EHA EUROPEAN HEMATOLOGY ASSOCIATION

STOCKHOLM 23RD CONGRESS JUNE 14 - 17 | 2018
European Hematology Association

we've BEEN PIONEERING CAR T CELL THERAPIES FOR OVER 20 YEARS AND WE'RE NOT STOPPING NOW.

It's a new day for research and patient care in CAR T cell therapies. City of Hope has been accelerating innovative CAR T research for more than 20 years, developing novel CAR T cell therapies for blood and solid tumors, as well as partnering with global biopharmaceutical companies for clinical trials.

- Over 180 patients currently being treated with CAR T cell therapies
- 14 open CAR T cell therapy trials with several more opening this year
- Authorized site for both tisagenlecluecel (Kymriah) and axicabtagene ciloleucel (Yescarta)

Find out more about City of Hope's CAR T cell therapies program. Go to **CityofHope.org/CAR-T** or call our dedicated CAR T cell therapy line: **+1 833-310-CART (2278)**

Author information

The abstract book of the 23rd Congress of the European Hematology Association is published as a supplement of HemaSphere and is also available online at www.hemaspherejournal.com.

HemaSphere is an open access journal, powered by the European Hematology Association and dedicated to support hematology patient care, research and education worldwide.

Please read our **instructions and guidelines** (http://edmgr.ovid.com/hemasphere/accounts/ifauth.htm) for preparing and submitting articles.

Manuscripts must be submitted online at: http://www.editorialmanager.com/hemasphere.

Article Processing Charges (APC)

Article types	EHA members	Non-members
Tier 1: Original articles, review articles & guidelines	Free**	€1,080* equivalent ($ 1,200)
Tier 2: Letters, case reports, editorials & perspectives	Free**	€540* equivalent ($600)
Tier 3: Comments, HemaTopics	Free	Free
All invited manuscripts*** (Invited review articles, invited guidelines, invited editorials and invited perspectives)	Free	Free

***USD/EUR equivalent rate of 1.110, please note that all payment will be in USD.**
**2018 Promotional Discounts on Article-Processing Charges (APC): 100% discount for EHA members (first and last author of a manuscript).
***APCs for all contributions *on invitation* by the Editors will be waived.

EUROPEAN HEMATOLOGY ASSOCIATION

Towards a cure for all blood disorders

The European Hematology Association (EHA) promotes excellence in patient care, research and education in hematology.

We achieve this by:

Connecting hematologists worldwide

EHA is the largest Europe-based organization that brings together all medical professionals, researchers and scientists with an active interest in hematology. We have more than 4,000 members from 100 countries and work with a vast network of national societies. Our annual congress is attended by more than 10,000 individuals with an interest in hematology who meet and learn together.

Supporting career development and research

To accelerate the careers of junior scientists, EHA provides research grants and training programs for basic, translational, and clinical researchers in the field of malignant and non-malignant hematology. EHA also honors the contribution of outstanding physicians and scientists for the advancement of hematology through awards.

Harmonizing hematology education

EHA is one of the largest international, independent providers of hematology education. A comprehensive and integral curriculum forms the basis of our Medical Education Program. Through this program, professionals acquire state-of-the-art knowledge by various means, such as an online learning platform, educational meetings and a European Hematology Exam.

Advocating the interests of hematologists and hematology

EHA represents hematology and hematologists in the European political and policy arena to achieve more and better research funding opportunities, improve regulation, increase the availability and affordability of medicines, and harmonize education and training of hematologists.

Are you looking for unique collaborations, mentorship, and excellent education?
Is raising a voice for hematology in Europe important to you?
Be part of the EHA community!

For more information, please visit ehaweb.org.

MCL-1, a BCL-2 family member, is an APOPTOSIS INHIBITOR in MCL-1–dependent AML[1-3]

MCL-1 dependence may drive progression of AML[1,2]

Acute myeloid leukemia (AML) is associated with high mortality and is challenging to treat, with an overall 5-year survival rate of 27%.[4,5] Standard therapies often fail to achieve the goal of inducing complete remission in 25%–50% of patients, and relapse is common even in patients who have an initial response to treatment.[1,5] Disease progression and treatment resistance in a subset* of AML have been associated with a key anti-apoptotic protein, myeloid cell leukemia 1 (MCL-1).[1,2] This is referred to as MCL-1 dependence.[6] Understanding the role of MCL-1 can inform therapeutic targeting strategies in AML.[7]

MCL-1 may have multiple roles in sustaining AML blasts[1,3]

MCL-1 is a member of the apoptosis-regulating BCL-2 family of proteins.[8] In normal function, MCL-1 is essential for early embryonic development and for the survival of multiple cell lineages, including lymphocytes and hematopoietic stem cells.[3]

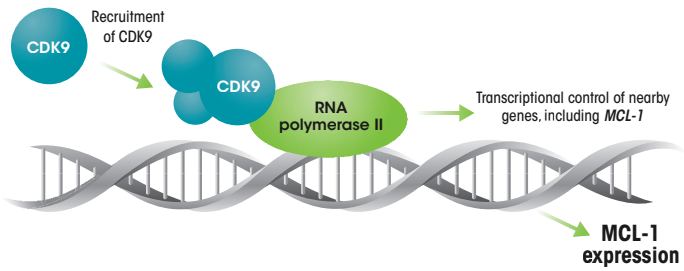
However, in MCL-1–dependent AML, MCL-1 has been shown to sustain the survival of AML cells, which may lead to relapse.[1] MCL-1 dependence is also associated with resistance to agents that typically have activity against leukemic blasts.[8]

A key function of MCL-1 is to inhibit apoptosis[1]

In addition, independently of its anti-apoptotic activity, MCL-1 has a role in mitochondrial function that may promote cancer cell survival and proliferation.[3] The anti-apoptotic and mitochondrial functions of MCL-1 may synergize to promote tumor progression by inhibiting apoptosis and supporting proliferation.[3]

Downregulation of MCL-1 to enable apoptosis of leukemic blasts may be a rational therapeutic strategy in MCL-1–dependent AML[7]

The activity of cyclin-dependent kinase 9 (CDK9) is essential for the transcription of *MCL-1* mRNA in leukemic blasts.[9,10]



Because of the short half-life of MCL-1 (2-4 hours), the effects of targeting upstream pathways are expected to reduce MCL-1 levels rapidly.[11] CDK9 inhibition has been shown to block *MCL-1* transcription, resulting in the rapid downregulation of MCL-1 protein, thus triggering apoptosis.[8,12,13]

*The prevalence of MCL-1–dependent AML is under investigation.

MCL-1 Dependence in AML

A matter of cell life and cell death

EUROPEAN HEMATOLOGY ASSOCIATION

Become an EHA member

Support our mission

EHA promotes excellence in patient care, research and education in hematology.

Join your fellow hematologists worldwide and enjoy membership benefits for both professional and personal development within the field of hematology.

Become a member

Now at 50% on membership fees for the remainder of 2018

- Full Membership from €155/year to €75/year
- Junior Membership from €20/year to €10/year
- Health Care Affiliated Professional Membership from €90/year to €45/year
- Emeritus Membership from €90/year to €45/year

Membership benefits

- Discount on article publication charges for the journal HemaSphere
- Eligibility for EHA Congress travel grants
- Access to EHA Membership Directory
- Nomination and voting rights
- Unlimited access to the EHA Learning Center
- Discount on EHA Congress and other EHA meetings
- Access to the curriculum Passport online
- Subscription to EHA newsletters

ehaweb.org

Word of Welcome

On behalf of the EHA Board and the Scientific Program Committee we are pleased to present to you this year's Abstract Program.

The Scientific Program Committee has compiled an exciting program of oral and poster presentations from close to 2600 submitted abstracts representing all fields of hematology. The six best abstracts will be presented during the Presidential Symposium on Friday afternoon. This will be a session not to miss.

The Oral Sessions are spread over three days (Friday to Sunday) providing you with ample opportunity to attend several of them and get updated on a broad range of topics and research areas. Several poster presenters will have the opportunity to pitch their abstract during an Oral Session. These Poster Pitches are an exciting opportunity to promote basic science and research, and to invite delegates to the Poster Sessions.

The Poster Session setup has changed significantly because the Scientific Program Committee has doubled the abstracts accepted for presentation. The posters will be on display for only one day, either during the Friday or Saturday Poster Session. All accepted posters can also be viewed on the e-poster screens from Friday, June 15, 09:30 to Sunday, June 17, 13:00. The Poster Session gives maximum exposure to the scientific work and allows direct interaction between poster authors and congress delegates. Don't miss this opportunity of interesting discussions and networking!

Nurturing the next generation is an important task of EHA and this year we are providing over 150 travel grants to Junior Members who received an abstract presentation in the program. In addition, during the Opening Ceremony, we are awarding the best submitted abstracts of trainees in four categories of career stages. These awardees and the travel grant winners can be found on the next page.

The late-breaking abstract program is intended for abstracts with novel data not available at the time of the regular abstract submission deadline. Only a few abstracts, with the most exciting results are selected for a presentation in the Late-Breaking Oral Session on Sunday morning, and a special slot is reserved during Plenary Session I on Saturday for the best late-breaking abstract.

All the abstracts are also available on the EHA Learning Center, for which you have complimentary access after the congress: learningcenter.ehaweb.org.

On behalf of the EHA Board, the committees and all the people involved in this year's EHA Congress and the abstract program, we trust you will enjoy reading this book, the abstracts and the research presented.

YoungEHA Best Abstract Awards

EHA supports young hematology clinicians and researchers. The YoungEHA Best Abstract Awards are awarded to the highest-ranking abstracts in the following four categories: Clinicians or medical students training for a PhD degree, PhD research students, postdoctoral fellows and clinical hematology trainees. We are honored these outstanding YoungEHA trainees will be presenting during the EHA congress: they are the future of hematology!

CLINICAL TRAINEE AWARD
R Shouval, Israel

MD-PHD AWARD
L Hinze, Germany

PHD RESEARCH STUDENT AWARD
F Ribezzo, Germany

POSTDOCTORAL RESEARCH
A Nai, Italy

Late-Breaking Oral Session

The best abstracts selected from the late-breaking abstract submission are presented during this oral session on Sunday, June 17 from 11:15 - 12:45 in Room A1, and a special slot is reserved during Plenary Session I on Saturday for the best late-breaking abstract.

A complete session overview is available via the mobile app or the online program at ehaweb.org

Background: R/R FL remains an area of unmet medical need and treatments with novel mechanisms of action are urgently needed. The histone methyltransferase EZH2 is an important regulator of the germinal center (GC) reaction that is involved in prevention of terminal differentiation of GC B-cells. EZH2 activating mutations are not uncommon in FL and are postulated to be oncogenic drivers. Tazemetostat, a potent, selective, oral EZH2 inhibitor has shown antitumor activity in a phase 1 study that included NHL patients with mutated (mt) or wild-type (wt) EZH2 tumors, providing rationale for further investigation.
Aims: This open-label, multicenter phase 2 study is enrolling patients with either mt or wt EZH2 R/R diffuse large B-cell lymphoma or FL (Grade 1-3b); Results of an interim analysis of FL patients are presented here.
Methods: Key inclusion criteria include: age ≥18 years old, ≥2 prior treatment regimens, measurable disease, and adequate organ function. Tazmetostat 800 mg is administered orally, twice daily (BID). Response is assessed every 8 weeks using 2007 IWG-NHL assessment criteria. Tumor tissue is analyzed for EZH2 hot spot activating mutations (Y646X, A682G, A692V) using a **cobas**® EZH2 Mutation Test (Roche Molecular Systems, investigational use only). The primary endpoint is overall response rate (ORR). Secondary endpoints include progression-free survival (PFS) and safety/tolerability.
Results: As of January 16, 2018, interim phase 2 safety and efficacy data were summarized from 76 FL patients (median 3 prior therapies; one patient who had not yet been evaluated at week 8 was excluded from the efficacy analysis). In patients with an activating EZH2 mutation (n=22), the ORR (complete response [CR] + partial response [PR]) was 82%, with best overall response of CR 5% (n=1), PR 77% (n=17), stable disease (SD) 18% (n=4), and no patients with progressive disease (PD). Median PFS was >48 weeks and median duration of response (DOR) was >32 weeks. Fifty-six percent of patients (10/18) have maintained their response and remain on study. In the EZH2 wt group (n=54), ORR was 35% (n=19), with best overall response of CR 6% (n=3), PR 30% (n=16), SD 30% (n=16), PD 30% (n=16); data not available for 3 patients. Median PFS was >30 weeks and median DOR >56 weeks. Fifty-eight percent of patients (11/19) have maintained their response and remain on study. Safety analysis showed that treatment-emergent adverse events (TEAE) leading to study drug discontinuation occurred in 12% of patients. Grade ≥3 treatment-related AEs were reported in 12% of patients. The most common (≥10%) treatment-related TEAEs (all grades) were: nausea (18%), anemia (13%), fatigue (13%), diarrhea (12%), and asthenia (10%).
Summary and Conclusions: Tazemetostat appears to be generally well tolerated at a dose of 800 mg BID with observed meaningful clinical activity and durability of response in FL patients who have had multiple prior therapies, as seen in this interim update. Clinical activity is pronounced in patients with EZH2 activating mutations; 100% had CR, PR, or SD as best response. For wt, 65% had CR, PR, or SD as best response. Late onset responses have been previously reported on tazemetostat, therefore clinical outcome in patients on continuing treatment may evolve from SD to PR and from PR to CR. These encouraging phase 2 data demonstrate that EZH2 inhibition may be an important and effective therapeutic target.

S101

PATIENTS WITH HIGH RISK FEATURES ACCORDING TO PRIMA PI HAVE SIGNIFICANTLY HIGHER RISK TO DIE EVEN IF THEY ARE LATE PROGRESSORS

M. Trneny[1,*], A. Janikova[2], D. Belada[3], H. Mocikova[4], V. Prochazka[5], K. Kopeckova[6], J. Duras[7], J. Pirnos[8], L. Barsova[9], J. Salkova[10], K. Benesova[10], J. Mayer[11], P. Blahovcova[12]

Budejovice, Ceske Budejovice, [9]Dept of Oncology, Hospital Liberec, Liberec, [10]1st Dept of Medicine, 1st Faculty of Medicine, Charles University & General University Hospital, Prague, [11]Dept. of Internal Medicine, Hematology and Oncology, Faculty Hospital, Brno, [12]Czech Lymphoma Study Group, Charles University & General University Hospital, Prague, Czech Republic

Background: Follicular lymphoma (FL) patients (pts) have high long-term survival probability in majority of cases, however some subgroups especially early progressors and pts with transformation poor outcome. Prognostic indexes could partially help and recently presented PRIMA PI (Bachy ASH2017) is the first one based on population of immunochemotherapy treated pts (PRIMA study).
Aims: Validation of PRIMA PI in large cohort of real world treated pts and analysis of impact of different PRIMA PI risk groups on progression within 24 months since start of therapy (POD24).
Methods: This analysis was part of NiHiL project (GovTrial No: NCT03199066). NiHiL project is based on prospective collection and analysis of diagnostic, epidemiologic and therapeutic data of NHL patients. All patients signed the informed consent approved by EC. The eligibility criteria were: all consecutively pts with confirmed FL dg, with confirmation of essential data (clinical characteristic, therapy, follow-up) treated with immunochemotherapy. Progression free survival (PFS) and Overall survival (OS) were counted since the therapy initiation. Pearson's Chi-square Test was used for group comparison, log rank test for survival analysis.
Results: Altogether 1179 pts diagnosed 1999-2015 and treated with

immunochemotherapy in 1st line 2000-2015 fulfilled eligibility criteria. The majority (893) had grade 1 or 2, followed by gr 3A (188) or without given grade (98). Median age was 59y (26-87), BM was involved in 50.4% cases, LDH was elevated in 42.1% cases and beta2microglobulin >3mg/l in 31.8% of pts. Low risk group (LRG) according to FLIPI, FLIPI2 and PRIMA PI resp. represent 20.5%, 35.5% and 39.0% pts resp., intermediate risk group (IRG) 31.3%, 25.6% and 29.2% pts resp., high risk group (HRG) 48.1%, 38.9% and 31.8% pts resp. All patients were treated with rituximab and majority of pts (76.3%) were treated with CHOP, CVP was used in 13.3% pts, bendamustine 2.8%, fludarabine 2.6% and the rest with other regimens according to centres policy (PACEBO, sequential protocol and others). ORR (Cheson 1999) was reached in 92.4% of pts, out of these 66.7% received rituximab maintenance. With the median follow-up 6.1y there was 7y PFS and OS probability 58.7% and 82.3%. According to FLIPI, FLIPI2 and PRIMA PI resp. there was 7y PFS probability in LRG 76.1%, 71.3% and 72.6% resp., in IRG 63.7%, 61.1% and 57.7% resp., in HRG 46.9%, 45.6% and 42.4% resp. (Figure 1A). OS probability at 7y according to FLIPI, FLIPI2 and PRIMA PI resp. was in LRG 90.8%, 90.8% and 88.2% resp., in IRG 87.0%, 82.7% and 89.2% resp. and in HRG 75.2%, 73.1% and 68.0% resp. OS probability at 7y was 51.9% for those with POD24 *vs* 91.9% (median 7.1 *vs* nr) for those without POD24 (HR 7.1, p <0.0001). We tested impact of HR *vs* LG and IG (pooled into one group) PRIMA PI characteristic on OS separately in those pts with and without POD24. Among POD24 pts There was trend (p<0.11) for shorter OS for HRG pts *vs* others with median 6.2y *vs* 9.1y (HR 1.5). More importantly among pts without POD24 there was significantly higher risk to die for HRG patients *vs* others, HR 2.6 (p<0.0001) with 7y OS 83.4% *vs* 93.0% (Figure 1B).

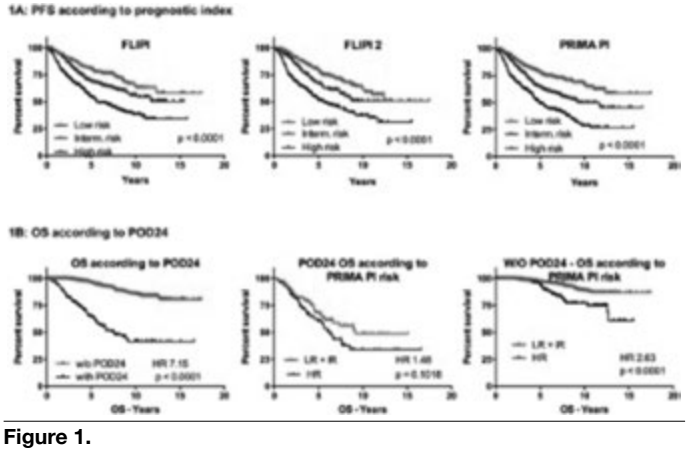

Figure 1.

Summary and Conclusions: PRIMA PI represents feasible prognostic index which works in real world practice. Worse outcome of HRG pts is not given only by higher proportion of POD24 pts, but HRG pts compared to the others have greater risk to die (2.5x) even if they are late progressors.
Supported by grant AZV 16-31092A and Progres Q28 UK.

Background: Rituximab (R) maintenance is part of a standard treatment for follicular lymphoma. In MZL, however, it is not yet common practice.
Aims: In this study we compared the effect of 2 years of R maintenance *vs* observation after first-line treatment with B-R in patients with previously untreated MZL.
Methods: Patients had stage II (bulky disease >7 cm), III, or IV disease. Nodal and splenic MZL were included but not MALT lymphomas. Primary endpoint was progression free survival (PFS). Secondary endpoints included response rates, overall survival (OS), and toxicity. For induction patients were treated with up to 6 cycles of B-R plus 2 additional R cycles. Only patients responding to B-R were then randomized to either R maintenance (q 2 months for 2 years) or observation.
Results: Median time of follow-up after registration was 76 months at the time of this analysis (February 2018). 119 patients with a median age of 65 years were evaluable for response. 108 (91%) responded to B-R induction, with 23 patients (19%) achieving a complete remission. Of 104 randomized patients, 53 (51%) were randomized to R maintenance and 51 (49%) to observation. Median age of randomized patients was 64 years, patient characteristics and toxicity were similar for both groups. PFS was superior for 2 years of R maintenance, with the median not yet reached *vs* 92.2 months for observation (hazard ratio (HR) 0.35, 95% CI 0.17 – 0.76, p=0.008). The OS rate at 6 years was 92% for R maintenance *vs* 86% for observation. The difference in OS was not statistically significant (HR 0.52, 95% CI 0.20 – 1.39).
Summary and Conclusions: Our results demonstrate a statistically significant PFS improvement of a 2-year R-maintenance *vs* observation after B-R induction in patients with MZL.

S103

TP53 MUTATIONS, BUT NOT NOTCH2 OR KLF2 MUTATIONS, IDENTIFY PATIENTS WITH POOR PROGNOSIS IN SPLENIC MARGINAL ZONE LYMPHOMA – INTERIM ANALYSIS OF THE IELSG46 STUDY

Background: Although the majority of SMZL displays an indolent course, the disease is still incurable. Moreover, a significant proportion of patients (~25-30%) experience poor outcome and survive <5 years. Molecular aspects of SMZL have been claimed as promising biomarkers and their incorporation into prognostic models for SMZL might improve risk stratification of patients.
Aims: The main objective of the study is to test the impact of molecular alterations on overall survival (OS) prognostication in newly diagnosed SMZL.
Methods: IELSG46 is a multicentre, international, retrospective, observa-

tional study in which already existing and coded health-related personal and biological material is further used. The study included adults, who received a diagnosis of SMZL on spleen histology, and for whom tumor material collected before initiation of medical therapy and clinical annotations were available. Mutation analysis was performed by CAPP-seq targeted deep next generation sequencing of tumor genomic DNA was performed on the NexSeq500 sequencer (Illumina). A stringent bioinformatic pipeline was applied to suppress the background noise allowing to call variants with a sensitivity of $5x10^{-2}$ in FFPE derived DNA. Deletion of 17p and of 7q were identified by using the sequencing reads-based GATK4-CNV algorithm. The adjusted association between exposure variables and OS was estimated by Cox regression. Cox regression included exposure variables showing an univariate association with OS with a Bonferroni corrected significant level <0.1.

Results: This interim analysis included 162 of the 316 cases enrolled in the study. The sample size allowed to identify 30% differences in OS for genetic lesions represented in at least 5% of cases. Median follow-up was 10 years. At 10 years, 74.6% of cases were alive, consistent with the general indolent behavior of this lymphoma. Genes recurrently affected by non-synonymous somatic mutations in >10% of SMZL included KLF2 (25.9%), NOTCH2 (22.2%), KMT2D (15.4%), TNFAIP3 (13.5%), ATM (11.1%) (Figure 1A). Deletion 7q was documented in 31.5% of cases. OS was not affected by either KLF2 mutations (Figure 1B), NOTCH2 mutations (Figure 1C), or the co-occurrence on NOTCH2 and KLF2 mutations. The only recurrent (>5%) lesion associated with inferior OS was TP53 mutation, which occurred in 7.4% cases (Figure 1D). Among TP53 mutated cases, the median OS was 6 years (10-year OS: 46%), while it was not reached among TP53 wild type cases (10-year OS: 76.9%, p=.01).

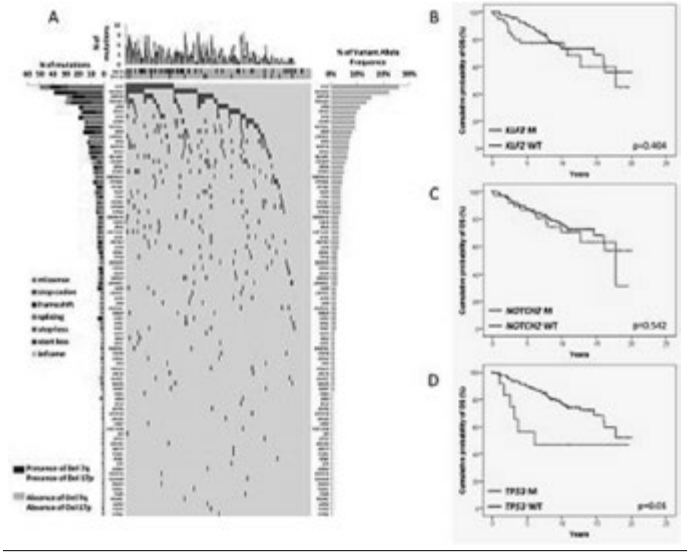

Figure 1.

Summary and Conclusions: The large sample size and the inclusion of SMZL confirmed on spleen pathology allowed to precisely estimate the prevalence of KLF2 and NOTCH2 mutations in this lymphoma, which were previously reported in the range of 10-40%. NOTCH2 and KLF2 mutations do not affect disease course, consistent with the hypothesis that they are early and founding molecular events in SMZL. As in other mature B-cell tumor, also SMZL outcome is affected by TP53 mutations.

S104

CC-122, A NOVEL CEREBLON-MODULATING AGENT, IN COMBINATION WITH OBINUTUZUMAB (GA101) IN PATIENTS WITH RELAPSED AND REFRACTORY (R/R) B-CELL NON-HODGKIN LYMPHOMA (NHL)

J.-M. Michot[1,*], R. Bouabdallah[2], J.K. Doorduijn[3], U. Vitolo[4], M.J. Kersten[5], A. Chiappella[4], P.L. Zinzani[6], G. Salles[7], R. Sarmiento[8], S. Mosulen[8], C. Mendez[8], M. Petrarca[9], M. Pourdehnad[9], L. Li[10], Z. Nikolova[8], V. Ribrag[1]

[1]Institut Gustave Roussy, Villejuif, [2]Institut Paoli-Calmettes, Marseille, France, [3]Erasmus MC Cancer Institute (on behalf of the HOVON/Lunenburg Lymphoma Phase I/II Consortium [HOVON/LLPC]), Rotterdam, Netherlands, [4]Azienda Ospedaliera Universitaria Città della Salute e della Scienza di Torino, Torino, Italy, [5]Academic Medical Center (on behalf of the HOVON/Lunenburg Lymphoma Phase I/II Consortium [HOVON/LLPC]), Amsterdam, Netherlands, [6]Institute of Hematology "Seràgnoli," University of Bologna, Bologna, Italy, [7]Centre Hospitalier Lyon-Sud, Pierre-Bénite, France, [8]Celgene Institute for Translational Research Europe, Seville, Spain, [9]Celgene Corporation, San Francisco, [10]Celgene Corporation, Berkeley Heights, United States

Background: There is an unmet need for more effective therapeutic options for patients (pts) with non-Hodgkin lymphoma (NHL), including pts with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL) and indolent lymphomas (Crump *et al., Blood* 2017). Pts with follicular lymphoma (FL) experiencing early relapse (ER) within 2 years of initial diagnosis and those double refractory (DR) to both rituximab and chemotherapy, have limited treatment options and particularly poor outcomes (Casulo *et al., JCO* 2015). CC-122 is a novel oral agent that modulates cereblon, resulting in the selective ubiquitination and degradation of the hematopoietic transcription factors, Aiolos and Ikaros (Hagner *et al., Blood* 2015; Ribrag *et al., Blood* 2014). Preliminary results from the CC-122-NHL-001 trial, the first study of CC-122 in combination with obinutuzumab, showed promising response rates in pts with R/R B-cell NHL (Michot *et al., Blood* 2017).

Aims: To report updated safety and efficacy from the CC-122-NHL-001 phase Ib study of CC-122 plus obinutuzumab in pts with R/R B-cell NHL (EUDRACT 2014-003333-26; NCT02417285).

Methods: Eligible pts had histologically/cytologically confirmed $CD20^+$B-cell R/R NHL after ≥1 prior regimen for FL/marginal zone lymphoma (MZL) or after ≥2 regimens and/or ASCT for DLBCL. Pts received dose escalated CC-122 active ingredient in capsule formulation (AIC) 1, 2, 3, or 4 mg and formulated capsule (F6) 3 or 4 mg for 5 out of 7 days (5/7d) per week in 28-day cycles with a fixed dose of obinutuzumab IV 1000 mg on days 2, 8, 15 of cycle 1 and day 1 of cycles 2-8. Primary endpoints included safety, NTD, and MTD. Response was assessed by Cheson 2007 criteria.

Results: As of January 10, 2018, 49 R/R B-cell NHL pts were enrolled, including 29 pts with FL (59%), 19 (39%) with DLBCL, and 1 with MZL. Of the 29 FL pts, 16 were characterized as ER or DR and considered high-risk pts. For all pts, the median age was 60 y (range, 26–83), 32 (65%) were male, and 38 (78%) had stage III/IV disease. The median number of prior anticancer therapies was 3 (range, 1–11), and 19 pts (39%) had 1 prior ASCT. As of data cutoff, 16 pts (33%) were ongoing. The median number of cycles of CC-122 was 6 (range, 1-29). Although 16 pts (33%) had ≥1 dose reduction (31% due to AEs), these pts remained on treatment and experienced clinical benefit. Forty-one pts (84%) had dose interruptions (71% due to AEs). Two pts had a DLT, consisting of grade 4 neutropenia (n=1, CC-122 AIC 3 mg) and grade 5 tumor flare (n=1, CC-122 F6 4 mg). The most common any-grade AEs included neutropenia (65%), thrombocytopenia (39%), and diarrhea (29%). Grade 3/4 TEAEs occurred in 41 (84%) pts; the most common (≥15%) were neutropenia (55%) and thrombocytopenia (22%). 47% of pts had SAEs. The ORR was 65% with a CR rate of 29%; median PFS was 13.8 mo (95% CI, 3.7-21.2) and the median DOR was 10.2 mo (95% CI, 8.4-NR) (Table 1). Among pts with FL, the ORR was 77% with a CR rate of 40%. A subgroup analysis of efficacy was performed to further examine the activity of the combination in standard-risk (no ER/DR) and high-risk (ER or DR) pts with FL, demonstrating similar outcomes in the FL subgroups (Table 1).

Table 1. Efficacy with CC-122 in combination with obinutuzumab in evaluable patients by subgroup.

	n	ORR	CR	Median PFS mo (95% CI)	6-mo PFS rate %, (95% CI)	Median DOR mo, (95% CI)
All patients	49	65%	29%	13.8 (3.7-21.2)	60 (43-73)	10.2 (8.4-NR)
DLBCL	19	47%	11%	4.7 (1.8-13.8)	40 (16-63)	10.2 (1.8-10.2)
FL + MZL	30	77%	40%	16.6 (5.4-NR)	72 (50-86)	19.4 (8.4-NR)
High-risk FL (ER or DR)	16	75%	38%	21.2 (3.7-NR)	64 (34-84)	19.4 (1.9-NR)
Standard-risk FL*	13	77%	46%	16.6 (5.4-16.6)	80 (39-95)	8.4 (3.6-NR)

Data cutoff was January 10, 2018. *Defined as neither early relapse (ER) nor double-refractory (DR).

Summary and Conclusions: The chemotherapy-free combination of CC-122 and obinutuzumab was well-tolerated and had favorable clinical activity and durable remissions in R/R B-cell NHL. Notably, subgroup analysis demonstrated that high-risk and standard-risk FL pts have comparable efficacy in response to CC-122 plus obinutuzumab. An expansion (Part B) study is ongoing for pts with R/R FL.

Advances in front-line treatment of newly diagnosed multiple myeloma

S105

A TRIPLET BORTEZOMIB- AND IMMUNOMODULATOR-BASED THERAPY BEFORE AND AFTER DOUBLE ASCT IMPROVES OVERALL SURVIVAL OF NEWLY DIAGNOSED MM PATIENTS: FINAL ANALYSIS OF PHASE 3 GIMEMA-MMY-3006 STUDY

P. Tacchetti[1,*], F. Patriarca[2], M.T. Petrucci[3], M. Galli[4], L. Pantani[1], L. Dozza[1], F. Di Raimondo[5], M. Boccadoro[6], M. Offidani[7], V. Montefusco[8], N. Pescosta[9], A. Ledda[10], T. Caravita[3], N. Cascavilla[11], B. Gamberi[12], P.M. Stefani[13], C. Terragna[1], G. Marzocchi[1], F. Ferrara[14], V. De Stefano[3], E. Zamagni[1], M. Cavo[1]

[1]Bologna University School of Medicine, Seràgnoli Institute of Hematology, Bologna, [2]GIMEMA Italian Myeloma Network, Udine, [3]GIMEMA Italian Myeloma Network, Roma, [4]GIMEMA Italian Myeloma Network, Bergamo, [5]GIMEMA Italian Myeloma Network, Catania, [6]GIMEMA Italian Myeloma Network, Torino, [7]GIMEMA Italian Myeloma Network, Ancona, [8]GIMEMA Italian Myeloma Network, Milano, [9]GIMEMA Italian Myeloma Network, Bolzano, [10]GIMEMA Italian Myeloma Network, Cagliari, [11]GIMEMA Italian Myeloma Network, Foggia, [12]GIMEMA Italian Myeloma Network, Reggio Emilia, [13]GIMEMA Italian Myeloma Network, Treviso, [14]GIMEMA Italian Myeloma Network, Napoli, Italy

Background: The phase 3 GIMEMA-MMY-3006 study comparing bortezomib-thalidomide-dexamethasone (VTD) *versus* thalidomide-dexamethasone (TD) as induction therapy before, and consolidation after, double autologous stem-cell transplantation (ASCT) for newly diagnosed multiple myeloma (MM) provided demonstration of prolonged PFS, but not OS, for patients randomized to the VTD arm (Cavo M *et al.*, Lancet 2010; Blood 2012). Based on superior rates of high quality response and PFS, a bortezomib-based triplet is currently considered as the standard induction therapy for ASCT-eligible MM patients. However, no data from prospective phase 3 trials have so far shown an OS benefit from incorporation of bortezomib and an immunomodulatory into ASCT.
Aims: The current analysis was aimed at evaluating long term results of the GIMEMA-MMY-3006 study.
Methods: Overall, 474 patients were included in the trial, and of these 236 were randomized to VTD and 238 to the TD arm. Median follow-up for surviving patients was 92.8 months (IQR: 59.6-123.0). Analyses were performed on an intention-to-treat basis.
Results: Median PFS was 56.5 months for patients randomly assigned to the VTD arm, and 41.3 months for those in the TD group (HR=0.66, p<0.001). PFS benefit with VTD was seen for patients with ISS stage II-III (HR=0.68, p=0.007) and ISS stage I (HR=0.60, p=0.005), as well as for those with t(4;14) and/or del(17p) positivity (HR=0.45, p<0.001) and negativity (HR=0.66, p=0.003). Median OS was not yet reached in the VTD arm and was 118.6 months in the TD arm (HR=0.71, p=0.024), representing a 29% reduction in the risk of death with incorporation of VTD into double ASCT (Figure 1).

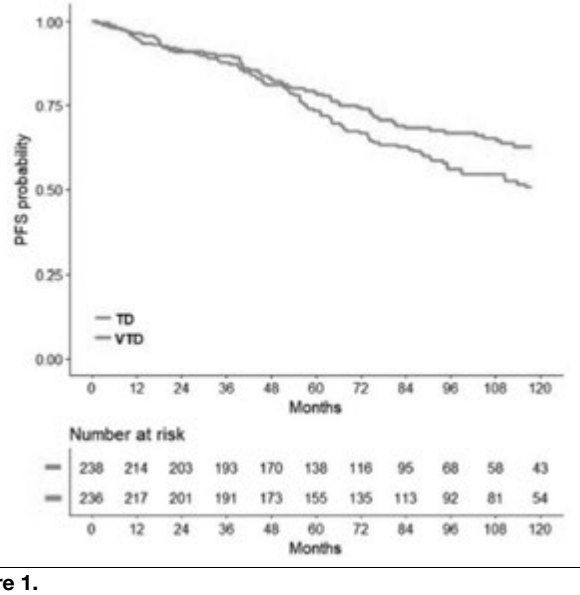

Figure 1.

Estimated rates of OS at 93 months were 67.6% and 58.5%, respectively. Superior OS benefit with VTD over TD was retained across prespecified subgroups of patients with both high-risk and low-risk disease, including those with ISS stages III (HR=0.52, p=0.056), ISS stage I (HR=0.56, p=0.033) and cytogenetics by FISH. In particular, VTD significantly prolonged the OS of patients with both t(4;14) and/or del(17p) positivity (HR=0.57, p=0.031) and negativity (HR=0.66, p=0.034). On multivariate Cox regression analysis, randomization to VTD was an independent factor predicting for prolonged PFS (HR=0.62, p<0.001) and OS (HR=0.61, p=0.001). Additional disease-related variables with a favorable impact on PFS and OS were absence of t(4;14) and/or del(17p) (HR=0.50, p<0.001; HR=0.49, p<0.001), and β2-microglobulin <3.5 mg/L (HR=0.60, p<0.001; HR=0.51, p<0.001). Further analyses of PFS2, time to second anti-MM therapy, and second primary malignancies will be presented at the meeting.
Summary and Conclusions: With an extended median follow-up of 7.6 years, a persistent PFS benefit with incorporation of VTD into ASCT was confirmed. Moreover, a longer OS from primary randomization to VTD *versus* TD was demonstrated in the overall population, as well as in subgroups of patients with high risk and low risk MM.

S106

AUTOLOGOUS STEM CELL TRANSPLANTATION IS SAFE AND EFFECTIVE FOR OLDER MYELOMA PATIENTS: RESULTS FROM THE MYELOMA XI TRIAL

C. Pawlyn[12,*], F. Davies[3], A. Striha[4], D. Cairns[4], J. Jones[1], B. Kishore[5], M. Garg[6], C. Williams[7], K. Karunanithi[8], J. Lindsay[9], M. Jenner[10], G. Cook[11], N. Russell[7], M. Drayson[12], M. Kaiser[12], R. Owen[13], W. Gregory[4], G. Morgan[3], G. Jackson[14]

Background: The introduction of high-dose therapy with autologous stem cell transplant (ASCT) for myeloma patients in the early 2000s led to a significant improvement in outcomes. Despite the further advances made with the introduction of novel agents, ASCT remains the standard of care for all eligible patients. Initial ASCT studies recruited only patients aged less than 65 years, but registry data suggests a recent increase in transplants for patients aged 65-75. There are few studies that directly compare ASCT to no ASCT in this age group and the upper age limit for ASCT in routine clinical practice varies around the world.
Aims: We sought to evaluate the outcomes of older patients receiving ASCT within the UK NCRI Myeloma XI trial.
Methods: The Myeloma XI trial, recruited patients to two pathways; one for younger/fitter patients considered transplant eligible (TE) and one for transplant ineligible patients (TNE). The choice of pathway was determined on an individual basis, based on performance status, clinician judgment and participant preference. Patients were randomized to receive either thalidomide or lenalidomide combined with cyclophosphamide and dexamethasone (CTD *vs* CRD, dose attenuated for TNE) for a minimum of 4 (TE) or 6 (TNE) cycles and to maximum response. Some patients with a suboptimal response received further induction therapy with a proteasome inhibitor based triplet (CVD). TE patients were planned to receive 200mg/m^2 melphalan prior to ASCT. There was a maintenance randomization to lenalidomide, lenalidomide/vorinostat or observation. This post-hoc analysis compared outcomes for TE patients of different ages and those of age-matched TNE patients.
Results: 2042 patients were recruited to the TE pathway of the study with median age 61 years(y), range 28-75. 27% (546/2042) of TE patients were aged 65-69y and 5% (101/2042) aged 70-75y. Older patients were less likely to ultimately undergo ASCT than younger patients, despite having entered the TE pathway, (<65y 67%, 65-69y 55%, ≥70y 44%). The reasons given for not undergoing ASCT were more often related to patient fitness in those over 65y. Median CD34+ cell collection also decreased with age from 4.6x10^6 <65y to 3.8 x10^6 65-69y to 3.1x10^6≥70y. For those patients who underwent ASCT having entered the TE pathway (<65y n=931, 65-69y n=299 and ≥70y n=44) median PFS shortened with increasing age but overall survival was not significantly different (Median PFS: <65y

46.5months, 65-69y 38.7m, ≥70y 30.1m and OS: <65y 69m, 65-69y 63.8m, ≥70y not reached). There was no difference in 100-day post ASCT mortality between age groups.
1852 patients were concurrently recruited to the TNE pathway with median age 74y, range 54-92. The TE and TNE patients' ages overlapped as shown in Figure 1. We defined a group of best-age-matched patients between the TE and TNE pathways that comprised 389 TE patients who received ASCT (TE-ASCT), 310 TE patients who did not (TE-noASCT) and 382 TNE patients. Patients undergoing transplantation had significantly improved outcomes compared to those that did not, irrespective of whether ASCT had been initially planned (Median PFS: TE-ASCT 42.9m, TE-noASCT 15.9m, TNE 17.2m and Median OS: TE-ASCT 63.8m, TE-noASCT 46,1m, TNE 45.8m). These differences were independent of the use of ongoing maintenance therapy.

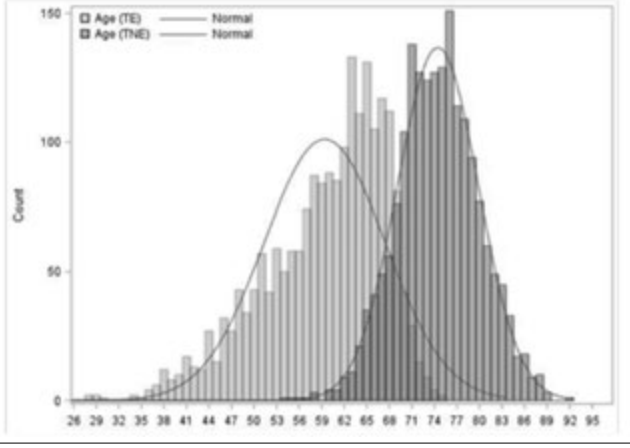

Figure 1. Histogram of age distribution in the TE and TNE pathways of the Myeloma XI trial.

Summary and Conclusions: Our data suggests that ASCT improves outcomes for newly diagnosed myeloma patients and supports its use as standard of care for all considered able to tolerate the procedure, without strict age limits.

Background: Daratumumab (D) plus VMP (D-VMP) prolonged progression-free survival compared with VMP and was well-tolerated in the phase 3 ALCYONE study (NCT02195479).
Aims: We examined the efficacy and safety profiles of D-VMP *vs* VMP in elderly (≥75 years of age) and non-elderly (<75 years of age) newly diagnosed multiple myeloma patients in ALCYONE.
Methods: Patients were 65 years of age or older or otherwise ineligible for high-dose chemotherapy with autologous stem cell transplantation. Patients received up to nine 6-week VMP cycles (V: 1.3 mg/m^2 subcutaneously Days 1, 4, 8, 11, 22, 25, 29, 32 [Cycle 1] and Days 1, 8, 22, 29 [Cycles 2-9]; M: 9 mg/m^2 orally and P: 60 mg/m^2 orally Days 1-4 [Cycles 1-9]) with or without D (16 mg/kg intravenously QW for Cycle 1, Q3W for Cycles 2-9, and Q4W for Cycles 10+ [post VMP-treatment phase] until progression). Minimal residual disease was assessed by clonoSEQ® assay (Adaptive Biotechnologies).
Results: 706 (350 D-VMP; 356 VMP) patients were randomized, including 211 patients ≥75 years of age (104 D-VMP; 107 VMP) and 495 patients <75 years of age (246 D-VMP; 249 VMP). For D-VMP *vs* VMP, the median duration of study treatment was 14.5 months *vs* 12.0 months for patients ≥75 years of age and 15.0 months *vs* 12.0 months for patients <75 years of age, respectively. The cumulative dose of bortezomib was 43.1 mg/m^2 and 34.1 mg/m^2 with D-VMP and VMP, respectively, for patients ≥75 years of age, and 48.6 mg/m^2 and 46.2 mg/m^2 with D-VMP and VMP, respectively, for patients <75 years of age.After median follow-up of 16.5 months, progression-free survival was prolonged with D-VMP *vs* VMP both in patients ≥75 years of age (median not reached [NR] *vs* 20.4 months; hazard ratio [HR] 0.53; 95% confidence interval [CI] 0.32-0.85) and patients <75 years of age (median NR *vs* 17.9 months; HR 0.49; 95% CI 0.36-0.68). Overall response rate (ORR) and ≥complete response (CR) rates were consistently higher for D-VMP *vs* VMP in patients ≥75 years of age (ORR: 88% *vs* 70%; ≥CR: 41% *vs* 24%) and <75 years of age (ORR: 92% *vs* 76%; ≥CR: 43% *vs* 25%). Minimal residual disease-negative rates (10^{-5}threshold) also increased with D-VMP *vs* VMP in patients ≥75 years of age (24% *vs* 8%) and <75 years of age (22% *vs* 6%).Rates of most common grade 3/4 (≥10%) treatment-emergent adverse events, peripheral sensory neuropathy, and infections are presented in the Table 1. D-associated infusion-related reactions were 36% (9% grade 3/4) in patients ≥75 years of age and 24% (3% grade 3/4) in patients <75 years of age.

Table 1.

	Total population		≥75 years of age		<75 years of age	
Grade 3/4, %	D-VMP	VMP	D-VMP	VMP	D-VMP	VMP
Most common TEAEs						
Neutropenia	40	39	52	42	35	38
Thrombocytopenia	34	38	51	43	28	35
Anemia	16	20	24	23	13	19
Leukopenia	8	9	13	9	6	9
Lymphopenia	8	6	10	10	7	4
Pneumonia	11	4	18	9	9	2
Peripheral sensory neuropathy	1	4	0	6	2	3
Infections	23	15	28	20	21	13

Summary and Conclusions: The efficacy of D-VMP *vs* VMP in patients ≥75 years of age was consistent with the overall study population. Furthermore, D in combination with VMP demonstrated acceptable tolerability regardless of age.

S108

CONSOLIDATION FOLLOWED BY MAINTENANCE *VS* MAINTENANCE ALONE IN NEWLY DIAGNOSED, TRANSPLANT ELIGIBLE MULTIPLE MYELOMA: A RANDOMIZED PHASE 3 STUDY OF THE EUROPEAN MYELOMA NETWORK (EMN02/HO95 MM TRIAL)

Background: The role of up-front consolidation therapy for newly diagnosed, transplant-eligible MM (NDMM) patients has not been prospectively addressed in the novel agent era.
Aims: To investigate the efficacy of consolidation therapy in NDMM patients following intensification therapy with VMP or HDM.
Methods: The EMN02/HOVON-95 trial was designed to compare [randomization (R) 1] intensification therapy with 4 cycles of bortezomib-melphalan-prednisone (VMP) *vs* high-dose melphalan (HDM) and autologous stem cell transplantation (ASCT), either single or double, after induction with bortezomib-cyclophosphamide-dexamethasone (VCD) (M. Cavo *et al.* ASCO 2016, abstract #8000; ASH 2017, abstract #397). A second randomization to consolidation therapy with bortezomib-lenalidomide-dexamethasone (VRD) *vs* no consolidation (R2) was performed after intensification, to be followed by lenalidomide maintenance until progression or toxicity in both arms. Primary study end points were progression-free survival (PFS) from R1 and PFS from R2. The second planned interim analysis for R2 was performed in February 2018 when at least 66% (= 343) of the required events for PFS had been observed.
Results: From February 2011 to April 2014, 1510 pts aged ≤65 years with symptomatic MM were enrolled, of whom 1499 were eligible. Of these, 1211 were randomized (stratification by ISS stage) to VMP (505 pts) or HDM (1 or 2 ASCT) (706 pts). For R2 892 eligible patients were randomized to no consolidation (arm A; 437 pts) or VRD consolidation (arm B; 455 pts). Median follow up from R2 was 42 months (mo) (IQR 32-49, maximum 71). Investigator assessed response status at time of R2 was ≥CR (20%), ≥VGPR (67%), ≥PR (92%). At the time of analysis, 366 events for PFS after R2 had been reported. 5-year PFS from R2 was 44% in all patients (median 55 mo), 41% in arm A (median 45 mo) and 48% in arm B (median 59 mo). PFS from R2 with adjustment for R1 was prolonged in pts randomized to VRD consolidation (HR=0.77; 95% CI=0.63-0.95; P=0.014), which is consistent with results of the first interim analysis (P. Sonneveld *et al.* ASH 2016, abstract #242). The PFS benefit from VRD was retained across most predefined subgroups, including revised ISS stage I (Hr=0.77, 95% CI 0.47-1.27) and III (HR=0.76, 95% C 0.40-1.45), low-risk cytogenetics (HR=0.79, 95% CI 0.60-1.05), in patients randomized to either VMP (HR=0.67, 95% CI 0.48-0.94) or HDM (HR=0.84, 95% CI 0.65-1.09), but not in patients with high-risk cytogenetics (del(17p) and/or t(4;14) and/or t(14;16) (HR=1.06, 95% CI 0.70-1.61). At 5 years, OS from R2 was 72% in arm A and 77% in arm B, respectively. Toxicity from VRD was limited with 5% CTCAE grade 4, mainly neutropenia (2%) and thrombocytopenia (2%). The actuarial probability of SPM at 4 years from R2 was 5% *vs* 6% in both arms.
Summary and Conclusions: This second interim analysis confirms the initial promising results of consolidation treatment with VRD followed by lenalidomide maintenance until progression or toxicity as compared to maintenance alone for younger NDMM patients, but further study follow-up is needed. This trial was supported by the Dutch Cancer Society (grant 2010-4798) and by unrestricted grants from Celgene and Janssen.

S109

UPDATED EFFICACY AND MRD DATA ACCORDING TO RISK-STATUS IN NEWLY DIAGNOSED MYELOMA PATIENTS TREATED WITH CARFILZOMIB PLUS LENALIDOMIDE OR CYCLOPHOSPHAMIDE: RESULTS FROM THE FORTE TRIAL

Città della Salute e della Scienza di Torino, Torino, [2]Italian Multiple Myeloma Network, GIMEMA, [3]Myeloma Unit, Division of Hematology, University of Torino, A.O.U. Città della Salute e della Scienza di Torino - Currently Takeda Pharmaceuticals Co., Torino, Italy

Background: Proteasome inhibitor-based induction is the standard of care in newly diagnosed multiple myeloma (NDMM) patients eligible for melphalan 200 mg/m^{2}followed by autologous stem cell transplant (MEL200-ASCT), but the treatment of patients with high-risk disease still represents an unmet medical need. The second-generation proteasome inhibitor Carfilzomib proved to be effective, either in combination with Lenalidomide-Dexamethasone (KRd) or with Cyclophosphamide-Dexamethasone (KCd).
Aims: The primary endpoint of this analysis was to evaluate the response rate of KRd *vs* KCd induction. Secondary endpoints were: 1) rate of minimal residual disease (MRD) negativity with KRd *vs* KCd; 2) efficacy of KRd *vs* KCd in different subgroups of patients according to baseline prognostic features: International Staging System (ISS), chromosomal abnormalities, and Revised-ISS (R-ISS).
Methods: NDMM patients ≤65 years were randomized (1:1:1; stratification ISS and age) to ARM A: 4 28-day induction cycles with KCd (carfilzomib 20/36 mg/m^2 IV days 1,2,8,9,15,16; cyclophosphamide 300 mg/m^2 days 1,8,15; dexamethasone 20 mg days 1,2,8,9,15,16) followed by MEL200-ASCT and consolidation with 4 KCd cycles; ARM B: 4 28-day cycles with KRd (carfilzomib 20/36 mg/m^2 IV days 1,2,8,9,15,16; lenalidomide 25 mg days 1-21; dexamethasone 20 mg days 1,2,8,9,15,16) followed by MEL200-ASCT and 4 KRd cycles; ARM C: 12 KRd cycles. Primary endpoint was very good partial response (VGPR) rate with KRd *vs* KCd induction. MRD evaluation - 8 color second generation flow cytometry, sensitivity 10^{-5} - was performed. For this analysis, the 2 KRd groups were pooled (2:1), since the treatment was the same until that point. Enrollment was completed in March, 2017. Data cut-off was November 30, 2017.
Results: 474 patients were randomized (KRd, n=315; KCd, n=159) and analyzed. Patients characteristics were well balanced with 49% KRd *vs* 49% KCd patients presenting at baseline with ISS Stage II/III, 31% *vs* 35% with high-risk chromosomal abnormalities [del17 and/or t(4;14) and/or t(14;16) detected by FISH], and 68% *vs* 74% with R-ISS Stage II/III disease. Rates of stringent complete response (sCR)/complete response (CR) (14% *vs* 4%; P=0.0004), ≥near CR (nCR) (33% *vs* 21%; P=0.0106) and ≥VGPR (75% *vs* 60%; P=0.0017) were significantly higher with KRd *vs* KCd. Partial response rate was 97% with KRd and 91% with KCd and only 1% of patients in each group was primary refractory. The advantage of KRd *vs* KCd was consistent in all the analyzed subgroups (Figure 1, Panel A). MRD evaluation was available in a subset of patients (144 KRd patients and 56 KCd patients). Rate of MRD negativity on evaluable patients was 56% with KRd *vs* 29% with KCd (P=0.008). MRD negativity in high-risk patients treated with KRd was comparable to the overall population (Figure 1, Panel B). Treatment was well tolerated, as previously presented (Gay F. ASCO 2017).

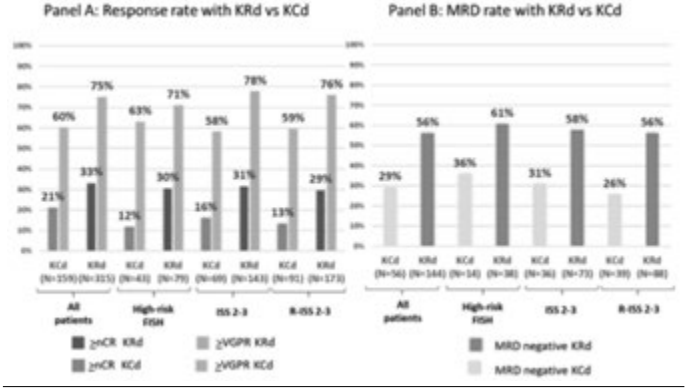

Figure 1.

Summary and Conclusions: K-based induction in transplant-eligible patients is well tolerated and induces deep responses. KRd induction significantly improved sCR/CR, ≥nCR and ≥VGPR *vs* KCd. Rate of MRD negativity on evaluable patients was also higher with KRd. The regimen was similarly effective in high-risk patients, currently representing an unmet medical need.

Hodgkin lymphoma: Clinical studies

Mondor, Creteil, France

Background: Escalated BEACOPP (BEAesc) improves PFS but not OS in pts with advanced Hodgkin Lymphoma (HL) compared to ABVD and is associated to a higher risk of hematological toxicity, secondary leukemia and infertility.
Aims: We hypothesized that PET performed after 2 cycles of upfront BEAesc (PET2) could identify early responding patients who might benefit from a strategy of dose intensity de-escalation, without impairing the disease control.
Methods: The AHL 2011 trial (NCT01358747) was designed to evaluate in 16 to 60 y old HL pts with stage III, IV or high risk IIB, a treatment strategy driven by PET after 2 BEAesc cycles, delivering 4 cycles of ABVD for PET2 negative pts and 4 cycles of BEAesc for PET2 positive pts. This PET driven strategy (arm B) was randomly compared to a standard treatment not adapted by PET delivering 6 cycles of BEAesc (arm A). The allocation of treatment in the experimental arm was based on the central review of PET2 interpreted according to Deauville criteria within 48 hours. PFS was the primary endpoint of the study with a hypothesis of non-inferiority of the PET driven arm compared to the standard arm.
Results: From May 2011 to May 2014, 823 pts were registered including 413 and 410 pts in the arms A and B respectively. Pts characteristics were well balanced in both arms: median age was 30 y, 63% were male, 74% had nodular sclerosis HL, 11% stage IIB, 28% stage III, 60% stage IV, and 58% an IPS ≥3.PET2 positivity rate was similar in arms A (12%) and B (13%). Based on PET2 results, 346 (84%) pts received 4 cycles of ABVD and 51 (12%) 4 additional cycles of BEAesc in the experimental arm.The treatment toxicity was significantly higher in pts receiving 6 cycles of BEAesc compared to those who received 2 cycles of BEAesc + 4 cycles of ABVD with more frequent grade ≥3 AE (anemia (11% *vs* 2%), leukopenia (85% *vs* 74%), thrombocytopenia (44% *vs* 15%), and sepsis (7% *vs* 3%). 204 serious adverse events (SAE) related to treatment occurred in 119 (26%) patients treated with 6 cycles of BEAesc (leading to death in 6 cases), compared to 102 SAE (leading to death in 2 cases) in 62 (17%) patients treated with 2 x BEAesc + 4 x ABVD (p<0.003). In these latter patients most of SAE (66%) occurred during the 2 first cycles of chemotherapy. With a median follow up of 50 months, the estimated 4y-PFS was similar in the standard (87.4%) and the PET driven arms (87.1%; p=0.68). PET2 positivity was related to a significantly lower 4y-PFS compared to PET2 negative patients in the whole population (70.7% *vs* 90.4%; p<0.0001) and in both randomization arms (75.1% *vs* 94% and 70.8% *vs* 91.6% in the standard and PET driven arms, respectively; p<0.0001 for both). OS was similar in both arms.
Summary and Conclusions: PET performed after 2 cycles of BEAesc can be safely used to guide subsequent treatment and supports the response-adapted strategy delivering 4 cycles of ABVD for pts with negative PET2 reducing the treatment-related immediate toxicity without impairing the disease control. PET positivity after 2 cycles of BEAesc is related to a higher risk of disease progression, encouraging to develop new treatment options in patients with PET2 positive advanced stage HL.

S111

PRETREATMENT VITAMIN D DEFICIENCY IS ASSOCIATED WITH LOWER PROGRESSION-FREE AND OVERALL SURVIVAL IN PROSPECTIVELY TREATED HODGKIN LYMPHOMA

S. Borchmann[123,*], H. Görgen[1], S. Sasse[1], S. Kreissl[1], P.J. Bröckelmann[1], B. von Tresckow[1], M. Fuchs[1], V. Diehl[1], A. Engert[1]

[1]Department I for Internal Medicine and German Hodgkin Study Group (GHSG), [2]Center for Molecular Medicine Cologne (CMMC), [3]Else Kröner Forschungskolleg Cologne, University of Cologne, Köln, Germany

Background: Vitamin D (25-OHD, VD) deficiency has been associated with a poor prognosis in a wide range of cancers. For Hodgkin lymphoma (HL), no data on pretreatment VD levels and their correlation with patient characteristics and outcome exists. Biologically, VD deficiency might render the characteristic T-cell rich microenvironment of HL more tumor-supportive due to a diminished anti-tumor T-cell response (von Essen, 2010).
Aims: To test the hypothesis that pretreatment VD deficiency reduces progression-free survival (PFS) and overall survival (OS) in HL.
Methods: Between 1998 and 2003, the GHSG prospectively recruited 2653 patients of all stages in the GHSG trials HD7, HD8 and HD9. The enriched analysis cohort included all patients with available pretreatment serum sample and documented progression or relapse (N=118), as well as two relapse-free patients each matched by trial and treatment arm (N= 236). VD was measured with a commercially available ELISA. Serum VD levels were categorized according to the Institute of Medicine, Food and Nutrition board (IOM) guidelines defining <30nmol/l as deficient, 30 to 50 nmol/l as insufficient and ≥50nmol/l as sufficient. VD levels and their correlation with other baseline characteristics and outcomes were analyzed descriptively and by linear or logistic regression where applicable. PFS and OS were analyzed with Kaplan-Meier methods and Cox regression; analyses were weighted to attain event rates of the total study cohort. All statistical tests were stratified by trial and treatment arm to account for the matched structure of the analysis cohort.
Results: VD levels could be quantified in 351/354 patients in the analysis cohort. VD levels did not correlate with age, sex, clinical stage, a large mediastinal mass, extranodal involvement, presence of 3 or more nodal areas, elevated ESR, B-symptoms, Karnofsky index, IPS, trial or treatment arm and thus were independent of tumor mass, the patients' clinical condition and the received treatment. VD levels were highly dependent on the season of diagnosis with median levels of 27.7, 42.9, 30.8 and 22.0 nmol/l for spring, summer, autumn and winter, respectively. Thus, according to the IOM cutoffs, 55%, 34%, 48% and 55% of patients diagnosed in spring, summer, autumn and winter, respectively, were deficient (p<0.0001 for summer *vs* other). Patients with progression or relapse had a lower median VD level than relapse-free patients (21.4 *vs* 35.5 nmol/l) and were more often deficient (68% *vs* 41%, p<0.0001). Similar trends were observed across all treatment arms. With a median observation time of 156 months, a lower 5-year PFS rate in deficient patients compared to non-deficient patients was observed (74.4% [95%>CI: 66.9-81.8] *vs* 84.6% [95%>CI: 78.9-90.3]) (Figure 1). In a multivariate Cox regression adjusted for season of diagnosis, age and sex, VD deficiency was associated with higher risk for a PFS event (HR: 2.13 [95%>CI: 1.84-2.48], p<0.0001). This difference also translated into a clinically significant OS difference with VD deficiency associated with a higher risk for death in a similarly adjusted Cox regression (HR: 1.82 [1.53-2.15], p<0.0001). More deaths in the VD deficient group were HL-related than in the non-deficient group.

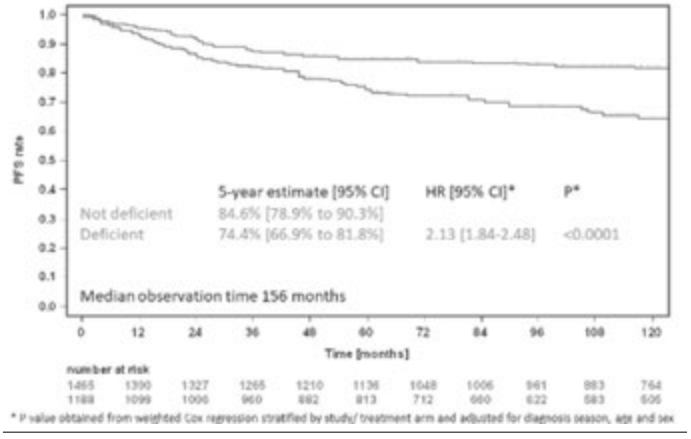

Figure 1.

Summary and Conclusions: Pretreatment VD is a modifiable, independent baseline risk factor for poorer outcome of HL in the present analysis. Supplementation with VD is cheap, generally safe and could potentially improve outcomes in HL patients. Interventional, ideally randomized studies should evaluate VD supplementation as an add-on treatment in HL.

Background: Primary results of the randomized, phase 3, ECHELON-1 study demonstrated a significant improvement in modified progression-free survival (mPFS), per independent review facility (IRF), in patients with stage III and IV cHL treated with frontline A+AVD *vs* doxorubicin, bleomycin, vinblastine, dacarbazine (ABVD). At 2 years, the mPFS rates were 82.1% (95% CI, 78.8 to 85.0) *vs* 77.2% (95% CI, 73.7 to 80.4), respectively, a 4.9% point difference (Hazard Ratio [HR] 0.77; 95% CI: 0.60-0.98; p=0.0351). We report data from pre-specified high risk subgroups of the ECHELON-1 data.
Aims: This prespecified subanalysis assessed the efficacy and safety of A+AVD *vs* ABVD in patients with cHL and high risk features including: ≥1 extranodal site of involvement, stage IV disease, or an International Prognostic Factor Project (IPFP) score of 4-7.
Methods: Patients were randomized 1:1 to receive up to six 28-day cycles of A+AVD (brentuximab vedotin 1.2 mg/kg, doxorubicin 25 mg/m^2, vinblastine 6 mg/m^2, dacarbazine 375 mg/m^2) or ABVD (AVD regimen + bleomycin 10 units/m^2) intravenously on Days 1 and 15 of each cycle. Patients were analyzed by Stage at diagnosis (III *vs* IV), IPFP score (0-1 *vs* 2-3 *vs* 4-7), and number of extranodal disease sites (0 *vs* 1 *vs* ≥1). The sub-group analyses were performed on the primary endpoint of mPFS (defined as time to progression, death, or evidence of non-complete response after completion of frontline therapy followed by subsequent anticancer therapy).
Results: In total, 664 and 670 patients were randomized to A+AVD and ABVD, respectively. High risk features at baseline were well balanced between treatment group with 64% and 63% having stage IV disease, 25% and 27% having an International Prognostic Score (IPS) of 4-7 in the A+AVD and ABVD arms respectively, 62% in each arm had ≥1 extranodal sites at baseline. Most prespecified subgroups demonstrated a consistent trend toward benefit with A+AVD. A+AVD showed the most improved mPFS compared with ABVD in the following sub-groups (Table 1): stage IV disease (2-year mPFS 82.0% *vs* 75.3% [HR=0.71, 95% CI: 0.53–0.96; p=0.023]), >1 extranodal sites (2-year mPFS 80.2% *vs* 71.1% [HR=0.67, 95% CI: 0.44-1.00; p=0.049], ≥1 extranodal sites (2-year mPFS 82.4% *vs* 74.9% [HR=0.70, 95% CI: 0.52-0.94; p=0.02]). Patients with an IPS of 4-7 also had a favorable improvement in mPFS with A+AVD (77.0% *vs* 69.2% [HR=0.70, 95% CI: 0.46-1.07; p=0.097]). Efficacy and safety analyses for combinations of high risk sub-groups will be presented in full.
Summary and Conclusions: Compared with standard ABVD, A+AVD in frontline trends favorably for mPFS outcomes for patients with high risk cHL (Stage IV disease, or ≥1 extranodal disease sites, or IPS of 4–7) and the mPFS benefit for high risk patients is more than the ITT population. These results suggest that patients with high risk cHL might have a greater treatment benefit with A+AVD compared with ABVD.

Table 1. mPFS by patient sub-groups.

Baseline characteristics		A+AVD vs ABVD Hazard Ratio (95% CI)	P-value
Ann Arbor stage	Stage III	0.92 (0.60–1.42)	p=0.712
	Stage IV	0.71 (0.53–0.96)	p=0.023
IPS	0–1	0.84 (0.47–1.49)	p=0.548
	2–3	0.79 (0.55–1.12)	p=0.183
	4–7	0.70 (0.46–1.07)	p=0.097
Extranodal sites	0	1.04 (0.67–1.62)	p=0.856
	1	0.75 (0.48–1.16)	p=0.191
	>1	0.67 (0.44–1.00)	p=0.049
	≥1*	0.70 (0.52-0.94)	p=0.018

*ad hoc analysis. IPS, International Prognostic Score.

BRENTUXIMAB VEDOTIN + ESHAP (BRESHAP) FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANT: HIGH COMPLETE REMISSION RATE AND LONG-TERM TIME TO TREATMENT FAILURE IN REFRACTORY/RELAPSED HODGKIN LYMPHOMA

R. Garcia-Sanz[1,*], A. Sureda[2], F. De la Cruz[3], A.P. González[4], A. Rodríguez[5], B. Sánchez-González[6], E. Domingo[2], M. Moreno[7], J. López[8], J.L. Piñana[9], G. Rodríguez-Macías[10], M. Canales[11], A. Gutierrez[12], M.J. Rodríguez Salazar[13], M.D. Caballero[1], C. Martínez[14]

[1]Hematology, University Hospital of Salamanca, Salamanca, [2]Hematology, Hospital Duran i Reynals, Barcelona, [3]Hematology, Hospital Virgen del Rocío, Sevilla, [4]Hematology, Hospital Central de Asturias, Oviedo, [5]Hematology, Hospital 12 de Octubre, Madrid, [6]Hematology, Hospital del Mar, Barcelona, [7]Hematology, Hospital Germans Trias i Pujol, Badalona, [8]Hematology, Hopital Ramón y Cajal, [9]Hematology, Hospital Clínico de Valencia, [10]Hematology, Hospital Gregorio Marañón, [11]Hematology, Hospital Universitario la Paz, Madrid, [12]Hematology, Hopsital Son Espases de Mallorca, Palma de Mallorca, [13]Hematology, Hospital Universitario de Canarias, Santa Cruz de Tenerife, [14]Hematology, Hospital Clínic i Provincial, Barcelona, Spain

Background: Refractory or Relapsed Hodgkin Lymphoma(RRHL) are treated with Salvage therapy and Autologous Peripheral Blood Stem Cell Transplantation (APBSCT). The addition of brentuximab vedotin (BV) is feasible and increases the CR rate.
Aims: To evaluate long-term results of a phase II trial with the combination of BV and ESHAP chemotherapy [BRESHAP] as 2nd line therapy for RRHL prior to APBSCT (ClinicalTrials.gov #NCT02243436).
Methods: Primary efficacy endpoint was complete responses (CR) pre-APBSCT after **BR**entuximab vedotin, **E**toposide, **S**olumedrol, **H**igh dose **A**raC and cis**P**latin.
Results: Patients with relapsed or refractory classical HL (cHL) after one prior line of therapy were eligible. 66 patients were included in the trial. There were 35 females and 31 males, with a median age of 36 years (18-66). At inclusion, 40 patients were primary refractory, 16 early relapses (CR ≤1 year) and 10 as late relapses (CR >1 year). In this update, all patients have completed all the protocol. During the follow-up, there have been 39 Severe Adverse Events (SAEs) reported in 22 patients (hospitalizations and AEs around transplant were not considered SAEs). Most frequent were fever (n=25, 35% neutropenic), hypomagnesemia and gastrointestinal alterations (n=3). There were 3 SAEs, terminating in death: pneumonia, abdominal sepsis and pulmonary embolism. Apart from APBSCT, there grade 3-4 hematologic toxicity presented in 28 cases: neutropenia (n=21), thrombocytopenia (n=14), and anemia (n=7). Grade 3-4 extra-hematologic adverse events present in ≥5% of cases were non-neutropenic fever (n=13) and hypomagnesemia (n=3). All patients except two underwent stem cell mobilization after the 1st (n=15), 2nd (n=36) or 3rd (n=13) cycle using subcutaneous G-CSF 5 mcg/Kg/12 h. for 5 days. All 64 patients collected >2·10e6/Kg peripheral blood CD34+ cells in all cases (median 5.75, range 2.12-33.4). The number of harvesting procedures was one in 48 patients, two in 13, three in 2 and four in 1. The transplant was done after BRESHAP in 61 patients: all engrafted with a median of 11 & 12 days for neutrophil and platelet recovery, respectively. Four other patients were transplanted after receiving

other therapies. No major events were registered during transplant period, except for the patient who died at day +110 due to pneumonia. Overall pre-transplant response was 93%, including a 71% and 22% complete and partial remission rates, respectively. Six patients were considered as non-responders: one who died before any evaluation, two who stable disease and three progressions. Status 3-months after the transplant was CR in 48 patients, PR in 6, SD in 2 and PD in 5. Three doses of BV were given in 50 patients; the remaining 16 patients did not receive the projected consolidation due to toxicity (cytopenias, n=6; neuropathy, n=1), progression (n=6), patient refusal (n=2) and death (n=1). At a mean follow-up of 27 months, 13 patients have progressed and 3 have died without progression, providing 3-year time to treatment failure and progression free survival of 75% and 71%, respectively. Six patients died: 3 due to progression, and the 3 already mentioned. Projected overall survival is 91% at one year.

Summary and Conclusions: BRESHAP is a highly effective regimen for remission induction prior to transplant, which maintains it in patients with refractory or relapsed Hodgkin lymphoma.

Background: Front-line multi-agent chemotherapy cures the majority of patients (pts) with classical Hodgkin lymphoma (cHL). However, pts with advanced-stage (AS) cHL have suboptimal outcomes and the high toxicity of intensive regimens limits their use in elderly/frail pts. Programmed death-1 (PD-1) ligands are commonly overexpressed in cHL and may contribute to an immunosuppressive tumor environment (Roemer MG *et al. J Clin Oncol* 2016;34:2690–7). Nivolumab, an immune checkpoint inhibitor targeting PD-1, enhances T-cell activation and has shown frequent and durable responses in pts with relapsed/refractory cHL after failure of autologous hematopoietic cell transplantation (Armand P *et al.* J Clin Oncol 2018;in press). Addition of nivolumab to chemotherapy may therefore be a promising treatment (Tx) strategy for newly diagnosed (ND) AS cHL.

Aims: To assess the safety and efficacy of nivolumab plus doxorubicin, vinblastine and dacarbazine (N-AVD) in pts with ND AS cHL.

Methods: In CheckMate 205 Cohort D (NCT02181738), pts ≥18 y of age with ND AS (stage IIB with unfavorable risk factors, III, or IV) cHL received 4 doses of nivolumab monotherapy (monoTx; 240 mg IV every 2 wk) followed by N-AVD combotherapy (comboTx; nivolumab 240 mg IV) for 6 cycles (12 doses), after informed consent. Primary endpoint was the proportion of pts with grade (G) 3+ Tx-related adverse events (TRAEs) ≤30 d after last dose. Secondary endpoints included complete remission (CR) rate (International Working Group 2007 criteria); exploratory endpoints included discontinuation rate, objective response rate (ORR, per Independent Radiology Review Committee [IRC]) at end of monoTx, after 2 combocycles, and at end of Tx (EOT), and modified progression-free survival (mPFS; time to progression, death, or first subsequent systemic therapy in pts without CR at EOT).

Results: At database lock (Oct 12, 2017), 51 pts had been treated; median follow-up (FU) was 11 mo. At baseline (BL), median age was 37 y and 31% of pts had bulky disease; at diagnosis, 57% had stage IV disease and 80% had B symptoms. MonoTx was completed by 49/51 (96%) pts and comboTx by 45/50 (90%); 1/5 pts who did not complete comboTx was lost to follow-up. 30 pts (59%) experienced a G3–4 TRAE, including neutropenia/decreased neutrophil count in 25 (49%) and febrile neutropenia (FN) in 5 (10%). 30 pts (59%) received growth factors (GFs), all during comboTx; 90% of GF use was secondary prophylaxis. 8 pts (16%) experienced Tx-related infections (excluding FN). No pneumonitis was reported and median change from BL in hemoglobin-corrected diffusing capacity for carbon monoxide was –3% predicted. The most common G3–4 immune-mediated AE was hepatitis (2 pts; 4%). 4 pts (8%) discontinued due to an AE, 1 G3–4. No G5 TRAEs occurred ≤30 d from last dose; 1 pt (age 68 y) died 38 d after last dose due to study drug toxicity. At EOT, ORR in the ITT population was 84% (67% CR) per IRC and 84% (80% CR) per investigator; 7/12 response-evaluable pts without CR per IRC were deemed in CR per investigator. Nearly all response-evaluable pts showed >50% reduction in tumor burden (Figure 1). Median (range) time to response was 2 (2–5) mo; with a minimum FU of 9 mo, 9-mo mPFS was 94% (95% CI 82, 98).

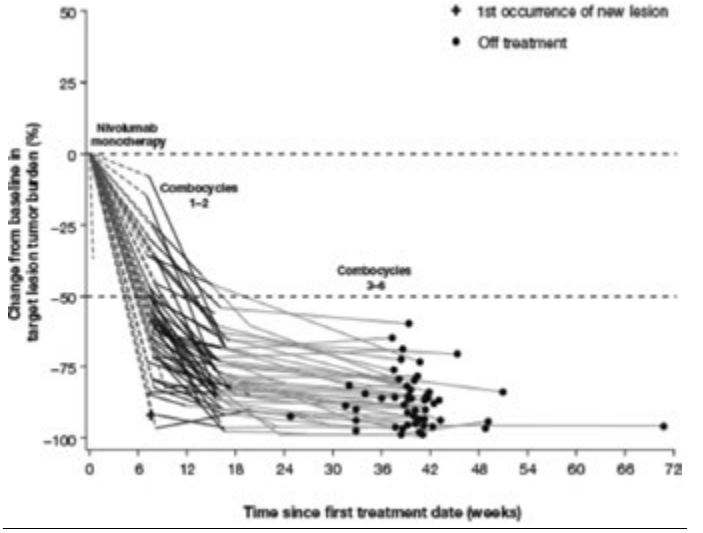

Figure 1. Tumor burden reduction in patients response-evaluable in at least 1 on-study timepoint.

Summary and Conclusions: Nivolumab followed by N-AVD was well tolerated, with a safety profile consistent with previous reports, including a favorable pulmonary toxicity profile. N-AVD had a high ORR, with 67% CR at EOT per IRC. Nivolumab followed by N-AVD warrants further study for ND AS cHL.

Miscellaneous treatments in AML

Background: All-*trans* retinoic acid (ATRA) and arsenic trioxide (ATO) combination therapy has been recently established as the new standard of care for non-high risk acute promyelocytic leukemia (APL). The Italian-German randomized trial APL0406 has first shown that this chemotherapy-free approach is at least not inferior to the ATRA and chemotherapy-based regimen. In addition to significantly improving EFS, OS and CIR rates, ATRA-ATO resulted in considerably reduced hematologic toxicity as compared to ATRA-chemotherapy, while ATO-specific side effects were frequent but manageable.
Aims: We hereby provide a very long-term outcome update (median f.up 66.4 months) on the 276 patients enrolled in APL0406 trial.
Methods: The APL0406 study was a prospective, randomized, multicenter, phase III non-inferiority trial designed by the Italian cooperative group GIMEMA and joined by German groups AMLSG and SAL. Enrolment started in Oct 2007 and was completed in Jan 2013. The present analysis has been performed in February 2018 and data were analyzed following an intent-to-treat principle. The primary objective of the study was EFS. The study enrolled patients aged 18-70 years with newly diagnosed, genetically proven low-intermediate risk APL. Survival distributions were estimated using the Kaplan-Meier method, while cumulative incidence of relapse (CIR) was calculated using the proper nonparametric method. Differences in terms of OS, EFS, and disease-free survival (DFS) were evaluated using the log-rank test. The Gray test was applied to compare cumulative incidence curves. All tests were two-sided.
Results: With a median follow-up of 66.4 months (range: 0.9-116.7), the EFS rate at 72 months for the 263 evaluable patients in the intention-to-treat analysis was 96.6% (95%CI: 93.4-99.9) in the ATRA-ATO group and 77.4% (95%CI: 70.2-85.4) in the ATRA-chemotherapy group (p<0.0001). The total number of events was 28 in the ATRA–chemotherapy (17 relapses, 4 induction deaths, 2 molecular resistant cases and 5 deaths in CR) as compared to the 23 published in the previous report (Platzbecker *et al*., JCO 2016). By contrast, no further events were recorded in the ATRA-ATO group in the present update in addition to the previously reported ones (2 relapses and 2 deaths in CR). Two cases of therapy-related myeloid neoplasms occured in the ATRA-chemotherapy group, while no cases of secondary malignancies were reported in the ATRA-ATO cohort. DFS rate in the ATRA-ATO group was 96.6% (95%CI: 93.4-99.9) and 79.8% (95%CI: 72.7-87.6) in the ATRA-chemotherapy group (p<0.0001) and CIR was 1.7 (95% CI: 0.0-4.0) and 15.5% (95% CI: 9.0-22.0) in the ATRA-ATO and in the ATRA-chemotherapy groups, respectively (p=0.00015). Finally, the OS rate at 72 months was 98.3% (95% CI: 96.0-100.0) and 89.8% (95% CI, 84.3-95.7) in the respective groups (P=0.0040). Survival outcomes are reported in Figure 1.

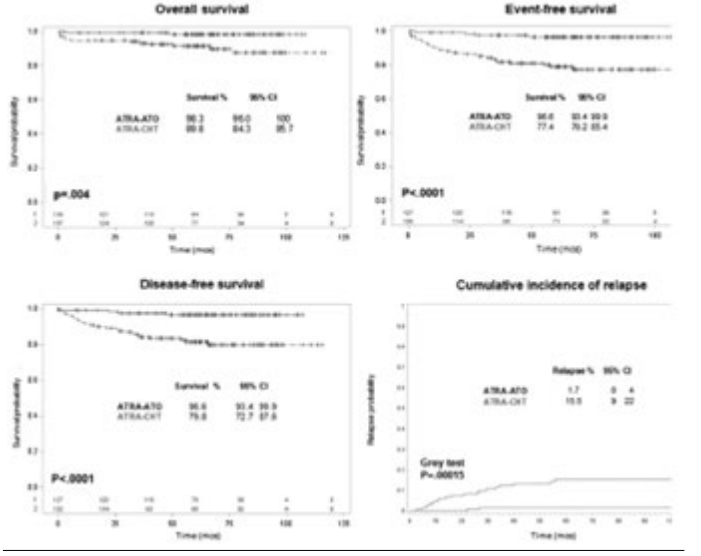

Figure 1.

Summary and Conclusions: This updated analysis of the APL0406 study establishes also in the very long-term the advantage of ATRA-ATO over ATRA-CHT with respect to both efficacy and safety.

S116

RESULTS OF PIVOTAL PHASE 2 TRIAL OF SL-401 IN PATIENTS WITH BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM

N. Pemmaraju[1,*], K. Sweet[2], A. Lane[3], A. Stein[4], S. Vasu[5], W. Blum[5], D. Rizzieri[6], E. Wang[7], M. Duvic[1], S. Spence[8], S. Shemesh[8], J. Chen[8], C. Brooks[8], I. Bergstein[8], P. McDonald[8], T. Goswami[8], J.M. Sloan[9], J. Lancet[2], H. Kantarjian[1], M. Konopleva[1]

[1]The University of Texas MD Anderson Cancer Center, Houston, [2]H. Lee Moffitt Cancer Center, Tampa, [3]Dana-Farber Cancer Institute, Boston, [4]City of Hope National Medical Center, Duarte, [5]The Ohio State University, Columbus, [6]Duke University Medical Center, Durham, [7]Roswell Park Cancer Institute, Buffalo, [8]Stemline Therapeutics, New York, [9]Boston University School of Medicine, Boston, United States

Background: SL-401 is a novel targeted therapy directed to the interleukin-3 receptor-α (CD123), a target expressed on blastic plasmacytoid dendritic cell neoplasm (BPDCN) and other malignancies. BPDCN is a highly aggressive hematologic malignancy with a historical overall survival (OS) of ~8-14 mos from diagnosis. BPDCN has no approved therapies or standard of care, highlighting the need for novel therapeutic approaches. SL-401 was granted Breakthrough Therapy Designation for treatment of BPDCN. Detailed results from the pivotal SL-401 Phase 2 trial in BPDCN will be presented.
Aims: Determine safety and efficacy of SL-401 in patients with BPDCN. Stage 3 was prospectively designed to support potential US registration.
Methods: This pivotal Phase 2 trial of SL-401 is a multicenter, open label, non-randomized, single-arm trial. In Stage 1 (lead-in), first line (1L) and relapsed/refractory (r/r) patients with BPDCN received SL-401 as a daily IV infusion at 7, 9, or 12 mcg/kg/day on days 1-5 of a 21-day cycle. BPDCN patients enrolled in subsequent Stages received SL-401 at the dose determined in Stage 1 (12 mcg/kg). Stage 2 (expansion) enrolled 1L and r/r patients, and Stage 3 (pivotal, confirmatory) enrolled only 1L patients. Enrollment in Stages 1, 2, and 3 has completed.
Results: 45 patients with BPDCN (Stages 1 and 2, n=32; Stage 3, n=13) were enrolled at 7 sites. Median age 70 yrs (range, 22-84 yrs); 82% male. In Stage 1, 12 mcg/kg was the highest tested dose for BPDCN. Median follow-up for all 1L patients treated at 12 mcg/kg (n=29) was 8.7 mos (range

0.2-29.1). The most common treatment-related adverse events (TRAEs) at 12 mcg/kg in Stages 1, 2, and 3 (n=42) were transaminitis (52%), hypoalbuminemia (50%), and thrombocytopenia (38%). TRAEs at 12 mcg/kg across BPDCN and other indications (AML, MPN, and MM) (n=114) were hypoalbuminemia (49%), transaminitis (48%), and thrombocytopenia (29%). Capillary leak syndrome (all grades) has been generally manageable and reversible, and occurred at 12 mcg/kg in 19% (8/42) of patients with BPDCN (Stages 1, 2, and 3) and 20% (23/114) of patients across all indications; 0.9% (1/114) and 2% (3/153) of cases resulted in death across all indications at 12 mcg/kg (n=114) and all doses (n=153), respectively. The Stage 3 pivotal cohort met its primary endpoint with a 54% (7/13) rate of CR+CRc (95% CI: 25.1, 80.8). Across Stages 1, 2 and 3, in 1L patients dosed at 12 mcg/kg (n=29), ORR was 90% (26/29; 95% CI: 72.6, 97.8) with a 72% (21/29; 95% CI: 52.8, 87.3) rate of CR+CRc+CRi (CR=complete response; CRc=clinical CR: absence of gross disease with minimal residual skin abnormality; CRi=CR with incomplete hematologic recovery). 45% (13/29) of patients were bridged to stem cell transplant (SCT) (10 allo+3 auto). Median OS not reached in 1L patients in Stages 1-2 or Stage 3. In r/r patients, ORR was 69% (9/13) with a 38% (5/13) rate of CR+CRc+CRi.

Summary and Conclusions: This pivotal trial of SL-401 in BPDCN met its primary endpoint. In 1L patients dosed at 12 mcg/kg across all 3 stages, ORR was 90% with a 72% rate of CR+CRc +CRi, with 45% of patients bridged to SCT. Across all 3 Stages, SL-401's side effect profile remained manageable and consistent over increasing patient exposure and experience. Based on these positive data, a BLA submission is in preparation. SL-401 is being evaluated in other trials (as single agent and in combination) including CMML, MF, high risk MDS, AML, and MM.

S117

A RANDOMISED EVALUATION OF LOW-DOSE ARA-C PLUS TOSEDOSTAT *VERSUS* LOW DOSE ARA-C IN OLDER PATIENTS WITH ACUTE MYELOID LEUKAEMIA: RESULTS OF THE LI-1 TRIAL

M. Dennis[1,*], R. Hills[2], I. Thomas[3], M. Kallenbach[4], C. Hemmaway[5], P. Greaves[6], M. Copland[7], A. Burnett[8], N. Russell[9]

[1]Department of Haematology, Christie Hospital NHS Trust, Manchester, [2]Centre for Trials Research, Cardiff University, Cardiff, [3]Centre for Trials Research, CARDIFF UNIVERSITY, Cardiff, United Kingdom, [4]Department of Haematology, Aalborg University Hospital, Aalborg, Denmark, [5]Department of Haematology, Auckland City Hospital, Auckland, New Zealand, [6]Department of Haematology, Queen's Hospital, Romford, [7]Institute of Cancer Sciences, University of Glasgow, Glasgow, [8]Blackwaterfoot, Isle of Arran, [9]Department of Haematology, Nottingham University Hospitals, Nottingham, United Kingdom*

Background: Among patients over the age of 60, a considerable number of patients with Acute Myeloid Leukaemia (AML) are not considered for conventional induction chemotherapy, so survival is poor, with only approximately 10% of patients surviving beyond 2 years when treated with standard of care (demethylation agents or low dose ara-C (LDAC)). In the pivotal trials demethylation agents improve median survival, but not overall survival. Therefore there remains a significant unmet need in this patient group. Tosedostat is a selective, oral aminopeptidase inhibitor. Since Phase I/II trials of tosedostat as monotherapy showed acceptable toxicity and potential activity in relapsed AML it was included, combined with LDAC, as an option in the LI-1 "pick-a-winner" trial.

Aims: To assess the efficacy of LDAC+tosedostat *versus* LDAC alone in patients aged 60+ unsuitable for intensive therapy in a "pick-a-winner" design. This design allows several treatments to be assessed simultaneously compared with LDAC in a randomised fashion, with the aim of doubling 2-year survival from 11% to 22% (HR 0.70). There are two interim assessments: after 50 patients per arm are recruited, remission rates must improve by ≥2.5%; the second interim analysis occurs after 170 deaths are seen, when the hazard ratio must be <0.85.

Methods: Tosedostat was given orally at 120mg once a day for up to 6 months. LDAC was given at 20mg bd subcutaneously on days 1-10 of each course, with courses of LDAC occurring at 4-6 wk intervals. To enter the randomisation patients needed to fulfil specific cardiac entry criteria. Toxicities were recorded using NCI-CTC version 3. At the second interim analysis after 183 events tosedostat failed to pass the second assessment, and the arm was therefore closed. Results here are based upon a median follow-up of 18.9 months.

Results: Between 6/2014 and 2/2017, 245 patients, median age 76 years (range 60-88) entered the randomisation. Overall 60% were male; 66% had *de Novo* AML, 28% secondary AML, and 6% high risk MDS; 1% had favourable, 73% intermediate and 26% adverse cytogenetics. By validated Wheatley index, 2% were good risk, 36% standard risk and 63% poor risk. A median of 2 courses was delivered in either arm (mean 2.9 LDAC+tosedostat *vs* 2.3 LDAC).

Overall, complete remission was achieved in 18% of patients (LDAC+tosedostat 22%, LDAC 14%, OR 0.59 (0.31-1.13) p=0.11). Thirty-day mortality was not significantly increased (17% *vs* 13%, HR 1.44 (0.75-2.78) p=0.3); but overall survival showed no difference (2-year OS 16% *vs* 12%, HR 0.99 (0.74-1.32) p=0.9) (Figure 1). Causes of death were: resistant/recurrent disease 39 *vs* 61; infection 20 *vs* 10; haemorrhage 8 *vs* 0; cardiac 5 *vs* 3; multiple 13 *vs* 8; other/unknown 5 *vs* 11. Relapse-free survival did not significantly differ (HR 0.93 (0.41-2.16) p=0.9) with median OS 28.4m *vs* 24.0m in responders (p=0.6); non-remitters had median OS 2.8m *vs* 3.3m (HR 1.20 (0.88-1.63) p=0.2). Stratified analyses failed to identify any subgroup of patients benefitting from tosedostat. Although rates of grade 3+ toxicity were low, tosedostat was associated with diarrhoea, increased cardiac toxicity, and increade use of platelets (mean 5.0 *vs* 3.5 p=0.006).

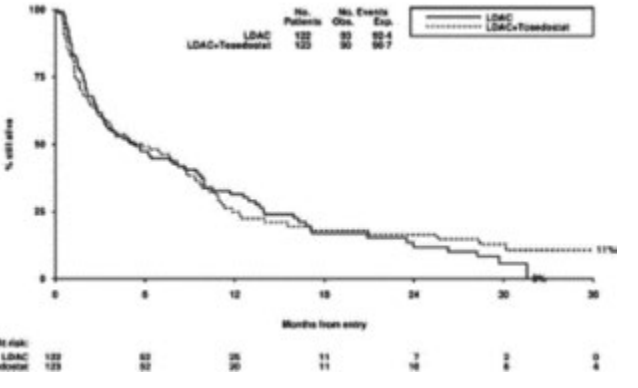

Figure 1. AML LI–1: Overall survival.

Summary and Conclusions: Despite promising early data and acceptable tolerability, we did not find evidence that the addition of tosedostat to LDAC produced a survival benefit in this group of patients, with the anticipated hazard ratio of 0.70 being outside the 95% confidence intervals at second interim analysis. Acknowledgements: We are grateful to CTI Biopharma for providing drug and support for this Investigator Initiated Study.

S118

RESULTS OF A PHASE 1B/2 STUDY OF ENTOSPLETINIB (GS-9973) MONOTHERAPY AND IN COMBINATION WITH INDUCTION CHEMOTHERAPY IN NEWLY DIAGNOSED PATIENTS WITH ACUTE MYELOID LEUKEMIA

A.R. Walker[1,*], J.C. Byrd[1], B. Bhatnagar[1], A. Mims[1], T. Lin[2], H.E. Croswell[3], D. Zhang[4], A.V. Rao[4], M.D. Minden[5], W. Blum[6]

[1]The Ohio State University, Columbus, [2]Kansas City Medical Center, Kansas City, [3]Bon Secours St. Francis Health System, Greenville, [4]Gilead Sciences, Inc., Foster City, United States, [5]Princess Margaret Cancer Centre, Toronto, Canada, [6]Winship Cancer Institute of Emory University, Atlanta, United States

Background: Spleen tyrosine kinase (SYK) is a non-receptor tyrosine kinase primarily expressed in hematopoietic cells. Constitutive activation of SYK in acute myeloid leukemia (AML) has been reported; targeted inhibition of SYK-induced differentiation *in vitro* demonstrated anti-leukemia activity in AML mouse models. SYK promotes leukemogenesis by directly phosphorylating the *FLT3* receptor, and inducing *MEIS1* in conjunction with *HOXA9* to form a regulatory loop in *KMT2A* (mixed lineage leukemia [MLL]) rearranged leukemia. Entospletinib (ENTO) is an orally bioavailable, selective inhibitor of SYK with activity in myeloid and B-lymphoid malignancies.

Aims: Evaluate the efficacy of ENTO in untreated AML patients (pts) as monotherapy followed by ENTO plus standard 7+3 induction chemotherapy (cytarabine 100 mg/m^2/d, days 1-7 plus daunorubicin 60 mg/m^2/d, days 1-3).

Methods: In this phase 1b/2 study (NCT02343939), pts aged 18 to 70 years with previously untreated AML, preserved organ function, and ECOG ≤2 were eligible to receive ENTO 400 mg BID for 14 days as monotherapy lead-in (days -14 to 0) followed by combination with standard 7+3 induction chemotherapy (ENTO+7+3) for a maximum of two induction cycles. Response assessments were made per the modified International Working Group criteria.

Results: Fifty-three pts (n=12 in Phase 1b and n=41 Phase 2) with *de novo*

and secondary AML were enrolled with a median age of 60 (range, 18-78) years. 58% pts were male and per the 2010 European LeukemiaNet guidelines, there were 7 (13%), 16 (30%), 12 (27%) and 18 (34%) pts in the favorable, intermediate I, intermediate II, and adverse risk groups, respectively. ENTO monotherapy and ENTO+7+3 were well tolerated. Most of the adverse events (AEs) that occurred in the ENTO+7+3 phase were consistent with those expected from 7+3 induction chemotherapy. Seven (13%) pts had a grade ≥3 rash and 8 (15%) pts had grade ≥3 transaminitis or hyperbilirubinemia. Overall, 16 (30%) pts needed ENTO dose interruptions or reduction due to AEs, and 8 (15%) pts discontinued study drug due to AEs. Forty-one (77%) pts had grade ≥3 febrile neutropenia. There were no deaths with 30-day induction mortality of 0%. With the 14-day lead-in one pt with t(11;19) translocation achieved a CR with ENTO monotherapy alone, prior to the combination phase. Of note, 15 (28%) pts did not get the full 14-day lead-in due to pt or physician preference, and 12 (23%) pts required concomitant hydroxyurea due to rising white blood cell counts. The CR rate with ENTO+7+3 was 70% (Table 1). Fourteen (26%) pts had secondary AML and the CR rate in this group was 64%. In addition, higher than historical control CR rates were noted in pts with *NPM1* mutation (n=15, CR 87%), *FLT3-ITD* (n=6, CR 83%) and *KMT2A* gene rearrangements (n=10, CR 90%). After a median follow-up (f/u) of 8 months (m), the median event-free survival, relapse-free survival and overall survival were 7m, 7m, and not reached, respectively. Fifteen (28%) pts received allogeneic stem cell transplantation in the post-remission setting.

Table 1. CR rates by risk-groups in newly-diagnosed AML patients treated with ENTO+7+3.

Risk-Group	Phase 1 CR n=12 (%)	Phase 2 CR n=41 (%)	Combined CR n=53 (%)
Favorable-risk	3/3 (100%)	3/4 (75%)	86%
Intermediate-I	0/0 (0%)	13/16 (81%)	81%
Intermediate-II	4/4 (100%)	5/8 (63%)	75%
Adverse-risk	3/5 (60%)	6/13 (46%)	50%
Secondary AML	3/3 (100%)	6/11 (55%)	64%
De novo AML	7/9 (78%)	21/30 (70%)	72%
KMT2A+ (MLL)	3/3 (100%)	6/7 (86%)	90%
NPM1+	3/3 (100%)	10/12 (83%)	87%
FLT3-ITD+	1/1 (100%)	4/5(80%)	83%
TOTAL	**10/12 (83%)**	**27/41 (66%)**	**37/53 (70%)**

Note: Some patients have overlapping mutations P
Phase 1b was the safety, dose finding phase, Phase 2 was for efficacy

Summary and Conclusions: In untreated AML patients, ENTO+7+3 is safe and demonstrates high remission rates in specific molecular subgroups. In our study, pts with secondary AML, *NPM1*, *FLT3-ITD* mutations, and *KMT2A* gene rearrangements were noted to have higher CR rates than historical controls. Durability of response with longer f/u is pending and correlative biomarker studies evaluating *HOXA9/MEIS1* in pts with *NPM1*, *FLT3-ITD* mutated and *KMT2A* rearranged leukemia treated with ENTO are being presented separately.

S119

RELAPSED AML IN CHILDREN: IMPROVED OUTCOME

Hematology/ Oncology, Bambino Gesù Children's Hospital, Rome, Italy, [19]Ped. Hematology/Oncology, Prinses Máxima Centrum, Utrecht, Netherlands

Background: The international AML relapse trial 2001/01 improved significantly the prognosis of children and adolescents with AML (Kaspers *et al.,* JCO 2013). Since the end of recruitment in 2009, most relapsed AML have been enrolled to national or international registries, mainly continuing the established protocol.

Aims: This study analyses the outcome of children with relapsed and refractory AML between 2009 and 2016 (2009 Registry), including patients from Germany, Austria, Czech Republic, Switzerland, Poland, Italy Slovakia, Belgium and the Netherlands.

Methods: In total, 435 patients were enrolled, 395 with relapse and 43 with refractory disease. Children with acute promyelocytic leukemia and myeloid leukemia of Down Syndrome were excluded. For comparison, the updated AML-BFM and Dutch cohort out of the International AMLRelapse Trial 2001/01 was used (n=391; relapse n=351; refractory n=51). The recommended reinduction therapy was liposomal daunorubicin / fludarabine / cytarabine (L-DNR-FLA) followed by FLA course. Allogeneic stem cell transplantation (HSCT) was recommended in all patients.

Results: Most patients (89%) have been treated with the recommended reinduction therapy, however, due to the lack of L-DNR in some countries, idarubicin was used instead of L-DNR. In particular subgroups (mainly children with an early relapse), clofarabine (5%) or gemtuzumab ozogamicin (4%) containing regimens have been applied. The event-free (2nd EFS, 3 years) and overall survival (OS, 3 years) following relapse/ primary refractory AML were 42±2% and 51±3%, respectively. These data show a remarkable improvement in comparison to both 2nd EFS and OS of children enrolled in the International AML-Relapse Trial 2001/01 (2nd EFS 33±3%; OS 38±3%; p<0.005). Duration of first remission and genetic lesions remain significant prognostic factors: Remission <1 year *vs* >1 year: 2nd EFS: 32±3% *vs* 57±4%; OS 36±3% *vs* 60±4%; p<0.00001; Core binding leukemia *vs* others: 2nd EFS: 57±4% *vs* 31±3%; OS 61±4% *vs* 37±3%; p<0.0001. This improved outcome could be partially explained by an amelioration of the results obtained with alloSCT in 2nd CR or refractory disease (2nd CR: 2001/01 EFS 41±6% *vs* 2009 52±6%, p=0.07; refractory AML 19±7% *vs* 33±6%; p<0.003). In addition, 3rd line therapy including 2nd SCT (12%) was applied more often with a curative intention. The approaches to reinduce 3rd remission were heterogenous. They include both conventional chemotherapy schemes such as clofarabine/liposomal daunorubicin/ cytarabine as well as targeted treatment with gemtuzumab ozogamicin (GO) or other experimental approaches. Overall, the patients (n=53) who underwent 2nd SCT showed an EFS of 42± 7% (2001/01: 18±6%, p<0.001). Due to low number in subgroups and selection bias, no significant differences were found in terms of conditioning regimen or type of donor employed (BuCyMel, treosulfan/fludarabine; MSD, MUD, MMD, haplo).

Summary and Conclusions: Children with relapsed AML have a reasonable option to be cured with intensive 2nd and 3rd line therapy. Further research and trials are warranted to identify those children who will experience relapse earlier, for either apply more effective therapy or to for treating patients already when a molecular relapse will be detected. Prospective, randomized trials are urgently needed to identify the best conditioning regimen to be employed.

