrosis (PMF), post essential thrombocythemia (PET-MF) and post polycythemia vera (PPV-MF). Recently, clinical benefits have been reported in patients receiving therapy with IMIDs, that are presumably derived from immune-modulating effects of these agents; however their exact mechanism remains unclear. Ruxolitinib is the-first-in-class Jak1/2 inhibitor recently approved for treatment for MF.
Aims: We proposed to probe further into myeloid-driven immune dysfunction in MF to identify surrogate markers to apply into clinical practice.
Methods: We studied 161 patients (85 males and 76 females, median age 61 years old, range 51-90) with a diagnosis of MF, including PMF (n = 137, 85%), post-ET MF (n = 12, 7.5%), and post-PV MF (n = 12, 7.5%). Fibrosis grade 0 was found in 38%, grade 1 in 33%, grade 2 in 26% and grade 3 in 3% of patients. According to mutational status 129 (80%) patients were Jak-2 positive for the mutation V617F, 9 (5.5%) for CALR, 2 (1.5%) for MPL and 9 (5.5%) triple negative; for 9 (5.5%) patients the driver mutation status was not studied. Starting from March 2012, ruxolitinib was administered to 52/161 patients (40 of them with PMF, 8 with post-PV MF and 4 with post-ET MF) with dosage according to drug label. Spleen diameters were evaluated by physical examination before treatment and after 12 and 24 weeks of ruxolitinib continuous treatment. Neutrophils/Lymphocytes Ratio (NLR), derived Neutrophils/Lymphocytes Ratio (dNLR) Lymphocytes/Monocytes Ratio (LMR), Platelet/Lymphocytes Ratio (PLR) and Neutrophils/Platelet Ratio were calculated respectively on ANC/ALC, ANC/(WBC-ANC), ALC/AMC, PLT/AMC and ANC/PLT, as derived by hemocromocitometric exam at diagnosis and before ruxolitinib start. 40 normal volunteer ratios were used as controls.
Results: In the whole cohort of patients, NLR mean±DS was 4.7±3.5; dNLR was 2.9±1.7; LMR was 4.6±6.3; PLR was 349±429.3 and ANC/PLT ratio was 0.03±0.05. Patients with lower bone marrow fibrosis had lower mean±DS NLR (grade 0: 4.1±3.5, G1: 4.8±3.7, G2: 5.2±2.9, G3: 8.1±6.3, p<0.001). Similarly, ANC/PLT ratio had a progressive increase (from 0.015±0.020 in patients with grade 0, to 0.054±0.075, 0.089±0.303 and 0.521±0.01 respectively for grade 1, 2 and 3); conversely PLR was progressively decreased according to fibrosis grade (p<0.001). Restricting the analysis only to the 52 ruxolitinib treated patients, those who obtained a spleen reduction >50% in the first 12 weeks showed a lower NLR and ANC/PLT ratio before starting treatment (p=0.001). At 24 weeks, patients with lower NLR and ANC/PLT ratio had more chances to reduce spleen size of 100% (p<0.001). Since in clinical trials the absolute number of monocytes and lymphocytes is not often captured, in other hematological settings the derived NLR (dNLR) has been tested as surrogate of NLR. Despite dNLR was positively associated to bone marrow fibrosis grading, it was not able to predict spleen reduction from baseline in patients treated with ruxolitinib.
Summary/Conclusion: NLR and ANC/PLT ratio are increased in MF compared to normal controls and positively associated to bone marrow fibrosis. In patients treated upfront with ruxolitinib, NLR (but not dNLR) and ANC/PLT could help to predict spleen reduction both at 12 and 24 weeks. Our results need to be validated in larger cohorts, taking care to use NLR instead of dNLR.

PS1348

POSSIBLE SOMATIC MOSAICISM OF THE JAK2 GENE IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS

N. Mori[1,2,*], M. Ohwashi-Miyazaki[3], K. Yoshinaga[1], M. Shiseki[4], H. Sakura[5], J. Tanaka[4]

[1]Hematology, Tokyo Women's Medical University, [2]Internal Medicine, Tokyo Women's Medical University Medical Center East , Tokyo, [3]Hematology, Tokyo Women's Medical University, Toyko, [4]Hematology, Tokyo Women's Medical University, [5]Internal Medicine, Tokyo Women's Medical University Medical Center East, Tokyo, Japan

Background: *JAK2* V617F mutation has been identified in 95% of patients with polycythemia vera (PV) and in half of patients with essential thrombocythemia (ET) and primary myelofibrosis. The majority of patients with these myeloproliferative neoplasms (MPN) are sporadic, while a familial predisposition to MPN has been reported. Previous studies failed to identify germline *JAK2* V617F mutations in familial PV. *JAK2* SNP 46/1 is associated with a weak predisposition to MPN, but the *JAK2* 46/1 haplotype does not explain familial MPN. Germline mosaicism was reported in the *NF1* gene in hereditary neurofibromatosis and *RB1* gene in hereditary retinoblastoma, causing tumors in their children. Moreover, somatic *APC* mosaicism was estimated at a rate of about 20% in *de novo* cases of familial adenomatous polyposis.
Aims: To elucidate the presence of *JAK2* V617F mutation mosaicism, we analyzed mutations in blood and other tissues from MPN patients including siblings.
Methods: Twenty-three patients with V617F-positive PV (n=12) and ET (n=11) were analyzed. Two of the 12 PV patients were siblings (PV1 and PV2). Both of their parents had a medical history of cerebrovascular events but lacked polycythemia. Peripheral blood (n=22), bone marrow (n=1), hair (n=4), and nail (n=23) samples from the 23 patients were collected after obtaining written informed consent. Neutrophils from peripheral blood were purified by dextran sedimentation followed by hypotonic lysis and centrifugation with Ficoll-Conray. For screening of *JAK2* V617F, allele specific-polymerase chain reaction (AS-PCR) was performed. Electrophoresis was repeated at least twice using independent PCR products. Direct sequencing was performed in both directions using a 3730xL DNA Analyzer (Life technologies, Carlsbad, CA, USA). Measurement of DNA levels was based on TaqMan Mutation Detection Assays using StepOnePlus (Life technologies). Absolute quantification was conducted using the standard curve method with serially diluted DNA prepared from HEL (homozygous mutation) and HL60 (wild-type) cell lines, and commercial control (Horizon Discovery, Cambridge, UK) for *JAK2* V617F. *JAK2* SNP 46/1 was analyzed by direct sequencing. The current study was conducted with the approval of ethical committee.
Results: We first performed AS-PCR in PV1 and PV2. Sensitivity to the V617F mutation was 0.5%. Aberrant bands were observed in nail and hair DNA, while the intensity was low. We next performed AS-PCR in the other 21 patients. Aberrant bands of variable intensity were detected in 8 of the 21 nail DNA samples and one of the three hair DNA samples but not in hair DNA from the mother of PV1 and PV2. Direct sequencing showed G to T transversion at nucleotide 1849 (V617F mutation) in 22 blood DNA and 1 bone marrow DNA sample. Sensitivity of direct sequencing was 10%. The mutation was also confirmed by direct sequencing in 6 of the 8 nail DNA samples showing aberrant bands by AS-PCR, while it was unclear in nail DNA samples from PV1 and PV2. Quantitative real-time PCR of the *JAK2* gene was performed in the 23 patients. The allele burden of V617F mutation was more than 10% (12.7-38.4%) in 5 of the 6 nail DNA samples showing mutations by direct sequencing. All the 5 samples were from patients with PV. *JAK2* SNP 46/1 was analyzed and the G allele associated with V617F mutation was identified in 21 of the 23 patients.
Summary/Conclusion: Although germline V617F transmission was not observed in the siblings, detection of *JAK2* V617F mutation in nail and blood samples from the same individuals suggests somatic mosaicism of *JAK2* V617F mutation in a certain proportion of PV patients.

Myeloproliferative neoplasms – Clinical

MULTICENTER SURVEY ON MANAGEMENT AND OUTCOME OF A RARE HEMATOLOGIC DISEASE: ADULT ONSET HISTIOCYTOSES

D. Lazzarotto[1,*], A. Candoni[1], L. Melillo[2], M. Criscuolo[3], D. Michela[4], F. Forghieri[5], P. Minetto[6], F. Vianello[7], D. Capelli[8], M. E. Zannier[1], C. Filì[1], L. Pagano[3], R. Fanin[1]

[1]Division of Hematology and Stem Cell Transplantation, Azienda Sanitaria Universitaria Integrata di Udine, Udine, [2]Division of Hematology, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, [3]Division of Hematology, Policlinico Gemelli, Rome, [4]Section of Hematology, Vito Fazzi Hospital, Lecce, [5]Section of Hematology, Department of Surgical and Medical Sciences, University of Modena and Reggio Emilia, Modena, [6]Division of Hematology, Policlinico San Martino, University of Genova, Genova, [7]Hematology and Immunology Unit, Department of Medicine, University of Padova School of Medicine, Padova, [8]Division of Hematology, Azienda Ospedaliero-Universitaria Ospedali Riuniti di Ancona, Ancona, Italy

Background: Histiocytoses are a group of diseases that mainly affect children. Adult onset Histiocytoses are very rare and their management is mainly derived from small retrospective studies, expert opinions and the pediatric experience. The history of the disease is widely variable and often unpredictable in the single patient.
Aims: For these reasons we started a multicenter survey on presentation, management and outcome of Adult Histiocytoses in the last 15 years (2002-2017). This survey is still open to recruitment.
Methods: We report the preliminary data regarding 22 adult patients (pts) diagnosed with Histiocytosis. Eighteen/22 (82%) were affected by Langerhans cells Histiocytosis (LCH), 2 (9%) by Rosai-Dorfman Disease (RDD) and 2 (9%) by Histiocytic Sarcoma (HS).
Results: Median age at diagnosis was 42 (range 18-67) and there is an important male prevalence (M/F ratio 2.7/1). Fifteen/22 (68%) pts presented with tumor mass symptoms and 10/22 (45%) with systemic symptoms. BRAF V600E mutation was tested in 8/22 pts (only in most recent cases) but none of them was positive. Eight/22 (36%) presented with a single site involvement (3 bone involvement, 3 lymph node involvement, 1 CNS involvement, 1 pulmonary involvement) [GROUP 1-Single Site]. The three pts with bone involvement were treated with surgery alone, while the others with a combination of surgery and systemic therapy (median of 1 therapy line, range 1-3). The 5-year OS of these pts is 80%, but 63% had an active disease at last follow up. Fourteen/22 (64%) pts presented with multiple site involvement (bone, lymph nodes, lung the main involved organs) [GROUP 2-Multiple Sites]. All these pts received systemic therapy (a median of 1,5 therapy lines, range 1-7) combined with surgery in 3 pts and radiotherapy in 2 pts. The best response achieved was a complete response in 4/14 pts (28%) and a partial response in 6/14 (44%) pts, 4/14 (28%) were refractory to treatments. The median duration of the best response was 24 months (range 1-83). The 5-year OS of these pts is 77% but 79% had an active disease at last follow up. OS and the percentage of pts with active disease at last follow up was not different in the two groups. Finally, 4/18 surviving pts developed irreversible organ damage (pulmonary emphysema, chronic pancreatitis, persistent diabetes insipidus, severe bone lesions) (Figure 1).

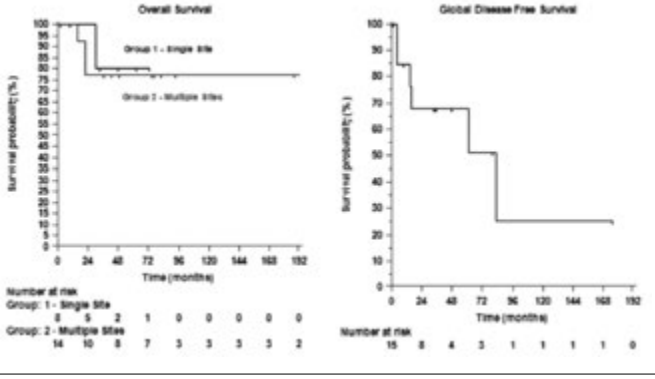

Figure 1.

Summary/Conclusion: Adult onset Histiocytoses are mainly chronic diseases in which the achievement of a complete and durable response with the current treatment options is unusual. Pts live together with their disease, its complications and the side effects of multiple therapies. Further studies are needed to discover other molecular alterations besides BRAF V600E (that is present in about 50% of cases) that can be targeted by specific therapies with the aim of improve response rates and allow pts to live without the disease and related complications.

PS1350

IS ANEMIA THE MAIN SURVIVAL MARKER IN PATIENTS WITH MYELOFIBROSIS IN THE RUXOLITINIB ERA?

M.I. Montero[1,*], E. Rodríguez-Arbolí[1], N. Alkadi[1], M. Reinoso[1], F.J. Márquez[1], E. Carrillo[1], F. de la Cruz[1], J. González[1], J. Falantes[1], I. Espigado[1], J.A. Pérez-Simón[1]

[1]Department of Hematology, Hospital Universitario Virgen del Rocío, Seville, Spain

Background: Approximately 50% of patients with myelofibrosis present with a haemoglobin concentration less than 100 g/L at diagnosis and one third of them will develop transfusion dependence during the course of their disease, which currently represents a clinical challenge without effective therapeutic options. The underlying mechanisms of anemia in this patient population are not well established, although it has been associated with ineffective hematopoiesis, elevated levels of proinflammatory cytokines, splenomegaly, mutations in several genes such as *UAF1* or downregulation of certain proteins such as in the case of GATA1.
Aims: Single centre analysis of the impact of anemia on survival and the association of response to erythropoietin treatment with JAK2 mutational status in a cohort of patients with myelofibrosis.
Methods: One-hundred nineteen patients diagnosed with myelofibrosis in our centre between June 1998 and July 2007 were included in the study. Average age at diagnosis was 67 years (range 19-88). Sixty-one percent of the patients were male and 39% female. Thirty-six percent had a previous diagnosis of another myeloproliferative neoplasm (polycythemia vera or essential thrombocythemia). Diagnosis of myelofibrosis was made based on bone marrow examination and according to the WHO criteria. V617F JAK2 status was assessed through allele-specific PCR in patients diagnosed after 2005. All patients with clinically significant anemia received treatment with erythropoietin. Statistical analyses were performed in SPSS 15.0.
Results: Average leucocyte, haemoglobin and platelet counts were $12{,}5x10^9$/L, 114 g/L and $344x10^9$/L, respectively. V617F JAK2 mutation was present in 61% of the patients. Thirty-one percent of the patients had a haemoglobin concentration less than 100 g/l at diagnosis and 47% developed transfusion dependence during the course of their disease.
Four-year overall survival (OS) was 69%. Four-year OS was 56% in patients with a haemoglobin concentration less than 100 g/l and 77% in those with a haemoglobin concentration of at least 100 g/l, statistical significance not being reached. Four-year OS in those patients who developed transfusion dependence was 60%, compared with 78%% in those without transfusion dependence (p=0.03). Only 20% of the patients with a V617F JAK2 mutation died compared with 56% of the patients with wild-type mutational status. However, four-year OS rates among patients developing transfusion dependence were similar irrespective of their mutational status (65% if V617F JAK2-positive vs. 60% if wild-type).
Summary/Conclusion: 1. Patients who develop transfusion dependence during the course of their disease show lower overall survival, with statistically significant differences, which is consistent with published data. 2. Patients with anemia and V617F JAK2 mutations respond better to erythropoietin treatment than those with JAK2 wild-type status, which indicates that the stimulation of the main pathogenic pathway in the disease may paradoxically contribute to overcome this problem.

Background: Deferasirox (DFX) is the currently available iron-chelation therapy (ICT) for the management of iron overload (IOL) in patients (pts) with myelodysplastic syndromes, while in myelofibrosis (MF) information are limited.
Aims: The primary endpoint of the study was the efficacy of DFX in terms of reduction of ferritin levels and improvement of erythroid response (according to IWG-MRT and Cheson IWG criteria). Additional endpoints were safety of DFX and survival.
Methods: We retrospectively collected 45 consecutive pts (M: 27; F: 18) with primary MF (n=30) or post-Polycythemia Vera MF (n=9) and post-Essential Thrombocythemia MF (n=6), according to WHO and IWG-MRT 2008 criteria, with transfusion-dependent anemia, treated with DFX since 2010. Data have been collected in 11 centers of Hematology belonging to the regional network REL (Rete Ematologica Lombarda). The protocol (IRON-M study) has been approved by each local ethic committee.
Results: The main features at diagnosis and at baseline of DFX treatment were reported in Table 1.

Table 1.

Clinical Features of patients at diagnosis and at baseline of Deferasirox treatment

Gender M/F, n (%)	27/18 (60/40)
Type of MF, n (%)	
Primary myelofibrosis	30 (66.6)
POST-PV myelofibrosis	9 (20)
POST-ET myelofibrosis	6 (13.3)
IPSS Classification, n (%)	
Low risk /Intermediate-1 risk	18 (40)
Intermediate-2 risk - High risk	27 (60)
Driver mutations, n (%)	
JAK2V617F positive	39 (86.6)
MPL positive	0
Calreticulin positive	3 (6.7)
Triple-negative	3 (6.7)
Median age at diagnosis, years (IR)	69.2 (40-80.4)
Median ferritin levels at diagnosis, ng/ml (IR)	446 (25-1994)
Median Hb at diagnosis, g/dl (IR)	10 (4.2 – 15.7)
Median WBC at diagnosis, /mm3 (IR)	6.68 (2.49-26.12)
Median PLT at diagnosis, /mm3 (IR)	253 (50-1360)
Median age at baseline, years (IR)	71.6 (47.6-81.5)
Median ferritin levels at baseline, ng/ml (IR)	1609 (900-4000)
Median Hb at baseline, g/dl (IR)	8.6 (5.7-10.9)
Median WBC at baseline, /mm3 (IR)	8.49 (0.78-38.63)
Median PLT at baseline, /mm3 (IR)	150 (12-1050)
Median time between initiation of transfusion dependence and start DFX, months (IR)	12.5 (1-146)
Median of packed red cells units/patient received, at baseline, n (IR)	28 (5-150)

ET: Essential Thrombocythemia; PV: Polycythemia Vera; IPSS: International Prognostic Scoring System; HB. Hemoglobin; WBC: White Blood cells; PLT: platelet count; IR: interquartile range.

According to the IPSS classification, 18 pts (40%) resulted low/intermediate-1 risk and 27 (60%) intermediate-2 risk/high-risk. Pts started DFX after a median time from MF diagnosis of 26.5 months (IR 2.6-208.7) and from transfusion dependency of 12.5 months (IR 1.2-146). Median value of packed red cells units/patient received was 28 (IR 5-150). The median ferritin levels at baseline was 1609 ng/mL (IR 900-4000). The median starting dose of DFX was 750 mg/day (10 mg/kg/day).
41/45 pts (91.1%) were evaluable for efficacy (> 3 months of DFX) and the median time of DFX exposure was 15.6 months (IR 3-59.5); among these pts, 12 (29.3%) pts obtained a stable reduction of ferritin levels < 1000 ng/mL, defined as iron chelation response (IRC). An erythroid response (ER) with DFX were observed in 18/41 pts (43.9%), 7 of them (17%) obtained transfusion independency (TI). The median time to best ER was 2.4 months. After a median follow-up of 52.8 months (IR 14.4-267.2) from diagnosis, 18/41 pts (43.9%) died, 8 of them for leukemic evolution or progression of disease. Overall, pts with ER receiving DFX showed a progressive reduction of ferritin levels at 6, 12 and 18 months respect to baseline, in contrast to non-responder (NR) pts. We did not observe a significant difference in OS from DFX initiation in ER respect to NR pts (31.7 vs 42.2 months, p=0.57). Conversely, 2-year survival from DFX initiation was 100% in pts who obtained a IRC compared to 68% in pts without IRC (p=0.001). All 45 patients were evaluable for toxicity: extra-hematological drug-related adverse events (AEs) were reported in 16 (35.5%) pts, principally consisting in renal (17.7%) or hepatic impairment (8.9%) and skin reaction (6.7%). Eleven (24.4%) pts discontinued definitively treatment due to toxicity of grade ≥2.
Summary/Conclusion: The present multicenter study reported a large retrospective series of MF pts treated with DSX. We showed that ICT with DFX is effective and safe in MF. Hematological improvement with erythroid responses can occur in a significant proportion of pts. Obtainment of ICR seems to be predictive for better survival. Further larger and prospective investigations are required.

PS1352

MYELOID AND LYMPHOID NEOPLASMS ASSOCIATED WITH PDGFRA AND PDGFRB REARRANGEMENTS: CLINICAL CORRELATES AND SURVIVAL OUTCOMES

A. Mangaonkar[1,*], N. Gangat[1], A. Al-Kali[1], K. Begna[1], M. Elliott[1], C. Hook[1], W. Hogan[1], M. Litzow[1], R. Ketterling[1], A. Tefferi[1], A. Pardanani[1], M. Patnaik[1]

[1]Hematology, Mayo Clinic, Rochester, United States

Background: Myeloid/lymphoid neoplasms with *PDGFRA* & *PDGFRB* rearrangements are incorporated under a separate category as per the 2016 World Health Organization (WHO) classification, due to their unique disease biology & sensitivity to tyrosine kinase inhibitors.
Aims: We undertook this study to describe clinical correlates and survival outcomes in patients with WHO-defined myeloid/lymphoid neoplasms associated with *PDGFRA & PDGFRB* rearrangements.
Methods: Consecutive cases of WHO-defined myeloid/lymphoid neoplasms with FISH detectable *PDGFRA* & *PDGFRB* rearrangements were identified from our institutional database, from years 1997-2017 & bone marrow biopsy/cytogenetic reports were re-reviewed.
Results: Twenty five patients were included in this study (Table 1); 23 (92%) males with a median age of 43 years (range: 19-84). Twenty one had FISH detectable *PDGFRA* [20 *CHIC2* deletions &/or t(4;12)(q12;p13) and 1 t(4;22)(q12;11.2)], while 4 had *PDGFRB* [2 *ETV6-PDGFRB* or t(5;12)(q32;p13.2), 1 t(5;19)(q32;p13.3) & 1 t(5:16)(q32;p22)] rearrangements. Of these, only 2 (9.5%) *PDGFRA* and 3 (75%) *PDGFRB* rearrangements were detected by metaphase cytogenetics. Clinical phenotypes associated with *PDGFRA* rearrangements at diagnosis included, chronic eosinophilic leukemia (CEL) 9 (43%), systemic mastocytosis with an associated hematological neoplasm 6 (29%), acute myeloid leukemia (AML) 3 (14%), myeloproliferative neoplasms-unclassifiable 2 (10%) & T-cell lymphoblastic leukemia (ALL) 1 (5%); while those for *PDGFRB* rearrangements included, chronic myelomonocytic leukemia 2 (50%), CEL 1 (25%) & B-cell ALL 1 (25%). Concurrent cytogenetic abnormalities at diagnosis were seen in 4 (18%) of 22 assessable patients and included trisomy 12, del(7q), t(2;22)(q11.2;p11.2), trisomy 5, del(9)(p21.1) & t(18;21)(q21;q22); while two patients acquired del(3q) and a FISH detectable duplication of 3q26 (3 copies of MECOM) correlating with transformation to AML. Of the 22 (88%) patients with available treatment data, 20 (91%) received imatinib, with median doses of 100 & 400 mg daily for *PDGFRA* & *PDGFRB* rearrangements respectively. Overall response rate was 100% for both *PDGFRA* & *PDGFRB* rearrangements [Complete response (CR)-15, partial response (PR)-2, hematologic response (HR)-2, & stable disease-1] with median response durations of 25 (range: 5-170) months. All 4 (20%) patients that did not achieve a CR with imatinib had *CHIC2* deletions; 3 (75%) with a CEL clinical phenotype, while one had an MPN-U. Three (12%) patients (*PDGFRA-100%)* had evidence of eosinophilic cardiomyopathy at diagnosis, 1 (4%) of whom developed worsening cardiomyopathy after starting therapy with imatinib. At last follow-up (median 40 months), 2 (9%) transformations into AML (both AML with MDS-related changes) & 3 (12%) deaths (1-AML, 1-unknown, 1-nonhematologic medical complications) were documented. Within significant limitations of a small sample size, patients with *PDGFRA* rearragments have a better median OS (median not reached) in comparison to those with *PDGFRB* rearrangements (median 66 months, Figure 1).

Table 1.

Variable; Median value (range or %)	Cohort (n=25)	PDGFRA (n=21)	PDGFRB (n=4)	P value
Age (Range in years)	43 (19-84)	43 (19-71)	47 (30-84)	0.5
No. of Males (%)	23 (92)	20 (95)	3 (75)	0.24
Hemoglobin (Range; g/dL)	12.9 (7.2-15.4)	13.3 (7.2-15.4)	8.9 (7.9-10.9)	0.05*
WBC count X 10^9 per L	10 (0.4-116.2)	10.9 (3.5-75.4)	7.2 (0.4-116.2)	0.24
Platelet count X 10^9 per L	152 (24-355)	156.5 (31-355)	103 (24-166)	0.06
Absolute eosinophil count X 10^9 per L	2 (0-23)	2 (0-23)	1.4 (0.6-3.5)	0.44
Absolute monocyte count X 10^9 per L	0.4 (0-35)	0.4 (0-1.5)	1.1 (0.4-35)	0.02
Lactate dehydrogenase (U/L)	165 (107-1517)	164 (107-1117)	823 (166-1517)	0.006*
BM blasts % (Range)	2 (0-97)	2 (0-53)	2 (0-97)	0.25
Concurrent diagnostic cytogenetic abnormalities not involving PDGFRA/PDGFRB rearrangements (%)	4 (18)	2 (10) [Trisomy 12, del(7q)]	2 (50) [t(2;22)(q11.2;p11.2), trisomy 5, del(9)(p21.1) & t(18;21)(q21;q22)]	0.1
Imatinib treatment (%)	20 (91)	17 (89)	3 (75)	0.4
Median imatinib induction dose (Range in mg)	100 (100-400)	100 (100-400)	400 (100-400)	0.02*
Transfoemation into AML after diagnosis (%)	2 (9)	2 (9.5)	0 (0)	0.4
Number of deaths (%)	3 (12)	1 (5)	2 (50)	0.03*
Allogeneic SCT (%)	2 (8)	1 (5)	1 (25)	0.24
Overall survival (OS, range in months)	Median not reached	Median not reached	66 (4-102)	-

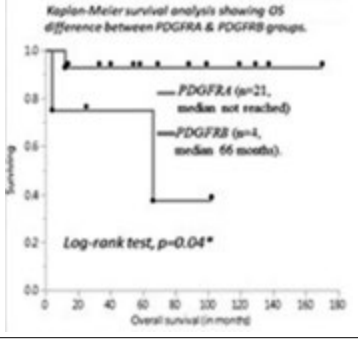

Figure 1.

Summary/Conclusion: Myeloid and lymphoid neoplasms associated with *PDGFRA* and *PDGFRB* rearrangements present with a spectrum of clinical phenotypes often characterized by eosinophilia (*PDGFRA*) and monocytosis (*PDGFRB*), can be karyotypically occult (*CHIC2* deletions), and in general have a good response to tyrosine kinase inhibitor therapy (ORR-100%). The impact of additional cytogenetic abnormalities at diagnosis, cytogenetic clonal evolution on therapy and suboptimal responses to imatinib, on outcomes, needs to be explored in a larger cohort.

PS1353

ASSESSING SERUM ALBUMIN CONCENTRATION, LYMPHOCYTE COUNT AND PROGNOSTIC NUTRITIONAL INDEX MIGHT IMPROVE PROGNOSTICATION IN PATIENTS WITH MYELOFIBROSIS

M. Lucijanic[1,*], T. Stoos-Veic[2], A. Livun[3], V. Pejsa[1], D. Cicic[4], A. Maglicic[5], R. Kusec[1]

[1]Hematology Department, [2]Cytology and Cytometry Department, [3]Clinical Department of Laboratory Diagnostics, University Hospital Dubrava, [4]Hematology department, Clinical Hospital Dubrava, Zagreb, [5]Health Care Center Vojnic, Vojnic, Croatia

Background: Primary and secondary myelofibrosis (PMF; SMF) are malignant diseases of the hematopoietic stem-cell characterized by the neoplastic myeloproliferation and strong inflammatory milieu. Prognostic-Nutritional-Index (PNI) integrates information on albumin and absolute-lymphocyte-count (ALC) and reflects inflammatory, nutritional and immune status of a patient. Clinical and prognostic significance of albumin, ALC and PNI in patients with myelofibrosis have not been previously investigated.

Aims: To assess clinical and prognostic significance of albumin, ALC and PNI in a population of myelofibrosis patients.

Methods: We retrospectively analyzed a cohort of 83 myelofibrosis patients treated in our institution from 2006 to 2017, 63 (75%) had PMF and 20 (25%) had SMF. A total of 69 (83%) patients were evaluated at the time of establishing diagnosis. Albumin, ALC and PNI were assessed in addition to other disease-specific parameters. The Kruskal Wallis test, the Mann Whitney U test, the Chi squared test, the Spearman rank correlation, the log-rank test and the Cox regression analysis were used. Optimal cut-off values were determined using the ROC curve analysis.

Results: Mean patient age was 65.6 ±10.4 years, 61% were males. Median follow up was 54 months. PMF and SMF patients had significantly lower ALC and PNI ($p<0.05$) and similar albumin (n.s.) compared to controls, there was no difference between PMF and SMF patients (n.s.). Lower albumin was significantly associated ($p<0.05$) with older age and parameters reflecting more aggressive disease biology (anemia, lower platelets, higher LDH, circulatory-blasts, transfusion-dependency, blast-phase-disease), inflammation (higher CRP, constitutional-symptoms) and higher degree of bone-marrow-fibrosis. Lower ALC was significantly associated ($p<0.05$) with lower white-blood-cells (WBC) and lower circulatory-blasts. Low PNI was significantly associated ($p<0.05$) with lower albumin, lower ALC, anemia, lower WBCs, lower serum-iron and lower transferrin-saturation. There was no difference in albumin, ALC and PNI regarding the driver-mutations. Low-albumin, low-ALC and low-PNI were all significantly associated with inferior survival ($p<0.05$) as shown in a Figure 1. In multivariate analysis adjusted for age and gender, low-albumin (HR=4.61, p=0.001), low-ALC (HR=3.54, p=0.004) and DIPSS (HR=2.45, p=0.001) were able to predict inferior survival independently of each other. Accordingly, low-PNI (HR=4.32, $p<0.001$) predicted poor survival independently of DIPSS (HR=3.31, $p<0.001$).

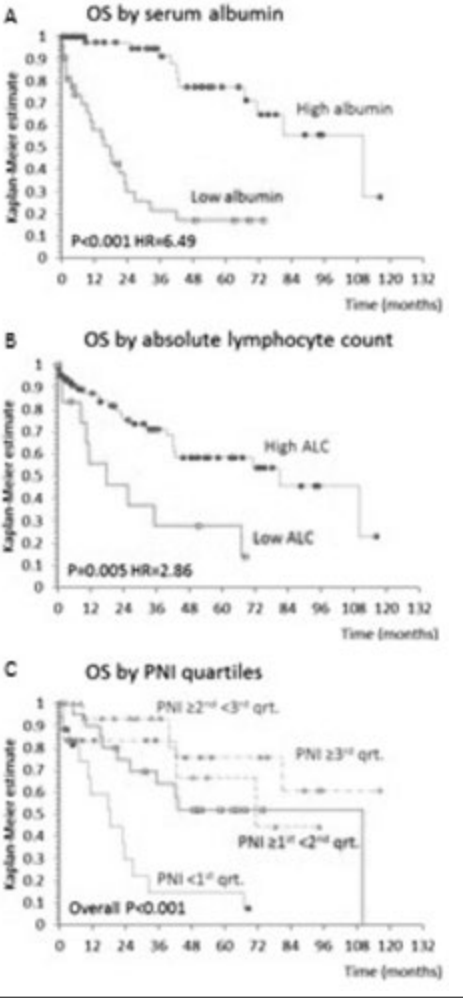

Figure 1.

Summary/Conclusion: Assessing albumin, ALC and PNI might improve prognostication in patients with myelofibrosis and could assist in recognition of patients under increased risk of death.

PS1354

LONG-TERM OUTCOME OF PATIENTS WITH SPLANCHNIC VEIN THROMBOSIS AND MYELOPROLIFERATIVE NEOPLASMS: A SINGLE CENTER EXPERIENCE

D. Lekovic[1,2,*], P. Miljic[1,2], J. Bodrozic[1], D. Culafic[2,3], D. Sefer[1], S. Bizic[1], V. Djordjevic[1], R. Jesic[2,3], M. Gotic[1,2]

[1]Clinic for Hematology, Clinical Center of Serbia, [2]Medical Faculty, University of Belgrade, [3]Clinic of Gastroenterology and Hepatology, Clinical Center of Serbia, Belgrade, Serbia

Background: According to literature data splanchnic vein thrombosis (SVT) involving portal, splenic, mesenteric or hepatic (Budd–Chiari sy,BCS) veins occur in about 1-23% of patients with MPNs. However, there is little data about influence of SVT on long-term outcome in these patients (pts).
Aims: Aim of our study was to analyze clinical course and to identify parameters influencing long-term outcomes in MPNs pts with SVT.
Methods: We retrospectively analyzed 42 consecutive MPNs pts with SVT (15 PV, 17 PMF, 3 ET, 7 latent MPN) who were diagnosed and followed in our clinic from July 1994 to November 2017. Diagnosis of MPN was established according to the WHO criteria. Latent MPN was characterized with positive *JAK2V617F* mutation or/and presence of spontaneous erythroid colony formation but without clear hematological criteria for MPNs. In all pts, SVT was confirmed by Doppler ultrasound examination of portal system or/and CT. In this study we analyzed following outcomes: occurrence of gastrointestinal (GI) bleeding episodes, SVT rethrombosis and overall survival (OS). Following parameters potentially influencing clinical outcomes were investigated: location of thrombosis, *JAK2V617* mutation, CBC, cytogenetics, treatment modalities, presence of portal hypertension, cardiovascular traditional risk factors and additional risk factors for thrombosis.
Results: Median age at MPN diagnosis was 43 years (range 19-67). Patients with BCS were significantly younger with median age of 30.5 years (p=0.007). Female gender was prevalent (59.5%). In 50% of pts, MPN was diagnosed within 3 months after onset of SVT. Additional risk factors for thrombosis had 14pts (33.3%). SVT type was BCS in 14.3% (1 latent, 4 PV, 1 ET), portal thrombosis in 83.3% (6 latent, 10 PV, 17 PMF, 2 ET) and isolated splenic thrombosis in 2.4% of pts (1 PV). According to the initial grade (Gr) of esophageal varices (EV) in 34 analyzed cases, pts were distributed as follows: Gr1 had 7pts (20.6%), Gr2 had 9 (26.5%), Gr3 had 9 (26.5%), Gr4 had 3 (8.8%), while 6pts (17.6%) didn't have EV at all. Treatment included hydroxyurea (HU) plus OACs in 16pts (38.1%), HU plus LMWH in 4 (9.5%), HU in 12 (28.6%), OACs only in 6 (14.3%), HU plus ASA in 1(2.4%), ASA only in 1(2.4%). Two pts (4.8%) were untreated. During median follow-up of 90.5 months (range 4-276) at least one GI bleeding experienced 15pts (35.7%), recurrence of SVT had 2pts (4.8%) while 10pts (23.8%) had died at median age of 51 years (range 37-72). The OS at 5, 10 and 15 years was 87.8%, 73,3% and 59,6% respectively. Median follow up until death was 76 months (range 25-192). Death was directly related to liver failure in 4 pts, GI bleeding in 3, AML in 1, while in 2 pts cause of death was unknown. Out of analyzed factors potentially influencing survival significant association with shorter OS was found for avoidance of cytoreductive treatment (p=0.001), age>60 years (p=0.005), Le>15x10^9/L (p=0.003) and initial Gr of EV>1 (p=0.019). However in multivariable Cox-regression model, cytoreductive treatment retained a statistical significance for OS only (HR 0.91, 95% CI 0.837-0.989 p=0.026).
Summary/Conclusion: Our results confirmed that SVT is often first clinical manifestation of an underlying disease, highlighting the need for thorough screening for MPNs. Introduction of cytoreductive treatment favorably influenced long-term outcomes in pts with SVT and MPN. Mortality was mainly caused by liver failure and esophageal varices bleeds, so successful management of these pts requires long-term team work of haematology and hepatology specialists.

PS1355

GENDER EFFECT ON PHENOTYPE AND GENOTYPE IN PATIENTS WITH POST-POLYCYTHEMIA VERA AND POST-ESSENTIAL THROMBOCYTHEMIA MYELOFIBROSIS: RESULTS FROM THE MYSEC PROJECT

Bortolo, Vicenza, Italy, [15]Hematology, Weill Cornell Medical College, New York, United States, [16]Hematology, SC Hematology, A.O. Città della Salute e della Scienza, Turin, [17]Hematology, Università di Bari, Bari, [18]Hematology, Research Foundation, ASST Papa Giovanni XXIII, Bergamo, Italy

Background: Survival difference between men and women in the general population is well recognized and consistent sex-discrepancies are common within hematologic malignancies. Additionally, there is developing interest in understanding how gender influences the pathogenesis, phenotype and outcome in myeloproliferative neoplasms (MPN).
Aims: The aim of the current study is to evaluate the prognostic impact of gender in the study-population of the multicentric MYSEC (Myelofibrosis Secondary to PV and ET Collaboration) project including 781 patients with post-polycythemia vera (PPV-MF) and post-essential thrombocythemia (PET-MF) myelofibrosis.
Methods: The study was approved by the Ethical Committee of each Institution and conducted in accordance with the Declaration of Helsinki. Diagnoses of secondary myelofibrosis (SMF) were performed between 1981 and 2015 and were locally reviewed according to the International Working Group on Myeloproliferative Neoplasm Research and Treatment criteria (IWG-MRT 2008). Wilcoxon rank sum and Pearson's chi-squared tests were performed to report differences between groups whereas Kaplan-Meier estimators, log-rank tests and Cox regression models were used for time-to-event analysis.

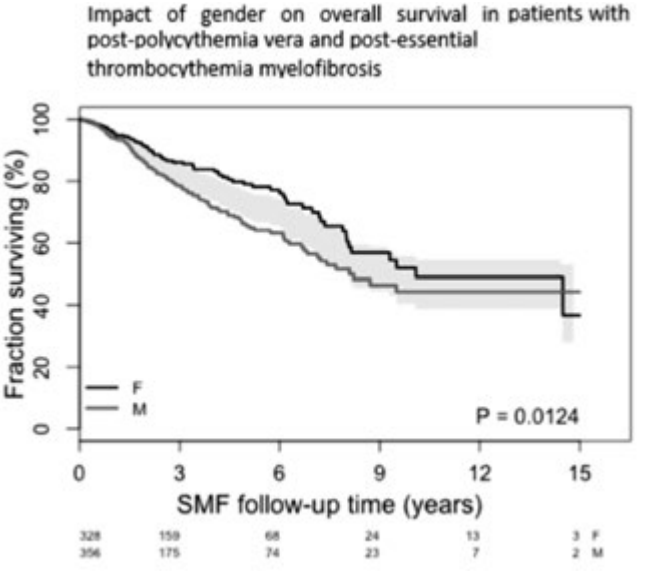

Figure 1.

Results: Within the whole cohort of 781 SMF patients, 684 had the driver mutational status available. Overall, 328 patients were female (48%): the female/male ratio was 0.92. The cohort consisted of 332 PET-MF and 352 PPV-MF, of which 167 (50%) and 161 (46%) females, respectively (p=0.23). The driver mutational status of females was *JAK2* in 257 (78%), *CALR* in 47 (14%), *MPL* in 17 (5%), triple negative in 7 (TN, 2%). Within PET-MF cohort, the distribution of driver mutations in females was as follow: 96 *JAK2*-pos (57%), 47 *CALR*-pos (28%), 17 *MPL*-pos (10%), 7 TN (4%). No significant differences have been found respect to males (p=0.57). Female gender distribution per genotypes was as follows: 46% in *JAK2*-pos PPV MF, 53% in *JAK2*-pos PET MF, 46% in *CALR*-pos, 57% in *MPL*-pos, 37% in TN cases (P =0.9). In the whole cohort, female sex was associated

with lower hemoglobin values (p=0.036), higher platelet count (p=0.041), smaller spleen size (p=0.016). Within the PET-MF cohort, female sex was significantly associated with smaller spleen size (p=0.024) and higher LDH values (p=0.021) and lower frequency of peripheral blood blasts ≥ 1% (p=0.027). No significant gender-related differences were found in terms of thrombotic events and leukemic transformation during follow-up. It is intriguing to observe that diagnosis of ET and PV occurred at younger age in females when compared to males (median 50 *vs.* 53 years, p=0.027), but the time to SMF progression resulted longer in females (median 11.3 *vs.* 10.1 years, p=0.015), eventually resulting in a superimposable age at the time of SMF transformation between gender (median 63 *vs.* 65 years, p=0.23). Overall survival from diagnosis of SMF was significantly inferior in male patients (p=0.012, log rank test, Figure 1), even after adjusting for age (HR 1.30, 95% CI 0.87-1.94; p=0.03, Cox regression model). When adding gender to the MYSEC-PM risk categories, we obtained a minor improvement of survival prediction (HR 1.36, 95% CI: 1.0-1.9; p=0.078).
Summary/Conclusion: Observations from the current study suggest that women are characterized by a specific phenotype and superior survival. Although the underlying causes remain unknown, host factors such as hormonal influences, occupational exposures, and lifestyle factors could influence the pathogenesis of MPN.

PS1356

TARGETED TREATMENT WITH DIVERSE TYROSINE KINASE INHIBITORS IN PATIENTS WITH PCM1-JAK2, BCR-JAK2 AND ETV6-ABL1 POSITIVE EOSINOPHILIA-ASSOCIATED MYELOID/LYMPHOID NEOPLASMS

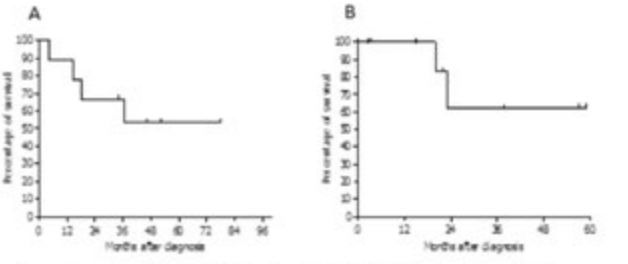
Background: More than 70 different tyrosine kinase (TK) fusion genes have been identified in clinically and morphologically distinct eosinophilia-associated myeloid/lymphoid neoplasms (MLN-eo) in chronic or blast phase (BP). Targeted treatment with TK inhibitors (TKI) may be highly effective, e.g. rapid and durable complete remissions on imatinib in patients with *PDGFRA* or *PDGFRB* fusion genes. Patients with fusions involving other TK tend to have more aggressive phenotypes, but clinically significant responses have been reported with ruxolitinib (ruxo) for cases with *JAK2*, e.g. *PCM1-JAK2* in t(8;9)(p22;p24), and imatinib/nilotinib/dasatinib (nilo/ima/dasa) for cases with *ETV6-ABL1* fusions in t(9;12)(q34;p13).
Aims: We here report on phenotype and clinical course of 18 patients who have been treated with ruxo (*PCM1-JAK2*, n=8; *BCR-JAK2*, n=1) or ima/nilo/dasa (*ETV6-ABL1*, n=9), respectively.
Methods: -
Results: Figure 1 A. *PCM1*- and *BCR-JAK2* fusion genes. The median age was 63 years (range 29-73), 8/9 patients were male. Significant clinical findings included leukocytosis (9/9), eosinophilia ≥1.5x10^9/l (5/8) and splenomegaly (5/9), and in the bone marrow abnormal erythropoiesis (6/8) and marked fibrosis (7/8). At diagnosis, 2/9 patients were in BP. On ruxo (median 24 months, range 2-36), 5/9 patients achieved a complete hematologic remission (CHR) after a median of 4 months (range 2-18), and 2 of those patients even a complete cytogenetic remission (CCR). Five patients underwent allogeneic stem cell transplantation (allo SCT) because of loss of CHR (n=1), loss of CCR (n=1), clonal evolution (n=1) or as planned prior to ruxo treatment (n=2). Following allo SCT, 2 patients died due to a high-grade B-cell lymphoma with complex karyotype at month +5 or due to ruxo-resistant relapse at month +6 in a patient with initial diagnosis of BP. One patient developed a Hodgkin's lymphoma at month +43 after allo SCT while in CCR. After a median of 37 months (range 4-78) from diagnosis, 4/9 patients are alive after allo SCT (n=3) or on ruxo only (n=1), respectively. Figure 1B. *ETV6-ABL1* fusion gene. The median age was 46 years (range 20-68), 7/9 patients were male. Significant clinical findings included leukocytosis (6/7), eosinophilia ≥1.5x10^9/l (9/9) and splenomegaly (4/6). At diagnosis, 3/9 patients were in BP. All patients received a TKI up-front (ima, n=5; nilo, n=3; dasa, n=1). On ima, 4/5 patients had no response or had progressive disease while 3/4 patients on nilo (n=2) or dasa (n=1) achieved at least a CHR after a median of 5 months (range 2-18). In due course, 6/9 patients (ima, n=5; nilo, n=1) were switched to nilo or dasa because of inadequate response or progressive disease. Two patients underwent allo SCT while in CCR or because of progressive disease. After a median of 23 months (range 3-60) from diagnosis, 2 patients died because of resistant disease, 1 patient is alive with progressive disease and 6 patients are in CCR or complete molecular remission on dasa (n=3), nilo (n=2) or following allo SCT (n=1).



Overall survival (A) of 9 patients with a *PCM1-JAK2* or *BCR- JAK2* fusion gene (median follow-up 37 months, range 4-78) and (B) 9 patients with an *ETV6-ABL1* fusion gene (median follow-up 23 months, range 3-60), respectively.

Figure 1.

Summary/Conclusion: a) Patients with MLN-eo and *PCM1-JAK2*, *BCR-JAK2* or *ETV6-ABL* fusion genes are predominantly male, do not always present with eosinophilia and have an aggressive clinical phenotype, b) treatment with TKI (ruxo for *JAK2* and ima/nilo/dasa for *ABL1* fusion genes) can induce responses, however, lack of response or resistance may be observed in a significant proportion of patients, d) nilo and dasa should be preferred in *ETV6-ABL1* positive MPN-eo and e) allo SCT should be considered in all eligible patients but optimal timing remains to be defined.

PS1357

MANAGEMENT AND OUTCOME OF 25 PREGNANCIES IN WOMEN WITH POLYCYTHAEMIA VERA

I. Bertozzi[1,*], E. Rumi[2,3], C. Cavalloni[3], M. Cazzola[2,3], F. Fabris[1], M.L. Randi[1]

[1]Department of Internal Medicine - DIMED, University of Padova, Padova, [2]Department of Molecular Medicine, University of Pavia, [3]Department of Hematology Oncology, Fondazione Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS) Policlinico San Matteo, Pavia, Italy

Background: Polycythaemia Vera (PV) may occur in women of childbearing age, although more rarely than Essential Thrombocythemia (ET). Pregnancy may therefore be an issue in the clinical management of rare young women with PV. In previous papers, we observed that about 1/3 of pregnancies in ET patients ends with an abortion and that there is an association between JAK2V617F mutation and late foetal loss. Data about pregnancy outcomes in PV are lacking. The largest series so far published reports 18 pregnancies in 8 PV patients with an overall rate of healthy neonates of 61% and mother complications of 22.2% (Robinson *et al.* Haematologica 2005). Then we found interesting to describe our experience in 25 pregnancies in PV.
Aims: We retrospectively analysed pregnancy outcomes and complications in our cohort of 15 young females with PV.
Methods: Our study includes 25 pregnancies in 15 females affected by PV (mean age 29.5±7.8 y at diagnosis and 34.3±3.9 y at conception; median follow-up 17 y range 2.9-33.3) who were diagnosed and followed between

1984 and 2017 at the First Medical Clinic of Department of Medicine, University of Padova and the Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo, Pavia. PV diagnosis has been performed or revised in agreement with WHO 2016 criteria. All but one of our 15 patients had available JAK2 mutational status: 12 (85.7%) carried V617F (mean allele burden 36±19%) and 2 carried Exon 12 mutation. Therapeutic approach has been assessed. The Fisher's exact test was adopted for the comparison of categorical variables.
Results: Within our 15 PV patients, 7 (28%) had one, 6 had two and 2 had three pregnancies. One pregnancy, ended by voluntary abortion, was excluded from the analysis of pregnancy outcome. Three out of our 15 patients developed multiple abortion during follow-up. Among 24 pregnancies, 10 (41.7%) ended with a full term and 5 (20.8%) with preterm delivery, while 9 (37.5%) were complicated by foetal loss (5 in the first-trimester, 2 in the second and 2 in the third), 4 (16.7%) by maternal complications, and 1 (5%) by intrauterine growth retardation. Each of the 2 patients with Exon 12 mutation experienced one pregnancy without complications. The total live birth rate was 62.5%. All patients received phlebotomies as required. One patient has been administered with IFN-a during both pregnancies. Eleven patients (73.3%) received antithrombotic drugs: 9 received low-dose aspirin during 16 pregnancies, 2 received low-dose aspirin and LMWH during 3 pregnancies.
Summary/Conclusion: On the best of our knowledge, this is the largest series of pregnancies described in PV patients. Our data shows that PV patients develop pregnancy complication in about 1/3 of cases, similarly to that reported by us for ET, and the live birth rate is in agreement with the paper of Robinson *et al.*; however maternal complications seem less frequent in our cohort. The high rate of late foetal loss that we have observed (16.7%) could be related to the presence of JAK2V617F mutation as described in ET. Interestingly the two patients carrying Exon12 mutation had both uneventful pregnancies. While most of our patients received antiplatelet drugs during pregnancy and post-partum LMWH, all but one was managed before the CYTO-PV study and therefore haematocrit was not aggressively controlled. Considering that at present the therapeutic approach in PV is more aggressive, we can surmise a future improvement in the outcome of pregnancy in PV patients.

PS1358

PEGYLATED INTERFERON ALPHA-2B VERSUS ALPHA-2A FOR THE TREATMENT OF ESSENTIAL THROMBOCYTHEMIA: EFFICACY AND SAFETY PROFILE

N. Pugliese[1,*], I. Cappuccio[1], A. Casoria[1], M. Raimondo[1], L. Simeone[1], G. Campagna[1], D. De Novellis[1], F. Pane[1], V. Martinelli[1]

[1]University of Naples Federico II, Naples, Italy

Background: Interferon-alfa (IFN-α) is a non-leukemogenic and effective therapy in controlling platelet count in patients with Essential Thrombocythemia (ET). However, this therapy is associated with significant adverse events and a discontinuation rate greater than 20%. Some studies demonstrated that PEGylated interferon α-2b and α-2a in ET (PEG-IFN-α-2b and PEG-IFN-α-2a) has a superior pharmacokinetic and toxicity profile compared to IFN- α. PEG-IFN has effectively been used to induce hematologic and molecular responses in ET patients. To the best of our knowledge, no study has been performed to compare the efficacy and safety of PEG-IFN-α-2a and PEG-IFN-α-2b.
Aims: The aim of our study was to compare the efficacy and toxicity profile of two formulations of PEG-IFN for the treatment of ET patients.
Methods: Patients with ET treated at our Department, Hematology of Federico II University of Naples, with PEG-IFNα-2b subcutaneously at a starting dose of 50 or 80 μg weekly, or with PEG-IFNα-2a, subcutaneously at a starting dose of 135μg weekly were examined. Therapeutic response was calculated by the revised ELN/IWG-MRT criteria including complete remission (CR), partial remission (PR) and no response (NR). Toxicity to therapy was assessed using the CTCAE 4.0 criteria.
Results: From January 2003 to January 2018, fifty-five patients received PEG-IFNα-2b, whereas forty patients received PEG-IFNα-2a. The median follow-up time was 52.1 months for the PEG-IFNα-2b group vs 38 months for the PEG-IFNα-2a group. A total of 41 (74.5%) patients in the PEG-IFNα-2b group achieved CR, as compared with 36 (90%) in the PEG-IFNα-2a group (p=0.06), the median time to achieve CR was 1 month for both groups. PR rate was higher in the PEG-IFNα-2b group compared with the PEG-IFNα-2a group (20% vs 2.5%, p=0.01), NR rate was similar (PEG-IFNα-2b 5.5% vs PEG-IFNα-2a 7.5%, p=0.79). Eleven patients who received PEG-IFNα-2b (20%) and one patient who received PEGIFN-α-2a (4.3%) discontinued the treatment because of flu like symptoms, p=0.06.
Non-hematologic adverse events of any grade occurred more frequently in the PEG-IFNα-2b group compared with PEG-IFNα-2a group: flu like symptoms (70.9% vs 57.5%, p<0.001), fatigue (58.2% vs 35%, p<0.026), injection site reaction (36.4% vs 20%, p=0.081) and autoimmune disorders (25.5% vs 20%, p=0.12), (predominantly grade 1 or 2). Lymphopenia, neutropenia and anemia were the most frequent hematologic adverse events (predominantly grade 1 or 2), and in no case have they represented a reason for treatment discontinuation.
Summary/Conclusion: Our data confirmed the efficacy and safety of both PEG-IFN for ET treatment. No difference was found regarding the CR rate between the two formulations, even if PEG-IFNα-2a showed a slightly higher rate of CR. Furthermore, PEG-IFN α-2a seems to have a better tolerability profile compared with PEG-IFNα-2b, leading to a low discontinuation rate due to adverse events.

PS1359

LIMITATIONS OF PREVIOUS PROGNOSTIC MODELS FOR THROMBOSIS AND EXPLORATION OF MODIFIED MODELS IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

Y. Hashimoto[1,*], H. Nakamae[2], T. Tanaka[1], H. Omura[1], T. Fukuta[1], M. Horiuchi[3], T. Yoshimura[3], T. Takakuwa[4], A. Mugitani[5], A. Hirose[2], M. Nakamae[2], H. Koh[2], M. Hino[2]

[1]Department of Hematology, Tottori Prefectural Central Hospital, Tottori, [2]Hematology, Graduate School of Medicine, Osaka City University, [3]Department of Hematology, Osaka City General Hospital, [4]Department of Hematology, Saiseikai Nakatsu Hospital, [5]Department of Hematology, Seichokai Fuchu Hospital, Osaka, Japan

Background: Although life expectancy of essential thrombocythemia (ET) patients is similar to that of the general population, thrombotic complications have reported to be the main causes of death in those. Therefore, the focus of treatment is prevention of complication by thrombosis. Regarding thrombosis risk stratification, conventional system is widely used in general, but recently the International Prognostic Score of thrombosis for ET (IPSET-T) and the revised IPSET-T were developed. These prognostic models are useful risk stratifications, however, the revised IPSET-T classifies young patients positive for the *JAK2* mutation, the high incidence of thrombotic events, into the low-risk category. Hence, this model may be underestimated.
Aims: We examined the prognostic factors to validate previous prognostic models for survival and thrombosis with large-scale data on Japanese patients with ET.
Methods: This study included 352 patients diagnosed with ET between 1999 and 2017. Using medical records, we investigated patient background, history of thrombohemorrhagic events (THE), causes of death, THE development after diagnosis, transformation to leukemia or myelofibrosis, and development of secondary cancer.

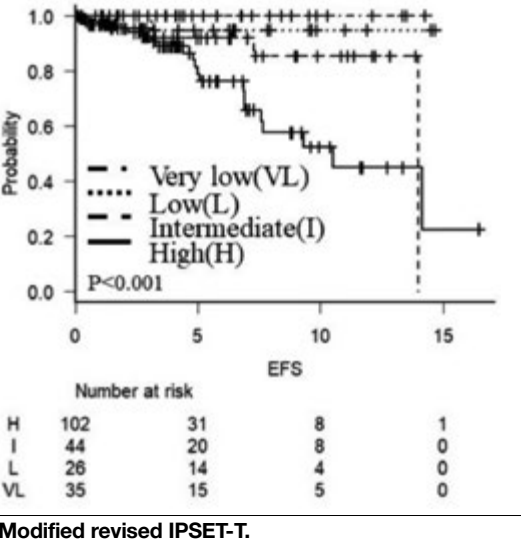


Figure 1. Modified revised IPSET-T.

Results: The median age at diagnosis was 67.0 years (range, 23-92 years). The median leukocyte count was 9.9×10^9/L; hemoglobin level, 13.5 g/dL; and platelet count, 873×10^9/L. Antiplatelet drugs were used in 69% of patients. Of the 207 patients screened for *JAK2* mutation, 139 (67%) showed positive results. Approximately 24.4% of patients had history of THE, and 13.1% and 5.1% developed THE and transformation after diag-

nosis, respectively. The reproducibility of the IPSET-survival, conventional system, IPSET-T, and the revised IPSET-T was also confirmed in Japanese patients. No significant differences were observed between patients with low scores and those with intermediate scores on the revised IPSET-T, and a comparison of patients receiving cytoreductive therapy showed that the incidence of thrombotic events was higher in those with low scores. Thus, the modified revised IPSET-T assigns 1 point for age >60 years, 2 points for history of thrombosis, and 2 points for *JAK2* mutation positivity; patients were stratified into four risk categories by total score: very low, 0 point; low, 1 point; intermediate, 2 points; and high, ≥3 points. The results demonstrated that the modified revised IPSET-T might be more useful to predict the need for treatment interventions in patients with ET than the original revised IPSET-T (Figure 1).

Summary/Conclusion: Although the revised IPSET-T is a superior risk stratification model, incidence rates of thrombotic events tended to reverse between low- and intermediate-risk categories due to the differences in treatment details. Thus, it cannot be used to compare the risk categories. The revised IPSET-T classifies 10-20% of patients with a high score on the IPSET-T into the low-risk category. They are young patients positive for the *JAK2* mutation. Attention should be paid to the high incidence of thrombotic events in these patients. Previous studies reported that advanced age, history of thrombosis, and *JAK2* mutation are strong risk factors for thrombosis. The modified revised IPSET-T allows subdivision of the risk categories on IPSET-T. Further studies with a large sample size are needed to assess the usefulness of the modified revised IPSET-T and identify patients who require antiplatelet or cytoreductive therapy.

PS1360

SERVICE EVALUATION OF PATIENTS WITH MYELOPROLIFERATIVE NEOPLASM AND SPLANCHNIC VEIN THROMBOSIS (MPN-SVT)

S. Wharin[1,*], J. Zheng[2], H. Network[3], R. Shaw[4], A. Zaidi[5], M. Desborough[6], N. M. Butt[7], M. Sekhar[2]

[1]Haematology, University Hospitals of Leicester, Leicester, [2]Haematology, Royal Free Hospital, London, [3]Haematology, National Institute Health Research Clinical Research Network, Oxford, [4]Haematology, Royal Liverpool Hospital, Liverpool, [5]Haematology, Royal London Hospital, London, [6]Haematology, Milton Keynes Hospital, Milton Keynes, [7]Royal Liverpool Hospital, Liverpool, United Kingdom

Background: SVT comprises thrombosis of hepatic vein (Budd Chiari syndrome, BCS), portal vein (PV), superior mesenteric vein (SMV) and splenic vein (SpV). The clinical and service needs of patients with MPN-SVT are complex. There is no systematic process in U.K. to assess clinical pathways and outcomes of these patients. A survey of MPN-SVT patients was undertaken at 6 sites using a validated database.

Aims: Assess feasibility of using a registry to assess outcome, clinical and service needs of MPN-SVT patients in U.K.

Methods: Between Nov 2017 and Feb 2018 patients with MPN-SVT at 6 hospitals over the past 8 years were identified. 5 hospitals were centres with specialist Haematology and interventional radiology, 1 was a regional liver transplant centre. Patient data were anonymised and analysed centrally. All data were collected by Haematology trainees via the NIHR HaemSTAR network. Service outputs were recorded including radiology and endoscopy procedures and time to referral to expert centres. User feedback was sought.

Table 1. MPN diagnosis and cytoreductive treatment.

Diagnosis	Number	HC	Rux	PEGIFN	None	Unknown
PV	9	6		1	2	
ET	3	2		1		
PMF	3	1	2			
PPV-MF	4	1	2	1		
PPV-ET	1		1			
MPN-U	11	3				8

Results: Data was obtained for 31 patients from 5 pilot centres; 16 males, 15 females. Age range 25-72 years, median 45. *MPN:* MPN diagnoses cytoreduction is shown in Table 1. 'MPN-U' includes 10 patients with *JAK2*V617f without haematological evidence of MPN. 19 patients presented with SVT. Mean time from SVT to diagnosis of MPN was 223 days (range 2- 912, median 75). *SVT:* 27 patients had PVT, 9 SpVT, 11 SMVT, 10 BCS. 15 developed varices, 6 had variceal bleeding, 9 required banding. 20 patients received warfarin, 3 warfarin+aspirin, 2 heparin, 2 DOACS, 1 antiplatelets only, 2 did not receive anticoagulation. 6 patients had a TIPPS procedure, 4 required dilation. 2 patients had a liver transplant. 26% achieved thrombus resolution or recanalization, 13% extension or recurrence, 61% had stable disease. *Patient pathways and health resources*: 24 patients were managed at an expert centre. Mean time to referral was 40 weeks (range 0- 416, median 1). Mean number of imaging episodes per patient was 5 (range 1-24, median 4). *Feasibility of database:* Case ascertainment at 4/6 sites was incomplete. Chief obstacles were lack of systematic registering of MPN-SVT patients and inaccessibility to IT infrastructure. Data was incomplete in all cases. User feedback indicated that the database was lengthy and complex. *Limitations:* 70% of participants were from one transplant centre, therefore not representative of UK practice overall.

Summary/Conclusion: Our study was initiated to test the feasibility of a national MPN-SVT registry to inform practice. The results demonstrate variation in patient pathway with respect to specialist referral anticoagulation and cytoreductive practices, reflecting lack of consensus in management of patients. MPN-SVT is a rare but serious, resource intensive complication of MPNs. Retrospective collection of data poses problems of quality and completeness. A prospective national registry with a concise dataset is likely to yield important data to address these needs.

PS1361

FAMILIAL MYELOPROLIFERATIVE NEOPLASMS: A SINGLE-INSTITUTION ANALYSIS OF 22 FAMILIES

M. Maffioli[1,*], B. Mora[1], D. Barraco[1], D. Caramazza[1], L. Elli[2], R. Accetta[2], A. Bussini[2], F. Pallotti[2,3], S. Uccella[4], R. Casalone[2], T. Giorgino[5], F. Passamonti[13]

[1]Hematology, Department of Specialist Medicine, Ospedale di Circolo, ASST Sette Laghi, Varese, Italy, [2]Cytogenetics and Medical Genetics Laboratory, ASST Sette Laghi, Varese, Italy, Varese, [3]Department of Medicine and Surgery, University of Insubria, Varese, Italy, [4]Department of Medicine and Surgery, Unit of Pathology, University of Insubria, Varese, Italy, [5]Biophysics Institute, National Research Council of Italy, Milan, Italy

Background: The majority of myeloproliferative neoplasms (MPNs), including essential thrombocythemia (ET), polycythemia vera (PV), primary myelofibrosis (PMF), and chronic myeloid leukemia (CML), have a sporadic occurrence. However, around 10% of MPNs are characterized as familial.

Aims: Familial MPNs constitute a rare opportunity to gain insight into MPN genetics. We therefore set out to characterize a cohort of familial MPN patients followed at our Institution.

Methods: We reviewed our institutional MPN database to identify familial cases (i.e., pedigrees with ≥2 subjects with an MPN). The nonparametric Wilcoxon signed rank test was used to compare age at diagnosis. The study was approved by the Institutional Ethics Committee; procedures are in accordance with the Helsinki Declaration.

Results: We identified 22 pedigrees with familial MPN, for a total of 45 MPN patients. Four pedigrees also included an individual with a non-MPN hematologic neoplasm (multiple myeloma, 1; Hodgkin lymphoma, 1; leukemia not otherwise specified, 1; acute myeloid leukemia, 1). Median follow-up of the whole cohort was 9.2 years (range, 1.2-22.0 years). The clinical and molecular features of analyzed patients are summarized in Table 1. Overall, MPN occurrence was vertical in 17 families (all but one with two consecutive generations involved), whereas in 5 families MPN cases were documented in a single generation. In families with vertical occurrence, patients of the second generation almost invariably had a younger age at diagnosis than those of the first generation (median 35 vs 65 years; paired Wilcoxon signed rank test p=0.002). Six out of seven patients with a thrombotic event were *JAK2*V617F-positive (vs 17/26 without a thrombosis). The Figure 1 reports a pedigree with phenotypically and genotypically homogeneous vertical MPN occurrence with a skipped generation (proband and grandfather both affected with *JAK2*V617F-positive PV with a splanchnic vein thrombosis – SVT – at diagnosis; mother unmutated for *JAK2* and with normal blood counts; 36-year-old sister without an MPN-phenotype but harboring *JAK2*V617F with an allele burden of 3%). Lastly, NGS analyses are ongoing in 24 subjects with available DNA (of which 4 familial pairs).

Summary/Conclusion: Within our cohort of 22 familial MPN pedigrees disease phenotype and genotype are heterogeneously distributed and occurrence is more frequently vertical. Disease anticipation is confirmed in our cases. Of great interest for perspective considerations is the family with two *JAK2*V617F-positive PV patients both experiencing SVT. It is intriguing to speculate as to whether an MPN-independent inherited genetic factor could have played a role in the pathogenesis of the thrombotic events and how this genetic event might interplay with MPN genotypes. A second point of interest is the *JAK2*V617F-positive subject without an MPN phenotype, especially considering the role of *JAK2* mutations in the context of clonal hematopoiesis of indeterminate potential.

Table 1. Clinical and molecular features of familial MPN patients (n = 45, 22 pedigrees).

Diagnosis WHO 2017: ET/PV/Pre-PMF/Overt PMF/CML/MPN-U		25 / 11 / 1 / 4 / 3 / 1
Driver mutations (n/genotyped)	- *JAK2*V617F+	27/32
	- *CALR* mut	2/12 (both Type 1)
	- *MPL* mut	2/7 (both W515L)
	- Triple negative	1/7
Homogeneous vs heterogeneous MPN phenotype within pedigree		10 vs 12
Vertical vs single generation occurrence		17 vs 5
Thrombotic events		12/38
Transformation to MF		3/38 (1 subseq. AML)
Transformation to accelerated/blast phase		5/38 (2 CML-BP)

PS1362

THROMBOEMBOLIC EVENTS AFTER DIAGNOSIS OF POLYCYTHAEMIA VERA IN A SINGLE CENTER POPULATION

N. Curto-Garcia[1,*], J.C. Ianotto[2], J. O'Sullivan[3], P. Harrington[1], Y. Francis[1], C. Woodley[1], D. Mclornan[1], D. Radia[1], C. Harrison[1]

[1]Haematology , Guy's and St Thomas NHS Foundation Trust, [2]Haematology , Guy's and St Thomas Foundation Trust, London , [3]Haematology , Guy's and St Thomas NHS Foundation Trust , Londonf, United Kingdom

Background: Polycythaemia vera (PV), a myeloproliferative neoplasm associated with *JAK2*V617F and Exon 12 mutations, usually affects patients >60 years old, and is associated with thromboembolic (TE) or bleeding events; and symptoms including hyperviscosity, erythromelalgia or pruritus. Progression to myelofibrosis and acute leukaemia can also occur. Studies suggest the incidence of TE events post diagnosis is up to 22% thus representing a significant problem for patients in terms of morbidity and mortality.
Aims: We report a large contemporaneous cohort of PV patients from a single centre describing TE occurring after diagnosis.
Methods: 220 patients were analysed (116 male), mean age of patients at time of diagnosis was 52 years (range 24-83).
Results: Cardiovascular (CV) risk factors were present in 106/220 (48%) of PV population, 28% patients had hypertension, 9% diabetes mellitus and 10% hypercholesterolaemia. Mean follow up was 91 months (range 2-324). Considering TE overall 94 patients had TE at any time, 42/220 of the total population (20%) experienced 50 TE events after PV diagnosis including 14 recurrent events (2 events in 5 patients and 4 in 1). Mean age at time of TE was 59 years (range 28-86). Concerning timing of TE the median time was 58 months (CI 95% (38-77) and 74% of TE had occurred by 120 months. The annual incidence of post diagnosis TE was 1.9% patient/year. CV factors were present in 15/42(35.7%) and the patient with 4 recurrent events had complicated diabetes with severe neuropathy and nephropathy, below knee amputation due to vascular disease and a renal transplant. The most frequent post diagnosis TE was in fact abdominal thrombosis (12/50), followed by cerebrovascular accident (7/50), myocardial infarct (7/50) and deep venous thrombosis (6/50). Immediately prior to TE for 26/50 events, patients were on cytoreductive agents (CRT) and antithrombotic drugs, mainly hydroxycarbamide (HC=15), ruxolitinib (Rux=4), interferon (IFN=3); 18/50 had only antithrombotic drugs (aspirin=16). For 15/50 TE events the patients had received a venesection (VS) during the year beforehand (7 had 1; 3 had 2; 4 had 3 and 1 had 4), aspirin was the most common antithrombotic therapy (n=34/50). Concerning haematological response (per European Leukemianet), at time of TE most patients were in complete or partial response (CR=14/42 and PR=19/42). For those patients on CRT (n=16) at time of TE, 10 were in CR, 5 PR, and 1 unknown. Those not on CRT, 2 were in CR, 5 in PR, 2 in NR and 2 unknown. After the occurrence of TE for 35/50 occasions, CRT was unchanged (Figure 1). Regarding recurrent events (n=14), 6 cases happened on CRT, VS and antithrombotic drugs immediately prior to event (HC=3,Rux=2, Busulfan=1), whereas 7 TE occurred without CRT; but 3/7 were treated with VS. Only 5/220 patients died during follow up and no deaths were related to TE.

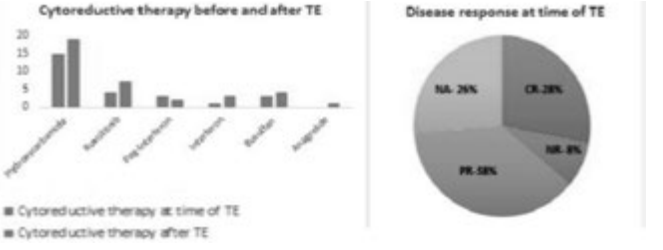

Figure 1.

Summary/Conclusion: Despite current treatments with high rates of overall responses (CR & PR per ELN), TE are a frequent complication for PV after the time of diagnosis as we have shown in our patient population; only 50% of these events occurred within the first 5 years of diagnosis, interestingly abdominal and arterial thrombosis were equally prevalent. Most patients were either in CR or PR, at the time of TE suggesting that other factors are likely to be relevant in this population in triggering thrombosis. Finally, new therapeutic approaches are required to address thrombosis free survival which remains a significant issue of concern for PV patients.

PS1363

MIPSS70 AND TRANSFUSION DEPENDENCE PREDICT SURVIVAL IN MYELOFIBROSIS PATIENTS TREATED WITH JAK1/2 INHIBITOR THERAPY

C. Mcnamara[1,*], J. Spiegel[2], E. Atenafu[3], D. Maze[1], H. Sibai[1], V. Gupta[1]

[1]Department of Medical Oncology and Hematology , Princess Margaret Cancer Centre, Toronto , Canada, [2]Department of Hematology, Stanford University, Stanford, United States, [3]Department of Biostatistics, Princess Margaret Cancer Centre, Toronto , Canada

Background: Mutation enhanced international prognostic score system for transplantation age patients with primary myelofibrosis (MIPSS70) heralds a new era in the prognostication of patients with myelofibrosis (MF). It is the first classification system to integrate clinical variables, bone marrow histology and the recent advances in molecular knowledge. Namely, the favorable risk of calreticulin (CALR) type 1-like driver mutations and the adverse impact of mutations in high molecular risk (HMR) genes both individually and cumulatively. However, transfusion status was not investigated in the construct of MIPSS70. Transfusion dependence has been independently associated with inferior survival in MF and is incorporated into the dynamic international prognostic scoring system (DIPSS) plus classification. Our group and others have shown that a high-risk DIPSS score, pre-JAK1/2 inhibitor transfusion dependence and mutations in *ASXL1/ EZH2* predicted shorter time to treatment failure (TTF) and overall survival (OS) in patients undergoing JAK1/2 inhibitor therapy.
Aims: To evaluate the impact of transfusion status and MIPSS70 on TTF and OS in MF patients treated with JAK1/2 inhibitor therapy.
Methods: Patients with a diagnosis of MPN in chronic phase and treated with JAK 1/2 inhibitor therapy were identified from the MPN database. MIPSS70 was calculated at the time of starting JAK1/2 inhibitor therapy. Molecular analysis was performed by targeted sequencing of a 54 myeloid gene panel. Univariate and multivariable analysis for TTF and OS was conducted using for the Cox proportional hazards model.
Results: One hundred patients with a diagnosis of MPN in chronic phase (2 pre-fibrotic MF; 48 overt MF; 27 PPV-MF; 23 PET-MF) and treated with JAK 1/2 inhibitor therapy (77 ruxolitinib; 23 momelotinib) were included

in the study. Forty-three patients had at least one mutation consistent with HMR profile and nine patients had ≥2 HMR mutations. CALR type 1-like mutation was present in 10 patients. As expected, this patient cohort had more advanced disease as stratified by MIPSS70 with two patients classified with low-risk, 35 with intermediate-risk and 63 with high-risk. With a median follow-up of 3.0 years, the median survival of the low/ intermediate- and high-risk groups were 6.7 and 3.0 years respectively. High-risk MIPSS70 was associated with inferior OS (HR, 2.28; 95% CI, 1.24-4.19; p=0.01; Figure 1) but not TTF. Pre-treatment transfusion dependence predicted shorter TTF (HR, 2.00; 95% CI, 1.24-3.23; p=0.01) and OS (HR, 2.10; 95% CI, 1.23-3.59; p=0.01) and remained significant on the multivariable analysis. High-risk MIPSS70 patients requiring transfusions had a shorter median survival of 2.5 years compared to 4.6 years in patients who were not requiring transfusions (p=0.002). Older age and abnormal cytogenetics were not predictive of shorter TTF or OS on multivariable analysis.

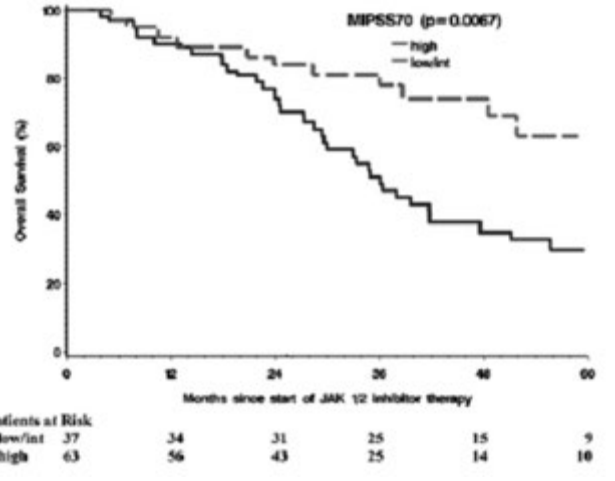

Figure 1.

Summary/Conclusion: Our data validates that MIPSS70 is useful in predicting OS in MF patients treated with JAK1/2 inhibitor therapy. Pre-treatment transfusion dependence is an independent factor for shorter TTF as well as OS. These data suggest that further enhancement of MIPSS70 may be possible by integrating transfusion status into the scoring system.

PS1364

JAK2 ALLELIC RATIO PREDICT HIGHER TROMBOTIC RISK IN MYELOFIBROSIS PATIENTS. A SINGLE CENTER EXPERIENCE ON 143 PATIENTS

M. Farina[1,*], N. Polverelli[2], E. Cerqui[1], F. Schieppati[1], M. D'Adda[1], G. Rossi[1]

[1]Hematology Unit, [2]Unit of Blood Diseases and Stem Cells Transplantation, University of Brescia, ASST Spedali Civili, Brescia, Italy

Background: Thrombosis is a recognized as a major complication in Myelofibrosis (MF) patients, representing the ultimate cause of death in about 10% of patients. So far, few studies have focused on characteristics, outcome and possible risk factors for thrombotic complications in this group of patients.
Aims: To evaluate the characteristic, incidence and prognostic factors for thrombotic events in a cohort of MF patients.
Methods: Clinical and laboratory data of 143 patients, diagnosed with MF from 2000 to 2017 at the Unit of Hematology of ASST Spedali Civili in Brescia were retrospectively collected. A competing-risk analysis was carried out to identify possible risk factors associated to thrombosis.
Results: Overall, 18 out of 143 (13%) patients developed one or more thrombosis after a median follow-up of 44 months (3-484) from diagnosis, for and cumulative incidence of 10.7%, 16.2% and 20.5% at 5, 10 and 20 years, respectively. Thrombosis frequency increased over time: 2.1% of patients developed thrombotic events during the first year, 3.15% between 1 and 2 years, 2% between 2 and 3 years, 11.25% thereafter (p=0.003). Thrombosis were venous in 11 (61%) of cases (6 splancnic, 2 deep venous thrombosis, 2 pulmonary embolism), arterial in 7 cases (3 AMI, 1 stroke, 1 TIA, 2 peripheral arterial occlusioe disease). A MF treatment was ongoing in 15 out of 18 patients (83%) at the time of thrombosis; specifically, ruxolitinib (5) and hydroxyurea (10). Clinical characteristics of the cohort are detailed in Table 1, according the occurrence of thrombotic events. Overall 58 (40.5%) patients received antiplatelet agents after MF diagnosis, in 13 cases (22.4%) after a previous thrombosis. Patients developing thrombosis had more frequently a JAK2 allele burden >75% (p=0.03), and presented a positive history for thrombotic events (p=0.05). A lower antiplatelet use was recorded among patients with thrombosis (p=0.033). At last follow-up 47 (33%) of patients had died. Causes of death were related to: AL evolution in 10 cases (21%), MF progression without evolution in 10 (21%), hemorrhage in 3 (6%), infectious complication in 7 (15%), allogeneic transplant complication in 1 (2%), unrelated 29%. Thrombosis represented the final event in 2 patients (4% of cases). Among clinical parameters, antiplatelet agents (p=0.06), JAK2 allele burden >75% (p=0.015) and previous thrombosis (p=0.084) did correlate with higher thrombotic risk. By multivariable analysis, only JAK2 allele burden maintained the statistical significance in predicting thrombotic complications (HR 4.77, CI95% 1.57-14.5, p=0.0059).

Table 1.

Patients' characteristics according to the occurrence of thrombotic event.

Characteristics	No thrombotic complications (n.125)	Thrombotic complications (n.18)	P
Male sex, n. (%)	78 (62.4%)	13 (72.2%)	0.601
Median age, years (range)	66 (28-85)	66 (26-76)	0.42
Median hemoglobin, g/dl (range)	10.8 (6.7-17.1)	10.9 (8.3-20.2)	0.55
Median leukocyte, x10³/l, (range)	9 (1.1-72.5)	9.9 (2.9-35.5)	0.86
Median platelet, x10³/l (range)	304 (11-1440)	280 (109-721)	0.76
Constitutional symptoms, n. (%)	18 (14.4%)	1 (5.5%)	0.46
Circulating blast cells, n. (%)	28 (22.4%)	3 (16.7%)	1
Palpable splenomegaly, n. (%)	80 (64%)	14 (77.8%)	0.42
PMF, n. (%)	95 (76%)	12 (66.7%)	0.39
Grade 2-3 fibrosis, n. on evaluable pts (%)	91 (72.8%)	16 (88.9%)	0.30
Intermediate2/high IPSS risk	45 (36%)	7 (38.9%)	0.59
Mutational status, n. (%)			
Jak2 mutation, n. (%)	79 (63.2%)	16 (88.9%)	0.095
Jak2 allele ratio >75%, n. (%)	5 (4%)	4 (22.2%)	**0.047**
Antiplatelet therapy, n. (%)	52 (41.6%)	6 (33.3%)	**0.033**
Previous thrombotic complication, n. (%)	22 (17.6%)	7 (38.9%)	**0.05**

Summary/Conclusion: In our experience a higher JAK2 allelic burden is the only predictive factor for thrombotic events in MF patients, confirming previous experiences in Essential Thrombocythemia and Polycythemia Vera. A more strict anti-thrombotic surveillance should be advised in this subset of MF patients.

PS1365

RUXOLITINIB AND HYDROXYUREA COMBINATION FOR THE TREATMENT OF MYELOFIBROSIS

N. Pugliese[1,*], C. Giordano[1], D. Nappi[1], L. Luciano[1], C. Cerchione[1], M. Annunziata[1], B. Casale[2], E. Crisà[3], M. R. Villa[4], L. Pezzullo[5], M. Iovine[6], M. Picardi[1], L. Simeone[7], F. Pane[1], V. Martinelli[1]

[1]University of Naples Federico II, [2]AO Ospedali dei Colli Napoli, PO Monaldi, Naples, Italy, Naples, [3]Università degli Studi del Piemonte Orientale "Amedeo Avogadro", Novara, [4]Ospedale Ascalesi, Naples, Italy, Naples, [5]Hematology and Hematopoietic Stem Cell Transplant Center. A.U.O. "San Giovanni di Dio e Ruggi D'Aragona" Salerno., Salerno, [6]AO Caserta Sant'Anna e San Sebastiano, Caserta, Italy, Caserta, [7]University of Naples Federico II, Nples, Italy

Background: Ruxolitinib, an orally bioavailable and selective inhibitor of JAK1 and JAK2, has been shown to significantly reduce splenomegaly and disease-related symptoms in patients with myelofibrosis (MF). However, no clear survival benefit has been demonstrated, which may in part reflect suboptimal drug exposure related to lower dosages needed to minimize hematological toxicity, specifically cytopenias. Furthermore, the optimal management of specific conditions such as leukocytosis or thrombocytosis is still undefined. Therefore, combining ruxolitinib with a cytoreductive agent like hydroxyurea (HU) may improve hematological response.
Aims: We evaluate the efficacy and safety of ruxolitinib in combination with HU.
Methods: This observational multi-center study analyzed 20 adult patients with a diagnosis of intermediate or high-risk primary MF, post-polycythemia

vera MF, or post-essential thrombocythemia MF requiring the addition of HU to ruxolitinib treatment to control WBC or platelet count. Ruxolitinib was initially given at a dose of 5, 15, or 20 mg twice daily, depending on baseline platelet count, adjusted in response to platelet/neutrophil count and/or lack of efficacy. HU was added when WBC or platelet counts were unsatisfactory. Patients response was assessed considering spleen size, symptoms, WBC and platelets count, according to ELN response criteria.
Results: Initially, all patients received ruxolitinib as monotherapy after a median time from MF diagnosis of 15.9 months (range 1.6–181 months). The starting dose of ruxolitinib as monotherapy was 20 mg BID in the 40% of cases, 15 mg BID in the 35%, 10 mg BID in the 5%, 5 mg BID for the 20%. Three patients temporarily discontinued ruxolitinib administration due to severe thrombocytopenia. 17 patients started HU treatment due to insufficient WBC control and 3 patients for unsatisfactory platelet control. HU was added after a median time of ruxolitinib monotherapy of 6.5 months (range 1–49.6 months). The median time of combination therapy was 14.5 months (range 2–195).
During the co-administration period, two patients temporarily reduced ruxolitinib treatment and only one discontinued ruxolitinib, due to severe thrombocytopenia. On the other hand, 8 patients reduced HU due to hematological toxicity that mostly occurred in the first 8 to 12 weeks of treatment. Toxicity was generally manageable with dose reductions and/or supportive treatment. A symptomatic response was obtained in 6 patients during ruxolitinib monotherapy and in 12 patients during combination ruxolitinib-hydroxyurea. A spleen response was obtained in 5 patients during ruxolitinib monotherapy and 8 patients with combination therapy. After a median duration of 14.5 months of combination therapy, 16/20 patients had a hematological response; 14/17 patients who had started combination therapy to control WBC count and 2/3 who started in order to reduce platelets count. The number of patients requiring ruxolitinib dosage reduction or discontinuations was lower during combination therapy, and ruxolitinib dosage was increased in 50% of patients.
Summary/Conclusion: From our experience, ruxolitinib-hydroxyurea in combination yields a clinical and hematological benefit that did not elicit cumulative or overlapping toxicities. When ruxolitinib resistance, with regard to WBC and platelet counts, is documented in the hyperproliferative phase of MF, the addition of hydroxyurea could improve hematological control and disease-related symptoms and splenomegaly.

PS1366

THE "MYMPN" PATIENT REGISTRY: VALIDATION OF A PROSPECTIVE MYELOPROLIFERATIVE NEOPLASM PATIENT REGISTRY

R. Scherber[1,*], L. Whyte[2], M. Woehrle[2], A. Dueck[3], S. Verstovsek[4], C. Harrison[5], R. Mesa[6]

[1]Hematology and Oncology, Mayo Clinic/Oregon Health and Sciences University, Portland, [2]MPN Research Foundation, Chicago, [3]Biostatistics, Mayo Clinic, Scottsdale, [4]MD Anderson Cancer Center, Houston, United States, [5]Guys St. Thomas, London, United Kingdom, [6]Mays MD Anderson Cancer Center, San Antonio, United States

Background: The myeloproliferative neoplasms (MPNs) are an uncommon hematologic malignancy that affects approximately 350,000 individuals in the United States (Blood. 2012;120(21)A2834). The disease course can be complicated for patients, including severe disease related symptom burden, thrombosis, bleeding, multimodal treatment plans, and risk of disease progression (Blood. 2017 Feb 9; 129(6): 680–92). Disease-related patient registries can be a useful and important tool for rare disease research and surveillance.
Aims: The advisors and board of the MPN Research Foundation aimed to create a prospective patient-reported MPN registry to capture demographics, disease related events, and symptom burden.
Methods: Using the platform of the Genetic Alliance an online registry was created which assessed MPN patients' baseline demographics and disease history with prospective patient-reported disease events and symptom burden. Symptom burden was assessed via the Myeloproliferative Neoplasm Symptom Assessment Form Total Symptom Score (MPN SAF TSS; Blood 2011; 118(2):402-8). Approximately 50 MPN patients were utilized for beta testing of the registry. The registry was approved by the Genetic Alliance IRB prior to launch. The link to join the registry was disseminated among multiple MPN-related websites.
Results: *Accrual:* A total of 454 US MPN patients initiated the online registry process. Of these, 355 individuals completed the introductory demographic and disease information surveys. Respondents were predominantly female (63.7%). Registry enrollment by date since registry initiation is demonstrated in Figure 1a.
Disease-related information: The disease distribution of participants was similar to previously published data in the US, including 45.1% with essential thrombocythemia (ET), 39.9% with polycythemia vera (PV), and 12.6% with myelofibrosis (MF). 318/344 participants endorsed having disease-specific genetic testing. 57.4% of respondents reported having low blood counts, hemorrhage or thrombosis. Most frequent therapies included aspirin (75.5%), hydroxyurea (42.1%), JAK inhibitor (17.6%), interferon (6.0%) or no therapies (9.9%). Thus far, 303 participants prospectively reported 902 disease-related events such as blood draws (37.3%), phlebotomy (14.2%), change in MPN medicines (9.6%), bone marrow biopsies (6.9%), transfusion (4.8%), unplanned hospital stays (4.5%), thrombotic or bleeding events (2.4%), or pregnancy (0.2%).
Disease Symptom Burden: At the time of data analysis, 250 participants completed a 418 MPN-10 symptom surveys. Mean MPN10 scores were similar to previously published results for ET and PV (Figure 1b-c). Analysis to compare symptom scores for MF are ongoing.

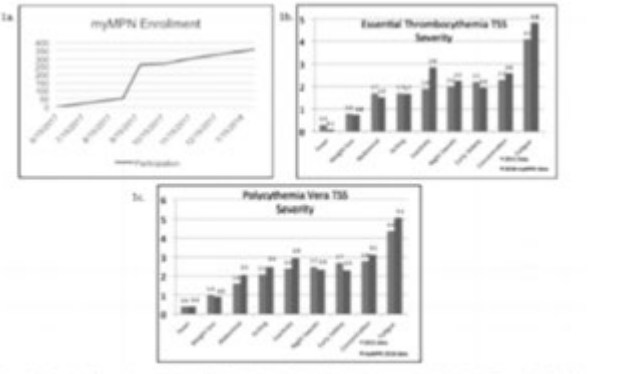

Figure 1a: Number of registrants in the MPN patient registry by date since registry initiation. Figures 1b-1c: Average MPN SAF TSS symptom score item severity as compared to previous MPN cohorts by disease subtype for essential thrombocythemia and polycythemia vera (Blood 2011; 118(2):402-8).

Figure 1.

Summary/Conclusion: An MPN patient registry has the capabilities of addressing key critical questions regarding MPN patient symptom and treatment needs. Its dynamic nature allows researchers and patient advocates to prospectively connect with individual patients regarding additional information and unmet needs in this rare population. At this time, registration is only available to individuals in the United States, although ongoing efforts are planned to recruit English-speaking MPN patients from the United Kingdom, Australia, New Zealand, and Canada. Further efforts in regards to grow patient registry enrollment and disease questionnaires are ongoing.

PS1367

THE RELATIONSHIP OF BODY MASS INDEX TO SYMPTOM BURDEN IN THE MYELOPROLIFERATIVE NEOPLASMS

R. Scherber[1,*], B. Langlais[2], H. Geyer[3], A. Dueck[2], J. Huberty[4], L. Padrnos[5], J. Palmer[5], A. Fleischman[6], R. Mesa[7]

[1]Hematology and Oncology, Mayo Clinic/Oregon Health and Sciences University, Portland, [2]Biostatistics, [3]Internal Medicine, Mayo Clinic, Scottsdale, [4]Arizona State University, [5]Hematology and Oncology, Mayo Clinic, Phoenix, [6]Hematology and Oncology, University of Califonia Irvine, Irvine, [7]Mays MD Anderson Cancer Center, San Antonio, United States

Background: The myeloproliferative neoplasms (MPNs) are a chronic hematologic malignancy with elevated symptom burden (i.e., fatigue, pain) and significantly reduced lifespan compared to general populations (JCO. 2012; 30(24):2995-3001). Elevated body mass index (BMI) is a risk factor for MPN disease development (Int. J. Cancer. 2014;134:1741–50), but little information is available on the relevance of BMI in MPN symptomatology. Understanding the relevance of BMI to symptoms may help to guide future efforts regarding disease development, progression, symptom burden or QOL.
Aims: To investigate the role of BMI in MPN related symptom burden.
Methods: This was a cross-sectional study. We used data from NUTRIENT, a large international survey conducted in MPN patients (Blood, 2017) to investigate nutrition, supplement use, and symptoms. This secondary analysis investigates the relationship of BMI to disease characteristics and symptom burden. Symptom burden was assessed using the validated MPN10 symptom assessment (JCO. 2012;30(33):4098-103).
Results: *Study group*: A total of 1,025 surveys had complete data on MPN type, weight, height, and symptom burden. MPN types included essential

thrombocythemia (ET; n=392), polycythemia vera (PV; n=390), and myelofibrosis (MF; n=243). Patients were of typical median age (60.0 years) and female predominance (74.9%) of prior MPN patient symptom investigations. *MPN Characteristics and BMI:* Overall self-reported mean BMI of respondents was overweight (25.9, SD=5.13). The distribution of respondent weight categories included 2.8% underweight, 45.7% normal weight, 32.4% overweight, and 19.1% obese. Mean BMI was not significantly different among MPN subtypes (25.8 ET, 26.3 PV, and 25.6 MF; p=0.30). *Characteristics of Patients with Elevated BMI:* Male respondents were significantly more likely to have a BMI ≥25 than female (59.9% vs 48.7%, p=0.0018). Among all MPN types, those with BMI score ≥25 demonstrated significantly higher symptom burden than those with BMI <25 (Table 1). This association persisted among patients with PV and MF subtypes, but not ET. Weak but significant positive correlations were observed between burden and BMI among all MPN subtypes (r = 0.14; p<0.001). When looking within disease subtypes, this correlation was higher for PV patients (r = 0.18; p<0.001) than for ET (r = 0.11; p<0.001) or MF patients (r = 0.11; p<0.001).

Table 1.

Differences between Overweight/Obese (BMI ≥25) vs Normal weight/underweight (<25) MPN patients (N=1025).

	BMI < 25	BMI ≥25	p
Age, mean (SD)	58.9 (12)	57.9 (12)	0.20
Female	79.3%	70.8%	0.0018
MPN10, mean (SD)	3.1 (1.6)	3.6 (1.7)	<0.001
ET subtype (n=392)	3.3 (1.6)	3.5 (1.7)	0.22
PV subtype (n=390)	2.9 (1.6)	3.7 (1.8)	<0.001
MF subtype (n=243)	3.1 (2.1)	3.5 (1.6)	0.026

Summary/Conclusion: Overweight or obese BMI is associated with significantly worsened disease-related symptom burden for most MPN subtypes. This relationship was less clear for ET, where weak but significant correlations were observed between BMI as a continuous measure and symptom burden but not when BMI was evaluated as dichotomous variable. A limitation to the data reported here is that weight and height was self-reported. A caveat to our data acquisition is the self-reported weight and height, which is unable to be externally validated in this analysis. Investigations regarding the relationship between weight loss and symptom burden during the disease course, which can be experienced by up to 67% of MF patients (Blood. 2008;112(11):A5224), should be explored further. However, these data suggest that interventions to reduce weight in MPN patients may be a strategy to combine with traditional therapy to improve symptomatology.

PS1368

MANAGEMENT AND OUTCOME OF PATIENTS DIAGNOSED WITH POLYCYTHEMIA VERA IN YOUNG AGE

G. Bogoni[1,*], G. Biagetti[1], I. Bertozzi[1], E. Cosi[1], F. Fabris[1], M. L. Randi[1]

[1]Medical Clinic 1, University of Padua, Padova, Italy

Background: Polycythemia Vera (PV) is a myeloproliferative neoplasm mainly diagnosed at a median age of 60 years. PV is rarely found in patients younger than 45 years of age and their clinical features and management is not clearly defined. Moreover, younger patients are followed for a long period of time and it is not known if their disease evolves more often in myelofibrosis or acute leukaemia compared to older patients.
Aims: In this work we evaluate the management and outcome of young patients with PV followed in a single center.
Methods: We report data of 199 patients diagnosed with PV in agreement with WHO criteria 2008 between 1986 and 2018. We divided the patients into two groups: 44 patients (23 males and 21 females, median age 37.5, range 18.6-44.9) were younger and 155 patients (81 males and 74 females median age 65 y, range 50-82) were older than 45 years at the time of PV diagnosis. We recorded the length of follow-up, the occurrence of arterial and venous thromboses both at diagnosis or during follow up, the presence of cardiovascular risk factors (diabetes, smoke, arterial hypertension, dyslipidaemia), the evolution in Myelofibrosis (MF) or Acute Leukaemia (AL). All the patients underwent phlebotomies to maintain haematocrit lower than 45% and received low-dose aspirin associated or shifted to anticoagulant in case of venous thrombosis. 135 of them received cytoreductive drugs (68%). Statistical analysis was performed using the Mann-Whitney test, the χ^2 test or Fisher's exact test and the Kaplan-Meier method.
Results: There was no difference in sex distribution, while the follow up duration was significantly longer in younger patients (median 12.8 y, range 1-31 vs median 6.7 y, range 1-22, p 0.003). 17 young (38.6%) and 45 old (29%) patients developed thrombotic complications (p= NS). Venous thromboses were more frequent in younger than in older patients (14 in young-PV and 26 in old-PV, p 0.0342), mainly due to thrombosis in unusual sites (12 in younger and 7 in older PV, p= 0.0001). Arterial thromboses (3 in young-PV and 19 in old-PV, p=NS) had a similar frequency in the two age groups, while the occurrence of cardiovascular risk factor was significantly different: 23 patients in younger PV (52.2%) and 111 in older PV (71.6%) had at least a cardiovascular risk factor (p=0.0098).
9 young and 12 old patients evolved in MF (p= 0.024). However, considering the median follow up in the two groups, the difference is not significant, as no difference was observed in AL transformation between the two groups (respectively 1 = 2.3% and 3 = 1.9%). In agreement, MF and AL free survival are the same.
Summary/Conclusion: Our study shows that there are no differences between younger than 45 years at diagnosis of PV and older patients in sex, total and arterial thrombotic events, and acute leukaemia evolution. Patients diagnosed under 45 years have an increased risk of venous thrombosis in unusual sites i.e. splanchnic venous thrombosis and cerebral veins thrombosis. Considering that cardiovascular risk factors are more common in older than in younger patients, the lack of significant difference in the occurrence of arterial thrombosis in the two groups is surprising. Indeed, in young patients with PV, the disease seems to be an independent risk factor for arterial thrombosis. Progression of myelofibrosis is more incident in young, but the matching of follow up duration and age at diagnosis suggests that the length of follow up allows more frequently the evolution.

PS1369

RUXOLITINIB IN MYELOFIBROSIS: A MULTICENTRE EXPERIENCE IN ENGLAND, NORTHERN IRELAND AND WALES

J. Russell[1,*], A. Daly[2], R. Fisken[3], A. Dicu[4], J. Cunningham[5], D. Sparksman[4], S. Docherty[4], A. Santarsieri[6], C. Saha[6], I. Lentell[6], Y.J. Lim[7], K. Maw[5], A. Fowler[8], S. Knapper[9], A. Collins[4], N. Butt[7], F. Wadelin[3], I. Whalley[10], E. Gudgin[6], A. Godfrey[6], M.F. McMullin[2], S. Sadullah[5]

[1]Haematology, Cambridge University Hospitals NHS Foundation Trust, Cambridge, [2]Belfast City Hospital, Belfast, [3]Nottingham University Hospital, Nottingham, [4]Norfolk and Norwich University Hospitals NHS Foundation Trust, Norwich, [5]James Paget University Hospitals NHS Foundation Trust, Great Yarmouth, [6]Cambridge University Hospitals NHS Foundation Trust, Cambridge, [7]Royal Liverpool University Hospital, Liverpool, [8]Peterborough City Hospital, Peterborough, [9]University Hospital of Wales, Cardiff, [10]Ipswich Hospital, Ipswich, United Kingdom

Background: Ruxolitinib (RUX), the oral Janus kinase (JAK)-1/2 inhibitor, is licensed to treat disease-related splenomegaly or symptoms in adults with primary myelofibrosis (PMF), post-essential thrombocythaemia (PET)-MF or post-polycythaemia vera (PPV)-MF. From August 2012, MF patients with intermediate (int)-1/2 or high-risk disease, based on the International Prognostic Scoring System (IPSS), could receive RUX via the Cancer Drugs Fund (CDF) in England. At that time, access to RUX in Northern Ireland (NI) and Wales was limited mainly to clinical trials. In 2016, RUX was commissioned by the NHS for int-2 and high-risk patients, but there is increasing evidence that lower-risk patients also benefit significantly from treatment.
Aims: To assess the efficacy and safety of RUX in MF in the 'real-world' setting and compare outcomes of lower- (int-1) vs higher-risk patients.
Methods: A multicentre retrospective analysis of MF patients treated with RUX at 13 centres in England, Wales and NI from Jan 2011-Dec 2017. Data were collected using electronic and paper records. Survival analysis was estimated using the Kaplan-Meier method and standard log-rank test.
Results: We identified 158 patients and excluded 8 with insufficient data and 2 who had received another JAK inhibitor. Of 148 evaluable patients, the median age at the start of therapy was 69 years (29-91) and 58% were male. There were 67 (45%) PMF, 40 (27%) PPV-MF, 30 (20%) PET-MF and 11 (7%) post-myeloproliferative neoplasm-unclassified MF patients, consisting of 1 (1%) low-risk, 29 (20%) int-1, 56 (38%) int-2 and 62 (42%) high-risk patients. A driver mutation was found in 111 patients (103 JAK2+, 6 CALR+, 2 MPL+). RUX was used first-line in 39 (32%) patients, and 111 (75%) were treated via the CDF. Median OS was 3.5 years (0–7) for all patients, 1.5 years for high-risk patients and not reached for low- or int-1/2 risk patients. IPSS/DIPSS remained prognostic with 3-year OS of 77%, 67%, and 29% for int-1, int-2 and high-risk patients (HR 2.75; 95% CI 1.8–4.1, p<0.0005). Median time on RUX was 2.2 years with estimated 1, 3 and 5-year discontinuation rates of 31%, 59% and 72%. Data collection of objective response measures, including spleen size, weight and symptom-burden, is underway. As previously observed, spleen reduction (56 of 86 patients; p=0.051) and weight gain (40 of 57 patients; p=0.07) were associated with improved survival. The most common grade 3/4 AEs were thrombocytopaenia (27%) and anaemia (42%) and 37 patients required dose modification.

Infections were common, with 53 patients receiving antimicrobial therapy. At the time of analysis, 82 (55%) patients had stopped RUX; 31 had progressive disease, 25 had died, 17 had AEs, 7 had stem cell transplantation and 2 were patient choice. Median survival after stopping was 2.3 months, but only 10 days for the 13 patients who transformed to acute leukaemia. In total, 62 (42%) patients have died; including 16 from disease progression, 14 from infection, 5 from bleeding, 2 from second cancers, and 1 from myocardial infarction. Sixty-six (45%) patients remain on therapy.

Summary/Conclusion: Our data reflect contemporary clinical trials that show the efficacy of RUX in improving MF-related splenomegaly and symptoms in both int-1/2 and high-risk patients. As expected, haematological AEs were common but readily managed. Longer follow-up is needed to assess the impact on survival and further studies into the use of RUX in lower-risk patients are required.

PS1370

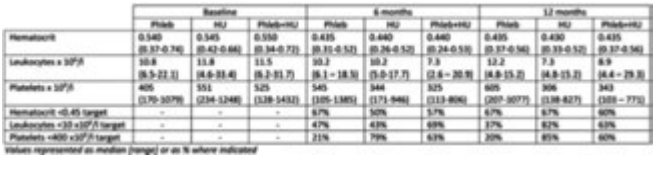
TREATMENT STRATEGIES FOR POLYCYTHEMIA VERA: OBSERVATIONS IN A DUTCH 'REAL-WORLD' COHORT STUDY

C. van de Ree- Pellikaan[1], A. de Kreuk[2], C. Schaar[3], A. Beeker[4], E. Dompeling[5], C. Gerrits[6], A. van Houten[7], M. Schipperus[8], L. Strobbe[9], W. Posthuma[10], K. Klauke[11], P. Westerweel[1,*]

[1]Internal Medicine, Albert Schweitzer Hospital, Dordrecht, [2]Internal Medicine, OLVG, Amsterdam, [3]Internal Medicine, Gelre Hospital, Apeldoorn, [4]Internal Medicine, Spaarne Gasthuis, Hoofddorp, [5]Internal Medicine, Isala Klinieken, Zwolle, [6]Internal Medicine, Ziekenhuisgroep Twente, Hengelo, [7]Internal Medicine, Maasstad Hospital, Rotterdam, [8]Hematology, Haga Teaching Hospital, The Hague, [9]Internal Medicine, Gelre Hospital, Zutphen, [10]Internal Medicine, Reinier de Graaf Hospital, Delft, [11]Novartis Pharma B.V., Arnhem, Netherlands

Background: Major thrombotic events are the main cause of mortality in Polycythemia Vera (PV) and therefore the primary focus of therapy. Treatment of PV requires control of circulating erythrocyte volume in addition to antiplatelet and/or anticoagulant treatment. Reduction of erythrocyte volume may be achieved by phlebotomy/erythrocytaferesis (Phleb), hydroxyurea treatment (HU) or a combination of both (Phleb+HU). Other treatments such as JAK2 inhibition and interferon are used in selected cases. In the absence of data from clinical trials comparing treatment strategies, there is a large variation in clinical practice.
Aims: Assessment of 'real-world' clinical practice of choice of treatment strategies for cytoreduction in PV patients and effects on the course of haematological control and patient outcome.
Methods: A retrospective chart review was performed in 150 PV patients from 10 major non-academic hospitals in the Netherlands to reflect a 'real-world' population of non-referred patients. Patients were required to meet the WHO 2008 diagnostic criteria. All patients provided written informed consent. Data were retrospectively collected from the time of diagnosis to inclusion based on the hospital records by trained data managers.

Table 1. Laboratory parameters at baseline and after 6 and 12 months of tretment.



Results: Patients had a median age of 64 (range 30-91) at diagnosis and 49% was male. 96.4% was JAK2 mutation positive. There was a high prevalence of a history of prior vascular events (37%) and concomitant cardiovascular risk factors (hypertension 59%, hypercholesterolemia 20%, diabetes 12%). A majority of patients received a combination of Phleb+HU (n=60, 40%), while others received HU only (n=32, 21%), only Phleb (n=37, 35%) or other treatment combinations (n=21, 14%). Table 1 shows the haematological parameters at baseline and at 6 and 12 months for patients treated with Phleb, HU or Phleb+HU. There were no statistically significant differences. The average (±SD) time to achieve a hematocrit target of 0.45 was the shortest in Phleb only patients (148±225 days) compared to HU (490±620 days) and Phleb+HU (346±426 days) treated patients. Leukocyte and platelet levels were numerically lower in HU-treated patients and ELN response targets were more often reached (p<0.05 in ANOVA). During the median follow-up period of 4.1 years after PV diagnosis, 22 patients (15%) suffered from a thrombotic vascular event despite treatment. In patients experiencing an event, the distribution between treatment strategies was similar and 59% used HU, while this was 61% in patients that remained event-free.
Summary/Conclusion: We observed major clinical variation in treatment strategies for PV in Dutch clinical practice. Although phlebotomizing patients shortens the time to achieving hematocrit control, median hematocrit levels were very similar after 6-12 months of treatment to that with HU alone or in combination with phlebotomies. In contrast, achievement of platelet and leukocyte ELN responses was higher in HU treated patients. Interestingly, the median hematocrit values achieved in Dutch clinical practice (43.0-44.0%) are comparable to the low-hematocrit arm of the CYTO-PV trial (44.4%). Nonetheless, the thrombotic vascular event rate in our cohort of Dutch PV patients remained clinically significant.

PS1371

PREGNANCY OUTCOMES IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS – PALG (POLISH ADULT LEUKEMIA GROUP) A RETROSPECTIVE ANALYSIS

B. Sokołowska[1,*], M. Sobas[2], M. Robak[3], K. Chojnowski[3], J. Treliński[3], J. Hałka[4], J. Niesiobędzka - Krężel[5], B. Stella - Hołowiecka[6], D. Jawniak[1], M. Kozioł[1], M. Hus[1], M. Bieniaszewska[7]

[1]Department of Haematooncology and Bone Marrow Transplantation, Medical University of Lublin, Lublin, [2]Department of Haematology, Blood Neoplasms and Bone Marrow Transplantation, Medical University of Wrocław, Wrocław, [3]Department of Hematology , Medical University of Łódź, Łódź, [4]Department of Hematology, Military Institute of Medicine, [5]Department of Hematology, Oncology and Internal Medicine, Medical University of Warsaw, Warsaw, [6]Outpatient Care Warsaw Katowice Branch, Medicover Poland, Katowice, [7]Department of Hematology and Transplantology, Medical University of Gdańsk, Gdańsk, Poland

Background: Philadelphia negative myeloproliferative neoplasms (MPNs) include polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis(PMF). Pregnant women with MPNs are not only at a higher risk of thrombosis but also of various gestational complications such as recurrent abortions, premature deliveries and fetal growth restriction which result in a low live birth rate estimated at 60%.
Aims: The aim of the study was a retrospective analysis of pregnancy outcomes in patients with Philadelphia negative MPNs in PALG centers.
Methods: The study group comprised forty nine women treated in seven centers in Poland. The patients' mean age at diagnosis was 27 years of age (range 18-35) and at the time of pregnancy 37 years of age (range 19-49). ET was diagnosed in 38 patients (77.6%), PV in three patients (6.1%) whereas PMF in eight patients (16.3%). The JAK2V617F mutation was detected in 30 patients (61.2%), the CARL mutation (type 1 or 2) was discovered in 8 patients (16.3%) and seven patients were JAK2 negative. The mutational status was not measured in a group of 4 patients (8.25%). The retrospective analysis covered the period of 21 years when 82 pregnancies were reported. Before the pregnancies 47 women (57.3%) received cytoreductive therapy hydroksycarbamide (HU), Anagrelide(ANA) or interferon alfa (INF).
Results: Mean platelet count at the beginning of pregnancies was 451 G/l(215-1500) and at the time of delivery it reached 455G/l(153-1008). Anticoagulation therapy using LMWH was given during 19 pregnancies (23.2%), LMWH with aspirin(ASA) during 9 pregnancies (11%) and ASA alone during 24 pregnancies (29.3%). Cytoreductive therapy using interferon alfa(INF) was given in the course of 44 pregnancies (53.7%) and in one pregnancy apheresis was performed. A total of 13 abortions during the first trimester, two abortions and three cases of stillbirth during the second trimester and three cases of stillbirth during the third trimester were observed. Other complications such as threatened abortion and threatened premature delivery, hypertension, gestational diabetes and teratoma were reported in the second trimester. Until the end of gestation the number of 61 fetuses (74.4%) were alive. Cesarean sections were performed in 32 patients (39%) and 24 women delivered fetuses vaginally (29.3%) (no information about the type of 5 deliveries was provided). Delivery was usually succeeded at 37 week of gestation. Mean weight of fetus was 3230g. More than 50% of fetuses had APGAR scale ratio 10.
Summary/Conclusion: According to our results, a live birth rate was approximately 70%, more than it was previously expected. We observed a statistically significant correlation between the presence of vascular complications before pregnancy and the presence of JAK2 mutation and complications during the second trimester. Vascular complications before pregnancy caused 3.5 fold higher risk of occurrence of complications during the second trimester. A total of 92.3% of complications during the second trimester were observed in JAK2 positive women.

PS1372

SECOND MALIGNANCIES IN HIDROXYUREA AND INTERFERON TREATED PATIENTS

T. Nascimento[1,*], D. Luis[1], A. T. Simões [1], M. Coucelo [1], J.C. Almeida[1], M. L. Riberio[1]

[1]Hematology, Centro Hospitar e Universitário de Coimbra, Coimbra, Portugal

Background: Philadelphia –negative myeloproliferative neoplasm (MPNs) include Essential Trombocythaemia (ET), Polycythaemia Vera (PV) and Primary Myelofibrosis (PMF). Hydroxyureia (HU) treatment involves the concern of potential mutagenicity. Treatment with alfa 2 –Interferon (IFN) is being increasingly used.
Aims: to describe the frequencies of second malignancies in a cohort of MPNs patients treated with Hydroxyurea (HU), IFN Pegylated alfa 2 or the combination of these drugs (started with HU and subsequently Peg IFN Pegylated alfa 2) and compare the prevalence of cardiovascular risk factors and associated thrombotic events in this groups .
Methods: Observational, descriptive and retrospective study of patients with the diagnosis of myeloproliferative neoplasms (MPNs) followed in our centre between January 2011 and February 2018. Clinical records were reviewed and patients were divided in three groups, according to their therapy: Group 1 was treated with HU, group 2 with IFN, and group 3 with both agents. Data analysis with SPSS®.
Results: We Identified 100 patents diagnosed with MPNs with criteria for cytoreductive treatment, according to ELN criteria for haematologic response . 48 patients were treated with HU, 11 with IFN and 41 patients with both HU and IFN subsequently. Key characteristics of the patients and treatments are shown in Table 1.

Table 1.

	HU treatment N= 48	IFN treatment N=11	HU-IFN treatment N=41
Gender, n (%)			
Female	26 (54.2%)	8 (72, 7%)	20(48, 8%)
Male	22 (45, 8%)	3 (27, 3%)	21 (51, 2%)
Age at time diagnosis (median)	69 [36-89]	51 [30-58]	64 [44-85]
MPN diagnosis, n (%)			
TE	24(50%)	9(81, 8%)	14(34, 1%)
PV	14 (29,2)	1 (9,1)	14 (34,1)
PMF	8 (16,7)	1(9,1)	11(26.8%)
MPN unclassified	2(4.2%)		2(4.9%)
Overall haematologic response, n (%)			
Complete (CR)	37 (77%)	10 (90%)	27(65.8%)
Partial (PR)	9 (18.7%)	1 (10%)	12 (29.2%)
None (NR)	2(4.2%)		2(4,9%)
Comorbidity, n (%)			
Hypertension	29(60, 4%)	3(27, 3%)	19(46.3%)
dyslipidemia	23(47, 9%)	0(0%)	17(41, 5. %)
Diabetes	6(125%)	0(0%)	9 (22.0%)
thrombosis	9 (18, 8 %)	0 (0%)	11 (26, 8%)
Antiplatelet therapy n, %	42 (87,5%)	11 (100%)	35 (85,5)
AAS or clopidogrel			
Anticoagulant therapy n, % warfarin	7 (14,6)	0 (0%)	5 (12,2%)
Time of follow up months (median)	25 (1-192)	50 (3-144)	73 (3-216)

	HU treatment N= 48	IFN treatment N=11	HU-IFN treatment N=41
All others non haematological neoplasms n (%) (Pvalue 0,195)	11 (22, 9%)	0	7(39,9%)
basal cell carcinoma	1 (2, 1%)		1 (2, 4%)
Baselioma	1 (2, 1%)		
Spinocelular Carcinoma	8 (16,6%)		3 (7,3%)
Prostate carcinoma	1 (2, 1%)		1 (2, 4%)
Renal cells Carcinoma			1 (2, 4%)
Thyroid Papilary carcinoma			1 (2, 4%)

Summary/Conclusion: We registered an occurrence of second malignancies in a total of 11 in patients under HU (22.9%), none in patients under IFN and 7 in the HU-IFN patients group (39.9%).Median age at diagnosis of MPNs was higher in HU patients group (69 years, vs 51 for IFN and 64 years for HU-INF).As also reported by others, in our cohort there appears to be a tendency for an increased risk of developing a second neoplasm in the patients treated with HU , especially when compared to patients receiving interferon therapy (OR of 1.283 (95% CI, pvalue 0.77 (chi-square test). Patients treated with HU-IFN combination (mean 36 months treatment with HU in grupe 3) had fewer cutaneous neoplasms when compared to the group 1 (HU therapy mean 25 months) , (Mann Witney test (p value <05 com 95%).There was a better control hematological in patients of group 2 and lower cardiovascular risk, however, the median age of these patients was lower, requiring more follow-up time for evaluation.

PS1373

CORRELATIONS BETWEEN GENETIC AND CLINICAL CHARACTERISTICS IN PATIENTS WITH PRIMARY MYELOFIBROSIS

L. Polushkina[1,*], I. Martynkevich[1], V. Shuvaev[1], E. Motyko[1], M. Fominykh[1], L. Martynenko[1], M. Bakai[1], N. Tsybakova[1], Y. Ruzhenkova[1], N. Pavlenko[1], S. Voloshin[1], S. Bessmeltsev[1], A. Chechetkin[1]

[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Mutations in *JAK2*, *CALR*, *MPL* genes which trigger the process of autonomous cell proliferation are specific genetic lesions of classic Ph-negative myeloproliferative neoplasms including primary myelofibrosis (PMF). Also, the patients with PMF frequently have somatic defects of epigenetic regulators, primarily in *ASXL1* gene. Combined molecular abnormalities cause a diversity of tumor cells properties and determine the PMF clinical manifestations heterogeneity. The identification of "phenotypic signature" of mutations can become an important tool for clonal myelopoiesis disorders workup at the diagnosis.
Aims: The study aims to identify correlation between PMF clinical manifestations and the mutational status of *JAK2, CALR, MPL, ASXL1* genes.
Methods: We examined 110 patients with PMF (35% males). Median age was 59 years (16-82), median follow up – 2.6 years (0.1-23.0). For all patients the detection of *JAK2*V617F was done. *JAK2* negative samples were subsequently tested for *MPL* and *CALR* mutations. All patients except 4 underwent the analysis of mutations in exon 12 of *ASXL1* gene by direct sequencing. When comparing categorical variables Fisher exact test and chi-square test were used. The Kruskal-Wallis test and the Mann-Whitney U test were used for continuous data. P values less than 0.05 were considered statistically significant.
Results: Driver mutations (DM) were detected in 82% patients: $JAK2^+$ - 50%, $CALR^+$ - 26%, MPL^+ - 6% cases. No DM were found in 18% patients considered triple-negative (TN). Mutations in *ASXL1* gene were detected in 20% patients: $CALR^+$ - 29%, TN- 30%, $JAK2^+$ - 12%, MPL^+ - 29% cases. When compared TN and DM+ patients the former had lower hemoglobin level (here and after median values are shown) (10.1g/dL vs 12.1g/dL, p=0.006), lower platelet counts (266×10^9/L vs 506×10^9/L, p=0.041) and higher white blood cell counts (27×10^9/L vs 12×10^9/L, p=0.001). Blast counts ≥1% in peripheral blood was more often detected in $CALR^+$ (58%, p=0.001) and TN patients (60%, p=0.003) compared to $JAK2^+$ (20%). Hemoglobin level was higher in $JAK2^+$ patients compared with $JAK2^-$ (12.9g/dL vs 10.9 g/dL, p=0.021). *ASXL1* mutations were associated with a lower platelet counts (184×10^9/L vs 530×10^9/L, p=0.016), leukocytosis > 25×10^9/L (40% vs 16%, p=0.046), palpable splenomegaly (93% vs 68%, p=0.050) and blasts ≥1% (87% vs 27%, p<0.001). The median platelet counts differed in the $CALR^+$ and $CALR^-$ patients only when the *ASXL1* status was taken into account: 799×10^9/L vs 510×10^9/L (p=0.046) in $ASXL1^-$ and 313×10^9/L vs 164×10^9/L (p=0.175) in $ASXL1^+$ subgroup. Hemoglobin levels in TN patients were significantly lower than in the DM^+ASXL1^- group regardless of the *ASXL1* status (10.1g/dLin DM^-ASXL1^- and 100g/L in DM^-ASXL1^+ vs 124g/L in DM^+ASXL1^- group, p=0.050 and p=0.001, respectively). The maximum value of leukocyte counts was revealed in DM^-ASXL1^+ group (51×10^9/L) whereas in the DM^-ASXL^- group it was lower (22×10^9/L, p=0.155). White blood cell levels differed significantly between DM^+ and TN groups when *ASXL1* status was identical: 8×10^9/L vs 52×10^9/L in $ASXL1^+$ (p=0.050) and 12×10^9/L vs 22×10^9/L in$ASXL1^-$ (p=0.022) subgroup.
Summary/Conclusion: The presence of *JAK2*, *CALR*, *ASXL1* mutations as well as triple-negative status correlates with clinical manifestations of PMF. These genetic factors in different combinations can cause the variety in hematological features of the disease. Received data confirms the importance of both driver and *ASXL1* mutations screening at the diagnosis of PMF.

MUTATIONAL PROFILES OF CLASSIC MYELOPROLIFERATIVE NEOPLASMS IN TAIWANESE PATIENTS: FREQUENCY AND CLINICAL CORRELATION

H.-C. Lin[1,*], Y.-C. Chang[1,2], Y.-H. Chiang[1], L. Huang[13], W.-T. Wang[1], C.-C. Cheng[1], N.-W. Su[1], C. G.-S. Chen[1,2], J. Lin[1], R.-K. Hsieh[1], M.-C. Chang[1], Y.-F. Chang[1,2], D.-Y. Hwang[4], K.-H. Lim[1,2]

[1]Department of Internal Medicine, Division of Hematology and Oncology, MacKay Memorial Hospital, Taipei City, [2]Department of Medicine, MacKay Medical College, [3]Department of Medical Research, Good Clinical Research Center Laboratory, MacKay Memorial Hospital, New Taipei City, [4]Department of Internal Medicine, Division of Nephrology, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan, Republic of China

Background: The *JAK2*V617F, *CALR* exon 9 and *MPL* exon 10 mutations are three major driver mutations in classic *BCR-ABL1*-negative myeloproliferative neoplasms (MPNs). In addition, MPN patients can harbor other non-driver mutations such as *TET2*, *DNMT3A*, *AXSL1* and *TP53*.
Aims: The aims of this study were to determine the mutational profiles of MPN in a cohort of Taiwanese patients, and to correlate the mutations with clinical characteristics.
Methods: MPN patients seen at MacKay Memorial Hospital from Oct 2009 to Oct 2015 were enrolled into this study. The clinical and laboratory characteristics at the time of diagnosis or referral were determined retrospectively by chart review. Patient genomic DNA was derived from bone marrow or peripheral blood. Targeted next generation sequencing (NGS) was carried out using a customized myeloid-related panel including 33 genes. The Illumina *MiSeq* system was used to run NGS experiment. *MiSeq Reporter* Software and the Burrows-Wheeler Aligner were used for bioinformatics analysis.

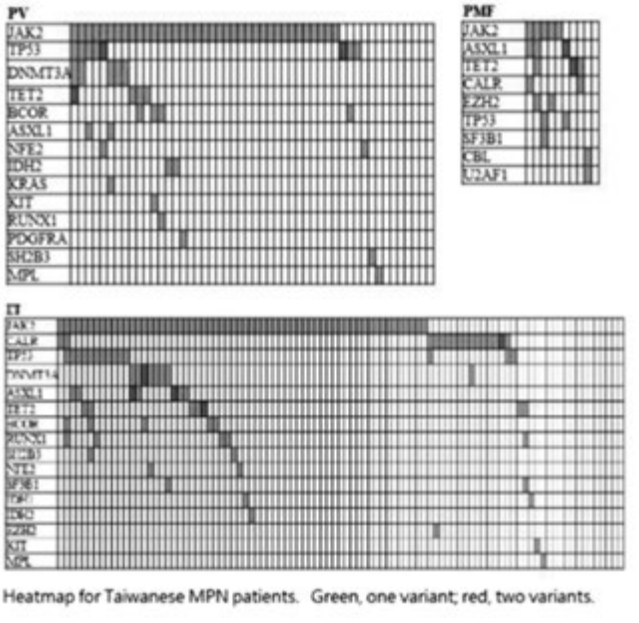

Figure 1.

Results: A total of 155 MPN patients (median age at diagnosis 57 years; 51.6% females). Our cohort was comprised of 95 essential thrombocythemia (ET, 61.3%), 50 polycythemia vera (PV, 32.3%) and 10 primary myelofibrosis (PMF, 6.5%). Frequencies of the 3 driver mutations were 67.1% for *JAK2*V617F, 11.6% for *CALR* and 1.3% for *MPL*. 22.6% of patients were classified as triple-negative. The frequencies of non-driver mutations were 15.5% for TP53, 9% TET2, 8.4% DNMT3A, 7.7% ASXL1, 5.8% BCOR, and 3.9% RUNX1 (Figure 1). The frequencies of mutations in other 11 genes occurred in less than 3% of patients. Median number of mutation was 1 (range 0-5): 12.9% no mutation, 40% 1 mutation, 27.1% 2 mutations, 14.2% 3 mutations, 3.9% 4 mutations, and 1.9% 5 mutations. Mutations in an epigenetic regulation gene (*TET2*, *DNMT3A*, *IDH1/2*) were most frequently detected (20%, one patient harbored both *TET2* and *DNMT3A* mutations) in this cohort. 9% mutations in a gene involved in histone modification/chromatin regulation (*ASXL1*, *EZH2*, one patient harbored both mutations). *JAK2*V617F mutation was significantly associated with older age at diagnosis (median 62 vs 54, p=0.02), higher hemoglobin level (median 14.7 vs 13g/dL, p=0.02) and higher leukocyte count (median 13.3 vs 8.5/uL, p<0.001). Whereas, *CALR* mutations were significantly associated with higher platelet count (median 1119 vs 731/uL, p<0.01) and lower hemoglobin level (median 11 vs 14.7g/dL, p<0.01). Patients with PMF had inferior overall survival (OS) (median 3.4 years vs. not reach vs. not reach; p<0.001). *ASXL1* mutations were associated with inferior OS (median 8.7 years vs. not reach; p<0.001). Mutations in an epigenetic regulation gene or an increased number of somatic mutations were not associated with worse OS.
Summary/Conclusion: In this cohort of Taiwanese MPNs, driver mutations correlate with clinical features. Consistence with the results from Western populations, *ASXL1* mutations had prognostic significance in MPNs.

CYCLIN D1-MEDIATED GENE EXPRESSION DYSREGULATION IMPACTS MANTLE CELL LYMPHOMA PATHOGENESIS

S. Demajo[1,*], R. Albero[1], G. Castellano[2], C. Capdevila[1], A. Navarro[1,3], G. Clot[1,3], F. Nadeu[1], H. Suárez-Cisneros[4], A. Enjuanes[4], M. Pinyol[4], S. Beà[1,3], E. Campo[1,3,5], P. Jares[1,3,5]

[1]Lymphoid Neoplasm Program, Institut d'investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), [2]Molecular Biology Core, Hospital Clínic de Barcelona, [3]Centro de Investigación Biomédica en Red de Cáncer (CIBERONC), [4]Genomics Unit, Institut d'investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), [5]Laboratory of Anatomic Pathology, Hospital Clínic de Barcelona, Barcelona, Spain

Background: Mantle cell lymphoma (MCL) is a B-cell neoplasm that usually follows an aggressive clinical course. It is characterized by the t(11;14) translocation that leads to cyclin D1 overexpression. Although the classical MCL tumorigenesis model considers that cyclin D1 mediates its oncogenic effect through cell cycle activation, emerging roles of cyclin D1 in other cellular contexts suggest a more complex scenario.
Aims: To study the potential function of cyclin D1 as a transcriptional regulator in MCL and its impact in the pathogenesis of this neoplasm.
Methods: In order to identify the genes potentially dysregulated by cyclin D1 overexpression in MCL, we generated cyclin D1-silenced MCL cell lines and a lymphoid cell model of exogenous cyclin D1 overexpression and performed genome-wide expression analysis. We next combined these results with cyclin D1 ChIP-sequencing in MCL cell lines to robustly identify cyclin D1 directly regulated genes. Bioinformatic analyses of the promoters of these genes together with co-immunoprecipitation experiments were used to investigate the mechanism of cyclin D1-mediated gene regulation. We then studied the expression of the genes directly activated by cyclin D1 in MCL patients in order to define the biological and clinical relevance of this cyclin D1-regulated gene program. For that, we used different microarray data sets, including MCL primary blood (n=53) and tissue (n=106) samples, non-neoplastic lymphoid tissues (n=21), and several other B-cell lymphoid neoplasms (n=101).
Results: We identified the gene expression program transcriptionally activated by cyclin D1 in MCL, consisting of 295 genes that were downregulated in the cyclin D1 silencing cell models, upregulated in the cyclin D1 overexpression cell model and had a cyclin D1 peak in their promoters. Gene ontology analysis of these cyclin D1-activated genes showed that most of them belong to cell cycle and DNA damage response pathways. Motif enrichment analysis of cyclin D1 peaks present in their promoters together with several analyses using the ENCODE ChIP-sequencing database identified E2F4 as potential recruiting factor of cyclin D1 to its target genes. The interaction of cyclin D1 with E2F4 was confirmed by co-immunoprecipitation, as well as its interaction with the coactivator CBP, which may explain its transcriptional activation mechanism. To analyze the clinical impact of the cyclin D1-activated gene program in MCL patients, we defined a cyclin D1 signature score based on the expression of the 295 genes. We found that cyclin D1 signature was overexpressed in MCL compared with non-neoplastic samples ($p<0.001$) and with other -cyclin D1 negative- lymphoid neoplasms ($p=0.006$). Additionally, cyclin D1 signature expression levels were directly correlated to the cyclin D1 expression levels in MCL cases, both considering blood ($r=0.617$, $p<0.001$) and tissue ($r=0.493$, $p<0.001$) samples. Finally, we found that increasing cyclin D1 signature expression levels were associated with shorter overall survival in MCL patients in a continuous manner, both in blood ($p=0.001$) and tissue ($p<0.001$) samples.
Summary/Conclusion: Our results expand the oncogenic function of cyclin D1 in MCL, showing the importance of cyclin D1 as a transcriptional regulator in this disease. We have found that cyclin D1 activates a gene expression program that could have a critical impact in cell cycle and DNA damage response dysregulation in MCL and therefore in the pathogenesis of this neoplasm. Accordingly, high expression levels of cyclin D1-activated genes correlate with poor survival in MCL patients.

PS1377

SPLENIC MARGINAL ZONE B-CELL LYMPHOMAS DEPENDS ON PROGRAMMED DEATH-LIGAND 1 FOR CLONAL EMERGENCE AND ARE CONTROLLED BY T-CELLS FOR PROLIFERATION RATE

C. Vincent-Fabert[1], I. Soubeyran[2], A. Saintamand[3], F. Boyer[1], U. Zimber-Strobl[4], J. Feuillard[1], N. Faumont[1,*]

[1]UMR CNRS 7276 / INSERM U1262 - CRIBL, LIMOGES, [2]Laboratory of Pathology, Institut Bergonié, Bordeaux, France, BORDEAUX, [3]UMR INSERM U1236, University of Rennes [1], Rennes, France, LIMOGES, France, [4]Research Unit Gene Vectors, Helmholtz Center Munich, German Research Center for Environmental Health GmbH, Munich, Germany, MUNICH, Germany

Background: Marginal zone B-cell lymphomas (MZLs) are incurable indolent cancers. Presence of PD1 positive T-cells in these lymphomas has been reported. This raises the question of the escape from immune control.
Aims: To search for PDL1 expression in splenic MZLs (SMZLs) and to explore the reciprocal control between tumor cells and the immune system in a mouse model of SMZL.
Methods: Immunochemistry for PD-L1 was done on 74 ZML tumor samples. Functional studies were performed on the L.CD40 transgenic mouse model, one of the very few preclinical models for splenic MZL. These mice are characterized by B-cell specific continuous CD40 signaling responsible for a spleen indolent monoclonal B-cell tumor after one year in 60% of cases. L.CD40 mice were injected with anti-PD-L1 antibody. T-cell depletion was done by injection of a mix of anti-CD4, anti-CD8, and anti-Thy-1 antibodies. L.CD40 mice were also treated with cyclosporin A.
Results: In humans, about 60% of SZML tumor samples significantly expressed the PD-L1 molecule. Like SMZL in humans, L.CD40 mouse B-cells tumors expressed high levels of PD-L1. Treatment of L.CD40 mice with an anti-PD-L1 monoclonal antibody induced tumor regression with decreased activation, proliferation rate and spleen content of B-cells as well as a marked increase in T cell activation, that T-cells strongly expressing PD1. L.CD40 mice were next immunosuppressed (IS) either by T and NK cell depletion or with the immune suppressive drug, cyclosporin A. Spleen enlargement was increased due to increased B-cell content. Tumor B-cells from IS L.CD40 mice had an immunoblastic high-grade aspect. *In vivo* proliferation rate and expression of activation markers were also increased after IS treatment. Long term IS was associated with acceleration of B-cell clonal emergence in the spleen and blood passage of large tumor B-cells.
Summary/Conclusion: Collectively, these features suggest that emergence of SMZL is under the dependence of the PD1/PD-L1 axis and that proliferation rate of SMZL remains under the strict T-cell control. In other words, SMZL tumor B cells partially escape immune surveillance due to PD-L1 expression but immune control was still exerted against the more aggressive B-cells. Additionally, these results highlight the interest of therapies targeting the PD-1/PD-L1 axis in indolent lymphomas with PD-L1 expression.

PS1378

TPL2 KINASE HAS A TUMOR SUPPRESSIVE ROLE IN MYC-INDUCED LYMPHOMAGENESIS

E. Stagakis[1,2,*], D. Vyrla[1], H. Papadaki[2], E. Drakos[3], A.G. Eliopoulos[1]

[1]Department of Biology, National & Kapodistrian University of Athens, Athens, [2]Department of Hematology, University Hospital of Heraklion, [3]Department of Pathology, University of Crete, Heraklion, Greece

Background: MYC-induced lymphomagenesis is a complex biological process and many of its aspects remain poorly understood. Burkitt lymphoma (BL) is considered the prototypical example of a disease caused by a t(8;14)(q24;q32) translocation bringing *myc* under the control of the IgH locus. Nevertheless, other B-cell lymphomas with aggressive clinical behavior and poor treatment response can also overexpress MYC. Therefore, in order to gain a better insight into MYC-induced lymphomagenesis, it is necessary to identify new signaling pathways that cooperate with MYC. TPL2 (MAP3K8) is a MAP3 kinase with a crucial role in innate immunity and inflammation but its involvement in lymphomagenesis remains unknown. By using text mining algorithms and by inspecting transcriptome profiles registered in the Oncomine database (http://www.oncomine.org) we identified putative links between MYC and TPL2.
Aims: The aim of this study is to define the impact of and the mechanism by which TPL2 kinase affects MYC-induced lymphomagenesis.
Methods: The TPL2 mRNA and protein expression levels were assessed by qPCR and Western blot analysis, respectively. Mouse CD19+ B cells were isolated by magnetic separation from spleens of WT (C57BL/6; non-Tg) and *Eμ-myc* transgenic mice engineered to overexpress c-*myc* in B cell pro-

genitor cells under the control of the IgH chain enhancer. Mouse pre-B lymphocytes (B220+. IgM-) were isolated from bone marrow by cell sorting. The extent of apoptosis and proliferation was estimated by immunohistochemical evaluation of activated caspase-3 and phospho-histone H3 in paraffin embedded mouse lymphoma tissues. Malignant cells were cultured *ex vivo* following cytokine deprivation or treatment with chemotherapeutic reagents. Apoptosis was further assessed with flow cytometry using Annexin and PI staining. Cell proliferation was assessed using MTS assay.
Results: TPL2 mRNA levels were dramatically reduced in human Burkitt cell lines and primary BL biopsies compared to B-lymphocytes of healthy individuals. Accordingly, analysis of TPL2 expression in pre-B and B lymphomas of Eμ-myc transgenic mice revealed very low levels of TPL2 both at RNA and protein level, compared to pre-B and splenic B lymphocytes isolated from WT mice. Moreover, TPL2 expression levels correlated with the age of disease onset in Eμ-myc mice with the lowest TPL2 expression levels to be associated with a younger age of disease onset. In this regard, genetic ablation of TPL2 in *Eμ-myc* mice (*Eμ-myc/tpl2*$^{-/-}$) significantly shortened their survival to 92 days from 131 days of *Eμ-myc/tpl2*$^{+/+}$ mice ($p<0.05$). The acceleration of lymphomagenesis is not attributable to the absence of TPL2 in the tumor microenvironment as adoptive transfer of malignant *Eμ-myc* lymphocytes to mice with *tpl2*$^{+/+}$ versus *tpl2*$^{-/-}$ genetic background resulted in a similar median survival. Compared to *Eμ-myc/tpl2*$^{+/+}$, *Eμ-myc/tpl2*$^{-/-}$ lymphomas display reduced levels of activated caspase-3 and increased levels of phospho-histone H3. *Eμ-myc/tpl2*$^{-/-}$ lymphoma cells cultured *in vitro* were resistant to apoptosis following cytokine deprivation or treatment with chemotherapeutic agents, such as doxorubicin, cyclophosphamide and etoposide.
Summary/Conclusion: This work reveals a novel role for TPL2 as suppressor of myc-driven lymphomagenesis which is supported by: (a) the dramatic reduction in TPL2 expression in human and mouse lymphomas bearing oncogenic MYC activation, (b) the acceleration of disease onset in mice lacking TPL2 and, (c) the higher proliferative index and lower levels of apoptosis in MYC lymphomas that arise on a TPL2-null background.

PS1379

MECHANISMS CONFERRING RESISTANCE TO VENETOCLAX IN CHRONIC LYMPHOCYTIC LEUKEMIA AND MANTLE CELL LYMPHOMA

D. Steinbrecher[1,*], F. Seyfried[2], J. Bloehdorn[1], B.M.C. Jebaraj[1], L.-H. Meyer[2], C. Schneider[1], S. Stilgenbauer[1]

[1]Department of Internal Medicine III, [2]Department of Pediatrics and Adolescent Medicine, Ulm University, Ulm, Germany

Background: The BCL-2 family consists of important regulators of apoptosis which have been found to be deregulated in cancer. BCL-2 dependent cancers including chronic lymphocytic leukemia and mantle cell lymphoma (MCL) are highly sensitive to venetoclax (VEN). Despite presenting a highly efficient therapeutic agent, acquired resistance can develop. Understanding the underlying mechanisms of resistance to VEN is essential to identify the best possible treatment options in refractory patients.
Aims: To gain a better understanding of the molecular mechanism triggering VEN resistance, we developed *in vitro* resistance models and investigated BCL-2 family member expression changes.
Methods: In this study, we generated VEN-resistant MCL cell lines (MINO and MAVER-1) by chronic exposure to increasing doses of VEN. Apoptosis was assessed by Annexin V/7AAD staining. Protein expression of BCL-2 family members was assessed by western blot. BH3 profiling was used to assess the interplay of pro- and anti-apoptotic proteins.
Results: In VEN-resistant MINO cells, MCL-1 was not deregulated as compared to parental cells, while MCL-1 was significantly downregulated in VEN-resistant MAVER-1 cells. In variance to previous reports in diffuse large B cell lymphoma (DLBCL), linking resistance to upregulation of MCL-1 and BCL-XL (Choudhary *et al.*, Cell Death Dis 2015), our results indicate that resistance in MCL cell lines is not mediated by MCL-1. Also, dynamic BH3 profiling confirmed that VEN resistance is not mediated by and dependent on MCL-1. Actually, MCL-1 upregulation occurred in both parental and resistant cells upon treatment with VEN and normalized when treatment was stopped, suggesting that MCL-1 is stabilized by binding to proteins released from BCL-2. In line with results obtained in DLBCL (Choudhary *et al.*, Cell Death Dis 2015), we could identify a permanent BCL-XL upregulation as important mechanism conferring resistance to VEN. Additionally, BH3 profiling confirmed a dependency on BCL-XL in resistant cells. The significance of BCL-XL in mediating resistance to VEN was underlined by exposing the cells to navitoclax. In contrast to VEN, navitoclax inhibits BCL-2, BCL-W and BCL-XL and was sufficient to induce apoptosis in both parental and resistant cells. In addition to deregulation of anti-apoptotic proteins, the acquisition of resistance to VEN in MINO and MAVER-1 cells led to reduced protein expression of pro-apoptotic BCL-2 family members. In VEN-resistant MAVER-1 cells downregulation of multiple pro-apoptotic proteins including BAK, BAX, PUMA, BIM and NOXA was found, while in VEN-resistant MINO cells only pro-apoptotic BID and BAD were downregulated. Additionally, BH3 profiling confirmed this result by showing that in both resistant cell lines induction of apoptosis was hampered as compared to parental cells. In contrast to the BH3 domain inhibitor VEN, the BCL-2 inhibitor BDA-366 acts by inhibiting the BH4 domain and thereby inducing a conversion of BCL-2 into a BAX-like death molecule. BDA-366 was effectively inducing cell death in both parental and VEN-resistant cell lines (MINO and MAVER-1). Therefore, targeting BCL-2 by inhibiting its BH4 domain could be a potential alternative treatment strategy for BCL-2 dependent cancers resistant to VEN.
Summary/Conclusion: Overall, these results suggest that VEN resistance is mostly mediated by permanent upregulation of BCL-XL while MCL-1 is upregulated temporarily upon treatment in parental and resistant cells. In addition to BCL-XL upregulation, a complex deregulation of pro-apoptotic BCL-2 family members plays a role in inducing resistance to VEN.

PS1380

CLINICAL, PATHOLOGICAL AND MOLECULAR STUDY OF 46 PATIENTS WITH A DIAGNOSIS OF CD5-POSITIVE DIFFUSE LARGE B-CELL LYMPHOMA

V. Allain[1,2,*], J. Dupuis[1], L. Roulin[1], C. Robe[2], M. Baia[2], A. Nicolae[2], H. Fouché[3], M. Fusaro[3], M.-H. Delfau-Larue[3], P. Gaulard[2], C. Haioun[1], C. Copie-Bergman[2]

[1]Unité Hémopathies Lymphoïdes, [2]Département de Pathologie, [3]Département d'Hématologie et Immunologie Biologiques , Hôpital Henri Mondor - APHP, Créteil, France

Background: CD5-positive diffuse large B-cell lymphomas (CD5+ DLBCL) are aggressive lymphomas of poor prognosis, with specific clinical characteristics (adverse prognostic factors, extranodal tropism, high rate of central nervous system (CNS) relapses), and a predominant "activated B-cell like" (ABC) expression profile. However, physiopathological mechanisms explaining these peculiarities remain mostly unknown, and cure is still a therapeutic challenge.
Aims: Our goal was to describe clinical, pathological and molecular features of a CD5+ DLBCL patients series, in order to give new insights possibly leading to a better understanding of these lymphomas.
Methods: Forty six CD5+ DLBCL patients were included in this monocentric retrospective study. Association with a chronic lymphocytic leukemia or a mantle-cell lymphoma were exclusion criteria. All tumor samples were reviewed by an expert hematopathologist and classified according to the 2016 WHO classification, with an extensive immunochemistry panel and fluorescent *in situ* hybridization analysis (FISH) for *MYC*, *BCL2*, *BCL6* and *IRF4* gene rearrangements. Gene expression analysis by Reverse Transcriptase-Multiplex Ligation-dependent Probe Amplification (RT-MLPA) and mutational analysis by next-generation sequencing (NGS) on a dedicated gene panel were performed on a subset of patients.
Results: Median age at diagnosis was 68 years (range 22-83). Twenty percent of patients had a past history of solid cancer, and 17% history of autoimmune disease. DLBCL "not otherwise specified" (NOS) was the main diagnosis (89%). We found an association with a prior or concomitant low-grade B-cell lymphoma in 26% of cases. International prognostic index classified 63% of patients in the high-risk group. Extranodal tropism and a high CNS relapse rate (9%) were observed as previously described. Cell-of-origin classification revealed "non germinal-center B-cell like (non-GCB)"/ABC profile in most cases (72% by Hans algorithm and 80% by RT-MLPA). Of note, only 2 of 10 GCB CD5+ DLBCL (according to Hans algorithm) harbored a GCB profile by RT-MLPA showing the poor reliability of the Hans classifier in this specific DLBCL population. Nearly all cases (98%) showed BCL2 protein overexpression whereas *BCL2* rearrangement was rare (n=1). MYC overexpression was observed in 53% of cases. *BCL6* and *MYC* breaks were detected in 17% of cases for both genes. Preliminary results showed that none of 4 tested lymphomas harbored an *IRF4* translocation. PD-L1 was overexpressed on tumor cells in 20% of cases and a clear although heterogeneous PD1 expression by tumor cells was noted in 2/15 biopsies. Over the 36 diagnostic biopsies assessed for the presence of EBV (either by *in situ* hybridization or by RT-MLPA), 5 cases were positive (14%). The preliminary molecular analysis by NGS (performed on 32 samples) showed mutations of *MYD88* and *CD79B* in 31% and 19% of lymphomas at diagnosis, respectively. 4/6 cases with a *CD79B* mutation also harbored a *MYD88* mutation. Interestingly, all 9 *MYD88* L265P mutations were also detected by the RT-MLPA specific assay.

Summary/Conclusion: We report the clinical, pathological and molecular features of 46 CD5+ DLBCL patients. We confirm the already reported non-GCB/ABC profile and recurrent *MYD88* and *CD79B* mutations. NGS molecular analysis is still ongoing. This series highlights new findings such as a frequent association with solid cancer and PD-L1/PD1 expression in a significant number of cases which warrants further investigations.

PS1381

THE NOVEL TUMOR SUPPRESSOR SAMHD1 IS FREQUENTLY DOWNREGULATED AND CORRELATES WITH GERMINAL CENTER PHENOTYPE IN DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL)

I. Xagoraris[1,*], N. Herold[2], K. Ekstrom Smedby[3], J. Khoury[1], G.Z. Rassidakis[3]

[1]Department of Hematopathology, The University of Texas MD Anderson Cancer Center, Houston, United States, [2]Department of Women's and Children's Health, [3]Department of Oncology-Pathology, Karolinska Institute, Stockholm, Sweden

Background: The SAM domain and HD domain 1 (SAMHD1) protein is a deoxynucleoside triphosphate (dNTP) triphosphohydrolase, which has been initially described to restrict human immunodeficiency virus type 1 (HIV-1) in certain cell types through depletion of intracellular dNTP substrates for HIV-1 reverse transcription. Mutations of SAMHD1 gene have been linked to Aicardi-Goutières syndrome (AGS) and have been identified as putative drivers of chronic lymphocytic leukemia resulting in decreased SAMHD1 mRNA and protein levels. Therefore, SAMHD1 may play a role in oncogenesis as a tumor suppressor. In addition, SAMHD1 may confer resistance to nucleoside-based chemotherapies such as cytarabine in acute myeloid leukemia (Herold *et al.*, Nat Med 2017; 23(2):256-263). The expression levels and the potential role of SAMHD1 in the pathogenesis of diffuse large B-cell lymphoma (DLBCL) are not yet known.
Aims: To investigate the expression patterns and regulation of SAMHD1 tumor suppressor in diffuse large B-cell lymphoma (DLBCL).
Methods: SAMHD1 protein levels were assessed by Western blot analysis in 3 diffuse large B-cell lymphoma (DLBCL) cell lines including SU-DHL-4, MS, and OCI-Ly3. As our findings from in silico analysis revealed potential binding sites for MYC on the SAMHD1 gene promoter, DLBCL cell lines were treated with JQ-1, a BET and MYC inhibitor to assess possible MYC- associated regulation of SAMHD1. The patient cohort included 72 cases of *de novo* or transformed, previously untreated DLBCL diagnosed and treated at Karolinska University Hospital (Sweden) as well as 4 reactive lymph nodes for comparison. SAMHD1 expression was assessed by immunohistochemistry performed on tissue microarrays with duplicate tumor cores from each case or full tissue sections using a monoclonal antibody. The percentage of SAMHD1-positive cells was provided by counting at least 500 tumor cells in each case. Overall survival (OS) and event-free survival (EFS) were the clinical outcome endpoints. Survival analyses were performed using the Kaplan-Meier method (log-rank test) and Cox regression models.
Results: SAMHD1 was expressed in all 3 DLBCL at a variable level. Inhibition of MYC activity by JQ-1 resulted in a substantial increase in the SAMHD1 protein level suggesting a possible MYC-associated gene regulation. The highest change in the SAMHD1 levels was observed in the OCI-Ly3 cells that carries a wild-type p53 gene. In reactive lymph nodes, strong SAMHD1 expression was detected in the reactive small T-cells, whereas the large germinal center cells showed moderate expression levels. The median percentage of SAMHD1 in the neoplastic cells of DLBCL cases was 16.6% (SD=30%, range 0-95%). High SAMHD1 levels (>10% positive cells) were seen in 25% of DLBCL suggesting downregulation of SAMHD1 gene in the majority of DLBCL. The level of SAMHD1 expression (% positive tumor cells) was significantly higher in DLBCL with germinal center (GC) phenotype, in transformed versus *de novo* DLBCL, and in advanced Ann Arbor stage ($p<0.05$ in all associations). The SAMHD1 levels were also statistically associated with p53 expression as a continuous variable (% of positive cells). High SAMHD1 levels (>10%) showed a statistical trend towards worse EFS and OS, however, statistical significance was not reached ($p>0.05$) likely due to the small number of cases in the patient group with high SAMHD1.
Summary/Conclusion: SAMHD1 expression is shown for the first time in DLBCL and correlates with GC phenotype and tumor aggressiveness.

PS1382

DUAL TARGETING OF BRD4 BY AZD5153 AND BCL2 BY AZD4320 FOR HIGH-RISK B-CELL LYMPHOMAS CONCOMITANTLY OVEREXPRESSING C-MYC AND BCL2

T. Shimomura Takimoto[1,*], S. Maegawa[1], T. Tsukamoto[1], Y. Chinen[1], Y. Shimura[1], S. Mizutani[1], T. Kobayashi[1], T. Taki[2], S. Horiike[1], J. Kuroda[1]

[1]Hematology and Oncology, [2]Molecular Diagnostics and Therapeutics, Kyoto Prefectural University of Medicine, Kyoto, Japan

Background: The treatment outcomes of most B-cell lymphomas (BCLs) have been greatly improved by the advent of rituximab-containing immunochemotherapy; however, the prognoses of high-risk BCLs such as double hit lymphoma (DHL) and double expressing lymphoma (DEL) that concomitantly overexpress c-Myc and BCL2 have remained poor due to treatment resistance. Therefore, development of a new therapeutic strategy for DHL and DEL is urgently needed.
Aims: The effects of a novel BRD4 inhibitor, AZD5153, and a novel BH3-mimicking BCL2 inhibitor, AZD4320, were investigated in BCL-derived cell lines concomitantly overexpressing c-MYC and BCL2.
Methods: Conventional BRD4 inhibitors, JQ1 and I-BET151, and a BH3-mimetic, ABT-263, were obtained commercially. AZD5153 and AZD4320 were provided by AstraZeneca. Two DEL-derived cell lines, KPUM-UH1 and KPUM-MS3, established in our laboratory (Sasaki N, Exp Hematol 2011), and a DHL-derived cell line, STR-428 (JCRB Cell Bank) were used in the study. The growth inhibitory effects of the three BRD4 inhibitors and two BH3-mimetics were examined in the three cell lines using a modified MTT assay. Comparative gene expression profile (GEP) analyses and an ingenuity canonical signal pathway analysis based on the GEP results for untreated cells and cells treated with AZD5153 were performed in the three cell lines. Protein and mRNA expression levels were examined by Western blot and RT-PCR analysis, respectively.
Results: The growth inhibitory effect of AZD5153 was approximately 10 to 20 times greater than those of JQ-1 and I-BET151 in all three cell lines (IC_{50} values for AZD5151, JQ-1 and I-BET151 were 0.202-0.263mM, 2.039-4.355mM and 2.821-5.196mM, respectively). AZD4320 was approximately 2 to 100 times more effective than ABT-263 in inhibiting the growth of the three cell lines (IC_{50} values for AZD4320 and ABT-263 were 0.017-0.17mM and 0.304-1.908mM, respectively). The growth inhibitory effect of AZD5153 was mainly mediated by G1/S cell cycle blockade, while that of AZD4320 occurred through induction of apoptosis. GEP analyses identified 272 genes that were commonly upregulated by more than 1.5-fold, and 494 genes, including *c-MYC*, that were downregulated by 0.67-fold or more in the three cell lines. The ingenuity canonical signal pathway analysis of these genes revealed that BRD4 inhibition by AZD5153 inactivates the "B-cell receptor (BCR) signaling", "PI3K signaling in B-lymphocytes" and "CD27 signaling in lymphocytes" pathways. This suggests that BRD4 targeting potently inhibits pathways for B cell activation, survival and proliferation. Western blot and RT-PCR validated the finding that AZD5153 downregulated expression of genes associated with the B-cell receptor signaling pathway and c-MYC, without significant changes in expression of pro-apoptotic BH3-only proteins and anti-apoptotic BCL2 proteins such as BCL2 and $BCLX_L$. The combination of AZD5153 and AZD4320 showed synergistic and additive growth inhibitory effects in the three cell lines examined.
Summary/Conclusion: This study shows that blockade of BRD4, which potentially inhibits c-Myc and the BCR and PI3K pathways, is a rationale therapeutic strategy for DHL and DEL, and that AZD5153 may be a new BRD4 inhibitor of therapeutic interest. Furthermore, addition of AZD4320 to AZD5153 augmented the cell eradication effect in DHL- or DEL-derived cell lines. These results provide the rationale for dual targeting of BRD4 and antiapoptotic BCL2 proteins as a possible therapeutic strategy against BCLs with concomitant overexpression of c-MYC and BCL2.

INTEGRATIVE GENOME-WIDE ANALYSIS REVEALS REGULATION OF CELL PROLIFERATION INVOLVING MULTIPLE SIGNALING PATHWAYS BY BRD4-BINDING TARGET GENES IN MANTLE CELL LYMPHOMA CELL LINES

T. Tsukamoto[1,*], S. Nakahata[2], R. Sato[3], A. Kanai[4], M. Nakano[3], T. Inaba[4], M. Taniwaki[1], K. Tashiro[3], K. Morishita[2], J. Kuroda[1]

[1]Division of Hematology and Oncology, Department of Medicine, Kyoto Prefectural University of Medicine, Kyoto, [2]Division of Tumor and Cellular Biochemistry, Department of Medical Science, Faculty of Medicine, University of Miyazaki, Miyazaki, [3]Department of Genomic Medical Sciences, Kyoto Prefectural University of Medicine,

Kyoto, [4]Department of Molecular Oncology, Research Institute of Radiation Biology and Medicine, Hiroshima University, Hiroshima, Japan

Background: Mantle cell lymphoma (MCL) remains mostly incurable, despite introduction of new therapeutic agents, and there is an urgent need to identify targetable molecules for rationale development of a more effective treatment strategy. BRD4 associates with acetylated histones and facilitates transcription of target genes. In addition, super-enhancers have been recognized as regulatory regions with a high level of acetylated histones, mediator complexes and BRD4, and super-enhancers in cancer cells are enriched at oncogenes. Importantly, several studies have highlighted the crucial functional involvement of BRD4 in oncogenes in various cancers. Therefore, broad screening of BRD4-regulated molecules might be translated into selection of therapeutic targets in MCL.
Aims: To identify therapeutic targets for MCL through broad screening of BRD4-regulated molecules using genome-wide approaches.
Methods: The human MCL-derived cell lines, Jeko-1, JVM-2, MINO and Z138, were used in the study. Growth-inhibitory effects of I-BET 151, a BRD4 inhibitor, were analyzed by MTT assay. For evaluation of apoptosis, cells were counterstained with Annexin V-FITC and propidium iodide (PI) and subjected to flow cytometric analysis. Gene expression profile (GEP) analysis was performed for JVM2 and Z138 cells with or without I-BET151 treatment. BRD4 ChIP-Seq was performed in JVM2 cells treated with 10 nM I-BET151 or DMSO. The interaction of candidate genes was examined using the Reactome Pathway Database.
Results: Treatment with I-BET151 for 72 h showed a dose-dependent inhibitory effect on cell proliferation in all of the four MCL cell lines. I-BET151 treatment induced G1/S cell cycle arrest and apoptosis in these MCL cell lines. GEP analyses revealed that 609 and 665 genes were commonly upregulated by more than 1.5-fold and downregulated by less than 0.67-fold, respectively. ChIP-Seq showed that 7988 BRD4-binding regions were dysregulated by I-BET151, with most of these sites in enhancer regions, and 547 regions were characterized as super-enhancers. Integrated analysis using the Reactome Pathway Database and the results of GEP and ChIP-Seq showed that a series of genes involved in the B cell receptor (BCR) signaling pathway and IKZF-MYC axis are regulated by BRD4, including *BLNK*, *IKZF2*, *IKZF3* and *MYB*. To confirm whether each BRD4 target contributes to survival and proliferation of MCL cells, we focused on several candidate targets: the BCR pathway, *IKZF* and *MYB*. However, ibrutinib, a Bruton kinase inhibitor, suppressed cell growth in only two of the four cell lines (MINO and JVM2), while lenalidomide, an inhibitor of the IKZF family, did not affect cell survival, despite its potency in decreasing IKZF1 and IKZF3 protein levels. *MYB* silencing using shMYB did not decrease cell proliferation in any of the four MCL cell lines.
Summary/Conclusion: Our results showed that BRD4 regulates transcription of multiple genes by binding to enhancer regions, partly involving super-enhancers and multiple known pathways such as BCR signaling and the IKZF-MYC axis. Indeed, MCL is already treated by several agents targeting these pathways in clinical practice or trial settings. The efficacies of these agents are limited because they have a single target, whereas I-BET151 concomitantly inactivated the BCR pathway and IKZF and had a high growth inhibitory efficacy in MCL cells. These results suggest that simultaneous targeting of multiple molecules involved in the BCR pathway and IKZF-MYC axis may overcome drug resistance in MCL, and that BRD4 inhibitors are promising candidates for MCL treatment.

TRANSCRIPTOME SEQUENCING IN DIFFUSE LARGE B-CELL LYMPHOMA - RIBOSOME BIOGENESIS AND DYSREGULATION OF THE ACTIN CYTOSKELETON ARE ASSOCIATED WITH IMMUNOCHEMOTHERAPY RESISTANCE

M. Stern[1,2,*], M. Stenson[2,3], S. Bram Ednersson[2,4], A. Skaftason[5], S. Hasselblom[6], H. Herman Nilsson-Ehle[7], L. Mansouri[5], P.-O. Andersson[1,2]

[1]Section of Hematology, Department of Medicine, South Älvsborg Hospital, Borås, [2]Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, [3]Section of Hematology, Department of Medicine, Kungälv Hospital, Kungälv, [4]Department of Pathology, Sahlgrenska University Hospital, Gothenburg, [5]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, [6]Department of Research, Development and Education, Region Halland, Halmstad, [7]Section of Hematology and Coagulation, Sahlgrenska University Hospital, Gothenburg, Sweden

Background: Diffuse large B-cell lymphoma (DLBCL) patients with early relapse or refractory disease have a very poor outcome. Immunochemotherapy resistance will, also in the era of targeted drugs, remain the major cause of treatment failure. Thus, there is a strong need to further characterize underlying molecular mechanisms. Given the heterogeneous nature of DLBCL, we hypothesized that a comparison of the transcriptome in patients with a distinctly diverse clinical response to immunochemotherapy, would give a higher probability to find relevant biological correlates.
Aims: To investigate if global RNA expression (RNA-seq) could reveal new mechanisms involved in immunochemotherapy resistance in DLBCL.
Methods: We derived total RNA from formalin-fixed paraffin-embedded (FFPE) tumour tissue from 2 groups of DLBCL patients, treated with immunochemotherapy, i) primary refractory or relapse within one year from diagnosis (n=26, REF/REL) and ii) progression-free more than 5 years after diagnosis (n=30, CURED). RNA-sequencing was performed on an Illumina HiSeq 2500 instrument (2x125bp paired end). Sequences were aligned to human reference genome version hg19 using STAR aligner and multiple quality control steps validated data integrity. Differentially expressed genes (DEGs) were identified and subjected to functional enrichment, protein-protein interaction networks and canonical pathway analyses, using NetworkAnalyst and Ingenuity Pathway Analysis (IPA).
Results: In total, we identified 327 DEGs (Benjamin-Hochberg adjusted *p*-value <0.05) of which 221 and 106 were upregulated in the REF/REL and CURED group, respectively. For genes upregulated in the REF/REL group, the most enriched pathways were RNA-transport (p=0.02) and ribosome biogenesis (p=0.03). Increased ribosome biogenesis and protein synthesis play essential roles in sustaining tumour cell growth and upregulation of ribosomal proteins has been associated chemotherapy resistance in different cancer forms. The top canonical pathway identified by IPA was actin cytoskeleton signaling (p<0.0001) and several of the enriched biological processes associated with upregulated genes in the CURED group were related to the actin cytoskeleton, e.g. focal adhesion (p<0.001), adherens junction (p=0.006), FcγR-mediated phagocytosis (p=0.01) and regulation of actin cytoskeleton (p=0.01). Emerging data indicate that remodeling of the actin cytoskeleton might play a role in chemoresistance, also for drugs included in the R-CHOP-regimen.
Among individual genes overexpressed in the REF/REL group we found several genes that previously have been described as negative prognostic factors, both in DLBCL in other malignancies, e.g. RAN, PDE4B, CD79B and PAK2. Conversely, in the CURED group, some genes have been associated with good prognosis (GDPD5, ankyrin 3), sustained remission (neuraminidase 3) or tumor suppression (USP20, HOPX) in other cancers.
Summary/Conclusion: We found an upregulation of genes related to actin cytoskeleton regulation in long-term progression-free DLBCL patients. In addition, genes upregulated in patients with early relapse or refractory disease were enriched in RNA-transport and ribosome biogenesis. In a recent study using a proteomic approach, we found a similar pattern (Stenson *et al.*, ASH 2016). Consequently, these RNA-seq data support that dysregulation of actin organization as well as ribosome biogenesis contributes to immunochemotherapy resistance in DLBCL, indicating that genes or proteins in these networks could become novel therapeutic targets.

PS1385

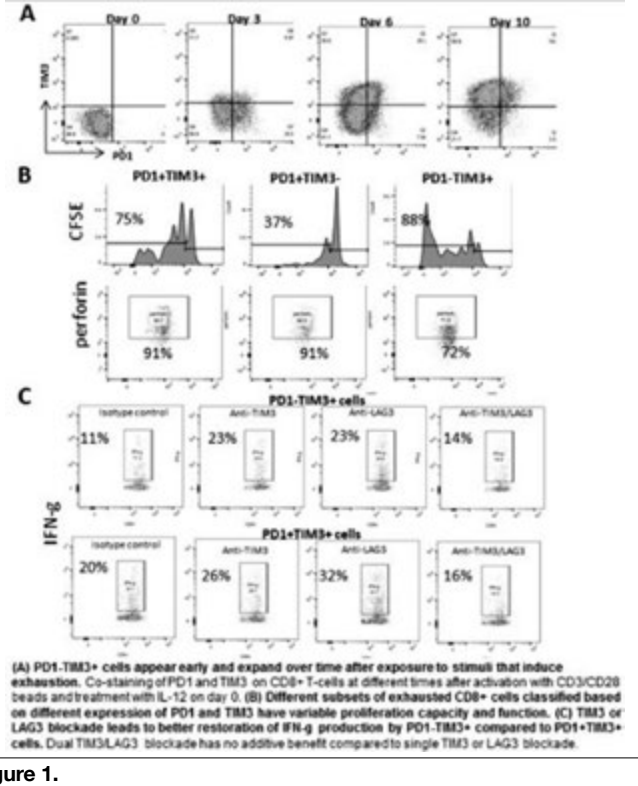
PD1-TIM3+ CELLS ARE THE PREDOMINANT POPULATION OF EXHAUSTED CD8+ CELLS IN FOLLICULAR LYMPHOMA WITH HIGH REACTIVATION POTENTIAL

T. Anagnostou[1,*], Z. Z. Yang[1], H.J. Kim[1], S. Jalali [1], J. Villasboas Bisneto[1], H. Wu[1], T.L. Price-Troska[1], A.J. Novak[1], S. M. Ansell[1]

[1]Hematology, Mayo Clinic, Rochester, United States

Background: Objective response rates to nivolumab are approximately 70% in classical Hodgkin lymphoma, but much lower in follicular lymphoma (FL) at around 11%, due to inability of these agents to activate exhausted T-cells in the tumor microenvironment (TME). The TME consists of different subsets of exhausted T-cells with variable expression of inhibitory receptors (including PD1, TIM3, LAG3) and function, which creates a spectrum of exhausted states.
Aims: In this study we compared the reactivation potential of different exhausted T-cell subsets in FL classified based on expression of PD1, TIM3 and LAG3.
Methods: We analyzed 13 healthy donor peripheral blood samples and 4 samples from FL lymph nodes. We activated healthy donor T-cells with CD3/CD28 and treated them with IL-12 to induce exhaustion as we have previously shown (Yang *et al.* J Clin Invest 2012). Flow cytometry was performed to assess expression of inhibitory receptors (PD1, TIM3, LAG3), T-cell function (perforin, granzyme B, IL-2 and IFN-g production) and proliferation (by CFSE labeling). Data was analyzed with FlowJo and we gated on different subpopulations of $CD8^+$ cells based on PD1, TIM3 and LAG3 expression. We then blocked PD1, TIM3 and LAG3 signaling, either alone and in combination at different times, and compared the reactivation poten-

tial of different CD8+ subsets.
Results: We first compared the proliferation and cytokine production between CD8+ cells activated through their T-cell receptor (TCR) with or without IL-12 treatment. We found that cells treated with IL-12 had significantly lower proliferation (60% with IL-12 vs. 84% without IL-12, p=0.003) and perforin production (16% with IL-12 vs. 24% without IL-12, p=0.002), suggesting that they were functionally exhausted. We then compared the frequencies of different T-cell subsets over time. PD1-TIM3+ cells appeared early and expanded over time following treatment with IL-12, comprising over 50% of all CD8+ cells by day 10 (Figure 1A). Similarly, in our FL samples, PD1-TIM3+ cells comprised 25-50% of all CD8+ cells. Subsequently, we compared the proliferation and function of the different exhausted T-cell subsets. T-cell subsets with variable PD1 and TIM3 expression differed in proliferation (75% in PD1+TIM3+ vs 37% in PD1+TIM3- vs 88% in PD1-TIM3+, p=0.03) and perforin production (91% in PD1-TIM3- vs 91% in PD1+TIM3+ vs 72% in PD1+TIM3- vs 78% in PD1-TIM3+, p=0.01) (Figure 1B). Of note, PD1-TIM3+ cells expressing LAG3 had lower proliferation compared to cells not expressing LAG3. Finally, we assessed the reactivation potential of different cell populations by blocking PD1, TIM3 and LAG3 alone and in combination. Although inhibitory receptor blockade was unable to prevent exhaustion, blockade of PD1, TIM3 or LAG3 on day 3 restored perforin and IFN-g production by total CD8+ cells. Since PD1-TIM3+ cells were the predominant CD8+ cell subset we tested the effect of blocking antibodies on them. TIM3 blockade was able to restore both proliferation of PD1-TIM3+ cells and IFN-g production, and LAG3 blockade had similar effects. However, TIM3/LAG3 dual blockade did not lead to greater improvement in IFN-g production compared to TIM3 or LAG3 blockade alone. Also, the effect of either TIM3 or LAG3 blockade on PD1-TIM3+ cells was higher compared to the effect on PD1+TIM3+ cells, suggesting that PD1-TIM3+ cells have better reactivation potential (Figure 1C).



(A) PD1-TIM3+ cells appear early and expand over time after exposure to stimuli that induce exhaustion. Co-staining of PD1 and TIM3 on CD8+ T-cells at different times after activation with CD3/CD28 beads and treatment with IL-12 on day 0. **(B) Different subsets of exhausted CD8+ cells classified based on different expression of PD1 and TIM3 have variable proliferation capacity and function. (C) TIM3 or LAG3 blockade leads to better restoration of IFN-g production by PD1-TIM3+ compared to PD1+TIM3+ cells.** Dual TIM3/LAG3 blockade has no additive benefit compared to single TIM3 or LAG3 blockade.

Figure 1.

Summary/Conclusion: PD1-TIM3+ cells are the predominant population of exhausted CD8+ cells in FL and have high reactivation potential, suggesting that they may serve as a target for future immunotherapies.

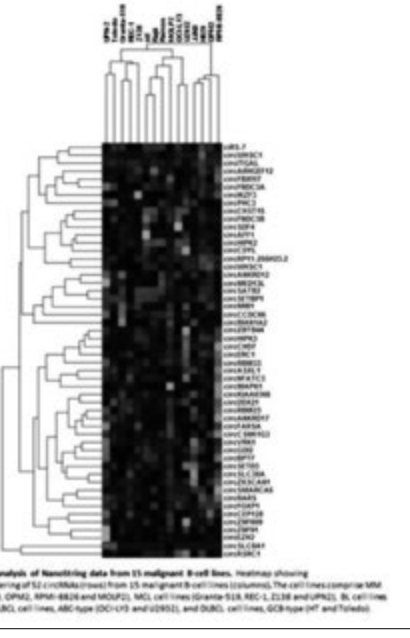
PS1386

ENZYME-FREE DIGITAL COUNTING OF ENDOGENOUS CIRCULAR RNA MOLECULES IN FORMALIN-FIXED PARAFFIN-EMBEDDED TISSUES FROM PATIENTS WITH B-CELL MALIGNANCIES

M. Dahl[1,2,*], I. Daugaard[3,4], M. S. Andersen[3,4], T.B. Hansen[3,4], K. Grønbæk[1,2], J. Kjems[3,4], L.S. Kristensen[3,4]

[1]Department of Hematology, Rigshospitalet, [2]Biotech Research and Innovation Centre, BRIC, Copenhagen University, Copenhagen, [3]Department of Molecular Biology and Genetics (MBG), [4]Interdisciplinary Nanoscience Center (iNANO), Aarhus University, Aarhus, Denmark

Background: Circular RNAs (circRNAs) are covalently closed endogenous RNA molecules with tissue- and disease specific expression patterns, which have potential as diagnostic and prognostic biomarkers in cancer. These molecules exert diverse regulatory functions including direct and indirect regulation of host gene expression (Ashwal-Fluss *et al.* 2014; Li *et al.* 2015), sponging of miRNAs (Hansen *et al.* 2013; Memczak *et al.* 2013), protein scaffolding (Du *et al.* 2016) and regulation of protein translation (Abdelmohsen *et al.* 2017). Several studies have reported prognostic relevance and functional significance of circRNAs in cancer (Kristensen *et al.* 2017), but no studies have yet examined the expression in B-cell malignancies. However, current methods for circRNA quantification have several limitations that prevent the development of clinically applicable assays. In particular, template switching and rolling circle transcription during reverse transcription (RT) and amplification bias during PCR may lead to misinterpretation of results (Szabo and Salzman 2016; Kristensen *et al.* 2017). Therefore, Northern Blotting, which does not rely on RT and PCR amplification, is currently the gold standard for circRNA detection. However, this method requires large quantities of RNA, is labor-intensive and not quantitatively accurate.
Aims: In this study, we aimed at developing an assay for accurate quantification of circRNAs that is clinically applicable. The NanoString platform, a technology for quantifying gene expression, is enzyme-free and suitable for low quality samples such as RNA isolated from formalin-fixed, paraffin-embedded (FFPE) tissues. First, we examined whether the NanoString technology could be adapted for circRNA detection and quantification. Second, we examined the expression of circRNAs in different B-cell malignancies to assess whether circRNAs might represent novel oncogenic drivers in these diseases.
Methods: We profiled the genome-wide landscape of circRNA expression in cell lines of mantle cell lymphoma (MCL) and multiple myeloma (MM) using high-throughput RNA-sequencing (RNA-seq). Based on these data, we designed assays for simultaneous analyses of 52 unique circRNAs using the NanoString technology, in 15 different cell lines and paired fresh frozen and formalin-fixed, paraffin-embedded (FFPE) cell lines and patient samples including MCL, MM, follicular lymphoma (FL), diffuse large B-cell lymphoma (DLBCL), Burkitt lymphoma (BL) and chronic lymphocytic leukemia (CLL). To evaluate the specificity of the assays for circRNA detection, we treated RNA samples from two cell lines with RNase R, an exonuclease specifically degrading linear RNA.
Results: RNA-seq of the MCL and MM cell lines detected circRNAs known to be deregulated in other cancers, and identified a novel circRNA from the *IKZF3* oncogene. Interestingly, circRNA expression profiles were able to distinguish different B-cell malignancies, as shown in Figure 1. Enrichment of circRNAs upon treatment with RNase R proved that assays were specific for circRNA detection. The NanoString data were more reproducible and quantitatively more accurate than RNA-seq data and the technology works well for low quality RNA samples.



Hierarchical cluster analysis of NanoString data from 15 malignant B-cell lines. Heatmap showing expression and clustering of 52 circRNAs (rows) from 15 malignant B-cell lines (columns). The cell lines comprise MM cell lines (UM3, H929, OPM2, RPMI-8826 and MOLP2), MCL cell lines (Granta-519, REC-1, Z138 and UPN2), BL cell lines (Rajiand Ramos), DLBCL cell lines, ABC-type (OCI-Ly3 and U2932), and DLBCL cell lines, GCB-type (HT and Toledo).

Figure 1.

Summary/Conclusion: Together, we demonstrate that the NanoString technology enables specific, sensitive and accurate quantification of circRNAs in FFPE samples and provide a map of circRNA expression in B-cell malignancies. Our study provides a basis for future research focusing on circRNAs as functional drivers in lymphomagenesis and as potential novel biomarkers of prognostic relevance in these diseases.

PS1387

PROTEIN KINASE CK1 ALPHA SUSTAINS MANTLE CELL LYMPHOMA SURVIVAL BY IMPINGING ON BCR-LINKED SIGNALING PATHWAYS

S. Manni[1,2,*], E. Daniele[2], M. Carrino[1,2], K. Gianesin[2], L. Quotti Tubi[1,2], A. Visentin[1], L. Trentin[1,2], G. Semenzato[1,2], F. Piazza[1,2]

[1]Department of Medicine, Hematology and Clinical Immunology Branch, University of Padova, [2]Venetian Institute of Molecular Medicine, Padova, Italy

Background: Mantle Cell lymphoma (MCL) is a B-cell neoplasm that accounts for around 5-10% of all lymphomas, which urgently needs new therapeutic strategies. The Ser/Thr protein kinase CK1α has been found pivotal for multiple myeloma and Diffuse Large B cell Lymphoma survival. We recently demonstrated that CK1α plays a key role in myeloma cell growth and its inactivation determines myeloma cell death. CK1α is essential in the regulation of several growth signaling cascades (such as Wnt/βcatenin, NF- B, AKT, the p53-driven response), which are important for MCL clone expansion. Nevertheless, the role of CK1α in MCL pathogenesis and in associated survival signaling events has never been studied.
Aims: In this study, we have investigated CK1α expression, cellular localization and contribution to MCL survival. We evaluated the potential therapeutic role of CK1α inhibition with chemical compounds or gene silencing through RNA interference on MCL cell growth and proliferation. Moreover, the consequences on survival signaling pathways associated to resistance to chemotherapeutics have been investigated.
Methods: CK1α expression and localization were analyzed in MCL cells and controls by western blot (WB) analysis and confocal immunofluorescence microscopy. CK1α silencing was performed through the generation of CK1α IPTG shRNA inducible MCL clones or through electroporation of double strand CK1α-directed siRNA in MCL cell lines. The consequences of CK1α inhibition with D4476, a small ATP-competitive compound, or by RNA interference on MCL cell survival and proliferation were investigated with MTT test, Annexin V/Propidium Iodide labeling and cytofluorimetric analysis, analysis of PARP cleavage, analysis of pro-apoptotic/pro-survival proteins expression in WB. CK1α-dependent signaling events were analyzed by WB.
Results: We found that CK1α was highly expressed in purified primary MCL B cells and cell lines, compared with healthy controls. Differently from normal B cells, in which it was only cytosolic, in MCL cells CK1α localized both in the cytoplasm and in the nucleus. Inhibiting CK1α in MCL cells with D4476 or RNAi reduced cell viability, determined apoptosis and proliferation arrest, which were confirmed by an increase in the subG1/apoptotic peak and by the reduction of the S phase of the cell cycle. The apoptotic effects of CK1α inhibition was confirmed by an increase of the PARP cleavage and caspase activity and by a reduction of the prosurvival Mcl1 protein. From a molecular standpoint, CK1α inhibition caused a reduction of IKKα/β and RelA/p65 phosphorylation on Ser176/180 and Ser536 respectively, and of AKT phosphorylation on Ser473, indicating an important role upstream of critical B-cell receptor-dependent signaling pathways.
Summary/Conclusion: Our findings suggest that CK1α is a growth-propelling kinase in MCL, representing a new potential molecular therapeutic target. The identification of the exact mechanism(s) of action on the pathways targeted by CK1α in MCL will be the subject of future research.

PS1388

WEE1 INHIBITION ENHANCES ANTI-APOPTOTIC DEPENDENCY OF DIFFUSE LARGE B-CELL LYMPHOMA CAUSED BY CELL CYCLE ARREST AND DNA DAMAGE INDUCTION

M. De Jong[1,*], M. Langendonk[1], B. Reitsma[1], P. Herbers[1], A. Mulder[2], G. Huls[1], A. Van den Berg[3], E. Ammatuna[1], L. Visser[3], T. van Meerten[1]

[1]Hematology, [2]Laboratory medicine, [3]Pathology, University Medical Center Groningen, Groningen, Netherlands

Background: Patients with refractory or relapsed diffuse large B cell lymphoma (DLBCL) after first-line immuno-chemotherapy have a poor prognosis. Drug resistance has been attributed to intrinsic features of DLBCL such as high levels of DNA damage, impaired cell cycle checkpoints, and upregulation of intrinsic anti-apoptotic proteins. Targeting DNA repair and cell cycle checkpoint proteins and subsequently overcoming apoptotic resistance would therefore be a promising strategy. We recently demonstrated that inhibition of WEE1, a replication checkpoint kinase that prevents the onset of mitosis in cells that have incompletely replicated or have damaged genomes, resulted in apoptosis in DLBCL (MRW de Jong *et al.*, 2018). However, many tumors, including DLBCL, show apoptotic defects, which can be characterized using BH3 profiling, a rapid and functional method for determining the cellular dependency on individual pro-apoptotic and anti-apoptotic molecules (BCL-2 family proteins) and might be able to predict which treatment.
Aims: To determine the effects of WEE1 inhibition on cell cycle arrest, DNA damage and apoptosis and to determine the cellular dependency of DLBCL on individual pro-apoptotic and anti-apoptotic proteins after WEE1 inhibition, by employing BH3 profiling.
Methods: We established static BH3 profiles of eight DLBCL cell lines and DLBCL patient samples. A dynamic BH3 profile (DBP) was acquired for DLBCL cell lines SC-1, SUDHL-10 and a DLBCL patient after 18 hours of WEE1 inhibition by AZD1775 treatment. As controls, cell cycle arresting agents and/or DNA damage inducing agents Palbociclib, RO3306, Nocodazole and UV radiation were tested after 18 hours before establishing a DBP.
Results: We demonstrated that WEE1 inhibition by the anti-WEE1 inhibitor AZD1775 results in both a G2/M arrest and DNA damage. The static BH3 profiles showed that DLBCL cell lines have either a BAD-dependent profile or a BAD-independent profile. SC-1 cell line (BAD-dependent) showed increased dependency for BCL-2/BCL-XL/BCL-W, whereas SUDHL-10 (BAD-independent) showed increased dependency for MCL-1. Further validation of these anti-apoptotic dependencies showed that SC-1 had 10-fold increased sensitivity to BCL-2 inhibitor venetoclax (p=0.0012) after pretreatment with sub-optimal dose of AZD1775 (IC-50), but no increased sensitivity to MCL-1 inhibition (p=0.2370). SUDHL-10 showed 2-fold increased sensitivity to MCL-1 inhibitor A-1210477 (p=0.002), but no increased sensitivity to BCL-2 inhibition (p=0.8302) after WEE1 pretreatment. These results agree with the anti-apoptotic dependencies obtained with DBP. DBP of a chemotherapy-refractory DLBCL patient showed increased dependency BCL-2/BCL-W, which could be validated with the BCL-2/BCL-XL/BCL-W inhibitor navitoclax, but not with venetoclax, suggesting increased dependency on BCL-W after AZD1775 treatment. These DBP could be replicated by both induction of G2/M arrest and induction of DNA damage.
Summary/Conclusion: These data show that WEE1 inhibition causes both G2/M arrest and DNA damage, which leads to apoptosis in DLBCL. In addition, we demonstrate that WEE1 inhibition alters the dependence on anti-apoptotic proteins in DLBCL. Where DLBCL cell lines and patient samples exhibit unique anti-apoptotic dependencies upon WEE1 treatment, DBP was able to determine these profiles, and could therefore be used to personalize treatment of DLBCL with BH3 mimetics.

PS1389

INFLUENCE OF PLASMA EBV LOAD ON PROGNOSIS OF HIV-RELATED LYMPHOMAS

J. Muncunill[1,*], M.J. Baptista[1], A. Hernandez-Rodriguez[2], J. Dalmau[3], O. Garcia[1], G. Tapia[4], J.-M. Sancho[1], J. Martinez-Picado[3], E. Feliu[1], J.-L. Mate[4], J.-M. Ribera[1], J.-T. Navarro[1]

[1]Department of Hematology, ICO-Hospital Universitari Germans Trias i Pujol, Josep Carreras Leukaemia Research Institute, Universitat Autònoma de Barcelona, [2]Department of Microbiology, Hospital Universitari Germans Trias i Pujol, [3]AIDS Research Institute-IrsiCaixa, Institut d'Investigació en Ciències de la Salut Germans Trias i Pujol, Universitat Autònoma de Barcelona, Institució Catalana de Recerca i Estudis Avançats (ICREA), [4]Department of Pathology, Hospital Universitari Germans Trias i Pujol, Universitat Autònoma de Barcelona, Badalona, Spain

Background: The detection of Epstein Barr virus (EBV) in tumoral cells (EBER+) has been associated with more aggressiveness of lymphoma and poorer prognosis. The addition of rituximab to chemotherapy, seems to have improved the prognosis of EBV-related lymphomas. Some studies have shown that plasma EBV load has impact on lymphoma prognosis. However, the influence of plasma EBV load on prognosis of HIV-related lymphomas has been scarcely studied.
Aims: We aimed to evaluate the usefulness of plasma EBV load as prognostic factor in HIV-related lymphomas. Additionally, we analyzed the impact of rituximab on prognosis among NHL-HIV patients taking into account the

plasma EBV load.
Methods: Eighty HIV-related lymphoma cases (61 B-cell aggressive NHL and 19 HL) were studied. Plasma EBV load was determined at lymphoma diagnosis by a commercial real-time PCR technique (Abbott Real Time EBV, Abbott Molecular, Illinois, USA) and was considered as dichotomous variable according to two different cutoffs: detectable load provided by technique limitation (cutoff > 110 copies/ml), and high load (cutoff > 5000 copies/ml), determined by maxstat technique. We studied the association between the main clinical-biological variables and both, detectable and high EBV load in plasma. Wilcoxon test were used to compare qualitative variables. We studied the differences in overall survival (OS) and progression-free survival (PFS) of the patients regarding the EBV load, taking into account the two cutoffs, as well as the addition of rituximab to chemotherapy. Survival analyses were performed using the Kaplan-Meier method. Cox proportional risks regression models were performed for both univariate and multivariate analyses. P-values of less than 0.05 were considered statistically significant.
Results: Patients with detectable plasma EBV load (n=42) had more frequently EBV in the tumor (assessed by EBER) than patients with negative load (n=38) (68% vs 19%, p=0.005). More patients with high EBV load (n=19) had elevated LDH and EBER positivity than those with low load (n=61) (72% vs 36%, p=0.016 and 88% vs 31%, p=0.006, respectively). Patients with high EBV load had worse OS and PFS than those with low load [2-year OS (95% CI): 65% (54-78%) vs. 42% (25-71%), p=0.025, and 2-year PFS (95% CI): 55% (44-70%) vs. 42% (25-71%), p=0.05, respectively]. In the multivariate analysis, high EBV load was an independent factor for worse prognosis for both OS and PFS [HR (95% CI): 2.4 (1.1-5.3), p=0.03; 2.2 (1.01-4.6), p=0.045, respectively]. In HL patients, those with high EBV load (n= 6) had significantly worse prognosis than those with low load (n=13) for OS [2-year OS (95% CI): 33%, (11-100%) vs. 92%, (79-100%), p=0.003], and for PFS [2-year PFS (95% CI): 33% (11-100%) vs. 73% (45-100%), p=0.007]. In NHL patients, detectable EBV load had impact on OS and PFS only in those patients treated without the addition of rituximab to chemotherapy (n=32) (Figure 1A and B). The impact of EBV load remained significant in the multivariate analysis for OS and PFS [HR (95% CI): 2.7 (1.2-5.9), p=0.012; 2.4 (1.6-5.09), p=0.01, respectively]. Furthermore, high EBV load also had negative influence on prognosis of NHL lymphomas treated without rituximab.