Background: Circular RNAs (circRNAs) constitute a novel class of non-coding RNAs characterized by an out-of-order arrangement of exons called "back-splicing". While individual circRNAs have been linked to cancer pathogenesis, the prognostic value and biologic implications of circRNA expression in CN-AML pts have not been studied.
Aims: The aims of our study were to determine whether circRNA expression associates with clinical outcome of CN-AML pts, and to gain biological insights into circRNA function in CN-AML.
Methods: We conducted whole transcriptome profiling (RNAseq) in a training (n=254) and a validation (n=111) set of younger adults (aged <60 years) with *de novo* CN-AML. We applied a novel algorithm (MScircRNA) to quantify circRNA expression in both datasets. All pts were treated on frontline Cancer and Leukemia Group B (CALGB)/Alliance trials.
Results: We first performed RNAseq in RNAseR (a linear RNA-degrading exonuclease) v mock-treated samples of 7 AML pts and 3 AML cell lines (EOL-1, K562, OCI-AML3). We found 85% of the MScircRNA algorithm-predicted circRNAs to represent true circularized transcripts, as shown by enrichment upon RNAseR treatment. We next studied 180 circRNAs in the training set, and identified 4 (*circCFLAR*, *circFCHO2*, *circKHLH8*, *circSMC1A*) that associated with disease-free (DFS), overall (OS), and event-free (EFS) survival in both the training and validation sets. *circKHLH8* was most strongly associated with clinical outcome. Using median expression values, we dichotomized the pts into high and low *circKHLH8* expressers. In the validation set, high *circKHLH8* expressers had longer 5-year DFS (50% *vs* 21%, *P*<.001), OS (53% *vs* 29%, *P*<.001) and EFS (45% v 18%, *P*<.001) than low *circKHLH8* expressers. Regarding pretreatment clinical and molecular features, pts with high *circKHLH8* expression had higher platelet counts (*P*=.05) and lower % of blasts in blood (*P*=.002) and bone marrow (*P*=.05). High *circKHLH8* expressers also had more often *FLT3*-TKD (*P*=.05) and less often *FLT3*-ITD (*P*<.001) or high expression of miR-155 (*P*<.001) and *ERG* (*P*<.001) than low *circKHLH8* expressers. In multivariable analyses, high *circKHLH8* expression independently associated with longer DFS (*P*=.02; HR: 0.53), OS (*P*=.03; HR: 0.54) and EFS (*P*=.02; HR: 0.54) after adjusting for other co-variates. To ensure that our findings on *circKHLH8* were not merely reflecting the prognostic significance of the linear *KHLH8*, we confirmed that the correlation between the transcripts was weak (Pearson's r: 0.29) and that linear *KHLH8* expression was not prognostic for clinical outcome in either of the 2 datasets. To study the biologic significance of circRNA expression, we performed knock-down (KD)-based screening of candidate circRNAs associated with outcome or ELN prognostic gene mutations in KG1a and OCI-AML3 cells. We used back-splice site-targeting locked nucleic acid-modified oligonucleotides, which depleted circRNAs without affecting the corresponding linear transcripts. Of the circRNAs tested, *circFBXW7* KD increased the proliferative capacity of KG1a and OCI-AML3 cells, as measured by WST1 reagent degradation (*P*=.001 and *P*<.001, respectively) and bromodeoxyuridine-based cell cycle analysis (*P*=.02 and *P*=.01, respectively). Colony forming unit assays with blasts of 3 AML pts revealed a consistent increase in the number of colonies formed upon *circFBXW7* KD (*P*=.03, *P*=.04 and *P*=.02, respectively). Altogether, our data suggest that *circFBXW7* has a tumor suppressor function in CN-AML.
Summary and Conclusions: We conclude that circRNA expression has prognostic and biologic significance in CN-AML.

S121

PHARMACOLOGIC DISPLACEMENT OF LSD1 FROM GFI1 ACTIVATES PRIMED ENHANCERS TO INDUCE DIFFERENTIATION IN ACUTE MYELOID LEUKEMIA

A. Maiques-Diaz[1,*], G.J. Spencer[1], J.T. Lynch[1], F.M.R. Amaral[1], S. Sahoo[2], T C. Somervaille[1]

[1]Leukaemia Biology Laboratory, [2]Computational Biology Group, Cancer Research UK Manchester Institute, University of Manchester, Manchester, United Kingdom

Background: Treatment of patients with MLL-translocated acute myeloid leukemia (AML) with a tranylcypromine-derivative inhibitor of Lysine Specific Demethylase 1 (LSD1/KDM1A) induces differentiation of blast cells in blood and bone marrow (Somervaille *et al*., Blood 2016). The assumption has been that LSD1 contributes to gene repression by removing monomethyl and dimethyl histone marks from lysine 4 of histone H3 (H3K4me1/me2) and that this is the key activity targeted for potential therapeutic effect. LSD1 also interacts with multiple transcription factors raising the possibility that other mechanisms may be significant.
Aims: We aimed to better characterize and understand LSD1 inhibitors mechanisms of action.
Methods: RNAseq, ATACseq and ChIPseq in human THP1 AML cell line treated with a tranylcypromine-derivative inhibitor (OG86, Oryzon Genomics).
Results: Contrary to what has been assumed, human THP1 AML cells treated with the LSD1 inhibitor OG86 induced rapid transcriptional changes without significant H3K4me1/2 changes in the upregulated LSD1-bound promoters (214/766, 28%) compared with those lacking an LSD1 binding peak (552/766, 72%). Regarding putative enhancer regions, only a modest H3K4me1 reduction in LSD1-bound *versus* LSD1-unbound enhancers was observed, but a highly significant increase in H3K9ac and H3K27ac, consistently with increase activation of LSD1-bound enhancers. Intriguingly, the transcriptional consequences of LSD1 inhibition mimicked the transcriptional changes of SNAG-domain transcription repressor GFI1 knockdown in THP1 AML cells, and we found that GFI1:LSD1/RCOR1 interaction was disrupted by OG86 treatment in THP1 and MV4,11 AML cells using several unrelated inhibitors.
Interestingly all the strongest GFI1 ChIPseq peaks (based on MACS2 pileup value) exhibited coincident LSD1 and RCOR1 binding (*i.e.* 98.6% and 88.4% respectively), and a significant GFI1 consensus-binding motif was found on LSD1 and RCOR1 ChIPseq bound regions surrounding the peak centers (MEME-ChIP, p=10-686 and p=10-55 respectively). We observed a loss of LSD1, RCOR1 and GFI1 ChIPseq signal in OG86-treated THP1 AML cells, with the greatest proportional reduction found at the 1,867 sites co-occupied by the three proteins together. The selective loss of LSD1/RCOR1 from GFI1 sites upon inhibition was further supported by the absence of any GFI1 consensus motif found on the residual LSD1 and RCOR1 binding peak sequences in OG86-treated cells. The loss of chromatin binding of the three proteins was also observed using subcellular fractionation analysis. Moreover, LSD1 inhibition in THP1 AML cells promoted differentiation (*i.e.* increased CD86 expression and reduced clonogenic potential), but cells expressing a doxycycline-regulated GFI1-ZNF DNA binding domain-LSD1 fusion protein completely blocked this differentiation effect, indicating that the myeloid differentiation induced by LSD1 inhibition results from the physical separation of LSD1 and GFI1. Finally, we did not observe any changes on chromatin accessibility (using ATACseq) surrounding sites co-occupied by GFI1, LSD1 and RCOR1 following LSD1 inhibition, but a significant increase of ChIPseq signal for H3K9ac and H3K27ac.
Summary and Conclusions: Our data illustrate a paradigm for epigenetic therapy whereby, through disruption of the protein:protein interaction between a transcription repressor and an epigenetic regulator, repression is released and dynamic enhancer acetylation and gene expression ensue.

S122

ALTERED COHESIN ACTIVITY AT DIFFERENTIATION-SPECIFIC ACTIVE CIS-REGULATORY ELEMENTS PREDICTS THE FATE OF COHESIN-PERTURBED HAEMATOPOIESIS

D. Sasca[1,2,3,4,*], G. Giotopoulos[1,2,3], H. Yun[1,2,3], T. Evan[1,2,3], B.J. Huntly[1,2,3]

[1]Wellcome Trust-MRC Cambridge Stem Cell Institute, [2]Department of Haematology, University of Cambridge, [3]Cambridge Institute for Medical Research, Cambridge,

United Kingdom, [4]Department of Internal Medicine III (Hematology, Oncology, Pneumology), University Medical Center Mainz, Mainz, Germany

Background: Myeloid malignancies are a heterogeneous continuum of neoplasia that share many common characteristics, such as altered transcriptional regulation caused by recurrent mutations of signalling, transcription and epigenetic factors. With a frequency of 15% across all myeloid malignancies, several of these mutations occur in members of the cohesin complex (*STAG2, RAD21, SMC1a* or *SMC3*, less frequent *STAG1).* The mutations are mutually exclusive, are predicted to cause loss of function alleles and a decrease of complex activity.
Aims: To determine a mechanism for the establishment of cohesin-deficient myeloid neoplasia.
Methods: Utilizing a model of haematopoietic stem and progenitor differentiation (HPC-7), we performed integrative analysis of cohesin binding, gene expression, chromatin state and 3D-DNA topology at genome scale, assessing different cellular states - haematopoietic progenitors, erythroid and myeloid cells - followed by matched analysis after inducible shRNA-mediated knockdown (KD) of multiple cohesin members. We finally validated the observed patterns *in vitro* and *in vivo* using a murine model of *Flt3-ITD/Npm1c* AML after inducible KD of Stag2 or Smc1a.
Results: We demonstrated alterations of cohesin member expression upon commitment down the erythroid but not myeloid lineage. This variable expression of cohesin translated into differing dosages at chromatin during differentiation; cohesin binding increased in the erythroid lineage at active *cis*-regulatory elements (enhancers/promoters), while the global cohesin dosage remained low in the myeloid lineage. Binding dynamics correlated to the H3K27 acetylation (H3K27ac), but not to gene expression, Ctcf binding or promoter interaction frequency. Suprisingly, KD of cohesin members only minimally affected binding of the residual cohesin complex to active promoters/enhancers in immature cells, resulting in discrete changes of H3K27ac and gene expression. However, during differentiation of Stag2-perturbed haematopoiesis, significant biases of cohesin binding to active *cis*-regulatory elements were seen, with impaired dosage of cohesin demonstrated at many promoters. In erythroid progenitors, these promoters consistently specified for key erythroid genes, such as Klf1 or Gata1, which we had shown to require increased cohesin binding during erythropoiesis. The lack of cohesin complex binding led to impairment of H3K27ac, promoter interactions, gene expression and, functionally, a block of differentiation. Conversely, in the myeloid lineage, cohesin redistribution following Stag2-KD led to a relative increase at promoters of genes that are crucial for proliferation, including *Myc*, *Id1* and *Foxo1*, inducing myeloid expansion.
We confirmed our findings in a murine model of *Flt3-ITD/Npm1c* AML where limiting concentrations of Stag2, by shRNA-KD, caused genome-wide cohesin and H3K27ac redistribution. This generated significant alterations of transcription, a more primitive and aggressive phenotype and, in limiting dilution transplants, a marked increase in leukemia stem cell frequency (1/2812 for WT-AML to 1/25 for shS2-AML).
Summary and Conclusions: Cohesin member perturbation redistributes the binding of the remaining cohesin proteins to active promoters/enhancers, altering H3K27ac, 3D-DNA interactions and transcription. This leads to distinct and opposite patterns in the erythroid and myeloid lineages and explain the loss of differentiation, increased self-renewal and proliferation phenotypes, thereby providing a mechanistic model for (pre)leukaemic development of cohesin-impaired haematopoiesis.

S123

STAG2 REGULATES HEMATOPOIETIC DIFFERENTIATION AND SELF-RENEWAL

Y. Ochi[12,*], A. Kon[1], M.M. Nakagawa[1], K. Kataoka[1], K. Yoshida[1], H. Koseki[3], M. Nakayama[4], A. Yoda[1], H. Makishima[1], A. Takaori-Kondo[2], S. Ogawa[15]

[1]Department of Pathology and Tumor Biology, Graduate School of Medicine, [2]Department of Hematology and Oncology, Graduate School of Medicine, Kyoto University, Kyoto, [3]Laboratory for Developmental Genetics, RIKEN Center for Integrative Medical Sciences, Yokohama, [4]Chromosome Engineering Team, Department of Technology Development, Kazusa DNA Research Institute, Kisarazu, Japan, [5]Center for Hematology and Regenerative Medicine, Department of Medicine, Karolinska Institutet, Stockholm, Sweden

Background: Cohesin is a multimeric protein complex, which was originally implicated in sister chromatid cohesion and more recently, in long-range regulation of gene expression by stabilizing 3-dememsional structure of the genome. Recently, multiple components of the cohesin complex are identified as recurrent targets of somatic mutations in various myeloid malignancies, of which *STAG2* is most frequently mutated and inactivated; however, the leukemogenic mechanism of mutated-*STAG2* remain largely unknown.
Aims: The aim of the study is to investigate the functional role of *STAG2* in leukemogenesis as well as normal hematopoiesis.
Methods: We generated *Stag2* conditional knockout (cKO) mice having an Mx1-cre allele, in which *Stag2* deletion was induced by polyIC injection.
Results: *Stag2* cKO mice showed a mild leukocytopenia. Flow cytometry of bone marrow cells revealed an increase in the frequency of hematopoietic stem and progenitor cells (HSPCs) defined as $Lin^-Sca\text{-}1^+Kit^+$(LSK) cells in *Stag2* cKO mice. In the cell cycle kinetics analysis, *Stag2* cKO HSPCs were characterized by an increase in the proportion of cells in S/G2/M phases. Within the myeloid progenitor (MP) compartment, we observed increased common myeloid progenitors (CMPs) and granulocyte-macrophage progenitors (GMPs), and decreased megakaryocyte/erythroid (MEPs) and common lymphoid progenitors (CLPs). Moreover, $CD11b^+Gr\text{-}1^+$ myeloid cells were increased in the bone marrow of *Stag2* cKO mice. These results suggest that *Stag2* deficiency causes skewing toward myeloid lineage. In repeated methylcellulose cultures, *Stag2* deficient BM cells showed an enhanced serial replating capacity, suggesting an increased self-renewal potential of *Stag2* deficient hematopoietic stem cells (HSCs). In competitive repopulation assays, *Stag2* cKO-derived cells showed reduced chimerism in the peripheral blood compared to wild-type mice-derived cells. In the bone marrow, by contrast, the chimerism of *Stag2* cKO cells was not significantly changed, but tended to increase in the LSK, CMP and GMP fractions and decrease in the MEP and CLP fractions. These results suggest that *Stag2* deficiency could enhance the self-renewal capacity of HSCs, while differentially impacting on their contribution to different hematopoietic cell fractions due most likely to the deregulated differentiation of HSCs. We next investigated differential expression profiles between *Stag2* WT and cKO cells using RNA sequencing of HSPC fractions. We observed significant up-regulation of key hematopoietic regulators, including *Gata1*, *Gata2* and *Runx1*, which are implicated in the differentiation of HSCs. Of particular interest in this regard, assays for transposase accessible chromatin with sequencing (ATAC-seq) revealed a significant enrichment of the binding sites for Gata1, Gata2, and Runx1 in the open chromatin regions in *Stag2*-deleted HSPCs. We also observed up-regulated expression of genes related to myeloid programs, such as *Mpo* and *Cebpa*, while expression of several genes involved in the lymphoid development such as *Cd9* and *Irf4* were down regulated. These results indicate that *Stag2*-deficient HSCs are primed to differentiate toward myeloid lineage, which is in agreement with *in vivo* hematopoietic phenotypes.
Summary and Conclusions: Our results demonstrate that *Stag2* loss leads to the impaired hematopoietic differentiation and enhances the self-renewal potential of HSCs, likely through the modulation of gene expression and chromatin accessibility, which may contribute to leukemogenesis in *STAG2*-mutated cells.

Stem cell transplantation – Clinical I

S124

BUSULFAN + MELPHALAN WAS ASSOCIATED WITH A LONGER PFS COMPARED TO MELPHALAN ALONE IN HIGH-RISK MULTIPLE MYELOMA IN A RANDOMIZED PHASE 3 CLINICAL TRIAL

Ahmed[1], C. Hosing[1], U. Popat[1], E. Shpall[1], D. Weber[4], S. Thomas[4], E. Manasanch[4], H. Lee[4], R. Orlowski[4], R. Champlin[1]

[1]Stem Cell Transplantation, [2]Biostatistics, MD Anderson Cancer Center, Houston, [3]Medicine, University of California San Francisco, San Francisco, [4]Lymphoma/Myeloma, [5]Pharmacy Pharmacology Research, MD Anderson Cancer Center, Houston, United States

Background: High-dose melphalan (Mel) 200 mg/m2 is considered the standard of care preparative regimen for autologous hematopoietic stem cell transplantation (auto-HCT) for multiple myeloma. Two recent retrospective analyses suggested that a combination of busulfan (Bu) and Mel (Bu-Mel) may be associated with a longer progression-free survival (PFS) compared to Mel alone. In this randomized phase III trial we compared the safety and efficacy of Bu-Mel *vs* Mel.
Aims: The primary objective was to compare PFS between the two arms.
Methods: Patients were randomized to either Bu-Mel or Mel using the Pocock-Simon method within 12 months of the start of induction therapy. The trial was designed to detect a 14-month increase in median PFS in the Bu-Mel arm with two-sided tests having nominal overall type I error .029 and power .80, with up to 3 tests using O'Brien-Fleming decision boundaries.
Results: Two-hundred and four patients (Bu-Mel: 104, Mel: 100) were enrolled from October 2011 to March 2017. There was no significant difference between the two arms in age, gender, race, cytogenetic risk status, ISS stage, serum LDH, induction regimens, response to induction, or maintenance therapy. Sixty-two patients, 31 each in Bu-Mel (30%) and Mel (31%) arms, respectively, had high-risk (HR) chromosomal abnormalities as defined by IMWG criteria. At day 90 after auto-HCT, 11 (35%) HR MM patients had achieved complete remission (CR) in each arm (p=1.00). At last evaluation, 16 (52%) and 14 (45%) HR MM patients had achieved a CR (p=0.80) in Bu-Mel and Mel, respectively. Minimal residual disease (MRD) analysis by multiparametric flow cytometry (MFC) was performed at day 100 in 26 and 22 patients with HR MM in Bu-Mel and Mel, respectively. Fifteen (58%) and 13 (59%) achieved MRD negative status in Bu-Mel and Mel arms, respectively (p=1.00). -Meier estimates of median PFS for HR MM was not reached in the Bu-Mel arm, and 25.0 months in the Mel only arm (p=0.021) (Figure 1).

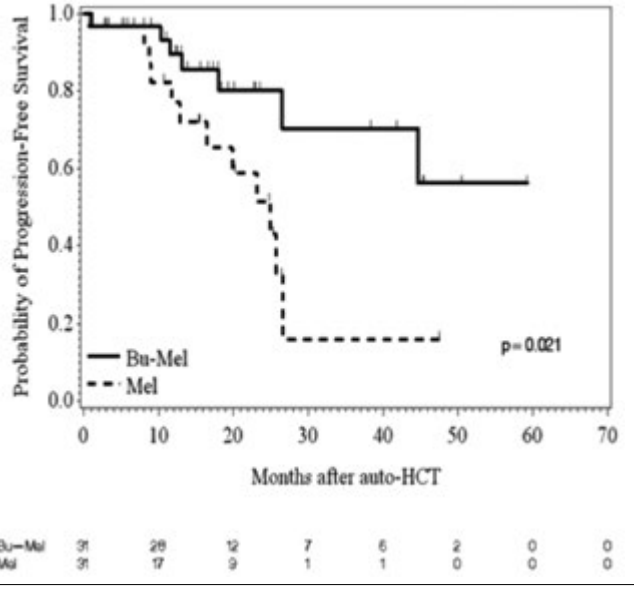

Figure 1.

This significant difference in PFS was maintained after adjusting for the type of maintenance therapy received (p=0.035). There was no difference in OS between HR MM patients in the Bu-Mel or Mel only arms (p=0.37). In a fitted Bayesian regression model that included age, race, ISS stage, and response to induction therapy, the posterior probability that patients receiving Bu-Mel had a smaller risk of progression and/or death compared with patients receiving Mel alone is 0.989, which is highly significant.
Summary and Conclusions: In this phase III trial, Bu-Mel regimen was safe, and associated with a significantly longer PFS than Mel alone. This significant difference in PFS was also observed for patients with high-risk disease. Potential explanations for a longer PFS without a significant difference in response rates include a deeper MRD negativity or selective targeting of clonogenic myeloma progenitor cells by Bu-Mel.

S125

THE ROLE OF MINIMAL RESIDUAL DISEASE AT THE TIME OF TRANSPLANTATION IN PATIENTS WITH AML IN CR2 AFTER ALLOGENEIC STEM CELL TRANSPLANTATION. A STUDY OF THE ACUTE LEUKEMIA WORKING PARTY OF THE EBMT

A. Shimoni[1,*], M. Labopin[2], S. Robinson[3], D. Beelen[4], G. Socié[5], A. Unal[6], A. Ganser[7], A. Vitek[8], H. Sengeloev[9], I. Yakoub-Agha[10], E. Tholouli[11], M. Mohty[12], A. Nagler[1]

[1]CHAIM SHEBA MEDICAL CENTER, Tel-Hashomer, Israel, [2]ALWP office, Paris, France, [3]Bristol Royal Hospital for Children, Bristol, United Kingdom, [4]Essen University Hospital, Essen, Germany, [5]Hopital St. Louis, Paris, France, [6]Erciyes Medical School, Kayseri, Turkey, [7]Hannover Medical School, Hannover, Germany, [8]Institute of Hematology and Blood Transfusion, Prague, Czech Republic, [9]National University Hospita, Copenhagen, Denmark, [10]Hôpital HURIEZ UAM, Lille, France, [11]Manchester Royal Infirmary, Manchester, United Kingdom, [12]Saint Antoine Hospital, Paris, France

Background: The current definition of complete remission (CR) in patients with acute myeloid leukemia (AML) is based on recovery of normal blood counts after treatment and morphological assessment of the marrow. However, patients in CR can still harbor significant number of leukemic cells that may result in relapse. Minimal residual disease (MRD) assessment can establish, by different methods, the presence of $1:10^3$- $1:10^6$ leukemia cells. The level of MRD as assessed at particular time-points during AML treatment, and in particular prior to stem-cell transplantation (SCT), is an independent and important predictor of outcome. However, most of the existing data are available for CR1 and there is only limited data on the role of MRD in patients achieving CR2 following leukemic relapse.
Aims: To assess the impact of MRD status on transplantation outcomes in patients in CR2 at the time SCT.
Methods: We retrospectively analyzed SCT outcomes in a group of 1042 patients with *de-novo* AML in CR2 given SCT between 2006 and 2016 from HLA- matched siblings (n=719) or 10/10 matched unrelated donors (n=293), who had available MRD status data at the time of SCT and were registered in the data base of the ALWP of the EBMT. MRD methodology and allocation to MRD negative or MRD positive groups were determined by the individual participating centers and utilized molecular and/or immunophenotyping criteria.
Results: The median age was 49 years (range, 18-73), 558 males and 484 females. The conditioning regimen was myeloablative (n=610) or reduced-intensity (n=432) and 566 patients (54%) had *in-vivo* T-cell depletion. In all, 749 patients (72%) were MRD negative and 293 (28%) had positive MRD at the time of SCT. The only difference in patient characteristics between the MRD (-) and MRD (+) groups was a longer time from diagnosis to SCT in the MRD (-) group, 18 *vs* 16 months, respectively (P<0.001). In particular, there was no difference in the cytogenetic or molecular characteristics between the groups. The 2-year relapse rate was 24% (95%CI, 21-28) and 40% (95%CI, 34-46) in the MRD (-) and MRD (+) groups, respectively (P<0.001). The predicting factors for relapse in multivariate analysis were MRD (-) status (HR 0.57, P<0.001), good cytogenetics (HR 0.62, P=0.001), longer time from diagnosis to SCT (HR=0.97, P<0.001) and *in-vivo* T-cell depletion (HR 1.35, P=0.03). The 2-year LFS was 57% (53-61) and 46% (40-52%), respectively (P=0.001). The predicting factors for LFS were MRD (-) status (HR 0.76, P=0.01), good cytogenetics (HR 0.79, P=0.04) and longer time from diagnosis to SCT (HR=0.99, P<0.001). Age, gender, donor or conditioning type did not predict relapse or LFS rates.
Summary and Conclusions: Achieving a negative MRD status after second-line treatment for relapsed AML is associated with lower relapse rates and improved LFS after SCT. These observations are similar to the effect of MRD status in the frontline setting. MRD status pre SCT for AML relapsing patients achieving CR2 should dictate therapeutic strategies in this patient population.

S126

THE IMPACT OF RECIPIENT AGE ON ALLOGENEIC STEM CELL TRANSPLANTATION OUTCOME –A COMPARISON BETWEEN SIBLINGS *VERSUS* UNRELATED *VERSUS* ALTERNATIVE DONORS: AN ANALYSIS ON BEHALF OF THE ALWP OF THE EBMT

Gaslini Chidlren's Hospital, Genova, Italy, [10]Leiden University Medical Centre, Leiden, Netherlands, [11]Barts Cancer Institute, London, [12]Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom, [13]Collegium Medicum, Nicolaus Copernicus University, Bydgoszcz, Poland, [14]Hopital Saint-Antoine, Université Pierre & Marie Curie, Paris, France

Background: Contemporary practice in allogeneic stem cell transplantation (SCT) has increased the likelihood of finding donors for nearly all transplantation candidates. Furthermore, older patients (pts) are being transplanted.
Aims: We sought to explore the relationship between increasing age, donor selection, and risk of non-relapse mortality (NRM).
Methods: A retrospective study including 55,941 adult pts treated for hematologic malignancies who underwent first SCT from sibling (MSD), matched (MUD) or mismatched (MMUD) unrelated, cord blood (CB) or haploidentical (Haplo) donors between 2010 and 2015 in European Society for Blood and Marrow Transplantation (EBMT) centers. We compared outcomes across four consecutive age groups (18-39 [I], 40-49 [II], 50-59 [III], ≥60 [IV]). The primary outcome was NRM. Within each age group, using a Cox regression model adjusted for key variables, we studied the risk associated with different donor types. MSDs were the reference category.
Results: Younger patients were more likely to receive MSD grafts (39% [group I], 39% [II], 38% [III], and 26% [IV]) and myeloablative conditioning (76% [I], 61% [II], 40% [III], and 23 [IV]. Unrelated donors were increasingly used with increasing age (49% [I], 53% [II], 56% [III], 66% [IV]). Haplo and CB transplant were more prevalent in ages 18-39 (9% and 4%, respectively), compared to all other age groups. The probability of 3-year NRM increased with age, regardless of donor type. (Table 1).

Table 1.

		18-39	40-49	50-59	60-83
3-year Non-Relapse Mortality (95% CI)	MSD	15.8 (14.7-17.0)	19.7 (18.4-21.1)	24.3 (23.1-25.6)	28.5 (26.9-30.2)
	MUD	21.9 (20.5-23.4)	24.4 (22.8-26.1)	29.4 (28.0-30.8)	34.5 (33.1-36.0)

3-year Overall Survival (95% CI)	MSD	59.8 (58.1-61.4)	58.4 (56.7-60.2)	52.4 (50.9-54.0)	45.3 (43.5-47.3)
	MUD	59.4 (57.6-61.2)	55.6 (53.6-57.6)	49.5 (47.9-51.1)	44.5 (43.0-46.0)
	Haplo	49.8 (46.7-53.1)	42.6 (38.1-47.6)	41.5 (37.6-45.8)	38.5 (34.6-42.7)
	MMUD	47.5 (44.5-50.8)	44.2 (40.7-47.9)	41.1 (38.3-44.2)	33.1 (30.2-36.2)
	Cord	25.5 (21.9-29.6)	32.3 (27.2-38.2)	26.7 (22.3-31.9)	22.9 (18.5-28.5)

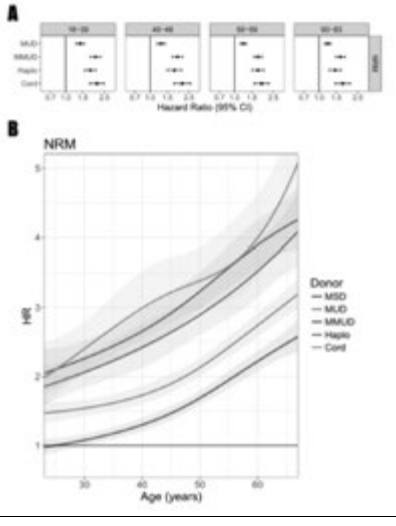

Figure 1.

Across all age groups, NRM was lowest with MSD followed by MUD and Haplo, while the highest incidence was in transplants from MMUD and CB. 3-year overall survival (OS) was also higher with MSDs and MUDs in all age groups. Notably, among older pts (group IV) receiving grafts from alternative donors, Haplo was associated with better OS (38.5%) compared to MMUD (33.1%) and CB (22.9%). MUD transplants had increased risk for NRM compared to MSDs regardless of age group (HR ranging from 1.2 to 1.4, Figure 1A). Alternative donors had an overlapping risk for NRM ranging from 1.5-2.1 (reference MSD). Using cubic splines, we further validated these findings by modeling the risk of donors across age as a continuous factor (Figure 1B).
Summary and Conclusions: MSDs remains the safest option in all age groups. In older pts with no conventional donor available, Haplo may be preferable because of reduced NRM in comparison to MMUD and CB.

S127

TRENDS IN THE USE OF HEMATOPOIETIC STEM CELL TRANSPLANTATION IN THE MANAGEMENT OF RELAPSED/ REFRACTORY HODGKIN LYMPHOMA. A RETROSPECTIVE ANALYSIS OF THE LYMPHOMA WORKING PARTY OF THE EBMT

A. Sureda[1,*], S. Genadieva Stavrik[2], A. Boumendil[3], H. Finel[3], I. Khvedelidze[3], S. Dietrich[4], P. Dreger[4], O. Hermine[5], C. Kyriakou[6], S. Robinson[7], N. Schmitz[8], H. Schouten[9], A. Tanase[10], S. Montoto[11]

Background: Both autologous (auto-HSCT) and allogeneic stem cell transplantation (allo-HSCT) represent well-accepted treatment strategies for patients with relapsed / refractory (RR) Hodgkin lymphoma (HL). Nevertheless, both transplant modalities have evolved over time and the recent advent of new drugs might have modified the indications and timing of HSCT.
Aims: We have therefore analysed the transplant activity for patients with RR HL reported to the EBMT registry over the last three decades.
Methods: Patients were included if they had RR (primary refractory or relapsed disease) HL, were above 18 years of age and had undergone an auto-HSCT as 1st HSCT or an allo-HSCT either as a 1st HSCT or after a prior auto-HSCT between January 1990 to December 2014. Med A level data were retrieved from the EBMT database.
Results: 13639 patients [11435 auto-HSCT and 2204 allo-HSCT (555 1st allo-HSCT and 1649 allo-HSCT after an auto-HSCT)] were registered in the EBMT database during the study period. The number of auto-HSCT steadily increased from 129 in 1990 up to a maximum of 811 in 2010; the number of allo-HSCT also increased from 6 in 1990 up to a peak of 243 in 2014. With regards to autologous recipients, over time there was a significant increase in age at HSCT [31 yrs (1990-1994) *vs* 35 yrs (2010-2014), p<0.0001], time between diagnosis and HSCT was shorter [31 (1990-1994) *vs* 23 mo (2010-2014), p<0.0001], peripheral blood (PB) has become the universally used stem cell source [30% (1990-1994] *vs* 98% (2010-2014), p<0.0001] and total body irradiation has almost been abandoned [4% (1990-1994) *vs* 1.7% (2010-2014), p<0.0001]. 36-mo overall survival (OS) has significantly improved over time [63% (1990-1994) *vs* 79% (2010-2014), p<0.0001] as well as non-relapse mortality (NRM) [12% (1990-12994) *vs* 6% (2010-2014), p<0.0001]. Interestingly, allo-HSCT has been less used as the 1st HSCT [88% (1990-1994) *vs* 23% (2010-1014)] whereas the number of allo-HSCT after a first auto-HSCT has steadily increased [12% (1990-1994) *vs* 77% (2010-2014), p<0.0001]. Time between diagnosis and HSCT has decreased over time also in allogeneic recipients [36 mo (1990-1994) *vs* 34 mo (2010-2014), p<0.04]]. Performance status >80% at HSCT has improved [62% (1990-1994) *vs* 94% (2010-2014), p<0.0001], PB has become the universal source of stem cells [6% (1990-1994) *vs* 84% (2010-2014), p<0.0001], and there has been a more frequent use of reduced intensity conditioning protocols [0% (1990-1994) *vs* 70% (2010-2014), p<0.0001] as well as of matched unrelated donors and haploidentical donors [0% (1990-1994) *vs* 48% (2010-2014) and 0% (1990-1994) *vs* 17% (2010-2014), respectively, p<0.0001]. 36-month OS estimates have also significantly improved [21% (1990-1994) *vs* 61% (2010-2014), p<0.001)] as well

as those for progression free survival [15% (1990-1994) *vs* 43% (2010-2014), p<0.001] and NRM [58% (1990-1994) *vs* 22% (2010-2014), p<0.001].
Summary and Conclusions: Transplantation activity, the clinical pattern of patients undergoing this treatment and the characteristics of the procedure have significantly changed over the study period and results in terms of OS and NRM for both auto-HSCT and allo-HSCT are much better. Improvement of supportive measures as well as in the experience of the transplant centers and a better selection of patients could account for these changes. The impact of the introduction of new treatment modalities (anti-CD30 monoclonal antibodies, check point inhibitors) in the number of HSCT is difficult to ascertain at this point.

S128

REDUCED-INTENSITY ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION FOR DIFFUSE LARGE B-CELL LYMPHOMA: COMPARABLE OUTCOMES OF HAPLO-IDENTICAL *VS* FULLY MATCHED RELATED DONORS. A CIBMTR AND EBMT ANALYSIS

P. Dreger[1,*], A. Sureda[1], K. Ahn[2], H. Finel[1], J. Tischer[1], L. Castagna[1], D. Blaise[1], A. Dominietto[1], C. Schmid[1], F. Ciceri[1], A. Boumendil[1], C. Litovich[2], S. Smith[2], T. Fenske[2], S. Dietrich[1], S. Robinson[1], S. Montoto[1], M. Hamadani[2]

[1]Lymphoma Working Party, EBMT, Paris, France, [2]CIBMTR, Milwaukee, United States

Background: Allogeneic hematopoietic cell transplantation (alloHCT) from haplo-identical donors using immunosuppression with post-transplant cyclophosphamide (ptCY) is increasingly performed in patients with relapsed/refractory diffuse large B-cell lymphoma (DLBCL). Disease-specific outcome data for ptCY-based haplo-transplantation (haploHCT) have not been reported for DLBCL to date.
Aims: To compare the outcomes of haploHCT with that of fully matched sibling transplants (msdHCT) as standard reference donor source in patients with DLBCL.
Methods: Eligible for this retrospective registry study were patients aged 18 or older who had undergone a reduced-intensity conditioning (RIC) haploHCT or msdHCT for DLBCL between January 2008 and June 2015 and were registered with the CIBMTR or the EBMT. Primary endpoint was overall survival (OS); secondary endpoints included engraftment, acute and chronic GVHD, non-relapse mortality (NRM), relapse/progression incidence (REL) and progression-free survival (PFS).
Results: Altogether 657 patients were eligible (haploHCT 132; msdHCT 525). HaploHCT and msdHCT recipients were comparable for gender, comorbidity score, time from diagnosis, and disease status at alloHCT. However, haploHCT patients were significantly older (58 *vs* 55 years), more likely to have a Karnofsky score of 90-100 (73% *vs* 62%), had less often received a prior autoHCT (42% *vs* 55%), and had been allotransplanted more recently. Moreover, haploHCT and msdHCT recipients differed fundamentally in terms of use of TBI-based conditioning (86% *vs* 21%) and graft source bone marrow (76% *vs* 2%).
On univariate and multivariate comparisons, OS, PFS, REL, and NRM were not significantly different between haploHCT and msdHCT with 3-year estimates of 46% *vs* 50%, 38% *vs* 37%, 41% v 47%, and 22% v 17%, respectively. Engraftment was significantly delayed after haploHCT *vs* msdHCT (neutrophils >0.5/nl at d +28 90% *vs* 97%, p=0.01; platelets >20/nl at d +28 61% *vs* 92%, p<0.001). Whilst the cumulative incidence of d +180 grade 3-4 acute GVHD was comparable (haploHCT *vs* msdHCT 7% *vs* 11%, p=0.07), there was a significantly lower 1-year incidence of chronic GVHD after haploHCT *vs* msdHCT (15% *vs* 41%; p<0.001; relative risk (RR) 0.31 (95%CI 0.27-0.47) after multivariate adjustment for confounders). Factors significantly impairing OS, PFS, REL (but not NRM) on multivariate analysis were lower Karnofsky performance status and advanced disease status at alloHCT.
Summary and Conclusions: This data suggests that in DLBCL survival, REL and NRM after RIC haploHCT is comparable to that after RIC msdHCT despite a lower risk of chronic GVHD. Although delayed engraftment has to be taken into account, RIC haploHCT might be a reasonable substitute for RIC msdHCT in the absence of a matched related donor.

Myeloproliferative neoplasms – Clinical

Background: A recent model using clinical-molecular features of patients with secondary myelofibrosis (sMF) was developed by MYSEC (MYelofibrosis SECondary to PV and ET project) showing better prediction of outcome compared with the International Prognostic Scoring System (IPSS); and although the dynamic IPSS (DIPSS) is validated for primary myelofibrosis but also currently used for risk stratification in sMF patients receiving transplant, evaluations of the actual performance of these scores are lacking.
Aims: We aimed to validate and compare the MYSEC and DIPSS in sMF patients undergoing allogeneic stem-cell transplantation.
Methods: We identified 159 sMF patients who received stem-cell transplant from related (n=59) or unrelated donors (n=100) between 2007 and 2015 with available data on blood levels at transplant and presence of mutations at diagnosis. The MYSEC model was calculated as follows: one point was assigned to presence of constitutional symptoms and platelets <150 x10^9/L. Two points were assigned to hemoglobin <11 g/dl, circulating blasts ≥3% and a CALR-unmutated genotype, whereas 0.15 points were assigned for each year of age. Risk groups (number of patients) according to MYSEC and DIPSS were: low (n=27 and n=16), intermediate-1 (n=70 and n=59), intermediate-2 (n=40 and n=70), and high (n=22 and n=14). Scores were validated using Kaplan-Meier estimates while C-statistics were applied to evaluate their discriminatory power.
Results: Median follow-up was 41 months (range, 29 to 52) while the median time between diagnosis and transplant was 128 months (range, 2 to 526). The median age of sMF patients was 52 years (range, 32 to 75). Overall survival at three years was 55.9% (95% confidence interval [CI], 47.5 to 64.3). By stratifying sMF according to evolution from either polycythemia vera (post-PV) or essential thrombocythemia (post-ET), no difference was found in survival at three years being 57.7% (95% CI, 45.5 to 70.0) for post-PV and 54.6% (95% CI, 43.0 to 66.2; p=0.92) for post-ET. Overall survival rates at three years according to each risk group of the DIPSS were as follows: 79.5% (95% CI, 58.5 to 100) for the low-risk, 56.3% (95% CI, 42.6 to 70.0) for the intermediate-1-risk, 53.9% (95% CI, 41.2 to 66.6) for the intermediate-2-risk, and 40.8% (95% CI, 14.1 to 67.5) for the high-risk group. Overall, DIPSS was not predictive of outcome (p=0.30). Regarding MYSEC, probabilities of survival at three years was 69.3% (95% CI, 51.5 to 87.1) for the low-risk, 64.5% (95% CI, 52.5 to 76.5) for the intermediate-1-risk, 46.8 (95% CI, 29.7 to 63.9) for the intermediate-2-risk, and 21.7% (95% CI, 0 to 45.4) for the high-risk group (Figure 1). The MYSEC model was predictive of survival overall (p=0.03). When used to assign patients to the four discrete risk categories, the test retained moderate predictability for MYSEC (C-index=0.585). Prognostic ability was improved in comparison with DIPSS (C-index=0.546) leading to a significant re-classification of patients (p <0.001). Due to a considerable difference in age distribution between our transplant cohort and the originally published MYSEC cohort, the score was adjusted by age as continuous variable which even increased the performance of the score showing C-statistics of 0.627.
Summary and Conclusions: In comparison to DIPSS, the clinical-molecular system by MYSEC provides a significant re-classification of patients leading

to improved prognostic capability in sMF after transplantation. Furthermore, transplant-specific age-adjustment of the MYSEC resulted in an even better predictive power.

Background: Inhibition of Janus-kinase 1/2 (JAK1/2) is a mainstay to treat myeloproliferative neoplasms (MPN). Besides driving MPN, the JAK-STAT pathway is involved in the development of malignant lymphoma. Recent reports point towards a slightly increased risk of lymphoid neoplasms in MPN patients with JAK2 V617F mutations. Moreover, sporadic cases of diffuse large B-cell lymphomas (DLBCL) have been reported in patients with MPN under ruxolitinib treatment. The frequency and potential causes of lymphomas under JAK2 inhibition remain unclear.
Aims: We aimed at identifying the global frequency and the potential causes of aggressive B-cell lymphomas under JAK2 inhibition as well as at early diagnosing patients at risk.
Methods: 626 MPN patients (557 with conventional, 59 with JAK1/2 inhibitor treatment) from Vienna and 929 (872 *vs* 57) from Paris were included in the study. Immunoglobulin rearrangement (IgR) and MPN associated mutations were tested by PCR. IGHV–D–J sequence was assessed by Sanger sequencing according to ERIC recommendations.11 For the detection of BCL2/IGH gene rearrangements, an Identiclone BCL2/JH Translocation Assay Gel Detection Kit was applied according to the manufacturer's instructions. Targeted next generation sequencing was provided by Foundation OneTM Heme (Roche Austria GmbH, Vienna).
Results: 16.7% of JAK 1/2 inhibitor (N=54) and 15.9% of 44 age- and sex-matched conventionally treated patients were positively tested for IgR in the bone marrow of patients with myelofibrosis (MF) (Figure 1). In the Viennese cohort, 4 out of 69 (5.8%) developed aggressive lymphomas upon JAK1/2 inhibitor treatment while only 2 lymphomas evolved in 557 patients (0.36%) without inhibitor (Odds ratio (OR) 16, 95% confidence interval (95%CI) 3 to 87; p=0.0017). These results have been validated in an independent cohort from Paris (5.51 *vs* 0.23%, OR 15, 95%CI 2 - 92, p=0.0205). The median time from start of JAK1/2 inhibitor-treatment to lymphoma diagnosis was 25 months (range 13-35 months). Subgroup analysis of 216 patients with primary myelofibrosis (31 with and 185 without JAK1/2 inhibitor therapy) revealed 3 DLBCL (9.68%) under ruxolitinib and only one (0.54%) in the controls (OR 19, 95%CI 2 - 196, p=0.01). Results remained unchanged after adjustment for age (OR 21, 95%CI 2-218) or sex (OR 25, 95%CI 2-266). 3 of 4 JAK 1/2 inhibitor associated lymphomas were IgR-positive as long as 6 years before overt lymphoma and preceded JAK1/2 inhibition. From one patient no material was available. Sequencing verified clonal identity in 2 patients. The effects of JAK1/2 inhibition were mirrored in *Stat1*$^{-/-}$ mice: 16/24 mice developed a spontaneous myeloid hyperplasia with the concomitant presence of aberrant B-cells. Transplantations of bone marrow from diseased mice unmasked the outgrowth of a malignant B-cell clone evolving into aggressive B-cell leukemia-lymphoma.

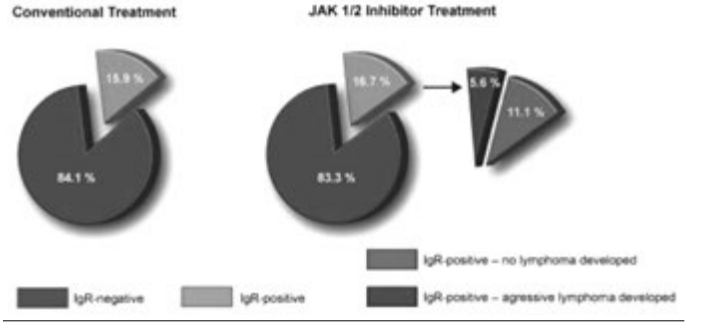

Figure 1.

Summary and Conclusions: Our results indicate that clonal B-cells are detectable in 15-17% of MF patients. Aggressive lymphomas during JAK1/2 inhibitor treatment occur with increased frequency, have uniform clinicpathological features and arise from a pre-existent B-cell clone. Early detection of IgR, at the time point of MPN diagnosis, offers the opportunity to determine patients at risk.

S131

INTERIM ANALYSIS OF THE DALIAH TRIAL - A RANDOMIZED CONTROLLED PHASE III CLINICAL TRIAL COMPARING RECOMBINANT INTERFERON ALPHA-2 *VS* HYDROXYUREA IN MPN PATIENTS

Background: Hydroxyurea (HU) is considered first line cytoreductive therapy in most parts of the world for patients with Myeloproliferative Neoplasms (MPNs). The drug effectively lowers the risk of thrombosis but there is a concern with regard to its possible leukemogenic potential. Recombinant Interferon Alpha-2a (r-IFNα), which is used off label, is non-leukemogenic and has been demonstrated to induce high rates of both clinical, haematological and molecular responses in MPN patients.
Aims: To investigate efficacy and toxicity of low-dose r-IFNα compared to HU in patients with MPN in a randomized controlled clinical phase III trial.
Methods: Patients with newly diagnosed or previously untreated (cytoreductive agents) MPN according to WHO criteria were enrolled in the DALIAH trial (NCT01387763). Written informed consent was obtained from all patients. Patients >60 years were randomized (I:I:I) to either r-IFNα-2a or r-IFNα-2b at a starting dose of 45 or 35 µg/week, respectively, or to HU at doses of 500 to 2000 mg/day. Patients ≤60 were randomized (I:I) to either r-IFNα-2a or r-IFNα-2b. The protocol allowed addition of HU in patients randomized to r-

IFNα with major thrombosis or platelets >1500 10^9/L. A planned interim analysis was performed after 18 months of therapy. The molecular and hematological response rates were assessed by the European Leukemia Net (ELN) 2009 and the EUMNET 2005 criteria. JAK2 V617F was analysed by qPCR.

Results: A total of 205 patients were enrolled between 2012 and 2015 (Table 1). The interim analysis was performed after a median of 17.7 months (range 17.1 – 18.2). Overall response rates (ORR) were 75% (24/32) for HU and 49% (73/149) for r-IFNα among patients with essential thrombocythemia (ET), polycythemia vera (PV) and prefibrotic myelofibrosis (pre-MF). Partial hematologic response (PHR) and complete hematologic response (CHR) were observed in 6 (19%) and 18 (56%) patients treated with HU and in 20 (13%) and 53 (36%) patients treated with r-IFNα. CHR was significantly higher in patients treated with HU (Fisher's exact test, p=0.04). In primary myelofibrosis ORR was 100% (6/6) for patients on HU and 33% (6/18) for r-IFNα. For patients still on study medication at 18 months the ORR were 88% (30/34) for HU and 81% (79/98) for r-IFNα. The median treatment doses were 811 mg/day, (range 576 – 977) for HU and 53 µg/week (range 44 – 78) and 44 µg/week (range 33 – 46), for r-IFNα-2a or r-IFNα-2b, respectively. Ninety-six patients were available for molecular response analysis at 18 months. A complete molecular response was obtained in one patient treated with r-IFNα. Partial molecular response (PMR) was observed in 23% (7/31) and 16% (19/120) patients treated with HU and r-IFNα, respectively. The observed difference in PMR was not significant (Fisher's exact test, p=0.42). Discontinuation of study medication for any reason after 18 months was 4 (11%) for HU and 69 (41%) for r-IFNα. Toxicity dependent drop-out was 5% for HU and 27% for r-IFNα. Grade 3-4 adverse events occurred in 7 (18%) HU patients and in 58 (35%) r-IFNα patients.

Table 1. Baseline characteristics.

	HU n = 38	r-IFNα n = 167
Age, median years	68 (64-71)	58 (46-67)

Microcirculatory disturbances	9/37 (24%)	44/166 (27%)
Hypermetabolic symptoms	10 (26%)	49 (29%)
Phlebotomy	0 (0-2)	0 (0-2)
Low risk	0	74 (45%)

Data are median (IQR) and n (%)

Summary and Conclusions: This planned analysis of efficacy and toxicity at 18 months shows a significant difference in the CHR rate (p=0.04) for patients treated with HU compared to low-dose r-IFNα. However, ORR was almost similar for patients still on study medication. Toxicity dependent discontinuation from r-IFNα was higher than expected (27%) even in this low-dose setting. Due to the study design patients treated with r-IFNα were younger than those treated with HU.

S132

COMPARISON OF LONG-TERM EFFICACY AND SAFETY OF ROPEGINTERFERON ALFA-2B *VS* HU IN POLYCYTHEMIA VERA PATIENTS AGED BELOW OR ABOVE 60 YEARS: TWO-YEAR ANALYSIS FROM THE PROUD/CONTINUATION PHASE III TRIALS

Background: Ropeginterferon alfa-2b (Ropeg) is a novel mono-pegylated IFNα, allowing convenient self-administration every 2 to 4 weeks. It is currently being developed for treatment of MPNs in particular PV. Hydroxyurea (HU) is the only licensed first-line therapy in high-risk patients with PV of all ages. Off-label IFNα as first-line therapy is primarily used in patients of younger age, partly because of the misconception that the risk-benefit ratio is not so favorable in elderly patients.

Aims: To analyse the difference in efficacy and safety of Ropeg and HU in two age cohorts (<60 years and ≥60 years).

Methods: 254 PV patients (WHO2008 criteria) had been randomized to receive Ropeg or HU in the PROUD Study. After 12 months of treatment, 89.6% of Ropeg treated patients and 68.5% of HU treated patients continued treatment in the CONTINUATION Study. Efficacy assessment consisted of complete hematological response (CHR) rate according ELN criteria, and the rate of CHR including symptom improvement (disease-related signs including clinically significant splenomegaly and PV-related symptoms). Secondary endpoints included *JAK2*V617F allelic burden assessed as rate of molecular response (modified ELN criteria). Efficacy and safety analysis was done for patients <60 years (Ropeg: n=49; HU: n=39) and ≥60 years (Ropeg: n=46; HU: n=37).

Results: After 24 months of treatment, Ropeg induced higher CHR rates compared to HU, irrespective of age: 77.6% *vs* 55.9% (<60 years); 63.0% *vs* 42.4% (≥60 years). Higher response rates were also shown for Ropeg *vs* HU for CHR including symptom improvement, similar for both age cohorts: 55.1% *vs* 37.1% (<60 years); 43.5% *vs* 36.1% (≥60 years). CHR rate maintenance (response maintained from first occurrence to 24 months assessment) was also higher for Ropeg and age-independent for both study treatments (Ropeg <60 years: 49.0%, ≥60 years: 37.0%; HU <60 years: 17.9%, ≥60 years: 18.9%). A similar observation for response maintenance was shown for CHR rate including symptom improvement (Ropeg <60 years: 32.7%, ≥60 years: 28.3%; HU <60 years: 15.4%, ≥60 years: 18.9%). After 24 months of treatment, partial molecular response rates were higher for Ropeg compared to HU, irrespective of age: 78.1% *vs* 33.3% (<60 years) and 59.5% *vs* 25.0% (≥60 years). Regarding safety, Ropeg and HU treated patients showed comparable numbers of both, adverse events (89.8% *vs* 92.3% <60 years, 93.5% *vs* 91.9% ≥60 years) and serious adverse events (6.1% *vs* 10.3% <60 years, 21.7% *vs* 24.3% ≥60 years) irrespective of age. The number of adverse drug reactions (ADRs) was comparable below 60 years (77.6% *vs* 74.4%) but interestingly in the cohort ≥60 years, a trend towards a lower number of ADRs was evident for Ropeg (63.0%) *vs* HU (89.2%). No serious ADRs were reported for Ropeg, but there were 4 serious ADRs (*Acute Leukemia*, *Anemia*, *Leukopenia*, *Granulocytopenia*) reported for HU (all patients aged ≥60 years).

Summary and Conclusions: A high CHR, symptom improvement and molecular response (*JAK2*V617F) achieved by long-term treatment with Ropeg was shown, with an advantage over HU independent of age. The safety analysis in patients ≥60 years also showed a positive trend regarding less ADRs and less serious ADRs for Ropeg *vs* HU. These data indicate that Ropeg provides a valuable, efficacious and safe new treatment option for PV patients of all ages including elderly.

S133

RESURRECTING RESPONSE TO RUXOLITINIB: A PHASE I STUDY TESTING THE COMBINATION OF RUXOLITINIB AND THE PI3K DELTA INHIBITOR UMBRALISIB IN RUXOLITINIB-EXPERIENCED MYELOFIBROSIS

T. Moyo[12,*], J. Palmer[3], Y. Huang[24], O. Oluwole[12], S. Mohan[12], R. Caza[2], G. Ayers[24], L. Berry[24], C. Dudley[2], L. Dugger[2], H. Miskin[5], A. Cavers[5], P. Sportelli[5], B. McMahon[6], S. Strickland[12], R. Mesa[7], L. Michaelis[8], M. Savona[12]

Medical Center, Nashville, TN, [3]Mayo Clinic, Scottsdale, AZ, [4]Center for Quantitative Sciences, Vanderbilt University Medical Center, Nashville, TN, [5]TG Therapeutics, New York, NY, [6]University of Colorado, Denver, CO, [7]University of Texas Health Science Center, San Antonio, TX, [8]Medical College of Wisconsin, Madison, WI, United States

Background: JAK inhibition with ruxolitinib (rux) reduces spleen size and myelofibrosis (MF)-related symptoms and improves survival, but nearly half of responders relapse within 5 years. Treatment options for MF after failure of rux are scant. Inhibition of PI3Kδ and AKT signaling reduces proliferation and clonogenic potential of JAK2-mutated cell lines, and synergizes with rux in patient samples. Umbralisib, a novel next-generation PI3K inhibitor highly selective for the delta isoform was well-tolerated in clinical trials in lymphoid malignancies. We tested the combination of umbralisib and rux in previously rux-treated MF.
Aims: 1. To assess safety of the combination of umbralisib + ruxolitinib 2. To evaluate preliminary efficacy of the combination in MF
Methods: This study has three stages. In Escalation Stage (ES) 1, 12 MF subjects, on a stable ruxolitinib dose for ≥8 weeks with a suboptimal or lost response at the highest tolerated dose were treated with once daily doses of umbralisib in a 3+3 design. In ES2, 4 additional MF patients were treated with the umbralisib dose from ES1 and escalating rux doses to complete the safety analysis. In the Expansion Stage, 7 additional MF patients continued their stable dose of rux, and umbralisib was added at the ES1 recommended dose. Adverse events (AEs) were graded by NCI-CTCAE v4.03. Efficacy was assessed by IWG-MRT consensus response criteria. Symptoms were assessed by the MPN symptom assessment form total symptom score (MPN-SAF TSS).
Results: All 23 subjects enrolled as of the data cutoff on December 31, 2017 were included in safety analyses. Median number of cycles was 5 (range 1-29). Median age at study entry was 67 years; 61% were male; 91% had ECOG PS<2. Dose-limiting toxicities (DLTs) of asymptomatic pancreatic enzyme elevation were experienced by one subject each treated with 10mg or 15mg rux + 800mg umbralisib in ES1. No DLTs were seen in subjects at lower umbralisib doses. Thus, all subsequently enrolled subjects were treated with 600mg umbralisib. The most common Gr3/4 AE was anemia reported by 3 patients (Table 1). Two patients each experienced Gr 3 diarrhea, neutropenia, and elevations in serum amylase and lipase. There was one case of colitis in a patient with chronic intermittent diarrhea. Three subjects were removed from study due to AEs, 1 to pursue HSCT; 10 remained on study. Of 23 response-evaluable rux-experienced MF subjects, 2 achieved CR after 5 and 15 cycles. An additional 11 met IWG-MRT criteria for clinical improvement based on anemia, spleen and/or symptoms responses. Mean improvement in hemoglobin was 1.2g/dL (range 0-3.7g/dL). Mean reduction in TSS was 33% (Figure 1).

Table 1. Most common (>5%) all-cause AEs and AEs of special interest.

	Grade 1 n (%)	Grade 2 n (%)	Grade 3 n (%)	Grade 4 n (%)
Anemia	1 (4%)	6 (11%)	3 (13%)	-
Neutrophil decreased	-	-	2 (9%)	-
Platelet count decreased	3 (13%)	2 (9%)	-	-
AST increased	6 (26%)	-	-	-
ALT increased	3 (13%)	-	-	-
Amylase increased	1 (4%)	-	2 (9%)	-
Lipase increased	1 (4%)	-	2 (9%)	-
Diarrhea	-	-	2 (9%)	-
Colitis	-	-	1 (4%)	-
Dyspnea	-	-	1 (4%)	-
Upper respiratory infection	-	2 (9%)	-	-
Pneumonia	1 (4%)	2 (9%)	1 (4%)	-
Sepsis	-	-	-	1 (4%)

Summary and Conclusions: Enhancing suppression of pathologic JAK-STAT signaling with PI3Kδ inhibition represents a viable treatment strategy for MF patients with inadequate or lost response to ruxolitinib. The addition of umbralisib to rux was well-tolerated. Pancreatic enzyme elevation was not seen with doses of umbralisib <800mg. Significant LFT abnormalities were absent and colitis uncommon, distinguishing umbralisib from other PI3Kδ inhibitors. Hematologic AEs were largely unrelated to drug and occurred in the context of extensive marrow fibrosis and disease progression. An IWG-MRT response (CR, PR or CI) was observed in 56.5% of rux-experienced MF subjects. Two patients who had lost response after >1y of ruxolitinib monotherapy achieved CR on study, demonstrating that umbralisib can augment and resurrect a response in subjects with suboptimal or lost response to ruxolitinib. The addition of umbralisib to rux was well-tolerated. Pancreatic enzyme elevation was not seen with doses of umbralisib <800mg. Significant LFT abnormalities were absent and colitis uncommon, distinguishing umbralisib from other PI3Kδ inhibitors. Hematologic AEs were largely unrelated to drug and occurred in the context of extensive marrow fibrosis and disease progression. An IWG-MRT response (CR, PR or CI) was observed in 56.5% of rux-experienced MF subjects. Two patients who had lost response after >1y of ruxolitinib monotherapy achieved CR on study, demonstrating that umbralisib can augment and resurrect a response in subjects with suboptimal or lost response to ruxolitinib alone.

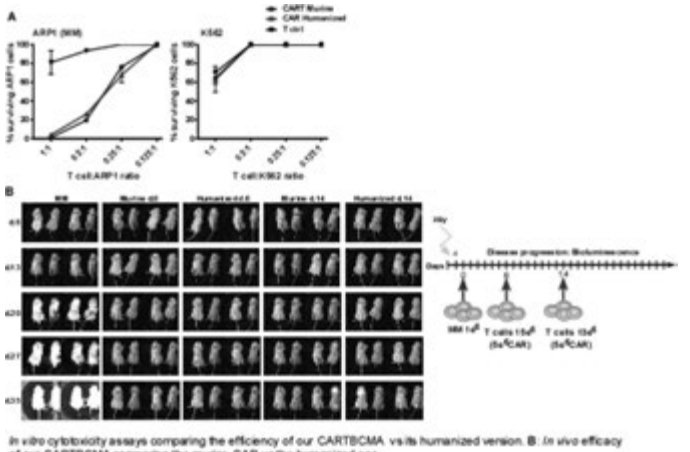
PRE-CLINICAL RESULTS OF A HUMANIZED CART-BCMA FOR MULTIPLE MYELOMA PATIENTS

L. Pérez-Amill[1,*], G. Suñe [1], M. Castella Castella[1], A. Najjar[2], M. Juan[3], C. Fernández-de Larrea[1], A. Urbano-Ispizua[14], B. Martín-Antonio[14]

[1]Hematology, IDIBAPS, Hospital Clínic, Barcelona, Spain, [2]Stem Cell Transplantation & Cellular Therapy, University of Texas, MD Anderson Cancer Center, Houston, United States, [3]Immunology, IDIBAPS, Hospital Clínic, [4]Josep Carreras Leukaemia Research Institute, Barcelona, Spain

Background: B Cell Maturation Antigen (BCMA) has appeared as a promising antigen to be used in CAR immunotherapy against Multiple Myeloma (MM) patients due to specific BCMA expression in plasma cells and its absence in most tissues. Recent clinical results infusing CART BCMA cells in patients with relapsed/refractory MM with a median of 7 prior lines of therapy (*i.e.*: NCT02658929) have shown 94% of objective responses, including 56% of complete remissions at 10 months. Deepening of response over time was detected. One of the main problems limiting the success of CART immunotherapy is the early disappearance of CART cells, occurring in approximately 30% of patients receiving CART19, which might be attenuated by the use of a humanized CART. Moreover, the high inflammatory response, termed cytokine release syndrome (CRS), could be detrimental to the patient and needs to be carefully monitored.
Aims: We decided to create a humanized CART-BCMA for the treatment of MM patients, and investigate possible ways of decreasing inflammation associated to CART expansion without impacting in the anti-MM CART activity.
Methods: We designed a 2nd generation murine CAR against BCMA with 4-1BB as co-stimulatory domain, and after confirming its functionality, we humanized the scFv of BCMA. *In vitro* studies were performed with MM cell lines (RPMI-8226, ARP1, U266) and K562 as a negative control cell line. *In vivo* studies were performed in NSG mice receiving $1{\cdot}10^6$ of MM (ARP1) cells i.v. injected at day 1. Then, mice received $5{\cdot}10^6$ i.v. injected of either CAR-T or Ctrl non-transduced T cells, both murine and humanized. CART cells were infused at day 6 and day 14 of MM injection to have an early and advanced MM model.
Results: We successfully humanized the scFv of BCMA maintaining the cytotoxicity activity obtained by the murine CAR-BCMA. Moreover, both CARs were specific against MM (Figure 1A), as K562 cells were not eliminated by CART cells. *In vivo* results showed that both murine and humanized CART-BCMA injected at day 6 were equally efficient in abrogating MM growth at an early-stage of the MM disease. When CART cells were infused at day 14, both murine and humanized CART-BCMA significantly reduced the advanced-stage of the MM disease but could not avoid the total progression of the disease (Figure 1B). Moreover, a-MSH, a molecule with ant-inflammatory properties which does not decrease CD8 cytotoxic activity was evaluated as anti-inflammatory agent and its potential effect in CART activity. *In vitro* functional assays showed that a-MSH partially increased the cytotoxic activity of the CART-BCMA and decreased the IL6 and TNFa *in vitro* production.



In vitro cytotoxicity assays comparing the efficiency of our CARTBCMA vs its humanized version. B: *In vivo* efficacy of our CARTBCMA comparing the murine CAR vs the humanized one.

Figure 1.

Summary and Conclusions: We generated a humanized CART-BCMA that is as efficient as the murine one, but might favor a longer persistence of CART cells in patients. In the next months, this CAR will be translated into the clinic for MM patients. Furthermore, a-MSH potentially could be used as an adjuvant to ameliorate CRS without impacting negatively in the CART activity.

S135

CLINICAL-GRADE PRODUCTION, PRECLINICAL EFFICACY AND SAFETY OF ALLOGENEIC CD19CAR CYTOKINE-INDUCED KILLER CELLS TRANSFECTED WITH SLEEPING BEAUTY TRANSPOSON FOR ACUTE LYMPHOBLASTIC LEUKEMIA TREATMENT

C.F. Magnani[1,*], C. Mezzanotte[1], C. Cappuzzello[1], F. Benedicenti[2], D. Belotti[3], B. Cabiati[3], M. Bardini[1], G. Fazio[1], G. Cazzaniga[1], L. Cooper[4], E. Montini[2], G. Dastoli[1], G. Gaipa[1], E. Biagi[1], A. Biondi[1]

[1]Tettamanti Research Center, Department of Pediatrics, University of Milano-Bicocca, San Gerardo Hospital/Fondazione MBBM, Monza, [2]San Raffaele Telethon Institute for Gene Therapy (HSR-TIGET), Milan, [3]Laboratorio di Terapia Cellulare e Genica Stefano Verri, ASST-Monza, San Gerardo Hospital, Monza, Italy, [4]University of Texas, MD Anderson Cancer Center, Houston, United States

Background: Infusion of patient-derived CD19-specific chimeric antigen receptor (CAR) T cells engineered by viral vectors achieved complete remission and durable response in relapsed and refractory (r/r) B-lineage neoplasms. Here, we expanded on those finding by providing a preclinical evaluation of allogeneic non-viral cytokine-induced killer (CIK) cells transfected with Sleeping Beauty (SB) CD19CAR (CARCIK-CD19).
Aims: Since both non-clinical pharmacology studies in patient-derived xenograft (PDX) and toxicology of SB-transfected T cells are lacking, here we have performed a pre-clinical evaluation of donor-derived CARCIK-CD19, including validation of the GMP-compliant protocol, efficacy and biodistribution studies.
Methods: PBMC non-viral modification and CIK cell differentiation were performed according to the method enclosed in the filed patent EP20140192371 with electro-transfer of the SB GMP-grade DNA plasmids using 4D-Nucleofector (Lonza). The manufacturing process was performed in an academic Cell Factory, authorized by Agenzia Italiana del Farmaco (AIFA). Integration site (IS) analysis was performed by Sonication Linker Mediated (SLiM)-PCR and Illumina MiSeq sequencing. Human leukemia xenografts were generated in NOD.Cg-Prkdcscid Il2rgtm1Wj1/SzJ (NSG) mice. The good laboratory practice (GLP) toxicity study was conducted at GLP SR-TIGET (Milan) in absence of tumor.
Results: In a pre-GMP large-scale 18-day manufacturing process, we achieved stable CD19CAR expression (62.425%±6.399, n=8), efficient T-cell expansion (23.36±3.00-fold) and features of *in vitro* T-cell potency. Three lots was GMP manufactured by seeding 46.0x10^6, 56.8x10^6 and 140.4x10^6 PBMCs respectively. After 21-22 days of culture, we harvested 15.998x10^9, 1.436x10^9, and 3.897x10^9 total nucleated cells, with a mean viability of 96.96%. The median expression of CD3+CD19CAR+ cells was 46.90%, median vector copy number (VCN) was 2.0 VCN/cells and average killing was 75.29 (E:T ratio 5:1). Cell products appear to be highly polyclonal and no signs of genotoxicity by transposon insertions could be observed by IS analysis. Frozen/thawed CARCIK-CD19 remained fully functional both *in vitro* and in a established PDX of MLL–ENL rearranged acute lymphoblastic leukemia (ALL). CARCIK-CD19 showed a dose-dependent antitumor response and prolonged persistence in a PDX, bearing the feature of a Philadelphia-like ALL with PAX5/AUTS2 translocation, and in a survival model of lymphoma, achieving complete eradication of disseminated tumors. CARCIK-CD19 induced long-term tumor regression along with a statistically significant survival prolongation compared to untreated mice (n=11, p=0.0495, Log-rank Test). Interestingly, CARCIK-CD19 cells persisted in PB and organs up to 3 months. Finally, the infusion of CARCIK-CD19 proved to be safe and well tolerated in a bio-distribution and toxicity model. In the engrafted animals, transfected cells persisted, mainly with a constant VCN value, in the hematopoietic and post-injection perfused organs untill the end of the study (60 days) and consisted of CD8+, CD56+ and CAR+ T cells.
Summary and Conclusions: Overall, our findings provide important implications for non-viral technology and the proof-of-concept that donor-derived CARCIK-CD19 are indeed effective against relapsed ALL. A clinical trial investigating allogeneic CARCIK-CD19 in r/r pediatric and adult ALL post HSCT is currently ongoing (NCT03389035).

P53 ISOFORM D133P53A: A NEW TRANSCRIPTIONAL ENHANCER OF T-CELL EFFECTOR FUNCTION

K. Legscha[1,*], E. Antunes[1], E. Amann[12], B. Guezguez[12], M. Theobald[123], H. Echchannaoui[12]

[1]Hematology, Oncology, and Pneumology, University Medical Center, Mainz, [2]German Consortium for Translational Cancer Research (DKTK), Frankfurt/Mainz, [3]Research Center for Immunotherapy, University Medical Center, Mainz, Germany

Background: Adoptive transfer of genetically modified T lymphocytes with tumor antigen-specific receptor has proven efficacy in cancer immunotherapy. However, in many patients the overall benefit is still limited due to various tumor escape mechanisms. Cell damage and metabolic/hypoxic stress in the tumor microenvironment (TME) can lead to a dysfunctional anti-tumor T cell response called T cell senescence. The tumor suppressor TP53 is a master molecule in the regulation of cell cycle and senescence. Few studies have demonstrated the critical role of p53 isoforms in the regulation of cellular senescence mainly in tumor cells. However, their role in tumor infiltrating lymphocytes (TILs) remains largely unexplored.
Aims: Strategies to prevent T cell senescence in the TME could improve T cell function leading to a more effective anti-tumor response. To better understand the role of Δ133p53α isoform in regulating the cell cycle and senescence we studied the cellular and metabolic phenotype as well as the effector function of the Δ133p53α-modified tumor-antigen (TA) specific human T cells.
Methods: T cells form healthy donors were retrovirally co-transduced with a TA-specific T cell receptor (TCR) together with the Δ133p53α isoform or an empty control vector. Modified T cells were characterized for the expression of key activating/inhibitory molecules, homing markers and their proliferation capacity by flow cytometry. Additionally, we determined the metabolic phenotype of the cells with an Agilent Seahorse XFp Analyzer. The effector functions *i.e.* cytokine secretion and antigen-specific killing capacity were assessed by Luminex immunoassay and long-term tumor colony-forming assay, respectively.
Results: Our analyses of human T cells simultaneously engineered with Δ133p53α-isoform and a TA-specific TCR revealed reduced cell surface expression of T-cell inhibitory molecules (*i.e.* PD-1 or TIGIT), senescence markers (CD57, CD160) and increased expression of the homing receptor CD62L upon TA stimulation. Interestingly, first comparative analyses between Δ133p53α-modified and control T-cells revealed changes in the cell's metabolic program similar to quiescent/naïve T cells. Δ133p53α-T cells exhibited lower ATP production, oxygen consumption as well as lower glucose utilization. Upon antigen-specific stimulation, however, they increased their metabolic activity up to the levels of control cells or even slightly above. Importantly, while control T cells exhibited cellular senescence after several rounds in culture, Δ133p53α-expressing T cells remained highly proliferative, showed superior cytokine secretion and enhanced tumor-specific killing capacity.
Summary and Conclusions: Genetic modulation of p53 isoforms in human T lymphocytes represents a novel approach to circumvent tumor-mediated T-cell replicative senescence and to preserve long-term effector function of tumor-reactive T cells. We believe that this new approach could improve current adoptive T cell-based therapies.

LEUKEMIA CELL-DERIVED MICROVESICLES INDUCE T CELL EXHAUSTION VIA MIRNA DELIVERY

J. Cui[1,*], Q. Li[2], L. Jiang[1], Y. You[1], Z. Zhong[1], X. Zhu[3], P. Zou[1]

[1]Institute of Hematology, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, [2]Department of Hematology,, Wuhan No.1 Hospital, Wuhan, [3]Department of Hematology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: Acute leukemia is a heterogeneous malignancy characterized by the clonal expansion of hematopoietic blasts in the peripheral blood, bone marrow, and/or other tissues. A majority of acute leukemia patients have poor prognosis with traditional therapies. T cell therapy, especially with chimeric antigen receptor T (CAR-T) cells, is promising for the treatment of leukemia and other cancers. However, in the context of persistent antigen exposure in chronic viral infections and cancer, both native and adoptive T cells can become exhausted/dysfunctional. Cancer cells can generate large membrane-enclosed structures, known as microvesicles (MVs). Our previous work has demonstrated that BCR-ABL1$^+$ MVs can induce malignant transformation of mononuclear cells from bone marrow.
Aims: The aim of this study was to investigate whether MVs can play a role in leukemia associated T cell exhaustion.
Methods: T cells isolated from healthy donor peripheral were incubated with leukemia-derived MVs. The immune checkpoints inhibitors and function of T cells were examined to explicit the effect of MVs on T cell *in vitro*. In addition, leukemia-derived MVs were injected into BALB/c mice to detect the effect of MVs on T cells *in vivo*. The transcriptomes RNA-seq of T cells on day 0, 3 and 7 after incubation with MVs was conducted to excavate the mechanism of T cell exhaustion. Furthermore, bone marrow of leukemia patients were collection to isolated CD3$^+$ T cells through microbeads, then the isolated T cells were cultured *in vitro* to examined the change of immune checkpoint inhibitors on day 0 and 7.
Results: Following incubation with MVs from various sources, all T cell subtypes exhibited the exhaustion phonotype and impaired cytokine secretion *in vitro*. Mice models also showed the connection between immune checkpoint inhibitors and MV injection. Sequencing and bioinformatics analyses indicated that a number of transcription factors and microRNAs (miRNAs) were attributable to the dysregulation of pathways and exhaustion in T cells. Further work revealed that functional miR-92a-3p, miR-21-5p, miR-16-5p, miR-126 and miR-182-5p in MVs could be delivered into T cells to induce the exhaustion phenotype. SerpinB2, IL-1β and CXCL5, which are mediators of the NF- B pathway, were identified as the targets of the miRNAs mentioned above.Interestingly, the immune checkpoint inhibitors of T cells isolated from leukemia patients reduced after culture *in vitro*, which show that the exhaustion of T cells might be reversed once T cells were separated from tumor environment (Figure 1).

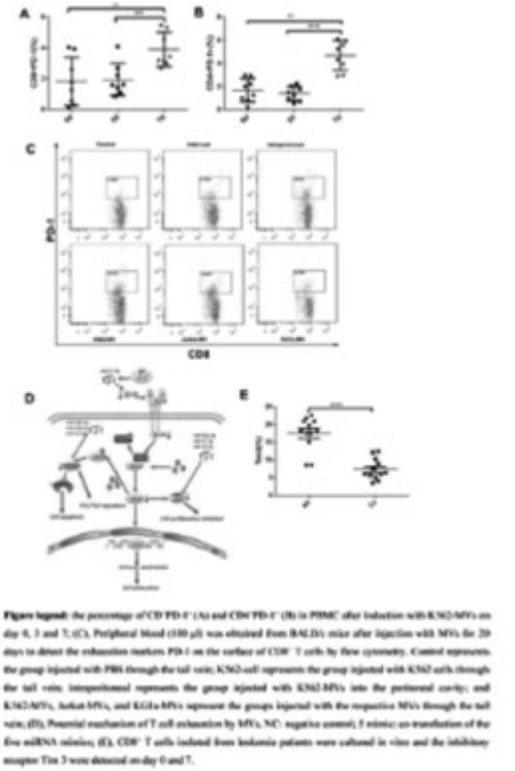

Figure 1.

Summary and Conclusions: We demonstrated that leukemia-derived MVs could initiate T cell exhaustion via the progressive temporal delivery of multiple exogenous miRNAs into T cells and the subsequent interaction of these miRNAs with their targets. Therefore, MVs can be expected not only to become new indicators of the T cell status in patients but also to be used as novel targets for personalized patient treatment.

[1]Massachusetts General Hospital Cancer Center, Boston, [2]Sarah Cannon Research Institute and Tennessee Oncology, Nashville, [3]Mayo Clinic, Rochester, [4]Dana-Farber Cancer Institute, Boston, [5]Hackensack University Medical Center, Hackensack, [6]Stanford University Medical Center, Palo Alto, [7]Mount Sinai Medical Center, New York, [8]Beth Israel Deaconess Medical Center, Boston, [9]Bluebird Bio Inc., Cambridge, [10]Celgene Corporation, San Francisco, [11]Experimental Transplantation and Immunology Branch, National Cancer Institute/Institutes of Health, Bethesda, United States

Background: bb2121 is a second-generation chimeric antigen receptor (CAR) T cell therapy targeting B-cell maturation antigen (BCMA) to redirect T cells to recognize and kill malignant myeloma cells. Initial data from the dose-escalation phase of CRB-401, a first-in-human study of bb2121 in relapsed/refractory multiple myeloma (RRMM), have shown promising efficacy and safety.
Aims: Here, we report updated safety and efficacy results on 43 subjects enrolled in this ongoing study.
Methods: CRB-401 (NCT02658929) is a two-part, phase I study of bb2121 in patients with RRMM. Patients in the dose-escalation had received ≥3 prior lines of therapy including a proteasome inhibitor and an immunomodulatory agent, or were double refractory, and had ≥50% BCMA expression on plasma cells. In the dose-expansion phase, patients had to have received daratumumab and been refractory to their last line of therapy; no BCMA expression was required. Following lymphodepletion with fludarabine (30 mg/m^2)/cyclophosphamide (300 mg/m^2) given daily for 3 days, patients received 1 infusion of bb2121.
Results: As of 02 Oct 2017, 21 patients had received bb2121 in the 4 dose-escalation cohorts (median follow-up, 35 weeks); no dose-limiting toxicities and no grade ≥3 neurotoxicities were observed. Cytokine release syndrome (CRS), primarily grade 1-2, was reported in 15 of 21 (71%) patients; 2 patients had grade ≥3 CRS that resolved in 24 hours. There were 2 deaths on study; both patients had achieved complete response (CR) and had not progressed. Overall response rate in the 18 evaluable patients in dose-escalation cohorts ≥150 × 10^6 CAR T cells was 94%; 10 of 18 (56%) patients had CR or unconfirmed CR, and 9 of 10 evaluable patients were minimal residual disease (MRD)-negative. With a median follow-up of 40 weeks in the ≥150 × 10^{6}dose-escalation cohorts, median response duration and progression-free survival (PFS) had not been reached; PFS rates at 6 and 9 months were 81% and 71%, respectively. Doses of 150 to 300 × 10^6 CAR T cells were selected for the expansion phase. Results from an additional 5 months of follow-up and initial data from ~20 patients from the expansion cohort will be presented.
Summary and Conclusions: bb2121 shows promising efficacy at dose levels ≥150 × 10^6 CAR T cells with deep and durable ongoing responses and manageable CRS and neurotoxicities. These data support the potential of bb2121 anti-BCMA CAR T cell therapy as a new treatment paradigm for RRMM.

Platelet and bleeding disorders I

S139

COMPARISON OF STANDARD- AND LOW-DOSE RITUXIMAB IN PRIMARY IMMUNE THROMBOCYTOPENIA (ITP): DATA FROM THE UK ITP REGISTRY

C. Gracie[1,*], A. Zaidi[2], U. Doobaree[1], L. Taylor[2], D. Provan[2], A. Newland[2], V. McDonald[2]

[1]The ITP Registry, Queen Mary University, [2]Clinical Haematology, Bartshealth NHS Trust, London, United Kingdom

Background: Rituximab is reported to give response rates, partial or complete, (platelets >30 x10^9/L and >2 baseline) of up to 60% in patients with ITP. The efficacy of lower doses of rituximab (<375mg/m2) have been published successfully but there have been no large-scale comparative randomised trials.
Aims: To compare the efficacy of low and high dose rituximab in patients with primary ITP.
Methods: We performed a retrospective review of the efficacy of two main dosing regimens in ITP patients (100mg weekly x 4 weeks (low dose) *vs* 375mg/m2 weekly x 4 weeks (standard dose)) using data from the UK Adult ITP registry, a large national registry of primary ITP. Choice of dosing was based on physician preference and funding.
Results: The UK Adult ITP registry database was reviewed for all patients who received rituximab. There were 301 patients who had sufficient data input for analysis. Of these 301 patients, 179 had received low dose rituximab dose and 122 had received standard dose. There was no significant difference in the demographics between the two groups: (female 56% and 46% respectively; median age of 56.6years and 56.4 years respectively). 10% patients in the low dose group and 17% in the high dose group underwent splenectomy prior to receiving rituximab and the average number of courses of treatments given before rituximab was 6 in both groups (including corticosteroids and intravenous immunoglobulin). The median time from diagnosis to rituximab therapy in the low dose group was 13.7 months and in the standard dose group was 14.4 months. There was no difference in the median patient platelet count before treatment between the groups (28.1 and 26.4 x10^9/L respectively for low dose and standard doss regimes). The median platelet count was not significantly different at 2, 4 and 6 months after rituximab therapy between the low and standard doses (46, 72, 74 x10^9/L and 43, 65, 81 x10^9/L respectively). There was, however, some ongoing increase in platelet count between 2 and 4 months for both dosing schedules showing ongoing delayed response. At 2 months after therapy, complete remission (defined as platelets >100 x 10^9/L) was achieved in 21.1% and 32% patients in the low dose and standard dose regimes respectively. This increased to 37.7% and 43.1% at 6 months. Partial remission at 2 months was achieved in 36 and 27.1% patients for 100mg and 375mg/m2 doses. By 6 months this was 34% and 27% respectively. Bleeding episodes (all bleeds) before and after therapy were reported in 63.7% and 44.7% of patients in the 100mg dose group and 63.9% and 39.3% patients in the 375mg/m2 group. The median number of bleeding events per patient prior to treatment was 2 in both groups (range 0-4). After rituximab the median was 1 in both groups (range 0-2). For those that did bleed, the median time was 4.0 months for 100mg (range 1.6 – 18.7) and 2.8 months for 375mg/m2 (range 1.1 – 12.3). There was no statistically significant difference between these two. For those that required another line of treatment, the median time was 4 months for 100mg and 3 months for the 375mg/m2 dose.
Summary and Conclusions: In conclusion, in this large cohort, 100mg rituximab appears to be as effective as 375mg/m2 in improving platelet count and achieving PR. These data show that both doses are equally as effective in reducing bleeds with no difference in the median time to next treatment. This would suggest, that for patients with primary ITP, 100mg rituximab weekly x 4 weeks may be a more cost-effective option than the standard dosing regimen (375mg/m^2 weekly x 4).

S140

FACTORS INFLUENCING MANAGEMENT OF ANTIPLATELET DRUGS IN THROMBOCYTOPENIC PATIENTS WITH HEMATOLOGICAL MALIGNANCY

A. Leader[1,2,3,*], V. ten Cate[4], A. ten Cate-Hoek[1,5], G. Spectre[3,6], E. Beckers[7], P. Raanani[2,3], H. Schouten[7], A. Falanga[8], H. ten Cate[1,5]

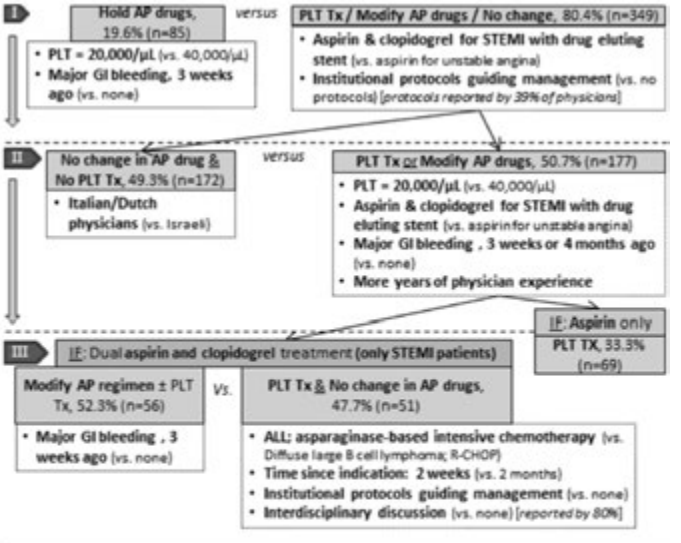
Center, Petah Tikva, [3]Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, [4]Epidemiology Department, Maastricht University, [5]Thrombosis Expert Center, Maastricht University Medical Center (MUMC+), Maastricht, Netherlands, [6]Institute of Hematology, Davidoff Cancer Center, Rabin Medical Center, Petah Tikva, Israel, Petah Tikva, Israel, [7]Department of Hematology, Maastricht University Medical Center (MUMC+), Maastricht, Netherlands, [8]Immunohematology and Transfusion Medicine Department, Hospital Papa Giovanni XXIII, Bergamo, Italy

Background: The use of antiplatelet (AP) drugs in thrombocytopenic (TCP) cancer patients is not uncommon. Balancing the increased risks of arterial thrombosis and bleeding is complex and informed only by retrospective studies on aspirin in acute coronary syndrome. Choice experiments can provide insight into management, in the absence of patient data.
Aims: (1) Identify patient and physician characteristics associated with AP drug management in TCP patients with hematological malignancies; (2) Evaluate whether physician assessments of bleeding risk (bl_risk) and thrombotic risk (thr_risk) correlate with AP drug management.
Methods: We designed a clinical vignette-based choice experiment. *First*, 11 Israeli/Dutch hematologists were interviewed, identifying 5 relevant attributes (*i.e.* malignancy & treatment type, platelet level, AP drug indication, time-since-indication, gastrointestinal bleeding) with 2-3 levels each. The case constants were: 50 year old male with normal renal function and coagulation tests. *Second*, an algorithm was used to create a fractional factorial design using these variables, generating 18 unique case vignettes each comprised of all 5 attributes, but different combinations of levels. The survey was piloted in Italy and distributed in Israel, Italy and the Netherlands (N=886). Each physician received 3 vignettes and was asked to assess bl_risk & thr_risk (scale: 1-10), and AP drug management (*i.e.* hold; no change; transfuse platelets; modify). *Third*, for analysis, management was split into 3 consecutive steps (I, II, III), each with a choice between 2 options (Figure 1). At each step, multivariate mixed-effects binomial logistic regression was used to calculate odds ratios (OR) and 95% confidence intervals (CI) of using one management option (over the other), for each physician/patient variable in comparison to a reference level within that attribute group. This was also done using thr_risk/bl_risk as independent variables.
Results: 145 hematologists or thrombosis/transfusion specialists, mainly from Italy (48), Israel (46) and the Netherlands (44), responded to 434 cases. Figure 1 schematically depicts variables with statistically significant higher odds of choosing one management strategy over the other, compared to the reference variable. For instance, cases with platelet counts of 20,000/μL were 3.45 times more likely to have AP drugs held over not holding, than cases with platelet counts of 40,000/μL [OR for not holding, 0.29 (95% CI, 0.12-0.70)]. Stepwise: (I) continuing AP drugs (*vs* holding) was associated with increasing thr_risk (p<0.0001) and decreasing bl_risk (p<0.0001); (II) modifying AP drugs or transfusing platelets (*vs* neither) correlated with rising bl_risk (p<0.0001); (III) transfusing platelets without modifying AP drugs (*vs* modifying) was associated with increasing thr_risk (p<0.05) and decreasing bl_risk (p<0.005). There was virtually no variance between physicians and countries in how risk assessment affected management (data not shown).



shows the AP management process and associated variables in these thrombocytopenic cases. The 3 steps of management (I→II→III) are depicted in gray boxes, together with the % of cases (n) in which each strategy was selected. The white box shows variables with statistically significant higher odds of choosing the adjacent management strategy over the competing one, compared to the reference variable in parentheses. Odds ratios not shown (multivariate analysis). *ALL*, acute lymphoblastic leukemia; *AP*, antiplatelet; *GI*, gastrointestinal; *PLT*, platelets; *STEMI*, ST elevation myocardial infarction; *Tx*, transfusion

Figure 1.

Summary and Conclusions: Physician-assessed bleeding and thrombotic risk consistently and logically influence all levels of management, with surprisingly little variance between physicians. The decision process is complex and affected by physician characteristics as well as a large number of patient variables. Platelet transfusions were frequently chosen to support continuing AP drugs, although no evidence supports this practice. The factors identified in this analysis should be considered when planning prospective management studies in this population.

S141

LONG-TERM SAFETY AND EFFICACY OF RITUXIMAB IN 248 ADULT IMMUNE THROMBOCYTOPENIA PATIENTS: RESULTS WITH MORE THAN 5 YEARS OF FOLLOW-UP FROM A FRENCH PROSPECTIVE REGISTRY ITP-RITUX

S. Deshayes[1,2,*], M. Khellaf[2], A. Zarour[3], R. Layese[3], O. Fain[4], L. Terriou[5], J.-F. Viallard[6], S. Cheze[7], J. Graveleau[8], B. Slama[9], S. Audia[10], M. Ebbo[11], M. Cliquennois[12], G. Le Guenno[13], G. Salles[14], F. Canoui-Poitrine[3], M. Michel[2], B. Godeau[2]

Background: The long-term safety and efficacy of rituximab (RTX) in adult's immune thrombocytopenia (ITP) are not well known and current data are only based on retrospective studies.
Aims: To assess long-term (5 to 7 years of follow-up) safety and efficacy of RTX in ITP throughout the prospective registry set up in France in 2010 in which 248 adult patients were included (ClinicalTrials.Gov: NCT1101295).
Methods: All consecutive patients ≥18 years of age who received RTX for a diagnosis of primary ITP based on international criteria were prospectively included between 2010 and 2012. Patients with secondary ITP or who had received a previous course of RTX were excluded. A prospective and periodic assessment of the safety and the efficacy of RTX were recorded through an electronic case report form. In accordance to international guidelines, complete response (CR) was defined by a platelet count >100x10^9/L and response (R) by a platelet count between 30-100x10^9/L with at least a 2-fold increase from baseline. One-year follow-up data have already been published (Khellaf *et al.*, Blood 2014).
Results: Among the 248 patients included in the registry (64% of females, mean age at ITP diagnosis: 51±20 years), 102 (41%) patients had persistent ITP and 146 (59%) chronic ITP at time of first RTX administration, and 10% were splenectomized. The median follow-up duration after the first RTX infusion was 69 [IQR, 55-79] months, with a follow-up ≥60 months for 177 (71%) patients. In terms of efficacy, at last follow-up visit, 77 (31%) patients had a lasting response (70 CR; 7 R). Among the 177 patients with a follow-up ≥60 months, 50 (28%) had a lasting response (46 CR; 4 R). According to National Cancer Institute Common Terminology Criteria, 34 (14%) grade 3 or 4 infections were observed, but only 10 (4%) of them occurred within the 12 months following the last RTX infusion, including 1 pneumocystis pneumonia and 1 aspergillosis sinusitis. No case of progressive multifocal encephalopathy was observed. Malignancies were observed in 24 (10%) patients and occurred at a median age of 71 [62-79] years of age after a median of 48 [39-62] months from RTX (incidence rate of 1.4 [IC95%, 1.1-2.5] for 100 patient-years, similar to the one observed in the French general population). No over-representation of a type of malignancy was found. Moreover, there were 47 adverse effects (AE) related to RTX infusion; 22 (9%) patients developed or exacerbated another autoimmune disease; 21 (8%) patients had cardiovascular complications; and 16 (6%) experienced at least 1 venous thromboembolic event. Overall, 31 (12%) patients died (median age: 80 [IQR, 71-84] years) after a median time of 30 [IQR, 14-54] months after the first RTX infusion, corresponding to a mortality rate of 2.4 [IC95%, 1.7-3.4] for 100 patient-years. Deaths were mainly related to infections (n=6), malignancies (n=5) or bleeding (n=4). Among these AEs, only 24 AE ≥grade 3 were possibly related to RTX: 10 (4%) infections, 10 (4%) AE related to RTX infusion, 4 (2%) deaths (3 from infectious origin, 1 from unexplained cause). Gammaglobulin levels were not systematically monitored. Among the 142 (57%) patients from whom the data was available, 6 (2%) patients developed a hypogammaglobulinemia <5 g/L during follow-up.

Summary and Conclusions: This large nationwide prospective registry shows that a durable response is achieved in almost one third (31%) of adults with persistent or chronic ITP treated by RTX, and that no unexpected long-term complications occur beyond 12 months of follow-up.

S142

ABNORMAL BLEEDING ASSOCIATED WITH COAGULATION ABNORMALITIES IN SYSTEMIC AMYLOIDOSIS

K. Sun[1,*], X. Nan[1], S. Kasparian[1], C. Gentille[1], L. Rice[2], I. Ibrahim[2], S.R. Pingali[2], S. Iyer[2]

[1]Internal Medicine, [2]Hematology, Houston Methodist Hospital, Houston, United States

Background: Abnormal bleeding is a common complication of systemic Amyloidosis. Proposed mechanisms include Amyloid angiopathy and coagulation abnormalities among which Factor X deficiency is the most common. Prolongation of prothrombin time (PT) and partial thromboplastin time (PTT) were also reported.
Aims: We performed a retrospective review of different coagulation factors of systemic Amyloidosis patients from the Amyloid Database at the Houston Methodist Hospital between 2006 and 2015 to investigate the mechanisms of abnormal bleeding.
Methods: The patient data was queried from METEOR (Methodist Environment for Translational Enhancement and Outcomes Research), a clinical data warehouse that contains records dating back to January 1, 2006. We queried for the diagnosis of systemic Amyloidosis, clinically significant bleeding events, coagulation factors and other laboratory results along with patient demographics. The diagnosis of systemic Amyloidosis was further confirmed by reviewing tissue biopsy reports. The degree of bleeding was categorized into 4 grades according to World Health Organization standardized grading scale. Grade 2 or higher was defined as clinically significant bleeding. Grade 3 or 4 was considered as severe bleeding. Laboratory data including Factor X activity, PT, PTT, international normalized ratio (INR), platelets and fibrinogen were reviewed. Average laboratory test values in each clinical visit were used in univariate logistic regression test to investigate association of coagulation abnormalities with clinical significant bleeding and severe bleeding events.
Results: 230 patients and 2178 encounters were identified after excluding patients on anticoagulation. The type of the Amyloidosis was confirmed in 168 patients, 148 of which are primary Amyloidosis with the rest listed as unknown. 26 patients had at least one clinically significant bleeding event. 140 patients had PT and INR measured; 138 patients had PTT measured; 162 patients had platelet measured; 48 patients had fibrinogen measured and 34 had Factor X level measured. Elevated PT and INR were identified in 86/140 (61%) patients, elevated PTT in 61/138 (44%) patients, thrombocytopenia in 79/162 (48%) patients, abnormal Factor X (<70%) in 19/34 (56%) patients and decreased fibrinogen level (<200) in 5/48 (11%) patients. In univariate logistic regression analysis, prolongation of PT, INR, PTT and thrombocytopenia were independent variables associated with clinically significant bleeding (p=0.0011, p=0.0007, p=0.0044 and p= 0.0002 respectively). The same variables are also independently associated with severe bleeding events (p=0.0006, p=0.0004, p=0.0013 and p<0.0001 respectively). Factor X and fibrinogen level were not significantly associated with clinically significant bleeding or severe bleeding events (Table 1).

Table 1. The percentage of bleeding event with normal and abnormal laboratory studies.

Lab studies		%Bleeding	%Severe bleeding
PT	Normal PT	9.3%	1.9%
	Abnormal PT	23.3%	18.6%
	P value	0.0011	0.0006
PTT	Normal PTT	13.0%	6.5%
	Abnormal PTT	21.3%	18.0%
	P value	0.0044	0.0013
Platelet	Normal platelet	13.3%	8.4%
	Abnormal platelet	19.0%	13.9%
	P value	0.0002	< 0.0001
Factor X	>70%	33.3%	26.7%
	<70%	47.4%	36.8%
	P value	0.411	0.530
Fibrinogen	>200	30.2%	26.8%
	<200	20.0%	20.0%
	P value	0.9850	0.8067

Summary and Conclusions: Prolonged PT, INR and PTT are common in systemic Amyloidosis and correlate with increased bleeding events. Factor X deficiency is common but contrary to observations from previous studies, no correlation of it with abnormal bleeding was seen in our review. This could be explained by our low number of Factor X measurements. Studies with systemic measurements of PT, PTT, platelet and factor X activity are needed to further investigate the bleeding mechanisms in systemic Amyloidosis.

S143

A NOVEL BETA1-TUBULIN-BASED MEGAKARYOCYTE REPORTER SYSTEM IDENTIFIES COMPOUNDS THAT PROMOTE MEGAKARYOCYTE MATURATION AND PLATELET PRODUCTION

S.J. Chen[1,*], H. Seo[1], A. Hotta[1], Y. Nishi[1], A. Ohta[1], H. Hayashi[2], N. Koseki[2], N. Sugimoto[1], K. Eto[1]

[1]Center for iPS Cell Research and Application, Kyoto University, Kyoto, [2]New Drug Research Division, Otsuka Pharmaceutical Co. Ltd., Tokushima, Japan

Background: Transfusion of donor-derived platelets is commonly employed to treat patients with thrombocytopenia, while current supply system confronts challenges including limited donors, short shelf life of platelet products, the risk of bacterial and viral contamination and transfusion refractoriness. These limitations have motivated the development of alternative donor-independent platelet sources to meet the growing need of clinical transfusion. Human induced pluripotent stem cells (iPSCs) have been proposed as a potential source of megakaryocytes (MKs) and platelets to meet the demands of clinical transfusion.
Aims: Our group previously established immortalized megakaryocyte cell lines (imMKCLs) derived from iPSCs as cryopreservable master cells that can be robustly expanded and then produce platelets upon maturation (Nakamura *et al.,* Cell Stem Cell, 2014). However, the low platelet yield and requirement of mouse somatic feeder cells are the major hurdles that must be overcome before clinical realization. This study aimed to efficiently identify small molecules that could facilitate *in vitro* platelet generation from imMKCLs under the feeder-free culture condition.
Methods: We herein established a genetically modified imMKCL that express the β1-tubulin-Venus reporter to identify optimal feeder-free culture condition by monitoring *in vitro* MK maturation in a high throughput manner. The Venus transgene was inserted downstream of the *TUBB1* locus in imMKCLs using CRISPR/Cas9 technology, and the expression was visualized by Venus fluorescence intensity. The imMKCL reporter line enabled visible real-time studies under a confocal quantitative image system. This reporter line was then employed for a high throughput screening (HTS) to identify compounds that significantly improved the efficiency of platelet production.
Results: The HTS of five thousand compounds successfully identified several compounds from diverse categories (*i.e.* a WNT inhibitor and a FLT3 inhibitor) that facilitate *in vitro* MK maturation and platelet release from imMKCLs under feeder-free conditions. The *in vitro* thrombopoietic effects of candidate compounds was also confirmed in two common MK lineages, one was cord blood derived CD34+ cells and another was iPSC directly derived MKs. In addition, candidate compounds improved *in vivo* recovery of thrombopoiesis in two mouse thrombocytopenia models, which were induced by irradiation or anti-GPIbα antibody administration. Given that WNT and FLT3 inhibitors are used to treat leukemia and cancers, that often manifest thrombocytopenia due to the diseases themself or as a result of chemotherapy. This finding may also facilitate clinical settings of cancer therapy. Interestingly, according to a luciferase aryl hydrocarbon receptor (AhR) reporter gene assay, most of these compounds, including a WNT signaling inhibitor, facilitated thrombopoiesis by antagonizing AhR signaling, in accordance with the crucial role of AhR inhibition in MK maturation reported by some groups. Others promoted thrombopoiesis independently of AhR signaling.
Summary and Conclusions: In summary, we have established a comprehensive, real-time monitoring system for MK maturation based on β1-tubulin expression, which thereby allows to identify novel small molecule inducers of MK maturation and platelet production through HTS as well as to perform more in depth studies of thrombopoiesis.