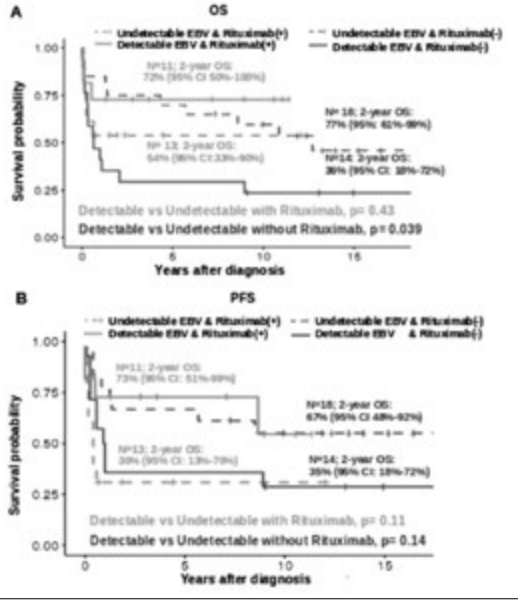


Figure 1.

Summary/Conclusion: Plasma EBV load is a prognostic factor with negative impact on HIV-related lymphoma. Among HIV-NHL cases, rituximab eliminates the negative influence of EBV load on prognosis.

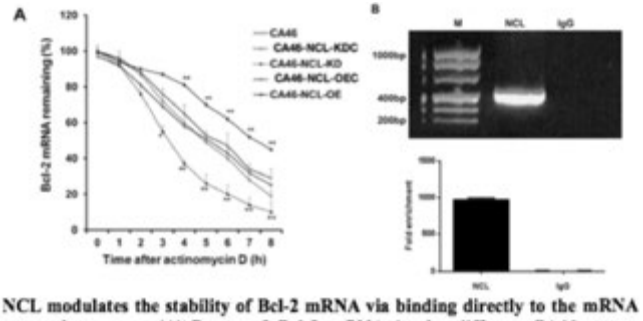
PS1390

NUCLEOLIN ENHANCED ADRIAMYCIN RESISTANCE VIA THE REGULATION OF BCL-2 EXPRESSION IN CA46 BURKITT'S LYMPHOMA CELLS

J. Hu[1,*], X. Mei[1], Y. Chen[1], Y. Chen[1], L. Wang[1], Y. Cao[1], M. Lin[1]

[1]*Department of Hematology, Fujian Institute of Hematology, Fujian Medical University Union Hospital, Fuzhou, China*

Background: The nucleo-cytoplasmic protein nucleolin (NCL, C23) is an important nucleo-cytoplasmic multifunctional protein, which is abundantly expressed in the nucleolus, the nucleoplasm, the cytoplasm and the cell membrane, playing various roles in cell proliferation, apoptosis and angiogenesis. Due to its multifaceted profile and high expression in cancer, nucleolin is considered a marker of drug resistance to chemotherapy. However, the biochemical mechanisms by which the increased expression of nucleolin suppressed the senstivity of chemotherapeutic drugs in several cancers have not been fully elucidated.
Aims: To explore the effect of NCL on drug senstivity and potential menchanism in Burkitt's lymphoma cells.
Methods: CA46 Burkitt's lymphoma cells were transfected with lentiviruses carrying the nucleolin gene (CA46-NCL-Overexpression, CA46-NCL-OE) or shRNA sequences that target the endogenous nucleolin gene (CA46-NCL-Knockdown, CA46-NCL-KD). Effect of NCL on cellular drug senstivity and apoptosis were examined by MTT assay and flow cytometry analysis respectively. Bcl-2 level was determinded using q-PCR and western blot test. Stability of Bcl-2 mRNA was measured by Actinomycin D treatment assay. Finally, RNA-immunoprecipitation assays(RIP) was used to identify the binding and interaction of Bcl-2 mRNA and NCL complexes.
Results: The results showed that CA46-NCL-OE cells exhibited significantly higher IC50 for Adriamycin compared to CA46-NCL-Overexpression negative control cells(CA46-NCL-OEC) ($p<0.01$). The IC50 of the CA46-NCL-OEC was increased from 0.39±0.08 μg/ml to 0.68±0.06 μg/ml in the CA46-NCL-OE cells. The IC50s of the CA46-NCL-KDC and CA46-NCL-KD cells were 0.30±0.04 μg/ml and 0.15±0.02 μg/ml respectively. In CA46-NCL-KD cells, the rate of apoptosis was significantly increased compared to CA46-NCL-Knockdown negative control cells(CA46-NCL-KDC) ($p<0.05$), whereas the opposite effect was noted in CA46-NCL-OE cells. A significant reduction in the mRNA and protein levels of Bcl-2 expression was observed in the CA46-NCL-KD cells compared with CA46-NCL-KDC cells ($p<0.01$), while in the CA46-NCL-OE cells the Bcl-2 expression levels were significantly increased compared with CA46-NCL-OEC cells ($p<0.01$). In addition, the decay rate of Bcl-2 mRNA in CA46-NCL-KD cells after Actinomycin D treatment was much faster than that in CA46-NCL-KDC cells. The half-life of Bcl-2 mRNA was extended from 5.2h in CA46-NCL-OEC cells to 7.4h in CA46-NCL-OE cells, whereas it was reduced from 4.9h in CA46-NCL-KDC cells to 3.2h in CA46-NCL-KD cells, suggesting that the expression of NCL could influence the stability of Bcl-2 mRNA. Finally, RNA-immunoprecipitation assays(RIP) demonstrated a significant enrichment of Bcl-2 mRNA in NCL immunoprecipitated complexes compared with control, indicating NCL could bind and interact with Bcl-2 mRNA in CA46 cells. (Figure 1).



NCL modulates the stability of Bcl-2 mRNA via binding directly to the mRNA transcript. (A) Decay of Bcl-2 mRNA in the different CA46 groups following treatment with actinomycin D (2μg/ml) for the indicated time periods. The results are expressed as percentage of the Bcl-2/β-actin ratio at the indicated time points compared with the Bcl-2/β-actin mRNA ratio at time 0 h. (CA46-NCL-KD vs CA46-NCL-KDC, CA46-NCL-OE vs CA46-NCL-OEC, *P<0.05, ** P<0.01). (B) Bcl-2 mRNA enrichment by RIP assay with an anti-NCL antibody. M:molecular marker.NCL: Bcl-2 mRNA was immunoprecipated with an anti-NCL antibody. IgG: negative control , Bcl-2 mRNA was immunoprecipated with a normal mouse IgG antibody.

Figure 1.

Summary/Conclusion: All above results indicated that nucleolin could mediate BCL-2 expression and stability, subsquently enhance adriamycin resistance in CA46 Burkitt's lymphoma cells.

PS1391

DOMINANT CYTOTOXIC NK CELL SUBSET WITHIN CLPD-NK PATIENTS IDENTIFIES A MORE AGGRESSIVE NK CELL PROLIFERATION

G. Barila'[1,2,*], A. Teramo[1,2], G. Calabretto[1,2], V. Trimarco[1], S. Carraro[1], M. Leoncin[1,2], C. Vicenzetto[1,2], V. R. Gasparini[1,2], M. Facco[1,2], F. Piazza[1,2], G. Semenzato[1,2], R. Zambello[1,2]

[1]Dept of Medicine, Hematology and Clinical Immunology section, Padua University School of Medicine, [2]Venetian Institute of Molecular Medicine (VIMM), Padua, Italy., Padua, Italy

Background: Natural Killer (NK) cells represent a class of innate cytotoxic lymphocytes characterized by CD3-/CD16+/CD56+ phenotype. Two major NK cell subsets can be recognized, $CD56^{high}/CD16^{dim/neg}$ NK cells with cytokines producing function and $CD56^{dim}/CD16^{high}$ NK cells displaying cytotoxic ability. Moreover, a subtype of NK cells with $CD56^{dim}/CD16^{high}$/CD57+ phenotype and memory properties was recently discovered. Chronic Lymphoproliferative disorder of NK cells (CLPD-NK) is a provisional entity, characterized by the chronic expansion of NK cells with restricted Killer Immunoglobuline-like Receptor (KIR) pattern. CLPD-NK still remains a heterogeneous disease with most patients being asymptomatic and the main feature of the disease being represented by neutropenia. The discovery of somatic *STAT3* and *STAT5b* mutations in CLPD-NK and T-Large Granular Lymphocyte Leukemia (LGLL) focused the attention on a constitutive activation of JAK-STAT pathway in the development of these disorders.
Aims: Using flow cytometry and regardless of KIR expression, the aim of this study was to identify different biological and clinical NK-CLPD patient subsets.
Methods: NK cells of 25 CLPD-NK patients were analysed with FACS for CD3, CD16, CD56, CD57, CD158a, CD158b, CD158e, CD94, NKG2A and NKG2C antibodies. Clinical characteristics of these patients were studied. *STAT3* exon 21 mutation analysis and *STAT5b* exon 16-18 mutation analysis was performed by Sanger sequencing and ARMS PCR
Results: By flow analysis, NK cells of 25 CLPD-NK patients were analysed for CD16 and CD56 expression, recognizing two major NK cell subsets, patients with $CD56^{dim}/CD16^{dim}$ NK cells (4/25, 16%) and patients with $CD56^{neg/dim}/CD16^{high}$ NK cells (21/25, 84%) (Panel A to C). Neutropenia (ANC<1,500/mm^3) was the most relevant feature of our cohort, detected in 10/25 patients (40%), with 5 patients (20%) presenting severe neutropenia (ANC<500/mm^3). Almost all symptomatic patients were included in $CD56^{neg/dim}/CD16^{high}$ subgroup with 8/21 (38%) patients presenting neutropenia, 5/21 (24%) severe neutropenia and 3/21 patients (14%) requiring treatment. NK cells of these patients were studied for CD57 expression and all 5 patients who experienced severe neutropenia and all treated patients presented a significantly lower CD57 mean expression toward other $CD56^{neg/dim}/CD16^{high}$ patients (12.48%±2.87 *vs* 60.43%±4.38, p<0.0001). In conclusion, three major NK cell subgroups of patients can be identified, $CD56^{dim}/CD16^{dim}$ subgroup, $CD56^{neg/dim}/CD16^{high}$/CD57- "Cytotoxic" subgroup and $CD56^{neg/dim}/CD16^{high}$/CD57+ "Memory" subgroup (Panel D-E). Among the three subgroups, no significant differences in CD94-NKG2A/C and KIR expression were found, although CD94/NKG2C phenotype and KIR restriction for CD158b and CD158e was almost exclusively a distinct feature of NK "memory" subgroup. Whereas, $CD56^{dim}/CD16^{dim}$ and NK "cytotoxic" subgroups displayed CD94-NKG2A phenotype and presented a skewed KIR pattern characterized by lack of KIR expression. Finally, *STAT3* exon 21 mutations analysis was performed with only two (8%) mutated patients found, these latters characterized by "Cytotoxic" NK immunophenotype. On the contrary, none *STAT5b* mutated patient was found (Figure 1).

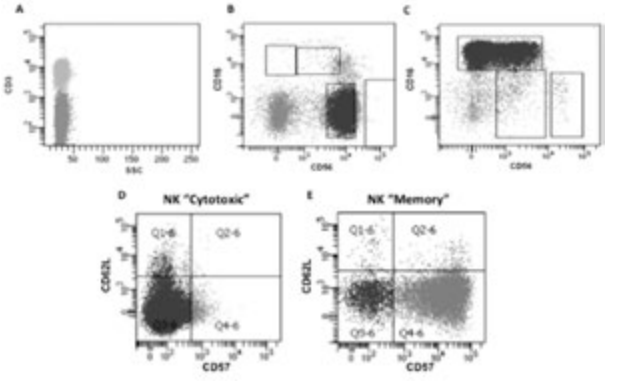


Figure 1.

Summary/Conclusion: Through NK cells flow analysis, discrete subtypes of CLPD-NK can be identified. Independently from KIR expression, patients characterized by $CD56^{neg/dim}/CD16^{high}$/CD57- cytotoxic NK cells expansion represent a unique phenotypic subgroup characterized by more symptomatic disease and the presence of *STAT3* mutation, suggesting a more aggressive proliferation of NK cells.

PS1392

IDENTIFICATION OF A MIR-146B-FASL AXIS IN THE DEVELOPMENT OF NEUTROPENIA IN T-LARGE GRANULAR LYMPHOCYTES LEUKEMIA

G. Calabretto[1,*], A. Teramo[1], B. Mariotti[2], M. Rossato[2], M. Castellucci[2], G. Barilà[1], M. Leoncin[1], C. Vicenzetto[1], V.R. Gasparini[1], M. Facco[1], G. Semenzato[1], F. Bazzoni[2], R. Zambello[1]

[1]Department of Medicine, Venetian Institute of Molecular Medicine, Padua, [2]Department of Medicine, Division of General Pathology, Verona, Italy

Background: T-Large Granular Lymphocytes (T-LGLs) leukemia (T-LGLL) is a chronic lymphoproliferation of clonal CD3+ LGLs, which can be separated in $CD3^+CD8^+CD4^-$ T-LGLs (CD8 T-LGLL) or $CD3^+CD8^{-/dim}CD4^+$ T-LGLs (CD4 T-LGLL). LGLs proliferation is maintained through an impairment of the apoptotic machinery, due to the constitutive activation of several pro-survival signaling pathways. Among these, one of the most important is the JAK/STAT axis. STAT3 over-expression represents a hallmark of leukemic LGLs and 30-40% of patients harbors STAT3 somatic mutations, that lead to STAT3 activation. These genetic lesions were recently correlated to an increased incidence of neutropenia, which represents the most frequent clinical manifestation in T-LGLL patients. The mechanism leading to neutropenia development is not completely established, although literature data provided evidence that soluble Fas Ligand (FasL) is involved in this process. Consistently, we recently demonstrated that a subset of neutropenic CD8 T-LGLL patients were characterized by high levels of FasL, whose transcription was mediated by their high STAT3 activation. These data provided a molecular explanation for the correlation between STAT3 activation and neutropenia in CD8 T-LGLL patients. However, the mechanism through which FasL production is regulated in these patients has not been clarified yet. Many microRNAs (miRNAs) are reported to act both as tumour suppressors and oncogenes in several haematological malignancies. Although STAT3 is an inducer of transcription of several oncogenes, its relationship with miRNAs has not been evaluated in T-LGLL patients yet.
Aims: The aim of this study was to investigate whether STAT3 could carry out its pathogenetic role in T-LGLL through an altered expression of miRNAs.
Methods: LGLs were purified by FACSAria cell sorter from peripheral blood mononuclear cells (PBMCs) of untreated LGLL patients and healthy donors (HD). High throughput and single miRNA analysis were carried out on purified LGLs by using the TaqMan® Human microRNA Array and Assays, respectively. Transfection with miR-146b mimic was performed in Jurkat cells or purified T-LGLs using the Amaxa Nucleofactor and the Ingenio Electroporation Solution. Transcriptional and protein expression was evaluated by real time-PCR and western blot assays.
Results: We assessed the expression of 756 mature miRNAs on purified T-LGLs, identifying two clusters: one characterized by neutropenic CD8 T-LGLL patients, with high STAT3 activation, the other characterized by HD and CD4 T-LGLL patients, with normal absolute neutrophil count (ANC) and low STAT3 activation. miRNA differentially expressed in CD8 and CD4 T-LGLs were subsequently analyzed for correlation with ANC. The expression of miR-146b, found down-regulated in patients with high STAT3 activation, was the only one correlated with ANC. Therefore, we transfected Jurkat cells and CD8 T-LGLs with a miR-146b mimic, to investigate the role of miR-146b in neutropenia development. Our data demonstrated that miR-146b downregulation increased the expression of Human Antigen R (HuR), which is a miR-146b target and a known mRNA stabilizer, reported to be required for FasL expression in T-lymphocytes. HuR protein mediated FasL mRNA stabilization, leading to increased FasL production and, consequently, to neutropenia development.
Summary/Conclusion: The current study, for the first time, demonstrated a direct role of miR-146b in the development of neutropenia reported in a subset of T-LGLL patients, representing potential targets for an individualized therapeutic approach.

PS1393

GENOMIC AND CLINICAL CHARACTERIZATION OF THE ROLE OF MYD88 MUTATION STATUS IN WALDENSTROM'S MACROGLOBULINEMIA

Z. Hunter[1,2,*], J. Castillo[3], J. Gustine[3], S. Treon[1]

[1]Harvard Medical School, [2]Dana-Farber Cancer Instutite, [3]Dana-Farber Cancer Institute, Boston, United States

Background: Waldenstrom's Macroglobulinemia (WM) is characterized by bone marrow (BM) involvement of IgM secreting lymphoplasmacytic lymphoma and somatic activating mutations in MYD88 and CXCR4 in 95% and 35-40% of patients, respectively. Deletions in in chromosome 6q were also observed in half of MYD88 mutated ($MYD88^{MUT}$) patients. Patients with wild-type MYD88 ($MYD88^{WT}$) have an increased mortality risk compared to their $MYD88^{MUT}$ counterparts (Treon *et al*., BJH 2017) and demonstrate inferior response to the BTK inhibitor, ibrutinib (Treon *et al*., NEJM 2015). These findings point to fundamental genomic differences in tumor biology between MYD88 mutated and wild-type patients.
Aims: To improve the care and clinical management of all WM patients we sought to study the clinical characteristics and genetic lesions that differ in WM patients based on MYD88 mutation status.
Methods: We identified 46 $MYD88^{WT}$ and 262 $MYD88^{MUT}$ patients diagnosed during the same time period. Clinical characteristics were compared at time of diagnosis and patients were followed for disease transformation and overall survival. Bone marrow (BM) $CD19^{+}$ WM cells were isolated from 18 $MYD88^{WT}$ patients following informed consent. DNA and RNA from these cells were submitted for next generation whole exome and RNA sequencing. Findings were compared to our existing whole genome and RNA sequencing data of 57 WM patients (Hunter *et al*., Blood 2014; 2016). A cohort of 9 $CD19^{+}CD27^{+}$ memory B-cells (MB), 9 $CD19^{+}CD27^{-}$ peripheral blood B-cells, and 16 $CD138^{+}$ plasma cells from healthy donors (HD) were also included.
Results: The median follow-up for all patients was 64.1 and 73.7 months for $MYD88^{WT}$ and $MYD88^{MUT}$ patients, respectively (p=NS). To date 11 (23.9%) and 15 (5.7%) deaths have been recorded among the $MYD88^{WT}$ and $MYD88^{MUT}$ patients, respectively (p=0.003). The estimated 10-year survival was 73% (95% CI 52-86%) for $MYD88^{WT}$ and 90% (95% CI 82-95%) for $MYD88^{MUT}$ patients (Log-rank p<0.001). Transformation to diffuse large B-cell lymphoma occurred in 7 (15.2%) of $MYD88^{WT}$ and 2 (0.76%) of $MYD88^{MUT}$ patients (p<0.0001), with an odds ratio of transformation of 23.3 (95% CI 4.2-233.8; p<0.001). Whole exome sequencing analysis of the $MYD88^{WT}$ patients revealed somatic mutations in TBL1XR1 (28%), PTPN13 (22%), KMT2D (17%), CXCR4 (17%), MALT1 (11%), NFKB2 (11%), TP53 (11%) and with BCL10, NFKB1, NFKBIB, NFKBIZ, NOTCH1, ATM, IGFR1, KDM6A, and KMT2C each observed once (6%). No deletions were observed in chromosome 6q in $MYD88^{WT}$ WM. $MYD88^{WT}$ samples displayed a distinct transcriptional profile. However, 82/100 (82%) of the top differentially expressed genes between $MYD88^{WT}$ and HD MB samples were seen in a comparison of $MYD88^{MUT}$ WM compared with HD MB. These genes included distinctive WM associated findings from our previous $MYD88^{MUT}$ analysis such as DNTT, RAG1, RAG2, CXCL12 and VCAM1. Gene set enrichment analysis indicated a down regulation of NFKB induced TNFA signaling relative to $MYD88^{L265P}$ WM and a corresponding increase in AKT/MTOR signaling compared with either HD MB cells or $MYD88^{MUT}$ WM (p<0.005) (Figure 1).

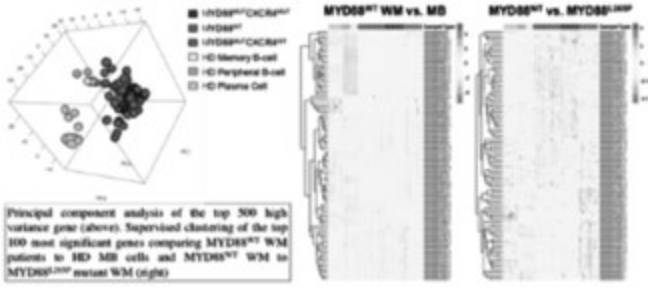

Figure 1.

Summary/Conclusion: Our findings confirm the prognostic significance for MYD88 mutation status as an important determinant of overall survival and risk of disease transformation. While genomic drivers differ between the two populations, the overall transcriptional profile seems largely comparably with the overall $MYD88^{MUT}$ gene expression signature. Additional studies and comparisons to related lymphomas are planned.

D'Alessandro", University of Palermo, Palermo, [6]Pathology Department, IRCCS-Istituto Tumori "Giovanni Paolo II", Bari, [7]Department of Experimental, Diagnostic, and Specialty Medicine (DIMES), Bologna University School of Medicine, Bologna, [8]Hematology Unit, Azienda Ospedaliero Universitaria Città della Salute e della Scienza di Torino, Torino, Italy, [9]Hematopathology Unit, Pathology Department, University of Barcelona, Institute of Biomedical Research August Pi i Sunyer (IDIBAPS), Barcelona, Spain

Background: Diffuse large B cell lymphoma (DLBCL) comprises a large group of disease entities with high molecular heterogeneity and variable treatment responsiveness. Results from gene expression profiling (GEP) studies highlighted the role of cell of origin, namely activated B cell-like cells (ABC) and germinal center B cells (GCB), and stromal gene signatures for predicting clinical outcome and stratifying patient risk. However, GEP failed in recognizing definite target cell populations of the tumor microenvironment endowed with prognostic significance, and its clinical use was limited by the lack of standardized, commercially available assays applicable to routine - formalin-fixed, paraffin-embedded (FFPE) - tissue sample. Recently, a deconvolution method based on GEP (CIBERSORT) has been demonstrated to discriminate with high sensitivity different cell subsets within complex tissues, including tumors.
Aims: We applied CIBERSORT to dissect the DLBCL mileu and used *in silico* results to generate an easy-to-use gene panel that predicts clinical outcome of patients based on their tumor microenvironment composition.
Methods: A 1,028-gene matrix was generated to distinguish among 17 immune and stromal cell types; CIBERSORT was applied on publicly available GEP from 482 untreated DLBCL. *In silico* stratification of cases according to clinical outcome revealed significant differences among proportions of putative tumor-infiltrating cell types, whose related genes were selected and incorporated in a 45-gene panel. NanoString technology was applied to validate the prognostic power of the panel in a set of 203 FFPE samples from advanced-stage DLBCL patients treated with comparable first-line regimens.

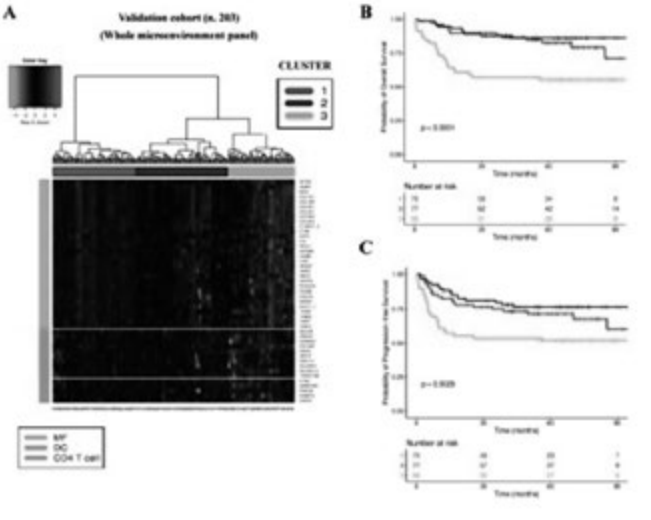

Figure 1.

Results: Higher amounts of myofibroblasts (MF), dendritic cells (DC), and CD4+ T-cells correlated with better outcomes *in silico*. Unsupervised clustering analysis stratified cases into three different subgroups with high, intermediate and low expression of genes included in the panel (Figure 1A). In particular, patients from validation cohort segregated in three separate clusters identifying two main prognostic subgroups with significantly different OS (Figure 1B) and PFS (Figure 1C). When stratified according to the expression of specific cytotype-related genes, the unsupervised clustering generated subgroups with similar prognostic trend. Interestingly, the prognostic value of microenvironment genes was independent of cell of origin categorization, and integration of the two models remarkably improved survival prediction. Furthermore, the prominent contribution of MF-related genes (30/45) in the panel, along with the results from Gene Set Enrichment Analysis (GSEA) and *in situ* immunostainings suggested a strong influence of stromal and extracellular matrix determinants of DLBCL biology.
Summary/Conclusion: Our computational dissection of DLBCL microenvironment identified new prognostic categories and provided an easy-to-apply NanoString-based gene panel that powerfully predicts patient survival. Moreover, owing to its relation with specific stromal and immune components, the panel may acquire a predictive relevance in clinical trials exploring new drugs with known impact on DLBCL microenvironment.

PS1395

GENOMIC CHARACTERISATION OF CIRCULATING TUMOUR DNA (CTDNA) PREFERENTIALLY IDENTIFIES EARLY CLINICALLY RELEVANT GENOMIC EVENTS AND PROVIDES INSIGHT INTO THE CLONAL ARCHITECTURE OF LYMPHOID MALIGNANCY

P. Blombery[1,2,*], G. Ryland[1], J. Markham[1], J. Guinto[1], M. Wall[2,3,4], M. McBean[1], K. Jones[1], E. Thompson[1,2], D. Cameron[5], T. Papenfuss[1,2,5], M. Prince[1,2], M. Dickinson[1], D. Westerman[1,2]

[1]Peter MacCallum Cancer Centre, [2]Sir Peter MacCallum Department of Oncology, University of Melbourne, [3]Victorian Cancer Cytogenetics Service, St. Vincent's Hospital, [4]St Vincent's Institute of Medical Research, [5]Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia

Background: DNA shed from tumour cells (known as "circulating tumour DNA" or ctDNA) can be detected in the peripheral blood of patients with haematological malignancy offering a less invasive approach to obtaining tissue for genomic characterisation to guide management of patients.
Aims: We aimed to perform comprehensive sequence variant, copy number and translocation characterisation from ctDNA in a diverse range of lymphoid malignancies to gain insight into underlying lymphoma biology and to detect diverse genomic lesions that may impact patient care.
Methods: Libraries were made from ctDNA collected from patients at Peter MacCallum Cancer Centre (PMCC) during routine clinical sequencing. Libraries were captured using the PMCC PanHaem hybridisation-based next generation sequencing panel and sequenced on an Illumina NextSeq. The PMCC PanHaem panel targets 313 genes recurrently mutated in haematological malignancy, provides genome-wide copy number calls as well as detects translocations involving IGH/TCR loci.
Results: ctDNA from patients with a broad range of lymphoid malignancies (including diffuse large B-cell lymphoma (DLBCL), Burkitt lymphoma (BL), chronic lymphocytic leukaemia (CLL), mantle cell lymphoma (MCL), cutaneous T-cell lymphoma (CTCL), peripheral T-cell lymphoma not otherwise specified (PTCL-NOS), angioimmunoblastic T-cell lymphoma (AITL) and multiple myeloma(MM)) was assessed. Comprehensive genomic characterisation including detection of sequence variants, genome-wide copy number changes and IGH/TCR translocations was possible from ctDNA and revealed significant differences in the spectrum and relative burdens of sequence variants, copy number changes and translocations between the tumour and the ctDNA compartments across all histologies.
Genomic lesions that are classically considered "early" establishing events in lymphomagenesis (e.g. IGH-CCND1 in MCL/ MM, IGH-MYC in BL, TET2 mutations in AITL) were uniformly detectable in both ctDNA and biopsied tumour compartments. Moreover, these early lesions were present at relatively high allelic burden in the ctDNA compared to genomic lesions that are classically considered to occur later in lymphomagenesis (e.g. RAS mutations and TP53 mutations/ copy number changes). This phenomenon was most pronounced in the observation of a marked difference in the spectrum of aberrant somatic hypermutation (aSHM) that was observed between the biopsied tumour and ctDNA compartments including identification of multiple individual variants and genes exclusively mutated in ctDNA versus the biopsied tumour compartment (including BCL2, SOCS1, PIM1 and MYC). This is supportive of the hypothesis of aSHM being an ongoing and, in some cases, a highly spatial and tumour site-specific process in lymphoid malignancy.
Summary/Conclusion: We have demonstrated that comprehensive genomic characterisation of lymphoid malignancy is possible from ctDNA and assessment of this compartment is particularly suited for detecting early clonal events in lymphomagenesis. Given the diagnostic, prognostic and therapeutic relevance of these early lesions in lymphoid malignancies this approach is of significant clinical value. Moreover, the observation of the differential representation of genomic lesions between tumour and ctDNA compartments in our data contributes to furthering the understanding of clonal architecture in lymphoid malignancy.

PS1396

THE DIALOG BETWEEN MANTLE CELL LYMPHOMA AND MONOCYTES/MACROPHAGES CAN BE DISRUPTED BY BTK INHIBITION AND MONITORED THROUGH CD163 MODULATION *IN VIVO*

A. Papin[1,*], C. Bellanger[1,2], B. Tessoulin[1,2], M. Amiot[1], S. Le Gouill[1,2], C. Pellat-Deceunynck[1], D. Chiron[1]

[1]CRCINA, INSERM, CNRS, Université de Nantes, Université d'Angers, [2]CHU de Nantes, Nantes, France

Background: The aggressive clinical behavior of mantle cell lymphoma (MCL) and its short response to current treatment highlight a need for continuing exploring rational novel option. Recently it has been demonstrated that tumor microenvironment strongly influences MCL expansion and chemoresistance. However, there is little information regarding the nature of extrinsic signaling and their resulting molecular regulations.
Aims: Here we aimed to study the dynamic interactions between primary MCL cells and its myeloid microenvironment through 3 axes: 1) Determine the protumoral role of myeloid cells using primary coculture models *ex vivo*. 2) Characterize the phenotype of MCL associated monocytes (M-MCL) *in vivo*. 3) Assess the role of targeted therapies to disrupt the dialog between MCL and monocytes/macrophages.
Methods: Primary MCL cells (n>20) were cocultured 7 days with monocytes or pre-differentiated M1 (GMCSF, IFNg) or M2 (MCSF, IL10) macrophages. Macrophages derived from monocytes cocultured with MCL cells (M-MCL) were characterized using a panel of markers (CD14, CD68, CD163, CD11b, CD86, HLA-DR, CD16, CD23) as well as cytokine production (IL10, TGFb, IL6, BAFF, IGF1). To validate the specific phenotype of M-MCL *in vivo* the same markers were assessed on circulating monocytes of MCL patients at diagnosis (n= 10), or treated with a combination of ibrutinib and obinutuzumab (n= 9; OASIS trial NCT02558816).
Results: Whereas primary MCL cells alone rapidly undergo spontaneous apoptosis *ex vivo*, we observed that M-MCL and M1/M2 macrophages greatly support cell survival after 7 days of coculture in all samples tested (n=14; p<.0005). Of interest, both M-MCL and M2, but not M1, macrophages induced cell-cycle progression in clinically aggressive (n=6) but not indolent (n=4) MCL subtype. Multiple factor analysis highlights that M-MCL were closely related to M2 ($CD163^{high}$, $CD11b^{low}$, $IL10^{+}$, $IGF1^{+}$). We next confirmed that primary MCL cells overexpressed the M2-promoting factors MCSF and IL10 compared to normal B cells (p<.005), the level of MCSF being higher in aggressive forms of MCL (p< .05). Accordingly circulating monocytes from MCL patients expressed a higher level of CD163 compared to healthy donors (median 9.7 vs. 6.2; p<.05), suggesting that MCL reprograms monocytes into M-MCL *in vivo*.
We then demonstrated that targeting BTK with ibrutinib (500nM) inhibited IL10 and MCSF secretion by MCL *in vitro* and consequently IL10/MCSF-mediated CD163 induction on M-MCL, suggesting that BTK inhibition disrupts molecular communication between both cell types. Accordingly, ibrutinib counteracted monocyte-dependent survival (n=9; p< .05) and proliferation (n= 4) of primary MCL cells. These observations were confirmed *in vivo* through analysis of the peripheral blood of patients included in the OASIS trial. We observed a decrease of the CD163 level on circulating monocytes (median: -49%, range: -16% to -98%) in 8 patients and an increase in 1 patient (+ 27%) after 8 days of ibrutinib (560 mg/day) and obinutuzumab (1000 mg/8 days). Importantly, longitudinal follow-up after several cycles highlighted that CD163 increase at day 8 (n=1) was associated to clinical progression whereas CD163 decrease (n=3) was associated to complete response.
Summary/Conclusion: Through secretion of IL10 and MCSF, MCL reprograms monocytes into M2 macrophages that in turn favor tumor survival and proliferation. Ibrutinib counteracts this dialog and ibrutinib-dependent CD163 modulation on circulating monocytes *in vivo* appears as an early marker of patients' response to treatment.

PS1397

MYD88 CONSTITUTIVE ACTIVATION IS DIRECTLY ABLE TO INDUCE INDOLENT LYMPHOPLASMACYTIC LYMPHOMA WITH MONOCLONAL IGM PEAK SECRETION IN 1 YEAR OLD MICE: A MODEL FOR WALDENSTROM'S MACROGLOBULINEMIA

C. Vincent-Fabert[1,*], L. Roland[1], C. Ouk[1], M. Deveza[2], N. Gachard[2], N. Faumont[1], J. Feuillard[1]

[1]Contrôle de la Réponse Immune B et des Lymphoprolifération (CRIBL) UMR CNRS 7276 INSERM 1262, Centre de Biologie et de Recherche en Santé, [2]Hématologie Biologique, CHU , Limoges, France

Background: Waldenström's Macroglobulinemia (WM) is an incurable lymphoplasmacytic indolent B cell lymphoma with a monoclonal IgM peak. The MYD88 L265P mutation, activator of NF-kappa B (NF-kB), is found in 80% to 90% of WM. So far, there is no existing animal model for WM to evaluate the role of MYD88 activation, and the only published mouse model harboring the ortholog MYD88 L252P mutation develops aggressive B-cell lymphomas in aged mice.
Aims: The aim of this study is to developp a mouse model harboring the MYD88 L252P mutation in order to better understand the oncogenic history of the disease since the aquisition of the first event, the MYD88 mutation.
Methods: The MYD88 L252P coding sequence was attached to YFP cDNA with an IRES sequence. This construct was flanked with loxP sites and inserted in the Rosa26 locus. Here, we present the first results of the corresponding CD19_CRE/LoxP MYD88 L252P mouse model.
Results: *Ex vivo* TAT-CRE induction of MYD88 L252P expression in purified B-cells from spleen induced activation, proliferation and protection against cell death. *In vivo*, B-specific expression of MYD88 L252P in CD19_CRE/LoxP MYD88 in 3.5 month old mice, led to mild splenomegaly due to expansion of B cells with an activated phenotype. In parallel, the presence of CD138 positive cells that cytologically resembled plasma cells was observed in blood. In one-year-old mice, we observed an increase in white blood cells, with again presence of CD138 positive cells. Serological studies revealed the presence of an immunoglobulin M (IgM) peak in the mutant mice associated with a decrease in circulating IgG levels. These mice had a large splenomegaly that was correlated with infiltration of tumor B-cells with a marked lymphoplasmocytic aspect at both cytological and histopathological levels. Compared to controls, the proliferative index was moderately increased, ranging 10% - 20% and spontaneous apoptosis was decreased. In parallel, we established the direct signature of MYD88 L265P deregulated genes. In addition to MYD88 itself, expression of NF-kB signature genes such as ICAM1, EBI3, FAS or TNFAIP3 was increased. MYD88 L265P also induced over expression of CCND2, of the anti-apoptotic molecules BCL2A1 and MCL1 with decreased expression of BAX, of genes involved in the formation of the Golgi apparatus, as well as of the immunosuppressive CD274 molecule.
Summary/Conclusion: These preliminary results suggest that the constitutive activation of MYD88 is able to promote B cell clonal emergence with a moderate increase of proliferation rate, protection against apoptosis, engagement in plasma cell differentiation, and monoclonal IgM peak, leading to a murine disease strongly resembling human Waldenström's Macroglobulinemia.

PS1398

CELL OF ORIGIN AND GENOMIC PROFILE OF PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA DETERMINED USING THE NANOSTRING LST ASSAY AND ULTRA DEEP TARGETED NEXT GENERATION SEQUENCING

C. Bödör[1,*], D. Alpar[1], D. Marosvari[2], H. Rajnai[2], B. Kajtar[3], B. Deak[4], T. Schneider[4], H. Alizadeh[5], A. Matolcsy[2], S. Brandner[6], J. Storhoff[7], L. Reiniger[2]

[1]1st Department of Pathology and Experimental Cancer Research, [2]1st Department of Pathology and Cancer Research, Semmelweis University, Budapest, [3]Department of Pathology, University of Pecs, Pecs, [4]National Institute of Oncology, Budapest, [5]Department of Hematology, University of Pecs, Pecs, Hungary, [6]Division of Neuropathology and Department of Neurodegenerative Disease, Institute of Neurology, University College London, London, United Kingdom, [7]Nanostring, Seattle, United States

Background: Primary central nervous system lymphoma (PCNSL) is characterized by a consistently inferior outcome compared to systemic diffuse large B-cell lymphoma (DLBCL). The distinction of DLBCL into cell of origin (COO) categories based on patterns of gene expression reminiscent of germinal center B-cell (GC-) type and activated B-cell (ABC-) type has profound prognostic and potential therapeutic implications with many novel therapies displaying differential efficacy between the GC and ABC groups.The NanoString LST assay is a digital gene-expression based test for COO assignment, representing a more accurate means of COO determination compared to standard immunohistochemistry (IHC) based algorithms, and was recently successfully applied in nodal DLBCLs.
Aims: In the present study, we tested the LST assay on a cohort of PCNSL patients and performed a complementary targeted genomic profiling on a subset of these patients.
Methods: The COO of 77 PCNSL patients was determined with the NanoString LST assay using RNAs extracted from FFPE samples and compared with the results obtained by the Hans IHC algorithm. The genomic profiles of 62 PCNSL cases were determined using ultra-deep targeted next generation sequencing (NGS) of 13 recurrently mutated target genes, including *CARD11, CCND3, CD79B, CSMD2, CSMD3, IRF4, C-MYC, MYD88, PAX5, PIM1, PRDM1, PTPRD* and *TP53* using the TruSeq Custom Amplicon approach on a HiSeq4000 Instrument (Illumina) to an average depth of 30.000x.
Results: The LST assay resulted in the following subtype calls: 80.5% ABC, 12.9% GC and 6.5% unclassified (UC). Using the Hans IHC algorithm, 94.8% (73/77) of the PCNSL cases were classified as ABC subtype with 5.2% (4/77) representing the GC subtype. Interestingly, the COO classification obtained using the LST assay showed a different outcome in 16.9% (13/77) of the cases: Out of the 12 cases classified as ABC subtype with the IHC algorithm, 7 cases presented as GC subtype and 5 showed an UC profile using the LST assay. On the other hand, one case characterized as GC subtype with the IHC assay was classified as ABC when analyzed using the LST assay. As for the mutation analysis, we detected a total of 402 somatic mutations in the 62 PCNSL cases across the 13 genes analyzed with individual cases harboring mutations in 4 genes on average (range: 1-11). The most frequently mutated genes were *MYD88* (76%), *PIM1* (55%) and *PRMD1* (50%). The mutation frequencies in the remaining genes were as follows: *CD79B* (40%), *PTPRD* (32%), *MYC* (31%), *PAX-5* (31%), *CARD11* (26%), *TP53* (26%), *IRF4* (23%), *CCND3* (19%), *CSMD2* (19%) and *CSMD3* (18%). Analyzing the mutation profiles of the ABC and GC subtypes, we observed an enrichment of *CD79B* (47% vs 20%) and *PIM1* (59% vs 20%) in cases with ABC subtype, with *IRF4* mutations being present in ABC cases only (29% vs 0%).
Summary/Conclusion: We successfully applied, for the first time, the NanoString LST assay for COO determination using FFPE derived RNA samples from a cohort of 77 PCNSL patients. Interestingly, the LST assay revealed a lower proportion of patients with ABC subtype compared our IHC findings (80.5% vs 94.8%). This may reflect the genuine biology of these cases, as the NanoString LST assay represents the most reliable COO determination approach compared to the original gold standard GEP method. The frequent mutations revealed in components of different actionable pathways including the BCR pathway, cell cycle regulation and CNS development highlights the role of these variants in the pathogenesis of PCNSL.

PS1399

IMMUNOPROFILING OF HIV-ASSOCIATED LYMPHADENOPATHY: HIGH-THROUGHPUT ANALYSIS OF THE T CELL RECEPTOR GENE REPERTOIRE SUPPORTS EPITOPE-SPECIFIC T CELL RESPONSES

E. Stalika[1,*], K. Gemenetzi[1], A. Vardi[2], F. Psomopoulos[1], E. Vlachonikola[1], C. Galigalidou[1], T. Koletsa[3], K. Stamatopoulos[1], M. Papaioannou[4], A. Hadzidimitriou[1]

[1]Institute of Applied Biosciences, CERTH, [2]Hematology Department and HCT Unit, G. Papanicolaou Hospital, [3]Pathology Department, Faculty of Medicine, Aristotle University of Thessaloniki, [4]First Department of Medicine, Medical School, Thessaloniki, Greece

Background: Non-neoplastic lymphadenopathy is a characteristic, though certainly not specific, finding in HIV/AIDS patients. It may arise with the onset of HIV viremia (acute retroviral syndrome) that can persist beyond the acute phase. Histopathological findings at this early phase mainly pertain to hyperplastic changes with large lymphoid follicles; with time, the number of lymphoid follicles diminishes, while plasma cells increase; at the extreme is a pattern characterized by sclerosis of the germinal centers in the residual follicles. Moreover, a heightened turnover of both $CD4^+$ and $CD8^+$ T cell populations in peripheral blood and lymphoid tissues of these patients has been reported. Overall, these findings allude to a dynamic, ongoing immune response that is still incompletely characterized at the molecular level.
Aims: In order to obtain a truly comprehensive view into the dynamics of the T cell responses in HIV-associated lympadenopathy, we interrogated the TR repertoire of biopsy samples from 12 patients with HIV infection.
Methods: TRBV-TRBD-TRBJ gene rearrangements were amplified on

gDNA isolated from paraffin-embedded tissues according to the BIOMED2 protocol. PCR products were subjected to NGS on the MiSeq Illumina Platform. Dedicated bioinformatics pipeline was developed for the analysis of raw NGS data which includes quality filtering, merging of pair-end read, preparation of fasta files for the IMGT/High V-QUEST tool; and, IMGT/High V-QUEST metadata analysis, interpretation and visualization.
Results: Overall, 1,474,718 productive rearrangements were included in the analysis. Rearrangements with identical TRBV gene usage and CDR3 sequence were defined as clonotypes. For repertoire analyses, clonotypes rather than single rearrangement sequences were considered. A total of 16,039 unique clonotypes were identified (median 1337; range 340-6,473/case), of which 9,882 represented singletons. Amongst the 46 functional TRBV genes identified, the most frequent were: TRBV6-5 (14.6%), TRBV19 (13.1%), TRBV29-1 (10.4%) and TRBV12-3 (9.2%), collectively accounting for 47.3% of the TRBV repertoire; the TRBV29-1 gene predominated in 7/12 cases. Analyzed HIV samples carry expanded clonotypes (median 513; range 131-2411/case). The predominant clonotype ranged in frequency from 8 to 87.5% of the total clonotypes observed in each case. Cluster analysis of the CDR3 sequences identified 564 different clonotypes shared by different patients (public clonotypes), albeit at low frequency. Of note, a particular clonotype (TRBV29-1/ SVDPSGTGGEGYT) was detected in all samples, representing the dominant clonotype in 7/12 cases. The chance that this may happen randomly is negligible. In order to confirm that this represents a true biological phenomenon rather than an artifact e.g. due to contamination, we applied PCR reaction re-set up, Sanger sequencing of monoclonal PCR products and exclusion of index hopping, all leading to findings suggestive of the former possibility. Additionally, in 4/12 cases, the above clonotype appeared at high frequency shaping further an oligoclonal profile, whereas in one case the frequency was 0,15%, arguing against contamination. Interestingly, highly similar clonotypes were also detected differing by single aminoacids within the CDR3.
Summary/Conclusion: In conclusion, the TR gene repertoire of HIV-associated lymphadenopathy appears profoundly skewed, displaying striking homology of the CDR3 regions of major clones; oligoclonal profiles; and TRBV gene usage restriction. On these grounds, we argue that this profile is likely reflecting epitope-specific T cell responses.

Platelets disorders

PS1400

INSUFFICIENT RECEPTOR EDITING LEADS TO DEFECTIVE B CELL CENTRAL TOLERANCE IN PRIMARY IMMUNE THROMBOCYTOPENIA (ITP)

Z. Sheng[1,*], Y. Gao[1], M. Hou[1], S. Li[2], J. Peng[1]

[1]Department of Hematology, [2]Department of Oncology, Qili Hospital, Shandong University, Jinan, China

Background: The antibody-mediated platelet destruction is the most important pathogenic mechanism in primary immune thrombocytopenia (ITP). However, it is not clear how these anti-platelet antibodies are generated in ITP patients. Receptor editing and VH replacement are processes to change the specificity of immature B cell receptors (BCR) by a secondary recombination of immunoglobulin genes, which are the main part of central tolerance of B cells.
Aims: The aim of this study is to investigate how the anti-platelet antibodies are generated and overcome the central B cell tolerance in patients with ITP.
Methods: We first performed next-generation sequencing on peripheral B cells of ITP patients and found a distinct immunoglobulin gene κ chain (Igκ) repertoire from the healthy control. We then performed single cell RT-PCR on naïve B cells to clone both Ig heavy chain (IgH) and Ig light chain (IgL) genes from the same cells. The paired IgH and IgL were co-transfected and the recombinant monoclonal antibodies were expressed and purified. The reactivity of these antibodies against platelet antigens was determined by ELISA, immunofluorescence assays, and flow cytometry with human platelets. Cross-reactivity of these antibodies was tested by ELISA coated with double strand DNA, insulin and lipopolysaccharides. Ig gene sequence features were analyzed by programs including IMGT, IgBLAST, and VHRFA-1.
Results: Deep sequencing revealed that the ITP-derived Igκ preferentially used the downstream Vκ (Vκ1-20) (44.65% vs. 42.20%, p=0.0210) and upstream Jκ (Jκ1-2) (27.82% vs. 23.38%, p=0.0210) segments compared with those derived from healthy controls, which indicated a defective receptor editing of B cells. Utilizing single cell RT-PCR, 228 recombinant antibodies were cloned and expressed derived from naïve B cells in 4 ITP patients and 4 healthy controls. Low numbers of somatic mutations validated that the antibodies were derived from naive B cells. ELISA assay showed that 17.0% (21/124) of the ITP-derived naïve B cells were platelet-reactive, in contrast to the 2.8% (3/104) in healthy donor-derived naïve B cells, suggesting a defective B cell tolerance in the early developing stage. The anti-platelet reactivity was also confirmed by immunofluorescence assays and flow cytometry. Cross-reactivity test revealed that the anti-platelet antibodies were polyreactive to multiple antigens. Sequence analysis revealed that positively charged amino acids were highly enriched in the complementarity determining region 3 (CDR3) of the anti-platelet antibodies, which possibly generates the potential to interact with the negatively charged glycoproteins. The Igκ genes derived from ITP patients preferentially used upstream Jκ segments (49.1% vs. 25.7%, p<0.01) compared to healthy controls, indicating an insufficient IgL receptor editing in ITP patients. In addition, the frequencies of VH replacement products were elevated in IgH genes from ITP patients (8.6% vs. 4.4%, p<0.05) compared to healthy controls.

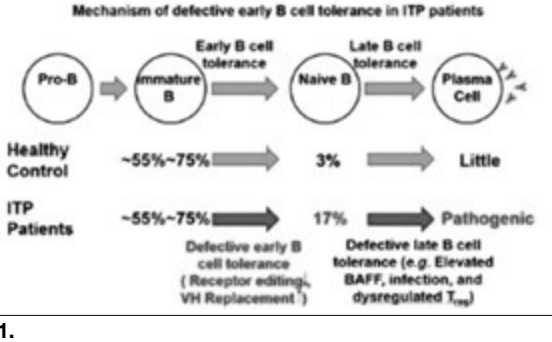

Figure 1.

Summary/Conclusion: In summary, this study provides evidence of defective early B cell tolerance and accumulation of anti-platelet naïve B cells in patients with ITP. This defect might be a result of insufficient receptor editing in IgL as well as excessive VH replacement in IgH.

PS1401

SUPERIORITY OF AVATROMBOPAG TO PLACEBO IN I REDUCING PLATELET TRANSFUSIONS IN PATIENTS WITH THROMBOCYTOPENIA AND CHRONIC LIVER DISEASE UNDERGOING SCHEDULED PROCEDURES- POOLED ANALYSIS OF 2 STUDIES

F. Poordad[1], L. F. Allen[2], K. Aggarwal[2,*], M. Vredenburg[2], N. Alkhouri[1]

[1]Texas Liver Institute, San Antonio, [2]Dova Pharmaceuticals, Durham, United States

Background: Thrombocytopenia (TCP) is common in patients with chronic liver disease (CLD) and complicates clinical management with these patients requiring multiple invasive procedures. Prophylactic platelet transfusions are used to reduce bleeding risk, but have multiple associated safety risks. Avatrombopag (AVA), an oral thrombopoietin receptor agonist, has completed Phase 3 studies as an alternative to platelet transfusions for patients with TCP and CLD.
Aims: To report the results of 2 randomized, double-blind, placebo (PBO)-controlled Phase 3 trials (ADAPT-1 and ADAPT-2).
Methods: ADAPT-1 and ADAPT-2 enrolled adults with CLD and platelet count (PC) <50x10^9/L undergoing a procedure. Patients were divided by Baseline PC into **Cohort 1**- PC <40x10^9/L and Cohort 2- PC 40 to <50x10^9/L, and randomized 2:1 to once-daily oral AVA (Cohort 1- 60 mg; Cohort 2- 40 mg) or PBO for 5 days, with the procedure 5 to 8 days after the last dose. The primary efficacy endpoint was the proportion of patients not requiring a platelet transfusion or rescue procedure. Secondary endpoints assessed the proportion of patients achieving the target PC (>=50x10^9/L) by Procedure Day, change in PC from Baseline to Procedure Day, and safety.
Results: 435 patients were randomized in the 2 studies. AVA was superior to PBO in both cohorts in the number of patients not requiring a platelet transfusion or bleeding rescue (Cohort 1: AVA- 66.9%, PBO- 28.6%; p< 0.0001; Cohort 2: AVA- 88.0%, PBO 35.8%; p< 0.0001). A greater number of AVA-treated patients also achieved the target PC in both Cohort 1 (AVA- 68.1%, PBO- 5.5%; p<0.0001) and Cohort 2 (AVA- 90.6%, PBO- 29.9%; p<0.0001). Mean increases in PCs were also greater with AVA compared with PBO in both cohorts (**Cohort 1**: AVA- 31.7x10^9, PBO- 1.8x10^9/L; **Cohort 2**: AVA- 41.0x10^9, PBO 3.5x10^9/L). The most common TEAEs were pyrexia, abdominal pain, nausea, and headache.
Summary/Conclusion: AVA was superior to placebo in reducing the need for PLT transfusions, the proportion of patients achieving the target PC, and increasing the PC.

Background: Systemic lupus erythematosus (SLE) beginning at pediatric age is reported to be more severe than that SLE beginning during adulthood, and may be associated with autoimmune cytopenia (AIC). The incidence of SLE in the long-term follow-up of AIC in children is not known, especially when significant titers of anti-nuclear antibodies (ANA) are documented.
Aims: The objectives of this study were to define predictive factors to develop SLE in the follow-up of childhood AIC.
Methods: In this national prospective observational cohort, children with chronic immunologic thrombocytopenic purpura (ITP), autoimmune hemolytic anemia (AIHA) or Evans syndrome (ES) before the age of 18 and a subsequent SLE (SLICC criteria) were analyzed. A uni and multivariate study of the factors associated with the occurrence of SLE was performed.
Results: Of the 1245 children with AIC registered in this national cohort, 192 had ANA ≥ 1/160 at least once in evolution (15%) and with a median follow-up of 5.1 years (0.6-26), 49 patients (4%) developed an SLE at a median age of 14.7 years (0.9-24.5). These 49 children had chronic ITP in 22 cases, ES in 20 cases or AIHA in 7 cases. The clinical manifestations of SLE were rheumatologic in 55% of cases, cutaneous in 48% of cases, renal in 13% of cases, seritis in 8% of cases, neuro-lupus in 4% of cases. Twelve of those patients only had biological manifestations of SLE. Among the treatments proposed for those AIC, splenectomy was used in 21% of cases, rituximab in 20% of cases and hydroxychloroquine in 79% of cases. The impact of hydroxychloroquine on the clinical manifestations of SLE is currently being analyzed. In unvaried preliminary analysis, factors associated with progression from AIC to SLE are female sex, family history of autoimmune disease, advanced age at initial diagnosis (12.1 vs 5.6 years), initial severity of AIC and a high ANA titer. In multivariate analysis the female sex (RR = 7.18 (IC95% [1.99-25.8], p =0.003)) and ANA titer ≥1 / 320 (RR = 25(IC95% [8.33-50], p<10-4)) were significantly associated with SLE occurrence.
Summary/Conclusion: In this prospective national study of rare diseases, 25% of children with AIC and high ANA titers developed SLE during adolescence and young adulthood. Long-term specialized survey should be proposed for patients with CAI discovered in childhood, especially girls with ANA ≥ 1/320, with a particular attention during the transition phase between pediatrics and adult health care. Early use of hydroxychloroquine could decrease the frequency of severe organ complications of these SLEs.

PS1404

THE POLYMORPHISM OF CASPASE RECRUITMENT DOMAIN-CONTAINING PROTEIN 9 GENE MAY CONTRIBUTE TO RISK OF IMMUNE THROMBOCYTOPENIA

Z. Sheng[1,*], J. Li[1], M. Hou[1], J. Peng[1]

[1]Department of Hematology, Qilu Hospital, Shandong University, Jinan, China

Background: Primary immune thrombocytopenia (ITP) is an acquired autoimmune disease characterized by thrombocytopenia and increased risk of bleeding. The etiology remains unclear. It has been widely accepted that the genetic factors play a significant role in the pathogenesis of ITP. Single nucleotide polymorphisms (SNPs) are the most common structure of human genetic variation. There are a few studies which found that three SNPs including rs4077515 and rs59902911 in the caspase recruitment domain-containing protein 9 (CARD9) gene and rs7216796 in the mitogen-activated protein 3 kinase 14 (MAP3K14) gene were involved in the immune regulation and development of autoimmune diseases. It is well recognized that many autoimmune diseases have similar underlying etiology and have shared susceptible genes.
Aims: The aim of our study was to investigate the possible association between the three SNPs and the incidence of primary ITP in the Chinese Han population.
Methods: In this case-control study, the total subjects included 84 Chinese primary ITP patients who were admitted to Department of Hematology, Qilu Hospital, Shandong University, and 89 ethnically matched healthy controls. To explore the association between these polymorphisms and more complete clinical data, the cases were stratified by susceptibility, severity, corticosteroid sensitivity, and refractoriness based on the standardized definitions. Written informed consent was obtained from each participant in accordance with the Declaration of Helsinki. Genomic DNA was extracted from peripheral blood mononuclear cells (PBMCs) that had been isolated from whole blood samples from participants by a standard protocol. These three SNPs genotyping was performed on Sanger sequencing. Statistical analysis was performed using SPSS 21.0, and associations between the SNPs and ITP were calculated by a chi-squared (χ^2) test or Fisher's exact test. A two-tailed p<0.05 (or adjusted p value by Bonferroni multiple testing) was considered statistically significant.
Results: Demographic and clinical characteristics of healthy controls and ITP patients were summarized in Table 1. Four genetic models were used to analyze the association between the three SNPs and ITP. Our results demonstrated significantly different genotype distributions of CARD9 rs4077515 between the ITP and control groups under the codominant and dominant models (p=0.001 and p=0.006, respectively, Table 2). Univariate logistic regression analysis further revealed that for rs4077515 in CARD9, AG and AA/AG genotypes were both statistically significant compared to GG after Bonferroni multiple correction (p=0.001 and p=0.005, respectively, Table 2). And, this SNP locus was a risk factor. However, there was no obvious difference in the genotype or allele frequencies on the other two genes between ITP and control groups. With regard to severity, corticosteroid sensitivity and refractoriness, we did not find any significant differences in

genotype and allele frequencies.
Summary/Conclusion: The obtained data indicate that the AG of CARD9 rs4077515 is more frequent in patients than in controls and that this polymorphism may be a genetic risk factor associated with the development of ITP in the Chinese Han population. Further studies on larger samples are needed to investigate the role of CARD9 rs4077515 polymorphism in etiology of ITP.

Table 1. Demographic and clinical characteristics.

	Controls	ITP patients

LABORATORY CHARACTERIZATION OF PATIENTS WITH (SUSPECTED) INHERITED PLATELET DISORDERS: RESULTS FROM THE 'THROMBOCYTOPATHY IN THE NETHERLANDS' STUDY

M. Blaauwgeers[1,*], I. van Asten[2], A. Huisman[2], S. Korporaal[2], M. Coppens[3], M. Kruip[4], E. Beckers[5], J. Eikenboom[6], R. Tamminga[7], R. Urbanus[2], R. Schutgens[1]

[1]Van Creveldkliniek, [2]Clinical Chemistry and Hematology, UMC Utrecht, Utrecht, [3]AMC, Amsterdam, [4]Erasmus MC, Rotterdam, [5]Maastricht UMC, Maastricht, [6]LUMC, Leiden, [7]UMCG, Groningen, Netherlands

Background: Inherited platelet disorders (IPDs) are rare disorders of the primary hemostasis, caused by defects in platelet function (inherited platelet function disorders, IPFD) and/or platelet production (inherited thrombocytopenia, IT). Most IPDs are a challenge to diagnose due to a paucity of distinctive clinical and laboratory features and poor standardization of laboratory tests. However, an accurate diagnosis is essential to optimize treatment and improve patient care. There is a large variation in the diagnostic strategy used to assess platelet function, despite recommendations on a standardized approach. This study reports the results of a diagnostic strategy used in a cohort of (suspected) IPDs in the Netherlands
Aims: To describe the results of the diagnostic work-up for patients with (suspected) IPDs
Methods: Adult patients with a clinical and/or laboratory suspicion for having an IT or IPFD were included in a nationwide cross-sectional study on IPDs ('Thrombocytopathy in the Netherlands' (TiN)) between February 2016 and December 2017. All participants gave written informed consent. The ISTH-BAT was used to evaluate bleeding symptoms. Laboratory testing consisted of a complete blood count, MPV, peripheral blood smear, von Willebrand factor activity, light transmission aggregometry (LTA) (ADP/collagen/arachidonic acid/ristocetin), flow cytometry (P-selectin expression, fibrinogen binding, glycoprotein expression and mepacrine uptake), nucleotide content analysis (platelet lysates using bioluminescence) and genetic analysis (89-gene NGS platform). An IT was diagnosed if the platelet count was below the normal range and if a candidate genetic defect was identified or, in the absence of a genetic defect, when clinical characteristics and family history pointed towards a genetic origin. An IPFD was diagnosed if one or more platelet function assays and/or platelet nucleotide content were abnormal, regardless of the identification of a genetic defect
Results: A total of 159 patients with a suspected IT (n=26) or IPFD (n=133) were included. Clinical and laboratory features are shown in Table 1. In 7 of the 26 suspected IT patients (27%) a candidate genetic defect was identified: mutations were found in the genes ACTN1 (2), TUBB1 (2), MYH9 (1) and GP9 (2). Thirteen patients had a final diagnosis of IT, of whom 5 had an additional platelet function defect. We were able to diagnose an IPFD in 63 of the 133 patients (47%) with a suspected IPFD: 51 patients had abnormal LTA results, 9 patients showed abnormalities in flow cytometry analysis. One patient had normal LTA and flow cytometry results but an abnormal platelet nucleotide content. Two patients had normal platelet function assays but a possible pathogenic genetic mutation in GFI1B. In the other 70 patients with normal platelet function assays, no candidate genetic defect was found. We identified 7 patients with δ-SPD, 2 with α-SPD, 5 with an ADP-receptor defect, 2 with a thromboxane receptor defect, 1 with GPVI deficiency and 46 with uncharacterized functional defects. 1 patient had a combination of δ-SPD and an ADP-receptor defect. A genetic defect was found In 13 of the 63 (21%) patients. Mutations were found in GFI1B (2), P2RY12 (6), PTGS1 (2), RUNX1, SLFN14 and TBXA2R.

Table 1. Clinical and laboratory features of patients included in the TiN study.

	IT (n=26)	IPFD (n=133)
Female sex (%)	12 (46)	118 (89)
Age (years), median (IQR)		
Male	30 (21-46)	40 (28-59)
Female	32 (23-37)	41 (31-53)
BS, median (IQR)		
Male	4 (2-7)	7 (5-9)
Female	7 (3-12)	10 (7-13)
Platelet count (10^9/L), median (IQR)	78 (37-93)	238 (199-288)
MPV (fL), median (IQR)	9.8 (8.9 -12.6)	7.9 (7.1-8.4)
Abnormal platelet function assay, n (%)	14 (54)	61 (46)
Genetic defect identified, n (%)	7 (27)	13 (10)
Final diagnosis of IPD, n (%)	13* (50)	63 (47)
Genetic defects	ACTN1, GP9, MYH9, TUBB1	GFI1B, P2RY12, PTGS1, RUNX1, SLFN14, TBXA2R

BS: bleeding score; IT: inherited thrombocytopenia; IPD: inherited platelet disorder; IPFD: inherited platelet function disorder; IQR: interquartile range; MPV: mean platelet
* in 5 patients an additional platelet function defect was identified

Summary/Conclusion: Clinical management of patients with an inherited platelet disorder will benefit from a conclusive diagnosis. By adding flow cytometry, platelet nucleotide content and genetic analysis to the diagnostic strategy of patients with suspected IPDs, more patients will receive a definitive diagnosis, which will improve patient care

PS1406

FEATURES OF PRN1008, A BRUTON'S TYROSINE KINASE INHIBITOR, IN CLINICAL DEVELOPMENT FOR IMMUNE THROMBOCYTOPENIC PURPURA

S. Gourlay[1,*], C. Langrish[2], M. Bradshaw[3], M. Francesco[3], P. Nunn[4], D. Kuter[5]

[1]Clinical Development, [2]Immunology Research, [3]Biology, [4]Early Development, Principia Biopharma, San Francisco, [5]Center for Hematology, Massachucetts General Hospital, Boston, United States

Background: PRN1008 is an oral, reversible covalent inhibitor of Bruton's tyrosine kinase (BTK) in clinical development for the treatment of multiple autoimmune diseases. BTK is an essential signaling element downstream of the B cell receptor and Fc receptor pathways. BTK activation is critical for B cell activation, and also regulates antibody mediated activation of other immune cells, such as macrophages, neutrophils and mast cells through Fc receptor signaling. Although BTK is expressed in platelets, alternative signaling pathways exist which bypass BTK signaling to retain normal platelet function.
Aims: Assessment of the potential clinical profile of the BTK inhibitor PRN1008 for the treatment of immune thrombocytopenia.
Methods: *In vivo* assessments of PRN1008 pre-treatment were conducted in a mouse anti-CD41 ITP model and an autoantibody-mediated rat arthus model. The ex vivo effects of PRN1008 on platelet aggregation to a panel of agonists in healthy subject and ITP patient blood (n=5 each) were studied. Platelet counts and any adverse effects pertinent to bleeding or bruising were summarized from prior PRN1008 healthy volunteer and a pemphigus Phase 2 clinical study (NCT02704429). Changes in autoantibody levels over a 12-week treatment period in that study were characterized, using doses of between 400 mg and 600 mg twice daily. An adaptive, open-label, dose-finding, phase 1/2 study investigating the safety, PK, and clinical activity of PRN1008 in patients with relapsed or refractory ITP has been initiated (NCT03395210). The 12 week study has an intrapatient dose escalation design with 12 weeks of active therapy and 12 weeks of follow-up.
Results: Preclinically, treatment with PRN1008 *in vitro* profoundly inhibited B cell activation and blocked antibody-mediated activation of immune cells via Fc receptor signaling. *In vivo*, PRN1008 demonstrated a significant dose-dependent reduction of platelet-loss in an anti-CD41 induced mouse model of immune thrombocytopenia, and robust anti-inflammatory effects in an antibody driven rat arthus model. In human blood, PRN1008 treatment *ex vivo* did not interfere with platelet aggregation in healthy subjects or in ITP patients. In humans, PRN1008 has been well tolerated to date, without safety signals of thrombocytopenia, bleeding or bruising. Reductions in anti-desmoglein 3 levels within 4 weeks were seen in 10/15 (67%) of pemphigus vulgaris patients with elevated pre-treatment levels, on a background of 0-30 mg of prednisone or equivalent corticosteroid. By 12 weeks the mean reduction in both anti-desmoglein 3 and 1 antibodies was approximately 50%. The Phase 1/2 immune thrombocytopenia study builds on these data with a design that can rapidly identify doses that can safely raise platelet counts.
Summary/Conclusion: Preclinical and clinical data suggest that PRN1008 will reduce platelet destruction in ITP via inhibition of autoantibody/Fc-gamma receptor signaling in splenic macrophages, and also reduce autoantibody generation, to diminish platelet loss in ITP. Initial clinical studies have not identified lowered platelet counts, bleeding or bruising as safety signals. A Phase 1/2 clinical study has been initiated to explore efficacy and safety in immune thrombocytopenia at several dose levels.

PS1407

ATRA CORRECTS IMPAIRED MACROPHAGE FUNCTION IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA THROUGH A20/NLRP3 SIGNALING PATHWAY

Y. He[1,2,3,*], J. Xue[1,2,3], X. Liu[1,2,3], X.-L. Zhu[1,2,3], J.-M. Zhang[1,2,3], C.-C. Wang[1,2,3], Q.-M. Wang[1,2,3], Y.-N. Wang[1,2,3], Q. Chen[1,2,3], H.-X. Fu[1,2,3], L.-P. Xu[1,2,3], K.-Y. Liu[1,2,3], X.-J. Huang[1,2,3], X.-H. Zhang[1,2,3]

[1]Peking University Institute of Hematology, Peking University People's Hospital, [2]Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, [3]Collaborative Innovation Center of Hematology, Peking University, Beijing, China

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by increased platelet destruction and impaired platelet production. Mesenchymal stem cells (MSCs) in ITP patients displayed enhanced senescence and apoptosis. We previously found a pathological reduction in TNFAIP3 (Tumor necrosis factor alpha-induced protein 3, A20) levels, which induced NF-κB/SMAD7 pathway activation, causing a deficiency in MSCs in ITP patients (He Y 2018). MSCs promote the balance of macrophage polarization (M1/M2) toward the M2 phenotype. Our previous clinical study finds that all-trans retinoic acid (ATRA) is safe and effective in achieving a rapid and long-lasting response in ITP (Feng FE 2017). However, there is no information available on the role of macrophage polarization in megakaryocyte maturation and platelet production in ITP patients to date.
Aims: The aim of the present study was to explore the role of macrophage polarization in megakaryocyte maturation and platelet production and explore whether ATRA has a role in macrophage polarization.
Methods: Immunofluorescence pathology analysis of the M1 (CD68 and iNOS) and M2 (CD163 and CD206) polarization of macrophages in the bone marrow (BM) of the ITP patient, and the liver, spleen and BM of murine model of ITP. Bone marrow derived MSCs, macrophage and CD34+ cells were isolated and expanded. Cell proliferation and apoptosis of MSCs were assessed. The cytokines of MSCs were detected by ELISA. Macrophages were treated with either IFN-ɣ or IL-4, and M1 and M2 activation was analyzed by flow cytometry. Western blot and RT-PCR was employed for the expression of A20, NF-kB and NLRP3 at the mRNA and protein level in the ITP macrophage. MSCs were cocultured with macrophages, and macrophages were cocultured with CD34+ cells. We compared the influence of the ITP macrophage to megakaryocytopoiesis by estimating the relative percentages of megakaryocytes and platelets using flow cytometry. Megakaryocyte ploidy and pro-platelet forming (PPF) cells were also analyzed.
Results: Immunofluorescence pathology showed an aberrantly higher M1/M2 polarization ratio both in ITP patients and mouse model. ITP macrophages showed the enhanced phagocytic activity of platelets. There was a significantly decreased expression in A20 and activated NF-κB/NLRP3 in the macrophages of ITP patients. MSCs from ITP patients showed enhanced senescence and apoptosis, as well as a higher expression of TNF-α. MSCs of ITP facilitate higher M1 polarization through secreting TNF-α compared with HC-MSCs. To assess the influence of ITP macrophages to megakaryocytopoiesis, co-cultures systems were performed. We found that when CD34+ cells were cocultured with ITP macrophage, the relative pre-platelet and platelet count were significantly lower in the ITP-macrophage group than the HC-macrophage group. The treatment of ATRA could inhibit the activated NF-κB/NLRP3 signaling in the ITP-macrophage and redress the abnormal A20/NF-κB/NLRP3 signaling pathway. ATRA modulated macrophages towards the M2-like phenotype and improved the megakaryocytopoiesis in ITP.
Summary/Conclusion: The abnormal A20/NLRP3 signaling pathway in the macrophages of ITP contribute to a higher M1/M2 polarization, which impaired the megakaryocyte maturation, PPF and platelet production in ITP patients. ATRA modulated macrophages toward the M2-like phenotype and improved the megakaryocytopoiesis in ITP.

RH-TPO RESTORES MEGAKARYOCYTES AND BONE MARROW NICHE COMPONENTS IN THE TREATMENT OF SEVERE THROMBOCYTOPENIA IN PATIENTS WITH CIRRHOSIS ASSOCIATED WITH HEPATITIS B

W.-Y. Zhai[1,*], X. Liu[1], Q.-S. Huang[1], Q. Jiang[1], H. Jiang[1], J. Lu[1], H. Wang[2], Y.-D. Xie[2], H. Ma[2], L.-P. Xu[1], K.-Y. Liu[1], X.-J. Huang[1], X.-H. Zhang[1]

[1]Peking University Institute of Hematology, [2]Institute of Hepatic Diseases, Peking University People's Hospital, Beijing, China

Background: Hepatitis B virus is a widespread virus that severely affects people's health. People infected with hepatitis B virus may develop liver cirrhosis. Thrombocytopenia is commonly seen in patients with liver cirrhosis. Thrombocytopenia plays a key role in thrombin generation and possibly bleeding tendencies in patients who have cirrhosis. However, its pathogenesis is considered to be complicated and still remains poorly understood. Rh-TPO can promote megakaryocyte development and platelet production, regarding an elevation in platelet counts both *in vitro* and *in vivo*. Its effect of elevating platelet counts has been proven in ITP patients, post-transplantation patients and aplastic anemia patients, while there is still no information available for its effect in cirrhotic patients with concomitant thrombocytopenia.
Aims: The aim of the study is to explore the effectiveness and mechanism of action of rh-TPO in the treatment of severe thrombocytopenia in patients with cirrhosis associated with hepatitis B.
Methods: This was multi-center research conducted in the People's Republic of China between January 2005 and December 2017. Patients with HBV-related liver cirrhosis (HBV LC) accompanied with severe thrombocytopenia (defined as a platelet count of <30 000 per cubic millimeter) were enrolled and divided into 2 groups by the occurrence of splenomegaly. Each patient received nucleoside analog (NA) alone treatment, or NA plus prednisone or NA plus rh-TPO treatment. Platelet counts, serum TPO levels, immature platelet fraction(IPF), reticulated platelets, glycocalicin, bone marrow biopsy, occurrence of bleeding events and adverse events were evaluated before and after treatment. Samples provided by healthy donors were also investigated.
Results: Patients with HBV LC associated severe thrombocytopenia had significantly lower serum TPO levels, higher IPF, higher reticulated platelets and higher glycocalicin compared to healthy donors. The platelet counts of HBV LC patients with splenomegaly were lower than those without

splenomegaly. A decrease in the number of megakaryocytes accompanied by impaired differentiation and maturation, a decrease in the number of CD34+ hematopoietic stem cells (HSCs) and a decrease in the number of mesenchymal stem cells along with abnormal senescence and apoptosis could be observed in the bone marrow of HBV LC patients. M1 polarization could also be observed in both the bone marrow and spleen of HBV LC patients. After rh-TPO treatment, a decrease in IPF and reticulated platelets could be observed in patients, while there was no significant change in glycocalicin. Compared with bone marrow samples before treatment, the number of megakaryocytes was elevated, along with a promotion of their differentiation and maturation. The number of CD34+ HSCs and MSCs was also increased. The abnormally activated M1 polarization was corrected after treatment. A significant elevation in platelet counts could be observed in patients who received NA plus prednisone and patients who received NA plus rh-TPO, along with fewer bleeding events compared to the patients who received NA alone. Patients without splenomegaly had a better reaction to treatment than those with splenomegaly.
Summary/Conclusion: Treatment with rh-TPO could restore megakaryocytes and bone marrow niche components, thus elevating the platelet counts and reducing the risk of bleeding events in HBV LC with severe thrombocytopenia, especially in patients without splenomegaly.

PS1409

A HIGH-THROUGHPUT SCREENING ASSAY TO EVALUATE CHEMOTHERAPY-INDUCED MYELOSUPPRESSION USING HEALTHY PERIPHERAL BLOOD AND BONE MARROW

K.K. Javarappa[1,*], D. Tsallos[1], C. Heckman[1]

[1]Institute for Molecular Medicine, Finland (FIMM), University of Helsinki, Helsinki, Finland

Background: Myelosuppression is a major side effect of chemotherapy and can result in infections, bleeding complications, increased risk of morbidity and mortality, and also limit the drug dose and frequency of administration contributing to poorer outcomes. It is therefore essential to understand the effects of novel chemotherapies on healthy hematopoiesis to avoid drug-induced myelosuppression. High throughput flow cytometry (HTFC) technologies and methods to detect rare hematopoietic cell populations are critical in advancing our understanding of how different blood cell types in complex biological samples respond to chemotherapeutic drugs.
Aims: The aim of this study was to develop an easily implementable HTFC assay that can monitor the cytotoxic effects of multiple chemotherapeutic drugs in a wide concentration range on megakaryocytes and myeloid progenitors in healthy human peripheral blood (PB) and bone marrow (BM).
Methods: Megakaryocytes and other myeloid progenitor cells are rare in PB and can be difficult to detect. However, culturing the SPCs in supplemented serum free medium induced the expansion of megakaryocytes and myeloid cells after 8-10 days. Using the 9-color panel, we were able to detect immature megakaryocytes (CD41a+CD42b-), mature megakaryocytes (CD41a+CD42b+), classical monocytes (CD14+CD16-), intermediate monocytes (CD14+CD16+) and non-classical monocytes (CD14-CD16+). By using antibodies for CD3, CD19 and CD56 labelled with fluorophores in the same colour channel, we were able to remove other cell types that were not of interest. With the addition of drugs, we were able to identify chemotherapies that inhibited expnsion of the different stages of megakaryocytes and myeloid cell populations, and the concentration range where the cells were most affected.
Results: Megakaryocytes and other myeloid progenitor cells are rare in PB and can be difficult to detect. However, culturing the SPCs in supplemented serum free medium induced the expansion of megakaryocytes and myeloid cells after 8-10 days. Using the 8-color panel, we were able to detect immature megakaryocytes (CD41+CD42b-), mature megakaryocytes (CD41a+CD42b+), classical monocytes (CD14+CD16-), intermediate monocytes (CD14+CD16+) and non-classical monocytes (CD14-CD16+). By using antibodies for CD3, CD19 and CD56 labelled with fluorophores in the same colour channel, we were able to remove other cell types that were not of interest. With the addition of drugs, we were able to identify chemotherapies that inhibited expansion of the different stages of megakaryocytes and myeloid cell populations, and the concentration range where the cells were most affected.
Summary/Conclusion: We developed a high throughput assay based on a multicolor flow cytometry panel that allows for simultaneous detection of different stages of megakaryocytes and myeloid progenitor cell populations in healthy peripheral blood and bone marrow. Applying the assay to a HTFC platform provides a sensitive, reproducible and rapid tool for screening hundreds of chemotherapeutic drugs and understanding the cytotoxic effects on rare cell types. The assay may be a more appealing method to evaluate the myelosuppressive potential of novel drugs and drug combinations compared to traditional lower throughput, time consuming and labor-intensive methods.

PS1410

A NOVEL ACQUIRED RUNX1 VARIANT IS RESPONSIBLE FOR ANKRD26 DYSREGULATION AND THROMBOCYTOPENIA IN SPORADIC FORM OF MYELODYSPLASTIC SYNDROME

S. Ferrari[1], D. Ragazzo[2], A. Lombardi[1], E. Omenetto[1], C. Scaroni[2], G. Semenzato[3], F. Vianello[3,*], F. Fabris[1]

[1]Medicine, Chair of Medicine, [2]Medicine, Endocrinology Unit, [3]Medicine, Haematology and Clinical Immunology, Padova, Italy

Background: RUNX1 and ANKRD26 dysregulation has been shown to play a role in familial thrombocytopenia with predisposition to acute leukaemia. Whether the same mechanism may contribute to thrombocytopenia of patients with myelodysplastic syndromes (MDS) is unknown.
Aims: We aim to evaluate the genetic status of ANKRD26 and related hematopoietic transcription factors like *RUNX1* and *ETV6* in subjects with MDS, in the presence or absence of thrombocytopenia.
Methods: 31 MDS subjects have been considered for the study. 18 of them had thrombocytopenia. 7 subjects with inherited thrombocytopenia were enrolled as a control. *ETV6*, *RUNX1*, *ANKRD26* gene were investigated. Functional studies were performed in the megakaryoblastic cell line MEG-01. Gene and protein expression were evaluated by mRNA with ddPCR system analysis and WT. The impact of the RUNX1 variant was evaluated by site-specific mutagenesis of the vector containing the wild type (wt) human *RUNX1* coding sequence (hRUNX-wt-pCMV6), inserted in the pCMV6-AC-Myc-DDK plasmid vector. To evaluate whether the variant found may modulate *RUNX1* expression itself at mRNA and protein level, MEG-01 were transfected with hRUNX-wt-pCMV6 or hRUNX-mut-pCMV6 expression vectors. To investigate the effects on transcriptional activity of *RUNX1* new variant, MEG-01 cells were transfected with ANKRD26-pGL3-basic reporter vector, which contains the luciferase sequence under control of the 5'UTR of the ANKRD26 gene. Dominant negative effect of mutant RUNX1 on wild type RUNX1 was studied by transfection of MEG-01 cells with different amounts of wild type and mutant RUNX1. Finally, the effect of RUNX1 mutant on platelet factor-4 expression has been also evaluated.

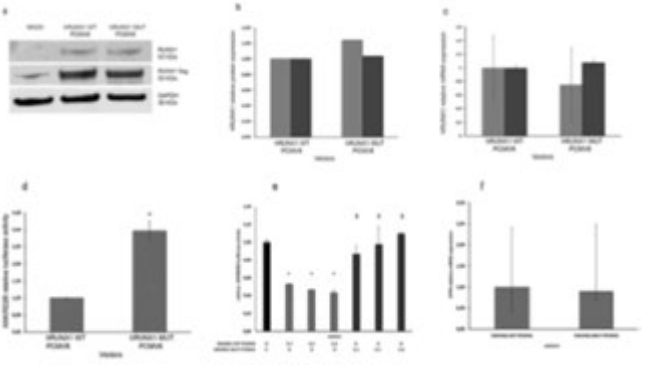

Figure 1.

Results: None of MDS and control subjects showed alterations in the *ETV6* gene or in the *ANKRD26* gene. Four patients among MDS subjects with thrombocytopenia showed previously undescribed *RUNX1* variants, namely p.Pro76Arg, p.Trp79Gly, c.934_935delA, c.1214_1215insTG and none of them was found in databases. We did not find *RUNX1* known mutations in MDS patients with normal platelet count. Not unexpectedly, all 4 patients with *RUNX1* variants progressed to AML. Expression studies showed that the variant p.Pro76Arg in *RUNX1* gene does not significantly affect the expression of *RUNX1* protein (Figure 1a,b) or the expression of MEG-01 total *RUNX1* mRNA (Figure 1c). As shown in Figure 1d, hRUNX-mut-pCMV6 vector, compared to hRUNX-wt-pCMV6, significantly increased *ANKRD26* luciferase activity, and this was achieved in a dose-dependent manner, suggesting that *RUNX1* variant p.Pro76Arg decreases the ability of *RUNX1* to bind DNA responsive elements, leading to increase transcriptional activity of *ANKRD26*.
Co-transfection of MEG-01 cells with different amounts of hRUNX-wt-

pCMV6 in presence of increasing quantities of hRUNX-mut-pCMV6 plasmid showed no dominant negative effect of mutant-RUNX1 on wt-RUNX (Figure 1e). As RUNX1 has been shown to affect PF4 expression in previous studies, we sought to evaluate if this was also the case for the mutant studied. However, we did not observe an effect of RUNX1 haplodeficiency on platelet PF4 expression (Figure 1f).
Summary/Conclusion: Our data are consistent with RUNX1 haploinsufficiency in subjects with thrombocytopenia in the context of MDS. The novel described *RUNX1* variant dysregulates *ANKRD26* by inducing its persistent expression. Whether and how *ANKRD26* dysregulation may play a role in the prognosis of these patients and in the identification of novel therapeutic targets in subjects with MDS would reserve future studies.

PS1411

FACTORS AFFECTING THROMBOPOIETIN RECEPTOR AGONIST REINITIATION AFTER DISCONTINUATION IN WELL-CONTROLLED PATIENTS WITH IMMUNE THROMBOCYTOPENIA IN THE UK: RESULTS FROM A MODIFIED DELPHI CONSENSUS PANEL

N. Cooper[1,*], Q. Hill[2], J. Grainger[3], J.-P. Westwood[4], C. Bradbury[5], D. Provan[6], J. Thachil[7], N. Ramscar[8], A. Roy[9]

[1]Hammersmith Hospital, London, [2]The Leeds Teaching Hospital, Leeds, [3]Royal Manchester Children's Hospital, Manchester, [4]University College Hospital London, London, [5]University of Bristol, Bristol, [6]Barts and the London School of Medicine, London, [7]Central Manchester University Hospital, Manchester, [8]Novartis UK, London, United Kingdom, [9]Novartis Pharmaceuticals, East Hanover, United States

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder resulting in reduced platelet production and increased platelet destruction. Peer-reviewed literature indicates that in a real-world setting, prescribers are sometimes able to obtain prolonged responses in ITP using thrombopoietin receptor agonists (TPO-RAs), allowing for a 'drug holiday', with monitoring to reinitiate therapy when platelet levels fall below a threshold. However, a clear treatment framework for tapering and discontinuation is lacking. Currently it is also not possible to predict with confidence which patients with ITP will sustain their responses after going off therapy, and the subsequent length of the response. It is thus unclear which patients could be suitable candidates for TPO-RA tapering.
Aims: To develop guiding principles on determining optimal TPO-RA treatment regimens, treatment duration, criteria for discontinuation, and the approach to reintroducing treatment in relapsing patients with ITP.
Methods: Drawing on real-world experience from leading experts involved in treating patients with ITP, a consensus meeting was organized using a modified Delphi panel approach. Experts participated in a structured technology-based platform that captured individual uninfluenced opinion, followed by a panel debate and discussion in which consensus was sought. Discussion topics included criteria for tapering and discontinuation of TPO-RAs and criteria for reinitiating treatment in patients who relapse. Elsewhere we describe the outcome of the panel's discussion on the criteria for tapering and discontinuation; here we focus on the criteria for reinitiation of treatment. Prescribers with experience of using this TPO-RA discontinuation-reinitiation approach were asked to estimate the duration of discontinuation in their last 3 patients.
Results: Seven ITP experts participated in the June 2017 consensus meeting. The experts agreed that tapering and discontinuation of TPO-RAs at the point where the patient feels better and is deemed clinically improved is a rational approach. Experts reported that, in their last 3 patients, the average duration of TPO-RA discontinuation was 2–3 months, with the highest reported estimate being 4–5 years. They also reported that where therapy had to be reinstated, a decrease in platelet counts was the reason to reinstate therapy, with presence of symptoms such as clinically significant bleeding being the second most common reason. In the case of such adverse patient outcomes, the physician, in conjunction with the patient, should re-evaluate tapering and revert back to the previous TPO-RA dose. In certain patients with a high risk of life-threatening bleeding, or where effective rapid rescue therapy is unavailable, tapering and discontinuation of TPO-RAs may not be suitable.
Summary/Conclusion: A decrease in platelets is the primary driver of reinstating treatment with TPO-RAs. This suggests that physicians do not wait for symptoms before reinstating therapy and illustrates the importance of continued monitoring of lab values. In general, patients prefer treatments that they can use intermittently or even discontinue. Thus, there is a need for stronger evidence around how best to achieve sustained remission with a more real-world-aligned patient behavior.

PS1412

IMMATURE PLATELET FRACTION (IPF): AN INTERESTING TOOL TO INVESTIGATE THROMBOCYTOPENIA

Z. Van De Wyngaert[1,*], E. Fournier[2,3], V. Soenen[2], J. Gauthier[1], C. Preudhomme[2], T. Boyer[2]

[1]Maladies du Sang, CHU Lille, [2]Laboratoire d'hématologie, Centre de Biologie Pathologie, CHU Lille, Lille, [3]Laboratoire d'hématologie, CH de Dunkerque, Dunkerque, France

Background: Immature platelet fraction (IPF) is a parameter available on new generation hemocytometers. Reticulated, or immature platelets, are measured by fluorescence, and reflect bone marrow capacity to produce platelets. However, reference range on newest hemocytometers, as well as applicability of this parameter in daily practice, are not well defined so far.
Aims: We aimed at evaluating how IPF can be used in management and diagnosis of a thrombocytopenia of unknown origin.
Methods: Measurements were done on a Sysmex XN hemocytometer. First, we established reference range in normal subjects with normal complete blood counts. We then measured IPF values among patients with thrombocytopenia who underwent bone marrow aspiration.
Our objectives were to establish a cut-off value to distinguish peripheral from central causes of thrombocytopenia. We chose to exclude myelodysplastic syndromes because of the multiple mechanisms of thrombocytopenia in these patients.
Results: We analyzed 307 adult subjects, recruited inside our university hospital. Median IPF% was 3.8% [IQ 2.8 – 4.975] and min-max [0.7 – 8]. 73 patients underwent bone marrow aspiration. Median age was 59, IQR[45 – 75], 48% of patients were males. Thrombocytopenia was the only anomaly in 21 patients (29%), or associated with anemia (n=31, 42%), macrocytosis (n=3, 4%), neutropenia (n=2, 3%), or pancytopenia (n=16, 22%). Thrombocytopenia was peripheral (PT) in 49 patients (67%) and central (CT) in 24 (33%). Mean platelet count was similar in both groups (40 *vs.* 41 G/l respectively). In the PT group, mechanisms for thrombocytopenia were platelet consumption (n=23, 32%), immunological destruction (n=23, 32%) or hypersplenism (n=3, 4%). In the CT group, diagnosis were aplastic anemia (n=3, 4%), drug toxicity or malnutrition (n=10, 14%), severe sepsis in intensive care unit (n=7, 10%), absence of bone marrow recovery after stem cell transplantation (n=2, 3%).
Median IPF was 6% [3 – 8] in CT and 15% [10 – 21] in PT. Using a ROC curve, a cut-off value of IPF ≥13% predicts peripheral thrombocytopenia; specificity and predictive positive values (PPV) are 100%, sensitivity is 59% and predictive negative value is 55%.
Summary/Conclusion: An IPF% value ≥13% predicts a peripheral mechanism for thrombocytopenia (PPV = 100%). In our series of patients, bone marrow aspirations could have been avoided in 40% of cases.