Anemia and quality of life

S144

A ROLE OF PIEZO1 IN ERYTHROID DIFFERENTIATION OF NORMAL AND HEREDITARY XEROCYTOSIS DERIVED HEMATOPOIETIC PROGENITORS

A. Caulier[1,*], N. Jankovsky[1], H. Ouled-Haddou[1], Y. Demont[1], D. Bastit[2], C. Rose[3], H. Guizouarn[4], A. Lahary[5], L. Merlusca[6], C. Guitton[7], D. Lebon[1], M. Thuillier[1], C. Badens[8], J.-P. Marolleau[1], V. Picard[9], L. Garçon[1]

[1]EA HEMATIM, Université Picardie Jules Verne, Amiens, [2]EFS Normandie, Bois-Guillaume, [3]Hématologie, Hôpital Saint-Vincent, Lille, [4]UMR 7277, Institut de Biologie Valrose, Nice, [5]Laboratoire d'hématologie, CHU Rouen, Rouen, [6]Hematologie clinique, CHU Amiens, Amiens, [7]Hématologie pédiatrique, Hôpital Kremlin-Bicêtre, Paris, [8]Département de Génétique Médicale, Hôpital de La Timone, Marseille, [9]Laboratoire d'hématologie, Hôpital Kremlin-Bicêtre, Paris, France

Background: Activation of the mechanotransductor PIEZO1 plays a central role in the red cell dehydration observed in hereditary xerocytosis (HX). Data recently published in epithelial and endothelial cells suggested that PIEZO1 was involved in the balance between cell proliferation and differentiation. Preliminary expression study confirmed that PIEZO1 was expressed in immature erythroblasts. However, its role during erythropoiesis and the consequences of its gain-of-function mutations in HX have not been evaluated so far.
Aims: We studied the role of PIEZO1 activation in erythroid differentiation of normal and hereditary xerocytosis derived hematopoietic progenitors.
Methods: *In vitro* human erythropoiesis was conducted during 21 days using normal peripheral CD34+ cells after PIEZO1 activation by Yoda1 (Y1, n=4) and CD34+ (n=6) or total mononuclear cells (MNC, n=9) from 10 HX patients displaying 9 different mutations. Cell proliferation, apoptosis, and differentiation were assessed using cell count, flow cytometry (FC) and cytology at day 10. The erythroleukemic cell line UT7/EPO was used in parallel for Piezo1 knock-down experiments using shRNA lentiviruses, for calcium signaling and for transduction pathways studies.
Results: PIEZO1 activation by Y1 1µM in normal CD34+ cells induced a slow-down in erythroid differentiation as shown by a decrease in mature CD71+/Glycophorin A (GPA)+expressing cells at day 10 of culture (20.9%±10.8 *vs* 77.6%±8.5, $p<10^{-3}$), with no effect on cell proliferation and a slight increase in the apoptosis rate (Annexin V: 14.7±2.3% *vs* 5.1±0.8, p=0.049). A drastic decrease in GPA expression was also observed in UT7/EPO cells after Y1 exposure (reduction by 88%±0.7; $p<10^{-3}$). This decrease was transcriptional, as shown by RQ-PCR, and was abolished after shRNA-mediated PIEZO1 knock down or after PIEZO1-inhibition using Gadolinium. Functional studies using flow imaging revealed that Y1 induced a calcium influx inside UT7/EPO cells. EGTA reverted the Y1-induced GPA repression, showing that Ca^{2+} signaling mediated the phenotype. Of note, a secondary Ca^{2+} dependant activation of Gardos channel was not involved, since Senicapoc did not correct the phenotype. Investigating the PIEZO1 downstream signaling pathways, we observed that phospho-ERK blockade by either chemical inhibitor UO126 or retroviral dominant-negative MEK transduction prevented Y1-induced GPA repression (76%±3 *versus* 9%±1.1; $p<10^{-3}$), showing that a functional ERK was necessary to the PIEZO1-mediated effects in human erythropoiesis. *In vitro* erythroid differentiation of progenitors from HX patients showed heterogeneous results. A similar phenotype than described after Y1 exposure was clearly observed for 5 mutations. Among them, 1 patient carrying the *PIEZO1* mutation G1792A was tested in triplicate: the mature CD71+/GPA+population at day 10 was significantly decreased in comparison with controls (13.8%±12.6 *versus* 62.2%±20.7; p<0.01). This delay was confirmed by cytology after MGG staining, showing a significant increase in the proportion of immature precursors (pro+basophilic erythroblasts) at day 10 (99%±1 *versus* 58.2%±19.3; p<0.01).
Summary and Conclusions: We described here for the first time a role of PIEZO1 during human erythroid differentiation. PIEZO1 activation repressed erythroid terminal maturation through Calcium entry and secondary phosphorylation of the ERK pathway. A similar phenotype was observed in the majority of PIEZO1-mutated HX patients but not all, underlying the high heterogeneity in the phenotype and the pathophysiology of this disease.

S145

FOSTAMATINIB, A SPLEEN TYROSINE KINASE INHIBITOR, FOR THE TREATMENT OF WARM ANTIBODY AUTOIMMUNE HEMOLYTIC ANEMIA: PRELIMINARY RESULTS OF THE SOAR PHASE 2, MULTICENTER, OPEN-LABEL STUDY

D.J. Kuter[1,*], D. Arnold[2], A. Lichtin[3], R. Agajanian[4], M. Choi[5], K.A. Rogers[6], M.A. Boxer[7], C. Broome[8], J.J. Field[9], I. Murakhovskaya[10], A.M. Lowe[11], B. Cadieux[12], H. Zayed[12], S. Tong[12], A.-M. Duliege[12]

[1]Massachusetts General Hospital, Boston, Massachusetts, United States, [2]Michael G. DeGroote School of Medicine, Department of Medicine, McMaster, Hamilton, Ontario, Canada, [3]Hematologic Malignancies and Blood Disorders, Taussig Cancer Center, Cleveland Clinic, Cleveland, Ohio, [4]The Oncology Institute of Hope and Innovation, Downey, California, [5]University of California, San Diego, San Diego, California, [6]Division of Hematology, The Ohio State University, Columbus, Ohio, [7]Arizona Oncology, Tucson, Arizona, [8]Division of Hematology, Georgetown University, Washington, D.C., [9]Blood Center of Wisconsin, Medical College of Wisconsin, Milwaukee, Wisconsin, [10]Montefiore Medical Center, Bronx, New York, [11]Rigel Pharmaceuticals, Inc., West Lake Hills, Texas, [12]Rigel Pharmaceuticals, Inc., South San Francisco, California, United States

Background: Spleen tyrosine kinase (Syk), a signaling component of Fc receptors, is associated with macrophage destruction of red blood cells (RBCs) in warm antibody autoimmune hemolytic anemia (wAIHA). The Syk inhibitor fostamatinib diminishes antibody-induced anemia in mice (Podolanczuk *et al.*, Blood 2009;113(14):3154-60).
Aims: This Phase 2 study (NCT02612558) assessed the efficacy and safety of fostamatinib in wAIHA.
Methods: Eligible adult patients had primary or secondary wAIHA with more than one prior failed treatment, hemoglobin (Hgb) <10 g/dL, IgG-positive direct antiglobulin test (DAT), haptoglobin <10 mg/dL, and lactate dehydrogenase (LDH) >ULN. Patients received fostamatinib 150 mg BID for up to 24 weeks. In this Simon two-stage design, if ≥4 patients in Stage 1 achieved the primary efficacy endpoint (Hgb >10 g/dL with an increase of ≥2 g/dL from baseline by Week 24 without rescue therapy or RBC transfusion), suggesting a true response rate of greater than 20% (at alpha=0.10), then Stage 2 would begin enrollment. Data as of February 23, 2018, from Stage 1, are presented.
Results: Of 19 patients with post-baseline assessments, 1 (5%) had a history of lymphoproliferative disease, 5 (26%) had prior splenectomy, 12 (63%) had prior steroids, 1 (5%) had prior ESAs, and none had prior rituximab. The median baseline Hgb was 9.1 g/dL (range: 6.8-9.9). The primary endpoint was met: 9 of 17 (53%) patients had a response, including 1 late responder. Response was generally rapid and sustained; 5 of 9 responses were achieved within 4 weeks. The median duration of the first response was 16.6 weeks (range: 0.1 to >30 weeks). Trends for decreasing LDH and reticulocytes and increasing haptoglobin were observed. The most common adverse events were diarrhea and dizziness. Serious adverse events were reported in 3 patients. None were related to fostamatinib. One patient recovered and continued on treatment. Two patients had serious adverse events resulting in fatalities: one with skin necrosis and infection (immunosuppressed due to steroids) and one elderly patient with pneumonia (immunosuppressed due to steroids and prior CLL).
Summary and Conclusions: Fostamatinib markedly improved Hgb levels in some patients with wAIHA. Side effects were manageable and consistent with those previously reported with fostamatinib in other conditions. Based on these results, Stage 2 of this study is currently enrolling patients. Long-term follow-up will provide additional efficacy and safety data for fostamatinib in patients with wAIHA.

S146

LONG TERM SURVIVAL OF PATIENTS WITH EVANS SYNDROME: A POPULATION-BASED COHORT STUDY

D.L. Hansen[1,*], S. Möller[2], N. Mannering[1], K. Andersen[3], D. Gaist[4], H. Frederiksen[1]

[1]Department of Haematology, Odense University Hospital, [2]OPEN, Odense University Hospital and University of Southern Denmark, [3]Department of Psychiatry, Region of Southern Denmark, [4]Department of Neurology, Odense University Hospital, Odense, Denmark

Background: Evans syndrome (ES) is defined by either simultaneous or sequential diagnoses of both immune thrombocytopenia (ITP) and autoimmune haemolytic anaemia (AIHA). The syndrome is rare, and data on frequency and prognosis are lacking. Earlier reports have focused mainly on complications and relapse (*e.g.*: Michel, Blood. 2009, Costallat, Joint Bone Spine. 2012). Here we report novel epidemiological data on primary and secondary ES from a nationwide register.
Aims: To provide population-based estimates of incidence, prevalence and survival of adults with ES.
Methods: To estimate these parameters we followed a nationwide cohort of patients with at least one diagnosis of ITP or haemolysis according to the Danish National Patient Register, January 1977 to December 2015. We

excluded patients less than thirteen years of age, due to the usually self-limiting nature of childhood ITP. A comparison cohort comprised individuals from the general population matched to the patient cohort (50:1) on age, and gender. The patient cohort was classified as either primary or secondary ES based on the following diagnoses (recorded at any time before or up to one year after date of ES diagnosis): hereditary and non-familial hypogammaglobulinemia, systemic lupus erythematosus (SLE), HIV/AIDS, hepatitis C, liver cirrhosis, autoimmune lymphoproliferative syndrome type I and haematological malignancies including myelofibrosis.

Results: The patient cohort included 25,238 patients with a haemolysis diagnosis or ITP. From this cohort we identified 209 patients with ES aged 13-97 years. Simultaneous diagnoses were present in 32.5%, and ITP was the first symptom in 44.5% of the patients. Mean time between the two diagnoses was 3 years [95%CI: 2.2-3.7]. The patients with ES made up 2% [95%CI: 1.8-2.3] of all ITP cases, and 8% [95%CI: 7-9] of the AIHA patients. 54.1% [95%CI: 46.0-62.0] of the primary ES patients, and 46.0% [95%CI: 31.8-60.7] of the secondary cases were women. Age at diagnosis was 57.3 years [95%CI: 54.1-60.6] in the primary ES group and 62.6 [95%CI: 57.6-67.6] years in the secondary ES group. 23.9% [95%CI: 18.3-30.3] were secondary ES, with haematological malignancy as the predominant cause (68.0%). The five-year cumulated incidence of ES (primary or secondary) in number of new cases per 1 million inhabitants, was 6.1 [95%CI: 3.8-9.4] in 1981-1985; 4.5 [95%CI: 2.6-7.3] in 1996-2000; and 12.6 [95%CI: 9.3-16.7] in 2011-2015. The prevalence in number of cases per 1 million inhabitants was in 1985 5.1 [95%CI: 3.2-7.7]; increasing to 8.7 [95%CI: 6.2-11.9] in 2000; and 18.2 [95%CI: 14.6-22.4] in 2015. Age at death was 64.6 years [95%CI: 61.7-67.4] in patients with primary ES and 65.9 years [95%CI: 61.3-70.5] in those with secondary ES. Median survival was 7.9 years [95%CI: 5.5-11.7] in primary ES, and 2.2 years [95%CI: 1.1-10.4] in secondary ES, compared to 21.6 years [95%CI: 20.9-22.4] in the comparison cohort from the general population (Figure 1). Median survival was stable during the period.

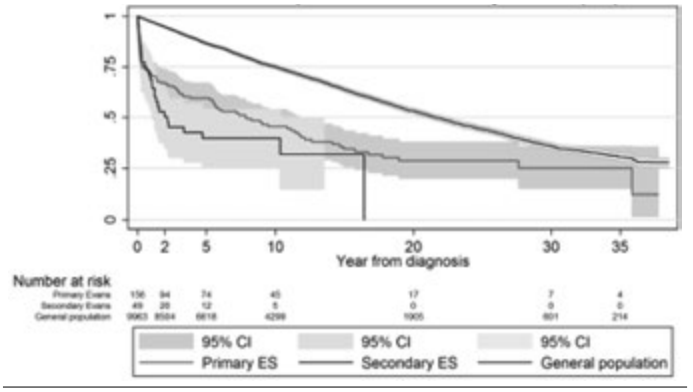

Figure 1. Survival for patients with Evans syndrome (ES).

Summary and Conclusions: ES is associated with a significant increase in mortality, especially among secondary cases. Incidence and prevalence are increasing, but survival does not seem to improve.

S147

IMPROVEMENTS IN CARDIAC BIOMARKERS ARE ASSOCIATED WITH BETTER HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS

K. L. McCausland[1], S. Guthrie[2], T. Quock[3,*], M. Yokota[1], M. Bayliss[1], M.K. White[1], V. Sanchorawala[4]

[1]Optum, Johnston, [2]Biopharma Strategic Consulting, LLC, San Francisco, [3]Prothena Biosciences Inc, South San Francisco, [4]Boston University School of Medicine, Boston, United States

Background: Light-chain (AL) amyloidosis is a rare, progressive and typically fatal disease in which misfolded light chains are deposited in tissues and organs, which may lead to organ failure, disability, and death. The cardiac biomarker B-type natriuretic peptide (BNP) or N-terminal pro B-type natriuretic peptide (NT-proBNP) is used to monitor disease progression and response to treatment among patients with cardiac involvement from AL amyloidosis. The relationships between these cardiac biomarkers and health-related quality of life (HRQoL) are poorly understood in this condition.

Aims: To examine whether HRQoL in patients with cardiac AL amyloidosis differs significantly by changes in BNP or NT-proBNP.

Methods: We obtained cardiac biomarker and HRQoL data from AL amyloidosis patients from two data sources: a community-based sample (n=108) and a clinical sample of patients seen at the Amyloidosis Center at Boston University School of Medicine at Boston Medical Center (n=95). In the community-based sample, HRQoL scores (based on the SF-36® Health Survey [SF-36] and the Kansas City Cardiomyopathy Short Form [KCCQ-12]) were examined by patients with and without a self-reported decline in NT-proBNP ≥30%. Separate generalized linear models, adjusted for complete hematologic response, were used to compare HRQoL scores by NT-proBNP response to treatment. HRQoL scores were reported relative to existing benchmarks, including: 1) mean SF-36 scores from both a general population sample and patients with congestive heart failure (CHF); 2) mean KCCQ scores according to New York Heart Association functional classes. Analysis of variance was used to compare SF-36 scores to age- and gender-adjusted benchmarks. In the clinical sample, both pre- and post-treatment SF-36 scores and BNP lab values were obtained from medical record reviews. Generalized linear models, controlling for baseline SF-36 scores, were used to test for significant differences in SF-36 change scores among patients with and without a decline in BNP ≥30%.

Results: In the community-based sample, patients with an NT-proBNP response had significantly better HRQoL than those without for all SF-36 and KCCQ scales and summary scores (P <0.05 for all; Figure 1). Patients without an NT-proBNP response had SF-36 scores that were comparable to CHF benchmarks. Analyses in the clinical sample further supported longitudinal associations between changes in cardiac biomarkers and changes in SF-36 scores.

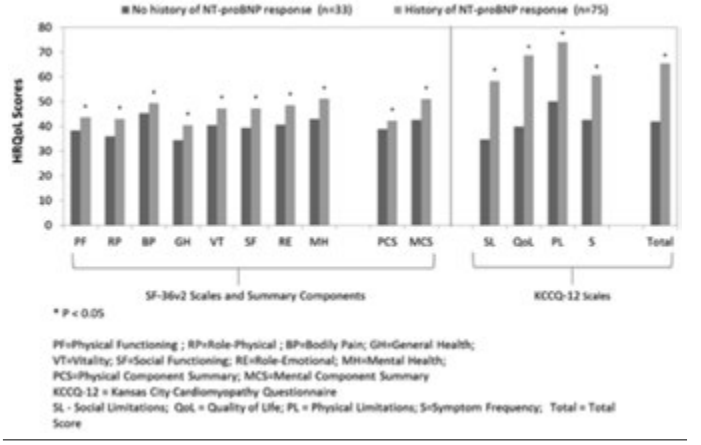

Figure 1. Health-related quality of life (HRQoL) by history of NT-proBNP response in a community-based sample of AL amyloidosis patients with cardiac involvement.

Summary and Conclusions: This study provided consistent preliminary evidence of a relationship between cardiac biomarkers and HRQoL using multiple data sources and different analytic approaches. These findings should be replicated in larger, longitudinal samples. A clearer understanding of the relationship between these frequently-used biomarkers and HRQoL can aid those in the scientific community who want to continue using these biomarkers to develop prognoses, evaluate treatment efficacy, and develop relevant and meaningful endpoints for clinical trials in patients with AL amyloidosis.

FATIGUE AT BASELINE IS ASSOCIATED WITH GERIATRIC IMPAIRMENTS AND PREDICTS SHORTER SURVIVAL IN OLDER PATIENTS WITH A HEMATOLOGICAL MALIGNANCY

F. Hofer[1], K. Koinig[1], L. Nagl[1], R. Stauder[1,*]

[1]Department of Internal Medicine V (Haematology and Oncology) , Innsbruck Medical University, Innsbruck, Austria

Background: Hematological malignancies represent typical diseases at advanced age. The relevance of the patient-reported outcome (PRO) fatigue in decision making and as an endpoint in clinical studies in older persons has been propagated recently. However, prospective data on the distribution and clinical impact on fatigue in elderly patients with a hematological malignancy are rare.

Aims: We set out to determine the prevalence and the association of self-reported fatigue with clinical outcome and geriatric impairments in older individuals newly diagnosed with blood cancer.

Methods: The EORTC QLQ-C30 and a multidimensional geriatric assessment (MGA) were performed in parallel in 149 consecutive patients aged >67 years (median 77.8 years) newly diagnosed with a hematologic malignancy at Innsbruck University Hospital between January 2009 and April 2016.
Results: Self-reported fatigue as defined by EORTC QLQ-C30 was the most prevalent symptom (84 %). Other symptoms namely insomnia, dyspnea, loss of appetite, pain and constipation were reported by about a half to a quarter of patients. Moreover, functional impairments, namely in physical, role and emotional functioning, were observed in a relevant proportion of patients. Increased fatigue was significantly associated with reduced self-reported role, physical functioning as well as global health status as defined by EORTC QLQ-C30. Remarkably, pronounced fatigue was associated with impaired performance status and objective functional capacities in MGA, with altered depression scoring, G8-screening, and elevation of serum markers of inflammation ($p < 0.001$). Patients with minor fatigue had a median overall survival of 26.4 months, whereas those with marked fatigue had a median OS of 7.0 months ($p < 0.001$). The association of fatigue with shortened OS was supported in multivariate analyses (hazard ratio 1.74, CI 1.09 – 2.76; $p=0.021$).
Summary and Conclusions: Fatigue reveals a high prevalence and represents an adverse prognostic factor in elderly patients with a hematological malignancy. The strong impact of fatigue on clinical performance and overall survival emphasizes the relevance of patient reported outcomes for individualized treatment algorithms. Patients will particularly benefit from early identification of fatigue, allowing for timely interventions. The correlation of fatigue, reduced performance capacities, nutritional status and inflammation might suggest an underlying common pathway.

FIRST-IN-HUMAN CLL1-CD33 COMPOUND CAR T CELLS AS A TWO-PRONGED APPROACH FOR THE TREATMENT OF REFRACTORY ACUTE MYELOID LEUKEMIA

This abstract is embargoed until Friday, June 15, 08:30 local time.

F. Liu[1,*], K. Pinz[2], Y. Ma[3], M. Wada[2], K. Chen[2], G. Ma[2], Y. Su[1], S. Zhang[1], G. He[1], Y. Ma[2]

[1]Department of Hematology, Chengdu Military General Hospital, Chengdu, China, [2]Research and Development, iCell Gene Therapeutics, Stony Brook, United States, [3]Manufacturing Division, iCAR Bio Therapeutics Ltd, Zhongshan, China

Background: Anti-CD19 CAR T cells have shown impressive efficacy in B-ALL (acute lymphoblastic leukemia) and lymphoma, and have obtained FDA approval. However, treatment of relapsed/refractory acute myeloid leukemia (AML) remains a substantial clinical challenge. AML bears heterogeneous cells that can offset killing by single CAR-based therapies, resulting in disease relapse. Leukemic stem cells (LSCs) associated with CLL1 expression comprise a rare population that also plays an important role in disease progression and relapse. CD33 is a myeloid marker found on bulk AML disease cells in the majority of AML patients. Here, we report on the robust anti-tumor activity of compound CAR (cCAR) T cells possessing discrete scFv domains targeting two different AML antigens, CLL1 and CD33, simultaneously.
Aims: To develop a first-in-human treatment of refractory acute myeloid leukemia using Compound CAR T Cells simultaneously targeting two AML antigens, in order to avoid antigen escape, and to be safe and well tolerated.
Methods: We have generated a cCAR bearing two complete CAR constructs connected by a self-cleavable peptide linker, P2A. The anti-leukemic activities of CLL1-CD33 cCAR T cells were evaluated *in vitro* with killing assays using multiple AML cell lines, primary human AML samples as well as REH cells expressing either CLL1 or CD33. We tested cCAR in multiple mouse models in which mice were injected with REH expressing CLL1 or CD33 or U937 cell line. We also tested an alemtuzumab safety switch that allows for rapid cCAR therapy termination *in vivo*.
Results: We report on the robust anti-tumor activity of a compound CAR (cCAR) T-cell possessing discrete scFv domains targeting two different AML antigens, CLL1 and CD33, simultaneously. We showed that the CLL1-CD33 cCAR was able to ablate both the CLL1- or CD33-expressing REH cells independently both in co-culture assays and in mouse models. Mice treated with CLL1-CD33 cCAR showed significantly improved survival as compared to control-treated mice. We also showed that CLL1-CD33 cCAR promoted sustained *in vivo* anti-leukemic activity against the AML U937 cell line, as well as superior murine survival in both models. As a safety-switch to protect against the high potency of our cCAR, we developed a strategy to the rapid cCAR therapy termination in mouse models. Our findings indicate that targeting both CLL1 and CD33 on AML cells may be an effective strategy for eliminating both AML bulk disease and LSCs, potentially preventing relapse due to antigen escape or LSC persistence.
In the context of a first-in-human phase 1 clinical trial, informed consent from patients was obtained and CLL1-CD33 cCAR T cells expanded in AML patients. CLL1-CD33 cCAR T therapy was safe and well tolerated, and achieved complete response (CR).
Summary and Conclusions: Our study supports the development of CLL1-CD33 cCAR as a promising immunotherapy for AML. In the first-in-human clinical trial of CLL1-CD33 cCAR T cell therapy, we demonstrated the feasibility and safety of targeting both CLL1 and CD33 to achieve complete response (CR). Our findings suggest further exploration of CLL1-CD33 cCAR T therapy as a stand-alone therapy or "bridge to transplant" for patients with aggressive, relapsing/refractory AML leukemia.

RIBOSOMAL LESIONS PROMOTE ONCOGENIC MUTAGENESIS

S. Sulima[1,*], K. Kampen [1], S. Vereecke[1], J. Verbeeck[1], J. Dinman[2], K. De Keersmaecker[1]

[1]Oncology, KU Leuven, Leuven, Belgium, [2]Cell Biology and Molecular Genetics, University of Maryland, College Park, United States

Background: Ribosomopathies are congenital disorders with mutations in ribosomal proteins (RPs) or assembly factors, characterized by cellular hypo-proliferation which particularly affects blood lineages. Intriguingly, ribosomopathies with hematopoietic insufficiency carry an increased risk to develop cancer, such as AML, later in life. The transition from hypo- to hyper-proliferation fits within an unexplained paradox known as Dameshek's Riddle (Dameshek, *Blood* 1967). Somatically acquired RP mutations have recently also been described, primarily in blood cancers such as T-ALL and CLL. Of these, the R98S mutation in ribosomal protein L10 (RPL10 R98S) is the most recurrent missense mutation, found in 8% of pediatric T-ALL. We have previously shown that this mutation interferes with ribosome function and cell proliferation. Moreover, RPL10 interacts with the SBDS protein during ribosome assembly, and *SBDS* mutations cause similar cellular defects in the ribosomopathy Shwachman-Diamond Syndrome (SDS).
Aims: To investigate how an early ribosomal mutation, exemplified by RPL10 R98S which negatively affects cell proliferation, can ultimately have an oncogenic impact.
Methods: Analysis of isogenic models expressing RPL10 R98S or WT including Ba/F3, lineage-negative cells from transgenic Rpl10-R98S and control mice, and pro-T cell cultures. NOTCH1-hyperactivation was attained by DL4 stimulation or expression of active NOTCH1 forms (NOTCH1-ICN or NOTCH1-L1601P-ØPEST found in T-ALL patients).
Results: RPL10 R98S induced a proliferation deficiency in lymphoid mouse cells, which was rescued with time by acquisition of additional mutations. Specifically, exome sequencing revealed that RPL10 R98S promoted a ~5-fold higher acquisition of additional mutations compared to WT. Analysis of two sets of previously generated T-ALL exomes (De Keersmaecker, *Nat. Genet.* 2013; Liu, *Nat. Genet.* 2017) revealed a ~2-fold higher load of mutations and oncogenic drivers in patients with RPL10 R98S or other RP mutations compared to patients with WT ribosomes. Further, RP-mutant patients from both cohorts displayed a significant enrichment for NOTCH1 pathway activating lesions. NOTCH1 expression rescued the proliferation defect of RPL10 R98S cell lines, which was reversible with NOTCH1 inhibition. In particular, RPL10 R98S specifically increased oxidative stress levels, which in turn promoted DNA damage, and both of these phenotypes were eliminated by NOTCH1 expression. Analysis of CLL patient exomes (Landau, *Nature* 2015) also demonstrated a higher mutational burden in cases with RP lesions (*i.e.* RPS15), and an enrichment in TP53 aberrations in RP mutant CLL cases. A recent study moreover described the acquisition of TP53 mutations in SDS patients as early events in the transformation to AML (Xia, *Blood* 2018). The role of TP53 mutations in RP mutant CLL and SDS is unclear, but it may also alleviate oxidative stress as TP53 activation upon cellular burden (*i.e.* ribosome assembly defects) is known to promote oxidative stress (Figure 1).

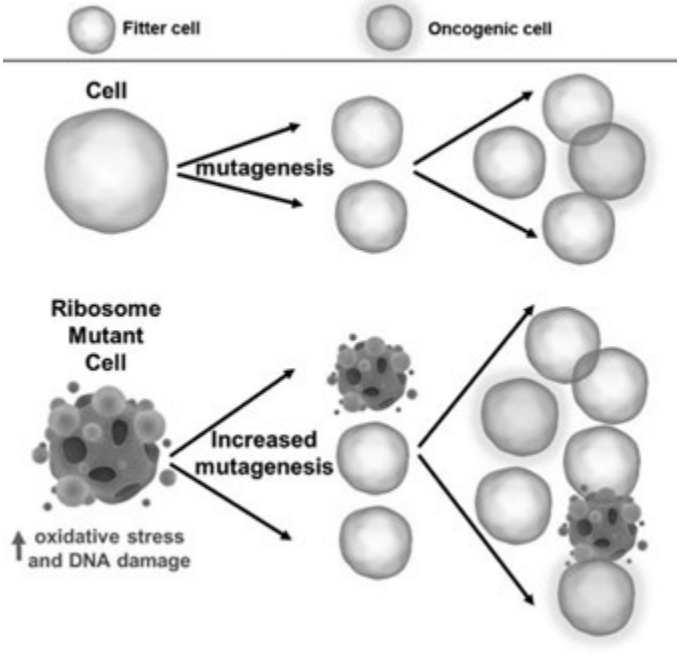

Figure 1.

Summary and Conclusions: We propose that RP lesions in ribosomopathies and cancer cause ribosome dysfunction-driven oxidative stress and consequently DNA damage, hypo-proliferation and hematopoietic insufficiency.

This drives surviving blood cells to acquire rescuing mutations which, potentiated by genomic instability, leads to a larger mutagenic pool. RP mutations may thus act as intrinsic cellular stressors that make transformation more accessible by opening the oncogenic window in disease-specific pathways. This in turn opens the window for novel prognosis and therapy potential for RP mutant patients.

OVERALL SURVIVAL BENEFIT OF OBINUTUZUMAB OVER RITUXIMAB WHEN COMBINED WITH CHLORAMBUCIL IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA AND COMORBIDITIES: FINAL SURVIVAL ANALYSIS OF THE CLL11 STUDY

This abstract is embargoed until Friday, June 15, 08:30 local time.

V. Goede[1,2,*], K. Fischer[1], M.J. Dyer[3], L. Müller[4], L. Smolej[5], M.C. Di Bernardo[6], A. Knapp[7], T. Nielsen[7], M. Hallek[18]

[1]German CLL Study Group, Department I of Internal Medicine, Center of Integrated Oncology, University Hospital, [2]Oncogeriatric Unit, Department of Geriatric Medicine, St Marien Hospital, Cologne, Germany, [3]The Ernest and Helen Scott Haematological Research Institute, University of Leicester, Leicester, United Kingdom, [4]Oncology Practice, Leer, Germany, [5]Charles University Faculty of Medicine, University Hospital, Hradec Králové, Czech Republic, [6]On assignment to F. Hoffmann-La Roche Ltd, [7]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [8]Cologne Cluster of Excellence in Cellular Stress Responses in Aging-Associated Diseases, University of Cologne, Cologne, Germany

Background: Obinutuzumab (GA101; G), a glycoengineered type II anti-CD20 monoclonal antibody, has been developed as an effective treatment for chronic lymphocytic leukemia (CLL). The phase III CLL11 study evaluated the efficacy and safety of G plus chlorambucil (Clb; G-Clb) and rituximab (R) plus Clb (R-Clb) *vs* Clb alone (Stage 1), as well as G-Clb *vs* R-Clb (Stage 2), in patients with previously untreated CLL and comorbidities. Previous pre-planned analyses have established superiority of G-Clb over Clb alone and R-Clb.
Aims: We report the final analysis of the CLL11 study (data cut-off, 10 October 2017), with approximately 2 years of additional follow-up compared with previous analyses.
Methods: Patients were randomised 1:2:2 to receive six 28-day cycles (C) of Clb, R-Clb or G-Clb. Clb (0.5 mg/kg) was administered orally on Day (D) 1 and D15 of C1–6. R was administered intravenously (IV) at a dose of 375 mg/m^2 on D1 of C1 and 500 mg/m^{2}on D1 of C2–6. G (1000 mg) was administered IV on D1 (dose split over two days; 100 mg D1, 900 mg D2), D8 and D15 of C1, and D1 of C2–6. Eligible patients had previously untreated CD20+ CLL, a total Cumulative Illness Rating Scale (CIRS) score of >6 and/or a creatinine clearance (CrCl) of <70 mL/min. The primary endpoint was investigator-assessed progression-free survival (PFS). Secondary endpoints included overall survival (OS), time to new treatment (TTNT) and safety. Comparison of PFS was performed by log rank test. Treatment effects were expressed as hazard ratios (HR) using a stratified Cox regression model.
Results: A total of 781 patients were enrolled and received treatment (median: age, 73 years; CIRS score, 8; CrCl, 62 mL/min). No new safety signals were identified at this update. After a median observation time of 62.5 months, treatment with G-Clb (n=238) was associated with improved outcomes compared with Clb alone (n=118); median: PFS, 31.1 *vs* 11.1 months (HR 0.21, 95% CI 0.16–0.28, p<0.0001); OS, not reached *vs* 66.7 months (HR 0.68, 95% CI 0.49–0.94, p=0.0196); and TTNT, 55.7 *vs* 15.1 months (HR 0.25, 95% CI 0.19–0.35, p<0.0001). After a median observation time of 59.4 months, G-Clb (n=333) also demonstrated a clinically meaningful improvement in outcomes compared with R-Clb (n=330); median: PFS, 28.9 *vs* 15.7 months (HR 0.49, 95% CI 0.41–0.58, p<0.0001) and TTNT, 56.4 *vs* 34.9 months (HR 0.58, 95% CI 0.46–0.73, p<0.0001) (Figure 1A and 1B). Notably, G-Clb also provided a clinically meaningful improvement in OS compared with R-Clb; median OS, not reached *vs* 73.1 months (HR 0.76, 95% CI 0.60–0.97, p=0.0245) (Figure 1C). Two- and five-year survival rates were 91% *vs* 84% and 66% *vs* 57% for G-Clb *vs* R-Clb, respectively. Overall, fewer patients died in the G-Clb arm (37%) than in the R-Clb arm (45%). During the survival follow-up period, the most common cause of death was disease progression (G-Clb, 10%; R-Clb, 15%).
Summary and Conclusions: This final survival analysis from the CLL11 study confirms that G-Clb provides clinically meaningful benefits in CLL patients with comorbidities, including prolongation of PFS and OS, when compared with R-Clb and Clb alone, and an absolute treatment-free duration of approximately four and a half years, while maintaining an acceptable and manageable safety profile. These findings support the use of G-Clb as first-line treatment for CLL patients with comorbidities, and suggest G as the preferred anti-CD20 antibody in future combination regimens for CLL.

CHRONIC RED BLOOD CELL TRANSFUSIONS IMPAIR THE INNATE IMMUNE RESPONSE TO INFECTIOUS CUES BY SHAPING MACROPHAGES TOWARDS AN ANTI-INFLAMMATORY FUNCTIONAL PHENOTYPE

This abstract is embargoed until Friday, June 15, 08:30 local time.

F. Vinchi[1,*], R. Sparla[2], H. Weidner[3], M. Rauner[3], U. Platzbecker[3], M. Muckenthaler[2]

[1]Iron Research Program, New York Blood Center, New York, United States, [2]Iron Homeostasis Group, University Hospital Heidelberg, Heidelberg, [3]University Hospital Dresden, Dresden, Germany

Background: Chronic iron overload is common in thalassemia (thal), sickle cell disease (SCD) and myelodysplastic syndromes (MDS), due to red blood cell transfusions and increased intestinal iron absorption to support ineffective erythropoiesis. Chronically transfused patients show increased susceptibility to infections. Iron overload may increase the risk of infections by supporting bacterial growth and altering the response of the adaptive immunity. Likewise, transfusional iron overload may impact on the innate immune response, in particular on macrophage function.
Aims: We aimed to study the impact of transfusions on the phenotypic plasticity of monocytes and macrophages and their responses to infectious cues.
Methods: The functionality of hepatic and splenic macrophages as well as of recruited monocytes was studied in transfused and non-transfused wild-type and myelodysplastic mice, subjected or not to LPS challenge.
Results: Repeated transfusions of fresh RBCs in mice cause macrophage iron overload and cell death as well as recruitment of monocytes to the liver and spleen. After transfusion, macrophages acquire an M2-like anti-inflammatory phenotype, hallmarked by elevated expression of M2 markers

(CD206, Arg-1, Ym1) and reduced expression of M1 markers (MHCII, CD86). Consistently, pro-inflammatory cytokines (IL-6, CCL2, INFg, IL1b) are reduced compared to steady-state levels and anti-inflammatory cytokines (IL-10, IL-4) increased. These results indicate that transfusion-induced erythrophagocytosis likely suppresses the inflammatory response. These findings contrast previous observations, which support a pro-inflammatory role of free heme and iron on macrophage activation. This indicates that not only iron overload but also the route of iron acquisition (*e.g.* RBC phagocytosis *vs* free iron uptake) may shape the macrophage phenotype. After LPS challenge (15hours), macrophages from both transfused and non-transfused mice show an upregulation of M1 markers and pro-inflammatory cytokines. Nevertheless, M1 marker expression is drastically reduced and M2 markers increased in cells isolated from transfused compared to non-transfused mice. This is further reflected by reduced levels of circulating inflammatory cytokines. Our *in vivo* experiments support the concept that transfusions shape macrophages towards an M2-like anti-inflammatory phenotype after LPS stimulation, highlighting a novel adverse anti-inflammatory effect of transfusions upon infections. These findings do not only apply to wild-type mice but also to a mouse model of transfusion-dependent myelodysplastic syndrome.

Summary and Conclusions: Our data provide evidence that transfusions show a negative impact on the innate immune system and blunt the inflammatory response of macrophages to infectious stimuli. Our observations indicate that transfusions dampen macrophage immune effector functions by inducing their switching towards an anti-inflammatory phenotype, which is unlikely to efficiently counteract infections. The weak pro-inflammatory response of the macrophage might contribute to the increased propensity of transfused patients to develop infections, having potential implications for conditions associated with chronic transfusions, as in MDS, thalassemia and SCD. Finally these results suggest that transfusion practice might increase the risk of infections not solely by promoting the growth of microorganisms through increasing iron availability, but also by impairing the innate immune system, through the alteration of macrophage plasticity. The underlying mechanisms are currently under investigation.

S153

MPN CALR MUTANTS PROMOTE CELL-SURFACE LOCALIZATION OF TPOR WHICH IS OBLIGATORY FOR ONCOGENESIS: NOVEL THERAPEUTIC AVENUES AND RESCUE OF CONGENITAL THROMBOCYTOPENIA TPOR MUTANTS

C. Pecquet[1,*], I. Chachoua[1], A. Roy[1], T. Balligand[1], G. Vertenoeil[1], J.-P. Defour[1], C. Marty[2], I. Plo[2], H. Nivarthi[3], E. Xu[4], E. Hug[4], R. Kralovics[3], W. Vainchenker[2], S. N. Constantinescu[1]

[1]Signal Transduction Unit, Ludwig Institut for Cancer Research Ltd, Brussels, Belgium, [2]INSERM U 1170, Institut Gustave Roussy, Villejuif, France, [3]Genetics of Hematological Disorders, CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, [4]Myelopro Diagnostics and Research GmbH, Vienna, Austria

Background: Mutant calreticulins are major drivers of myeloproliferative neoplasms (MPNs) by activating TpoR/MPL and JAK2 signaling. However how exactly this interaction occurs, and in which cell compartment this abnormal TpoR activation will lead to an oncogenic signaling remains unknown.

Aims: Our objectives were: 1) to determine the precise sequences of CALR mutant and TpoR required for interaction, traffic and activation, 2) whether disease-inducing TpoR signaling occurs from intracellular compartments or cell-surface, 3) whether CALR mutants can also interact and activate defective TpoR mutants, such as TpoR mutants in congenital amegakaryocytic thrombocytopenia (CAMT) and 4) whether CALR mutants are secreted.

Methods: Engineered CALR and TpoR mutants were analyzed by a combination of biochemical approaches (thermal shift assay in cells and on protein), functional assay (cell growth assay, luciferase assay, flow cytometry, primary megakaryocytic clonogenic assay) and cell imaging (confocal microscopy).

Results: 1) We map the required sequences for interaction between mutant CALR and TpoR extracellular domain. A minimum of 10 proximal aminoacids of the new CALR tail and sequences of the N-terminal globular domain, but not the P-domain are required for TpoR activation. We also isolated a complex between extracellular domain of TpoR and CALR del52 produced in insect cells and mapped the required N-glycosylation profile required for complex formation. 2) We identify a specific region of 8 aminoacids in D1 TpoR that can confer the ability to activate JAK2-STAT5 to another receptor (EpoR) after binding of mutant CALR. Mutation to alanines of this TpoR region (TpoR 8A) abolishes response to CALR mutant. 3) As a direct consequence of mutant CALR-TpoR interaction, the thermal stability of TpoR was found to significantly increase in the presence of CALR del52. Such an increase was not observed with EpoR. However, engineered EpoR that can induce CALR del52 dependent JAK2-STAT5 activation also showed increased thermal stability with CALR del52. Concurrently, neither TpoR mutated at key asparagine residues involved in N-glycosylation nor TpoR with Alanine mutations could show enhanced thermal stability with CALRdel52. 4) We provide genetic evidence that the cell-surface TpoR-CALR mutant complexes are obligatory for hematopoietic cell transformation. Mutant CALRs and TpoR must pass via the Golgi apparatus to transform, and they co-localize in the Golgi compartments. The cell-surface complexes of active tyrosine phosphorylated forms of TpoR-JAK2 induced by mutant CALRs are internalized and can be detected in early endosomes, suggesting prolonged signaling in that compartment. 5) We show that both CALR del52 and ins5, but not wild type CALR are able to rescue traffic and cell-surface localization and signaling by the CAMT TpoR R102P mutant. Mutant CALRs promote folding and stability of TpoR R102P. This effect can also be seen with TpoR P106L and other defective engineered TpoRs. 6) Mutant CALRs are secreted to levels of 0.1-0.2 g/ml in patients.

Summary and Conclusions: We show that mutant CALRs act as rogue chaperones, leading to folding and cell-surface localization of TpoR, which is obligatory for hematopoietic cell transformation. Mutant CALRs can rescue defective TpoR in CAMT to cell-surface localization and activation. Moreover our data indicate that cell-surface mutant CALR is crucial for oncogenicity. We discuss avenues of targeting mutant CALRs on the cell-surface and potential effects of secreted mutant CALR.

Background: Standard of care for advanced stage, high tumor burden, previously untreated follicular lymphoma (FL) has been rituximab plus chemotherapy (R-chemo) followed by rituximab maintenance. Combination

immunotherapy with lenalidomide and rituximab (R^2) is a chemotherapy-free regimen that has shown promising efficacy and safety in previously untreated patients with FL.

Aims: This is the first report of the co-primary endpoints: i) complete response (CR)/CR unconfirmed (CRu) at 120 weeks and ii) interim analysis of progression-free survival (PFS; ~50% of the target of 456 events by 1999 IWG criteria) for R^2 *vs* R-chemo followed by rituximab in previously untreated patients with FL.

Methods: RELEVANCE is a global, randomized, open-label phase III trial (NCT01650701; EUDRACT2011-002792-42) in patients with grade 1-3a FL who required systemic therapy (per GELF criteria). In the R^2 arm, lenalidomide 20 mg/day on days 2-22/28 was given cycles 1 to 6-12, continued in responders at 10 mg/day for a total of 18 cycles. Rituximab was 375 mg/m^{2}weekly in cycle 1, day 1 in cycles 2-6, and continued in responders for 12 additional cycles (q8wk). R-chemo was given per investigator's choice of standard R-CHOP, R-bendamustine (R-B), or R-CVP, followed by 12 cycles of rituximab (q8wk).

Results: As of the cutoff date of 31May2017, 1030 patients with high tumor burden FL were randomized to R^2(n=513) or R-chemo (n=517; 72% R-CHOP, 23% R-B, 5% R-CVP). Both groups had similar baseline characteristics; overall median age was 59 years (range, 23-89), 49% with FLIPI score ≥3, 93% stage III/IV, and 41% bulky disease (>7 cm). The superiority of both co-primary endpoints for R^2 over R-chemo was not established after a median follow-up of 37.9 months. CR/CRu at 120 weeks was similar in the R^2 v R-chemo groups (48% v 53%, *P*=0.13 per central review; 55% v 58%, *P*=0.38 per investigator assessment). R^2 and R-chemo groups demonstrated similar 3-year PFS rates by both central review (77% v 78%) and investigator assessment (77% v 78%), respectively (Figure 1). 3-year overall survival was 94% for both arms. The toxicity profiles for R^2 *vs* R-chemo were different, with lower rates of any grade fatigue (23% *vs* 29%), nausea (20% *vs* 42%), peripheral neuropathy (11% v 22%), vomiting (7% v 19%), stomatitis (3% *vs* 7%), and alopecia (1% *vs* 9%), and higher rates of cutaneous reactions (43% *vs* 24%), diarrhea (37% *vs* 19%), and tumor flare reaction (6% *vs* 0.2%) associated with R^2. Rates of thromboembolic events were similar in both groups. Higher grade 3/4 lab neutropenia (34% *vs* 50%) and febrile neutropenia (2% *vs* 6%) were associated with R-chemo, whereas higher grade 3/4 cutaneous reactions (7% *vs* 1%) were associated with R^2. Adverse events (AEs) led to treatment discontinuation in 11% of R^2 and 3% of R-chemo patients. Grade 5 AEs were 1% for both arms, and SPMs were reported in 7% (n=38) R^2 and 9% (n=48) R-chemo patients (5% invasive SPMs for both). 69% R^2 and 71% R-chemo patients completed 30 months of treatment. For the R^2 group, 76% of patients completed all 18 cycles of lenalidomide.

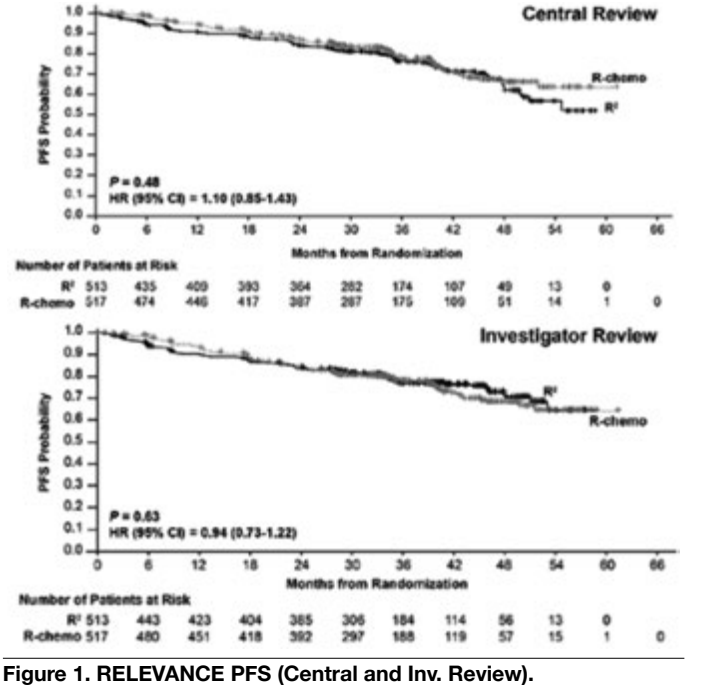

Figure 1. RELEVANCE PFS (Central and Inv. Review).

Summary and Conclusions: RELEVANCE is the first randomized phase III trial comparing the chemotherapy-free regimen R^2 v standard R-chemo followed by rituximab maintenance in previously untreated patients with FL. The superiority of R^2 over R-chemo was not demonstrated in this phase III trial, however, compared with R-chemo, R^2 appeared to show similar efficacy with a different toxicity profile.

SENSITIVITY TO VENETOCLAX IN BCP-ALL IS CLOSELY CORRELATED TO HIGH FUNCTIONAL BCL-2 DEPENDENCE AND CAN BE ENHANCED BY DEPLETION OF MCL-1

Background: Deregulated cell death pathways contribute to leukemogenesis and treatment failure in B-cell precursor acute lymphoblastic leukemia (BCP-ALL). Members of the BCL-2 family are key apoptosis regulators, therefore serving as potential targets for therapeutic intervention.
Aims: In this study, we evaluated activity and predictive models for the BCL-2 inhibitor venetoclax (VEN) in BCP-ALL and investigated co-targeting of MCL-1 to increase VEN sensitivity.
Methods: Activities of BH3-mimetics were assessed by cell viability assays analyzing half maximal effective concentrations (EC_{50}). Genetic alterations were assessed by multiplex ligation probe amplification (MLPA) and targeted sequencing. Gene expression profiling (GEP) was performed (HG 133 Plus 2.0, Affymetrix). Apoptosis signaling parameters were assessed by western blot and functional BH3-profiling. *In vivo* treatment was performed in preclinical xenograft models.
Results: In a series of N=27 BCP-ALL PDX samples different sensitivities to VEN upon *ex vivo* exposure were observed with high (EC_{50}<100 nM, n=12, 44%), intermediate (EC_{50} 100 nM - 1 µM n=8, 30%) or insensitivity (EC_{50}>1 µM, n=7, 26%). Moreover, we also assessed *in vivo* anti-leukemia activity of VEN in a preclinical trial treating ALL-bearing recipients transplanted with different BCP-ALL samples (N=8) and found distinct leukemia-free survival times reflecting the heterogeneity of VEN-sensitivity observed *ex vivo*. Interestingly, response to VEN was not associated with recurrent genetic alterations including *JAK1*, *IKZF1*, *KRAS* mutations and *CDKN2A*, *CDKN2B*, *BTG1*, *RB1*, *JAK2*, *IKZF1*, *PAX5*, *EBF1* and *ETV6* deletions, however high VEN sensitivities were identified in one sample with a *MLL-AF4* fusion, in line with previous reports, and in two *TP53* mutated cases. Importantly, no mutations in *BCL2* or *BAX* were found. Analysis of GEP comparing VEN-sensitive and -resistant ALL revealed a signature, which did not include genes coding for apoptosis regulators and which was not found to be associated with cell death pathways (gene ontology analysis). In line, transcript or protein expression of BCL-2, MCL-1 and ratios of BCL-2/MCL-1 were not or only weakly associated with *in vivo* VEN activity, indicating the necessity to globally assess apoptosis signaling. Therefore, we analyzed the impact of different apoptosis regulators on the functional interplay of mitochondrial apoptosis signaling using synthetic pro-apoptotic peptides. Importantly, mitochondrial BCL-2 dependence showed a clear significant correlation with leukemia-free survival times after *in vivo* VEN therapy (Spearman, r_s=0.955; p=0.0006). In order to overcome resistance and increase sensitivity for VEN, we evaluated the effects of co-targeting MCL-1. MCL-1 knockout in VEN-resistant ALL resulted in a clear sensitization to VEN and co-treatment with S63845 showed a clear synergism in cell line and PDX BCP-ALL samples.
Summary and Conclusions: We identified a heterogeneous sensitivity to VEN in a series of primary PDX BCP-ALL samples upon *ex vivo* and *in vivo* VEN treatment. VEN activity was not found to be associated with recurrent genetic alterations and no mutations in *BCL-2* or *BAX* were found. Importantly, mitochondrial BCL-2 dependence assessed by integrative analysis of mitochondrial apoptosis signaling (BH3-profiling) showed the most significant correlation with *in vivo* response to VEN treatment, providing a marker to identify patients who would respond to BCL-2 inhibition. Moreover, pharmacological MCL-1 depletion clearly enhanced VEN activity, pointing to co-targeting of BCL-2 and MCL-1 as effective anti-leukemia strategy.

PF156

A NEW HUMANIZED MONOCLONAL ANTIBODY AGAINST A SPECIFIC GLYCOSYLATED EPITOPE OF CD43 ANTIGEN FOR THE THERAPEUTIC TARGETING OF ACUTE LYMPHOBLASTIC LEUKEMIA T (T-ALL)

C. Botta[1,*], M.E. Gallo Cantafio[1], C. Buracchi[2], M.A. Siciliano[1], C. Riillo[1], A. Gulino[3], M. Cucè[1], K. Grillone[1], F.M. Tuccillo[4], M.T. Di Martino[1], C. Tripodo[5], M. Rossi[1], A. Biondi[6], G. Gaipa[7], P. Tagliaferri[1], P. Tassone[1]

[1]"Magna Graecia" University of Catanzaro, Catanzaro, [2]Tettamanti Research Center - Centro Maria Letizia Verga, Monza, [3]A.O.U.P " Paolo Giaccone, Palermo, [4]IRCCS Fondazione Pascale, Napoli, [5]A.O.U.P " Paolo Giaccone", Palermo, [6]University of Milano-Bicocca, [7]Tettamanti Research Center - Centro Maria Letizia Verga, Monza, Italy

Background: T-cell acute lymphoblastic leukemia (T-ALL) accounts for about 20% of ALL cases. Despite the introduction of intensive chemotherapy protocols, about 25% of children and 50% of adult patients fail to respond or relapse. The prognosis for these patients remains poor and novel treatment options are eagerly awaited. The targeting of tumor-associated antigens by monoclonal antibodies (mAb) is among the most investigated immunotherapeutic strategies. Accordingly, we previously developed a murine mAb, directed against a heavy glycosylated oncofetal epitope of CD43 (CD43/UN1) which present a high reactivity against human immature thymocytes, and T-ALL cell lines.
Aims: To investigate the therapeutic activity and mechanisms of action of a new humanized mAb directed to CD43/UN1 in experimental models of T-ALL.
Methods: The expression of CD43/UN1 was assessed on tumor cell lines, blood samples from T-ALL patients and healthy donors by flow-cytometry. Humanized mAbs were generated by combining the variable domains of the murine antibody to the corresponding human IgG1 constant domains. A tissue microarray of 30 different human normal tissues was screened by immunohistochemistry according to FDA/CE guidelines. Complement-mediated cytotoxicity (CDC), antibody-dependent cell-mediated cytotoxicity (ADCC) and cellular phagocytosis (ADCP) on primary T-ALL cells T-ALL cell lines were evaluated by flow cytometry. 6 different *in vivo* models on NSG mice (3 with administration of NK-92-CD16+ effectors) have been performed to evaluate mAbs activity in different disease settings: orthotopic, subcutaneous advanced disease (treatments started after tumor reached 100 mmc) and subcutaneous limited disease (treatments started the day after injection).
Results: By screening different cancer cell lines, we observed CD43/UN1 to be highly expressed on malignant T-ALL cells. We then tested a series of 43 T-ALL patients-derived blasts and we observed that CD43/UN1 was specifically expressed on a subset of patients (about 80%) belonging to the cortical T-ALL (EGIL T3) group. A humanized mAb, named UMG1, and an afucosylated engineered version of this mAb, named a-UMG1, were then developed. To investigate CDC, ADCC or ADCP, T-ALL cells were cultured in the presence of complement, peripheral blood mononuclear cells (PBMCs) or macrophages, at increasing concentrations of both antibodies. Neither UMG1 nor a-UMG1 were able to induce CDC on target cells. Conversely, both mAbs induced CD16 downregulation, IFN-g production and degranulation (evaluated as CD107+ cells increase) on NK cells (more evident with a-UMG1) and T-ALL cell lines or primary blasts cytotoxicity. Additionally, both mAbs induced ADCP. Furthermore, we demonstrated potent activity of both mAbs in different T-ALL models *in vivo*. Specifically, in an orthotopic model we observed 5 out of 20 treated mice free of disease after 100 days from injection as compared to none of the control group. In both subcutaneous models, we observed a strong ability of our antibody to delay tumor growth and to increase mice survival. Of note, the addition of NK-92-CD16+ strongly improved the activity of a-UMG1. Furthermore, to explore the possibility of combination therapy, we investigated the modulation of CD43/UN1 expression by several chemotherapeutics. Interestingly, methotrexate and doxorubicin, alone or in combination, increased antigen expression, thus resulting in improved ADCC.
Summary and Conclusions: On these bases, we demonstrated that UMG1 and a-UMG1 represent novel promising immune-therapeutic tools for the treatment T-ALL patients.

PF157

CDK8 DEGRADATION - PREPARING THE GROUND FOR MTOR NHIBITION IN BCR/ABL+ ALL

I. Menzl[1,*], T. Zhang[2], R. Grausenburger[1], K. Bauer[3], F. Grebien[4,5], S. Kubicek[6], P. Valent[7], J. Zuber[8], N. Gray[2], V. Sexl[1]

[1]Department for Biomedical Science, Institute of Pharmacology and Toxicology VetMed university Vienna, Vienna, Austria, [2]Department of Cancer Biology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States, [3]Department of Internal Medicine I, Devision of Hematology & Hemostaseology and Ludwig Boltzmann Cluster Oncology, Medical University of Vienna, [4]Ludwig Boltzmann Institute for Cancer Research, [5]Department for Biomedical Science, Institute of Medical Biochemistry, [6]Research Center for Molecular Medicine of the Austrian Academy of Sciences (CeMM), [7]Devision of Hematology & Hemostaseology and Ludwig Boltzmann Cluster Oncology, Medical University of Vienna, [8]Research Institute of Molecular Pathology (IMP), Vienna, Austria

Background: Cyclin-dependent kinases (CDKs) trigger important cellular processes including cell cycle progression, transcriptional regulation and gene expression. It is therefore not surprising that CDKs are frequently deregulated in various types of cancer.
Aims: Investigate the role of CDK8 as a new potential therapeutic target in BCR/ABL^{p185+} leukemia.
Methods: We established an inducible knock-down system for CDK6, CDK7, CDK8 and CDK9 in murine BCR/ABL^{p185+}cells. Knock-out mouse models were generated and used to validate our findings including *Cdk8$^{fl/fl}$ Vav-Cre* or inducibly *Cdk8$^{fl/fl}$ Mx1Cre* mice. RNASeq was performed to reveal transcriptional changes upon kinase-inhibition or loss of CDK8 in murine BCR/ABL^{p185+} cells. Pathways that were identified to be differentially regulated were blocked with specific inhibitors *in vitro*. Human relevance was studied in *in vitro* experiments using different human leukemic cell lines and primary patient samples. Degradation of CDK8 and dual inhibition of mTOR was accomplished with a new compound named YKL-101-06 in human leukemic cells and patient primary samples.
Results: Inducible knock-down of various CDKs revealed a dependency of murine BCR/ABL^{p185+} cells on CDK8 expression. BCR/ABL^{p185+} *Cdk8$^{\Delta/\Delta}$* cells induced leukemia with significantly enhanced disease latency *in vivo*. Most importantly, when we deleted *Cdk8 in vivo* after the establishment of leukemia to mimic a therapeutic situation, the inducible deletion of *Cdk8* significantly prolonged survival of the affected animals. In contrast to our expectations, inhibitors targeting CDK8 kinase activity failed to mimic the effects of CDK8 knock-down. RNASeq validated these findings; whereas CDK8 kinase inhibition has minimal effects deletion of the protein induced major transcriptional changes including alteration in the mTOR, PI3K and NF-kB pathway. Accordingly, CDK8-deficient cells were 20-fold more sensitive to mTOR inhibition when compared to wildtype. These findings were reflected in human patient Ph$^+$ samples where the simultaneous degradation of CDK8 and inhibition of the mTOR pathway significantly decreased cell viability. This was achieved by a single molecule degrading CDK8 and targeting mTOR.
Summary and Conclusions: CDK8 degradation prepares the ground for mTOR inhibition in Ph+ ALL which opens novel therapeutic opportunities.

PF158

CD123 X CD3 BISPECIFIC DART® MOLECULE EFFICIENTLY ACTIVATES T CELLS TO KILL PRIMARY B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA CELLS

D. Slavkovic Lukic[1,*], J. Duell[1], J. Davidson-Moncada[2], A. Schlagowsky[1], H. Einsele[1], M. Szczepanowski[3], D. Schewe[4], M. Brüggemann[3], M.S. Topp[1]

[1]Medizinische Klinik und Poliklinik II, Universitätsklinikum Würzburg, Würzburg, Germany, [2]MacroGenics, Rockville, United States, [3]Medizinische Klinik und Poliklinik II, [4]Klinik für Kinder- und Jugendmedizin I, Universitätsklinikum Schleswig-Holstein Campus Kiel, Kiel, Germany

Background: Targeting tumor antigens and recruiting T cells by bispecific antibodies has a great potential in cancer immunotherapy. Flotetuzumab, a CD123 X CD3 bispecific DART molecule, is currently being evaluated in a Phase 1 clinical study (NCT02152956) for treatment of acute myeloid leukemia (AML). In addition to AML, CD123 antigen is expressed in B-cell precursor cell acute lymphoblastic leukemia (B-ALL) blasts and therefore is a promising antigen for treatment of B-cell precursor ALL.
Aims: To evaluate *in vitro* activation, proliferation, and cytotoxicity of T cells by flotetuzumab in the presence of B-ALL cell lines or primary B-cell precursor ALL.
Methods: Human T cells were isolated from healthy donors and incubated with flotetuzumab (0.01 to 100 ng/ml) or control DART molecule (100 ng/ml) and ALL cell lines (E:T ratio 1:1) without exogenous cytokines. T-cell activation and cytokine production were measured after 24h. Proliferation was examined by CFSE dilution and cytotoxicity by 7AAD-AnnexinV FACS staining. To test the potential of patient T cells to kill primary tumor cells we incubated bone marrow material of 7 B-ALL patients with flotetuzumab for 6 days without addition of cytokines. The number of T cells and blasts was determined on day 2, 4 and 6. To evaluate the efficacy of flotetuzumab in the presence of drugs commonly used to treat or described to control cytokine release syndrome, T cells or bone marrow samples were preincubated with dexamethasone, tocilizumab or JAK1 and JAK2 inhibitor ruxolitinib (1h, 37°C).
Results: Flotetuzumab induced dose-dependent T-cell activation, proliferation and cytotoxicity. In the presence of ALL cell lines maximal T-cell activation was achieved with 1ng/ml flotetuzumab (Kasumi-2: 82.6±9.1% CD3$^+$CD25$^+$, *vs* 4.1±2.1% with control DART, p=0,00014, n=3). This amount of flotetuzumab resulted in significant proliferation of T cells 96h after incubation with Kasumi-2 (90.2±3.7, p=0,000002) or Nalm6 (84.9±7.6, p=0,00049) cell lines. At E:T ratio 1:1 and 1ng/ml flotetuzumab 51,6±9,7% Kasumi-2 cells were 7AAD+Annexin+, while no killing of K562 cell line was observed under the same conditions. Incubation of ALL patients' bone marrow samples with flotetuzumab resulted in response in 5 of 7 tested samples (up to E:T ratio of 0.025:1). After 6 days T cell number significantly increased (22.3±14.9 fold *vs* control group 0.6±0.3, p=0.01, n=5) and the number of blasts decreased for 99.2±0.4% (*vs* 49.4±33.1% in control group, p=0.01, n=5). Since one of the most common side effects of bispecific antibodies is cytokine release syndrome (CRS) we tested the efficacy of flotetuzumab in the presence of anti-CRS agents. 300 nM ruxolitinib significantly reduced cytotoxic potential of T cells 48h after their incubation with Kasumi-2 cell line and flotetuzumab compared to the same amounts of dexamethasone or tocilizumab (p=0.02). Similarly, dexamethasone and tocilizumab didn't influence the capacity of patients' T cells to kill their own tumor cells. However, ruxolitinib resulted in increased percentages of tumor cells due to reduced proliferation capacity and/or cytotoxic activity of T cells. Both ruxolitinib and dexamethasone reduced production of IL-6 while the effect on other cytokines was inconsistent. As expected, tocilizumab didn't change the production of cytokines.
Summary and Conclusions: These results demonstrate that targeting CD123 antigen in ALL tumors with flotetuzumab may be a promising strategy for ALL treatment. In addition, we show that dexamethasone and tocilizumab do not reduce the efficacy of flotetuzumab.

PF159

POTENT PRECLINICAL ACTIVITIES OF CD9 ANTIBODIES AGAINST HIGH-RISK PEDIATRIC B-PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA

K.T. Leung[1,*], C. Zhang[1], K.Y.Y. Chan[1], J.T.K. Cheung[1], K. Li[1], C.K. Li[1]

[1]Paediatrics, The Chinese University of Hong Kong, Shatin, Hong Kong

Background: B-precursor acute lymphoblastic leukemia (B-ALL) is the most common malignancy and the leading cause of cancer-related death in children. Despite advances in risk-adapted multi-agent chemotherapy, specific subtypes of high-risk and relapsed/refractory B-ALL are still associated with dismal outcomes, underscoring the need for development of novel and effective therapeutic strategies.
Aims: CD9, a tetraspanin family protein, regulates multiple physiologic processes and has been associated with metastasis and disease progression in various types of cancers. We recently reported that CD9 expression was associated with inferior 5-year overall and relapse-free survival in a cohort of pediatric B-ALL patients (Leung *et al.*, EHA 2017). In this study, we aim to comprehensively evaluate the preclinical efficacy and mechanisms of targeting CD9 with neutralizing antibodies as a new treatment strategy for childhood B-ALL.
Methods: NOD/SCID mice were transplanted with patient-derived B-ALL blasts or cell lines, and randomized to receive CD9 antibody or IgG control, in addition to conventional chemotherapy consisting of vincristine, dexamethasone and L-asparaginase. Leukemic burden was assessed by bioluminescence imaging or flow cytometric identification of human CD45+CD19+ cells in murine bone marrow, spleen, blood and liver. Animals transplanted with cord blood CD34+ cells were used to evaluate the effect of CD9 antibody on normal hematopoiesis. Leukemic cell proliferation and apoptosis were measured in cultures with or without bone marrow stroma by Trypan blue exclusion and Annexin V-7AAD staining, respectively. Co-immunoprecipitation assay was performed in B-ALL cell lines to identify CD9-binding proteins.
Results: Administration of CD9 antibody as a single agent substantially reduced multi-organ leukemic burden by >90% and significantly prolonged survival of animals xenografted with the intermediate-risk *TCF3-PBX1*+ 697 and high-risk *MLL-AF4*+ RS4;11, but not the standard-risk *ETV6-RUNX1*+ Reh cell lines. In addition, CD9 blockade effectively suppressed disease progression of patient-derived xenografts of high-risk and relapsed/refractory B-ALL with distinct cytogenetic features, including *MLL*-rearrangements, *TCF3-HLF* translocation and hypodiploidy. We also showed that CD9 antibody did not affect overall and multilineage engraftment of cord blood hematopoietic stem cells, which could be attributed to low expression of CD9 in the primitive CD34+CD38- subpopulation. Combining CD9 antibody with conventional chemotherapy further reduced leukemic burden and prolonged animal survival, when compared with animals treated with CD9 antibody or chemotherapy alone. *In vitro*, CD9 blockade significantly decreased proliferation of leukemic cells and enhanced vincristine-, dexamethasone- and L-asparaginase-induced apoptosis in both mono- and stromal co-cultures. Mechanistic studies revealed that CD9 was functionally involved in leukemia-stroma interaction through binding and modulating the affinity of integrin very late antigen-4.

Summary and Conclusions: Our results collectively suggest that CD9 blockade, in adjunct to chemotherapy, could be a novel and promising strategy for treatment of high-risk and relapsed/refractory pediatric B-ALL, possibly mediated by disruption of leukemia-stroma interaction in the bone marrow microenvironment.

PF160

PRECLINICAL DEMONSTRATION OF INTRACELLULAR ACTIVITY OF ASPARAGINASE ENCAPSULATED IN RED BLOOD CELLS BOTH IN THE ABSENCE AND IN THE PRESENCE OF NEUTRALIZING ANTI-ASPARAGINASE ANTIBODIES

K. Aguera[1,*], A. Scheer[1], F. Gallix[1], F. Tavernier[1], F. Gay[1], F. Horand[1], O. Leveneur[2], T. Mezzasalma[3], K. Swart[4], I. El Hariri[1]

[1]Erytech Pharma, [2]Institut Claude Bourgelat (ICLB), Lyon, [3]Amatsigroup, Fontenilles, France, [4]PAREXEL, Durham, United States

Background: L-asparaginase (ASNase) is an integral component of chemotherapy for acute lymphoblastic leukemia (ALL) in children and adults. ASNase is an enzyme, usually derived from the bacteria *E. coli*, that hydrolyzes asparagine (ASN) to aspartic acid. This lowers the plasma levels of ASN required for protein synthesis but no critical minimum value for efficacy has yet been established. Eryaspase is an ASNase encapsulated in human red blood cells (RBCs). Following infusion of eryaspase, ASN is actively transported into RBCs where it is hydrolyzed by the encapsulated ASNase (confirmed by previous *in vitro* studies). An open-label Phase 2/3 clinical study in 80 children and adults with relapsed or refractory ALL assessed the safety and efficacy of eryaspase compared with native ASNase. Results showed prolonged ASNase activity for eryaspase compared with native ASNase. This prolongation activity is believed to be attributable to the intracellular ASNase.
Aims: The aim of preclinical studies was to further validate the mechanism of action of eryaspase to evaluate hypothesis that ASNase activity of eryaspase is protected against degradation by encapsulation. The further objective was to elucidate the relative contribution of the intracellular and the extracellular ASNase to the depletion of ASN to low or undetectable levels.
Methods: Extracellular ASNase activity provided by eryaspase was silenced using neutralizing anti-ASNase antibodies (nAbs) *in vitro* and *in vivo.* An *in vivo* experiment was first performed in mice. The pharmacokinetic and pharmacodynamic properties of mouse RBCs (mRBCs) encapsulating ASNase were assessed in the presence or absence of nAbs (15 mice per arm). In addition, the level of ASNase activity and ASN depletion were measured in both whole blood and plasma. Mice welfare was also assessed. During the *in vitro* experiments, human RBCs encapsulating ASNase (eryaspase) were exposed to nAbs under conditions providing long-term stability of RBCs for up to 4 hours. Hemoglobin level, ASNase activity and amino-acid concentrations were measured.
Results: *In vivo* results showed that after 6 hours of exposure to free ASNase, only 12% of ASNase activity could be detected and, after 24 hours, no significant ASNase activity was detectable. In the presence of nAbs, no significant ASNase activity could be measured at any time point. In contrast, mRBCs encapsulating ASNase displayed a sustained ASN depletion (≥74%) for at least 9 days, independent of the presence or absence of nAbs. In a previous *in vivo* experiment, similar levels of ASN depletion were observed and maintained for up to 19 days. The data demonstrate that sustained ASN depletion was associated with the encapsulated ASNase, as any free ASNase activity was inhibited using nAbs. These findings were later confirmed by the *in vitro* experiments using eryaspase.
Summary and Conclusions: Eryaspase was demonstrated to effectively reduce ASN levels, also in the presence of nAbs. Silencing of free ASNase using nAbs demonstrated that the activity of eryaspase is attributed to intracellular ASNase, which must therefore be responsible for the sustained effect on ASN reduction. Eryaspase may provide a more effective approach for the delivery of ASNase in patients with ALL, especially in patients who have developed nAbs.

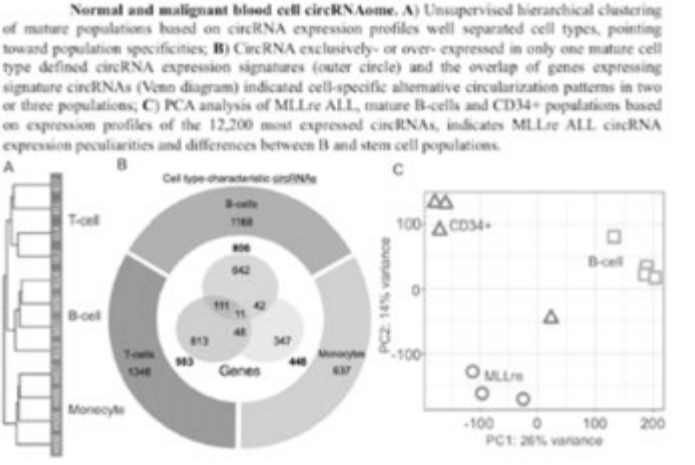
PF161

CIRCULAR RNAOME VARIATION IN NORMAL HEMATOPOIESIS AND MLL REARRANGED ACUTE LYMPHOBLASTIC LEUKEMIA

S. Bortoluzzi[1,*], E. Gaffo[1], E. Boldrin[2], A. Dal Molin[1], S. Bresolin[3], L. Trentin[3], C. Frasson[3], P. Guglielmelli[4], A. Vannucchi[4], K.-M. Debatin[2], G. Basso[3], L.H. Meyer[2], G. te Kronnie[3]

[1]Department of Molecular Medicine, University of Padova, Padova, Italy, [2]Department of Pediatrics and Adolescent Medicine, Ulm University Medical Center, Ulm, Germany, [3]Department of Women's and Children's Health, University of Padova, Padova, [4]CRIMM, Center for Research and Innovation of Myeloproliferative Neoplasms, AOU Careggi, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy

Background: Circular RNAs (circRNAs) are transcripts in which the splice donor site is covalently bound to an upstream acceptor site. Functionally, circRNAs can act as microRNA sponges controlling key microRNA-involving axes, interact with RNA-binding proteins, and regulate cellular processes. CircRNAs can be translated into biologically active peptides not encoded by linear transcripts. CircRNAs are expressed in all human tissues, including the hematopoietic compartment (*Bonizzato et al. BCJ 2016*). Even if investigation of circRNA expression in hematopoietic malignancies is in its infancy, there is evidence of circRNA deregulation in acute myeloid leukemia and of oncogenic potential of fusion-derived circRNAs in cells with chromosomal translocations.
Aims: We aimed to describe circRNAome variations in normal haematopoiesis and to disclose how circRNAs are affected in MLL rearranged (MLLre) acute lymphoblastic leukemia (ALL), an aggressive malignancy of childhood.
Methods: High depth RNA-seq was performed in B-cells, T-cells, monocytes and CD34+ cells from healthy donors (four replicates per population), and in three MLLre specimens. The CirComPara pipeline (*Gaffo et al. ncRNA J. 2017*) was used to detect circRNAs applying four algorithms, and to compare circular abundance to linear gene expression. Expression of selected circRNAs was validated by RT-PCR in PBMCs from healthy donors and in BCP-ALL samples; circularity and backsplice junctions were confirmed by RNase R treatment and Sanger sequencing.
Results: Considering all the mature blood cell populations, over 36,000 circRNAs were identified, 34% of which were novel. Notably, new circRNA-genes were uncovered. Alternative circularization was frequent: over 67% of circRNA host genes expressed multiple circular isoforms, and 33% produced 5 up to 78 circRNAs. CircRNA and linear gene expression were in general poorly correlated. CircRNA expression was sufficient to discriminate the populations (Figure 1A). Over 5,000 circRNAs differentially expressed between mature cell types were uncovered, mostly (88%) not deriving from differentially expressed genes. CircRNA expression signatures (1,168 circRNAs of B-cells, 1,346 of T-cells, and 637 of monocytes) were defined and revealed cell population specific patterns of alternative circularization (Figure 1B). Several circRNAs were validated, including newly uncovered ones and others expressed by the leukemia-associated genes *IKZF1* and *PAX5*. To identify specificities of leukemic cells, we then analysed the circRNAs expressed in MLLre ALL, mature B-cell and CD34+ populations. MLLre samples clustered together and apart from both the B- and CD34+ cell samples (Figure 1C). Of 12,200 highly expressed circRNAs, 15% were specific of MLLre samples and conversely, 9% were specific of B-cells (8%), CD34+ cells (0.3%), or expressed in both (0.7%) but not in malignant cells. Considering circRNAs expressed in both normal and malignant cells (76%), striking differences of circRNA expression in MLLre samples emerged. CircRNAs with MLLre-characteristic expression belonged to known leukemia-associated loci, non-coding RNA genes, and newly detected circRNA genes that were validated in this study.



Normal and malignant blood cell circRNAome. A) Unsupervised hierarchical clustering of mature populations based on circRNA expression profiles well separated cell types, pointing toward population specificities; **B)** CircRNA exclusively- or over- expressed in only one mature cell type defined circRNA expression signatures (outer circle) and the overlap of genes expressing signature circRNAs (Venn diagram) indicated cell-specific alternative circularization patterns in two or three populations; **C)** PCA analysis of MLLre ALL, mature B-cells and CD34+ populations based on expression profiles of the 12,200 most expressed circRNAs, indicates MLLre ALL circRNA expression peculiarities and differences between B and stem cell populations.

Figure 1.

Summary and Conclusions: We provide here an unprecedented view of the circRNAome complexity in different blood cell populations, uncovering new circRNAs potentially involved in leukemogenesis.

PF162

TARGETING G9A/EHMT2 IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

A. Montanaro[1,*], S. Kitara[2], R. Fioretzaki[1], A. Su[2], A. Gherli[1], J. Jin[3], F. Quani[14], F. Aversa[14], B. Knoechel[5], K. Stegmaier[2], G. Roti[14]

[1]University of Parma, Parma, Italy, [2]Dana-Farber Cancer Institute, Boston, [3]Department of Pharmacological Science, Icahn School of Medicine at Mt. Sinai, New York, United States, [4]Hematology, Azienda Ospedaliero-Universitaria di Parma, Parma, Italy, [5]Department of Pediatric Oncology, Dana-Farber Cancer Institute, Boston, United States

Background: T-cell acute lymphoblastic leukemia (T-ALL) is an aggressive subgroup of genetically heterogeneous lymphoid neoplasms caused by the oncogenic transformation of immature T-cell progenitors. Although T-ALL is potentially curable in children, in adults the outcome is dismal especially for relapsed and refractory disease suggesting the urgent need for novel agents and cell therapies for poor responders. Landscape genomic studies have identified somatic alterations in genes involved in DNA methylation and post-translational histone modifications in ALL, suggesting emerging opportunities for novel therapeutic strategies.
Aims: In this study, we identified G9a/*EHMT2* as a potential target in T-ALL. G9a/*EHMT2* and GLP/*EHMT1* are conserved protein lysine methyltransferases that localize in euchromatin regions and control transcriptional repression. Despite recent evidence that G9a is involved in several tumor types, the role of the G9a/GLP complex has not been systematically studied in T-ALL.
Methods: To date several inhibitors of protein methyltransferase (PMTs), histone methyltransferases (HMTs) and demethylases have been reported, including those that target G9a and GLP with high specificity. In our initial experiments, the G9a inhibitors BIX01294 and UNC0638 demonstrated an enhanced activity in a panel of T-ALL cell lines compared to other tumors. Next, the dependency of T-ALL on *EHMT2* was validated by the intersection of an epigenome-centered shRNA screen and low throughput sgRNA CRISPR studies targeting the enzymatic domain of G9a (SET). Finally, we focused on the phenotypic consequences of G9a loss at cellular and metabolic level.
Results: Because the response to targeted therapies correlates with the transcriptional activation of cancer driver genes, we analyzed several gene expression databases including the Differentiation Map, the Cancer Cell Line Encyclopedia, and primary T-ALL dataset. Collectively these results suggest that *EHMT2* is a marker of lymphoid differentiation and it is differentially expressed in T-ALL compared to other cancer subtypes or normal bone marrow cells. Furthermore, T-ALL was the most dependent cancer on G9a suppression in the Genomic of Drug Sensitivity Database supporting our initial observation. Competitive inhibition of G9a with G9a suppressors BIX01294, UNC0638, and UNC0642 impaired T-ALL proliferation and induced apoptosis. Consistent with this observation, sgRNA-CRISPR guided loss of G9a resulted in altered cellular proliferation and induction of cell death. Interestingly G9a suppression triggered autophagy as measured by LC3-II immunostaining and cytoplasmic vacuoles formation. Because autophagic vacuoles frequently entrapped glycoproteins, we speculated as to whether vacuoles contained glycogen. We next stained T-ALL treated cells with the periodic acid-Schiff and demonstrated the accumulation of the insoluble magenta complex (PAS reaction) in the cytoplasm of treated T-ALL cell lines. Electron microscopy analysis confirmed the deposition of intracellular glycogen granules. Next, we hypothesized that G9a might control glycogen synthesis. Thus we measured the activity of Glycogen Synthase Kinase-3 (GSK3) by western blotting and observed an increase of the inhibitory site phosphorylated Ser9-GSK3β upon drug treatment consistent with the inhibition of GSK kinase activity.
Summary and Conclusions: In this study, the intersection of multiple "omics" approaches led to the identification of *EHMT2*/G9a as a new druggable target in T-ALL. Our data support the notion that G9a controls GSK kinases, suggesting an epigenetic control of glycogen metabolism in T-ALL.

Background: Children with Down syndrome (DS), which caused by an extra copy of chromosome 21, have a 20-fold increased risk for acute lymphoblastic leukemia (ALL) compared with non-DS children. Recent genome-wide studies have revealed that DS-ALL has uncommon genetic alterations such as mutations in *JAK2*, *NRAS*, and *KRAS*, mutations or overexpression of *CRLF2*, suggesting the unique biological features of DS-ALL distinct from non-DS ALL. However, most of previous studies regarding of molecular analysis of DS-ALL have been limited to genomic and transcriptomic characterizations, and no study showed comprehensive genetic/epigenetic overview in DS-ALL.
Aims: To get better understanding of the molecular pathogenesis of DS-ALL, we conducted integrated genetic/epigenetic analyses.
Methods: Our cohort included 179 pediatric B-cell precursor ALL samples (61 DS-ALL and 118 non-DS-ALL). We performed targeted deep sequencing for seven ALL-related genes in 61 DS-ALL, SNP array analysis in 43 DS-ALL, and whole transcriptome sequencing (WTS) in 25 DS-ALL and 118 non-DS-ALL samples. Additionally, methylation array analysis was performed in 36 DS-ALL, 17 non-DS-ALL, and 20 DS patients without ALL.
Results: Targeted deep sequencing revealed frequent gene mutations of *JAK2* (23%) and *RAS* (31%) pathway. SNP array analysis elucidated several recurrent chromosomal deletions affecting actionable gene loci; *IKZF1* (33%), *PAX5* (30%), *EBF1* (15%), *CDKN2A* (34%), and *RB1* (7%). Gains of whole chromosome X (18%) and 8 (10%) were also recurrently identified. Expression profiling stratified 143 samples into 6 clusters (E1-E6 clusters), which were well correlated with biological subtypes of ALL. Intriguingly, DS-ALL cases were clustered into four clusters, suggesting the heterogeneity of DS-ALL. Cluster E3 included one DS-ALL, which was clustered into the branch of *PAX5*-rearranged cases. SNP array analysis revealed that this case had focal amplification of *PAX5*. All DS-ALL cases with *ETV6-RUNX1* fusion were classified into cluster E4, which also included all *ETV6-RUNX1* fusion cases of non-DS-ALL. This cluster included one DS-ALL case without *ETV6-RUNX1* fusion. This particular case had a homozygous deletion of *ETV6*, implicating *ETV6-RUNX1*-like signature. DS-ALL with high hyperdiploidy (HeH) were classified into cluster E5, which also included most of HeH samples of non-DS-ALL. Among other 5 DS-ALL cases in E5, 2 cases showed *IGH-CEBPA* fusion and *IGH-CEBPD* fusion, respectively. Cluster E6 was characterized by *BCR-ABL1* fusion and Ph-like expression profiles. In our cohort, we identified 7 DS-ALL cases with Ph-like signature, which included all *JAK2* mutated samples. In E6, *PAX5* mutation and *IKZF1* mutation were detected in 2 DS-ALL cases, respectively. DNA methylation array analysis suggested DS-ALL samples were also heterogeneous. Same as expression analysis, DNA methylation analysis revealed DS-ALL samples were clustered corresponding to each subtype same as non-DS-ALL. In addition, DNA methylation array analysis revealed unique hypermethylation of promoter regions of *RUNX1* in DS-ALL. DNA hyper methylation of this region was confirmed in normal B-cell of DS without ALL, but not in non-DS-ALL.
Summary and Conclusions: We confirmed DS-ALL was highly heterogeneous due to inclusion of many subtypes, and each subtype had similar expression and methylation profiles as non-DS-ALL. Hypermethylation of *RUNX1* in chromosome 21 was a unique characteristic in DS patients and may be associated with an increasing incidence of ALL in DS patients.

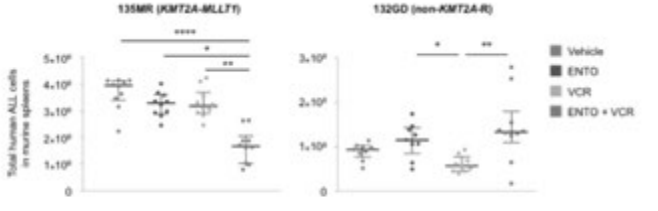
PF164

ENHANCED EFFICACY OF THE SYK INHIBITOR ENTOSPLETINIB AND VINCRISTINE IN KMT2A-REARRANGED ACUTE LYMPHOBLASTIC LEUKEMIA

J.P. Loftus[1], A. Yahiaoui[2], F. Shen[1], C. Hurtz[3], P.A. Brown[4], S. Tannheimer[2], A. Forslund[2], S. Tasian[56,*]

[1]Division of Oncology and Center for Childhood Cancer Research, Children's Hospital of Philadelphia, Philadelphia, [2]Gilead Sciences, Foster City, [3]Department of Medicine, Division of Hematology/Oncology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, [4]Pediatrics, Division of Oncology, John Hopkins University and Sidney Kimmel Comprehensive Cancer Center, Baltimore, [5]Division of Oncology and Center for Childhood Cancer Research, Children's Hospital of Philadelphia, [6]Pediatrics, Perelman School of Medicine at the University of Pennsylvania and Abramson Cancer Center, Philadelphia, United States

Background: Survival of infants with *KMT2A*-rearranged (R) B-cell acute lymphoblastic leukemia (ALL) remains dismal despite intensive chemotherapy. We previously reported constitutive phosphorylation of spleen tyrosine kinase (SYK) in infant ALL specimens (Yahiaoui EHA 2017, Loftus ASH 2017) and hypothesized that the selective SYK inhibitor (i) Entospletinib (ENTO) would inhibit activated kinase signaling *in vitro* and leukemia burden *in vivo*. We further predicted that combination treatment with ENTO and chemotherapy would have greater activity against *KMT2A*-R ALL.
Aims: (**1**) Determine effect of combined ENTO and vincristine (VCR) treatment of *KMT2A*-R and non-R ALL patient-derived xenograft (PDX) models *versus* monotherapy and (**2**) Identify constitutive signaling activation in infant ALL cells and potential biomarkers of ENTO sensitivity.
Methods: We first measured total and phosphorylated (p) SYK and SRC family kinases (SFK), FLT3, Ras/MAPK, JAK/STAT, PI3K/mTOR, and pre-BCR-associated proteins via Simple Western (SW) analysis of murine splenic lysates from infant *KMT2A*-R (n=8), infant non-*KMT2A*-R (n=3), and adult *KMT2A*-R (n=1) ALL PDX models. We then incubated ALL PDX cells *in vitro* with clinically-relevant concentrations of ENTO to assess abrogation of kinase signaling via SW and alterations in gene expression by NanoString analysis compared to non-ENTO-treated ALL cells. Finally, we treated ALL PDX models *in vivo* with control or ENTO chow *ad libitum*, VCR intraperitoneally once weekly, or both ENTO and VCR for 14-28 days and quantified human ALL burden in harvested murine tissues. Additional ALL PDX mice were treated with ENTO for 3 days to assess pharmacokinetic and pharmacodynamic effects of SYK inhibition.
Results: Basal kinase signaling activation differed among *KMT2A*-R and non-R ALLs and stratified by genetic subgroup (*KMT2A-AFF1* from t(4;11), *KMT2A-MLLT3* from t(9;11), *KMT2A-MLLT1* from t(11;19), other). *In vitro* incubation of *KMT2A*-R ALL cells with ENTO inhibited SYK pathway signaling, pAKT, and pERK. *In vivo* treatment of PDX models with ENTO showed sensitivity in 4 of 6 *KMT2A*-R and no activity in non-*KMT2A*-R ALL models. ENTO responses occurred in 1 RAS-wild-type *KMT2A-AFF1*, 1 *KMT2A-MLLT3*, 2 *KMT2A-MLLT1* ALL PDX models, but not in 2 RAS-mutant *KMT2A-AFF1* models. Greater inhibition of ALL burden with combined ENTO+VCR treatment was further observed in 2 of the 4 ENTO-sensitive *KMT2A*-R models *versus* single-agent ENTO or VCR (Figure 1). Enhanced sensitivity to ENTO/VCR appeared to occur in ALL PDXs with some surface Igm expression (pre-B lymphoblasts) and increased *HOXA9* and *MEIS1* gene expression, while mimimal response to combination treatment occurred in leukemias with concomitant *NRAS* or *KRAS* mutations. Gene expression analyses of *KMT2A*-R ALL cells from control and ENTO-treated mice also showed SYKi-induced downregulation of genes involved in DNA repair.



***In vivo* activity of entospletinib and vincristine in *KMT2A*-R and non-*KMT2A*-R ALL PDX models.** Human CD45+ CD19+ ALL cells were quantified by flow cytometry in murine spleens after 14 days of treatment. *p <0.05, **p <0.01, ****p <0.0001 by 1-way ANOVA Kruskal-Wallis with Dunn's multiple comparison test.

Figure 1.

Summary and Conclusions: Constitutive activation of SYK signaling occurs in multiple genetic subtypes of *KMT2A*-R ALL. We observed decreased SYK and other kinase signaling in *KMT2A*-R ALL treated with ENTO *in vitro* and, as well as potent ENTO-induced inhibition of leukemic burden *in vivo* in *KMT2A*-R R ALL PDX models. Combined ENTO and VCR treatment further enhanced anti-leukemia effects in some models. Clinical study of entospletinib and chemotherapy specifically in patients with *KMT2A*-R leukemias may be warranted.

PF165

NOVEL TARGETED THERAPIES FOR RESISTANT CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

S. Bhatia[1,*], V. Krieger[2], H. Ahlert[1], D. Diedrich[3], B. Frieg[3], N. Ressing[2], A. Herrlich[1], A. Borkhardt[1], H. Gohlke[3], T. Kurz[3], F.K. Hansen[2], J. Hauer[1]

[1]Department of Pediatric Oncology, Hematology and Clinical Immunology, Heinrich Heine University, Duesseldorf, [2]Institute for Pharmaceutical and Medicinal Chemistry, Leipzig University, Leipzig, [3]Institute for Pharmaceutical and Medicinal Chemistry, Heinrich Heine University, Duesseldorf, Germany

Background: During recent decade, the event-free survival of childhood acute lymphoblastic leukemia (ALL) has improved up to 80%, but there are still subgroups with a dismal prognosis. This potentiates the need to develop novel therapeutic compounds, with a low toxicity profile. We, therefore, aimed to develop and characterize novel precision compounds, which target oncogene stabilization by HSP90 and by the proteasome-HDAC6 axis.
Aims: We developed an HSP90 inhibitor (aminoxyrone) which is active as a pan-leukemia inhibitor against LSCs without the induction of any HSR and a dual proteasome-HDAC6 hybrid inhibitor (RTS-V), with sensitivity in BCR-ABL1+ TKI resistant BCP-ALL.
Methods: The specificity of aminoxyrone was evaluated by microscale thermophoresis (MST), cell-based luciferase refolding assay, 2D NMR spectroscopy, circular dichroism (CD) spectroscopy, analytical ultracentrifugation and molecular dynamics simulations.
Co-crystal structure determination was performed to analyze the binding mode of RTS-V into the β5/β6 active site of 20S yeast proteasome.
Results: HSP90 act as molecular chaperone and is highly expressed in several therapy-resistant leukemia subtypes thereby ensuring correct protein folding of several oncogenic proteins such as BCR-ABL1, FLT3-ITD and AKT. Therefore, targeting HSP90 could be a promising option in the treatment of therapy-refractory leukemia. Majority of available HSP90 inhibitors target the N-terminal domain thereby induce a protective mechanism called heat shock response (HSR), which potentially weakens the cytotoxic effect of HSP90 inhibitors and induce toxicity. We have developed first in class HSP90 inhibitor 'aminoxyrone' through structure-based molecular design and chemical synthesis which specifically targets C-terminal dimerization of HSP90. Aminoxyrone is effective in preclinical TKI (2nd and 3rd generation) resistant cell line models *in vitro* and *in vivo*, induces apoptosis in primary BCR-ABL1+ BCP-ALL and in Ph-like BCP-ALL patient-derived LSCs, without inducing any HSR. We furthermore developed a novel dual proteasome-HDAC6 hybrid inhibitor 'RTS-V'. Aggresomes are used by many malignant cells as an alternative route to degrade proteins that accumulate after proteasome inhibition. However, this mechanism depends on HDAC6 to transport ubiquitinated proteins by microtubules. Thus, inhibition of the proteasome and HDAC6 results in synergistic anticancer activity by induction of apoptosis in cancer cells. We found out that RTS-V specifically blocks chymotrypsin-like proteasome activity and at the same time causes preferential inhibition of HDAC6. The screening of RTS-V in more than 20 cell lines (including TKI-resistant BCP-ALL) and in primary relapse BCP-ALL samples revealed >20-fold higher specificity of RTS-V against leukemic cells as opposed to healthy PBMNCs. Besides that, we could show that in selected leukemic cell lines RTS-V specifically inhibits cell proliferation, induces apoptosis, accumulates cells in S phase, induces early differentiation and inhibits colony formation. Our next aim would be to test its efficacy in *in vivo* studies.
Summary and Conclusions: Taken together, 'aminoxyrone' and 'RTS-V' represents a promising starting point for future efforts towards the development of novel targeted inhibitors to overcome drug resistance and reduce toxicity, especially for the treatment of relapsed/refractory ALL.

PF166

DEHYDROPEPTIDASE 1 ENHANCED THE GROWTH AND SURVIVAL OF LEUKEMIA CELLS *IN VIVO* AND IDENTIFIED A HIGH RISK OF RELAPSE IN PATIENTS WITH COMMON B-CELL ALL

J.-M. Zhang[1,*], S.-J. Wang[1], J. Zhang[1], Y. Xu[1], L.-X. Wu[1], X.-J. Huang[1], K.-Y. Liu[1], G.-R. Ruan[#1]

[1]Peking University People's Hospital, Beijing, China

Background: Relapse remains the major cause of therapy-failure in adults with B-cell acute lymphoblastic leukaemia (ALL). Many pre-therapy variables correlate with relapse risk but a substantial part of the uncertainty in predicting relapse is unknown and new variables independently-correlated to relapse risk are needed. Dehydropeptidase-1 (DPEP1) is a zinc-dependent metalloproteinase. Abnormal DPEP1 expression is implicated in many neoplasms. High DPEP1 transcript levels are reported in persons with B-cell ALL compared with normal, but its role, if any, in adults B-cell ALL is unclear.
Aims: To investigate the role of DPEP1 in leukemia growth *in vivo* and compare the outcome of common B-cell ALL depending on the transcription level of DPEP1.
Methods: A xeno-transplant mouse model was used to assess effects of DPEP1 on tumor development. Bone marrow samples were obtained from

adults with Common B-cell ALL (N=87) and normal individuals (N=28) recruited at the Hematology Department of Peking University People's Hospital from March, 2009 to March, 2016. Subjects achieving complete remission were analyzed for cumulative incidence of relapse (CIR) and relapse free survival (RFS).
Results: In subjects with common-B-cell ALL, high transcript levels of DPEP1 was associated with a higher 5-year CIR (55%, [40, 69%] *vs* 23% [10, 35%]; P=0.021) and worse 5-year RFS (39% [24, 53%] *vs* 73% [60–86%]; P=0.037) compared with subjects with low transcript levels. This correlation was detected in subjects receiving chemotherapy (N=32; CIR: HR=5.09 [1.546, 16.78]; P=0.007) but not in those who also received an allotransplant (N=55; CIR: HR=1.52 [0.42, 5.41]; P=0.517). In subjects with common B-cell ALL, a high DPEP1 transcript level was independently-associated with CIR (HR=3.17 [1.41–7.14]; P=0.005) and RFS (HR=2.84 [1.34–6.02]; P=0.006) in multivariate analyses. Knockdown (KD) of DPEP1 in BV173, a B-cell ALL cell line reduced proliferation and survival in the presence of chemotherapy. In contrast, DPEP1 over-expression (OE) had a converse effect. Xeno-transplants were done with DPEP1-OE and DPEP1-KD cells to further investigate *in vivo* effects of DPEP1 expression. Knockdown of DPEP1 markedly decreased tumor growth compared with controls. In contrast, tumors were larger in mice bearing DPEP1-OE cells compared with controls. Histological examination showed more abundant blood sinuses in DPEP1-OE cell-derived tumors but a larger necrotic area in tumors derived from DPEP1-KD cells. TUNEL staining confirmed the increased apoptosis in specimens from the DPEP1-KD group compared with those from the vector controls.
Summary and Conclusions: In summary, our data support a proliferation and pro-survival role of DPEP1 in B-cell ALL cells *in vivo* and provide the first demonstration that in adults with common-B-cell ALL, high DPEP1 transcript levels is correlated with a higher CIR and worse RFS compared with subjects with low transcript levels. This correlation is observed in patients treated with chemotherapy only but not those with an allotransplant, which give an indication that adults with common B-cell ALL and high DPEP1 expression might benefit more from an allotransplant, although this indication needs further randomized validation.

PF167

TARGETING WNT10B*R-MEDIATED AUTOCRINE WNT SIGNALING ACTIVATION IN ACUTE LYMPHOBLASTIC LEUKEMIA

A. Cassaro[1,2,*], F. Lazzaroni[1,3], I. Esposito[1], G. Reda[4], R. Cairoli[2], A. Beghini[1]

[1]Department of Health Sciences, University of Milan, [2]Hematology Unit, Niguarda Cancer Center, Milan, Italy, [3]Department of Biochemistry, University of Losanna, Losanna, Switzerland, [4]Hematology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: Acute lymphoblastic leukemia (ALL) is an aggressive malignancy of hematopoietic progenitors with poor clinical outcomes. Wnt signaling is linked to many malignancies, including ALL, dysregulation of Wnt pathway has been implicated in the rising and maintenance of leukemic initiating stem cells (LICs), a subpopulation of blast cells responsible of refractory to, or relapse after chemotherapy in acute leukemia (AL) patients. Our lab has previously showed a ligand-dependent activation of Wnt pathway through a diffuse expression and release of the hematopoietic regeneration-associated molecule WNT10B in acute myeloid leukemia. The analysis of WNT10B locus revealed the presence of a recurrent rearrangement (WNT10B*R), leading to expression of the transcript variant WNT10B*IVS1 in a cohort of acute myeloid leukemia (AML) patients with intermediate/unfavourable risk. Although these evidences suggest that aberrant Wnt pathway activation may promote the development and persistence of LICs in acute leukemia, it is still unclear the mechanism of WNT10B*Rmediated activation in acute leukemic cells.
Aims: In this study, we investigated the occurrence of WNT10B*R in T- and B-ALL patients, and determined the Frizzled (FZD) receptor component/s involved in the WNT10B-mediated activation.Moreover, we evaluated if the small molecule-mediated interference of WNTs secretion by the porcupine acyltransferase inhibitor WNT974, may represent a new potential strategy to interfere with the ligand-dependent autocrine Wnt signaling.
Methods: Detection of WNT10B*R has been evaluated in 34 primary acute lymphoblastic leukemia (5 T-ALL and 29 B-ALL) cells samples. The interaction between WNT10B*IVS1 and FZD receptors was evaluated in MOLT4 model cell line, expressing the WNT10B*R as unique Wnt ligand, by proximity ligation assay (PLA) at single cell level. MOLT4 cell line was subsequently treated with increased concentration of WNT974 inhibitor and cell viability was measured by MTT assay.
Results: We detected the WNT10B*R rearrangement in 19/34 ALL patients analyzed, supporting our hypothesis of its broad involvement in the acute leukemogenesis. In order to characterize WNT10B*IVS1molecule we selected MOLT4 cell line as cell line model, since the expression analysis by RT-PCR on several myeloid and lymphoid cell lines revealed the exclusive expression of rearrangement by MOLT4. We also confirmed the expression of WNT10B*IVS1 in MOLT4 through *in situ*-mRNA detection method. In order to determine which FZD receptor/s binds WNT10B in the T-ALL cell model MOLT4 we performed specific PLA for FZD4/5/6. Interestingly, we detected high intensity signals only for the WNT10B/FZD6 ligand/receptor-interaction, the subsequent expression analysis confirms the univocal expression of FZD6 in the MOLT4. The treatment with increasing concentration of WNT974 porcupine inhibitor decreased the MOLT4 cell viability in a dose-dependent manner, suggesting the autocrine mechanism of Wnt signaling activation.
Summary and Conclusions: Overall, these preliminary data confirm the WNT10B*R -mediated autocrine Wnt signaling activation also in ALL, and identified FZD6 as the potential receptor functionally involved in the interaction with WNT10B. Thus, our studies suggest possible molecular elements in ALL cells that may need to be targeted for more durable remissions.

PF168

MIR-451 IS A NEW BIOMARKER THAT IDENTIFIES ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS WHO MAY BENEFIT FROM TREATMENT WITH NAMPT INHIBITORS

K. Shichrur[1,2,*], I. Yaniv[1,2], J. Yarden[3], S. Avigad[1,2]

[1]Pediatric Hematology Oncology, Schneider Children's Medical Center of Israel, Petah Tikva, [2]Felsenstein Medical Research Center, Tel Aviv University, Tel Aviv, [3]Curewize Health Ltd., Yokneam, Israel

Background: MicroRNAs (miRs) are a group of small noncoding RNAs that post-transcriptionally regulate gene expression by direct binding to their corresponding targets. Aberrant miR expression has been identified in various types of cancer playing essential roles in cancer initiation and progression. Thus, miRs represent a great potential as novel diagnostic and prognostic biomarkers of cancer as well as novel targets for cancer treatment. Previously we have demonstrated that low expression levels of miR-451 could act as a biomarker that could predict high risk of relapse in pediatric acute lymphoblastic leukemia (ALL) patients (Avigad *et al.* 2016).
Aims: Our aim in this study was to explore the role of miR-451 and its target in ALL.
Methods: The relevance of various miR-451 expression levels on the growth rate of leukemic cells was evaluated using a xenograft mice model. A novel target of miR-451, identified by bioinformatic analysis, was validated for direct binding and regulation by miR-451 utilizing several putative assays. The correlation between miR-451 and it's novel target was studied also in other malignancies. Using this model we explored miR-451 as a biomarker for detecting the sensitivity to a specific pathway inhibitor of its target.
Results: We demonstrated that the growth rate of leukemic cells over expressing miR-451 was significantly reduced compared to miR-451 silenced cells in the mice (p=0.03). In this study, we identified an association between miR-451 and a putative target, NAMPT (Nicotinamide Phosphoribosyltransferase) which is a key enzyme in the NAD^+ pathway. We detected a significant inverse correlation between miR-451 expression levels and NAMPT protein levels and provided evidence for the direct binding of miR-451 to NAMPT in ALL cell line. This correlation was also evident in other malignant cell lines such as breast, colon and prostate cancer cell lines. We used a mice xenograft ALL model to demonstrate the inverse correlation between miR-451 expression levels and the sensitivity to a potent NAMPT inhibitor (FK866). ALL cells expressing low levels of miR-451 demonstrated significantly increased sensitivity to treatment with the NAMPT inhibitor compared to high expressing cells. The sensitivity of each line to FK866 treatment was examined on a group of 89 mice. At the end of the experiments the mean tumor volume of the FK866 treated group injected with low miR-451 cells was 117 ±81mm^3 compared to 1104 ±134mm^3 in the non-treated group (p = 0.000118) while in the treated mice injected with high expressing cells the mean tumor volume was 544 ±64mm^3 compared to 851 ±110mm^3 in the non-treated group (p =0.028). This specific sensitivity was also evident in a prostate cancer xenograft model.
Summary and Conclusions: NAMPT was identified as a novel target of miR-451. miR-451 may play an important role in ALL progression via NAMPT regulation. Thus, miR-451 expression levels could be used as a biomarker for the identification of patients who may benefit from treatment with NAMPT inhibitors.

PF169

NOVEL PROGNOSTIC MARKER ARID5B LOW EXPRESSION IN ACUTE LYMPHOBLASTIC LEUKEMIA

Z. Ge[1], Y. Gu[1], Q. Han[1], S. Dovat[2], C. Song[2,*]

[1]Hematology, Zhongda Hospital, Southeast University Medical School, Nanjing, China, [2]Pediatrics, Penn State University College of Medicine, Hershey, United States

Background: AT-rich interactive domain-containing protein 5B (ARID5B) forms a complex with PHD finger protein 2 (PHF2) and the ARID5B-PHF2 complex then induces the demethylation of di-methylated 'Lys-9' of histone H3 (H3K9me2) leading to transcription activation target genes. Mutations and single nucleotide polymorphisms of *ARID5B* are associated with the development of acute lymphoblastic leukemia (ALL) and treatment outcome. So far there have been no reports about *ARID5B* expression in ALL and the clinical significance of *ARID5B*^{low} and *ARID5B*^{low}*PHF2*^{low}expression in ALL patients. ChIP-seq data show the obvious binding peaks of Ikaros, the leukemia suppressor in promoter of *ARID5B*.
Aims: This study is to examine clinical significance of *ARID5B*^{low} and *ARID5B*^{low}*PHF2*^{low}expression in ALL patients and the regulatory role of Ikaros on *ARID5B* expression in ALL cells.
Methods: 164 Subjects with newly-diagnosed ALL (107 B-cell and 57 T-cell ALL; 12-77 years old) were studied. The study was approved by the Ethics Committee of the institutes. Subjects were allocated in a high or low *ARID5B* expression cohort (4th quartile *vs* 1st-3rd quartiles) with a cut-off value determined by SPSS 20.0. Median and frequency differences between the cohorts were evaluated using a Mann–Whitney U-test and uni- and multivariate Cox model. Relapse-free survival (RFS) and overall survival (OS) were estimated by the Kaplan-Meier method and compared by log-rank test.
Results: We observed the *ARID5B* mRNA level is significantly down-regulated in subset of ALL patients. *ARID5B*^{low} mRNA levels were associated with leukemic cell proliferation and poor prognostic indicators. Low *ARID5B* mRNA levels were associated with a higher median percentage of bone marrow blasts (90.0% *vs* 84.6%, *P*=0.037), a higher percentage of stem cell marker CD34+(88.8% *vs* 37.5%, *P*=0.000) and myeloid marker CD33+ (48.5% *vs* 25.0%, *P*=0.046), a higher frequency of Ik6(+), the most common *IKZF1* deletion (42.5% *vs* 20.0%, *P*=0.042), and also a lower median hemoglobin and platelet count compared to patients with high *ARID5B* expression. B-ALL patients with *ARID5B*^{low} expression represented a significantly higher percentage of the cohort of patients who took more than 4 weeks to reach complete remission (CR) (51.4% *vs* 16.0%, *P*=0.002) , a poor prognostic indicator in ALL, compared to those with high *ARID5B* expression. Particularly *ARID5B* expression is positively correlated with *PHF2* expression in ALL. The *ARID5B*^{low}*PHF2*^{low} was associated with a higher percentage of bone marrow blasts (91.2% *vs* 82.4%, *P*=0.000), stem cell marker CD34+ (88.2% *vs* 55.6%, *P*=0.000), myeloid marker CD33+ (50.9% *vs* 28.6%, *P*=0.036), splenomegaly (50.0% *vs* 22.9%, *P*=0.008), a CR time ≥4 weeks (53% *vs* 21%, *P*=0.003) and higher frequency of *Ik6*(+) (49.3% *vs* 15.8%, *P*=0.001) and lower median PLT count (10^9/L) (32.0 *vs* 58.5, *P*=0.020) compared to patients with non-*ARID5B*^{low}*PHF2*^{low} cohort. The multivariable analysis confirmed the association with bone marrow blasts, *Ik6* (+) and a CR time ≥4 weeks. We also found *ARID5B* expression was significantly lower in B-ALL with Ik6(+) (0.3153±0.0938 *vs.*1.2052±0.58441, *P*=0.02439); and Ikaros directly promotes *ARID5B* expression.
Summary and Conclusions: *ARID5B*^{low}, particularly *ARID5B*^{low}*PHF2*^{low}expression is associated with leukemia proliferation and poor prognostic markers. Our results also revealed the oncogenic effect of *ARID5B*^{low}*PHF2*^{low} expression in ALL, and identified a high-risk subgroup of ALL characterized by Ikaros dysfunction and *ARID5B*^{low}*PHF2*^{low} expression.

PF170

NOVEL IKAROS TARGET RAG1 HIGH EXPRESSION IN B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

Q. Han[1], Y. Gu[1], C. Song[2], Z. Ge[1,*]

[1]Hematology, Zhongda Hospital, Medical School of Southeast University, Nanjing, China, [2]Pediatrics, Penn State University College of Medicine, Hershey, United States

Background: The recombination activating gene (RAG)-mediated recombination is the dominant mutational process and is the predominant driver of oncogenic genomic rearrangement in acute lymphoblastic leukemia (ALL). This then leads to further leukemic clonal evolution. *IKZF1* encodes a krupel-like zinc finger protein, IKAROS that is essential for normal hematopoiesis and acts as a tumor suppressor in ALL. We found Casein Kinase II (CK2) –mediated IKAROS phosphorylation is a key mechanism responsible for IKAROS dysfunction in ALL, and CK2 inhibitor CX-4945 treatment could restore IKAROS tumor suppressor function in high-risk ALL. ChIP-seg data showed obvious IKAROS binding peaks on the promoter of *RAG1* in B-ALL patients' samples, suggesting its regulation role on *RAG1* expression.
Aims: We will explore the clinical significance of *RAG1* expression in B-ALL and IKAROS regulation on *RAG1* expression in B-ALL cells.
Methods: The 131 subjects with newly-diagnosed B-ALL (age 12-77 years old) were recruited. *RAG1* mRNA level was examined by qPCR and allocated into a high or low expression cohort (1-2th quartile *vs* 3-4th quartiles) with a cut-off value determined by SPSS 20.0. Median or frequency differences between the cohorts were evaluated using a Mann–Whitney U-test or uni- and multivariate Cox mode. The retroviral gene expression, shRNA knockdown, and chromatin-immunoprecipitation are used to observe IKAROS regulation on *RAG1* transcription.
Results: We observed that *RAG1* is significantly increased in subsets of B-ALL patients. High *RAG1* expression correlates with higher percentage of white blood cell (WBC) ≥30x10^9/L (67.7% *vs* 38.5%, P<0.001), higher blasts in peripheral blood (75.0% *vs* 61.0%, P=0.026) and higher median WBC (47.9×10^9/L *vs* 17.0×10^9/L, P=0.025), the markers of poorer prognosis and proliferation in B-ALL. We found a higher incidence of *IK*6, the most common protein produced by *IKZF1* deletion in B-ALL patients with the high *RAG1* expression group (45.5% *vs* 26.2%, P=0.021); and *RAG1* mRNA level was significantly higher in patients with *IKZF1* deletion than those without. These data indicate that *IKZF1* deletion has the key role on up-regulating *RAG1* expression in primary B-ALL cells. Moreover, ChIP-seq and qChIP data showed that IKAROS directly binds to the *RAG1* promoter and regulates *RAG1* expression in leukemic cells and patients' samples. CK2 inhibitor, CX-4945 by increasing IKAROS activity significantly increases IKAROS binding in ALL cells and suppresses *RAG1* expression in an IKAROS-dependent manner. *RAG1* expression is significantly higher in patients with *IKZF1* deletion, as compared to patients without *IKZF1* deletion. Treatment with CX-4945 also results in an increase in IKZF1 binding to the *RAG1* promoter and suppression of *RAG1* expression in primary ALL cells.
Summary and Conclusions: This is the first time to demonstrate that IKAROS directly suppresses *RAG1* expression. High expression of *RAG1* correlates with high proliferation markers in B-ALL. Our data suggest *RAG1* high expression works together with IKAROS dysfunction to drive oncogenesis of B-ALL, which have significance in an integrated prognostic model for adult ALL.

PF171

S100A16 INHIBITED PROLIFERATION AND PROMOTED APOPTOSIS THROUGH REGULATION OF ERK PATHWAY IN B CELL ALL

J. Zhang[1,2,*], W.-Y. Lu[1,2], J.-M. Zhang[1,2], Y. Xu[1,2], X.-J. Huang[1,2], K.-Y. Liu[#1,2], G.-R. Ruan[#1,2]

[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China

Background: Outcome of adults with B-cell acute lymphoblastic leukemia (ALL) remains poor and relapse is the major cause of treatment-failure. Although several biomarkers of leukemia have been reported recently, the biomarker for B-cell ALL is still lack. Identifying novel biomarkers in B-cell ALL will contribute to the exploration of disease mechanisms, the refinement of prognostic stratification and the discovery of the new therapeutic targets. S100A16 is a novel member of S100 superfamily and is abnormally expressed in lots of cancers, but its role still remains controversial. In our previously conducted microarray analysis, S100A16 was identified as one of the most differentially expressed genes which were over-expressed in B-cell ALL compared with normal bone marrow, but its physiological and pathological roles in B-cell ALL are largely unclear.
Aims: To investigate the expression levels of S100A16 in adults with B-cell ALL and to explore the biological function of S100A16 in the cell lines derived from B-cell ALL.
Methods: A real-time quantitative RT-PCR was used to examine S100A16 transcript levels in bone marrow samples from 140 adults with newly diagnosed B-cell ALL, 20 adults with newly diagnosed T-cell ALL, 20 adults with newly diagnosed AML and 35 healthy donors. We constructed two B-cell lines: S100A16 over-expressing (OE) Nalm-6 cell line and S100A16 knock-down (KD) SupB15 cell line to study the biological function of S100A16 in B-cell ALL. The cell proliferation was detected by CCK-8 and the early apoptosis was analyzed by flow cytometry. Western blot was used to determine the protein level of signaling pathways.
Results: The results showed that the relative gene expression levels of

S100A16 in bone marrow from 140 newly diagnosed B-cell ALL (median 243%; range 0-10339%) were significantly higher than those from the healthy donors (1.27%; 0-5.29%; $p<0.001$), whereas no significant difference was detected in newly diagnosed T-cell ALL and AML patients compared with health donors (Figure 1A). S100A16 gene expression was higher in BCR/ABL positive B-cell ALL lines (BV173, SupB15), CML cell line (K562), but lower in EBV-LCL, BCR/ABL negative B-cell ALL lines (Nalm-6, BALL-1), T-cell ALL(6T-CEM), AML (NB4, HL-60, KG-1), NHL (Ramos, Raji, MAVER). Proliferation was decreased in S100A16-OE cells compared with cells transfected with control lentivirus (OD value: 0.131±0.003 *vs* 0.158±0.005, $p<0.05$). Conversely, silencing of S100A16 expression markedly increased the proliferation of the transfected cells (OD value: 1.534±0.032 *vs* 0.953±0.101, $p<0.05$)(Figure 1B). The early apoptotic cells in S100A16-OE cells were higher than S100A16-OE control cells (76.8±0.286% *vs* 13.54±0.165%, p<0.0001). Instead, the early apoptotic cells in S100A16-KD cells was lower than that in the control group (11.33±0.0.176% *vs* 31.29±0.478%, $p<0.0001$)(Figure 1C). In addition, we found that silencing of S100A16 obviously inhibited the expression of p-ERK1+2 compared with the control group (Figure 1D).

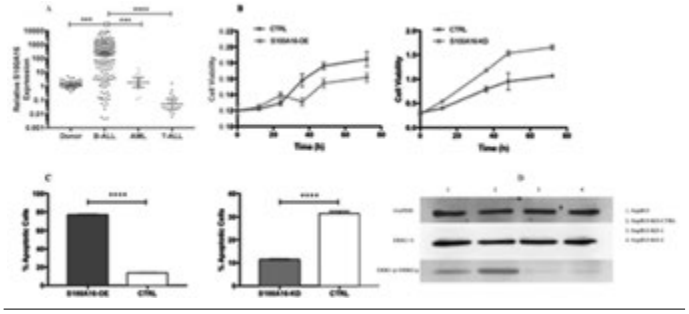


Figure 1.

Summary and Conclusions: These findings suggest that aberrant expression of S100A16 might be involved in the physiopathological mechanism of B-cell ALL. S100A16 might inhibit proliferation and promote apoptosis of B-cell ALL via the ERK signaling pathway.

PF172

MELATONIN INHIBITS MLL-REARRANGED LEUKEMIA VIA RBFOX3/HTERT AND NF-KB/COX-2 SIGNALING PATHWAYS

Y.-L. Tang[1], L.-B. Huang[1], X.-J. Lui[2,*]

[1]Department of Pediatrics, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China, [2]The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: MLL-rearranged leukemia is an aggressive malignancy associated with poor outcome, which is refractory to conventional treatment.
Aims: Melatonin has been proven to exert anti-tumor activity, but the effect of melatonin on MLL-r leukemia and the underlying mechanism remain poorly understood.
Methods: Firstly, the cell viability was determined by the CCK-8 assay and the apoptosis was examined by a FACS analysis. Secondly, qRT-PCR and Western blot were used to examine the expression of RBFOX3,hTERT, NF- B and COX-2. Furthermore, streptavidin-agarose pulldown assays and ChIP assay were used to test the RBFOX3 binding to hTERT promoter and NF- B p65 subunit binding to COX-2 promoter. Moreover, We investigated the effect of melatonin on the growth in a MLL-r ALL xenograft mouse model.
Results: In this study, we showed that melatonin inhibited cell proliferation and induced apoptosis by activating the caspase-dependent apoptotic pathway in MLL-r leukemia cells. Mechanistic investigations revealed that melatonin suppressed the expression of hTERT by abrogating the binding activity of RBFOX3 to the hTERT promoter. Melatonin also blocked NF- B nuclear translocation and suppressed NF- B binding to the COX-2 promoter, thereby suppressing the expression of COX-2. In addition, clinical samples revealed that melatonin exerts anti-leukemic activity in primary MLL-r leukemia blasts *ex vivo*. *In vivo*, the mice treated with melatonin experienced a larger reduction in leukemic burden than the control group in a MLL-r leukemia xenograft mouse model.
Summary and Conclusions: These results suggested that melatonin inhibited MLL-rearranged leukemia through suppressing the RBFOX3/hTERT and NF- B/COX-2 signaling pathways. Our findings provide new insights into the role of melatonin for MLL-r leukemia treatment.

PF173

INVESTIGATING THE SYNERGISM BETWEEN CHK1 AND WEE1 PROTEINS INHIBITION IN THE TREATMENT OF ACUTE LYMPHOBLASTIC LEUKEMIA

A. Ghelli Luserna Di Rora'[1,*], A. Ferrari[1], V. Robustelli[1], E. Imbrogno[1], C. Papayannidis[1], M.C. Abbenante[1], G. Marconi[1], S. Paolini[1], M. Cavo[1], G. Martinelli[2]

[1]Department of Experimental, Diagnostic and Specialty Medicine,Department of Hematology and Medical Sciences "L. and A. Seràgnoli, Bologna, [2]Scientific Directorate, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy, Meldola, Italy

Background: Although several innovative therapies are today improving the outcome for adult acute lymphoblastic leukemia (ALL) patients, a large percentage frequently relapse or became refractory to treatments. Thus, there is a need to improve the efficacy of actual treatments or to identify novel therapeutic strategy. The inhibition of cell cycle checkpoints has become a promising therapeutic option for the treatment of different tumors. The preclinical data available, led the basis for the clinical evaluation of this class of compounds. On ALL only few preclinical and clinical data on the effectiveness of cell cycle checkpoint inhibitors has been reported. It has been showed that the simultaneous inhibition of CHK1 and WEE1 kinases synergizes in term of reduction of cell viability, induction of apoptosis and inhibition of proliferative capacity.
Aims: To evaluate the effectiveness of the concomitant inhibition of Wee1 and Chk1 kinases in the treatment of ALL as single agent and in combination with the S-phase specific chemotherapy agent, methotrexate.
Methods: Gene expression analysis was performed using Affymetrix GeneChip Human Transcriptome Array 2.0 on leukemic cells isolated from the bone marrow and the peripheral blood of adult B-ALL patients. B-/T-ALL cell lines and primary cells were treated with PF-00477736 and/or AZD-1775 *in vitro* and *ex vivo*. The effectiveness of the combination was evaluated in term of reduction of the cell viability, reduction of cell proliferation, cell cycle modification, induction of apoptosis and protein modification.
Results: We showed that in primary B-ALL samples at diagnosis (n=39) WEE1 and CHEK1 transcripts are highly expressed and positively co-expressed (Pearson r=0.5770, p=0.0001). Having established that the abundance of WEE1 and CHEK1 is significantly high this raised the possibility that ALL cells may be reliant on both kinases for survival. We therefore next evaluated the efficacy of the concomitant inhibition of both kinases on ALL cell lines. The two small inhibitors PF-00477736 (Chk1 inhibitor) and AZD-1775 (Wee1 inhibitor) synergized in the reduction of cell viability (CI. between 0.17-0.9), induction of DNA damages, activation of cell apoptosis and increment of S phase cells in different ALL cell lines. Interestingly the combination compromised the viability also of primary leukemic cells isolated from the bone marrow and the peripheral blood of adult B-ALL patients. To further evaluate the potential of the combination, ALL cell lines were treated with methotrexate after being exposed to PF-00477736 and/or AZD-1775. Interestingly the treatment with combination deeply sensitized different leukemic cell lines to the cytotoxicity of methotrexate. The specificity of the pharmacological schedule on S phase was confirmed using the G2/M phase specific inhibitor, doxorubicin, which showed no significant reduction of the cell viability.
Summary and Conclusions: Here we extended the already available results on this potent therapeutic strategy on ALL cell lines and primary cells. We confirmed that the concomitant inhibition of WEE1 and CHK1 mine the viability of leukemic blasts inducing DNA damages and triggering apoptosis. We demonstrated that the inhibition of WEE1 and CHK1 kinases could be a winning strategy to enhance the toxicity of conventional chemotherapy.

Background: Tisagenlecleucel, an autologous T-cell product expressing a CD19-specific chimeric antigen receptor (CAR), demonstrated a high rate of durable responses and manageable safety profile in a single-center phase 1/2a trial in pediatric/young adult patients (pts) with r/r B-ALL.
Aims: To establish safety and efficacy of tisagenlecleucel for transfer from an academic to a centralized industry-based manufacturing process, a multicenter phase 2 trial (ENSIGN; NCT02228096) was initiated.
Methods: 13 US sites participated. Leukapheresis products were shipped for centralized manufacturing by the University of Pennsylvania for the first 26 pts or Novartis for subsequent pts. Following lymphodepletion with fludarabine and cyclophosphamide, a single dose of tisagenlecleucel cells was administered (dose range: ≤50 kg, 2.0-5.0x10^6 cells/kg; >50 kg, 1.0-2.5x10^8 cells). The primary endpoint was overall remission (ORR=complete remission [CR]+ CR with incomplete blood count recovery [CRi] maintained for ≥28 d) ≤6 mo after infusion. Efficacy analyses were performed on pts who completed 6 mo follow-up or discontinued earlier; OS and safety were evaluated for all infused pts.
Results: At data cutoff (6 Oct 2017) 58/73 enrolled pts (79%) were infused with tisagenlecleucel, 42 completed 6 mo follow-up, 11 withdrew prior to infusion (5 product related issues; 6 deaths), 4 were pending infusion. 3 pts did not receive lymphodepleting chemotherapy due to leukopenia. Median time from enrollment to infusion, 41 d. Median time from infusion to data cutoff, 19.6 mo. Median infused dose was 3.55x10^6 (range, 0.2-5.0x10^6) CAR+ transduced viable T cells/kg; 49/58 (84%) infused pts were within and 9 below the dose range. The ORR was 69% (29/42 evaluable pts; 95% CI 52.9, 82.4). 13 pts did not achieve CR/CRi (6 did not achieve remission, 3 relapsed <28 days after remission onset, 2 were not evaluable [proceeded to SCT shortly after remission onset without subsequent response assessment], 2 died before day 28 [1 ALL; 1 embolic stroke]). Of 29 pts in CR/CRi, 27 (93%) were minimal residual disease-negative (<0.01%) by multiparameter flow cytometry. Relapse-free survival at 6 and 12 mo was 71% (95% CI, 48.5-85.5) and 61% (95% CI, 38-78); median duration of remission was not reached. Overall survival for all infused pts at 6 and 12 mo was 79% (95% CI, 65-88) and 63% (95% CI, 46-76); median, 23.8 mo (95% CI, 9-NE). Tisagenlecleucel was detected in peripheral blood for up to 764 d. 17 infused pts died >30 days after infusion (16 ALL; 1 complication of transplant); no deaths were attributed to tisagenlecleucel. The most common adverse event was cytokine release syndrome (CRS; all grade [G], 81%; G 3 or 4, 33%; graded on the Penn scale). For CRS treatment, 13 pts (22%) had systemic anti-cytokine therapy, 14 (24%) had high dose vasopressors for hypotension, 6 (10%) had intubation, and 4 (7%) had dialysis. No deaths were attributed to CRS. Neurological events occurred in 19 pts (32.8%; 4 G 3; no G 4; all reversible), including seizures in 3 pts; there were no cases of cerebral edema. Efficacy and safety were consistent across manufacturing processes.
Summary and Conclusions: In this first multicenter trial, tisagenlecleucel showed a high ORR with durable remissions in pediatric/young adult pts with r/r B-ALL. CRS was effectively managed with a protocol-specific algorithm by appropriately trained site staff. ENSIGN was instrumental in establishing transfer from an academic to a centralized industry-based manufacturing process, and laid the foundation for the larger global ELIANA trial.

PF175

PHASE I STUDY OF UCART19, AN ALLOGENEIC ANTI-CD19 CAR T-CELL PRODUCT, IN HIGH RISK PEDIATRIC PATIENTS WITH CD19+ RELAPSED/REFRACTORY (R/R) B-CELL ALL: PRELIMINARY RESULTS OF PALL STUDY

W. Qasim[1,*], O. Ciocarlie[1], S. Adams[1], S. Inglott[1], C. Murphy[2], K. Gilmour[2], C. Rivat[1], G. Wright[1], G. Lucchini[1], J. Silva[1], K. Rao[1], A. Zinaï[3], S. Dupouy[3], S. Balandraud[3], F. Simon[3], J. Pauly[3], C. Bermingham[4], C. Konto[4], R. Chiesa[1], S. Samarasinghe[1], H. Hara[1], A. Boyle[1], J. Chu[1], D. Pinner[1], P.J. Amrolia[1], A. Vora[1], A. Rao[1], P. Ancliffe[1], P. Veys[1]

[1]Bone Marrow Transplantation Department, [2]Clinical Immunology, Great Ormond Street hospital NHS trust, London, United Kingdom, [3]Servier, Suresnes, France, [4]Pfizer Inc, San Francisco, CA, United States

Background: UCART19 is a genetically modified CAR T-cell product (anti-CD19 scFv- 41BB- CD3) manufactured from healthy donor cells, in which *TRAC* and *CD52* genes have been disrupted to allow administration in non-HLA matched patients.
Aims: Preliminary results of the PALL trial, an open-label phase I study of UCART19 in pediatric patients (pts) with R/R B-ALL are reported.
Methods: Pediatric pts (≥6 months to <18 years) with morphological disease or minimal residual disease (MRD) level ≥1x10^{-3} and who had exhausted available treatment options were eligible for the study. Prior to UCART19 single dose infusion, a lymphodepletion regimen combining high-dose fludarabine-cyclophosphamide, with or without alemtuzumab (FCA or FC) was administered. A fixed dose of UCART19 (2x10^7 total CAR+ cells corresponding to 1.1 to 2.3x10^6 cells/kg) in 4 different weight-bands was infused on Day 0. The safety and tolerability of UCART19 and its ability to achieve molecular remission at day (D) 28 ahead of allogeneic stem cell transplantation (allo-SCT) were assessed as primary and secondary objectives, respectively.
Results: As of February 02 2018, 6 children (3 males and 3 females) between 08 months and 16.4 years have been treated. Of the 6 pts, 5 had received 3 or more previous lines of treatment and 2 had previously received allo-SCT. Prior to lymphodepletion, 5 patients had low disease burden (<10% blasts) and 1 patient had high disease burden (80% blasts). All pts experienced reversible cytokine release syndrome (CRS): 1 grade (G) 1, 4 G2, 1 G3. CRS were manageable by supportive care±tocilizumab. Time to onset of first CRS symptoms ranged between D5 and D9. One patient experienced a G1 acute skin GvHD confirmed by biopsy and recovered with topical steroids. Five out of 6 patients received FCA, viral reactivation (CMV, ADV, BK, metapneumovirus) was observed in 4/5 pts and 3/5 had persisting G4 neutropenia by D42. Out of 6 patients, 5 achieved CRi at D28-D42, with 5/5 MRD negative (<0.01%) by flow cytometry and 3/5 MRD negative by PCR. Only 1/6 pts received FC and had a refractory disease on D28. All 5 CRi pts with negative MRD underwent allo-SCT, between 50 and 63 days following UCART19 infusion. Two patients relapsed 3 months after allo-SCT (one CD19- and one CD19+; both MRD positive by PCR prior to SCT), and died from disease progression 7 and 8 months after UCART19 infusion, respectively. One patient died 2.5 months after allo-SCT from thrombotic microangiopathy in a context of severe BK virus infection. Two patients are alive with molecular remission >6 months post-transplant and continue to be monitored in the study. Out of the 5 first patients treated with FCA, levels of UCART19 vector copy number showed a peak around D14 and were detectable in blood from D7 up to D42. UCART19 was also detectable by molecular signatures of UCART19 T-cell donor chimerism up to D42 in 4 patients and up to D57 in one patient. In the last patient treated by FC without alemtuzumab, UCART19 was detectable neither by qPCR nor by chimerism.
Summary and Conclusions: UCART19 shows an acceptable safety profile and was able to induce molecular remission in 5 out of 6 patients enabling allogeneic transplantation to proceed. The study is open and recruiting at multiple sites.

PF176

CHARACTERISTICS AND OUTCOMES OF ADULTS WITH ACUTE LYMPHOBLASTIC LEUKAEMIA RELAPSING POST-ALLOGENEIC HAEMATOPOIETIC CELL TRANSPLANTATION IN THE PROSPECTIVE UKALL14 TRIAL (ISRCTN 665421317).

A. Castleton[1,*], A.A. Kirkwood[2], L. Clifton-Hadley[2], L. Micklewright[2], P. Patrick[2], A. V. Moorman[3], C. Rowntree[4], A.K. Fielding[5], D.I. Marks[6]

[1]Haematology, The Christie NHS Foundation Trust, Manchester, [2]CRUK & UCL Cancer trials centre, University College London, London, [3]Leukaemia Research Cytogenetics Group, Wolfson Childhood Cancer Research Centre, Newcastle-upon-tyne, [4]Haematology, University Hospital of Wales, Cardiff, [5]Haematology, University College London Hospitals NHS Foundation Trust, London, [6]Haematology, University Hospitals Bristol NHS Foundation Trust, Bristol, United Kingdom

Background: The outcome of relapsed adult acute lymphoblastic leukaemia is poor. In particular, patients (pts) relapsing after allogeneic haematopoietic cell transplant (alloHCT) have limited treatment options which have recently broadened with the advent of immunotherapies.
Aims: To evaluate factors influencing post-alloHCT relapse risk and survival for pts on the UKALL14 trial.
Methods: Within UKALL14, pts ≤40 years received myeloablative conditioned (MAC) alloHCT (cyclophosphamide/TBI 13.2Gy) in first complete remission (CR1) for high risk disease (high baseline WBC count; t4;11; low hypodiploidy/near triploidy; complex karyotype; Ph+; minimal residual disease (MRD) positivity post-induction cycle 2). MAC alloHCT for standard risk disease was advised if suitable sibling donor. All >40 years were high risk and eligible for reduced intensity conditioned (RIC) (fludarabine, melphalan, alemtuzumab) alloHCT in CR1, with pre-emptive donor leucocyte infusions for mixed T-cell chimerism or positive MRD, plus 8x3-monthly intrathecal chemotherapy doses to reduce CNS relapse. No specific interventions to reduce relapse were advised for the MAC group.
Results: As of January 2018, 804 pts were enrolled, with 359 receiving alloHCT (242 RIC; 117 MAC; median age 50 (25-65) and 31 years (22-51) respectively). Of these, 325 (90.5%) had high risk disease, 301 (83.8%) were B-lineage, and 159 (44.3%) had high risk cytogenetics including 101 (28.1%) with Ph+ disease. Post-alloHCT relapses occurred in 73 pts (14/117 (11.9%) post-MAC *vs* 59/242 (24.4%) post-RIC; p=0.025). For relapsing pts, median time to relapse was 8.8 months (1.8-70.5) with no significant difference for RIC *vs* MAC. Of these, 52/73 had post-induction MRD data available, with 27/52 (51.9%) MRD+, and no difference in median time to relapse for MRD+ *vs* MRD-/positive outside quantitative range (7.43 *vs* 11.2 months respectively; HR 1.35, p=0.24). Univariable analysis showed MRD+, RIC alloHCT, age 51-65 years and lack of graft *versus* host disease (GvHD) to be associated with an increased relapse risk (Figure 1).

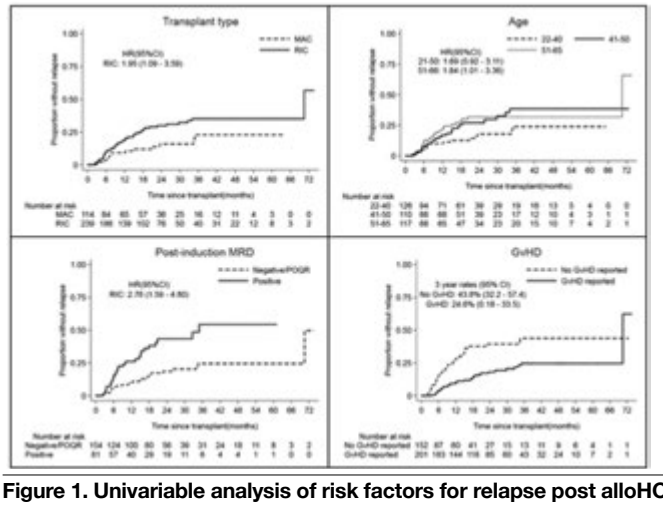

Figure 1. Univariable analysis of risk factors for relapse post alloHCT.

By transplant type, MRD+ (MAC HR 7.09, p=0.012; RIC HR 2.59, p=0.003), and lack of GvHD (MAC HR 0.33, p=0.031; RIC HR 0.45, p=0.0017) remained risk factors in both groups, whilst multivariable analysis showed MRD+ (HR 2.89, p=0.004) and sibling donor (HR 0.41, p=0.019) to independently increase risk for the RIC group. To date, 48/73 relapsed pts have died with a median survival of 6.7 months (median follow-up 5.7 months), and no survival difference between RIC and MAC. Second remission (CR2) was achieved in 22/42, with 5 remaining alive in CR2 with more than 1 year follow-up (event-free survival 5.2 months (1 day-35.2 months)). Factors influencing survival include relapse ≤*vs*.>12 months post-alloHCT (p=0.043), therapy intent (palliative *vs* CR/'cure'; p=0.007), and achievement of CR2 (p<0.001), with possible improved outcomes for those receiving targeted therapies at relapse (p=0.042).
Summary and Conclusions: MRD positivity, RIC alloHCT, age, and lack of GvHD associate with an increased risk of relapse in this series, whilst other standard prognostic factors were not significantly associated with relapse or survival. MRD negativity and unrelated donor type independently associated with a reduced relapse risk in the RIC group, the latter providing evidence for a graft *vs* leukaemia effect that may be manipulated. Novel targeted therapies should be investigated in this setting and may improve survival for pts relapsing post-alloHCT.

PF177

INOTUZUMAB OZOGAMICIN TREATMENT IN PATIENTS WITH RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA: ANALYSIS FROM INO-VATE BY BONE MARROW BLAST PERCENTAGE

D. Marks[1,*], D. DeAngelo[2], M. Stelljes[3], M. Liedtke[4], W. Stock[5], N. Gökbuget[6], S. O'Brien[7], E. Jabbour[8], A. Merchant[9], T. Wang[10], E. Vandendries[11], A. Neuhof[12], A. Advani[13], H. Kantarjian[8]

[1]University Hospitals Bristol, Bristol, United Kingdom, [2]Dana-Farber Cancer Institute, Boston, United States, [3]Universitätsklinikum Münster, Munster, Germany, [4]Stanford Cancer Center, Stanford, [5]University of Chicago, Chicago, United States, [6]Goethe University, Frankfurt, Germany, [7]University of California, Orange, [8]University of Texas MD Anderson Cancer Center, Houston, [9]University of Southern California, Los Angeles, [10]Pfizer, Groton, [11]Pfizer, Cambridge, United States, [12]Pfizer Pharma GmbH, Berlin, Germany, [13]Cleveland Clinic Taussig Cancer Institute, Cleveland, United States

Background: Inotuzumab ozogamicin (InO) is a calicheamicin-conjugated antibody targeting CD22 on acute lymphoblastic leukemia (ALL) blast cells.
Aims: Here we report outcomes in relapsed/refractory (R/R) ALL patients receiving InO or standard of care chemotherapy (SC) in the phase 3 INO-VATE trial according to baseline bone marrow blast percentage (BMB%), an indicator of disease burden.
Methods: Adults with CD22+ ALL due to receive salvage treatment were randomized 1:1 to InO (n=164) or SC (n=162). Dosing and methods were published previously (Kantarjian *et al.*, NEJM 2016). Informed consent was obtained from all patients. BMB% was defined as low (<50%), moderate (50–90%), and high (>90%) at start of treatment.
Results: At baseline, characteristics across all groups were balanced and median BMB% was 28%, 78%, and 95% in the low, moderate, and high disease burden subgroups. Complete remission rates were significantly higher in InO *vs* SC patients, with 74% *vs* 46%, 75% *vs* 48%, and 70% *vs* 17% achieving CR/CRi in low, moderate, and high BMB% subgroups. Significantly, more patients in the InO arm achieved minimal residual disease negativity: 29/53 (55%), 52/79 (66%), and 16/30 (53%) for low, moderate, and high BMB% compared with 10/48 (21%), 11/83 (13%), and 2/30 (7%) for SC, respectively. InO-treated patients also had improved progression-free survival *vs* SC, with hazard ratios of 0.44 (97.5% CI, 0.26–0.74, 1-sided *P*=0.0001) for low, 0.50 (97.5% CI, 0.34–0.75, *P*<0.0001) for moderate, and 0.33 (97.5% CI, 0.16–0.69, *P*=0.0002) for high BMB%. Overall survival (OS) was favoured in the InO arm across groups (Table 1), with potentially the greatest difference seen in patients with high BMB% (HR=0.60 [97.5% CI 0.32–1.129, 1-sided *P*=0.03]).

Table 1.

	OS Probability, Months (95% CI)		
BMB%	**6**	**12**	**24**
Low			
InO (n=53)	56.6 (42.3–68.7)	34.0 (21.7–46.6)	30.0 (18.3–42.5)
SC (n=48)	59.5 (43.7–72.3)	38.8 (24.6–52.8)	2.4 (0.2–11.0)
Moderate			
InO (n=79)	61.7 (50.0–71.4)	35.6 (25.1–46.2)	21.1 (12.8–30.8)
SC (n=83)	51.3 (39.7–61.8)	34.0 (23.7–44.6)	15.0 (8.0–24.0)
High			
InO (n=30)	53.3 (34.3–69.1)	26.7 (12.6–43.0)	13.3 (4.2–27.8)
SC (n=30)	32.6 (16.4–49.8)	12.2 (3.2–27.8)	8.1 (1.4–22.6)

Summary and Conclusions: InO treatment resulted in superior efficacy over SC across all BMB% subgroups out to 2 years follow-up, particularly in patients with the greatest disease burden by BMB%.

PF178

UCART19, AN ALLOGENEIC ANTI-CD19 CAR T-CELL PRODUCT, IN HIGH RISK ADULT PATIENTS WITH CD19+ RELAPSED/REFRACTORY B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA: PRELIMINARY RESULTS OF PHASE I CALM STUDY

N. Jain[1], C. Graham[2,3], M. Konopleva[1], D. Yallop[2], A. Jozwik[3], P. Patten[2,3], R. Ellard[2], O. Stewart[2], K. Cuthill[2], V. Potter[2], S. Kassam[2], S. Devereux[2], A. Pagliuca[2], G. Mufti[2,3], H. Kantarjian[1], E. Jabbour[1], A. Zinai[4], S. Dupouy[4], S. Balandraud[4], C. Poirot[4], A. Philippe[4], F. Simon[4], C. Konto[5], C. Bermingham[5], R. Benjamin[2,3,*]

[1]MD Anderson Cancer Center, Houston, United States, [2]King's College Hospital NHS Foundation Trust, [3]King's College London, London, United Kingdom, [4]Institut de Recherches Internationales Servier, Suresnes, France, [5]Pfizer, San Francisco, United States

Background: UCART19 is a genetically modified CAR T-cell product (anti-CD19 scFv- 41BB- CD3) manufactured from healthy donor T cells, in which *TRAC* and *CD52* genes have been knocked out to allow its administration in non-HLA matched patients (pts) and the use of alemtuzumab as lymphodepleting agent, respectively.
Aims: Preliminary results of the CALM trial, a phase I dose finding study of UCART19 in adult patients with R/R B-ALL are reported.
Methods: Adult CD19+ R/R B-ALL pts (age ≥16 years) with morphological disease or minimal residual disease (MRD) load $\geq 1x10^{-3}$ were eligible. A lymphodepletion regimen (cyclophosphamide 1500mg/m² and fludarabine 90mg/m² with or without alemtuzumab 1mg/kg), was administered prior to UCART19 single dose infusion. The primary objective of this study is to evaluate the safety and tolerability and to determine the maximum tolerated dose of UCART19 by investigating up to four dose levels (DL). Anti-leukemic activity is assessed as a secondary objective.
Results: As of 2 February 2018, 9 pts have been treated in the dose escalation part (6 at DL1 and 3 at DL2 with $6x10^6$ and 6 or $8x10^7$ UCART19 respectively). Median age was 23 years (range 18-49). Pts received a median of 4 prior treatment lines (range 1-5). 7/9 pts had undergone a previous allogeneic stem cell transplant (allo-SCT) and had relapsed at a median of 5.9 months post transplant (range 4-11). Prior to lymphodepletion, 3 pts had low disease burden <5% blasts, 6 pts had disease burden above 5% blasts including 2 pts with very high values (88% and 95%). All pts but one experienced cytokine release syndrome (CRS): 1 G1, 6 G2 and 1 G4 (considered as a DLT). The pt with CRS G4 also developed neutropenic sepsis leading to multiple organ failure and death at D15. Tocilizumab was needed in 5/8 pts. Time to onset ranged from D5 to D12. CRS correlated with serum cytokine increase (IL-6, IL-10 and IFNg) and UCART19 expansion in blood in all pts but one. 1 pt developed G1 skin GvHD. G1 neurotoxicity was observed in 2 pts. Viral reactivations (CMV and/or adenovirus) occured in 4 pts (3 G1, 1 G3). 3/9 pts developed prolonged cytopenia defined as persistent grade 4 beyond D42 post-UCART19 infusion (after allo-SCT, 2 recovered and 1 pt died from pulmonary haemorrhage that occurred in the context of prolonged cytopenia and infection, this was considered as a DLT). 5 out of 9 pts achieved complete remission (CR) with MRD- at D28, 1 achieved CR with MRD+ at D28, 1 relapsed and 1 had refractory disease at D28 (no UCART19 expansion in both pts) and 1 died at D15. Of the 5 pts who achieved MRD negativity, 1 relapsed with CD19+ve disease at D61, received a 2nd dose of UCART19 and became MRD- again. All 5 pts who achieved MRD- proceeded to an allo-SCT with a median time of 66 days (range 51-140) post-UCART19 infusion. The pt that achieved MRD+ relapsed at D47. Post allo-SCT, 3 pts remain alive and 2 early deaths occurred at D17 and D19 secondary toinfection and pulmonary haemorrhage respectively. Out of 3 pts alive, 1 pt remains MRD- and 2 became transiently MRD+ at D52 and D97 respectively but reverted to MRD- status following withdrawal of immunosuppression. Among these 2 pts, 1 remains MRD- and 1 relapsed with CD19+ extramedullary disease at D183.
Summary and Conclusions: UCART19 shows an acceptable safety profile. 6/9 pts achieved complete remission of which 5 became MRD- enabling a second allo-SCT. Recruitment is ongoing at DL2.

PF179

LONG-TERM SURVIVAL OF ADULTS WITH B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA (BCP-ALL) AFTER TREATMENT WITH BLINATUMOMAB AND SUBSEQUENT ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

N. Goekbuget[1,*], A. Stein[2], G. Zugmaier[3], H. Dombret[4], M. Brueggemann[5], M. Bonifacio[6], X. Dong[7], H. Kantarjian[8], R. Bargou[9], M. Topp[10]

[1]Department for Internal Medicine II, Hematology/Oncology, University Hospital Frankfurt, Frankfurt, Germany, [2]City of Hope, Duarte (CA), United States, [3]Amgen Research (Munich) GmbH, Munich, Germany, [4]Hôpital Saint-Louis, University of Paris Diderot, Paris, France, [5]University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany, [6]Department of Medicine, Section of Hematology, University of Verona, Verona, Italy, [7]Global Biostatistical Science, Amgen Inc., Thousand Oaks (CA), United States, [8]Department of Leukemia, MD Anderson Cancer Center, University of Texas, Houston (TX), United States, [9]Comprehensive Cancer Center Mainfranken, Universitaetsklinikum Wuerzburg, Wuerzburg, Germany, [10]Department of Internal Medicine II, Universitaetsklinikum Wuerzburg, Wuerzburg, Germany

Background: In B-cell precursor (BCP) acute lymphoblastic leukemia (ALL), blinatumomab has demonstrated efficacy in two phase 2 trials: MT103-203 (Gökbuget *et al., Blood* 2017) in minimal residual disease (MRD) and MT103-211 in relapsed/refractory (R/R) disease (Topp *et al Lancet Oncology* 2014).
Aims: To describe the long-term outcomes after blinatumomab followed by allogeneic hematopoietic stem cell transplantation (alloHSCT).
Methods: Survival after blinatumomab and alloHSCT in continuous complete remission (CCR) was evaluated from two phase 2 trials, MT103-203 (MRD trial) and MT103-211 (R/R trial). In the MRD trial, 116 patients were treated with blinatumomab between November 2010 and February 2014. In the R/R trial, 189 patients were treated with blinatumomab between January 2012 and October 2013. For both trials, patients were followed up through 2017.
Results: Patient characteristics and outcomes are summarized in Table 1. Among blinatumomab patients in CCR, most patients who received alloHSCT in the MRD trial were >35 years of age whereas those in the R/R trial were younger (≤35 years). After a follow-up of at least 3 years, survival of blinatumomab patients with or without alloHSCT in the MRD trial according to age ≤35 years or >35 years was as follows: among patients ≤35 years, 16/26 (62%) patients with alloHSCT were alive *versus* 2/9 (22%) non-alloHSCT patients; among patients >35 yrs, 19/48 (40%) patients with alloHSCT were alive compared with 13/27 (48%) non-alloHSCT patients. Median overall survival (OS) from time of alloHSCT was not reached in patients ≤35 years in either trial (Table 1).

Table 1. Patients with allogeneic hematopoietic stem cell transplantation (HSCT) in continuous complete remission (CRR).

Outcomes		
Median OS from alloHSCT, months		
Age ≤35 years	NE	NE
Age >35 years	25.7	15.9
Median RFS from alloHSCT, months		
Age ≤35 years	NE	16.4
Age >35 years	15.5	15.9

AlloHSCT: allogeneic hematopoietic stem cell transplantation; NE: not estimable; OS: overall survival; RFS: relapse-free survival.
[a]74 patients received on-study HSCT in CR; Ph+ and patients not in CR at treatment
[b]1 haploidentical start excluded
[c]No venous occlusive disease related deaths

Summary and Conclusions: These results suggest that in transplant-eligible patients in CCR, alloHSCT following blinatumomab is a potential option.

PF180

RE-THINKING THE PROGNOSTIC RELEVANCE OF A CD20 EXPRESSION CUT-OFF OF 20% IN ACUTE LYMPHOBLASTIC LEUKAEMIA: INITIAL RESULTS FROM THE UKALL14 TRIAL

K. Bailey[1,*], B. Beaton[1], A. A. Kirkwood[2], M. Aguiar[1], K. Alapi[1], L. Clifton-Hadley[2], P. Patrick[2], E. Lawrie[2], A. Douglas[2], D.I. Marks[3], A. McMillan[4], C.J. Rowntree[5], T. Menne[6], B. Wrench[7], A.V. Moorman[8], A.K. Fielding[1]

[1]Cancer Institute, University College London, [2]CRUK and UCL Cancer Trials Centre, London, [3]Bristol Haematology and Oncology Centre, United Bristol Healthcare Trust, Bristol, [4]Centre for Clinical Haematology, Nottingham City Hospital, Nottingham, [5]Cardiff and Vale UHB, Cardiff, [6]Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne, [7]Barts Cancer Institute, Queen Mary University of London, London, [8]Northern Institute for Cancer Research, Newcastle Upon Tyne, United Kingdom

Background: The prognostic significance of CD20 expression in B-precursor acute lymphoblastic leukaemia (B-ALL) remains unclear. 'CD20 positivity' has traditionally been taken as 20% of blasts expressing the CD20 antigen. The significance of antigen density is unknown.
Aims: We examined the prognostic significance of CD20 in patients with B-ALL who had been enrolled into the rituximab randomisation of the UKALL14 (ISRCTN 66541317), irrespective of CD20 status. We determined whether measuring CD20 antigen density could improve risk stratification.
Methods: An 8-colour flow panel was employed on BD Fortessa™ cytometers with blasts gated on CD45, CD34, CD19 and CD10. Data was analysed using Flowjo® software. CD20 positivity was determined by comparison to fluorescence minus one and isotype control. CD20 antigen density was estimated by standard curves of geometric mean fluorescence intensity using BD QuantiBRITE™ beads.
Results: Of 655 patients enrolled, 145 had excess cells stored with suitable viability for flow analysis. Compared to those without samples, the patients analysed had a higher median white cell count at presentation (30.3 x10^9/l *vs* 5.9 x10^9/l, P=<0.001) and were more likely to be Philadelphia chromosome (Ph) positive (39.9% *vs* 28.3%, P=0.009). The median follow-up was 32.3 months. Seventy-three (49.6%) had CD20 expression ≥20% and 95 (65.5%) ≥10%. The percentage of CD20 positive blasts was significantly associated with inferior 3 year EFS [HR (1 log increase) 1.31(1.09 - 1.56) p=0.003] and OS [HR 1.29 (1.06 – 1.58) p=0.01] when analysed as a continuous variable. When data was analysed at 3 different CD20 percentage cut-offs of <10%, 10-19%, and ≥20%, 3 year EFS was 51.0%, 37.7%, 28.7% (p=0.014) and OS 65.1%, 35.6%, and 36.3% (p=0.012), as shown in the Kaplan Meier plots. When the data were analysed by CD20 antigen density in tertiles, the EFS and OS were similar and both remained statistically significant when adjusted for age, baseline WCC and adverse cytogenetics in a multivariable model. Percentage blasts was compared with antigen density to determine the optimal sensitivity and specificity of CD20 as a marker of outcome by logistic regression and receiver operator characteristic (ROC). The area under the curve was 0.6305 (0.52 – 0.74) for% blast method and 0.6829 (0.58-0.79) for the antigen density method. Youden's cut-off, a method which can be used to determine the best cut-off for a continuous variable, suggested a CD20% of 11.7% as optimal. Using our existing risk stratification, we calculated that the addition of CD20 >11.7% as an additional factor at baseline would include 6% more patients at high risk, increasing modestly to 7% if antigen density were included instead. In an analysis by Ph+ status, we showed impact of CD20 on survival to be confined to patients who were Ph-; there was no separation of outcome by CD20 expression in Ph+ ALL whilst the significant separation by CD20 status for patients with Ph- ALL remained by all methods of analysis (Figure 1).

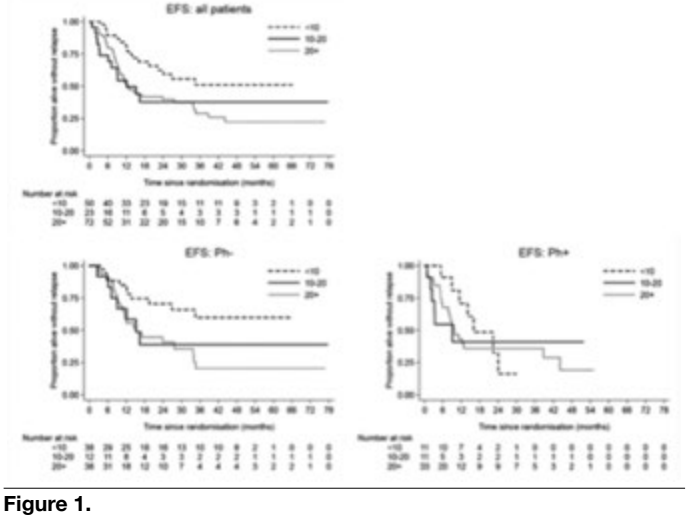

Figure 1.

Summary and Conclusions: Higher CD20 expression in Ph- (but not Ph+) adult B-ALL is associated with inferior EFS and OS. The higher risk extends to patients whose blasts express CD20 at or above 10%. Although measuring antigen density improved sensitivity and specificity over blast percentage alone, this difference was marginal, suggesting that blast percentage remains a reasonable way to assess CD20 status. Patients in this trial were randomised to receive rituximab and we anticipate presenting the un-blinded outcome results later in 2018.

PF181

IMPROVEMENT OF PATIENT-REPORTED QUALITY OF LIFE FOLLOWING TISAGENLECLEUCEL INFUSION IN PEDIATRIC AND YOUNG ADULT PATIENTS WITH RELAPSED/REFRACTORY B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

Background: The global trial ELIANA (NCT02435849) evaluated the efficacy and safety of tisagenlecleucel, an autologous T-cell chimeric antigen receptor therapy targeting CD19+ cells, in pediatric and young adult patients with relapsed or refractory (R/R) B-cell acute lymphoblastic leukemia (B-ALL). As of the data cutoff (25 April 2017), an overall remission rate (complete remission [CR] with or without complete blood count recovery [CRi]) of 81% at ≤3 months was observed. Increasingly, patient quality of life (QOL) has become an important component in evaluating new oncology therapies.
Aims: To evaluate patient-reported QOL before and after infusion with tisagenlecleucel.
Methods: Infused patients were 3-23 years old with CD19+ B-ALL and were chemorefractory, relapsed after allogeneic stem cell transplant (SCT), or otherwise ineligible for SCT. Patients ≥8 years old completed the Pediatric Quality of Life Inventory (PedsQL) and the EuroQOL (EQ-5D/EQ-5D-Y) at baseline, day 28, and months 3, 6, 9 and 12 to evaluate QOL. Both instruments are validated measures of QOL and were summarized with descriptive statistics at the cross-sectional level and through changes from baseline. The minimal clinically important differences for the PedsQL and the EuroQOL visual analog scale (EQ-VAS) are 4.4 and 7-10, respectively. The normative mean values for healthy children are 83 and 86.2 for the PedsQL and EQ-VAS, respectively. Here we report changes in QOL in patients with a best overall response of CR/CRi.
Results: At the data cutoff, 75 of 92 enrolled patients had been infused; the median number of previous lines of therapy was 3 (range, 1 to 8). Of the infused patients, 58 patients (77%) who were ≥8 years old completed QOL instruments; 48 (83%) of whom were responders (CR/CRi). Mean baseline scores for responding patients were 58 and 68 for the PedsQL and EQ-

VAS, respectively (Figure 1A-B). Mean baseline scores for nonresponding patients (N=10) were 60 and 63 for the PedsQL and EQ-VAS scales, respectively. Both assessments demonstrated clinically meaningful improvements in the QOL of responders as observed by the mean change from baseline at day 28 (PedsQL, 6; EQ-VAS, 11), month 3 (PedsQL, 13.5; EQ-VAS, 16.5), month 6 (PedsQL, 17; EQ-VAS, 16), month 9 (PedsQL, 18; EQ-VAS, 19) and month 12 (PedsQL, 27; EQ-VAS, 25) (Figure 1A-B). 3- and 6-month assessments were completed by ≤3 nonresponders. The percentage of patients who achieved the normative mean or greater (PedsQL, ≥83; EQ-VAS, ≥86.3) increased from 12% at baseline to 64% by month 12 for the PedsQL total score (Figure 1C) and 18% at baseline to 64% by month 12 for the EQ-VAS total score (Figure 1D). Sustained improvements in patient QOL were observed for each PedsQL subscale. Notable decreases in the proportion of problems reported by responding patients in each of the EQ-5D dimensions were observed at each time point.

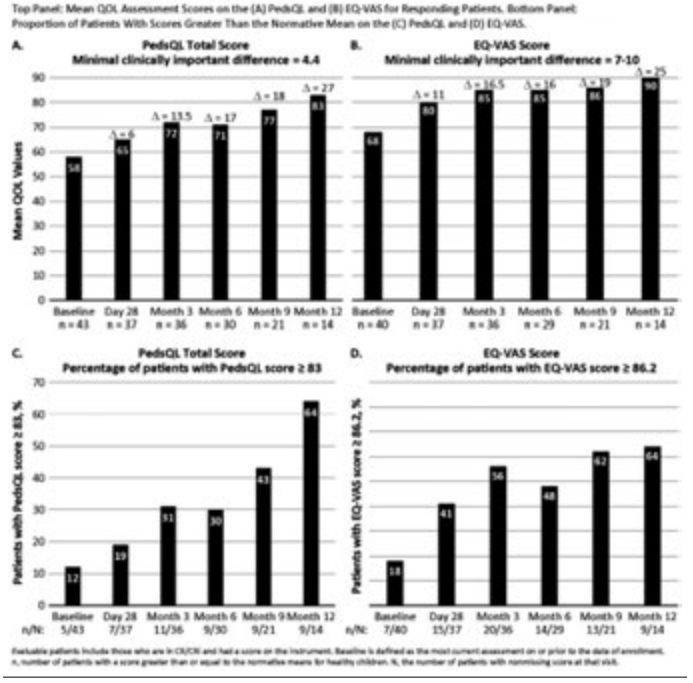

Figure 1.

Summary and Conclusions: Improvements in QOL observed at day 28 and months 3 and 6 were sustained at months 9 and 12. For pediatric and young adult patients with R/R B-ALL who achieved CR or CRi, clinically meaningful, even dramatic, improvements in QOL were observed after tisagenlecleucel infusion.

PF182

OUTCOMES WITH INOTUZUMAB OZOGAMICIN IN PATIENTS WITH PHILADELPHIA CHROMOSOME–POSITIVE RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA

G. Martinelli[1,2,*], W. Stock[3], M. Stelljes[4], D. DeAngelo[5], N. Gökbuget[6], A. Advani[7], S. O'Brien[8], M. Liedtke[9], A. Merchant[10], R. Cassaday[11], T. Wang[12], E. Vandendries[13], D. Marks[14], H. Kantarjian[15]

[1]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola (FC), [2]Institute Seragnoli, University of Bologna, Bologna, Italy, [3]University of Chicago, Chicago, [4]Universitätsklinikum Münster, Munster, [5]Dana-Farber Cancer Institute, Boston, United States, [6]Goethe University, Frankfurt, Germany, [7]Cleveland Clinic, Cleveland, [8]University of California, Orange, [9]Stanford Cancer Institute, Stanford, [10]University of Southern California, Los Angeles, [11]University of Washington School of Medicine and Fred Hutchinson Cancer Research Center, Seattle, [12]Pfizer, Groton, [13]Pfizer, Cambridge, United States, [14]University Hospitals Bristol, Bristol, United Kingdom, [15]MD Anderson Cancer Center, Houston, United States

Background: Inotuzumab ozogamicin (InO), a CD22-directed antibody-drug conjugate, is approved to treat adults with refractory/relapsed (R/R) acute lymphoblastic leukemia (ALL). Historically, patients with Philadelphia chromosome-positive (Ph+) ALL (~20–30%) have had poor prognoses compared with Ph– patients.
Aims: Here we report outcomes in Ph+ R/R ALL patients who received InO or standard of care chemotherapy (SC) as salvage therapy in two clinical studies.
Methods: Patients with R/R ALL received inotuzumab ozogamicin (InO) in a phase 1 dose-finding/phase 2 study (1010; DeAngelo *et al.*, Blood Adv 2017) and a phase 3 trial (1022; Kantarjian *et al.*, NEJM 2016) comparing InO *vs* SC. Informed consent was obtained from all patients. We analyzed outcomes in Ph+ patients (Ph chromosome or BCR-ABL gene by FISH) treated with InO (InO-1010 or InO-1022) or SC based on final data from each study.
Results: In 1010 and 1022, respectively, 16 and 22 Ph+ patients received InO; 27 Ph+ patients were randomized to SC in 1022 (22 received SC). Patients in 1010 were heavily pretreated. Among Ph+ patients in 1022, 19 (86%) InO patients and 26 (96%) SC patients had previous tyrosine kinase inhibitors (TKIs). Prior stem cell transplants (SCT) were 8 (50%) for InO-1010, 7 (32%) for InO-1022, and 9 (33%) for SC. Also, 15 (94%), 10 (45%), and 15 (56%) patients were treated in ≥2nd salvage for InO-1010, InO-1022, and SC, respectively. Efficacy outcomes are shown (Table 1). A total of 3 (19%) InO-1010 patients, 9 (41%) InO-1022 patients, and 5 (19%) SC patients proceeded to SCT after treatment. The most common nonhematologic grade 3-4 adverse events with InO in Ph+ patients were gastrointestinal disorders (31%) in 1010 and multi-organ laboratory abnormalities (41%) in 1022; 2 Ph+ patients in each InO study had veno-occlusive liver disease. Among SC patients, infections (55%) were the most common grade 3-4 nonhematologic events.

Table 1.

Efficacy Endpoints	InO-1010 (n=16)	InO-1022 (n=22)	SC (1022) (n=27)
Complete remission (CR/CRi), n (%)	9 (56)	16 (73)	15 (56)
Minimal residual disease (MRD) negativity, n (%)	10 (63)	14 (64)	5 (19)
Overall survival (mos), median (95% CI)	7.4 (4.3–11.3)	8.7 (3.6–14.1)	8.4 (5.0–14.3)
Progression-free survival (mos), median (95% CI)	4.4 (1.8–5.9)	3.9 (2.1–9.2)	3.1 (1.1–6.2)

Summary and Conclusions: In Ph+ patients with R/R ALL who failed prior TKIs +/- SCT, InO-treated patients had higher rates of CR/CRi, MRD negativity, and subsequent SCT. However, overall outcomes in 1022 InO *vs* SC were still inferior to those reported in Ph– patients; thus additional treatment combinations should be explored.

PF183

IMPACT OF MINIMAL RESIDUAL DISEASE STATUS IN CLINICAL OUTCOMES OF PATIENTS WITH RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH INOTUZUMAB OZOGAMICIN IN THE PHASE 3 INO-VATE TRIAL

N. Gökbuget[1,*], E. Jabbour[2], A. Advani[3], M. Stelljes[4], W. Stock[5], M. Liedtke[6], G. Martinelli[7,8], S. O'Brien[9], T. Wang[10], A.D. Laird[11], E. Vandendries[12], A. Neuhof[13], D. DeAngelo[14], H. Kantarjian[2]

[1]Goethe University, Frankfurt, Germany, [2]University of Texas MD Anderson Cancer Center, Houston, [3]Cleveland Clinic, Cleveland, [4]Universitätsklinikum Münster, Munster, [5]University of Chicago, Chicago, [6]Stanford Cancer Institute, Stanford, United States, [7]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola (FC), [8]Institute Seragnoli, University of Bologna, Bologna, Italy, [9]University of California, Orange, [10]Pfizer, Groton, [11]Pfizer, San Diego, [12]Pfizer, Cambridge, United States, [13]Pfizer Pharma GmbH, Berlin, Germany, [14]Dana-Farber Cancer Institute, Boston, United States

Background: Minimal residual disease (MRD) negativity is a key prognostic indicator of patient outcome in acute lymphoblastic leukemia (ALL) and is predictive of improved survival and disease-free status. In the INO-VATE ALL trial (Kantarjian, NEJM 2016), patients with relapsed refractory (R/R) ALL who received inotuzumab ozogamicin (InO) *vs* standard chemotherapy (SC) achieved greater remission (CR/CRi; 81% *vs* 29%) and MRD-negativity (78% *vs* 28%, in patients with CR/CRi) and had longer overall survival (OS): 7.7 *vs* 6.7 months, HR=0.77 (97.5% CI, 0.58–1.03, P=0.04).
Aims: This analysis was conducted to assess the prognostic value of MRD negativity by end of treatment in R/R ALL patients receiving InO as salvage therapy in the INO-VATE trial.
Methods: INO-VATE patients who received InO (n=164) were included. Informed consent was obtained from all patients. Among patients with CR/CRi, MRD status (by multiparametric flow cytometry at a central lab) was defined as negative (MRD–) if $<1 \times 10^{-4}$ blasts/nucleated cells (n=81), or as positive (MRD+; n=83), based on assessment by end of treatment. OS, progression-free survival (PFS), and predictors of MRD status (by

multivariate logistic regression) are reported from final study data as of Jan 4, 2017.
Results: MRD– status with CR/CRi was associated with significantly improved OS and PFS (Table 1) *vs* MRD+ status with CR/CRi: unstratified HR 0.512; 1-sided P=0.0009 for OS and HR 0.423; P<0.0001 for PFS. Exploratory multivariate analyses indicated that 2nd salvage compared to 1st salvage (OR 0.499, 2-sided P=0.058) was associated with lower likelihood of having MRD– status, while <1x109/L absolute circulating blast count at baseline (OR 3.231, P=0.002) and longer duration of remission (OR 1.033, P=0.005) were associated with increased likelihood of having MRD– status.

Table 1.

	CR/CRi and MRD– (n=76)	CR/CRi and MRD+* (n=45)	No CR/CRi (n=43)
Median OS, mos [95% CI]	14.1 [8.6–23.0]	7.2 [5.8–10.8]	2.6 [1.9–3.6]
Median PFS, mos [95% CI]	8.6 [6.2–11.4]	5.4 [3.9–6.2]	1.4 [1.0–1.9]
*includes 6 patients with no MRD assessment			

Summary and Conclusions: Among patients who received InO in the INO-VATE trial, having CR/CRi and MRD– status at end of treatment was associated with the greatest survival outcomes. However, patients who achieved an MRD+ CR/CRi had much greater survival than those who did not have CR/CRi. In R/R ALL, use of InO may optimize chances to attain the primary goal of complete remission and MRD– status.

PF184

EXTENSIVE SAFETY PROFILE OF INOTUZUMAB OZOGAMICIN IN RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS ENROLLED IN THE PHASE 3 INO-VATE TRIAL

D. DeAngelo[1,*], R. Cassaday[2], G. Martinelli[3,4], W. Stock[5], M. Stelljes[6], N. Gökbuget[7], A. Advani[8], S. O'Brien[9], M. Liedtke[10], A. Merchant[11], T. Wang[12], E. Vandendries[13], D. Marks[14], E. Jabbour[15], H. Kantarjian[15]

[1]Dana-Farber Cancer Institute, Boston, [2]University of Washington School of Medicine and Fred Hutchinson Cancer Research Center, Seattle, United States, [3]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola (FC), [4]University of Bologna, Bologna, Italy, [5]University of Chicago, Chicago, United States, [6]Universitätsklinikum Münster, Munster, [7]Goethe University, Frankfurt, Germany, [8]Cleveland Clinic Taussig Cancer Institute, Cleveland, [9]University of California, Orange, [10]Stanford Cancer Center, Stanford, [11]University of Southern California, Los Angeles, [12]Pfizer, Groton, [13]Pfizer, Cambridge, United States, [14]University Hospitals Bristol, Bristol, United Kingdom, [15]University of Texas MD Anderson Cancer Center, Houston, United States

Background: In INO-VATE, patients treated with inotuzumab ozogamicin (InO) *vs* standard chemotherapy (SC) had significantly greater remission rates and longer overall survival (OS), with 23% reduced risk of death (Kantarjian *et al.*, NEJM 2016).
Aims: Here we report long-term, extensive safety outcomes in relapsed or refractory acute lymphoblastic leukemia (ALL) patients receiving InO as salvage therapy in the INO-VATE trial.
Methods: Study methods were previously published. Adults with CD22+ acute lymphoblastic leukemia (ALL) in 1st or 2nd salvage were randomized 1:1 to InO (n=164) or SC (n=162). Informed consent was obtained from all patients. Data up to Jan 4, 2017 are reported.
Results: Patients who received InO had a median of 3 treatment cycles (range 1–6), while those on SC had a median of 1 cycle (range 1–4). Adverse event (AE) and serious AE rates were similar between arms even though more cycles of InO than SC were administered (Table 1). Grade 3-4 AE rates were higher with SC, while more grade 5 AEs occurred with InO *vs* SC (6% *vs* 2%); 5 cases (3%) were veno-occlusive disease (VOD). More patients taking InO discontinued due to AEs, most often from infections (10 [6%]) including pneumonia and sepsis, hepatobiliary disorders (7 [4%]), or blood/lymphatic disorders including cytopenias (5 [3%]). For SC, discontinuations were most often from infections (6 [4%]) or blood/lymphatic disorders (3 [2%]). More hepatic AEs (any grade) occurred with InO: 83 (51%) *vs* 52 (36%), including VOD (23 [14%] *vs* 3 [2%]). Five cases of VOD with Ino occurred during therapy, while all other cases for Ino and SC groups occurred following post-study stem cell transplantation. A lower percentage of death was seen with InO: 131 (80%) *vs* 126 (88%) for SC. Fewer InO patients died from ALL: 80 (49%) *vs* 100 (70%) for SC.
Summary and Conclusions: Safety data from the final report of INO-VATE are consistent with previous reports of data that also include greater efficacy (longer survival) seen with InO *vs* SC. Temporary discontinuation and dose reduction of InO were used to manage serious or severe AEs. Data suggest vigilant monitoring, treatment, and/or prevention for the most common events such as VOD and infections are needed to optimize outcomes.

Table 1.

	Treatment-emergent AEs (TEAEs)		Treatment-related TEAEs	
	InO (n=164)	SC (n=143)	InO (n=164)	SC (n=143)
Total AEs	2023	2112	764	980
Patients with AEs, n (%)	163 (99)	143 (100)	144 (88)	130 (91)
Serious AEs	85 (52)	72 (50)	52 (32)	42 (29)
Grade 3-4 AEs	147 (90)	138 (97)	114 (70)	114 (80)
Grade 5 AEs	26 (16)	16 (11)	9 (6)	3 (2)
Post AE, n (%):				
Discontinued	31 (19)	11 (8)	15 (9)	6 (4)
Dose reduced	5 (3)	3 (2)	4 (2)	1 (1)
Temporary discontinuation	72 (44)	17 (12)	51 (31)	12 (8)

PF185

BLINATUMOMAB AND TYROSINE KINASE INHIBITORS COMBINATION IN RELAPSED/REFRACTORY ACUTE LYMPHOBALTIC LEUKEMIA: PRIMARY RESULTS AND LATE EVENTS

A. Sokolov[1,*], E. Parovichnikova[1], V. Troitskaya[1], L. Kuzmina[1], I. Galtseva[1], S. Kulikov[1], S. Bondarenko[2], I. Lukyanova[1], T. Lobanova[1], E. Usikova[1], K. Zarubina[1], O. Gavrilina[1], J. Davidova[1], N. Kapranov[1], V. Savchenko[1]

[1]National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, [2]R. Gorbacheva memorial Institute of Oncology, Hematology and Transplantation, Saint-Petersburg, Russian Federation

Background: Bispecific monoclonal antibody blinatumomab has antileukemic activity in CD19+ relapsed/refractory both Ph-positive and Ph-negative acute lymphoblastic leukemia (R/R ALL). We established combined treatment approach with blinatumomab and tyrosine kinase inhibitors (TKI) in some targeted ALL subsets – BCR-ABL-positive, IKZF1-deleted and FLT3-ITD mutated.
Aims: To assess clinical efficacy, toxicity and long term results.
Methods: 11 patients (pts) with R/R ALL from October 2015 to February 2018 were treated with blinatumomab+TKI, 3 male and 8 female. Median age was 32 years. 8 pts had BCR-ABL-positive R/R ALL (P190), 2 pts – IKZF1-deleted R/R ALL, 1 pt – FLT3-ITD-positive R/R ALL. 2 pts with BCR-ABL-positive ALL had ABL mutation T315I. The treatment consisted of 4-5 cycles of Blinatumomab 28 mcg/day continuous infusion 28 days each cycle with 2 week intervals between cycles. All pts were treated with one of TKI from 1 day of treatment continuously. 9 pts with BCR-ABL-positive ALL and IKZF1-deleted ALL received dasatinib 140 mg/day, 1 pt with T315I mutated ABL received ponatinib 45 mg/day, 1 pt with FLT3-ITD received sorafenib 800 mg/day. 2 pts with IKZF1 deletions received ATRA 45 mg/m^2 60 days from 1 day of treatment and then 2-week cycles with 4 week intervals. Peripheral blood flow cytometry was performed weekly in each cycle of blinatumomab.
Results: Median follow up is 19 months (14-31). Neurological toxicity of 1 – 2 grade observed in 2 pts (headaches in 1 pt and ulnar neuropathy in 1 pt). Hypogammaglobulinemia was common and 8 pts received intravevous human normal immunoglobulin replacement. Hand-foot syndrome observed in 1 pt on sorafenib. The syndrome completely resolved after temporary sorafenib interruption. Diarrhea on dasatinib was observed in 3 pts. Diarrhea resolved after dasatinib replacement with bosutinib in 2 pt and nilotinib in 1 pt. CMV colitis was diagnosed in 2 pts. 1 of them has multiple intestinal ulceration with massive intestinal bleeding. Face edema and hyperemia in 1 pt on dasatinib resolved after switch to nilotinib. T-cytotoxic, NK, T -helper and T-regulatory cells were decreased during 1st blinatumomab cycle. From 2nd to 4th cycles T-cytotoxic and NK returned into normal range while T-helper and T-regulatory remained slightly decreased. 10 pts achieved complete remission (CR) and 1 pt had progressive disease after 1st blinatumomab cycle. 9 pts achieved molecular remission (MolCR) and 1 – cytogenetic remission (CyCR) on subsequent blinatumomab cycles. AlloBMT was performed in 9 pts and AutoBMT – in1 pt in MolCR. 7 pts received TKI/TKI+ATRA maintenance. 4 curable relapses observed. 1 pt on bosutinib awaiting Allo-BMT has overt hematological relapse and MolR was achieved on bortezomib-based chemotherapy+dasatinib. 1 pt with CytCR on dasatinib had cytogenetic relapse before AlloBMT. 1 pt on dasatinib after AutoBMT had molecular relapse and blinatumomab retreatment+dasatinib+ATRA was started. 1 pt on ponatinib maintenance had CNS relapse and CNS lesion regressed after intrathecal chemotherapy+ponatinib treatment and cranial irradiation is performing.
Summary and Conclusions: The combination of blinatumomab with TKI/TKI+ATRA has high MolCR rate and low toxicity profile in R/R ALL.

High incidence of relapse suggests that maintenance/preemptive treatment strategy should be revised.

PF186

CHIMERIC ANTIGEN RECEPTOR T-CELL THERAPY IN PEDIATRIC/ADOLESCENT/YOUNG ADULT PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA IN FIRST RELAPSE AFTER ALLOGENEIC STEM CELL TRANSPLANT IN CR1

P. Bader[1,*], S.A. Grupp[2,3], P.L. Martin[4], M.W. Boyer[5], K. Schlis[6], L.K. Eldjerou[7], E. Bleickardt[7], L. Yi[7], S. Davies[8]

[1]Division for Stem Cell Transplantation and Immunology, Hospital for Children and Adolescents, University Hospital Frankfurt, Frankfurt, Germany, [2]Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, [3]Division of Oncology, Center for Childhood Cancer Research and Cancer Immunotherapy Program, Children's Hospital of Philadelphia, Philadelphia, [4]Division of Pediatric Blood and Marrow Transplant, Duke University Medical Center, Durham, [5]Department of Pediatrics and Internal Medicine, University of Utah, Salt Lake City, [6]Department of Pediatrics, Stanford University School of Medicine, Stanford, [7]Novartis Pharmaceuticals Corporation, East Hanover, [8]Cincinnati Children's Hospital Medical Center, Cincinnati, United States

Background: Patients with B-cell acute lymphoblastic leukemia (ALL) who relapse after first allogeneic stem cell transplant (alloSCT) have a poor prognosis; a recent study using the CIBMTR database reported a median survival of 7.4 months (95% CI, 6.0-9.6 months) (Crotta, 2017). ELIANA and ENSIGN trials of the chimeric antigen receptor (CAR) T-cell therapy tisagenlecleucel in pediatric and adolescent/young adult (AYA) patients with relapsed/refractory (R/R) ALL included patients who relapsed after alloSCT (54%). Most relapsed patients were in ≥2nd relapse. Here we evaluate the outcomes of patients who received tisagenlecleucel following their first relapse after alloSCT performed in first complete remission (CR1).
Aims: The goal of this study was to examine efficacy and safety outcomes in this subset of patients who received tisagenlecleucel for first relapse following alloSCT in CR1.
Methods: Pooled data from 2 single-arm, multicenter, phase 2 trials (ELIANA, N=75 [NCT02435849] and ENSIGN, N=58 [NCT02228096]) evaluated the efficacy and safety of tisagenlecleucel in pediatric and AYA patients with R/R ALL. Five patients received alloSCT as part of their initial therapy in CR1. After relapsing after alloSCT, they received tisagenlecleucel and were thus considered to be in their first relapse.

Table 1.

Characteristics of Patients Treated With Tisagenlecleucel in First Relapse Following AlloSCT in CR1

	Patient 1	Patient 2	Patient 3[a]	Patient 4	Patient 5
Age, years	7	10	9	4	18
Donor type	MUD	MSD	MSD	MSD	MSD
Time from transplant to relapse, months	4.5	12.4	18.6	17.5	5.8
Time from relapse to infusion, months	4.4	1.5	2.0	1.3	3.1
Best overall response	CR	CR	CR	CR	UNK[b]
MRD status	Negative	Negative	Negative	Negative	Negative
Overall survival, months	10.8+	18.8+	15.1+	33.3+	1.8+
Maximum grade CRS	-	Grade 3	-	-	-
Neurotoxicity	-	-	-	-	-

[a] Patient had Philadelphia chromosome–positive ALL.
[b] Bone marrow remission was observed, but cerebral spinal fluid assessment was not done.
AE, adverse event; CR, complete remission; CRS, cytokine release syndrome; MRD, minimal residual disease; MSD, matched sibling donor; MUD, matched unrelated donor; UNK, unknown.

Results: All 5 patients who received tisagenlecleucel in first relapse underwent chemotherapy after initial diagnosis followed by alloSCT in CR1; 1 patient received a transplant from a matched unrelated donor while the other 4 received transplants from matched siblings. Patients relapsed 4.5, 5.8, 12.4, 17.5 and 18.6 months following alloSCT with myeloablative conditioning. Blast counts at enrollment were 7%, 29%, 34%, 73%, and 79%; in the pooled ELIANA/ENSIGN cohort (N=133), bone marrow blasts ranged from 5% to 99%. Four patients were male-aged 4, 7, 9 and 10 years at enrollment. One patient was female-aged 18 years at enrollment. Infusion with tisagenlecleucel took place 1.3, 1.5, 2.0, 3.1, and 4.4 months after relapse, a range comparable to that in the ELIANA/ENSIGN cohort (1-14 months). Four of 5 patients achieved minimal residual disease (MRD)-negative CRs (overall remission rate, 80%). One patient had unknown overall response because cerebral spinal fluid assessment was not done, although MRD-negative bone marrow remission was observed. Durations of remission in patients who achieved CR starting from onset of remission were 3.2+ months (proceeded to SCT while in remission), 7.5+ months (non-SCT new therapy while in remission), 14.2+ months (ongoing remission), and 29.6+ months (non-SCT new therapy for secondary malignancy). All patients are still alive. Overall survival is 1.8+, 10.8+, 15.1+, 18.8+, and 33.3+ months after infusion. Only 1 patient experienced CRS (grade 3), and no patients experienced neurological toxicity. In the pooled cohort, 79% of patients experienced CRS (41% grade 3 or 4), and 37% experienced neurological events of any grade (Table 1).
Summary and Conclusions: Patients with ALL who received tisagenlecleucel for their first relapse following alloSCT tolerated the therapy well without increased toxicities and achieved MRD-negative and durable remissions.

PF187

INDIRECT TREATMENT COMPARISON OF BLINATUMOMAB *VS* INOTUZUMAB OZOGAMICIN FOR TREATING ADULT PATIENTS WITH RELAPSED OR REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA RECEIVING ZERO OR ONE PRIOR SALVAGE THERAPY

J. Song[1], Q. Ma[2], W. Gao[3], Z. Cong[2,*], J. Xie[1], Z. Zimmerman[2], L. Belton[4], J. Franklin[2], S. Palmer[5]

[1]Analysis Group, Inc., Los Angeles, [2]Amgen Inc., Thousand Oaks, [3]Analysis Group, Inc., Boston, United States, [4]Amgen Inc., Uxbridge, [5]University of York, York, United Kingdom

Background: Blinatumomab (BLIN) and inotuzumab ozogamicin (INO) have demonstrated improved outcomes against standard of care (SOC) among adult patients with relapsed or refractory acute lymphoblastic leukemia (R/R ALL) in phase 3 clinical trials. In the absence of head-to-head studies, indirect comparisons provide valuable information to guide the appropriate use of alternative therapies.
Aims: This study aimed to indirectly compare the efficacy of BLIN *versus* INO among adult patients with R/R ALL.
Methods: Matching-adjusted indirect comparisons were conducted using patient-level data from the BLIN trial (TOWER) and published aggregated data from the INO trial (INO-VATE). Patients with 2+ prior salvage therapies from TOWER were excluded since these patients were not included in INO-VATE. To ensure balance in the remaining patients, TOWER population was reweighted to match the average baseline characteristics in INO-VATE, including sex, age, race, performance status, bone marrow blast, previous salvage therapy, previous allogeneic transplantation, complete remission with complete hematologic recovery (CR) to most recent induction therapy, and duration of first remission. The endpoints were overall survival (OS) and CR. Relative restricted mean survival time (RMST) at 12 months was also estimated.
Results: After excluding patients with 2+ prior salvage therapies, 310 patients in TOWER were included (BLIN: 203; SOC: 107). After reweighting, all baseline characteristics listed above were balanced between the two trials. The median OS was 9.3 months for BLIN and 7.7 months for INO (weighted log-rank test p=Not Significant [NS]). The RMST at 12 months was 1.6 months longer for BLIN than for INO (95% CI=[0.1, 3.2], p =0.042). The CR rates were similar ([BLIN-SOC in TOWER]-[INO-SOC in INO-VATE]=-2.8%, 95% CI=[-17.5%, 11.9%], p=NS).
Summary and Conclusions: After adjusting for heterogeneities in patient characteristics, BLIN demonstrated a potential survival benefit *versus* INO among adult patients with R/R ALL receiving zero or one prior salvage therapy. Our findings indicate potentially important differences in efficacy which help to inform treatment choices. Additional head-to-head studies would help to confirm our findings.

PF188

LONG TERM OUTCOME OF 138 ALO TRANSPLANTS IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA ON A SINGLE TRANSPLANT CENTER IN SPAIN

I. Ormazabal Velez[1,*], A. Figuera[1], B. González Ferrer[2], J. Cornago Navascués[1], B. Aguado Bueno[1], E. Sola[1], R. de la Cámara Llanza[1], A. García-Noblejas Moya[1], A. Alegre Amor[1], N. González Ruiz[2]

[1]Hematología y Hemoterapia, Hospital Universitario La Princesa, [2]Universidad Autónoma de Madrid, Universidad Autónoma de Madrid, Madrid, Spain

Background: Leukemia relapse remains the main cause of failure for long term survival in adult ALL, despite high rates of first complete remission (CR1) after induction and consolidation with risk adapted modern chemotherapy schemes. Further consolidation with allogeneic hematopoietic stem cell transplantation (HSCT) offers the best chance of cure for high-risk and relapsed patients. Long term follow of large patient cohorts should be evaluated for better definition of HSCT indication and timing.
Aims: The primary endpoint was disease-free survival (DFS) and overall survival (OS). Secondary endpoints refined acute graft *vs* host disease (aGvHD) and chronic GvHD (cGvHD) incidence, relapse incidence (RI), and non-relapse mortality (NRM). We also described separately the 2nd HSCT and the available cases of Minimal residual disease (MRD) by flow cytometry (FCM) before HSCT in ALL Ph-.
Methods: Between 1990 and 2016, 138 HSCT were performed in 128 patients with ALL in our hospital (10 double alloHSCT; 7,2%). Median age was 28 years (12-65). 76% of patients were younger than 40 y. 27,5% of cases (n=38) were Ph+ALL. Disease status before transplant was distributed as follows: 42% CR1, 60,5% (n=23) Ph+ALL and 35% (n=35) Ph-ALL. 58% had advanced disease (AD=≥RC2, MRD+, or active disease), 39,5% (n=15) Ph+ALL and 65% (n=65) Ph-ALL. Bone marrow (BM) progenitors were initially the preferred HSCT source (65,2%), but changed to peripheral blood (PB) after 2001. Antithymocyte globulin was administered with conditioning in case of HLA disparity (n=13; 9,4%).
Results: Focusing on the 38 cases with available MRD by FCM before HSCT in ALL Ph- , there were 11 relapses in the 18 positive cases (MRD ≥0,01%) whereas there were only 2 relapses in the 20 negative (MRD <0,01%) cases (61% *vs* 10%; p=0,03). In the case of 2nd HSCT (n=10), only 1 case was Ph+ (10%), there were 3 ALL with complex caryotype (30%) and 4 patients developed extramedular disease. Two patients remain alive. The main cause of death was relapse (n=5; 50%) followed by SOS (n=3; 30%). MRD before HSCT was available in 4 four cases, being all of them positive (1 molecular MRD+in ALL Ph+, 3 FCM ≥0,01%) (Figure 1).

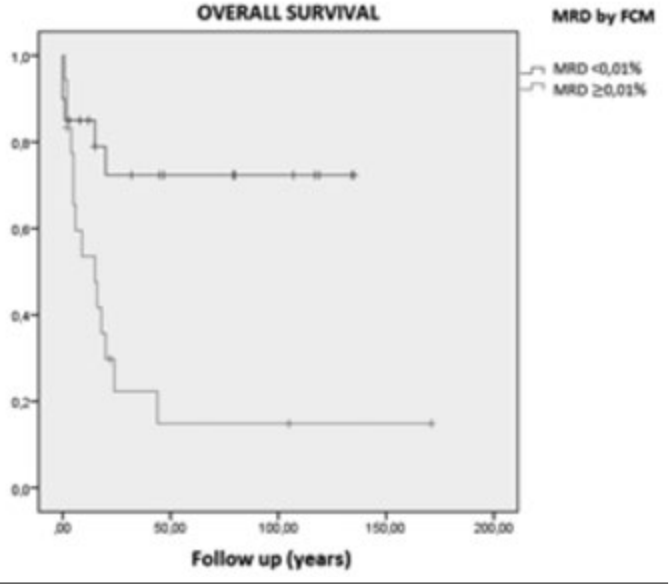

Figure 1.

Summary and Conclusions: Our serie shows a quite high, over 65%, long term DFS, for both Ph+ and Ph- ALL in patients who underwent HSCT in CR1, specially if it was MRD by FCM <0,01%. However it also shows that a fair proportion of advance disease patients could also be cured (25-30%).

EPIGENOMIC ANALYSIS REVEALS STEM CELL-LIKE RELAPSE SIGNATURE IN PEDIATRIC ACUTE MYELOID LEUKEMIA

C. Wiggers[1,2,*], M. Baak[2], M. Creyghton[2], M. Bartels[1]

[1]Pediatrics, University Medical Center Utrecht, [2]Hubrecht Insitute, Utrecht, Netherlands

Background: Pediatric acute myeloid leukemia (AML) is characterized by a high relapse rate (~30%) and overall survival rates of 60-70%. This high relapse rate has been unchanged over the past years, illustrating the importance to increase our insights in pathophysiological mechanisms underlying AML relapse, including chemotherapy resistance and clonal selection. There is increasing evidence that epigenetic deregulation, which involves the activity of non-coding regulatory DNA elements such as promoters and enhancers, is involved in the initiation and progression of cancers, including adult AML. Since little is known concerning epigenetic (de)regulation during relapse in children, it is crucial to gain more insights into the epigenetic landscape of relapsed pediatric AML.
Aims: Identify epigenomic regulatory pathways involved in AML relapse in children.
Methods: The epigenome was investigated using ChIP-seq experiments of H3K27acetylation. This epigenetic mark is associated with active promoters and enhancers, and can therefore be used to identify active regulatory pathways. We investigated 27 (non-)relapsed pediatric AML patients, which harboured common molecular aberrations such as MLL-rearrangement, CBF-related and Flt3-ITD. Our ChIP-seq data was validated by RNA-seq experiments of several patient samples, as well as public RNA-seq data (TARGET AML study). Transcription factor motif enrichment was analysed using AME MEME Suite to evaluate potential upstream regulators.
Results: We successfully identified active promoters and enhancers marked by H3K27ac, resulting in a genome-wide epigenomic network for each pediatric AML patient. Upon sample clustering using these H3K27ac enriched regions, we observed 1) sub-clustering of samples based on molecular aberration, 2) high correlation between matched Dx-Rel samples except for 1 patient, and 3) - mainly in MLL-AF9 patient samples - a separation between relapsed (RP) and non-relapsed patients (NRP). We further investigated this separation based on relapse by linking differentially enriched (DE) regions between MLL-AF9 RP and NRP with their closest genes, resulting in RP and NRP specific gene sets. These gene sets were also differential expressed in our AML samples and publically available RNA-seq samples when analysed as one gene set. The "RP gene set" contained genes higher expressed in hematopoietic stem cells compared to monocytes and was associated with cell proliferation, proto-oncogenes as well as signalling pathways including sphingolipid signalling, a pathway involved in pro-survival and anti-apoptotic processes. Furthermore, transcription factor (TF) motif enrichment in DE regions identified motifs of which some TFs were also part of our gene sets such as GATA2, a known marker for poor prognosis in pediatric AML. At last, we were able to separate RPs from NRPs of other molecular subtypes based on a subset of regions identified in the MLL-AF9 relapse signature, suggesting that this signature also accounts for multiple pediatric AML subtypes.
Summary and Conclusions: We analysed the active chromatin landscape of pediatric AML patient samples using H3K27ac ChIP-seq experiments. Our results led to the identification of a stem cell-like gene signature associated with AML relapse, what could be used as a relapse prognostic gene set in pediatric AML. Additionally, identified signalling pathways and TFs could potentially play a role in chemotherapy resistance leading to relapse, of which sphingosine deregulation by SPHK1 inhibition is already shown to have anti-proliferation and anti-survival effects in AML cells.

PF190

ROBUST *IN VIVO* SYNERGY BETWEEN THE ANTI-CD33 ADC, IMGN779 AND THE FLT3 INHIBITOR QUIZARTINIB IN HUMAN FLT3-ITD AML MODELS

K. Watkins[1,*], L. Flaherty[1], R. McCarthy[2], K. Francisco[2], S. Adams[2], C. Sloss[1], A. Romanelli[3]

[1]Translational Medicine, [2]Pharmacology, [3]Heme Product Development, ImmunoGen, Inc, Waltham, United States

Background: Acute myeloid leukemia (AML) patients harboring a FLT3

Internal Tandem Duplication (FLT3-ITD) have a poor prognosis and high rates of relapse following treatment with standard agents. Midostaurin has been approved recently for the treatment of newly diagnosed FLT3 mutant AML patients. Due to efficacy and toxicity concerns with Midostaurin, additional FLT3 inhibitors, such as the more potent and specific quizartinib, are currently being evaluated in clinical trials for frontline and relapsed AML patients. In pre-clinical models, FLT3 inhibitors decrease anti-apoptotic signaling and re-sensitize FLT3-ITD-positive leukemia to cytotoxic drugs. IMGN779 is a next-generation anti-CD33 antibody-drug conjugate (ADC) with a novel DNA-alkylating IGN payload and a cleavable s-SPDB linker, currently in Phase 1 development for AML. Here we show that the combination of IMGN779 with the FLT3 inhibitor quizartinib leads to increased efficacy in pre-clinical models of FLT3-ITD AML.

Aims: To investigate the anti-leukemic efficacy of IMGN779 and quizartinib in FLT3-ITD-positive AML models.

Methods: *In vitro* cell viability of FLT3-ITD AML cell lines (Molm-13 and MV4-11) treated with IMGN779, quizartinib, or the combination of both were assessed by WST-8 after 4 days of culture. Mechanistic studies were carried out by immunoblotting techniques and by flow cytometry. IMGN779 and quizartinib were evaluated *in vivo* for antitumor activity, against two disseminated AML xenografts. Mice engrafted with AML cells were treated with: vehicle control; quizartinib daily for 14 days; IMGN779 weekly for 3 weeks; or the combination of both.

Results: The *in vitro* combination of IMGN779 and quizartinib in both FLT3-ITD-positive cell lines led to dose-dependent additive or synergistic anti-leukemic activity and increases in the apoptotic proteins cleaved Caspase3 and cleaved PARP1. Cells treated with quizartinib showed decreases in the anti-apoptotic protein Mcl-1, in the pro-survival/proliferative proteins p-Stat5 and p-Erk, and in the DNA repair protein, Rad51. The combination of IMGN779 and quizartinib was also investigated *in vivo*: Molm-13-engrafted mice treated with IMGN779 and quizartinib had a 500% increased life span (ILS) over the vehicle-treated mice, superior to either single agent treatment (IMGN779=71% ILS or quizartinib=55% ILS *vs* vehicle control). Importantly, 4 out of 6 mice treated with the combination were alive at 126 days, which was twice as long as the last surviving mouse treated with either single agent (56 days with IMGN779 and 39 days with quizartinib). Similarly, MV4-11-engrafted mice treated with IMGN779 and quizartinib had a significant 134% ILS over the vehicle-treated mice. Matched dose, single agent treatment resulted in only modest increases in survival (40% ILS *vs* vehicle control) (Figure 1).

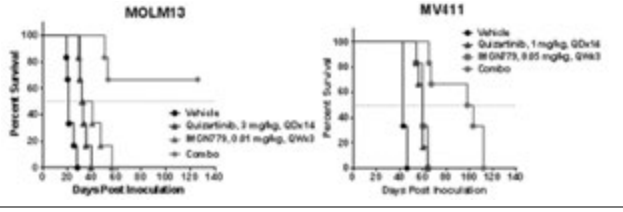

Figure 1.

Summary and Conclusions: In pre-clinical studies of FLT3-ITD AML, the combination of IMGN779 and quizartinib results in a robust anti-leukemic effect, well beyond that of either agent alone. *In vivo* studies have shown this effect in two disseminated models, suggesting cooperativity of their distinct anti-leukemic mechanisms of action without overt increases in toxicity. *In vitro* studies indicate that this effect correlates with quizartinib-driven decreases in anti-apoptotic/pro-survival signaling (Mcl-1; p-Erk; p-Stat5) and in DNA damage repair capacity (Rad51), as well as subsequent increases in apoptosis (c-PARP1; c-Caspase3). Collectively, these findings support testing the combination of IMGN779 and FLT3 inhibition in a clinical trial with FLT3-ITD mutant AML patients.

PF191

NOVEL MUTATIONS AND TRANSLOCATIONS INVOLVING NUCLEOPHOSMIN (NPM1) GENE IN ACUTE MYELOID LEUKEMIA (AML) AND LEADING TO ABERRANT CYTOPLASMIC NPM1

M.P. Martelli[1,*], R. Rossi[1], A. Venanzi[1], M. Meggendorfer[2], V. Perriello[1], O. Spinelli[3], R. Ciurnelli[1], L. Brunetti[1], S. Ascani[1], C. Quadalti[1], G. Specchia[4], F. Di Raimondo[5], G. Avvisati[6], A. Rambaldi[7], F. Falzetti[1], E. Tiacci[1], P. Sportoletti[1], T. Haferlach[2], C. Haferlach[2], B. Falini[1]

[1]Hematology, University of Perugia, Perugia, Italy, [2]MLL, Munich Leukemia Laboratory, München, Germany, [3]ASST Papa Giovanni XXIII, Bergamo, [4]Hematology, University of Bari, Bari, [5]Hematology, University of Catania, Catania, [6]Hematology, Campus Bio-medico University of Rome, Rome, [7]Hematology, University of Milan, ASST Papa Giovanni XXIII,, Bergamo, Italy

Background: Nucleophosmin (*NPM1*) gene mutations occur in 50–60% of adult AML with normal karyotype (Falini *et al.,* NEJM 2005). About 50 *NPM1* mutations have been so far identified, all clustering in exon-12 but few sporadic cases involving either exon-9 (one) (Mariano *et al.,* Oncogene 2006) or exon-11 (two) (Albiero *et al.,* Leukemia 2007). More recently, rare NPM1 fusion proteins have been also described in AML (Paulo Vidal Campreger *et al.* Haematologica, 2016). In spite of molecular heterogeneity, all mutations cause common changes at the C-terminus of NPM1 mutants, *i.e.* loss of tryptophans 288 and 290 (or 290 alone) and creation of a new nuclear export signal (NES) motif, which binds to Exportin1/Crm1 and mediates its aberrant accumulation in the cytoplasm of leukemic cells, an event which is detectable by immunohistochemistry (Falini *et al.,* Blood 2006b).

Aims: Here, we aimed to identify novel *NPM1* genetic lesions, either mutations or NPM1 fusion proteins, leading to aberrant cytoplasmic NPM1 in AML, a critical event in leukemia development and maintenance (Brunetti, ASH Abs 877, 2017).

Methods: We applied a combinatorial approach of immunohistochemistry (IHC), western blot (WB) with specific antibodies for either the mutated or the wild-type NPM1 protein, *NPM1* gene sequencing and RNAseq to a large number (about 900) of patients from either our center or other Italian centers and the MLL laboratory in Munich, and focused on the discordant cases for IHC, WB or gene sequencing to identify novel *NPM1* genetic lesions. In the newly discovered *NPM1* mutated genes/fusion transcripts, search for acquisition of a NES motif in their protein sequence and strength of the NES were functionally evaluated in an overexpression ectopic cellular system.

Results: This research approach confirmed the rarity of mutations involving exons other that exon 12 in NPM1-mutated AML, and allowed the discovery of different novel mutations in exon 6 (n=3, Italian center) and exon 5 (n=1, MLL laboratory). An example of a mutation involving exon 6 is shown in Figure 1A. As a consequence of an in-frame 21 nucleotides insertion, a NES sequence was newly inserted whilst the rest of the protein sequence was conserved, explaining WB results. The new NES was experimentally confirmed to be active leading to cytoplasmic dislocation of the mutant (Figure 1A). In another series of patients, RNAseq analysis (MLL laboratory) lead to identification of 3 novel NPM1 gene translocation involving i) *RPP30,* t(5;10)(q35;q23); ii) *SETBP1,* t(5;18)(q34;q12); and iii) *CCDC28A,* t(5;6)(q35;q23). The latter was found also in one patient followed at our center where cytoplasmic positivity of the new fusion protein was confirmed by either IHC on patient bone marrow biopsy or immunofluorescence microscopy detection of the eGFP-NPM1/CCDC28A fusion protein (Figure 1B). Strikingly, in all cases, as shown in the representative cases in Figure 1, the predicted new protein sequence harboured a strong NES domain, either newly created or present in the partner protein sequence, which ensured its cytoplasmic accumulation, confirming the concept that *NPM1* mutation in AML are 'born to be exported'(Bolli *et al.,* Cancer Res 2007).

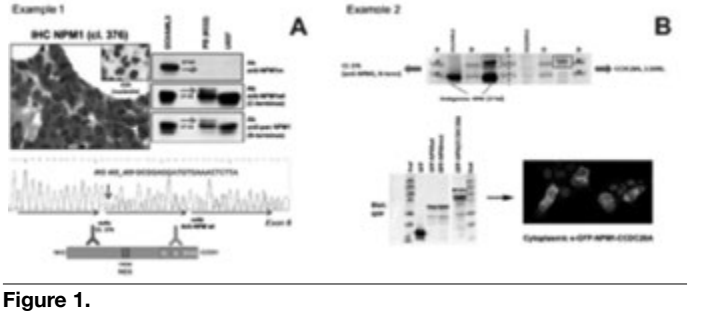

Figure 1.

Summary and Conclusions: Here, we report on the identification and functional characterization of novel *NPM1* mutations/fusion transcript in AML. Our observations further support the view that cytoplasmic NPM1 dislocation is a critical event in leukemogenesis, and that immunohistochemistry, that detects, through cytoplasmic dislocation of NPM, 'all types' of *NPM1* mutations, might be used as first step for directing further molecular studies.

PF192

THE LSC17 SCORE ALLOWS RISK STRATIFICATION IN PEDIATRIC ACUTE MYELOID LEUKEMIA

N. Duployez[1,*], A. Marceau-Renaut[1], C. Villenet[2], A. Petit[3], S.W.K. Ng[4], F. Gonzales[5], N. Pottier[6], A. Paquet[7], B. Nelken[8], G. Michel[9], A. Baruchel[10], Y. Bertrand[11], G. Leverger[3], H. Lapillonne[12], M. Figeac[2], J.E. Dick[13], C. Preudhomme[1], M. Cheok[14]

Background: Despite major treatment improvements over the past decades, pediatric acute myeloid leukemia (AML) is still a life threatening with relapse rates up to 30% and survival rates below 75%. While strong pretherapeutic prognostic factors have emerged, especially based on cytogenetic and molecular aberrations, some patients still relapse despite the lack of adverse risk factors. Recently, we participated in a study reporting a stemness-associated 17-gene expression signature (LSC17 score) as an independent prognostic factor in adult AML, irrespective of genetic alterations (Ng *et al.*, *Nature* 2016). However, the relevance of the LSC17 score in childhood AML needs further investigations.
Aims: We retrospectively evaluated the prognostic value of the LSC17 score in a well-annotated cohort of *de novo* pediatric AML.
Methods: This study focused on 163 children (0-18 years) enrolled in the ELAM02 trial (ClinicalTrials.gov NCT00149162) with available RNA material from AML diagnosis. The Nanostring assay was performed as previously described (Ng *et al.*). Similarly, high and low scores were defined as above and below the median.