PS1413

INTERLEUKIN-1 RECEPTOR ANTAGONIST GENE POLYMORPHISM IN EGYPTIAN CHILDREN AND ADOLESCENTS WITH IMMUNE THROMBOCYTOPENIA: ASSOCIATION WITH DISEASE SUSCEPTIBILITY, RESPONSE TO THERAPY AND OUTCOME

M.M. Al-Tawil[1,*], T.M. Kamal[2], S.M. Abd El-Ghany[1], O.M. Borham[1]

[1]Pediatric Hematology / Oncology, [2]Genetics, Children hospital, ain shams university, Cairo, Egypt

Background: Immune thrombocytopenia (ITP) is one of the most common hematologic disorders with poorly predictable clinical course and outcome. Scanty studies showed possible association between interleukin-1 receptor antagonist (IL-1Ra) gene polymorphism and susceptibility to ITP. No similar studies were done on Egyptian children. Moreover, no studies linked IL-1Ra gene polymorphism to disease severity or outcome
Aims: To study the distribution of IL-1Ra gene polymorphism (introns 2) among Egyptian children and adolescents with ITP and among healthy controls. Also, to correlate IL-1Ra gene polymorphism to disease severity, response to treatment modalities and outcome
Methods: This is a prospective case control study that included 60 Egyptian children and adolescents from unrelated families, diagnosed with ITP (37 females and 23 males; aged 1-17 years with mean of 9.2± 4.5 years). Patients included 22 subjects with acute ITP (disease duration less than 3 months), 7 patients with persistent ITP (disease duration 3-12 months) and 31 patients with chronic ITP (disease duration more than 1 year). The study also included 50 age and sex Egyptian matched healthy controls. subjects and controls were analyzed for IL-1Ra allele and genotype distribution using VNTR polymorphism of IL-1 receptor antagonist (IL-1Ra) intron-2. All patients were followed up for a minimum of one year to study disease outcome and

response to therapy in association with IL-1Ra genotypes and gene alleles. Bleeding everity was assessed with skin, mucosae, organs, grading (SMOG) score

Results: The frequencies of the polymorphic allele (A2) as well as genotype A1A2 were significantly higher in cases of ITP compared to controls (p value =0.0007, 0.0002; respectively). Allele A2 conferred 3.1 times increased relative risk for disease development. Also, allele A2 as well as genotype A1A2 were significantly more frequent among remitted cases (p value= 0.028, 0.029; respectively), but there was no significant difference between different genotypes and alleles regarding bleeding score(p values> 0.05). Patients with polymorphic allele A2 showed significantly better response to steroids than those with homozygous wild allele A1 (p 0.028), with insignificant difference in IVIG response (p0.44)

Summary/Conclusion: IL-1Ra polymorphism might contribute to the susceptibility to ITP in Egyptian children. The presence of A2 polymorphic allele of IL-1Ra gene was found to have better disease outcome and response to steroids than those with homozygous wild alleles

PS1414

CLINICAL CHARACTERISTICS AND TREATMENT COURSES FOR CYTOMEGALOVIRUS-ASSOCIATED THROMBOCYTOPENIA IN IMMUNOCOMPETENT CHILDREN AFTER NEONATAL PERIOD

Y.J. Shim[1,*], J.K. Suh[2], J. Y. Kim[3], J.M. Lee[4], E. J. Yang[5]

[1]Pediatrics, Keimyung University School of Medicine and Dongsan Medical Center, Daegu, [2]Pediatrics, Gachon University Gil Medical Center, Incheon, [3]Pediatrics, Kyungpook National University Hospital, [4]Pediatrics, College of Medicine, Yeungnam University, Daegu, [5]Pediatrics, Pusan National University Children's Hospital, Busan, Korea, Republic Of

Background: Cytomegalovirus (CMV) causes severe diseases in premature infants and immunocompromised hosts, and antiviral therapy is often required for disease control. However, the clinical manifestations and treatment courses for CMV-associated thrombocytopenia in immunocompetent children are unclear.

Aims: We reviewed the clinical characteristics and treatment courses for CMV-associated thrombocytopenia in immunocompetent children by conducting a multicenter retrospective study.

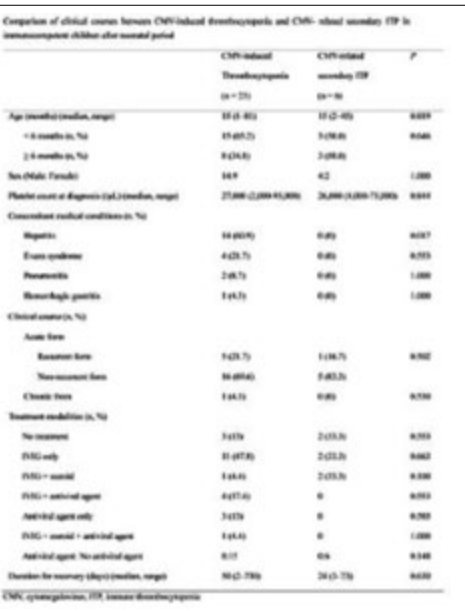
Methods: Children > 1 month and < 15 years of age with thrombocytopenia and positive CMV polymerase chain reaction (PCR) being treated at 3 tertiary medical centers in Daegu from January 2000 to March 2017 were included. Medical records of patients from all three institutes were retrospectively reviewed. This study targeted the previously healthy and immunocompetent children. Patients with primary immunodeficiency, leukemia, inherited bone marrow failure syndrome, or acquired immune deficiency syndrome were excluded from the final analysis. Additionally, patients suffering from non-CMV infections were also excluded.

CMV infection was defined as the detection of virus by quantitative or qualitative PCR in the blood or urine samples, performed on the day of detection of thrombocytopenia. CMV-induced thrombocytopenia caused by direct infection of megakaryocytes by CMV was defined as the state in which the patients showed CMV-positive PCR and CMV infection-like symptoms (fever, elevated transaminases, jaundice, hepatomegaly, splenomegaly, pneumonitis, gastritis, or myalgia) at the time of thrombocytopenia diagnosis. While, CMV-related secondary ITP caused by immunologic reactions after recent CMV infection was defined as the state in which the patients displayed CMV-like symptoms a few weeks before the diagnosis of thrombocytopenia. Altogether, in the present study, both of them referred to as CMV-associated thrombocytopenia.

Results: Among 1,065 children with thrombocytopenia, 29 (2.7%) displayed CMV-associated thrombocytopenia. The median age at diagnosis was 15 months and the median platelet count was 26,000/μL. They were classified into the CMV-induced thrombocytopenia (23/29) and CMV-related secondary immune thrombocytopenia (ITP, 6/29) groups. Fourteen subjects had hepatic dysfunction, four had Evans syndrome, two had pneumonitis, and one had gastritis. IVIG was used for 21 patients, and six patients among them showed recurrence, for whom IVIG or antiviral therapy was used. All, except one, recurrent or chronic cases belonged to the CMV-induced thrombocytopenia group. Antiviral therapy was used more frequently for the CMV-induced thrombocytopenia group (8/23, 34.8%) than for the CMV-related secondary ITP group (0/6); however, the results were not statistically significant (p=0.148) (Table 1).

Summary/Conclusion: CMV is a rare but unique etiology of thrombocytopenia, and observed even in healthy children after the neonatal period. About one-third patients need antiviral therapy for disease control. Further, CMV-induced thrombocytopenia is more complex than CMV-related secondary ITP.

Table 1.



PS1415

RAISED EXPRESSION OF APRIL IN THE PLATELET WITH IMMUNE THROMBOCYTOPENIA AND ITS CLINICAL IMPLICATIONS

Y. Hao[1,*], S. Wang[2], H. Li[2], R. Yang[2], Z. Zhou[3]

[1]Second Affiliated Hospital of Kunming Medical University, [2]Institute of Hematology, Chinese Academy of Medical Sciences, Tianjin, [3]Second Affiliated Hospital of Kunming Medical University, Kunming, China

Background: Immune thrombocytopaenia (ITP) is an antibodymediated autoimmune disease characterized by accelerated platelet destruction and suboptimal platelet production. A proliferation-inducing ligand (APRIL or TNFSF13), a member of TNF superfamily, structurally and functionally related to B cell activation factor of the TNF family (BAFF,TNFSF13b), has been shown to regulate lymphocyte survival and activation through interaction with its receptors transmembrane activator and calcium-modulating cyclophilin ligand interactor (TACI) and B cell maturation antigen (BCMA). APRIL is secreted as a soluble factor by various cells including inactive B cells, T cells, monocytes, neutrophils, macrophages, and dendritic cells, as well as by epithelial cells, osteoclasts, and megakaryocytes. APRIL has also been reported to be released by activated platelets. Recent studies have suggested an important role for APRIL, not only in normal immune responses, but also in the establishment and/or maintenance of autoimmune and inflammatory diseases. Patients with ITP has increased plasma levels of APRIL, however, the correlation between the enhanced expression of APRIL in platelets and the clinical relevance in the ITP patients is still unknown. The enhanced expression of APRIL in platelets may suggest a potential involvement of APRIL in the ITP autoimmune disorder.

Aims: To investigate the correlation between the expression of APRIL platelet levels and clinical indicators with ITP patients, and the relationship between different drug therapy and the expression of ITP platelet levels.

Methods: 1. Peripheral blood was collected from ITP patients and healthy controls with EDTA-anticoagulated vacuum tubes. Platelet-rich-plasma (PRP) was separated by centrifugation of the blood for 10 minutes at 800rpm. The PRP was then centrifuged again at 1700 g for 10 min at 20 °C to separate plasma from the platelets.

2. Flow cytometry and real time quantitative PCR were used for detecting the level of APRIL from platelets of healthy controls and ITP patients.

3. The relationship between APRIL levels and the disease severity of ITP and the platelets count and the effect of glucocorticoid treatment were analyzed.

Results: 1. The APRIL levels in the platelets from newly diagnosed ITP patients were significantly higher than those from healthy controls(p=0.00) and CITP patients (p=0.01).,while there was no significant difference between CITP patients and healthy controls. 2. Compared to healthy controls, the mRNA expression of APRIL was increased in ITP patients (p=0.04). 3. The level of APRIL in the platelets was slightly correlated with platelet count (p=0.05) and also directly correlated with the positive serum platelet-specific antibody. 4. After the treatment of conventional immuno-

suppressive drugs (glucocorticoids, GC) such as dexamethasone and prednisolone to the ITP patients, the level of APRIL was higher in NR patients than complete response (CR) patients(p=0.01),however, there was no statistics difference between CR patients and PR patients or partial response (PR) patients and no response (NR) patients Figure 1).

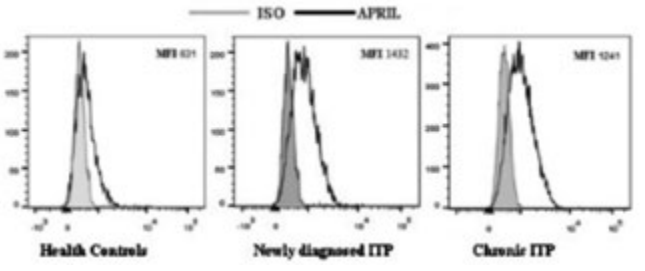


Figure 1.

Summary/Conclusion: Immune thrombocytopenia platelets showed increased levels of APRIL and the increased was associated with low platelet count, and APRIL might play a pathogenic role in the development of this disease.

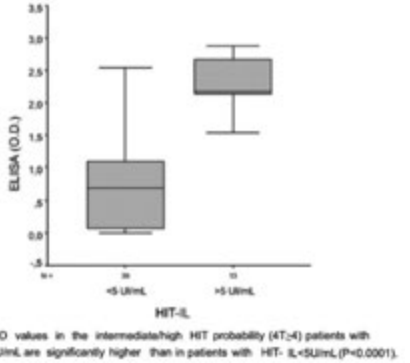
PS1416

EVALUATION OF HIT SYNDROME WITH AN AUTOMATED IMMUNOASSAY IN CORRELATION WITH THE 4T SCORE IN CARDIOVASCULAR PATIENTS

E. Iliopoulou[1], G. Soufla[1], S. Georgantis[1], T. Kanellopoulou[1,*], M. Katafygioti[1], T. Kostelidou[1]

[1]Department of Haematology, Blood Transfusion Unit and Coagulation and Haemostasis, Onassis Cardiac Surgery Center, Athens, Greece

Background: Heparin-induced thrombocytopenia (HIT), a serious complication of heparin therapy results in heparin/platelet-factor4 complexes (antiPF4/H antibodies-Abs). Upon clinical suspicion, laboratory evaluation for HIT syndrome should be performed.
Aims: To evaluate the reliability of a rapid, automated assay for HIT diagnosis along with the "4Ts" before cardiac surgery.
Methods: We analysed clinical and laboratory characteristics of 118 patients for HIT syndrome presence. Clinical suspicion was determined by "4T score" (≤3 low, ≥ 4intermediate/high probability). Patients were screened for HIT Abs with both HemosIL HIT-$Ab_{(PF4-H)}$ (HIT-IL) and ELISA-IgG (EIA). A HIT-IL value ≥1.0 U/mL was considered positive. We considered EIA (Asserachrom Stago) OD<1.0 as negative, OD 1.0-2.0 as intermediate and OD>2.0 as strongly positive for HIT-Abs presence. Functional test was performed with heparin-induced platelet aggregation test (HIPA) in selected cases to confirm a positive result.
Results: Both HIT-IL and EIA results were statistically associated (p<0.001), as well as with the "4T score" (p<0.001). In the intermediate/high probability group, 77% with a positive HIT-IL>5U/mL had an EIA OD>2.0 (p<0.0001); a positive HIT-IL between 1.8-5U/mL was correlated with 50% probability of an EIA OD>2.0, whereas HIT-IL 1.0-1.8U/mL yielded an EIA OD<1.0. Overall, in the same group, HIT-IL had a 50% positive and 84% negative predictive value of HIT-Abs presence. Interestingly in thirty patients with 4T score 3, HIT-IL had a 100% negative and 59% positive predictive value and HIT-IL>5U/mL was correlated with an EIA OD>2.0 (p=0.018) (Figure 1).



ELISA OD values in the intermediate/high HIT probability (4T≥4) patients with HIT-IL>5UI/mL are significantly higher than in patients with HIT- IL<5UI/mL (P<0.0001).

Figure 1.

Summary/Conclusion: The use of a rapid automated assay for HIT diagnosis overrides time consuming and expensive tests. Our results confirmed a strong association of HIT-IL>5U/mL with 4T≥4 and EIA OD>2.0 indicating its value in assessing strong probability of HIT. Further including patients with 4T score 3, a HIT-IL>5U/mL is still correlated with EIA OD>2.0 confirming our previous observation. HIT-IL<5U/mL should in any case be evaluated with EIA and HIPA.

PS1417

IMMATURE PLATELET FRACTION AS A MARKER OF THROMBOPOIESIS IN THROMBOCYTOPENIC PATIENTS

M. Farrugia[1], A. Gatt[1], D. J. Camilleri[1,*]

[1]Pathology Department, Mater Dei Hospital, Tal-Qroqq, Malta

Background: Thrombocytopenia manifests from a myriad of diseases most of which are secondary to peripheral platelet destruction or due to bone marrow (BM) failure. Distinguishing between the two is of utmost importance particularly for clinical management and treatment decisions. A novel parameter, the Immature Platelet Fraction (IPF), measures young reticulated platelets and is comparable to reticulocytes in erythropoiesis.
Aims: To explore the value of IPF in the diagnostic workup of immune thrombocytopenic purpura (ITP) patients, and to investigate the usefulness of IPF in the clinical management of haemato-oncology patients on chemotherapy.
Methods: Cohort A consisted of 20 patients diagnosed with refractory ITP, 6 newly diagnosed ITPs and 14 follow up cases. Cohort B comprised of 20 haemato-oncology patients undergoing chemotherapy. Twenty healthy controls were included in the study. Samples were consecutively selected with different age groups. Platelet count was measured by the fluorescent platelet channel (PLT–F) on XN-20 analyser (Sysmex, Kobe, Japan) and included an IPF–% and absolute count (IPF–A). Paired sample t-test was performed to study statistical significance at p-value<0.05 between cohorts, both for IPF–A and IPF–%.
Results: The mean platelet count (PLT-F) for cohort A and B was 30 and $25x10^9$/L respectively, and $304x10^9$/L for controls. A significant increase was observed in Cohort A when compared to Cohort B for both IPF–A and IPF–% (p=0.0009 and p = < 0.00001 respectively). ITP cohort A showed a higher IPF–% then Controls (p<0.00001) but lower IPF–A (p=0.00478). Three patients from the ITP cohort had a very low IPF–A (<$1.0×10^9$/L). BM studies were available for 2 of these patients in which megakaryocytes were normal to increased in number with atypical forms. When compared to controls, the haemato-oncology cohort B had very low IPF–A, but similar IPF–% (p=< 0.00001 and 0.8249 respectively) (Figure 1).

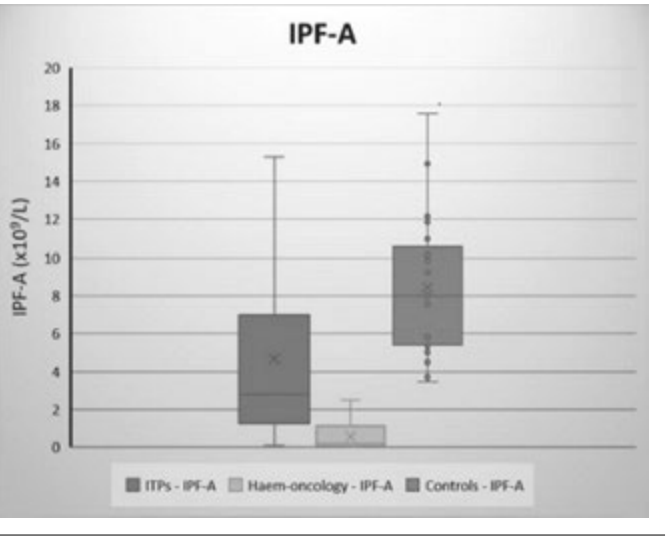


Figure 1.

Summary/Conclusion: Autoimmune idiopathic thrombocytopenic purpura (aITP) manifests in low platelet counts through increased peripheral platelet consumption, explaining the higher IPF–A/IPF–% counts when compared to patients on chemotherapy. This results from increased demand and supply of young platelets from the bone marrow. Correct distinction is of utmost importance for clinical and therapeutic decisions. However, this study possibly identified 3 ITP patients with abnormal thrombopoiesis (ITP with very

low IPF–A) possibly indicating defective platelet production due to possible dysmegakaryopoiesis. When the ITP cohort was compared to controls, IPF–A was lower for ITP, suggesting a platelet feedback loop mechanism that is different from that seen in reticulocytes. This can be related to an insignificant increase in thrombopoietin levels seen in ITP. These patients may in fact benefit mostly from thrombopoietin analogues. Since a rise in immature platelets can predict platelet recovery, the absolute count IPF–A could be useful in the clinical management of patients receiving chemotherapy. IPF–A can be useful to limit the number of platelet transfusions thereby minimizing adverse platelet reactions. Further research could establish a cut–off value for the optimum platelet recovery to administer chemotherapy and/or platelet transfusions. This study identifies a novel biomarker of BM status and activity.

PS1418

A DECREASED PLATELET-TO-LYMPHOCYTE RATIO IS ASSOCIATED WITH A LOW PLATELETCRIT IN PRE-DIABETES

B. Nkambule[1,*], Z. Mkandla[1], T. Mutize[1]

[1]Laboratory Medicine and Medical Science, University of Kwazulu-Natal, Durban, South Africa

Background: People living with type 2 diabetes are at an increased risk of cardiovascular disease. Chronic immune activation and elevated levels of circulating platelets exacerbate the inflammatory milieu in diabetic patients. Platelets play a crucial role that links inflammation with thrombosis. Different indices of platelet function indicate increased platelet activation and sequestration in diabetic individuals. The platelet-to-lymphocyte ratio (PLR) and platelet-to-neutrophil ratio (PNR) have been reported as reliable markers of systemic inflammation.
Aims: To evaluate the platelet-to-lymphocyte (PLR), platelet-to-neutrophil ratio (PNR) and plateletcrit (PCT) in prediabetes using an animal model of prediabetes.
Methods: Seventeen (n=17) male C57BL/6 mice were randomised into two separate diet groups; 10 kcal% fat control diet group (diet code: D12450J) (n=4) and a 60 kcal% fat diet group (diet code: D12492) (n=13). After 3 weeks of feeding, oral glucose tolerance testing was performed to determine the glucose metabolism status of the animals. Two hundred microliters (200µl) of blood was then collected from the lateral tail vein into 3.2% sodium citrate coated tubes. Platelet indices (mean platelet volume; platelet count); absolute lymphocyte count and neutrophil count were measured using the AcT hematology analyser. The plateletcrit, platelet-to-lymphocyte and platelet-to-neutrophil ratio were also calculated
Results: The control and pre-diabetic group showed no sign of thrombocytopenia or leukopenia as the lymphocyte and neutrophil counts were comparable between the two groups (p>0.05). However the PCT was decreased in pre-diabetic mice, mean PCT% 3.75±0.35 vs. 4.99±0.8375. The pre-diabetic had a decreased PLR; 983.4±100.02 vs.1589±393.8 control group, p=0.04. In the pre-diabetic group, decreased PLR levels correlated with; PCT% (r=0.57, p=0.03) and PNR (r=0.613,p=0.02) Furthermore, the PNR was also decreased in pre-diabetic mice, 97.20±7.41 vs. 140.1±24.45 control group, p=0.03.
Summary/Conclusion: In pre-diabetes the PCT is decreased and these decreased levels directly correlate with the decreased PLR. Moreover, pre-diabetics have a low PNR which is associated with a low PLR. These findings may suggest that in pre-diabetic individuals platelet indices are affected and these may suggest increased platelet adhesion and localised inflammation

PS1419

CHANGES IN PLATELET AGGREGATION DURING PREGNANCY AND THE IMMEDIATE POSTPARTUM PERIOD

B. Hussein[1,*], A. Maarouf[1], K. Gomez[2], J. Davies[2], D. Obeng-Tuudah[2], R. Kadir[2]

[1]Haematology Department, Nanakali Hospital for Blood Disease and Oncology, Erbil, Iraq, [2]Haemophilia Center and Thrombosis Unit, Royal Free Hospital, London, United Kingdom

Background: Platelet dysfunction is implicated in uteroplacental disorders. During the early stages of gestation platelets have important roles in the process of placentation. Platelet function contributes to enhanced haemostasis at delivery. However, there is limited data on the changes of platelet function during normal pregnancy. Understanding physiological changes of platelet aggregation during different stages of pregnancy is helpful for better understanding of pathophysiology of abnormal placentation.
Aims: To assess platelet aggregation during three trimesters of pregnancy and immediate postnatal period in normal healthy women compared to control non-pregnant group.
Methods: Cross-sectional cohort study including a total of 46 women: 10 participants for each trimester, 10 postnatal cases and 6 control non-pregnant women. Case selection was based on specific inclusion criteria. 30mL of venous blood was obtained from each participant following consent. Light transmission aggregometry was performed with Dual channel Payton 600B aggregometer using six platelet aggregating agonist (epinephrine, adenosine triphosphate, collagen, ristocetin, arachidonic acid and U46619).
Results: The findings included reduced secondary aggregation curve appearance in pregnant and postnatal women when compared to control group, which was most apparent in the third trimester. Compared to non-pregnant controls, platelet aggregation induced by ADP and collagen were reduced during third trimester while epinephrine-induced aggregation was reduced during the first trimester.
Summary/Conclusion: Reduced platelet reactivity in response to epinephrine during early pregnancy can be considered as a mechanism to reduce thrombosis and allow normal placentation while diminished ADP and collagen induced aggregation in third trimester could be a compensatory mechanism since pregnancy associated with hyper-coagulation particularly in late stages.

PS1420

CHANGING PROFILE OF PLATELET ACTIVITY AND TURNOVER INDICES DURING TREATMENT RESPONSE OF IMMUNE THROMBOCYTOPENIA: PREDICATIVE VALUE OF REPONSE BY GLYCOCALICIN AND SOLUBLE CD40 LIGAND

H. Chang[1,*], P.-L. Li[1], Y.-S. Hung[1], T.-C. Tang[1], C.-W. Ou[1], P.-N. Wang[1]

[1]Hematology, Chang Gung Memorial Hospital, Kweishan, Taoyuan, Taiwan, Republic of China

Background: Immune thrombocytopenia (ITP) is characterized by relatively active platelet function and rapid platelet turnover. Platelet-related plasma markers may be useful in distinguishing ITP from other etiologies of thrombocytopenia. Measurable plasma markers include platelet activity markers (e.g. soluble P-selectin [sP-selectin] and soluble CD40 ligand [sCD40L]) and platelet turnover markers (e.g. glycocalicin [GC]). It has been reported that some of these plasma markers change with treatment response of ITP. It is unclear whether changes of these plasma markers may be predicative of treatment response in patients with ITP.
Aims: We intended to determine changes of activity (sP-selectin, sCD40L) and turnover (GC) markers in various phases of ITP.
Methods: Patients with ITP were classified by their platelet counts in response to treatment, which included no response (NR, including new diagnosis), partial response (PR) and complete response (CR) according to previously defined criteria. Plasma markers of platelet activity (sP-selectin and sCD40L), and platelet turnover (GC) were measured by ELISA. Platelet counts and mean platelet volume (MPV) were obtained in the clinical laboratory using GenS System-2. Plasma markers in ITP subjects were compared with patients with myelodysplastic syndrome and among different phases of ITP. For patients with paired samples collected in different periods, levels of plasma markers were compared (NR *vs.* PR and PR *vs.* CR) in a paired analysis.
Results: One hundred and sixteen samples (29 CR, 32 PR, 55 NR) from 79 patients were collected for this study. Compared to myelodysplastic syndrome and acute myeloid leukemia with comparable platelet counts, ITP patients had significantly different plasma levels of sP-selectin (p=0.026). There is no difference in sCD40L, MPV, GC and GC index. Patients with increased platelet counts (PR+CR) had higher levels of sP-selectin (p=0.026) and sCD40L (p=0.001) than those with new diagnosis or NR. There was no significant difference in platelet turnover markers MPV (p=0.077) or GC (p=0.078). However, there was a marked decrease of GC index (p<0.001) in patients with PR and CR, compared to the NR group. Thirteen patients had paired samples in NR and PR. Analysis showed no difference in sP-selectin, sCD40L, MPV or GC but significant difference in GC index (p=0.017) (Figure 1A). Another 12 patients had paired samples in PR and CR. Analysis showed no difference in sP-selectin, sCD40L, MPV or GC but significant difference in GC index (p=0.029) (Figure 1B). To explore the role of biomarkers in predicting treatment response, patients with low platelet counts (NR) were divided into refractory disease and new diagnosis disease which later responded to treatment. Significant difference was found in GC (p=0.020) and sCD40L (p=0.001). Such results suggested plasma levels of sCD40L and GC may in potential predict treatment response in patients with ITP.
Summary/Conclusion: Patients with ITP have a different platelet activity profile from myelodysplastic syndrome, as characterized by plasma sP-selectin levels. Platelet activity markers (sP-selectin and sCD40L) and GC indices change in parallel with treatment response. Plasma levels of GC and

sCD40L are different between new diagnosis of and refractory ITP patients. Such findings suggest plasma GC and sCD40L not only change with treatment but also predict likelihood of treatment response.

PS1421

THE IMPACT OF HIGH MOBILITY GROUP BOX 1 IN THE PATHOGENESIS OF IMMUNE THROMBOCYTOPENIA

E. G. Umit[1], M. Baysal[1,*], H. Goze[1], V. Asoglu[1], A.C. Ozdover[1], O. Kirkizlar[1], M. Demir[1]

[1]Hematology, Trakya University Faculty of Medicine, Edirne, Turkey

Background: High-mobility group box 1 (HMGB1) was originally defined as a ubiquitious nuclear protein regulating chromatin structure and gene transcription. Later, new roles for a cytosolic component as inflammasome activation and autophagy were discovered. Extracellular HMGB1 was demonstrated to be related with cell signalling for certain receptors such as Toll-like receptors (TLR) which may contribute to the pathogenesis of inflammatory disorders.
Aims: The aim of our study is to evaluate the value of HMGB1 and integrate the pre-clinical knowledge regarding HMGB1 and their related receptors of TLR into the clinical knowledge of immune thrombocytopenia (ITP) to derive future therapeutic options.
Methods: Newly diagnosed and treatment naive 50 ITP patients and 30 healthy age and sex matched controls were enrolled in the study. Clinical and demographic features were recorded and whole blood counts and HMGB1 levels with ELISA method were determined.
Results: Within patients group, 34 were female (68,0%) while 16 were male (32,0%); and in control group 17 were female (56,7%) and 13 were male (43,3%). In the patient group, mean age was 53,56 years, mean values of platelet count 20,772/mm^3 MPV 10,7 fL, hemoglobin 12,1 g/dL, leucocyte 9721/mm^3 and HMGB1 was 15.093,4 ng/mL. In the control group, mean age was 53,23 years, mean values of platelet count 251.900/mm^3, MPV 8,8 fL, hemoglobin 12,9 g/dL, leucocyte 7820/mm^3 and HMGB1 was 5.606,06 ng/mL. Age was not related with HMGB1 levels in both groups. Platelet levels were significantly related with HMGB1, especially in the very low and treatment needing group of platelet <30.000/mm^3 showed the highest levels of HMGB1 (p levels <0,005). Likewise, MPV, as a surrogate for increased platelet turnover fort he pathogenesis of platelet destruction in ITP was significantly related with HMGB1 levels (p<0,005). In the control group, though not proven with logistical analysis, low normal platelet counts showed relatively higher HMGB1 levels.
Summary/Conclusion: The role of extracellular HMGB1 was demonstrated as being as a proinflammatory cytokine, secreted by activated macrophages as a late mediator of inflammation (1). The absence of HGMB1 resulted with increased vulnerability to macrophage conducted innate immunity and lack of autophagy (2). As a damage associated molecular pattern (DAMP) molecule, HMGB1 should be regarded as an inflammatory and non-inflammatory molecule and a possible therapeutic target (3). HMGB1 stimulates the release of tumor necrosis factor (TNF) alpha and other inflammatory cytokines in macrophages and has two important binding sites for TLRs and receptor for advanced glycation end products (RAGE). In our study we observed an increase in HMGB1 levels in patients with ITP, related with platelet counts which may be explained with an immune response that cannot be detected with IL-6 related acute phase proteins such as C reactive protein. Levels of HMGB1 during remission and their impact on treatment responses and relapses should be studied further with large prospective studies. Likewise, patients with ITP who reach normal platelet counts may be followed up with HMGB1 levels for relapse prediction and other thrombocytopenias which have increased destruction as their pathogenesis may be investigated for HMGB1 levels for disease and prognosis predictions.

PS1422

WHAT ARE THE UNDERLYING CAUSES AND CLINICAL CHARACTERISTICS OF CHILDREN WITH REACTIVE THROMBOCYTOSIS AT A KOREAN TERTIARY MEDICAL CENTER?

Y. J. Shim[1,*], E.J. Yang[2], N. Jung[1]

[1]Pediatrics, Keimyung University School of Medicine and Dongsan Medical Center, Daegu, [2]Pediatrics, Pusan National University Children's Hospital, Busan, Korea, Republic Of

Background: Reactive thrombocytosis (RT) is a common condition among children, although no studies have examined the etiology or clinical characteristics of RT among Korean children.
Aims: The present retrospective study aimed to determine the etiology and clinical characteristics of RT among children who were admitted to a single Korean center during a 10-year period.
Methods: This retrospective study collected data from <18-year-old children with a platelet count of >500×10^9/L who were admitted to pediatric wards in the Keimyung University Dongsan Medical Center between January 2006 to December 2016. The study protocol was approved by the institutional review board of Keimyung University Dongsan Medical Center (2017-11-038).
Cases of RT were classified as mild (grade 1, platelet count of 501–700×10^9/L), moderate (grade 2, platelet count of 701–900×10^9/L), severe (grade 3, platelet count of 901–1,000×10^9/L), and extreme (grade 4, platelet count of >1,000×10^9/L).
Analysis of variance with Bonferroni adjustment was used to compare the mean values between the groups, and intra-group comparisons of proportions were performed using the linear by linear chi-square statistic. Pearson's correlation analysis was performed to define the correlations between the variables. All statistical analyses were performed using IBM SPSS software (version 23.0; IBM Corp., Armonk, NY), and *P*-values of <0.05 were considered statistically significant.

Table 1. Comparing the variables according to the severity of reactive thrombocytosis.

	Mild (N = 3,400)	Moderate (N = 580)	Severe (N = 46)	Extreme (N = 87)	*P*
Age (years)	1.3 (1.2–1.4)	1.0 (0.8–1.2)	0.9 (0.4–1.3)	1.2 (0.7–1.7)	0.013
Sex (male : female)	1,466 : 1,934	247 : 333	25 : 21	42 : 45	0.348
WBC (×10^9/L)	12.4 (12.2–12.6)	13.6 (13.1–14.1)	14.6 (12.9–16.2)	16.2 (14.3–18.1)	< 0.001
Hb (g/dL)	11.2 (11.1–11.2)	10.9 (10.8–11.0)	10.6 (10.0–11.0)	10.7 (10.3–11.1)	< 0.001
AST (IU/L)	48 (45–51)	44 (41–47)	40 (33–47)	52 (39–66)	0.707
ALT (IU/L)	39 (36–42)	39 (35–43)	35 (25–46)	44 (29–60)	0.950
ESR (mm/h)	25 (24–26)	30 (27–33)	33 (21–44)	38 (29–46)	< 0.001
CRP (mg/dL)	1.5 (1.4–1.5)	1.6 (1.3–1.8)	1.2 (0.5–2.0)	2.2 (1.3–3.1)	0.054
LDH (IU/L)	655 (626–684)	690 (608–774)	654 (520–787)	764 (544–983)	0.540
Admission duration (days)	6.2 (6.0–6.4)	7.1 (6.6–7.5)	8.7 (6.3–11.1)	14.4 (10.6–18.2)	< 0.001

The values are presented as mean values and 95% confidence intervals.
WBC, white blood cells; Hb, hemoglobin; AST, aspartate transaminase; ALT, alanine transaminase; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein; LDH, lactate dehydrogenase.

Results: During the study period, RT accounted for 13.5% of children who were admitted to the pediatric wards (4,113/30,355). The median age of children with RT was 0.3 years, and the proportion of children who were <1-year-old was 71.0%. Among the 4,133 children, 82.7% of cases involved mild RT, 14.1% of cases involved moderate RT, 1.1% of cases involved severe RT, and 2.1% of cases involved extreme RT. The underlying causes of RT were as follows: infection (78.1%), Kawasaki disease (KD) (6.0%), tissue damage (3.7%), neurologic disease (2.8%), allergy (1.9%), perinatal disease (1.8%), hemato-oncologic disease (1.5%), non-KD autoimmune inflammation (1.3%), and others (2.9%). Significant differences according to RT severity were detected for hemoglobin (Hb) levels, white blood cell (WBC) count, erythrocyte sedimentation rate (ESR), and admission duration (Table 1). After controlling for patient age, disease category, liver function, C-reactive protein levels, and lactate dehydrogenase levels, there was a negative correlation between platelet count and hemoglobin level (r = –0.251, p=0.008). And there were positive correlations between platelet count and white blood cell count (r = 0.305, p=0.001), between platelet count and erythrocyte sedimentation rate (r = 0.252, p=0.007), and between platelet count and admission duration (r = 0.257, p=0.006).
The proportion of KD was highest in the extreme RT subgroup (p<0.001) and in the 1–7.9-year-old group (p<0.001). Non-KD autoimmune inflam-

mation (Henoch–Schönlein purpura, juvenile idiopathic arthritis, and inflammatory bowel diseases) was only observed in mild/moderate RT cases, and its proportion was highest in the 8–18-year-old group (p<0.001).
Summary/Conclusion: The most common cause of RT among Korean children was infection, and extreme RT was associated with prolonged admission. KD was prevalent in the extreme RT and 1–7.9-year-old groups. Non-KD autoimmune inflammation was prevalent in the mild/moderate RT and ≥8-year-old groups.

PS1423

EFFECT OF PERAMIVIR ON PLATELET COUNTS IN PATIENTS WITH SUSPECTED OR CONFIRMED INFLUENZA INFECTION

S.-Y. Ko[1,*]

[1]*Laboratory Medicine, Korea University Hospital, Seoul, Korea, Republic Of*

Background: Several cases and one retrospective study have been reported of an increase of platelet counts in patients with suspected influenza after oseltamivir treatment.
Aims: The purpose of this study was to assess the effect of peramivir, an intravenous neuraminidase inhibitor which was approved by FDA in 2014, on platelet counts for the first time.
Methods: We retrospectively analyzed consecutive patients who were treated with peramivir or were tested for influenza from January 2015 to December 2017 in a tertiary hospital. Patients were divided into three groups: patients with peramivir treatment and proven influenza (group 1), with peramivir treatment but without influenza (group 2), and without peramivir treatment and proven influenza which was redefined as those with oseltamivir treatment and proven influenza (group 3), since most of the influenza-proven patients without peramivir treatment were treated with oseltamivir. Platelet counts were collected from three intervals: day (-30)-(-10) (baseline), day 0, and day 5-15 (after treatment). Day 0 was the day of peramivir injection or the first day of oseltamivir treatment.
Results: A total of 1,763 patients were treated with peramivir and 3,796 were tested positive for influenza. The number of patients in each group were 1,542, 221, and 2,162, and the number of patients whose platelet counts were available from all three intervals were 347, 93, and 88 for group 1, 2, and 3, respectively. Intragroup analysis revealed significant decrease in platelet counts from baseline to day 0 in all groups. After treatment, platelet counts of group 1 and group 2 recovered to those of the baseline while of platelet count of group 3 got significantly higher (Table 1)

Table 1.

Platelet counts	Baseline (day (-30)-(-10))	Day 0	After treatment (day 5-15)	P-value between baseline and day 0	P-value between baseline and after treatment
Group 1	261.6k	204.7k	266.8k	<0.0001	0.3606
Group 2	253.4k	214.2k	252.2k	0.0034	0.8411
Group 3	249.2k	197.4k	279.5k	<0.0001	0.0106

Summary/Conclusion: The increase of platelet counts after treatment that exceeds that of the baseline was observed only in patient group treated with oseltamivir but not in those with peramivir. The exact reason for this different finding between the two neuraminidase inhibitors on platelet counts needs further investigation.

PS1424

STUDIES ON PLATELET FUNCTION IN A GROUP OF CLL PATIENTS DURING THE FIRST YEAR OF IBRUTINIB TREATMENT

B. Sokołowska[1,*], D. Jawniak[1], A. Nowaczyńska[1], A. Szymczyk[1], E. Wąsik - Szczepanek[1], E. Drab - Urbanek[1], W. Tomczak[1], J. Kozińska[1], M. Kozioł[1], M. Hus[1]

[1]*Department of Haematooncology and Bone Marrow Transplantation, Medical University of Lublin, Lublin, Poland*

Background: Ibrutinib, an inhibitor of Bruton's tyrosine kinase (BTK) has a significant activity in chronic lymphocytic leukemia (CLL). Although the treatment is well tolerated, some clinical studies reported mucocutaneous bleeding complications occurring during the first months of the treatment. Such complications may be caused by platelet or vessel abnormalities.
Aims: The aim of the study was to evaluate platelet function before and during the first year of ibrutinib therapy.
Methods: We examined 16 patients with CLL (6 females and 10 males, mean age 66 (49-82). All patients started with 420 mg Ibrutinib but then in one patient the dose was reduced to 140 because of atrial fibrillation. In all group of patients platelet aggregation studies were performed in whole blood samples using Multiplate technology, in which platelets were activated by adenosine diphosphate (ADPtest), arachidonic acid (ASPItest), collagen (COLtest), TRAP-6 (TRAPtest). Platelet function was evaluated four times: before Ibrutinib treatment, after 1month, after 2 – 4 months and after one year of the therapy. Control group (CG) consisted of 20 healthy persons: six males and 14 females, mean age 44 (26-59).
Results: Statistically significant impaired platelet function in a group of patients in all the tests and in all the points was detected compared to the control group p=0.001-0.05. Exacerbation of platelet defects in the course of the treatment measured by COLtest was observed. COLtest was diminished after 12 months compared to the value before the treatment [COLtest 1: M: 33U(6-70); COLtest 4 M: 11U(0-22). In the remaining three tests a very interesting tendency occurred. The value of the fourth point was raised indicating some improvement in ADP, arachidonic acid and TRAP induced platelet aggregation[ADPtest1: M:27U(0-58), ADPtest4: M :34U(3-84), ASPItest 1:M:45U(21-101), ASPItest4:M:56U(2-123), TRAPtest1:M: 56U(28-95), TRATtest4:M:86U(15-140).This tendency was the most pronounced in TRAPtest but not statistically significant.Bleeding complications in five patients occurring during the first three to six months of ibrutinib therapy were observed (in two patients: nose bleeding, in three patients: skin petechiae). Lower platelet count (75-85G/l) was detected in three out of five patients just before Ibrutinib therapy. Platelet count in the group of patients without bleeding complications was as follows: before ibrutinib therapy: M:141G/l (106-204) and after one year M:166.5G/l (126-209). Whereas, in the group of patients with bleeding complications was as follows: before therapy: M:85G/l(52-171) and after one-year treatment: M:132G/l(87-188).
Summary/Conclusion: We detected impaired platelet aggregation measured by Multiplate technology in all the patients. The impairment of collagen induced platelet aggregation was exacerbated during ibrutinib treatment. On the other hand, ADP, arachidonic acid and TRAP induced platelet aggregation tended to improve during the treatment. Only 31% of ibrutinib patients presented some mild bleeding complications at the beginning of the treatment.

PS1425

VALIDATION OF THE PLASMIC SCORE FOR THROMBOTIC MICROANGIOPATIES IN A SINGLE UNVERSITY HOSPITAL

M.D.C. Ballester[1,*], B. Lopez[1], J.M. Sanchez[1], G. Aspas[1], A. Perez[1], M.G. Uriol[2], S. Cabello[2], A. Sampol[1]

[1]*Hematology Deparment,* [2]*Nephrology Department, Hospital Universitario Son Espases, Palma de Mallorca, Spain*

Background: Dr.Pavan and collegues have developed a new score "the PLASMIC score" to stratify patients with thrombotic microangiopathies (TMA) according to the risk of having severe ADAMTS 13 deficiency.This will allow us to know the probability the patient has to present a Thrombotyc Thrombocytopenic Purpura (TTP) before counting on the result of ADAMTS 13 and thus facilitate therapeutic decisions.
Aims: To validate the PLASMIC score in a single center cohort.
Methods: We have collected retrospectively all consecutive 44 patients (including adults and children) presenting to one large academic center in Palma de Mallorca, SPAIN, with TMA between Jan 2010 to Feb 2018.We have collected the data proposed in the score of all patients from the date of diagnosis of the TMA. We have used contingency tables in the SPSS software v.18 to calculate the association between a high score result and the probability of having a TTP. We also calculated the sensitivity, specificity, positive and negative predictive value of the score.
Results: Our validation cohort includes previously diagnosed patients, 11 for Hemolytic uremic syndrome (SHU), 20 for atypical Hemolytic uremic syndrom (SHUa), 6 for TTP and 7 for Transplant related TMA. For the PTT group, the score identified 5 of them with high probability of presenting severe deficit of ADAMTS 13, classifying the other one of intermediate risk, with a diagnostic sensitivity of 83%. Likewise, the score identified 4 patients, 3 of them SHUA and 1 MAT-AT with a high risk of developing ADATMS 13 deficiency, these results being false positive. The specificity of the test was 89%, the positive predictive value 55% and the negative predictive value 97% (Figure 1).
Summary/Conclusion: "The plasmic" score is a very useful tool for the

early detection of patients with PTT in those centers that do not have a result of ADAMTS 13 quickly available. The score along with clinical judgment would help medical teams make quick therapeutic decisions.
Our results confirm the external validation of this score.

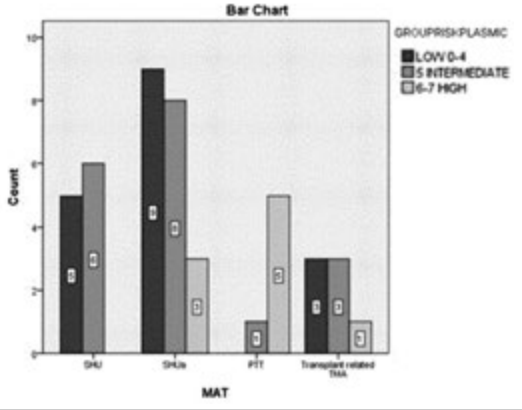

Figure 1.

PS1426

OCCURRENCE AND MANAGEMENT OF HEPATOBILIARY ADVERSE EVENTS (AES) IN ADULTS WITH IMMUNE THROMBOCYTOPENIA (ITP) DURING LONG-TERM TREATMENT WITH ELTROMBOPAG: RESULTS FROM THE EXTEND STUDY

A. Khelif[1,*], M.N. Saleh[2], R.S. Wong[3], O. Meyer[4], O. Ocak Arikan[5], J. Maier[5], J. B. Bussel[6]

[1]Hôpital Farhat Hached, Sousse, Tunisia, [2]Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, United States, [3]Sir YK Pao Centre for Cancer & Department of Medicine and Therapeutics, Chinese University of Hong Kong, Shatin, NT, Hong Kong, [4]Institute of Transfusion Medicine, Charité-Universitätsmedizin Berlin, Berlin, Germany, [5]Novartis Pharma AG, Basel, Switzerland, [6]Pediatric Hematology/Oncology, Weill Cornell Medicine, New York, United States

Background: ITP is an autoimmune disorder of reduced production and accelerated destruction of platelets. Eltrombopag (EPAG), an oral thrombopoietin receptor agonist metabolized and eliminated by the liver, is approved for previously treated chronic ITP patients (pts) aged ≥1 yr. In randomized trials of ≤6-months' duration, liver test abnormalities were recorded in 11% (EPAG) and 7% (placebo) of pts. EXTEND (Wong *et al. Blood* 2017;130:2527–2536) was an open-label, long-term extension study of ITP pts who participated in prior EPAG studies.
Aims: Describe hepatobiliary AE (HAE) occurrence and management during EXTEND.
Methods: In EXTEND, pts started EPAG at 50 mg/day, with dose titrated as appropriate to achieve platelet counts of ≥50–200x10^9/L. This analysis describes HAEs during EXTEND; HAEs with missing assessments were deemed drug-related.
Results: 302 pts received ≥1 EPAG dose: 67% female; 17% ≥65 yrs old (median, 50). Median exposure duration was 2.4 yrs (range, 2 days–8.8 yrs) and mean daily dose was 50.2 mg/day (SD, 21.6).
Forty-five pts (15%; Table 1 i) experienced 177 HAEs, and 34/45 had >1 HAE; 111/177 (63%) HAEs were considered drug-related. Most HAEs resolved (n=171, 97%) and required no change in dose (n=143, 81%); 17 (10%) led to treatment withdrawal in 7/302 pts (2%), 10 (6%) required dose interruption, and two (1%) dose reduction. Most HAEs were of mild severity (Grade 1, n=115 [65%]; Grade 2, n=44 [25%]; Grade 3, n=18 [10%]), with 17 (10%) considered serious AEs (none fatal). Most HAEs occurred within the first yr; median (range) time to first HAE in the 45 pts was 155 (7–1576) days. Increased alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were the most common HAEs: 25 pts had 41 AEs of increased ALT, and 23 pts had 41 AEs of increased AST (Table ii). Of 25 pts with AEs of increased ALT, 21 also had increased AST. Almost all AEs of increased ALT and AST resolved; most required no change in EPAG dose and few led to EPAG withdrawal (Table 1 ii). Seventeen pts had 22 AEs of increased blood bilirubin (Grade 1, n=15 [68%]; Grade 2, n=5 [23%]; Grade 3, n=2 [9%]), of which 95% (n=21) resolved. Most required no change in EPAG dose (n=14, 64%); four pts (18%) discontinued EPAG because of increased blood bilirubin, with increased ALT and AST also listed as concomitant causes for 3/4 pts. Twelve pts had 39 AEs of hyperbilirubinemia (Grade 1, n=28 [72%]; Grade 2, n=9 [23%]; Grade 3, n=2 [5%]); all resolved and only one (3%) led to EPAG withdrawal. Nine pts experienced ALT and/or AST >3x upper limit of normal (ULN) and total bilirubin >1.5xULN. HAEs of elevated alkaline phosphatase (n=18) were recorded in 10 pts; most resolved without a change in dose (n=16, 89%), and only one (6%) led to EPAG withdrawal (also attributed to increased ALT, AST, and bilirubin).
Summary/Conclusion: HAEs during long-term (up to 8.8 yrs) treatment of ITP pts with EPAG in EXTEND were observed in <1/6 pts, and were usually mild and transient, resolving without change in EPAG dose in ~4/5 cases. Only 2% (7/302) of pts discontinued EPAG because of HAEs. Assessment of drug-induced HAEs in this analysis is complicated by pts' various confounding factors (eg comorbidities). In line with the product label, our findings support measurement of serum ALT, AST, and bilirubin prior to initiating and during treatment with EPAG to effectively manage potential HAEs; if abnormalities arise, further liver tests should be performed and levels monitored weekly until resolved or stabilized, with dose modifications (if required) performed as appropriate.

Table 1.

Proportion of patients with a hepatobiliary adverse event during EXTEND (i) occurrence and outcomes from adverse events of increased ALT and AST (ii)

i

	Eltrombopag (N=302)	
Preferred term*	All	Drug related
Any hepatobiliary event, n (%)	45 (15)	33 (11)
ALT increased	25 (8)	16 (5)
AST increased	23 (8)	15 (5)
Blood bilirubin increased	17 (6)	12 (4)
Hyperbilirubinemia	12 (4)	9 (3)
Blood alkaline phosphatase increased	10 (3)	5 (2)
Transaminases increased	4 (1)	3 (<1)
Hepatic enzyme increased	3 (<1)	1 (<1)
Hepatic function abnormal	3 (<1)	3 (<1)
Bilirubin conjugated increased	2 (<1)	2 (<1)
Urine bilirubin increased	1 (<1)	1 (<1)
Gallbladder pain	1 (<1)	0
Abdominal discomfort	1 (<1)	1 (<1)
Abdominal pain	1 (<1)	0

*Hepatobiliary events were coded using MedDRA v18.0
Hepatobiliary events leading to withdrawal: increased ALT, n=5; increased AST, n=3; blood bilirubin increased, n=4; hyperbilirubinemia, alkaline phosphatase increased, transaminase increased, hepatic enzyme increased, bilirubin conjugated increased (all n=1)

BENEFIT OF EARLY TREATMENT WITH BLINATUMOMAB: LONG-TERM SURVIVAL OUTCOMES FOR ADULT PATIENTS WITH RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA RECEIVING FIRST VS SUBSEQUENT SALVAGE THERAPY

F. Severin[1,*], T. Delea[2], J. Amdahl[2], M. Hagiwara[2], D. Boyko[2], L. Sabatelli[1], S. Gonzalez-McQuire[1], Z. Cong[3]

[1]Amgen (Europe) GmbH, Zug, Switzerland, [2]Policy Analysis Inc. (PAI), Brookline, MA, [3]Amgen Inc, Thousand Oaks, CA, United States

Background: In the randomized, phase 3 TOWER trial, blinatumomab significantly improved overall survival (OS) and delayed time to clinically meaningful health-related quality of life (HRQoL) deterioration compared with standard of care (SOC) chemotherapy in adult patients with Philadelphia negative (Ph–) relapsed/refractory (R/R) B-precursor acute lymphoblastic leukemia (ALL).
Aims: To estimate long-term survival outcomes in adult patients with Ph– R/R B-precursor ALL receiving blinatumomab, and to quantify the value of treating patients with blinatumomab as first salvage (early treatment) versus subsequent salvage therapy (late treatment).
Methods: A partitioned survival model with a lifetime (50-year) time horizon was used to estimate expected life-years (LYs) and quality-adjusted LYs (QALYs) gained for blinatumomab versus SOC in subgroups of patients receiving early versus late treatment, a pre-specified 2:1 stratification factor in TOWER (blinatumomab: N = 107 early and N = 164 late; SOC: N = 54 early and N = 80 late). Model health states were defined based on response to treatment, relapse and survival. OS and event-free survival (EFS) among responders were estimated by fitting parametric survival distributions to failure-time data from TOWER (23-month maximum follow-up), with distributions selected based on visual and statistical fit (Bayesian information criterion), and plausibility of long-term projections against historical data. Based on these methods a restricted Gompertz model was selected to model OS and a restricted generalized gamma model was selected to model EFS among responders. Utility values for model health states were estimated by mapping from EORTC QLQ-C30 questionnaire data collected in TOWER to the EQ-5D, using a published response mapping algorithm and United Kingdom (UK) tariffs, then analyzed using generalized linear model regression. HRQoL for patients surviving for 4 years was assumed to be similar to that of the general population of the UK.
Results: Utility values for the same health states were higher for blinatumomab than for SOC, and for early versus late treatment. Projected OS probabilities at 5 years were 22.4% versus 10.3% for blinatumomab versus SOC in patients receiving early treatment, and 13.2% versus 7.5% in those receiving late treatment. In patients receiving early treatment, blinatumomab was projected to more than double expected LYs and QALYs over the model time horizon compared with SOC (4.21 LYs and 3.36 QALYs gained, Table 1); the projected gains in LYs and QALYs with blinatumomab in patients receiving late treatment were smaller (2.35 LYs and 1.88 QALYs gained, Table 1).

Table 1.

Expected LYs and QALYs blinatumomab vs SOC in subgroups of patients receiving early vs late treatment

	Early treatment	Late treatment
LYs		
Blinatumomab	8.41	5.79
SOC	4.20	3.44
Incremental benefit	*4.21*	*2.35*
(% compared with SOC)	*(100.2%)*	*(68.3%)*
QALYs		
Blinatumomab	6.48	4.43
SOC	3.12	2.55
Incremental benefit	*3.36*	*1.88*
(% compared with SOC)	*(107.7%)*	*(73.7%)*

LY, life-year; QALY, quality-adjusted life-year; SOC, standard of care.

Summary/Conclusion: Use of blinatumomab in Ph– R/R B-precursor ALL is projected to result in substantial gains in LYs and QALYs, with a greater projected benefit in patients treated at first salvage versus subsequent salvage therapy. These results suggest that blinatumomab should be used as early as possible in the treatment pathway for patients with Ph– R/R B-precursor ALL.

PS1428

HEALTH-RELATED QUALITY OF LIFE AND RATES OF EMERGENCY ROOM VISITS AND HOSPITALIZATION IN PATIENTS WITH AL AMYLOIDOSIS: A PROSPECTIVE ANALYSIS

K. L. McCausland[1], T. Quock[2,*], S. Guthrie[3], M. K. White[1], M. Bayliss[1]

[1]Optum, Johnston, [2]Prothena Biosciences Inc, South San Francisco, [3]Biopharma Strategic Consulting, LLC, San Francisco, United States

Background: Light-chain (AL) amyloidosis is a rare, progressive and typically fatal disease in which misfolded light chains are deposited in tissues and organs, which may lead to organ failure, disability, and death. Health-related quality of life (HRQoL) has been shown to be a significant prognostic factor associated with clinical outcomes such as survival and response to treatment. A better understanding of how HRQoL may be prospectively associated with costly healthcare resource utilization outcomes is warranted.
Aims: To examine whether health-related quality of life (HRQoL) is prospectively associated with rates of emergency room (ER) visits and hospital admissions, independent of other patient characteristics, during 12 months of observation.
Methods: A diverse sample of patients (n=224) with AL amyloidosis from the United States, Europe, and other countries participated in a non-interventional, longitudinal online study at three time-points (initial, 6-month, and 12-months). Negative binomial regression models, adjusted for potential demographic and disease characteristic confounders, were used to examine the association between initial HRQoL scores (the physical and mental component [PCS, MCS] summary scores of the SF-36v2® Health Survey) and the cumulative number of each HCRU outcome (ER visits and hospital admissions). Incident rate ratios (IRR) were interpreted in terms of 5 point decrements in HRQoL scores.
Results: A five-point lower PCS score, indicating decreased physical function, was associated with a 44% higher rate of ER visits ($p<0.001$) and a 36% higher rate of hospital admissions ($p<0.001$). A five-point lower MCS score was associated with a 27% greater rate of ER visits ($p<0.001$) and a 31% greater rate of hospitalizations ($p<0.001$).
Summary/Conclusion: Both physical and mental HRQoL impairment were significantly associated with higher rates of ER visits and hospital admissions, independent of other patient characteristics. Scores from patient-reported HRQoL surveys may serve as a proxy for disease severity and could be used to predict future ER visits and hospital admissions. Such information can provide stakeholders insight into the humanistic and societal cost associated with this condition.

PS1429

COST COMPARISON OF TREATMENT STRATEGIES FOLLOWING INITIATION WITH RD VERSUS VMP PLUS DARATUMUMAB IN NEWLY DIAGNOSED PATIENTS INELIGIBLE FOR ASCT

G. Jackson[1,*], R. Dutton[2], S. Dhanasiri[3]

[1]Clinical Hematology, NCCC Freeman Road Hospital, Newcastle Upon Tyne, [2]Dolon, London, United Kingdom, [3]Celgene International, Boudry, Switzerland

Background: For newly-diagnosed multiple myeloma patients (NDMM) ineligible to receive autologous stem cell transplant (ASCT) lenalidomide/low-dose dexamethasone (Rd) and bortezomib/melphalan/prednisone (VMP) are recommended and widely used as first-line treatments. Newer agents and combinations are in development and may become alternative options for first-line therapy. These include VMP + Daratumumab (Dara), which has demonstrated a statistically significant improvement in progression-free survival (PFS) over VMP. While clinical considerations are important in treatment decisions, combination regimens involving newer agents are costly and thus have a potential impact on health system budgets. Assessment of the economic impact of new treatments is also important in decision-making.
Aims: This analysis examines the cost impact from the perspective of the EU5 health systems (i.e. France, Germany, Italy, Spain, and the United Kingdom) of initiating therapy with VMP+Dara compared with Rd for patients ineligible to receive ASCT.
Methods: A cost pathway model was developed to follow an average patient through three lines of therapy. Possible therapies given in second- and third-

line following Rd or VMP+Dara were based on clinical guidelines or expert opinion. A pragmatic assumption around subsequent treatment distribution was made i.e. treatments given in earlier lines are not repeated. Duration of treatment (DoT) and duration of response (DoR) were taken from published sources where available. Since DoR for VMP+Dara is not reported yet, it was assumed to be the same as for Rd. Only drug acquisition costs (at list price or public prices) and administration costs were included. Two scenarios are considered: A) Rd followed by VD, DaraVd or carfilzomib/d; followed by Dara monotherapy or pomalidomide/d; or B) VMP+Dara followed by Rd or Rd combinations with elotuzumab, ixazomib, or carfilzomib; followed by carfilzomib/d or pomalidomide/d.

Results: In the Rd scenario, costs were €337,143 over an average patient pathway covering three lines of treatment, compared with €452,734 for the VMP+Dara scenario. An incremental increase of €59,145 (83%) was observed in year 1 for the VMP+Dara scenario, reflecting the higher monthly drug costs for the 4-agent regimen vs Rd (€9,830 vs €5,943), and the cost of administering Dara intravenously vs oral Rd. In years 2–4, treatment costs were similar in both scenarios, while in years 5+ costs were again considerably higher in the VMP+Dara scenario, reflecting the longer duration of treatment of 3L regimens used within the VMP+Dara scenario (Figure 1).

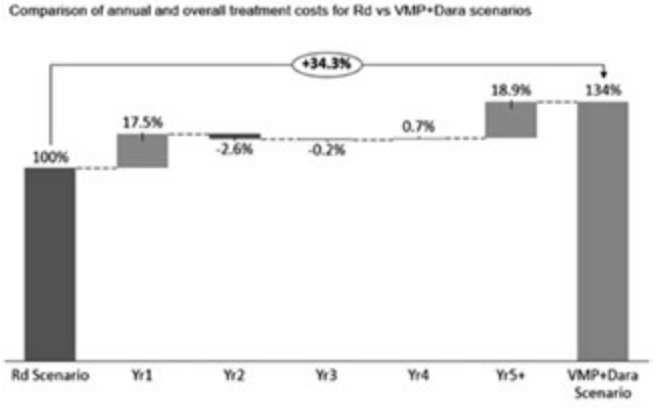

Figure 1.

Summary/Conclusion: The results of this analysis suggest that initiating therapy with VMP+Dara is likely to significantly increase treatment costs compared with Rd, both in the first year of therapy and across the total treatment pathway. Results are largely driven by the cost of VMP+Dara, administration costs of Dara and costs of combination treatments received post relapse. Costs for AE management such as infusion related or peripheral neuropathy have not been considered. Rd has a well-established acceptable safety profile, has demonstrated a 4-year OS of approximately 60%, and has been shown to delay progression to second-line therapy to a median of 69.5 months in patients achieving a ≥VGPR. Whilst VMP+Dara has demonstrated efficacy vs. VMP alone, more long-term safety and survival data are awaited. This analysis suggests that Rd is a cost-efficient use of NHS resources in EU5 for treating patients with NDMM ineligible for ASCT.

PS1430

IMPROVABLE LIFESTYLE FACTORS IN LYMPHOMA SURVIVORS

C. Minoia[1,*], S. Ciavarella[1], G. Lerario[1], A. Daniele[2], S. De Summa[3], M. Napolitano[4], A. Guarini[1]

[1]Haematology Unit, [2]Clinical Pathology Unit, [3]Molecular diagnostics and Pathogenetic Unit, National Cancer Research Centre "Giovanni Paolo II" Bari, Italy, Bari, [4]Research Coordination and Support Service, Istituto Superiore di Sanità, Rome, Italy

Background: Lifestyles (LS) represent the unique modifiable and improvable risk factors for secondary neoplasms and cardiovascular late events in cancer survivors. The impact of adherence to correct LS on quality of life (QoL) and late toxicities has been investigated mainly in breast, prostate and colorectal cancers, whereas only a minority of studies have dealt with lymphoma survivors.

Aims: As part of the "Center for Disease Control Program 2014 (CCM2014)" launched by the Italian Ministry of Health, from November 2016 to October 2017 our group evaluated LS risk factors in a population of lymphoma survivors and planned subsequent strategy for prevention.

Methods: We prospectively included in the study 70 consecutive patients, who were in continuous remission of lymphoma for at least 3 years. Patients took part in a survey including specific LS items in accordance with current international guidelines, such as smoking cessation, adherence to the Mediterranean diet (daily intake of more than 3 portions of fruit/vegetables, weekly intake of less than 2 portions of meat), physical activity (at least a moderate physical activity for 150 minutes a week) and body mass index (BMI) and to a nutritional evaluation assessing the metabolic status (anthropometry, plicometry according to Durnin-Womerslay, indirect calorimetry and plurimetabolic risk).

Results: We observed that 15.7% of subjects smoked, 89.7% did not follow the Mediterranean diet and 75.3% had insufficient physical activity. Almost two/thirds (64.7%) had at least 2 negative LS factors and 14.7% 3 negative factors. Moreover, 33% of patients presented a metabolic syndrome, 30.8% of patients were overweight (BMI 25–29.9) and 26.4% obese (BMI >30). Notably, 12 (17.1%) subjects had developed a cardiac toxicity as late event. Out of 11 subjects who had developed a therapy-related cardiomyopathy, 10 (90.9%) had at least 2 negative LS factors. Even with the limited number of subjects, some features related to the initial disease and to the administered anti-cancer treatment were found at risk for the development of metabolic syndrome, in particular a diagnosis of NHL (OR 3.9, 95%CI[1,15÷14,479], p=0.03), a anti-cancer therapy including high dose steroid (OR 3.5, 95%CI [1,06÷13,28], p=0.04) and an age at evaluation of 60 years or above (OR 8.2, 95%CI[1,69÷61,84], p=0.01), with the first two parameters directly related to an increased BMI (> 25): OR 5.7, 95%CI[1,48÷28,98] for NHL (p=0.01), and OR 3.4, 95%CI [0,98÷13,14] for high dose steroid (p=0.06).

Summary/Conclusion: The analysis provides a general evaluation of a subset of patients potentially cured from lymphoma, but who could develop late chronic morbidities which impact on quality of life and prognosis. The application of prevention strategies in this context may positively influence the clinical outcome of these patients, thus making the activation of dedicated educational programs on healthy LS desirable, with particular regard to smoking cessation, nutritional intervention and physical activity, all according to current guidelines.

PS1431

QUALITY OF LIFE IN ADVANCED-STAGE,ASYMPTOMATIC,NON-BULKY FOLLICULAR LYMPHOMA TREATED WITH RITUXIMAB SHOWS SIGNIFICANT IMPROVEMENT COMPARED WITH WATCHFUL-WAITING: PHASE 3 RANDOMISED INTERNATIONAL STUDY

M. A. V. Marzolini[1,*], W. Qian[2], L. Clifton-Hadley[3], P. Patrick[3], W. June[4], L. Stevens[3], C. Pocock[5], F. Miall[6], D. Cunningham[7], J. Davies[8], A. Jack[9], R. Stephens[10], J. Walewski[11], B. Ferhanoglu[12], K. Bradstock[13], D. Linch[14], K.M. Ardeshna[1]

[1]Haematology, University College London Hospital, London, [2]Cambridge Clinical Trials Unit - Cancer Theme, Cambridge, [3]Cancer Research UK and UCL Cancer Trials Centre, London, [4]University of Manchester, Manchester, [5]Haematology, East Kent Hospitals, Canterbury, [6]Haematology, University Hospitals of Leicester NHS Trust, Leicester, [7]Medicine, Royal Marsden Hospital, London, [8]Haematology, Western General Hospital, Edinburgh, [9]St James' Institute, Leeds, [10]MRC Clinical Trials Unit, London, United Kingdom, [11]Maria Sklodowska-Curie Memorial Institute and Cancer Centre, Warsaw, Poland, [12]Istanbul University, Istanbul, Turkey, [13]Westmead Hospital, University of Sydney, Sydney, Australia, [14]Haematology, UCL Cancer Institute, London, United Kingdom

Background: Traditionally, pts with asymptomatic, advanced stage, nonbulky follicular lymphoma (FL) have been managed with a watchful waiting approach until disease progression. The 'Watch and Wait' trial (NCT00112931) was an international Phase 3 randomised study examining whether rituximab could delay the need for chemotherapy or radiotherapy and the effect on quality of life (QoL) over time. The long term results of the QoL sub-study are presented here.

Aims: To evaluate QoL changes in pts with asymptomatic, advanced stage FL treated with rituximab monotherapy or managed using a watch-and-wait approach.

Methods: The pts were aged ≥18 years, Stage II – IV, asymptomatic FL (Grades 1, 2 & 3a) ECOG PS 0-1. Pts were randomised to either watchful waiting (**Arm A**; 187 patients) or to receive rituximab 375mg/m^2 weekly for 4 weeks followed by rituximab maintenance every 2 months for 2 years (**Arm C**; 192 patients). QoL questionnaires were completed at baseline (before & after randomisation), at Month (Mo) 7, Mo 13, Mo 25 and Mo 37. Questionnaires included the Mental Adjustment to Cancer (MAC), Illness Coping Style (ICS), the Hospital Anxiety and Depression Scales (HAD) scales and some additional concerns. All subscales (except HAD) were standardised on a 100-point score with a higher score indicating better QoL. A change of 5-10 points for a 100-point scale was regarded as a minimal clin-

ically important difference. We have previously reported QoL only at Month 7 (Ardeshna, Lancet Oncol, 2014; 15: 424-35).
Results: The pts in the maintenance rituximab arm were significantly more likely to feel in control of their situation, as demonstrated by the MAC scores, than those patients in the watchful waiting arm (Month 7: p=0.0035; Month 13, p= 0.0587; Month 25; p=0.0006; Month 37; p=0.0555).
The pts in the watchful waiting arm were significantly more likely to avoid learning or thinking about their illness and to have unpleasant connotations associated with their clinic visits, as shown by the ICS scores, when compared with those in the rituximab maintenance arm (Month 7, p= 0.0035; Month 13, p= 0.0020; Month 25, p=0.0106) though this effect was not seen at Month 37 (p= 0.2020). With respect to some specific concerns we had enquired about: the pts in the watchful waiting arm were significantly more likely to be more worried about their disease becoming more aggressive over time (Month 7, p=0.0333; Month 13, p=0.0001; Month 25, p=0.0002; Month 37, p=0.0010). They were also significantly more likely to be concerned regarding being able to support themselves or their family due to their illness over time, when compared to the patients in the maintenance rituximab arm (Month 7, p= 0.4289; Month 13, p=0.0052; Month 25, p=0.0132; Month 37, p=0.0015). The pts in the maintenance rituximab arm were less likely to worry about requiring or needing more treatment in the future when compared with the watchful waiting group (Month 7, p=0.0037; Month 13, p=0.0170; Month 25; p=0.0346; Month 37, p=0.0104).
There was no significant difference between the two study arms in the HAD-Anxiety and HAD-Depression sub-scores over time. We did not find any QoL score to be significantly worse in the rituximab maintenance group.
Summary/Conclusion: These results demonstrate improved QoL scores in the pts in the maintenance rituximab arm when compared with those in the watchful waiting arm, indicating that rituximab maintenance, and the potential side-effects associated with this, was not detrimental to the pts' quality of life and indeed resulted in an improved quality of life in some domains.

PS1432

HOW TO IDENTIFY PATIENTS WITH MALIGNANT HEMOPATHIES WHO DON'T BENEFIT FROM STANDARD DOSE CHEMOTHERAPY

S. Dubruille[1,*], C. Kenis[2], Y. Libert[3], M. Delforge[4], L. Dal Lago[5], M. Roos[5], C. Borghgraef [5], T. Pepersack[5], H. Wildiers[2], D. Bron[1]

[1]Department of Hematology, Institut Jules Bordet, Brussels, [2]Department of Oncology, University Hospitals Leuven, Leuven, [3]Clinic of Psycho-Oncology, Institut Jules Bordet, Brussels, [4]Department of Hematology, University Hospitals Leuven, Leuven, [5]Onco-geriatrics Unit, Institut Jules Bordet, Brussels, Belgium

Background: Major progresses have been achieved to identify older patients with malignant hemopathies who should be treated with standard doses of chemotherapy. However, a reliable frailty score remains urgently needed to better define the unsuspected vulnerable population that does not benefit from chemotherapy. In the literature, three clinical (functional decline, cognitive impairment (CI) and comorbidities) and two biological (low albumin level and IL-6 level) factors are frequently correlated with a poor overall survival (OS) and/or chemotherapy-related toxicities.
Aims: To investigate the reliability of a simple clinico-biological tool for the screening of frail patients with malignant hemopathies to predict unacceptable chemotherapy-related toxicity (toxic death) or poor survival (<6 months).
Methods: 270 consecutive patients (65-90yrs) with malignant hemopathies admitted to receive chemotherapy where included in a prospective multicentric study conducted in the Inst. J. Bordet (ULB, Brussels) and in the University Hospitals (KUL, Leuven). A Comprehensive Geriatric Assessment (CGA) was performed. Univariate and multivariate Cox proportional hazards model were used to evaluate the respective value of functional decline, abnormal cognitive function, comorbidities, low albumin and CRP level to predict 1-year survival.
Results: One hundred and seventy-nine patients were evaluable for the clinico-biological screening tool (NHL, n=107; CLL, n=19; MM, n=26; AML, n=14; ALL, n=3; LMMC, n=7, MDS, n=3). Eighty-five percent were considered to have a more favorable prognosis (NHL, CLL or MM). Functional decline was associated with abnormal cognitive function (p=0.026) and inflammation (p<.001). Based on our previous analyses in the Charlson Comorbidity Index we took the strongest prognostic factor: gastro-intestinal (GI) ulcer (p<.001). A "frailty" scoring system was thus developed, based on our 4 independent predictive factors for poor survival: CI (MMSE<27, n=56), presence of GI ulcer (n=23), low albumin level (alb<3.5 mmol, n=50) and surrogate of IL-6 level (CRP≥2mg/l, n=135). The population was stratified into 3 groups: "fit" (score=0-1, n=97), "vulnerable" (score= 2, n=53) and "frail" (score= 3-4, n=29). The one-year survival was 80% in "fit" and 57% in "vulnerable" patients (HR=2.59; 95% CI=1.41-4.75; p=.002). In "frail" patients 38% were alive at one-year (HR=4.83; 95% CI=2.53-9.23; p<.001) with a median survival of 5 months. Causes of death remain disease-related in a majority of the patients (73%). In our largest group of older NHL patients (n=107), the "frailty" scoring was also studied (MMSE<27, n=30; GI ulcer, n=12; alb<3.5 mmol, n=26, CRP≥2mg/l, n=80): the OS was 82% in fit (n=67) and 68% in vulnerable (n=25) (HR=2.00; 95% CI=0.82-4.90; p=.129) patients. In "frail" patients 40% were alive at one-year (n=15) (HR=5.46; 95% CI=2.29-13.03; p<.001) with a median survival of 5 months and thus, also reliable in this lymphoma population.
Summary/Conclusion: In our selected population of fit patients referred to receive chemotherapy for malignant hemopathies, our frailty score helps the clinician to predict a very poor outcome. This frailty score detects unsuspected frailty in patients who may benefit from palliative care. Further prospective analyses in a larger cohort of malignant hemopathies are ongoing to validate the reliability of this score.

PS1433

THE ROLE OF MENTAL AND BEHAVIORAL DISORDERS IN LEUKEMIA PREDISPOSITION: A NATIONWIDE CASE-CONTROL STUDY

H. Moisander-Joyce[1,*], A. Nikkilä[2], J. Raitanen[2,3], O. Lohi[4], A. Auvinen[1,2]

[1]Tampere Center for Child Health Research, Tampere University and University Hospital, [2]Tampere University, [3]UKK Institute for Health Promotion, [4]Tampere Center for Child Health Research, Tampere University Hospital and University of Tampere, Tampere, Finland

Background: Many studies have discussed the increased mental health and behavioral problems in pediatric cancer patients and survivors. Less is known, however, about the prevalence of congenital mental and behavioral disorders in the pediatric leukemia population. Their role in cancer predisposition is being actively studied: multiple cancer predisposing syndromes present with intellectual disability either as monogenic (e.g. Ataxia-telangiectasia) or chromosomal aberrations (e.g. Down syndrome).
Aims: We studied the prevalence of mental and behavioral disorders the Finnish pediatric leukemia population with the aim to assess the role of congenital mental and behavioral disorders as risk factors for leukemia.
Methods: We used a nationwide, register-based case-control study to investigate the prevalence of mental and behavioral disorders in pediatric leukemia patients. We identified all pediatric leukemia cases (0-15 year old) from 1990 to 2011 (N=1100) in Finland and randomly selected three times as many controls (N=3272) from the Population Registry, individually matched by gender and year of birth. 81% (N=885) of the cases had acute lymphoblastic leukemia and 13% (N=142) acute myeloid leukemia. We used the Care Register for Health Care by the Finnish National Institute for Health and Welfare to obtain information about ICD-10 Chapter V diagnoses (Mental and Behavioral Disorders) based on inpatient care and specialist outpatient visits for the above population. We used the Register for Congenital Malformations to exclude the patients with Down syndrome. There were no patients with other known leukemia predisposition syndromes which present with mental or behavioral symptoms. This left us with 1058 cases and 3270 controls for analysis.

Table 1. Odds ratios of mental and behavioral disorders for pediatric leukemia patients.*

	Cases	Controls	OR (95% CI)	p value
All diagnoses (0-15 year old)				
Neurotic, stress-related and somatoform disorders (F40-48)	73 (6.90 %)	42 (1.28%)	5.77 (3.87, 8.70)	<0.01
Behavioral syndromes (F50-59)	62 (5.86%)	26 (0,80%)	7.76 (4.80, 12.85)	<0.01
Mental retardation (F70-79)	16 (1.51%)	24 (0.73%)	2.07 (1.03, 4.09)	0.02
Disorders of psychological development (F80-89)	73 (6.90%)	157 (4.80%)	1.47 (1.09, 1.97)	0.01
Diagnoses > 2 years prior to leukemia diagnosis				
Neurotic, stress-related and somatoform disorders (F40-48)	1 (0.09%)	4 (0.12%)	0.77 (0.12, 7.82)	0.82
Behavioral syndromes (F50-59)	1 (0.09%)	4 (0.12%)	0.77 (0.02, 7.82)	0.82
Mental retardation (F70-79)	4 (0.38%)	3 (0.09%)	4.13 (0.70, 28.27)	0.04
Disorders of psychological development (F80-89)	10 (0.95%)	29 (0.89%)	1.07 (0.46, 2.27)	0.86

*Patients with Down Syndrome are excluded from this analysis.

Results: Overall, 708 patients (442 controls, 266 cases) had at least one ICD-10 Chapter V diagnosis. This equals 14% and 25% of the controls and cases, respectively. We focused on our study on the four areas most relevant to pediatric leukemia patients: 1) neurotic, stress-related and somatoform disorders (F40-48), 2) behavioral syndromes associated with physiological disturbances and physical factors (F50-59), 3) mental retardation

(F70-79) and 4) disorders of psychological development (F80-89). In conditional logistic regression analysis pediatric leukemia patients had significantly more mental and behavioral disorders in all the above areas (see Table 1). However, when the analysis was restricted to the period prior to the date of leukemia diagnosis (and the corresponding date for matched controls) with a two-year latency period, only mental retardation was a statistically significant risk factor for leukemia (p=0.04).
Summary/Conclusion: Our preliminary analysis suggests that mental retardation is a statistically significant risk factor for leukemia. The majority of pediatric leukemia cases were diagnosed prior to school age (mean 5.7 years, median 4.7 years) and thus, mental retardation diagnosed prior to leukemia is often of congenital origin, possibly due to yet-to-be-discovered genetic syndromes which affect both brain development and cancer predisposition.

PS1434

IMPACT OF CMV PROPHYLAXIS ON RATES OF REHOSPITALIZATION IN ADULT CMV SEROPOSITIVE ALLOGENEIC HSCT RECIPIENT: EXPERIENCE FROM THE LETERMOVIR PHASE 3 CLINICAL TRIAL

S. Mt-Isa[1], H. Wan[1], C. Badshah[1], V. Teal[1], R. Leavitt[1], J. Schelfhout[1,*]

[1]MSD, Whitehouse Station, NJ, United States

Background: In a Phase III randomized, double-blind, placebo-controlled study of cytomegalovirus (CMV)-seropositive Hematopoietic Cell Transplant (HCT) recipients, letermovir prophylaxis significantly reduced the incidence of clinically significant CMV infection through 24 weeks post-HCT. This research describes the impact of letermovir prophylaxis on the rate of rehospitalization in the clinical trial.
Aims: The aim of this research is to describe the impact of letermovir prophylaxis on the rate of rehospitalization in the clinical trial.
Methods: Rehospitalization was recorded as an exploratory endpoint in the clinical trial at end of treatment (Week 14), time of primary endpoint (Week 24) and through an extended follow-up period (Week 48). The trial further recorded whether the rehospitalization was related to CMV (referred to as CMV-related rehospitalization). Prespecified analyses describe the observed rates of rehospitalization for the letermovir and placebo groups at the specified times. Fine-Gray cumulative incidence function (CIF) regression models were used to explore the rate of all-cause, and CMV-related rehospitalization accounting for the competing risk of mortality. A multiple linear regression model was used to describe the cumulative length of stay (LOS) for all-cause rehospitalizations that occurred through Week 48 (excluding time of initial transplant stay).
Results: Observed rates of all-cause rehospitalization were lower for the letermovir group compared to placebo at end of treatment (36.6% vs. 47.6%), time of primary endpoint (48.6% vs. 55.3%), and through extended follow-up (55.7% vs. 60.6%). The CIF regression model demonstrated rates of all-cause rehospitalization were significantly lower through Week 14 (HR=0.72; p=0.021) but did not reach significance at Week 24 (HR=0.81; p=0.109) or Week 48 (HR=0.84; p=0.173); and CMV-related rehospitalizations were significantly reduced at Week 14 (0.6% vs. 7.1%; HR=0.09; p=0.001), Week 24 (2.8% vs. 7.6%; HR= 0.36; p=0.015), and Week 48 (3.1% vs. 8.8%; HR=0.34; p=0.007). The adjusted mean cumulative LOS was shorter for letermovir subjects compared to placebo subjects but did not reach statistical significance (3.1 fewer days p= 0.333).
Summary/Conclusion: Letermovir was shown to significantly reduce the rate of clinically significant CMV infection in a placebo-controlled randomized clinical trial. These analyses suggest that there is also a reduction in the rate and cumulative days of rehospitalization. Caution is warranted as the trial was not sufficiently powered to detect differences in this exploratory endpoint. Nonetheless, these data provide valuable insights into the economic burden of CMV. Real world data and findings from future clinical trials are needed to better understand the nature of the association between CMV and rehospitalizations.

PS1435

QUALITY OF LIFE IN PATIENTS WITH RARE HEREDITARY HEMOLYTIC ANEMIA, THE IMPORTANCE OF SOCIAL SUPPORT

S. Van Straaten[1,2,*], S. Hagens[1,2], J. Verhoeven[1,2], W. van Solinge[1], R. Schutgens[2], R. van Wijk[1], E. J. van Beers[2]

[1]Laboratory of Clinical Chemistry & Haematology, [2]Van Creveldkliniek, UMC Utrecht, Utrecht, Netherlands

Background: Over the past few decades, life expectancy of patients with rare hereditary hemolytic anemia has shown remarkable improvement. The availability of blood transfusions, chelation therapy and other supportive treatment options have improved life expectancy to well into adulthood. However, whether this improved life expectancy is accompanied by improved quality of life (QoL) is not well known.
Aims: The aim was to analyze QoL in patients with hereditary hemolytic anemia as compared to normative data and to define specific subgroups of patients with impaired QoL.
Methods: This is a cross sectional, observational study of 83 patients with rare hereditary hemolytic anemia. Patients were divided into 3 main categories: hemoglobin disorders (e.g. sickle cell disease(SCD), β-thalassemia), red cell enzyme disorders (e.g. pyruvate kinase deficiency) and red cell membrane disorders (e.g. hereditary spherocytosis). All patients completed FACT-An, a validated questionnaire developed within the Functional Assessment of Chronic Illness Therapy (FACIT) system. The questionnaire consists of 5 subdomains. The first 4 domains: physical, social/family, emotional and functional well-being (PWB, SWB, EWB, FWB) are combined to create a general QoL-scale (FACT-G) that can be compared to available normative data provided by FACIT, based on a sample of the general US adult population. The last domain (Fact-AnS) measures additional symptoms of anemia. To analyze clinically meaningful differences between patients and normative data we used established "Minimally Important Difference" (MID) based on anchor- and distribution-based methods. For Fact-G total score the difference was 5 points, for individual subdomains 2 points. We performed non-parametric correlation tests between QoL and documented clinical and laboratory parameters and results of the 6-minute walk test (6MWT, expressed as percentage of predicted distance). To minimize risk of confounders, patients with transfusion dependency or SCD were excluded from correlation analyses with hematological parameters.
Results: Patients had a median age of 43 years (range 18-84) and a median Hb of 11,4g/dL(range 6,4-16,4). The total patient population did not score a clinically meaningful difference on general QoL (Fact-G) compared to the normal population. However, patients with enzyme or membrane disorders and patients who had never received a transfusion had a clinically meaningful higher Fact-G score compared to normative data. Patients who were transfusion dependent had a lower Fact-G score. The subdomain SWB was the most important influencer of differences in Fact-G. There was a significant negative correlation between SWB and age(ρ=-0,428, p=0,002). There was no correlation between QoL and Hb, reticulocyte count or 6MWT. (Table 1).

Table 1.

	Haemoglobin disorders	Red cell enzyme disorders	Red cell membrane disorders	Transfusion dependent patients	Transfusion independent patients	Never transfused	All patients
PWB	**-3,5000**	0,5000	**2,0000**	-1,5000	0,5000	0,5000	0,5000
SWB	-0,6000	**3,5667**	**2,5667**	-0,6000	**2,5667**	**2,5667**	**2,4000**
EWB	**-2,0000**	0,5000	0,0000	**-2,0000**	0,0000	0,0000	-1,0000
FWB	-1,1000	**2,4000**	1,9000	0,4000	1,4000	1,4000	1,4000
Fact-G	-3,2000	**5,6000**	**6,1000**	**-5,9000**	2,1000	**5,1000**	2,1000
Fact-AnS	*52*	*58,5*	*63,5*	*51*	*60*	*60*	*59*

Differences in median scores compared to normative data of normal population. Clinically meaningful differences are marked bold.

Summary/Conclusion: Patients with enzyme and membrane disorders report higher QoL than the general population. This effect is mostly based on high scores in the social/family well-being subdomain. The same pattern is reported in patients with cancer and it might reflect a higher social support need caused by serious illness. Our study shows a decreased QoL in transfusion dependent patients, and increased QoL in patients who were never transfused. The difference is also mostly based on differences in social/family well-being. Our study clearly shows the importance of social/family well-being for QoL of patients with hereditary hemolytic anemia. Improving social support could be an interesting future focus to increase QoL, especially in older, transfusion dependent patients, or patients with hemoglobin disorders.

PS1436

HOW PHYSICIANS' AND PATIENTS' CHARACTERISTICS AFFECT THE LENGTH OF PATIENTS' VISIT IN THE HEMATO-ONCOLOGICAL CLINIC

A. Shacham-Abulafia[1,2], I. Amitai[1,*], O. Uziel[3,4], O. Pasvolsky[1,2], A. Yosefi[1], P. Raanani[1,2], U. Rozovski[1,2]

[1]Institute of Hematology, Davidoff Cancer Center, Rabin Medical Center, Petah-Tikva, [2]Sackler Faculty of Medicine, Tel Aviv University, Tel-Aviv, [3]Felsenstein Medical Research Center, Rabin Medical Center, [4]Sackler Faculty of Medicine, Tel Aviv Uni-

versity, Petah-Tikva, Israel

Background: The relationship between doctors and their patients has received philosophical, sociological and literary attention throughout history. In this study we narrowed our perspective on patient-doctor bonding to a single dimension, the length of time doctors spend with their patients. In a recently published study, doctors estimated spending on average 13 to 16 minutes on each patient's visit. However, to our knowledge, no published studies quantified the duration of patients' visit time. Numerous studies in the field of social psychology confirmed that as most of us implicitly assume, people tend to spend more time with people that resemble them.
Aims: 1. quantify length of patients' visits; 2. determine whether patients' and doctors' characteristics affect the visit time.
Methods: This study was conducted at the adult hemato-oncology department at Rabin Medical Center, an Israeli 1300 bed tertiary medical center. Since 2005 a customer-time management software (Q-Flow®) entered routine use at our institute. This software records the length of patients-doctors' meetings and provides patients' demographic data. With this software we collected data on all consecutive visits in the hemato-oncology clinics during 2017. Additional data was collected from electronic medical records.
Results: In 2017, 22,516 visits of 3314 patients that were seen by 22 doctors were recorded. The median age of the patients was 68 years (range: 17 to 99), male to female ratio was 1/1.07 and 83% (n=1722) were married. Patients were classified according to their country of origin: Israel (52%, 1734), Western countries (6%, 187), Eastern European countries (19%, 615), Arab countries (22%, 738) or others (1%, 40). The most common hematological diagnosis was lymphoma (38%, 1203) followed by plasma cell dyscrasia (16%, 498), myeloproliferative neoplasms (12%, 394) and chronic lymphocytic leukemia (10%, 316). The median length of patients'-doctors' visit was 12.3 minutes (range 3.7 to 36), and although the variance in length of visits was relatively narrow, it differed significantly according to patients' and doctors' characteristics. Fellows had the longest visits (median visit length 14.9 minutes compared to 13.2 minutes for young seniors and 10.9 minutes for older seniors, $p<0.0001$). Compared to male doctors, female doctors had longer visits ($p=0.029$). Yet, both patients' and doctors' gender predicted visits' length. The shortest being when both the doctor and the patient were males ($p<0.004$ compared to *female-patient*, *female-doctor* pair and $p<0.047$ compared to *female-patient*, *male-doctor* pair). Likewise, Country of origin also had minor, yet significant impact on length of visits, being longer for patients born in Israel of Jewish descendent compared to patients born in Israel of Arab descendent ($p= 0.002$) and shorter compared to patients of Eastern European descendent ($p=0.019$). Conversely, patients' age and family status had no impact on visits' length.
Summary/Conclusion: There is a relative narrow variance in doctors'-patients' visit time with shorter professional experience being the strongest predictor of longer visit time. Yet, doctors' and patients' characteristics impact this time significantly. As expected by the similarity-attraction theory and since most of our doctors are of Jewish-descendent and were born in Israel or in Western European countries, the length of patients' visit of similar country of origin was longest. Additionally, as expected by cultural stereotypes, when a male doctor meets a male patient the interaction time was the shortest.

PS1437

SYSTEMATIC REVIEWS OF ECONOMIC BURDEN AND HEALTH-RELATED QUALITY OF LIFE (HRQOL) IN PATIENTS WITH ACUTE MYELOID LEUKAEMIA (AML)

R. Bosshard[1,*], S. Ralston[2], K. O'Reilly[1], S. Chadda[2], D. Cork[2]

[1]Otsuka Pharmaceutical Europe Ltd, Wexford, [2]SIRIUS Market Access, London, United Kingdom

Background: AML is the most common acute leukaemia in adults, with high mortality rates, especially among elderly individuals who account for a large and increasing percentage of the AML population. Treatment of AML is ideally intensive chemotherapy followed by potentially curative haematopoietic stem cell transplant. However, elderly patients and those with significant comorbidities may be considered unfit for intensive chemotherapy (IC) because of an inability to tolerate the therapy. These patients are often treated with lower-intensity therapies such as azacitidine, decitabine, or low dose cytarabine. Due to the relapsing course of AML these patients are likely to run out of treatment options leading to death.
Aims: To conduct systematic reviews to assess firstly the impact of AML on HRQoL and secondly the economic implications at patient, carer, and health service levels for treatment of AML in elderly patients and other patients considered unfit for IC and in patients with relapsed/refractory AML (rr-AML).
Methods: Two independent systematic reviews were conducted to assess HRQoL and economic burden. Electronic databases were searched using specific search strings to identify studies between 2001-2016 that met predefined patient/intervention/comparison/outcome (PICO) criteria, including PubMed, EMBASE, and EconLit. Electronic searches were supplemented with hand searching of conference abstract databases, registries, and HTA agency websites. Conference abstracts from 2015-2016 were included.
Results: Ten studies meeting the specific criteria were identified for each systematic review. EORTC QLQ-C30 was the instrument most commonly used to measure HRQoL. FACT-Leu, FACT-An, SF-12, EQ-5D, and QOL-E were also used. No validated AML specific instruments have been identified. HRQoL was worse in patients who were considered unfit for intensive chemotherapy than in patients assigned to intensive treatments. Poor HRQoL at diagnosis was associated with shorter overall survival, especially in older patients receiving non-intensive treatments. High levels of fatigue were associated with poor HRQoL at diagnosis. Non-intensive treatments did not significantly improve HRQoL in any study, whereas HRQoL did improve in patients receiving IC. Hospitalisation was identified as having a detrimental effect on HRQoL in one study of patients receiving IC. The cost studies identified in the second systematic review reported transfusion costs as the most significant contributor for patients receiving supportive care, and drug costs as the most significant for patients receiving low intensity treatments. However, hospitalisation costs were not included in this model, and were shown to be the most significant contributor for patients receiving IC. Another study identified that hospitalisation costs were not significantly lower for older patients receiving low intensity treatment. No studies specifically assessed burden of relapsed/refractory AML, caregiver burden, or indirect costs.
Summary/Conclusion: Patients considered unfit to receive IC have poor survival and poor HRQoL, and current low intensity treatments do not appear to significantly improve HRQoL. The main cost drivers were dependent on treatment regimen, but included drugs, transfusions, and hospitalisation. Novel treatments which improve survival and HRQoL are needed in this difficult, treatment naïve population. No studies have been identified which specifically describe HRQoL or economic burden associated with rr-AML, further research to understand the burden in this population is required.