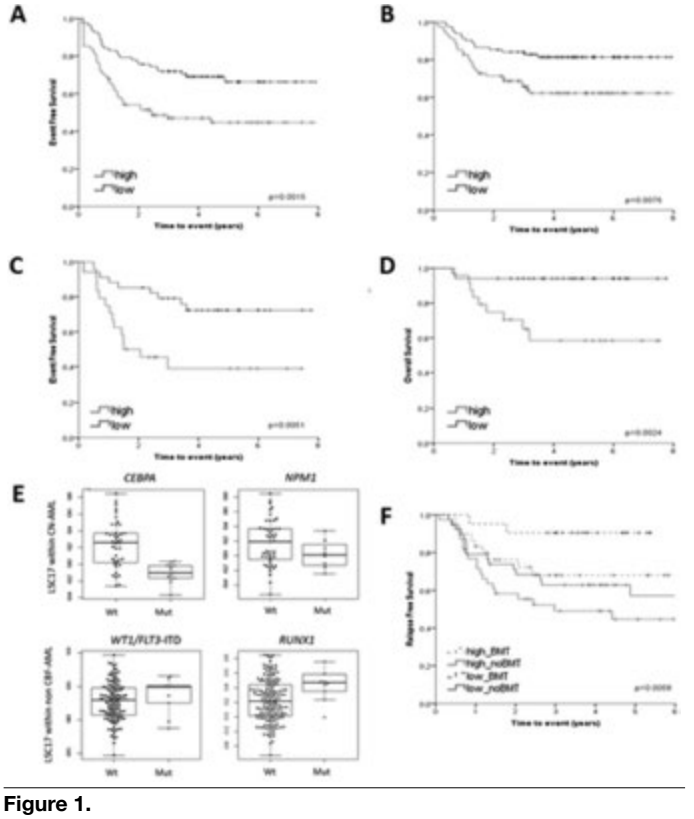

Figure 1.

Results: The distribution in the cytogenetic subgroups was: Normal karyotype (n=58), *KMT2A*-rearranged (n=48), abnormal karyotype (n=57). CBF AML were excluded from the analysis. No difference in routine clinical parameters (age, sex, WBC at diagnosis) was found between the global ELAM02 cohort and the LSC17 sub cohort, which were selected based on available RNA material. All patients received chemotherapy as induction treatment. Children with low LSC17 score had significantly better overall survival (OS) and event free survival (EFS) compared to patients with high LSC17 score. (5y-OS: 81.4% *vs* 62.2%, p=0.0034; 5y-EFS: 66.3% *vs* 44.7%, p=0.0076)(Figure 1A-B). Notably, a strong prognostic value was observed in cytogenetically normal (CN)-AML both on OS and EFS (5y-OS: 94.1% *vs* 58.5%, p=0.0024; 5y-EFS: 72.3% *vs* 39.0% p=0.0051)(Figure 1C-D). Importantly, LSC17 as a continuous variable remained a powerful prognostic factor in multivariate analysis, including WBC and genetic risk categories (accoridng to MyeChild stratification) for both EFS (hazard ratio [HR]: 5.14; IC95%: 1.97-13.40]; p=0.0008) and OS (HR: 4.88, IC95% 1.47-16.23; p=0.0098). The LSC17 score was not associated with high initial white blood cell count. High and low LSC17 scores were distributed in all cytogenetic subgroups with no significant association (Figure 1E). However, among CN-AML, a low LSC17 score was associated with favorable genotypes such as *CEBPA* biallelic mutations and *NPM1* mutations (Figure 1E). On the other hand, *RUNX1* and *WT1/FLT3*-ITD-mutated AML were associated with high LSC17 scores. Finally, allogeneic stem cell transplantation (allo-SCT) in first complete remission improved relapse free survival (RFS) in intermediate or poor genetic-risk patients with low LSC17 score (5-y RFS: 90.5% *vs* 57.1%, p=0.021) and high LSC17 score (5-y RFS: 68.0% *vs* 44.6%, p=0.101) respectively (Figure 1F).
Summary and Conclusions: As in adult AML, our study in pediatric AML shows that the LSC17 score is of comparable clinical prognostic relevance, irrespective of known adverse prognostic factors. Specifically, in AML with no cytogenetic lesion (CN-AML), which makes up 25% of all pediatric AML and forms a heterogeneous subgroup, the LSC17 score maybe a clinical useful prognostic marker. Allo-SCT still improved prognostic in patients with intermediate or poor genetic-risk although it did not reach statistical significance in patients with high LSC17 score.

PF193

MUTATION PROFILE AND BENEFIT OF GEMTUZUMAB OZOGAMICIN IN ACUTE MYELOID LEUKEMIA PATIENTS TREATED IN THE ALFA-0701 TRIAL

E. Fournier[1,*], D. Lara[2], M. Bucci[1], N. Duployez[1], A. Marceau-Renault[1], J. Lambert[2], A. Renneville[1], D. Hervé[3], S. Castaigne[2], C. Preudhomme[1], N. Boissel[3]

[1]59, CHRU Lille, Lille, [2]78, Versailles hospital, Le Chesnay, [3]75, Saint Louis hospital, Paris, France

Background: The molecular landscape of AML has led to the discovery of a number of recurrent mutations in AML with a complex and dynamic clonal architecture. The prognostic relevance of these events has been evaluated in large cohorts of adult patients and is progressively incorporated into risk stratification (ELN-2017). However, the predictive impact of these mutations is less well known, particularly in non-targeted therapies.
Aims: We described the molecular landscape in a cohort of AML patients aged 50-70 years old randomized in the ALFA-0701 trial to receive gemtuzumab ozogamicin (GO) in combination with standard chemotherapy. We retrospectively addressed the question of the predictive value of these molecular events on the benefit of GO.
Methods: This study focus on 250 patients enrolled in the ALFA-0701 trial (NCT00927498) with available DNA at AML diagnosis. High-throughput sequencing was targeted on 43 genes recurrently mutated in myeloid malignancies. Genes were classified as follow: signaling pathway effectors (class I), transcription factors (class II), spliceosome, cohesin-complex, epigenetic regulators (including chromatin modifications and DNA methylation), tumor-suppressors and *NPM1*.
Results: The median age at AML diagnosis was 62.1 years (range 50.1-70.9). Among 250 patients, we identified 709 mutations involving 37 genes, and 233 patients (93%) had at least 1 mutation. Eleven genes were recurrently mutated in more than 10% of patients including *NPM1* (33%), *DNMT3A* (28%), *FLT3-ITD* (20%), *TET2* (20%), *RUNX1* (20%), *NRAS* (14%), *IDH2* (14%), *ASXL1* (13%), *SRSF2* (12%), *IDH1* (10%) and *TP53* (10%). Mutations involving epigenetic regulators were by far the most frequent lesions, encountered in 68% of the whole cohort. *NPM1*, *FLT3*-ITD, *DNMT3A* and *IDH2* mutations were associated with intermediate cytogenetic while *TP53* were more frequent in the poor-risk cytogenetic subgroup. The benefit of GO appeared quite heterogeneous with discrepancies according to mutational profiles. In term of event-free survival, a benefit of GO was mostly observed in patients with class I mutations (HR 0.43, 95%CI[0.29;0.66]) but also in patients with spliceosome (HR 0.47, 95%CI[0.26;0.86]), *NPM1* (HR 0.47, 95%CI[0.28;0.80]), or epigenetic mutations (HR 0.63, 95%CI[0.44;0.89]) but not in other subgroups. The benefit of GO was correlated to CD33 expression levels among the different gene mutations, with particularly high levels observed in class I mutated genes (Pearson -0.67, Figure 1A). Most importantly we observed that, among the different mutation groups that benefit from GO, this benefit was restricted to patients with cooccurring class I mutations. Indeed, a sig-

nificant interaction between class I mutation and GO administration was noted in patients with *NPM1* mutation (p=0.037) or epigenetic mutations (p=0.016, Figure 1B).

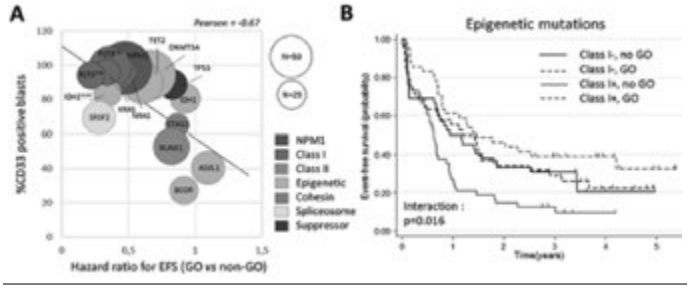

Figure 1.

Summary and Conclusions: In the present study, we showed that the benefit of GO in AML was heterogeneously distributed among the different molecular aberrations and correlated with mutation-associated CD33 expression levels. The benefit of GO was mostly restricted to the group of class I mutation whatever the associated mutation profile.

PF194

MOLECULAR PATHOGENESIS OF DISEASE PROGRESSION IN MLL-REARRANGED AML

S. Kotani[1,2], K. Kataoka[1], A. Yoda[1,3], A. Kon[1], Y. Ochi[1,2], Y. Shiozawa[1], C. Hirsch[4], J. Takeda[1,2], H. Ueno[1], T. Yoshizato[1], K. Yoshida[1], Y. Nannya[1], T. Yamauchi[5,6], N. Kakiuchi[1], K. Aoki[1], Y. Shiraishi[7], S. Miyano[7], T. Maeda[5,8], J. Maciejewski[4], A. Takaori-Kondo[2], S. Ogawa[1,9], H. Makishima[1,4,*]

Background: Despite advanced therapeutics, many leukemia patients become refractory to additional therapy, accounting for a major cause of leukemic deaths. Among major human acute myeloid leukemias (AMLs), *MLL*-rearranged AML (*MLL*-AML) is characterized by poor prognosis due to chemo-resistance and a shorter period to relapse. While many groups reported secondary somatic mutations in *MLL*-rearranged AML, their roles in disease progression and refractoriness or relapse have not fully been elucidated.
Aims: In this study, we investigated the role of secondary mutations acquired during the progression of *MLL*-AML,using a mouse model of *MLL*-AML.
Methods: We retrovirally transduced mouse stem cells with *MLL/AF9*, which were serially transplanted in C57BL/6 mice, where clonal evolution was monitored in each transplant, in terms of gene mutations using whole exome sequencing. To clarify the role of candidate driver genes, we examined their expression levels in human samples, and also performed *in vitro* functional studies using forced expression, shRNA-mediated knockdown, and CRISPR/Cas9-knockout experiments.
Results: The onset of leukemia was progressively accelerated with advanced transplants, during which increasing numbers of somatic mutations were identified with a median of 25 and 37 mutations after the first (n=2) and the fourth (n=9) transplants, respectively (P<0.001). Interestingly, these mutations included *Polr2a* and *Polr3d*, which are biologically related to Mll complex and a mutation affecting *Ptpn11* (p.G60R), which was recurrently mutated in human *MLL*-AML. Another mutation of interest was a *Gnb2* mutation affecting Gly77 that is adjacent to the residues recurrently mutated in other cancers. Allele specific quantitative PCR showed that a clonal burden of *Gnb2* mutation (p.G77R) had a significant trend to increase during serial transplantations (P=0.0012). In human *MLL*-AML cases, *GNB2* transcripts were significantly upregulated compared to *MLL*-rearrangement-negative AML cases, based on the publically available data sets for RNA sequencing (n=173) (P=0.03) and expression array (n=542) (P=0.009). Elevated *GNB2* expression was also found in human *MLL/AF9*-positive cell lines, THP1, MOLM13, and NOMO1. In functional studies, we demonstrated that overexpression of the mutant *GNB2* (p.G77R) conferred cytokine-independence to an interleukin 3 (IL-3)-dependent leukemic cell line, Ba/F3 (Figure 1a). By contrast, knock-down of *GNB2* resulted in a significantly reduced proliferation in an *MLL*-AML cell line highly expressing *GNB2* (MOLM13), compared to control (P<0.05) (Figure 1b). Furthermore, we transfected a CRISPR-Cas9 library to *MLL/AF9*-transformed mouse cells to see an enrichment or depletion of *Gnb2*-targetted sgRNA. In line with the result of the knock-down experiment, we observed a significant depletion of the *Gnb2*-targetted sgRNA after the culture (P=0.004), confirming a potential oncogenic function of *Gnb2* in *MLL*-AML.

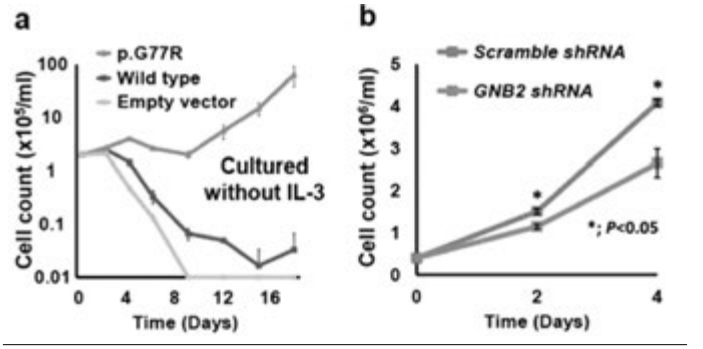

Figure 1.

Summary and Conclusions: The role of secondary mutations in the progression of *MLL*-AML was investigated using a retrovirus model, combined with whole exome sequencing and a genome-wide screen. Our findings suggest that *MLL*-fusion genes as initial drivers may cooperate subsequently with various genetic events, resulting in aggressive clinical course due to leukemic progression.

PF195

LEUKAEMIC BLASTS OUTSOURCE MITOPHAGY TO THEIR MICROENVIRONMENT

R. Horton[1,*], C. Marlein[1], T. Wileman[2], K. Bowles[3], M. Jefferson[2], S. Rushworth[1]

[1]Molecular Haematology, [2]UEA, [3]Haematology, Norfolk and Norwich University Hospital, Norwich, United Kingdom

Background: Acute myeloid leukaemia (AML) is a tumour dependant on the bone marrow microenvironment for survival and proliferation. We have recently shown that mitochondria are transferred from bone marrow stromal cells (BMSC) to leukaemic blasts to enhance leukaemic metabolic potential (1). Mitochondria, however, are highly dynamic organelles and their morphology is both tightly regulated and intimately intertwined with a cell's fate. Just as a lack of functional mitochondria leads to a metabolic deficit and stalls cellular proliferation, clearance of damaged mitochondria is equally critical for cellular fitness. Autophagy is an intracellular degradation process involved in the removal of pathogens, damaged organelles and misfolded proteins. Mitophagy is a subset of autophagy for mitochondria. Where mitophagy is inadequate, a build up of dysfunctional mitochondria leads to impaired electron transport chain function and increased oxidative stress. Here, we hypothesise that leukaemic blasts outsource their mitophagy by transferring their dysfunctional mitochondria to the bone marrow microenvironment for recycling.
Aims: To determine whether AML transfers mitochondria to its microenvironment for recycling by autophagy, and whether this response inhibits chemotherapy-induced apoptosis.
Methods: Primary acute myeloid leukaemia cells (AML) and BMSC were isolated from bone marrow aspirates following informed consent and under approval from the UK NHS Health Research Authority. Wild type and autophagy deficient mouse embryonic fibroblasts (MEF) were used. Mitochondrial membrane potential was measured by tetramethylrhodamine methyl ester (TMRM). Mitochondrial transfer was monitored using AML transduced with a rLV.EF1 mCherry-Mito-9 Lentivirus. Autophagy was measured by immunoblotting for P62 and conversion of LC3-I to LC3-II. Autophagosomes were visualised by fluorescent microscopy of BMSC transduced with adenoviral green fluorescent protein for LC-3, and this was quantified using imiris software.
Results: We report that AML is dependent on its microenvironment for the maintenance of mitochondrial membrane potential. Moreover, this protective effect of the microenvironment is seen when AML is cultured with wild-

type, but not with autophagy deficient, BMSC. In *ex-vivo* co-culture experiments, we find that AML increases the formation of LC3 puncta in BMSC, and by western blotting conversion of LC3I-LC3II. We employ a control experiment using media previously cultured with AML to demonstrate that these effects are surplus to starvation-induced autophagy. Next, we describe that AML transfers mitochondria to both wild-type and autophagy deficient MEF when in direct culture and that greater numbers of mitochondria remain in autophagy deficient MEF after 24 -hour co-culture. Furthermore, this export of mitochondria is upregulated in response to chemotherapy drugs. Finally we report that blocking the export of mitochondria increases AML apoptosis in response to chemotherapy.
Summary and Conclusions: Here, we report that AML transfers mitochondria to BMSCs where they undergo mitophagy. This response is upregulated in response to chemotherapy and may provide a novel target for overcoming chemotherapy resistant AML.

THERAPEUTIC TARGETING OF THE LEUKAEMIC FUSION GENE RUNX1/ETO VIA RNAI

H. Issa[1,*], H. Blair[1], N. Jyotsana[2], M. Heuser[2], O. Heidenreich[1]

[1]Wolfson Childhood Cancer Research Centre - Northern Institute for Cancer Research, Newcastle University, Newcastle upon Tyne, United Kingdom, [2]Department of Hematology, Hemostaseology, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany

Background: The t(8,21) translocation is the most prevalent chromosomal translocation in Acute Myeloid Leukaemia (AML), which leads to the expression of chimaeric RUNX1/ETO oncogene protein. Our previous work showed that RNAi-mediated *RUNX1/ETO* knockdown *in vitro* inhibits cell proliferation, reduces clonogenicity, causes G1 cell cycle arrest and impairs engraftment in immunocompromised host.
Aims: To silence *RUNX1/ETO* expression by an LNP/siRNA system *in vitro* and *in vivo* and to exploit its therapeutic potential.
Methods: We introduced several modifications on the 2'-position of the ribose and on the phosphodiester backbone. siRNA were encapsulated into Dlin-MC3-DMA lipid nanoparticles (LNP) using a microfluidic system for controlled mixing conditions on a NanoAssembr instrument. The activity of the modefied siRNA and LNP/siRNA were measured *in vitro* using t(8;21) AML cell lines: Kasumi-1, SKNO-1 and Kasumi-1 p.SLIEW stable cell line expressing EGFP and Luciferase. Patient primary t(8;21) cells were cultured on a Mesenchymal Stem Cells (MSC) feeder layer. 250,000 cells of Kasumi-1 p.SLIEW were transplanted intra-hepatically into new-born $Rag2^{-/-}$ $\gamma c^{-/-}$ mice. Engraftment was monitored by bioluminescent imaging (IVIS). LNP was functionalised with sulfo-cyanine 7.5 dye for live fluorescence imaging in the pharmacodynamic studies.
Results: *In vitro* studies demonstrated that the chemically modified siRNA substantially inhibited *RUNX1/ETO* and provided prolonged phenotypic and greater effect on AML cell lines in comparison with unmodified siRNA. Single treatment with modified LNP/siRNA induced a long-lasting inhibition of *RUNX1/ETO in vitro* and in t(8;21) AML primary patient cells as well as in t(8;21) PDX. Pharmacodynamic studies showed that a single dose of LNP/siRNA by systematic delivery routes provides global body distribution in immunocompromised mice including leukaemic tissues, liver, spleen, bone marrow and brain. Harvested human leukaemic cells from siRNA-treated $Rag2^{-/-}$ $\gamma c^{-/-}$ mice showed substantial reduction of RUNX1/ETO level with low dose of LNP/siRNA. This knockdown was associated with significant downregulation of *RUNX1/ETO* target genes such as *CCND2* and *TERT*. *RUNX1/ETO* depletion also severely impaired the clonogenic potential of the harvested leukaemic cells from LNP/siRNA treated mice and triggered senescence. Notably, only three doses of LNP/*RUNX1/ETO* siRNA entirely prevented the expansion of leukaemic cells in secondary transplanted recipients. LNP/siRNA mediated *RUNX1/ETO* depletion *in vivo* significantly enhanced the survival of immunocompromised mice. The LNP/siRNA treatment resulted in a prolonged median survival of 80 days comapred with 44 days for the control group. In line with these findings, RNA-seq indicated that *in vivo* depletion of RUNX1/ETO activates a myeloid differentiation programme.
Summary and Conclusions: Taken together, we have demonstrated that liposomal delivery of chemically modified *RUNX1/ETO* siRNA impairs RUNX1/ETO-driven transcriptional networks and therewith associated leukaemic self-renewal function and initiates differentiation, which may have a therapeutic potential.

PF197

PREVALENCE AND CLINICAL IMPLICATIONS OF PPM1D TRUNCATING MUTATIONS IN THERAPY-RELATED MYELOID NEOPLASMS

Background: Therapy-related myeloid dysplastic syndrome (t-MDS) and therapy-related acute myeloid leukemia (t-AML), collectively termed therapy-related myeloid neoplasms (t-MNs), are rare but fatal complications of prior chemotherapy and/or radiotherapy. T-MNs have significantly worse clinical outcomes compared to *de novo* AML/MDS. However, the molecular underpinnings that distinguish t-MN from *de novo* AML/MDS are poorly understood. Truncating mutations in exon 6 of *PPM1D* (Protein Phosphatase Mg/Mn2+ 1D) have recently been identified in therapy-related clonal hematopoiesis and t-MDS (Coombs *et al.* 2017 and Lindsley *et al.* 2017), but the mutations are rarely detected in *de novo* AML/MDS. This suggests that selective pressure from prior therapy may be the key to the expansion and potential leukemogenic role of *PPM1D* mutant clones.
Aims: To understand the prevalence and clinical implications of *PPM1D* truncating mutations in t-MN.
Methods: We studied 156 patients with t-AML (N=77) or t-MDS (N=79). Diagnostic bone marrow samples from these patients were analyzed by targeted-capture deep sequencing of 295 cancer genes as well as *PPM1D* truncating mutations. The mutational landscape of t-MN was compared to that of *de novo* AML (N=120) and MDS (N=108), which were sequenced by the same platform.

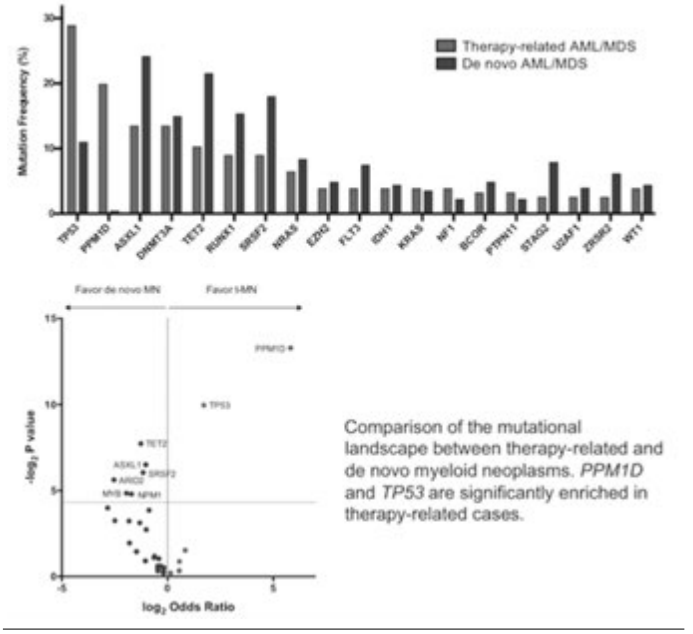

Figure 1.

Results: Of the 156 t-MN patients, *PPM1D* was mutated in 31 (20%) patients, making it the second most commonly mutated gene in t-MN after *TP53* (29%). *PPM1D* mutations were detected in only 0.5% of the matched *de novo* MDS/AML patient cohort, confirming a specific enrichment of *PPM1D* mutations in therapy-related diseases. The prevalence of *PPM1D* mutations

was similar between t-MDS and t-AML (19% *vs* 21%, p=0.904). *PPM1D* did not significantly co-mutate with other driver gene mutations or cytogenetic aberrations. All 31 *PPM1D* mutations identified in this t-MN cohort were protein-truncating variants spanning the final exon of the gene. The mean variant allele frequency (VAF) of *PPM1D* mutations was 0.105 (range 0.02-0.41). *PPM1D* VAF was higher in t-AML than t-MDS (0.148 *vs* 0.065, p=0.0065). 81% of the *PPM1D* mutations were considered sub-clonal and 19% clonal, based on VAF cutoff of 0.2. In 3 *PPM1D* mutated cases where there were available lymphoid (CD3+/CD19+) and non-lymphoid (CD3-/CD19-) fractions, *PPM1D* mutations were detected in both cellular fractions, suggesting a progenitor/stem cell origin. An analysis of prior cytotoxic exposures revealed that *PPM1D* mutations are significantly associated with prior exposure to platinum agents (p=0.004), etoposide (p=0.021), and self-reported alcohol use (p=0.015). Patients with *PPM1D* mutations did not have a statistically significant worse overall median survival compared to patients without *PPM1D* mutations (10 months *vs* 12.8 months respectively, p=0.513). Overall response rate to therapy with hypomethylating agents and cytarabine was also comparable between patients with and without *PPM1D* mutations (p=0.456 and 0.501, respectively) (Figure 1).

Summary and Conclusions: *PPM1D* is one of the top mutated genes in t-AML and t-MDS, and is specific to t-MN. The majority of the mutations were sub-clonal and *PPM1D* mutation status did not affect survival or response to therapy. *PPM1D* mutations are significantly associated with prior exposure to cisplatin and etoposide. These findings can potentially inform the choice of chemotherapeutic regimens for patients with primary cancers when clonal hematopoiesis with *PPM1D* mutations is detected.

LONGITUDINAL GENOMIC AND TRANSCRIPTOMIC TRACKING OF CORE BINDING FACTOR ACUTE MYELOID LEUKEMIA

T. Kim[1,2,*], J.H. Moon[3], J.-S. Ahn[4,5], M. Tyndel[2,6], Y.-K. Kim[4,5], S.-S. Lee[4], S.-Y. Ahn[4], S.-H. Jung[4], D.-H. Yang[4], J.-J. Lee[4], S.H. Choi[5], J.-Y. Lee[5], Y.J. Lee[3], S.K. Sohn[3], H.-J. Kim[4,5], Z. Zhang[1,2,7], D.D.H. Kim[8]

[1]Department of Computer Science, [2]Donnelly Centre, University of Toronto, Toronto, Canada, [3]Department of Hematology-Oncology, Kyungpook National University Hospital, Daegu, [4]Department of Hematology-Oncology, [5]Genomic Research Center for Hematopoietic Diseases, Chonnam National University Hwasun Hospital, Jeollanam-do, Korea, Republic Of, [6]The Edward S. Rogers Sr. Department of Electrical and Computer Engineering, [7]Department of Molecular Genetics, University of Toronto, [8]Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, Canada

Background: Core binding factor acute myeloid leukemia (CBF-AML) is a subgroup of AML, mainly defined by two gene rearrangements affecting CBF; t(8;21)/*RUNX1-RUNX1T1* and inv(16)/*CBFB-MYH11*. Although their somatic mutation and expression profiles at diagnosis have been revealed, these profiles have not been tracked longitudinally.

Aims: To assess transcriptomic and genomic landscape of CBF-AML and identify their dynamics using serial samples

Methods: This study included bone marrow samples from 42 patients (23 t(8;21) and 19 inv(16) AML) taken at diagnosis and complete remission (CR). Using a custom myeloid gene panel covering exonic regions of 84 genes (Agilent SureSelect), we performed targeted DNA sequencing on 126 trio-samples (42 T-cell, diagnosis, and CR samples). During variant calling procedures, T-cell fraction (CD3+) was used as a control. Average on-target coverage was 1606x. Eighty-four samples (42 diagnosis and CR paired samples) were subject for RNA sequencing using Illumina TruSight Pan-Cancer panel. After read mapping, gene count was measured using HTSeq followed by DEseq2 for down-stream analyses. Gene fusion was detected using EricScript. Average number of mapped reads was 3.1M with 87% average mapping rate.

Results: At diagnosis, we detected 74 mutations from 38 patients (90%) (Figure 1A). Most frequently mutated genes were *NRAS* (n=15), *KIT* (n=15), *KRAS* (n=7) and, *ASXL2* (n=5). Chromatin modifiers and cohesin complex were exclusively mutated in t(8; 21) AML. At CR, although allelic burdens were nearly cleared (Mean VAF from 22.4% to 0.2%), residual allelic burden of 36 mutations (n=26) were still detected, commonly in *KIT* (n=11), *NRAS* (n=7), and *KRAS* (n=3) (Figure 1B-C). When projecting RNA expressions onto 2D space using principal component analyses, samples at diagnosis were distinctively clustered according to their subtype (Figure 1D). All CR samples were clustered regardless of subtypes. In addition to subtype-defining gene fusions, two additional gene fusions; *SLC45A3-ELK4* (n=3) and *CSNK1G2-JAK2* (n=2) were recurrent in t(8;21) AML. However, their presence did not result in distinct expression profile. At CR, t(8;21) was detected in 8 patients. By three-way comparisons of differentially expressed genes (DEGs), we identified 524 DEGs (Figure 1E). At diagnosis, we identified 297 DEGs, where 175 DEGs including *RUNX1T1* were highly expressed in t(8;21) AML and 122 DEGs including *MYH11* were expressed higher in inv(16) AML. When paired samples at diagnosis and CR were compared, we found 402 and 286 DEGs in t(8;21) AML and inv(16) AML, where 200 genes were shared. Interestingly, 177/200 shared DEGs showed same direction of abnormal expression. In addition, 200 shared DEGs (colored regions, Figure 1E) were enriched in KEGG terms related to immune response such as cytokine-cytokine receptor interaction (q <2.2e-5), allograft rejection (q <0.02) and, graft–*versus*–host disease (q <0.02).

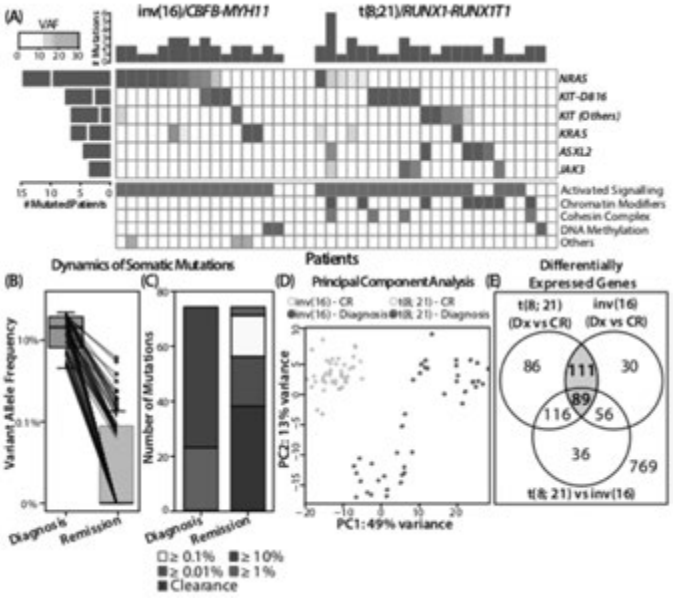

Figure 1.

Summary and Conclusions: Transcriptomic and genomic tracking of CBF AML using serial samples provided dynamics of mutation and RNA expression. With longitudinal tracking of somatic mutations, we showed residual allelic burden was detected in 62% of patients at CR. Second, RNA profiles of two subtypes of CBF-AML were distinct, but shared DEGs were enriched in immune response-related terms.

PF199

GENOMIC CHARACTERISTICS OF ACUTE ERYTHROID LEUKEMIA

Background: Acute erythroid leukemia (AEL) is a subtype of acute myeloid leukemia (AML) characterized by the predominance of erythroid proliferation as well as frequent myelodysplasia. However, it is controversial whether

or not AEL represents a discrete pathological entity; in fact, AEL has partly been integrated into a subtype of myelodysplastic syndromes (MDS) in the revised 4th edition of World Health Organization (WHO) classification. Characteristic mutational profiles of myeloid neoplasms with erythroid proliferation have not fully been elucidated except for frequent *TP53* mutations.
Aims: This study was designed to characterize the mutational profile of myeloid neoplasms with erythroid proliferation and to clarify its differences from, as well as, similarities to that of other types of AML and MDS.
Methods: We performed a comprehensive genetic study, in which paired tumor/normal DNA from 27 AMLs with increased erythroid precursors (AEL according to WHO 2000) were analyzed using whole-exome sequencing (WES). Three cases with AEL analyzed by The Cancer Genome Atlas (TCGA) were also included. We also analyzed mutations and copy number alterations in known/putative driver genes/chromosomes associated with myeloid malignancies in a total of 96 AEL cases using targeted-capture sequencing. The results were compared with those found in 1,540 AML targeted sequencing data (Papaemmanuil *et al.* NEJM. 2016).
Results: All patients were over 20 years old. The median age at diagnosis was 59 years old. Among the 59 patients whose blast count was available, 52 (88%) and 7 (12%) were classified into M6a and M6b by the French–American–British (FAB) classification, respectively. Most frequently observed in the total cohort were *TP53* mutations (n=35, 36%), of which 97% were accompanied by complex karyotype and *TP53* mutations were associated with a significantly shorter overall survival ($p < 0.001$). According to the genomic classification of AML proposed by Papaemmanuil et. al., the majority of samples (85%) were classified into 3 subgroups: those with *TP53* mutations/chromosomal aneuploidy (n=33), with *NPM1* mutation (n=15) and with mutated chromatin/RNA-splicing genes (n=34). Notably, among cases having *TP53* mutations/chromosomal aneuploidy, 12 (34%) and 14 (40%) cases had amplification in 19p and 21q, respectively, where the minimally affected regions included *EPOR* and *ERG*. In the subgroup with mutated chromatin/RNA-splicing genes, *STAG2 (53%), ASXL1* (33%) and *WT1* (20%) were enriched in AMLs with erythroid proliferation compared to other subtypes of AML. By contrast, mutations in *FLT3*, *DNMT3A* and *SF3B1* were significantly less frequent in our cohort.
Summary and Conclusions: Whole exome and targeted-capture sequencing revealed the landscape of genetic alterations in AML with erythroid proliferation. Our findings suggested that AML with erythroid proliferation is classified into 3 major subgroups having unique genetic and clinical features. Further molecular/biological characterization of each entity should be warranted.

PF200

FUNCTIONAL PROTEOMICS ANALYSIS OF AML-RELATED NUP98-FUSION PROTEIN INTERACTOMES

S. Terlecki-Zaniewicz[1,*], J. Schmöllerl[1], T. Eder[1], K. Parapatics[2], A. Müller[2], F. Grebien[1,3]

[1]Ludwig Boltzmann Institute for Cancer Research, [2]CeMM Research Center for Molecular Medicine, [3]University of Veterinary Medicine, Vienna, Austria

Background: Chromosomal translocations in cancer can result in the production of oncogenic fusion proteins (FPs). In leukemia, a particularly high number of fusion oncogenes has been identified. FPs involving the Nucleoporin 98 (*NUP98*) gene are found in ~2% of acute myeloid leukemia (AML) patients. AML patients with NUP98-rearrangements have a significant worse event-free survival compared to other AML patients and are often refractory to standard treatment. The NUP98 multi-partner translocation family (MPTF) features more than 25 different FPs, all harbouring an N-terminal fragment of the NUP98 gene fused to distinct C-terminal partners. Nup98-fusion proteins can be divided into two major categories. NUP98-homeodomain (HD) fusions link NUP98 to HD-containing transcription factors, including members of the HOXA, HOXC or PMX families. In contrast, non-HD NUP98-fusions contain plant HD (PHD) fingers or Su(var)3-9 Enhancer-of-zeste Trithorax (SET) domains, which are known to act as epigenetic modulators. Most prominently, however, coiled-coil domains are found in almost all non-HD fusion partners. Despite the heterogeneity of this MPTF, previous studies and preliminary data in our laboratory showed that different NUP98-FPs cause similar AML phenotypes in humans and mouse models.
Aims: We postulate that NUP98-FPs share molecular mechanisms that depend on conserved protein-protein interactions to modulate leukemogenic pathways. Thus, we aim to identify critical effector proteins through mass spectrometry (MS)-based profiling of the interactomes of five representative, yet distinct NUP98-fusion proteins.
Methods: Affinity-tagged variants of five selected NUP98-FPs (NUP98-HOXA9, -JARID1A, -DDX10, -NSD1 and -PSIP1) were stably expressed in a Doxycycline (Dox)-inducible fashion in human AML cells. Transgene induction was reported by expression of GFP. Routinely, 70% - 90% GFP+ cells could be detected 24 hours after Dox treatment. Protein complexes were purified from nuclear lysates and their composition was characterized by MS. Lysates from mock-transduced cells were used as negative controls. MS data were analysed using SearchGUI and PeptideShaker to identify the interactomes of NUP98-FPs.
Results: Exogenous NUP98 and known NUP98-binding partners, such as RAE1 and RAN, were highly abundant in all datasets. Upon stringent filtering, NUP98-FP interactomes revealed a network of 296 proteins, of which 103 interacted with three or more NUP98-FP. Functional annotation of conserved NUP98-FP-interactors revealed a significant enrichment for proteins involved in transcriptional regulation. In contrast, no components of the nuclear pore complex (NPC) were found, indicating that NUP98-FPs have active roles in transcriptional control but do not co-localise with the NPC.
Summary and Conclusions: In summary, this study provides the first comprehensive protein interactome of five NUP98-FPs. Together with the future functional investigation of common NUP98-FP interactors, this study will significantly enhance our understanding of the molecular mechanisms of NUP98-FP driven AML.

PF201

THE PNT DOMAIN OF ERG REGULATES HEMATOPOIETIC STEMNESS, YET IS NOT ESSENTIAL FOR ERG INDUCED ACUTE MYELOID LEUKEMIA

E. Kugler[1,*], Y. Birger[1,2], D. Yong[3,4], A. Rein[1], G. Prive[*3,4], S. Izraeli[1,2]

[1]Human Molecular Genetics and Biochemsitry, Tel Aviv University, Tel Aviv, [2]Genes Development and Cancer Childhood Research Institute, Sheba medical center, Ramat Gan, Israel, [3]Department of Biochemistry, University of Toronto, [4]Princess Margaret Cancer Centre, Toronto, Canada

Background: The ETS transcription factor ERG has a key role in hematopoiesis. It is essential for hematopoietic stem cells maintenance and megakaryopoiesis. Increased expression of ERG is associated with poor prognosis in AML. Previous studies by us and others established ERG as an oncogene in human leukemia. The PNT domain of ERG is a conserved domain that in some other ETS factors is required for protein-protein interactions. The PNT domain is deleted in ERG fusion translocations in AML, in ALL with "ERG deletion" and in Ewing Sarcoma but is conserved in prostate cancer. The function of ERG PNT domain is, however, unknown.
Aims: We aimed to establish the role of the PNT domain in ERG leukemogenic pathway.
Methods: Murine fetal liver (FL)-derived-HSPCs transduced with human WT- and deleted PNT (DelPNT) domain ERG were studied for self-renewal and differentiation in methyl cellulose cultures and for transforming ability by in C57B6 mice. To study how the PNT domain affects ERG regulation of gene expression in pre-leukemic and leukemic conditions, we performed RNA sequencing on murine fetal liver-derived-HSPC transduced with ERG variants and on blasts derived from acute myeloid leukemia induced by ERG. To characterize the ERG protein interactome and the role of its PNT, a BioID proximity ligation analysis was conducted on 293T cells transfected with ERG variants.
Results: Re-plating assays in methycellulose has shown that the PNT domain was not essential for HSPC self-renewal. Remarkably, DelPNT-*ERG* transduced cells demonstrated markedly enhanced proliferation capacity with a scattered morphology of very small colonies. Flow cytometry analysis showed decreased expression of hematopoietic stem cell markers (Ckit, Sca1) for DelPNT-ERG transduced cells. Consistent with these findings RNA sequencing demonstrated enrichment of genes associated with myeloid differentiation and loss of hematopoietic stem cell signature in HSPC transduced with DelPNT-*ERG*. Thus, *in-vitro*, the expression of DelPNT-ERG caused marked proliferation of myeloid progenitors. Transduction transplantation assays in C57B6 mice demonstrated that the PNT domain is not essential for leukemia development. However, time to leukemia development was significantly delayed for delPNT-ERG transduced mice (33.1±7.9 and 54.67±17.53 days for WT-ERG *vs* DelPNT ERG respectively, P=0.015). Further analysis of these leukemias by RNA-Sequencing demonstrated that compared with leukemia caused by DelPNT ERG, WT-ERG induced leukemia had higher expression of cell cycle and c-Myc target genes. Interestingly, DelPNT-ERG leukemia demonstrated enhanced fibroblast growth factor signaling as was described before for the ETS related oncogenic fusion, EWS-FLI1, in Ewing Sarcoma where the PNT domain of FLI1 is absent. Bio-ID analysis demonstrated that the PNT domain is essential for ERG association with chromatin remodeling complexes and epigenetic regulators.
Summary and Conclusions: These results suggest that in pre-leukemic con-

ditions, the PNT domain have a role in maintaining the stem cell phenotype associated with ERG and prevention of premature differentiation possibly through regulation of chromatin structure and accessibility. It may also be necessary for the suppression of HSC proliferation. In its absence, HSC differentiate to highly proliferative myeloid precursors that can cause leukemia as is for example in AML caused by the FUS-ERG translocation that lacks the PNT domain.

PF202

FUNCTIONAL ANALYSIS OF EPIGENETIC AND TRANSCRIPTOMIC EFFECTS OF CEBPA MUTATIONS IN ACUTE MYELOID LEUKEMIA

E. Heyes[1,*], L. Schmidt[1], T. Eder[1], G. Volpe[2], C. Nerlov[3], J. Frampton[2], F. Grebien[14]

[1]Ludwig Boltzmann Institute for Cancer Research, Vienna, Austria, [2]Institute of Cancer and Genomic Sciences, College of Medical and Dental Sciences, University of Birmingham, Birmingham, [3]MRC Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom, [4]Institute for Medical Biochemistry, University of Veterinary Medicine, Vienna, Austria

Background: The transcription factor CCAAT-enhancer-binding protein alpha (C/EBPα) is a master regulator of granulopoiesis and regulates the switch between proliferating, uncommitted progenitors and cell-cycle-arrested, differentiated myeloid cells. Usage of two alternative translation initiation sites in the *CEBPA* mRNA results in expression of a full-length C/EBPα protein p42 (42 kDa) and a shorter p30 isoform (30 kDa). *CEBPA* is mutated in 9% of adult patients with Acute Myeloid Leukemia (AML). The most predominant type of mutations represents N-terminal frameshifts, and patients harboring monoallelic N-terminal *CEBPA* mutations exhibit low overall survival rates. *CEBPA* N-terminal mutations ablate the expression of p42 and result in exclusive expression of p30, but the molecular mechanisms underlying the oncogenic effect of C/EBPα p30 are largely unknown.
Aims: We aim to understand the molecular mechanisms of C/EBPα p30-specific effects on gene expression and chromatin modulation to elucidate the role of C/EBPα p30 in oncogenic transformation.
Methods: We generated myeloid progenitor cell lines from a mouse model of C/EBPα N-terminal AML, which exclusively expresses the p30 variant of C/EBPα (*Cebpa*$^{p30/p30}$ genotype). We developed an inducible RNAi system in this cell line model to investigate the global genomic and transcriptomic effects upon C/EBPα p30 knockdown (KD). Using this model, we mapped C/EBPα p30 binding sites and promoter and enhancer regions via C/EBPα and H3K27ac ChIP-Seq, respectively. In addition, we performed RNA-Seq analysis to characterize C/EBPα p30-dependent transcriptomic programs and ATAC-Seq to profile the global landscape of accessible chromatin in *Cebpa*$^{p30/p30}$ cells.
Results: Analysis of RNA-Seq data showed that C/EBPα p30 is required for the regulation of pathways involved in proliferation and self-renewal. p30-down-regulation caused significant changes of global gene expression programs, with 2103 genes down- and 1985 genes up-regulated upon p30 KD. In particular, KD of p30 led to up-regulation of gene expression programs associated with myeloid differentiation. This effect was confirmed by increased surface expression of differentiation markers, such as Mac-1. Analysis of C/EBPα ChIP-Seq data revealed genome binding of p30 in the proximity of 43% of all genes that were differentially expressed upon p30 KD. Furthermore, we found that 28% of p30-bound regions were located in promoter regions, while 35% of p30-bound regions localized to distal intergenic regions, implicating the involvement of p30 in regulation of the enhancer landscape.
Summary and Conclusions: In summary, we have created a robust dataset for a global analysis of C/EBPα p30-dependent effects on the epigenomic and transcriptomic landscape in *CEBPA* N-terminal mutant AML. Detailed integrative bioinformatics analysis will enable the identification of specific genomic regions essential for p30-mediated leukemogenesis. This will contribute to a comprehensive understanding of the role of p30 in AML development and provide starting points for the development of novel treatments.

PF203

DETECTION OF MEASURABLE RESIDUAL DISEASE (MRD) BY ULTRADEEP NEXT GENERATION SEQUENCING (NGS) IS HIGHLY PREDICTIVE OF OUTCOME IN NPM1 MUTATED ACUTE MYELOID LEUKEMIA (AML)

N. Patkar[1,*], R. Kodgule[1], C. Kakirde[1], G. Raval[1], P. Bhanshe[1], Y. Badrinath[1], S. Ghoghale[1], S. Kadechkar[1], S.H. Khizer[2], S. Kannan[3], D. Shetty[4], A. Gokarn[2], S. Punatkar[2], H. Jain[2], B. Bagal[2], H. Menon[5], M. Sengar[2], N. Khattry[2], P. Tembhare[1], P. Subramanian[1], S. Gujral[1]

[1]Haematopathology, [2]Adult Haematolymphoid Disease Management Group, [3]Biostatistics, [4]Cytogenetics, Tata Memorial Center, Navi Mumbai, [5]Haemato-Oncology, Cytecare Cancer Hospitals, Bangalore, India

Background: Serial monitoring of *NPM1* mutations from the blood or bone marrow using mutation specific assays during chemotherapy of AML with mutated *NPM1* (*NPM1*mut AML) has been shown to be highly predictive of relapse. DNA based NGS is a promising scalable solution that has the potential to detect MRD in AML. We demonstrate that ultradeep NGS based MRD (NGS-MRD) is independently predictive of outcome for *NPM1*mut AML.
Aims: To evaluate the clinical relevance of highly sensitive NGS-MRD in NPM1 mutated AML
Methods: A total of 83 patients of *NPM1*mut AML were diagnosed over a 5-year period from October 2012 to May 2017. These patients were treated with standard 3+7 induction followed by high dose cytarabine. MRD was assessed at the end of induction (PI) from the bone marrow (BM) and the end of consolidation (PC) using BM or blood. FCM-MRD was performed using 10 colour MRD assay using a combination of difference from normal and leukemia associated immunophenotype (LAIP) based approaches. Exon 12 of NPM1 (DNA) was amplified using adapter tagged primers and a dual indexed strategy. The library was sequenced at more than 500,000x coverage to have a sensitivity of 0.001%. Based on receiver operating characteristic (ROC) and Youden analysis, we used a 1 log cut-off between paired PI and PC MRD samples to classify patients as NGS MRD positive or negative. Overall survival (OS) and relapse free survival (RFS) were calculated as per standard recommendations. FCM and NGS-MRD were factored against OS and RFS using log-rank test and displayed using the Kaplan-Meier technique. Multivariate analysis was performed for PI FCM-MRD, NGS-MRD and *FLT3*-ITD at diagnosis using cox proportional hazards regression.
Results: The median RFS and OS were 19.4 & 20.6 months respectively (median follow-up 23.5 months). We could detect and monitor 12 different types of *NPM1* mutations of which type A mutation was the commonest (69.6%). FCM-MRD could be detected in 31.7% of PI and 24.4% of PC samples. Presence of FCM-MRD at end of induction was predictive of inferior OS (p=0.006) and RFS (p=0.0098). NPM1 NGS-MRD positive patients were significantly associated with inferior OS and RFS (p=0.0009 and p<0.0001 respectively). Multivariate analysis was performed when factoring for *NPM1* NGS-MRD, FCM-MRD (PI) and *FLT3*-ITD. When factored for OS (p=0. 0018, HR:3.88[95%CI:1.66-9.04]) & RFS (p=0.0001, HR:4.9[95%CI:2.28-10.58]), NGS-MRD emerged as the most significant independent prognostic factor with a rising trend predictive of poor outcome. FCM-MRD showed a tendency to predict poor survival when factored for OS (p=0.05, HR:2.38[95%CI:1.02-5.55]) and was significantly associated with inferior outcome when factored for RFS (p=0.016, HR:2.59[95%CI:1.2-5.59]). We further analysed the impact of *NPM1* NGS-MRD in patients who were FCM-MRD negative at either time points. We detected that FCM-MRD negative group (PI &/or PC) was dichotomized by *NPM1* NGS-MRD and patients who were NGS-MRD positive had a significantly worse OS (p=0.0014) and RFS(p<0.0001) as compared to those patients who were NGS-MRD negative. Patients who were negative by both MRD assays had a significantly improved OS & RFS as compared to the rest (p=0.0014 & p=0.0001 respectively) (Figure 1).

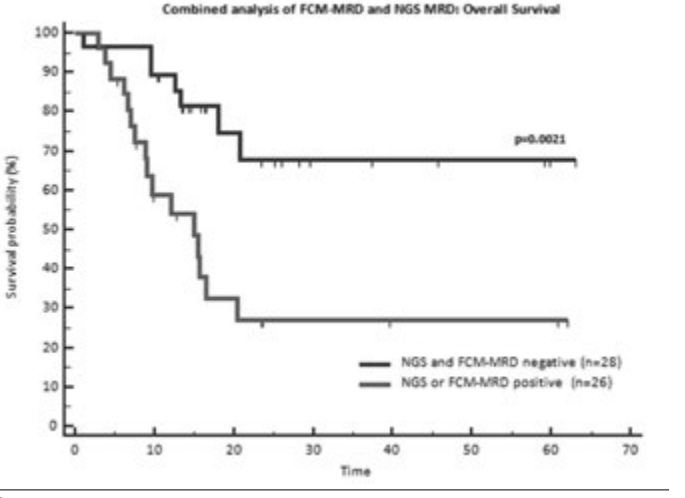

Figure 1.

Summary and Conclusions: We establish that DNA based *NPM1* NGS MRD is a highly useful test for prediction of relapse and survival in *NPM1*mut

AML. FCM and NGS-MRD for *NPM1*mut AML may be complementary in nature with patients who are negative for both FCM-MRD and NGS-MRD having excellent outcome.

PF204

PREFERENTIAL *IN VITRO* AND *IN VIVO* INDUCTION OF ENDOGENOUS RETROVIRUS TRANSCRIPTION FROM A MONOALLELIC CHROMOSOME 7Q IN DECITABINE (DAC) TREATED AML BLASTS

G. Greve[1,*], S. Bengel[1], D. Pfeifer[1], M. Lübbert[1]

[1]Hematology, Oncology and SCT, University of Freiburg Medical Center, Freiburg, Germany

Background: DNMT inhibitors (DNMTi) show an encouraging but not yet well-understood activity in AML patients (pts) with adverse cytogenetics, such as -7/7q-, (Lübbert *et al.*, Haematologica 2012). Integrative methylome/transcriptome studies have provided evidence for aberrant hypermethylation/silencing on monoallelic gene loci, including tumor suppressor genes (TSGs, Kotini *et al.*, Nat. Biotechnol. 2015). Recently, an alternative mechanism of DNMTi action was described (Roulois *et al.*, Chiappinelli et. al, Cell 2015): induction of silenced endogenous retroviral (ERV) dsRNA transcription, resulting in activation of an interferon-mediated, antitumor immune response ("viral mimicry").
Aims: We hypothesized that in AML haploinsufficient for 7q, transcriptional repression of monoallelic genes in this region may be preferentially reversed by DNMTi treatment.
Methods: The two AML cell lines ELF-153 (ELF, loss of 7p) and UCSD-AML1 (AML1, monosomy 7) were treated with DAC at equitoxic concentrations for 4 days, harvested on day 5. cDNA libraries (rRNA-depleted) were sequenced with 30 million paired-end reads, alignment to the reference genome was performed with TopHat2, read-counting with HTseq, differential expression testing with DESeq2. Selected target genes were validated by RT-qPCR. PBMCs were collected from 9 AML pts (5 pts with 7q-, 4 cytogenetically normal [CN] pts) treated with DAC (i.v. 20 mg/m^2 for 5 days) within the DECIDER trial (NCT00867672). Leukemic blasts at day 0 and day 8 were isolated using autoMACS with anti-human CD34 and CD117 microbeads. RNA-seq of these patients was performed with 60 million paired-end reads and analyzed as described for the cell lines.
Results: DAC treatment of AML1 and ELF cells resulted in massive transcriptome changes in both cell lines. Comparing DAC-induced expression changes only of genes on 7q, we identified 43 genes significantly differentially expressed only in AML1 cells, 24 only in ELF, and 19 in both. Among the genes on 7q that were selectively upregulated in AML1 were 3 with TSG features: *ZYX* (6.0-fold up), *HIPK2* (3.8-fold up), and *HBP1 (*3.1-fold up). However, the most heavily upregulated transcripts in AML1 were the endogenous retrovirus *ERV3-1* (86.4-fold up in AML1 *vs* 14.3-fold in ELF) and the neighboring *ZNF117 (*119.4-fold up in AML1 *vs* 6.5-fold in ELF). *ERV3-1* induction was accompanied by induction of the interferon response genes *RIG-I* and *IRF7* in both cell lines. Therefore, we next interrogated induction of these genes by DAC *in vivo*, utilizing sorted, matched primary AML blasts. Stronger induction of *ERV3-1* and *RIG-I* mRNA was seen in the 7q- pts compared to the CN pts: By qRT-PCR, median *ERV3-1* and *RIG-I* expression was induced 1.5- and 1.4-fold in the pts with 7q-, respectively, and 1.1- and 0.7-fold, respectively, in the CN pts. RNA-seq confirmed distinct expression changes after DAC treatment in 7q- and CN patients with 407 and 419 uniquely regulated transcripts, respectively, and only a small overlap of 22 transcripts.
Summary and Conclusions: We successfully developed an unbiased RNA-seq approach of AML cell lines either mono- or bi-allelic for 7q, demonstrating that DAC treatment preferential upregulates several monoallelic TSGs, and massively activates the *ERV3-1* gene. Induction of ERV3-1 and the dsRNA sensor RIG-I was validated *in vivo,* and preferentially seen in 7q- AML purified primary blasts. Thus, under clinically established treatment conditions, both the ERV and an interferon response gene can be activated by DAC, supporting a combination with immunotherapy.

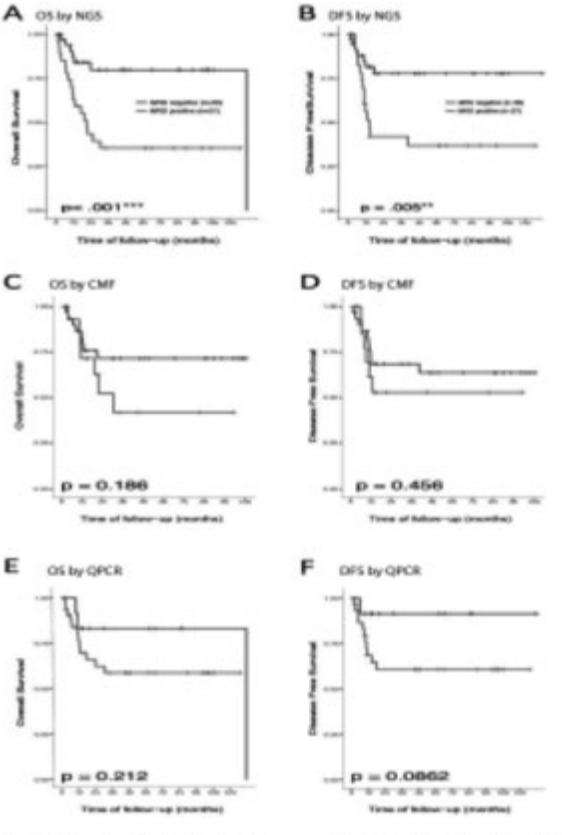
PF205

NOVEL DEEP TARGETED SEQUENCING METHOD FOR MINIMAL RESIDUAL DISEASE MONITORING IN ACUTE MYELOID LEUKEMIA

E. Onecha De La Fuente[1,*], M. Linares[1], I. Rapado[1], Y. Ruiz[1], J. Perez-Oteyza[2], P. Herrera[3], E. Barragan[4], P. Montesinos[4], J. Nomdedeu[5], M. Gallardo[1], J. Martinez-Lopez[6], R. Ayala[7]

[1]Haematological Malignancies Clinical Research Unit, H12O-CNIO, CNIO, [2]Hospital Universitario Sanchinarro,, [3]Hospital Universitario Ramon y Cajal,, Madrid, [4]Hospital Universitario La Fe, Valencia, [5]Hospital Santa Creu i Sant Pau, Barcelona, [6]Hospital Universitario 12 de Octubre,, [7]Hospital Universitario 12 de Octubre, Madrid, Spain

Background: A high percent of AML patients who achieved MRD negative status eventually relapses due a fraction of pathological clones remains undetectable by standard methods, multiparameter flow cytometry (MFC) and q-PCR, suggesting the need to improve MRD evaluation techniques.
Aims: Simplifies and standardizes MRD evaluation, with high applicability in AML, thought developing of NGS-based method.
Methods: DNA from 190 AML patients with *de novo* or secondary non-M3 AML was analyzed at diagnosis using a custom next-generation sequencing (NGS) AML panel; in addition, NPM1 was analyzed by quantitative (q)-PCR (n=233). Predictive value of MRD status by NGS, MFC, or q-PCR was determined by survival analysis.Patients were treated according to *PETHEMA* (Programa Español de Tratamientos en Hematología) or *CETLAM* (Grupo cooperativo de Estudio y Tratamiento de Leucemias Agudas y Mielodisplasias) protocols. We performed a new selection for retrospective MRD assessment using the following criteria: presence of the NPM1 type A mutation, or SNVs in FLT3, IDH1 and/or IDH2 at diagnosis, and availability of at least one follow-up genomic (g)-DNA sample. Thus, 51 (48%) follow-up samples were taken at post-induction and 55 (52%) at post-consolidation corresponding to 63 patients diagnosed between 2006 and 2016 were studied. All patients achieved CR by cytomorphological criteria after induction therapy (<5% of bone marrow blasts). Median follow-up was 73 days (range 20-596).



Analysis of OS and DFS in AML patients stratified according to MRD levels by NGS, CMF or qPCR. Kaplan-Meier plots of (A) OS and (B) DFS with respect to MRD analysis, using NGS method (A and B respectively); using MFC method (C and D respectively) and using qPCR method (E and F respectively). Only NGS method revealed better significant OS and DFS.

Figure 1.

Results: We designed and optimized a new high-throughput sequencing method for MRD assessment, measuring levels mutated clonotypes of NPM1, IDH1/2 or FLT3-SNV. The NGS-MRD workflow included one first study at diagnosis and a second study at follow-up. NGS results was contrasted with digital PCR (dPCR), for NPM1 (R2=0.98); and IDH1 or IDH2 from commercial standard (R2=0.91, R2=0.98, respectively). Clinical validation was perfomed in 2 steps. First: Study mutational profile of AML patients at diagnosis by a custom NSG AML panel of 32 genes (n=190), plus NPM1 by q-PCR and FLT3-ITD by GENESCAN (n=233). Second: Choose the best markers to follow-up the outcome of the patient

(n=106).The method achieved an applicability of 92% of AML patients and the sensitivity equates to one mutated cell per millon cells (LOQ 10-6) for InDels and one mutated cell per 10,000 cells (LOQ 10-4) for SNVs. Survival analysis showed that positive MRD status (patients with MRD levels >0.035%) was associated with a higher risks of death (37% *vs* 81%; HR:4.2; 95%CI:1.6-10.7; p<0.001) and relapse (48% *vs* 81%; HR:3.4; 95%CI:1.4-8.5; p=0.005). Multivariate analysis showed that MRD-positive status by NGS was an independent factor associated with risk of death (HR 3.91, P=0.030) and the only independent factor conferring risk of relapse (HR 4.37, P=0.015). It also improves upon MFC and q-PCR to predict AML outcome. There were not significant differences between positive and negative MRD groups of patients tested by MFC for OS (p=0.193) nor for DFS (p=0.117) (Figure 1).

Summary and Conclusions: We designed and validated a high-throughput sequencing method for MRD assessment of cell clonotypes with mutations of NPM1, IDH1/2 and/or FLT3 single nucleotide variants (SNVs). Simplifies and standardizes experimental process of MRD evaluation. MRD status measured by NGS offers prognostic clinical information and improves the power to predict AML outcome during therapy, in regard to currents techniques, MFC or q-PCR., could be incorporated in clinical settings and clinical trials.

PF206

A SYSTEMATIC EVALUATION OF PROGNOSTIC GENE EXPRESSION SIGNATURES IN 1208 ACUTE MYELOID LEUKEMIA PATIENTS REVEALS NOVEL INSIGHTS FOR FUTURE RESEARCH AND CLINICAL APPLICATION

D. Beck[1,*], A. Braytee[1], Y. Huang[1], M. Sauerland[2], S. Bohlander[3], J. Braess[4], B. Wörmann[5], W. Berdel[6], W. Hiddemann[7], K. Metzeler[8], T. Herold[7], J. Pimanda[9]

[1]Centre for Health Technologies and Lowy Cancer Centre, UTS Australia and UNSW Australia, Sydeny, Australia, [2]Institute of Biostatistics and Clinical Research, University of Muenster, Muenster, Germany, [3]University of Auckland, Auckland, New Zealand, [4]Krankenhaus Barmherzige Brüder, Regensburg, [5]Department of Medicine, Hematology, Oncology, Universitätsmedizin Berlin, Berlin, [6]Department of Medicine, Hematology and Oncology, University of Münster, Münster, [7]Department of Internal Medicine III, University Hospital Grosshadern, Munich, [8]Medizinische Klinik und Poliklinik III, Ludwig-Maximilians-Universität München, München, Germany, [9]UNSW Australia, Sydeny, Australia

Background: Prognostic gene expression signatures (pGES) have been proposed as tools to assess risk and to therapeutic options for patients with acute myeloid leukaemia (AML). However, given uncertainties about the relationship of pGES to underlying cell biology, and difficulties generalising their utility across patient populations, none have been routinely adopted in clinical trial design or practise.

Aims: We investigated 7 pGES accorss 4 independent patient cohorts.

Methods: We implemented pGES proposed by Marcucci-7, Ng-17, Li-24, Eppert-LSCR-48, Metzeler-86, Eppert-HSCR-105, Bullinger-133. We compared the identities of these pGES at the gene and pathway level and profiled their expression across 7 healthy hematopoietic stem and progenitor cell (HSPC) subtypes. Prognostic significance was evaluated in 1208 intensively treated patients from the Netherlands (HOVON), Germany (AMLCG) and United States of America (TCGA) using univariate the Kaplan-Meier estimator and Cox-regression (age, gender, white blood cell count).

Results: A comparison of the gene identities revealed that there were no common genes or enriched leukaemia associated pathways across the 7 pGES. Surprisingly, only 27/327 genes were members of at least 2 to 4 pGES (1, 8, 18 genes in 4, 3 and 2 pGES, respectively) and only 14/64 leukaemia associated pathways were enriched in at least two to four pGES (2, 5, 7 pathways in 4, 3 and 2 pGES, respectively). Similarly, interrogation of 7 HSPC populations revealed no common association with specific cell types. Interrogation of the 7 pGES across 4 independent cohorts of intensively treated patients revealed that the majority of pGES were associated with overall survival (OS) in univariate and multivariate models (Figure 1A). These included 6/7, 4/7, 5/7 and 3/7 pGES in univariate and 6/7, 4/7, 5/7 and 4/7 pGES in multivariate models when applied to the HOVON, TCGA, AMLCG-1999 and AMLCG-2008 cohorts, respectively. However, there was little agreement whether a particular patient was classified as favourable or adverse risk using the 7 pGES (Figure 1B). In the HOVON cohort, we found that 43/519 patients were classified to identical risk-groups by all 7 pGES (high consensus, CH), 189/519 and 143/519 patients were classified into the same risk-group by six and five pGES (intermediate consensus 1 and 2, CI-1 and CI-2). However, 144/512 patients were classified to opposing risk-groups by 3/4 pGES (low consensus, CL; Figure 1C). An independent re-analysis of patients in CH and CL revealed that those with CH were dichotomised into favourable or unfavourable risk-groups with significantly higher patient-consensus (Figure 1D) by twice as many pGES (Figure 1E). Interestingly, patients with CH and CL had overlapping clinical characteristics but could be distinguished based on the expression of 17 genes (Figure 1F). Therefore, we developed a 17-gene linear classifier to stratify the 43 patients with CH and 144 patients with CL (HOVON). Applied to two independent cohorts, we were able to classify 69 and 101 patients as CH, 70 and 33 patients as CL (AMLCG-2008 and TCGA, respectively). Strikingly, for patients in CH, 5/7 and 6/7 pGES and for patients with CL 1/7 pGES and 0/7 pGES were associated with patient-overall survival (Figure 1G).

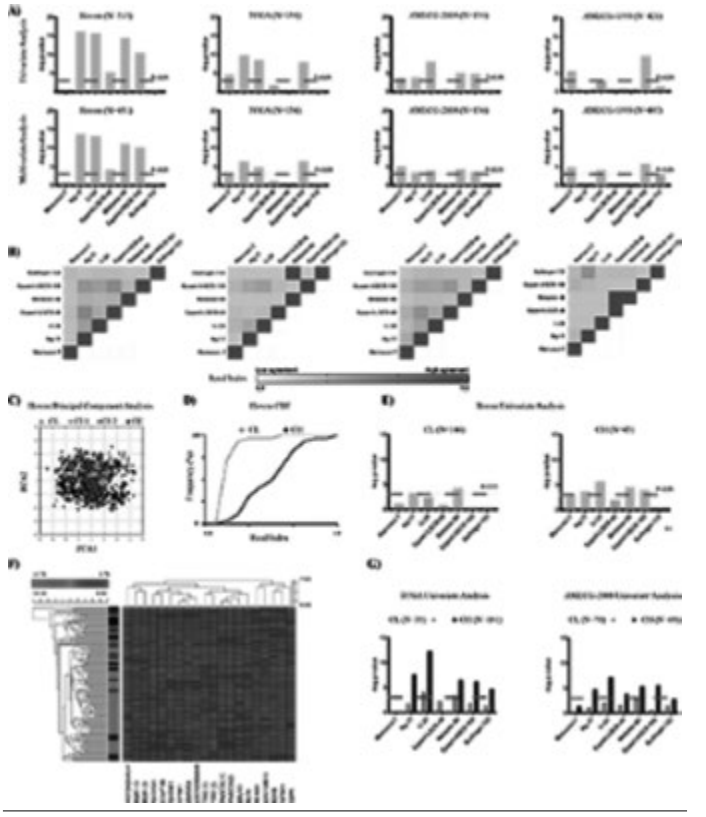


Figure 1.

Summary and Conclusions: For a subset of patients, most pGES were prognostic for overall survival despite any overt biological relationship of their constitutent genes. Importantly, these patients (30%) can be identified prospectively using a classifier of 17 genes.

PF207

AN ARTIFICIAL NEURAL NETWORK-BASED APPROACH IDENTIFIES A POWERFUL 3-GENE PREDICTOR OF ADVERSE PROGNOSIS IN ACUTE MYELOID LEUKAEMIA

S. Wagner[1,*], G. Ball[1], S. Rutella[1]

[1]John van Geest Cancer Research Centre, Nottingham Trent University, Nottingham, United Kingdom

Background: Acute myeloid leukaemia (AML) is a clonal disorder of haematopoietic stem cells with a high degree of molecular complexity. Prognosis is currently determined by response to induction chemotherapy and by cytogenetic risk features. There is an urgent need to discover better biomarkers to enable testing of investigational therapeutic strategies in clinical trials, especially for patients with high-risk AML.

Aims: We applied an artificial neural network (ANN)-based integrative data mining approach to the analysis of transcriptomic data from four cohorts of patients with newly diagnosed AML. ANNs, unlike conventional statistical approaches, are not limited by linear functionality and allow for improved representation of biological features. We compared the ranked orders of genes identified across a clinical class question (overall survival [OS] for the study period) within a given dataset.

Methods: Data sets were retrieved from publicly available sources and included a discovery AML cohort (E-MTAB-3444; n=641 patients) and three validation AML cohorts, namely, The Cancer Genome Atlas (n=145), cytogenetically normal AMLs (n=79; GSE12417) and TARGET-AML

(n=142 children with AML).
Results: ANN analysis identified the top 10 ranked genes associated with survival in the discovery AML cohort. Using Cox regression analysis, 3 genes were further investigated as they featured prominently, namely, calcitonin receptor-like receptor (*CALCRL*; a receptor for adrenomedullin), *CD109* (TGF-b co-receptor) and Leukocyte-Specific Protein 1 (*LSP1*; a gatekeeper of leukocyte trans-endothelial migration). *CALCRL*, *CD109* and *LSP1* transcript expression levels (dichotomised as median) could individually discriminate patients with longer and shorter OS (2.61 *vs* 1 year, p<0.001; 2.95 *vs* 1.01y, p<0.001; and 3.28 *vs* 1y, p<0.001, respectively). A prognostic index (PI) was then generated using b-values from Cox regression analyses together with min-max normalised gene expression levels according to the formula: (1.670×*CALCRL*)+(1.006×*LSP1*)+(0.844×*CD109*). Patients with a PI between 0 and 1 were considered to be low-risk (LR) whereas patients with a PI between 1 and 1.4 and patients with a PI >1.4 were considered to be intermediate-risk (IR) and high-risk (HR), respectively. Patients in the HR group had unfavourable cytogenetic features more often than patients in the IR and LR group. Median OS was 4.75y, 1.57y and 0.77y in LR, IR and HR patients, respectively (p<0.001). Patients in the HR group had a significantly shorter OS irrespective of their *FLT3*-ITD status, suggesting that our 3-gene PI could outperform conventional molecular prognosticators. Also, a low-risk PI identified a subgroup of *NPM1*-mutated patients and *KMT2A*-nonrearranged patients with particularly favourable clinical outcome compared with *NPM1*-mutated and *KMT2A*-rearranged patients assigned to the IR+HR score (58% *vs* 38% OS, and 50% *vs* 22% OS, respectively; p=0.0078). The clinical validity of the 3-gene PI was confirmed across the other adult AML data sets. Interestingly, 142 out of 145 childhood cases in TARGET-AML were assigned to the LR group based on the expression levels of *CALCRL*, *CD109* and *LSP1*.
Summary and Conclusions: Our 3-gene PI accurately stratifies adult patients with AML into risk categories with different OS probabilities. The functional implications of the age-related heterogeneity in *CALCRL*, *CD109* and *LSP1* expression in the AML microenvironment, and whether these surface molecules could be therapeutically targeted, remain to be determined.

PF208

PROFILING AND FUNCTIONAL ANALYSIS OF CIRCULAR RNAS IN ACUTE PROMYELOCYTIC LEUKEMIA AND THEIR DYNAMIC REGULATION DURING ALL-TRANS RETINOIC ACID TREATMENT

S. Li[1,*], Y. Ma[1], K. Wang[1]

[1]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Circular RNAs (circRNAs) are a novel class of powerful regulators in gene expression and participate in the pathogenesis of disease, including cancer. However, little is known about the roles of circRNAs in the development and treatment of acute promyelocytic leukemia (APL).
Aims: We aimed to examine the expression profiling of circRNAs in APL, including their dynamic regulation during all-*trans* retinoic acid (ATRA)-induced differentiation. Additionally, we wanted to explore the impact and mechanism of circ-HIPK2, one circRNA that was most up-regulated during ATRA-induced APL cell differentiation, in regulating APL cell function.
Methods: Three ribo-minus RNA-seq libraries (*i.e.* untreated NB4 cells, NB4 cells treated with ATRA for 24 hours, NB4 cells treated with ATRA for 48 hours) were prepared with Ribo-Zero Globin kit and sequenced on the Illumina HiSeq 2500 platform with 2x125 bp paired-end reads. STAR and DCC were used to detect circRNAs, and TopHat2 and Cufflinks were employed to calculate the FPKM value of each host gene. Cell growth and granulocytic differentiation of the NB4 cells were detected after circHIPK2 knockdown. MicroRNA sponging potential of circHIPK2 were predicted and determined by luciferase assay.
Results: We identified a total of 4,620 circRNAs, of which 1,430 were newly identified. Detailed analysis showed that circRNAs expressed in APL cells were mostly exon-derived, not by-products during splicing and could be distinguished from hematopoietic stem cells, neutrophils and lymphocytes. The true presence and stability of circRNAs were verified both in NB4 cells and primary APL patient samples. The time-series analysis of circRNAs on ATRA-treated NB4 cells demonstrated that 196 up-regulated and 138 down-regulated circRNAs were identified at 24 hours of ATRA treatment, and 188 up-regulated and 138 down-regulated circRNAs were identified at 48 hours of ATRA treatment. Among these, 95 circRNAs were constantly up-regulated and 60 were constantly down-regulated at both time points of ATRA treatment. Further evidence demonstrated that the majority of circRNAs were regulated independently of their host linear mRNAs. Specific knockdown of one of differentially expressed circRNAs, circ-HIPK2, significantly reduced ATRA-induced differentiation of APL cells, indicating that circ-HIPK2 was indispensable for the differentiation of APL. Finally, the mechanistic study revealed that circ-HIPK2 was located in cytoplasm and served as a sponge for miR-124-3p that regulates CEBPA, thereby contributing to the differentiation process of APL cells.
Summary and Conclusions: Our study identified a large number of dynamically regulated circRNAs during ATRA-induced APL cell differentiation, thus providing an important basis for further studies addressing their function and suitability as biomarkers. Moreover, we determined the biological function and mechanisms of circ-HIPK2 in the regulation of APL differentiation. Further investigation is warranted to uncover more circRNAs that participate in APL occurrence and development.

PF209

PML-RARA INTERACTS WITH NRF2, INHIBITS ITS ACTIVITY AND INCREASES THE SENSITIVITY OF ACUTE PROMYELOCITIC LEUKEMIA CELLS TO ASCORBATE

N.I. Noguera[1,2,*], G. Catalano[2], S. Travaglini[2], C. Banella[1,2], M. T. Voso[2], F. Lo Coco[1,2]

[1]Neuro-Oncohematology, Santa Lucia Foundation, [2]Biomedicine and Prevention, Tor Vergata University, Roma, Italy

Background: Nrf2 is a leucine zipper transcription factor that regulates the expression of antioxidant proteins and protects the cells against oxidative damage triggered by injury and inflammation. Nrf2 activity is controlled through a complex network that ensures its increase during redox perturbation, inflammation, growth factor stimulation and nutrient/energy fluxes. We previously showed that high doses of ascorbic acid (ASC) selectively kill leukemic cells from APL patients.
Aims: Since APL blasts are more sensitive to oxidant treatment than other AML blasts, we aimed to study the effect of PML-RARA on the cellular redox activity, in relation to Nrf2 function.
Methods: We studied primary blasts from APL, AML and normal bone marrow (NBM) patients, PR9 cells, which derive from U937 cells and are PML-RARA-inducible. By RQ-PCR and Western Blot (WB) we assessed the expression of Nrf2 and its effectors: heme-oxigenase 1 (HO-1), NQO-1 and AKR1C1 enzymes. Co-immunoprecipitation experiments, CHIP assay, confocal microscopy. MTS viability test were performed on PR9 cells after PML/RARa induction and ASC at 1mM treatment.
Results: We observed that Nrf2 protein is lower in APL cells as compared to other AML subtypes and that decreased expression is largely due to protein life span reduction, since expression at mRNA level is almost the same. Nrf2 effectors are as well down regulated (Table 1). In PR9 cells protein half-life was indeed reduced in the presence of PML/RARA (residual 15% at 1 hr and 6% at 3 hrs *versus* 58% and 48% in control cells (P=0.005). In untreated cells localization of Nrf2 protein was prevalent in the nucleus, in PML-NBs (confocal microcscopy). Eight hours following PML/RARA expression, coincident with PML NBs disruption, Nrf2 was exported to the cytoplasm and its nuclear function was abrogated, as indicated by the down regulation of HO-1 expression (PR9 cells+Zn: 1.8±0.6, *vs* Mock+Zn: 42.6±3.6 at 6 hours p=0.003). WB analysis confirmed that NRF2 protein was mainly nuclear in control cells, while mainly cytoplasmic after PML/RARA induction (p= 0.02). Co-immunoprecipitation experiments showed that NRF2 physically interacts with the PML/RARA protein. Using CHIP analysis we demonstrated that PML/RARA inhibits Nrf2 binding to antioxidant response elemente (ARE) sites on target genes. By MTS in the same system we showed that sensitivity to ASC significantly increased upon PML/RARA expression (p=0.003). HO-1 protein expression does not increase in the presence of PML/RARa upon ASC treatment, as does in control cells.

Table 1. Expression levels of Nrf-2 and its target genes.

	APL(n=15)	AML(n=12)	NBM(n=5)	p(APL vs AML)
Nrf-2	0.12 ± 0.1	0.24 ± 0.2	0.03 ± 0.01	n.s
HO-1	1.7 ± 1.8	30.6 ± 30.2	1,6 ±1.8	0.0007
NQO-1	10.5 ± 9.8	44.0 ± 46.0	1.1 ± 0.5	0.0016
AKR1C-1	0.25 ± 0.37	0.9 ± 1.8	1.0 ± 0.3	0.005

NBM: normal bone marrow; n.s.: no significative

Summary and Conclusions: Our data disclose a novel regulatory effect of the PML/RARA oncoprotein on Nrf2 function. Actually, following PML/RARA expression and NBs disruption, Nrf2 protein is clearly exported to the cytoplasm thereby deregulating cellular metabolism. In these conditions ASC treatment directly targets the cellular metabiolic abasement and causes an unredeemable stress leading to apoptosis.

PF210

A POSSIBLE FIRST TIER SCREENING TEST TO DETECT TRANSLOCATIONS IN LEUKEMIAS USING TARGETED LOCUS AMPLIFICATION

E. Van Den Berg[1,*], M.Z. Alimohamed[1], L.F. Johansson[1,2], E.N. de Boer[1], E. Splinter[3], P. Klous[3], A. Bosga[1], M. van Min[3], A.B. Mulder[4], E. Vellenga[5], R.J. Sinke[1], R.H. Sijmons[1], B. Sikkema-Raddatz[1]

[1]Genetics, [2]Genomics Coordination Center, UMCG, Groningen, [3]Cergentis BV, Utrecht, [4]Laboratory Medicine, [5]Hematology, UMCG, Groningen, Netherlands

Background: Patients with acute leukemias carry a wide range of chromosomal abnormalities, which affect their prognosis and treatment options. Currently, over 500 different translocations are reported to be involved in the disease progression. Traditional methods to detect chromosomal abnormalities involve a combination of techniques such as karyotyping, FISH, and RT-PCR. However, these methods are laborious and at times inadequate. Targeted Locus Amplification (TLA), a targeted next generation sequencing technology, can overcome these shortcomings and allows the translocation partner of a specific gene to be detected, regardless of its chromosomal origin. It is based on proximity ligation (crosslinking) of DNA and outward oriented probes for enrichment and can therefore identify chromosomal translocation partners regardless of their identities.
Aims: We aimed to develop a TLA assay as a first-tier screening test to detect translocations in acute leukemia. Here we present a comprehensive, multiplex gene panel designed to cover 17 common genes involved in acute leukemias and known to be associated with hundreds of fusion gene partners. In this proof of principle study, we compared the clinical utility of targeted translocation detection using our acute leukemia NGS gene panel with the results from current genetic diagnostic tests in a series of patient bone marrow samples.
Methods: For the panel we selected 17 genes known to be involved in many translocations present in acute leukemias. Procedures were optimized using a training set of cell line dilutions and 17 leukemia patient bone marrow samples and were then validated using a test set of cell line dilutions and bone marrow samples from a further 19 patients. Per gene we determined if its region was involved in a translocation and if so, the translocation partner. Benchmarking was performed using results from three standard diagnostic tests. A multiplex TLA panel was designed using primer sets covering known break-point regions of the 17 selected genes involved in acute leukemia's. Also, TLA was performed on five different cell lines carrying translocations detectable by our panel. [t(12;21), t(6;11), t(11;19)t(8;13), t(6;9), t(17;19)]. Various combinations of cell line mixtures in multiple dilution series were used to determine the specificity and sensitivity of the panel, and to set sample quality thresholds during analysis. Samples were processed using standard TLA protocol (de Vree *et al*., 2014). Targets were enriched by PCR amplification with the multiplex panel and subjected for sequencing on Illumina Nextseq 500. To facilitate an easy analysis workflow a semi-automated data analysis was developed.
Results: We achieved a concordance with benchmarking tests of 81% in the training set and 100% in the test set. In our sample cohort we obtained 100% specificity, with no false positives. In cell line dilution series translocations could be detected in as few as 10% aberrant cells with no false positives as no translocations other than expected for cell lines were detected.
Summary and Conclusions: This multiplex TLA proof of principle study shows promising results to be suitable as a first-tier screening test not only in acute leukemia, but also CML and lymhoma. It offers a competitive option for screening of unknown and cryptic translocations involvoing the selected genes, without prior knowledge of their translocation partners. Further optimization may make the assay suitable for diagnostic use.

PF211

FUNCTIONAL EVALUATION AND MECHANISM RESEARCH OF KEL AND CIRC-KEL IN AEL

H. Jin[1,*], H. Sun[2], Z. Sun[1], Z. Wu[1], J. Li[1]

[1]Department of Hematology, The First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, [2]Department of Oncology Surgery, Nanjing First Hospital, Nanjing Medical University, Nanjing, China

Background: Acute erythroleukemia (AEL) is defined as an distinct subtype (<5%) of AML characterized by predominant erythropoiesis. It is associated with a poor prognosis. No recurrent cytogenetic abnormality is specific of AEL. Through "Oncomine" Database, we found KEL was significantly upregulated in AEL patients, compared with other types of AML and normal patients. It has been reported that KEL promoter exhibited a strong transcriptional erythroid activity in K562 cells, but its role in the development of AEL remains unclear. Circular RNAs (CircRNAs) are a novel type of endogenous noncoding RNAs that regulate target gene expression by interacting with microRNAs (miRNAs). Emerging evidence shows that circRNAs play important roles in biological and pathological processes. Here we found one circRNA transcripted from KEL gene (circ-KEL), which had a high expression in AEL, may play a role of coordinate regulation with KELL (a protein encoded by KEL mRNA).
Aims: Our present study aims to investigate the function of KEL and circ-KEL and enrich the potential modulation mechansim on erythroid differentiation in AEL.
Methods: In our study, we collected blood samples from 45 AEL patient, 121 other types of AML patients and 88 normal patients. Two AEL cells lines (K562 and HEL) were used as the erythroid differentiation models *in vitro*, induced with 50 M hemin from day 1 to day 7. We knocked down and/or over-expressed KEL and circ-KEL separately in AEL cell lines by using lenti-virus and siRNAs. The expression levels of γ-globin and FUT1 as well as the erythroid surface markers TER119 and GPA were examined to evaluate their function in erythroid differentiation. Initial characterization (RNase R and Actinomycin D treatment) has been performed to identify circ-KEL. Dual-luciferase reporter system, FISH assay and RIP assay have been performed to validate the interaction of circRNAs, miRNAs and mRNA. To test the protein-coding ability of circ-KEL, we took advantage of an expression vector that contained a 3×FLAG and circ-KEL sequence, which was able to produce circular transcripts. QRT-PCR and Western blot were performed to examine the expression of related RNA and protein.
Results: KEL and circ-KEL were significantly higher expressed in AEL clinical samples/cells lines, and the results were consistent with the database. When KEL was over-expressed, the relative expression of circ-KEL was increased significantly, resulted in the up-regulation of erythroid differentiation. Similar effects occured when circ-KEL was over-expressed. On the contrary, when KEL was knocked down, the relative expression of circ-KEL was significantly decreased, led to a down-regulation of erythroid differentiation. Moreover, we found that increased circ-KEL levels could rescue the erythroid differentiation inhibition when KEL was knocked down in AEL. Circ-KEL could serve as a sponge for miR-671 and up-regulate miR-671 functional target KEL mRNA, thus promote the erythroid differentiation. Combined with bioinformatics analysis, we found circ-KEL contains m6A motif in initiation codon region and an open reading frame (ORF) that could encode polypeptides (293aa). Circ-KEL translation can be modified by m6A. The function of the circ-KEL encoding protein and its influence on erythroid differentiation in AEL will be futher explored (Figure 1).

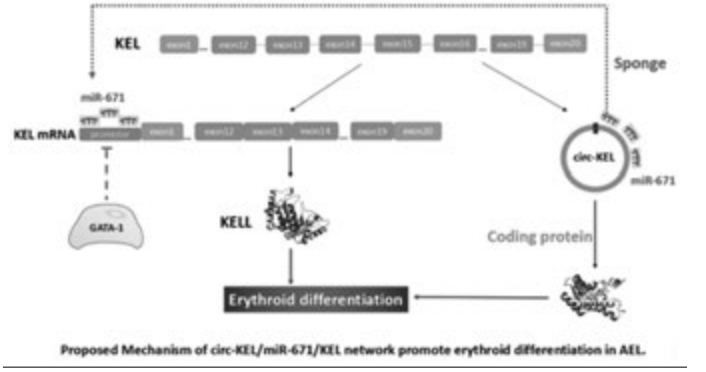

Figure 1.

Summary and Conclusions: Our study reveals a novel regulatory mechanism of KEL and circ-KEL in erythroid differentiation, suggesting that circ-KEL can be used as a potential diagnostic biomarker of AEL. This provides a promising strategy for future diagnosis, biomarker discoveries and treatment of AEL.

PF212

A NOVEL BET-BROMODOMAIN INHIBITOR, ODM-207, AS A POTENTIAL THERAPY FOR ACUTE MYELOID LEUKEMIA

J.J. Miettinen[1,*], T. Ikonen[2], T. af Hällström[2], A. Moilanen[2], K. Porkka[3], C.A. Heckman[1]

[1]Institute for Molecular Medicine Finland (FIMM), University of Helsinki, Helsinki, [2]Orion Pharma, Orion Corporation, Espoo, [3]Helsinki University Hospital and Comprehensive Cancer Center (HUS), Helsinki, Finland

Background: Bromodomain and extra-terminal (BET) family proteins are

regulators of gene transcription. Their inhibition has been shown to suppress oncogenic pathways, survival, and growth in haematological malignancies and in solid tumors. Acute myeloid leukemia (AML) is the most frequent form of myeloid cell derived haematological malignancies in adults. Currently there are only a limited number of treatments available for AML with limited efficacy. BET inhibitors have shown promise as a new targeted therapy for treating the disease. BET inhibitor ODM-207 has been shown to have anti-proliferative activity in AML cell lines, and in cell lines from other haematological malignancies (Moilanen *et al.*, Cancer Res, 2017). Its effects on AML patient samples have not been studied.
Aims: The aim of the study was to test the drug response of ODM-207 in AML patient samples, and to compare these to drug responses obtained using a set of commercially available BET inhibitors in the same samples.
Methods: Bone marrow aspirate (BM) or peripheral blood (PB) derived mononuclear cells (MNC) were enriched by Ficoll separation from 23 AML patient samples (14 diagnostic, 6 relapsed, 2 refractory, 1 relapsed/refractory) from 21 different patients, and from 4 healthy individuals. *Ex vivo* drug sensitivity and resistance testing (DSRT) (Pemovska *et al.*, Cancer Discov, 2013) was performed by treating the cells for 72 h with the desired compounds, and CellTiter-Glo (CTG) and CellTox Green (CTxG) readouts were measured. Cells were tested against ODM-207 in 9 different concentrations (3-30000 nM), and in 5 different concentrations (1-10000 nM) for the other 5 BET inhibitors (GSK525762, I-BET151, JQ1, OTX015, PFI-1) to generate dose response data. Drug sensitivity scores were calculated based on the normalized area under the dose response curve (Yadav *et al.*, Sci Rep, 2014).
Results: ODM-207 reduced cell viability in a subgroup of AML patients. There were 5 AML patients that were extremely sensitive to ODM-207, and an additional 8 sensitive patients. In 6 patients ODM-207 showed a cytotoxic effect, and in 5 a cytostatic effect. Cytostatic activity was evident in an additional 3 patients, but cytotoxicity could not be confirmed from these samples. There were also 8 AML patients not responding to ODM-207. When comparing ODM-207 response in the tested AML patient samples with responses obtained using the other 5 BET inhibitors, ODM-207 generated responses similar to JQ1 and OTX015. ODM-207 was however slightly more cytotoxic in a subgroup of patients, whereas JQ1 and OTX015 were more cytostatic in general. Other inhibitors, GSK525762, I-BET151 and PFI-1, generated a weaker drug response than ODM-207. They were not as effective in reducing cell viability in the tested AML patient samples, and their effects were mainly cytostatic.
Summary and Conclusions: ODM-207 was extremely effective in reducing cell viability *ex vivo* in 5/21 AML patients, and effective in an additional 8 patients. In 6 patients ODM-207 showed a cytotoxic effect, and in 5 a cytostatic effect. ODM-207 has a similar drug response profile as JQ1 and OTX015 in the tested AML patient samples, but ODM-207 is slightly more cytotoxic in a subgroup of patients. The current results also indicate variation in response between groups of patients whose samples were extremely sensitive or resistant to ODM-207. Therefore the molecular features defining the different ODM-207 response groups are being investigated by exome and RNA sequence analyses. Also, more AML patient samples are being DSRT tested to confirm the already analysed drug response results.

PF213

MOLECULAR PROFILES IN AML PATIENTS OLDER THAN 70 YEARS OF AGE

M. Hoyos Colell[1,2,*], A. Dolnik[1], T.J. Blätte[1], S. Skambraks[1], S. Lux[1], Z. Xia[1], V.I. Gaidzik[1], P. Paschka[1], D. Weber[1], M. Wattad[3], G. Held[4], H.A. Horst[5], F. Thol[6], M. Heuser[6], A. Ganser[6], V. Teleanu[1], J. Sierra[2], H. Döhner[1], K. Döhner[1], L. Bullinger[1]

[1]Klinik für Innere Medizin III, Universitätsklinikum Ulm, Ulm, Germany, [2]Hematology, Hospital de la Santa Creu i Sant Pau, IIB Sant Pau and Jose Carreras Research Institute. Universitat Autonoma de Barcelona, Barcelona, Spain, [3]Klinik für Hämatologie, internistische Onkologie und Stammzelltransplantation, Evangelisches Krankenhaus Essen-Werden, Essen, [4]Innere Medizin I, Universitätsklinikum des Saarlandes und Medizinische Fakultät der Universität des Saarlandes, Homburg, [5]Klinik für Innere Medizin II, Universitätsklinikum Schleswig-Holstein Campus Kiel, Kiel, [6]Klinik für Hämatologie, Hämostaseologie, Onkologie und Stammzelltransplantation, Medizinische Hochschule Hannover, Hannover, Germany

Background: Acute myeloid leukemia (AML) arises in all age groups, but it is mainly a disease of the older patients with a median age of about 70 years at diagnosis. Age has a major impact on both the management and outcome of patients with AML. Older patients frequently present with unfavorable prognostic factors that are related to patient characteristics (general health condition, specific comorbidities), but also to those related to the leukemia cells, including a higher frequency of secondary AML arising from previous myelodysplastic syndrome and adverse genetic changes. While in the past, large cohorts of younger AML patients treated within multicenter clinical trials have been extensively studied on the molecular level, the genomic aberrations underlying the AML of older patients have by far been less well characterized.
Aims: In accordance, the aim of this study was the evaluation of the mutational spectrum of a large cohort of AML patients ≥70 years (median age 77 yrs) who have been entered into the AMLSG BiO Registry (ClinicalTrials.gov Identifier: NCT01252485).
Methods: Patients included into the study were treated with low dose cytarabine, decitabine or azacitidine, or best supportive care. In total, we studied n=295 cases by an in-house targeted resequencing panel covering the entire coding region of 94 myeloid disease related genes. We used the Haloplex High Sensitivity enrichment system (Agilent), followed by Illumina sequencing and an in-house data analysis workflow. Using a respective high sensitivity molecular barcode approach, we could reliably detect low abundance mutations with a variant allele frequency (VAF) ≤1%.
Results: In 295 cases the average gene coverage was 350x(fold) for consensus reads. In line with other smaller studies, we found a very high incidence of *TP53* (30%), *ASXL1* (11%), and *RUNX1* (21%) mutations, along with a high incidence of *TET2* (31.5%) and *DNMT3A* (24%) as well as splicing factor *SRSF2* (24%) mutations (Figure 1). While we found on average three mutations per patient using our 94-gene panel, we found a broad distribution of the VAF. Most patients presented with a dominant clone displaying a VAF of ~50%, *i.e.* all tumor cells harbor the respective mutation. In agreement with findings in younger patients, these mutations often affect genes involved in DNA methylation, chromatin modification, the cohesin or spliceosome complex. Often, the subclonal mutations with VAF ≤30% involve mutations in tumor-relevant signaling pathways.

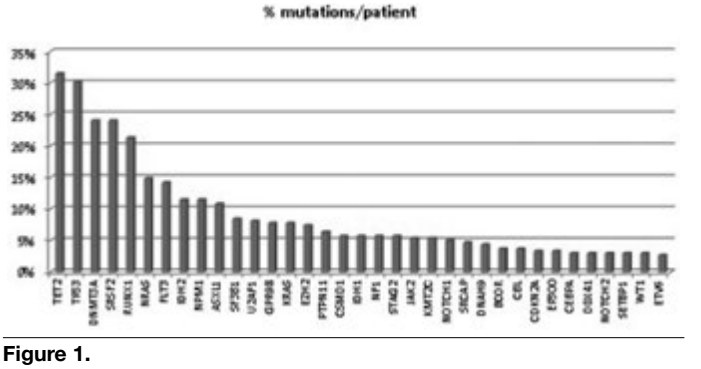

Figure 1.

Summary and Conclusions: In summary, our study demonstrates that the mutational spectrum of older AML patients differs significantly from that of young patients with a high incidence of high-risk molecular aberrations. Results from correlation of molecular with clinical data will be presented at the meeting.

PF214

COMPARISON OF WHOLE GENOME ANALYSIS APPROACHES FOR DETECTION OF MAJOR CHROMOSOMAL ABERRATIONS USING A DIVERSE SET OF LEUKEMIA PATIENTS

S. Twardziok[1,*], N. Nadarajah[1], C. Bär[1], M. Meggendorfer[1], A. Stengel[1], W. Kern[1], T. Haferlach[1], C. Haferlach[1]

[1]MLL Münchner Leukämielabor GmbH, München, Germany

Background: To date chromosome banding analysis (CBA) is the gold standard technique for the detection of structural chromosomal rearrangements and copy number changes in the diagnostic setting of hematological malignancies. However, additional techniques have been established that are capable of providing genome wide information such as genomic arrays (GA), optical mapping technologies (OM) and whole genome sequencing (WGS).
Aims: We evaluated the performance of these three whole genome analysis approaches to detect structural variations (SV) and copy number variations (CNV) using a comprehensive set of leukemia samples in comparison to CBA.
Methods: We applied WGS with 90x coverage using diagnostic peripheral blood or bone marrow samples of 129 patients from diverse leukemia entities. Library preparation was performed using Truseq DNA PCR-Free HT sample preparation kit (Illumina, San Diego, CA) according to manufacturer's protocol using fresh/frozen samples and sequenced on NovaSeq sequencing instruments. Reads were aligned by BaseSpace WGS app with

default parameters. CNV analysis was performed using software GATK4 and SVs were called using MANTA software accounting for missing matched-normal samples. For a subset of 20 samples including AML and ALL patients with a complex karyotype we also performed GA for CNV detection. Additionally, for a set of 5 samples we used data from high resolution OM provided by BioNano genomics for a cross technology comparison of SV calls and CNV calls.
Results: WGS analysis detected reciprocal translocations identified by CBA in 98/104 patients including 81/85 *BCR-ABL1* fusions, 8/9 *RUNX1-RUNX1T1* fusions and 8/10 *PML-RARA* fusions and it was also able to resolve several complex fusions not fully clarified by CBA Comparing CNV detection to CBA we found equivalent copy number changes for 59/98 chromosomes with array-CGH and for 71/98 chromosomes with WGS. Missing detections by WGS and GA were due to small subclones (<1%). Comparing WGS and GA we found 90.1% equivalence over all genomes including 11.1% aberrations undetected by CBA. Further, compared to GA WGS predicted additional 6.6% lost regions and compared to WGS GA predicted additional 3.2% gained regions. Comparing WGS and OM for SV detection with CBA set as the gold standard resulted in detection of 10/18 interchromosomal fusions by WGS and detection of 15/18 interchromosomal fusions using OM. Fusions missed by WGS were in low complexity regions or uncalled by the algorithm due to low fusion signals. For the copy number variation data, WGS identified 23/29 CNV segments and OM identified 13/29 CNV segments in accordance to orthogonal data.
Summary and Conclusions: In principle, only WGS and OM have the potential to substitute CBA as GA cannot detect balanced rearrangements. Applying WGS with current algorithms 94.2% of diagnostically significant fusions were identified. In addition, WGS found several aberrations not detected by CBA. In direct comparison, we found more fusion events using OM than with WGS although both approaches detected most fusions in specific regions of the chromosomes. Compared to CBA the resolution of GA, OM and WGS is strikingly higher leading to the identification of several additional abnormalities confirmed by at least two of the latter technologies. Such abnormalities might provide new insights into leukemia evolution and give improved sub-classification of patients for precision medicine.

PF215

SOMATIC MUTATIONS IN RELAPSED ACUTE MYELOID LEUKEMIA

S. Eldfors[1,*], M. Kontro[2], Y. Akimov[1], C. Engen[3], M. Wolf[1], B.T. Gjertsen[3,4], O. Kallioniemi[1,5,6], K. Porkka[2], C. Heckman[1]

[1]Institute for Molecular Medicine Finland, [2]Helsinki University Central Hospital Cancer Center, University of Helsinki, Helsinki, Finland, [3]Centre for Cancer Biomarkers (CCBIO), University of Bergen, [4]Department of Internal Medicine, Haukeland University Hospital, Bergen, Norway, [5]Department of Oncology-Pathology, Karolinska Institutet, [6]Science for Life Laboratory, Stockholm, Sweden

Background: Most patients with acute myeloid leukemia (AML) achieve complete remission with initial treatment, but many relapse with a therapy-resistant disease. The somatic mutations in newly diagnosed AML have been extensively characterized. However, the role of mutations in relapsed AML remains poorly understood.
Aims: We aimed to identify somatic mutations selected at relapse in AML.
Methods: We analyzed 142 bone marrow or peripheral blood samples from 124 AML patients by exome sequencing. Skin biopsy samples were sequenced as the normal tissue controls. We compared somatic mutations, copy number, and cytogenetic aberrations in newly diagnosed AML (n=81) with the mutations in relapsed AML (n=61). Matched diagnosis and relapse samples were available from 18 patients. The relapsed patients were treated with chemotherapy (n=49) or allogeneic stem cell transplantation (n=12). The acquisition and increase in variant allele frequency of mutations in matched diagnosis and relapse sample pairs provide strong evidence for mutation selection in response to therapy. Therefore, we regarded mutations that both showed enrichment in the cohort comparison and were acquired or selected for in matched diagnosis-relapse sample pairs as the most likely to contribute to therapy resistance.
Results: We found that mutations in *CBL*, *PTPN11*, *NF1* and *KRAS* were enriched in relapsed AML. Mutations in these genes have been shown to induce hypersensitivity to cytokine stimulation in hematopoietic cells. A *CBL* mutation was present in 2/81 patients (2%) with newly diagnosed AML and 6/61 patients (10%) with relapsed AML. A *CBL* and *PTPN11* mutation was acquired or increased in variant allele frequency in 2/18 patients with matched diagnosis and relapse samples (Figure 1A,B). A *PTPN11* mutation was present in 5/81 patients (6%) with newly diagnosed AML and 6/61 patients (10%) with relapsed AML. *NF1* mutations or deletions were present in 4/81 patients (5%) with newly diagnosed AML and 7/61 patients (11%) with relapsed AML. Notably, we identified biallelic *NF1* mutations or a homozygous deletion in three patients at relapse. In all, a *CBL*, *PTPN11*, *NF1* or *KRAS* mutation was present in 36% of the patients with relapsed AML and 17% of the patients with newly diagnosed AML. Our relapsed AML cohort was significantly enriched for mutations in these genes compared with the previously published TCGA AML cohort of newly diagnosed patients (Figure 1C). To determine whether *CBL*, *PTPN11*, *NF1* and *KRAS* mutations are associated with shorter survival when present at the time of diagnosis, we analyzed survival data for the TCGA patients. Patients with a *CBL*, *PTPN11*, *KRAS* or *NF1* mutation had shorter overall survival than patients who lacked mutations in these genes (Figure 1D). Other genes that were enriched for mutations at relapse and showed selection of mutations in serial samples included *TP53*, *WT1*, *PHF6* and *RUNX1*. Cytogenetic aberrations that were selected in relapsed AML included -7/-7q and +8/+8q.

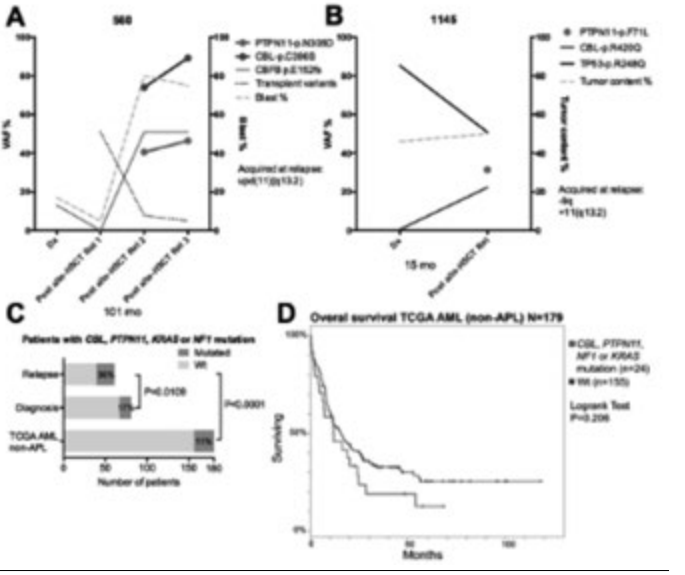

Figure 1.

Summary and Conclusions: We found that mutations in *CBL*, *PTPN11*, *NF1* and *KRAS*, which can lead to cytokine signaling activation and hypersensitivity to survival signals, are frequent and selected in relapsed AML. *TP53* mutations were present in 10% of the relapsed patients. Mutations to genes encoding transcriptional and epigenetic regulators, and monosomy 7/-7q and trisomy 8/+8q are more prevalent in relapsed AML. In contrast, mutations leading to drug resistance via impaired drug metabolism are rare. The identified genes can potentially be used to stratify patients who lack conventional prognostic markers.

PF216

EXPRESSION OF PIWI-INTERACTING RNAS (PIRNAS) AND ITS PROGNOSTIC IMPLICATION IN ACUTE MYELOID LEUKEMIA (AML): A 3-PIRNA SCORING SYSTEM PREDICTS PROGNOSIS IN AML PATIENTS

T.-C. Yu[1,*], C.-H. Tsai[1,2], M. Yao[1], Y.-Y. Kuo[3], M.-H. Tseng[1], C.-C. Li[2], S.-Y. Huang[1], B.-S. Ko[1], S.-C. Hsu[4], C.-T. Lin[2], S.-J. Wu[1], C.-Y. Chen[1], W. Tsai[1], J.-L. Tang[1,2], H.-A. Hou[1], W.-C. Chou[4], H.-F. Tien[1]

Background: PIWI-interacting RNAs (piRNAs), a group of small RNAs with 24-31 nucleotides in length, play important roles in gene silencing, epigenetic regulations and stem-cell maintenance. The piRNAs were found dysregulated in various kinds of tumor tissues, but their roles in tumorigenesis are largely unknown. Recently, it was found that piRNAs expressions could predict prognosis in Hodgkin lymphoma. However, the biologic and prognostic relevance of piRNAs in AML remain unclear.
Aims: The aim of this study was to establish a concise scoring system based on piRNA expression and to elucidate its clinical implications.
Methods: The global gene expression profiles, including 2,041 piRNAs, of 176 adult patients with *de novo* non-M3 AML who received standard

chemotherapy were analyzed using the Affymetrix Human Transcriptome Array 2.0 chips. We randomly divided patients into the training cohort (n=88) and validation cohort (n=88). We used the multivariate Cox proportional hazards regression analysis to build the piRNA risk score system and explored its clinico-biological significances. This piRNA risk score system was further verified in the validation cohort.
Results: We identified three piRNAs, which were significantly associated with disease free survival (DFS). A robust risk scoring system composed of the sum of the piRNAs was constructed. The piRNA risk score=0.327*[TC15000168.hg.1]+0.424*[TC15000551.hg.1]+0.394*[TC15001906.hg.1]. The median of risk scores was used as the cut-off to divide patients into lower- and higher-score groups. The clinical parameters including hemoglobin, white blood cell, and platelet counts at diagnosis and the distribution of cytogenetic changes were similar between the two groups. Patients with higher scores had significantly less *CEBPA* double-mutations (*CEBPA*$^{double\text{-}mutation}$) (P=0.044). The higher-score group had a lower complete remission rate (61.4% *vs* 84.1%, P=0.030), higher relapse rate (77.8% *vs* 48.6%, P=0.022), shorter DFS (median 10.0 *vs* 78.3 months, P=0.003) and overall survival (OS) (median 17.6 months *vs* not reached, P= 0.001, Figure 1) compared with the lower-score group. In multivariate analysis, the independent poor prognostic factors for both OS and DFS included age more than 50 years, white blood cell counts at diagnosis more than 50,000 /micro-liter, unfavorable-risk cytogenetics, *RUNX1* mutations, and higher piRNA risk scores, while *CEBPA*$^{double\text{-}mutation}$, *IDH2*, and *NRAS* mutations were independent favorable prognostic factors regarding OS. The higher piRNA risk score remained to be an independent poor prognostic factor for OS and DFS (both P<0.001) in the validation cohort. We utilized Ingenuity Pathway Analysis to analyze the potential underlying pathway associated with higher piRNA risk score and constructed a network centered by *ERK* and *HOX* family genes.

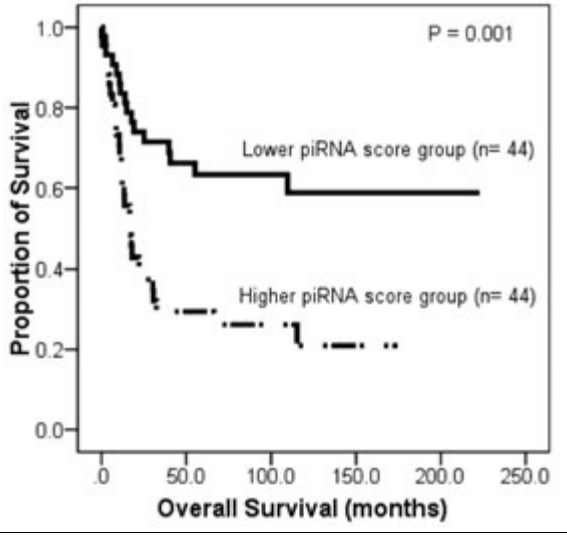

Figure 1.

Summary and Conclusions: This piRNA risk score system is a robust and easy to use risk-stratification tool. The piRNA scores were associated with distinct molecular alterations and independently correlated with clinical outcomes. Further prospective studies are warranted to validate our findings.

Background: Severe hemorrhagic events occur in a significant fraction of acute promyelocytic leukemia patients, either at presentation and/or early after starting therapy, leading to treatment failure and early deaths. However, identification of independent predictors for high-risk of severe bleeding at diagnosis, remains a challenge.
Aims: We investigated the immunophenotype of bone marrow leukemic cells from 109 newly-diagnosed acute promyelocytic leukemia patients, particularly focusing on the identification of basophil-related features, and their potential association with severe bleeding episodes and patient overall survival.
Methods: A total of 109 newly-diagnosed and previously untreated acute promyelocytic leukemia patients were investigated for the presence of phenotypes associated with basophil maturation on bone marrow leukemic promyelocytes, using the standardized 8-color *EuroFlow* AML/MDS antibody panel. Diagnosis was based on morphological and immunophenotypic criteria, together with the presence of *PML-RARA* gene rearrangements by iFISH and molecular techniques.
Results: From all 109 cases analyzed, 72% showed signs of bleeding. Thus, mild bleeding was observed at diagnosis and during/after starting therapy in 50% and 19% patients, respectively, while severe bleeding occurred in 14% and 21% cases, respectively. From all phenotypic markers investigated, partial expression of the CD203c and/or CD22 basophil-associated antigens on bone marrow leukemic cells showed the strongest association with both the occurrence and the severity of bleeding at diagnosis and after starting therapy. Thus, an increasing frequency of cases with CD203c$^+$ leukemic cells was observed among patients with severe hemorrhage *vs* those with mild and no signs of bleeding, both at diagnosis (87% *vs* 25% and 13%; p<0.001) and after starting therapy (80% *vs* 20% and 18%, respectively; p<0.001). Multivariate analysis of prognostic factors showed that high peripheral blood leukemic cell counts (>30 x10^9/L) was the only parameter showing an independent predictive value for severe bleeding at any time point evaluated (HR: 22.4; p=0.007), while CD203c expression on leukemic promyelocytes (HR: 26.4; p=0.003) together with an older age (HR: 5.4; p=0.03) was the best combination of prognostic factors for cumulative incidence of severe bleeding after starting therapy. In turn, low fibrinogen levels (HR: 8.8; p=0.001), age >70 years (HR: 9.0 p=0.002), high (>30 x10^9/L) leukocyte count (HR: 5.6; p=0.02) and CD203c expression on bone marrow leukemic cells (HR: 4.4; p=0.01), were the most informative independent predictors for overall survival of acute promyelocytic leukemia patients.
Summary and Conclusions: In summary, here we show for the first time that basophil maturation of leukemic promyelocytes defined on immunophenotypic grounds occurs in around one third of promyelocytic leukemia patients, providing a greater risk of severe bleeding both at diagnosis and (particularly) after starting therapy. Thus, expression of the CD203c basophil maturation-associated marker on leukemic cells showed a strong and independent predictive value for both the occurrence of severe bleeding after starting therapy and overall survival of these patients. Further studies in larger series of promyelocytic leukemia patients are required to confirm our findings, and to establish preventive and/or treatment measures for an improved management of patients at increased risk for severe bleeding, particularly among this unique subgroup of CD203c$^+$ promyelocytic leukemia cases.

ogy, The Cancer Institute, Japanese Foundation for Cancer Research, [5]Department of Hematology, Juntendo University School of Medicine, Tokyo, [6]Department of Hematopathology, Tohoku University Graduate School of Medicine, Sendai, [7]Department of Surgical Pathology, Hokkaido University Hospital, Sapporo, [8]Division of Hematology, Department of Medicine, Keio University School of Medicine, Tokyo, [9]Department of Hematology, Endocrinology, and Metabolism, Faculty of Medicine, Niigata University, Niigata, [10]Department of Community Medicine, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, [11]Laboratory of Hematology and Oncology, Graduate School of Health Sciences, Niigata University, Niigata, [12]Department of Hematology, National Cancer Center Hospital, Tokyo, [13]Department of Pathology, Kurume University, School of Medicine, Kurume, Japan

Background: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare skin-tropic hematological malignancy with poor outcomes and uncertain pathogenesis. Under the microscope, classic BPDCN cells appear as medium-sized blasts containing nuclei with variable irregularities and fine chromatin. Nucleoli are either inconspicuous or one to several small nucleoli are observed. However, in 2001, we identified a case, wherein, cells morphologically resembled immunoblasts (activated B cells characterized by a round vesicular nucleus with a large centrally-located nucleolus) and have unofficially referred to cases with such cytomorphology as the "immunoblastoid" variant. Meanwhile, 8q24 (*MYC* locus) rearrangement has been sporadically reported in BPDCN but is still unclear about the positivity rate and the biological and clinical relevance. Recently, we encountered an "immunoblastoid" BPDCN case with 8q24 rearrangement and MYC expression, which suggested a genotype-phenotype correlation in BPDCN.
Aims: We aimed to elucidate the presence of subgroups in BPDCN based on such genotype-phenotype correlations and to evaluate the therapeutic significance of this subclassification.
Methods: Specimens and clinical information from 154 patients diagnosed with BPDCN or with an equivalent diagnosis were collected from 52 institutions in Japan. By histopathological analysis, 118 cases were confirmed to be BPDCN and were included in the present study. The cytomorphology of these cases was examined using the formalin-fixed paraffin-embedded tissues. Subsequently, 8q24 rearrangement and MYC expression was evaluated by fluorescence *in situ* hybridization and immunohistochemistry, respectively. We also performed *in vitro* functional analyses using BPDCN cell lines with and without 8q24 rearrangement.

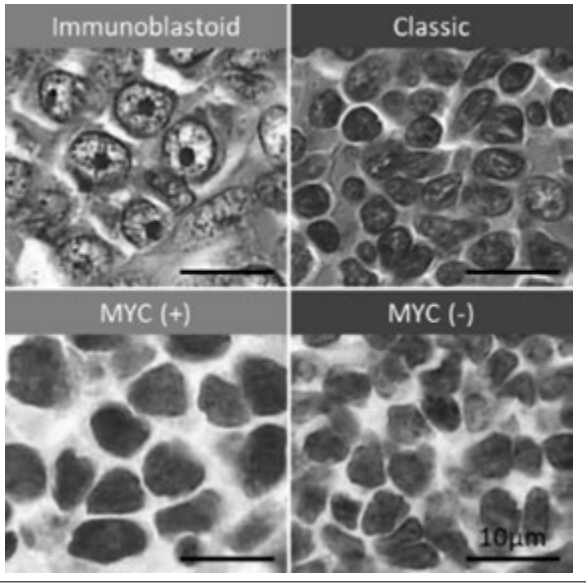

Figure 1.

Results: Among the 118 BPDCN patients, 62 (53%) and 41 (35%) exhibited the classic and immunoblastoid cytomorphology, respectively. Forty-one (38%) MYC$^+$BPDCN (positive for rearrangement and expression) and 59 (54%) MYC$^-$BPDCN (both negative) cases were identified. All immunoblastoid BPDCN cases examined were MYC$^+$BPDCN (39/39, 100%) and nearly all classic BPDCN cases were MYC$^-$BPDCN (54/56, 96%). All examined MYC$^+$BPDCN samples were negative for *MYB*/*MYBL1* rearrangement (0/36). Clinically, MYC$^+$BPDCN patients showed late onset, poor outcomes, and localized skin tumors more commonly than MYC$^-$BPDCN patients. *MYC* was demonstrated by expression profiling as one of the clearest discriminators between CAL-1 (MYC$^+$BPDCN) and PMDC05 (MYC$^-$BPDCN) cell lines, and shRNA knockdown of *MYC* suppressed CAL-1 viability. Inhibitors for bromodomain and extraterminal protein (BETis) and aurora kinases (AKis) inhibited CAL-1 growth more effectively than that of PMDC05. We further showed that a BCL2 inhibitor was effective in both CAL-1 and PMDC05, indicating that this inhibitor can be used to treat MYC$^-$BPDCN cases, for which BETis and AKis are probably less effective (Figure 1).
Summary and Conclusions: We revealed that 8q24 rearrangement was recurrent (approximately 40%) in BPDCN and was associated with immunoblastoid cytomorphology, MYC expression, and higher sensitivity to BETis and AKis. In addition, the characteristics of MYC$^+$BPDCN and MYC$^-$BPDCN patients were found to be appreciably different in clinical respects. Our data will provide a rationale for the development of new treatment strategies for patients with BPDCN in accordance with precision medicine.

PF219

COMBINATION OF FLT3 INHIBITOR QUIZARTINIB AND MDM2 INHIBITOR MILADEMETAN RESULTS IN GREATER PRE-CLINICAL ANTI-LEUKEMIC ACTIVITY IN FLT3-ITD MUTANT/P53 WILD-TYPE ACUTE MYELOID LEUKEMIA MODELS

M. Andreeff[1,*], T. Seki[2], W. Zhang[1], T. Isoyama[3], K. Iwanaga[2], N. Togashi[2], P. Kumar[4], O. Zernovak[4], N. Daver[1]

[1]MD Anderson Cancer Center, Houston, United States, [2]Daiichi Sankyo, Ltd., Tokyo, Japan, [3]Daiichi Sankyo, Ltd., Tokyo, [4]Daiichi Sanyko, Inc., Basking Ridge, United States

Background: Quizartinib, a highly selective and potent FLT3 inhibitor, and milademetan (DS-3032b), a small molecule MDM2 inhibitor, have both demonstrated single-agent treatment activity in pre-clinical and clinical studies in acute myeloid leukemia (AML). These pre-clinical studies explored the rationale and molecular basis for the combination of quizartinib and milademetan for the treatment of FLT3-ITD mutant/TP53 wild-type AML.
Aims: Evaluate pre-clinically the feasibility of combining quizartinib and milademetan for treatment of FLT3-ITD mutant/TP53 WT AML.
Methods: We investigated the effect of quizartinib and milademetan combination on cell viability and apoptosis in established AML cell lines, including MV-4-11, MOLM-13 and MOLM-14, which harbor FLT3 ITD mutations and p53 wild type. We further investigated the effect of the combination regimen by using quizartinib and murine specific MDM2 inhibitor DS-5272 in murine leukemia cell lines Ba/F3-FLT3-ITD, Ba/F3-FLT3-ITD+F691L and Ba/F3-FLT3-ITD+D835Y, which harbor FLT3 ITD, ITD plus F691L and ITD plus D835Y mutations, respectively. F691L or D835Y mutations are associated with resistance to FLT3-targeted AML therapy. Combination efficacy was investigated in subcutaneous and intravenous xenograft models generated in male NOD/SCID mice inoculated with MOLM-13 and MV-4-11 human AML cells.

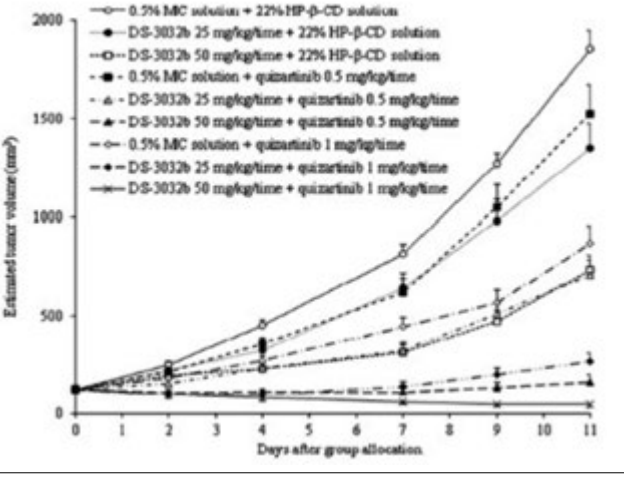

Figure 1.

Results: Combination treatment with milademetan (or DS-5272) and quizartinib demonstrated greater anti-leukemic activity compared to the respective single-agent treatments in FLT3 mutated and TP53 wild type cells. Combination indexes (CIs) were 0.25±0.06, 0.61±0.03, 0.62±0.06, 0.29±0.004 and 0.50±0.03, respectively, in MV-4-11, MOLM-13, MOLM-14, Ba/F3-FLT3-ITD+F691L and D835Y cell lines. All these cell lines harbor FLT3 ITD or ITD plus TKD point mutations. The combination regimen triggered synergistic pro-apoptotic effect in a p53 dependent manner. Mechanistically, the combination treatment triggered significant suppression of phospho-FLT3, -ERK

and -AKT compared to single agent treatments; and also up-regulated p53, p21 and the pro-apoptotic Bim proteins. In an *in vivo* study using the MOLM-13 subcutaneous xenograft model, quizartinib treatment at 0.5 and 1 mg/kg and milademetan treatment at 25 and 50 mg/kg demonstrated a significant tumor growth inhibition compared with the vehicle treatment or compared with the respective single-agent treatments. In MV-4-11 intravenous xenograft model, the combination of quizartinib plus milademetan showed a significantly prolonged survival (no mouse death during the study period) compared to their respective single agent treatments and the untreated control. Additional preclinical combination studies are ongoing (Figure 1).
Summary and Conclusions: Greater pre-clinical combination activity was observed for quizartinib plus milademetan treatment. A phase I clinical trial is planned to start in May 2018.

PF220

A GROUP OF EMA-APPROVED IMMUNOMODULATORS TARGETS AML STEM CELLS BY SABOTAGING THE CELLULAR RECYCLING MACHINERY

J.M. Cornet Masana[1,2,3,*], A. Banús-Mulet[1,4], A. Etxabe[1,4], M.C. Lara-Castillo[1], M.Á. Torrente[5], J. Esteve[3,5,6,7], R.M. Risueño[1]

[1]Leukaemia Stem Cell Lab, Josep Carreras Leukaemia Research Institute, Barcelona, [2]Institut d'Investigació en Ciències de la Salut Germans Trias i Pujol, Badalona, [3]Faculty of Medicine, [4]Faculty of Pharmacy, University of Barcelona, [5]Department of Hematology, Hospital Clínic, [6]Josep Carreras Leukaemia Research Institute, [7]Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain

Background: A number of different genetic alterations are known to be involved in leukemogenesis and a handful of novel treatments aim at specific targeting of features related to those alterations. Nevertheless, diverse broad cellular and molecular elements are thought to be involved in sustaining Acute Myeloid Leukemia (AML) independently of specific genetic lesions. Using an AML-transformation gene signature and thanks to connectivity maps, an *in silico* screening identified several EMA-approved immunomodulators (IM) reverting that leukemogenic signature. Here, we describe the preclinical activity of those drugs and its targeting of the cellular recycling machinery.
Aims: The main objective of the study was to identify novel drugs against AML stem cells based on broad transformation-associated signatures and characterize its mechanism of action.
Methods: For the *in silico* screening, an MLL-AF9 gene signature was used in connectivity maps, and drugs were ranked according to its potential to revert the signature. To study the cytotoxic effects of IMs, cell viability was assessed by flow cytometry (7-AAD exclusion, volumetric count) at 48h using 4 human AML cell lines, cells from 9 AML patients and Mononuclear cells (MNCs) from 5 healthy-donor buffy coats. Clonogenicity assays were executed in AML cell lines and patient samples and lineage-depleted umbilical cord blood (UCB) cells by 18h IM treatment followed by 14-day culture in complete Methocult medium. *In vivo* studies were performed with busulfan-conditioned NOD-scid IL2Rg null (NSG) mice xenotransplanted with AML or UCB cells treated with IMs for 18h. Engraftment was analyzed after 8 weeks by flow cytometric determination of human CD45-expressing cells in bone marrow. To study the previously described GPCR target for the IMs, cells were cultured with IMs and high concentrations of the endogenous ligand, followed by a cytotoxicity assay as above described. Effects on lysosomes and autophagy were studied by Lysotracker and CytoID staining and by western blot detection of LC3BII.
Results: 4 structurally similar immunomodulators (IM) induced cytotoxicity in the low micromolar range in AML cell lines and patient samples, while displaying limited effects in healthy-donor and UCB MNCs. Clonogenicity studies yielded similar results, with a dramatic decrease of CFU formation in leukemic cells and mild effects in healthy HSCs, suggesting a differential effect on the more primitive AML stem cell fraction. Interestingly, cytotoxic effects were observed irrespective of specific AML subtypes and mutations. *In vivo* studies further corroborated the results, with IM treatment practically abolishing AML engraftment while sparing healthy hematopoiesis. When the mechanism of action was interrogated, the previously described target for IMs, a GPCR, was found not to be implicated in its antileukemic capacity, as the effects could not be reverted with the endogenous ligand for the receptor. Further studies concerning the mechanism of action found a disruption of lysosomal and autophagic homeostasis, with the study of specific targets currently ongoing.
Summary and Conclusions: 4 EMA-approved IMs have been identified as antileukemic candidates affecting AML stem cells independently of their immune target by affecting a broad cellular process known to be dysregulated in AML, namely the cellular recycling machinery, rather than a specific mutation-related feature.

PF221

EXPLORING ALTERNATIVE TREATMENTS TO IMPROVE OUTCOME FOR PEDIATRIC PATIENTS WITH ACUTE MYELOID LEUKEMIA

K. Lappin[1,*], J. Blayney[1], K. Matchett[1], K. Mills[1]

[1]CCRCB, Queen's University Belfast, Belfast, United Kingdom

Background: Leukemia is the most frequently (30%) occurring type of paediatric cancer. Of these, approximately 80% are acute lymphoblastic leukaemia (ALL) with acute myeloid leukemia (AML) cases making up the remaining 20%. Management of ALL has improved dramatically in recent years with around 90% of patients surviving 5 years or more. Unfortunately, children with AML do not have the same promising outlook with only 60% surviving 5 years or longer and a high risk (20%) of not responding to the standard of care induction therapy. In addition, the high rate of relapse which when combined with the side effects of the harsh chemotherapy regimen give a bleak outlook. Recent data (Bolouri *et al.*, 2017), strongly indicates the need for age specific therapies for AML patients.
Aims: The aim of this study is to generate a gene signature that can signpost pediatric AML patients who will not benefit from the standard of care therapy and identify alternative therapies that have the potential to be used in the treatment for these patients.
Methods: *In silico* analysis of RNA-sequencing data from the Therapeutically Applicable Research to Generate Effective Treatments (TARGET) study generated by the National Cancer Institute (NCI) was performed on the gene count tables provided and gene expression analysis was determined using Galaxy DESeq2 software comparing each subgroup to the patients who survived without relapse following treatment. High throughput compound screening was performed on several cell lines, representative of pediatric AML cases with different cytogenetics and mutational status backgrounds to identify effective compounds across the different patient groups. Compounds were used at varying doses and assayed at 24, 48 and 72 hours post treatment using CellTox™ Green reagent.
Results: *In silico* analysis of RNA sequencing data collated as part of the TARGET study, identified a number of key pathways deregulated amongst non-responder patients who died within 1 year compared to those who survived without relapse, the most common pathways deregulated in non-responders were associated with DNA damage response (DDR). Thirty-seven DDR genes were deregulated with 89% up-regulated in comparison to patients who survived without relapse. Up-regulation of DDR genes has been shown to interfere with a patient's response to chemotherapy (Broustas and Lieberman, 2014), providing a possible explanation to why non-responders do not respond to Cytarabine+Daunorubicin induction therapy. Furthermore, we have developed a gene signature that can signpost patients who will not benefit from standard of care therapy. Due to the severe side effects of the standard therapy and the considerably high percentage of patients who will not respond, we also sought to identify possible alternative therapies for the treatment of these patients. In an *in vitro* paediatric setting, we have screened libraries of experimental compounds and FDA approved therapies. This screen has identified several compounds with repurposing potential for age-specific AML treatment, such as Venetoclax.
Summary and Conclusions: To improve the outcome for children and young people diagnosed with AML, it is imperative that alternative therapies are identified which when combined with a means of identifying non-responders will lead to improved outcomes for pediatric patients with AML.

PF222

INTEGRATIVE ANALYSIS OF GENOMIC DATA REPOSITIONS THE USE OF 5'-AZACYTIDINE AND DECITABINE IN BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM TREATMENT

M.R. Sapienza[1,*], F. Abate[2]

[1]Department of Experimental, Diagnostic, and Specialty Medicine, University of Bologna, Bologna, Italy, [2]Department of Systems Biology, Columbia University College of Physicians and Surgeons, New York, United States

Background: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare hematological malignancy derived from precursors of plasmacytoid dendritic cells (pDCs) and classified among acute myeloid leukemia. BPDCN patients show a very aggressive clinical course (median overall survival of 12 months), and, despite an initial response to chemotherapy, regularly relapse. To date, no standardized therapy has been established and the optimal treatment remains to be defined. Recent studies suggested new therapeutic options mainly derived from the investigation of the BPDCN transcriptome. On the contrary, the BPDCN DNA features were scarcely evaluated.

Aims: We aimed to design the first therapeutic strategy derived from the mutational profile of the BPDCN exome.
Methods: We analyzed by whole-exome sequencing (WES) fourteen BPDCN samples and the BPDCN patient-derived CAL-1 cell line, the largest case series sequenced so far. To evaluate the mutational impact at gene expression and epigenetic levels, we investigated by RNA sequencing all the BPDCN transcriptome and analyzed by chip-sequencing the genome-wide distribution of H3K27me3 and H3K27Ac, two epigenetic marks of transcriptional repression and induction, respectively. The integration of sequencing data led to identify a new therapeutic approach that we tested in a preclinical BPDCN-mouse model, established by the CAL-1 cell line xenografting.
Results: Mutations were accumulating in the epigenetic program, involving 25 epigenetic modifier genes, and, among them, *ASXL1* was the highest recurrently affected (28.6% of cases) (Figure 1a).The functional enrichment analysis of WES data, recognized the epigenetic process as the most undermined by mutational events (P<.0001)(Figure 1b). Gene set enrichment analysis reported the significant deregulation of gene-signatures involved in the methylation pathway and responsive to hypomethylating agents, namely Decitabine (NES>2, FDR q<.001) (Figure 1c). The BPDCN patients converged on the same H3K27-acetylated regions and the integration with transcriptomic data highlighted a set of genes marked by promoter-acetylation, aberrantly up-regulated and involved in the cell-cycle regulation Figure 1d). Globally, the integrative analysis of genomic data suggested to use a therapy based on epigenetic drugs. We tested *in vivo* the efficacy of epigenetic agents FDA approved: 5'-Azacytine, Decitabine, Romidepsine and Bortezomib, alone and in combination (Figure 1e). The combined use of 5'-Azacytine and Decitabine reached the best results demonstrating to significantly arrest the *in vivo* BPDCN tumor growth (Figure 1f,g).

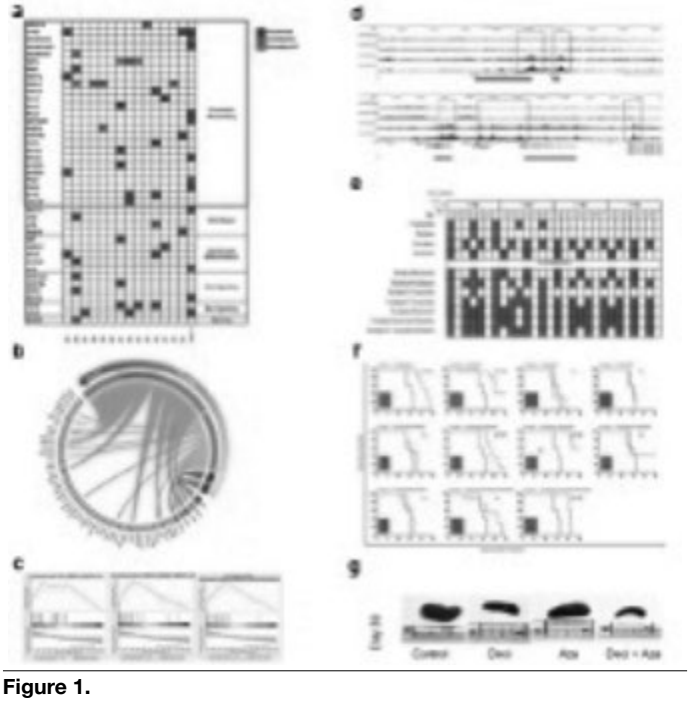

Figure 1.

Summary and Conclusions: In conclusion, we identified the deregulation of epigenetic program as a genetic hallmark of BPDCN and suggested a novel therapeutic approach based on the combination of two hypomethylating agents 5'-Azacytidine and Decitabine to be tested in future clinical trials.

PF223

LOSS OF TET2 FOLLOWED BY ACQUISITION OF ACTIVATING KRAS MUTATION LEADS TO COOPERATIVE MALIGNANT MYELOPROLIFERATION THROUGH AMPLIFICATION OF RAS SIGNALING IN A DOSE- AND TIME-DEPENDENT MANNER

M. Miller[1,*], J. Rogers[2], P. Narayanan[3], R. Gupta[2], M. Redell[1], M. Goodell[4], R. Rau[1]

[1]Cancer Center, [2]Baylor College of Medicine, Houston, United States, [3]Texas Children's Cancer and Hematology Center, [4]Center for Cell and Gene Therapy, Baylor College of Medicine, Houston, United States

Background: Mutations of epigenetic modifiers and activated signaling mutations frequently co-occur in myeloid malignancies, suggesting cooperative leukemogenesis. In acute myeloid leukemia (AML) and chronic myelomonocytic leukemia (CMML), TET2 loss-of-function mutations non-randomly co-occur with activating RAS pathway mutations. Thus, we hypothesized that Tet2 loss and activating Ras-pathway mutations collaborate to promote the development of myeloid malignancies.
Aims: Using a novel murine model, we aimed to: 1) Determine if loss of Tet2 followed by acquisition of a Ras-pathway mutation synergistically drives the development of myeloid malignancies; and 2) Define the mechanisms by which Tet2 loss contributes to the development of Ras-driven malignancy.
Methods: We crossed Tet2 knock-out mice to mice with Cre-inducible $Kras^{G12D}$ and the ER-T2Cre driver. We transplanted Sca1-enriched stem/progenitor bone marrow cells from 6-8 week old CD45.2+ C57BL/6 mice with the genotypes of interest into lethally irradiated CD45.1+ recipients. After engraftment, we induced $Kras^{G12D}$ expression by tamoxifen treatment at either 1 or 3 months post-transplant. We tracked mice for evidence of disease, comparing mice with both Tet2 loss and Kras mutation to mice with either mutation alone. We analyzed activation of the Ras-pathway by phospho-flow and gene expression studies.
Results: All mice with $Kras^{G12D}$ had anemia, thrombocytopenia, and splenomegaly as well as myeloid expansion in the peripheral blood and spleens by 4-weeks post Ras-pathway activation; Tet2 loss increased the severity of these symptoms in a dose-dependent manner (Figure 1 and Figure 2). Tet2 dose also impacted disease phenotype, with $Tet2^{-/-}/Kras^{G12D}$ mice dying exclusively of myeloid disease whereas mice with $Kras^{G12D}$ alone and $Tet^{+/-}/Kras^{G12D}$mice developed either myeloid or T cell disease. Disease latency was dependent upon both the dose and duration of Tet2 loss. When $Kras^{G12D}$ was activated at 3 months post-transplant, $Tet2^{-/-}/Kras^{G12D}$ had the shortest survival followed by $Tet^{+/-}/Kras^{G12D}$, both significantly shorter than mice with $Kras^{G12D}$ alone. However, there was no difference in survival if tamoxifen was injected 1 month post-transplant. We found evidence that loss of Tet2 amplifies Ras-signaling with increased pErk and pS6 in $Tet2^{-/-}/ Kras^{G12D}$ bone marrow cells compared to $Kras^{G12D}$ alone.

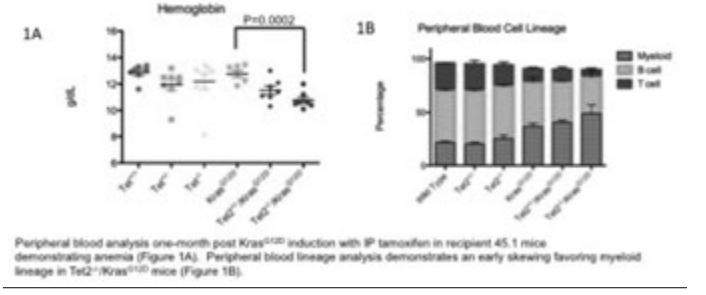

Figure 1.

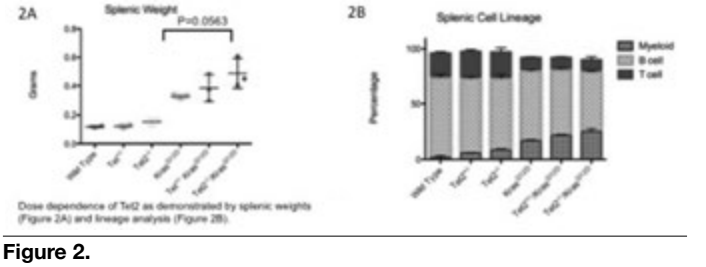

Figure 2.

Summary and Conclusions: TET2 mutations are typically founder mutations in AML and CMML and are frequent in age-related clonal hematopoiesis. This mutational pattern suggests that loss of Tet2 leads to gradual expansion of an aberrant hematopoietic stem/progenitor population that may be primed for malignant transformation. Using a novel murine model, we found that Tet2 loss impacts Kras-induced myeloproliferation in a dose-dependent manner. Further, we found that prolonged loss of Tet2 decreased disease latency after the acquisition of a Ras pathway mutation, possibly mimicking the disease process in adults with TET2 mutant myeloid malignancies arising from a clonal population of TET2-mutant cells that has expanded over time. These results suggest that the extent of aberrant DNA methylation determined by the dose and duration of Tet2 loss is critical to the development of TET2 mutant malignancies. Our mechanistic work indicates that loss of Tet2 cooperates with RAS pathway mutations by amplifying Ras signaling, consistent with recent data (Kunimoto, Cancer Cell, 2017). Thus, targeting the methylation defects with hypomethylating agents and the RAS-pathway with available inhibitors could be therapeutically effective.

PF224

5-AZACYTIDINE ENHANCES THE ANTI-LEUKEMIC ACTIVITIY OF IDH1 INHIBITOR BAY 1436032 *IN VIVO* IN IDH1 MUTANT ACUTE MYELOID LEUKEMIA

A. Chaturvedi[1,*], C. Gupta[1], R. Goparaju[1], R. Gabdoulline[1], S. Kaulfuss[2], K. Görlich[1], R. Schottmann[1], B. Othman[1], O. Panknin[2], M. Wagner[2], R. Geffers[3], A. Ganser[1], F. Thol[1], M. Jeffers[4], A. Haegebarth[2], M. Heuser[1]

[1]Department of Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, [2]Bayer AG, Berlin, [3]Genome Analytics Research Group, Helmholtz Centre for Infection Research, Braunschweig, Germany, [4]Bayer AG, Whippany, NJ, United States

Background: Early data for IDH1 inhibitors show that 30-40% of AML patients respond to monotherapy with a median duration of response of 8 months, suggesting that IDH1 inhibitors should be combined with other agents to improve efficacy. BAY 1436032 (BAY) is an oral pan-mutant IDH1 inhibitor currently undergoing phase 1 clinical trials. 5-Azacitidine (AZA) is a hypomethylating agent and can activate key epigenetically silenced pathways in AML cells, leading to an arrest of AML cell proliferation.
Aims: To investigate the efficacy of IDH1 inhibitor BAY 1436032 in combination with AZA in a preclinical AML model.
Methods: For *in vitro* studies IDH1 wildtype (IDH1wt) or IDH1mut AML cells from patients were incubated with BAY alone or in combination with escalating doses of AZA. For *in vivo* studies leukemic cells from an AML patient with mutated IDH1 were xenografted in NSG mice and treated with either vehicle, BAY 150 mg/kg once daily p.o. continuously, and/or AZA 1 mg/kg once daily s.c. for 5 days. To quantify the stem cell frequency serial dilution transplantation with 20 to 200,000 cells was performed after four weeks of treatment (3 mice/dose).
Results: Combination of 100 nM (IC50 on IDH1mut AML cells) of BAY with 1 µM AZA reduced colony formation by 98% in mIDH1 AML cells but only by 18% in IDH1wt AML cells. IDH1mut human AML cells cultured in suspension medium *ex vivo* and treated with the combination of BAY (100 nM)+AZA (100 nM) proliferated significantly less compared to single agent treatment. For *in vivo* experiments IDH1mut xenografted mice in test groups were treated with BAY and AZA in the doses mentioned above either starting both drugs on day 1 (simultaneous group) or starting AZA on day 1 but BAY 1436032 on day 6 (sequential group). Treatment stopped at 84 days. Leukemic cells in peripheral blood constantly increased in vehicle and AZA treated mice, while leukemic cells declined from week 4 until the end of treatment at week 12 in mice treated with BAY alone as well as in the simultaneous and sequential combination groups treated with BAY and AZA. However, in week 20 (8 weeks after stopping BAY) leukemia relapsed in the BAY alone as well as the sequential BAY+AZA groups and all mice died by week 24. Interestingly, the frequency of leukemic cells remained low in peripheral blood of mice treated simultaneously with BAY+AZA and 2/6 mice from this cohort remained negative until the end of the study at 36 weeks. To assess the effect of simultaneous and sequential treatment with AZA+BAY on leukemia stem cell self-renewal we performed a limiting dilution transplantation experiment. The LSC frequency was 1 in 304 cells in AZA, 1 in 8,580 in BAY and 1 in 34,314 in BAY+AZA sequentially treated mice, respectively, while it was less than 1 in 200,000 transplanted cells in mice treated with BAY+AZA simultaneously (Table 1). Gene expression analysis showed additive suppression of MAP kinase (*ELK1, ETS1* and *CCND1*) and E2F signaling (*E2F1, CCNA2* and *CCNE1*), which are involved in cell survival and proliferation, whereas myeloid differentiation genes (*PU.1, CEBPA* and *GABPA*) were upregulated by BAY+AZA compared to single agents. This suggests synergy in induction of differentiation and inhibition of self-renewal of the combination treatment through distinct pathways.

Table 1.

Limiting dilution transplantation of bone marrow cells from PDX mice treated with vehicle, 150 mg/kg BAY 1436032 and/or 1 mg/kg azacitidine. 200,000, 20,000, 2,000, 200 or 20 cells per mouse were transplanted into 3 recipient mice per group. LSC frequencies are shown (mean ± SEM, n = 3).

Group	Stem cell frequency	± SEM	P value
Vehicle	1/74	19-287	0.2
AZA	1/304	48-1,944	0.005
BAY-1436032	1/8,580	2,440-30,176	0.2
BAY+AZA Sequential	1/34,314	5,913-199,114	0.005
BAY+AZA Simultaneous	>200,000		

Summary and Conclusions: Our study provides evidence that simultaneous combination of an IDH inhibitor with a hypomethylating agent synergistically inhibits leukemia stem cells. Clinical development is ongoing with phase 1 studies using BAY 1436032 in IDH1 mutant solid tumors and AML, and simultaneous combination of BAY with AZA is warranted.

PF225

COMBINATORIAL CSF3R AND RUNX1 MUTATIONS INVOLVED IN THE LEUKEMIC PROGRESSION OF SEVERE CONGENITAL NEUTROPENIA CONFER A G-CSF-DEPENDENT PREMALIGNANT STATE IN MICE TERMINATING IN G-CSF INDEPENDENT AML

P. Olofsen[1,*], S. Fatrai[1], P. van Strien[1], J. Obenauer[1], I. Touw[1]

[1]Hematology, Erasmus MC, Rotterdam, Netherlands

Background: Severe congenital neutropenia (SCN) is a bone marrow failure syndrome characterized by a block in neutrophil development. In the majority of patients neutrophil production is restored by sustained G-CSF treatment. During G-CSF treatment, SCN patients frequently acquire clones with truncated *CSF3R* mutations which are associated with progression to MDS or AML. At this stage the majority (~75%) acquired secondary mutations in *RUNX1*, mainly affecting the Runt homology domain (RHD). The combination of *CSF3R* and *RUNX1* mutations is unique for SCN-MDS/AML, but the consequences of having both mutations and the effect of G-CSF therapy on leukemic progression are unknown.
Aims: To determine the effects of mutations in *CSF3R* and *RUNX1,* and to assess the impact of G-CSF treatment, in the leukemic transformation of mouse bone marrow cells.
Methods: Csf3r-d715 mutant lineage depleted mouse bone marrow cells were transduced with RUNX1 RHD mutant (D171N), or empty vector control, IRES-GFP lentivirus. These cells were transplanted into 8.5 Gy irradiated wildtype recipients and the recipient mice (n=9 per group) were injected 3x a week with G-CSF or solvent control (PBS). Peripheral blood was analysed biweekly for GFP-marked engraftment, immunophenotypes and cytology. *In vitro* progenitor cell colony assays were performed, and bone marrow, spleen and liver samples were used for phenotypic analyses and secondary/tertiary transplantations.
Results: Analyses of the peripheral blood showed rapidly decreasing GFP+ numbers in all groups except for the mice transplanted with CSF3R/RUNX1 mutant cells that were treated with G-CSF, where GFP+ cells could be detected till the end of the experiment, 35 weeks after transplantation. These CSF3R/RUNX1 mutant cells did not show clonal dominance as fluctuations in GFP+ blood cells were observed. When analysing the cellular content of the blood we found an accumulation of cKit+ cells in the CSF3R/RUNX1 mutant G-CSF treated group, which had a blast morphology and colony forming potential *in vitro.* These mice also showed elevated extramedullary hematopoiesis in the spleen. However, the CSF3R/RUNX1 mutant cells were still capable of forming mature neutrophils and mice did not succumb to this pre-leukemic condition. CSF3R/RUNX1 mutant bone marrow cells could successfully engraft sub-lethally irradiated secondary recipients, again resulting in accumulation of cKit+ blast cells in the blood. The GFP+ cells were vastly accumulating and >90% myeloblast infiltration was observed in the bone marrow of these mice 10 weeks after transplantation, indicating that the mice had developed AML. Re-transplantation of these mutant bone marrow cells showed G-CSF independent accumulation of GFP+ cKit+ cells in the blood, bone marrow, spleen and liver. G-CSF independent proliferation of SCN-AML cells has been linked previously to autoactivating mutations in the already truncated CSF3R mutant. To interrogate this and the possible acquisition of other secondary mutations, we are currently completing whole exome DNA sequencing.
Summary and Conclusions: The combination of *Csf3r* and *RUNX1* mutations and sustained G-CSF treatment results in selective accumulation of blast-like cells in an *in vivo* transplant model. This pre-leukemic state is seen in primary recipients and progresses to a fully transformed AML in secondary recipients. These leukemic cells can be re-transplanted and become G-CSF independent. This model is attractive for unravelling the molecular steps of leukemic transformation in SCN-MDS/AML, and for preclinical testing of potential new therapeutic options.

PF226

IDENTIFYING NEW DISEASE GENES IN FAMILIAL MYELODYSPLASIA/ ACUTE MYELOID LEUKEMIA

A. Rio-Machin[1,*], S. Cardoso[2], A. Ellison[2], K. Tawana[1], J. Wang[3], C. Chelala[3], V. Plagnol[4], N. Pontikos[5], P. Page[6], K. Reay[6], Y. Wallis[6],

G. Ryan[6], A. Al Seraihi[1], A. Walne[2], H. Tummala[2], J. Fitzgibbon[1], I. Dokal[2], T. Vulliamy[2]

[1]Centre for Haemato-Oncology, Barts Cancer Institute, [2]Centre for Genomics and Child Health, Blizard Institute, [3]Centre for Molecular Oncology, Barts Cancer Institute, [4]UCL Genetics Institute, [5]UCL Institute of Ophthalmology, University College London, London, [6]Cancer Programme, West Midlands Regional Genetics Laboratory, Birmingham, United Kingdom

Background: Myeloid neoplasms with germ line predisposition is included in the World Health Organization (WHO) classification 2016 as a new diagnostic category, encompassing multiple inherited hematological syndromes and typically characterized by familial myelodysplasia/acute myeloid leukemia (MDS/AML) with two or more affected individuals within the same family. Although it is considered that these familial cases represent <5% of all MDS/AML cases, they constitute a high-risk population that requires unique management and genetic counselling.
Aims: To identify novel loci associated to familial MDS/AML development.
Methods: Eighty eight families where two or more members have been diagnosed with hematological disease (leukemia, MDS or bone marrow failure) including at least one individual with MDS or AML in each family, were enrolled into the study. Twelve genes (*ACD, ANKRD26, CEBPA, DDX41, ERCC6L2, ETV6, GATA2, MECOM, RUNX1, SRP72, TERC* and *TERT*) were analyzed using a targeted Next Generation Sequencing panel (Agilent SureSelect QXT target enrichment, Illumina MiSeq platform). Families where variants were not identified underwent Whole Exome Sequencing (WES) analysis (Illumina Nextera reagents, HiSeq2000, GATK v3.2).
Results: Forty four of the eighty eight families in our cohort (50%) have likely pathogenic variants in 10 of the 12 known loci analyzed by targeted sequencing: *CEBPA* (7), *DDX41* (6), *ERCC6L2* (1), *ETV6* (1), *GATA2* (7), *MECOM* (1), *RUNX1* (12), *SRP72* (2), *TERC* (3) and *TERT* (4). WES was performed in the remaining 44 families. In phase I of these studies, we focused attention on genes linked with other inherited hematological syndromes, assigning a likely causal germline variant in 4 additional families: a novel *WASP* variant (p.Lys446fs), two known pathogenic biallelic *SBDS* variants (c.258+2T>C and p.Lys62*) and novel *SAMD9L* variants (p.Ser1473Asn and p.Asn140Ser) in two families. Based on the characteristics of known germline disease causing variants in familial MDS/AML, we established the following criteria to enrich for genes with pathogenic relevance in the remaining 40 families: (i) genes with variants in at least three families; (ii) novel variants not described in ExAC or gnomAD; and (iii) variants predicted to be pathogenic with two out of four tools for functional annotation (PolyPhen2, MutationTaster, SIFT and Provean). The chosen criteria allowed us to limit the search to the two most relevant genes with germline variants in our cohort, *PRR23B* (N=3) and *CPEB2* (N=3). However when these criteria are relaxed, in particular the number of families or ExAC frequency, we observed a significant increase in credible candidates including *ADA, DNAH11, CSNK1A1L, DHX34, HELQ, LTK, PDCD4, PPM1J, PRUNE2, SLC13A2, TMIUSP31, VPS13C, VWDE or ZNF208.*
Summary and Conclusions: Our results demonstrate that the intra and inter family clinical variability is likely to be mirrored by significant genetic heterogeneity. It is notable, that our candidate genes mutated in small fractions of families are rarely detected in sporadic MDS/AML, suggesting that the identification of novel loci will provide fresh insight into the biology of AML. Our ongoing functional studies and the investigation of additional patient cohorts will establish whether these candidate genes can be assigned as true 'familial MDS/AML' disease loci. Full knowledge of the diversity of predisposing variants is critical to improve the management and counselling of these families.

Acute myeloid leukemia – Clinical

PF227

ADDITION OF CRENOLANIB TO STANDARD INDUCTION AND CONSOLIDATION THERAPIES IMPROVED LONG-TERM OUTCOMES IN NEWLY DIAGNOSED FLT3-MUTANT AML PATIENTS ≤60 YEARS OLD

R.B. Walter[1,*], R.H. Collins[2], R.M. Stone[3], M.S. Tallman[4], C. Karanes[5], C. E. Vigil[6], J.R. Eckardt[7], E.S. Wang[8]

[1]Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, WA, [2]University of Texas Southwestern Medical Center, Dallas, TX, [3]Dana-Farber Cancer Institute, Boston, MA, [4]Division of Hematologic Oncology, Leukemia Service, Memorial Sloan Kettering Cancer Center, New York, NY, [5]Gehr Family Center for Leukemia Research, City of Hope, Duarte, CA, [6]Division of Hematology, Oncology, and Blood & Marrow Transplantation, The University of Iowa, Iowa City, IA, [7]AROG Pharmaceuticals, Inc., Dallas, TX, [8]Roswell Park Comprehensive Cancer Center, Buffalo, NY, United States

Background: The multikinase inhibitor midostaurin was recently approved in combination with chemotherapy based on the RATIFY trial of younger patients with treatment-naïve *FLT3*-mutant AML demonstrating a survival benefit (2yr OS: 60% midostaurin *vs* 51% placebo). We hypothesized that a more selective *FLT3*-targeted agent such as crenolanib, a potent and specific FLT3 tyrosine kinase inhibitor (TKI) which inhibits both FLT3ITD and FLT3TKD mutations, would further improve patient outcomes when combined with chemotherapy. We here report an analysis of patients treated with crenolanib combined with chemotherapy similar to the population studied in the RATIFY trial.
Aims: To assess the outcomes of a sub-group of newly diagnosed FLT3-mutant AML patients treated with crenolanib and standard chemotherapy to be targeted in a pivotal phase III trial comparing crenolanib with midostaurin.
Methods: Twenty-seven of 29 consecutive patients ≤60 years old enrolled in a phase II study of crenolanib combined with chemotherapy in newly diagnosed FLT3-mutant AML (NCT02283177) were included in this analysis. Two patients were excluded due to 1) prior treatment for a myeloproliferative disorder and 2) pre-existing liver cirrhosis. Patients received 7+3 induction with cytarabine 100 mg/m^2 for 7 days and either daunorubicin 90 mg/m^2 (n=16) or idarubicin 12 mg/m^2 (n=11) for 3 days. Crenolanib 100 mg TID was administered continuously starting 24 hours after chemotherapy until 72 hours prior to the next chemotherapy cycle. Consolidation consisted of up to four cycles of high-dose cytarabine (HiDAC: 3 g/m^2 for <60 years and 1 g/m^2 for 60 years) q12 hours on days 1, 3, and 5 with crenolanib starting 24 hours after the final HiDAC dose in each cycle. Eligible patients proceeded to allogeneic hematopoietic stem cell transplant (HSCT). Maintenance crenolanib at 100mg TID was started after HiDAC or 30-90 days after HSCT for a maximum of 12 cycles.

Table 1.

Characteristic	n = 27
Age, median (range)	51 (19 – 60)
Baseline WBC per μL, median (range)	33,010 (2,300 – 248,800)
Baseline WBC ≥100,000 per μL	6 (22%)
FLT3 mutation status	
FLT3-ITD (± TKD)	23 (85%)
FLT3-TKD	4 (15%)
FLT3-ITD/NPM1/DNMT3A mutant	6 (26%)
Cytogenetic risk classification	
Intermediate	24 (89%)
Adverse	2 (7%)
Not available	1 (4%)
OS, median (2yr)	Not reached (81%)
EFS, median (2yr)	Not reached (62%)
CIR, median (2yr)	Not reached (17%)

Results: Patients included in the analysis were generally older (median 51 *vs* 47 years for RATIFY) and most patients (85%) had FLT3-ITD mutations. Six patients had concurrent NPM1 and DNMT3A mutations, a constellation associated with poor prognosis. Only 4 (15%) patients had more favorable FLT3-TKD mutations compared with 23% in the RATIFY study. As of February 2018, 22/27 (81%) patients are alive with a median follow-up of 20.8 months. Median overall survival (OS), event-free survival (EFS), and cumu-

lative incidence of relapse (CIR) have not been reached. Fourteen patients received HSCT of which 11 are alive free of disease. Seven patients were consolidated with HiDAC and did not undergo HSCT. Only one of these seven patients has relapsed and the other six remain alive free of disease, suggesting that standard chemotherapy plus crenolanib can provide durable remissions without HSCT. 4/6 (67%) patients with high-risk concomitant mutations in FLT3-ITD, DNMT3A and NPM1 are alive free of disease. Overall, only 3/21 patients have relapsed, none of whom received >1 week of crenolanib maintenance (Table 1).

Summary and Conclusions: This analysis suggests that outcomes in younger patients with newly diagnosed FLT3-mutant AML may be improved by adding a potent pan-FLT3 inhibitor to chemotherapy. A phase III randomized multicenter trial has been initiated to compare the efficacy of crenolanib *versus* midostaurin combined with standard chemotherapy for newly diagnosed patients with FLT3-mutant AML (NCT03258931).

COMBINATION OF IDARUBICIN, CYTARABINE AND CLADRIBINE AS INDUCTION REGIMEN FOR UNTREATED ADULT AML AGED 60 OR YOUNGER: A PHASE III RANDOMIZED CLINICAL TRIAL

J. Chen[1,*], Y. Han[1], C. Chen[1], A. Sun[1], H. Qiu[1], X. Tang[1], C. Fu[1], Z. Jin[1], M. Miao[1], Y. Wang[1], C. Li[1], S. Chen[1], Y. Xu[1], Y. Fan[1], X. Zhang[1], T. Song[1], D. Wu[1]

[1]The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: A successful treatment for AML relies on the ability of inducing long-term remission, in which the induction therapy is quite important. DA regimen has become the standard induction therapy for decades. Although great efforts have been made to improve the outcome including intensifying the dose of anthracycline agents or applying HiDAC regimens, complete remission rarely exceed 70% in younger patients or 50% in older patients. Recently the Polish Adult Leukemia Group has proved the value of adding cladribine into DA regimen (DAC regimen). Since idarubicin plus cytarabine (IA regimen) is another standard induction regimen which is well-accepted in China, we conducted a randomized clinical trial to evaluate the efficacy and safety of IAC regimen (consisted of idarubicin, cytarabine and cladribine) as induction therapy for untreated adult AML patients with age of 60 or younger.

Aims: We conducted a randomized clinical trial to evaluate the efficacy and safety of IAC regimen (consisted of idarubicin, cytarabine and cladribine) as induction therapy for untreated adult AML patients with age of 60 or younger.

Methods: We conducted a phase III randomized study (NCT02323022) to compare the efficacy of following three induction regimens: Arm A: idarubicin 10 mg/m^2 for 3 days plus cytarabine 100 mg/m^2 for 7 days; Arm B: idarubicin 12 mg/m^2 for 3 days plus cytarabine 100 mg/m^2 for 7days; Arm C: idarubicin 8 mg/m^2 for 3 days, cytarabine 100 mg/m^2 for 7 days and cladribine 5 mg/m^2 for 5 days. Patient fulfilled following criteria was recruited and randomized allocated into the three arms above: 1) diagnosed as AML (expect APL); 2) aged 18 – 60; 3) with an ECOG score of 0 – 3 and tolerated to chemotherapies. The primary endpoint in this trial was completion remission (CR) rate after induction.

Results: From December, 2014 through June, 2017, totally 306 cases were recruited in this trial (characterized in Table 1). As a result, compared to the CR rate of Arm C (80.39%), the CR rate of Arm A (67.32%) was significantly inferior (P=0.034) despite that of Arm B (73.79%) was similar. In the subgroup analyses, Arm C revealed the highest CR rate (76.27%) in AML patients with unfavorable-risk cytogenetic and molecular abnormalities (according to NCCN guidelines) compare to Arm A and Arm B (55.85% and 57.44% respectively) with statistical difference (P=0.033). In addition, Arm C also exhibited better CR rate in patients with higher WBC counts (≥30 × 10^9/L) and higher blast proportion in bone marrow (≥50%) at diagnosis, with P value of 0.039 and 0.012 respectively. Toxicity among the three groups were comparable. Multivariate risk factor analysis showed blast proportion in bone marrow at diagnosis and NCCN risk stratification were independent risk factors affecting CR, while induction regimens had a marginal significance (P=0.055) due to the inapparent difference between Arm B and Arm C.

Summary and Conclusions: We concluded that IAC regimen could decrease the dose of anthracycline agents and achieve at least comparable CR rate with standard IA regimen without additional toxicity in adult AML patients aged 60 or younger. For patients with genetic or non-genetic risk factors, IAC regimen had potential superiority to induce CR. Reducing the dose of idarubicin in IA regimen had negative impact on CR rate.

PF229

REASSESSING THE PROGNOSTIC SIGNIFICANCE OF RECURRING CHROMOSOMAL ABNORMALITIES AND FLT3-ITD IN ACUTE MYELOID LEUKEMIA PATIENTS UNDERGOING ALLOGENEIC STEM CELL TRANSPLANTATION: AN ALWP/EBMT ANALYSIS

J. Canaani[1,*], M. Labopin[2], M. Itälä-Remes[3], D. Blaise [4], G. Socié[5], E. Forcade [6], J. Maertens[7], D. Wu[8], R. Malladi[9], J.J. Cornelissen[10], A. Huynh[11], J.H. Bourhis[12], J. Esteve[13], M. Mohty[2], A. Nagler[12]

Background: Baseline cytogenetics remain the single most important determinant of outcome in patients with acute myeloid leukemia (AML). The Medical Research Council (MRC) prognostic model is currently the benchmark for risk assessment in this patient population (Grimwade *et al.* Blood 2010). However, the prognostic role of the complete gamut of cytogenetic aberrations reported above in AML patients undergoing allogeneic stem cell transplantation (allo-HSCT) is currently undefined. In addition, their significance in conjunction with *FLT3-ITD* status has not been addressed thus far.

Aims: Using the ALWP/EBMT international database we conducted a retrospective analysis to determine the clinical outcomes of AML patients undergoing allo-HSCT with respect to specific recurring cytogenetic abnormalities complemented with *FLT3-ITD* status.

Methods: Using cox regression analyses with forward selection for each cytogenetic aberrancy allowed classification of patients into favorable, intermediate or adverse risk groups. Factoring in the presence or absence of a complex karyotype, defined as 3 or more cytogenetic abnormalities, classified patients into 4 prognostically distinct groups. We then assessed the prognostic impact of *FLT3-ITD* status in each subgroup.

Results: We analyzed a cohort consisting of 9113 adult AML patients who underwent allo-HSCT in first remission from either a matched sibling (n=4167) or a matched unrelated donor (n=4946), respectively in 2006-2016. Patients with inv(3)(q21q26)/t(3;3)(q21;q26), del(5q), del(7q), del(17p)/i(17q), and monosomies of chromosomes 4,5,7,8,17,21 as well as those patients with t(10;11) and t(6;11) experienced significantly inferior leukemia-free survival (LFS) compared to patients with a normal karyotype (P<0.0001). Del 9q [including add(9q)] and loss of chromosome X were associated with improved LFS rates (P<0.0001). Diverging from the MRC data, monosomies 4,8,21, trisomies 19,21 and abnormality of 16q [other than inv(16)] were determined to be poor prognostic factors. The presence of a complex karyotype was independently associated with outcome in the non-favorable risk groups, allowing us to identify 4 prognostic groups in the entire cohort analyzed. *FLT3-ITD* positivity (data available for 3997 patients) was also found to be an independent prognostic factor resulting in refinement of the model and the identification of 3 subgroups defined according to the presence of individual chromosomal abnormalities, complex karyotype, and *FLT3-ITD* status, with significant prognostic implications (Figure 1).

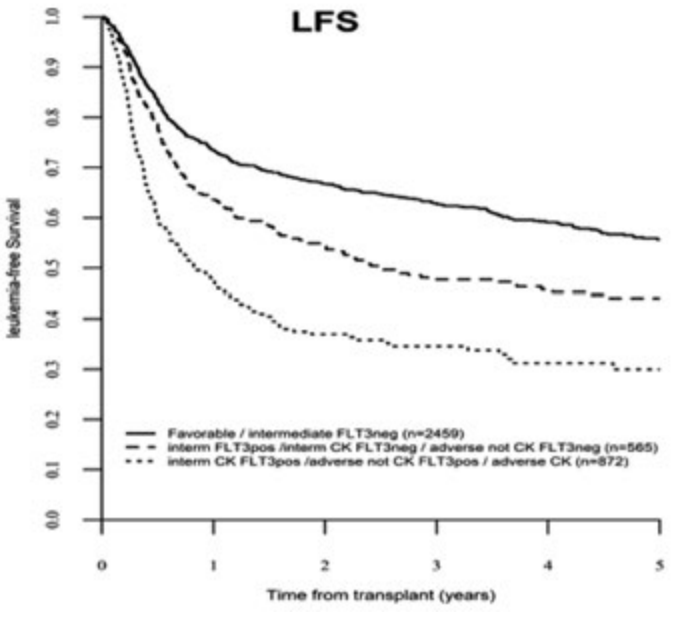

Figure 1.

Summary and Conclusions: In this analysis of a large cohort of more than 9000 AML patients, we confirm the prognostic significance of the MRC prognostic model in patients undergoing allo-HSCT in CR1 with some specific modifications. Furthermore, consideration of *FLT3-ITD* and complex karyotype improved the predictive capacity of the MRC model in transplanted patients.

Background: Outcome for elderly AML patients is disappointing (median OS <6 months). The MD Anderson CC has identified as OS risk factors for elderly AML patients treated with intensive chemotherapy: age >80 yrs, ECOG ≥2, creatinine >1.3mg/dL and adverse cytogenetic (0 as opposed to 4 risk factors OS: 11.3 and 0.5 months respectively); *Kantarjian et al Blood 2010*. Decitabine (Dec) has been EMA approved for first line AML patients not fit for intensive chemotherapy, ECOG, cytogenetic and high WBC has been suggested as risk factors (Daco16) *Kantarjian et al JCO 2012*.

Aims: The aim of this study is to analyze effectiveness and tolerance of Dec as first line in AML in day to day practice and to identify risk factors.
Methods: We carried out the analysis on patients with previously untreated AML included in the MDA-AML-2017-05 study on 25 Spanish sites. Inclusion criteria as follows Age >18, diagnosis of AML under WHO criteria, treated with Dec during the period 01/09/2014 to 31/12/2016. We evaluated effectiveness as ELN-2010 criteria, toxicity as CTCAE v3.0 scale, OS by Kaplan-Meier and the mortality within the first 8 weeks (M8wks). This study has been approved by the Spanish Medicines Agency AEMPS code MDA-AML-2017-05.
Results: Of the 228 patients included in the MDA-AML-2017-05 study 126p (77M, 49F) received Dec as first line. Average age 75.7 (48-91), 80 yrs and above 57p, ECOG≥2: 38p, Creatinine>1.3 mg/dL: 23p, adverse cytogenetic: 39p, WBC pre-Dec >15.000/µL: 21p. A total of 716 cycles were analyzed, median 4 (1-31) per patient, 26 cases of hospitalization due to adverse events. No cases of treatment related mortality. One hundred and three patients were studied for effectiveness ORR 49% (CR 20p, PR 21p, ED 28p). With a mean follow up of 8 mths 77 died. The M8wks was 24.5% and the median OS 8 months. OS for patients who met the Daco16 inclusion criteria (83p) was 11 montrhs. In this study WBC pre-Dec >15.000/µL (p <0.01) creatinine >1.3 mg/dL (p0.02), ECOG≥2 (p<0.01) and adverse cytogenetics (p<0.01) resulted in statistical differences for OS. Age >80 revealed no differences. We observed OS benefit in patients with CR 20 mths (p <0.01) and for PR+ED *vs* PD 11.5 *vs* 3 mths (p<0.01). The DecLAM scale (WBC pre-Dec >15.000/µL, creatinine >1.3 mg/dL, ECOG≥2 and adverse cytogenetics) allows us to identify risk groups with 0 *vs* 1-2 *vs* 3-4 risk factors with differences for OS (19 *vs* 5.5 *vs* 3.5 m p<0.01) (Figure 1).

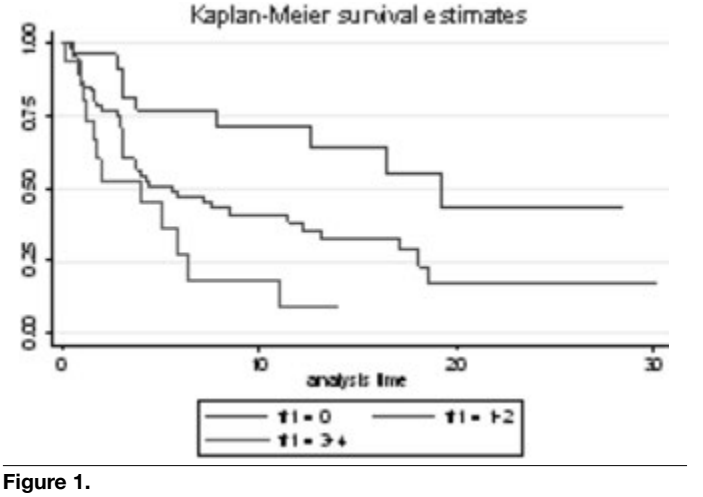

Figure 1.

Summary and Conclusions: The results of this study confirm Dec as an effective and well tolerated first line treatment in AML patients not candidates for intensive chemo. The OS observed in our study seems better that previously reported. The DecLAM scale identifies risk groups with differences in OS.

PF232

INITIAL PHASE 1 RESULTS OF THE FIRST-IN-CLASS ANTI-CD47 ANTIBODY HU5F9-G4 IN RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA PATIENTS

P. Vyas[1,*], S. Knapper[2], R. Kelly[3], R. Salim[4], M. Lubowiecki[1], D. Royston[1], H. Johnson[5], C. Roberts[6], J. Chen[7], B. Agoram[7], J. Liu[7], J.-P. Volkmer[7], R. Majeti[8], I. Weissman[8], S. Goudar[7], C. Takimoto[7], M. Chao[7], M. Dennis[9]

[1]University of Oxford and Oxford University Hospitals, Oxford, [2]Cardiff University School of Medicine, Cardiff, [3]Leeds Teaching Hospital NHS Trust, Leeds, [4]Royal Liverpool University Hospital, Liverpool, [5]Oncology Clinical Trials Office, [6]Centre for Statistics in Medicine, Nuffield Department of Orthopaedics, Rhuematology and Muscoloskeletal Sciences, University of Oxford, Oxford, United Kingdom, [7]Forty Seven, Inc., Menlo Park, [8]Stanford University, Stanford, United States, [9]The Christie NHS Foundation Trust, Manchester, United Kingdom

Background: Novel and well tolerated therapies are needed in relapsed/refractory (r/r) acute myeloid leukemia (AML). Hu5F9-G4 (5F9) is a first-in-class humanized antibody targeting CD47, a protective "don't eat me" signal on cancers, that stimulates tumor cell phagocytosis and an

anti-tumor T cell response. Pre-clinically, 5F9 eliminates leukemic disease and induces durable remissions in patient-derived xenograft mouse models. This trial is the first to investigate an anti-CD47 antibody in AML patients.
Aims: The main objectives were to determine the safety, tolerability and recommended Phase 2 dose of 5F9 in r/r AML.
Methods: This Phase 1 trial enrolled r/r AML patients in a 3+3 dose escalation design (NCT02678338). An intra-patient dose escalation design was used with escalation from 0.1 to 30 mg/kg twice weekly dosing of 5F9. Safety, preliminary efficacy, pharmacokinetic and pharmacodynamic parameters were measured.
Results: 15 r/r AML patients were enrolled across 5 dose cohorts as of 19 January 2018. Median age was 71 years (range 31-78) with a median of 2 prior therapies (range 1-5). 47% were relapsed, 47% relapsed/refractory and 7% primary refractory. 80% were intermediate to poor cytogenetic risk (20% not performed). 5F9 was well tolerated. Common treatment-related AEs were anemia (93%), hemagglutination (87%), pyrexia (27%), and headache (27%). All AEs were grade 1 or 2 (except anemia, a known on target effect of CD47 blockade). No patient developed a grade 4 or 5 treatment-related AE. 79% of these patients had grade 3 anemia prior to study. RBC transfusions were successfully administered and well tolerated with treatment despite interference with cross-matching in some patients due to 5F9 RBC binding. Hemagglutination was observed on peripheral smear in most patients with no significant clinical sequelae. No other significant myelosuppression was observed. No DLTs were observed with no patients discontinuing therapy due to AEs. The maximum tolerated dose (MTD) has not yet been reached up to 30 mg/kg twice weekly of 5F9 dosing. CD47 receptor occupancy >90% was achieved on blood and bone marrow WBCs, indicating near-maximal leukemic cell target saturation. A Phase 2 dose of 30 mg/kg 5F9 weekly after two weeks was selected. 73% of patients achieved stable disease with no objective responses. 40% of patients had a reduction in bone marrow blast count (mean decrease of 27%, range 5% - 67%). Two patients had biologic activity, defined as significant reduction in marrow cellularity observed similarly in pre-clinical models. Somatic mutation sequencing demonstrated that the first patient with an ASXL1 mutation had a 92% decrease in variant allele frequency (VAF) on treatment. Significant reduction in myeloid mutation VAFs was observed in several patients (range 7.4 – 95% decrease in VAF). The 2nd patient achieved a >50% blast count reduction and was on therapy for 11.8 months. This patient had a significant increase in T cell infiltrate in the bone marrow during treatment, suggesting activation of the adaptive immune system by Hu5F9-G4.
Summary and Conclusions: 5F9 is a novel immunotherapy inhibiting a key macrophage/cancer checkpoint. It is well tolerated in r/r AML with no DLTs or an MTD observed. Biologic activity was seen with T cell bone marrow infiltration in a long-term treated patient and reduction in somatic myeloid mutations in several patients. A Phase 1b trial of 5F9 in combination with azacitidine has been initiated based on these initial Phase 1 results (NCT03248479).

PF233

IMPACT OF CONCOMITANT EXPRESSION OF CD200 AND BCL2 ON OUTCOME OF ACUTE MYELOID LEUKEMIA

M. Tiribelli[1,*], A. Geromin[1], D. Raspadori[2], A. Michelutti[1], M. Cavallin[1], S. Sirianni[2], S. Di Giusto[1], E. Toffoletti[1], R. Fanin[1], M. Bocchia[2], D. Damiani[1]

[1]Division of Hematology and BMT, Azienda Sanitaria Universitaria Integrata di Udine, Udine, [2]Division of Hematology, University of Siena, Siena, Italy

Background: In the last years, evidence emerged that CD200 overexpression is associated with poor prognosis acute myeloid leukemia (AML) and that inhibition of apoptotic pathways mediated by bcl2 proteins has a role in myeloid malignancies. Moreover, we have observed a frequent association of bcl2 positivity and CD200 overexpression in AML patients; however, no data are available on the role of concomitant aberrant CD200 and bcl2 expression on outcomes of patients.
Aims: We aimed to elucidate the prognostic role of CD200/bcl2 co-expression and the association with specific leukemia subsets, to identify patients suitable for new target treatments.
Methods: .Two hundred and ninety-one patients diagnosed with AML and treated at our Institutions between 2009 and 2015 were included in this analysis. Median age was 60 (range: 18-84) years, and 183/291 (63%) patients were older than 55 years. Ninety-one patients (27%) had secondary leukemia, 109 (37%) had WBC count ≥30x109/L, 81 (28%) had unfavorable karyotype and 82 (28%) had an unfavorable cytogenetic/molecular risk. CD200 was evaluated by multi-parametric flow cytometry (MCF), with high intensity of expression defined by a MFI >11; bcl2 was evaluated by MFC, with a positivity defined by a MFI >17
Results: CD200 was expressed in 172/291 patients (59%) and bcl2 was overexpressed in 136/291 (45%) cases. CD200 positivity and concomitant bcl2 overexpression (double-positive, DP) was found in 93/291 (32%) patients, while 77 (26%) were double negative (DN) and 120 (41%) expressed only CD200 or bcl2. CD200/bcl2 DP cases were more frequent in patients with secondary leukemia (43% *vs* 27%, p=0.008), in CD34+ AML (39% *vs* 24%,p=0.006) and in CD56- patients (38% *vs* 20%, p=0.002). Overall, 274 patients were evaluable for response to induction therapy, and 175 (64%) attained a complete remission (CR). CR rate was lower in CD200+ patients (60% *vs* 75%, p=0.007); co-expression of CD200 and bcl2 (*i.e.* DP cases) did not worsen CR probability, but DN patients have significantly higher CR rate compared to all the other groups (77% *vs* 59% p=0.01). At the time of analysis 60/175 patients have relapsed and 115/175 remained in CR, with a 3-year DFS of 59%. Neither CD200 nor bcl2, alone or in association, influenced DFS. Of 291 patients included in the study, 174 (60%) have died, with a 3-years OS in the whole population of 36%. CD200 and bcl2 DP patients had a 3-year OS of 23%, compared to 35% in patients with isolated CD200 or bcl2 overexpression and 54% in DN ones (p=0.004). In multivariate analysis (MVA) statistical significance was found for age ≥55, CD34 positivity, high WBC count and CD200/bcl2 DP. Combining the four variables resulting from MVA, we designed a score predicting very different OS probability: 3-year OS was 91% in patients without risk factors compared to 51%, 29%, 13% and 0% in those with 1, 2, 3 or 4 risk factors, respectively (p<0.00001) (Figure 1).

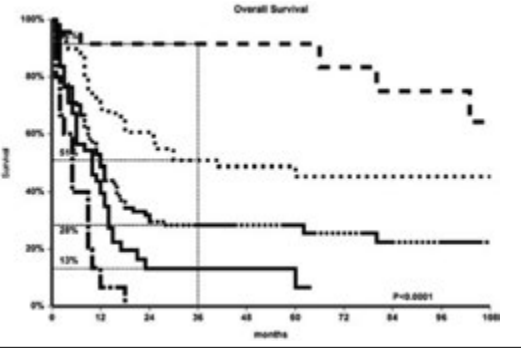

Figure 1.

Summary and Conclusions: CD200 and bcl2 concomitant expression was associated with lower survival probability compared to that of isolated bcl2 or CD200 expression or double negativity, a negative impact maintained also in MVA, along with known prognostic factors such as age, WBC count and CD34 positivity. The combination of these four factors in a risk score based on their presence or absence defined five subgroups with very different survival probabilities. These data may foster the use of bcl2 inhibitors and anti-CD200 antibodies in DP AML patients.

PF234

TP53 MUTATIONS NEGATIVELY IMPACT SURVIVAL OF ACUTE MYELOID LEUKEMIA PATIENTS TREATED WITH STANDARD DOSES OF HYPOMETHYLATING AGENTS

P. Bories[1,2,*], N. Prade[2], S. Lagarde[2], B. Cabarrou[3], I. Luquet[2], V. De Mas[2], J. Plenecassagnes[4], M. Cassou[4], A. Sarry[5], L.-M. Fornecker[6], C. Simand[6], S. Bertoli[5], C. Recher[5], E. Delabesse[2]

[1]Onco-occitanie regional cancer network, [2]Department of Haematology, [3]Biostatistic Unit, Institut Claudius Regaud, [4]Bioinformatics Unit, Institut Claudius Regaud, [5]Department of Hematology, Toulouse University Institute of Cancer-Oncopole, Toulouse, [6]Department of Hematology, Strasbourg University Hospital, Strasbourg, France

Background: Despite little improvement in their overall survival (OS) over the last decade, older patients (pts) with acute myeloid leukemia (AML) still harbor dismal prognosis and validated therapeutic options are limited. Patient selection for these options remains controversial. The AZA-AML-001 and DACO-16 phase III studies failed to demonstrate the superiority of hypomethylating agents (HMA, azacitidine and decitabine, respectively) over intensive chemotherapy (ICT) for pts over 65 years with non-prolif-

erative AML, which increases the uncertainty regarding the optimum strategy for any individual pt. There is currently no validated molecular biomarker which can been used to guide therapeutic decision. *TP53* mutations which are known to negatively impact AML pts outcome when treated with ICT, have been recently described as a positive prognosis factor for blast clearance with a 10-days regimen of decitabine (N England J Med 2016;375:2023-36).
Aims: To evaluate the impact of *TP53* mutational status on outcome of a real-world, well characterized cohort of pts, treated frontline with standard schemes of HMA.
Methods: Characteristics of non-M3 AML patients, consecutively enrolled in the regional cancer network ONCOMIP registry between 2007 and 2016 and treated frontline with HMA were reviewed. Cytogenetic risk was assessed according to the MRC classification and karyotype were all reviewed for the presence of a chr. 17 monosomy (-17) or deletion chr.17p (del17p). For pts with an available bone marrow baseline DNA sample, *TP53* mutations were screened with next-generation sequencing (NGS) on an Illumina® MiSeq sequencer. Sequencing results were filtered with the IARC *TP53* mutations database and a variant allele frequency (VAF) >10%, strengthening the specificity of the data of this cohort. Response to HMA and overall survival (OS) were analyzed for all pts and according to *TP53* mutational status and cytogenetics.
Results: From January 1st 2007 to December 31st 2016, we identified 289 AML pts treated frontline with HMA (azacitidine n=279, decitabine n=6; guadecitabine n=4). Median age was 75 years (IQR: 71-81), karyotype was adverse in 135 pts (47%), including 54 pts with -17 or del17p (23.7%). Seventy-five pts had secondary AML to myelodysplastic syndrome (MDS, 25.9%) and 24 pts to myeloproliferative neoplasm (MPN, 8.3%). Forty-nine pts had therapy-related AML (t-AML, 17%). Pts received a median of 6 cycles (range 1-67). Fifty-five pts obtained CR or CRi (19%) and median OS was 10.3 months (95%CI: 9.3-11.9). Over the 228 pts with a baseline DNA sample, 55 pts (24.1%) had a *TP53* mutation (*TP53*mut). Of those, 53pts had adverse cytogenetics (96.4%), 16 pts had secondary AML to MDS or MPN (29.1%) and 13 pts had t-AML (23.6%). Response rates did not differ between *TP53*mut (21.8% CR/CRi) and *TP53*wt (24.2% CR/CRi, p=0.92), nor between pts with *TP53*mut and/or -17/del17p (20.5%CR/CRi) and pts without *TP53* abnormality (25.6%CR/CRi, p=0.41). Median OS was 7.9 months in pts with *TP53*mut and 12.6 months in TP53wt (p<.0001). With regards to the group of 109 pts with adverse karyotype, response rates did not differ between *TP53*mut pts (20.7% CR/CRi) and *TP53*wt (14.3%, p=0.37) and median OS was 7.9 months for *TP53*mut pts *versus* 9.6 for *TP53*wt pts (p=0.01).
Summary and Conclusions: Overall the response rate was not influenced by the *TP53*mut status, but median OS was negatively impacted by the *TP53*mut status in the entire cohort and in the sub-group of pts with adverse karyotype.

PF235

CHARACTERISTICS AND OUTCOME OF PATIENTS WITH ACUTE MYELOID LEUKEMIA AND T(8;16)(P11;P13): RESULTS FROM AN INTERNATIONAL COLLABORATION

S. Kayser[1,*], R.K. Hills[2], M. Kramer[3], Z. Sustkova[4], E.H. Estey[5], C. Shaw[5], J. Mayer[4], P. Zak[6], T. Szotkowski[7], P. Cetkovsky[8], D. Grimwade[9], U. Platzbecker[3], A. Krämer[1], A.K. Burnett[10], A.D. Ho[1], R.B. Walter[5], C. Thiede[3], G. Ehninger[3], C. Röllig[3], C. Müller-Tidow[1], N.H. Russell[11], R.F. Schlenk[12], M. Levis[13]

[1]University Hospital of Heidelberg, Heidelberg, Germany, [2]Cardiff University School of Medicine, Cardiff, United Kingdom, [3]University Hospital Carl-Gustav-Carus, Dresden, Germany, [4]Masaryk University and University Hospital Brno, Brno, Czech Republic, [5]Fred Hutchinson Cancer Research Center, Seattle, United States, [6]Charles University and University Hospital Hradec Králové, Hradec Kralove, [7]Palacky University Olomouc and University Hospital Olomouc, Olomouc, [8]Institute of Hematology and Blood Transfusion, Prague, Czech Republic, [9]King's College London, London, United Kingdom, [10]Cardiff University School of Medicine, Cardiff, Germany, [11]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom, [12]National Center for Tumor Diseases, Heidelberg, Germany, [13]Johns Hopkins University, Baltimore, United States

Background: In adult patients (pts) with acute myeloid leukemia (AML), the balanced translocation t(8;16)(p11;p13) is a very rare abnormality resulting in the fusion of *MYST3* and *CREBBP*. Both genes encode proteins with histone acetyltransferase activity and are involved in transcriptional regulation. Previous small series suggested a poor outcome but neither prospective nor larger retrospective cohort studies are available to support these results.
Aims: To characterize AML with t(8;16) and compare outcomes with different treatment strategies.
Methods: We retrospectively studied 48 AML pts with t(8;16) (median age at diagnosis, 52 yrs; range, 16-72 yrs) diagnosed between 1992 and 2016 within five study groups/institutions of the US and Europe. Pts with CBF-AML or APL were excluded.
Results: Median white blood cell and platelet counts at diagnosis were 8.7/nl (range, 1.79-235.9/nl) and 58.5/nl (range, 10-388/nl), respectively. Type of AML was *de novo* in 31 (65%), secondary after MDS/MPN (sAML) in 3 (6%), and therapy-related (tAML) in 14 (29%) of the pts. Thirty-three pts (69%) were female. Cytogenetic analysis revealed additional abnormalities (abn) in 34 (71%) pts, most frequently ≥3 abn (n=23) including further balanced (n=2) or unbalanced translocations (n=13). Breakpoint of t(8;16) was typical in n=33 pts. None of 32 pts tested harbored a *NPM1* mutation and only one of 35 was *FLT3*-ITD positive. Two pts died prior to initiation of therapy due to severe bleeding or rapid progressive disease and one patient died 5 days after initiation of therapy with pazopanib. CR after intensive anthracycline-based induction therapy was achieved in 76% (n=34/45), additionally 4 pts responded to salvage treatment. Five pts were primary refractory and additionally 2 pts experienced early death after therapy initiation, one due to CNS hemorrhage. Seventeen (38%) pts underwent allogeneic hematopoietic cell transplantation (allo-HCT). Of those, 12 pts were transplanted in 1st CR, 2 pts in 2nd CR and 3 with refractory disease, respectively. Type of donor was matched-related in 5, matched-unrelated in 8 and haplo-identical in 4 pts, respectively. Median follow-up for the entire cohort was 55.4 months (95%>CI, 26.2 months-not reached). Median and 4-year overall survival (OS) were 6.7 months (95%>CI, 5.0-9.0 months) and 14.7% (95%>CI, 7.1-30.2%). Median and 4-year relapse-free survival were 5.7 months (95%>CI, 3.9-9.5 months) and 14.4% (95%>CI, 6.4-32.4%). Median and 4-year OS in pts achieving a 1st CR and proceeding to allo-HCT were 15.8 months and 36.4% (95%>CI, 14.5-79.5%) as compared to 6.7 months and 12.5% (95%>CI, 4.4-36.1%) after consolidation with chemotherapy. There was no difference in OS if a typical or atypical breakpoint of t(8;16) was present (p=0.43). Of note, pts proceeding to allo-HCT in 1st CR with a typical breakpoint (n=8) had a favorable OS at 4 years with 57%, whereas none of the pts (n=4) with an atypical breakpoint survived beyond 2 years. Neither additional chromosomal abn nor presence of a complex karyotype (≥3 abn) had a prognostic impact on OS (p=0.44 and p=0.32; respectively). Pts with *de novo* AML had better outcome as compared to those with s-/tAML. (p=0.04).
Summary and Conclusions: Our cohort of AML pts with t(8;16) showed a high CR rate after intensive induction therapy; however, most pts rapidly relapsed and succumbed of their disease. Those pts with a typical breakpoint who proceeded to allo-HCT in 1st CR achieved encouraging OS rates, suggesting that an early transplant in 1st CR should be standard of care when possible for these pts.

PF236

A PHASE 1 DOSE ESCALATION STUDY OF THE IDH1M INHIBITOR, FT-2102, IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) OR MYELODYSPLASTIC SYNDROME (MDS)

M. Baer[1,*], J. Watts[2], S. Lee[3], J. Yang[4], S. Dinner[5], T. Prebet[6], G. Schiller[7], K. Seiter[8], P.B. Ferrell[9], P. Kelly[10], P. Li[10], J. Sweeney[10], C. Watson[10], H. Mohamed[10], J. Cortes[11]

[1]University of Maryland Greenebaum Comprehensive Cancer Center, Baltimore, [2]University of Miami, Miami, [3]Cornell University, New York, [4]Karmanos Cancer Center, Detroit, [5]Northwestern University, Chicago, [6]Yale University, New Haven, [7]Ronald Reagan UCLA Medical Center, Los Angeles, [8]New York Medical College, Valhalla, [9]Vanderbilt University, Nashville, [10]FORMA Therapeutics, Inc., Watertown, [11]MD Anderson Cancer Center, Houston, United States

Background: *Isocitrate dehydrogenase 1* mutations (*IDH1*m) occur in 7-14% of AML patients (pts) and 3% of MDS pts. FT-2102 is a highly potent, selective small molecule inhibitor of *IDH1*m without anticipated CYP or QTc liabilities at the recommended phase 2 dose.
Aims: A Phase 1/2 study to evaluate the safety, pharmacokinetics and pharmacodynamics (PK/PD), and clinical activity of FT-2102 alone or in combination with azacitidine (AZA) in *IDH1*m AML/MDS pts.
Methods: In the phase 1 portion of the study, FT-2102 was dose escalated in a 3+3 design to define the maximum tolerated doses (MTDs) or maximum evaluated doses (MEDs) as a single-agent (SA) and in combination with AZA (CO) followed by expansion cohorts. Doses evaluated were 150 mg QD (SA, CO), 300 mg QD (SA), and 150 mg BID (SA, CO). Safety was assessed by incidence and severity of treatment-emergent adverse events (TEAEs) for all pts and efficacy derived by IWG criteria (2003 AML and 2006 MDS) based on investigator assessment for evaluable pts.
Results: At the data cutoff, 35 pts with a median of 2 prior treatments (range

0-9) had received FT-2102 in dose-escalation, including 22 SA pts and 13 CO pts. Sixteen pts remain on treatment (SA, n=10; CO, n=6) with a median of 2 treatment cycles (range 1-16); 4 pts discontinued for transplant. FT-2102 has been well tolerated both as SA and in combination with AZA. Overall, regardless of causality, most TEAEs were grade (gr) 1/2; most common (>20%) TEAEs were fatigue (34%), nausea (29%), and febrile neutropenia (23%). The most common (>15%) gr 3/4 TEAEs were febrile neutropenia (23%), anemia (20%), and pneumonia (17%). Five (14%) pts had gr 3 differentiation syndrome that was manageable and did not result in discontinuation. Administration of FT-2102, both as SA and in CO at 150 mg BID, enabled all pts to achieve the target steady-state exposure (Css) that exceeded the IC90 of *IDH1*m while staying below the exposures projected from the monkey toxicology studies to possibly be associated with QTc prolongation. PK data were available through Cycle 6; steady-state plasma drug levels were maintained at target Css over the evaluated period. A reduction of 2-HG was observed across all dose levels, with pts receiving 150 mg BID having a median within the normal 2-HG limits. Best response in all evaluable SA pts (n=16) included: 2 (13%) complete remissions (CR), 4 (25%) complete remissions with incomplete hematologic recovery (CRi), and 5 (31%) clinical benefit (CB; stable disease lasting ≥8 weeks), including 2 with >50% reduction of marrow blasts (MB). Best response in evaluable CO pts (n=11) included: 2 (18%) CR, 1 (9%) CRi, and 5 (45%) CB, including 2 with >50% reduction of MB.

Summary and Conclusions: FT-2102 has shown favorable safety, PK/PD, and clinical activity in *IDH1*m AML/MDS pts with a single agent complete response rate (CR/CRi) of 38% and a complete response rate of 27% in combination with AZA. Current data support the continued evaluation of 150 mg BID in the Phase 1 expansion and Phase 2 stages of the study.

Background: Over 60% of patients with AML require salvage therapy. The following risk factors have been described, age, cytogenetics, length of relapse-free interval and previous SCT *Breems et al JCO2005*. Decitabine (Dec) has been EMA approved for first line AML patients not fit for intensive chemotherapy in base on the results of phase 3 study *Kantarjian et al JCO 2012*.

Aims: The aim of this study is to analyze effectiveness and tolerance of Dec as salvage therapy in AML and to identify risk factors.

Methods: We carried out the analysis on patients with relapse/refractory (R/R) included in the MDA-AML-2017-05 study on 25 Spanish sites. Inclusion criteria as follows Age >18 yrs, diagnosis of AML under WHO criteria, treated with Dec during the period 01/09/2014 to 31/12/2016. We evaluated effectiveness as ELN-2010 criteria, toxicity as CTCAE v3.0 scale, OS by Kaplan-Meier and the mortality within the first 8 weeks (M8wks). This study has been approved by the Spanish Medicines Agency AEMPS code MDA-AML-2017-05.

Results: Of the 228 patients included in the MDA-AML-2017-05 study 61p (36M, 25F) received Dec as salvage therapy. Average age 68.6 (34-86), ECOG≥2: 11p, Creatinine>1.3 mg/dL: 3p, adverse cytogenetics: 13p, WBC pre-Dec >15.000/µL: 13p, previous azacitidine 26p, relapse-free interval <12m: 47p. A total of 292 cycles were administered, median 5 (1-23) per patient, 5 cases of hospitalization due to adverse events. No cases of treatment related mortality. Fifty one patients were studied for effectiveness ORR 39% (CR 10p, PR 14p, ED 10p). With a median follow up of 5mths 53p progressed and 39 died. The M8wks was 22% and the median OS 6.9 months (1yr OS 28%). In this study WBC pre-Dec >15.000/µL (11.1 *vs* 4 ms p 0.02) and previous azacitidine (9 *vs* 4 ms p0.05) resulted in statistical differences for OS, ECOG≥2, adverse cytogenetics and relapse-free interval <12m showed differences but with no statistical significance. Neither Age 65/70/75/80 nor creatinine >1.3 mg/dL revealed differences. No differences were observed comparing Dec as second line or later (8.7 *vs* 5.5 ms p0.37). We observed OS benefit in patients with CR 14.4 mths (p 0.05), as for PR+ED *vs* PD 11.4 *vs* 3.8 mths (p<0.01). The DecLAMRR scale (WBC pre-Dec >15.000/µL, previous azacitidine, ECOG≥2 and adverse cytogenetics) allows us to identify risk groups with 0 *vs* 1-2 *vs* 3-4 risk factors with differences for OS (21 *vs* 6.2 *vs* 3m p0.015) (Figure 1).

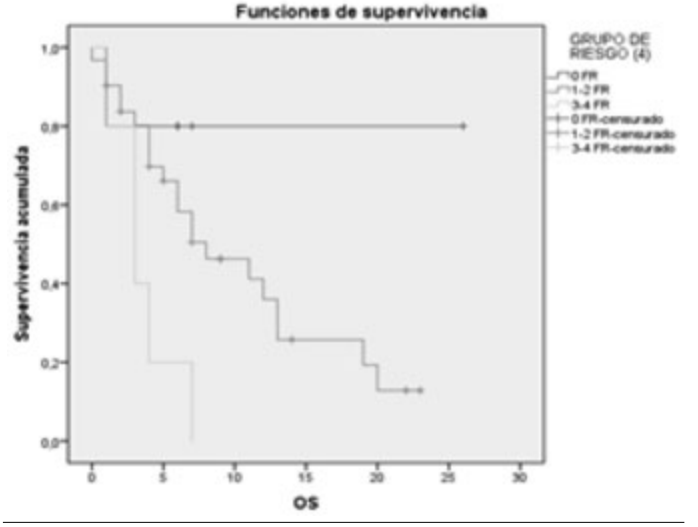

Figure 1.

Summary and Conclusions: The results of this study suggest that Dec is feasible as salvage therapy in AML patients who are not candidates for intensive chemo even in those patients that do not reach a CR. The DecLAMRR scale identifies risk groups with differences in OS

PF238

SAFETY AND PHARMACOKINETICS OF A NOVEL ORAL CAPSULE FORMULATION OF ARSENIC TRIOXIDE, ORH-2014, IN PATIENTS WITH ADVANCED HEMATOLOGIC DISORDERS

F. Ravandi-Kashani[1,*], K. Vaddi[2], A. Johri[3], M. Pudipeddi[4], S. Nidamarthy[5], G. Garcia-Manero[6], G. Borthakur[6], K. Naqvi[6], M. Meyer[6], I. Koumenis[5], H. Kantarjian[6]

[1]Dept of Leukemia, MD Anderson Cancer Center, Houston, [2]Founder Orsenix, Wilmington, [3]Consultant, N Jersey, [4]Consultant, [5]Orsenix, Wilmington, [6]MD Anderson, Houston, United States

Background: The management of Acute Promyelocytic Leukemia (APL) has evolved significantly with the concurrent use of ATRA and ATO for induction, considered as standard of care, as proven by large randomized studies. These studies have demonstrated that non-high-risk APL patients (WBC<$10*10^9$/L) can achieve sustained and prolonged clinical and molecular remission using ATRA and intravenous (IV) Arsenic Trioxide (ATO), without chemotherapy. Similar results using oral arsenic formulations have been reported by Chinese investigators. Given the need for prolonged daily administration of intravenous arsenic trioxide, oral arsenic derivatives represent an important advance in the treatment of APL.

Aims: Orsenix set out to develop a simple, scalable and orally bioavailable capsule formulation manufactured by a unique lyophilization process that results in a drug substance, ORH-2014, that demonstrates high surface area and rapid dissolution.

Methods: A multicenter Phase I study, started in Dec 2016, to identify the

recommended dose of ORH-2014 in patients with relapsed and/or refractory hematologic disorders. ORH-2014 was administered orally, once a day in the fasted state. A total of seven patients were enrolled in two cohorts: 3 patients in Cohort 1 at the 5 mg dose and 4 in cohort 2, at 10mg dose. The primary endpoint was to assess safety and tolerability of ORH-2014 and identify the recommended Phase II dose. Secondary endpoints were: pharmacokinetics (PK), effect on QTc, and efficacy. Dose Limiting Toxicities (DLT) were monitored for Days 1-29 of dosing, and plasma samples were collected for PK between Days 1-22 of dosing. Total arsenic concentrations in plasma were measured by a validated method using inductively coupled plasma mass spectrometry (ICP-MS).

Results: Patients with advanced myelodysplastic syndrome or acute myeloid leukemia were enrolled. The median age of patients was 76 (45-78) years. There were no significant safety issues with no drug related severe adverse events including no significant QT prolongation and no DLTs. Two patients were replaced due to progression of AML and early withdrawal from study (25 days and 22 days). Following oral administration of 10 mg QD ORH-2014, for 15 days, geometric mean (geo CV% [min, max]) C_{max} and AUC_{0-24} values of total arsenic were were 64.5 (43.2% [43.0, 115]) ng/mL and 1340 (43.9% [839, 2330]) h*ng/mL, respectively. The measured plasma exposure at Day 15 (AUC_{0-24}) following 10 mg QD oral dosing was similar to that reported for the approved dose of IV ATO. Total Arsenic plasma concentrations after 5 and 10 mg ORH-2014 QD ranged 21.8-36.9 ng/mL and 30.5-83.4 ng/mL, respectively, and these levels were similar to the Day 8 trough levels of 21.0-35.0 ng/mL following IV administration of 0.15 mg/kg Trisenox.

Summary and Conclusions: The 10 mg QD oral dose of ORH2014 provides similar exposure of total arsenic, measured in plasma, to that of the approved dose of IV ATO (0.15mg/kg). This safe and well tolerated dose of ORH104 is recommended for a future randomized trial for frontline therapy in standard risk APL patients.

Lee Moffitt Cancer Center & Research Institute, Tampa, FL, United States

Background: CPX-351, a liposomal co-encapsulation of cytarabine and daunorubicin at a synergistic 5:1 molar ratio, is approved in the United States for the treatment of adults with newly diagnosed therapy-related AML or AML with myelodysplasia-related changes. In a randomized, phase 3 study, CPX-351 significantly improved overall survival and remission rates compared with conventional cytarabine/daunorubicin (7+3) in patients aged 60-75 years with newly diagnosed high-risk or sAML.

Aims: This exploratory analysis of the phase 3 data compared efficacy and safety outcomes in patients treated with CPX-351 *versus* 7+3 who received 1 or 2 induction cycles.

Methods: In the phase 3 study (NCT01696084), patients were randomized 1:1 to receive 1-2 induction cycles with CPX-351 (100 units/m^2 [cytarabine 100 mg/m^2+daunorubicin 44 mg/m^2] on Days 1, 3, and 5 [2nd induction: Days 1 and 3]) or 7+3 (cytarabine 100 mg/m^2/day continuously for 7 days [2nd induction: 5 days]+daunorubicin 60 mg/m^2 on Days 1-3 [2nd induction: Days 1-2]). Patients who achieved complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 consolidation cycles. All patients provided informed consent.

Results: In total, 304 patients were treated with CPX-351 (n=153) or 7+3 (n=151). A greater proportion of patients treated with CPX-351 achieved remission after 1 induction cycle than with 7+3 (CR: 47/105 [45%] *vs* 28/100 [28%]; CR+CRi: 58/105 [55%] *vs* 34/100 [34%], respectively; Table 1). Remission rates after 2 induction cycles were comparable between treatment arms (CR: 10/48 [21%] *vs* 12/51 [24%]; CR+CRi: 15/48 [31%] *vs* 18/51 [35%], respectively; Table 1). The frequency of grade 3-5 TEAEs in patients with 1 induction cycle was similar for CPX-351 (75/105 [71%]) and 7+3 (74/100 [74%]; Table 2). Among patients who received 2 induction cycles, fewer patients treated with CPX-351 experienced grade 3-5 TEAEs (38/48 [79%]) compared with those treated with 7+3 (48/51 [94%]). Febrile neutropenia was the most common grade 3-5 TEAE in both treatment arms (Table 2). The incidence of serious TEAEs was similar in the CPX-351 and 7+3 treatment arms (1 induction: 35/105 [33%] *vs* 33/100 [33%]; 2 inductions: 14/48 [29%] *vs* 13/51 [25%], respectively).

Table 1.

	1 induction			2 inductions		
	CPX-351 (n = 105)	7+3 (n = 100)	Odds ratio (95% CI)	CPX-351 (n = 48)	7+3 (n = 51)	Odds ratio (95% CI)
CR, n (%)	47 (45)	28 (28)	2.08 (1.17, 3.73)	10 (21)	12 (24)	0.86 (0.33, 2.21)
CR+CRi, n (%)	58 (55)	34 (34)	2.40 (1.36, 4.21)	15 (31)	18 (35)	0.83 (0.36, 1.93)

Table 2.