PS1438

VENETOCLAX IMPROVES QUALITY OF LIFE FOR PATIENTS WITH RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA

T. Cochrane[1,*], T. Chagorova[2], T. Robak[3], S.-P. Yeh[4], A. Masud[5], K. Sail[5], V. Komlosi[5], M. A. Anderson[6]

[1]Gold Coast Hospital, Southport, Australia, [2]Penza Regional Cancer Center, Penza, Russian Federation, [3]Medical University of Lodz and Copernicus Memorial Hospital, Lodz, Poland, [4]China Medical University, Taichung, Taiwan, Republic of China, [5]AbbVie, Inc, North Chicago, IL, United States, [6]Integrated Department of Hematology, Peter MacCallum Cancer Centre and Royal Melbourne Hospital, Melbourne, Australia

Background: Patients with chronic lymphocytic leukemia (CLL) have significantly decreased health related quality of life (HRQoL), particularly related to severe and progressive fatigue. Side effects of chemotherapies and the emotional burden of living with an often poor prognosis disease also negatively impact patient HRQoL. Venetoclax (Ven), an oral BCL-2 inhibitor, has demonstrated high rates of deep and durable response in CLL patients, including those with 17p deletions or relapsed/refractory (R/R) disease, and has been shown to facilitate clinically relevant improvement in several key aspects of functioning and HRQoL.
Aims: To evaluate the impact of Ven monotherapy on the quality of life of patients with R/R CLL.
Methods: This is an open-label, phase 3b, multicenter study (NCT02980731) that assessed patient-reported HRQoL at baseline and every 4 weeks, using the European Organization for Research and Treatment of Cancer Quality of Life Core Questionnaire (EORTC QLQ-C30). Patients were ≥18 years old with R/R CLL, including those with 17p deletion, *TP53* mutations, and/or prior experience with B-cell receptor inhibitor-containing (BCRi) therapy, treated with Ven monotherapy. HRQoL subscales analyzed included: Global Health Status, Role Functioning, Emotional Functioning, Cognitive Functioning, Social Functioning, and Fatigue. Relevance of mean changes in HRQoL measures from baseline were analyzed based on minimum important difference (MID); a 5-10 point change was defined as MID, and >10 points was clinically meaningful. Safety and adverse events (AEs) were also monitored.
Results: Data cutoff was November 3, 2017; the current median time on study is 17 weeks. Of 92 patients, 66% were male; the median age was 64

years (range: 37–86). Among those with available data, 17p deletions and *TP53* mutations were confirmed in 35% (25/72) and 27% (8/30) of patients, respectively. Overall, 36%, 20%, and 45% of patients had one, two, and three (or more) prior lines of therapy respectively; 23% of patients had prior BCRi therapy. Clinically meaningful improvements in global health status, role functioning and fatigue were observed as early as week 12 post-treatment. Mean change in these parameters from baseline is shown in the Table 1, and mean change over time (compared to baseline) is shown in the graph. On average, patients' fatigue dropped by 37% by treatment week 12, and maintained improvement (23%) at 24 weeks. AEs occurring in ≥10% of patients were neutropenia (25%), thrombocytopenia (15%), anemia (14%), and diarrhea (14%). Serious AEs occurred in 25% of patients, of which the most common were febrile neutropenia (4%) and pyrexia (4%).

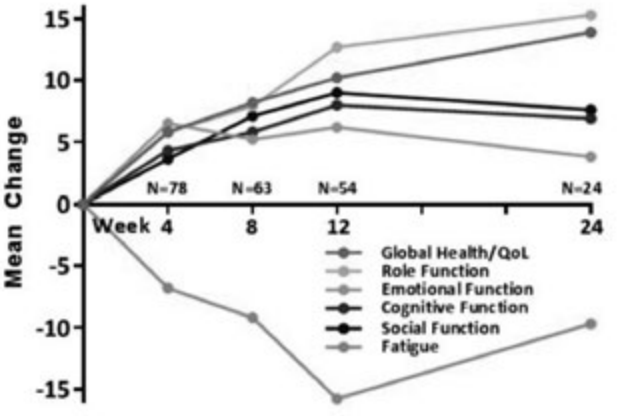

Figure 1.

Table 1.

EORTC QLQ-C30 Parameter	Baseline Mean N=91	Mean (95% CI) change, week 24 N=24
Global Health Status/QoL	57.1	+13.9 (6.1 – 21.7)
Role Functioning	65.8	+15.3 (6.7 – 23.8)
Emotional Functioning	76.6	+3.8 (-2.0 – 9.7)
Cognitive Functioning	80.8	+6.9 (0.1 – 13.8)
Social Functioning	71.1	+7.6 (1.4 – 13.9)
Fatigue*	42.7	-9.7 (-18.1 – -1.4)
* Negative mean change denotes improvement		

Summary/Conclusion: Preliminary data suggest that patients with R/R CLL, receiving venetoclax monotherapy, experience improvement in several key aspects of functioning and quality of life. These findings are consistent with previous studies of R/R CLL patients that received venetoclax monotherapy.

PS1439

NO ASSOCIATION BETWEEN INDOOR RADON AND CHILDHOOD LEUKEMIA IN FRECCLE (FINNISH REGISTER-BASED CASE-CONTROL STUDY OF CHILDHOOD LEUKEMIA)

A. Nikkilä[1,*], J. Raitanen[1], O. Lohi[2], A. Auvinen[1]

[1]University of Tamepre, [2]Tampere Center for Child Health Research, Tampere University and University Hospital, Tampere, Finland

Background: Leukemia is the most common malignancy of childhood. Its etiology remains unknown apart from few established risk factors (Down syndrome and high-dose ionizing radiation). The association between indoor radon and childhood leukemia has been studied before but the results have been conflicting[1-6].
Aims: We aim to characterize the association between indoor radon and childhood leukemia more accurately with high-quality data.
Methods: We created a log-linear model for prediction of residential radon levels based on 6008 dwellings with measured indoor radon concentrations. The predictors in the model included building type, building material, basement, radon protection, floor area, floor number, soil uranium concentration, average indoor radon by postal code area, terrain elevation and location on any landform formed by the latest ice age. Missing data of predictive variables (0 – 11%) was replaced with multiple imputation. In addition, a categorical model was created by dividing indoor radon levels into three groups: <50% (<36Bq/m^3), 50–90% (36 - 200Bq/m^3), >90% (>200Bq/m^3). The robustness of the models was evaluated with multiple sensitivity analyses. Our childhood leukemia dataset comprises of all childhood leukemia cases diagnosed in Finland between 1990 and 2011 (N=1093) and thrice as many controls matched by gender and year of birth[7]. We applied the log-linear radon prediction model to the nationwide register-based case-control dataset and estimated the cumulative indoor radon exposure throughout the study subjects' complete residential histories.
Results: The log-linear model predicted observed radon levels adequately (r^2 = 0.23). It showed robust behavior with no signs of overfitting in sensitivity analyses and k-fold cross-validation. Spearman correlation between measured and predicted values was 0.48 and Cohen's kappa for the model with categorical radon levels was 0.34. When the predicted average indoor radon concentration was divided into quartiles and the group with lowest exposure (9.0 Bq/m^3) was used as the reference group, the OR for the 2nd quartile (29 Bq/m^3) was 0.89 (95% CI 0.72, 1.10); third (45 Bq/m^3) OR=0.82 (95% CI 0.66, 1.01); and highest (68 Bq/m^3) OR=0.95 (95% CI 0.77, 1.17) relative to the lowest quartile. (Figure 1).

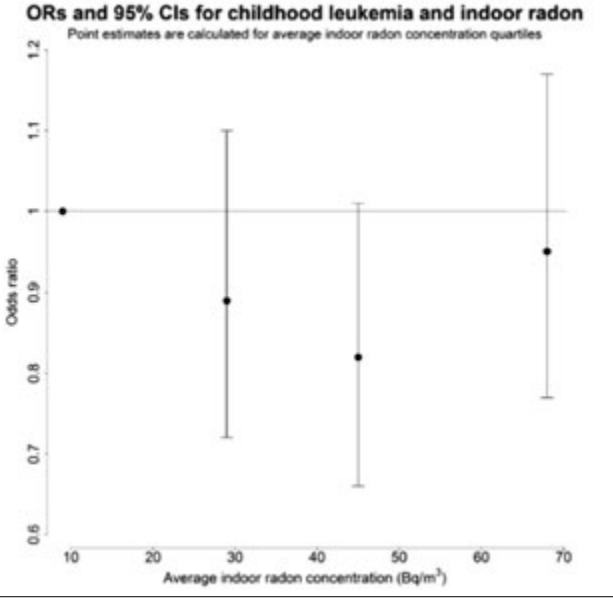

Figure 1.

Summary/Conclusion: The prediction model developed for residential radon performed reasonably well. However, it was unable to robustly identify the dwellings with the highest radon concentrations. No increase in leukemia risk with predicted indoor radon was found. The results should be interpreted cautiously as the exposure modelling has significant uncertainties.

CLARITHROMYCIN ADDED TO THE VCD REGIMEN CAUSES REDUCED HEALTH-RELATED QUALITY OF LIFE IN MULTIPLE MYELOMA PATIENTS

L. K. Nielsen[1,*], T.W. Klausen[2], T. Do[2], I.B. Kristensen[3], U.C. Frølund[4], N.F. Andersen[5], C.L. Andersen[4], A.J. Vangsted[6], N. Abildgaard[7], H. Gregersen[8]

[1]Quality of Life Research Center, Department of Haematology, Odense University Hospital, Odense, [2]Department of Haematology, Herlev Hospital, Copenhagen, [3]Department of Haematology, Vejle Hospital, Vejle, [4]Department of Haematology, Zealand University Hospital, Roskilde, [5]Department of Haematology, Aarhus University Hospital, [6]Department of Haematology, Copenhagen University Hospital, Copenhagen, [7]Department of Haematology, Odense University Hospital, Odense, [8]Department of Haematology, Aalborg University Hospital, Aalborg, Denmark

Background: Newly diagnosed multiple myeloma (MM) patients report improved health-related quality of life (HRQoL) during induction treatment and autologous stem cell transplantation (ASCT). The Danish Myeloma Study Group initiated the CLAIM study; a randomized, placebo-controlled, double-blinded phase II study with the aim of investigating the efficacy and safety of adding clarithromycin (CLA) or placebo (PLA) to cyclophosphamide-bortezomib-dexamethasone (VCD) induction therapy in transplant eligible, newly diagnosed MM patients. The study was prematurely stopped due to severe gastrointestinal complications in the CLA-group. The response data suggested no effect of the addition of CLA to the VCD regimen *(Gregersen et al., ASH 2017, abstract 3129).*
Aims: The objective was to compare patient-reported HRQoL between the two treatment groups.
Methods: The patients answered three validated HRQoL questionnaires at inclusion and after two and six months. The European Organisation For Research And Treatment Of Cancer Quality Of Life Questionnaire (QLQ-C30), the Multiple Myeloma module (MY20) and the Functional Assessment of Cancer Therapy/Gynecologic Oncology Group Neurotoxicity (FACT/GOG-ntx) subscale were used. Mean score for each domain in each group were calculated by mixed model repeated measures. The mean score difference between the two groups were interpreted by clinically relevant difference between groups. For the QLQ-C30 and MY20 domains the threshold of ≥ 5 points was used (*Cocks et al.*, J Clin Oncol. 2011;29:88-96) and for the FACT/GOG-ntx subscale the threshold of ≥ 11.8 was used (*Calhoun et al.*, Int J Gynecol Cancer 2003, 13,1-8). Sensitivity analyses were carried out to explore the impact of unanswered questionnaires by identifying auxiliary variables for missing response and adding this information to the analysis.
Results: Of the 58 included patients, 55 patients participated in the HRQoL reporting; 25 in the CLA-group and 30 in the PLA-group with compliance of 84% and 89% in the CLA- and PLA- group, respectively. At two months follow-up the patients in the CLA-group reported clinically relevant reduced global quality of life (QoL), physical, role, emotional and social functioning, body image and more fatigue, insomnia, disease symptoms, side effect of treatment, and peripheral neuropathy compared to the patients in the PLA-group. For physical, role and social functioning, and insomnia the reduced HRQoL were persistent at six months follow-up. In the investigation of the pattern of missing answers to questionnaires, grade 3 and 4 adverse events were identified as auxiliary variables. When these were incorporating into the analysis of the global QoL domain, the mean score difference became larger.
Summary/Conclusion: The results are underpowered because of lower sample size than planned. Still, the results demonstrate that MM patients report a clinically relevant reduced HRQoL, when clarithromycin is added to the VCD regimen. A possible explanation to these findings could be an interaction between bortezomib and clarithromycin, and the reduced HRQoL could be a result of increased exposure to bortezomib in the CLA-group. The study emphasizes the importance of including HRQoL as an endpoint in clinical trials and has a potential role as part of real-time safety monitoring of symptomatic toxicities in clinical trials. Even though the compliance rate was high, we found that unanswered questionnaires should be incorporated in the interpretation of HRQoL results.

Background: Lymphomas are a heterogeneous group of disease entities with well-defined clinical, morphological, immunophenotypic, and cytogenetic characteristics. Furthermore, regional and racial differences have been reported in their incidence and subtype distribution.
Aims: Due to the lack of epidemiological Lymphoma Registries in Spain, on 2014 GELTAMO Group start a prospective Registry with the aim of our study determine the incidence and distribution of lymphomas in Spain
Methods: We designed an online platform for the prospective registry. All GELTAMO group centers who expressed their intention to participate in the study were endowed with a password to access the platform. The start of data collection was in January 2014. Since then, all patients diagnosed with lymphoid neoplasms according to 2008 WHO classification are being consecutively registered in the platform. The data cut for this analysis was made in January 2018. The variables to collect are: alphanumeric code, reference hospital, gender, date of birth, diagnosis, date of diagnosis, status and date of last follow-up.

Results: Since 2014 to January 2018, 9163 patients have been registered in 47 different hospital centers across Spain. The median follow up for alive patients was 18 month. The overall survival of the global series at 18 month was 85%. Median age was 54.78 years old (IQR: 38.7-67.6). Distribution by gender was 52% male and 48% female. The incidence according to histological types was: precursor B/T-cell neoplasms 0.9%, mature B-cell neoplasms (B-NHL) 80%, T and NK neoplasms (T/NK-NHL T/NK) 6%, Hodgkin (HL) 12% and post-transplant lymphoproliferative disorders (PTLDSL) 0.3%. (Table 1). As expected, within B-NHL, diffuse large B cell lymphoma NOS and follicular lymphoma were the most frequent entities reported (28.3% and 22.2% respectively) (Table 1). A total of 870 patients with marginal lymphoma (11.3% of mature B lymphomas) were registered, distributed in nodal (246, 3.3%), extranodal (370, 5%) and splenic (253, 3.4%) subtypes. Among the T/NK-NHL (Table 1), the most frequent were peripheral T lymphomas (123, 23.2%) and anaplastic lymphomas (ALK+ 46 (8.3%), ALK- 33 (5.9%). Among the HL (Table 1), the classic subtype represented 93.7% of the cases, being nodular sclerosis the most frequent

variant (60.4%). Among the PTLD groups, 88% had monomorphic subtype. In a non-detachable number of patients, the histological subtype could not be specified, 78 cases of B-NHL, 73 cases of HL and 11 cases of T-NHL. This was mainly due to the sort of biopsy (trucut), technical problems, or absence of specific diagnostic techniques.
Summary/Conclusion: This is the first prospective registry to know the incidence and distribution of lymphomas in Spain. Knowing the local epidemiology is essential to optimize the use of resources, design clinical trials and identify minority entities focus on their study our incidences are in accordance to those previously reported in occidental countries. Currently, we are adapting our platform to the new 2016 WHO classification.

PS1442

A HEALTH STATE UTILITY MODEL ESTIMATING THE IMPACT OF IVOSIDENIB ON QUALITY OF LIFE IN PATIENTS WITH RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA

E. Wehler[1], M. Storm[2,*], S. Kowal[1], C. Campbell[1], A. Boscoe[2]

[1]HEOR, IQVIA, Fairfax, [2]HEOR, Agios Pharmaceuticals Inc., Cambridge, United States

Background: Acute myeloid leukemia (AML) is the most common form of leukemia in adults in the United States (US). Prognosis is poor, especially for patients with relapsed/refractory (R/R) disease. Treatment options for R/R AML are limited and, until recently, no new drugs had been approved in over 4 decades. Ivosidenib is an oral monotherapy in clinical trials for the treatment of IDH1-mutated (mIDH1) R/R AML. The phase 1, single-arm trial showed a complete remission or complete remission with partial hematologic recovery rate of 30.4% and a favorable adverse event (AE) profile. As health-related quality of life (HRQoL) data was not collected in the trial, a modeling exercise was undertaken to understand the potential utility benefit associated with ivosidenib compared to other treatments used for R/R AML.
Aims: The objective of the study was to estimate the lifetime HRQoL impact of ivosidenib in R/R AML.
Methods: A partitioned survival model leveraging event-free survival (EFS) and overall survival (OS) curves considered the impact of clinical performance and AEs on HRQoL. No directly comparable clinical trials were found for mIDH1 patients, and available evidence for non-mIDH1 comparators had missing data metrics and poorly matched populations. As such, two modeling approaches were considered: 1. Using survival data from the phase 1 ivosidenib trial for all interventions (AE differences only) and 2. Using published survival data from a phase 3 R/R AML clinical trial of clofarabine + cytarabine (AE and EFS/OS differences) for all comparators. Grade ≥3 AEs occurring in ≥5% of patients were included. The model considered time to remission, number of treatment cycles, and two rounds of induction/consolidation therapy, where applicable. AE rates were derived from available clinical studies. Utility values for each disease phase and disutilities for each AE were from the published literature. The total disutility attributed to AEs for each intervention was calculated using an additive approach.

Table 1. Base case results.

Intervention	Using ivosidenib survival data for all treatments		Using literature-based survival for comparators		Total AE disutility
	Life-Years	QALYs	Life-Years	QALYs	
Ivosidenib	0.915	0.399	0.915	0.399	-0.129
LoDAC	0.915	0.369	0.834	0.341	-0.166
HMAs	0.915	0.301	0.834	0.278	-0.225
Daunorubicin and cytarabine fixed dose	0.915	0.264	0.834	0.245	-0.244
7+3	0.915	0.257	0.834	0.239	-0.251
HiDAC	0.915	0.135	0.834	0.123	-0.377
Other HIC	0.915	0.319	0.834	0.298	-0.187
Midostaurin+ chemotherapy	0.915	0.000	0.834	0.000	-0.570

LoDAC: low dose cytarabine; HMAs: hypomethylating agents; HiDAC: high dose cytarabine; IC: other high intensity chemotherapy

Results: Assuming ivosidenib survival is representative of other comparators (no survival benefit), ivosidenib produces slightly more quality-adjusted life years (QALYs) [range: 0.030 vs LoDAC to 0.399 vs midostaurin+ chemotherapy], largely driven by benefits of AE reductions in infections and hematologic disorders. Applying the clofarabine+cytarabine survival data to the comparators increases incremental QALYs [range: 0.058 vs. LoDAC to 0.399 vs. midostaurin+chemotherapy] due to gains in life years for ivosidenib [0.081 vs. all comparators]. Baseline estimates are conservative, as the model did not include several potential benefits of ivosidenib (e.g. impact of stable disease, hospitalization rates and transfusions). Further, given the limited published studies with both EFS and OS data, the modeled comparator data was based on a trial of patients who had received ≤2 prior regimens and thus would be expected to demonstrate better EFS and OS than patients in the ivosidenib trial who had received a median of 2 prior regimens. The additive disutility approach for AEs potentially over-estimates overall AE impact on HRQoL for more toxic therapies, however, scenario analyses comparing only the single most impactful AE event across comparators still result in incremental QALY gains for ivosidenib, reinforcing baseline findings (Table 1).
Summary/Conclusion: Given the potential for improved survival and its favorable AE profile versus other R/R AML therapies, ivosidenib is expected to improve HRQoL over patients' lifetimes in the mIDH1 R/R AML population.

PS1443

ASSESSMENT OF ADHERENCE IN HAEMOPHILIA PATIENTS - EVALUATION OF AN US INSTRUMENT AND DEVELOPMENT OF A NEW QUESTIONNAIRE FOR USE IN GERMANY

S. Von Mackensen[1,*], S. Halimeh[2]

[1]Institute of Medical Psychology, University Medical Centre Hamburg-Eppendorf, Hamburg, [2]Gerinnungszentrum Rrhein-Rruhr (GZRR), Duisburg, Germany

Background: Non-adherence is a major public health problem leading to financial burden on healthcare systems. Adherence is influenced by social, economic, healthcare system related and condition-related aspects. Due to high treatment costs, the evaluation of adherence in people with haemophilia (PWH) is important. In Europe no haemophilia-specific adherence instrument exists; only an US instrument from a different health-care system is available (VERITAS-PRO for prophylaxis PWH, VERITAS-PRN for on-demand PWH).
Aims: To verify whether this US instrument is relevant for other healthcare systems and to which extent the single items are important to PWH and Healthcare professionals (HCP). To develop an adherence questionnaire for Germany.
Methods: The study consists of three phases (evaluation of US instrument, conduct of focus groups with different stakeholders, construction of new adherence questionnaire). PWH from a haemophilia treatment centre (HTC) in Duisburg and HCP were asked to evaluate the single questions of the US instruments concerning their relevance for German PWH on a 5-point-Likert-scale (ranging from not important to very important). Suggestions for additional questions were possible. The level of agreement was based on the calculation of the content validity ratio (CVR) defined as a linear transformation of a proportional level of agreement on how many raters within a panel rate an item very important. Separate focus groups were conducted with HCP (paediatricians, internists), PWH (adults, adolescents, parents of haemophilic children) and health insurance companies.
Results: So far, the first 2 phases were performed. Fifty PWH (23 adults, 27 parents of haemophilic children) participated with a mean age of 35.78±11.0 years. Most PWH had haemophilia A (78%), were severely affected (62%) and on prophylaxis (62%). Based on the content validity ratio (CVR ≥0.300) across all respondents only 1 question ("*I use the doctor-recommended dose for infusion*") of the Veritas-PRO and 3 questions of the Veritas-PRN ("*I use the correct number of factor boxes to total my recommended dose*", "*I have enough factor and supplies at home to infuse when needed*", "*I call the treatment centre before medical interventions*") were considered as "very important" for use in Germany. Few suggestions for additional adherence questions were made by PWh, e.g. distance from home to HTC, educational level, confidence in physician, barriers of non-adherence and improvement of adherence. In general, questions concerning dosing were considered only relevant for the US. 25 out of 27 HCP sent back their evaluation forms (62.5% physicians, 25% nurses, and 2 study/haemostaseology assistants). 36% treated only adult PWH, 16% only paediatric PWH and 48% treated both. HCPs were treating PWH since 15.5±6.7 years (range 9-30). Based on the content validity ratio (CVR ≥0.440) four questions of the Veritas-PRO domains 'timing', 'planning', 'dosing' and 'communicating' (e.g., "*I call the treatment center when I have questions about hemophilia or treatment*") and seven questions of the Veritas-PRN domains 'treating', 'dosing'

(e.g. "*I infuse the prescribed dosage for bleeds*"), 'planning', and 'communicating' were considered "very important" by HCPs for use in Germany. HCP suggested adding a variety of questions concerning substitution diary, visits and commun-ication with HTC, etc. In general, questions concerning novel therapies were missing.
Summary/Conclusion: The evaluation has proven that there is a need of an appropriate adherence instrument different from the US ones applicable for the health care system in Germany.

PS1444

HEALTH-RELATED QUALITY OF LIFE (HRQOL) IN PEDIATRIC PATIENTS WITH RED CELL PYRUVATE KINASE DEFICIENCY

P. Klothaki[1,*], R. Grace[2], S. Eber[3], M. Wlodarski[4], J. Kunz[5], P. Bianchi[6], E. Fermo[7], S. Burdach[8], O. Andres[9], M. Nathrath[1], N. Kollmar[1]

[1]Pädiatrische Hämatologie und Onkologie, Klinikum Kassel, Kassel, Germany, [2]Dana-Farber Boston Children´s Cancer and Blood Disorder Center, Boston, United States, [3]Praxis für Kinder und Jugendmedizin, Munich, [4]Pädiatrische Hämatologie und Onkologie, Universitätsklinik Freiburg, Freiburg, [5]Pädiatrische Hämatologie und Onkologie, Universität Heidelberg, Heidelberg, Germany, [6]Fondazione IRCCS Ca´Granda, Ospedale Maggiore Policlinico, [7]Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico , Milan, Italy, [8]Medizinische Fakultät, Technische Universität München, Munich, [9]Erythrozytenlabor Universitäts-Kinderklinik Würzburg, Universitäts-Kinderklinik Würzburg, Würzburg, Germany

Background: Pyruvate kinase deficiency (PKD) is the most common enzymopathy of anaerobic glycolysis in erythrocytes. PKD is a rare autosomal recessive disease with a prevalence of 1 in 20.000 people causing a hereditary non- spherocytic hemolytic anemia (Zanella *et al.* 2005). There are no published studies concerning health-related quality of life (HRQoL) in patients with PKD.
Aims: This study describes HRQoL in children with PKD in Germany.
Methods: 16 pediatric patients with compound heterozygous or homozygous PKD who participated in Germany in the PKD Natural History Study were included in the analysis. The German version of the PedsQL 4.0 (Pediatric Quality of Life) questionnaire was used to assess HRQoL. The patients were divided into 3 groups according to age in years: 2-4 (n=8), 5-7 (n=2), 8-18 (n=6). 63% of the patients (n=10) had severe anemia (Hb< 8 g/dl), 4% (n=1) moderate anemia (Hb 8-10 g/dl) and 33% (n=5) mild anemia (Hb 10-12 g/dl). The questionnaire was answered by all children ages≥5 years and by parents of children of all ages. The answers were transformed into a score from 0 to 100 (with 100 representing the best HRQoL) and were compared using the Mann-Whitney Test. PedsQL≥81 is considered an indicator of a good HRQoL, 61-80 intermediate HRQoL and ≤60 poor HRQoL (Beverung *et al.* 2015).
Results: The mean parental PedsQL scores of all 16 children were 79.10 (range: 0-100) in the physical- and 79.81 (range: 21.15 -100) in the psychosocial health summary score.
The mean PedsQL scores of children≥5 years were 89.45 (range: 78.13 - 100) in the physical - and 84.10 (range: 63.33 -100) in the psychosocial health summary score. These were not significantly different in comparison to the mean scores given by their parents (83.59, range: 46.86-100 in the physical, p=0.42- and 81.02, range: 43.33-93.33 in the psychosocial health summary score, p=0.13), with the mean scores suggesting a good HRQoL. 63% (n=5) of the children in this group had mild- and 37% (n=3) severe anemia. The mean PedsQL scores reported by the parents of children <5 years were not significantly different than parental report of children ≥ 5 years (74.60, range: 59.3-100, versus 83.59, range: 46.86-100 in the physical, p=0.28 - and 78.60, range: 21.15-100, versus 81.02, range: 43.33-93.33 in the psychosocial health summary score, p= 0.33). The mean parental PedsQL scores of children <5 years are consistent with an intermediate HRQoL. 88% (n=7) of children < 5 years had severe- and 12% (n=1) moderate anemia.
Summary/Conclusion: This is the first study concerning HRQoL in pediatric patients with PKD. Using the PedsQL 4.0, mean child reported scores are consistent with a good HRQoL and parental scores are consistent with an intermediate HRQoL. Parents of children≥5 years give higher scores than parents of children <5 years. Given the severity of anemia in the children in this study, the PedsQL measure may not sufficiently detect the symptoms and impacts of children with PKD. Future studies of disease specific HRQoL measures may be helpful in detecting the impact of this rare anemia in children.

PS1445

QUALITY OF LIFE IS REDUCED IN PATIENTS WITH (SUSPECTED) PLATELET FUNCTION DISORDERS

M. Blaauwgeers[1,*], I. van Asten[2], A. Huisman[2], S. Korporaal[2], M. Coppens[3], M. Kruip[4], E. Beckers[5], J. Eikenboom[6], R. Tamminga[7], R. Urbanus[2], R. Schutgens[1]

[1]Van Creveldkliniek, [2]Clinical Chemistry and Haematology, UMC Utrecht, Utrecht, [3]AMC, Amsterdam, [4]Erasmus MC, Rotterdam, [5]Maastricht UMC, Maastricht, [6]LUMC, Leiden, [7]UMCG, Groningen, Netherlands

Background: Platelet function disorders (PFDs) are rare bleeding disorders, characterized by mucocutaneous bleeding and prolonged bleeding after surgery or childbirth. Repeated bleeds throughout life can have a significant impact on health related quality of life (HR-QoL). Studies investigating HR-QoL in patients with PFDs are limited.
Aims: To determine HR-QoL in patients with (suspected) PFDs and to assess the association between bleeding severity and HR-QoL.
Methods: Adult patients with an increased bleeding tendency, suspected for having a PFD, were included in a nationwide cross-sectional study on PFDs ('Thrombocytopathy in the Netherlands'). All participants gave written informed consent. HR-QoL was assessed using the Short Form (SF)-36 survey, including 8 domain scores ranging from 0 to 100 (optimal). Bleeding symptoms were evaluated using the ISTH Bleeding Assessment Tool (BAT), resulting in a bleeding score (BS, range 0-48 for men, 0-56 for women). Mann Whitney U test was used to compare SF36 domain scores to the general Dutch population scores. Multivariate regression analysis was used to assess the association between BS and HR-QoL.
Results: A total of 159 patients were included of whom 129 (81%) were female. The males and females had a median age of 46 (interquartile range 32-61) and 41 (interquartile range 31-55), respectively. The median BS for males and females was 9 (interquartile range 5-13) and 10 (interquartile range 8-14), respectively. Ninety-seven patients (61%) had an objective platelet function defect based on platelet function testing. Compared to the general population, patients with a (suspected) PFD showed significantly lower ($p<0.05$) scores on all domains of the SF36 except the domain role emotional. HR-QoL was not significantly different between patients with an objective platelet function defect and those with normal results. A higher bleeding score, indicating a more severe bleeding phenotype, was associated with a lower score on the domains physical functioning, role limitations due to physical functioning and general health perception ($p<0.05$).
Summary/Conclusion: Patients with PFDs have a lower HR-QoL as compared to the general Dutch population. HR-QoL is not significantly different between patients with and without an objective platelet function defect, indicating that an increased bleeding tendency has a significant impact on QoL, regardless of an objective explanatory diagnosis. A more severe bleeding phenotype was associated with a lower HR-QoL score on most of the physical domains of the SF-36.

PS1446

PALLIATIVE CARE INDICATION IN ONCOHEMATOLOGIC PATIENTS: A COMPARISON TO SOLID TUMOR PATIENTS

L. Morais[1,*], M. Diaz-Valdes[2], A. Pola[2], S. Bernal[2], S. Alonso-Alvarez[1], E. Colado[1], T. Bernal[1,2]

[1]Servicio de Hematología, Hospital Universitario Central de Asturias, [2]Departamento de Medicina, Universidad de Oviedo, Oviedo, Spain

Background: In spite of recent diagnostic and treatment progress, the prognosis of elderly patients diagnosed of acute myeloid leukemia or higher-risk myelodysplastic (AML-MDS) syndrome remains dismal; even in those patients who are fitted enough to receive chemotherapy or hypomethylating agents, median survival is near 12 months. According to actual end-of-life care (EOL) standards, this population should receive early palliative care (PC), integrated with standard oncologic care. Conversely, recent evidence shows and excess of aggressiveness in this population. The reasons of this need to be determined, but it is suggested that poor performance status and transfusion dependency of hematological patients are barriers that restrict the applicability of palliative care.
Aims: To compare EOL care in AML-MDS and stage-IV lung cancer in a tertiary care center and identify factors related to late or no palliative care (PC) referral.
Methods: Consecutive AML > 65 years and stage-IV lung cancer patients were studied. Data is shown as percentage or median (interquartilic range). Univariant comparisons of the main indicators of EOL aggressiveness between the 2 cohorts were done using Chi-square or Wilcoxon tests as

appropriate. Survival was calculated from diagnosis to death or last follow up using Kaplan-Meier curves and log-rank tests.
Results: From 1st June 2006 to 8th February 2017, 77 patients with AML-MDS and 98 stage-IV lung cancer patients were recorded. Median age at diagnosis was 75 (70-79) and 63 (59-71) years respectively (p<0.001). There were no differences in gender or ECOG. Number of comorbidities according to the Charlson comorbidity index were 1 (0-2) vs 2 (1-3), (p=0.02). Regarding first line therapy, 21% AML-MDS were treated with chemotherapy, 64% with hypomethylating agents and 15% with supportive care exclusively. Fourteen patients received second line therapy for progression or relapse after first response. Of them, 10 patients received chemotherapy and 3 hypomethylating agents. There were no differences in survival between the 2 cohorts (AML-MDS 13[10-19] vs 12[9-19] months form AML-MDS and lung cancer respectively, p=0.37). Discussion between patients and physician about prognosis was documented in 29% AML-MDS patients as opposed to 85% lung cancer patients (p<0.001). There were no statistical differences regarding the frequency of hospital admissions, days spent in hospital or the proportion of patients receiving chemotherapy within the 14 last days of life. However, more AML-MDS patients were admitted into hospital in their last month of life (86 vs 44%, p<0.001). More AML patients were transfusion dependent and received more red blood cells or platelet transfusion in their last 2 months of life. (75% vs 3%, p<0.0001.) Referral to PC Unit was documented in 19% LAM-MDS compared to 48% lung cancer patients (p<0.001).
Summary/Conclusion: Although transfusion dependency is a major need of AML patients, rate of referral to palliative care unit is disproportionately low, indicating the need of earlier PC referral.

PS1447

COST PER MEDIAN MONTH OF PROGRESSION-FREE SURVIVAL FOR DARATUMUMAB PLUS BORTEZOMIB AND DEXAMETHASONE COMPARED WITH CARFILZOMIB PLUS DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

E. Maiese[1,*], C.N. Graham[2], E. Hawe[3], J.-G. Le Moine[3]

[1]Janssen Scientific Affairs LLC, Horsham, PA, [2]RTI Health Solutions, Research Triangle Park, NC, United States, [3]RTI Health Solutions, Manchester, United Kingdom

Background: New treatments for relapsed/refractory multiple myeloma have recently been FDA approved in the United States (US). For FDA approval, these treatments are compared to historic standards of care in randomized controlled trials (RCTs), therefore, limited information regarding safety/efficacy comparisons between newer treatments is available to utilize in comparisons of costs.
Aims: We sought to compare the average cost per median month of progression-free survival (PFS) for daratumumab plus bortezomib and dexamethasone (DVd) compared with carfilzomib plus dexamethasone (Kd) in patients who have received at least one prior line of therapy.

Table 1. Results.

Cost Category	DVd	Kd
Total drug acquisition	$183,903	$161,753
Total adverse event	$4,616	$3,265
Total administration	$7,237	$5,393
Total Costs	**$195,755**	**$170,411**
Calculated median PFS (months)	**16.9**	**10.0**
Cost per median month of PFS	**$11,597**	**$16,984**

Methods: PFS for DVd was estimated via parametric survival analysis of patient-level data from the CASTOR RCT. PFS for Kd was estimated by applying the PFS hazard ratio (HR) for DVd vs. Kd (HR=0.59), calculated through a network meta-analysis (NMA), to the best-fit DVd PFS curve. Treatment duration was estimated by applying the ratio of median duration of treatment and reported median PFS from the trials to the median PFS calculated via the survival analysis and NMA. HRs, dosing amounts, dosing schedules, relative dose intensity, and adverse event (AE) incidence were extracted from the CASTOR and ENDEAVOR RCTs. Wholesale acquisition costs and administration costs were based on standard US sources. AE costs were sourced from published literature.
Results: Median PFS estimates from the analysis for DVd and Kd were 16.9 and 10.0 months, respectively. Total costs were similar between the two treatments. However, average cost per median month of PFS was lower for DVd than for Kd. Results are presented in Table 1.
Summary/Conclusion: Based on this analysis, average monthly cost per median month of PFS is lower for DVd compared to Kd in the treatment of multiple myeloma patients with at least one prior line of therapy.

PS1448

EFFICACY AND SAFETY OF FACILITATED SUBCUTANEOUS IGG ADMINISTRATION IN PATIENTS WITH SECONDARY IMMUNODEFICIENCY DUE TO HEMATOLOGICAL MALIGNANCIES. A SINGLE-CENTER RETROSPECTIVE ANALYSIS

M. Dimou[1,*], T. Iliakis[1], D. Maltezas[1], A. Bitsani[1], S. Kalyva[1], S. Kotsanti[1], A. Koudouna[1], P. Petsa[1], P. Papaioannou[1], M.-C. Kyrtsonis[1], P. Panayiotidis[1]

[1]1st Propedeutic Internal Medicine Clinic, Medical School of Athens, Laikon General Hospital, Athens, Greece

Background: Hematologic malignancies are often complicated by secondary immunodeficiency(SID), namely hypogammaglobulinemia, the cause of common and opportunistic infections. Immunoglobulin replacement with intravenous gamma globulin administration(IVIg) reduces the number of infections, antibiotics' need and hospitalization days. The subcutaneous(sc) route of IgG is equally effective, with certain constraints (reduced bioavailability, multiple injection sites, frequent infusions). The facilitated sc IgG(fSCIg) method uses the action of recombinant human hyaluronidase(rHuPH20) and has been studied in primary immune deficiency(PID) syndromes with similar efficacy to IVIg, with several advantages (self-administration, same bioavailability, long infusion intervals, few adverse drug reactions-ADRs). fSCIg has been less extensively studied in SID.
Aims: We present our retrospective single-center data from fSCIg administration in SID of hematological patients, focusing on safety and efficacy issues.
Methods: Thirty-three hematological patients with SID have been treated with fSCIg, according to ESMO 2015 guidelines, between mid-October 2015 and mid-January 2018. Baseline patients' characteristics are shown in Table 1.

Table 1. Baseline patients' characteristics.

Patients	n=33 (16 female, 17 male)
age	66,1 yr. (38-88)
type of preexisting hematologic malignancy	• CLL (n=25) • Multiple Myeloma (n=3) • B- Non-Hodgkin Lymphoma (n=3) • Hodgkin's Lymphoma (n=1)
disease treatment status before fSCIg initiation	• treatment naive (n=5 all CLL pts) • pretreated (n=28), prior treatment lines: 3(1-7)
IgG replacement before fSCIg initiation	n=13, all with IVIg median time on IVIg 26,2 months (6,2-82,2)
median IgG levels before fSCIg initiation	• pts on IVIg (n=13): 532 mg/dL (80-982) • IVIg naive pts (n=18): 403,5 mg/dl (102-632) (trough IgG levels)
Infections during the last 12 months before fSCIg initiation	7 pts (all on IVIg): no infectious episode 26 pts* (6 on IVIg, 20 without IVIg) • 15 cases with recurrent lower respiratory tract infections • 7 cases with recurrent upper respiratory tract infections • 3 cases with recurrent kidney infections • 2 cases with recurrent soft tissue infections • 1 case with multiple Herpes zoster reactivation episodes *: pts may have presented more than one type of infection

Treatment goal was IgG trough levels around 600 mg/dL. fSCIg(10% IgG) dosage was 0.4-0.8 mg/Kg/month. Treatment modifications were made according to infection occurrence. fSCIg was given with a variable rate portable pump and a sc 24G needle . First, patients were treated with rHuPH20 (1-2 ml/min). Ten min after rHuPH20, fSCIg(10%) was infused through the same sc needle, at the same injection site. The rate of the 1st fSCIg infusion was gradually increased from 10 ml/min to 300 ml/min. If well tolerated, patients were treated with the rate of 300 ml/min for all subsequent infusions. The first 4 infusions took place at our department and the patients/relatives were instructed how to use the pump. The subsequent infusions took place at patients' home.

Results: Between mid-October 2015 and mid-January 2018, 33 patients have been treated at our department with fSCIg(10%). Four hundred forty-four uncomplicated infusions were administered. Median number of infusions:11(2-31), median time of follow-up: 11,2 months(0,5-27). Available trough IgG levels at various time points are shown in Table 2. Thirty-two (97%) patients were able either to self-administer the formulation or to be treated by the aid of a relative after the 4th training session. Six patients (18,1%) presented at least 1 infection while on fSCIg. Four patients: an episode of lower tract infection, 1 patient: an episode of nail infection of a lower extremity and 1 patient: a flu-like infection and a dermal infection. All 6 patients had IgG levels <600 mg/dL at the time of infection. They started receiving fSCIg in shorter time intervals(q3W). There was no infection after this modification. Three patients(9%) presented mild ADRs(grade 1): low grade fever/headache the evening of the 1st and/or 2nd fSCIg infusion. Among the 444 fSCIg infusions, 298 took place outside hospital facilities, at patients' home.

Table 2. Madian IgG trough level at several time points of fSCIg administration.

month of treatment	IgG trough levels (mg/dL)
3rd (n=21)	787 (231-1254)
6th (n=17)	945 (664-2760)
12th (n=14)	789 (476-1290)
24th (n=5)	895 (497-1350)

Summary/Conclusion: Our retrospective single-center data from fSCIg administration in hematological patients with hypogammaglobulinemia and recurrent infections show that this method is very effective in reducing infections, with few ADRs. These findings compare favorably to those observed with IVIg method. Finally, fSCIg method manages to reduce the everyday nursery/hospital burden of a tertiary hospital.

PS1449

IMPACT OF LOW GRADE ADVERSE EVENTS OF TYROSINE KINASE INHIBITORS ON THE QUALITY OF LIFE OF PATIENTS TREATED FOR CHRONIC MYELOID LEUKEMIA

B. Sidi Mohamed El Amine[1,*], H. Asma[1], O. Fouzia[1], S.A. Nadjet[1], C. Malika[1], B. Soraya[1], Z. Zahia[1]

[1]Universitary Hospital of Sidi Bel Abbés, Sidi Bel Abbes, Algeria

Background: Patients with chronic myeloid leukemia (CML) have a better life expectancy after treatment with a tyrosine kinase inhibitor (TKIs). The possibility of adverse events (AEs) with long-term treatment may result in dose adjustments and discontinuation of therapy, or non-adherence, which may negatively affect treatment efficacy and patients' quality of life (QoL).
Aims: The aim of our work is to identify low grade AEs of TKIs and their impact on QoL of patients with CML.
Methods: Data of 79 patients with CML were analyzed. We used the FACT-Leu questionnaire, which is a validated tool for assessing QoL during leukemia treatment.
Patients were seen either at day hospital or during biological evaluations and clinical controls. The low grade of TKIs were reported at each control and then grouped according to their severity, using the NCI CTCAE terminology (version 3.0). The correlation between low grade AEs and QoL scores was assessed using the Spearman test. The ANOVA test was used to determine the change in QoL depending on the grade of TKIs side effects.
Results: Of the 79 patients, 30 (38%) experienced side effects with TKIs, with dose adjustments in 15 (19%) patients, and therapeutic discontinuation in 8 (10%). According to NCI CTCAE terminology, AEs were of grade 1 in 8 (10%) patients, and grade 2 in 8 (10%) others. The average FACT-Leu QoL score for all patients who received TKIs was 129 [84-170], lower in patients with low grade AEs (118 [87-155]) , but higher for those without AEs: 135 [84-170]. The FACT-Leu QoL score was correlated with the appearance of a TKI related low grade AEs (p=0.01). The ANOVA showed a variability in the FACT-Leu score based on severity of TKIs side effects (p=0.04).
Summary/Conclusion: This study shows that low grade AEs of TKIs can alter QoL of patients treated for CML. Their impact as well as other factors must be taken into account for the optimal treatment of newly diagnosed CML patients.

Sickle cell disease

HEME-INDUCIBLE LIPID OXIDATION PATTERN SUPPORTS MONITORING OF CELL-FREE HEMOGLOBIN ACTIVITY IN PATIENTS WITH SICKLE CELL DISEASE

J. Deuel[1,2,*], S. Di Palma[3], A. Yalamanoglu[4], B. Paul[4], S. Dominik[1]

[1]Division of Internal Medicine, [2]Division of Haematology, University Hospital of Zurich, [3]Functional Genomics Center Zurich FGCZ, University of Zurich, Zürich, Switzerland, [4]Laboratory of Biochemistry and Vascular Biology, DBCD/ OBRR/ CBER FDA, Silver Spring MD, United States

Background: Sickle cell disease (SCD) is a genetic disease based on a hemoglobinopathy leading to sickling of red blood cells in the circulation. This phenomenon leads to a state of chronic hemolysis as well as to occasional sickle cell crises with accelerated release of cell-free hemoglobin (Hb) into plasma. Low density lipoprotein (LDL) is a lipid transport particle present at relatively high levels in human and oxidized LDL (oxLDL) is supposed to be a driver of pathology in a number of vascular diseases. The lipid core of LDL is composed of a range of different lipid classes with unsaturated and thus oxidation-prone species. Due to its specific characteristics, LDL appears to represent an interesting indicator-compartment to monitor Hb-driven lipid-oxidation in hemolytic diseases.
Aims: To characterize a specific plasma-lipid oxidative pattern as a biomarker of Hb-driven pathology in SCD-patients.
Methods: We developed a novel mass spectrometry (MS) method to *de novo* identify and quantify oxidized lipid species by detecting unique features of lipid oxidation. We used this method to characterize the degree of LDL oxidation in 10 SCD patients by comparing the oxidation-pattern to control patients without hemolytic disease. To extract and correlate a heme/Hb induced LDL oxidation pattern, guinea pigs were infused with cell-free Hb. LDL was harvested from these animals and oxidized LDL characterized and quantified with the same MS-based method.
Results: By infusing free Hb into guinea pigs, we could reproducibly induce a specific pattern of LDL oxidation. A highly similar pattern was detected very pronounced in half of the SCD patients studied. None of the control patients showed significant LDL oxidation (Figure 1).

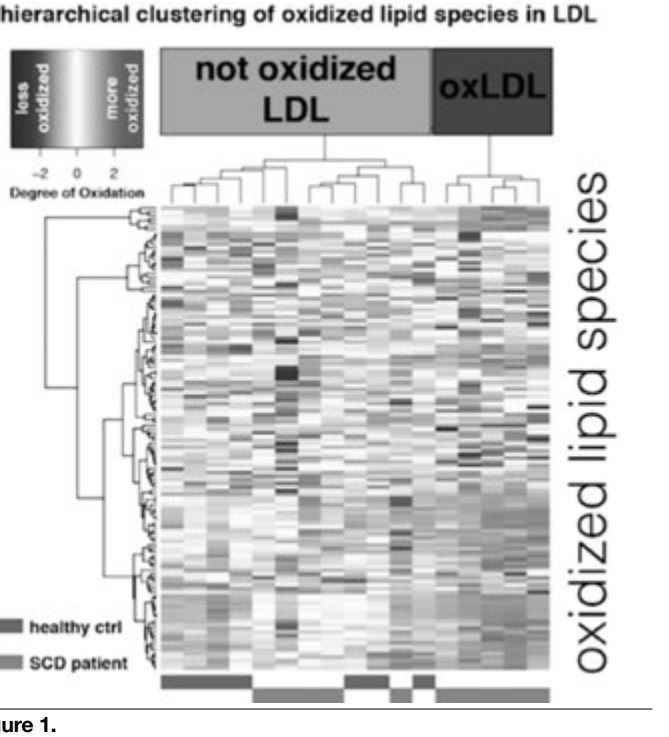

Figure 1.

Summary/Conclusion: We characterized a Hb-induced plasma-lipid oxidation pattern, which may serve as a biomarker for hemolysis-driven pathology in patients with sickle cell disease and other hemolytic conditions.

PS1451

COMPLEMENT ACTIVATION IN HOMOZYGOUS SICKLE CELL DISEASE PATIENTS IS MODULATED BY HYDROXYUREA

L. Roumenina[1,*], P. Chadebech[2,3,4], G. Bodivit[2,3,4], P. Vieira-Martins[5], L. Kiger[6], A. Jouard[2], F. Pirenne[2], F. Galactéros[7], V. Frémeaux Bacchi[5], P. Bartolucci[3,7,8]

[1]INSERM UMRS1138 Cordeliers Research Center, INSERM UMRS1138 Cordeliers Research Center, Paris, [2]Etablissement Français du Sang, Hôpital Henri-Mondor, [3] UPEC, INSERM U955 Team [2] and IMRB (Institut Modor de Recherche Biomédicale), Créteil, [4]Laboratoire d'Excellence GR-Ex, [5]Service d'Immunologie Biologique, Hôpital Européen Georges Pompidou, Assistance Publique – Hôpitaux de Paris, Paris, [6]INSERM U955, team [2], [7]Sickle Cell Referral Center, Service de Médecine Interne, Hôpital Henri-Mondor, Créteil, [8]Laboratoire d'Excellence GR-Ex, Paris, France

Background: Markers of alternative complement pathway activation have been detected in patients with sickle cell disease (SCD). The mechanism of this process is poorly understood, and could be related to complement activation at the surface of sickle red blood cells or by hemolysis-derived products. Altered membrane phospholipids exposure on sickle erythrocytes was shown to mediate complement activation. However the progression of the complement cascade to its terminal steps and its modulation by hydroxyurea have never been studied in a cohort of SCD patients.
Aims: The objective of this study was to screen for plasmatic complement biomarkers in a cohort of SCD patients, treated or not with hydroxyurea.
Methods: Blood samples were obtained from homozygous SCD patients followed in our Sickle cell referral center after receiving their written consent. Two groups were constituted according to treatment: Hydroxyurea (HU) and untreated (CT). Exclusion criteria were secondary causes of complement activation, transfusion in the 3 last months, or pregnancy. Steady state was defined as >1 month after a vaso occlusive crisis or acute event. Plasma samples were collected and stored frozen for exploration of complement. Plasmatic C3, C4 and Factor H protein levels, CH50 activity, soluble sC5b-9 and presence of anti-Factor H autoantibodies were screened. Membrane expression of CD55 and CD59 was measured on erythrocytes. All samples were analyzed at the French Sickle Cell Referral Center and at the French complement referral laboratory. The normal upper value of C5b9s was 450 ng/ml. Results are expressed as medians with [interquartile range] or percentages. Mann Whitney non parametric test, and Chi² test where used for comparison between HU and CT; Pearson's correlation coefficients were computed to assess the relationship between sC5b9 and collected biological parameters.
Results: Seventy two patients were included, 3 patients were secondary excluded due to positivity for anti-Factor H antibodies. Sixty nine patients were analyzed, with a median age of 31.4 years [23.7-40.7]; 27/69 patients were treated by HU, with similar age in HU and CT patients, (29.9 and 33 years, respectively). sC5b9 was abnormally high (>450 ng/ml) in 46 patients (66%), without significant difference between VOC (9/69) and steady state (respectively 741 and 611 ng/ml). In the group of patients treated by HU the abnormal complement activation was less frequent compared to CT patients (52% vs 76%, p=0.03) with significantly lower levels of sC5b9 (457 vs 812, p=0.04). There was no difference in CD55 or CD59 that could explain the difference between groups. Linear regression showed that sC5b9 increase was associated with lower hemoglobin concentration in the HU group (p=0.05) and higher% dense red blood cells (DRBC) (p=0.04) which present higher HbS concentration and polymerization levels. No correlation was found with LDH or HbF values.
Summary/Conclusion: Our results show that terminal complement activation is common in SCD. HU treatment, known to decrease the hemolysis level and%DRBC, decreased significantly the complement activation in association with increase of hemoglobin. Mechanisms of complement modulation by HU are not elucidated but could be related to the%DRBC decrease. Further studies are necessary to evaluate the complement activation relationship with chronic organ damages, known to be associated with hemolysis and DRBC.

PS1452

THE OXYGENSCAN: CONTINUOUS MEASUREMENT AND QUANTIFICATION OF SICKLING DURING DE- AND REOXYGENATION TO MONITOR DISEASE SEVERITY AND TREATMENT EFFECT IN SICKLE CELL DISEASE

M. Rab[1,2,*], B. van Oirschot[1], T. Merkx[1], A. van Wesel[1], S. Hendriks[3], J. de Zoeten[3], O. Abdulmalik[4], M. Safo[5], B. Versluijs[6], R. Schutgens[2], G. Pasterkamp[7], E. van Beers[8], R. van Wijk[9]

[1]Department of Clinical Chemistry and Haematology, [2]Van Creveldkliniek, University Medical Center Utrecht, Utrecht, [3]RR Mechatronics, Zwaag, Netherlands, [4]Division of Hematology, The Children's Hospital of Philadelphia, Philadelphia, [5]Medicinal Chemistry, Institute for Structural Biology, Drug Discovery and Development, School of Pharmacy, Virginia Commonwealth University, Richmond, United States, [6]Pediatric Hematology, [7]Laboratoy of Clinical Chemistry and Haematology, University Medical Center Utrecht, [8]Van Creveldkliniek, University Medical Center, [9]Laboratory of Clinical Chemistry and Haematology, University Medical Center Utrecht, Utrecht, Netherlands

Background: In sickle cell disease (SCD) a single point mutation in the gene encoding for beta-globin chain underlies the production of the abnormal hemoglobin S (HbS). Upon deoxygenation HbS can polymerize, resulting in sickling of red blood cells (RBCs). These sickled RBCs have strongly reduced deformability, leading to vaso-occlusive crises and chronic hemolytic anemia. To date, there are no laboratory parameters or assays capable of predicting disease severity or directly monitoring treatment effects.
Aims: To develop and validate the Oxygenscan: a new method to investigate RBC deformability as a function of oxygen tension and thereby quantify sickling behavior in patients with SCD.
Methods: Red blood cell deformability (expressed as Elongation Index – EI) was measured as a function of oxygen tension by ektacytometry using the Laser Optical Rotational Red Cell Analyzer (Lorrca, Zwaag, The Netherlands). This 'Oxygenscan' measures EI during one round of deoxygenation (nitrogen gas) followed by reoxygenation while exposed to a fixed shear stress of 30 pascal. Main Oxygenscan read out parameters were defined as follows (Figure 1A): EImax: maximum elongation during deoxygenation, EImin: minimum elongation after deoxygenation, ΔEI: difference between EImax and EImin, Point of Sickling (POS): pO2 (mmHg) at which >5% decrease in EI during deoxygenation is observed. Blood samples of SCD patients and healthy controls were used to validate the technique.

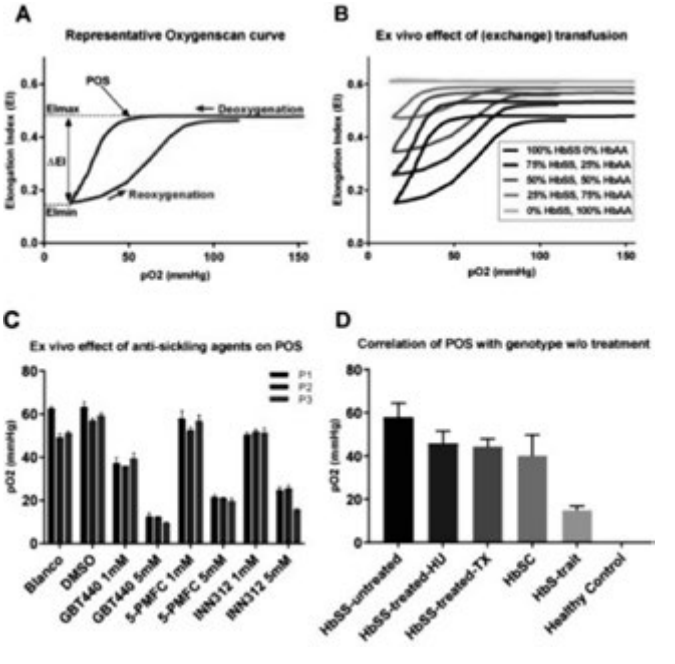

Figure 1.

Results: Oxygenscan curves were highly reproducible with a coefficient of variation (CV) below 5% for all four main parameters. See Figure 1A for a representative example. When whole blood from SCD patients (n=3) was mixed in various proportions with a ABO compatible healthy control blood sample the Oxygenscan curve accordingly shifted upwards towards normal, with a most pronounced effect on EImin and ΔEI, data of 1 patient is shown in Figure 1B. Multiple Oxygenscan variables were related with HbS% but with a linear correlation of r= 0.998 (p=0.00013) in this patient, EImin was the strongest one. This suggests that exchange transfusion primarily effects EImin. Notably, RBCs from healthy control blood samples show no change in EI during de-/reoxygenation. POS likely reflects directly the properties of an individual patient's hemoglobin dissociation curve. When factors that influence the dissociation curve were altered, e.g. temperature and pH, a shift in POS was observed. ΔEI appears to reflect the tendency of an individual patient to sickle as it increases upon higher temperatures and lower pH. Upon *ex vivo* exposure to anti-sickling agents, altering the oxygen affinity of hemoglobin, a left-shift of the POS was observed, indicating improved

deformability at lower oxygen tensions (Figure 1C). In addition, a substantial decrease in ΔEI was observed, suggesting less cells are able to sickle. When RBCs from 19 SCD patients with different genotypes and treatment regimens (homozygous SCD (HbSS), untreated, n=5; treated with hydroxyurea (HU), n=4; or with exchange transfusion (TX), n=3; compound heterozygous for HbC and HbS, n=3, heterozygous HbS, n=4; healthy controls, n=5) were analyzed the POS was highest in untreated HbSS patients (Figure 1D). Treatment with either HU or TX caused a decrease in the POS, and an increase in EImax and EImin.
Summary/Conclusion: The Oxygenscan brings the sickling assay to a new level with unparalleled repeatability, and with multiple parameters that quantify different aspects of sickling biology. We suggest that the Oxygenscan can be used to assess an individual patient's disease severity and monitor treatment effect.

PS1453

VOXELOTOR DOSE EXTRAPOLATION IN A PHASE 3, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY IN PEDIATRIC PATIENTS WITH SICKLE CELL DISEASE (GBT440-032, HOPE KIDS 2)

C. B. Washington[1,*], B. Goldstein[1], S. Dixon[1], C. Hoppe[2], R.E. Ware[3], J. Lehrer[1]

[1]Global Blood Therapeutics, South San Francisco, CA, [2]UCSF Benioff Children's Hospital Oakland, Oakland, CA, [3]Cincinnati Children's Hospital, Cincinnati, OH, United States

Background: The phase 3 HOPE Kids 2 study (GBT440-032) design includes a novel approach to determine initial voxelotor dosing in pediatric patients aged 9 months to <12 years with sickle cell disease (SCD). The dosing strategy is based on population pharmacokinetics (PPK), physiologically based PK (PBPK) modeling, and dose extrapolation from studies of voxelotor in adults and adolescents (12 to <18 years old). PBPK modeling is considered a "bottom-up" approach as it uses patient-specific parameters (eg, anatomy, physiology, and pathophysiology) and drug-specific data (eg, absorption and metabolism). In pediatrics, PBPK models provide an opportunity to integrate known developmental changes in organ function to predict drug disposition and PK exposures across age groups. Extrapolation of data from adults to children is an important emerging tool in pediatric drug development and regulatory decision making and allows for the use of fewer patients in trials.
Aims: Currently, dose selection for the phase 3 HOPE adult and adolescent study is evaluating 2 doses, 900 mg and 1500 mg, for final dose selection. One or both doses may be used. The phase 3 HOPE Kids 2 study will use the final selected dose(s) from HOPE to provide equivalent voxelotor exposures in infants and children.
Methods: Planned PK data collection will confirm exposures in infants and in children and validate the PK and PBPK models. Clinical events (eg, vaso-occlusive crises, spleen loss, dactylitis, sepsis, aplastic crisis, stroke, and silent infarcts) will also be analyzed via PK/pharmacodynamic modeling.
Results: Based on existing data, including PK data from adults, adolescents, and children (6 to <12 years of age), the PPK models for voxelotor in whole blood and plasma are 2-compartment models with first-order absorption and elimination. Simulations based on age-based and weight-based groups were compared. Although age-based groups were able to maintain the older pediatric groups (2 to <6 years and 6 to <12 years) within the target range of exposures, lower or higher weight patients within those groups were likely to fall outside the target exposure range. Baseline body weight was a statistically significant covariate on volume and clearance in the pooled analysis. Therefore, current models support a weight band-based dosing approach based on PPK and PBPK, both of which resulted in similar extrapolated dosing schemes for children (Table 1). Once a larger pediatric dataset is available, a covariate analysis will be conducted to evaluate other potential covariates (eg, age, sex, baseline hemoglobin, and concomitant hydroxyurea use) on voxelotor whole blood and plasma exposures.

Table 1.

Voxelotor Projected Doses for Children Based on PPK and PBPK Modeling

Population Weight Band	900 mg-Equivalent Adult Dose*	1500 mg-Equivalent Adult Dose*
5 to <10 kg	200 mg	400 mg
10 to <20 kg	400 mg	600 mg
20 to <40 kg	600 mg	900 mg
≥40 kg	900 mg	1500 mg

*Note that the 900 mg, 1500 mg, or both doses may be used in the HOPE Kids 2 study.

Summary/Conclusion: The HOPE KIDS 2 trial uses a novel approach to identify a weight band-based voxelotor dosing regimen for infants and children with SCD which will help simplify dosing in the pediatric population.

PS1454

EARLY RECOGNITION OF THE SICKLING PROCESS OF ERYTHROCYTES BY LABEL-FREE LIGHT MICROSCOPIC IMAGING IN PATIENTS WITH SICKLE CELL DISEASE

I. Metze[1,*], F. Borges da Silva[2], K. Metze[3]

[1]Hematology - Hemotherapy Center, [2]University of Campinas, Campinas, Brazil, [3]Pathology, University of Campinas, Campinas, Brazil

Background: Fluorescence lifetime imaging microscopy (FLIM) is able to reveal physicochemical characteristics of the cells. In former works, we have shown with this technique that does not need staining, that it is possible to identify the lineage of immature hemopoietic precursors with this technique.
Aims: Sickle cell disease is characterized by hemoglobin polymerization in erythrocytes and FLIM could be able to recognize these conformational changes.
Methods: unstained air-dried peripheral blood smears of 32 patients with sickle cell diseases (23 cases homozygous SS, 4 cases Sβ, 3 cases Sαtal and 2 SC) and of 31 patients without hematologic disease were analyzed. Images were captured with a confocal Zeiss Upright LSM780-NLO microscope and single-photon counting equipment [Becker&Hickl] to acquire the FLIM images. Pseudo-colors according to the rainbow spectrum were attributed to different fluorescence lifetimes.
Results: Normal erythrocytes (Figure 2a) from the controls had short lifetimes (205.2±51.0 ps). Normally shaped erythrocytes in smears of homozygous SS patients (Figure 2b-d) had 183.3±36.1 ps, crenated erythrocytes had 272.5±74.1 ps and drepanocytes had 345.8±85.8 ps. Concerning mixed hemoglobinopathies normally shaped erythrocytes had 241.6±19.9 ps and drepanocytes had 390.3±68.3. Normally shaped erythrocytes were significantly different among the 3 groups p=0.004 although homozygous SS patients had lower values than mixed hemoglobinopathies. However, drepanocytes had similar values for all hemoglobinopathies. We could exactly localize the regions of higher lifetime values which are equivalent to areas of hemoglobin polymerization, when compared with electron microscopy (Figure 2e).

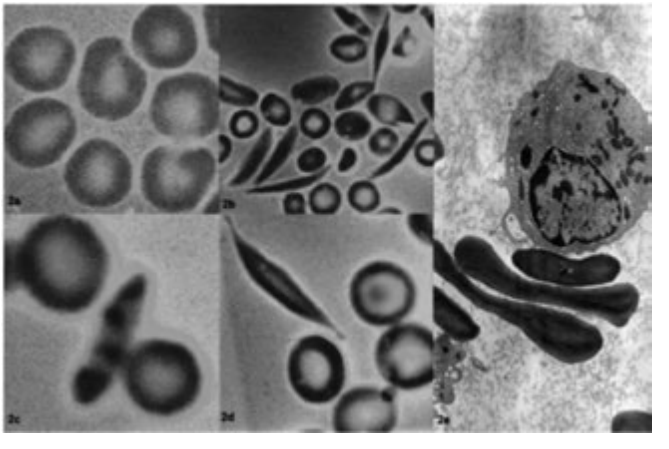

Figure 1.

Summary/Conclusion: The FLIM technique could show differences among normal cases and sickle cell diseases in normally shaped erythrocytes. It also could show increased lifetimes of hemoglobin autofluorescence in polymerized areas, thus demonstrating precisely the topographic distribution of polymerized hemoglobin.

SICKLE CELL DISEASE SEVERITY MEASURE: DEVELOPMENT, TRANSLATION, AND PATIENT CULTURAL SENSITIVITY VALIDATION

L. Burke[1], K. M. Fox[2], K. Bridges[3,*], M. Kraus[3], J. Lehrer[3], J. Hobart[4]

[1]LORA Group, LLC, Royal Oak, MD, [2]HealthiVibe, LLC, Arlington, VA, [3]Global Blood Therapeutics, South San Francisco, CA, United States, [4]Plymouth University Penin-

sula Schools of Medicine and Dentistry, Plymouth, United Kingdom

Background: Sickle cell disease (SCD) is an autosomal recessive disorder where polymerization of deoxygenated sickle hemoglobin leads to red blood cell sickling, hemolysis, anemia, fatigue, tissue ischemia, severe pain crisis, and organ damage, all of which lower quality of life. The Sickle Cell Disease Severity Measure (SCDSM) is a novel 9-item electronic patient-reported outcome (PRO) instrument designed to evaluate changes in SCD symptom burden-the first created in strict accord with US Food and Drug Administration (FDA) guidance for clinical trial endpoints. Subjective language use around pain and fatigue, the core symptoms of SCD, made the proper translation and cultural adaptation of the instrument paramount for the global phase 3 Hemoglobin Oxygen affinity modulation to inhibit sickle hemoglobin PolymErization (HOPE) trial (GBT440-031) of voxelotor (GBT440).
Aims: To translate and culturally adapt the SCDSM for use in the HOPE trial.
Methods: The SCDSM was developed to assess the core symptoms of SCD according to FDA requirements (21 CFR 314.126) in patients with SCD in the US and UK. Translation and cultural adaptation adhered to the guidelines of the International Society for Pharmacoeconomics and Outcomes Research. The SCDSM was forward-translated twice by in-country native speakers of the given language, with discrepancies between translations resolved during reconciliation. The SCDSM was then back-translated into English and reviewed against the original version of the PRO, with discrepancies addressed during harmonization. The cognitive debriefing interviews were conducted face-to-face, with in-country native speakers of the target language as translators. Five qualified respondents per target country/language provided feedback on the translated material. During the interviews, each item was discussed separately to determine whether the wording made items difficult to answer or understand, and whether the respondent would have phrased the text differently. Last, the cognitive debriefing results were reviewed and finalized.
Results: The penultimate SCDSM version comprised 10 questions that were reduced to a final set of 9 when cognitive debriefing showed ambiguity around 1 question between US and UK English speakers. Longitudinal evaluation during part A of the HOPE trial involved 2821 person-screening days in the total dataset and 2515 PRO completions. Patients completed 3 anchor questions daily to evaluate sensitivity to change and estimate meaningful change score. The SCDSM quantitated daily patient symptoms reliably and precisely and detected clinically meaningful symptom changes reliably and reproducibly. Symptom exacerbations were much more frequent than vaso-occlusive crisis events. The SCDSM was translated and culturally adapted into Dutch, French, Italian, German, Turkish, Arabic, Swahili, Twi, and Luo. High fidelity of translation and cultural adaptation was found for all languages irrespective of language root or the overarching social/economic milieu of a language. The validation of the SCDSM showed that it is appropriate for use in the languages spoken in the countries enrolling adolescents and adults with SCD in the HOPE trial.
Summary/Conclusion: The SCDSM is an instrument designed to capture core signs and daily symptoms of SCD. As language and its cultural equivalence present an important hurdle to PRO instrument use across cultures, the real-world experience of developing and adapting the SCDSM is a prototype for developing PROs that meet the FDA bar for trial endpoints across therapeutic areas.

PS1456

IMPROVEMENT OF THE MULTIDISCIPLINARY MANAGEMENT OF SICKLE CELL DISEASE PATIENTS: IMPLEMENTATION OF A SICKLE CELL DISEASE PATIENT'S CLINICAL DATABASE: BELGIAN REGISTER OF SICKLE CELL DISEASE PATIENTS

S. Wambacq[1], B. Gulbis[2,*], A. Ferster[1,3], L. Phu Quoc[1,4,5]

[1]Pediatric Hemato-Oncology, Hopital des Enfants Reine Fabiola, Brussels (Laeken), [2]Department of Clinical Chemistry, LHUB-ULB - Hôpital Erasme, Brussels, [3]Faculty of Medicine, ULB, Brussels (Laeken), [4]Faculty of Medicine, ULB, Brussels, [5]Peadiatrics, HIS, Brussels (Etterbeek), Belgium

Background: Sickle Cell Disease (SCD) is the most frequent genetic disease in the Brussels region, with a total amount of cases which is keeping on growing. The disease targets merely patients of African origin. This pathology has a low recognition and disease modifying therapies have been developed only in the last 20 years. The number of cases will increase due to reduction of mortality during childhood. We do not have reliable data on the demographical profile of the Sickle Cell Anemia population in Belgium, on the survival rate, amount and type of infections, frequency of follow up, amount of patients treated with hydroxyurea, chronic transfusion or bone marrow transplantations, number of transfusions, socio-economical situations and schooling. The exploitation of the existing clinical database (2008, financed by IRIS research) allowed major improvements and gives us unique data about mortality of the Sickle Cell Anemia patients as well as the benefit of the neonatal screening.[1]
This database included patients of eight centers. From 2008 until 2012 al available data were recorded retrospectively and prospectively. Data were registered from neonatal screening or from diagnosis (first contact) until last follow-up or death. Data included diagnosis, demography, and outcome data.
Aims: 1. To keep the data of the existing register and build a new register with a larger amount of participating institutes (national). 12 centers are included, and at least 3 more centers are candidate to participate. This will result in coverage of approximatively 90% of the Belgian SCD patients (approximatively 1000 cases). 2. To maintain a biological, clinical database of Sickle Cell Disease patients and improve knowledge and collaboration in Sickle Cell Disease. The register has been adapted in a new IRIS project with following aims : a) Follow up of mortality and morbidity; b) Keep a national surveillance tool to improve the prevention and screening of complications; c) Establish new recommendations based upon the collected results; d) Most important data easy accessible and visible; e) FAIR Data – SNOMED coded; f) Management of statistics; g) Easily operated. 3. The collected data will be used to have a continued and actual vision of the number of cases and to emit public health recommendations. The results will be published in an annual report. These data will be scientifically exploited and compared with international data. This observation and collection of data will endorse communication with the actors of public health, families, patient associations and authorities. The database is secured and respects the legal requirements of privacy (anonymized).
Methods: See aims.
Results: The Belgian SCD register is operational since March 2018 at https://www.drepano.be/drepano. In 2019 a first annual report of the registered data will be generated (Figure 1).

Figure 1.

Summary/Conclusion: We developed an easily operable database to improve of the multidisciplinary management of sickle cell disease patients. Finally, this database could serve as framework for other chronical pathologies. Later on it could be picked up in the framework of the registers of 'rare diseases', shared with other EU countries and be inter-operable with other platforms respecting the legal and privacy requirements.

PS1457

VARIATIONS IN COMPLICATIONS RELATED TO VASO-OCCLUSIVE CRISES AND HYDROXYUREA USE IN PATIENTS WITH SICKLE CELL DISEASE: OBSERVATIONS FROM STUDIES IN THE USA, SPAIN AND THE GULF REGION

E. Cela[1,*], Y. Wali[2], L. Bronte[3,4], L. Debonnett[5], M. Heeney[6]

[1]Pediatric Hematology Unit, Hospital General Universitario Gregorio Marañón, Facultad de Medicina, Universidad Complutense de Madrid, Madrid, Spain, [2]Pediatric Hematology Unit, Sultan Qaboos University Hospital, Muscat, Oman, [3]Department of Epidemiology and Public Health, University of Miami, Miller School of Medicine, Miami, FL, [4]Foundation for Sickle Cell Disease Research, Hollywood, FL, [5]Novartis Pharmaceuticals, East Hanover, NJ, [6]Harvard Medical School, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA, United States

Background: Sickle cell disease (SCD) is a complex genetic disease and a

global health problem, with a changing geographical distribution due to migration. Vaso-occlusive crises (VOCs) can cause episodes of acute, intense pain, which are the primary cause of hospitalization in SCD and can lead to life-threatening complications such as acute chest syndrome (ACS) and stroke. Repeated vaso-occlusive episodes can result in end-organ damage. Hydroxyurea (HU) is widely used for preventing VOCs, however many pts experience recurrence while receiving HU or are unwilling to use it. Although regional variations in SCD genetics have been reported, data on regional differences in VOCs and other complications are lacking.
Aims: To evaluate variations in SCD patient characteristics from studies conducted in the USA, Spain and the Gulf region (Qatar, UAE and Oman).
Methods: We analyzed data from four observational studies. CICL670A2418 (NCT01441375) was a retrospective study of the medical records of 254 SCD pts aged ≥16 years in three US centers (US study 1). An objective of the study was to evaluate SCD complication rates and utilization of healthcare delivery, during an average of 7.7 years' observational data (Jordan *et al. Curr Med Res Opin* 2015). CICL670AUS38 (NCT01220115) was a prospective study documenting clinical outcomes in 498 SCD pts (2–<18 years, n=317; ≥18 years, n=181). Pts were enrolled from 57 US centers (US study 2), with data collected from medical histories ≤5 years before enrollment (Heeney *et al. Blood* 2014). CICL670AES15T was a retrospective/prospective study in 615 SCD pts aged <18 years enrolled in the Hemoglobinopathy Pediatric Spanish Registry. Data were collected from 50 hospitals, with a mean follow-up of 5.8 years (Cela *et al. Pediatr Blood Cancer* 2017). CICL670AAE02 was a cross-sectional study of 410 SCD pts aged 2–16 years that described SCD patient characteristics, disease and treatment profile. It was conducted in 3 centers in the Gulf region, with data collected from the previous 3 years. Assessments performed in each study included: patient characteristics; SCD genotype; the proportion of pts with VOCs, ACS, priapism and stroke; hospitalization information; and HU use.
Results: The proportion of pts with the HbSS genotype ranged from 52.9% (the Gulf study) to 87.4% (US study 1) (Table 1). The US and Gulf studies reported acute pain crisis/VOC in 74.4–84.4% of pts, compared with 21.3% in the Spanish study. ACS was reported in 15.9% to 35.1% of pts across the studies. Priapism was reported in 5.1–10.2% of pts in the US, while in the Spanish and Gulf studies these proportions were 0.3–0.7%. In US study 1, stroke was reported in 13.4% of pts compared with a range of 1.0–4.6% in the other studies. HU use ranged from 25.8% to 47.4%, whereas 66.9% to 82.9% of pts across the studies were hospitalized at least once.

Table 1.

Patient characteristics, complications, HU use and hospitalizations from four studies in the USA, Spain and the Gulf

	US study 1 (N=254)	US study 2 (N=498)*	Spain (N=615)[a]	Gulf (N=410)
Study/analysis dates	July 2011 – July 2012	Jan 2010 – Sept 2014	Jan 2014 – May 2015	Feb 2014 – Aug 2016
Patient characteristics				
Mean age ± SD, years	27 ± 11	18.5 ± 15.2	8.1	9.3
HbSS patients, n (%)	222 (87.4)	369 (74.1)	497 (80.8)	214 (52.2)
Black/African American patients, n (%)	254 (100)	469 (94.2)	NR	53 (12.9)
Complication rate				
Acute pain crises/VOCs, n (%)	189 (74.4)[b]	385 (77.3)[b]	131 (21.3)	346 (84.4)**
ACS, n (%)	44 (17.3)[b]	175 (35.1)[b]	99 (15.9)	74 (18.0)**
Stroke, n (%)	34 (13.4)[b]	23 (4.6)[b]	16 (2.6)	4 (1.0)**
Priapism[††], n (%)	13 (5.1)[b]	27 (10.2)[b]	2 (0.3)	3 (0.7)**
HU use				
Patients receiving HU, n (%)	NR	236 (47.4)[b]	159 (25.8)	184 (44.9)
Hospitalization data				
Patients hospitalized[‡‡], n (%)	170 (66.9)	413 (82.9)[b]	NR	319 (77.8)

*Data for pediatric and adult patients combined. [a]Median age shown; ethnicity not recorded in the registry. [b]Data from observation period (7.7 years); stroke data are from the history and observation period. [c]Data from the 5 years prior to enrollment. **Data from the previous 3 years. Percentages calculated based on the total number of patients, not the number of patients who experienced complications (n=222). ††Priapism calculated based on all patients. ‡‡For SCD-related complications in US study 1, for any reason in US study 2, and for VOCs or other complications in the Gulf study. ACS, acute chest syndrome; HU, hydroxyurea; NR, not reported; SD, standard deviation; VOC, vaso-occlusive crisis.

Summary/Conclusion: The results highlight the significant burden of complications related to VOCs in SCD, most notably acute pain crises and other serious manifestations. The results also indicate that many pts with SCD are hospitalized despite receiving HU. Regional differences in the frequency of complications were observed (see Table 1). These may be related, but not limited to, differences in the population characteristics (e.g. age, proportion of HbSS genotype) and the non-interventional nature of data collection. Migration patterns also contribute to the changing demographics of SCD in different countries. Individually tailored therapies are needed to help improve well-being in this under-served patient population.

PS1458

CORRELATION BETWEEN HEMOLYSIS AND HYPERCOAGULABILITY MARKERS AND EFFECTS OF HYDROXYUREA THERAPY IN SICKLE CELL PATIENTS

W. V. Tonassé[1,*], F. Chénou[1], I. F. Domingos[2], T.H.C. Batista[2], R.M. Santana[2], A. S. Araújo[3], M.A.C. Bezerra[2], F.F. Costa[4], M.F. Sonati[5], M.N.N. dos Santos[5]

[1]Department of Clinical Pathology, School of Medical Sciences, State University of Campinas-UNICAMP, CAMPINAS, [2]Department of Genetics, Federal University of Pernambuco (UFPE), [3]Hematology and Hemotherapy Foundation of Pernambuco (HEMOPE), Recife-PE, [4]Hematology and Hemotherapy Center, State University of Campinas-UNICAMP, [5]Department of Clinical Pathology, School of Medical Sciences, State University of Campinas-UNICAMP, Campinas-SP, Brazil

Background: Sickle cell anemia (SCA) is characterized by chronic hemolysis and vasculopathy complications as the process of hemolysis with the release of hemoglobin (Hb) contained in erythrocytes is an important mediator in vascular diseases. Plasma Hb (pHb) and its heme component have been found to trigger specific pathophysiologies, such as acute and chronic vascular disease, inflammation, abnormal endothelial activation, vasoocclusion, thrombosis, stroke and renal impairment, all associated with adverse clinical outcomes in patients with hemolysis. However, the role of intravascular hemolysis (IH) on hemostatic alterations remains unclear.
Aims: This cross-sectional study aimed to evaluate the relation between plasmatic levels of hemolysis and hypercoagulability markers in Brazilian patients with SCA hydroxyurea-naïve and SCA patients on hydroxyurea therapy.
Methods: A total of 62 adults (19 – 42 years) SCA patients: 32 hydroxyurea-naïve (HbSS) and 30 on hydroxyurea therapy (HbSS-HU) were included in the study, all in steady state, followed in Pernambuco s Blood Center HEMOPE. The Hb profile was investigated by high-performance liquid chromatography. Levels of pHb and Lactate Dehydrogenase (LDH), as IH markers, were measured by enzyme-linked immunoassay and Cobas C501 analyzer, respectively. Hypercoagulation markers such as D-dimer and fibrinogen levels were quantified using Dade Thrombin Reagent Multifibren® U and immunoturbidimetric assay Innovance D-DIMER in Sysmex® CA-1500. Data were analyzed with GraphPad Prism 6 and SPSS v23 and significance set at $P \leq 0.05$. Correlation coefficients (r) and P values are based on Spearman correlation test. Mann-Whitney U test was used to compare data between HbSS and HbSS-HU groups.
Results: The study findings suggest that there is a significant positive correlation between pHb and LDH (r=0.396, p=0.030) and a negative correlation between both pHb, LDH and fibrinogen in HbSS patients. [r = -0.377 (p=0.036) and r = -0.405 (p=0.032) respectively]. In addition, HbSS patients had higher hemolysis rate in comparison to HbSS-HU patients as evidenced by pHb levels (3.29 mg/dL vs 1.59 mg/dL, $P_{pHb} = 0.003$) and LDH levels (644.0 U/L vs 426.5 U/L, $P_{LDH} = 0.05$). Similarly, D-dimer levels were higher in HbSS when compared to HbSS-HU patients (2144 ng/mL vs 1496 ng/mL, p=0.045). Although, there was no statistically significant difference between fibrinogen levels in HbSS patients and HbSS-HU patients (Median: 238,8 mg/dl and 279.8 mg/dl, p=0.06).
Summary/Conclusion: Overall, higher IH rate was associated with more activation of coagulation in SCA patients and fibrinogen consumption, suggesting an important role of the pHb in the activation process of coagulation in this disease. Hydroxyurea therapy is associated with a reduction in the IH and hypercoagulation state in SCA patients, suggesting a new clinical benefit for the use of hydroxyurea in SCA patients.

PS1459

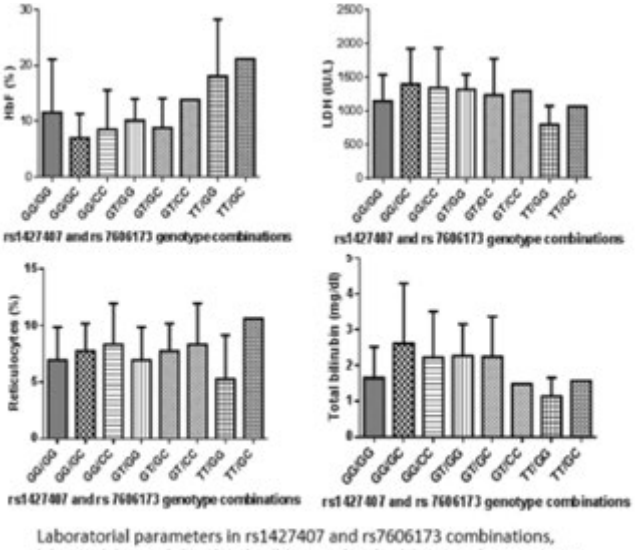
INFLUENCE OF BCL11A POLYMORPHYSMS ON FETAL HEMOGLOBIN LEVELS AND HAEMOLYSIS MARKERS IN SICKLE CELL ANEMIA PEDIATRIC PATIENTS NOT RECEIVING HYDROXYUREA

R.M.L. Rahimy[1,2], C.S.A. Adanho[1,2], R.P. Santiago[2,3], C. Vieira[2], C.C. Guarda[1], S.S. Santana[1,2], S.C.M.A. Yahouedehou[1,2], K.B.C. Caetano[1,4], T.N. Pitanga[1], J.R.D. Ferreira[4], L.D.C. Oliveira[3], V.V. Maffili[1], I.M. Lyra[2], D.L. Zanette[1,*], M.S. Goncalves[1]

[1]Laboratory of Investigation in Genetics and Translational Hematology, Gonçalo Muniz Institute / Fiocruz, [2]Faculty of Medicine, Federal University of Bahia, [3]Laboratory of Investigation in Genetics and Translational Hematology , Gonçalo Muniz Institute /Fiocruz, [4]Faculty of Pharmacy, Federal University of Bahia, Salvador, Brazil

Background: Fetal hemoglobin (HbF) levels are one of the main determinants of the clinical presentation of sickle cell anemia, since high levels of HbF are associated with reduced polymerization of hemoglobin S, thus alle-

viating vaso-occlusion and hemolysis. Certain polymorphisms of the *BCL11A* gene are capable of modulating basal levels of HbF, even in the absence of any therapeutic intervention.
Aims: The main objective of this study was to analyze the influence of two polymorphisms in the *BCL11A* gene (rs1427407 and rs7606173), on the levels of HbF, bilirubin, lactate dehydrogenase (LDH) and reticulocytes count in pediatric patients with sickle cell anemia that were not under hydroxyurea treatment.
Methods: Whole blood and serum samples were used for hematological and biochemical analysis. DNA was extracted from EDTA-whole blood samples, and the fragments containing the gene polymorphisms were amplified by PCR followed by Sanger sequencing with specific primers. Free and informed consent was obtained from the legal guardians of all patients included in this study.
Results: Seventy-three patients fulfilled the inclusion criteria, aged 2 to 17 years. The frequency of the mutant T allele of rs1427407 was 0.22 and that of the wild-type G allele of rs7606173 was 0.57. The TT mutant genotype of rs1427407 showed the highest HbF levels as compared to GT and GG genotypes (p=0.0382). On the other hand, for the wild-type GG genotype of rs7606173 no significant increase in HbF level was observed, when compared to the GC and CC genotypes. The mean reticulocyte and LDH values were lower in the mutant TT and wild-type GG genotypes of rs1427407 and rs7606173, respectively, although the differences were not significant. The lowest bilirubin levels were found in the mutant TT genotype of rs1427407 and wild type GG polymorphisms of rs7606173, when compared to the other genotypes. Total and indirect bilirubin levels were significantly different between GG and GT genotypes of rs1427407 for (p=0.0102 and p=0.0108, respectively). Regarding bilirubin levels, it is important to take into consideration the high frequency of rs8175347 polymorphism of *UGT1A1* gene in the population analyzed in previous observations of the research group. This polymorphism corresponds to the presence of additional thymine-adenine (TA) repeats in the promoter region of *UGT1A1*, which results in increased indirect bilirubin levels. Lower levels of indirect bilirubin were found in individuals that simultaneously carried the TT mutant genotypes for *BCL11A* rs1427407 and *UGT1A1* rs8175347 (7 to 8 TA repeats). By combining the genotypes of the two polymorphisms of *BCL11A*, rs1427407 and rs7606173, no individuals with the mutant TT / CC association were found. The individuals carrying the TT/GG combination had lower percentage of reticulocytes and lower levels of LDH and bilirubin; while HbF average levels were twice higher than in individuals carrying the GG/CC combination. Accordingly, the mean number of painful crises was three times lower in the GG / CC group in the year prior to data collection. Figure 1 summarizes the data described here.



Laboratorial parameters in rs1427407 and rs7606173 combinations, (a): Fetal hemoglobin levels. (b): LDH levels. (c): Reticulocytes count. (d): Total bilirubin. HbF: Fetal hemoglobin, LDH: lactate dehydrogenase

Figure 1.

Summary/Conclusion: The mutant T allele of rs1427407 and the ancestral G allele of rs7606173 of *BCL11A* gene were associated with higher HbF levels and lower values of some laboratory hemolysis markers, showing more evident effect for rs1427407 T allele. We also report that the effect of rs1427407 and rs7606173 appears to overcome the effect of rs8175347 on bilirubin levels in patients with $(TA)_{7/7}$ and $(TA)_{7/8}$ polymorphisms in the promoter region of the *UGT1A1* gene.

TICAGRELOR VERSUS PLACEBO FOR THE REDUCTION OF VASO-OCCLUSIVE CRISES IN PEDIATRIC SICKLE CELL DISEASE: DESIGN OF A RANDOMIZED, DOUBLE-BLIND, PARALLEL-GROUP, MULTICENTER PHASE 3 STUDY (HESTIA3)

M.M. Heeney[1,*], M.R. Abboud[2], C. Amilon[3], M. Andersson[4], J. Githanga[5], B. Inusa[6], J. Kanter[7], M. Leonsson-Zachrisson[8], A. D. Michelson[9], A.R. Berggren[8]

[1]Hematology, Sickle Cell Program, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Harvard Medical School, Boston, United States, [2]American University of Beirut Medical Center, Beirut, Lebanon, [3]Early Clinical Development, IMED Biotech Unit, [4]Global Medicines Development, AstraZeneca, Gothenburg, Sweden, [5]Haematology and Blood Transfusion Unit, Department of Human Pathology, University of Nairobi, Nairobi, Kenya, [6]Paediatric Haematology, Evelina London Children's Hospital, Guy's and St Thomas' NHS Trust, London, United Kingdom, [7]Sickle Cell Disease Research, Pediatric Hematology-Oncology, Medical University of South Carolina, Charleston, United States, [8]Global Medicines Development, AstraZeneca R&D, Gothenburg, Sweden, [9]Center for Platelet Research Studies, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Harvard Medical School, Boston, United States

Background: There is a high unmet need for therapies to reduce the complications of sickle cell disease (SCD), including vaso-occlusive crises (VOCs), in pediatric patients. Activated platelets contribute to the formation of cell aggregates during sickling. Platelet inhibition, therefore, has the potential to reduce VOC rates. Ticagrelor is an oral, direct-acting, and reversible $P2Y_{12}$ receptor antagonist that inhibits adenosine diphosphate–mediated platelet activation and aggregation. Ticagrelor has a wealth of data in adult cardiac patients and is approved to reduce the rate of cardiovascular death, myocardial infarction (MI), and stroke in adults with acute coronary syndrome (90 mg BID) and adults with a history of MI (60 mg BID). The HESTIA program is currently ongoing to explore the potential therapeutic benefits of ticagrelor for the reduction of VOCs in SCD; the pharmacokinetics (PK), pharmacodynamics (PD), and tolerability of a broad range of ticagrelor doses were investigated in phase 2 studies in children (3-17 y; HESTIA1) and young adults (18-30 y; HESTIA2) with SCD. Though ticagrelor was well tolerated in SCD patients, larger and longer-term studies are needed to assess its safety and ability to reduce VOC rates.
Aims: HESTIA3 will evaluate the efficacy, safety, and tolerability of ticagrelor *versus* placebo over a period of 1 y and up to approximately 2 y in pediatric patients with SCD
Methods: Planned enrollment is approximately 182 patients with SCD (randomized 1:1 to receive either ticagrelor or placebo) confirmed for homozygous sickle cell (HbSS) or sickle beta zero thalassemia (HbS/β^0) and with ≥2 VOCs in the year prior to Visit 1 (Figure 1). At least 50 evaluable patients in each age group (≥2 to <12 y and ≥12 to <18 y) will be recruited from approximately 20 countries worldwide, including Ghana, Kenya, South Africa, Tanzania, Egypt, Lebanon, Canada, US, Italy, UK, and India. The study drug will be given in addition to standard, locally available treatments for SCD (*e.g.*, stable dose hydroxyurea). Body-weight adjusted ticagrelor doses (15, 30, or 45 mg BID) were identified based on PK/PD modeling and simulation of phase 2 data. The selected ticagrelor doses are projected to achieve greater platelet inhibition than that observed in earlier efficacy trials of platelet inhibition in pediatric SCD. The predicted level of platelet inhibition with the selected doses is ~35% to 80% reduction in $P2Y_{12}$ reaction units from baseline compared with placebo.