	1 induction		2 inductions	
	CPX-351 (n = 105)	7+3 (n = 100)	CPX-351 (n = 48)	7+3 (n = 51)
Any TEAE, n (%)	83 (79)	88 (88)	44 (92)	48 (94)
Grade 3-5 TEAE, n (%)	75 (71)	74 (74)	38 (79)	48 (94)
Febrile neutropenia	61 (58)	57 (57)	29 (60)	41 (80)
Hypoxia	11 (11)	15 (15)	7 (15)	8 (16)
Pneumonia	14 (13)	14 (14)	7 (15)	5 (10)
Hypertension	10 (10)	4 (4)	5 (10)	4 (8)
Bacteremia	7 (7)	1 (1)	5 (10)	1 (2)
Enterococcal bacteremia	3 (3)	0	1 (2)	6 (12)
Serious TEAE, n (%)	35 (33)	33 (33)	14 (29)	13 (25)

Summary and Conclusions: In this population of older adults with newly diagnosed high-risk/sAML, the majority of patients who responded to CPX-351 achieved remission after 1 induction cycle and CPX-351-treated patients were more likely to achieve remission after 1 induction cycle than those treated with conventional 7+3; remission rates were similar between treatment arms among patients who received 2 induction cycles. Patients who received 1 induction cycle of CPX-351 had a similar frequency of grade 3-5 TEAEs compared with 7+3, while those who received 2 induction cycles of CPX-351 experienced fewer grade 3-5 TEAEs compared with 7+3.

PF240

POST HOC EXPLORATORY ANALYSIS OF TWO PHASE 2 TRIALS OF QUIZARTINIB MONOTHERAPY IN PATIENTS WITH FLT3-ITD MUTATED RELAPSED/REFRACTORY AML AND PRIOR FLT3 TYROSINE KINASE INHIBITOR TREATMENT

J. Cortes[1,*], C. Smith[2], K. Ishizuka[3], K. Kobayashi[3], M. Arunachalam[3], Y. Wang[3], D. Lazzaretto[4], M. Levis[5]

[1]MD Anderson Cancer Center, Houston, [2]University of California, San Francisco, San Francisco, [3]Daiichi Sankyo, Inc., Basking Ridge, [4]Daiichi Sankyo, Inc., San Diego, [5]The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, United States

Background: First-generation tyrosine kinase inhibitors (TKIs) such as sorafenib and midostaurin target FMS-like tyrosine kinase 3 (FLT3) in addition to other kinases, and are increasingly used for treatment of *FLT3* mutated acute myeloid leukemia (AML). Quizartinib is a highly potent and selective next-generation FLT3 inhibitor with strong clinical anti-leukemic activity in patients with *FLT3*-internal tandem duplication (ITD) mutated relapsed/refractory (R/R) AML.

Aims: To analyze the clinical activity of quizartinib in patients with prior exposure to first-generation FLT3 TKIs and gain early clinical insights into the potential benefit of agents with varying kinase and safety profiles.

Methods: This post hoc exploratory analysis was performed using data from two phase 2 trials of quizartinib monotherapy in patients with *FLT3* mutated

R/R AML (Studies (A) NCT01565668, (B) NCT00989261) to assess quizartinib activity in patients with *versus* patients without prior therapy with first-generation FLT3 TKIs. Patients with *FLT3*-ITD allelic frequency ≥3% were considered *FLT3*-ITD positive for this analysis. In both studies, patients received quizartinib for 28-day cycles until relapse, intolerance, or proceeding to hematopoietic stem cell transplant (HSCT). In Study A, patients received 90, 135, or 200 mg of quizartinib daily, administered as quizartinib dihydrochloride and equivalent to 79.5, 119.3, or 176.7 mg free-base, respectively. In Study B, patients received 30 or 60 mg of quizartinib daily, administered as quizartinib dihydrochloride and equivalent to 26.5 or 53 mg free-base, respectively.
Results: In Study A, 27 of 261 patients with *FLT3*-ITD mutations received prior sorafenib and/or midostaurin (24 sorafenib, 1 sorafenib and midostaurin, 2 midostaurin). In Study B, 11 of 72 patients with *FLT3*-ITD mutations received prior TKIs (10 sorafenib, 1 sorafenib and midostaurin). Clinical activity of quizartinib, as demonstrated by composite complete remission (CRc, defined as complete response with or without hematologic and platelet recovery), overall response rates (ORR, defined as CRc+partial responses [PR]), and median survival duration, was meaningful and similar in patients with or without prior TKI treatment (Table 1).

Table 1.

CRc, ORR, and survival in quizartinib-treated patients with *FLT3*-ITD mutated R/R AML and prior exposure to first-generation FLT3 TKIs

	Study A NCT01565668		Study B NCT00989261	
	With prior TKI N = 27	Without prior TKI N = 221	With prior TKI N = 11	Without prior TKI N = 61
CRc, % (n)	33 (9)	53 (117)	36 (4)	48 (29)
ORR, % (n)	67 (18)	75 (165)	45 (5)	69 (42)
Median survival, weeks	24.6	24.7	20.9	23.7

Summary and Conclusions: This analysis demonstrates meaningful clinical activity of quizartinib in patients with *FLT3*-ITD mutated R/R AML who have prior exposure to first-generation FLT3 TKIs. Limitations are small sample size and post hoc analysis. Additional studies, including mutational analyses, are warranted to further characterize the potential mechanism(s) of response to quizartinib in patients who have failed prior FLT3 TKI.

Abstract withdrawn.

PF242

RISK FACTORS OF EARLY DEATH FOR PATIENTS WITH NEWLY DIAGNOSED ACUTE PROMYELOCYTIC LEUKEMIA UNDER THE TREATMENT OF ATRA, ATO WITH OR WITHOUT CHEMOTHERAPY

L. Chen[1,*], H. Zhu[1], F. Dong[1], L. Wang[1], S. Li[2], H. Zhao[1], Q. Chen[1], Y. Chen[1], Z. Shen[1], K. Wang[2], J. Li[1]

[1]Hematology, Shanghai Institute of Hematology, Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, [2]State Key Laboratory of Medical Genomics and Shanghai Institute of Hematology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: The combination of all-trans retinoic acid (ATRA) and arsenic trioxide (ATO) has converted acute promyelocytic leukemia (APL) from highly fatal to nearly curable. Yet, early death remains a formidable problem of treatment failure in APL, which strongly affects the prognosis of patients with APL. Mounting evidence from epidemiological studies suggests that the early death rate for APL is underestimated in clinical trials, and most of these studies are focused on patients treated with ATRA plus chemotherapy. Early death for patients treated with ATRA and ATO needs to be addressed.
Aims: We aimed to investigate the risk factors of early death for patients with APL receiving the treatment of ATRA and ATO plus chemotherapy.
Methods: This study retrospectively analyzed 291 patients with newly diagnosed APL from 2001 to 2012. The clinical manifestations, blood test, coagulation index between early death and non-early-death patients were compared.
Results: This study included 149 males and 142 females and the median age was 38 years (13 to 79 years). The early death rate (EDR) was 10.0% (29/291) in all patients: 2.6% (2/77), 8.5% (12/142) and 20.8% (15/72) were in low-, intermediate- and high-risk patients (P<0.001), respectively. Most of the early death occurred within the first week of diagnosis. Hemorrhage, especially intracranial hemorrhage, was the most common reason. Among 29 early death patients, 18 cases suffered from hemorrhage, accounting for 62.1% of early death, in which intracranial hemorrhage was the most common cause (13 cases), and the remaining 5 cases suffered from disseminated intravascular coagulation (DIC) (2 cases), gastrointestinal bleeding (2 cases) and pulmonary hemorrhage (1 case). In addition, 4 cases suffered from severe pulmonary infection, 2 from differentiation syndrome, 2 from cardiac events (1 case of arrhythmia and the other of acute heart failure), 1 from cerebral infarction, 1 from acute renal failure and one patient died of unknown cause (Figure 1). Multivariate analysis showed that the age more than 60, the high white blood cell (WBC), the decreased prothrombin time (PT) and the reduced fibrinogen (Fg) levels were independent risk factors of early death (*P*=0.013, 0.004, 0.013 and 0.033, respectively).

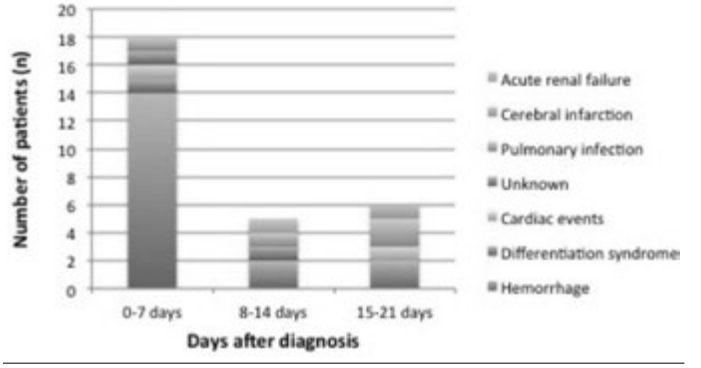

Figure 1. Causes of APL early death and distribution of death time.

Summary and Conclusions: Collectively, this study suggests that early death is still the greatest contributor to treatment failure in APL under the treatment of ATRA and ATO, and highlight a need of timely control of white blood cells and the correction of clotting disorders to reduce the early death rate of APL.

PF243

PHASE II STUDY INCORPORATING A NOVEL BH3-PROFILING BIOMARKER APPROACH OF ALVOCIDIB FOLLOWED BY CYTARABINE AND MITOXANTRONE IN RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA (AML)

J.F. Zeidner[1,*], C.E. Vigil[2], T. Lin[3], M.Y. Levy[4], M. Frattini[5], A. Dalovisio[6], S. Anthony[7], D. Bearss[7], S. Weitman[7], B.D. Smith[8]

[1]Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC, [2]University of Iowa, Iowa City, IA, [3]University of Kansas Medical Center, Westwood, KS, [4]Baylor Sammons Cancer Center, Dallas, TX, [5]Columbia University Medical Center, New York, NY, [6]Ocshner Clinic Foundation, New Orleans, LA, [7]Tolero Pharmaceuticals, Inc, Lehi, UT, [8]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins Hospital, Baltimore, MD, United States

Background: Serial studies have shown the activity of alvocidib, followed by cytarabine and mitoxantrone, in newly diagnosed and relapsed/refractory (R/R) AML. Alvocidib's anti-leukemic pharmacologic activity appears to be predominantly due to the inhibition of transcriptional regulator, CDK9, resulting in suppression of CDK9-regulated genes, such as the BCL-2 family member, MCL-1. Retrospective correlative analyses showed that leukemic cells dependent on MCL-1 have heightened sensitivity to alvocidib-containing regimens.
Aims: To evaluate the efficacy and safety of alvocidib, in combination with cytarabine and mitoxantrone, in R/R AML patients (pts) dependent on MCL-1.
Methods: We are conducting a multicenter, international, open-label, phase II clinical study of alvocidib given as timed sequential therapy prior to cytarabine and mitoxantrone for adults with R/R AML. The key eligibility criteria are: ages 18-65 years; refractory to 1-2 cycles of induction therapy, or in first

relapse AML with complete remission (CR) duration ≤2 years; ≥40% myeloblast MCL-1 dependency determined by BH3 profiling; ECOG PS 0-2; and no major organ dysfunction. Pts who received prior allogeneic stem cell transplant (alloSCT) were not excluded. All pts gave appropriate informed consent prior to enrollment. Treatment consisted of alvocidib 30 mg/m^{2}as a 30-minute IV bolus followed by 60 mg/m^2 over 4 hours on Days 1-3, cytarabine 667 mg/m^2/day by continuous IV infusion days 6-8, and mitoxantrone 40 mg/m^2 IV on day 9 starting 12 hours after completing cytarabine. Up to 3 additional cycles of the same regimen (with or without mitoxantrone) were permitted in responders. The primary endpoint is the rate of CR+CR with incomplete recovery (CRi). The null hypothesis that the CR rate=50% will be tested against a one-sided alternative hypothesis=70% CR rate, yielding a type 1 error rate and power=5% and 80%, respectively. Stage I of this study was considered positive if ≥13 CRs were seen in first 23 enrolled pts. Key secondary endpoints are overall survival, event free survival, combined response rate and safety assessed by adverse events and laboratory results.

Results: A total of 17 pts have been enrolled to date (Table 1). The median MCL-1 dependency was 61% (range 41%>98%). The overall CR rate is 59% (n=10). Six out of eight (75%) pts with refractory (no response to induction therapy or CR1 duration <90 days) AML achieved an overall CR and 5 of these pts proceeded to an alloSCT. The most common NCI CTCAE ≥Grade 3 treatment-emergent nonhematologic AEs noted in >1 pt in the safety population were hypophosphatemia (41%); tumor lysis syndrome (35%; 5-Grade 3 and 1-Grade 4); hypokalemia (29%); increased AST and diarrhea (23%); hyponatremia, sepsis and increased ALT (18%); acute kidney injury, syncope and hypoalbuminemia (12%).

Table 1.

Patient Characteristics	N=17
Age (Median; Range)	47 (26-65)
Male/Female	5 (29%)/12 (71%)
ECOG PS (0/1/2)	10 (59%)/6 (35%)/1 (6%)
Response to First-Line Therapy (n=patients)	
Refractory (Persistent Disease or CR <90 days)	8 (47%)
Early Relapse (90 days to 1 year)	5 (29%)
Late Relapse (>1 year but <18 months)	1 (6%)
Baseline WBC Prior to Treatment (Median; Range)	2.8 (1.2-34.5)
2017 ELN Risk Stratification	
Favorable	1 (6%)
Intermediate	14 (82%)
Adverse	2 (12%)
Secondary AML	4 (24%)
Prior alloSCT	3 (18%)
Responses	
CR	9 (53%)
CRi	1 (6%)
CR + CRi	10 (59%)
Morphologic Leukemia Free State (MLFS)	1 (6%)
PR	0
No Response	3 (18%)
Non-Evaluable	3 (18%)
60 Day Mortality	3 (17%)

Summary and Conclusions: Alvocidib given as time sequential therapy prior to cytarabine and mitoxantrone in MCL-1 dependent AML has shown encouraging activity, with the majority of patients treated achieving CR. Future directions include a randomized phase 2 expansion comparing cytarabine and mitoxantrone with or without preceding timed sequential alvocidib, and a phase I study of alvocidib followed by 7+3 induction in newly diagnosed AML with prospective BH3 profiling assessed.

PF244

OUTCOME OF A REAL-LIFE POPULATION OF ACUTE PROMYELOCYTIC LEUKEMIA TREATED ACCORDING TO PETHEMA LPA 2005 PROTOCOL: THE POLISH ADULT LEUKEMIA GROUP (PALG) EXPERIENCE

M. Sobas[1,*], A. Holowiecka[2], P. Montesinos[3], W. Miśkiewicz[1], E. Zarzycka[4], A. Pluta[5], M. Paluszewska[6], M. Podhorecka[7], M. Majcherek[8], B. Piątkowska-Jakubas[9], A. Armatys[2], G. [1]Department of Hematology, Blood Neoplasms and Bone Marrow Transplantation, Medical University, Wroclaw, [2]Medical University of Silesia, Katowice, Poland, [3]Hospital Universitario La Fe, Valencia, Spain, [4]Medical University School, Gdańsk, [5]Medical University, Lodz, [6]Medical University, Warsaw, [7]Medical University, Lublin, [8]University of Medical Science, Poznan, [9]Collegium Medicum Jagiellonian University, Krakow, [10]Institute of Hematology, [11]Institute of Hematology Warsaw, Warsaw, [12]City Hospital, Rzeszow, [13]Nicolaus Copernicus Hospital, Torun, [14]Pomeranian Medical University, Szczecin, [15]Medical University, Bialystok, [16]Holy Cross Cancer Center, Kielce, [17]Medical University, Lublin, [18]City Hospital, Chorzow, [19]City Hospital, Legnica, [20]Hospital Brzozow, Brzozow, [21]Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice Branch, Poland

Background: Acute promyelocytic leukemia (APL) is associated with favourable prognosis. According to results of clinical trials based on the use of all-*trans* retinoic acid (ATRA) in combination with chemotherapy the cure rates may exceed 80%. However, prospective studies may not include the whole population of APL patients and therefore real-life results may not necessarily be as favourable.

Aims: To analyze the outcome and prognostic factors of unselected Polish patients with APL intended for the treatment according to PETHEMA LPA 2005 protocol.

Methods: Between 2005 and 2017, 289 Polish patients were diagnosed APL. The diagnosis was confirmed either by t(15;17) or PML/RARA. Clinical and analytical data were collected at diagnosis and during the follow-up. Sanz risk score was calculated. Treatment was based on PETHEMA LPA 2005 which consisted of Induction therapy with oral ATRA (45 mg/m2/d) and intravenous idarubicin (12 mg/m2/d x4 days) followed by three courses of consolidation with anthracyclines. Ara-C was added in consolidation for high-risk patients. The maintenance therapy consisted of intermittent ATRA and low dose chemotherapy with methotrexate and 6-mercaptopurine.

Results: Out of 289 registered patients, 129 (44.6%) were men. The median age at diagnosis was 45 years (range, 14 – 90 years). Sanz risk score was calculated in 279 patients and assessed as low (n=64), intermediate (n=128) or high (n=87). Fourteen (4.8%) patients died before start of the treatment mainly because of coagulopathy (50%). Data concerning response were available for 270 patients: complete remission (CR) was achieved in 217 (80.4%) cases, no response (NR) in 3 (1.1%) while 50 (18.5%) patients died early during induction: 16 (32%) because of coagulopathy, 15 (30%) of differentiation syndrome (DS) and 13 (26%) of infection, there were no data in 6 (12%) patients. Differentiation syndrome was observed in 25% patients. With the median follow-up of 4.1 years the probability of the overall survival at 4 years was 69% (+/-3%). In a univariate analysis, the OS rate was higher in patients with white blood count (WBC) ≤10G/l *vs* WBC >10G/l (76% *vs* 52%; p=0.0001), in patients with no history of bleeding at diagnosis (72 *vs* 65%; p=0.04), with lower Sanz risk score (low *vs* intermediate *vs* high: 80 *vs* 75 *vs* 52%, respectively; p<0.0001), with lower ECOG at diagnosis (level 0 *vs* 1 *vs* 2 *vs* 3 *vs* 4: 97 *vs* 80 *vs* 57 *vs* 32 *vs* 0%, respectively; p<0.0001; Figure 1). The 4-years OS rate was higher in CD2(+) APL *vs* CD2(-) APL (93 *vs* 62%; p=0.02) while was lower in CD56(+) APL *vs* CD56(-) APL (46 *vs* 74%; p=0.04). In a multivariate analysis, ECOG (for each grade) retained the only independent predictive factor with HR=2.3 (95% CI, 1.74-2.61); p<0.000001. The incidence of relapse at 4-years was 14% (+/-3%). The relapse rate was lower for APL with WBC count ≤10 G/l *vs* >10 G/l (8 *vs* 30%; p=0.01), for a lower Sanz risk grups (p=0.04) and lower ECOG grade (p=0.005). In a multivariate analysis, WBC (>10G/L) retained the only independent predictive for the risk of relapse: HR=6.69 (1.59-8.54); p=0.002.

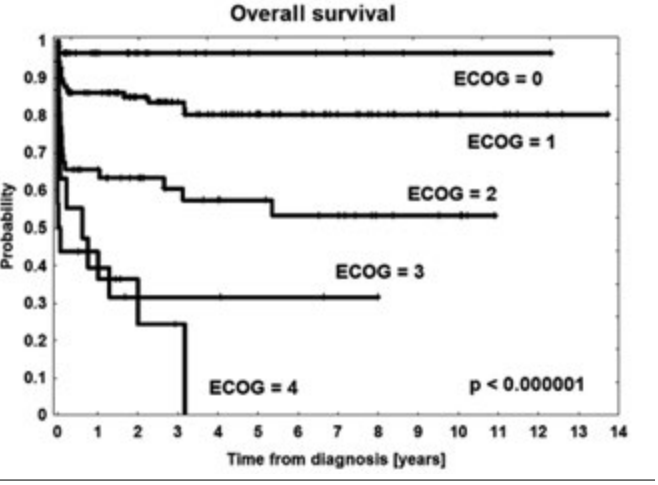

Figure 1.

Summary and Conclusions: In a real–life population there is a high proportion of patients who die before start of the treatment or during induction. Therefore, despite high response rate the OS rate is lower than previously reported in clinical trials. The performance status at diagnosis is the strongest predictor of survival.

PF245

GLASDEGIB IMPROVED OVERALL SURVIVAL IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) OR MYELODYSPLASTIC SYNDROME (MDS) WHO ACHIEVED COMPLETE REMISSION (CR) AND THOSE WHO DID NOT ACHIEVE CR

J. Cortes[1,*], F. Heidel[2,3], W. Fiedler[4], B.D. Smith[5], T. Robak[6], P. Montesinos[7,8], A. Candoni[9], B. Leber[10], M. Sekeres[11], D. Pollyea[12], M. Zeremski[13], W.W. Ma[13], T. O'Brien[13], A. O'Connell[13], G. Chan[13], M. Heuser[14]

Background: Glasdegib is a potent and selective oral inhibitor of the Hedgehog signaling pathway. In a phase 2 randomized trial in patients with AML or high-risk MDS, the addition of glasdegib to low-dose cytarabine (LDAC) improved median overall survival (OS) *versus* LDAC alone (8.8 *vs* 4.9 months; hazard ratio [HR] 0.51; 80% confidence interval [CI], 0.39–0.67; *P*=0.0004), with benefit consistent across subgroups by risk and disease.
Aims: We evaluated the efficacy of glasdegib+LDAC *versus* LDAC alone by disease response (CR *vs* no CR) and baseline mutational analyses.
Methods: Patients randomized to receive glasdegib+LDAC (n=88) or LDAC alone (n=44) were classified into 2 subgroups: those who achieved CR (defined as neutrophils ≥1000 µL, platelets ≥100000 µL, hemoglobin ≥11 g/dL [MDS only], with <5% bone marrow blasts), and those that did not achieve CR. Biomarker assessments included mutational status of the following genes: CEBPA, DNMT3A, FLT3, IDH1, IDH2, KIT, KRAS, NPM1, NRAS, RUNX1, TET2, and WT1. OS in CR-defined subgroups was summarized using the Kaplan–Meier (K-M) method; OS in biomarker-defined subgroups was summarized by K-M method and Cox proportional hazards model.
Results: 15 out of 88 patients treated with glasdegib+LDAC and 1 out of 44 patients treated with LDAC alone achieved CR at any point during the study. Demographics of the two CR-defined subgroups were balanced with respect to age, comorbidities, and European LeukemiaNet cytogenetic risk group. Median duration of treatment was 16.5 months (range, 0.9–31.9) in patients who achieved CR with glasdegib+LDAC, and 7.3 months in the one patient who achieved CR with LDAC alone. In patients without CR, median duration of treatment was 2.0 months (range, 0.1–27.8) with glasdegib+LDAC, and 1.5 months (range, 0.2–7.9) with LDAC alone. In patients who achieved CR with glasdegib+LDAC, median duration of response was 9.9 months (range, 0.03–28.8). In patients who achieved CR, median OS was 26.8 months (95% CI, 12.3–not reached) with glasdegib+LDAC *versus* 12.9 months for the one patient who achieved CR with LDAC alone; HR and *P* value were not estimated due to small sample size. In patients without CR, median OS was 6.5 months (95% CI, 3.7–9.1) with glasdegib+LDAC *versus* 4.8 months (95% CI, 2.3–6.4) with LDAC alone (HR 0.65; 95%CI 0.43–0.98; *P*=0.018). Responses were observed across all mutations assessed, and of the 4 genes with a mutation frequency of ≥5 mutations in each arm (DNMT3A, IDH2, RUNX1, and TET2), the HR of median OS for glasdegib+LDAC *versus* LDAC alone was similar in mutated and non-mutated subgroups.
Summary and Conclusions: The addition of glasdegib to LDAC *versus* LDAC alone improved OS in the entire population, and even in those patients not achieving CR. Baseline mutations did not affect response or survival benefit, although data for each mutation are limited by the small sample size. Together these data suggests that glasdegib improves OS by preventing or delaying disease relapse or progression regardless of baseline mutation status. Randomized studies with glasdegib in combination with standard therapies are underway.

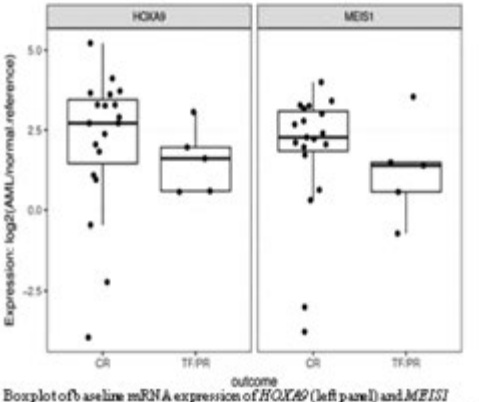
PF246

HIGH COMPLETE REMISSION RATES WITH ORAL SYK INHIBITOR ENTOSPLETINIB (GS-9973) IN ACUTE MYELOID LEUKEMIA PATIENTS ASSOCIATED WITH HIGH HOXA9/MEIS1 EXPRESSION

J. Liu[1], V. Munugalavadla[1,*], T. Oellerich[2345], H. Serve[23], J.C. Byrd[6], A.R. Walker [6], M. Peach[1], S.D. Patterson[1], A. . Rao[1], Y. Pan[1]

[1]Gilead Sciences, Inc., Foster City, United States, [2]Department of Medicine II, Hematology/Oncology, Goethe University, Frankfurt am Main, [3]German Cancer Research Center and German Cancer Consortium, Heidelberg, Germany, [4]Department of Haematology, University of Cambridge, [5]Cambridge Institute for Medical Research, Wellcome Trust/MRC Stem Cell Institute, Cambridge, United Kingdom, [6]The Ohio State University, Columbus, United States

Background: Acute myeloid leukemia (AML) is an aggressive hematopoietic malignancy characterized by diverse genetic and molecular abnormalities which contribute to poor response and survival rates. Spleen tyrosine kinase (SYK) signaling pathway induces cell survival and proliferation in AML by activating multiple signaling pathways including STATs and MYC. Entospletinib (ENTO), an oral selective SYK inhibitor, is currently in clinical trials in AML. Recently, a novel signaling pathway was identified linking *HOXA9* and *MEIS1* (*H/M*) overexpression to addiction to SYK pathway in AML. This analysis aims at exploring the relationship between clinical response and baseline *H/M* levels in the myeloid blasts of newly diagnosed AML patients treated with ENTO plus induction chemotherapy.
Aims: (1) Retrospective analysis of baseline *H/M* gene expression levels from subjects enrolled in NCT02343939 and their correlation with clinical response (2) Correlate *H/M* expression with baseline common cytogenetic and molecular AML subgroups.
Methods: Baseline bone marrow mono-nuclear samples from 34 AML patients treated with ENTO monotherapy for up to 14 days and subsequently in combination with induction chemotherapy (7+3*;* cytarabine 100 mg/m^2 for 7 days plus daunorubicin 60 mg/m^2 for 3 days) were analyzed for mRNA expression of *H/M* using a custom NanoString assay. *H/M* expression level was evaluated in the context of clinical outcome, event free survival (EFS), and overall survival (OS). Key molecular mutations including *NPM1*, *FLT3-ITD/TKD* and *KMT2A/*mixed lineage leukemia *[MLL]* gene rearrangements were utilized for potential associations with the expression of *H/M.*
Results: Median *H/M* expression in patients with CR (n=24) was approximately two-fold higher than in patients with treatment failure (TF, n=4) or partial response (n=1) (Figure 1). Significantly (p<0.05) higher *H/M* expression was observed in AML patients with *KMT2A/MLL* gene rearrangements (n=6), and *NPM1* mutations (n=10, 3 with concomitant *FLT3-ITD*). Among patients with high *H/M* expression (*i.e.* ≥3-fold higher than a pooled (n=20) healthy donor sample), 84% (16/19) achieved a CR with ENTO plus induction chemotherapy, compared with 53% (8/15) of the patients with lower *H/M* expression. Furthermore, we explored the performance of key molecular, cytogenetic factors along with baseline *H/M* expression levels and disease burden to distinguish CR from TF/PR. Among the best predictors for CR were *H/M* expression (PPV=0.94, NPV=0.33) and alterations in either *NPM1* or *MLL* (PPV=0.96, NPV=0.32). Analysis of the preliminary survival data showed trends of better EFS and OS in patients with high *H/M* expression. Data from non-evaluable (n=2) and early treatment assessed (n=3) subjects and an updated analysis of EFS/OS will be presented.



Boxplot of baseline mRNA expression of *HOXA9* (left panel) and *MEIS1* (right panel) in AML patients from clinical trial NCT02343939. Plotted values on Y- axis are normalized to expression from pooled healthy BM-MNCs (0 indicates expression values in healthy BM-MNCs). CR: complete remission (n=24), PR: partial remission(n=1), TF: treatment failure (n=4)

Figure 1.

Summary and Conclusions: Response rates to ENTO are enriched in biomarker defined sub-groups, *i.e.* patients with high *H/M* expression including *MLL* rearrangement, and *NPM1* mutation. Increased response rates in the high baseline *H/M* expression population are consistent with pre-clinical findings suggesting that AML patients addictive to SYK signaling may be more sensitive to ENTO treatment. The predictive utility of *H/M* expression should be tested further in a large study.
First two authors contributed equally.

PF247

WEEKEND *VERSUS* WEEKDAY DIAGNOSIS AND EARLY MORTALITY IN ACUTE PROMYELOCYTIC LEUKEMIA: A POPULATION-BASED ANALYSIS IN THE NETHERLANDS

A. Dinmohamed[1,2,3,*], R. Damhuis[1], O. Visser[4], J. Janssen[5], G. Huls[6], A. van de Losodrecht[5]

[1]Research, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [2]Public Health, Erasmus University Medical Center, [3]Hematology, Erasmus MC Cancer Institute, Rotterdam, [4]Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [5]Hematology, VU University Medical Center, Amsterdam, [6]Hematology, University Medical Center Groningen, Groningen, Netherlands

Background: Acute promyelocytic leukemia (APL) represents a serious medical emergency associated with complications that may lead to early death (ED) if not promptly recognized and subsequently treated. Despite the widespread availability of all-*trans* retinoic acid since the late 1980s, data from the few available population-based studies demonstrated that ED rates in APL remain high. Prior studies in a wide range of diseases have demonstrated that hospital admissions on the weekend, as compared with weekdays, are associated with ED (also known as "the weekend effect"). However, the weekend effect has never been explored in APL at the population level.
Aims: In this nationwide, population-based study, we set out to assess the weekend effect in APL during a 27-year period in the Netherlands.
Methods: We selected all adult (≥18 years) APL patients diagnosed between 1989-2015 from the nationwide Netherlands Cancer Registry (NCR) with survival follow-up through February 1, 2017. The date of diagnosis was defined as the date of diagnostic bone marrow sampling. Patients were categorized into two age groups (18-60 and >60 years). The primary endpoint was the risk of death within 30 days after diagnosis (ie, ED). We used multivariable Cox regression to assess the risk of ED associated with weekend *versus* weekday diagnosis, adjusted for age, sex, year and hospital type of diagnosis, and receipt of anti-leukemic therapy. A $P<0.05$ indicated statistical significance.
Results: Our analytical cohort included 675 APL patients (median age 53 years; 36.6% age >60; 47.8% males), of whom 46 (6.8%) were diagnosed on weekends. No significant differences were noted in the aforementioned characteristics between patients diagnosed on weekends and those diagnosed on weekdays for the overall cohort and the two age groups (*P* for Fisher's exact test >0.05 for all comparisons). The rate (18.8% *v* 28.3%; *P* for Fisher's exact test=0.123) and risk of ED (hazard ratio [HR], 2.59; 95% confidence interval [CI], 1.43-4.66; *P*=0.002) was higher for patients diagnosed on weekends (Figure 1A). Subgroup analysis by age group showed for patients aged 18-60 diagnosed on weekends that there were no significant differences in the rate (12.1 *v* 15.6; *P*=0.575) and risk of ED (HR, 1.99; 95% CI: 0.76-5.22; *P*=0.163; Figure 1B). However, for patients aged >60, the rate (30.0% *v* 57.1%; *P* for Fisher's exact test=0.042) and risk of ED (HR, 3.42; 95% CI, 1.59-7.37; *P*=0.002) were significantly higher for those diagnosed on weekends (Figure 1C).

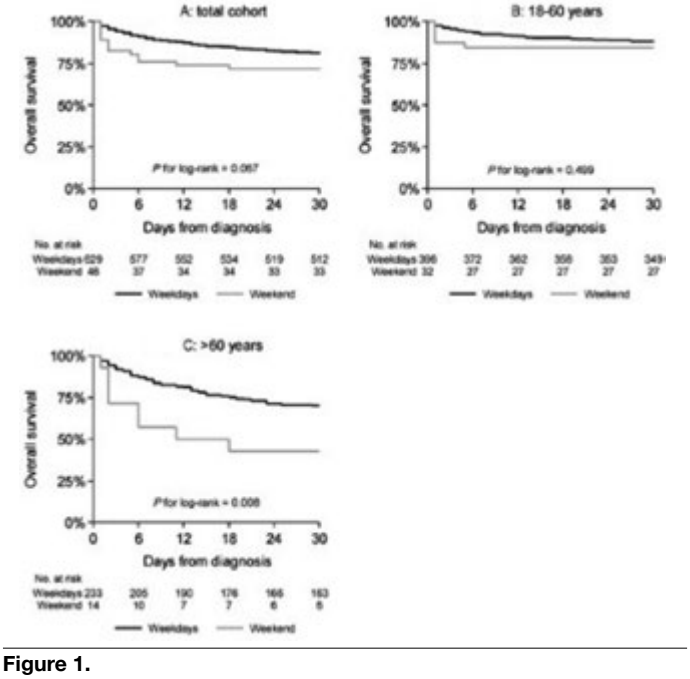


Figure 1.

Summary and Conclusions: In this nationwide, population-based study, we demonstrated that higher ED was confined to elderly (aged >60) APL patients diagnosed on weekends. Delayed institution of therapy among elderly patients diagnosed on weekends might explain the weekend effect. However, assessment of time from diagnosis to therapy is only possible in the NCR for patients diagnosed from 2014 onwards. Although our analysis is somewhat limited by relatively small patients numbers, it generally remains of vital importance that medical providers should act promptly when APL is suspected—especially among elderly patients admitted on the weekends—which in turn may prevent ED. Future research should center on validating our population-based findings and effective education strategies to increase the level of vigilance among a broad range of medical providers regarding this diagnosis in a contemporary era with well-established APL management.

PF248

DECITABINE IN PATIENTS WITH NEWLY DIAGNOSED AND RELAPSED ACUTE MYELOID LEUKEMIA (AML): THE REAL LIFE EXPERIENCE FROM THE "ITALIAN TRIVENETO REGISTRY"

C. Fili'[1,*], A. Candoni[1], S. Imbergamo[2], G. Festini[3], G. Nadali[4], E. Di Bona[5], A. Ermacora[6], M. Gottardi[7], M. Michieli[8], M. Caizzi[3], D. Facchinelli[4], R. Ciancia[8], D. Lazzarotto[1], M.E. Zannier[1], M.V. Dubbini[1], F. Gherlinzoni[7], G. Semenzato[2], R. Fanin[1]

[1]SOC Clinica Ematologica ASUIUD Udine, Udine, [2]Ematologia e Immunologia Clinica Azienda Ospedaliera, Padova, [3]SC Ematologia Clinica ASUITS, Trieste, [4]UOC Ematologia Policlinico GB Rossi, Verona, [5]Unità Operativa Ematologia, Ospedale S.Bortolo, Vicenza, [6]SC Medicina Interna Azienda Ospedaliera S.Maria Angeli, Pordenone, [7]Struttura Complessa Ematologia Ospedale Cà Foncello, Treviso, [8]SOSDTerapia Cellulare e Chemioterapia alte dosi (CRO), Aviano, Italy

Background: The hypomethylating agent Decitabine (DAC) has emerged as an alternative to first line and salvage therapy in acute myeloid leukemia (AML), particularly in elderly patients (pts) which may not benefit from intensive chemotherapy (CHT).The use of hypomethilating agents for the treatment of AML is currently evolving however no many data are available regarding efficacy and safety of DAC in daily clinical practice.
Aims: We retrospectively reviewed data of 104 AML pts treated with DAC in 8 Italian Hematological Centers (Udine, Padua, Trieste, Verona, Vicenza, Pordenone, Treviso, Aviano) from February 2015 to August 2017.The objective of this study was to review the treatment outcomes of newly diagnosed older pts with AML and pts with relapsed AML aged ≥18 years treated with DAC outside of clinical trial.
Methods: Seventy-five (75%) pts received DAC as first line treatment (Cohort 1) and 29 pts as salvage therapy (Cohort 2).All pts received the same DAC schedule, 20 mg/mq intravenously over 1 h for repeated 5-day cycles approximately every 28 days.In the total population the median age was 72,5 years (74 in cohort 1 and 66 in cohort 2) and 16,3% of pts had a ECOG scale >2 at the moment of DAC treatment (with non significant difference in the two cohorts).The cumulative illness rating scale (CIRS) was >6 in the 27% of pts.Forty-five pts (43,2%) had secondary AML. Bone marrow blast count was >30% in 67 patients (64,4%).In the relapsed cohort 17/29 (59%) patients were treated with DAC after conventional chemotherapy, 5/29 (17%) after allogeneic stem cell transplantation and 7/29 (24%) after azacitidine therapy.
Results: A total of 469 DAC cycles were given to the 104 pts with a median of 3 cycles (range 1-21) in cohort 1 and 2 cycles (range 1-7) in cohort 2; 45/104 (43,2%) pts received ≥4 cycles.The Overall Response Rate (ORR=CR+PR) was 32,9%, significantly higher in Cohort 1 (41,5%) compared to Cohort 2 (13,8%) (p=0.009).CR was achieved in 30,8% pts of newly diagnosed AML whereas in the salvage AML group no CR was obtained.The median duration of response was 6 months (range 1-20).In Cohort 1 time to best response (70% of CR and 74% ORR) was obtained between 3 and 6 cycles.In multivariate Cox regression analysis, CR or PR (HR=0.78; p=0,0004), CIRS <6 (HR=0,9; p=0,04) and complex karyotype (HR=0,8; p=0,03) represent significant predictors of improved overall survival.After a median follow up of 4,5 months (range 0,3-22) median overall survival (OS) from the start of DAC therapy was 11 months for the whole population with a significant OS advantage in Cohort 1 (median OS 12,7 mths *vs* 6,3 mths-p=0,003).Not surprisingly median OS was significantly longer among responders, 22,6 mths *vs* 5,7 mths of non- responders (p<0,0001).At the moment of this analysis, 56 patients (53,8%) are still alive and 48 (46,2%) are dead.The main cause of death was disease progression (70,8%).The most common toxicities

were myelosuppression and documented infectious complications, mainly in the first 4 cycles.
Summary and Conclusions: These data show the efficacy and the emerging role of DAC in the real life management of AML, with a significant better performance in first line therapy, even in elderly and unfit pts unsuitable for intensive CHT (ORR 41,5%, median OS 12,7 mths).The efficacy of DAC, as a single agent for salvage therapy, may probably be improved with combined treatment strategies and/or with different DAC schedules that increase its anti-leukemic effect.

PF249

PROGNOSTIC IMPACT OF SKELETAL MUSCLE ASSESSED BY COMPUTED TOMOGRAPHY SCAN IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

N. Nakamura[1,*], S. Ninomiya[1], H. Nakamura[1], J. Kitagawa[1], T. Hara[1], K. Saito[2], M. Shimizu[1], H. Tsurumi[13]

[1]Department of Hematology, Gifu University Graduate School of Medicine, [2]Department of Internal Medicine, Gihoku Kosei Hospital, Gifu, [3]Department of Hematology, Matsunami General Hospital, Hashima, Japan

Background: Skeletal muscle atrophy, referred to as a sarcopenia, is often observed in cancer patients, especially elderly patients. Sarcopenia has been demonstrated to be associated with the risk of morbidity and mortality in some kinds of cancer patients, including hematological malignancies. We previously reported that sarcopenia was an independent prognostic factor in patients with diffuse large B-cell lymphoma. Fat tissue is also one of the important components which is an energy store reserve. However, the clinical values of sarcopenia and adipopenia in adult AML have not been studied and remain unclear.
Aims: The aim of this study was to reveal the impact of sarcopenia and adipopenia on clinical outcomes in patients with AML.
Methods: We retrospectively analyzed 90 patients (age ≥18 years) with *de novo* AML who received chemotherapy in Gifu University Hospital between December 2004 and October 2016. Sixty-five patients underwent standard intensive chemotherapy consisting of anthracycline and cytarabine (Ara-C). Twenty-eight patients received HSCT. The patients who received only palliative care were excluded. Skeletal muscles and visceral and subcutaneous fat areas were assessed from a single axial slice at the third lumbar (L3) level by using CT scans performed prior to any treatment.. This value was normalized for stature to calculate the lumbar L3 skeletal muscle index (SMI, in cm^2/m^2), the lumbar L3 adipose tissue index (ATI, in cm^2/m^2).
Results: The median SMI was 42.5 cm^2/m^2 (26.8-61.8 cm^2/m^2) and the median ATI was 73.9 cm^2/m^2 (2.1-188.9 cm^2/m^2). Thirty-nine (43%) patients were defined as sarcopenia and 35(39%) patients were adipopenia. 39% of patients with PS ≤1were sarcopenia, whereas 67% of patients with PS ≥2 were sarcopenia (P <0.05). Of the 90 patients, 62 (78%) achieved CR within 2 cycles of induction chemotherapy. The CRs rate in the patients with adverse chromosome, less intensive chemotherapy and BMI under 25, were significantly low. Patients with sarcopenia or adipopenia tended to have a lower CR rate, but were not significant. OS, EFS and DFS at 3 years in all patients were 53%, 35% and 52%, respectively. OS at 3 years was 35% and 67% for sarcopenia and non-sarcopenia groups, respectively (P <0.001), and DFS at 3 years was 25% and 58% (P <0.0001). OS at 3 years was 33% and 67% for adipopenia and non-adipopenia groups, respectively (P <0.005), and DFS at 3 years was 31% and 64% (P <0.05). Multivariate analysis showed an association between sarcopenia and lower OS (hazard ratio 2.27, 95% confidence interval 1.11-4.79, P <0.05), with other prognostic factors being worse PS (>2) (P <0.05) and adverse cytogenetic risk (P <0.05). Next, we investigated the impact of sarcopenia in the elderly patients over age 60, who need the careful assessment to decide their treatment strategies. Nine (20%) patients were then defined as sarcopenia. 12% of patients with PS ≤1 were sarcopenia, whereas 50% in PS ≥2 were sarcopenia (P <0.05). OS at 3 years was 0% and 49% for sarcopenia and non-sarcopenia groups, respectively (P <0.0005), DFS at 3 years was 0% and 61% (P <0.0001), and EFS at 3 years was 0% and 46% (P<0.005).
Summary and Conclusions: Our data illustrates a marked clinical impact of sarcopenia and adipopenia in the patients with AML. Evaluation of skeletal muscle and adipose tissue depletion by CT imaging is a useful objective tool for predicting AML patient outcomes. Moreover in the elderly patients, presence of sarcopenia before treatment may be useful factor for avoiding intensive therapeutic strategies for AML.

PF250

INCIDENCE OF MARROW NEOPLASMS IN BREAST CANCER SURVIVORS: A NATIONAL POPULATION-BASED COHORT STUDY

M.J. Jabagi[1,*], N. Vey[2], A. Goncalves [2], M. Zureik[1], R. Dray-Spira[1]

[1]ANSM, Agence Nationale de la Securité du Medicament ANSM, Paris, [2]IPC, Institut Paoli Calmettes, Marseille, France

Background: Patients with a history of cancer are at a higher risk of certain types of Marrow neoplasms (MN) including Acute Myeloid Leukemia (AML) and Myelodysplastic Syndrome (MDS). However, information on the frequency of these MN after cancer in real life are scarce, especially in the recent context of increased cancer survival. In addition, little is known about the incidence of other MN types after cancer.
Aims: The aim of this study was to estimate the incidence of the various types of marrow neoplasms in breast cancer (BC) survivors in France.
Methods: Data from the French National Health Data System (SNDS) were used. All female patients covered by the general health insurance scheme (*i.e.* about 75% of the French population), aged 20 to 85 years and with an incident primary breast cancer between 2006 and 2015 were included and followed until MN occurrence, death or December 31, 2016. The main outcomes were cases of MN occurring at least 6 months after breast cancer diagnosis and identified in the database using ICD-10 codes of hospital discharge and/or long-term disease diagnoses. Incidence rates of the various types of MN in the breast cancer cohort were estimated and compared to those in the general population using direct age-standardization.
Results: 439 704 female patients were included (mean age, 59.3 years) and followed for a mean of 5.2 years. Overall, 2 991 cases of MN occurred: 509 Acute Myeloid Leukemia (AML), 832 Myelodysplastic syndrome (MDS), 365 Multiple Myeloma (MM), 912 Hodgkin and Non Hodgkin Lymphoma (HL/NHL), 106 lymphocytic Leukemia/Lymphoma (LLL), and 267 Myeloproliferatif Neoplasm (MPN). Mean time between BC diagnosis and MN occurrence was 3.9 years overall, ranging from 3.5 years for AML to 4.2 years for MPN. Crude incidence rates per 100 000 person-years of the different types of MN were: 22.2 (95% CI 20.3-24.2) for AML; 36.3 (95% CI, 33.9-38.9) for MDS; 15.9 (95% CI, 14.3-17.6) for MM; 39.9 (95% CI, 37.3-42.5) HL/NHL; 4.6 (95% CI, 3.7-5.6) for LLL; 11.7 (95% CI, 10.3-13.1) for MPN. Compared to the general population, these incidence rates were higher for AML (Standardized Incidence Rate Ratio, SIRR 2.5; 95% CI, 2.2-2.9), MDS (SIRR 4.5; 95% CI, 3.9-5.1), MM (SIRR 1.1; 95% CI, 1.0-1.3) and LLL (SIRR 1.8; 95% CI, 1.2-2.7), while they did not differ for the other types of MN.
Summary and Conclusions: Incidences of AML and MDS and, to a lower extent, MM and LLL are higher among breast cancer survivors than in the general population. Further investigations are necessary to assess the role of cancer therapies in explaining these increases.

PF251

WILMS TUMOR 1 EXPRESSION IN ACUTE MYELOID LEUKEMIA CORRELATES WITH CYTOGENETICS OR COLLABORATIVE MUTATIONS: HOKKAIDO LEUKEMIA NET STUDY

[1]Hematology, Hokkaido University, [2]Laboratory and Transfusion Medicine, Hokkaido University Hospital, [3]Sapporo City General Hospital, Sapporo, [4]Hakodate Municipal Hospital, Hakodate, [5]Tonan Hospital, Sapporo, [6]Japanese Red Cross Kitami Hospital, Kitami, [7]Aiiku Hospital, [8]Sapporo Hokuyu Hospital, Sapporo, [9]Kushiro Rosai Hospital, Kushiro, [10]Asahikawa City Hospital, Asahikawa, [11]Hokkaido Cancer Center, [12]Sapporo Kosei General Hospital, Sapporo, Japan

Background: The prognostic impact of WT1 expression at diagnosis of acute myeloid leukemia (AML) has been controversial. Some studies showed a correlation of higher expression of WT1 with poor prognosis, whereas other studies showed lower expression of WT1 was related to poor prognosis. The relationship between WT1 expression and each cytogenetic category has not been fully determined. Further, prognostic impact of WT1 expression has not been elucidated in each cytogenetic category.
Aims: To determine the relationship between WT1 expression at diagnosis of AML and established prognostic cytogenetics and molecular abnormalities.

Methods: Diagnostic bone marrow samples of AML patients were collected from all over Hokkaido district and studied for relevant molecular markers. Total 252 patients (17 – 89 years old; median 57) who were diagnosed with AML from 2007 to 2017 were enrolled in this study. WT1 expression and Flt3-ITD mutation were analyzed for all patients. The WT1 transcript levels in samples were determined by reference to the corresponding transcript levels of K562 cells (/ 10^4 x K562 RNA). NPM1 mutation and CEBPA double mutation were analyzed for cytogenetically normal (CN)-AML. KIT mutation was analyzed for core-binding factor (CBF)-AML.
Results: Expression of WT1 at diagnosis of AML varied from <1 to 25118.9 (median, 1156.15). WT1 levels were not associated with overall survival (OS) in our entire AML cohort (p=0.393). The patients were divided into six groups depending on cytogenetic abnormalities, including t(8;21) (N=34), inv(16) (N=23), t(15;17) (N=27), cytogenetically normal (CN) (N=93), poor cytogenetics (N=34), and others (N=41). WT1 expression was correlated with certain cytogenetics or molecular mutations that were already known prognostic factors. Within the cytogenetically favorable prognosis group, WT1 expression in AML with inv(16) or t(15;17) was significantly higher than that in AML with t(8;21) (median WT1 1778.3, 3388.4 *vs* 468.95, respectively, p=0.001, p<0.001). Patients with KIT mutation in the t(8;21) group tended to show lower WT1 expression (median WT1 117.5 *vs* 575.4, p=0.073) and poor prognosis (p=0.409), but the tendency was not statistically significant. In cases with CN-AML, Flt3-ITD and NPM1 mutations were both correlated with higher expression of WT1 (respectively, median WT1 3706.8 *vs* 600.6, 3351.65 *vs* 653.1, p<0.001, p<0.001), whereas CEBPA double mutation was related to lower WT1 expression (WT1 median 524.8 *vs* 1520.0, p=0.023). The existence of both Flt3-ITD and NPM1 mutations showed synergistically higher expression of WT1 in CN-AML (WT-1 median 4466.8 *vs* 436.5, p<0.001). After divided into cytogenetic category, the expression levels of WT1 still did not show a significant prognostic impact in each cytogenetic category (Figure 1).

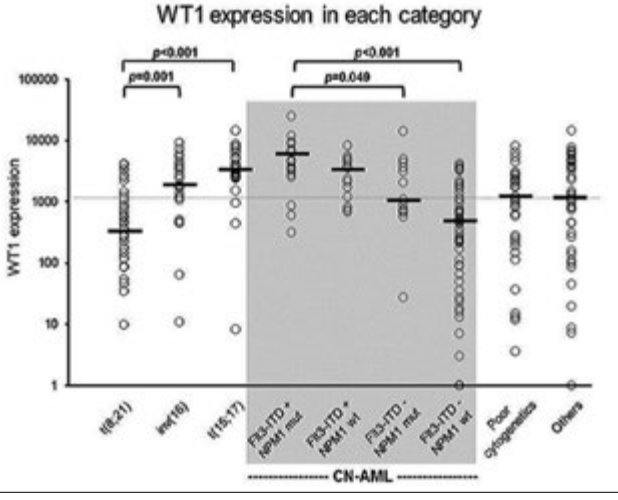

Figure 1.

Summary and Conclusions: Some favorable prognostic markers (inv(16), t(15;17), NPM1 mutation) and poor prognostic marker (Flt3-ITD mutation) were independently associated with higher WT1 expression. In each cytogenetic category, WT1 expression did not show clear prognostic significance in our series. So the prognostic significance of WT1 at diagnosis of AML was weak compared to other established prognostic factors. Inconsistency of previous reports describing both favorable and poor prognostic impact of higher WT1 expression at AML diagnosis could be due to the correlation of WT1 expression with these cytogenetic or molecular abnormalities. Distribution of the patients' cytogenetics could affect interpretation of WT1 expression as a prognostic marker.

PF252

OUTCOMES FOR T(9;11) PATIENTS ARE NO BETTER THAN FOR OTHER REARRANGEMENT PARTNERS IN 11Q23-REARRANGED ADULT AML: A COMPREHENSIVE REVIEW OF MLL-R AML TREATED AT MEMORIAL SLOAN KETTERING CANCER CENTER

K. Menghrajani[1,*], Y. Zhang[2], C. Famulare[3], S. Devlin[4], M. Tallman[1,5]

[1]Leukemia, [2]Pathology, [3]Sloan Kettering Institute, [4]Epidemiology-Biostatistics, Memorial Sloan Kettering Cancer Center, [5]Medicine, Weill Cornell Medical College, New York, United States

Background: Cytogenetic abnormalities involving 11q23, the site of the mixed-lineage leukemia (*MLL*) gene, are seen in approximately 5-10% of adult AML. These rearrangements commonly occur in patients previously treated with a topoisomerase II inhibitor, such as an anthracycline. Previous studies have shown that t(9;11) has an intermediate prognosis by OS whereas other 11q23 translocations have a poor prognosis [Chen *et al. Leukemia* 2013]. There are limited data on why such a difference may exist.
Aims: 1. Identify translocation partners in 11q23-rearranged adult AML; 2. Classify the most common translocations in therapy-related disease; 3. Assess if achieving CR with a single induction is predictive of one-year OS; 4. Identify the frequency of post-transplant relapse.
Methods: Patients seen at MSKCC between 1997 and 2017 were included in the analysis. 11q23-rearranged AML was identified centrally by the cytogenetics core. Additional patients were found through a search of the electronic medical record for all malignancies with 11q23 alterations. Manual review and selection of 11q23 rearrangements in AML patients ≥18 years of age at diagnosis was performed. Data on patient characteristics, diagnosis, disease characteristics, treatment, response, and transplantation were collected from the EMR. "Therapy-related disease" was noted in patients who had achieved anthracycline-based chemotherapy prior to AML diagnosis. Given that CRi, CRp, and CRh were not defined at the time of diagnosis for many patients, composite CR was used.
Results: We evaluated the clinical characteristics of 65 adult patients with AML and a translocation involving 11q23 who were seen at MSKCC between 1997 and 2017. Data on the translocation partner for 11q23 was available for 61 patients. Translocations of 11q23 with 9p22 occurred in 48% of patients; with 19p13 in 25% of patients; and with other partners in 27% of patients (including 6q27 in 10% of patients). The 23 patients with therapy-related disease were significantly more likely to have a translocation involving 9p22 than any other partner (p=0.01). There was no difference in CR rate between translocations involving 9p22 and translocations with other partners (p=0.66). For those who received their initial induction therapy at MSKCC (31 patients) and achieved a CR, the one-year overall survival was 50%, as opposed to 12% in those who did not achieve a CR (p=0.008). Thirty-two patients were able to undergo allogeneic HSCT; of these, 10 relapsed after transplant (31%) (Figure 1).

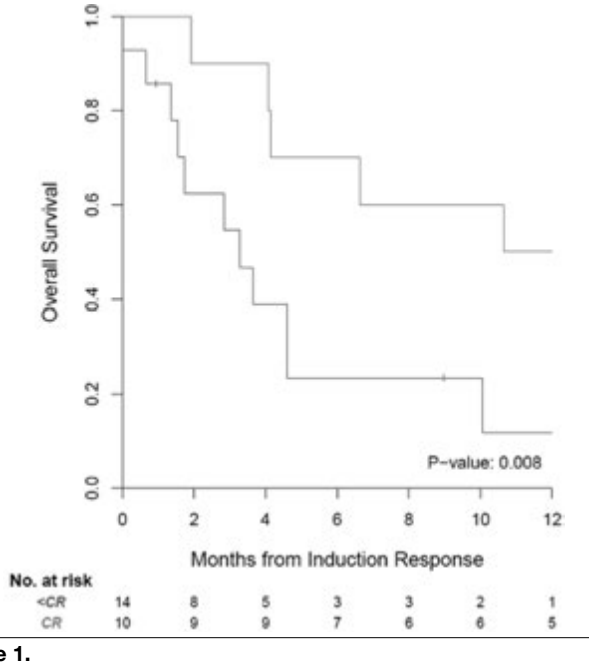

Figure 1.

Summary and Conclusions: - Therapy-related 11q23-rearranged AML was most likely to occur with 9p22 as the translocation partner. - The presence of a 9p22 translocation did not predict a higher likelihood of achieving CR despite being classified as intermediate risk by ELN. - Factors which may drive a difference in OS despite no difference in CR rate, such as relapse rate or the presence of molecular alterations which modify disease biology, require further study. - Achievement of CR after first induction appears to be a strong predictor of survival at one year. - Post-transplant relapse remains a significant challenge in this disease. - Prospective studies evaluating novel treatment options for these patients will be critical to meeting a clear unmet need.

HYPOMETILATING AGENTS (HMA) AS SALVAGE THERAPY IN RELAPSED OR REFRACTORY AML: AN ITALIAN 9-CENTER RETROSPECTIVE STUDY

M. Laurino[1,*], F. Lessi[1], A. Candoni[2], D. Lazzarotto[2], C. Papayannidis[3], M. Gottardi[4], O. Vitagliano[5], G. Reda[6], M. Riva[7], E. Crisà[8], M. Ermani[9], G. Semenzato[1], F. Ferrara[10]

[1]Department of Medicine, Hematology and Clinical Immunology Unit, University of Padua, Padua, [2]Hematology, University of Udine, Udine, [3] Institute of Hematology and Oncology L. and A. Seràgnoli, University of Bologna, Bologna, [4]Division of Hematology, Hospital of Treviso, Treviso, [5]Department of Clinical Medicine and Surgery, Federico II University Medical School, Naples, [6]Hematology, Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico, [7]Niguarda Cancer Center, ASST Grande Ospedale Metropolitano Niguarda, Milan, [8]Hematology, Ospedale Maggiore della Carità, Novara, [9]Department of Neurosciences, Statistics and Informatics Unit, University of Padua, Padua, [10]Hematology, Cardarelli Hospital, Naples, Italy

Background: 5-azacytidine and decitabine have been widely studied as first line chemotherapy in acute myeloid leukemia (AML) patients not eligible for allogenic stem cell transplantation, but data on their use as salvage chemotherapy are limited.
Aims: We tried to define efficacy and feasibility of hypometilating agents (HMA) as salvage chemotherapy in patients refractory or relapsed after one or more lines of therapy, with or without previous allogenic stem cell transplantation.
Methods: We retrospectively reviewed clinical records of 79 patients treated with HMA as salvage therapy in our 9 institutions since their introduction in clinical practice for AML patients.
Results: Median age was 64 years. 53 patients were men and 26 women. One patient was AML with t(9;11), 2 were AML with t(8;21),one was AML with inv(3), one patient was AML with inv(16), 23 were AML MRC, 2 were therapy related AML, 49 were AML NOS. 10 patients were favorable risk sec ELN 2017, 35 were intermediate, 30 were adverse risk. Cytogenetic risk was not available for 4 patients. 29% of patients were secondary AML. 61% of patients received HMA as second line therapy for their disease, 26% as third line and 13% were beyond the third line. 18% of patients underwent allogenic stem cell transplantation before HMA. 64 patients were treated with azacitidine and 15 with decitabine. All patients underwent intensive chemotherapy (*i.e.* FLAI or 3+7 like) as first line induction, and we excluded patients who had an HMA as first line chemotherapy and another one as second line. Median number of hospitalization days during HMA therapy was 0.5 (0-112). 42 patients showed no response to HMA, 14 patients showed response to HMA (CR, PR, or CRi) and 23 patients showed stable disease (SD). Median OS from HMA in patients with *de novo* AML was 5,3 months, while OS in patients with secondary AML was 43,4 months (p=0,012). This extremely good OS is surprising, it could be due to the small number of secondary AML, and it should be confirmed. Median OS in patients with refractory disease before HMA therapy was 5,1 months, while OS in patients with relapsed disease was 14,9 months (p=0,033). Median OS after HMA in patients with SD as best response to HMA was similar to median OS in patients with response to HMA (26,1 months *vs* 24,88 months), while OS in non responsive patients was 3,6 months (p<0,00001). 50% of patients with adverse cytogenetic risk and 42% of patients with favorable/intermediate cytogenetic risk reached a response or a stable disease with HMA, but we did not find significant difference in median OS between these two groups of patients. On multivariate analysis, OS differences between the SD+response group and the progressive disease group and between the secondary AML and *de novo* AML remained significant. We did not find significant differences between packed red blood cells transfusion needs before and after best response to therapy, and we find a worsen in platelets transfusion needs after best response to HMA (mean 1,5 platelet concentrates before HMA, mean 2,4 after HMA, p=0,0013).
Summary and Conclusions: HMA showed efficacy and a considerable OS in a subgroup of patiets (relapsed patients and secondary AMLs). Hospitalization was limited, and we can argue that this could lead to costs saving and improve quality of life, but further studies are needed. HMA could be a good clinical option in a selected population of relapsed patients, apparently regardless of cytogenetic risk, especially in those not suitable for allogenic bone marrow transplantation, in whom the prognosis is generally extremely poor.

PF254

COMPREHENSIVE ANALYSIS OF THE CORE-BINDING FACTOR ACUTE MYELOID LEUKEMIA WITH KOREAN AML REGISTRY

H.-J. Shin[1,*], W.-S. Min[2], Y. H. Min[3], J.-W. Cheong[3], J.-H. Lee[4], I.-H. Kim[5], D. S. Hong[6], J.-S. Ahn[7], H.-J. Kim[7], W.-S. Lee[8], C. W. Jung[9], J.-H. Jang[9], Y. Park[10], H.-J. Kim[2]

[1]Pusan National University Hospital, Busan, [2]The Catholic Blood and Marrow Transplantation Centre, [3]Yonsei University College of Medicine, [4]Asan Medical Center, [5]Seoul National University Hospital, [6]Soonchunhyang University Bucheon Hospital, Seoul, [7]Chonnam National University Hwasun Hospital, Jeollanam-do, [8]Inje University Busan Paik Hospital, Busan, [9]Samsung Medical Center, [10]Korea University Medical Center, Seoul, Korea, Republic Of

Background: The registry data for core-binding factor acute myeloid leukemia (CBF-AML) in Asian countries have rarely been reported.
Aims: The aims of this study were to evaluate clinical characteristics, treatment outcomes including SCT, and prognostic factors for CBF-AML using Korean AML registry.
Methods: We analyzed data of 392 patients with CBF-AML from among data for 3,041 AML patients in the Korean AML Registry.
Results: Interestingly, del(9q) was less frequently detected in Korean patients with t(8;21) than German patients (7.5% *vs* 17%), and del(7q) was more frequently detected (9.9%) in Korean patients with inv(16). Overall survival (OS) was similar between patients in first complete remission (CR) who received allogeneic stem cell transplantation (alloSCT) and those who received autologous SCT (ASCT) for both t(8;21) and inv(16) AML. Three-year OS of t(8;21) patients was poor when undergoing alloSCT in second or third CR, while OS of inv(16) patients in second or third CR was similar with that in first CR. Patients with a more than 3-log reduction of RUNX1/RUNX1T1 qPCR had improved 3-year event-free survival (EFS) than those without 3-log reduction (73.2% *vs* 50.3%). Poor outcome of <3-log reduction of qPCR can be overcome by alloSCT/ASCT as post-remission treatment. The t(8;21) AML patients with D816 mutation showed inferior EFS and OS and this poor outcome might be overcome by alloSCT. Multivariate analysis for OS in patients with t(8;21) revealed older age, >1 course of induction chemotherapy to achieve CR, loss of sex chromosome, del(7q), and second/third CR or not in CR before SCT as the independent prognostic variables. Especially del(7q) in t(8;21) patients showed significantly poor OS and all patients with del(7q) died less than 2 years after diagnosis (P <0.001). On the contrary, inv(16) patients with del(7q) had better OS than those without del(7q).
Summary and Conclusions: The prognostic significance of del(7q) in different subtypes of CBF-AML greatly varies and should be focused on future studies.

PF255

REAL WORLD EVIDENCE ON THE BURDEN OF ILLNESS EXPERIENCED BY PATIENTS WITH HEMATOLOGICAL MALIGNANCIES AND SYSTEMIC MYCOSES

A. Forsythe[1,*], J. Hearnden[1], G. Lewis[2], R. Schreiber[2]

[1]Purple Squirrel Economics, New York, [2]Mayne Pharma, Raleigh, United States

Background: Invasive fungal infections, also called systemic mycoses, affect immunocompromised populations disproportionately.
Aims: This investigation focused on the burden of illness experienced by patients with hematological malignancies and concurrent systemic mycoses.
Methods: Patients with systemic mycoses including aspergillosis, histoplasmosis, and blastomycosis were identified by strategically querying a database of electronic medical records *via* ICD-10 codes. The database features information on over 34 million patients in 30 US hospital institutions. Two cohorts were established consisting of patients with systemic mycoses and 1) Neither cancers nor another form of immunosuppression (immunosuppressant treatment, transplants, HIV), or 2) Cancer diagnoses. A third control cohort (3) consisting of patients with cancer diagnoses but without systemic mycoses was also established. A range of constitutional, respiratory, metabolic, and gastrointestinal symptoms were analyzed within six months of: 1&2) Initial treatment with antifungal medications (primarily itraconazole, fluconazole, nystatin, amphotericin, and voriconazole) and 3) Cancer diagnosis. The proportion of patients in each cohort who experienced a given symptom was determined. Comparisons were performed using two-tailed t-tests (95% percent confidence limits). Comparison of Cohorts 1 and 2 addressed the added burden experienced by patients with both systemic mycoses and cancers. Comparison of Cohorts 2 and 3 isolated the burden of systemic mycoses opposed to a concurrent cancer.
Results: A search conducted on October 26th, 2017 spanning five years identified 11,619 patients with systemic mycoses who were treated with antifungals. Cohorts 1 (N=2370), 2 (N=3284), and 3 (N=1139) were established. Among cancer patients with systemic mycoses, 59% had hematological malignancies (35% myeloid leukemia, 22% lymphoid leukemia,

22% leukemia of unspecified cell type). Across cohorts, systemic mycoses patients had consistent mean age (no cancer: 52, cancer: 57) and similar proportions of male (no cancer: 51%, cancer: 53%) and white (no cancer: 65%, cancer: 78%) patients. Cancer patients without systemic mycoses were assigned to Cohort 3 (N=774313). Cancer patients with systemic mycoses experienced the highest rates of all constitutional, respiratory, metabolic, and gastrointestinal symptoms *versus* mycoses patients without cancer (>100% increase in all symptoms, p<0.001 for all comparisons). The symptomatic burden experienced by cancer patients with systemic mycoses also significantly exceeded the burden on cancer patients without systemic mycoses (>330% increase in all symptoms, p <0.001) (Figure 1).
Summary and Conclusions: Patients with cancers and systemic mycoses experienced far greater rates of all symptoms than patients with either condition alone. This study served to illustrate the high symptomatic burden experienced by patients with cancers, primarily hematological malignancies, due to systemic mycoses.

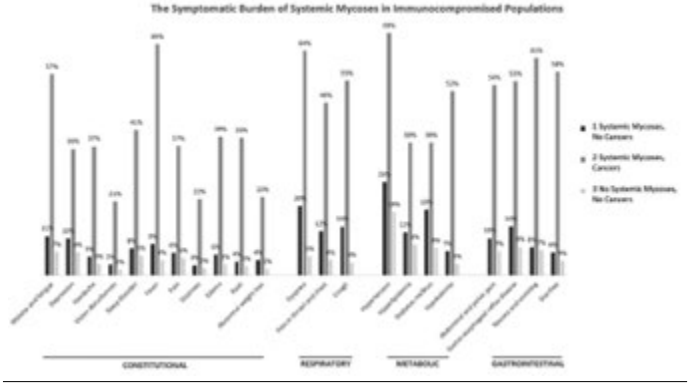

Figure 1.

PF256

EVALUATION OF FOOD EFFECT ON PHARMACOKINETICS OF IVOSIDENIB (AG-120), AN ORAL, POTENT, TARGETED, SMALL MOLECULE INHIBITOR OF MUTANT IDH1, IN HEALTHY SUBJECTS

B. Fan[1,*], D. Dai[1], G. Connor[1], H. Liu[1], G. Liu[1], S. V. Agresta[1], H. Yang[1]

[1]*Agios Pharmaceuticals, Inc., Cambridge, United States*

Background: Ivosidenib (IVO; AG-120) is an oral, potent, targeted, small molecule inhibitor of mutant isocitrate dehydrogenase 1 (mIDH1). Somatic mutations in IDH1 result in gain-of-function activity, catalyzing the reduction of α-ketoglutarate to the oncometabolite D-2-hydroxyglutarate (2-HG), leading to oncogenesis. IVO is a highly targeted therapeutic candidate for the treatment of mIDH1-driven cancers, including relapsed or refractory acute myeloid leukemia, which is currently being investigated in clinical trials. As IVO is orally administered, it is important to determine the relative bioavailability in relation to meal consumption.
Aims: To investigate the effect of a high-fat, high-calorie meal on the pharmacokinetics (PK) of IVO in healthy subjects.
Methods: In this randomized, two-period, two-way crossover design study (Clinicaltrials.gov NCT02579707), a single 500 mg dose (two 250 mg tablets) of IVO was administered under fasting conditions (10-hr overnight fast before IVO dosing) and after a high-fat meal (standardized FDA high fat content breakfast [approximately 900–1000 calories; 56%–60% fat] consumed within 30 minutes prior to IVO dosing) to 30 healthy subjects (aged 18 55 years). Of the 30 subjects enrolled, 15 were randomized to sequence 1 (fasted, then fed) and 15 were randomized to sequence 2 (fed, then fasted). There was a washout period of at least 25 days between the two treatments in each sequence. Blood samples for the analysis of IVO concentrations were collected predose and up to 504 hr postdose. The plasma PK parameters in the fed (test) and fasted (reference) groups were analyzed using analysis of variance.
Results: Following administration of IVO 500 mg in the high-fat fed and fasted states, IVO was readily absorbed, with similar median T_{max} values of 3.00 and 3.03 hr postdose, respectively (Table 1). After reaching C_{max}, plasma concentrations slowly declined in a multiphasic manner, with similar mean $t_{1/2}$ values of 53.2 hr in the fed state and 55.4 hr in the fasted state. An approximately 2-fold increase in mean C_{max} was observed, and mean AUC was 25% greater, when IVO was administered following a high-fat meal compared with fasted conditions. Following administration of single doses of IVO 500 mg, intersubject variability (assessed by geometric coefficient of variation for AUC and C_{max}) was similar and moderate for both fed and fasted states.

Table 1. Plasma PK parameters of IVO under fasted and fed conditions.

PK parameter	500 mg IVO (fasted)	500 mg IVO (fed)
$AUC_{0\text{-}t}$ (hr·ng/mL)[a]	136,000 (31.6)	166,000 (31.2)
$AUC_{0\text{-}\infty}$ (hr·ng/mL)[a]	143,000 (31.1)	174,000 (31.2)
C_{max} (ng/mL)[a]	2270 (21.3)	4490 (24.3)
T_{max} (hr)[b]	3.03 (1.00–24.0)	3.00 (1.00–6.00)
$t_{1/2}$ (hr)[c]	55.4 (20.5)	53.2 (18.3)

[a]Geometric mean (coefficient of variation, %)
[b]Median (min–max)
[c]Arithmetic mean (standard deviation)

Summary and Conclusions: There was an effect of a high-fat meal on IVO exposure, with an increase in C_{max} of approximately 98%.

PF257

AZACITIDINE FRONTLINE AND SALVAGE THERAPY FOR ACUTE MYELOID LEUKEMIA PATIENTS. CLINICAL EXPERIENCE AND DEVELOPMENT OF RISK SCORE

S. Imbergamo[1,*], A. Visentin[1], I. Kostic[1], S. Pravato[1], E. Scomazzon[1], M. Laurino[1], L. Ammirati[1], M. Riva[1], F. Lessi[1], G. Binotto[1], T. Berno[1], C. Gurrieri[1], G. Semenzato[1], L. Trentin[1]

[1]*Department of Medicine, Hematology and Clinical Immunology Unit, Padua University School of Medicine, Padova, Italy*

Background: Acute myeloid leukemia (AML) is an aggressive hematological malignancy characterized by a poor prognosis. Azacitidine (AZA) therapy has shown significant response and increased survival in clinical trial in patients with treatment naive (TN) or relapsed/refractory (R/R) AML.
Aims: The aim of this study was to evaluate the overall survival (OS) of AZA in patients with TN, not eligible for intensive chemotherapy, and R/R AML and to identify clinical and biological variables associated with increase survival.
Methods: A retrospective analysis was conducted on 39 patients with AML treated with AZA followed at Padua University Hospital from April 2012 to January 2018. The diagnosis was made according to 2016 WHO criteria. All patients received s.c. 5-Azacitidine 75 mg/m^2 for 7 days every 4 weeks until disease progression.
Results: The median age at diagnosis was 64 years (range 49-81). 30 (76%) patients were TN and 9 (24%) were R/R. Eighteen patients (46%) were considered at high, 19 (48%) intermediate and 2 (6%) low-cytogenetic risk. The complete remission was in 47% patients. The median OS for the whole cohort was 10.7 months, without any difference between TN and R/R patients (p=0.2743). In univariate analysis, variables associated with increased OS were age >70y (p=0.036), adverse cytogenetic-risk (p=0.021), reaching a partial remission (p=0.0037). All these variables were confirmed in multivariate analysis. There were no differences in OS for the percentage of peripheral and bone marrow blast cells. Based on hazard ratios obtained by multivariate analysis we assigned a risk-values to each significant variables. A risk score was then calculated as the sum of each risk values, ranging from 0 to 10. We found that median OS were 16.9 and 6.9 months for patients with ≤4 points and those with 5-10 score, respectivelly (p<0.0001).
Summary and Conclusions: We herein provide evidence that 5-Azacitidine is feasible and effective in patients with acute myeloid leukemia, regardless the lines of treatment. Moreover, we developed a scoring system able to identify patients with long lasting response and improved survival.

PF258

MYELOID SARCOMAS IN AML TRANSLOCATION (8;21) IS IT STILL A FAVOURABLE RISK GROUP?

R. Halder[1,*], M. Aggarwal[1], M. Mahapatra[1], T. Seth[1], U. Kumar[1], R. Dhawan[1], H.P. Pati[1], S. Tyagi[1], R. Saxena[1], S. Mirgh[1], S. Kothari[1], R. Chauhan[1]

[1]*Department of Hematology, All India Institute of Medical Sciences, New delhi, India*

Background: Acute Myeloid Leukemia(AML) with translocation (8;21) is a favourable disease. Prognostic impact of myeloid sarcomas on aml t(8;21) is not much studied.
Aims: To study and compare the outcome of patients of acute myeloid

leukemia with translocation (8;21) with and without myeloid sarcoma at presentation.
Methods: It was a retrospective analytical study of patients of acute myeloid leukemia with translocation (8;21) with and without myeloid sarcomas that were treated from 2014 to 2017 in our hospital.
Results: During the study period we treated 24 cases were of aml with t(8;21), 14 in the adult age group and 10 in pediatric(<18 years) age group. 9 out of 24 cases had myeloid sarcoma. C-kit mutation for D816V was done for 11 patients, none of whom were positive.
All patients were treated with standard Daunorubicin and Cytarabine (3+7) induction chemotherapy followed by 3 cycles of high dose cytarabine (@3gram/m2) once every 28 days as per standard of care.
4 out of the 9 cases(44.4%) of myeloid sarcoma with aml t(8;21) had either relapsed or died. Where as in the aml t(8;21) without myeloid sarcoma group 6 out of 15 patients (40%) relapsed or died. (p=0.2)
Summary and Conclusions: Presence of myeloid sarcomas in patients with aml t(8;21) does not seem to have an adverse prognostic impact on the course of disease.

Aggressive Non-Hodgkin lymphoma – Clinical

AXICABTAGENE CILOLEUCEL (AXI-CEL) IN PATIENTS WITH REFRACTORY LARGE B CELL LYMPHOMA: DURABILITY OF RESPONSE IN ZUMA-1

F.L. Locke[1], A. Ghobadi[2], C.A. Jacobson[3], E. Jacobsen[3], D.B. Miklos[4], L.J. Lekakis[5], I. Braunschweig[6], O.O. Oluwole[7,*], Y. Lin[8], T. Siddiqi[9], A. Deol[10], P.M. Reagan[11], U. Farooq[12], A. Bot[13], Y. Jiang[13], J.M. Rossi[13], A. Xue[13], W. Go[13], S.S. Neelapu[14]

[1]Moffitt Cancer Center, Tampa, [2]Washington University School of Medicine, St. Louis, [3]Dana-Farber Cancer Institute, Boston, [4]Stanford University, Stanford, [5]University of Miami Health System, Sylvester Comprehensive Care Center, Miami, [6]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, [7]Vanderbilt-Ingram Cancer Center, Nashville, [8]Mayo Clinic, Rochester, [9]City of Hope National Medical Center, Duarte, [10]Karmanos Cancer Center, Wayne State University, Detroit, [11]University of Rochester School of Medicine, Rochester, [12]University of Iowa, Iowa City, [13]Kite, a Gilead company, Santa Monica, [14]The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Axi-cel, an anti-CD19 CAR T cell therapy, demonstrated significant clinical benefit and a manageable safety profile for patients with refractory large B cell lymphoma in ZUMA-1 (Neelapu & Locke *et al. NEJM.* 2017). These results led to its approval by the US FDA for the treatment of adult patients with relapsed or refractory large B cell lymphoma after ≥2 prior lines of therapy.
Aims: To examine responses over time in Phase 2 of ZUMA-1.
Methods: All patients provided written informed consent. Patients with refractory large B cell lymphoma received 2×10^6 CAR T cells/kg after low-dose conditioning chemotherapy (Neelapu & Locke *et al. NEJM.* 2017). Best objective response rates (BORs) were analyzed locally by investigators and centrally by independent review committee (IRC; Cheson *et al. J Clin Oncol.* 2007); concordance was measured as the percentage of patients whose IRC matched local assessment.
Results: As of 8/11/17, median follow-up was 15.1 months for the 101 patients treated with axi-cel. While the BOR of 82% at the primary analysis (median follow-up 8.7 months) by local assessment remained consistent (83%) at long-term follow-up (LTFU; median of 15.1 months), complete response (CR) rates increased from 54% to 58% (Table 1). Out of 34 patients with partial response (PR) at 1 month, 11 (32%) converted to CR by the LTFU. High concordance (77%–79%) was observed for objective response rates (ORR [CR+PR]) between local assessment and IRC at all times assessed. Landmark analysis of progression-free survival (PFS) by response status (per local assessment) revealed that most of the 60 patients with disease control (stable disease or better) at 3 months had prolonged disease control with a 73% 12-month PFS rate. Of the 42 patients with CR and 9 with PR at 3 months, the 12-month PFS rates were 79% and 78%, respectively.

Table 1.

Data-cut; median follow-up, months N = 101	BOR, n (%)				ORR Concordance, %
	Local Assessment		IRC		
	ORR	CR	ORR	CR	
Primary analysis; 8.7	83 (82)	55 (54)	72 (71)	52 (51)	77
Axicabtagene ciloleucel US prescribing information; 11.6	84 (83)	55 (54)	73 (72)	52 (51)	79
LTFU; 15.1	84 (83)	59 (58)	73 (72)	52 (51)	79

Summary and Conclusions: Treatment with axi-cel induces high response rates in patients with refractory large B cell lymphoma. CR rates increased through the LTFU, suggesting that responses deepen over time and that patients with PR can achieve CR as late as a year post-infusion. ORR at 3 months may be prognostic for prolonged PFS.

PF260

IMPACT OF COMORBIDITY ON DISEASE CHARACTERISTICS, TREATMENT INTENT AND OUTCOME IN DIFFUSE LARGE B-CELL LYMPHOMA – A SWEDISH LYMPHOMA REGISTER STUDY

T. Wästerlid[1,*], K. Ekström Smedby[1], I. Glimelius[2], M. Jerkeman[3], S. Eloranta[1]

[1]Department of Medicine Solna, Division of Clinical Epidemiology, Karolinska Institutet, Stockholm, [2]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, [3]Department of Oncology, Skåne University Hospital, Lund, Sweden

Background: Presence of comorbid disease is known to impact overall survival among patients with diffuse large B-cell lymphoma (DLBCL). Thus far, studies that have evaluated the influence of comorbidity in DLBCL have been heterogeneous in study design and have often been restricted in size and to an elderly population. Therefore, associations of comorbidity with lymphoma characteristics, treatment selection and lymphoma-specific mortality in a real-world setting remain to be established.
Aims: We aimed to examine the relationship between history of comorbid disease and lymphoma characteristics, treatment intent and overall- and lymphoma-specific survival among adult patients with DLBCL in Sweden.
Methods: A total of 3905 adult patients diagnosed with DLBCL 2007-2013 were identified through the Swedish Lymphoma Register, with detailed clinical data available. Comorbid disease was defined according to the Charlson comorbidity index (CCI), with addition of psychiatric disorders. Data regarding comorbidities was collected from the Swedish National Patient register. To assess lymphoma-specific mortality, the study cohort was linked to the Cause-of-Death register. Associations of comorbid disease history with lymphoma characteristics and treatment intent were investigated using Relative Risk Ratios (RRR) from multinomial logistic regression models. Hazard ratios (HR) for all-cause and lymphoma-specific survival was estimated using flexible parametric survival models. These models were also used to estimate adjusted lymphoma-specific survival curves, as a complement to survival estimates obtained using the Kaplan-Meier method.
Results: Forty-five percent of patients (n=1737) had at least one comorbidity as classified according to the CCI, of which 997 (26% of the total population) had a CCI score of ≥2. As expected, presence of comorbidity increased with age (CCI>0 among 15% *vs* 65% of patients aged <50 *vs* ≥80, respectively). The relative probability of presenting with poor performance status *versus* being asymptomatic (PS=0) was higher among comorbid patients compared to those without a history of comorbidities ($RRR_{PS>2}$:2.02, 95% CI:1.63-2.51). No corresponding association was observed with stage, bulky disease, elevated levels of lactate dehydrogenase or extranodal involvement. Comorbid patients had a lower relative probability of receiving curative treatment (RRR:0.48, 95% CI:0.38-0.61). Comorbid patients selected for palliative treatment had an increased risk of both all-cause death (HR:2.12, 95% CI:1.53-2.94) and lymphoma-specific mortality (HR:1.74, 95% CI:1.21-2.51). In contrast, among comorbid patients selected for curative treatment, comorbidity was associated with an increased risk of all-cause death (HR:1.54, 95% CI:1.32-1.80), but not with inferior lymphoma-specific survival (HR:1.05, 95% CI:0.86-1.28, Figure 1).

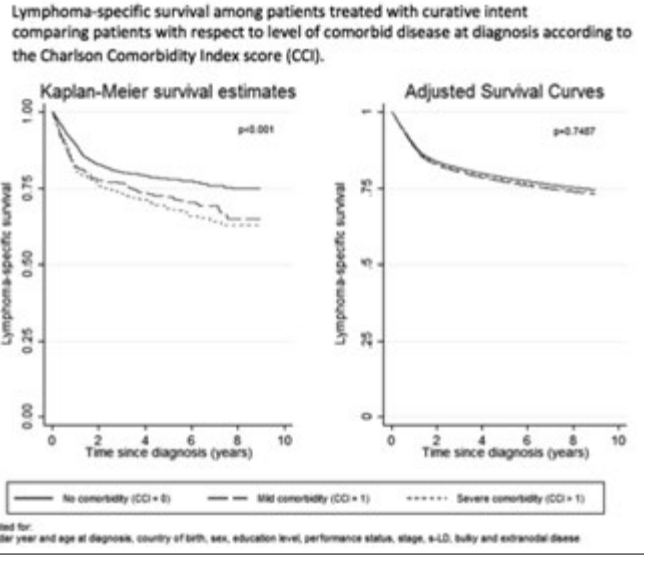

Figure 1.

Summary and Conclusions: In this population-based study we show that comorbid DLBCL patients more often present with poor performance status, but not more frequently with other disease characteristics associated with advanced disease. Moreover, we demonstrate that comorbidity is associated with lower likelihood of receiving treatment with curative

intent, leading to inferior lymphoma-specific outcome. Among comorbid patients treated with curative intent, inferior overall but not lymphoma-specific survival indicate a need for reduction of toxicity and optimization of comorbid conditions in parallel with DLBCL treatment.

PF261

THE NOVEL SYK/JAK INHIBITOR CERDULATINIB DEMONSTRATES GOOD TOLERABILITY AND CLINICAL RESPONSE IN A PHASE 2A STUDY IN RELAPSED/REFRACTORY PERIPHERAL T CELL LYMPHOMA

S. Horwitz[1,*], P.A. Hamlin[1], T.A. Feldman[2], B.T. Hess[3], A.R. Mato[4], J. Munoz[5], M.R. Patel[6], S.D. Smith[7], J.C. Ye[8], A.J. Steele[9], A. Pandey[9], M.R. Birrell[9], J.M. Leeds[9], G.P. Coffey[9], J.T. Curnutte[9]

[1]Department of Medical Oncology, Memorial Sloan-Kettering Cancer Ctr, New York, NY, [2]Hackensack University Medical Center, Hackensack, NJ, [3]Division of Hematology/Oncology; Hollings Medical Cancer Center, Medical University of South Carolina, Charleston, SC, [4]Hospital of the University of Pennsylvania, PA Cancer Immunotherapy, Philadelphia, PA, [5]Cancer Immunotherapy Program, Banner MD Anderson Cancer Center, Gilbert, AZ, [6]Drug Development Unit, Florida Cancer Specialists/Sarah Cannon Research Institute, Sarasota, FL, [7]University of Washington/Fred Hutchinson Cancer Research Center, Seattle Cancer Care Alliance, Seattle, WA, [8]University of Michigan Cancer Center, Ann Arbor, MI, [9]R&D, Portola Pharmaceuticals, South San Francisco, CA, United States

Background: Pre-clinical data suggest a role for SYK and JAK signaling pathways as oncogenic drivers in peripheral T cell lymphoma (PTCL). A published study described a unique translocation in 17% of PTCL specimens (t(5;9)(q33;q22)) resulting in a SYK-ITK fusion protein, in which the kinase domain of SYK was constitutively active. This fusion protein was expressed transgenically in CD4 positive T cells in mice, resulting in a lethal T cell proliferative disease. Transgenic expression of this fusion protein in CD19 positive B cells in mice did not result in clonal expansion. In an independent set of 141 PTCL specimens, wildtype SYK was expressed in 93% of all PTCL cases, including 100% of 35 AITL cases and 94% of 66 PTCL-NOS cases. This was independently confirmed, although SYK expression was observed at lower frequencies (45% of 71 systemic ALCL cases, and 0% of 20 PTCL-NOS cases). Additionally, gene expression profiling revealed two dominant sub-clusters implicating JAK/STAT signaling in this disease; one enriched for GATA-3 and its cytokine gene targets (eg, IL-4, IL-5, IL-13), while the other is enriched for T-bet and its cytokine gene targets (eg, IFN-γ and IFN-γ-inducible genes). Frequent activating mutations to common γ chain, JAK1, JAK3, or STAT5b are also observed. Overall, the data suggest that dual inhibition of SYK and JAK may perturb multiple and independent survival mechanisms in PTCL. Cerdulatinib is a small molecule reversible ATP competitive inhibitor of SYK and JAK family members. Phase 1 studies in patents with B cell malignancies demonstrated good tolerability and initial evidence of clinical activity, and the phase 2a extension study in patients with specific subtypes of B cell or T cell NHL or CLL/SLL is ongoing.
Aims: This is an interim analysis of an ongoing phase 2a study in a subpopulation of patients with relapsed/refractory PTCL.
Methods: Eighteen relapsed/refractory PTCL patients received 30 mg cerdulatinib orally BID. Response was assessed by Lugano classification criteria at the end of 2 months and every 3 cycles thereafter.
Results: Patents included PTCL-NOS (7), AITL (6), ALCL (2), HSTCL (1), Gamma-delta TCL (1), and MEITL (1). Median (range) age: 70 (48-84]); median prior therapies: 3 (1-9); 28% had prior transplant; and 44% was refractory to last therapy. Eleven patients were evaluated for clinical response, 3 discontinued prior to evaluation (2 due to progression; 1 withdrew consent), and 4 patients have yet to be evaluated. Six patients have responded (ORR 43%): 4 patients achieved a CR after 2 cycles, 2 achieved a PR, and 2 SD. Four responding patients remain on drug: 1 for 11+ months and the remaining for 3-7 months. A patient with CR was referred to allogeneic transplant and censored after cycle 2. An additional patient achieved complete remission of target lesions, but discontinued therapy due to a new lesion. The majority of responses were observed in PTCL-NOS and AITL. Importantly, CRs and PRs occurred in patients who failed multiple lines of therapy, including pralatrexate, romidepsin, belinostat, and an investigational PI3K inhibitor. The most common AEs of any grade were diarrhea (33%), fatigue (22%), lipase increase (17%), and nausea (17%). Grade 3+ AEs occurring in ≥2 patients are neutropenia (4), diarrhea (3), lipase increase (2), and pneumonia (2). The target PK range was achieved with an average SSCmin of ~0.8 μM.
Summary and Conclusions: These data suggest that cerdulatinib is well tolerated and capable of generating durable complete responses in heavily pretreated PTCL.

Background: Treatment outcomes for patients (pts) with R/R DLBCL are poor, particularly for those ineligible for hematopoietic stem cell transplantation (SCT). Ibrutinib (ibr), a first-in-class, once-daily inhibitor of Bruton's tyrosine kinase, is approved for the treatment of various B-cell malignancies. An ongoing phase 1b/2, open-label, multicenter study is evaluating the safety and efficacy of ibr in combination with lenalidomide (LEN) and rituximab (RTX) in SCT-ineligible pts with R/R DLBCL. During the dose escalation in phase 1b, a LEN dose of 20 mg on Days 1–21 in combination with once-daily 560 mg ibr and 375 mg/m^2 IV RTX on Day 1 of Cycles 1–6 in 28-day cycles (iR^2) was considered the recommended phase 2 dose (RP2D). Across phase 1b dose cohorts, iR^2 demonstrated promising activity, with an overall response rate (ORR) of 43% (all) and 61% (non-GCB) in response-evaluable pts; the median duration of response (DOR) was 16 months. Results from the phase 2 interim analysis are reported here.
Aims: To evaluate the safety and activity of the iR^2 regimenat the RP2D in SCT-ineligible pts ≥18 years with histologically confirmed R/R non-GCB DLBCL after ≥1 prior therapy.
Methods: All pts provided written informed consent. Ibr, LEN, and RTX were administered in 28-day cycles at the RP2D (Figure 1). The primary efficacy endpoint in phase 2 was ORR. The null hypothesis of an ORR of 40% will be tested against the alternative hypothesis of an ORR of >60%. An interim analysis including 28 evaluable pts with adequate tumor assessment could be performed per protocol. If only 11 or fewer responders (≤11/28) are observed, discontinuation of the study could be considered by the Sponsor as per the statistical framework of Simon's minimax 2-stage design (Simon 1989). Enrollment continued during the interim analysis. The secondary endpoints included complete response rate, DOR, progression-free survival (PFS), overall survival, and safety. For severe rash and neutropenia, study medication was withheld until improvement to grade ≥1 or resolution and managed with oral corticosteroids and antihistamines (rash) and hematopoietic growth factors (neutropenia), as applicable.
Results: At the interim analysis, 42 pts were enrolled and treated in phase 2. Median age was 63 years; 62% were male; 62% had stage IV disease; 26% had primary refractory disease; median prior DLBCL systemic therapies was 2 (range: 1–5). The iR^2 regimen demonstrated promising activity: among the initially enrolled 28 response-evaluable pts for the interim analysis, 17 had a response (9 complete [32%]; 8 [29%] partial), with an ORR of 61% (95% CI: 41%–79%) and a median DOR of 10 months. Two (7%) pts had stable disease. The study passed the interim analysis criteria, as the number of responders (n=17 of the first 28 evaluable pts) exceeded the 11 responders needed to continue study enrollment. Among all 42 pts, the median PFS was 5 months (95% CI: 3–12) as of this interim analysis, with 57% of pts still receiving treatment. Grade ≥3 TEAEs were experienced by 79% of pts, and 57% of pts experienced a grade ≥3 TEAE considered related to study drug. Grade 3–4 TEAEs in >5% of pts were neutropenia (19%), anemia (14%), and maculopapular rash (12%).

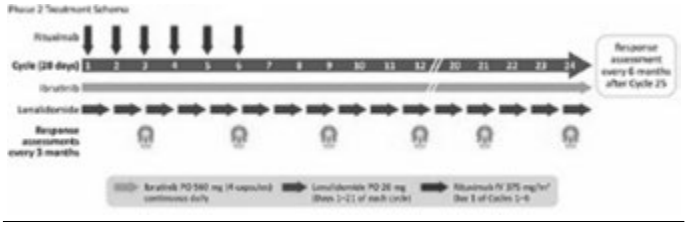

Figure 1.

Summary and Conclusions: The combination of ibr, LEN, and RTX demonstrated promising activity and a manageable safety profile at the RP2D in SCT-ineligible pts with R/R non-GCB DLBCL. Further evaluation of this combination, including a cohort with 25 mg LEN, is currently ongoing.

PF263

OVERWEIGHT LYMPHOMA PATIENTS TREATED BY ACTUAL BODY WEIGHT HAD NO EXCESS OF CHEMOTHERAPY TOXICITY: EXPERIENCE FROM TWO LARGE TRIALS

B. Merron[1,*], T. Maishman[1], A. Preston[2], J. Northey[1], A.A. Kirkwood[3], J. Caddy[1], L. Stevens[3], G. Griffiths[1], L. Clifton-Hadley[3], A. Davies[4], P.W. Johnson[4]

[1]Southampton Clinical Trials Unit, University of Southampton, Southampton, [2] Pharmacy Department, University Hospitals Bristol, Bristol, [3]Cancer Research UK & UCL Cancer Trials Centre, University College London, London, [4]Cancer Research UK Centre, University of Southampton, Southampton, United Kingdom

Background: The incidence of obesity in the western world has increased dramatically, with 1.9 billion overweight adults in 2016. ASCO guidelines on chemotherapy dosing in the obese population advocate the use of actual body weight but dose reductions (DRs) are often made owing to the perceived risk of greater toxicity. For diseases treated with curative intent such as Hodgkin lymphoma (HL) and diffuse large B-cell lymphoma (DLBL) DRs in the obese might result in reduced survival.
Aims: Using data from two large trials in HL (RATHL) and DLBL (REMoDL-B), we examined chemotherapy toxicity in the obese *versus* non-obese populations. We also studied survival outcomes in relation to BMI and dose reductions.
Methods: In RATHL, patients with newly diagnosed HL underwent paired baseline and interim PET-CT scans after 2 cycles of ABVD (PET2). Patients with a negative (Deauville 1-3) PET2 were randomized to ABVD/AVD for 4 more cycles. If the PET2 remained positive (Deauville 4-5), patients proceeded to intensification with BEACOPP-14/escalated BEACOPP. In REMoDL-B, patients newly diagnosed with DLBL commenced conventional R-CHOP chemotherapy whilst whole transcriptome profiling (GEP) was performed on their tumour sample. After successful GEP, patients were randomised to R-CHOP +/- bortezomib days 1+8 for cycles 2-6. In both studies baseline height and weight was recorded along with drug doses delivered and toxicities recorded.
Results: BMI data was available for 1199 eligible patients in RATHL and 1062 patients in REMoDL-B (Table 1). Within RATHL, 25.4% were overweight (BMI 25-29.9) and 16.2% obese (BMI≥30). In REMoDL-B, 38% were overweight, 25% obese. There was no difference in prognostic scores or stage in either study. In RATHL, obese patients were older, less likely to have 'B' symptoms and more likely to be female. In REMoDL-B, obese patients were younger than the non-obese. In both studies, obese patients were significantly more likely to undergo elective dose reductions (below 90% of dose based on actual body weight) of at least one drug in each cycle than the non-obese population. In both studies, obese patients who received full dose chemotherapy had no higher incidence of grade ≥3 haematological AEs or neuropathy in comparison to full dose, non-obese counterparts in both studies. In RATHL, there was no significant difference in the use of granulocyte colony-stimulating factor (GCSF) between obese and non-obese groups. In REMoDL-B non-obese patients were significantly more likely to receive GCSF than the obese population, in particular as secondary prophylaxis. This may reflect the older population and higher frequency of full dose chemotherapy in this BMI. In neither study was there a difference in PFS or OS in the obese population between those dose reduced and those not dose reduced. Across BMI groups there was no difference in PFS or OS.

Table 1. Table of baseline characteristics.

	REMoDL-B		RATHL	
Characteristic	**Non-obese**	**Obese**	**Non-obese**	**Obese**
BMI, N (%)	795	267	1004	195
Age, Median (range)	65 (20-86)	62.0 (28-83)*	31.0 (18-78)	39.0 (18-79)*
Male, N (%)	444 (55.8)	143 (53.6)	565 (56.3)	89 (45.6)*
B Symptoms present, N (%)	379 (48)	113 (42.3)	638 (63.5)	96 (49.2)*

* $p < 0.05$

Summary and Conclusions: Elective dose reductions were significantly more common in patients with BMI≥30 in both studies. In obese patients who were dosed according to actual body weight there was no increase in haematological toxicity. Those undergoing modest dose reductions did not experience inferior PFS or OS.

PF264

QUALITY OF LIFE IN CUTANEOUS T-CELL LYMPHOMA SUBJECTS TREATED WITH THE ANTI-CCR4 MONOCLONAL ANTIBODY MOGAMULIZUMAB *VERSUS* VORINOSTAT: RESULTS FROM THE PHASE 3 MAVORIC TRIAL

P. Quaglino[1,*], S. Hudgens[2], P. Porcu[3], R. Cowan[4], L. Floden[2], A. Tsianakas[5], M. Leoni[6], S. Dale[6], M. Duvic[7]

[1]University of Turin, Turin, Italy, [2]Clinical Outcomes Solutions, Tucson, AZ, [3]Thomas Jefferson University, Philadelphia, PA, United States, [4]Christie Hospital Foundation, Manchester, United Kingdom, [5]Specialist Clinic Bad Bentheim, Bad Bentheim, Germany, [6]Kyowa Kirin Pharmaceutical Development, Inc., Princeton, NJ, [7]MD Anderson Cancer Center, Houston, TX, United States

Background: Cutaneous T-cell lymphomas (CTCL) are rare non-Hodgkin's lymphomas that cause significant morbidity and adversely affect quality of life (QoL), most severely in Sezary syndrome (SS) patients.
Aims: To assess meaningful change on patient reported outcomes (PRO) for mogamulizumab *versus* vorinostat.
Methods: A large, multicenter Phase 3 trial compared mogamulizumab (MOGA) *vs* vorinostat (VOR) in patients with Stage IB-IV CTCL who had failed ≥1 systemic therapy. Progression free survival was the primary endpoint. Validated QoL measurements included the Skindex-29, Functional Assessment of Cancer Therapy-General (FACT-G) and EuroQol-5D-3L (EQ-5D-3L). Skindex-29 and FACT-G are reported here. Longitudinal modeling of symptoms, function, and QoL subdomains were evaluated using longitudinal mixed models on prespecified covariates. Meaningful change threshold (MCT) was evaluated and categorical change analyzed by group over time. Time to clinically meaningful symptom worsening was defined using distribution-based minimally important difference thresholds.
Results: 372 patients were randomized (186 in each arm). MOGA resulted in symptomatic and functional improvement with differences in Skindex-29 Symptoms (Cycles 3, 5, and 7; $p<0.05$) and Functional (Cycles 3 and 5; $p<0.05$) scales. The proportion of patients who improved by at least the MCT from baseline was significantly greater for MOGA *vs* VOR on Skindex-29 Symptoms at Cycle 3 (61.1% *vs* 45.3%), Cycle 5 (64.5% *vs* 42.4%), Cycle 7 (67.1% *vs* 47.5%), and Cycle 11 (84.1% *vs* 50.0%) and Skindex-29 Functioning domain at Cycle 5 (54.3% *vs* 28.8%). Significant difference in the FACT-G Physical Well-Being scale (Cycles 1, 3, and 5; $p<0.05$) were observed in favor of MOGA and a greater proportion of patients declined by at least the MCT in favor of MOGA *vs* VOR at Cycle 1 (19.3% *vs* 34.7%), Cycle 3 (17.4% *vs* 42.9%), Cycle 5 (13.1% *vs* 43.3%), and Cycle 7 (15.9% *vs* 37.5%). The median time to worsening of symptoms on Skindex-29 was 27.4 m for MOGA *vs* 6.6 m for Vor. In SS patients, the median time to worsening varied in favor of MOGA ($P<.005$) on all Skindex-29 domains. In mycosis fungoides (MF) patients, time to worsening on Skindex-29 did not vary between arms.
Summary and Conclusions: Symptoms, function, and overall QoL of CTCL patients favored MOGA over VOR across study time points in the MAVORIC trial. Patients with the highest symptom burden and functional impairment derived the most QoL benefit from MOGA.