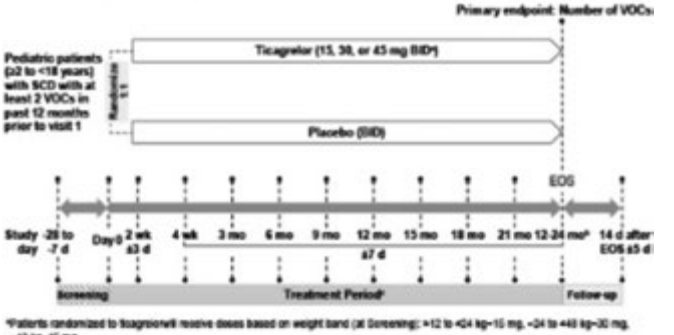

Figure 1. HESTIA3 study design.

Results: The primary endpoint is the number of VOCs (the composite of a

painful crisis of ≥2 h duration [treated in a medical setting or at home] and/or acute chest syndrome). Secondary endpoints include hospitalizations, symptomatic disease burden, pain intensity and analgesic use during VOCs, acceptability of formulation, and health-related quality of life as measured by the Pediatric Quality of Life Inventory (PedsQL) SCD Module and Fatigue total score and by dimension using the PedsQL Multidimensional Fatigue Scale. Safety will be assessed by adverse events, including bleeding events, and laboratory assessments. Platelet inhibition data, measured by the vasodilator-stimulated phosphoprotein (VASP) assay, will be collected for exploratory purposes.
Summary/Conclusion: HESTIA3 will provide long-term data on the effects of ticagrelor in the management of VOCs in pediatric patients with SCD. This trial will target therapeutic platelet inhibition, which is expected to translate into improved clinical results. The first patient is expected to be enrolled during the second quarter of 2018.

PS1461

NOVEL TRIAL DESIGN TO EVALUATE ORAL VOXELOTOR FOR THE TREATMENT OF SICKLE CELL DISEASE: THE PHASE 3 HEMOGLOBIN OXYGEN AFFINITY MODULATION TO INHIBIT SICKLE HEMOGLOBIN POLYMERIZATION (HOPE) TRIAL

K. I. Ataga[1,*], C.C. Hoppe[2], R.E. Ware[3], J. Howard[4], M. Tonda[5], J. Ganju[5], J. Lehrer[5]

[1]University of North Carolina Comprehensive Sickle Cell Program, Chapel Hill, NC, [2]UCSF Benioff Children's Hospital Oakland, Oakland, CA, [3]Cincinnati Children's Hospital, Cincinnati, OH, United States, [4]Guy's and St Thomas' NHS Foundation Trust and King's College London, London, United Kingdom, [5]Global Blood Therapeutics, South San Francisco, CA, United States

Background: Design of clinical trials for sickle cell disease (SCD) is challenging in part because of a lack of consistent end point definitions. Vaso-occlusive crisis (VOC), the most frequently used end point, does not measure full disease burden and reflects health care utilization and attitudes of patients and health care professionals. In phase 1/2 studies of patients with SCD, treatment with voxelotor (GBT440), an inhibitor of sickle hemoglobin polymerization, has resulted in increased hemoglobin (Hb) levels and reduced hemolysis and was well tolerated. Voxelotor is being evaluated in the ongoing HOPE trial using Hb as the primary study end point, along with novel secondary end points.
Aims: The innovative phase 2/3 HOPE trial design with novel primary and secondary end points to accelerate drug development will be presented.
Methods: HOPE (NCT03036813) is a randomized, placebo-controlled, multicenter study of oral voxelotor in patients with SCD (aged 12-65 years) with baseline Hb 5.5-10.5 g/dL and 1-10 episodes of VOC in the previous year. The study population consists of 3 patient cohorts: Group 1, Group 2, and Group 3. To accelerate clinical development of a potential SCD therapy, the study seamlessly combines phase 2 dose selection (Groups 1 and 2) and the phase 3 pivotal cohort (Groups 2 and 3). Patients in Group 1 (n=60) and Group 2 (n=180) will be randomly assigned 1:1:1 to voxelotor 900 or 1500 mg/day or placebo. Patients in Group 3 will be randomly assigned 1:1 to the selected voxelotor dose or placebo. Patients in Group 2 may be combined (up to 90 patients) with those in Group 1 for the dose selection analysis to provide flexibility in the sample size of the dose selection portion of the study. Analysis for voxelotor dose selection will occur when the final patient (up to 150 total patients from Groups 1 and 2) has received 12 weeks of treatment. Group 2 patients randomized to placebo and the selected dose who were not unblinded for the dose selection analysis will become part of the phase 3 pivotal cohort. Group 2 patients randomized to the nonselected dose will be offered enrollment in an open-label extension study. The primary end point, an increase in Hb >1 g/dL from baseline to 24 weeks, is an objective and clinically relevant laboratory measure of disease modification based on voxelotor mechanism of action. This trial is the first to use the 9-item Sickle Cell Disease Severity Measure, a patient-reported outcome (PRO) specifically developed for the HOPE study following FDA guidance, as a secondary end point. This novel electronic PRO will evaluate changes in severity and exacerbation of core SCD symptoms (eg, pain and fatigue-related symptoms) from baseline to 24 weeks. Additional secondary end points include measures of hemolysis, rates of VOC, transfusions, and opioid use. The study is designed to enable selection of PRO-defined symptom exacerbations or traditionally defined VOC as the key secondary end point based on the Group 1 analysis.
Results: This study is ongoing.
Summary/Conclusion: The HOPE trial, expected to complete enrollment by late 2018, will evaluate the efficacy and safety of voxelotor compared with placebo in patients with SCD. The phase 2/3 design with novel clinical end points may accelerate voxelotor development and provide objective and relevant measures of efficacy and clinical outcomes.

Stem cell transplantation – Clinical

PS1462

OUTCOME OF PHILADELPHIA CHROMOSOME-POSITIVE ADULT ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS RECEIVING TYROSINE KINASE INHIBITOR MAINTENANCE THERAPY AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

T. Tapaninen[1,*], A. Nihtinen[1], R. Niittyvuopio[1], V. Lindström[1], J. Heiskanen[1], E. Martelin[1], M. Itälä-Remes[1]

[1]Helsinki University Hospital Comprehensive Cancer Center, Helsinki, Finland

Background: Prognosis of Philadelphia chromosome-positive adult acute lymphoblastic leukemia (Ph+ALL) has improved with allogeneic hematopoietic stem cell transplantation (HSCT) and the addition of tyrosine kinase inhibitors (TKIs) to the front-line therapy. However, relapses occur. The role of post-transplant TKI maintenance therapy is unclear.
Aims: This study aimed to evaluate the efficacy of TKI maintenance after HSCT in adult patients with Ph+ALL.
Methods: A retrospective study of all adult Ph+ALL patients undergoing HSCT in Helsinki University Hospital between 2004-2015 was performed (Group 1). According to local practice, TKI maintenance for at least two years was recommended to all patients after HSCT regardless of the PCR-based minimal residual disease-status (MRD). Imatinib was the primary drug in 2004-2011, and since 2012, dasatinib was preferred. All patients in Group 1 had received TKI prior to HSCT. The outcomes were compared to a TKI-naïve historical cohort from 1996-2002 (Group 2).
Results: Group 1 consisted of 29 patients (62% male) with a median age at HSCT of 44 years (range 21-65). Median post-HSCT follow up of the living patients was 8.4 years (2.1-14). 34% had a sibling donor and 24% a bone marrow graft. All patients received a myeloablative conditioning (MAC), and 79% received TBI 12 Gy. Group 2 included 19 patients (58% male) with a median age of 47 years (19-60) and a median follow up of 18 years (15-20). 63% had a sibling donor and 53% a bone marrow graft. All had MAC, and 95% received TBI. 24 of the 29 patients (83%) in Group 1 had TKI maintenance. 15 patients received imatinib (max. 400 mg/day for all), and 9 dasatinib (median max. 70 mg/day). Median time to TKI initiation after HSCT was 7.6 weeks (2.9-68), and the median duration of maintenance 22 months (2.1-93). TKI was not initiated for 5 patients due to transplant-related complications. OS rates for Group 1 (n=29) and Group 2 (n=19) were 72.4% vs 36.8% (p=0.048), and the respective TRM rates 14.5% vs 16.1% (p=0.819). Subsequently, outcome of the 24 patients receiving TKI maintenance in Group 1 was studied according to their MRD status. MRD was detectable before HSCT in 17 patients and negative in 7. OS rates for these patients were 76.5% vs 85.7% (p=0.566), and PFS 58.8% vs 71.4% (p=0.578), respectively. For the 6 patients who were MRD-positive at 12 weeks and 18 that were MRD-negative, OS were 66.7% vs 83.3% (p=0.289), and PFS 50% vs 66.7% (p=0.307), respectively. Imatinib maintenance was started before the 12-week sample in 12 patients and dasatinib in 7. Latest relapse occurred 2.7 years after HSCT. Intolerance to TKI lead to interruption of the maintenance at some point in 11 of the 15 patients (73%) receiving imatinib (most commonly due to neutropenia) and 6 of the 9 patients (67%) receiving dasatinib (neutropenia or infection). Thus, 7 of the 29 patients (24%) in Group 1 had full-term TKI maintenance. OS for the imatinib-treated vs dasatinib-treated patients were 86.7% vs 66.7% (p=0.271), and PFS 73.3% vs 44.4% (p=0.126), respectively.
Summary/Conclusion: Outcome of Ph+ALL patients treated with TKI before and after HSCT was superior compared to TKI-naïve patients, explained by reduced leukemia-related mortality. In the TKI-era, MRD status prior to HSCT did not affect the outcome of patients receiving MAC. Due to the small sample size, no conclusions can be drawn about the potential benefits of starting TKI maintenance to all Ph+ALL patients regardless of their MRD status after HSCT.

PS1463

PD-1 OVEREXPRESSION ON BONE MARROW RESIDENT CD8+ MEMORY T-CELL SUBSETS COULD BE A PREDICTABLE MARKER FOR LEUKEMIA RELAPSE AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

N. Popova[1], M. Drokov[1,*], L. Kuzmina[1], Y. Davydova[2], N. Kapranov[2], E. Mikhalcova[1], O. Koroleva[1], V. Vasilyeva[1], Z. Konova[1], D. Dubnyak[1], E. Usikova[1], A. Sidorova[1], I. Galtseva[2], E. Parovichnikova[1], V. Savchenko[1]

[1]Bone marrow transplant, [2]Immunophenotyping laboratory , National Research Center for Hematology, Moscow, Russia, Moscow, Russian Federation

Background: Programmed cell death protein 1 (PD-1) is a surface receptor expressed normally on activated T- and B-cells, NK, dendritic cells and monocytes and is known to be a negative immune regulator of these immune cells that has detrimental effects on anti-tumor immunity. Ability of leukemia cells exploiting PD-1-axis to escape the immune system through expression of PD-1-ligand is associated with developing of a relapse. Leukemia relapse after allogeneic stem cell transplantation (allo-HSCT) is still the main post-transplant problem and its solving has not been found yet.
Aims: To evaluate PD-1 expression on bone marrow (BM) resident CD8+ memory T-cell subsets in leukemia patients after allo-HSCT and to assess its impact on a relapse developing after allo-HSCT.
Methods: 0,5 ml of BM was obtained from 19 leukemia patients with a median age of 36 years old (range, 20-60) who underwent allo-HSCT. All patients engrafted before day +30 and stayed in remission within the follow-up period in 100 days after allo-HSCT. The analysis was carried out on day +90. White blood cells count (WBC) in BM samples was evaluated by Sysmex XE-2100 hematology analyzer. 1×10^6 of WBC (excluded nucleated red blood cell) from BM were stained using "lyse-wash-stain" standard protocol. Flow cytometry analysis was performed on BD FACS Canto II (Becton Dickinson, USA). 7-AAD was used to exclude dead cells from the analysis. The anti-CD8-APC-Cy7, anti-CCR7-PE-Cy7, anti-CD28-PE, anti-CD45R0-FITC, PD1-APC antibodies (Becton Dickinson, USA) were used to define BM resident CD8+ memory T-cell subsets and expression of PD-1: T naive and T stem cell memory (Tnv+Tscm) – CD8+CD45R0-CCR7+CD28+PD-1+; T central memory (Tcm) - CD8+CD45R0+ CCR7+CD28+PD-1+; T transitional memory (Ttm) - CD8+CD45R0+ CCR7-CD28+PD-1+; T effector memory (Tem) - CD8+CD45R0+CCR7-CD28-PD-1+; T terminal effector (Tte) - CD8+CD45R0-CCR7-CD28-PD-1+.
Results: According to our data PD-1 was overexpressed on all BM CD8+ memory cell subsets on day +90 in those patients who relapsed after the day +100 compared to the patients who stayed in complete remission after the day +100. (Table 1).

Table 1.

Expression of PD-1 on BM resident CD8+ memory cell subsets on day +90 in leukemia patients after allo-HSCT.

Subsets on day +90	Patients in complete remission, n=12 mean (standard error)	Patients relapsed after +100 day, n=7 mean (standard error)	p-value
CD8+ PD1+	79,2% (9,4%)	91,3% (4,9%)	> 0,05
Tnv+scm PD1+	61% (16%)	85% (9%)	> 0,05
Tcm PD1+	81% (9%)	94% (4%)	> 0,05
Ttm PD1+	85% (9%)	96% (3%)	> 0,05
Tem PD1+	79% (12%)	91% (7%)	> 0,05
Tte PD1+	71,8% (9,8%)	79,9% (9,5%)	> 0,05

Summary/Conclusion: Overexpression of PD-1 on BM resident CD8+ distinct memory cells seems to be a useful predictable marker that can help to start preventive therapeutic approaches with anti-PD-1 activities (checkpoint inhibitors) and in its turn to improve posttransplant results. But this hypothesis needs to be confirmed in the largest cohort of patients.

PS1464

OUTCOME OF SECOND SOLID CANCER AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION: A COHORT STUDY ON 4065 PATIENTS ON BEHALF OF THE COMPLICATIONS AND QUALITY OF LIFE WORKING PARTY OF THE EBMT

A. Tichelli[1,*], E. Beohou[2], M. Labopin[2], G. Socié[3], A. Rovó[4], M. Badoglio[2], A. van Biezen[5], P. Bader[6], R.F. Duarte[7], G. Basak[8], N. Salooja[9]

[1]Hematology, University Hospital, Basel, Switzerland, [2]EBMT Paris Study Office, Hôpital Staint Antoine, [3]Dept. of Hematology, Hôpital St Louis, Paris, France, [4]Hematology and Central Hematology Laboratory , University Hospital Bern, Bern, Switzerland, [5]EBMT data office Leiden, LUMC, Leiden, Netherlands, [6]Hospital for Children and Adolescents, Frankurt a. Main, Germany, [7]Hematology, Hospital Universitario Puerta de Hierro, Majadahonda, Spain, [8]Hematology, Oncology and Internal Medicine, Central Clinical Hospital of the Medical University , Warsaw, Poland, [9]Center of Haematology, Imperial College, London, United Kingdom

Background: With the improved outcome of patients treated with hematopoietic stem cell transplantation (HSCT) the number of long-term survivors is steadily increasing. However, HSCT survivors are at risk of late complications. Second solid cancers are feared late complications after HSCT. Their incidence and risk factors have been established, but little is known on their outcome.
Aims: We assessed the outcome of second solid cancers from their time of diagnosis in HSCT survivors.
Methods: We performed a retrospective cohort study of patients registered with the EBMT who developed a second solid cancer between 2000 and 2014. Median and 5-year age-standardized overall survival (OS) from time of diagnosis of the second cancer, causes of death, risk factor multivariate analysis and standardized mortality ratio (SMR) were calculated for 18 different cancer types.
Results: There were 4065 second solid cancers (1443, allogeneic; 2622, autologous). Primary diagnoses were acute leukemia (23%), chronic leukemia (9%), lymphoma (34%), plasma cell disorders (22%), solid tumors (4%), myelodysplastic syndromes and myeloproliferative neoplasms (6%) and acquired marrow failure syndromes (1%). The median age at HSCT and at diagnosis of second cancer was 53 years (range 0.7-70) and 59 years (3.2-82), respectively. The median follow-up time from HSCT and diagnosis of second cancer was 121 months (range 3.6-409) and 34 months (range 0-187), respectively. The 5-years age-standardized OS was 47% (95% CI 45-49). Survival outcome was mainly depended on the type of second cancer (Table 1). 5 cancer types had a favourable outcome with median survival >10 years (thyroid, cervix, prostate, breast, melanoma), 7 had an intermediate outcome with median survival >1-9 years (renal, oropharyngeal, bladder, ovarian, sarcoma, endometrial, gastric), and 6 had poor outcome with median survival ≤1 year (brain, esophageal, hepatobiliary, lung, pancreas). Survival risk factors after diagnosis of second cancer were older age at HSCT, type of cancer, donor type, and graft-versus-host disease. Overall, 1777 (43·9%) patients died: 74·9% as a result of the second cancer. SMR was increased for melanoma, prostate, breast, renal, bladder, colorectal, and endometrial cancer, but normal for other second cancers.

Table 1.

Outcome of the different second solid cancer types after HSCT

outcome	Second cancer	No. patients	Median survival (y)	5-year OS % (95% CI)	Cumulative incidence* (95% CI)
favourable	Thyroid	149	nr	83 (76-92)	9 (4-17)
	Cervix	57	12.4	70 (57-86)	15 (6-26)
	Prostate	410	9.8	69 (64-75)	14 (10-18)
	Breast	547	10.6	69 (64-74)	13 (10-17)
	Melanoma	343	nr	68 (62-74)	22 (17-27)
intermediate	Kidney	177	5.2	55 (47-65)	24 (17-32)
	Oropharyngeal	207	8.2	53 (46-62)	31 (24-39)
	Bladder	144	4.9	49 (39-62)	25 (17-35)
	Ovarian	77	2.2	43(32-58)	42 (29-54)
	Sarcomas	215	3.3	42(34-51)	47 (39-55)
	Colorectal	446	3.2	41 (36-48)	39 (33-44)
	Endometrial	46	3.4	40 (26-63)	45 (27-61)
poor	Gastric	158	1	29 (21-39)	58 (48-66)
	Brain	156	0.9	21 (15-30)	63 (53-71)
	Oesophageal	88	0.9	21 (13-36)	61 (48-72)
	Hepatobiliary	90	0.9	18 (11-31)	74 (61-84)
	Lung	597	0.9	14 (11-19)	74 (69-78)
	Pancreas	145	0.6	8 (3-18)	89 (79-94)

nr: not reached; * of death due to second cancer

Summary/Conclusion: The outcome of second solid cancers after HCT is mainly dependent on cancer type. SMR is increased for some but not all cancers, which develop after HCT and risk factors for poor survival include age at HSCT, GVHD and donor type. Early diagnosis is likely to be facilitated by life-long follow up. There is no reason to treat these patients differently from the general population, but close cooperation between oncologists and hematologists is mandatory.

PS1465

SIMILAR OUTCOMES OF REDUCED INTENSITY HAPLOIDENTICAL TRANSPLANTATION WHEN COMPARED TO MATCHED UNRELATED DONOR TRANSPLANT IN DIFFUSE LARGE B CELL LYMPHOMA. A JOINT ANALYSIS FROM CIBMTR-LC & EBMT-LWP

A. Sureda[1,*], P. Dreger[2], K. W. Ahn[3], H. Finel[4], J. Tischer[5], L. Castagna[6], D. Blaise[7], A. Dominietto[8], C. Schmid[9], F. Ciceri[10], A. Boumedil[4], C. Litovich[3], S.M. Smith[11], T. Fenske[3], S. Dietricht[2], S. Robinson[12], S. Montoto[13], M. Hamadani[3]

[1]Institut Català d'Oncologia, Barcelona, Spain, [2]University of Heidelberg, Heidelberg, Germany, [3]Medical College of Wisconsin, Milwaukee, United States, [4]EBMT Office, Paris, France, [5]Klinikum Grosshadern, Muenchen, Germany, [6]Istituto Clinico Humanitas, Milano, Italy, [7]Institut Paoli Calmettes, Marseille, France, [8]Ospedale San Martino, Genoa, Italy, [9]Klinikum Augsburg, Augsburg, Germany, [10]Ospedale San Raffaele, Milano, Italy, [11]University of Chicago, Chicago, United States, [12]University Hospitals, Bristol, [13]St. Bartholomew's Hospital, Barts Health NHS Trust, London, United Kingdom

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a potentially curative treatment for patients with relapsed diffuse large B cell lymphoma (DLBCL). In the absence of an HLA-identical sibling, the use of 8/8 matched unrelated donors (MUDs) has been considered the standard of care. Preliminary data suggest that haploidentical donors could be an alternative to MUDs in lymphomas.
Aims: The aim of this study was to compare the long-term outcome of MUD-HSCT with that of haplo-HSCT with cyclophosphamide post-transplant (Cy-post) for the first time specifically in patients with DLBCL.
Methods: 913 adult patients with relapsed DLBCL treated with allo-HSCT [132, haplo-HSCT; 403, MUD with anti-thymocyte (ATG) / Campath and 378, MUD without (w/o) ATG / Campath] were reported from 2008 to 2015 to CIBMTR and EBMT databases. Only reduced intensity conditioning regimens, Cy-post in the haplo group and additional prophylaxis with calcineurin inhibitors in the MUD group were included. There were significant differences amongst the 3 groups of patients (Haplo-HSCT, MUD with ATG/Campath and MUD w/o ATG/Campath) with respect to age (yrs) [58 (20-75) *vs* 55 (19-75) *vs* 56 (23-73), p=0.003], Karnofsky score at HSCT ≥ 90% [73% *vs* 62% *vs* 57%, p<0.001], distribution of HSCT-comorbidity score (p<0.001) and a prior autologous-HSCT [43% *vs* 59% *vs* 61%, p=0.001]. As expected, total body irradiation and bone marrow stem cells were more frequently used in the haplo-HSCT setting (86% and 76% *vs* 7%, and 7% *vs* 32% and 5%, p<0.001 both, respectively).
Results: 28-day cumulative incidence (CI) platelet recovery was significantly lower in haplo-HSCT [61 (50-71)% *vs* 89 (85-92)% *vs* 89 (84-92)%, p<0.001]. Conversely, haplo-HSCT was associated with a lower 180-day CI of grade 3-4 acute graft versus host disease (aGVHD) [7 (3-12)% *vs* 13 (10-16)% *vs* 19 (15-23)%, p<0.001] and 2-yr chronic GVHD (cGVHD) [18 (12-26)% *vs* 32 (27-38)% *vs* 57 (52-63)%, p<0.001]. With a median follow up (range) for surviving patients of 47 (5-73), 39 (<1-100) and 36(3-96) mo for the 3 cohorts, there were no significant differences in terms of 3-yr non relapse mortality (NRM) [22 (15-30)% *vs* 26 (21-31)% *vs* 30 (25-35)%], relapse/progression (RP/P) [41 (32-49)% *vs* 38 (33-43)% *vs* 34 (29-39%)], progression free survival (PFS) [38 (29-47)% *vs* 36 (31-41)% *vs* 37 (31-42%)] and overall survival (OS) [46 (37-55)% *vs* 43 (38-49)% *vs* 46 (41-52)%]. Multivariate analysis indicated that the use of haplo donors was associated with a significant lower incidence of grade 3-4 aGVHD [RR 0.36 (0.18-0.73), p=0.0071] and that both haplo and MUD with ATG/Campath were associated with a lower incidence of cGVHD [RR 0.25 (0.16-0.38), p<0.001 and RR 0.53 (0.41-0.67), p<0.001, respectively]. Type of donor did not significantly influence any of the four major outcomes. Time from diagnosis to HSCT > 24 mo was the only independent prognostic factor for NRM (p=0.001) while R/P was adversely affected by both time between diagnosis and HSCT > 24 mo and by not being in complete remission (p=0.002 and p<0.001, respectively). Disease status at HSCT was the only independent prognostic factor predicting for both PFS and OS.
Summary/Conclusion: Haplo-HSCT with the Cy-post platform results in similar long-term outcomes than MUD-HSCT in patients with relapsed DLBCL with a lower incidence of grade 3-4 aGVHD and cGVHD. Our results suggest that haplo donors are an adequate alternative to MUD in this setting.

PS1466

TARGETING EXPANDED GUT HOMING EFFECTOR T CELL LINEAGES IN ACUTE INTESTINAL GRAFT VERSUS HOST DISEASE: IMPLICATIONS FOR VEDOLIZUMAB

P. Pavlidis[1,*], V. Mehra[2,3], S. Kottoor[4], E. Alberts[4], E. Shabbir[5], J. DigbyBell[4], T.-L. Tsui[6], C. Scotta[6], E. N. Lamperti[6], G. Emlyn[7], H. Abu Arqoub[7], C. Rice[2], L. Barber[6], D. Mclornan[8], H. de Lavallade[9], V. Potter[9], M. Silverman[5], Y. Jethava[5], T. Pagliuca[9], G. Mufti[3], K. Raj[2], G. Lombardi[6], B. Hayee[1], N. Powell[4]

[1]Gastroenterology, [2]Haematology, Kings College Hospital, London, [3]Division of Cancer Studies, [4]Department of Experimental Immunobiology, Kings College London, London, United Kingdom, [5]University of Iowa Hospitals and Clinics,, Roy and Lucille Carver College Of Medicine, University of Iowa, Iowa City, United States, [6]Kings College London, [7]Histopathology, Kings College Hospital, London, [8]Haematology, Kings College London, [9]Kings College Hospital, London, London, United Kingdom

Background: Acute graft versus host disease may affect the gastrointestinal tract (aGI-GvHD) in up to 60% of allogeneic haematopoetic stem cell transplant (HSCT) recipients who develop GvHD resulting in significant morbidity. Half of these patients will develop steroid refractory disease which is associated with high non-relapse mortality due to the lack of safe and efficacious therapies. Targeting gut homing lymphocytes with vedolizumab, an anti-α4β7 monoclonal antibody, has proven safe and effective for managing intestinal inflammation in the context of inflammatory bowel disease (IBD).
Aims: We tested the hypothesis that the gut trafficking α4β7/MADCAM-1 pathway is important in the pathogenesis of human aGI-GvHD and report our clinical experience of vedolizumab use for steroid dependent/refractory aGI-GVHD.
Methods: Prospective study (UK REC reference: 15/LO/1998), recruiting HSCT recipients with aGI-GvHD (n=10) and controls [IBD (n=36) and non-IBD controls (n=32)]. Samples collected included peripheral blood and distal colonic biopsies. The β7+ CD4+ compartment in peripheral blood was phenotyped with a multiparametric flow cytometry panel. MADCAM-1 and S100A8 (calprotectin subunit, biomarker of intestinal damage) expression in the gut were tested with RT-PCR. Clinical data on steroid dependent/refractory severe aGI-GvHD patients treated with vedolizumab (n=12) were retrospectively collected.

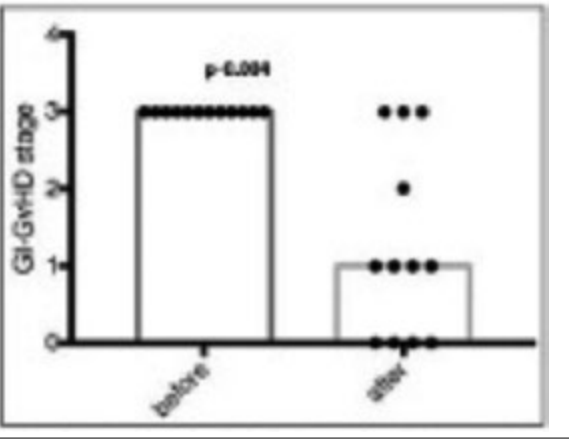

Figure 1. 75% median reduction in staging score of aGI-GvHD post Vedolizumab.

Results: Within the circulating effector memory population (CD3+CD4+CD45RA-CD45RO+CCR7-) there was significant enrichment of β7+ effector memory cells in both inflammatory conditions (IBD: 24% ±2.7, aGI-GvHD: 29%±6.5 *vs.* controls: 17%±1.1, both p<0.05). Analysis of each individual subtype of the effector T cell lineages demonstrated that β7 expression was especially enriched in Th1 (CXCR3+CCR6-), Th17(CCR6+CXCR3-) and Th1/17 (CXCR3+CCR6+) (p=0.0034). MADCAM-1 expression in aGI-GvHD is upregulated in comparison to non-IBD controls [fold change: 2(range 0, 5), p=0.006)] and at similar levels to patients with IBD, [fold change: 2 (range 0, 9)]. Levels of MADCAM-1 expression correlated to the expression of the calprotectin subunit S100A8 [r=0.90, 95%CI (0.34, 0.99), p=0.014]. Twelve patients with steroid refractory severe aGI-GvHD following T-deplete HSCTs were treated with vedolizumab, a monoclonal antibody targeting α4β7 on a compassionate basis. Nine patients had a sustained clinical improvement in gut symptoms (75% median reduction in clinical score, p=0.004, Figure 1) with a median aGI-GvHD free period of 5 months (range 0.5-28m) with 4 patients reporting rapid & complete resolution of GI symptoms. Seven of 12 patients are still alive at median follow up of 10 months (range 1-28m) with 3 patients dying of refractory GVHD, 1 from recurrent urosepsis and 1 from primary disease progression. Median number of vedolizumab doses required were 2 (range 1-15). Vedolizumab use was clinically safe and patients did not

suffer any infusion related adverse events. None of the patients had recurrence of symptoms on discontinuation of therapy.
Summary/Conclusion: We show that aGI-GvHD is associated with significant expansion of gut homing effector T cell lineages, most notably Th1 and Th17 cells. Interestingly the ligand for the α4β7 integrin (MAdCAM-1) is also highly expressed in gut tissue from aGI-GvHD patients, further supporting therapeutic targeting of this gut homing pathway. Our promising clinical data on vedolizumab, with its gut specific activity and low risk of systemic immunosuppression have the potential to change the landscape of treatment in this condition.

PS1467

ELTROMBOPAG TO IMPROVE PLATELET RECOVERY IN HAPLOIDENTICAL STEM CELL TRANSPLANTS (HAPLO-SCT): RESULTS OF A PHASE II TRIALPLUS A COMPARISON TO CONTROL PATIENTS

U. Popat[1,*], R. Bassett[1], F. Aung[1], B. Valdez[1], S. Ahmed[1], A. Alousi[1], Q. Bashir[1], C. Hosing[1], P. Kebriaei[1], I. Khouri[1], D. Marin[1], Y. Nieto[1], A. Olson[1], B. Oran[1], M. Qazilbash[1], K. Rezvani[1], R. Mehta[1], E. Shpall[1], S. Ciurea[1], B. Andersson[1], R. Champlin[1]

[1]*The University of Texas MD Anderson Cancer Center, Houston, United States*

Background: Slow platelet recovery is common after Haplo-SCT done with post-transplant cyclophosphamide (PCy) and bone marrow as a graft source. Improved platelet recovery may reduce the need for platelet transfusions and improve outcomes. Eltrombopag, a thrombopoietin receptor agonist, is indicated for use in ITP and aplastic anemia.
Aims: In this phase II study and comparison to a control group, we investigated the safety and efficacy of eltrombopag after Haplo-SCT.
Methods: Patients older than 18 receiving Haplo-SCT with PCy based GVHD prophylaxis were eligible for study. Patients received eltrombopag 300 mg per day for 60 days starting on day 5 after transplant. Median age was 57 (range 20-62). Primary endpoint of the study was to estimate the rate of platelet count > 50,000/μl on post-transplant day 60 without platelet transfusion support in the prior 7 days. We compared 37 patients who received at least one dose of eltrombopag to a control group of 83 patients transplanted during the same time period. Conditioning regimen was fludarabine, melphalan, and either thiotepa or 200cGy TBI and the graft source was bone marrow in all patients.
Results: All serious adverse events (SAEs) seen were those inherent in Haplo-SCT procedure. No eltrombopag-related ≥ grade 4 SAEs were seen. Patient characteristics were similar between eltrombopag and control groups, and study results are summarized in Table 1. Overall survival, progression free survival, GVHD rate, relapse rate, and non-relapse mortality were similar in the two groups.

Table 1.

	Control (n=83)	Eltrombopag (n=37)	P value
Primary Endpoint: number and proportion of successes	39 (47%)	24 (65%)	0.08
Median Time to platelet engraftment(>20K/μl)-days	34	30	0.05
Median Time to neutrophil engraftment	20	19	0.38
Cumulative incidence of platelet engraftment(>20K/μl)	63% (52-73)	81% (68-94)	0.05
Median platelet transfusions	19	12	0.20

Summary/Conclusion: Eltrombopag 300mg/day for 60 days is safe and appears to improve platelet recovery in patients receiving Haplo-SCT with PCy.

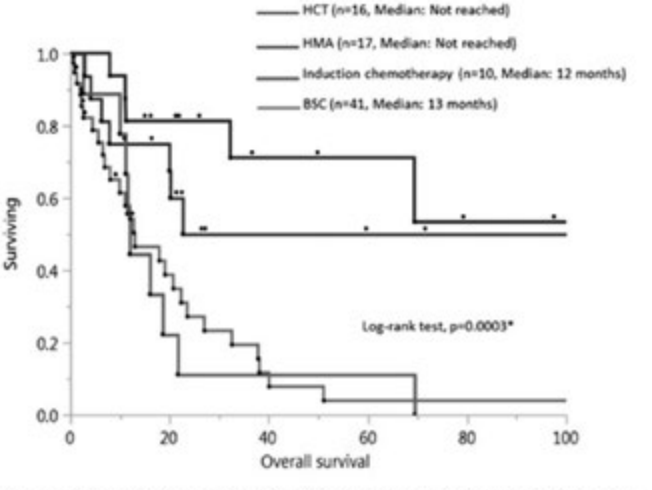
PS1468

ALLOGENEIC STEM CELL TRANSPLANTATION OVERCOMES THE NEGATIVE PROGNOSTIC IMPACT OF ASXL1 MUTATIONS IN TRANSPLANT ELIGIBLE PATIENTS WITH CHRONIC MYELOMONOCYTIC LEUKEMIA

P. Pophali[1,*], A. Mangaonkar[1], N. Gangat[1], A. Al-Kali[1], M. Elliott[1], K. Begna[1], H. Alkhateeb[1], W. Hogan[1], M. Litzow[1], M. Patnaik[1]

[1]*Hematology, Mayo Clinic, Rochester, United States*

Background: Chronic myelomonocytic leukemia (CMML) is an aggressive myeloid neoplasm with a median survival of <36 months. Mutations involving *TET2* (~60%), *SRSF2* (~50%) and *ASXL1* (~40%) are frequent, with frame shift and nonsense mutations in *ASXL1* independently and adversely impacting survival. Allogeneic stem cell transplantation (HCT) remains the only curative approach, with hypomethylating agents (HMA) not being able to modify disease biology.
Aims: We carried out this study to specifically assess the impact of HCT on survival outcomes in *ASXL1* mutant CMML patients.
Methods: Consecutive cases of CMML were identified from our CMML data base. Only patients below the age of 75 years were included (upper age limit for HCT). Targeted exome sequencing data for 36 genes was available at CMML diagnosis in all cases.
Results: 185 patients with a diagnosis of CMML with available molecular data at diagnosis were included; median age 67 years (range: 24-75); 122 (66%) males. Of these, 26 (14%) underwent allogeneic HCT (median age 57, range 26-74 years), while the remaining 159 (86%) patients (median age 68, range 24-75 years) were managed with HMA (n= 36), AML-like induction chemotherapy (n=18), and best supportive care (BSC, n=87). The most frequent genomic alterations in the cohort were *ASXL1* (49%), *SRSF2* (44%), *TET2* (35%), *NRAS* (16%), *SETBP1* (14%), and *CBL* (14%). In comparison to the non HCT group, patients in the HCT group were younger (p=0.0001), had lower HB levels (p=0.003), higher PB (p=0.0001) and BM (p=0.01) blast%, more likely to be classified as CMML-2 (p=0.01), had higher risk stratification by the Mayo model (p=0.005) and the Mayo Molecular Model (p=0.003), and were more likely to have received AML-like chemotherapy (p=0.0005). There were no differences in the cytogenetic risk stratification, with 53 (29%) patients having an abnormal karyotype.
In the HCT group, 11 (44%) patients received myeloablative conditioning (MAC) while 14 (56%) received reduced intensity conditioning (RIC). Donor sources included matched siblings (32%), matched unrelated (52%), mismatched unrelated (4%) haploidentical donors (8%), and umbilical cord blood (4%) (PB- 88%, BM-8% and cord blood- 4%). Acute GVHD grade 2-4 was reported in 58% patients while moderate to severe chronic GVHD was reported in 31% patients. Post-HCT disease relapse was seen in 6 (24%) patients. At a median follow up of 50 months, there were 102 (55%) deaths and 36 (19%) leukemic transformations. The median OS for all patients with *ASXL1* mutations was 20 months (95% CI: 12- 27 months). The median OS for *ASXL1* mutant patients that underwent HCT was not reached (95% CI: 32.2- NR months), while for those treated with non HCT options was 16 months (95% CI: 11.1-21.6 months) (p=0.0009) (Figure 1). There was no difference in survival between MAC vs RIC (p=0.34) or between the different graft sources. In the non-HCT cohort, patients treated with HMA had a median OS that was not reached (95% CI: 7.7- NR months), in comparison to 12 months (95% CI: 2.5-21.6 months) for AML type induction chemotherapy and 13 months (95% CI: 6.8-22.3 months) for BSC (p=0.02). Among the *ASXL1* mutant patients, the 3 year survival rate was 19%; 43% in HCT vs 13% in non HCT group (p=0.009).



Kaplan-Meier survival analysis for *ASXL1* mutated CMML patients treated with HCT and non-HCT therapies.

Figure 1.

Summary/Conclusion: Allogeneic HCT in eligible patients was able to overcome the adverse prognostic impact of *ASXL1* mutations. While HMA therapy does improve survival, the fact that it does not alter disease biology results in inevitable disease progression. Prospective studies are needed to validate our results.

PS1469

ASSOCIATION OF SOCIO-ECONOMIC FACTORS WITH SURVIVAL OF PATIENTS WHO EXPERIENCE SEVERE CLASSIC ACUTE GVHD AFTER ALLO-HSCT. A RETROSPECTIVE STUDY BY THE TRANSPLANT COMPLICATIONS WORKING PARTY, EBMT

Background: Acute graft-versus-host disease (GvHD) remains one of the main causes of non-relapse mortality (NRM) after allogeneic hematopoietic cell transplantation (alloHCT). The treatment of severe acute GvHD is complex and costly. The outcome may depend on many patient-, donor-, and transplant-related factors but potentially also on center activity and socio-economic issues.
Aims: The aim of this study was to identify factors associated with prognosis of patients who experience severe acute GvHD after alloHCT, including socio-economic measures and center experience.
Methods: Patients and methods: 4152 adults with hematological malignancies who received alloHCT from either HLA-matched sibling (n=1328) or unrelated donor (n=2824) between year 2011 and 2015, and developed grade 3 or 4 acute GvHD, were included in the analysis. Non-relapse mortality (NRM) was the primary study end-point. The following independent variables were considered together with clinical factors: current Health Care Expenditure (HCE), public HCE, private HCE, HCE as% of Gross Domestic Product per capita (GDP), Human Development Index (HDI), team experience. Median values were used as cut-off points for the analysis.
Results: In a univariate analysis, the probability of NRM at 2 years was increased for countries with lower current HCE (≤median vs. >median, 60% vs. 53%, respectively, p=0.009), lower HCE as% of GDP (57% vs. 52%, p=0.002), lower public HCE (60% vs. 53%, p=0.009) and lower HDI (57% vs 52%, p=0.007). Neither private HCE nor center experience affected NRM. In a multivariate model, among socio-economic factors, the risk of NRM was most strongly predicted by current HCE (>median vs. ≤median; HR=0.72, p=0.0007). In addition, the risk of NRM was increased with increasing patient age (HR=1.23 per each 10 years, p<0.0001), advanced disease stage (HR=1.17, p=0.005), previous autologous HCT (HR=1.33, p=0.011) and the use of unrelated donors (HR=1.3, p<0.0001), while reduced for CMV neg/neg donor/patient serological status compared to other combinations (HR=0.82, p=0.0007), the diagnosis of plasma cell disorders (HR=0.66, p=0.008), and the use of reduced intensity vs. myeloablative conditioning (HR=0.82, p=0.0005). HCE >median was also associated with reduced risk of the overall mortality (HR 0.73, p=0.0002) and reduced risk of treatment failure (either relapse or NRM, inverse of progression free survival; HR 0.78, p=0.003). No association of socio-economic factors with the risk of relapse or chronic GvHD could be documented.
Summary/Conclusion: Country-specific socio-economic factors, in particular current HCE, are strongly associated with survival of patients who experience severe acute GvHD. Our findings should be considered in interpretation of clinical studies in the field of alloHCT.

PS1470

COMPARISON OF REDUCED-INTENSITY CONDITIONING REGIMENS IN PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA > 45 YEARS UNDERGOING ALLOGENEIC STEM CELL TRANSPLANTATION – A RETROSPECTIVE STUDY BY THE ALWP/EBMT

Background: The optimal reduced-intensity conditioning (RIC) for patients (pts) >45 years (y) with acute lymphoblastic leukemia (ALL) undergoing allogeneic stem cell transplantation (allo-HSCT) is not defined.
Aims: We compared the 3 most popular RIC protocols used in this pts category.
Methods: 417 pts with ALL, age ≥ 45 y, who underwent a matched-sibling or unrelated allo-HSCT in first complete remission between 2005 and 2016 and reported to the EBMT were included. Allo-HSCT outcomes were assessed comparing fludarabine/busulfan (FLUBU, Bu at 6.4 mg/kg, n=127) vs fludarabine/melphalan (FLUMEL, Mel at 130-140 mg/m2, n=190) vs fludarabine-TBI (FLUTBI, TBI at 2 Gy, n=100).
Results: All pts received peripheral blood stem cell grafts. Most pts in the FLUBU group received ATG (88%), while most of the FLUMEL pts received Campath (71%) as GVHD prophylaxis. Only 12% of the patients received *in vivo* T cell depletion in the FLUTBI group (11 ATG and 1 campath). Pts in the FLUBU group were significantly older (median 59 y, range 45-71) than pts in the FLUMEL (median 54 y, range 45-74) and the FLUTBI (median 57 y, range 45-72) groups, respectively (p=0.001). Incidence of Ph+ ALL was lower in the FLUMEL group compared to FLUBU or FLUTBI groups (52% vs 69%, p<10-3). The rest of the demographics and transplant characteristics were comparable between the three groups.
At 2y , there were no significant differences between the groups in terms of cumulative incidence (CI) of relapse (FLUBU 40%, 95%CI 30-49; FLUMEL 36%, 95%CI 28-44; FLUTBI 41%, 95%CI 30-51, p=0.21); non-relapse mortality (NRM) (FLUBU 18%, 95%CI 11-26; FLUMEL 22%, 95%CI 16-29; FLUTBI 14%, 95%CI 8-22, p=0.09); overall survival (OS) (FLUBU 55%, 95%CI 45-65; FLUMEL 50%, 95%CI 42-59; FLUTBI 60%, 95%CI 49-70, p=0.62) or leukemia-free survival (LFS) (FLUBU 43%, 95%CI 33-52; FLUMEL 42%, 95%CI 34-51; FLUTBI 45%, 95%CI 35-56, p=0.99). In addition, all groups had similar CI of grade II-IV acute GVHD (FLUBU 23%, 95%CI 16-31; FLUMEL 27%, 95%CI 20-33; FLUTBI 32%, 95%CI 23-42, p=0.33). However, the CI of chronic (c) GVHD was significantly higher in the FLUTBI group (55%, 95%CI 44-65) in comparison to FLUBU (37%, 95%CI 27-46) and FLUMEL group (37%, 95%CI 28-46)(p=0.03). This difference resulted in significantly lower GVHD-relapse-free survival (GFRS) in the FLUTBI group (18%, 95%CI 10-26) compared to the FLUBU (35%, 95%CI 25-44) and the FLUMEL groups (28%, 95%CI 20-36) (p=0.02). In the multivariate analysis, there were no more differences in cGVHD and GRFS between the 3 conditioning regimens when adjusting for the use of *in vivo* T-cell depletion. Finally, the FLUMEL regimen (vs FLUBU) was shown to be an independent risk factor for a higher NRM (HR 1.97, 95% CI 1.05-3.72, p=0.04) mostly due to infections with CI of 11%, 95% CI 7-16 at 2 years.
Summary/Conclusion: Based on our current study the three most popular RIC preparative regimens (FLUBU, FLUMEL and FLUTBI) administred pre allo-HSCT for ALL patients >45y yield similar transplantation outcomes as for relapse, OS and LFS. The higher incidence of cGVHD and lower GRFS observed by univariate analysis in the FLUTBI group is mainly related to the low use of *in vivo* T-cell depletion in this group. Collectively, our results suggest that chemo/immunotherapeutic strategies prior and/or post-transplant should be improved to reduce relapse rather than adapting or intensifying the transplant-conditioning regimen.

PS1471

A PHASE I/II TRIAL OF INTRAVENOUS AZACITIDINE FOR ACUTE GVHD PROPHYLAXIS IN PATIENTS UNDERGOING MATCHED UNRELATED STEM CELL TRANSPLANTATION: INTERIM PHASE II RESULTS

M. Schroeder[1,*], J. Choi[1], M. Cooper[1], S. Marriott[1], K. Gerbic[1], J. Liu[1], A. Ghobadi[1], K. Stockerl-Goldstein[1], R. Vij[1], A. Cashen[1], A. Camille[1], M. Jacoby[1], I. Pusic[1], R. Romee[2], G. Uy[1], P. Westervelt[1], J. DiPersio[1]

[1]Washington University School of Medicine, Saint Louis, [2]Dana Farber Cancer Institute , Boston, United States

Background: The negative impact of acute graft-versus-host disease (GvHD) on morbidity and mortality after allogeneic transplant is significant; thus, finding a means to harness the beneficial Graft versus tumor effect (GVT) while reducing or eliminating GvHD is a major goal of transplant trials. Alterations in immune subsets present after transplant can work to suppress allo-reactive T-cell responses by increasing regulatory T-cells and suppressing allo-reactive T-cell proliferation. Azacitidine (AZA) treatment in pre-clincal models resulted in an increase in regulatory T-cells, a decrease in allo-reactive T-cell proliferation and prevention of acute GvHD while preserving GVT effects (Choi *et al.* Blood 2010, Cooper *et al.* J Immunol 2017). Based on these results a phase I/II study was designed to test the safety and efficacy of AZA administered shortly after transplant for the prevention of acute GvHD and relapse in subjects receiving transplants from matched unrelated stem cell donors. We are reporting the interim results for Phase II.
Aims: To define the maximum tolerated dose of AZA and the effect on grade II-IV GvHD when given after matched unrelated donor transplant (MUD).
Methods: Patients with hematologic malignancies in remission age 18 – 70 were eligible. Myeloablative or reduced intensity conditioning without antithymocyte globulin was used. All recipients in phase II were required to receive G-CSF mobilized peripheral blood grafts with at least 4×10^6 CD34/kg and have at least 1×10^6 CD34/kg cryopreserved as back up in case of primary graft failure. AZA was administered intravenously on day +7 for five consecutive days and repeated every 28 days for a total of 4 cycles after allogeneic transplant from a 10/10 HLA matched unrelated donor (Figure 1). GvHD prophylaxis with mini-methotrexate and tacrolimus was given. Phase I, 3+3 dose escalation design of 4 cohorts (AZA dose levels 15, 30, 37.5, and 45 mg/m^2) was used to determine the recommended phase II dose (RP2D). The primary outcome for phase II is the rate of grade II – IV acute GvHD at day 180 after transplant.
Results: The RP2D from phase I was 45 mg/m^2 (Schroeder *et al.* ASH 2015) with one DLT observed secondary to primary graft failure. To date in phase II we have transplanted 35 of 46 planned subjects and all 35 have received study drug. Recipient characteristics include: median age 59 (range 24 – 70); 54% male; diagnoses - AML in CR (22), MDS (13); conditioning - reduced intensity (12), myeloablative (23). Primary graft failure has occurred in one subject in phase II related to HHV6 infection. Median ANC engraftment was 14 days (range excluding case of graft failure 10 - 18 days). Median platelet engraftment was 19 days (range 10 – NR). To date, the phase II acute GvHD incidence grade II – IV has occurred in 15 (43%) and grade III/IV in 7 (20%). The majority of cases have responded to steroids with 7 cases of steroid refractory aGvHD. With a median follow up of 248 days (range 27 - 891), 4 subjects have relapsed and 25 (71%) remain alive. The most common non-hematologic grade 3 or 4 AEs were gastrointestinal toxicity, electrolyte abnormalities, and infections.

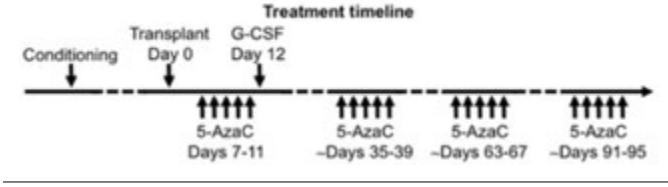

Figure 1.

Summary/Conclusion: In conclusion, AZA can be given safely starting at day +7 after MUD transplant up to a dose of 45mg/m^2. Phase II enrollment and follow up is ongoing and will be updated at the meeting. Correlative studies from banked bio-specimens evaluating T-cell subsets and methylation before and after treatment are ongoing.

PS1472

BUSULFAN FLUDARABINE (BU-FLU) COMPARED TO THIOTEPA BUSULFAN FLUDARABINE (TBF) FOR ALLOGENEIC TRANSPLANTS IN ACUTE MYELOID LEUKEMIA (AML) OR REFRACTORY ANEMIA WITH EXCESS BLASTS (RAEB) IN REMISSION

A. Bacigalupo[1,*], F. Sora'[1], S. Sica[1], C. Di Grazia[2], P. Chiusolo[1], N. Mordini[3], A. Olivieri[4], A.P. Iori[5], E. Angelucci[2]

[1]Hematology, Pliclinico Gemelli, Roma, [2]Hematology, IRCCS Azienda Ospedaliera Universitaria San Martino – IST, Genova, [3]Hematology, Ospedale S Croce, Cuneo, [4]Hematology, Ospedali Riuniti, Ancona, [5]Hematology, Policlinico Umberto 1, Roma, Italy

Background: The combination of Busulfan and fludarabine (BU-FLU) is considered a standard conditioning regimen for patients with acute myeloid leukemia undergoing an allogeneic hemopoietic stem cell transplant (HSCT), especially in patient older than 40 years of age. However, in a recent prospective study, designed for patients in first or second remission (CR1 or CR2) the incidence of leukemia relapse at 3 years was 38%, both for patients receiving BU-FLU as well as for patients randomized to BU-CY (Lancet Oncol 2015;16:1525). The addition of thiotepa to a BU-FLU regimen (referred to as TBF) has shown promising control of leukemia, and has emerged as a standard regimen in cord blood (CB) transplants (BMT 2012; 47: 1287). The question is whether this holds true also for transplants other than CB grafts.
Aims: to compare Bu-FLU with TBF in patients with AML or RAEB, grafted in remission from related or unrelated donors.
Methods: Eligible for this study were 336 patients allografted between January 2008 and April 2017 with AML or RAEB in hematologic remission : 165 patients received the BU-FLU regimen (busulfan 3.2 mg/kg/day x4; and fludarabine 40 mg/m^2/day x4), and 171 received TBF(thiotepa 5mg/kgx2, busulfan 3.2 mg/kg/dayx3, fludarabine 50 mg/m^{2}x3). Graft-versus-host disease (GVHD) prophylaxis was as follows: in HLA identical sibling transplants , cyclosporin (CyA) and Metothrexate (MTX); in unrelated donor transplants CyA+MTX+ antithymocyte globulin (ATG) and for family haploidentical donors (HAPLO) , CyA, mycophenolate mofetil (MMF) and cyclofosphamide 50mg/kg given on day +3 and +5, after transplantation (PT-CY) . Supportive care and infectious disease prophylaxis, or pre-emptive therapy, were provided as per Institutional protocols. The two groups (BUFLU and TBF) were comparable for age (p=0.3). The TBF group had more CR2 (27% vs 10%, p=0.001), more RAEB/sAML (29% vs 12%, p<0.01), more haploidentical transplants (62% vs 2%) as compared to BU FLU
Results: With a median follow up of 486 and 513 days (range, 8-3044 and 2-2322 respectively) after transplantation, the 5-year cumulative incidence of TRM was 15% and 9% for BU-FLU and TBF (p=0.1); the 5-year cumulative incidence of leukemia relapse related deaths (RRD) was 22% and 8% (P<0.001). The 5-year actuarial survival was 53% (43-62%) and 77% (69-85%) (p<0.001) respectively for the BUFLU and the TBF group. The survival advantage was seen also when looking only at HLA identical siblings and UD, excluding HAPLO grafts (52% vs 78%, p=0.01).
In a multivariate Cox analysis, after correcting for patients age, interval diagnosis transplant, first or second remission , and donor type, the use of TBF reduced the risk of death as compared to BU-FLU (RR 0.41, p=0.01) . In a Cox analysis on RRD, TBF showed a reduced risk (RR 0.35, p=0.04). The only significant predictor of TRM was age over 50 years (RR 2.5, p=0.01).
Summary/Conclusion: Superior survival of patients receiving TBF , as compared to BU-FLU appears to be due to reduced relapse, whereas TRM is comparable. The survival advantage is independent of donor type, and therefore of GvHD prophylaxis.

PS1473

EFFICACY AND SAFETY OF DEFIBROTIDE BY VENO-OCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME (VOD/SOS) DIAGNOSTIC CRITERIA IN AN EXPANDED-ACCESS (T-IND) STUDY

S. Corbacioglu[1,*], N. Kernan[2], A. Pagliuca[3], R. Ryan[4], R. Hume[4], W. Tappe[4], P. Richardson[5]

[1]Department of Pediatric Hematology, Oncology and Stem Cell Transplantation, University of Regensburg, Regensburg, Germany, [2]Pediatric BMT Service, Memorial Sloan Kettering Cancer Center, New York, United States, [3]King's College Hospital, London, United Kingdom, [4]Jazz Pharmaceuticals, Inc., Palo Alto, [5]Jerome Lipper Multiple Myeloma Center, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States

Background: Hepatic VOD/SOS is a potentially life-threatening complication of conditioning regimens for hematopoietic stem cell transplant (HSCT). VOD/SOS with multi-organ dysfunction (MOD; renal and/or pulmonary) may be associated with >80% mortality. Traditionally, VOD/SOS has been clinically diagnosed with Baltimore criteria (bilirubin ≥2 mg/dL [34 µmol/L] plus two or more of hepatomegaly, ascites, and weight gain ≥5%), modified Seattle criteria (2 or more of bilirubin >2 mg/dL, hepatomegaly or right upper quadrant pain, and weight gain >2% [sometimes >5%]), or by biopsy. VOD/SOS is dynamic and may be progressive, and traditional criteria require overt clinical manifestation (eg, Baltimore criteria requires hyperbilirubinemia), which may occur relatively late or not at all, even in the course of severe disease. Defibrotide is approved to treat severe VOD/SOS post-HSCT in patients aged >1 month in the European Union, and VOD/SOS with renal or pulmonary dysfunction post-HSCT in the United States and Canada.
Aims: To compare Day +100 survival in subgroups of post-HSCT patients who were diagnosed with VOD/SOS by Baltimore criteria, modified Seattle criteria, or biopsy, and were treated with defibrotide in the expanded-access T-IND program (2007-2016).
Methods: The original T-IND protocol (to 2012) required VOD/SOS post-HSCT per Baltimore criteria or biopsy, and MOD; it was amended to include patients without MOD, with VOD/SOS per modified Seattle criteria. Diagnosis criterion used was selected on the case report form by the investigator. Patients received defibrotide 25 mg/kg/d (6.25 mg/kg q6h) recommended for ≥21 days.
Results: Of 1000 patients in the T-IND with VOD/SOS post-HSCT, 635 (63.5%) were reported as being diagnosed by Baltimore criteria, 331 (33.1%) by modified Seattle criteria, and 34 (3.1%) by biopsy. MOD was present in 512 (51.2%) of all patients (378 [59.5%] in the Baltimore group, 112 [33.8%] modified Seattle group, and 22 [64.7%] biopsy group). Kaplan-Meier estimated Day +100 survival among all defibrotide-treated patients with VOD/SOS post-HSCT was 58.9% (95% CI, 55.7% 61.9%) with 51.6% (95% CI, 47.6% 55.5%) for the Baltimore group, 72.3% (95% CI, 67.0% 76.8%) for the modified Seattle group, and 67.6% (95% CI, 49.2% 80.6%) for the biopsy group. Similar patterns of Day +100 survival among patients diagnosed by Baltimore vs modified Seattle criteria were shown in subgroups with and without MOD (Figure 1). Treatment-emergent and treatment-related adverse events (AEs) occurred in 66.4% and 18.8% of all patients, 71.6% and 17.9% of Baltimore patients, 61.2% and 20.5% of modified Seattle patients, and 50.0% and 8.3% of biopsy-proven patients. Hemorrhage occurred in 25.4% of all patients, 28.4% of Baltimore criteria patients, 22.4% of modified Seattle patients, and 16.7% of biopsy-proven patients.

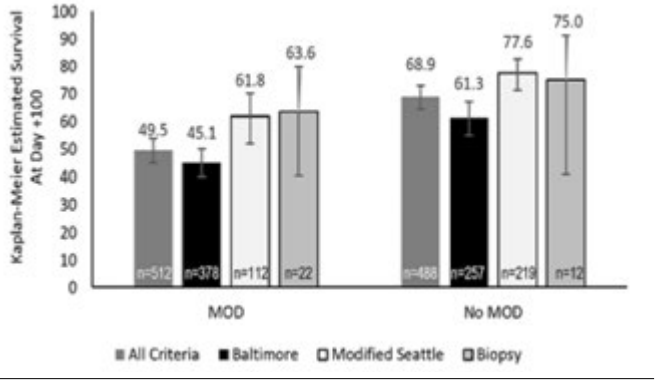

Figure 1.

Summary/Conclusion: Patients diagnosed by the more stringent Baltimore criteria, which requires hyperbilirubinemia, had lower survival rates vs patients diagnosed using modified Seattle criteria or biopsy. Treatment-emergent AEs were consistent with previous reports of defibrotide treatment. The lower overall survival in the Baltimore group suggests that requiring hyperbilirubinemia for VOD/SOS diagnosis may result in patients with more severe disease, leading to worse outcomes. These results corroborate data published by Yakushijin *et al.* (*Bone Marrow Transplant*, 2016).

PS1474

PLASMA PRESEPSIN LEVEL IS A PREDICTIVE MARKER OF SEVERE ACUTE GVHD AFTER ALLO-HSCT: USEFULNESS AS A BIOMARKER OF ALLO-HSCT RELATED COMPLICATION

T. Oyake[1,*], A. Otsu[1], M. Nishiya[1], T. Shimoyama[1], N. Sugawara[1], R. Sasaki[1], W. Izumita[1], Y. Tsukushi[1], S. Kowata[1], Y. Ishida[1], T. Ishida[1]

[1]Department of Hematology and Oncology, Internal Medicine, Iwate Medical University School of Medicine, Morioka, Japan

Background: Infectious complications including febrile neutropenia (FN) are often observed in patients with hematological disease after allogeneic hematopoietic stem cell transplantation (allo-HSCT). These Infectious complications sometimes cause of graft versus host disease (GVHD) or other allo-SCT related complications. Presepsin (Pre-SEP) is a subtype of soluble CD14, which is a receptor for lipopolysaccharide (LPS)/LPS-binding protein complexes and is expressed on the surface of monocytes and neutrophils. In cases of bacterial infections, Pre-SEP is produced from monocytes and neutrophils, and quickly elevated in plasma, due to phagocytes of bacteria by monocytes or neutrophils. Recently, it has been shown to be a useful biomarker for assessing the severity of sepsis and has come into use in the field of critical care medicine. However, little is known about the biological characteristics of Pre-SEP in patients with neutropenia including FN and other infectious complications after allo-HSCT.
Aims: we tried to clarify where it is a useful marker for diagnostic assessment of FN after allo-HSCT, and for predictive assessment of GVHD and other allo-HSCT related complications.
Methods: We prospectively measured the plasma concentration of Pre-SEP in the patients who received allo-HSCT, at Day-7, 0, 4, 7, 14, 21 and 28 after allo-SCT in our single institute: Iwate Medical University Hospital (N=30). And we evaluated the association between the Pre-SEP level and allo-HSCT related complications such as infections, GVHD and others. Furthermore, we analyzed the clinical significance of Pre-SEP as biomarker of life-threating complications after allo-HSCT. This study was approved by the institutional review board in Iwate Medical University.
Results: In most of cases after allo-SCT, Pre-SEP was elevated from the time at FN onset, and decreased to normal level along with improvement of FN due to the treatment of antibiotics and/or recovery from neutropenia. (N=30, Day-7: 182.5 pg/ml (104-356), Day0: 209 pg/ml (120-910), Day4: 258 pg/ml (145-862), Day7: 353 pg/ml (122-551), Day14: 470 pg/ml (165-835), Day21: 346 pg/ml (130-707), Day28: 348 pg/ml (114-861), median (range), cut off value: 314 pg/ml) Otherwise, Pre-SEP was continuously elevated in some cases after improvement of FN, and these continuously elevated cases tIended to be often accompanied with allo-HSCT related complications such as GVHD. In patients suffered from acute GVHD (grade2-4), the average of Pre-SEP level from the six points of following time in each case: at day0, Day4, day7, day14, day21 and day28 after allo-SCT were significantly higher compared to that in cases with no acute GVHD (p= 0.025). Similarly, in patients suffered from acute GVHD (grade3-4), the average of Pre-SEP level from the six points of following time in each case: at day0, day7, day14, day21 and day28 after allo-SCT were significantly higher compared to that in cases with acute GVHD (grade1-2) (p= 0.015). On the other hand, there was no deference in plasma Pre-SEP level at the above period after allo-SCT, between cases with chronic GVHD and without chronic GVHD.
Summary/Conclusion: Plasma Pre-SEP level is not only a reliable marker of FN after allo-SCT, but a predictive marker of severe acute GVHD. Closer monitoring of Pre-SEP could be a good help for the predictive assessment for allo-SCT related life-threating complications.

PS1475

ROLE OF IFN-GAMMA IN IMMUNE-MEDIATED GRAFT FAILURE AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

P. Merli[1,*], I. Caruana[1], R. De Vito[2], F. Del Bufalo[1], L. Strocchio[1], G.A. Weber[1], A. Pitisci[1], V. Cirillo[1], F. Galaverna[1], M. Algeri[1], G. Palumbo[1], P. Montanari[3], M. Ballabio[3], F. Locatelli[1,4], C. De Min[3]

[1]Department of Pediatric Hematology and Oncology, [2]Histopathology Unit, IRCCS Bambino Gesù Children's Hospital, Rome, Italy, [3]Novimmune SA, Geneva, Switzerland, [4]University of Pavia, Pavia, Italy

Background: Data from animal models suggested that interferon gamma (IFNγ) plays a central role in graft failure (GF), an important cause of morbidity and mortality after allogeneic hematopoietic stem cell transplantation (HSCT).
Aims: To characterize the pathophysiology of GF *in vivo*.
Methods: We characterized the cytokine/chemokine profile of patients experiencing GF after HSCT, through serial sampling (at day 0, +3, +7, +10, +14 and +30 after transplantation), comparing the results with matched-controls who achieved sustained donor engraftment. Cytokine levels in peripheral blood (PB) was evaluated using validated MesoScale Discovery

platform-based immunoassays (MSD, Rockville, USA). In 7 patients experiencing GF who underwent bone marrow sampling when GF was suspected, we also studied the lymphocyte infiltrate through flow-cytometry.
Results: Between December 2015 and August 2017, 15 patients developed GF, 14 primary and 1 secondary. Median age at transplant was 2.6 years (range 0.3-16). Patient's original diagnoses were: severe aplastic anemia (4 patients), familial hemophagocytic lymphohistiocytiosis (HLH, 3 patients), metabolic disorders (2 patients), acute lymphoblastic leukemia, acute myeloid leukemia, thalassemia major, congenital amegakaryocytic thrombocytopenia, malignant osteopetrosis, combined immunodeficiency (1 patient each). The donor was a partially matched family donor in 13 cases; either a matched unrelated donor or an unrelated cord blood unit was used for the remaining 2 patients. 50% of patients presented anti-HLA antibodies. Fifteen paired patients who underwent HSCT with sustained donor engraftment in the same period were used as controls.
The levels of IFNγ, CXCL9, CXCL10, sIL2Rα, IL10, sCD163 and TNFα differed significantly between GF patients and controls (Figure 1, panels A-C). In patients experiencing GF, IFNγ, CXCL9 and IL10 levels started to increase 3 days after infusion of stem cells. In details, IFNγ levels at day +3 were 8859±7502 pg/ml vs 0 pg/ml for controls (p=0.02), while CXCL9 levels were 1514.0±773 pg/ml vs 233.6 ±50.1 pg/ml for controls (p=0.0006). Regarding CXCL9 levels at day+3, ROC analysis showed an area under the curve of 0.905 (95% Confidence Interval 0.709-0.987) (p<0.0001) (Figure 1D); a cut-off value of 274.5 pg/ml had a sensibility of 88.89% and a specificity of 78.57%.
BM lymphocyte infiltrate showed an increased number of CD8+ positive cells; these cells displayed an effector memory phenotype (CD45RO+/CCR7-). Moreover, they expressed markers of both activation (e.g. over-expression of CD95 and down-regulation of CD127) and exhaustion (CD57, CD279 (PD1), CD223 and CD366). Finally, when the T-cell repertoire was analyzed by the evaluation of the Vβ chain on the CD3+ population, a polyclonal distribution of spectratypes across the TCR Vβ gene families was found.

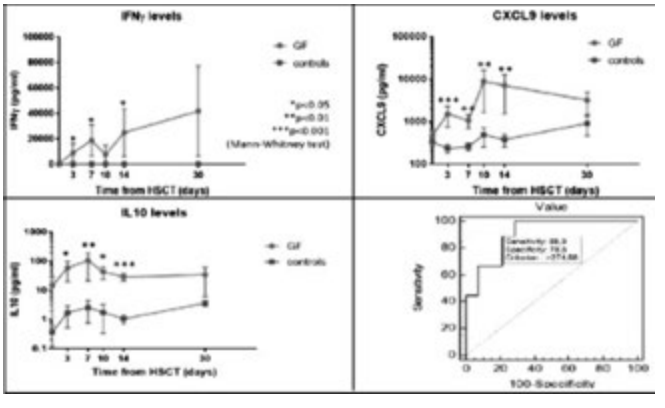

Figure 1.

Summary/Conclusion: We demonstrated a peculiar cytokine/chemokine profile in patients experiencing immune-mediated GF, characterized by high levels of IFNγ and CXCL9, as well as other "HLH-like" factors. These data suggest that the activation of IFNg-pathway, as shown by high CXCL9 levels, represents a biomarker for early diagnosis of GF. Moreover, our results offer the rationale for designing a study aimed at exploring the therapeutic/preventive role of a targeted neutralization of IFNg in patients undergoing HSCT using a monoclonal antibody such as emapalumab, already being studied for the treatment of HLH.

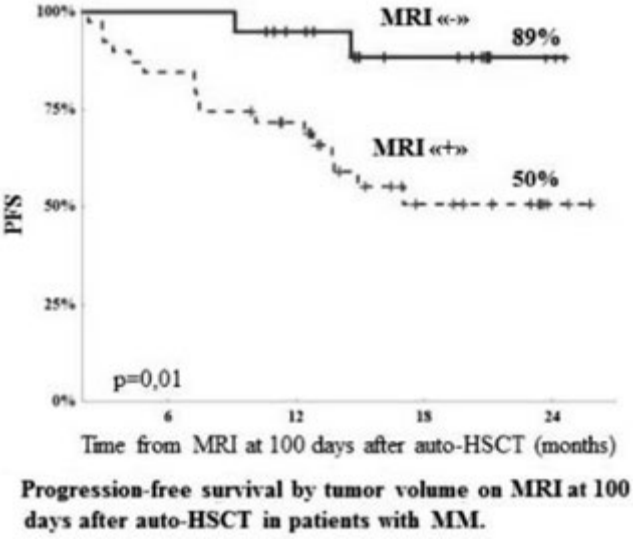
PS1476

EFFECTS OF POST-AUTO-HSCT MRI BONE MARROW LESIONS ON PROGRESSION-FREE SURVIVAL IN PATIENTS WITH MM

M. Solovev[1,*], L. Mendeleeva[1], G. Yatsyk[2], N. Lutsik[2], M. Firsova[1], V. Savchenko[1]

[1]Bone Marrow Transplantation, [2]Magnetic Resonance Tomography, National Research Center for Hematology, Moscow, Russian Federation

Background: In view of the pathogenic mechanisms of bone resorption by myeloma cells, visualization of lesions by MRI, the most sensitive method for the detection of infiltration, may become one of the criteria for subsequent differential treatment of patients with .
Aims: To determine the effect of bone marrow lesions detected by MRI in patients with following auto-HSCT on progression-free survival (PFS).
Methods: 60 patients with MM (26 male and 34 female) aged 36 to 66 years (median age 56) were enrolled in a prospective study in the period from December 2015 to June 2017. The ISS stages at the time of diagnosis were as follows: stage I in 22 patients, stage II in 22, and stage III in 16 subjects. Soft tissue components were observed in 23 patients (38%). All patients received induction therapy with bortezomib, immunomodulatory drugs were used in 10 cases. Following induction therapy, single auto-HSCT was performed in 47 patients and tandem auto-HSCT in 13. MRI of the spine and pelvic bones was carried out with a GE Signa Profile system without contrast enhancement 100 days after the first auto-HSCT. The nature of the lesions was determined and the bone marrow infiltration lesions (≥ 5 mm) counted. The total lesion volume was determined as follows: identified foci and bone marrow infiltration lesions were labeled based on signal intensity intervals using the Regions of interests tool; 3d reconstruction and the LINS MACHAON software were used for segmentation, with subsequent labeling of identified bone marrow lesions and comparison with the total labeled volume and the original image. After labeling of the infiltrative lesions, the abnormal MR signal area was calculated and recorded as the total tumour volume. Statistical analysis was done using Statistica 10.
Results: After auto-HSCT, the following antitumour response rates were observed: stringent CR in 19 patients (32%), CR in 13 (22%), VGPR in 23 (38%) and PR in 5 subjects (8%). MRI demonstrated bone marrow lesions in 47 patients: the number of lesions ranged from 1 to 56 (average 6). The distribution of subjects by number of detected lesions was as follows: 1 – 10 in 40 patients (85%), 11 - 20 in 5 (11%), and over 20 lesions in 2 cases (4%). The total tumour volume varied from 0 to 103 cm^3 (average 10 cm^3). At the time of the analysis, 58 patients were alive and 33 of them (57%) had maintained a CR for 13 to 29 months (median 17 months); 20 patients had a relapse 5 to 26 months after auto-HSCT (median 8 months). The two-year PFS for the entire sample was 55% (the median was not reached). In 20 out of 60 patients (33%), the tumour volume was found to be less than 1 cm^3, which was regarded as no minimal residual tumour or MRI negativity. Comparative PFS analysis conducted in patients with MM depending on the tumour volume at 100 days after auto-HSCT revealed a statistically significant difference (p=0.01): the two-year PFS in MRI-negative patients after auto-HSCT was 89% vs. 50% in MRI-positive subjects (Figure 1).



Progression-free survival by tumor volume on MRI at 100 days after auto-HSCT in patients with MM.

Figure 1.

Summary/Conclusion: MRI negativity after auto-HSCT is a favourable prognostic factor predicting long progression-free survival.

PS1477

COMBINED EVALUATION OF DISEASE RISK INDEX AND ABCG2 EXPRESSION IDENTIFY AML PATIENTS AT A VERY HIGH RISK OF RELAPSE AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

D. Damiani[1,*], M. Tiribelli[1], A. Michelutti[1], A. Sperotto[1], A. Geromin[1], E. Toffoletti[1], R. Fanin[1]

[1]Division of Hematology and BMT, Azienda Sanitaria Universitaria Integrata di Udine, Udine, Italy

Background: Despite the increased use of allogeneic stem cell transplantation (SCT) as a curative option in high risk hematologic malignancies, disease relapse remains a major challenge for long term survival and prediction of relapse risk after SCT is therefore a pivotal issue. In the past years, the disease risk index (DRI) has been specifically developed to predict transplantation failure focusing mainly on disease recurrence rather then on transplant-related toxicities. We have previously reported a significant correlation between ABCG2 overexpression and relapse probability in patients undergoing allogeneic SCT for acute myeloid leukemia (AML).
Aims: In this work we evaluated the impact of ABCG2 expression on the outcome of SCT in AML patients classified according to DRI.
Methods: We retrospectively analyzed 184 patients (87 males and 97 females, median age 50 years, range: 17-22) receiving allogeneic SCT for high risk AML; according to conditioning regimen, 108 patients underwent myeloablative (MAC) and 76 reduced intensity (RIC) transplant. Competing risk analysis and Fine-Gray proportional hazard regression were employed to explore the impact of ABCG2 expression, DRI risk group, and the most common patient-, donor- and transplant-related variables on cumulative incidence of relapse (CIR) and non-relapse mortality (NRM).
Results: At the time of analysis 71/184 (38.5%) patients were alive in complete remission (CR), 71/184 (38.5%) relapsed after SCT and 42/184 (23%) died without relapsing. In univariate analysis, factors affecting relapse were status at transplant (62%, 95%CI 52-75 in patients with detectable AML vs 24%, 95%CI 17-33 in CR patients; p=0.00001), ABCG2 over-expression (49%, 95%CI 39-61 vs 28%, 95%CI 21-38 in ABCG2- patients; p=0.005), non-sibling donor (43%, 95%CI 24-53 vs 30%, 95%CI 21-42 in SCT from HLA-identical sibling; p=0.046), absence of chronic GVHD (44%, 95%CI 35-55 vs 20%, 95%CI 11-33 in patients with chronic GVHD; p=0.003), DRI (70%, 95%CI 52-83 in very high risk vs 57% 95%CI 47-70 in high risk vs 16%, 95%CI 10-26 in intermediate risk vs 11%, 95%CI 2-18 in low risk; p<0.0001). In multivariable analysis statistical significance was retained by ABCG2 positivity (HR=2.7, 95%CI 1.71-4.30; p=0.0002) and DRI risk group (HR=1.77, 95%CI 1.36-2.30; p=0.0002). Combination of ABCG2 and DRI resulted in four groups with significantly different relapse risk (Figure 1). Notably, ABCG2 overexpression identified among DRI intermediate patients a subgroup with significantly higher relapse probability (28%, 95%CI 16-49 vs 16%, 95CI 10-26 of the whole intermediate DRI group), and a small cohort of DRI very high patients with dismal outcome.

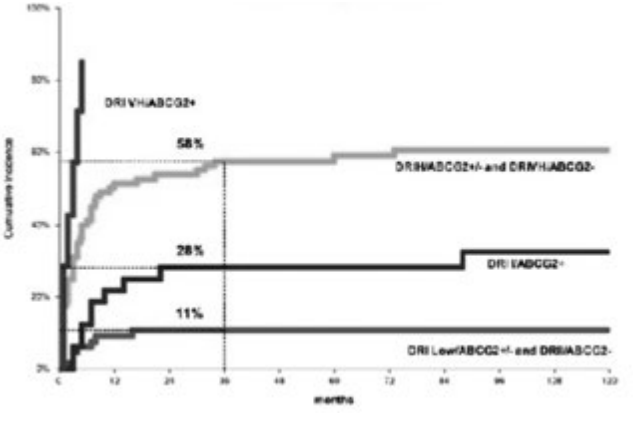


Figure 1. Relapse risk according to DRI and ABCG2.

Summary/Conclusion: ABCG2 overexpression confirmed its negative prognostic role after allogeneic SCT in AML and could be combined to DRI. A refined patient's stratification could be useful to tailor transplantation platforms to eradicate minimal residual disease or to develop preemptive therapies avoiding overt relapse.

PS1478

AFTER ALLOGENEIC HEMATOPOIETIC TRANSPLANTATION, A COMPOSITE SCORE BASED ON PLASMATIC LEVELS OF IL-2 RECEPTOR AND TIM-3, CAN PREDICT, AT DAY +18, TRM AND SEVERE A-GVHD

G. Milone[1,*], S. Leotta[1], A. Cupri[1], R. Crocchiolo[2], A.E. Marchese[3], G. Sapienza[4], A. Spadaro[4], G. Avola[4], L. Scalise[4], G. Tripepi[5]

[1]Hematology and BMT, Policlinico , Catania, [2]Hematology, Azienda Sanitaria Bergamo ovest, Bergamo, [3]Laboratory Medicine, [4]Hematology and BMT, Azienda Policlinico Vittorio Emanuele, Catania, [5]CNR, Ospedali Reggio Calabria, Reggio Calabria, Italy

Background: We have previously demonstrated that, at expected time of engraftment (day +18), patients that later showed acute GVHD, already at day +18, have a reduced colony growth in their marrow (Exp Hem 2015, 43:430) suggesting that at this time various degree of alloreactivity are already acting. On this basis we hypothesized that may be possible to identify early, at the time of engraftment (day +18), patients having distinctive levels of alloreactivity and hence distinctive prognosis.
Aims: In a prospective study, we determined, the prognostic value of plasma cytokines (IL-6, rec IL-2, ST-2, ICAM, IFN gamma, TIM-3) measured at expected time of engraftment (day+18/+19).
Methods: Plasma cytokines (IL-6, rec IL-2, ST-2, ICAM, IFN gamma, TIM-3) were measured using a ELISA assay, plasma was obtained on day+18/+19 after allogeneic hematopoietic transplantation. Eighty-five patients were studied, Mean age was 45 years (18-67), 53 were affected by myeloid malignancies, 32 by lymphoma or myeloma, donor type for allogeneic hematopoietic transplantation was in 38% an HLA-identical sibling and in 62% an alternative donor (MUD/HAPLO).
Results: In univariate analysis, negative factors important for OS were age (HR: 1.024, p=0.11), Alternative Donor (HR 1.913 p=0.07), Source of HSC from BM (HR 1.735, p=0.13), high level of Interleukin-2 receptor (HR 3.329, p=0.0004) and high level of TIM-3 in plasma. (HR: 10.087, p=0.002). In multivariable analysis high level of Interleukin-2 receptor and high level of TIM-3 were retained important for OS, (REC IL2: HR 3.140, p= 0.004; TIM-3: HR 10.940, p=0.003). ROC curve were used to identify in TIM-3 and REC IL-2 levels a cutoff having the best combination of sensitivity and specificity in respect to death for any cause and this cut-off value was used to divide continuous data in groups. A composite score from value on day +18 of TIM-3 and REC IL2 was developed and patients were classified in three groups based on number of cytokines over cut-off (none, one or two). Patients having both cytokines over the cut-off (24/85 patients) had a TRM of 40% versus a TRM of 12% in the group of remaining patient (61/85 pts), Gray test p=0.002. GVHD caused death in 25% of patients of high risk group while caused death in 6.8% of low risk patients.
Summary/Conclusion: The study of TIM.3 and REC IL-2 in plasma at day +18 allows the early identification of patients at high risk for NRM and of severe a-GVHD, such patients need increase of immunosuppressive therapy.

PS1479

A NEW ULTRASONOGRAPHY-BASED SCORING SYSTEM IS EFFECTIVE DIAGNOSTIC TOOL FOR SINUSOIDAL OBSTRUCTION SYNDROME AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION

M. Nishida[1,2,*], K. Kahata[3], E. Hayase[1,3], M. Sato[2], Y. Kudo[1,2], S. Omotehara[1,2], T. Iwai[2], S. Shiratori[3], K. Okada[3], H. Goto[3], J. Sugita[3], M. Onozawa[3], D. Hashimoto[3], T. Endo[3], T. Kondo[3], H. Shibuya[2], C. Shimizu[1], T. Teshima[3]

[1]Division of Laboratory and Transfusion Medicine, [2]Diagnostic Center for Sonography, Hokkaido University Hospital, [3]Department of Hematology, Hokkaido University Faculty of Medicine, Sapporo, Japan

Background: Sinusoidal obstruction syndrome (SOS) / veno-occulusive disease (VOD) is a well-documented complication after hematopoietic stem cell transplantation (HSCT). The diagnostic criteria of SOS/VOD are based on clinical findings. Considering the pathogenesis of SOS/VOD, that is endothelial damage in sinusoid leading to impairment of blood flow and congestion, transabdominal ultrasonography (US) would be a very feasible modality thanks to its capacity to detect alteration of blood flow.
Aims: This study aimed to establish a new diagnostic scoring system based on US findings by prospective study.
Methods: The patients who underwent allogeneic HSCT in our institute were enrolled. US scanning method consisting of 17 items was applied to all the patients before HSCT and on day 14 or when the signs of SOS/VOD appeared after HSCT. Based on the findings obtained from 17-item method, new diagnostic method by US was established and assessed its effectiveness.
Results: In total 106 patients were analyzed, of which 10 patients were diagnosed as SOS/VOD by Baltimore criteria, Seattle criteria or The European Society for Blood and Marrow Transplantation criteria. As a result of univariate analysis between control and SOS/VOD group, 10 findings and parameters were selected and weighed according to its significance to establish scoring system. This new scoring system (US-10) which consists of ten findings including hepatomegaly, gall bladder wall thickening, portal hypertention appeared in portal vein, paraumbilical vein and hepatic artery resitive index, and ascites, was assessed for its effectiveness to detect SOS/VOD. When cut-off value of US-10 was set 5, the sensitivity and specificity was 100% and 95.8%, respectively. Two patients underwent US when the weight gain and slight elevation of serum bilirubin before meeting diagnostic cri-

teria, and they exhibited US-10 scores higher than 5. This suggests that our new scoring system could catch SOS/VOD earlier than clinical criteria. Furthermore, two patients marked 5 before HSCT and both of them developed SOS/VOD after HSCT, on the other hand, none of the control group exceeded 5 before HSCT. US-10 scores before HSCT might predict SOS/VOD.
Summary/Conclusion: US-10 scoring system showed good correspondence with widely used diagnostic criteria. It would be a powerful diagnostic tool for SOS/VOD. In addition, it is expected that new scoring system detects early stage of SOS/VOD prior to clinical criteria and predicts the risk of SOS/VOD before HSCT.

PS1480

THE SIGNIFICANCE OF PERI-TRANSPLANTATION MINIMAL RESIDUAL DISEASE ASSESSED BY MULTIPARAMETER FLOW CYTOMETRY ON OUTCOMES FOR ADULT AML PATIENTS RECEIVING HAPLOIDENTICAL ALLOGRAFTS

J. Liu[1,*], R. Ma[1], Y.-R. Liu[1], L.-P. Xu[1], X.-H. Zhang[1], H. Chen[1], Y.-H. Chen[1], F.-R. Wang[1], W. Han[1], K.-Y. Liu[1], Q.-Z. Fan[2], X.-J. Huang[1], Y.-J. Chang[2]

[1]Haematology Department, [2]Peking University People's Hospital, Beijing, China

Background: Allogeneic stem cell transplantation (Allo-SCT) is an effective therapy for acute myeloid leukemia (AML) patients. Several researchers have suggested that minimal residual disease (MRD) detected by multicolor flow cytometry (MFC) before and after SCT identifies a subgroup of patients at high risk of hematological relapse and poor outcomes in human leukocyte antigen (HLA)-matched transplantation. But there was no effect of pre-transplant MRD determined by MFC on relapse of patients with AML receiving haploidentical allografts.
Aims: To explore the impact of post-MRD status and peri-transplant MRD kinetics, especially in adult AML patients on transplant outcomes in haplo-SCT settings.
Methods: Adult AML patients, 18 years of age or older, in their first or second morphologic remission, who received haplo-SCT in Peking University People's Hospital from 1 Jan 2012 to 30 June 2016 were included in this retrospective study. Relationship of pre-MRD status, post-MRD status, or MRD dynamics peri-SCT and transplant outcomes were analyzed using the Kaplan-Meier method and a Cox proportional hazards model with time-dependent variables.
Results: A retrospective study (n = 460) was performed to assess the relationship between MRD and transplant outcomes in a haplo-SCT setting. Patients from the pre-MRDneg group and the pre-MRDpos group had comparable outcomes. Compared to post-MRDneg patients, post-MRDpos patients had a higher incidence of relapse (100% vs. 8.3%, p=0.000), lower incidences of OS (16.9% vs. 78.2%, p=0.000) and LFS (0% vs. 76.5%, p=0.000), and comparable probability of NRM (13.4% vs. 16.9%, p=0.560). In a second set of analyses, all adult AML patients undergoing haplo-SCT were classified into MRDneg/MRDneg group, MRD descending group, and MRD ascending group according to MRD dynamics by flow cytometry peri-SCT. Compared to other two groups, patients from the MRD ascending group had higher cumulative incidences of relapse (MRD ascending, 100%; MRDneg/MRDneg, 9.6%; MRD descending, 19.2%; p=0.000) and worse probabilities of OS (MRD ascending, 28.5%; MRDneg/MRDneg, 76.3%; MRD descending, 76.0%; p=0.000) and LFS (MRD ascending, 0.0%; MRDneg/MRDneg, 73.9%; MRD descending, 74.0%; p=0.000).
Summary/Conclusion: The results indicated that unmanipulated haplo-SCT is superior to MSDT in eradicating pre-transplantation MRD, and MRD assessment peri-SCT is useful for risk stratification from a practical perspective.

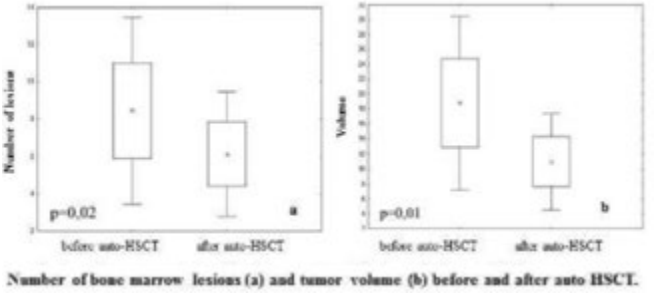
PS1481

CHANGES IN THE NUMBER OF BONE MARROW LESIONS AND TUMOUR MASS ON MRI IN PATIENTS WITH MM FOLLOWING AUTO-HSCT

M. Solovev[1,*], L. Mendeleeva[1], G. Yatsyk[2], N. Lutsik[2], M. Firsova[1], V. Savchenko[1]

[1]Bone Marrow Transplantation, [2]Magnetic Resonance Tomography, National Research Center for Hematology, Moscow, Russian Federation

Background: Despite the availability of results from several studies that evaluated the role of MR images in the diagnosis of MM, data on the value of MRI after antineoplastic treatment, in particular after auto-HSCT, are limited.
Aims: To determine the nature and scale of bone marrow involvement in patients with MM before and after auto-HSCT using MRI.
Methods: 40 patients with MM (15 male and 25 female) aged 36 to 66 years (median age 56 years) were enrolled in a prospective study in the period from December 2015 to March 2017. MRI of the spine and pelvic bones was performed before auto-HSCT and 100 days after it to track changes in bone marrow involvement after transplantation. MRI was carried out with a GE Signa Profile system without contrast enhancement. The nature of the lesions was determined and the bone marrow infiltration lesions (≥ 5 mm) counted. The total lesion volume was determined as follows: identified foci and bone marrow infiltration lesions were labeled based on signal intensity intervals using the Regions of interests tool; 3d reconstruction and the LINS MACHAON software were used for segmentation, with subsequent labeling of identified bone marrow lesions and comparison with the total labeled volume and the original image. After labeling of the infiltrative lesions, the abnormal MR signal area was calculated and recorded as the total tumour volume. Statistical analysis was done using Statistica 10.
Results: After completion of induction therapy, the following antitumour responses (according to the IMWG criteria) were observed: stringent CR in 7 patients (17.5%), CR in 9 (22.5%), VGPR in 17 (42.5%) and PR in 7 subjects (17.5%). Prior to auto-HSCT, normal bone marrow MR images were observed in 7 patients and focal lesions in 33: the number of lesions ranged from 1 to 80 (average 10). The distribution of subjects by number of detected lesions was as follows: 1 lesion in 10 out of 25 patients (75%), 11 - 20 in 5 (15%), and over 20 lesions in 3 cases (10%). The pre-auto-HSCT total lesion volume varied from 0 to 212 cm^3 (average 19 cm^3). At 100 days after auto-HSCT, a stringent CR was observed in 14 patients (35%), CR in 10 (25%), VGPR in 12 (30%) and PR in 4 subjects (10%). Post-auto-HSCT MRI revealed bone marrow lesions in 33 patients as well, their number ranged from 1 to 56 (average 7). The distribution of subjects by number of lesions detected after auto-HSCT was as follows: 1 lesion in 10 out of 27 patients (82%), 11 - 20 in 4 (12%), and over 20 lesions in 2 subjects (6%). The post-auto-HSCT total lesion volume varied from 0 to 103 cm^3 (average 10 cm^3). Analysis of changes in the number of lesions and tumour volume based on MRI findings revealed a lower number of lesions after auto-HSCT in 17 patients (52%) and a reduction of tumour volume in 30 cases (91%). High-dose chemotherapy with subsequent auto-HSCT was followed by a statistically significant (p=0.02) decrease in the number of bone marrow lesions on MRI (Figure 1a). Comparison of the tumour volumes detected by MRI before and after auto-HSCT also demonstrated a significant (p=0.01) reduction of the total lesion volume after auto-HSCT (Figure 1b).



Number of bone marrow lesions (a) and tumor volume (b) before and after auto HSCT.

Figure 1.

Summary/Conclusion: Auto-HSCT is an effective treatment stage for patients with MM that affects bone remodeling through reduction in bone marrow lesions and tumour volume.

PS1482

ACUTE INTESTINAL GRAFT-VERSUS-HOST DISEASE AMONG PATIENTS UNDERGOING ALLOGENEIC CELL TRANSPLANT FOR HEMATOLOGICAL MALIGNANCY IN THE UNITED STATES: A RETROSPECTIVE CLAIMS DATABASE ANALYSIS

A. Taylor[1,*], B. Johnson[2], G. Kim[2], J. Drahos[3], J. Yang[3], M. Akbari[3], N. Shah[4]

[1]Takeda Pharmaceuticals International, London, United Kingdom, [2]IBM Watson Health, Cambridge, [3]Takeda Pharmaceuticals International, Boston, [4]Medical College of Wisconsin, Milwaukee, United States

Background: While allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the only curative option for many hematological malignancies, its effectiveness is limited by the occurrence of serious infections and graft-ver-

sus-host disease (GvHD) which presents in 30-80% of allo-HSCT recipients. There are limited data on real-world outcomes after allo-HSCT, however, of allo-HSCT complications, acute intestinal GvHD is associated with the highest risk of mortality and morbidity.
Aims: Using a large, healthcare claims database this study aims to understand infectious complications and healthcare utilization among patients who received an allo-HSCT who developed acute intestinal GvHD.
Methods: Patients receiving an allo-HSCT procedure were identified in the MarketScan® Research Databases between 2009-15. From those identified, those developing acute GvHD (aGvHD) post allo-HSCT were selected using diagnosis codes. A claims algorithm, which ranked the severity of aGvHD symptoms, was developed to identify intestinal aGvHD grade. Patients were followed for 1 year, end of continuous insurance enrollment, end of study period (9/30/16) or death, whichever occurred first. Demographic and clinical characteristics were identified at index and six months prior to allo-HSCT, respectively. Generalized linear regression was used to estimate the probability of having a subsequent inpatient (IP) admission, emergency room (ER) visit and developing infection post-allo HSCT.
Results: A total of 1,288 patients (median age 54, range 53 to 55) m*et al.*l selection criteria; 43.9% (n=565) were identified as having aGvHD, of those 59.8% (n=338) were identified as having intestinal aGvHD. Age, gender and overall comorbidity were similar between those with intestinal aGvHD and those without aGvHD. The proportion of patients with an IP admission and ER visit after discharge from allo-HSCT was significantly higher among those with intestinal aGvHD compared to those without aGvHD (82.2% vs 54.8%) and (45.6% vs. 32.5%), respectively, both p<.0001. The most common infections in allo-HSCT patients were pneumonia (52.4%), septicemia (27.4%) and cytomegalovirus (22.1%) which were also significantly higher in patients with intestinal aGvHD compared to those without aGvHD (63.9% vs 46.9%), (39.3% vs. 23.1%) and (38.2% vs. 16.2%), respectively, all p<.0001. Patients with intestinal aGvHD were 4 times more likely to have a subsequent IP admission (odds ratio [OR], 4.02; 95%CI, 2.88-5.62; p<.0001) and nearly twice as likely to have an ER visit (OR, 1.78; 95%CI, 1.34-2.36; p<.0001) after discharge from their allo-HSCT than patients who did not develop aGvHD. Patients with intestinal aGvHD were nearly 4 times more likely to develop infections than patients who did not develop aGvHD (OR, 3,77; 95%CI, 2.43-5.86; p<.0001) (Table 1).

Table 1.

SELECTED DESCRIPTIVE METRICS	Intestinal aGVHD Patients	Non-aGVHD Patients	P Value
PATIENT CHARACTERISTICS MEASURED IN THE BASELINE PERIOD	N = 338	N = 723	
Age [Mean, SD]	56.3 (14.9)	56.9 (14.5)	0.5325

4 additional hospitalizations	33 (9.8)	33 (4.6)	0.0011
5+ additional hospitalizations	50 (14.8)	33 (4.6)	<0.0001

Summary/Conclusion: In this US claims analysis, patients who developed intestinal aGvHD after allo-HSCT had increased morbidity. Patients with intestinal aGvHD were nearly 4 times more likely to develop a major infection, 4 times more likely to have a subsequent IP admission and nearly twice as likely to have an ER visit than patients who did not develop aGvHD. Using real-world evidence to study patients undergoing allo-HSCT for hematological malignancy can augment clinical research leading the way to a better understanding of the therapeutic gaps for these patients. New strategies are indicated to optimize health care and minimize risk of morbidity among patients with intestinal aGvHD.

PS1483

ALLOGENEIC HEMATOPOIETIC STEM CELLS TRANSPLANTATION FOR NON-HODGKIN'S LYMPHOMA IN SWITZERLAND. 30 YEARS OF EXPERIENCE 1985-2017

E. Chigrinova[1,*], P. Stakia[2], M. Nabergoj[3], M. Medinger[4], H. Baldomero[5], S. Masouridi-Levrat[3], C. Dantin[3], K. Ritter[6], A. Stern [4], A. Rovó[1], U. Schanz[6], J. Passweg[4], Y. Chalandon[3]

[1]Hematology, University Hospital of Bern, Bern, [2]Hematology, Hôpital du Valais, Sion [3]Hematology, Geneva University Hospitals (HUG), Geneva, [4]Hematology, [5]Swiss National Stem Cell Transplant Registry/SBST, University Hospital of Basel, Basel, [6]Hematology, University Hospital of Zurich, Zurich, Switzerland

Background: Because of the relatively high transplant-related mortality rate, allo –HSCT in NHL often remains the ultimate line of treatment. However, despite of a quick development of new efficient targeted therapies, allo-HSCT represents so far the only potentially curable treatment for nearly all types of NHL. Introduction of reduced intensity conditioning regimens, graft's T-depletion, better supportive care and graft-versus-host disease (GvHD) prophylaxis and treatment have decreased non-relapse mortality (NRM) rates, making use of allo-HSCT an important alternative therapeutic option in the setting of relapsed/refractory NHL.
Aims: We report here the 30 years of Swiss experience in allo-HSCT for NHL.
Methods: The study included 254 allo-HSCT episodes performed in 3 University Hospitals of Switzerland (Zürich, Basel and Geneva) between September 1985 and August 2017 for NHL including: chronic lymphocytic leukemia (n=66), diffuse large B-cell lymphoma (n=60), mantle cell lymphoma (n=31), follicular lymphoma (n=22), marginal zone lymphoma (n=7), burkitt lymphoma (n= 8), Waldenstrom's macroglobulinemia (n=6), hairy cell leukemia (n=1), T-cell lymphoma, NOS (n=33), anaplastic large T-cell lymphoma (n=7) and angioimmunoblastic T-cell lymphoma (n=13). All patients relapsed after standard therapy. Impact on OS, DFS, RI and NRM was assessed in univariate and multivariate analysis for: year of allo-HSCT before and after the 2000; prior auto-HSCT or allo-HSCT; disease status including CR, PR, SD, PD; number of remission: 1st vs >1st; Karnofsky index >80% vs <80%; donor's type: identical siblings, MUD, MMUD; donor's age: >60 vs <60; stem cell source: BM vs PBSC; no vs graft's T-depletion; conditioning type: RIC vs MAC; no vs TBI use; no vs acute/chronic GvHD; T vs B-cell origin; indolent vs aggressive NHL; NHL type.
Results: Median follow up was 18.5 months (5-72) with 25 years of the maximum follow up. Median OS=168 months, DFS= 107 months. Patient's median age at the time of allo-HSCT was 50.7 (43.7-57.2). 5 and 10-years OS, DFS and NRM were 57±4%, 53±4%, 23±3% and 51±4%, 46±4%, 25±3.0% respectively. RI at 5 and 10 years was 30±3% and 38±4%. In univariate analysis, no prior auto/allo HSCT, Karnofsky > 80%, 1st remission at HSCT (Figure 1) and disease status (CR) were associated with both improved OS and DFS (p<0.05). TBI use showed also a trend toward better OS and DFS (p=0.058 and 0.06 respectively). Related donor (vs unrelated) was associated with better OS (p=0.017). In multivariate analysis Karnofsky > 80%, CR and PR, absence of prior auto/allo-HSCT were the most significant factors influencing OS and DFS (p<0.05). NRM was influenced by donor's type, with the worse survival for the MUD vs Identical-sibling (p=0.001) and >1st remission status (p=0.03). The highest RI was found in cases transplanted before the year 2000 (p=0.03) non being in 1st remission (p=0.01) and those with aGvHD (p=0.007).

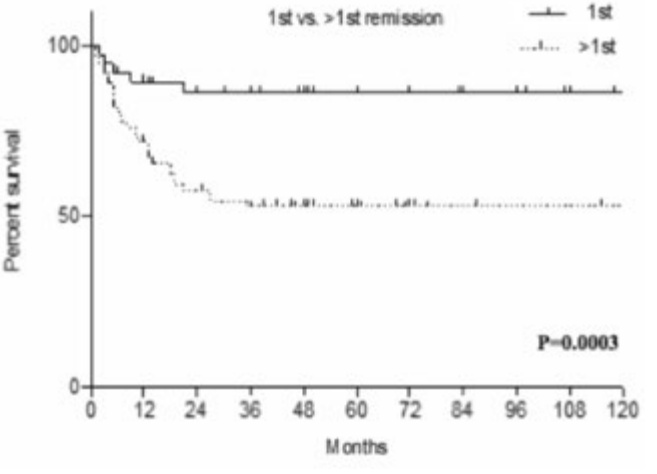

Figure 1.

Summary/Conclusion: Our analysis of a mixed-type NHL cohort at 25 years of maximum follow-up confirms the efficacy of allo-HSCT in pretreated/refractory patients showing promising 5 and 10 years OS and acceptable NRM rate. Interestingly, OS was found to be independent of NHL type and GvHD presence. Patient's status according to Karnofsky index, remission quality (CR and PR) and absence of heavy pretreatment were associated with better OS and DFS. These results should be interpreted

carefully due to the retrospective nature of the analysis; the heterogeneity of NHL and the conditioning regimen.

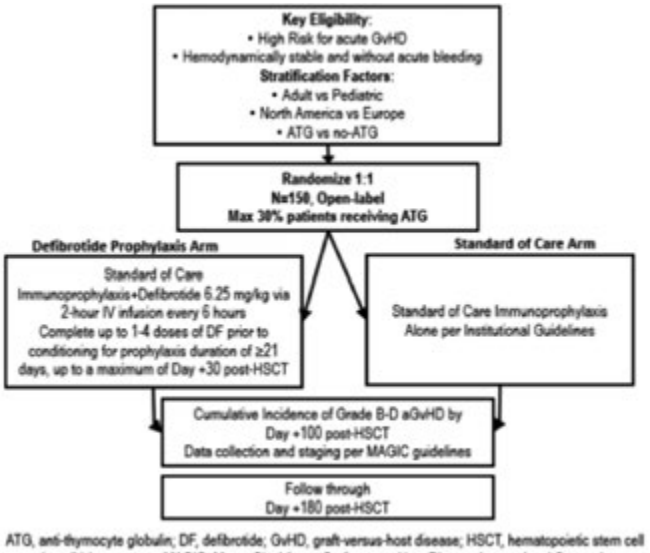
PS1484

PHASE 2, OPEN-LABEL STUDY OF DEFIBROTIDE FOR PREVENTION OF ACUTE GVHD FOLLOWING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANT (HSCT)

S. Corbacioglu[1,*], P. Kim[2], R. Hume[2], W. Tappe[2]

[1]Department of Pediatric Hematology, Oncology and Stem Cell Transplantation, University of Regensburg, Regensburg, Germany, [2]Jazz Pharmaceuticals, Inc., Palo Alto, United States

Background: GvHD, a life-threatening complication of HSCT, causes mortality in ~20% of patients who receive allogeneic HSCT (aHSCT). Current immunoprophylactic therapies for GvHD show variable efficacy and safety, indicating a need for additional strategies. Acute GvHD (aGvHD) usually arises within the first 100 days post-aHSCT. Defibrotide (DF) is approved for the treatment of severe VOD/SOS post-HSCT in patients aged >1 month in the European Union and VOD/SOS with renal or pulmonary dysfunction post-HSCT in the United States and Canada; the use of defibrotide (DF) for prophylaxis of aGvHD or VOD/SOS is off-label. In a study of DF for VOD/SOS prophylaxis (Corbacioglu, *Lancet* 2012), a secondary endpoint analysis suggested that DF may reduce aGvHD incidence; children receiving DF had a significantly reduced incidence of aGvHD at Day +100 post-HSCT versus controls. The hypothesis of DF activity in aGvHD based on this finding warranted further study.
Aims: To compare the efficacy of DF added to standard-of-care (SOC) immunoprophylaxis vs SOC immunoprophylaxis alone for the prevention of aGvHD.
Methods: This phase 2, prospective, randomized, open-label study (Figure 1) is targeting enrollment of 150 pediatric and adult patients with acute leukemia or myelodysplastic syndrome who are at high risk of aGVHD due to planned myeloablative or reduced-intensity conditioning prior to non-manipulated bone marrow or CD3+ T-cell replete peripheral blood stem cell grafts from unrelated donors. Inclusion criteria are leukemia in morphologic complete remission, normal liver function (total bilirubin <2x the upper limit of normal [ULN]; alanine aminotransferase and aspartate aminotransferase <3x ULN), and HLA-matched or single allele mismatch graft (high-resolution DNA-based typing). Exclusion criteria are prior HSCT, acute bleeding ≤24 hours before start of treatment, use of medication that increases bleeding risk, comorbid condition, pregnancy, lactation, and psychiatric illness. Diagnosis and staging of aGvHD follow the recommendations of the Mount Sinai aGvHD International Consortium. Grading of aGvHD uses the International Bone Marrow Transplant Registry Severity Index. Randomized patients (1:1) are administered SOC immunoprophylactic therapies without (control) or with DF (25 mg/kg/day) in four 2-hour infusions of 6.25 mg/kg every 6 hours beginning before the start of conditioning regimen (up to 4 doses) for a recommended duration of ≥21 days up to Day +30 post-HSCT.



ATG, anti-thymocyte globulin; DF, defibrotide; GvHD, graft-versus-host disease; HSCT, hematopoietic stem cell transplant; IV, intravenous; MAGIC, Mount Sinai Acute Graft-versus-Host Disease International Consortium.

Figure 1. Study design.

Results: The primary outcome measurement is the cumulative incidence of Grade B D aGvHD in the DF-treated and control groups by Day +100 post-HSCT. Secondary endpoints include Grade B–D aGvHD-free survival by Days +100 and +180 post-HSCT; cumulative incidence of Grade B–D aGvHD by Day +180 post-HSCT, Grade C–D aGvHD by Days +100 and +180 post-HSCT, and cumulative incidence of relapse by Days +100 and +180 post-HSCT; and comparison of health-related quality of life and safety profile. Enrollment is ongoing.
Summary/Conclusion: Results will help determine the safety and efficacy of DF for the prevention of aGvHD in high-risk pediatric and adult patients receiving aHSCT.

[1]Haematology and BMT Unit, [2]Vita-Salute San Raffaele University, [3]Immuno-Haematology and Transfusion Medicine Unit, [4]Experimental Haematology Unit, Division of Immunology, Transplantation and Infectious Diseases Programm in Immunology and Bio-Immunotherapy of Cancer (PBIC), San Raffaele Scientific Institute IRCCS, Milano, Italy

Background: Allogeneic stem cell transplantation (HCT) survivors are at risk of developing long-term complications such as chronic GvHD (cGvHD); a precise prognostic stratification of these patients (pts) emerged in recent years. Since 2011, the CIBMTR risk score is a validated tool to assess the prognosis of pts developing cGvHD, based on 10 clinical and easy-to-collect variables. A revised version has been published more recently taking into account the number of lymphocytes and eosinophils. Immune reconstitution (IR) impairment affects HCT survivors at very long-term follow-up (LTFU) which justifies the occurrence of late fatal infection especially in presence of GVHD-history.
Aims: We aimed at prospectively validating the CIBMTR score in our Center, plus finding correlation with IR data at time of cGvHD diagnosis to enhance prognostication.
Methods: We analyzed 111 consecutive adult pts who underwent an HCT between July 2012 and December 2016 at our Institution and developed cGvHD at any time point and of any severity (according to NIH 2014 guidelines). A written consent was given for the use of medical records for research in accordance with the Declaration of Helsinki. Median follow-up for surviving pts was 3.2 y (range 1.1-5.5). For the univariate analysis of overall survival (OS), we considered the following covariates: patient age, female to male gender mismatch, disease risk index, type of donor (matched-related vs matched-unrelated vs haploidentical), GvHD prophylaxis (ATG- vs CTX-based), Karnofsky performance status (PS), history of prior acute GvHD, lymphocytes and eosinophils counts at cGvHD diagnosis and IR variables at time of cGvHD onset. We built a multivariate model considering all variables significantly associated with OS (log rank p-value <0.05) and, once we identified the variables independently predicting OS, we derived a formula of a risk index predicting survival by using the B-coefficients (β) found in the model. Each pts was assigned a score and, then, we defined three prognostic risk-groups (low, intermediate, high) by dividing the population into three classes using the first and third quartiles.
Results: Our data confirmed the validity of the CIBMTR risk score - both the standard and the revised versions - in particular in identifying very high risk patients – ref Figure 1. We identified 4 variables that significantly ($p<0.05$) proved to be independently correlated to OS in our multivariate model: CD3CD4>233/mcL (HR 11,4, β 2.4, p 0.003), NK cell<115/mcL (HR 8.1, β 2.1, p0.003), IgM<0,45 g/L (HR 8, β2.1, p 0.007), Karnofsky PS<80% (HR 72, β 4.3, $p<0.001$). Final score was calculated as follows: 2,4 (if CD4>233/mcL) + 2,1 (if NK<115/mcL) + 2,1 (if IgM<0,45 g/L) + 4,3 (if Karnofsky<80%). Patients were stratified into 3 risk classes: low risk if score ≤2,4; intermediate risk if 2,4≤4,5; high risk if >4.5. These 3 different risk classes significantly predicted transplant-related mortality (TRM) and OS: the 3.5y cumulative incidences of TRM were 3.6%, 16.6% and 28.6% for low, intermediate and high-risk pts, respectively (p=0.006). OS at 3.5y was 96%, 71% and 27% for low, intermediate and high-risk pts, respectively ($p<0.001$).
Summary/Conclusion: Irrespective of donor, cGvHD affects 20-50% of HCT survivors. The CIBMTR risk score is able to provide a clear prediction of outcome in these pts, allowing a personalized therapeutic intervention. Monitoring of IR after HCT is strongly informative and could be an adjunc-

tive tool to identify high-risk patients at cGvHD onset.

PS1486

UTILIZATION AND OUTCOMES OF FERTILITY PRESERVATION TECHNIQUES IN WOMEN UNDERGOING ALLOGENIC HEMATOPOIETIC CELL TRANSPLANT

A. Higgins[1,*], Z. Khan[1], C. Coddington[1], S. Hashmi[1], M. Hefazi[1], H. Alkhateeb[1], M. R. Litzow[1], W.J. Hogan[1], E. Cathcart-Rake[1], C. Thompson[1], M.M. Patnaik[1]

[1]Mayo Clinic, Rochester, United States

Background: Iatrogenic menopause with consequent infertility is a major complication in reproductive aged women undergoing hematopoietic stem cell transplantation (HCT). Recent American Society of Clinical Oncology guidelines recommend a discussion of the possibility of infertility and the options for fertility preservation as part of informed consent before initiation of any cancer-directed therapy, including HCT.
Aims: We carried out this study in order to i) describe disease and reproductive variables in a cohort of reproductive aged women undergoing allogeneic HCT, ii) assess rates of fertility counseling provided, and iii) document utilization and outcomes of fertility preservation techniques.
Methods: After IRB approval, women aged 15-49 years at the time of allogeneic HCT, between the years 2001 and 2017, were identified from the Mayo Clinic Rochester institutional HCT database. Medical records were abstracted to obtain demographic data, treatment details, reproductive variables, and fertility counseling and outcomes. Data was analyzed primarily using descriptive statistics and chi-square test was used to compare frequencies.
Results: One hundred seventy-seven women were age eligible, of whom 49 (28%) were excluded due to documented post-menopausal state or prior hysterectomy. The median age of the cohort was 31 years (range, 15-49) with median gravidity and parity being G1P1 (range, G0-8P0-6). Fifty-four (42%) women were nulligravid at the time of HCT. Reasons for HCT included AML 49%, ALL 23%, MDS/MPN 13%, chronic myeloid neoplasms 2%, Hodgkin's lymphoma 2%, and non-malignant hematological disorders 11%. Eighty-six percent underwent a myeloablative conditioning (MAC) (65% CY+TBI 1200-1320cGY and 32% BU+CY), while 14% received a reduced intensity conditioning (RIC) (24% FLU+MEL, 20% CY+ATG, 4% FLU+BU, and 48% other). Only 34 women (27%) had documented fertility counseling within 72 hours of diagnosis and a total of 61 (48%) prior to HCT. Thirty-eight women (30%) were referred to a reproductive endocrinologist, of whom 13 (10%) underwent assisted reproductive technologies (ART; 9 oocyte cryopreservation, 4 embryo cryopreservation). Of these, 7 were successful, 4 were unsuccessful, and 2 had been previously completed at an outside institution prior to HCT. The median time to successful completion of the successful 7 ART procedures was 13 days. The remaining 25 women could not undergo ART due to disease severity (68%), low antral follicle count (12%), and financial barriers (20%). Ninety-three women (72.7%) received Lupron for ovarian suppression prior to conditioning although not all of these women had documented discussion of all fertility preservation options. Three (3%) of 105 women who underwent MAC had spontaneous menstrual recovery after HCT (median 14 months; range, 6-21 months), in comparison to 10 (43.5%) of 23 women who underwent RIC ($p < 0.0001$) (median 21.5 months; range, 5-83 months). In this cohort, there were two spontaneous pregnancies (8.7%), both occurring after RIC (CY+Campath+400 cGy TBI and CY+ATG) at 71 and 72 months after HCT, respectively.
Summary/Conclusion: Oncofertility is an emerging field due to an increasing number of young cancer survivors. Herein, we document that even at a large tertiary HCT center the rate of fertility counseling and reproductive endocrinology referrals was low and the rate of successful assisted reproductive interventions was even lower. Spontaneous menstrual recovery was rare, but more likely in the setting of RIC HCT. A concerted multidisciplinary effort is needed to improve oncofertility referral and outcomes.

PS1487

LOW INCIDENCE OF SYMPTOMATIC OSTEONECROSIS AFTER ALLOGENEIC HSCT IN CHILDREN WITH HIGH-RISK OR RELAPSED ALL – RESULTS OF THE ALL-SCT2003 TRIAL

Background: High-risk acute lymphoblastic leukemia (ALL) can currently be cured in up to 70% of children using hematopoietic stem cell transplantation (HSCT). However, long-term side-effects seriously impacting quality of life remain substantial. Although osteonecrosis (ON) accounts for one of the most debilitating long-term sequelae, reliable data remain scarce.
Aims: To determine incidence of and risk factors for symptomatic ON (sON) in children and adolescents undergoing allogeneic HSCT for high-risk or relapsed ALL in the ALL-SCT 2003 trial.
Methods: Children and adolescents with ALL enrolled in the prospective ALL-SCT-BFM 2003 trial between September 2003 and September 2011 were eligible for this analysis. ON assessment was performed prospectively by means of adverse event and routine follow-up reporting. In patients in whom sON had been reported, additional data were retrieved retrospectively via an ON-specific questionnaire.
Results: 557 patients were analyzed. Median age at HSCT was 10.3 years (range 0.5-26), median time from HSCT until last follow-up was 5.8 years (range 0.06-11.7). 55 patients were diagnosed with sON resulting in a CI of 7% at 5 years (SD 1%). Median time from HSCT to diagnosis of sON was 13.4 months (range 1-80). 43% of those patients were diagnosed within the first year after HSCT, 67% within two years. 14 patients had sON prior to HSCT. Most prominent localizations of sON were knees (26; 65%) followed by hips (20; 50%), and feet (18; 46%).
In univariate analysis, the CI of ON in children younger than 10 was 2% (SD 1%) at 5 years after HSCT. The CI in children aged 10-15 years and 16 years or older was 8% (SD 2%) and 11% (SD 4%) respectively

(p<0.001). Children with a history of ON prior to HSCT (CI of ON 45% SD 17% vs. 8% SD 2% without ON prior to HSCT, p<0.001) and those with aGvHD of grade 3 or 4 (hazard ratio (HR) 1.69; 95% CI, 1.2-2.7; p=0.017) or cGvHD (hazard ratio (HR) 1.655; 95% CI, 1.2-2.7; p=0.009) were at higher risk to develop ON. Neither gender (CI 8% (male) SD 1% vs. 5% (female) SD 2%, p=0.387), first or later remission (CI 7% SD 2% vs. 7% SD 1%, p=0.741), donor type (MSD CI 9% SD 2% vs. MD CI 6% SD 1% vs. MMD CI3% SD 2%, p=0.110), stem cell source (BM CI 6% SD 1% vs. PB CI 8% SD 2% vs. other CI 0% SD 0%; p=0.7662) or type of conditioning regimen (with TBI CI 5% SD 2% vs. without TBI 7% SD 1%; p=0.390) were significant risk factors.
In multivariate analysis, age at HSCT (10-15 years vs. <10 years HR 4.49, p=0.011; >15 years vs. <10 years HR 6.92, p=0.001), diagnosis of sON prior to HSCT, and cGVHD (yes vs no HR 2.99, p=0.020) proved to be significant independent risk factors for the development of ON.
Summary/Conclusion: CI of osteonecrosis was 7% in patients enrolled in the ALL-SCT 2003 trial. Apart from preexisting sON prior to HSCT, age and cGVHD turned out to be the most important prognostic factor for the development of sON. The impact of acute GvHD of grade 3 or 4 on the development of ON requires further study.

PS1488

EARLY BLOOD STREAM INFECTION AFTER BMT IS ASSOCIATED WITH CYTOKINE DYSREGULATION AND POOR OVERALL SURVIVAL

E. Catchpoole[1], C. Thirunavukarasu[2], A. Varelias[3], S. Schlebusch[4], S. Olver[5], N. Zomerdijk[2], E. Osland[2], G. Kennedy[2], S.-K. Tey[5], G. Hill[5], K. Markey[5,*]

[1]Pathology Queensland, [2]Royal Brisbane and Womens Hospital, [3]QIMR Berghofer Medical Resarch Institute, [4]Mater Pathology, [5]QIMR Berghofer Medical Research Institute, Brisbane, Australia

Background: The key complications of allogeneic bone marrow transplant (BMT) remain graft-versus-host disease (GVHD) and opportunistic infection.
Aims: We examined the rates of confirmed blood stream infection (BSI) in allogeneic BMT patients, the organisms isolated, and the association of BSI with other post-transplant outcomes and the dysregulation of inflammatory cytokines.
Methods: 184 patients in a prospective observational cohort of allogeneic BMT recipients treated at the RBWH between 2009 and 2015 were studied. Patients underwent either myeloablative conditioning (MAC; cyclophosphamide and total body irradiation) or reduced intensity conditioning (RIC; fludarabine and melphalan). We examined all blood cultures collected between day -7 and day 100, and assessed the results, along with other infectious complications and overall transplant outcome. IL-1, IL-6, IL-8, TNF and IFNγ were analysed in plasma samples collected at day -7, 0, +3, +7, +14, +21, +30, +60, +90 and +120 using cytokine bead array.
Results: Median patient age was 52±14 years (58.7% male), with 35.3% of transplants for acute myeloid leukemia, 18.5% for acute lymphoblastic leukemia and 16.8% for myelodysplastic syndrome. 167 of the 184 patients (91%) had blood cultures collected, and 69 (38%) patients had a confirmed BSI. *Enterobacteriaceae*, *Pseudomonas aeruginosa*, *Enterococcus* spp. and viridans *Streptococcus* spp. were the most commonly isolated organisms. Gender, conditioning (RIC vs. MAC) and donor type (sibling vs. unrelated) did not differ significantly between those with and without confirmed BSI. Elevated temperature (>38°C) at the time of culture collection was associated with an almost 2-fold increased rate of returning a positive blood culture (16.8% vs 9.3%; OR 1.9, 95% CI 1.21 – 3.23; p=0.0058). On a per-patient basis, CMV reactivation at any time before day 100 was not associated with BSI (OR 1.38, 95% CI 0.71 – 2.65; p=0.39). BSI-free status was associated with a significant improvement in 2 year overall survival (HR 0.59, 95% CI 0.37-0.95; p=0.01), due to a significant reduction in non-relapse mortality predominantly unrelated to the primary BSI.
The presence of a BSI prior to engraftment was associated with the dysregulation of IL-6 and IL-8. Significantly higher levels of IL-6 were seen at day 14 in recipients of RIC allografts with pre-engraftment BSI compared to those without. IL-8 was significantly elevated in patients who received either RIC or MAC allografts in the setting of pre-engraftment BSI, at day 7 in the RIC recipients and day 30 in the MAC group.
Summary/Conclusion: Our findings suggest that BSI early after BMT defines a group of high-risk patients with enhanced cytokine dysregulation and poor transplant outcome. This is the first study reporting the BSI-specific induction of IL-6 and IL-8 in the setting of the broader cytokine dysregulation after BMT. The contribution of BSI to cytokine dysregulation and transplant-related mortality now needs to be studied in large prospective multicenter studies, ideally in conjunction with microbiome analysis.

PS1489

REGRESSION TREE BASED MODEL FOR PREDICTING NON-RELAPSE MORTALITY IN AML PATIENTS ALLO-TRANSPLANTED IN FIRST COMPLETE REMISSION

A. Nair[1,2,*], G. Hill[3], D. Ritchie[4], J. Butler[5], A. Spencer[1,2], T.-Y. Wang[6], J. Muirhead[7], A. Mclean[6], K. Mason[8], J. Reynolds[2], D. Curtis[1,2]

[1]Haematology, Alfred Health, Melbourne, [2]Monash University, Melbourne, [3]QIMR Berghofer Research Institute, Brisbane, [4]Haematology, Royal Melbourne Hospital, Melbourne, [5]Haematology, [6]Royal Brisbane Hospital, Brisbane, [7]Alfred Health, Melbourne, [8]Royal Melbourne Hospital, Melbourne, Australia

Background: Allogeneic stem cell transplantation in first remission (CR1) remains the treatment of choice for many AML patients. However, the treatment is associated with significant complications and the decision to transplant should be based on pre-transplant prediction of procedure related mortality weighed against the benefit of potential cure. Previously published prognostic scores such as HCT-CI and EBMT score can be used for risk prediction, however, none of them has comprehensively addressed all the potential elements of risk. For example, HCT-CI does not address the donor and procedure related factors whereas EBMT score does not take the patient comorbidity into account.
Aims: To identify factors significantly associated with non-relapse mortality (NRM) in AML patients undergoing allogeneic stem cell transplantation in CR1 and to construct a simplified tool for risk stratification using regression tree approach.
Methods: We did a retrospective review of 242 AML patients transplanted in CR1 from HLA-matched sibling or unrelated donors at 3 Australian centres from 2008 to 2014. The factors considered for analysis were age at transplant, disease risk (complex and monosomal karyotypes, FLT3 ITD positivity, secondary and therapy related AML were considered high risk), comorbidity index (HCT-CI), donor age, sex, donor type, CMV status and conditioning intensity. We performed univariate analysis and multivariate competing risk regression, taking NRM and relapse as competing events. We then did recursive partitioning using regression tree model to further classify patients into risk groups based on NRM.

Table 1.

Total		242
Patient Age	Median (range)	53 (17-69)

	Unknown	9

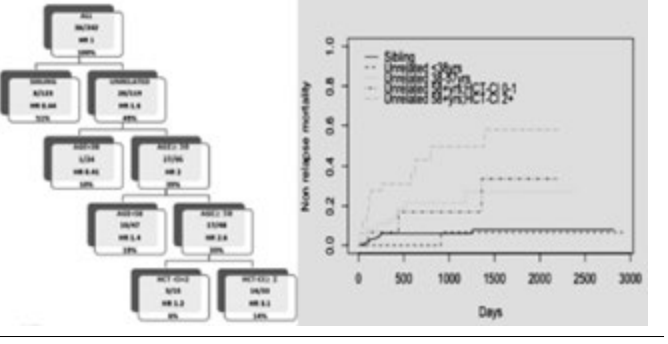

Figure 1.

Results: Patient characteristics are given in the Table 1. A significantly higher proportion of patients with lower HCT-CI (0-1) received myeloablative conditioning (66% vs 32%, p=<001). After a median follow up of 43.8 months, a total of 36 non-relapse deaths occurred (overall NRM-14.9%). Primary causes of death were GVHD (22), Infection (7), idiopathic pneumonia syndrome (3), graft failure (1), multi-organ failure (1), veno-occlusive disease

(1) and pulmonary embolism (1). On univariate analysis, cumulative incidence of NRM was significantly higher in patients older than 60 (p=0.02), HCT-CI≥2 (p=0.008), unrelated donor (p=0.0002) or less intense conditioning (p=0.01). On competing risk regression, age at transplant, as a continuous variable (HR: 1.04; CI (1.005-1.07); p=0.03) and unrelated donor (HR: 3.64; CI(1.65-8.02); p=0.001) were significant determinants of NRM. HCT-CI was no longer an independent predictor of NRM. However, using a regression tree model, we were able to formulate a step-wise risk stratification that incorporated donor type, age and HCT-CI (Figure 1). Three distinct risk groups were recognised where all patients with sibling donors and younger patients with unrelated donors were at the lowest risk and older patients with high HCT-CI having unrelated donors were at the highest risk of NRM.

Summary/Conclusion: Estimation of NRM is an important prerequisite to allogeneic stem cell transplantation. Here we show that a regression tree-based approach is an alternative and perhaps superior method of predicting NRM for patients with AML, allotransplanted in CR1.

PS1490

COMPARISON OF BUSULFAN/CYCLOPHOSPHAMIDE ALONE AND IN COMBINATION WITH THIOTEPA OR ANTI-THYMOCYTE GLOBULIN ON HEMATOPOIETIC STEM CELL TRANSPLANTATION OUTCOME AMONG BETA-THALASSEMIA PATIENTS

S. H. Ansari[1,*], T. Shamsi[1], T. Farzana[1], U. Zaidi[1], S. Siddiqui[1], A. Hanifa[1], T. Khan[1], B. Kaleem[1], J. Hassan[1], N. Anwar[1]

[1]National Institute of Blood Disease & Bone Marrow Transplantation, Karachi, Pakistan

Background: Beta thalassemia major (bTM) is one of the most common indications for hematopoietic stem cell transplantation (HSCT) in Pakistan. Prior to HSCT, the recipient is given a conditioning regimen, the goal of which is to provide sufficient immunoablation to prevent graft rejection.The most commonly used conditioning regimen combinations are (i)Busulfan and Cyclophosphamide (Bu/Cy), (ii) Busulfan, Cyclophosphamide and Thiotepa (Bu/Cy/Thiotepa) and (iii) Busulfan, Cyclophosphamide and Antithymocyte globulin (Bu/Cy/ATG).

Aims: The purpose of this study is to compare the disease free survival rates between patients receiving Bu/Cy, Bu/Cy/Thiotepa or Bu/Cy/ATG.

Methods: We used data of 78 patients who underwent HSCTs between 2000-2017. Of 78 patients 25 were on Bu/Cy, 21 were on Bu/Cy/Thiotepa while 32 were on Bu/Cy/ATG. The doses of these conditioning regimens are as follows: *Bu/Cy group:* Bu(4 mg/kg/day) for 4 Days, Cy(50 mg/kg/day) for 4 Days; *Bu/Cy/Thiotepa:* Bu(3.5mg/kg/day) for 4 Days, Cy(50 mg/kg/day) for 4 Days, Thiotepa(10 mg/kg)on day-6; B*u/Cy/ATG:* Bu(3.5mg/kg/day) for 4 Days, Cy(50 mg/kg/day) for 4 Days, ATG(10 mg/kg/day) for 4 Days.

Results: The disease free survival rate was 56% in Bu/Cy, 71.4% in Bu/CY/Thiotepa and 84% in Bu/Cy/ATG. Primary graft failure in Bu/Cy group was 12%, while 9.5% in Bu/CY/Thiotepa and 9% in Bu/Cy/ATG group. Relapse of the disease occurred in 20% of Bu/Cy group patients and 9.5% of Bu/CY/Thiotepa group patients, however, 6% patients in Bu/Cy/ATG group had relapse of beta-thalassemia major. In terms of overall survival, Bu/CY/ATG(90%) was better, however, 2 out of 21 patients had relapse of the disease compared to no relapse in Bu/Cy/Thiotepa group. The primary graft failure was similar among both groups.

Summary/Conclusion: The combination of Bu/Cy/ATG showed mos effective results in terms of disease free survival rates.

PS1491

SECOND TRANSPLANT FOR PRIMARY GRAFT FAILURE , FOLLOWING HAPLOIDENTICAL GRAFTS WITH POST-TRANSPLANT CYCLOPHOSPHAMIDE

S. Giammarco[1,*], A. M. Raiola[2], F. Sorà[3], S. Sica[3], C. Di Grazia[2], L. Laurenti[3], E. Angelucci[2], A. Bacigalupo[3]

[1]Fondazione Policlinico Universitario A Gemelli, Rome, [2]Hematology, IRCCS San Martino, Genova, [3]Hematology, Fondazione Policlinico Universitario A Gemelli, Rome, Italy

Background: Rejection, following haploidentical transplants (HAPLO) with post-transplant high dose cyclophosphamide (PT-CY) has been described and has been associated with donor specific antibodies (DSA) (BMT 2015;21:1392).

Aims: To assess the incidence of rejection in patients with hematologic malignancies , prepared with a myeloablative conditioning regimen and the outcome of a second transplant.

Methods: We studied 403 patients with hematologic malignancies, receiving an unmanipulated HAPLO marrow graft. Median age was 52 (17-74) and 38% had advanced disease. All patients received GvHD prophylaxis with Cyclosporin, mycophenolate and PTCY. The conditioning regimen used, was one of the following three: # Fludarabine (FLU) 40 mg/m^{2}x3 + Total body irradiation (TBI) 9.9-12 Gy (n=75)# Thiotepa (THIO) 5mg/kgx2, busulfan (BU) 3.2 mg/kg/dayx3, FLU 50 mg/m^{2}x3 (TBF) (n=180)# THIO 5mg/kgx2, BU 3.2 mg/kg/dayx2, FLU 50 mg/m^{2}x3 (n=148)

Results: *Rejection* was seen in 0/75 patients after TBI (0%), 5/180 after TBF with 3 days of Busulfan (2,7%) and in 10/148 in patients receiving TBF with 2 days of Busulfan (p=0.02). We could not find a correlation of rejection with donor age, patients age, diagnosis, phase of the disease, ABO mismatch, or bone marrow cell dose infused. *Busulfan.* We did find a trend for more rejections in Rome (6,8%) , where BU is given on 2 divided daily doses (q12 h), as compared to Genova (3,2%), where BU is given in a single daily dose, (q24h): rejection with full dose TBF (BU3 days) was 3/47 for patients receiving BU q12h (6.38%) , vs 2/133 (1,50%) for BU given q24h (p=0.08). *Second transplant:* 15 patients failed to recover neutrophils by day +28, and were found to have 100% recipient chimerism. Of these 15 patients, one was infused with CD34 selected cells from the same donor, without a conditioning regimen, and died without recovery, after having failed a third transplant.14 patients received a second graft (at a median interval of 43 days, range 33-66) with the Baltimore protocol and PB from the same donor (n=11) or another family member (n=3). GvHD prophylaxis was again CyA and PTCY. 11/13 had trilineage recovery (85%) and became 100% donor: a neutrophil count of 0.5x10^9/L was reached on day 18 (16-21) and a platelet count of 20x10^9/L on day 35 (18-80). Acute GvHD grade I occurred in 46% and grade II in 8%. Moderate-severe chronic GvHD developed in 23%. One year actuarial survival of the 14 patients who received a second graft is 85% (Table 1).

Table 1. Clinical characteristics of 403 patients.

conditioning	FLU-TBI 9.9-12 Gy	TBF (BU3)	TBF (BU2)
Number	75	180	148
Recipient's age	30 (15-58)	49 (17-72)	61 (18-74)
Year of Transplant	2012(11-17)	2015(11-17)	2015(11-17)
Advanced disease (>CR2)	24%	30%	44%
Donor : HLA HAPLO family	100%	100%	100%
Stem cell source BM	100%	100%	100%
Rejection : n.pts (%)	0 (0%)	5 (2,7%)	10 (6,7%)
Second Transplant (patients)			
Interval 1st- 2nd Tx :days (range)			43 (33-66)
Donor of 2nd Tx other HAPLO /id SIB/ same		2/ 1/ 11	
Engraftment : patients (%)			12 (85%)

Summary/Conclusion: (a) the risk of rejection is dependent on the intensity of the conditioning regimen: it does not occur after TBI, and is low with full dose TBF (2.7%); (b) there is a trend for more rejection with Busulfan given q12h; (c) full engraftment can be achieved with a second transplant, in over 80% of patients rejecting. Mortality due to rejection, in this series of 403 patients, was 0.75%.

PS1492

atrics, University Hospital Center Zagreb and Medical School University of Zagreb, [13]Department of Internal Medicine, Division of Clinical Immunology and Rheumatology, [14]Department of Internal Medicine, Section for Clinical Nutrition, [15]Department of Transfusion Medicine and Transplantation Biology, University Hospital Center Zagreb, [16]Department of Laboratory Medicine, University Hospital Center Zagreb and Medical School University of Zagreb, Zagreb, Croatia, [17]National Cancer Institute, National Institutes of Health, Bethesda, United States

Background: Chronic Graft-versus-Host Disease (cGVHD) is a major late complication after allogeneic hematopoietic stem cell transplantation influencing immune reconstitution and affecting different organs and tissues. Since cGVHD is a complex multisystemic allo- and autoimmune disease, different clinical presentations of cGVHD might have different biology with different immunological disturbances which may lead to specific target therapies.
Aims: To address this question, we analyzed the associations of subsets of monocytes and putative (by immunophenotype) B regulatory cells (Bregs) with organ-specific and other cGVHD manifestations.
Methods: Patients with cGVHD were enrolled into the multidisciplinary prospective study at the University Hospital Center Zagreb, Croatia, with extensive clinical assessments of different specialists, and with laboratory data collection. Since 2017 laboratory analyses included immunophenotypic subpopulations of monocytes (classical (CD14++CD16-), intermediate (CD14++CD16+) and non-classical (CD14+CD16++)) and Bregs (CD27-, CD27+, total Bregs) in peripheral blood by flow cytometry what we correlated with demographic, transplant and other cGVHD-related data. Descriptive and univariate analyses were undertaken to determine associations between monocytes and Bregs subsets and outcomes of interest.
Results: Twenty two adult patients with cGVHD were analyzed. The median age was 45 years [34-57], 54.5% were female. All were transplanted for hematologic malignancies, 50% underwent myeloablative conditioning, 63.6% had unrelated donor transplant, 81.8% received peripheral blood stem cells as a graft source, and 65% had previous acute GVHD. The median time from cGVHD diagnosis to this analysis was 23 months [1-60.1]. At the moment of analysis, 59.1% were receiving systemic immunosuppression, 40.0% had severe and 45.5% moderate NIH cGVHD global score, and 36.4% had active disease according to clinical impression. The most frequent organ involvement with cGVHD were eyes (68.2%), skin (55.5%), lung (55.5%) and liver (40.9%). Patients who had active disease by clinical impression had lower total B lymphocytes (p=0.031). Lower total Bregs (p=0.026) but not total B lymphocytes (p=0.715) were associated with worse cGVHD severity according to 10 point scale. Those who were receiving higher intensity of immunosuppression had lower total B lymphocytes (p=0.042), Bregs (p=0.043) and its subsets CD27- (p=0.039) and CD27+ (p=0.021). Higher Karnofsky score was associated with higher total (p=0.007), CD27- (p=0.008) and CD27+ (p=0.019) Bregs, and with higher percentage of non-classical monocytes (p=0.020). Patients with lung cGVHD had lower total (p=0.015), CD27- (p=0.021) and CD27+ (p=0.037) Bregs, those with liver cGVHD had lower percentage of intermediate (p=0.007) and non-classical (p=0.043) monocytes, but higher percentage of classical monocytes (p=0.004), those with joint/fascia cGVHD had lower percentage of non-classical monocytes (p=0.007), and those with skin cGVHD had lower percentage of CD27- (p=0.032) and lower percentage of total Bregs (p=0.029). Patients with mouth cGVHD (p=0.043) and those with more severe global NIH score (p=0.040) had higher classical monocytes.
Summary/Conclusion: This preliminary analysis suggested that several different organs affected by cGVHD had distinct associations with different subpopulations of monocytes and Bregs. Intensity of immunosuppression influenced levels of Bregs and its subsets, but not levels of monocytes and its subsets. Further study with larger cGVHD cohort is necessary for further research of complex cGVHD biology.

LIFESTYLE BEHAVIOR AMONG LYMPHOMA SURVIVORS AFTER HIGH DOSE THERAPY WITH AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION

H.S. Bersvendsen[1,2,*], H.S. Haugnes[3,4], U.-M. Fagerli[5,6], Ø. Fluge[7], H. Holte[8], K. B. Smeland[9], T. Wilsgaard[10], C.E. Kiserud[11]

[1]Oncology, University Hospital of North Norway, [2]Clinical Medicine, UIT- The Arctic University of Norway, Tromsoe, [3]Clinical Medicine, UIT-The Arctic University of Norway, [4]Oncology, Universityhospital of North Norway, Tromsø, [5]Department of Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, [6]Oncology, St. Olav`s Hospital, Trondheim, [7]Oncology, Haukeland University Hospital, Bergen, [8]Oncology, [9]National Advisory Unit for Late Effects After Cancer, Department of Oncology, Oslo University Hospital, Radiumhospitalet, Oslo, [10]Community Medicine, UIT- The Arctic University of Norway, Tromsø, [11]National Advisory Unit for Late Effects After Cancer, Department of Oncology, Oslo University Hospital, Radiumhospitalet, Oslo, Norway

Background: Lymphoma therapy is associated with increased risk of late effects such as secondary malignancies, cardiovascular disease, chronic fatigue (CF) and reduced quality of life. Due to the intensity and accumulated doses of chemotherapy given, the prevalence of late effects are presumably even higher after high dose therapy with autologous hematopoietic stem cell transplantation (auto-HSCT). A healthy lifestyle may positively influence the presence and outcome of late effects.
Aims: To assess prevalence of lifestyle behavior and associated risk factors among auto-HSCT treated lymphoma survivors.
Methods: We conducted a national cross-sectional study on an unselected group of lymphoma survivors treated with auto-HSCT from 1987 to 2008. Survivors under active lymphoma treatment were excluded. Among 399 eligible participants, 312 (78%) completed a questionnaire reporting on lifestyle factors, personality trait, CF, somatic and mental illness. We constructed a summary score on somatic and mental burden, (cut off ≥4 and ≥2 illnesses, respectively). The degree of unhealthy lifestyle was a sum score of physical inactivity (defined as moderate physical activity for <150 minutes/week or strenuous physical activity for <75 minutes/week), overweight (defined as body mass index >25), smoking and an alcohol consumption exceeding recommendations (defined as > 10 g and 20 g alcohol/week for women and men, respectively). Descriptive statistics, logistic and ordinal regression were used. Multivariable analyses were adjusted for age, gender and socioeconomic status (education and household income).
Results: Among auto-HSCT treated survivors; mean age 54.6 years and 60% men, 55% were physical sedate, 55% were overweight, 18% were smoking and 5% had an alcohol consumption exceeding recommendations. A sedate lifestyle was associated with older age (OR 1.23, 1.00-1.51 for every 10 years increase in age), low household income (OR 1.97, 1.18-3.29), CF (OR 2.30, 1.31-4.04) and somatic illness ≥4 (OR 2.39, 1.21-4.74) in multivariable analyses. In adjusted analyses male gender was associated with an increased risk of being overweight (OR 1.77, 1.10-2.86) while indolent non-Hodgkin lymphoma was associated with a lower risk (OR 0.39, 0.21-0.72). Smoking was more frequent among survivors <40 years (24%) than among those >65 years (7%). In multivariable analyses older age was related to lower risk of smoking (OR 0.70, 0.54-0.90 for every 10 years increase of age), while not being in a relationship (OR 2.38, 1.15-4.94) or CF (OR 2.12, 1.10-4.06) increased the risk of smoking. A less healthy lifestyle was associated with male gender (OR 1.79, 1.13-2.84), CF (OR 2.37, 1.44-3.88) and higher somatic burden (OR 2.62, 1.45-4.75), whereas ≥3 regimens prior to auto-HSCT was related to a more healthy lifestyle (OR 0.28, 0.14-0.59), on adjusted analyses.
Summary/Conclusion: The majority of auto-HSCT survivors were physical sedate and overweight. Surprisingly, one quarter of younger survivors were smoking. A higher burden of morbidity (somatic illness and CF) was associated with a less healthy lifestyle. Presumably, these survivors need more attention during follow-up in order to prevent and mitigate late effects, and to increase quality of life. Our results illustrate the necessity of incorporating recommendations and support for improving health-related behavior into cancer survivorship plans for auto-HSCT survivors.

CTLA-4 GENE POLIMORPHISM INFLUENCE THE OUTCOME OF HEMATOPOIETIC STEM CELL TRANSPLANTATION

P. Kovy[1,*], N. Meggyesi[1], K. Balassa[2], L. Varga[2], A. Bors[1], A. Batai[3], E. Torbagyi[3], L. Gopcsa[3], L. Lengyel[3], A. Barta[3], A. Tordai[4], T. Masszi[5], P. Remenyi[3], H. Andrikovics[1]

[1]Laboratory of Molecular Genetics, Central Hospital of Southern Pest National Institute of Hematology and Infectious Diseases, [2]School of PhD Studies, Semmelweis University, [3]Department of Haematology and Stem Cell Transplantation, Central Hospital of Southern Pest National Institute of Hematology and Infectious Diseases, [4]Department of Pathophysiology, [5]3rd Department of Internal Medicine, Semmelweis University, Budapest, Hungary

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a major curative therapeutic option for malignant hematopoietic diseases. T cell activation plays an important role in the development of graft versus leukemia and graft versus host disease (GvHD). Cytotoxic T-lymphocyte antigen-4 (CTLA-4) is an inhibitory regulator of T cell activation, that influence the predisposition to autoimmunity and the outcome hematopoietic stem cell and solid organ transplantation. Several single nucleotide polymorphisms (SNPs) have been reported to influence the function of CTLA-4, with contradictory results in the publications.
Aims: The aim of this study was to investigate the role of CTLA-4 +49A>G

(rs231775) polymorphism in the outcome of HSCT.
Methods: We investigated the correlation between recipient and donor CTLA-4 +49A>G and allo-HSCT outcome in a cohort of 411 adult patients who underwent first allo-HSCT between January 2007 and December 2013 at our single center. Donor type was HLA-matched sibling in 210 and matched unrelated donors (MUD) in 201 patients. Myeloablative conditioning (MAC) was performed in 263, and reduced intensity conditioning (RIC) in 148 patients. For identification of CTLA-4 from genomic DNA we applied LightCycler melting curve analysis (LightCycler 480II, Roche Diagnostics).
Results: We did not find any correlation between recipients' CTLA-4 +49A>G polymorphism and HSCT outcome. Nevertheless recipients who received graft from G allele carrier donors showed increased relapse rate in line with increasing G allele dosage [AA: 22% (38/171), AG: 26% (51/193), GG: 40% (19/479), p=0.043 in the genotypic model; p=0.019 in the recessive model]. On contrary, the frequency of the acute GvHD grades III-IV and cytomegalovirus (CMV) reactivation/disease decreased according to the presence of the G allele in the donor CTLA-4 genotype [aGvHD: AA: 20% (34/171), AG: 11% (22/193), GG: 6% (3/47); p=0.018; CMV: AA:24% (41/171), AG:16% (31/192), GG:9% (4/47); p=0.027] Overall survival was not different in patient subgroups according to donor genotypes. Cause of death was altered, patients with G allele carrier donors were more frequently died of the underlying malignant disease [AA: 30% (25/82), AG: 41% (39/95), GG: 59% (16/27); p=0.026]. Donor genotype similarly influenced outcome in acute leukemia, MUD donor, MAC conditioning subgroups.
Summary/Conclusion: In our patients cohort with hematologic malignancies treated with HSCT, CTLA-4 +49A>G polymorphism of HSCT donors influenced risk of relapse, aGvHD, CMV and cause of death, but not overall survival. The genotyping of CTLA-4 +49A>G polymorphism in donors may help in the choice of GvHD prophylaxis and personalised treatment.

ELDERLY PATIENTS WITH MULTIPLE MYELOMA: LONG-TERM OUTCOME FOLLOWING INDUCTION WITH NOVEL DRUGS AND AUTOLOGOUS STEM CELL TRANSPLANT

S. Rassool[1,*], L. Foster [1], Y. Li [1], S. Muhammad[2], A. Zhelyazkova[3], C. Patalappa[4], S. Jowitt[5], P. Carrington[2], H. Patel[6], E. Davies[2], P. Bulger[2], M. Pervaiz[3], S. Burns[2], C. Humphrey[2], N. Khaliq[2], A. Allameddine[3], S. Ravenscroft[5], H. Greenfield[3], J. Frazer[2], W. Ogden[2], E. Tholouli[2], A. Rocci[2,7]

[1]Medical School, The University of Manchester, [2]Haematology, Manchester Royal Infirmary, Manchester University NHS Foundation Trust, [3]Haematology, Royal Oldham Hospital, The Pennine Acute Hospitals NHS Trust, [4]Haematology, Royal Bolton Hospital, Bolton NHS Foundation Trust, [5]Haematology, Salford Royal Hospital, Salford Royal NHS Foundation Trust, [6]Haematology, Royal Albert Edward Infirmary, Wrightington, Wigan and Leigh NHS Foundation Trust, [7]Faculty of Biology, Medicine and Health, School of Medical Science, Division of Cancer Sciences, University of Manchester, Manchester, United Kingdom

Background: The autologous stem cell transplant (ASCT) is still the cornerstone of treatment for multiple myeloma (MM) despite the introduction of several novel agents. Initially limited to patients up to 65 years of age, the use of ASCT in patients over this age is now increasing. In this population, ASCT shows a similar safety profile to younger patients, however there are limited data available on the long-term outcome of patients above the age of 65 years receiving induction with novel-drugs and ASCT.
Aims: To evaluate the efficacy and safety of ASCT in patients over 65 years of age.
Methods: Over 300 patients underwent ASCT as first-line treatment for MM at Manchester Royal Infirmary between 01/01/2010 and 31/12/2016 and a randomly chosen sample from this was included in this study. Patients received 200 mg/m^2 of Melphalan, unless creatinine clearance was <30 ml/min or serum creatinine was >200 µmol/L, in which case they received 140 mg/m^2. No age-adjustment dose of Melphalan was performed. Kaplan–Meier curves were used to determine Time to Next Treatment (TTNT) and Overall Survival (OS), using log-rank test to compare results.
Results: One hundred and fifty-nine patients have been included in this study: 107 were ≤65 years old and 52 were >65 years old. Patients received a median of 6 cycles of induction treatment containing Thalidomide (102 patients), Bortezomib (52), Lenalidomide (39), Carfilzomib (14), Cyclophosphamide (132) and Doxorubicin (19). After induction treatment, among patients ≤65 years, 36% achieved CR, 45% VGPR, 17% PR, 1% MR and 1% had PD. Three months after the ASCT, the quality of response increased in all categories: CR 49%, VGPR 42% and PR 9%. In patients >65 years, after induction treatment 27% achieved CR, 55% achieved VGPR and 18% achieved PR. Three months after the ASCT, these increased to 42%, 42% and 12%, respectively, with 4% achieving MR. After a median follow-up of 50.6 months, the median TTNT was 87.3 months for those ≤65 years and 85.2 months for those >65 years (HR 1.025, CI 0.475-1.574, p=0.366). The 5-year OS was 87% vs 76% respectively (HR 0.509, CI 0.231-1.122, p=0.094). The length of hospitalisation was similar between the 2 groups (median of 19 days for ≤65 years vs 20 for >65 years) but the readmission rate in the 3 months following ASCT was higher in those >65 years at 22%, compared to 9% in those <65. However, the median length of readmission was the same, at 7.9 days per patient in both groups. Interestingly, the median number of days per patient with C-reactive protein >50 mg/L was similar in both groups (5 days vs 6 days respectively) but the proportion of patients transferred to intensive care was much higher in the younger population (8%) than in the older group (2%), likely reflecting the tendency to perform ASCT in younger patients even in the presence of several comorbidities. The haematopoietic recovery showed no differences between the ≤65 years group and the >65 years: median number of days before Absolute Neutrophil Count >1x10^9/L was 13 vs 12 respectively; median number of days before platelets >100x10^9/L was 19 vs 21. The Transplant Related Mortality at 3 months was 0% in both groups, whilst the rate of death at 12 months was 2.8% for patients ≤65 years old vs 1.9% for patients >65 years.
Summary/Conclusion: ASCT is feasible and safe in patients >65 years following treatment with induction regimens including novel agents. Consolidation with ASCT improves the depth of response in patients >65 years and translates into similar TTNT and OS compared to patients ≤65 years.

[1]Hematopoietic Transplant Unit, [2]Osatek, [3]Radiology Department, [4]Hematology Department, [5]Clinical Epidemiology, Donostia University Hospital, Donostia/San Sebastián, Spain

Background: Pre-transplant IO has been suggested to have a detrimental effect on long-term survival of HSCT recipients.
Aims: In this analysis, we wanted to check if IO affected adversely to the long-term outcome of our series de patients.
Methods: We retrospectively studied pts who consecutively underwent allo-HSCT in our center during the period 2015-2017. A Signal Intensity Ratio (SIR) method was employed to estimate the liver IO at pre-HSCT.
Results: 160 pts were studied. One hundred and nineteen were male, and 41 female. Median age was 52 years (7-69). The baseline diseases were: 62 AML, 30 NHL, 23 ALL, 13 MDS, 10 MM, 10 cMPD, 6 BMF, 4 cLPD, and 2 graft failure. One hundred and nine had underwent alternative donor transplants (81 unrelated, and 28 haplo-identical), and 51 HLA-id family donor transplants. Stem cell source was PB in 148, and BM in 12 cases. Conditioning regimen was intensive in 73 pts, and RIC in 87; no non-myeloablative allo-HSCT were performed. Pt CMV serology was positive in 133 (83.13%) pts. Majority of pts had been heavily transfused pre-HCST: 102 pts (73.75%) had received more than 15 PRBCs. The median of PRBCs was 20 [0-147]. Median pre-HSCT ferritinemia was 1208 ng/mL (18-6195), and 90 pts (56.96%) had > 1000 ng/mL. Strikingly, pre-HSCT chelation had been employed only in 23 pts (22.55% of the heavily transfused pts). Pre-HSCT MRI, performed in 71 pts, showed severe IO (LIC > 4.5 mg/g) in 21 pts (29.58%), moderate IO (LIC 2.2-4.4 mg/g) in 32 (45.07%) and no significant IO in 18 (25.35%). The numbers of pts with a follow-up > 180 days and > 365 days (or death before) were 130 and 112, respectively. Overall mortalities at day +180 and day +365 were 16.15% (21 pts), and 28.57% (32 pts), respectively. Long-term mortalities (at day +180, and day +365) of pts with pre-HSCT liver MRI are reflexed in the Tables 1 and 2.

Table 1. Mortality at day +180 based on pre-allo-HSCT iron overload (liver MRI).

	Pts without severe iron overload in pre-HSCT liver MRI	Pts with severe iron overload in pre-HSCT liver MRI	p
N	36	14	
Mortality	1 (2.78%)	3 (21.43%)	< 0.05

Only pts with a follow-up > 365 days (or death before).

Table 2. Mortality at day +365 based on pre-allo-HSCT iron overload (liver MRI).

	Pts without severe iron overload in pre-HSCT liver MRI	Pts with severe iron overload in pre-HSCT liver MRI	p
N	19	11	
Mortality	4 (21.05%)	6 (54.54%)	< 0.05

Only pts with a follow-up > 365 days (or death before).

Summary/Conclusion: 1) Our data shows that pre-allo-HSCT iron-overload is a major risk factor for post-transplant mortality. 2) Our real-life study also reflects that only a minority of the heavily transfused pts had received chelation therapy previously to the allo-HSCT. Considering the relevance of pre-allo-HSCT iron overload, we strongly suggest referring physicians to employ chelation therapy for patient candidates for transplant during the treatment of the underline disease.

PS1497

INCIDENCE AND RISK FACTORS FOR THE DEVELOPMENT OF HEMORRHAGIC CYSTITIS ON HAPLOIDENTICAL TRANSPLANTATION

M. Perera Alvarez[1,*], M. Saez-Perdomo[2,3], A. Suárez Cabrera[1], M. Torres Ochando[2], L. Guerra[2], E. González Pérez[2], C. Acosta Fleitas[2], S. Jiménez Bravo de Laguna[2]

[1]Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, [2]Hematology, Hospital Universitario de Gran Canaria Dr Negrín, [3]Universidad de las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain

Background: Hemorrhagic cystitis (HC) is a serious complication ocurring after allogenic hematopoietic stem cell transplantation (HSCT) more frequent on haploidentical (haplo) HSCT, with an incidence of 10% to 70% associated mainly with the effect of cytotoxic agents such as Cyclophosphamyde (Cy). The conditioning regimen, BKV infection and graft versus host disease have an implication in the incidence. Other authors related the reactivation of CMV and a previous transplantation as risk factors to HC development.
Aims: With this study we aim to describe the HC incidence and risk factors in our serie of haplo-HSCT.
Methods: We analyzed all consecutive haplo-HSCT from family donors performed at our Hospital between 2013 and January 2018. The conditioning regimen used for the transplant depend on the age, comorbidities and state of malignance disease. High dose Cy (50 mg/kg on days 3 and 4) posttransplantation (PTCy), cyclosporine and Micofenolate mofetil was used to prevent GVHS acute. We used as HC prophylaxis intense hydratation on the Cy administration day and the following 24 hours (using bladder wash only in 1 patient with cardiac dysfunction) and perfused MESNA at 100% of Cy dose beginning 15 minutes before the Cy administration on 16 pts and at 20% of the last dose at 0, 4 and 8 hours on all pts. We used SPSS V.23 to determine the cumulative incidence (CI) of HC.
Results: We performed 43 haplo-HSCT, of which 25 were males and 18 were women. The mean age was 43 (range 16-68). The pts presented the following diagnosis: AML (24), HD (6), ALL (3), LPCS (3), MDS (3), AA (2), NHL (2). 11 pts developed HC (28.7% CI) (Figure 1A) with a median time from haplo-HSCT to onset of 7 days (range 0-42). The grade of HC was: 1 (9%) grade I, 6 (55%) grade II and 4 (36%) grade IV. 7/11 (63,3%) developed HC before day +30 and 4/11 (36,3%) after that day. The group of pts who develop early HC, 2 had received another HSCT before and 4 (57%) were BKV PCR positive. All the pte developed HC after day +30 were BKV PCR positive and one was CMV positive in urine too. 1 (9%) was grade I, 6 (55%) grade II and 4 (36%) grade IV. No pts died due to HC and all cases resolved without sequelae. 26 pts received PTCy and 17 pts received Cy pre- and post-transplant. The CI at day +80 for the pts with PTCy was 26.1% and for Cy pre- and post-transplant 32.8% (Figure 1B). We found no statistically significant difference on the CI of HC between these two groups. The development of HC was related to Cy and thrombocytopenia in the first 30 days, for the rest of the pts (after day +30) the HC was related to BKV infection, as a consequence of the immunosuppression state of the patient, we observed that all these pts had positives. No pts died due to HC and all cases r esolved without sequelae.
Summary/Conclusion: The incidence of HC associated to post-HSCT high Cy dose in our series is 15% lower than other ones. Most of them on grade 1 or 2 and without mortality associated. The risk of HC is high, particularly in the setting of highly pre-treated patients (especially those undergoing a 2nd transplant). The development of HC after day +30 is evidently associated to BKV as a contributing factor for continuous inflammation and CMV reactivation (as an immunosuppression marker).

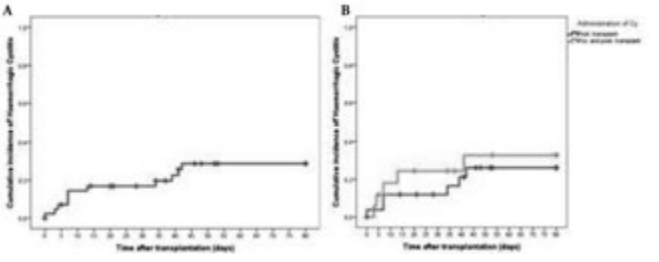

Figure 1.

PS1498

THREE MONTH FULL WHOLE BLOOD AND MIXED T CELL CHIMERISM IS ASSOCIATED WITH SUPERIOR OUTCOMES IN REDUCED-INTENSITY ALEMTUZUMAB-BASED ALLOGENEIC STEM CELL TRANSPLANTS FOR HAEMATOLOGICAL MALIGNANCIES

A. Kanellopoulos[1,*], G. Mcilroy[1], S. Paneesha[1], S. Elmoamly[1], B. Kishore[1], M. Kaparou[1], K. Holder[1], E. Nikolousis[1]

[1]Hematology, Birmingham Heartlands Hospital, Birmingham, United Kingdom

Background: Chimerism kinetics and HCT-CI are important tools for the success of reduced intensity conditioning (RIC) allogeneic stem cell transplants (SCT), although their impact on patient outcomes has been scarcely validated in Alemtuzumab based conditioning.
Aims: Exploratory Analysis of RIC Alemtuzumab based allogeneic stem cell transplants.
Methods: Retrospective analysis of 132 consecutive patients with myeloid (n=67) and lymphoid (n=65) malignancies receiving alemtuzumab-based RIC allogeneic SCT from matched sibling (32/132, alemtuzumab dose 30mg), or matched unrelated (97/132, alemtuzumab dose 50mg) donors. Median recipient age was 59 years (range 22 to 72) and 48 (36%) were female. For myeloid disease conditioning consisted of fludarabine and melphalan (34/67), fludarabine and busulphan (32/67) or fludarabine and cyclophosphamide (1/47); whilst lymphomas were treated with fludarabine and melphalan (32/65), BEAM (10/65), fludarabine and BEAM (22/65), or fludarabine, melphalan and gemcitabine (1/65).

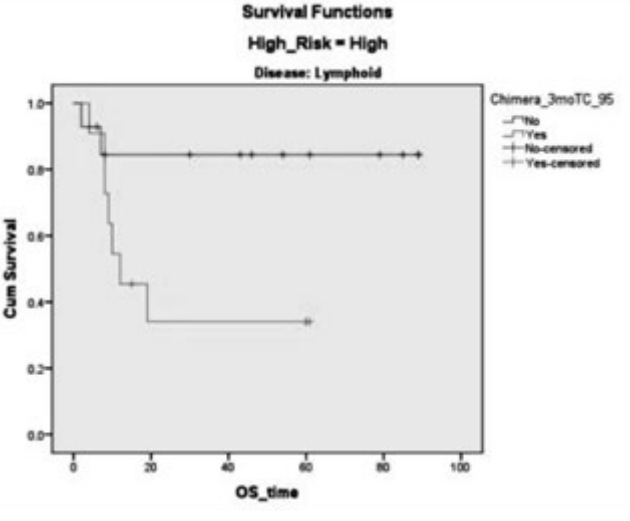

Figure 1.

Results: With a median follow-up of 13 months, the median overall survival (OS) and relapse free survival (RFS) were 24 months and 15 months, respectively. There were no statistical differences in outcomes between two disease categories (p=0.86). Time to transplant was significantly longer for lymphoid than myeloid transplants (median 25.5 vs 7 months, p<0.001) but it was not associated with the OS. OS was worse in patients with high-risk lymphoid disease (high-grade, T-cell, or lymphomas in partial remission at transplant) (HR 3.1 p=0.039). Estimated 2-year TRM was 21% (95% CI 13%

to 29%). Adjusting for age (OR 1.08, 0.01 to 1.14) and sex (p=0.46), 2-year TRM is associated with lymphoid disease, compared with myeloid (OR 3.33, 1.01 to 10.1). 2-year OS – 50% (40% to 60%); Myeloid – 51% (37% to 66%) and Lymphoid – 49% (35% to 63%). 2-year PFS – 58% (48% to 68%) whereas grade 2-4 acute GvHD was 44% (36% to 53%). Adjusting for age, sex, and disease class, full WB chimerism is associated with better OS (HR 0.24, 0.082 to 0.699, p= 0.009), whereas full T-cell chimerism is associated with worse OS (HR 2.97, 1.095 to 8.049, p=0.032). Similarly, full WB chimerism is associated with better PFS (HR 0.27, 0.11 to 0.638, p= 0.003), but full T-cell chimerism is associated with worse PFS (HR 2.48, 1.095 to 5.635, p= 0.029). 2-year TRM is higher in full T-cell chimeras (8/26, 31%), than mixed T-cell chimeras (0/34) (p=0.001). 2-year relapse-related mortality tends to be lower in full T-cell chimeras (4/26, 15%), than mixed T-cell chimeras (9/34, 26%) (p=0.358). Adjusting for age (60 years) (OR 1.065, 1.011 to 1.121, p=0.017), HCT-CI is not associated with OS (comparing 0-1 with 2+, p=0.34). Finally, age predicted OS (univariate, over vs under 60, HR 1.62, p=0.056; univariate, age as continuous variable, HR 1.034, 1.007 to 1.061, p=0.012). HCT-CI did not predict OS, comparing 0-1 with 2+ (p=0.66) (Figure 1).
Summary/Conclusion: In our patient series of RIC alemtuzumab-based allogeneic transplants, three-month full donor status in whole blood and three-month mixed T-cell chimerism are associated with favourable RFS and OS. HCT-CI was not predictive irrespectively of patient age.

PS1499

OUTCOMES OF SECOND ALLOGENEIC STEM CELL TRANSPLANTATION FOR RELAPSE OF HEMATOLOGICAL DISEASES OR GRAFT FAILURE: A SINGLE-CENTRE EXPERIENCE

M. Poiani[1,2,*], D. Salvatore[13], G. Battipaglia[1,3], R. Duléry[1], F. Giannotti[1], F. Malard[1], E. Brissot[1,4], S. Sestili[1], R. Belhocine[1], F. Isnard[1], S. Lapusan[1], R. Adaeva[1], O. Legrand[1,4], M. Labopin[1,4], A. Ruggeri[1], M. Mohty[1,4]

[1]Hopital Saint Antoine, Paris, France, [2]AOU Ospedali Riuniti, Ancona, [3]Federico II University, Naples, Italy, [4]Sorbonne Université UPMC Univ Paris 06, INSERM, Centre de recherche Saint-Antoine, Paris, France

Background: Second allogeneic hematopoietic stem cell transplantation (HSCT) might be considered an option in patients experiencing disease relapse or graft failure after first HSCT. However, its feasibility is hampered by high rates of toxicity and mortality.
Aims: We retrospectively analyzed outcomes of 44 consecutives patients (26 males and 18 females)
Methods: They underwent 2nd HSCT either for disease relapse (group 1, n=28) or graft failure (group 2, n=16) between 2005 and 2017.
Results: Median age at 2nd HSCT was 39 (range 15-69) years. Diagnosis were acute myeloid leukemia (group 1: n=20; group 2: n=5), acute lymphoblastic leukemia (group 1, n=3; group 2, n=4), myelodysplastic syndrome (group 1, n=1; group 2, n=2), myeloproliferative neoplasm (group 1, n=4; group 2, n=1), bone marrow failure (group 1, n=0; group 2, n=4). Median time from 1st HSCT was 23 (range 2.6-161) months in group 1 and 2.2 (range 1.6-17.3) months in group 2. All but 5 patients received graft from a different donor than 1st HSCT. Graft source were: matched related bone marrow (BM, group 1, n=1; group 2, n=0), matched related peripheral blood stem cells (PBSC, group 1, n=2; group 2, n=2), haploidentical BM (group 1, n=3; group 2, n=1), haploidentical PBSC, (group 1, n=8; group 2, n=2), cord blood (group 1, n=8; group 2, n=10), matched unrelated PBSC (group 1, n=6; group 2, n=1). At time of 2nd HSCT, 14 patients were in complete remission and 14 presented active disease in group 1. All but two patients underwent chemotherapy for disease relapse before 2nd HSCT. Conditioning regimen was myeloablative in 6 patients (group 1, n=5; group 2, n=1), reduced intensity (RIC) in 36 (group 1, n=23; group 2, n=13). A sequential schema consisting of a combination of thiotepa, etoposide and cyclophosphamide followed by a fludarabine and busulfan based RIC was used in 8 out of 14 patients with active disease in group 1. *in vivo* T-cell depletion was used in 22 patients (group 1, n=15; group 2, n=8). All but 2 patients engrafted (1 in each group), in a median time of 18 (range 6-51) days. Cumulative incidence (CI) of day 100 grade II-IV acute graft versus host disease (GVHD) and 5-years (5y) chronic GVHD were 32% (95% CI: 18-48) and 39% (95% CI: 24-55), respectively, for the entire cohort. With a median follow-up of 58 (range 2-107) months, 5y non-relapse-mortality (NRM) and relapse incidence (RI) were 33% (95% CI: 18-49) and 30% (95% CI: 16-45), respectively. At 5-years disease-free (DFS) and overall survival (OS) were 37% (95% CI: 21-53) and 40% (95% CI: 24-55). Globally, 25% patients died of infections (n=10), relapse (n=7), GVHD (n=3), SOS/VOD (n=2), failure/rejection (n=1) or for unknown causes (n=2). At 5 years, outcomes of patients in group 1 were: RI 33% [14-53], NRM 30%[11-51], aGVHD 36%[17-56], cGVHD 50%[27-70], DFS 37%[15-58], OS 41%[20-61], respectively. Outcomes of patients in group 2 were: RI 25% [7-48], NRM 38%[14.5-61], aGVHD 27%[8-51], cGVHD 25%[7-49], DFS 38%[14-61] and OS 38%[14-61].
Summary/Conclusion: Despite hampered by a non-negligible morbidity and mortality, 2nd HSCT might be considered as an option to rescue a certain number of patients experiencing disease relapse or graft failure, for which prognosis is very poor. Decision is to be discussed on a case-to-case basis. Further advances in supportive care and post-transplant treatment strategies, might be helpful in order to improve outcomes and to propose this strategy in a larger number of patients.

PS1500

CLOFARABINE- BASED CYTOREDUCTIVE TREATMENT FOLLOWED BY MYELOABLATIVE CONDITIONING AND ALLOGENEIC STEM CELL TRANSPLANTATION IN CHILDREN WITH HIGH-RISK, RELAPSED OR REFRACTORY HEMATOLOGIC MALIGNANCIES

D. Medina Valencia[1,*], M. Estacio[1], M. Rosales[1], L. Perafan[2], E. Manzi[2]

[1]Stem cell transplant, [2]Research department, Fundacion Valle del Lili, Cali, Colombia

Background: Patients with relapse/ refractory or MDR-high hematologic malignancies have a poor prognosis. Allogeneic stem cell transplantation (SCT) is the only curative option, however, this treatment is associated with a low survival and high risk of relapse posttransplant in this group of patients[1,2]. Previous studies in adults reported the feasibility of a sequential therapy consisting of a cytoreductive chemotherapy followed by SCT with different strategies, including clofarabine-based, with encouraging results[3–7]. Nevertheless, there are few reported of this strategy in the pediatric setting.
Aims: The aim of this retrospective analysis was to report outcomes using clofarabine-based cytoreduction followed by myeloablative intensity conditioning and allogeneic transplantation.
Methods: We retrospectively reviewed all pediatric with hematologic malignancies who underwent allogeneic SCT after treatment with clofarabine, between years 2012 and 2017. In patients with ALL the sequential regimen consisted of clofarabine (30 mg/m2/day or 40mg/m2/day) and steroid (Dexamethasone or methylprednisolone) plus cytosine arabinoside (2 g/m2/day) for 5 consecutive days. Additional patients with AML or MDS received G-CSF priming. Followed, after a 3-day rest, by myeloablative conditioning (BU-FLU-TBI 400 cgy or MEL) and allogeneic stem-cell transplantation.
Results: Eighteen patients received a clofarabine-based Cytoreduction. Were included 10 acute myeloid leukemia, 4 acute lymphoblastic leukemia, 2 juvenile myelomonocytic leukemia, 1 myelodysplastic síndrome and 1 myeloid sarcoma. Median age was 4.9 years (Range 1.6 -16.1). Donors were Haploidentical (n=12) and Identical sibling (n=6). The median pre-transplant marrow blast percentage was 1.65 (range 0.08- 89). At day +30, 14 patients were evaluable for response, 8 patients were in negative MDR and 6 patients were in positive MDR with a median marrow blast percentage of 0.45 (range 0.3-1.2). Full donor chimerism was found in all patients at day +30. The cumulative incidence of acute GVHD II-IV was 59%, only one patient has severe GVHD and for chronic GVHD was 27%. The 1-year overall (OS) was 59.5% (95% CI:30-80%) and event-free survival (EFS) was 46% (95% CI:18-70%). Transplant related mortality (TRM) at 100 days was 11.1%. Eleven patients developed liver toxicity, 2 grade III, 1 grade II and 8 grade I. We don't found increased in creatinine.
Summary/Conclusion: Clofarabine- based cytoreductive treatment can be safe and feasible option for children with high-risk, relapsed or refractory hematologic malignancies. However, our results require further support from prospective randomized studies to improve the efficacy of this strategy.

Stem cell transplantation – Experimental

SELECTIVE INHIBITION OF OXIDATIVE PHOSPHORYLATION PREVENTS LETHAL GRAFT-VERSUS-HOST DISEASE WHILE MAINTAINING ANTITUMOR IMMUNITY

Z. Mciver[1,*], R. Blevins[1], B. Coe[1], M. Detty[2], J. Grayson[3]

[1]Hematology and Oncology, Wake Forest School of Medicine, Winston Salem, NC, [2]Chemistry, University at Buffalo, Buffalo, NY, [3]Microbiology and Immunology, Wake Forest School of Medicine, Winston Salem, NC, United States

Background: Pathogenic T cells play a central role in many immunological disorders. In hematopoietic stem cell transplant (HSCT), acute graft-versus-host-disease (GVHD) is caused by an attack on the recipient's tissues by donor allogeneic T cells. *Ex vivo* application of phototherapy to selectively deplete GVHD-causing cells prior to transplant may prevent GVHD. However, none of the photosensitive agents in use today have demonstrated selectivity without significant toxicity occurring in resting cells. We have designed the first-in-class, novel photosensitizer 2-Se-Cl with the ability to accumulate in pathogenic T cells in proportion to degree of oxidative phosphorylation (OXPHOS). Unique to 2-Se-Cl is the ability to potently stimulate P-glycoprotein (P-pg). Enhanced P-gp activity promotes the efficient removal of photosensitizer not sequestered in mitochondria, and protects resting lymphocytes essential for antipathogen and antitumor responses.
Aims: We have previous demonstrated the ex vivo photodepletion of alloreactive T cells using 2-Se-Cl successfully prevented GVHD in a lethal model of the disease with full retention of antipathogen immunity and 3rd party responses. The aim of our study is to employ 2-Se-Cl to prevent acute GVHD while retaining robust antitumor activity in well established animal models of complete MHC-mismatched and MiHA-mismatched HSCT.
Methods: To evaluate for the retention of antitumor immunity, both MHC-mismatched (C57BL/6 ($H2^b$)→Balb/c (H2d)) and MiHA-mismatched (C3H.SW → C57Bl/6) transplantations were preformed. To prepare the cells for photodepletion, donor splenocytes were cocultured for 4 days with irradiated (20 Gy) recipient splenocytes, and then photodepleted (PD) with 2-Se-Cl. On the day of HSCT, recipient mice were irradiated (8.5Gy for Balb/c and 10.5Gy for C57BL/6), and received 10^7 T cell-depleted (TCD) donor-derived bone marrow cells accompanied by 5 x10^6 PD - treated cells, or recipient specific (A20, Balb/c-derived and FLT3+ AML C57BL/6-derived) leukemia cells engineered to express firefly luciferase, or both. To evaluate for the retention of 3rd party responses, C3H/HeJ were irradiated (9.5 Gy) and received a combination of 10^7 TCD donor-derived bone marrow cells accompanied by 5 x10^6 PD - treated cells. All mice were monitored for signs of GVHD according to a well-established mouse GVHD grading system, and all mice that received leukemia cells were evaluated weekly by IVIS for evidence of disease progression. Three to 5 animals underwent HSCT in each group in 3 independent experiments.
Results: Recipient mice that received PD-treated splenocytes survived > 60 days without evidence of GVHD or leukemia, equivalent to controls (recipients of TCD bone marrow cells only). In contrast, mice that were inoculated with leukemia at time of HSCT without the addition of PD-treated splenocytes died of leukemia progression. Additionally, all third-party C3H/HeJ mice that received the same number of PD-treated cells died of lethal GVHD, consistent with the selective depletion of the alloimmune response towards first-party recipient mice by 2-Se-Cl.
Summary/Conclusion: These results demonstrate that ex vivo application of 2-Se-Cl protects against lethal GVHD while maintaining antitumor immunity in both the complete MHC-mismatch and MiHA-mismatched settings. The high selectivity of this novel photosensitizer may have broad applications, including the rapid production of immune effector cell products with potent antitumor activity and a low potential for toxicity.

PS1502

AN UNBALANCED MONOCYTE MACROPHAGE POLARIZATION IN THE BONE MARROW MICROENVIRONMENT MAY CAUSE THE OCCURRENCE OF POOR GRAFT FUNCTION AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

H.-Y. Zhao[1,*], Z.-S. Lyu[1,2], C.-W. Duan[3], Y. Song[1,2], T.-T. Han[1], X.-D. Mo[1], Y. Wang[1], L.-P. Xu[1], X.-H. Zhang[1], X.-J. Huang[1,2], Y. Kong[1]

[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking-Tsinghua Center for Life Sciences, Peking University, Beijing, [3]Key Laboratory of Pediatric Hematology and Oncology Ministry of Health and Pediatric Translational Medicine Institute, Shanghai Jiao Tong University School of medicine, Shanghai, China

Background: Poor graft function (PGF) remains a life-threatening complication following allogeneic hematopoietic stem cell transplantation (allo-HSCT), and the underlying mechanisms have not yet been elucidated. Considerable evidence from murine studies has demonstrated that effective hematopoiesis depends on the specific bone marrow (BM) microenvironment, where hematopoietic stem cells reside. In this regard, we previously reported that PGF patients had impaired BM endosteal cells and endothelial progenitor cells, as well as dysregulated T cell responses in the BM microenvironment, which may be involved in the occurrence of PGF. Macrophage(MΦ) commonly exist in two distinct subsets: M1 and M2, is one of the important components of BM immune microenvironment. Meanwhile, Increasing murine studies show that BM resident MΦs are indispensable for HSCs function and BM erythroid output. However, little is known about the quantity and function of BM MΦs and whether BM MΦs directly interact with HSCs in PGF patients post allo-HSCT.
Aims: To compare the number and function of BM MΦs between patients with PGF and GGF after allo-HSCT. Moreover, to investigate whether the BM MΦs directly interact with HSCs in PGF patients.
Methods: This prospective nested case-control study enrolled 30 PGF patients, 60 matched patients with good graft function (GGF), and 30 healthy donors (HD). Standard monocyte subsets, defined by cluster of differentiation CD14 and CD16, as well as M1(CD68+CCR2+) and M2 (CX3CR1+CD163+) from BM samples were analyzed by flow cytometry. The functions of BM derived MΦs were evaluated by migration assay, phagocytosis assay and cytokine profile. CD34+ cells from HDs were co-cultured respectively with BM derived macrophages from PGF and GGF patients, and the levels of reactive oxygen species (ROS) and apoptosis in CD34+ cells were analyzed by flow cytometry after 5 days co-culture. Besides, colony-forming unit (CFU) assay was performed. Finally, intracellular proteins levels of CD34+ cells were evaluated by LSRFortessa software and expressed as the mean fluorescence intensity.
Results: Alterations in standard monocyte subsets (classical, intermediate and non-classical) were found when comparing subjects among PGF, GGF and HDs. Moreover, PGF patients displayed an unbalanced M1/M2 ratio compared with the GGF and HDs, attributable to an increased number of M1 and a reduced number of M2. Dysfunctional BM derived MΦs, which were characterized by impaired proliferation, migration and phagocytosis, were revealed in PGF patients. Moreover, PGF BM derived MΦs produce more proinflammatory cytokines than GGF BM derived MΦs, including IL-12 and TNF-α. While, GGF BM derived MΦs have a high production of TGF-β. The BM CD34+ cells co-cultured with PGF BM derived MΦs, characterized by higher levels of ROS and apoptosis, had a deficit in CFU outgrowth at baseline level compared with those cells co-cultured with GGF BM derived MΦs. Subsequently, the higher p-p38 and p-JNK expression was observed in the BM CD34+ cells which were co-cultured with PGF BM derived MΦs.
Summary/Conclusion: In summary, the current study demonstrated an unbalanced M1/M2 number and dysfunction of BM MΦs in PGF patients. Moreover, BM derived MΦs from PGF patient have a negative impact on CD34+ cells *in vitro* study. Therefore, it would be of value to investigate the appropriate approach to balance the M1/M2 and enhance function of BM MΦs, which may be a promising therapeutic approach for PGF patients.

PS1503

COMPLEMENT-RELATED GENETIC VARIANTS IN ADULT ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANT RECIPIENTS WITH TRANSPLANT-ASSOCIATED THROMBOTIC MICROANGIOPATHY

E. Gavriilaki[1,*], T. Touloumenidou[1], I. Batsis[1], D. Mallouri[1], A. Vardi[1], A. Marvaki[1], M. Koutra[1], P. Zerva[1], E.-E. Koravou[1], A. Papalexandri[1], M. Stamouli[2], K. Gkirkas[2], P. Tsirigotis[2], E. Yannaki[1], I. Sakellari[1], A. Anagnostopoulos[1]

[1]Hematology Department - BMT Unit, G. Papanicolaou Hospital, Thessaloniki, [2]Second Department of Internal Medicine, Division of Hematology, ATTIKO University Hospital, National and Kapodistrian University of Athens, Athens, Greece

Background: Transplant-associated thrombotic microangiopathy (TA-TMA) is a potentially life-threatening complication of allogeneic hematopoietic cell transplantation (HCT). In light of encouraging results by complement inhibition treatment, a few reports have documented complement-related genetic variants in TA-TMA patients. However, their incidence and the clinical importance of pre-transplant genetic profiling remain unclear.
Aims: To detect complement-related variants in TA-TMA patients using next-generation sequencing and investigate their association with clinical

outcomes.
Methods: We enrolled consecutive allogeneic HCT recipients diagnosed with TA-TMA according to the IWG criteria from 2014 to 2017. Patients' DNA was obtained from pre-transplant peripheral blood samples. Probes were designed using Illumina's Design studio. The amplicons cover exonic regions of complement regulatory genes (*CFH, CFH-related, CFI, CFB, CFD, C3, CD55, C5, MCP, thombomodulin, ADAMTS13*) spanning 15 bases into the intronic regions. We used 10ng of initial DNA material. Libraries were sequenced on a MiniSeq System in a 2x150 bp run. Analysis was performed using the TruSeq Amplicon application. We performed variant calling with the Illumina-developed Somatic Variant Caller in germline mode and variant allele frequency higher than 20%. Ensembl and Refseq were used for annotation of the output files. Variants were further annotated using the Variant Interpreter (Illumina).
Results: We studied 16 patients that presented TA-TMA at median + 80 (9-540) days, after full hematopoietic constitution. Patients were transplanted from sibling (4), matched (8) or mismatched (3) unrelated or haploidentical (1) donors, mainly with a myeloablative conditioning (8). The majority presented infectious complications (10) and severe acute (14) or extensive (11) chronic graft-versus-host disease.
In genetic analysis, patients presented heterogeneous variant profiles including pathogenic, likely pathogenic, benign and variants of unknown significance (median number of variants: 75, range: 53-99). Pathogenic complement-related variants were found in 15/16 patients. The majority (13/16) harbored pathogenic variants (SNVs) in *complement-factor H (CFH)*, that have been previously reported in patients with atypical hemolytic uremic syndrome (aHUS). 4 patients presented additional pathogenic variants in *ADAMTS13* and 2 patients in *CFB*. One patient presented pathogenic variants only in *ADAMTS13* and 1 only in *CFB*.
Regarding clinical outcomes, only 3 patients responded to conventional treatment. Interestingly, these patients harbored only 1 pathogenic variant (1 patient in *ADAMTS13*, 1 in *CFB* and 1 in *CFH*). Based on physician's decisions, 4 refractory patients received complement inhibition treatment. These patients harbored more than one pathogenic variant. Although all patients showed initial hematologic response to eculizumab treatment, TA-TMA resolved only in 1 patient after 4 eculizumab doses. 12/16 patients succumbed to transplant-related mortality.
Summary/Conclusion: The identification of pathogenic complement-related variants in TA-TMA patients suggests genetic susceptibility to impaired complement regulation. Despite increased morbidity and mortality, complement inhibition seems promising in selected patients. In this complex setting, genetic variants need to be further investigated in control groups in order to confirm their clinical importance and usefulness in early recognition of patients who may benefit from complement inhibition.

MURINE MODELS FOR ESTABLISHING STEROID REFRACTORY GVHD

T. Toubai[1,*], C. Rossi[2], I. Tawara[3], C. Liu[4], C. Zajac[5], K. Oravecz-Wilson[5], D. Peltier[5], Y. Sun[5], H. Fujiwara[5], J. Wu[5], M. Riwes[5], I. Henig[5], S. Kim[5], K. Ishizawa[1], P. Reddy[5]

[1]Yamagata University, Yamagata, Japan, [2]University of Heidelberg, Heidelberg, Germany, [3]Mie University, Tsu, Japan, [4]Rutgers-Robert Wood Johnson Medical School, New Brunswick, [5]University of Michigan, Ann Arbor, United States

Background: Steroids are the first line therapy for acute graft-versus-host disease (GVHD). However, the outcome of steroid refractory GVHD (SR-GVHD) is poor due to the lack of effective treatments. The development of therapies for SR-GVHD is limited by an incomplete understanding of its pathophysiology because of the lack of clinical animal models.
Aims: Here we address the need for a SR-GVHD animal model by developing a major histocompatibility (MHC) matched, multiple minor histocompatibility antigens (miHAs) mismatched model as well as a MHC mismatched haploidentical murine bone marrow transplantation (BMT) models.
Methods: We utilized the clinically relevant major histocompatibility (MHC) matched, multiple minor histocompatibility antigens (miHAs) mismatched model as well as a MHC mismatched haploidentical murine bone marrow transplantation (BMT) models. Dexamethasone (DEX) was administered from day +7 to day +21 at a dose of 0.1 mg/kg.
Results: We observed three phenotypes in response to DEX: 1) Steroid refractory (REF): progressive GVHD characterized by severe peak GVHD clinical scores, progressive weight loss and early mortality; 2) stable GVHD (ST) characterized by moderate GVHD clinical scores, moderate body weight loss, and minimal late mortality; 3) steroid responsive (RES) GVHD characterized by near complete normalization of GVHD clinical scores, near complete normalization of weight loss, and no mortality. We demonstrate that animals can develop SR-GVHD regardless of whether steroids are initiated early or late post allogeneic bone marrow transplantation (allo-BMT). In general, we observed increased GVHD specific histopathological damage of target organs in SR-GVHD animals relative to steroid responsive animals. Interestingly, we found no significant differences in donor T cell characteristics between steroid refractory and responsive animals
Summary/Conclusion: We propose using our models to decipher SR-GVHD pathogenesis and to develop SR-GVHD treatment. However, these models, like any model system, show some distinction from complex clinical realities and will need to be continuously optimized. Nonetheless, in this study, we established SR-GVHD models and found that donor T cell characteristics were not significantly different between groups treated with steroids. These data suggest that T cell independent mechanisms may also contribute to steroid refractoriness more so than was previously considered.

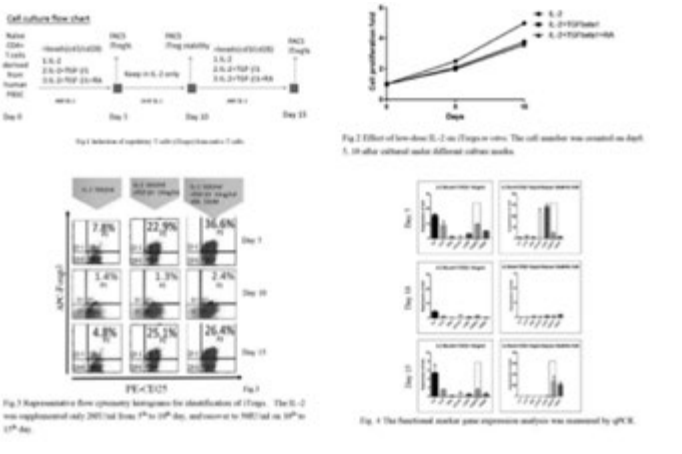
PS1505

LOW-DOSE INTERLEUKIN-2 RESTORING HUMAN REGULATORY T CELL FUNCTION *IN VITRO* AS A POTENTIAL APPLICATION FOR GVHD THERAPY AFTER TRANSPLANTATION

T.-J. Chiou[1,*], H.-H. Lin[1], W.-H. Wu[1], J.-Y. Jian[1], S.-T. Chu[2], W.-F. Tzeng[3]

[1]Division of Transfusion Medicine, Department of Medicine, Taipei Veterans General Hospital and National Yang-Ming University School of Medicine, [2]Institute of Biochemisty, National Taiwan University, Taipei, [3]Department of Life Science, Fu-Jen University, New Taipei City, Taiwan, Republic of China

Background: Currently, isolated and *in vitro*-expanded natural regulatory T cells (nTregs) was shown to be a potentially effective therapy for patients with GVHD after transplantation. However, shortage of nTregs in peripheral blood and time consumption of expansion *in vitro* would limit the clinical application. The activity of induced regulatory T cells (iTregs) to suppress the responder T cells should be maintained for longer time to improve the GVHD therapeutic efficiency. Low-dose IL-2 administration was ever tried to induce the functional Tregs *in vivo*, and improve the therapy of cGVHD. IL-2 may expand the T lymphocytes and restore the functional iTregs in a short time *in vitro*, then to ensure the successful therapy for acute GVHD.
Aims: As known, iTreg cells would decay after a period of time *in vivo* or *in vitro*. In order to provide more number of effective iTregs for clinical use, we try to develop a method for induction and expansion of iTregs via IL-2 restores Tregs *in vitro*.
Methods: Human PBSC were prepared from peripheral blood of healthy donor by Ficoll-Hypaque density gradient centrifugation. Naïve T cells were isolated by negative selection. The harvested naïve T cells were cultured and stimulated under cytokines-containing RPMI1640 medium. The flow chart was shown in Figure 1. For cell proliferation and activity maintenance, the cells were cultured under IL-2 supplemented medium. The harvested cells were analyzed by flow cytometry with fluorescence-conjugated CD antibodies, including CD4, CD25, CD127 and FoxP3. The identification of iTregs function was analyzed via gene marker qPCR analysis.



Figures 1,2,3,4.

Results: Amplification of the T cell number obtained more iTreg cells; therefore, cultivation of the iTreg cells under low-dose IL-2-containing medium would stimulate the T cell proliferation to about 4-fold on the 10th-day

(Figure 2). After the first cytokines stimulation, we harvested the iTregs, and then, keep the cells in low-dose IL-2 only medium for another 5 days to expand and maintain activity of the T cells. On the 10th-day, the expanded T cells would be performed with anti-CD3/CD28 antibodies and with cytokines supplement for the further induction. The IL-2 expanded-T cells would be further induced to iTregs (Figure 3). *FoxP3* gene and other marker genes expression measurement were as functional iTregs indicators, and showed high expression on the 5th- and 15th- day iTregs but lower on the 10th-day (Figure 4). Our data showed that the proliferation of cells would be maintained within the period under low-dose IL-2 medium, the *FoxP3* gene expression would decrease, but restored on 15th-day. Therefore, we could harvest more functional iTregs after the low-dose IL-2 incubation, because of the cell expansion during IL-2 medium incubation for 5 days. Using marker gene qPCR analysis, we have confirmed all of these functional iTregs, and the MLR assay also showed the suppression of the responder T cells.

Summary/Conclusion: Our study showed that after the activation and induction of naïve T cells, we could maintain the cells with IL-2 containing medium. After the second induction, we could restore the iTreg cells. Therefore, we may provide more functional iTregs cells for the potential use in the therapy of GVHD patients continuously in the future. PS1506

HYPOFRACTIONATED TOTAL LYMPHOID IRRADIATION BY HELICAL TOMOTHERAPY AND HIGH DOSE CHEMOTHERAPY AS CONDITIONING FOR AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH RELAPSED/REFRACTORY LYMPHOMA

F. Guolo[1,*], S. Vagge[2], A. Pepe[1], P. Minetto[1], A. Dominietto[3], F. Ballerini[1], C. Ghiggi[3], A. Ibatici[3], E. Angelucci[3], R. Corvo'[2], R.M. Lemoli[1], M. Gobbi[1]

[1]Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, [2]Department of Radiation Oncology, [3]Hematology Unit and Bone Marrow Transplantation, Ospedale Policlinico San Martino, IRCCS per l'Oncologia, Genoa, Italy

Background: Salvage chemotherapy followed by autologous stem cell transplantation (ASCT) is the standard of care for patients with relapsed/refractory (R/R) Hodgkin's Lymphoma (HL) and non-Hodgkin lymphoma (NHL). However conventional conditioning regimens have low efficacy in R/R patient and only a minority of them is cured by this approach. Promising results with hyperfractionated total lymphoid irradiation (TLI) followed by high-dose chemotherapy and ASCT have been reported in advanced HL patients, despite relevant toxicity due to radiation-induced damage of healthy tissues. Helical tomotherapy (tomo-TLI) is a novel rotational technique that delivers highly conformal radiation dose with significant sparing of critical organs thanks to integrated fan beam CT scan.
Aims: Assessing feasibility of a conditioning strategy based on high dose chemotherapy and tomo-TLI as preparation for ASCT in patients affected by R/R lymphoma.
Methods: From February 2011 to December 2017, 15 patients with R/R HL (n=7), diffuse Large B Cell NHL (n=6) and T-cell NHL (n=2) were treated. Median age was 42 years (range 20-68) and median number of previous lines of therapy was 3 (range 2-4). Of note, 4 patients had already received prior ASCT. Salvage chemotherapy was decided case by case and clinical response was determined by functional imaging prior to ASCT. Conditioning chemotherapy consisted of high-dose Bendamustine (400 mg/sqm) and Melphalan 140 (mg/sqm) for patients older than 40 years (n=10) and conventional FEAM (Fotemustine, Ethoposide, Cytarabine and Melphalan) for younger patients. Hypofractionated tomo-TLI at a daily dose of 400 cGy for 3 consecutive days was scheduled prior to chemo-conditioning. The total dose of 1200 cGy, biologically equivalent to 1600 cGy in classical daily fractionation, was delivered to all nodal sites including the spleen, with a simultaneous integrated boost over the region of residual disease. High dose chemotherapy was administered 4 days after tomo-TLI.
Results: Salvage chemotherapy induced CR in 7 patients (5 HL, 2 NHL), PR in 5 (2 HL,3 NHL), less than PR IN 3. Conditioning strategy was well tolerated. Six patients (40%) experienced fever of unknown origin and 5 patients (33%) developed grade 3/4 mucositis. None experienced grade 3/4 extra-hematological toxicity. The median number of CD34+ cells infused was $5{,}5\times10^6$/kg (range 2,1 -10,0). All patients showed complete engraftment and median time to neutrophil and platelet recovery was 11 (range 9-21) and 12 days (range 9-21) respectively. Median follow-up was 38 months (CI 95%: 1.3–66.1 months). All patients in PR or less before transplant achieved CR. There were no cases of treatment-related death. The 3-year overall PFS and OS were 78% and 93% (Figure 1) respectively.

Post-ASCT relapse occurred in 3 patients (HL=2 and NHL=1) at a median time of 8 months and 1 NHL patient subsequently died of progressive disease 7 months after ASCT.

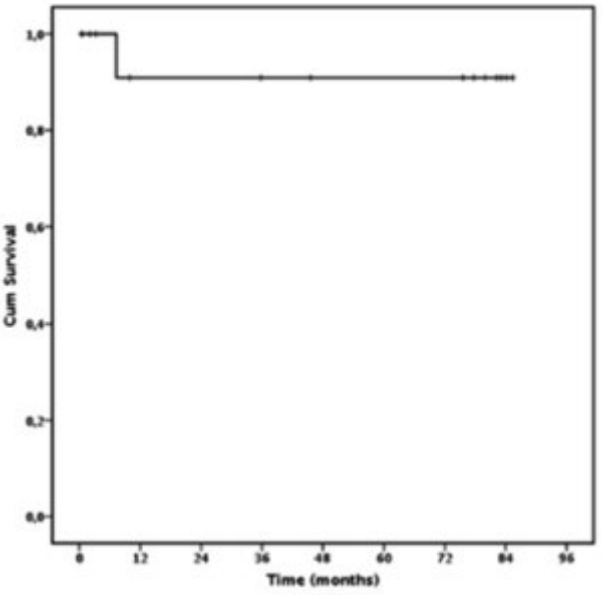

Figure 1. Overall survival.

Summary/Conclusion: Our preliminary results show that tomo-TLI can be safely used in advanced lymphomas. It greatly reduces the damage to healthy tissues and allows to deliver sequential high dose chemotherapy as combined conditioning. With the limit deriving from the small size of this series, we observe that all patients achieved CR after the procedure, even if heavily pretreated, and that relapse rate was low. Overall these results encourage the implementation of tomo-TLI in the standard conditioning for R/R lymphomas.

PS1507

THE RELATIONSHIP BETWEEN SELECTIVE PRE-TRANSPLANTATION IMMUNE PARAMETERS AND EARLY INFECTIONS IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES UNDERGOING ASCT – PRELIMINARY REPORT

J. Mańko[1], A. Szymczyk[2,*], A. Szymańska[2], A. Bojarska-Junak[3], A. Walter-Croneck[1], W. Legieć[2], D. Jawniak[1], J. Roliński[3], I. Hus[2]

[1]Chair and Department of Haematooncology and Bone Marrow Transplantation, [2]Independent Clinical Transplantology Unit, [3]Chair and Department of Clinical Immunology, Medical University of Lublin, Lublin, Poland

Background: Patients with hematological malignancies have a particularly high risk of infectious complications that is a consequence of impaired immunity resulting from the nature of the underlying diseases, co-morbidities as well as the therapy. Hematopoietic stem cell transplantation is currently the standard treatment for many hematological diseases and it is associated with long-term immunity deficits, resulting in severe, life-threatening bacterial, viral and fungal infections. The risk of infections is much lower after autologous transplantation (ASCT) compared to allogeneic transplantation, however serious life-threatening infections are observed in some patients after ASCT.
Aims: The aim of the study was to find the relationship between quantitative and qualitative disturbances concerning T-cells, B-cells, NK cells and monocytes, the concentration of intracellular cytokines and the frequency and severity of early infectious complications (until hematopoietic recovery) in patients with hematological malignancies after ASCT.
Methods: The study group consisted of 47 patients aged 18-68 years (51.2±13.9 years) who underwent ASCT. Eight patients were diagnosed with Hodgkin's lymphoma (HL), 13 with non-Hodgkin lymphoma (NHL), 26 patients with multiple myeloma (MM) and 1 patient with amyloidosis. Subpopulations of peripheral blood lymphocytes (B, Th0, Th1, Th2, Tc, Treg, anergic lymphocytes T, NKT) and monocytes (Tie2+, CD163+, HLA-DR+, CD1d+, 163+) were evaluated before ASCT and at the time of hematopoietic recovery using flow cytometry. For intracellular detection of cytokines (IFN-gamma, IL-4, IL-6, IL-10, IL-12, IL-17, TNF, TGFβ, IL-1β,) in the studied cell populations the Cytofix/Cytoperm Kit (BD Biosciences)

was used according to the manufacturer's recommendations.
Results: Early infectious complications were more frequent in the group of patients with HL or NHL than in the MM patients (11 vs. 5 cases). The percentage of CD3+/CD69+ (3.6±1.9% vs. 3.0±3.1) and CD3+/CD56+ T cells (6.8±5.0 vs. 3.4±3.0) decreased and the percentage of CD14+/TNF+ (1.5±1.6 vs. 2.0±1.8) and CD14/IL1β+ (2.0±2.2 vs. 3.3±2.2) monocytes increased after ASCT. In patients with post-transplantation early infections, the percentage of monocytes expressing pro-inflammatory cytokines, such as CD14+/TNF+ (1.0±1.5% vs. 1.8±1.7%), CD14+/IL1β+ (0.8±0.9% vs. 2.5±2.5%) and CD14+/IL-6+ (1.1±1.7% vs. 2.5±2.6%) before ASCT was significantly higher than in patients without infections ($p < 0.05$). In patients without colonization with highly pathogenic bacteria the percentage of CD14+/Tie2+ cells before transplantation was higher (53.6±19.7% vs. 33.8±15.5%, $p < 0.05$) than in patients with colonization. Before ASCT, the percentage of CD14+/IL12+, CD14+/TNF+, CD14+/TGFβ+, CD14+/IL1β+ cells was statistically lower ($p < 0.05$) in patients with mucositis after the transplantation comparing to the patients without mucositis, while the differences were more significant in patients with more severe mucosal lesions (stage III or IV according to WHO classification) compared to the group in which this complication was not observed.
Summary/Conclusion: Assessment of qualitative and quantitative disturbances of lymphocytes, monocytes expressing pro-inflammatory cytokines may allow to determine the factors predisposing to greater susceptibility to early infections after ASCT. However, in case of mucositis mechanism of development seems to be different. Further studies are necessary for a larger group of patients and assessing a larger number of parameters.

PS1508

SELECTIVE HSC-ABLATION USING ANTI-CD117 ANTIBODY DRUG CONJUGATE ENABLES SAFE AND EFFECTIVE AUTOLOGOUS AND ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

A. Czechowicz[1,*], R. Palchaudhuri[2], Z. Li[3], A. Scheck[4], Y. Hu[5], J. Hoggatt[6], B. Saez[7], M.K. Mansour[8], F. Winau[9], P. Murphy[10], D.T. Scadden[7], D.J. Rossi[5]

[1]Pediatrics, SCTRM, Stanford University School of Medicine, Stanford, [2]Magenta Therapeutics, Cabridge, MA, [3]NHLBI, National Institutes of Health, Bethesda, MD, [4]Pediatrics, SCTRM, Stanford University School of Medicine, Stanford, CA, [5]PCMM, Boston Children's Hospital, Boston, [6]CRM, Massachusetts General Hospital, Boston, MA, [7]SCRB, Harvard University, Cambridge, MA, [8]Massachusetts General Hospital, Boston, MA, [9]PCMM, Boston Children's Hospital, Boston, MA, [10]NIAID, National Institutes of Health, Bethesda, MD, United States

Background: Hematopoietic stem cell transplantation (HSCT) can be curative for many blood and immune diseases. However, today HSCT is primarily restricted to a small number of patients with deadly malignancies that have few other options. If made safer, HSCT could be applied to many more patients and disease settings. A large amount of toxicity of the procedure comes from the irradiation/chemotherapy conditioning currently employed to enable donor HSC engraftment. Eliminating genotoxic conditioning would dramatically improve HSCT, which would be especially beneficial in gene therapy/gene editing settings where this is the major limitation to expanded use. We and colleagues have previously developed multiple antibody-based conditioning approaches, but they each have had unique limitations.
Aims: Our goal is to develop a single-agent, potent, safe and effective conditioning approach that functions across all-diseased settings, that could be applied to non-malignant and malignant diseases and enables improved autologous or allogeneic HSCT.
Methods: We have previously shown that competition with host HSC limits donor HSC engraftment, and that antibodies depleting host HSC can be safe alternatives (Czechowicz, Science 2007). These antagonistic anti-CD117 antibodies were shown to be effective in immunodeficient mice, but additional strategies/agents were needed to enable donor engraftment in wild-type settings which caused toxicities (Xue Blood 2010, Chhabra Sci Trans Med 2016). Anti-CD45 antibody-drug conjugates overcame this limitation, however these induced a lymphopenia which is not desirable in many settings (Palchaudhuri, Nat Biotech 2016). To overcome this, here we generated an anti-CD117 antibody-drug conjugate (CD117-ADC) by linking anti-CD117 antibodies to protein synthesis toxin saporin. We tested this conditioning agent in syngeneic HSCT and in combination with transient immunosuppression in allogeneic HSCT.
Results: The CD117-ADC led to >99.9% depletion of host HSCs and enabled >99.9±0.1% engraftment of syngeneic donor murine whole bone marrow cells and >69.0±12.8% engraftment of syngeneic donor murine purified HSCs. The CD117-ADC in combination with transient immune suppression also induced robust mixed chimerism even in HLA-mismatched HSCT settings (Balb/c into B6 mice). Importantly and uniquely, this agent did not cause any significant toxicities. Rather it grossly spared red blood cells, platelets, and all major immune cells. The treated animals did not require transfusions, and immunity remained functionally intact. No gross tissue toxicity was observed apart from mild transient transaminitis, and animals remained fertile and did not require transplantation to maintain hematopoiesis.
Summary/Conclusion: CD117-ADCs provide the possibility of safe and effective autologous and allogeneic transplantation with a single-agent, one-time injection without major toxicities, cytopenias or perturbations to immunity. These agents are likely to become important agents in all forms of clinical transplantation, from malignant to non-malignant settings, and serve as important tools to study hematopoietic biology. As multiple anti-CD117 antibodies and ADCs are in development and being tested in clinical trials, such an approach may be rapidly translatable a range of patients with blood and immune diseases including leukemia, sickle cell anemia, beta thalassemia, immunodeficiencies, HIV and many others. Such agents may be especially beneficial in patients with high sensitivity to traditional conditioning, such as bone marrow failure patients with Fanconi Anemia or other DNA-repair defects.

Thalassemias

PS1509

HEMATOLOGICAL PHENOTYPES OF DIFFERENT ALPHA-THALASSAEMIA GENOTYPES CAUSING HYPOCHROMIC MICROCYTIC ANEMIA AT NEONATAL PERIOD

T. Suksangpleng[1,*], S. Ekwattanakit[1], S. Riolueang[1], V. Viprakasit[2]

[1]Thalassemia Center, [2]Division of Hematology/Oncology, Department of Pediatrics, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Thalassaemia (thal) is highly prevalent throughout subtropical regions including Thailand. In particular α-thal characterized by mutations and/or deletions involved the α globin genes (αα/αα) is extremely common in Southeast Asia in which 30-35% of the population carry either α^0-thal (--/αα) or α^+-thal (-α/αα). Homozygous or compound heterozygous α°-thal lead to severe anemia *in utero* and a fatal thal syndrome; Hb Bart's hydrops (100% of Hb Bart's). This serious condition is due to the fact that the α-globin genes are switched on and expressed early and throughout fetal haematopoiesis. However, the effects of less severe α-thal syndrome; Hb H disease (--/-α) and α°- or α^+-thal carriers for fetal haematopoiesis remain to be elucidated. Moreover, Hb Bart's could be detected in other α-thal conditions with various quantities and this could be used to screen α-thal at newborn screening program.
Aims: To determine hematological parameters in Thai neonates with different types of α-thal and identify a new screening tool for α-thal at birth.
Methods: After informed consent, 5 dried blood spot (DBS) and 300-µl EDTA whole blood samples were collected from healthy newborns (aged 48 hrs) by heel prick puncture. This study was approved by our local ethical committee at Siriraj Hospital. All of DBS were used for hemoglobin (Hb) analysis by using capillary electrophoresis (CE) and isoelectric focusing (IEF) followed by genomic DNA extraction for PCR-based molecular analysis including α-thal GAP-PCR, α-thal ARMS-PCR, β-thal ARMS-PCR, and PCR-RFLP for Hb E to detect >98% of abnormal globin alleles found in Thailand. In addition, complete blood count (CBC) was determined in whole blood EDTA samples using COULTER A^c·T 5diff Autoloader Hematology Analyzer (Beckman Couter, Brea, USA). The reference ranges and cut-off levels of hematological parameters were statistically analyzed by using PASW Statistics 18 Software (SPSS Inc, 2015).

Table 1.

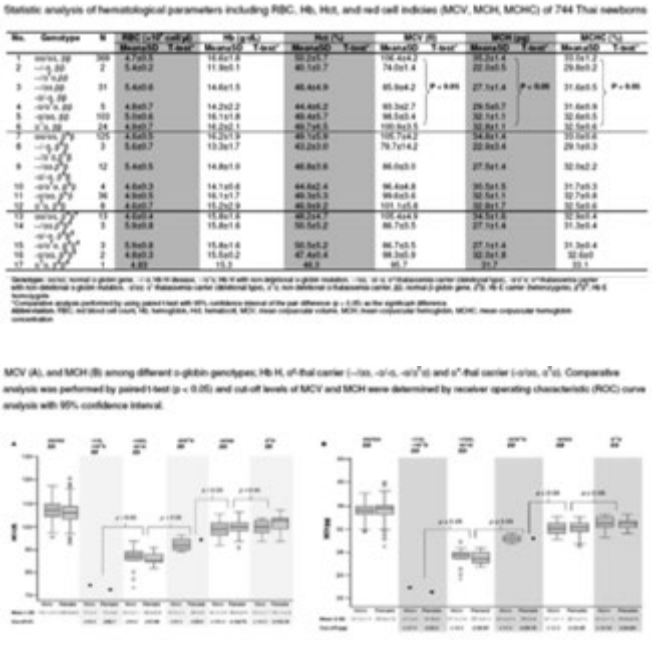

Figure 1.

Results: Average (mean) and standard deviation (SD) of hematological parameters (RBC, Hb, Hct, red cell indicies) of 744 newborns (excluding 5 individuals with HbE/β thal and β thal traits) based on different α and β globin genotypes were shown in Table 1. Out of 744 neonates, 188 (25.26%) were HbE carriers while 22 (2.95%) were homozygous Hb E (Hb EE). In neonates with normal β globin genes, we found red cell indicies; MCV, MCH, MCHC to be significant differences (t-test: $p<0.05$) among different α-globin mutation types. Interestingly, the levels of Hb and Hct seem to be positively correlated with number of intact normal α globin genes; those with 3 genes affected (Hb H disease) had the lowest Hb, Hct and all RBC indicies (Table 1). Coinheritance of Hb E, either Hb E trait or HbEE, appeared to have no additional effect on haematological parameters supporting the fact that the β globin genes switched on only at perinatal period but would be fully operational within the first two years of life. This finding was observed at both genders (Figure 2A and 2B).
Summary/Conclusion: For the first time, we showed that other forms of α-thal beyond Hb Bart's hydrops can also cause hypochromic microcytic anemia *in utero* resulting in neonatal anemia at 48 hrs. Mutations in the β globin genes showed no effects on neonatal haematology. Reductions in RBC indicies can be used as a screening tool for α thalassaemia in addition to the detection of Hb Bart's at birth by CE or IEF. A combination of both parameters (RBC indicies and Hb Bart's) could provide a better screening tool for α-thal in particular those with α^+-thal carriers.

PS1510

SERUM YKL-40 LEVELS IN PATIENTS WITH B-THALASSEMIA: RELATION TO VIRAL HEPATITIS, LIVER STIFFNESS AND HEPATIC IRON CONCENTRATION

S. Mostafa[1,2,*]

[1]Paediatrics, Cairo University, [2]Paediatrics, National Institute of Hepatology, Cairo, Egypt

Background: YKL-40 is an inflammatory glycoprotein expressed by infiltrating macrophages in various inflammatory conditions. It has been found to be elevated in patients with different pathological conditions like acute and chronic inflammations, increased remodeling of the extracellular matrix (ECM), development of fibrosis and cancer. Several studies have found elevated YKL-40 concentrations in sera of patients with liver diseases such as hepatic fibrosis by hepatitis C virus.it has been suggested that YKL-40 concentrations reflect the degree of liver fibrosis.
Aims: To evaluate serum YKL-40 Levels in patients with β-thalassemia and its relation to viral hepatitis, liver stiffness as assessed by Transient elastography (FibroScan, FS) and Hepatic Iron Concentration
Methods: A prospective study included 100 patients with β- TM (43 males and 57 females) with mean age 13.8±2.7 years (range: 5-18 years). Serum ferritin level, Liver enzymes (ALT and AST), HBs Ag, Anti HCV Ab and Serum YKL-40 using ELISA kit were evaluated. All patients were subjected to Liver MRI T2* to detect liver iron content by the sequence and Transient elastography (FibroScan, FS) to assess degree of liver stiffness.
Results: Mean fibroscan value was (10.99±11.5) kPa with a median 6.7 (range 1.3 to 47) kPa. 64 (64%) patients were categorized as F0-1 and 17 (17%) were stage F2-3, 19 (19%) patients had severe fibrosis. Their median serum ferritin was 3100 ng\ml, with 61 (61%) patients had values exceeding 2500 µg/L. Median cardiac T2* was 24.2 with 30 patients had values below 20 ms, and the median LIC was 16.21-mg/g DW with 68 patients showed readings above 7 mg/g dw. NYL-40 was evaluated as a marker of inflammation and liver fibrosis and showed mean value 1505.1 (±960.9) pg/ml, and range from 500 to 3529 pg/ml. Mean YKL-40 was significantly higher among males (p=0.03), patients on chelation therapy (p=0.002), patients on DFS ($p\leq0.001$), in those with abnormal liver enzymes, splenectomised patients, patients with HBV sero-positivity, those with moderate elevation of T2* and patients with high grades of liver fibrosis ($p<0.05$). YKL-40 showed positive correlation with the rate of transfusion, LIC, ferritin, ALT and AST but negative correlation with weight, height and T2*. ROC curve analysis revealed that the cutoff value of YKL-40 at 1500 pg/mL could differentiate β-TM patients with and without viral hepatitis with 86.7% sensitivity and specificity of 91.4%, area under the curve (AUC) 0.933, positive predictive value 81.2 and negative predictive value 94.1 ($p<0.001$). ROC curve analysis revealed that the cutoff value of YKL-40 at 1600 pg/mL could detect β-TM patients with liver cirrhosis with 93.4% sensitivity and specificity of 97.1%, area under the curve (AUC) 0.972, positive predictive value 93.7 and negative predictive value 97.1 ($p<0.001$).
Summary/Conclusion: Serum YKL-40 Levels are elevated in patients with β-thalassemia and can detect patients with active viral hepatitis and liver stiffness.

THE STRONG LINK BETWEEN PANCREAS AND HEART IN THALASSEMIA MAJOR

A. Meloni[1,*], L. Pistoia[1], A. Spiga[2], M. Fortini[3], L. Sardella[4], D. Maddaloni[5], C. Argento[6], M. Laura[7], M.G. Sanna[8], N. Dello Iacono[9], P. Fina[10], A. Riva[11], V. Positano[1], A. Pepe[1]

[1]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]P.O. Pediatrico Microcitemico "A.CAO", Cagliari, [3]Azienda Ospedaliero-Universitaria "S.Anna", Cona (FE), [4]A.S.L. di Bari, Bari, [5]Ospedale "Engles Profili", Fabriano, [6]Ospedale "San Giovanni Di Dio", Agrigento, [7]Ospedale "Sant'Eugenio", Roma, [8]ASL N°1 Sassari, Sassari, [9]Ospedale Casa Sollievo della Sofferenza IRCCS, San Giovanni Rotondo (FG), [10]Ospedale "Sandro Pertini", Roma, [11]Ospedale "SS. Annunziata" ASL Taranto , Taranto, Italy

Background: Some preliminary data have postulated a correlation between pancreatic iron overload and heart iron and function in thalassemia major (TM) patients.
Aims: In the present study we explored systematically in a multicenter study the link heart-pancreas in a large cohort of TM patients .
Methods: We considered the first 232 TM patients (129 M, mean age 36.95±9.83 years) enrolled in the E-MIOT (Extension-Myocardial Iron Overload in Thalassemia) project. T2* measurements were performed over pancreatic head, body and tail and global value was the mean. Myocardial iron overload (MIO) was quantified using a T2* segmental approach. Biventricular function parameters were assessed by cine images. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis.
Results: A significant correlation between pancreatic and cardiac iron was reconfirmed in this more numerous population and a normal pancreas T2* showed negative predictive value of 100% for cardiac iron. Pancreatic iron was correlated to the LV ejection fraction (EF), but not to the right ventricular (RV) EF. LGE sequences were acquired in 101 TM patients and 43 (42.57%) of them showed macroscopic myocardial fibrosis. Global pancreas T2* values were significantly lower in patients with fibrosis (6.27±4.12 ms vs 11.15±9.23 ms; p=0.021). Twenty-two patients showed cardiac complications (11 arrhythmias, 6 heart failure, 2 pulmonary hyperthension, 1 vascular disease, and 2 others) and of them 21 had pancreatic iron. Patients with cardiac complications showed a significant lower global pancreas T2* (7.55±6.11 ms vs 14.31±13.39 ms; p=0.024).
Summary/Conclusion: Pancreatic iron is a strong predictor not only for cardiac iron, but also for cardiac complications supporting a more profound link between pancreatic iron and heart disease in TM. More studies are needed to evaluate the prognostic role of pancreatic iron on cardiac complication.

PS1512

A SIMPLE NGS METHOD FOR DETECTION OF MUTATIONS CAUSING ALPHA AND BETA THALASSEMIA

M. Uzunel[1,*]

[1]Devyser, Hägersten, Stockholm, Sweden

Background: Thalassemias are inherited blood disorders characterized by abnormal hemoglobin production. Depending on the type and number of mutations, the symptoms can vary from none to severe forms where stem cell transplantation is the only curative treatment. Today, many different methods are available for mutation analysis of thalassemia patients. These include ARMS-PCR, restriction-enzyme PCR, GAP-PCR, Sanger sequencing, LIPA and MLPA. The use of different methods may be time-consuming and expensive, especially when analyzing less common deletions.
Aims: To develop a simple NGS method for detection of mutations causing alpha and beta Thalassemia.
Methods: We have developed an amplicon based NGS method using only ONE oligo-mix to detect virtually all known mutations for alpha and beta Thalassemia. The method includes sequencing of the HBB, HBA1 and HBA2 genes. We have also included primers for direct detection of the most common deletions in alpha and beta Thalassemia ("Gap-PCR"). In addition, we amplify regions upstream and downstream of the above-mentioned genes to find less common deletions using copy number variation (CNV) analysis. The upstream regions also include regulatory sequences, i.e. HS-40 (HBA) and LCRB (HBB). The protocol is user-friendly, requires less than one hour of hands-on time and only 10 ng of DNA is needed.
Results: Libraries have 100% uniformity at ≥ 0.3x mean coverage. We have analyzed 125 clinical samples with known mutations. All mutations were also detected with the Devyser Thalassemia kit. Interestingly, we could find additional mutations in 10% of the samples; mutations not previously detected or tested by the clinical laboratory. CNV analysis could successfully detect deletions and triplications (anti-3.7 triplication).
Summary/Conclusion: The Devyser Thalassemia kit is simple, user-friendly and efficiently detects mutations causing Thalassemia.

PS1513

PRE- AND POST-TRANSFUSION COMPLEMENT ACTIVATION IN TRANSFUSION-DEPENDENT B-THALASSAEMIA

E. Gavriilaki[1,*], I. Christodoulou[2], E.-E. Koravou[1], A. Paleta[1], M. Koutra[1], P. Zerva[1], T. Touloumenidou[1], A. Papalexandri[1], C. Apostolou[2], P. Klonizakis[2], A. Anagnostopoulos[1], E. Vlachaki[2]

[1]Hematology Department - BMT Unit, G. Papanicolaou Hospital, [2]Adults Thalassaemia Unit, [2]nd Department of Internal Medicine, Aristotle University of Thessaloniki, Hippokration General Hospital of Thessaloniki, Thessaloniki, Greece

Background: Introduction of safe transfusion and supportive practices has significantly improved survival of transfusion-dependent β-thalassaemia (TDT). Although regular RBC transfusions are the mainstay of treatment, their role in the pathophysiology of complications in TDT remains unclear. Transfusions may exacerbate the vicious cycle of thrombosis and complement activation. Nevertheless, limited data exist on complement activation in TDT.
Aims: We aimed to determine whether increased complement activation is evident in TDT; whether it is associated with disease characteristics and whether it is exacerbated post transfusion.
Methods: Consecutive TDT patients were enrolled prospectively from November to December 2017. Patient history, clinical and laboratory data were recorded. Sera were collected immediately before transfusion and 1 hour after completion of transfusion in each patient and stored at -80 °C. Complement activation was detected in patient sera measuring soluble human C5b-9 with a commercially available ELISA kit (AMSbio, Abingdon; United Kingdom). Normal human serum (NHS) from 10 age and gender-matched Caucasian healthy volunteers was used as a negative control.
Results: We studied 45 TDT patients (45.5±25.6 years of age, 21 male: 24 female), as shown in Table 1. Soluble C5b-9 levels before transfusion (median 68.2 ng/ml, interquartile range 62.1 ng/ml) were similar to C5b-9 detected in normal human serum (median 91.2 ng/ml, interquartile range 86.7 ng/ml, p=0.219). However, C5b-9 levels significantly increased 1 hour post transfusion (Figure 1, median 85.6 ng/ml, interquartile range 72.5 ng/ml, p=0.012). Then, we analysed clinical factors associated with increased C5b-9 levels post transfusion. Interestingly, C5b-9 levels post transfusion were significantly increased in patients traditionally classified as thalassaemia-intermedia (p=0.041) and patients post splenectomy (p=0.034). In addition, both patients with thalassaemia-intermedia and patients with splenectomy were older and had significantly higher platelet values compared to patients with thalassaemia-major (p=0.035 and p=0.021, respectively) and patients without splenectomy (p=0.008 and p<0.001, respectively). C5b-9 values did not correlate with other patient characteristics (iron overload, RBC volume/weight or development of red cell alloantibodies).

Table 1.

RBC volume / weight (ml/kg)	155.6±48.7
Platelets (10^9/L)	435.5±211.5
Ferritin (ng/mL)	1099.1±663.2
Deferasirox / Combined iron chelation (%)	17 (37.8%) / 19 (42.2%)
Hepatic / Cardiac T2* (ms)	14.7±10.6 / 31.4±6.1
Splenectomy (%)	28 (52.8%)
Red cell Alloantibodies (%)	5 (9.4%)

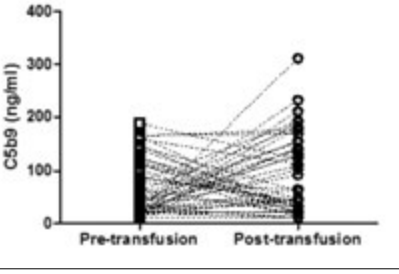

Figure 1.

Summary/Conclusion: Our study provides preliminary *in vitro* results of pre- and post-transfusion complement activation using a robust marker in a real-world patient population. We have found for the first time increased complement activation post transfusion in patients originally classified as thalassaemia-intermedia and in patients with splenectomy. These groups of patients have been traditionally considered to be of high thrombotic risk. The interplay between complement and thrombosis in these patients and the role of transfusions need to be further investigated in future studies.

PS1514

ASSOCIATION OF CLINICAL PHENOTYPE OF THALASSEMIA WITH COMMON FETAL HEMOGLOBIN VARIANTS IN LEBANESE PATIENTS BEARING THE CODON 29 BETA GENE MUTATION

V. Brancaleoni[1], H.M. Moukhadder[2], D. Consonni[3], E. Di Pierro[1], M.D. Cappellini[1,4], A. Taher[5,*]

[1]U.O.C. Medicina Generale, Fond. IRCCS Cà Granda Ospedale Maggiore Policlinico, Milano, Italy, [2]Internal Medicine, American University of Beirut Medical Center, Beirut, Lebanon, [3]U.O. Epidemiologia, Fond. IRCCS Cà Granda Ospedale Maggiore Policlinico, [4]Scienze cliniche e di comunità, Università degli Studi di Milano, Milano, [5]Internal Medicine, American University of Beirut Medical Center, Beirut, Italy

Background: Beta-thalassemia can present with a wide spectrum of phenotypes, ranging from almost absence of symptoms to severe anemia and regular transfusion dependence. The inheritance of α-thalassemia and hereditary persistence of fetal hemoglobin (HbF) have been identified among the genetic modifiers that can impart less severe phenotypes in β-thal. Other implicated influencers include polymorphic variants in the BCL11A, HMIP and HBB cluster, which have been shown to model the thalassemia phenotype through HbF induction. The codon 29 (Cod29) mutation in the beta gene (C/T) has been associated with a broad range of thalassemia phenotypes, possibly through genetic modifiers determining the genotype-phenotype relationship.
Aims: This study aimed to evaluate whether polymorphisms at known sites and/or coinheritance of α or βglobin gene deletions or duplication can influence HbF levels and eventually justify differences in the clinical presentation of β-thalassemia patients of Lebanese origin bearing the Cod29 mutation.
Methods: Twenty-one β-thal patients homozygous or compound heterozygous (with IVSI-1 or IVSII-1 mutations) for the Cod29 mutation and displaying heterogeneous clinical manifestations were recruited. Ten SNPs were selected based on previously published evidence of association with increased HbF levels (HBG2: rs7482144;HBBP: rs7482144;BCL11A: rs1427407, rs766432, rs11886868, rs4671393; HMIP: rs28384513, rs9399137, rs4895441, rs9402686). Genomic DNA was extracted from peripheral blood. HBG2 SNP was genotyped by PCR and direct sequencing. All other SNPs were genotyped by allelic discrimination using TaqMan assays. MLPA analysis on α and β clusters was performed using MRC Holland MLPA kits. Statistical analysis was performed with the Kruskal-Wallis and chi-square tests using Stata 15 software.
Results: Fourteen patients were homozygous for the Cod29 mutation (78.6% females), 3 were compound heterozygous for Cod29 and IVSI-1 (33.3% females) and 4 were compound heterozygous for Cod29 and IVSII-1 (75% females). HbF ranged from 4.9% to 66% and hemoglobin (Hb) levels from 5.6g/dL to 9.8g/dL. Our patients were divided according to transfusion frequency into two groups: patients who never or seldom did receive red blood cell transfusions during their lives (non-transfusion-dependent, NTD), and patients who were regularly transfused during their lives till the date of blood sampling for our study (transfusion-dependent, TD), with a transfusion frequency ranging from 15 to 30 days. None of the patients had β gene deletions and 2 patients co-inherited the $\alpha^{3.7}$ deletion. The minor allele frequencies (MAF) observed for the SNPs wil be presented. Hb, HbF and absolute HbF concentration were evaluated according to genotype. Heterozygotes or homozygotes for the effect allele in the BCL11A and HMIP SNPs had higher HbF percentages and absolute levels. Heterozygotes or homozygotes for rs1427407 and rs766432 on BCL11A had the highest HbF levels and least transfusion dependence (p=0.04). The proportions and absolute concentrations of HbF were found to be higher in the NTD than TD group (p=0.0002 and 0.0004). Hb levels did not differed much between the two groups.
Summary/Conclusion: Our preliminary results suggest that transfusion dependency in β-thal Lebanese patients bearing the Cod29 mutation correlates with HbF levels. Higher HbF levels were found to be associated with the presence of polymorphic bases in known loci, especially HMIP and BCL11A. Among these, rs1427407 and rs766432 were the most "favorable" SNPs, associated with better clinical outcomes in our patients.

PS1515

THALASSEMIA PREVENTION PROGRAM IN DEVELOPING WORLD SCENARIO: 13 YEARS EXPERIENCE

K. Perveen[1,*], G. Ahmed[1], S. H. Ansari[1], S. Siddiqui[1], S. Sharif[1], S. Ahmed[1], T. Shamsi[1]

[1]National Institute of Blood Disease and Bone Marrow Transplantation, Karachi, Pakistan

Background: β-thalassaemia is one of the most common monogenic disorders worldwide. In Pakistan around ten million people are carriers of β-thalassaemia. If both parents are thalassaemia carrier, expecting mothers must undergo prenatal diagnosis through Chorionic Villus Sampling (CVS) in each pregnancy. β-thalassaemia may exhaust existing health resources and there is a threat that it will become a major health issue in Pakistan as decline is observed in infection related deaths in children. Prevention is the only way to address the issue. This can be done through carrier screening, genetic counseling and prenatal diagnosis to control affected birth.
Aims: The aim of this study is to evaluate the outcomes of prenatal diagnosis for the establishment of thalassemia prevention program in Pakistan.
Methods: 2458 high risk mothers for β-thalassaemia with 12-16 weeks pregnancy were evaluated for CVS at National Institute of Blood Disease and Bone Marrow Transplantation, from January 2005 to January 2018. CVS results (fetuses with thalassemia major, minor or no mutation) were evaluated. Parents were counseled about the pattern of inheritance, the chances of having an affected child in the current or future pregnancy, the procedure of CVS, risk and complications of the procedure and the option of termination of pregnancy in case the fetus was detected to be homozygous for β-thalassaemia. Before the procedure an informed consent was obtained from both partners.
Results: 2458 procedures were performed. 624(25%) fetuses were diagnosed as major, 1253(51%) with trait, 2(0.08%) fetuses had undetected mutation, and 581(23.6%) were healthy. New mutations identified in our population were IVSI-30, IVSI-110, IVSII-1, Cd-39 and Fr 47-48. Placental site was posterior in 577(23.5%) pregnant mothers. Procedure related complications were seen in 20 cases (0.8%) which included bradycardia i.e <120pbm (0.08% fetuses) and bleeding (0.5%).Further complications included 2-3 attempts during performance of single procedure in 42(1.7%), missed abortions were observed in 6(0.24%). Mild, moderate and severe procedure related pain in 468(19%), 34(1.4%) and 2(0.08%) cases respectively. In 2458 procedures inadequate sampling was observed in 10(0.4%) cases. Seven (0.28%) couples refused abortion of β-thalassaemia major fetuses.
Summary/Conclusion: Recent acceptance of legal abortion with respect to Muslim rules has increased the effectiveness of the CVS procedure and made great advances in its application in Pakistan.Social knowledge has also improved but still there is a gap between the population at risk and the required prenatal diagnosis laboratories and sampling centers.

PS1516

ASSOCIATION OF VITAMIN D AND RETINOID×RECEPTORS EXPRESSION AND VITAMIN D BINDING PROTEIN VARIANTS WITH BONE DENSITY IN THALASSEMIA CHILDREN

S. Sahmoud[1,*], S. Elfiky[2], E. A. Toraih[34], M.S. Fawzy[5], N. Kamel[6], M.S. Ibrahim[7]

[1]Pediatric Hematology Department, Suez Canal University, [2]Pediatric Hematology Department, [3]Genetics Unit, Faculty of Medicine, Suez Canal University, [4]Center of Excellence in Molecular and Cellular Medicine, Suez Canal University, [5]Medical Biochemistry Department, [6]Clinical pathology Department, [7]Diagnostic Radiology Department, Faculty of Medicine, Suez Canal University, Ismailia, Egypt

Background: Studies previously conducted in 2 different cities in Egypt (Cairo, and Beni Suef) found that thalassemia (thal) patients were deficient for vitamin D and concluded an association with Bsm1, and Fok1 Vitamin D receptor (*VDR*) polymorphisms and rs7041 and rs4588 vitamin D binding protein (VDBP) polymorphisms.
Aims: This study aimed at evaluating vitamin D status in thal children in relation to *VDR* and retinoid×receptor (*RXRA*) expression as well as *VDBP* polymorphisms in Suez Canal area, Egypt.
Methods: 44 (24 male, 7.3±2.7 year old) thal children and 40 (19 male, 7.6±1.8 year old) healthy ones were subjected to bone chemistry profile, 25 (OH) vitamin D, dual energy X-ray absorptiometry (DEXA) scan, SNP identification of *VDBP* rs7041 and rs4588, and gene expression of *VDR* and *RXRA* genes.
Results: Vitamin D deficiency was significantly more frequent among healthy children (37, 92.5%) compared to children with thalassemia (16, 36.3%) (p=<0.001). All, and 40% of thalassemia and healthy children were regularly receiving the daily RDA of vitamin D and calcium (p=<0.01). Thal children

compared to controls had higher serum calcium (9±0.7, and 8.2±0.6, p=<0.001), and lower parathyroid hormone (22.2±13.1, and 38.4±21.2, p= 0.001). No significant difference in the bone mineral density (BMD) was found in both groups (p=0.54), but there was a negative correlation between BMD and age (r= - 0.51, p=<0.001). Serum *VDR* and *RXRA* mRNAs were significantly higher in thal children compared to controls (p=0.001 and <0.001). Expression levels of both genes were not associated with gender (p=0.786 and 0.548) nor bone density (p=0.208 and 0.176). Genotyping of the VDBP rs4701 and rs4588 polymorphisms revealed no significant difference between patients and controls (p=0.609). However, the TG genotype showed higher frequency of osteoporosis among thal children, while both homozygote carriers (TT and GG) were common among osteopenic patients (p=0.023).
Summary/Conclusion: Thalassemia children had higher expression levels of serum *VDR* and *RXRA*. VDBP polymorphisms were associated with bone osteoporosis in Thalassemia patients.

PS1517

NEW OCCURRENCES OF MACROSCOPIC MYOCARDIAL FIBROSIS IN THALASSEMIA AT LONG TERM BY MULTIPLE FOLLOW-UP

A. Meloni[1,*], L. Pistoia[1], A. Barone[2], A. Quarta[3], G. Roccamo[4], C. Paci[5], G. Colaci[6], N. Romano[7], M. Benni[8], F.M. Pasin[9], S. Bulgarelli[10], M. Missere[11], A. Vallone[12], V. Positano[1], A. Pepe[1]

[1]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Azienda Ospedaliero-Universitaria di Parma, Parma, [3]Ospedale "A. Perrino", Brindisi, [4]Ospedale "Civile", S. Agata di Militello (ME), [5]Ospedale "S Maria alla Gruccia", Montevarchi (AR), [6]Presidio Ospedaliero N°2 "S. Giuseppe da Copertino", Copertino (LE), [7]Azienda Ospedaliera Arcispedale "S. Maria Nuova", Reggio Emilia, [8]Policlinico S. Orsola "L. e A. Seragnoli", Bologna, [9]Ospedale S. Pertini, Roma, [10]Ospedale Bufalini, Cesena, [11]Fondazione di Ricerca e Cura "Giovanni Paolo II", Campobasso, [12]Azienda Ospedaliera "Garibaldi" Presidio Ospedaliero Nesima, Catania, Italy

Background: To date in thalassemia patients it is recommended to repeat cardiac magnetic resonance (CMR) scans for iron quantification every 1 or 2 years based on the myocardial iron overload (MIO). Also in these patients, late gadolinium enhancement (LGE) has been demonstrated to be a strong predictor for cardiac events. However, many studies have shown an association between intravenous gadolinium based contrast agents (GBCA) exposure and neuronal tissue deposition. So, it appears prudent at this time to revisit institutional protocols for GBCA administration, in particular in the follow up (FU) studies.
Aims: We investigated the evolution of myocardial fibrosis in terms of new occurrences over a period of 6 years in thalassemia patients who underwent to multiple FU.
Methods: We considered 52 patients with thalassemia major (28.78±8.59 years; 28 females) consecutively enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network who underwent 5 LGE CMRs (baseline + 4 follow-up) using Gadobutrol (0.2 mmoli/kg). The time interval between two subsequent scans was 18±3 months.
Results: At the baseline CMR, 44 patients (84.6%) were LGE negative.
Eight new occurrences of myocardial fibrosis were detected at the first follow-up (FU). At the second FU, 2 out of the 36 previously LGE-negative patients had myocardial fibrosis. At the third FU, 9 new occurrences of myocardial fibrosis were detected. At the forth FU, 3 patients showed myocardial fibrosis for the first time. The Figure 1 shows a simplifying flow-chart. The 22 patients who developed myocardial fibrosis during the follow-up showed comparable frequency of diabetes and HCV infection and comparable baseline cardiac iron than patients who remained always LGE-negative.

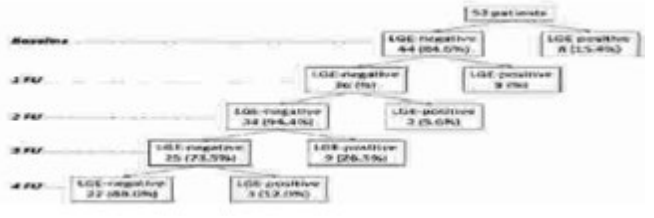

Figure 1.

Summary/Conclusion: A serial monitoring of thalassemia patients revealed an high number of new occurrences of myocardial fibrosis, suggesting the importance of repeating the LGE CMR over time using 'low risk' macrocyclic agents.

COMMON LINK BETWEEN BONE AND HEART HEALTH IN THALASSEMIA MAJOR

A. Meloni[1,*], L. Pistoia[1], C. Vassalle[1], S. Maffei[1], T. Casini[2], A. Filosa[3], P. Keilberg[1], A. Olivi[1], L. Rigoli[4], R. Rosso[5], M. Rocca[6], A. Massa[7], C.C. De Bari[8], V. Positano[1], A. Pepe[1]

[1]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Ospedale "Meyer", Firenze, [3]Azienda Ospedaliera di Rilievo Nazionale "A. Cardarelli, Napoli, [4]Policlinico "G. Martino", Messina, [5]Azienda Ospedaliero-Universitaria Policlinico "Vittorio Emanuele", Catania, [6]Presidio Ospedaliero ASL [5], Crotone, [7]Ospedale "Giovanni Paolo II", Olbia, [8]Ospedale "San Donato", Arezzo, Italy

Background: A common link between bone and heart health has been detected in the general population.
Aims: In the present study we evaluated the relationship between bone mineral density (BMD) and cardiac iron, cardiovascular complications, and cardiovascular risk factors in patients with thalassemia major (TM).
Methods: We considered 135 TM patients (68 M, mean age 37.79±7.74 years) enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) Network. BMDs of the lumbar vertebrae (L1-L4) and femoral neck were measured by dual X-ray absorptiometry (DEXA) and were expressed as T-scores. Myocardial iron overload (MIO) was quantified by the T2* Magnetic Resonance Imaging (MRI) technique.
Blood samples were drawn for the analysis of N-terminal pro-brain natriuretic peptide (NT-proBNP), the gold standard biomarker in determining the diagnosis and prognosis of heart failure.
Results: MIO (global heart t2*<20 ms) was detected in 20 (14.8%) patients. Patients with MIO showed significant lower femoral T-scores (-2.64±1.87 vs -1.96±0.99; p=0.045). Twelve patients showed cardiac complications (8 arrhythmias, 2 heart failure, 2 pulmonary hyperthension) and all of them had lumbar and femoral T-scores indicating osteopathy (osteopenia/osteoporosis). Patients with cardiac complications showed significant lower lumbar T-scores (-3.27±0.89 vs -2.43±1.29; p=0.031) and femoral T-scores (-2.96±2.02 vs -1.98±1.04; p=0.042). Patients with abnormal NTproBNP values (>157 ng/L) showed significantly lower femoral T-scores (-2.41±0.61 vs -1.79±1.16; p=0.048). Patients with diabetes (N=17) showed significant lower femoral T-scores (-2.45±0.79 vs -2.00±1.25; p=0.041).
Summary/Conclusion: Lower femoral BMD was associated with MIO, cardiac complications, elevated NTproBNP values, and diabetes in patients with thalassemia major. So, our data support and interaction between bone and cardiovascular diseases in TM, suggesting that prevention and treatment strategies targeted for one of the two diseases may be beneficial for the other one.

Background: Iron overload (IOL) in beta-thalassemia represents one of the

main cause of the complications of the disease, and it is invariably present both in transfusion dependent thalassemia (TDT), due to the transfusion burden, and in non transfusion dependent thalassemia (NTDT), due to the increased intestinal iron absorption. Heart, liver and endocrine glands are all known targets of IOL, while recent studies focus on kidneys and spleen, and ideally the non transferrin bound iron could accumulate in every body system. In the brain the presence of IOL has been rarely investigated, with uncertain results: IOL shown contemporarily in putamina, caudate nuclei and motor and temporal cortices, or only in some of these, or in none of the listed (Metafratzi *et al.* 2001, Akhlaghpoor *et al.* 2012, Qiu *et al.* 2014); moreover if cerebral IOL can affect cognitive functions has not been studied yet.
Aims: Aim of our study is to underline the presence, entity and distribution of IOL in cerebral structures, looking for any difference in the pattern of accumulation between TDT and NTDT and to clarify if it impacts on neurocognitive sphere.
Methods: We performed a cross-sectional multicenter study, enrolling patients with TDT, NTDT and healthy volunteers. After the signature of the informed consent, patients and controls underwent a 3 Tesla MRI with high resolution multi-echo 3D FLASH sequences for iron detection and quantification; Wechsler Adult Intelligence Scale-Fourth Edition (WAIS-IV) was administered to all study participants. Clinical chart review allowed the collection of clinical and laboratory data, with special regards to the disease history, the transfusion burden, ferritin, LIC and cardiac IOL by T2*.
Results: Seventy-one patients with beta thalassemia were enrolled in the study from 4 major Centers in the South of Italy: 48 with TDT (age: 36.9±10.3 years) and 23 NTDT (age: 29.2±11.7 years); fifty-seven age and sex-matched healthy controls (HC) (age: 33.9±10.8 years) were also enrolled. Comparing all patients (TD+NDT) to controls 4 clusters were found with R2* values higher in patients than in controls; these refer to the choroid plexuses in the left and right lateral ventricles and in proximity to the left and right Luschka foramina. Differences between beta-thalassemia patient subgroups were limited, anyway a regular blood transfusion treatment seemed to further accentuate brain iron content compared to controls; also, the R2* value was directly correlated with ferritin in the patients'group. Interestingly R2* did not correlate with the cognitive performance indices derived from the WAIS-IV test. Both in patients and in controls R2* values tend to increase with age.
Summary/Conclusion: Beta-thalassemia entails significant iron overload in small symmetric brain regions in correspondence of the choroid plexuses. Anyway these structures do not share any developmental, metabolic or functional characteristics, as proved also in our series by the lack of correlation with any degree of cognitive impairment. Moreover, the linear increase of iron in cerebral structures with age demonstrates a pattern of iron deposition in the brain for patients comparable to the general population. Based on our results routine MRI assessments in thalassemic patients to quantify cerebral iron overload would not be clinically indicated.

PS1521

LEPTIN IS ASSOCIATED WITH THE DEGREE OF ANEMIA AND THE ERYTHROPOIETIN LEVELS IN B THALASSEMIA PATIENTS

L. Mahajna[1], O. Tanous[2], T. Dujovny[3], H. Eitam[1], R. Masalha[1], R. Colodner[4], A. Koren[5], C. Levin[3,*]

[1]Endocrine Laboratory, [2]Ward A, [3]Pediatric Hematology Unit, [4]Yetzhak Rabin 20, 5Hematology Unit, Emek Medical Center, Afula, Israel

Background: Patients with thalassemia major often present with endocrine abnormalities due to dysfunction of the hypothalamic–pituitary axis (Poggi, 2016), and are frequently underweight with abnormally low body-fat percentage (Fung, 2010). Leptin plays a regulatory role in immunity and inflammation, and also seems to act synergistically with erythropoietin on mammalian hematopoiesis (Bennett, 1996). For example, a stimulatory effect of leptin on erythropoiesis among patients with end-stage renal disease was observed (Axelsson 2005). Previous studies on leptin in BT patients have shown lower levels than in healthy controls, and a negative correlation with the level of soluble transferrin receptor in transfused patients (Dedoussis, 2002). The reduced leptin levels were explained by a possible toxic effect of iron on adipocytes (Chaliasos, 2010).
Aims: In this study, we investigated the correlation between leptin level and anthropometric parameters in BT patients compared to heathy controls. We also explored the relationship between leptin and hematological and erythropoietic parameters, as well as iron-overload status in BT patients.
Methods: Transfusion-dependent BT patients (n = 33; 16 females, 17 males, mean age 23.5±8.6 [range 8–41] years), treated at the Pediatric Hematology Unit of Emek Medical Center, and 11 healthy controls (6 females, 5 males, mean age 26.4±10.4 [range 8–39] years) were studied. Patients were treated by regular blood transfusions and iron-chelation therapy. Anthropometric assessments included height, weight, fat percentage and BMI calculation. Blood samples were obtained at fasting and before blood transfusion. Serum leptin, complete blood count, hemoglobin and reticulocyte counts and serum erythropoietin were analyzed. These studies were performed twice, 3 months apart, and the mean values were utilized for the statistical analysis. Serum leptin levels were analyzed by radioimmunoassay, and leptin-normalized values were calculated (ng/dL leptin per% body fat).
Results: BT patients were found to have lower leptin levels than healthy controls (5.4±5.9 vs. 13±10.1 ng/dL; p=0.0006). Leptin levels were higher in females than in males (mean leptin 7.2±6.5 vs. 3.7±4.7 ng/dL; p=0.01), and increased with age (r = 0.4635, p=0.0066). A negative correlation was found between leptin and erythropoietin (r = -0.43473, p=0.0115), and a positive correlation between leptin and hemoglobin, as well as the mean pre-transfusion hemoglobin levels in the previous 5 years (r = 0.66884, p<0.001; r = 0.40261, p=0.0202, respectively). No correlation was observed between leptin levels and anthropometric parameters (weight, height, BMI), iron-overload parameters or reticulocyte count. Fasting and normalized leptin showed similar patterns.
Summary/Conclusion: This study confirms that BT patients are unable to maintain adequate leptin production, suggesting that adipose tissue dysfunction may be related to the chronic anemia. Our results correlate well with previous studies of lower leptin levels in BT patients. The positive correlation of leptin level with hemoglobin, together with the inverse correlation with erythropoietin provide further evidence of the effect of leptin on erythropoiesis. Additional studies are needed to examine the intricate interplay between adipose tissue, leptin and erythropoiesis in the environment of chronic anemia and iron overload present in BT patients.

PS1522

MUTATION SPECTRUM IN HBB, HBA1 AND HBA2 GENES IN PATIENTS FROM EUROPEAN PART OF RUSSIA

S. Mann[1,*], T. Varlamova[1], E. Raykina[1], E. Kazanets[2], E. Litvin[2], N. Smetanina[2]

[1]Laboratory of Molecular Biology, [2]Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background: Haemoglobinopathias as thalassaemia and abnormal haemoglobins are rare disorders for European part of Russia. Due to migration process from the North Caucasus and the other endemic regions of the post soviet republics the frequency of pediatric patients with haemoglobinopathias in European part of Russia has increased significantly.
Aims: The evaluation of mutation spectrum in HBB, HBA1 and HBA2 genes in patients from European part of Russia.
Methods: Allele-specific PCR was used for evaluation of the main α-thalassemia deletions (Y.T.Liu *et al.*, 2000), and Sanger sequencing - for detection of point mutations in exon 3 and polyA region of HBA1 or HBA2 genes and entire HBB gene.
Results: Totally 448 patients were tested during the 3-year period (2015-2017). Among 448 patients in 248 (55%) were found 280 causative genetic variants.β^0-thalassemia was the most frequent form of the disorder (60,7%), with CD8 -AA, IVS2-1 G>A, CD8/9 +G, IVS1-1 G>A, CD39 C>T, CD15 G>A, CD44 -C, CD41/42 -CTTT, IVS1-130 G>C, IVS1-2 T>C and few cases of CD36/37 -T, CD16 -C, CD5 -CT, CD37 G>A variants. β^+-thalassemia was less common (10%) (IVS1-110 G>A, IVS2-745 C>G, IVS2-654 C>T, CD26 G>A(HbE), IVS1-5 G>T and single cases of -30 T>A, IVS2-5 G>C , IVS1-128 T>G, IVS2-848 C>A variants). β^{++}- Thal was the most infrequent (1,4%), with only two variants found: -101 C>T promoter region, IVS1-6 T>C. Abnormal Hbs (7.8%) we found were Hb S (n=7), Hb Cheverly (n=3), Hb Southempton (n=2), Hb D-Los-Angeles (n=2), Hb Tacoma (n=3), single cases of Hb Louisville, Hb Tubingen, Hb Monroe, Hb Koln, Hb Mizuho. We identified two novel mutations in HBB gene: - 108 C>T in heterosygous state, leading to β^+-thal phenotype and CD70 G>A, in heterosygous state, leading to β^0–thal phenotype. For α-globin genes 56 genetic variants (20%) were revealed among all tested patients, most frequently were 3,7kb deletion (60.7%) and 20,5kb deletion (30%), and few cases of 4,2kb deletion, HBA2 PolyA (A>G) AATAAA>AATAAG and Hb Constant Spring.
Summary/Conclusion: The most prevalent HBB gene variants for European part of Russia can be divided in two groups: typical Mediterranean (CD8 -AA, IVS2-1 G>A, IVS1-1 G>A, CD39 C>T, IVS1-1 G>A, CD44-C, IVS2-745 C>G) and Chinese, Japan, Indian (CD8/9 +G, CD15 G>A, IVS2-654 C>T, CD 41/42-CTTT) variants. Novel mutations in HBB gene were found in patients Russian nationality. Among all β–thal variants the most common was CD8 -AA (33,6%), for α-thal variants the most common was deletion

3,7kb (60,7%) and 20,5kb (30%). Among abnormal Hbs the most frequent was HbS (28%).

PS1523

COMPREHENSIVE SCREENING FOR COEXISTING HETEROZYGOUS A0-THALASSEMIA IN HEMOGLOBIN E TRAIT

P. Wongprachar[1,*], P. Sutcharitchan[1], A. Suksusut[1], R. Setthaphiboon[1], N. Uaprasert[1], P. Rojnuckarin[1], C. Polprasert[1]

[1]Medicine, King Chulalongkorn Memorial Hospital, Bangkok, Thailand

Background: Detection of coexisting heterozygous α^0-thalassemia with hemoglobin E trait (HbE trait) is important to identify at-risk couples for Bart's hydrops fetalis. A very sensitive screening test is helpful to exclude cases that do not require DNA testing. A previous study showed that both low HbE levels by HPLC and low MCV were associated with α^0-thalassemia with 100% sensitivity. However, the data in patients with HbE ≥ 25% but MCV ≤ 75 fL are lacking. In this study, we aim to determine if we can omit DNA testing in this subgroup

Aims: To detect coexisting heterozygous α^0-thalassemia with hemoglobin E trait.

Methods: We collected 390 blood specimens from patients who were diagnosed as HbE trait by HPLC and/or IEF in King Chulalongkorn Memorial Hospital. The α^0-thalassemia ($--^{SEA}$, $--^{Thai}$, $--^{Philippine}$, $--^{Mediterranean}$ and $--^{20.5Kb}$ deletion) and α^+-thalassemia determinants (3.7 and 4.2 Kb deletion) were detected by multiplex gap polymerase chain reaction. The cut-off HbE level by HPLC from the previous study was validated (N = 274). The cut-off HbE level by HPLC was determined (N = 152) and then validated in the other set of patients (N=141). Finally, cases with HbE above the cut-off points by either techniques but MCV ≤75 fL were analyzed for the co-existing α-thalassemia (N=278).

Results: From 390 blood specimens, we found co-existing heterozygous α^0-thalassemia in HbE trait of 12.56% (12.31% in $-^{SEA}$ and 0.25% in $-^{Thai}$ deletion). Prevalence of α-thalassemia-thal-2 in HbE trait is 17.94% (15.38% in heterozygous 3.7 kb deletion, 1.53% in heterozygous 4.2 kb deletion and 1.02% in homozygous 3.7 kb deletion). Detection of HbE level by HPLC technique was done in 274 samples, by IEF technique in 290 samples and by both techniques in 174 samples. In specimen with HbE above the cut-off level (HbE levels 25-40% by HPLC technique), we could not detect co-inheritance of heterozygous α^0-thalassemia with low MCV (range 65-80 fL; 95%CI[0-1.5]). Upon further analysis, we found a suitable cut-off value for detection of co-inherited of heterozygous α^0-thalassemia in HbE trait are HbE level of < 21% by HPLC technique with 100% sensitivity, 91.2% specificity, 70.6% positive predictive value (PPV) and 100% negative predictive value (NPV). In IEF technique, HbE level of < 37.3% can achieve 100% sensitivity with 67% specificity, 29.8% PPV and NPV 100% to detect co-inherited of heterozygous α^0-thalassemia (Figure 1).

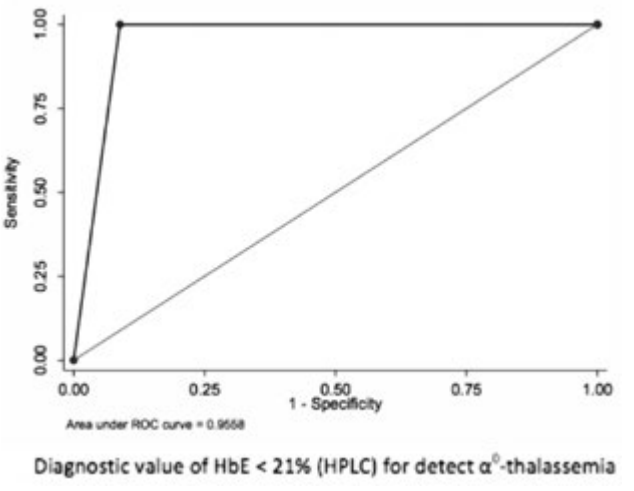

Figure 1.

Summary/Conclusion: In this study, HbE ≥25% by HPLC technique could be used for excluding co-inheritance of heterozygous α^0-thalassemia and Hb E trait despite of low MCV. For IEF technique, level of HbE >37.3% showed 100% sensitivity and 100% NPV in order to exclude heterozygous α^0-thalassemia.

PS1524

INVOLVEMENT OF LEUCOCYTE DERIVED EXTRACELLULAR VESICLES IN THE PROCOAGULANT STATE FOUND IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA-RELATED CONDITION

A. Wannez[1,2,*], C. Bouvy[2], B. Devalet[1], H. Jacqmin[1], H. Haguet[1], B. Chatelain[1], C. Chatelain[2], J.-M. Dogné[2], F. Mullier[1]

[1]CHU UCL Namur, Université catholique de Louvain, Yvoir, [2]Pharmacy, University of Namur, Namur, Belgium

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a disease characterized by the lack of complement regulatory proteins (CD55 and CD59) at the surface of hematological cells leading to complement-mediated hemolysis (Brodsky *et al.* Hematology, 2008). Complement can induce the production of extracellular vesicles (EVs) (Burnouf *et al.* Transfus Apher Sci, 2015). These EVs are cell-derived vesicles whose the size-range is around 50 and 1000nm. They can expose phosphatidylserine (PS-an anionic phospholipid) and tissue factor (TF), which explains their involvement in the coagulation cascade (Owens *et al.* Circ Res, 2011). Nowadays, the relevance of the EVs role in the pathophysiology of thrombosis in PNH is not fully understood even if there is some evidence about the contribution of EVs in the thromboembolic events.
Aims: This research aims to study the procoagulant activity of EVs potentially released during the complement attack by the cells who do not expose the glycophosphatidylinositol anchored proteins (PNH phenotype). The purpose is to better understand the thrombosis occurrence in PNH.
Methods: A cellular model of PNH was set up by removing glycophosphatidylinositol anchored proteins (GPI-AP) at the surface of endothelial cells and leucocytes with an enzyme in order to obtain PNH-like cells. Thereafter, these PNH-like cells and red blood cells (RBCs) derived from PNH patients were exposed to acidified serum to trigger the complement attack via the alternative pathway. Finally, thrombin generation assay with calibrated automated thrombogram was performed to study the procoagulant activity of EVs released by each cell type independently from other factors.
Results: This cell model was validated for all cell types. Indeed, endothelial cells and leucocytes treated with enzyme have a decrease in GPI-AP expression, which allows to obtain PNH-like cells. Thereafter, the complement attack has been checked with a calcein AM retention test for endothelial cells and leucocytes and by percentage of hemolysis measurement for the RBCs. These two experiments allowed to validate the complement attack. For the procoagulant activity, the results show that the EVs potentially released by PNH-like leucocytes have an increased procoagulant profile in comparison to healthy leucocytes (lag time for PNH-like leucocytes of 4.11 VS 6.94 for the healthy leucocytes, TTPeak of 7.22 VS 10.89, Peak of 1342 VS 1202 and ETP of 155.8 VS 99.78 $p<0.05$). Conversely, no difference in terms of procoagulant activity was observed between EVs isolated from GPI-AP positive and negative endothelial cells and between those from PNH RBCs and healthy RBCs.
Summary/Conclusion: This work enables to validate a model of PNH and to highlight a contribution of leucocyte-derived EVs in the hypercoagulable profile of PNH patients. Moreover, this PNH cellular model can be used to study other factors involved in this orphan disease, but also to test new treatment strategies.

PS1525

ARE ALL DIRECT ORAL ANTICOAGULANTS EQUAL TO SAFETY AND EFFICACY?

B. Navarro Almenzar[1,*], J.J. Cerezo Manchado[1], F. García Candel[1], V. Cabañas Perianes[1], M. Blanquer Blanquer[2], R. Pérez López[1], E. Fernández Poveda[1], A. Martínez Marín[1], M. Moya Arnao[1], F. Labbadia[2], M. Berenguer Piqueras[1], G. Elvira Ruiz[3], S. Manzano Fernández[3], C.S. Caro Martínez[4], J.M. Moraleda Jiménez[1]

[1]Hematology, Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, [2]Hematology, Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, [3]Cardiology, Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, [4]Cardiology, Hospital Vega Baja, Orihuela, Alicante, Spain

Background: Atrial fibrillation is the most common arrhythmia in our environment and the main cause of anticoagulation. Clinical trials and real-life records have shown that direct oral anticoagulants are at least as effective as non vitamin K oral anticoaulants in the prevention of thromboembolic stroke, becoming even safer. However, given their recent appearance, there is not a wide experience about theis use in real life, especially in the long term. Although safety and effectiveness have been well demonstrated in the context of clinical trials, there may be important differences in the selection, treatment and management of patients in actual clinical practice with respect to clinical trials.
Aims: To assess the clinical characteristics of patients with non-valvular atrial fibrillation (NVAF) that start direct oral anticoagulants (ACOD) and compare the effectiveness and safety of them in our environment.
Methods: From January 2013 to December 2014, patients with NVAF who started a direct-acting oral anticoagulant (Rivaroxaban, Apixaban and Dabigatran) for the first time were included. During the follow-up (646 [470-839] days), thromboembolic, hemorrhagic complications and mortality were recorded by reviewing electronic medical records and telephone contact (99.8% of patients).
Results: We recruited a total of 973 consecutive patients in three centres. We observed that patients who received Apixaban presented a higher frequency of chronic kidney disease, major global or digestive hemorrhage; and higher scores on thromboembolic and hemorrhagic risk scales. On the other hand, patients who received Dabigatran were the youngest and with the best renal function. The rate of thromboembolic events was higher in the Apixaban group (2.92/100 person-years) compared to Dabigatran and Rivaroxaban (1.91 and 1.53/100 person-years, $p<0.01$). Patients who showed lower rates of major bleeding were those treated with Dabigatran (1.92/100 person-years versus 2.90 / 100 person-years in Apixaban and 3.01/100 person-years in Rivaroxaban, $p<0,01$). Unadjusted mortality in the Apixaban group was 8.04/100 person-years, mainly at the expense of non-cardiovascular mortality, followed by those who received Dabigatran (5.94/100 person-years) and Rivaroxaban (4.96/100 people-year) ($p <0.01$). However, in multivariate Cox regression analysis, none of the ACODs were independent predictors of clinical events ($p>0.05$).
Summary/Conclusion: The prescription of direct anticoagulants differs according to the baseline clinical characteristics. In this way, elderly patients with comorbidities and, therefore, higher thromboembolic and hemorrhagic risk, receive Apixaban, while Dabigatran is prescribed in the youngest and with better renal function. In our population there were no differences in the effectiveness and safety of the different direct anticoagulants.

PS1526

INCREASED PLATELET RESPONSE TO ENDOGENOUS AGONISTS, IN PRE-DIABETIC C57BL/6 MICE

Z. Mkandla[1,*], B. Nkambule[1], P. Dludla[2]

[1]Human Physiology, University of KwaZulu-Natal, Durban, [2]Biomedical Research and Innovation Platform, South African Medical Research Council, Cape Town, South Africa

Background: Hyperinsulinemia, dyslipidaemia, hypertension and obesity are risk factors for the development of type 2 diabetes mellitus (T2DM). Obesity is associated with low-grade chronic inflammation characterized by pro-inflammatory signaling and abnormal adipokine production. Accelerated atherothrombotic conditions remain the main underlying factor contributing to the increased risk of atherosclerosis in diabetic patients. Activated platelets play a crucial role in the development of hypercoagulable states in type 2 diabetes.
Aims: To investigate platelet function and reactivity using a diet-induced pre-diabetes animal model.
Methods: A total of 18 male C57BL/6 mice were randomised into two diet groups; a 10 kcal% fat control diet group (diet code: D12450J) (n=5) and a 60 kcal% fat diet group (diet code: D12492) (n=13). The animals were kept on the diets for 3 weeks. Whole blood was collected from the lateral tail vein into 3.2% sodium citrate coated tubes. In order to assess platelet reactivity, twenty-five microliters (25ul) of citrated blood was stimulated with various endogenous agonists which included; 4µM and 20µM adenosine diphosphate (ADP), 0.19mg/mL collagen (COL) or 500µg/mL arachidonic acid (AA). These were then stained with 5ul of antibody (Ab) cocktail containing CD41-FITC (platelet marker), CD36-PE (platelet aggregation) and CD62P (platelet activation). Data acquisition was performed using the BD FACS Canto II flow cytometer within 1 hour of blood collection.
Results: At baseline, the levels of activated platelets were comparable between the two study groups p=0,5569. After stimulation with 4µM of ADP, the surface expression of CD62P was increased in the HFD group

compared to the control group;%CD62P control 0,91 [0,47-1,0] vs HFD 4,360[2,940-5,430], p=0,0028 and 20µM ADP%CD62P control 5,195[2,568-6,443] vs HFD%CD62P 9,880[8,270-11,23], p=0,0039. The control group showed increased levels of platelet expressing surface CD62P after stimulation with AA agonists compared to unstimulated controls,%CD62P 65,96[58,69-85,79] vs unstimulated%CD62P 6,430[3,883-9,863]; p=0,0286. In the HFD group, levels of platelet activation were increased after stimulation with 20µM ADP compared to 4µM ADP post stimulation. 4µM ADP%CD62P 4,370[2,940-8,005] vs 20µM ADP%CD62P 9,880[8,270-11,23], p<0,0001. In addition, the HFD group showed increased expression of CD36 compared to the control group after stimulation with AA; control group%CD36 44,02[41,40-57,44] vs HFD group%CD36 93,95[87,10-97,03], p=0,0039. The platelets showed biphasic response to stimulation with 20µM ADP compared to the 4µM ADP; 20µM ADP%CD36 1,460[1,355 -1,620] vs 4µM ADP%CD36 0,6500[0,4950 -1,000], p<0,0001. The platelet reactivity index (evaluated using CD36 expression), was increased in the HFD group compared to the control group after stimulation with 20 µM ADP; control group%CD36 median 12,13[8,337-18,07] vs HFD group%CD36 median 20,89[14,46-24,01], p=0,0362.

Summary/Conclusion: Platelets from pre-diabetic mice are hyper-responsive to endogenous agonists. This may indicate the hyperreactive nature of platelets in prediabetic individuals and an increased risk of CVD. We were able to demonstrate that all three major activation pathways; cyclooxygenase pathway, P_2Y_{12} receptor pathway and glycoprotein IV pathway, are hyperactivated in pre-diabetes. This may prompt the need for therapeutic strategies targeting these specific pathways in pre-diabetic individuals.

PS1527

ACQUIRED THROMBOTIC THROMBOCYTOPENIC PURPURA AND ACUTE PANCREATITIS: VARIABLE AND RECIPROCAL PATHOPHYSIOLOGIC RELATIONSHIPS

Q. Qin[1,*], X. Nan[1,2], C. Gentille Sanchez[1], L. Rice[34]

[1]Internal Medicine, Houston Methodist Hospital, Houston, [2]Hematology Oncology, University of California San Diego, San Diego, [3]Hematology, Houston Methodist Hospital, [4]Hematology, Weill Cornell Medical College, Houston, United States

Background: Acquired thrombotic thrombocytopenic purpura (TTP) is an aggressive thrombotic microangiopathy. Central to the pathophysiology is the loss of ADAMTS13 activity, due to inhibitors in the acquired form, allowing circulating ulVWF multimers to activate platelets and produce organ damage from microvascular thromboses. Autopsies uncover frequent pancreatic involvement, but clinically evident acute pancreatitis (AP) is uncommon. The relationship between TTP and AP may be variable and complex, with either capable of precipitating, exacerbating or mimicking the other.

Aims: In this observational, retrospective study, we review cases of TTP with AP (TTP-AP) and compare their clinical characteristics to those of TTP patients with severe ADAMTS13 deficiency (level <10%) but no clinical AP to highlight the pathophysiology associated with this unique organ.

Methods: We queried the Methodist Environmental for Translational Enhancement and Outcomes Research, a system that integrates all Houston Methodist Hospital patient data into a single, comprehensive data warehouse. Of the 149 identified encounters for TTP, 12 had TTP-AP and 41 had severe ADAMTS13 deficient TTP without AP. The rest of the encounters were excluded for no clinical pancreatitis or unknown/higher than 10% ADAMTS13 levels. In the TTP-AP group, the 7 cases where ADAMTS13 level was measured prior to plasma exchange (PEX) treatment also showed severe deficiency. Baseline demographics, variables associated with TTP, and complications were compared. Statistical analysis was performed using X2 test for dichotomous variables and the two-tailed Mann Whitney U test for the continuous parameters. Significance was defined as a p-value <0.05.

Results: In the TTP-AP group, 8 patients presented with concurrent TTP and AP with the other 4 having likely TTP induced AP with a time to AP between 3 to 28 days. The TTP-AP group had statistically higher initial median LDH (4610 U/L versus 1900 U/L, p=0.0038), gastrointestinal symptoms (92% versus 49%, p=0.0080), and renal involvement (81% versus 17%, p=0.0008, creatinine elevation at 3.3 mg/dL versus 1.0 mg/dL, p=0.0035) when compared to those in the TTP without AP group. No statistical differences were observed between the initial hemoglobin level and platelet counts. Statistical differences were also not observed for neurological and cardiac involvements, as well as percentage of refractory TTP, median PEX sessions, and overall mortality, although there was a trend toward higher incidence in the TTP-AP population. (Table 1).

Summary/Conclusion: We compared presenting features and clinical outcomes of 12 patients with TTP-AP to those of 41 patients with severe ADAMTS13 deficient TTP but no AP. Our results suggest a possible correlation between pancreatic involvement and more severe clinical outcomes. Pancreatic cytokine release observed in other studies may have contributed to ADAMTS13 depletion and the phenotypic severity (*Reiter et al.*, 2003; *Bernardo et al.*, 2004; *Mannucci et al.*, 2004; *Swisher et al.*, 2007; *Morioka et al.*, 2008). A review of literature also revealed the role of pancreatitis in nitric oxide depletion and complement activation, which may augment micro-thrombi formation and fuel TTP propagation. Whereas the relationship between TTP and other organ systems may be one of cause and effect, the relationship between AP and TTP may be one of reciprocal fueling. Early appreciation and treatment of pancreatitis might significantly decrease the severity of TTP and improve patient outcomes.

Table 1.

Clinical Features of Patients with TTP and Pancreatitis versus Those with Severe ADAMTS13 Deficiency but No Pancreatic Involvement

	TTP pancreatitis (n=12)	Severe TTP (n=41)*	P value (<0.05)
ADAMTS13 level <10%	7^	41	
Initial Hgb (Median)	9.6	8.7	0.45930

EVALUATION OF LUPUS ANTICOAGULANT TESTING: A THREE YEAR EXPERIENCE

S.F. Pinzon[1,*], M. Villalba Montaner[1], A.J. Garcia[1], J.M. Calvo Villas[1], N. Fernandez Mosteirin[1], E. Salvador Ruperez[1]

[1]Hematology, Hospital Universitario Miguel Servet, zaragoza, Spain

Background: The diagnosis of antiphospholipid syndrome (APS) requires, besides the clinical criteria, the demonstration of the presence of antiphospholipid antibodies which is constituted by cardiolipin, β -glycoprotein and lupus anticoagulant (LA) which is one of the three laboratory criteria to be persistently present. According to current guidelines it is sufficient to have one of the three laboratory criteria to classify a patient with thrombosis or pregnancy morbity as APS. Based upon consensus criteria from the International Society for Thrombosis and Haemostasis (ISTH), confirmation of LA requires that the following criteria are met; performing at last two phospholipid dependent clotting test, prolongation of at least one, evidence for inhibitory activity and the demonstration of phospholid dependence of the inhibitor on a confirmatory test.

Aims: The aim of our study was to evaluate retrospectively the frequency

testing of LA in our institution and the incidence of positive results and correct laboratory confirmation of them that lead to a diagnosis.
Methods: It was performed a cross-sectional study from the request for LA received over a period of three years, between 2015 and 2017. We examined which departments were requesting the test, the kind of results and the confirmation of the LA positive tests.
Results: From a total of 6344 of LA tests, 5837 (92%) were negative, 507 (8%) of the test demonstrated a positive LA. From these samples, 109 cases show a positive β -glycoprotein, 108 cardiolipin autoantibodies and 98 show both positive. After applying the confirmation tests criteria suggested by ISTH to all of the LA positive tests, 23 patients had a diagnosis of APS. The clinical specialities requesting the majority of tests were Internal Medicine (2075), Haematology (1158) and Neurology (606).
Summary/Conclusion: The results show a high frequency of LA requesting with a low of positive results (8%) and percentage of cases diagnosis for APS (0,36%), all the positive results was correctly confirmed. We consider the LA test is overclaimed leading to low diagnostic yield. Despite of using an adequate study protocol of the LA positive tests in our Laboratory based on ISTH recommendations, it is necessary to promote a better and more rational use of requesting LA test by clinical criteria, nevertheless, there is an adequate follow-up of international recommendations at the positive tests.

THE INFLUENCE OF PGP AND PGR PEPTIDES ON ANTICOAGULANT CAPACITY AND ANTITHROMBOTIC POTENTIAL OF BLOOD IN HEMOSTATIC DYSFUNCTION OF AGING RATS

T. Obergan[1,*], T. Shubina[1]

[1]Lomonosov Moscow State University, Moscow, Russian Federation

Background: Clinical data and results of experimental studies indicate that age-related changes of hemostatic system are accompanied by dysfunction of the coagulation and anticlotting processes. This is manifested in the raising of platelet aggregation, increased the activity of coagulation factors and inhibition of fibrinolytic system due to the limitation of the appearance in the blood of enzymatic fibrinolysis activators. In these conditions, the risk of thrombosis and thrombotic complications increases. It is known that short peptides, which are composed of amino acids proline and glycine, are involved in hemostatic processes, inhibiting blood coagulation and impeding the formation of blood clots. Previously, it was shown that tripeptide Pro-Gly-Arg-treatment in animals with experimental metabolic syndrome accompanied by hemostatic dysfunction increases the antiplatelet and fibrinolytic properties of blood, impeding the thrombus formation.
Aims: The aim of this study was to demonstrate the anticoagulant and antithrombotic effects of Pro-Gly-Pro (PGP) and Pro-Gly-Arg (PGR) peptides in conditions of hemostasis dysfunction in aging.
Methods: Male albino rats of Wistar strain 3 («young») and 15 months of age («old») were used in the study in accordance with ethical principles of the Helsinki Declaration. Animals were divided into four groups (in each group $n = 10$) and were given following treatments: Group 1 – Control (3-month young rats were given 0.85% saline as vehicle for peptides); Group 2 – Untreated rats (15-month aging rats were given 0.85% saline); Group 3 – PGP-treated rats (15-month aging rats were treated with PGP in dose 1 mg/kg body weight); Group 4 – PGR-treated rats (15-month aging rats were treated with PGR in dose 1 mg/kg body weight). The peptides or saline were injected by intranasal way for 20 µl per rat once daily for 5 days. Blood samples were obtained 1 h after the last administration of drugs. ADF-induced platelet aggregation, enzymatic fibrinolytic activity (non-stabilized fibrin plate method), activity of tissue plasminogen activator (stabilized fibrin plate method) and anticoagulant activity (APTT test) were determined in blood plasma.
Results: In this study, aging rats were found to have decreased anticoagulant and fibrinolytic activity of blood plasma, as well as increased platelet aggregation, i.e. confirmed the fact of dysfunction of the hemostatic system. Thus, the formation time of the clot (APTT) in old rats (Group 2) accelerated by 25%, the enzymatic fibrinolytic activity of plasma (EFA) and the activity of the tissue plasminogen activator (t-PA) decreased by 35% in both cases, platelet aggregation increased by 45% compared to Control (young rats). Intranasal 5-fold treatment of animals with peptides PGP and PGR led to a significant increase in APTT by 30% and 24%, respectively, against untreated old animals (Group 2). This was accompanied by an enhancement in EFA by 36% (PGP-treated) and 40% (PGR-treated) due to rising t-PA activity by 2.3 and 3 times, respectively, compared to Group 2. Herewith, PGR-treatment caused a decrease in platelet aggregation by 24%, while PGP-treatment did not lead to a significant change in this parameter.
Summary/Conclusion: The study has shown a protective role of PGP and PGR peptides in their application during aging. Under these conditions, treatment with peptides contributes to the normalization of the hemostatic function, thereby reducing the possibility of thrombotic complications.

APTT-BASED CLOT WAVEFORM ANALYSIS IN VARIOUS INFECTIONS

C.K. L. Ng[1,*], C.W. Tan[1], H.H.M. Cheen[2], W.H. Wong[1], M.H.Y. Chu[1], S.S. Lim[1], G.D.D. Yeo[3], G. Morvil[3], H.J. Ng[1]

[1]Haematology, [2]Pharmacy, Singapore General Hospital, [3]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

Background: Infections cause varying degrees of haemostatic dysfunction. Clot waveform analysis (CWA), as a global haemostatic marker, might detect such changes. Biphasic waveform on CWA observed in sepsis has previously been demonstrated to precede disseminated intravascular coagulopathy (DIC) and to predict poor clinical outcomes. The effect of infection, in the absence of biphasic waveform and DIC, on CWA has not been established.
Aims: To evaluate the influences of different infections on CWA.
Methods: Data from patients admitted for infections and with an activated partial thromboplastin time (aPTT) were retrospectively analyzed. APTT-based CWA was performed on CS2100i automated analyser using Dade Actin FSL reagent. The CWA parameters were maximum velocity (min1), maximum acceleration (min2) and maximum deceleration (max2). Results from control patients were compared. Subjects who were on anticoagulant, with active thrombosis and cancer were excluded.
Results: The means aPTT (±SD) for dengue (n=36), bacterial (n=52), respiratory viral infection (n=13) and controls (n=112) were 37.99±7.93s, 33.96±7.33s, 29.98±3.92s and 27.80±1.59s, respectively without biphasic waveform. The means of all the CWA parameters (min1; min2; max2) were highest in bacterial infection, followed by respiratory viral infection, controls and dengue infection (Table 1). Multivariate analysis confirmed that bacterial and dengue infection remained as independent predictor for higher and lower CWA parameters, respectively (Table 2). This CWA changes were independent of their underlying aPTT result (Figure 1).

Table 1. Comparison of clot waveform parameters between infected and control blood samples.

					p-value (p-value after adjustment*)		
Mean CWA Parameter	Bacterial infection (n= 52)	Dengue infection (n= 36)	Other viral infection (n= 13)	Control (n= 112)	Bacterial vs. Control	Dengue vs. Control	Other virus vs. Control
Min1 (SD)	6.92 (1.60)	3.93 (1.02)	6.19 (1.32)	5.53 (1.16)	<0.001 (<0.001)	<0.001 (<0.001)	NS (NS)
Min2 (SD)	1.04 (0.28)	0.57 (0.17)	0.95 (0.21)	0.93 (0.46)	<0.001 (<0.001)	<0.001 (<0.001)	NS (NS)