PF265

ANALYSIS OF CNS RELAPSES RISK FACTORS IN A POPULATION OF 1615 UPFRONT DLBCL PATIENTS TREATED IN LYSA PROTOCOLS LNH03 AND LNH07-3B

S. Bernard[1,*], N. Mounier[2], N. Ketterer[3], C. Recher [4], O. Fitoussi[5], R. Delarue[6], O. Casanovas[7], F. Morschhauser[8], T. Petrella[9], C. Copie [10], A. Bosly[11], C. Gisselbrecht[12], C. Haioun[13], T.-J. Molina[14], H. Tilly[15], C. Thieblemont[16]

[1]Hemato-oncology, Hôpital Saint Louis - APHP, PARIS, [2]Hemato-oncology, CHU Nice, Nice, France, [3]Oncology, Clinique Bois Cerf, Lausanne, Switzerland, [4]IUCT Oncopole, Toulouse, [5]Polyclinique Bordeaux Nord, Bordeaux, [6]Hematology, Hopital Necker, Paris, [7]Hematology, CHU, Dijon, [8]Hematology, CHU, Lille, [9]Pathology, CHU, Dijon, [10]Pathology, Hopital Mondor, Créteil, France, [11]Hematology, UCL Mont Godinne, Yvoir, Belgium, [12]LYSARC, LYON, [13]Hematolgy, CHU Mondor, Créteil, [14]Pathology, Hopital Necker, Paris, [15]Hematology, Centre Henri Bequerel, Rouen, [16]Hematology, Hopital Saint Louis, Paris, France

Background: Central Nervous system (CNS) relapse is a rare event in diffuse large B-cell lymphoma population (DLBCL), and is associated with a very poor prognosis. Indentification of CNS relapse risk factors has long been a subject of clinical research because of the fatal issue of these relapses. A better identification of high risk patients allow clinicians to stratify DLBCL patients and to propose optimized CNS relapses prophylaxis and thus, potentially, decrease the relapse rate.
Aims: The main objective of our study was to analyse CNS relapse risk factors in a population of 1615 *de novo* DLBCL patients, aged 18-80, and included in 6 prospective LYSA phase III studies. Secondary objectives were overall survival and progression-free survival datas of patients with CNS relapses.
Methods: Clinical, biological and histological data at diagnosis, treatments and prophylaxis received were collected and analyzed. The primary objective was the analysis of risk factors associated with CNS relapse in a cohort of patients treated in controlled trials. A statistical analysis was performed.
Results: Among the 1615 patients analyzed, 28 patients presented a CNS relapse (1.7%) and 330 presented another relapse (20.4%). Risk factors at diagnosis time significantly associated with CNS relapse were: age>60 years (p <.001), Performans Status 2-3 (p <.006), extranodal involvement>2 (p <.001), disseminated satge III / IV (p <.005), elevated LDH (p <.018), IPIaa 2-3 (p <.001), SNC-IPI score high risk(p <.001), renal involvment (p <.017), and protein expression of Cmyc>40% (p=0.003). In multi-variate analysis, high IPI, age>60 years, extranodal involvement >2 and a high CNS-IPI score (4-6) had an independent prognostic value. A high CNS-IPI score (>4) was associated with an independent risk of relapse or cerebral relapse in competitive models with HR=3.00 [1.28-7.01], P=0.011 for CNS and HR relapses=1.40 [1.07-1.84], P=0.014 for death due to cerebral relapse. The onset of CNS relapse occurred in 6.2% of patients with a high CNS-IPI score *vs* 2.3% of intermediate-risk patients and 0.2% of low-risk patients. The median OS of patients with CNS relapse was 11 months (not reached in the population without relapse), and the median PFS was 6.6 months.
Summary and Conclusions: This study confirms the predictive value of the CNS-IPI score and defines a population of patients with a high risk of CNS relapse.The poor prognosis of this population and the identification of a high risk population must lead to an optimization of CNS prophylaxis for high risk patients.

PF266

SUBSTITUTION OF CISPLATIN FOR CARBOPLATIN OR OXALIPLATIN IN THE DHAP REGIMEN IS ASSOCIATED WITH IMPROVED SURVIVAL IN RELAPSED/REFRACTORY NON-HODGKIN'S LYMPHOMAS

E. Martin[1,*]

[1]Department of Hematology, University Hospital of Tours, Tours, France

Background: Salvage of relapsed/refractory non-Hodgkin's lymphomas (NHL) is a therapeutic challenge, the multiple chemotherapy regimens published contrasting with the few comparative studies available. The DHAP (Dexamethasone, High-dose cytArabine and cisPlatine) regimen is commonly used in such cases. However, cisplatin nephrotoxicity is a major issue, which has been circumvented by the use of other platinum-related drugs such as carboplatin or oxaliplatin. However, evidence for a comparable efficacy and tolerance is lacking.
Aims: The aim of this retrospective multicenter study was to compare the effectiveness of cisplatin with that of oxaliplatin and carboplatin, in terms of complete response (CR), progression free-survival (PFS) and overall survival (OS).
Methods: Twenty-four volunteering centers of the LYSA group retrieved the medical records of patients treated between January 1, 2007 and December 31, 2012, with R-DHAP 100mg/m^2, R-DHAOx (Oxaliplatin) 130mg/m^2 or R-DHAC (Carboplatin) 5 Area Under Curve at day 1, with 21-day intervals. The study retrospectively included patients over 18 years old who received platinum salt for relapsed or refractory follicular lymphoma, transformed follicular lymphoma, other transformed indolent lymphoma or diffuse large B-cells lymphoma. A standardized electronic case report form (CRF) was set up and completed by a single clinical research assistant (CRA) who visited the centers and controlled the accuracy of all data. Comorbidities were retrieved according to medical records. An analysis adjusted on comorbidities, age, sex, number of previous treatment lines, FLIPI or IPI and histology, was planned.
Results: After exclusion of 235 observations with missing data, 462 patients were evaluable. Of them, 173 were treated with R-DHAP, 75 with R-DHAC, and 214 with R-DHAOx. Because of the specific toxicity profile of cisplatin, patients treated with R-DHAC and R-DHAOx were merged in a "non-cisplatin" group. Patients in this "non-cisplatin" group were significantly older (58.5y *vs* 54.8y, p<0.01). There was no statistical difference between the two groups for sex, IPI or FLIPI severity, comorbidities, histology and number of previous lines. The CR rate was similar, 43% in the both group (p=0.96). The PFS for the cisplatin and non-cisplatin groups was 16,8 and 18,9 months respectively (p=0.46). However, in multivariate analysis, with adjustment on age, FLIPI or IPI group, number of previous lines and comorbidities, the median OS was shorter in the cisplatin group compared to the non-cisplatin group (5,38y *vs* not reached, p=0.005). Other factors associated with death were number of previous treatment lines >1 (HR: 1.53, p=0.02), and FLIPI/IPI of 3 or above (HR: 1.56; p=0.007). In the FL group (n=140), there was no difference in term of PFS, but a statistically significant difference for OS (HR=3.2, p=0.03) in favour of non-cisplatin therapy. Similarly, in the DLBCL (n=238) group, there was no difference for PFS but a statistically significant difference in OS (HR=1.8, p=0,007) in favour of non-cisplatin therapy. However, there was no difference for PFS nor OS for transformed follicular (n=64) and other indolent transformed lymphomas (n=20). No statistical difference in the causes of death was noted (Figure 1).

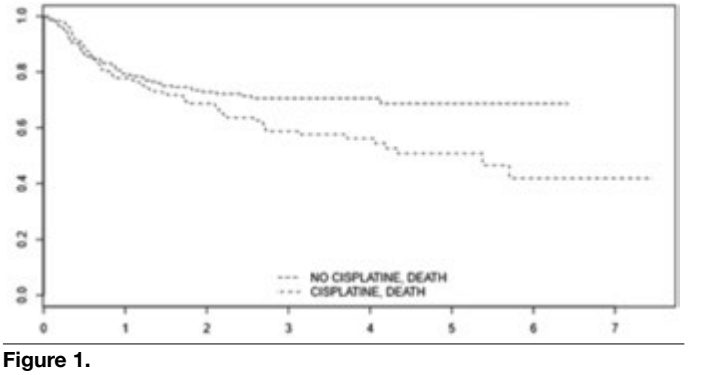

Figure 1.

Summary and Conclusions: This study suggests that when compared to cisplatin, the use of oxaliplatin and carboplatin yields a prolonged OS without differences in CR nor PFS, especially in FL and DLBCL. A corollary is that cisplatin can efficiently be replaced by other platinum salts in the treatment of NHL.

VCAP-AMP-VECP *VERSUS* CHOP AS FIRST-LINE CHEMOTHERAPY FOR AGGRESSIVE ADULT T-CELL LEUKEMIA-LYMPHOMA: A PROPENSITY SCORE ANALYSIS

S. Fuji[1,*], T. Yamaguchi[2], Y. Inoue[3], A. Utsunomiya[4], Y. Moriuchi[5], S. Owatari[6], T. Miyagi[7], Y. Sawayama[8], E. Otsuka[9], S.-I. Yoshida[10], T. Fukuda[11]

[1]Department of Hematolgoy, Osaka International Cancer Institute, Osaka, [2]Division of Biostatistics, Tohoku University Graduate School of Medicine, Sendai, [3]Department of Hematology, Kumamoto University Hospital, Kumamoto, [4]Department of Hematology, Imamura General Hospital, Kagoshima, [5]Department of Hematology, Sasebo City General Hospital, Sasebo, [6]Department of Hematology, National Hospital Organization Kagoshima Medical Center, Kagoshima, [7]Department of Hematology, Heart-Life Hospital, Okinawa, [8]Department of Hematology, Nagasaki University Hospital, [9]Department of Hematology, Oita Prefectural Hospital, Oita, [10]Department of Hematology, National Hospital Organization Nagasaki Medical Center, Nagasaki, [11]Department of Hematopoietic Stem Cell Transplantation, National Cancer Center Hospital, Tokyo, Japan

Background: Adult T-cell leukemia-lymphoma (ATL) is a distinct type of peripheral T-cell lymphoma (PTCL) caused by human T-cell lymphotropic virus type I. Patients with aggressive ATL have poor outcomes with intensive chemotherapy. To improve the clinical outcome in patients with aggressive ATL, dose-intensified multiagent chemotherapy called VCAP-AMP-VECP as first-line therapy was investigated in Japan, and a prospective randomized controlled study comparing biweekly CHOP with VCAP-AMP-VECP regimen demonstrated that the probability of overall survival (OS) at 3 years and CR rate with VCAP-AMP-VECP were higher compared with biweekly CHOP. However, the previous RCT was rather small, and there was no subsequent study to confirm the benefit of VCAP-AMP-VECP over CHOP.
Aims: The objective of the current study was to compare clinical outcomes of patients with aggressive ATL who were treated with front-line VCAP-AMP-VECP with those who were treated with front-line CHOP.
Methods: Using a database of a nationwide survey of patients with aggres-

sive ATL aged 70 years or younger, we conducted a retrospective analysis including patients only who received front-line VCAP-AMP-VECP or front-line CHOP. A propensity score analysis was used to balance patient characteristics.
Results: Overall, 947 patients and 513 patients were treated with VCAP-AMP-VECP and CHOP, respectively. The median follow-up of surviving patients was 1006 days. The probabilities of 2-year OS for patients in the VCAP-AMP-VECP and CHOP groups were 31.2% (95% CI, 28.2–34.3%) and 24.6% (95% CI, 20.7–28.7%), respectively (P <0.001). Using the IPTW method to compare the probability of OS, treatment with VCAP-AMP-VECP was associated with a significantly higher OS rate (HR 0.82; 95% CI 0.71–-0.94, P=0.003). Stratified by risk group according to modified ATL-PI score at diagnosis, the probabilities of 2-year OS in the VCAP-AMP-VECP and CHOP groups were 39.8% (95% CI, 33.0–46.5%) and 45.0% (95% CI, 35.5–54.0%) in the low-risk group (P=0.69), 32.2% (95% CI, 28.2–36.3%) and 21.6% (95% CI, 16.8–26.7%) in the intermediate-risk group (P <0.001), and 17.2% (95% CI, 11.8–23.4%) and 6.2% (95% CI, 2.2–13.4) in the high-risk group (P=0.005). Using the IPTW method, treatment with VCAP-AMP-VECP was associated with a favorable OS in the intermediate- and high-risk groups, but not in the low-risk group (low-risk group, HR 0.95, 95% CI 0.72–1.24, P=0.690; intermediate-risk group, HR 0.71, 95% CI 0.61–0.84, P <0.001; high-risk group, HR 0.67, 95% CI 0.51–0.89, P=0.005).
Summary and Conclusions: In conclusion, our current analysis incorporating propensity score analysis reinforced the recommendation of VCAP-AMP-VECP regimen as first-line therapy in patients aged up to 70 years with aggressive ATL in the intermediate- and high-risk groups.

PF268

POSSIBLE FACTORS ON EFFICACY AND SAFETY OF CAR–T THERAPY IN RELAPSED OR REFRACTORY AGGRESSIVE B-CELL LYMPHOMA

H. Huang[1,*], Y. Jiang[1], Z. Jln[1], C. Li[1], D. Wu[1]

[1]Department of Hematology, The First Affiliated Hospital of Soochow University, Suzhou, China

Background: Recent advances have improved the treatment of B-cell malignancies, but patients who have disease resistant to primary or salvage treatment or who relapse after transplantation have an extremely poor prognosis. Studies of chimeric antigen receptor T-cell (CAR-T) therapy have shown high response rates and long response duration in refractory B-cell lymphomas after the failure of conventional therapy, which suggest that this therapy may be potentially curative.
Aims: To explore the possible factors on efficacy and safety of CAR T-Cell therapy in relapsed or refractory aggressive B-cell lymphomas.
Methods: From March 2017 to January 2018, 20 patients were enrolled into our clinical trialNCT03196830). Different targets of CAR T-cells were infused, including only anti-CD19 (n=8), only anti-CD20 (n=2), combined anti-CD20 and anti-CD19 (n=7), combined anti-CD19 and anti-CD22 (n=3). Patients received conditioning treatment (low-dose cyclophosphamide, 300 mg/m² per day, and fludarabine, 30 mg/m² per day) on days -5, -4, and -3 before the administration of autologous CAR T-cells. The primary endpoint was the proportion of patients with an objective response.
Results: Among the 20 patients who were enrolled, the median age was 56 years (range, 27 to 68). Diffuse large B-cell lymphoma was the underlying disease in 16 patients, Burkitt lymphoma in 1, mantle cell lymphoma in 1, Richter's syndrome in 1, and transformed follicular lymphoma in 1. All of the patients received at least three lines of therapy.Before receive CAR-T therapy, 4/20 patients were in complete remission(CR), 4/20 were in partial remission(PR), and 12/20 were in stable disease(SD) or progressive disease(PD). At the time of the primary analysis (February 15, 2018), 6 of 9 evaluable patients who were in SD or PD had an objective response, with 3 (33%) achieving CR a and 3 (33%) achieving a PR, of which 4 patients had an ongoing response (from 2 to 10 months). 7 of 7 evaluable patients in CR or PR had an ongoing response. With a median follow-up of 4 months, including 16 evaluable patients showed a median progression-free survival of 4 months. The most common adverse events during treatment were pyrexia in 70% patients, hypogammaglobulin in 65% patients, neuropenia in 40% patients, and hypotension in 25% patients. The cytokine release syndrome(CRS) occurred in 14 patients (70%). 57% patients were of low grade, and 43% were of grade 3 or higher (21% of grade 3, 7% of grade 4, and 14% of grade 5). Grade 3 or higher neurologic events occurred in 15% of the patients. The total number of infused CAR-T cells and single or double target of CAR-T cells had no significant correlation with survival, efficacy or grade of cytokine release syndrome. Serum biochemical index analysis confirmed associations of interleukin-2, and -4 with the grade 3 or higher neurologic events, and the level of lactate dehydrogenase(LDH) before therapy with grade 3 or higher CRS.
Summary and Conclusions: Our study demonstrates the efficacy and safety of CAR-T therapy in relapsed or refractory aggressive B-cell lymphoma. The level of LDH before therapy was higher in patients who developed grade 3 or serious CRS, which suggest that we should improve safety by reducing tumor burden before CAR T-cells infusion. Due to the small number of enrolled cases, no significant improvement of efficacy was observed when anti-CD19 CAR T-cells was combined with anti-CD20 or anti-CD22 CAR T-cells. This result needs to be further confirmed by expanding the number of study cases.

PF269

TITLE: LENALIDOMIDE PLUS R-CHOP THERAPY PROVIDES DURABLE LONG-TERM REMISSIONS IN PATIENTS WITH NEWLY DIAGNOSED DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL): COMBINED ANALYSIS FROM TWO PHASE 2 TRIALS

A. Castellino[1,2,*], B.R. LaPlant[2], L. Pederson[2], A. Chiappella[1], G. Gaidano[3], W.R. Macon[4], A. Tucci[5], R.L. King[4], A. Congiu[6], T.E. Witzig[2], U. Vitolo[1], G.S. Nowakowski[2]

[1]Hematology, Citta' della salute e della Scienza, Torino, Italy, [2]Hematology, Mayo Clinic, Rochester, United States, [3]Hematology, Hospital and University of Novara, Novara, Italy, [4]Pathology, Mayo Clinic, Rochester, United States, [5]Hematology, Ospedali Civili, Brescia, [6]Hematology, Ospedale San Martino, Genova, Italy

Background: The combination of lenalidomide (Len) with Rituximab-CHOP (R2CHOP21) has been shown to be safe and effective. These early results [Nowakowski *et al.* JCO 2014, Vitolo *et al.* Lancet Oncol 2014] led to two currently ongoing randomized trials. However, long term efficacy and safety have not been reported.
Aims: The aim of the present analysis is to present the long-term FU of efficacy and safety in DLBCL patients (pts) who received R2CHOP21 in two independent phase 2 studies.
Methods: We included newly diagnosed histologically-confirmed *de-novo* DLBCL pts enrolled in two R2CHOP21 phase 2 trials, conducted by Mayo Clinic (MC) and Fondazione Italiana LinfomiItalian Lymphoma Foundation (FIL). All pts received R-CHOP21 plus Len at 25 mg/day for 10 days/cycle and 15 mg/day for 14 days/cycle in MC and FIL trial respectively. We analyzed the long term FU outcome in terms of progression-free survival (PFS), time to progression (TTP), overall survival (OS) and the cumulative incidence of late toxicities and second tumors.
Results: 108 DLBCL pts (59 MC, 49 FIL) were included. Median age was 69 years (y) (range 22-87), with 48 (44.4%) and 4 (3.7%) pts over 70 y and over 80 y respectively. Main characteristics were: male 65 (60.2%) pts, advanced stage III-IV in 94 (87.0%) pts, B symptoms in 38 (35.2%), International Prognostic Index (IPI) intermediate-low in 42 (38.5%), intermediate-high/high in 60 (61.5%), central nervous system (CNS)-IPI intermediate risk in 79 (73.1%) and high risk in 22 (20.4%). As for Cell of origin (COO), germinal center (GCB) phenotype *vs* non-GCB were 45 (41.7%) *vs* 41 (38%) pts respectively; 22 (20.4%) pts were not evaluable for COO. At a median FU of 5.1 years (y), 5y PFS was 65.4%, 5y TTP 69.9% and 5y OS 77.4% (Figure 1). In total 31 relapses were observed, with only 2 cases of CNS recurrences and only 4 relapses occurring beyond 3y. Outcome results in a subgroup analysis performed stratifying patients according to COO phenotype were: 5y PFS 55.8% *vs* 65.7%, 5y TTP 62.3 *vs* 68.0 and 5y OS 71.7% *vs* 75.3% in germinal center (GCB) phenotype *vs* non-GCB respectively. Only 4 pts experienced grade (gr) 4-5 late toxicities (one toxic death because of a gr 5 sepsis and 3 cases of gr 4 persistent neutropenia). Milder toxicities were infections (N 5, only 1 gr 3), thrombosis (N 1, gr 2) and persistent neuropathy (N 3 (2.8%), all gr 1-2). 3 cases of cardiovascular disease gr 3 were reported. Secondary malignancies were observed in 8 pts (6.4%): 1 (0.9%) acute myeloid leukemia, 2 (1.8%) second lymphoma (T-cell) and 5 (4.5%) other solid tumors.
Summary and Conclusions: Long term FU shows that R2CHOP21 efficacy was maintained over time with high rate of PFS, TTP and OS, considering high risk features of patients included. The addition of len to RCHOP appears to mitigate the negative prognostic impact of non-GCB phenotype. The incidence of second tumors was low and no new worrisome long-term safety signals were seen. Despite a large number of intermediate/high CNS-IPI pts, CNS recurrences were less than expected, suggesting a role of len combination with R-CHOP in decrease risk of CNS involvement. These long -term efficacy and safety data will aid interpretation of early results from randomized clinical trials, expected to be reported in near future.

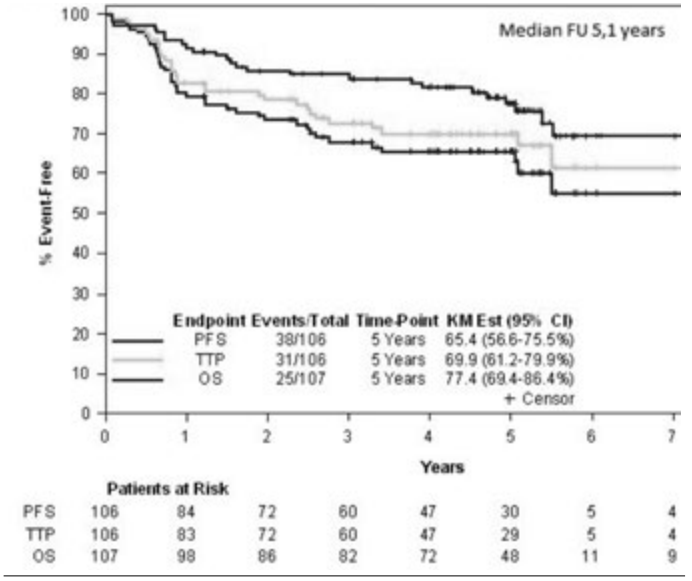

Figure 1. 5y PFS, TTP, OS in whole cohort DLBCL patients treated with R2CHOP.

DIFFUSE LARGE B CELL LYMPHOMA (DLBCL) PRESENTING WITH SYNCRHONOUS CNS AND SYSTEMIC DISEASE AT DIAGNOSIS: RESULTS FROM AN INTERNATIONAL COLLABORATIVE STUDY

J. Wight[1,*], L. Churilov[2], M. Yue[3], C. Keane[3], A. Johnston[45], K. Linton [6], C. Chin[7], S.H. Wai[8,9], C. Coombes[10], C. Cheah[11], G. Gregory[9], D. Talaulikar[10], E. Hawkes[8,12,13]

[1]Haematology, Austin Health, Heidleberg, [2]University of Melbourne, Melbourne, [3]Princess Alexandra Hospital, Brisbane, Australia, [4]The Christie Hospital, Manchester, United Kingdom, [5]Royal Hobart Hospital, Hobart, Australia, [6]Division of Cancer Sciences, University of Manchester Manchester Cancer Research Research Centre, Manchester, United Kingdom, [7]Haematology, Sir Charles Gairdner Hospital, Perth, [8]Austin Health, Heidleberg, [9]Monash Health, Clayton, [10]Canberra Hospital, Canberra, [11]Sir Charles Gairdner Hospital, Perth, [12]Box Hill Hospital, Box Hill, [13]La Trobe University, Melbourne, Australia

Background: DLBCL presenting with both CNS and systemic disease at first diagnosis is rare. Such patients are excluded from clinical trials; thus, the optimal treatment is unknown and outcomes are poorly described.
Aims: To describe treatment outcomes of patients with synchronous CNS and systemic DLBCL at first diagnosis.
Methods: Multicentre retrospective international study (6 Australian & UK sites). Cases were identified from clinical and pharmacy records. Eligible patients had histologically proven DLBCL, with radiological, histological, or CSF evidence of synchronous systemic & CNS disease, treated with combination chemotherapy and rituximab. Patients with relapsed disease were excluded. Primary Endpoint: OS. Secondary endpoints: CR rate, PFS, toxicity. P values of <0.05 were considered significant.
Results: Of 59 patients, 71% were male and the median age was 66yrs (range 17-86). 45 (76%) had NCCN-IPI ≥4. Median number of extranodal sites outside the CNS was 2 (range 0-8). 10% were double-hit by FISH, and 35% of those with data available were double-expressors of MYC and BCL2 protein. CNS disease was leptomeningeal only in 24 (41%); 35 (59%) had parenchymal disease, 8 (14%) had both. 34 (58%) received systemic therapy (predominantly R-CHOP, n=31) plus a CNS-directed treatment (group A). 25 (42%) underwent intensified MTX and/or Ara-C containing therapy: hyper-CVAD n=14, CODOX-M/IVAC n=10, DHAC=1 (group B). CNS-directed therapy in group A included: IV HD-MTX in 19 (56%), HD-MTX+Ara-C in 2 (6%), intrathecal therapy (IT) only in 10 (29%), radiotherapy (RT) only in 2 (6%). Specific CNS therapy was omitted in one patient due to early PD. Additional consolidative therapy included CNS RT in 18 (31%) (whole brain in 8, site-specific in 10), and autologous SCT in CR1 in 8 (13%) using BEAM (n=4) or BCNU+thiotepa (n=4) conditioning. All SCT patients were from group B. 23 (39%) required dose reductions and 23 (39%) required early cessation of therapy. Treatment-related mortality was 14% for the whole group (4 in each group, including 2 during transplant). End of treatment CR rate was 58%; 62% for group A and 57% for group B (p=0.69). 25% were primary refractory; 26% in group A and 20% in group B (p=0.68). Site of relapse was: CNS only in 14, systemic only in 8, both in 6. Incidence rate of CNS progression at 2 years was 40%. 19/20 patients with CNS relapse died with median OS of 7.2 months (mo). Of the CNS relapses, 12 occurred in group A and 8 in group B (p=0.79). The estimated 2yr OS for those without CNS relapse was 74%. Median OS: Whole cohort=11.1 mo, group A=11 mo, group B=11.8 mo (p=0.82). Median PFS: Whole cohort=10.1 mo, Group A=9.6 mo, Group B=10.6 mo B (p=0.65). The OS of transplanted *vs* non-transplanted was similar (p=0.18); 5/8 transplanted patients remain disease free with >1 year of follow-up. There was no survival difference between parenchymal *vs* leptomeningeal disease (p=0.56). The estimated 2yr PFS and OS was 41%, and 52% respectively, with no significant differences between groups (p=0.64, Figure 1).

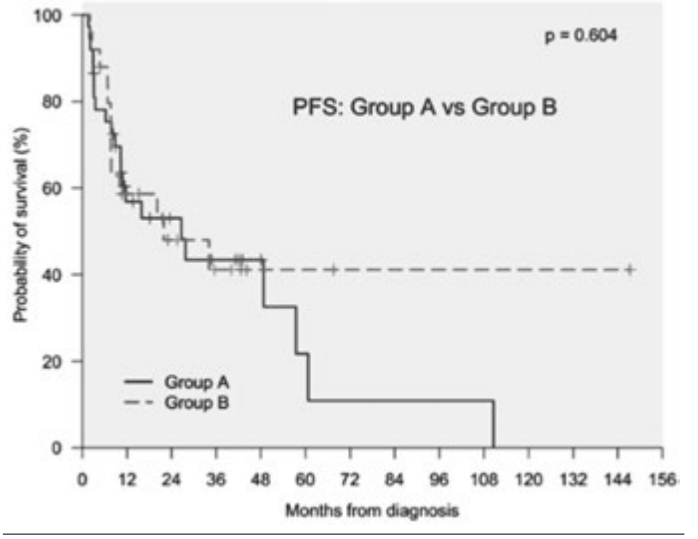

Figure 1.

Summary and Conclusions: Among this large cohort of synchronous+systemic DLBCL, intensified regimens and additional consolidation therapy were not associated with clinical benefit. The CNS is the most common site of treatment failure, which is associated with a dismal prognosis. OS is comparable to PCNSL (Ferreri, 2009), but those who achieve CNS control have 2yr outcomes similar to systemic DLBCL (Cunningham, 2013). Future efforts should focus on preventing CNS relapse. Biomarker tissue analysis is underway.

PF271

FRONT-LINE TREATMENT OF DLBCL WITH 6 *VERSUS* 8 CYCLES OF R-CHOP IS NOT ASSOCIATED WITH INFERIOR SURVIVAL IN ELDERLY PATIENTS: RESULTS FROM A RETROSPECTIVE ANALYSIS OF THE SEER-MEDICARE DATABASE

A. Shang[1,*], J. Black[1], A. Surinach[2], A. Kotb[1]

[1]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [2]Genesis Research, Hoboken, New Jersey, United States

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common histologic subtype of non-Hodgkin lymphoma (NHL). Immunochemotherapy with R-CHOP (rituximab plus cyclophosphamide, doxorubicin, vincristine and prednisone) is standard of care treatment for previously untreated DLBCL pts. Clinical practice guidelines recommend 6 to 8 cycles of R-CHOP for first-line treatment. In the United States (US) and Europe, many physicians prescribe 6 cycles, and elderly pts may benefit from this less intensive therapy. In this retrospective analysis, real-world use of R-CHOP as front-line DLBCL treatment for elderly pts in the US was evaluated using the linked Surveillance, Epidemiology and End Results (SEER)-Medicare database.
Aims: To compare overall survival (OS) with 8 *versus* 6 cycles of R-CHOP in previously untreated elderly pts with DLBCL.
Methods: SEER-Medicare data (2004 to 2011) for pts aged >65 years with a primary diagnosis of DLBCL who received R-CHOP after their initial diagnosis were analysed. Descriptive analyses were performed for R-CHOP and baseline characteristics. Multivariable Cox Regression (MCR) was used to estimate the HR of OS between 8 and 6 cycles of R-CHOP by adjusting for factors that may affect pts' health status (*e.g.* age, National Cancer Insti-

tute [NCI] comorbidity index, Ann Arbor stage, previous G-CSF treatment). To obtain better estimates of the treatment effect on survival, we also adjusted for occurrence of emergency department (ED) visits and inpatient stays prior to treatment and use of durable medical equipment (DME; *e.g.* wheelchairs). Multiple sensitivity analyses were performed.

Results: A total of 3953 pts received R-CHOP. Most pts (70.1%; n=2773) completed <6 cycles; only 955 pts (24.2%; median age 74 years) completed 6 cycles and 112 pts (2.8%; median age 72 years) completed 8 cycles. Of those pts with available baseline data who completed 8 cycles, a slightly higher proportion had stage III/IV disease (57%, 63/111) compared with 6 cycles (49%, 463/948). The median NCI comorbidity score was zero in both groups. Prior to treatment, more pts who completed 8 cycles had an inpatient stay (41%, 45/111) and/or ED visit (38%, 42/111), or required the use of DME (56%, 62/111), than pts who completed 6 cycles (35%, 328/948; 29%, 274/948; and 38%, 364/948, respectively). Previous G-CSF treatment was infrequent in both groups (8 cycles: 1%, 1/111; 6 cycles: 1%, 11/948). Median (interquartile range) duration of follow up was 1531 days (914, 2280) in the 8 cycle group and 1481 days (857, 2267) in the 6 cycle group. The Kaplan-Meier curves of OS for 8 cycles and 6 cycles overlap with each other (Figure 1). In a multivariate analysis, OS rates for pts receiving 8 cycles were comparable to those of pts receiving 6 cycles (HR: 1.12; 95% CI: 0.81–1.57; p=0.38). Sensitivity analyses using the inverse probability treatment weighting method confirmed the primary analyses.

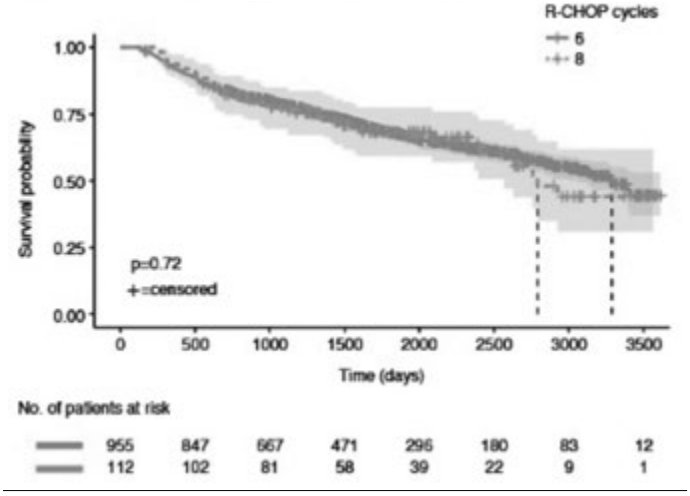

Figure 1. Overall survival probability over time by number of cycles of R-CHOP received.

Summary and Conclusions: Real-world data indicate that front-line DLBCL treatment with 6 *versus* 8 cycles of R-CHOP is not associated with inferior survival in elderly pts. Compared with 8 cycles, more elderly pts completed 6 cycles of R-CHOP as front-line treatment. Pts receiving 8 cycles tended to have more comorbidities than those receiving 6 cycles of R-CHOP. MCR suggests that pts receiving 8 cycles of R-CHOP may not benefit from longer OS *versus* pts receiving 6 cycles only. These findings confirm those recently reported from a similar analysis of real-world data using the Swedish and Danish lymphoma registries.

PF272

PRECLINICAL VALIDATION OF VECABRUTINIB (SNS-062) EFFICIENCY AGAINST BTK-C481S MUTATED LYMPHOMAS

C. Libre[1,*], L. Moro-Sibilot[1], P. Taverna[2], N. Bissay[1], G. Salles[1], L. Genestier[1], P. Sujobert[1]

[1]Centre de recherche en cancérologie de Lyon, Lyon, France, [2]Sunesis Pharmaceuticals, South San Francisco, United States

Background: The B cell receptor signaling pathway, and especially the Bruton Tyrosine Kinase (BTK), has become a therapeutic target in lymphoid malignancies. Ibrutinib, the first in class BTK inhibitor has proven to be highly efficient in chronic lymphocytic leukemia or mantle cell lymphoma, and is thought to be of potential interest in the Activated B cell subtype of diffuse large B cell lymphomas (ABC-DLBCL). However, the emergence of resistant clones has been described, especially through the p.C481S mutation of BTK that disrupts the covalent binding of ibrutinib to BTK. Given the very poor prognosis of ibrutinib resistant patients, the development of drugs able to inhibit BTK even in case of C481S mutation is of utmost importance. Vecabrutinib (formerly known as SNS-062) is a noncovalent, reversible inhibitor of BTK that retains activity against the C481S mutation at least in kinase assays.

Aims: The aim of this work was to assess the activity of vecabrutinib in models of ibrutinib resistant lymphoid malignancies.

Methods: First, we have tested *in vitro* the sensitivity of a panel of 6 lymphoma cell lines to ibrutinib and vecabrutinib (determination of the IC50 for apoptosis induction). Second, we have genetically modified 2 ibrutinib sensitive lymphoma cell lines (TMD8 and REC1) to overexpress either BTK WT and mCherry or BTK C481S and GFP. We performed 7 days co-culture competitive assays in the presence or absence of ibrutinib or vecabrutinib, and assessed by flow cytometry (GFP and mCherry) the clonal composition of the survivng cells.

Results: Lymphoma cell lines addicted to BTK signaling for survival (TMD8, REC1 and HBL1) were sensitive to vecabrutinib (IC 50 50-100nM), whereas cell lines not addicted to BTK signaling (RL, SUDHL4, Raji) were totally resistant to vecabrutinib (Figure 1). These results confirm that vecabrutinib is a highly specific BTK inhibitor. In competitive co-culture assays, we observed as expected that cell lines harboring the BTK C481S mutation were strongly selected under ibrutinib. Interestingly, this was not the case when we treated the cells with vecabrutinib, suggesting that vecabrutinib is able to overcome the resistance due to BTK C481S mutation. The validation of these results in the *in vivo* setting is ongoing and the results will be presented at the EHA congress. We will also present our mechanistic analysis of the modulation of the signaling pathways by vecabrutinib and ibrutinib in the different models of lymphoma.

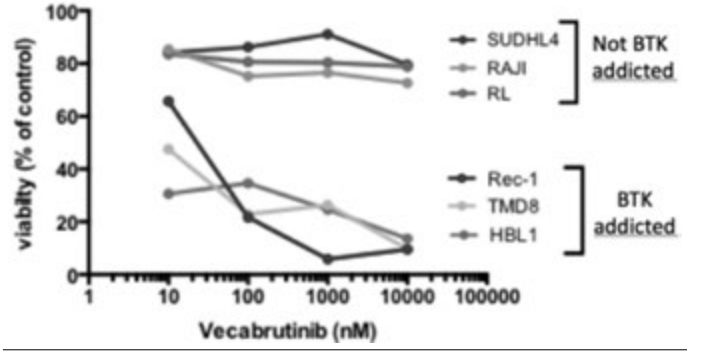

Figure 1.

Summary and Conclusions: These preclinical data suggest that vecabrutinib is a highly specific and potent drug that is able to overcome the resistance due to BTK C481S mutations. Given its very favorable pharmacokinetic and safety profile, a phase 1b/2 dose escalation and cohort expansion clinical trial has been recently launched in patients with previously treated B-lymphoid malignancies (NCT03037645).

PF273

MONITORING OF RHOA G17V MUTATION DURING THE COURSE OF THERAPY IN PATIENTS WITH ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA BY QUANTITATIVE ALLELE-SPECIFIC PCR WITH LNA-MODIFIED PRIMERS

Y. Sidorova[1,*], N. Chernova[1], M. Sinitsyna[1], M. Aleksenko[1], O. Glinshchikova[1], S. Smirnova[1], N. Ryzhikova[1], E. Nikulina[1], E. Zakharko[1], E. Rybkina[1], V. Dvirnyk[1], A. Kovrigina[1], E. Zvonkov[1], A. Sudarikov[1]

[1]National Research Center for Hematology, Moscow, Russian Federation

Background: Angioimmunoblastic T-cell lymphoma (AITL)characterized by a generalized tumor process and frequent extranodal involvement. In addition, approximately 2/3 of patients develop relapses in the first 2-3 years after therapy completion. Recently discovered point somatic RHOA Gly17Val mutation is present in 53-71% of angioimmunoblastic T-cell lymphomas and allows to quantify the tumor cells. We used allele-specific PCR with LNA (locked nucleotide acid) modified primers, which increase the sensitivity of the determination. LNA nucleotide has a greater binding ability in the complementary interaction and its presence at the 3 'end of the primer leads to an increase in the specificity of allele-specific amplification.

Aims: Development of a sensitive method for detection of RHOA Gly17Val mutation for the estimation of minimal residual disease (MRD).

Methods: RHOA Gly17Val mutation was analyzed by quantitative TaqMan allele-specific PCR with LNA-modified primers (qAS-PCR-LNA). Bone marrow (BM) and peripheral blood (PB) samples from 14 patients with AITL who achieved clinical and hematologic remission were studied at the diag-

nosis and during the therapy. Control points: before the start of therapy, after completion of induction chemotherapy, after 1, 2 years of maintenance therapy with small doses of cytotoxic drugs or immunomodulatory therapy, and also in some patients 3-4 years after the onset of the disease.
Results: The standard curve method based on serial dilutions showed that developed qAS-PCR-LNA quantitation method has 0.01% (10^{-4}) sensitivity (Figure 1A). The number of detectable cells with the mutation before and during therapy in blood (Figure 1C) was higher than in BM (Figure 1B). All examined patients achieved clinical remission after induction chemotherapy and they all had complete or partial molecular response. However, 10 of 14 patients had a tumor clone (0.02-2% of the total number of cells) after completion of induction chemotherapy in the blood and/or BM. During the maintenance therapy the number of tumor cells in PB/BM remained above 0.05% in two patients, and in three patients tumor cell growth was up to 0.15-0.3%. In patients No. 4 and No. 8 flow cytometry of blood sample confirmed the presence of tumor cells with a specific immunophenotype in the amount of 2.3% of lymphocytes (0.3% of all events) and 4.8% of lymphocytes (0.4% of all events). An increasing number of cells with a RHOA Gly17Val mutation may be a predictor of disease recurrence. The data obtained may be beneficial for the correction of antitumor therapy.

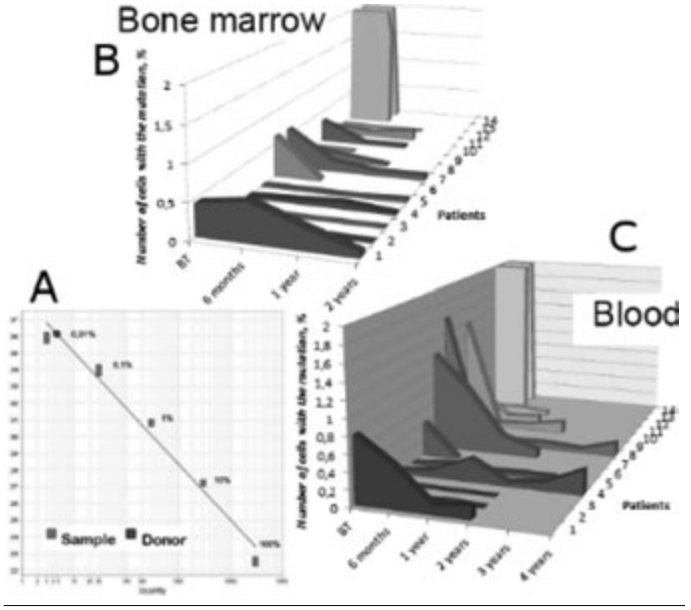

Figure 1.

Summary and Conclusions: The sensitivity of RHOA Gly17Val mutation quantification by LNA-modified primers is sufficient for MRD detection. The persistence of tumor cells with RHOA Gly17Val mutation was shown in most patients with AITL after the induction chemotherapy. This method should be included into the standard protocols for management of patients with AITL to monitor therapy efficacy and remission duration.

PF274

CHARACTERISTICS, TREATMENT PATTERNS AND OUTCOME OF ELDERLY SYSTEMIC T/NK CELL LYMPHOMA IN A RESOURCE-LIMITED COUNTRY: THE RESULT OF THAILAND NATIONWIDE LYMPHOMA REGISTRY

K. Wudhikarn[1,*], U. Bunworasate[1], J. Julamanee[2], A. Lekhakula[2], S. Ekwattanakit[3], A. Khuhapinant[3], S. Chuncharunee[4], P. Niparuck[4], T. Numbenjapon[5], K. Prayongratana[5], N. Kanitsap[6], S. Wongkhantee[7], N. Makruasi[8], P. Wong[9], L. Norasetthada[10], W. Nawarawong[10], C. Sirijerachai[11], K. Chansung[11], T. Suwanban[12], P. Praditsuktavorn[13], T. Intragumtornchai[1]

[1]Medicine, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, [2]Medicine, Prince of Songkla University, Songkhla, [3]Medicine, Siriraj Hospital, Mahidol University, [4]Medicine, Ramathibodi Hospital, Mahidol University, [5]Medicine, Phramongkutklao Hospital and College of Medicine, [6]Medicine, Thammasart University, Bangkok, [7]Medicine, Khonkaen Regional Hospital, Khon Kaen, [8]Medicine, Srinakharinwirot University, Nakhon Nayok, [9]Medicine, Naresuan University, Phitsanulok, [10]Medicine, Chiang Mai University, Chiang Mai, [11]Medicine, Khon Kaen University, Khon Kaen, [12]Medicine, Rajavithi Hospital, [13]Medicine, Chulabhorn Hospital, Bangkok, Thailand

Background: Systemic T/NK cell non-Hodgkin lymphoma (NHL) is an uncommon lymphoma subtypes but relatively more prevalent in Asia. Its natural history and prognosis generally fare worse compare to B cell NHL. However, data on systemic T/NK cell NHL especially in older patients was limitedly described. Proper management of this subgroup is not known and remains an unmet need. Herein, we reported clinical data, treatment delivery pattern and outcome of systemic T/NK cell NHL in the elderly from Thailand nationwide lymphoma registry.
Aims: To better characterize clinical data, treatment pattern, prognostic determinants and outcome of T/NK cell NHL in the eldery from real world setting.
Methods: From the nationwide multicenter registry of 4,371 newly diagnosed lymphoma patients in Thailand between 2007 and 2014, after excluding primary cutaneous T cell lymphoma, there were a total of 464 systemic T/NK cell lymphoma patients. We described clinical characteristics, treatment patterns and outcomes of PTCL in the elderly including exploring the effect of age and other clinical parameters affecting outcome in this group of patients.
Results: Of 464 systemic T/NK cell NHL, 127 (27.4%) were older than 60 years old. The median age was 67 years old (range; 60-91 years old) including 98 patients in 60–74 years and 29 patients in 75 years or older age group. Patients aged older than 75 years old had similar characteristics to 60-74 years old group except higher median score of Charlson's comorbidity index in patients aged older than 75 years. A total of 98 patients (77.2%) received chemotherapy. Of these, 79 patients (62.2%) received intensive multi-agent chemotherapy. The proportion of patients receiving intensive chemotherapy was lower in patients aged older than 75 years old (34.5% *vs* 70.4%, p<0.001). Among patients who received intensive chemotherapy, overall response rate was 58.2% (48% complete remission and 10.2% partial remission). After a median follow up of 17.3 months, 83 patients had died. Two-year progression free survival and overall survival (OS) for the entire cohort were 38.1% and 48.5% respectively. Univariate and multivariable analysis revealed that older age, poor performance status, high comorbidity index and absence of definite multi-agent chemotherapy were associated with inferior survival. Intensive multi-agent chemotherapy was independent prognostic factor for OS after adjusted for age, comorbidity index, performance status and prognostic index for T-cell lymphoma (p=0.04; Figure 1).

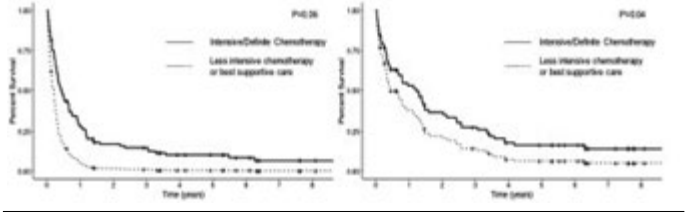

Figure 1.

Summary and Conclusions: Prognosis of T/NK cell lymphoma in elderly was dismal. Age, performance status and comorbidities were independent prognostic factors for survival. However, despite poor prognosis of elderly systemic T/NK cell NHL, chemotherapy could result in objective response and long term survival in selected patients thus emphasizing the importance of comprehensive geriatric evaluations. Incorporating geriatric assessment into management plan of elderly PTCL patients would be warranted.

PF275

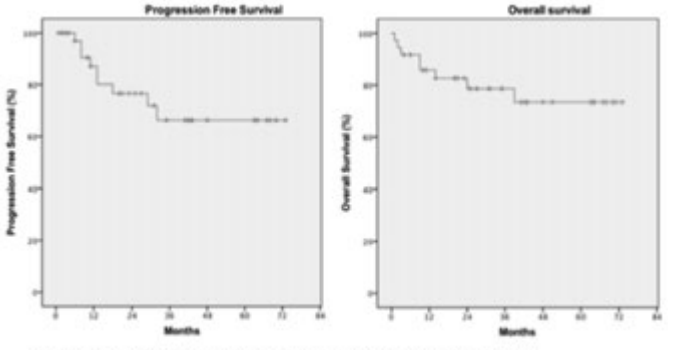
RETROSPECTIVE ANALYSIS OF PATIENTS WITH PRIMARY CENTRAL NERVOUS LYMPHOMAS TREATED WITH METHOTREXATE-BASED REGIMEN FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANT AND TEMOZOLOMIDE MAINTENANCE

M. Ljungqvist[1,2,*], F. Celsing[1], B. Wahlin[1,3], K. E. Smedby[1,2]

[1]Division of Hematology, Department of Medicine, Karolinska University Hospital, [2]Division of Clinical Epidemiology, Department of Medicine, Solna, [3]Division of Haematology, Department of Medicine, Huddinge, Karolinska Institutet, Stockholm, Sweden

Background: Primary central nervous lymphoma (PCNSL) is an uncommon lymphoma subtype with poor overall survival (OS). In clinical trials, long-term remissions have been achieved using high-dose methotrexate (HD-MTX)-based chemotherapy followed by intensive consolidation treatment. However, outcome of this regimen has seldom been evaluated in the population-based setting.
Aims: To retrospectively analyse outcome of patients with PCNSL treated,

in clinicla routine, with HD-MTX and Cytarabin followed by consolidation with high-dose chemotherapy and autologous stem-cell transplant (HDT-ASCT) and maintenance with temozolomide.
Methods: Patients aged 70 years or younger with newly diagnosed PCNSL at Karolinska University Hospital (Sweden) between 2011 and 2017 were eligible for treatment according to Arm B of IELSG32 trial. One cycle consisted of: MTX 3.5 mg/m² on day 1, Cytarabin 2 g/m² twice daily on days 2 and 3 and Rituximab 375mg/m². Patients with at least partial remission (PR) after 4 cycles of induction therapy received consolidation with HDT-ASC followed by maintenance with temozolomide 150mg/m² for five days, repeated every four weeks, for one year. During the study period, 46 patients aged ≤70 were diagnosed. Ten patients were not treated according to Arm B of IELSG32 trial; three patients were above the age of 65 and had an ECOG performance status of 3, two patients were above 65 years and had severe comorbidity, and two patients were below the age of 65 but had poor performance status (ECOG 3-4) and comorbidities. Main study endpoints were feasibility, progression-free survival (PFS) and OS.
Results: Altogether, 36 patients started treatment according to protocol. The median age at diagnosis was 59 years (range 35-70), with 6 (17%) being above 65 years of age. Twenty-three (64%) were men. Of the 36 patients with intention to treat according to IELSG32 trial, 26 patients (72%) received all four induction courses and 22 (61%) underwent HDT-ASCT. After a median follow-up time of 29 months (range 1-71 months), eight (22%) patients had died and nine (25%) had recurrent disease. One patient (3%) died from treatment complications, two (6%) from primary refractory lymphoma and five (14%) from recurrent disease. Median OS and PFS ware not reached during follow-up. The mean overall survival (OS) was 58 months (95% CI 48-67 months) and the mean PFS was 54 months (95% CI 44-64). The 3-year OS and PFS was 81% and 75% respectively (Figure 1).



Progression Free Survival and Overall Survival in 36 patients with Primary CNS-lymphoma starting treatment according to Arm B of IELSG32 trial.

Figure 1.

Summary and Conclusions: Intensive treatment with HD-MTX, Cytarabin and Rituximab followed by HDT-ASCT and maintenance with temozolomide is feasible and effective in clinical routine for fit patients with PCNSL diagnosed at 70 years or younger.

PF276

RITUXIMAB, GEMCITABINE AND OXALIPLATIN (R-GEMOX) IN REFRACTORY/RELAPSED PATIENTS NOT CANDIDATES FOR HIGH-DOSE THERAPY WITH DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL). A SINGLE CENTER STUDY OF 115 PATIENTS

C. Cazelles[1,*], K. Belhadj[2], N. Mounier[3], C. Copie-Bergman[4], A. Nicolae[4], F. Pirenne[5], A. Rahmouni[6], E. Itti[6], M. Carvalho[7], J. Dupuis[2], F. Lebras[2], F. Lemonnier[2], C. Salvado[2], E. Scherman[2], L. Roulin[2], T. El Gnaoui[2], P. Gaulard[4], C. Haioun[2]

[1]Hematology, Necker Hospital Paris, [2]Hematology, Henri Mondor Hospital, Paris, [3]Hematology, CHU Nice, Nice, [4]Pathology, [5]EFS, [6]Radiology, [7]Pharmacy, Henri Mondor Hospital, PARIS, France

Background: R-GemOx is one of the most common regimen used in France in relapsed/refractory patients with DLBCL non candidate for high dose therapy (HDT).
Aims: We here report the results of a single center retrospective study conducted, at Henri Mondor University Hospital, in order to evaluate the efficacy and good safety profile of this regimen in consecutive patients with DLBCL (*de novo* or transformed).
Methods: Between May 2002 and May 2017, 115 patients (pts) with refractory or relapsed DLBCL were treated. Forty-four pts received R-GemOx in first, 38 in second or subsequent relapses and 33 pts were refractory to the previous therapy. Treatment was given every 2 weeks as previously described (Mounier N. *et al.*[1]). Pts were planned to receive 8 cycles if at least a partial response (PR) was observed after 4 cycles. Median age was 71 years (range, 20-89). All pts have been previously treated with anthracyclines and rituximab and 17 (14.7%) were previously treated with consolidative HDT, 63 (53.9%) had an anteriority of indolent lymphoma. Age-adjusted international prognostic index at enrolment was >2 in 71 pts (62.7%). Median delay from last treatment to R-GemOx was 8 months (range 0.3-82). Median duration between initial diagnosis and R-GemOx was 12.8 months (range 0-185).
Results: 632 cycles were given. Median received dose intensities of gemcitabine and oxaliplatin were 68.9% and 67.8% of the theoretical dose, respectively. After 4 cycles, according to IWC (Cheson 1999 or 2007), the overall response rate (ORR) defined as the complete response (CR) plus PR was 60% and the CR rate was 28.6%. At the end of treatment, the ORR and CR rates were 29.6 and 26.9%, respectively. The median duration of response was 13 months (range 0-184 months). The CR rate at the end of treatment was significantly better for patients with a previous history of indolent lymphoma (32,3% *vs* 24,5%, p=0.0270). With a median follow-up of 17 months, progression-free survival and overall survival at 2 years were 36% (CI 95%=26.5-45.5%) and 17% (CI 95%=9.8-24%), respectively. Grade 3-4 toxicities occured in 35% of pts with 52 hospitalizations (8.2% of 632 cycles), including 16 hospitalizations for febrile neutropenia. The most common toxicities during treatment were hematological and were manageable. Thirty-four percent of pts required at least one red blood cell transfusion and 42% at least one platelet transfusion. Grade 1-2 peripheral neuropathy attributed to oxaliplatin was observed in 31% of pts, one patient had a grade 3 and dose reductions were required for 8% of pts. Two pts died during treatment from infection.
Summary and Conclusions: Given the patient characteristics in this real life study, results of R-GemOx show an ORR, a duration of response and a safety profile in line with published data. Improving outcome of pts with relapsed or refractory patients with DLBCL represents an unmet medical need. In the current context of development of more targeted therapies, such results could be improved by addition of new molecules, as it is proposed in the ongoing NIVEAU trial (NCT03366272).

THE HIGH EXPRESSION OF CD38 IS ASSOCIATED WITH POOR PROGNOSIS IN *DE NOVO* DIFFUSE LARGE B-CELL LYMPHOMA

K. Sueoka[1,*], T. Yabushita[2], H. Maruoka[1], Y. Shimomura[2], Y. Ono[2], N. Hiramoto[2], S. Yoshioka[2], N. Yonetani[2], A. Matsushita[2], H. Hashimoto[2], T. Ishikawa[2]

[1]Clinical Laboratory, [2]Hematology, Kobe City Medical Center General Hospital, Kobe, Japan

Background: Diffuse large B-cell lymphoma (DLBCL) is a heterogenous group of non-Hodgkin lymphomas which accounts for 30-40%. After the advent of rituximab, the survival of patients with DLBCL has apparently improved, but approximately one-third still have refractory or relapsed clinical course after standard R-CHOP. The progress of molecular technologies and targeted drugs has nearly shifted to subtype-specific treatment strategies for DLBCL. The surface antigen is one of the most important target in development of novel drugs for DLBCL. CD38 is one of the drugable surface antigens expressed on the surface of lymphoma cells with variable frequency in patients with DLBCL. On the other hand, the prognostic significance of CD38 for DLBCL remains elucidated in the immunochemotherapy era.
Aims: The purpose of this study was to estimate the prognostic impact of the high expression of CD38 in patients with DLBCL.
Methods: We retrospectively identified 109 consecutive patients diagnosed with *de novo* DLBCL at our institution and eligible for R-CHOP from January 2005 to June 2015. We excluded 28 patients with no available data of flow cytometry. The expression of CD38 on gated lymphoma cells (CD45brightCD19+FSC^{HIGH}) was evaluated using 6-color flow cytometry. The mean fluorescence intensity (MFI) for CD38 was calculated as the ratio of the fluorescence intensity of the test sample to that of the isotypic control. By the survival classification and regression tree (CART) analysis, we stratified *de novo* DLBCL patients into two groups: CD38^{HIGH} and CD38^{LOW}.The primary endpoint was 3-year overall survival (3-yr OS). The secondary end-

point was 3-year progression-free survival (3-yr PFS). OS and PFS were estimated using the log-rank test. Multivariate analysis using Cox proportional hazard ratio was performed for 3-yr OS. This study was approved by the institutional review board of the Ethics Committee and complied with the Declaration of Helsinki.

Results: Out of the 81 patients enrolled (median age: 69 years old), 46 patients (56.7%) had an advanced stage disease and 40 (49.3%) had a high-intermediate or high International Prognostic Index (IPI) score. The median follow-up was 37.8 months (2.0 – 58.8 months). The median MFI of CD38 were 5.41 (range: 0.97-78.2). The survival CART analysis revealed that the cutoff value for discrimination in 3-year OS was 6.307.We defined patients with MFI of CD38 over 6.307 as $CD38^{HIGH}$ group, and patients with MFI of CD38 less than this cutoff as $CD38^{LOW}$group. There was no statistical significance between $CD38^{HIGH}$ group (n=36) and $CD38^{LOW}$ group (n=45) in gender, age, laboratory data, number of extranodal lesions, bone involvement, stage or the presence of bulky lesions. Three-year OS and PFS were significantly better in the $CD38^{LOW}$group than in $CD38^{HIGH}$ group (Figure 1) (OS: 91.7% *vs* 66.3%, p=0.002; PFS: 70.3% *vs* 48.7%, p =0.014). In multivariate analysis adjusted by standard IPI risk, the high expression of CD38 was an independent prognostic factor for 3-yr OS (hazard ratio: 3.51; 95% CI: 1.06-11.62; p=0.04).

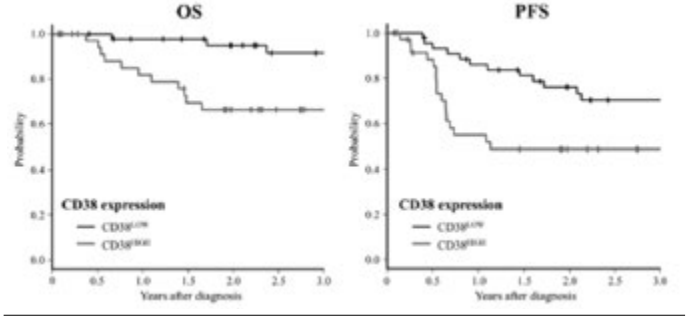

Figure 1.

Summary and Conclusions: In the present study, we demonstrated that the high expression of CD38 predicts poor clinical outcomes in newly diagnosed *de novo* DLBCL patients.

PF278

CLINICOPATHOLOGIC ANALYSIS OF PROGRAMMED CELL DEATH 1 AND ITS LIGANDS PD-L1/PD-L2 EXPRESSIONS IN PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA

C.-L. Cheng[1,*], S.-C. Yu[2,3], C.-W. Lin[3], H.-F. Tien[1]

[1]Internal Medicine, [2]National Taiwan University Hospital, Taipei, Taiwan, Republic of China, [3]Pathology, National Taiwan University Hospital, Taipei, Taiwan, Republic of China

Background: Primary central nervous system lymphoma (PCNSL) is a rare non-Hodgkin lymphoma confined to the CNS. PCNSL frequently exhibited copy number alterations and/or translocations involving 9p24.1, the locus containing the genes encoding programmed cell death-ligands 1 and 2 (PD-L1 and PD-L2). Besides, recent studies showed the effectiveness of programmed cell death-1 (PD-1) blockade therapy in relapsed/refractory PCNSL. The PD-1/PD-L1 and PD-L2 axis probably plays an important role in the tumoral biology of PCNSL. Up to now, little is known about the clinicopathologic features and prognostic implications of tumoral expressions of PD-1 and its ligands PD-L1/PD-L2 in patients with PCNSL.

Aims: To investigate the clinicopathologic characteristics of tumoral expressions of PD-1 and its ligands PD-L1/PD-L2, as well as their prognostic implications in immunocompetent patients with PCNSL.

Methods: We conducted a retrospective study in a tertiary referral hospital in Taiwan. From January 1996 to December 2016, patients with newly diagnosed CD20+ large B-cell PCNSL and had received high-dose methotrexate-based chemotherapy as the initial treatment were reviewed. Those without adequate samples for study or with HIV infection were excluded. We performed immunohistochemical analyses of tumoral PD-L1 and PD-L2 expression using a double-staining technique (PD-L1/PAX5 and PD-L2/PAX5, respectively). Except for PD-L1(+) or PD-L2(+) PCNSL, we defined an entity for microenvironmental PD-L1(+) (mPD-L1(+)) or mPD-L2(+) PCNSL which means PD-L1(-) or PD-L2(-) PCNSL in which PD-L1(+) or PD-L2(+) non-malignant cells are abundant in the tumor microenvironment. The number of PD-1(+) tumor-infiltrating lymphocytes (TILs) was also accessed. The cohort was followed up until the end of December 2017.

Results: Sixty-five patients were analyzed in our cohort, with a median age of 62.1 years and an equal sex ratio. The median overall survival and progression-free survival was 31.1 months and 12.7 months after a median follow-up time of 45 months. The prevalence rates of PD-L1(+) and mPD-L1(+) PCNSL were 15.4% and 27.7%, respectively. Interestingly, almost all of cases were PD-L2(+) PCNSL (61/65, 93.8%). Patients with PD-L1(+) PCNSL had a trend of poor ECOG performance status (P=0.303) compared to patients with mPD-L1(+) and PD-L1(-) PCNSL. Nevertheless, no significant difference was found in other clinical background comparisons. The tumoral expression of PD-L2 did not impact the clinical features. The number of PD-1(+) TILs was significantly higher in patients with age >60 years and in patients with CD79B exon 5 mutation. The quantity of PD-1 (+) TILs did not correlate with the level of PD-L1 or PD-L2 expression, respectively. Regarding to outcome, there were no significant differences in overall survival or progression-free survival according to the expression of PD-L1 or PD-L2, whether in tumor cells or in non-malignant cells, as well as the quantity of PD-1(+) TILs.

Summary and Conclusions: This is the first report to demonstrate the exact percentage of PD-L1(+) and PD-L2(+) tumor cells in PCNSL by PD-L1/PAX5 and PD-L2/PAX5 double immunostainings. The percentage of PD-L1(+) PCNSL is below the ratio we expected. In contrast, almost all patients were PD-L2(+) PCNSL. The tumoral expression of PD-1, PD-L1 or PD-L2 did not have prognostic implication in our cohort. Nevertheless, our results suggest that PD-L2 other than PD-L1 may be a more relevant biomarker and a potential therapeutic target in PCNSL due to its extensive expression in tumor cells.

Background: Prognostic factors (PFs) have not been extensively studied and prognostic models specifically applicable to PMLBCL have not been developed, mainly because PMLBCL is a rare entity. The International Prognostic Index (IPI) is applied based on the projection of DLBCL data, but its performance is questionable. R-CHOP provides satisfactory results in PMLBCL, minimizing failure rates. Only 2 moderately-sized studies have appeared regarding prognostic factors in PMLBCL after R-CHOP (96 and 123 patients from British Columbia and Japan). Given that more intensive

chemotherapy (R-da-EPOCH) might be better than R-CHOP, the applicability of various PFs, including the laboratory ones, needs to be urgently evaluated in the rituximab era in order to define subgroups of patients at high- or very low-risk for treatment failure and death

Aims: The identification of PFs for the outcome of patients with PMLBCL treated with RCHOP±RT.

Methods: 262 patients with PMLBCL were treated with RCHOP±RT (usually 6-8 cycles) in a multicenter setting in Greece and Cyprus (1 Center). The following potential prognostic factors were evaluated: Age (median 32; range 16-82; >60 years only 4%), gender (female 66%), B-symptoms (29%), stage III/IV (11%), infradiaphragmatic disease (6%), extranodal involvement (E or IV, 38%), pleuritis (32%), pericarditis (28%), any serositis (44%), bulky disease (≥10 cm; 60%), performance status (PS) ≥2 (15%), LDH levels (83%), anemia (39%), leukocytosis ≥10x10^9/L (25%), ESR ≥50 mm/h (40%), albumin <4 g/dL (45%), age-adjusted IPI (aaIPI; ≥2 in 20%).

Results: The median follow-up of currently alive patients was ~5 years (59 months, range 2-198). Among 61 failures, 58 occurred within 2 years (all within 4 years) from diagnosis. The 5-year freedom from progression (FFP) was 75%. With 30 deaths recorded (including 2 unrelated deaths), the 5-year overall survival (OS) was 87%. The aaIPI identified a very small minority of patients (aaIPI=3; 3% of total) with a 5-year FFP of 38% *vs* 74, 77% and 87%% for those with aaIPI 2,1 and 0 (p=0.02), being therefore of questionable value. On univariate analysis, any extranodal involvement (E/IV), elevated LDH, any serositis, bulky disease, infradiaphragmatic disease, leukocytosis and albumin <4 g/dL were significantly associated with inferior FFP. In multivariate analysis of FFP, any extranodal involvement and serositis were independent PFs (hazard ratios 2.2 and 1.9; p=0.01 and p=0.04 respectively). None, 1 or 2 of these factors were present in 41%, 36% and 24% of the patients with 5-year FFP of 90%, 69% and 60% (p=0.0001). OS (disease specific) at 5 years was 98%, 84% and 75% respectively (p=0.0005).

Summary and Conclusions: In the largest patient series reported so far, RCHOP±RT provided long-term disease control in 75% of patients with PMLBCL with an excellent OS of 87%. The aaIPI was moderately predictive of the outcome. The combination of any extranodal involvement (E/IV) and serositis defined a subgroup, comprising 1/4 of the patients, with ~40% risk of failure and 25% risk of death, who can be suitable for treatment intensification or incorporation novel agents in the 1st line. More importantly, the absence of both factors defined a subgroup comprising >40% of patients with only 10% failure rate and minimal disease-specific mortality (2%), who might not benefit from any treatment intensification, such as R-da-EPOCH.

PF280

SOLUBLE INTERLEUKIN-2 RECEPTOR AS A SURROGATE BIOMARKER OF METABOLIC TUMOR VOLUME MEASURED BY 18F-FDG PET/CT IN DIFFUSE LARGE B-CELL LYMPHOMA

H. Senjo[1,*], M. Kanaya[1], K. Izumiyama[1], K. Hirata[2], A. Mori[1], M. Saito[1], T. Irie[1], M. Tanaka[1], H. Iijima[3], E. Tsukamoto[4], D. Hashimoto[5], T. Teshima[5], M. Morioka[1]

[1]Hematology Department, Aiiku Hospital, [2]Nuclear Medicine Deparment, [3]Clinical Research and Medical Innovation Center, Hokkaido University, [4]Radiology Department, Central CI Clinic, [5]Hematology Department, Hokkaido University, Sapporo, Japan

Background: Diffuse large B cell lymphoma (DLBCL) is a heterogeneous disease and more than 30% of the patients treated with R-CHOP would not respond or relapse. The significant value of serum sIL-2R as a prognostic indicator of DLBCL had been actively reported (Goto *et al*., Annals of Hematology 2012; 91: 705). However, it remains to be clarified whether the serum level of sIL-2R directly correlates with tumor burden or is affected by activities of bystander immune cells in DLBCL patients.

Aims: In this work, we aimed to evaluate the correlation between serum level of sIL-2R at diagnosis and total metabolic tumor volume (TMTV) based on PET-CT scan images at initial staging in DLBCL patients.

Methods: We conducted a retrospective study of 64 patients with newly diagnosed DLBCL treated between 2008 and 2014 in our institute. All patients were measured baseline serum levels of sIL-2R and they underwent PET-CT scan before introduction of chemotherapy. SUV Computer-aided analysis of PET-CT images for TMTV calculations was performed using Metavol® (Hirata *et al*., PLoS ONE 2014; 9: e105682). TMTV was defined as the volume of lymphoma visualized on PET-CT scans with Standardized uptake value (SUV) greater than or equal to an absolute threshold of 4.0 as previously described (Kurtz *et al*., Blood 2015; 125: 3679). The correlation between sIL-2R and TMTV is assessed by using Pearson's product-moment correlation coefficient. Written informed consent was obtained from all patients.

Results: The median age was 73 years-old and 81% of the patients had advanced stage. With a median follow-up of 2.7 years in survivors, the estimated overall survival (OS) rate and event-free survival (EFS) rate at 5 years were 53.1% and 45.4%, respectively. Median TMTV and sIL-2R at diagnosis were 236 cm^3, and 1735 U/ml, respectively. Pearson's correlation tests demonstrated that serum levels of sIL-2R were significantly correlated with TMTV (r=0.490, P<0.001) (Figure 1A). We found TMTV ≥150 cm^3 and sIL-2R ≥1300 U/ml are associated with worse 5-year OS and 2-year EFS. In a multivariate analysis that included sIL-2R and all factors in NCCN-IPI, it was evident that age and sIL-2R were independently associated with a worse prognosis in terms of 5-year OS (age; HR, 4.44; 95% CI, 1.05 to 18.7; log-rank, P=0.0424, sIL-2R; HR, 4.45; 95% CI, 1.04 to 19.1; log-rank, P=0.0444). Another multivariate analysis that included TMTV and all factors for NCCN-IPI demonstrated that TMTV was an only independent prognostic factor for 5-year OS (HR,3.87; 95% CI, 1.08 to 13.8; log-rank, P=0.0373). Subgroup analyses included the 49 patients with NCCN-IPI High-int to High demonstrated that TMTV <150 cm^3 could find the patients with favorable OS and EFS from this poor prognostic group [OS; 75.0% *vs* 27.7%, P=0.0355 (Figure 1B), EFS; 66.7% *vs* 29.7%, P=0.0493]. Similar results were obtained using sIL-2R; sIL-2R <1300 U/mL could find the patients with better prognosis in this group [OS; 75.0% *vs* 25.9%, P=0.0182 (Figure 1C), EFS; 58.3% *vs* 29.7%, P=0.0499].

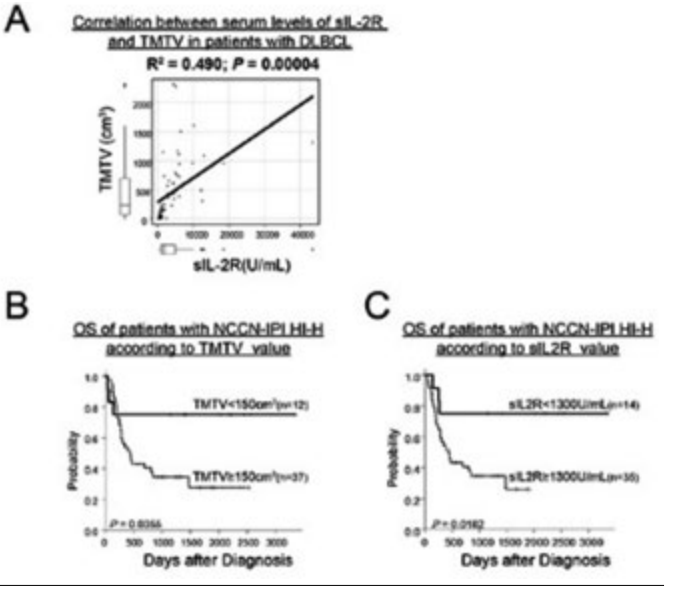

Figure 1.

Summary and Conclusions: We found that there was positive correlation between serum level of sIL-2R and TMTV in DLBCL patients. Our study demonstrated that serum sIL-2R, which measured easily in the clinical practice, can be used as a surrogate biomarker to assess tumor burden of DLBCL patients. Furthermore, we found that both sIL-2R and TMTV could predict treatment outcomes, independently of NCCN-IPI.

PF281

TAK-659 PLUS BENDAMUSTINE (+/-RITUXIMAB), GEMCITABINE, LENALIDOMIDE, OR IBRUTINIB IN PATIENTS (PTS) WITH ADVANCED NON-HODGKIN LYMPHOMA (NHL)

S. Assouline[1,*], M.-M. Keating[2], P.F. Caimi[3], A. Mattour[4], J. Zhu[5], S. Wang[5], Y. Shou[5], Y. Rong[5], J. Redman[5], C. Diefenbach[6]

[1]Jewish General Hospital, Montreal, Quebec, [2]Queen Elizabeth II Health Sciences Center, Halifax, Canada, [3]University Hospitals of Cleveland, Cleveland, OH, [4]Henry Ford Cancer Institute, Detroit, MI, [5]Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [6]New York University Cancer Institute, New York, NY, United States

Background: TAK-659 is an investigational, reversible, potent dual inhibitor of SYK and FLT-3. In preclinical studies using diffuse large B-cell lymphoma (DLBCL) models, TAK-659 in combination with bendamustine (BEND) or lenalidomide (LEN) demonstrated synergistic antitumor activity, and TAK-659 with gemcitabine (GEM) or ibrutinib (IBRU) demonstrated additive antitumor activity.

Aims: The primary objective of this phase 1b study (NCT02954406) was

to determine the maximum tolerated dose (MTD) of TAK-659 when combined with BEND (+/-rituximab [RITU]), GEM, LEN, or IBRU. Secondary objectives included pharmacokinetics (PK) of TAK-659 and preliminary efficacy.
Methods: This multicenter open-label, dose escalation (3+3) study enrolled adults with NHL who were refractory or relapsed after ≥1 prior line of therapy and for whom no effective standard therapy was available. Informed consent was received. For all treatment groups, pts received oral TAK-659 QD at a starting dose of 60 mg plus one of the following: intravenous (IV) BEND 90 mg/m^2 days 1 and 2 +/- IV RITU 375 mg/m^2 day 1 of a 21-day cycle; IV GEM 1000 mg/m^2 days 1 and 8 of a 21-day cycle; oral LEN 25 mg QD days 1–21 of a 28-day cycle; or oral IBRU 560 mg QD of a 28-day cycle. Treatment was given until progressive disease (PD) or unacceptable toxicity. PK samples were collected pre- and post-dose on days 1, 8 and 15 of cycle 1. Response was by investigator assessment per the International Working Group revised criteria for malignant lymphoma.
Results: As of 17-Nov-2017, 19 pts with advanced NHL (DLBCL n=14; mantle cell lymphoma [MCL] n=2; composite lymphoma [CL] n=2; and follicular lymphoma [FL] n=1) were enrolled to receive TAK-659+BEND (+/-RITU [n=6 each]), TAK-659+GEM (n=3), TAK-659+LEN (n=3), or TAK-659+IBRU (n=1). Median age was 64 years (range 44–92), 13 pts (68%) were male, 8 pts (42%) had ≥4 prior therapies, and 13 pts (68%) had an ECOG PS of 1. Across all cohorts, pts received a median of 2 treatment cycles (range 1–4); 17 pts discontinued (13 due to PD). Two pts who received TAK-659 60 mg+LEN had DLTs: one pt with grade 3 skin rash and one pt with grade 4 neutropenia for >7 days. The TAK-659 dose was escalated from 60 mg to 80 mg in three pts for each dose of the TAK-659+BEND and TAK-659+BEND+RITU treatment groups; dose escalation for the remaining cohorts is ongoing. Overall, 18 pts (95%) experienced any-grade adverse events (AEs), 8 pts (42%) had AEs related to TAK-659 and 6 pts (32%) had AEs related to the combination drug(s). Thirteen pts (68%) reported grade ≥3 AEs, 8 pts (42%) and 6 pts (32%) had AEs related to TAK-659 and combinations drug(s), respectively. Serious AEs were reported in 10 pts (53%). The most frequent any-grade and grade ≥3 AEs overall and by treatment groups are shown in the Table 1. There was one on-study death due to a cardiac event (TAK-659+IBRU) that was considered unrelated to treatment by the investigator. Of the 17 response-evaluable pts, 3 pts (18%) had complete remissions (CRs) (TAK-659 60 mg+BEND in DLBCL, TAK-659 60 mg+BEND+RITU in FL, TAK-659 60 mg+IBRU in MCL) and 2 pts had partial remissions (PRs) (TAK-659 80 mg+BEND in FL and TAK-659 80 mg+BEND+RITU in CL), giving an overall response rate (CR+PR) of 29%. Following co-administration of TAK-659 60 mg+BEND (+/-RITU), preliminary TAK-659 PK profiles were generally comparable with those from single-agent TAK-659 in lymphoma or solid tumor pts.

Table 1. Safety.

	TAK-659 plus:					All pts

BEND, bendamustine; GEM, gemcitabine; IBRU, ibrutinib; LEN, lenalidomide; pts, patients; RITU, rituximab; AE, adverse event

Summary and Conclusions: The MTDs were not reached and dose escalation is ongoing for each treatment group. Updated safety and efficacy data will be presented.

PF282

82RB PET FOR EARLY DETECTION OF DOXORUBICIN-INDUCED CARDIOTOXICITY

A.H. Laursen[1,*], M. Bayer Elming[2], R. Sejersten Ripa[3], P. Hasbak[3], A. Kjær[3], J. J. Thune[4], M. Hutchings[1]

[1]Department of Haematology, [2]Department of Cardiology, [3]Department of Clinical Physiology, Nuclear Medicine & PET, Rigshospitalet, [4]Department of Cardiology, Bispebjerg and Frederiksberg Hospitalt, Copenhagen, Denmark

Background: Doxorubicin is the most frequently used anthracycline and a cornerstone in lymphoma treatment. Doxorubicin treatment is limited by dose-dependent cardiotoxicity that is often recognized too late to avoid high mortality heart failure (HF). Several different pathophysiological mechanisms have been proposed including injury to non-cardiomyocyte cardiac cells, *e.g.* the endothelial cells of the coronary microcirculation. Myocardial perfusion imaging (MPI) with 82 Rubidium positron emission tomography (^{82}Rb PET) represents a novel imaging modality for assessment of coronary microvascular function. Acute doxorubicin-induced microvascular injury represents a potential early marker of cardiotoxicity.
Aims: To investigate the value of ^{82}Rb PET myocardial perfusion imaging for early detection of subclinical doxorubicin-induced cardiotoxicity.
Methods: We prospectively included 70 doxorubicin-naive lymphoma patients aged 19 to 86 years with normal cardiac function. All subjects provided written informed consent. ^{82}Rb PET MPI was performed prior to chemotherapy (baseline) and shortly thereafter (acute). The median time from chemotherapy to imaging was 3 days. 60 patients completed both baseline and acute imaging. Absolute myocardial perfusion (ml/g/min) was measured during rest and adenosine stress testing. The coronary flow reserve (CFR) was calculated as the ratio between maximal coronary blood flow and resting flow. Perfusion was also graded in a semiquantitative manner using a 17 segment model of the left ventricle and a 5-point scale ranging from normal (=0) to absent perfusion (=4) with intermediate scores representing mild (=1), moderate (=2) and severe (=3) perfusion defects. The summed rest score (SRS) and summed stress score (SSS) are the cumulative scores of all 17 segments during rest and stress, respectively. The SRS represents fixed perfusion defects while the SSS incorporates both myocardial scarring and stress-induced ischemia. The summed difference score (SDS=SSS-SRS) represents the ischemic burden. Left ventricular ejection fraction (LVEF) was also measured.
Results: CFR was significantly lower after the initial doxorubicin exposure (2.69 *vs* 2.51 ml/g/min, p=0.026, Figure 1). We also registered a non-significant decline in stress flow (3.18 ml/g/min *vs* 3.02 ml/g/min, p=0.084). Resting myocardial perfusion did not change. All results are shown in Table 1.

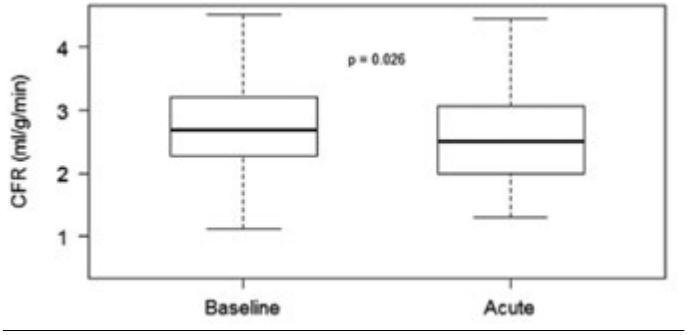

Figure 1. Coronary flow reserve before and after doxorubicin exposure.

Table 1.

	^{82}Rb PET results		
Variable, unit	Baseline	Acute	P-value
CFR, ml/g/min	2.69 (2.29-3.22)	2.51 (1.99-3.05)	0.026
Rest flow, ml/g/min	1.21 (0.96-1.38)	1.23 (0.99-1.48)	0.16
Stress flow, ml/g/min	3.18 (2.80-3.52)	3.02 (2.57-3.43)	0.084
SRS	0 (0-7)	0 (0-6)	0.38
SSS	1 (0-10)	2 (0-12)	0.80
SDS	1 (0-9)	1 (0-9)	0.81
LVEF rest, %	67 (63-71)	68 (63-71)	0.23
LVEF stress, %	74 (69-77)	75 (69-78)	0.32

Summary and Conclusions: - Using ^{82}Rb PET, we found a significant decline in CFR after initial doxorubicin exposure. - Decreases in CFR may represent injury to the myocardial microcirculation, a potential marker of doxorubicin-induced cardiotoxicity. - Future studies will elucidate whether acute decreases in CFR translate into an increased risk of later onset of myocardial fibrosis and HF

PF283

IMPACT OF OMISSION/REDUCTION OF VINCRISTINE FROM R-CHOP THERAPY IN TREATMENT OF GCB TYPE DLBCL

S. Marshall[1,*], N. Nishimura[2], A. Nishihara[2], N. Inoue[2], H. Yamauchi[2], Y. Kusano[2], N. Tsuyama[3], K. Takeuchi[3], Y. Mashima[2], M. Yokoyama[2], Y. Terui[2]

[1]Medical Oncology, [2]hematology, [3]Division of Pathology, The Cancer Institute Hospital of JFCR, Tokyo, Japan

Background: R-CHOP regimen (rituximab, cyclophosphamide, doxorubicin, vincristine, predonisolone) is the standard therapy for the patients with diffuse large B cell lymphoma (DLBCL). However, vincristine is sometimes omitted or reduced due to side effects.
Aims: The purpose of this study was to investigate whether omission/reduction of vincristine from the R-CHOP regimen reduced the efficacy of R-CHOP on DLBCL. We also aimed to illustrate the difference of the efficacy regarding GCB type (germinal center B-cell-like type) and non-GCB type.
Methods: We retrospectively reviewed patients with newly diagnosed DLBCL who received R-CHOP like chemotherapy in our institute from January 2005 to February 2018. We compared the overall survival (OS) and the progression free survival (PFS) with and without the omission/reduction of vincristine from the R-CHOP regimen. Clinical outcomes of R-CHOP with and without omission/reduction of vincristine regarding to GCB type and non GCB type were also evaluated.
Results: A total of 663 cases were reviewed. R-CHOP regimen was administered in all except 5 cases in which the R-CEOP regimen was used instead. The Median age was 66 (range 17-90). 25% had stage or , and 8% had PS 2-4. 25% had more than 2 extranodal sites involvement. Patients with IPI score of 0, 1, 2, 3, 4, and 5 were 15%, 30%, 23%, 18%, 11%, and 4%, respectively. 51% had GCB type, while 45% had non GCB type, but 4% of the patients' tumor type was unknown. Among the patients who were treated with R-CHOP like regimen, 56 patients (8%) omitted or reduced vincristine. The reason for omission/reduction was peripheral neuropathy (19 patients), ileus (18), constipation (9), SIADH (5), post operation (3), and others (4). Of the patients with vincristine omission/reduction, 32 patients had relative dose intensity (RDI) of less than 50%. Median observation time was 4.5 years for the survival patients. Four-year OS and PFS for all the patients was 80% and 72%. Patients with omission/reduction (RDI <50%) of vincristine had significantly worse OS compared to patients without omission/reduction of vincristine (4-year OS: 66% *vs* 80%, p=0.028), as well as PFS (56% *vs* 73%, p=0.037). In regard to GCB and non GCB type, 15 patients and 17 patients had less than 50% RDI of vincristine respectively. Among patients with GCB type, OS was significantly worse in patients with vincristine omission/reduction, with 4-year OS of 67% *vs* 85% (p=0.005). However, OS did not show the significance between with and without omission/reduction of vincristine.
Summary and Conclusions: The omission/reduction of vincristine from R-CHOP like regimen might lead to a substantial loss of efficacy especially in GCB type. High intensity of R-CHOP like therapy should be maintained when treating DLBCL with GCB type.

PF284

EPIDEMIOLOGY AND TREATMENT PATTERNS IN LATIN AMERICAN PATIENTS WITH NON-HODGKIN'S LYMPHOMA: FINDINGS FROM THE HEMATO-ONCOLOGY IN LATIN AMERICA (HOLA) OBSERVATIONAL REGISTRY STUDY

M. Pavlovsky[1,*], D. Cubero[2], G. Vásquez[3], A. Enrico[4], M. Osorio[1], J. Armenta[5], L. Foggliatto[6], R. Ovilla[7], O. Flores[8], T. Santos[9], P. Barreyro [10]

[1]Servicio de Hematología e Investigación Clínica, Fundación para Combatir la Leucemia (FUNDALEU), Buenos Aires, Argentina, [2]CEPHO/ABC School of Medicine, Santo André, Brazil, [3]Instituto Nacional de Ciências Médicas e Nutrição, Salvador Zubirán, Mexico City, Mexico, [4]Hospital Italiano La Plata, Buenos Aires, Argentina, [5]Centro Oncológico Estatal ISSEMYM, Toluca, Mexico, [6]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil, [7]Hospital Angeles Lomas, Huixquilucan, Mexico, [8]Medical Solutions S.A. , Guatemala City, Guatemala, [9]Janssen-Cilag Farmacêutica Ltda, São Paulo, Brazil, [10]Janssen-Cilag Farmacêutica Ltda, Buenos Aires, Argentina

Background: Real-world evidence concerning the epidemiologic characteristics and treatment patterns in Latin American patients with non-Hodgkin lymphoma (NHL) is limited.
Aims: Objectives of this study were to evaluate: 1) proportion of subtype presentation among all NHL's, 2) patient characteristics, and 3) treatment patterns.
Methods: This multicenter, observational, retrospective chart review included patients with T-cell or B-cell lymphomas, including diffuse large B-cell lymphoma (DLBCL), follicular lymphoma (FL), mantle-cell lymphoma (MCL), and mucosa-associated lymphoid tissue (MALT) lymphoma. Eligible for analysis were adults with NHL who received care at 30 tertiary-care centers (oncology concentration) in Argentina (n=5 sites), Brazil (n=9), Chile (n=1), Colombia (n=5), Mexico (n=6), Panama (n=3), and Guatemala (n=1). Patients who had ≥1 year of follow up from January 1, 2008, through December 31, 2015 were included. Chart abstractors were centrally trained in case ascertainment.
Results: Across the seven countries, 2,967 patients had a diagnosis of NHL. A total of 2,948 (99.3%) patients with subtype information were included in the analysis by subtype. Mexico, Argentina, Colombia, and Brazil contributed large proportions of patients with most forms of NHL (80.9%). Majorities of patients with NHL (2,518/2,948=85.4%) had B-cell subtypes, including 1,457/2,518 (57.9%) individuals with DLBCL; 578/2,518 (23.0%) with FL; 183/2,518 (7.3%) with MCL; 90/2,518 (3.6%) with chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma; 84/2,518 (3.3%) with MALT; 60/2,518 (2.4%) with Burkitt lymphoma; and <1.5% each with lymphoplasmacytic lymphoma (35/2,518; 1.4%) or B-lymphoblastic lymphoma (n=31/2,518; 1.2%). A further 250/2,948 (8.5%) patients had T-cell NHL, and 180/2,948 (6.1%) patients with all other types of lymphoma. MCL had the highest percentage of male patients (128/183; 69.9%), and MALT had the lowest percentage (36/84; 42/9%). Patients with DLBCL, CLL/small lymphocytic lymphoma, and B-lymphoblastic lymphoma were more gender balanced. The median age at diagnosis ranged from 32 years for B lymphoblastic lymphoma to 64 years for CLL/small lymphocytic lymphoma or lymphoplasmacytic lymphoma. The median age at diagnosis was 58 years for DLBCL. Most patients (54.0% FL; 59.1% DLBCL; 59.5% MCL; 65.0% other types of lymphomas; 65.5% MALT; 67.7% CLL/small lymphocytic lymphoma; 68.6% lymphoplasmacytic lymphoma) had prior comorbidities at the time of diagnosis, while 67.7% with B-lymphoblastic lymphoma and 50.4% with T-cell lymphoma had no previous comorbidities. For patients with most NHL subtypes, the most frequent chemotherapy was R-CHOP (rituximab–cyclophosphamide-doxorubicin-vincristine-prednisolone). Among patients receiving chemotherapy, R-CHOP was used in 998/1,420 (70.3%) patients with DLBCL, 280/546 (51.3%) with FL; 71/172 (41.3%) with MCL; and 24/67 (35.8%) with MALT. Other forms of chemotherapy included CHOP and RCVP (rituximab-cyclophosphamide-vincristine-prednisolone). Most patients (23/30; 76.7%) with B-lymphoblastic lymphoma treated using chemotherapy received hyperCVAD (hyperfractionated cyclophosphamide-vincristine-doxorubicin-dexamethasone).
Summary and Conclusions: Most Latin American residents with NHL had DLBCL, FL, T-cell lymphoma or MCL, and the median age at diagnosis ranged from 32 to 64 years. Most patients had prior comorbidities at diagnosis, and R-CHOP was the most frequent chemotherapy for most NHL subtypes.

PF285

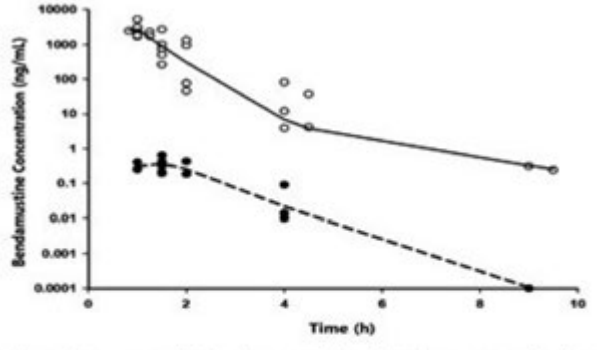
CLINICAL RESPONSE AND PHARMACOKINETICS OF BENDAMUSTINE AS A COMPONENT OF SALVAGE R-B(O)AD THERAPY FOR THE TREATMENT OF PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA (PCNSL)

D.-H. Yang[1,*], S.-Y. Ahn[1], S.-H. Jung[2], H.-J. Kim[3], J.-J. Lee[1], Y. R. Do[4]

[1]Hemato-Oncology, [2]Chonnam National University Hwasun Hospital, Jeollanam-do, Korea, Republic Of, [3]Hemato-oncololgy, Chonnam National University Hwasun Hospital, Jeollanam-do, [4]Hemato-oncology, Dongsan Medical Center, Daegu, Korea, Republic Of

Background: A relatively high proportion of patients diagnosed with primary CNS lymphoma will experience recurrent disease, yet therapy options are limited in salvage therapy. This was the first study to evaluate a bendamustine-based combination regimen for the treatment of relapsed/refractory (R/R) PCNSL and to characterize bendamustine pharmacokinetics in the human CSF.
Aims: This was a prospective, open-label, pilot study investigating the safety and efficacy of the bendamustine-based combination regimen R-B(O)AD, designed to define CSF and plasma PK profiles of bendamustine in R/R patients.

Methods: All patients received either R-BOAD or R-BAD intravenously (rituximab 375 mg/m^2 on day 1; vincristine 1.4 mg/m^2 on day 1, omitted in patients ≥70 years of age due to risk of neurotoxicity; bendamustine 75 mg/m^2 over 1 h on days 2 and 3; cytarabine 1000 mg/m^2 over 3 h on days 2-4; dexamethasone 20 mg on days 1-4), every 4 weeks up to 4 cycles. Response, survival outcomes, and adverse events of the regimen were assessed. A sparse sampling strategy and population based modeling approach was utilized for evaluation of plasma and CSF levels of bendamustine. CSF exposure was estimated as $C_{max,}$CSF/$C_{max,}$plasma and AUC_{CSF}/AUC_{plasma} ratios. Non-compartmental methods were used to calculate the area under the concentration–time curve ($AUC_{0\text{-}inf}$) in WinNonlin, version 5.2 (Pharsight, St. Louis, MO, USA).
Results: Ten patients were enrolled into study of whom 70% were of refractory disease and with high IELSG prognostic risk scores. Twenty-seven cycles of R-B(O)AD were administered, at a median of three cycles per patient, and vincristine was omitted in four patients. The ORR of R-BOAD was 50% (95% CI, 0.24 to 0.76) with one patient achieving CR and four PR. Primary toxicity of the regimen was reversible myelosuppression, mostly grade 3 or 4 neutropenia. Time of maximum concentration (t_{max}) was found at the end of infusion ($t_{max,plasma}$=1 h) for plasma and at 0.5 h after end of infusion ($t_{max,csf}$=1.5 h) for CSF. The mean maximum peak concentrations for plasma and CSF were 2669 ng/mL and 0.397 ng/mL, respectively, and patients with response at deep tumor sites displayed higher trends in peak exposure. Pharmacokinetic data was best described by a four-compartment model with first-order elimination of drug from central plasma and CSF compartments (Figure 1).



Bendamustine concentration-time profiles. Circles represent observed values for plasma (•) and CSF (◦) drug levels. Best-fit curves from the final population PK model are shown for plasma (–) and CSF (----).

Figure 1.

Summary and Conclusions: R-BOAD is an effective salvage option for PCNSL, but with significant hematologic toxicity. Bendamustine CSF levels are minimal; however correspond to plasma exposure and response.

PF286

OUTPATIENT SYSTEMIC HIGH-DOSE METHOTREXATE AS CNS PROPHYLAXIS IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

R. Fernández-Alvarez[1,*], S. Sánchez-Matías[1], A. Rubio-Castro[1], C. de Brabandere[1], M. Sarasa Valdés[1], J. Torres Varona[1], A. Silva Soto[1], E. González-García[1], A.-P. Gonzalez[2], C.-R. Fernández-Alvarez[1]

[1]Hematology, Hospital Universitario de Cabueñes, Gijon, [2]Hospital Universitario Central de Asturias, Oviedo, Spain

Background: Systemic high-dose methotrexate (HD-MTX) is increasingly used as CNS prophylaxis in high-risk patients with diffuse large B-cell lymphoma (DLBCL). To ensure safe administration and to prevent nephrotoxicity, conventional schedules for HD-MTX delivery require hospitalization for inpatient hydration and urine alkalinization. To improve patients' quality of life and reduce healthcare costs, we developed an institutional protocol for HD-MTX administration in the outpatient setting.
Aims: To analyze the safety and feasibility of an ambulatory HD-MTX regimen for CNS prophylaxis in DLBCL patients.
Methods: This single-center retrospective study included all DLBCL patients who received outpatient HD-MTX as CNS prophylaxis between 2015 and 2017. Patients were planned to receive 3 doses of HD-MTX after alternate R-CHOP courses. Requirements included: high-risk criteria for CNS involvement, good performance status, creatinine clearance (CrCl) >60 mL/min, absence of fluid retention and serum bilirubin ≤1.5xULN. Patients were instructed to keep an adequate oral hydration (2 l/m^2/day) and urine alkalinization by using sodium bicarbonate (2 grams QID) and acetazolamide (250 mg QID) from 72 hours previous to HD-MTX infusion. Comedications were reviewed to minimize the risk of interactions. HD-MTX (3.5 g/m^2) was infused over 4 hours, together with 1 liter of hydration and sodium bicarbonate 50 mEq. Urine pH was checked before HD-MTX administration, and for any value less than 7 a sodium bicarbonate bolus (1 mEq/kg) was given. Leucovorin at a standard dose (30 mg orally every 6 hours) was begun 24 hours after HD-MTX. MTX serum concentrations were monitored daily from 24 hours after administration until clearance (level ≤0.1 micromol/L). Examined parameters included: urine pH, MTX levels and toxicity according to Common Terminology Criteria for Adverse Events (CTCAE) version 4.
Results: A total of 37 ambulatory HD-MTX courses were given to 13 patients (median age 54, range 21-76), after a median of 14 days from R-CHOP administration (range 10-19). Initial dose of MTX was 3.5 g/m^2 in all cases and no dose reduction was required afterwards. All patients completed succesfully the planned 3 doses in an outpatient basis, except for one patient who received only one dose due to pneumonitis. Previous to MTX infusion, urinary pH >7 was achieved in 33 (89%) cycles. Median MTX levels at 24, 48 and 72 hours after administration were 1.40, 0.18 and 0.08 micromol/L, respectively. MTX clearance (≤0.1 micromol/L) was achieved by 72 hours in 27 courses (70%), and by 96 hours in 100%. There were no cases of delayed MTX elimination. Creatinine level increases grades I and II were observed in 29 (78%) and 4 (11%) cycles, respectively. No episode of severe (grade 3-4) nephrotoxicity was observed. The main hematological toxicity was neutropenia (grade 3 in 19%). Extra-hematological toxicities were mild and included: mucositis (grades 1-2, 24%), nausea and vomiting (grades 1-2, 8%) and hypokalemia (grades 1-2, 8%). Admission was required only in one case of pneumonitis.
Summary and Conclusions: Outpatient administration of HD-MTX as CNS prophylaxis is safe and feasible following the described approach. Emphasis should be put on careful selection of patients and strict adherence to ambulatory oral hydration and urine alkalinization. An inter-professional team approach including nurses, medical staff and pharmacists was key to the successful implementation of this ambulatory regimen.

PF287

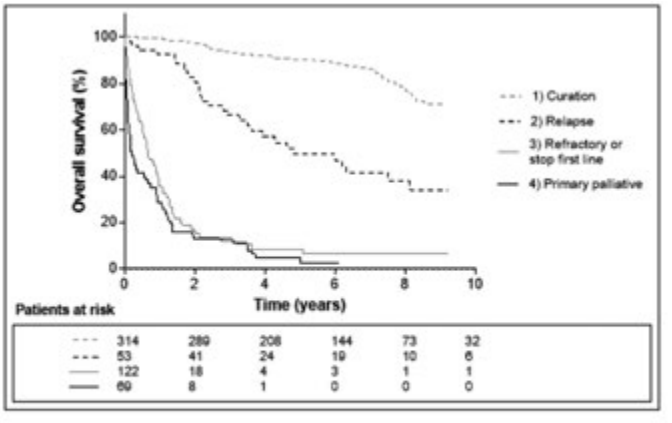
OUTCOME OF A 10-YEAR POPULATION-BASED COHORT OF DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS IN THE FIRST-LINE, REFRACTORY AND RELAPSED SETTING: 'REAL-WORLD' DATA IDENTIFY SUBGROUPS IN NEED OF NEW THERAPIES

H. van der Galien[1,*], H. Kooistra[1], N. Veeger[2], R. Kibbelaar[3], H. Storm[4], E. de Waal[1], M. Hoogendoorn[1], H. van Kamp[5], S. Hovenga[5], L. Schipper[5], G. Veldhuis[6], G. Woolthuis[6], B. van Rees[7], T. van Meerten[8], R. van Rijn[1]

[1]Department of Hematology, Medical Center Leeuwarden, [2]Department of Epidemiology, MCL Academy, [3]Department of Pathology, Pathology Friesland, [4]Department of Clinical Chemistry, Certe, Leeuwarden, [5]Department of Internal Medicine, Nij Smellinghe Hospital, Drachten, [6]Department of Internal Medicine, Antonius Hospital, Sneek, [7]Department of Internal Medicine, Tjongerschans Hospital, Heerenveen, [8]Department of Hematology, University Medical Center Groningen, Groningen, Netherlands

Background: In diffuse large B-cell lymphoma (DLBCL), with standard chemo-immunotherapy a high treatment failure rate remains of about 40%. For relapsed or refractory (R/R) patients who are ineligible for salvage therapy with autologous stem cell transplantation (ASCT) outcome is poor. Recently, several novel agents have demonstrated promising results in R/R DLBCL patients. However, the applicability of these results to 'real-world' patients is unclear as patient details from population-based cohorts in DLBCL are scarce.
Aims: To obtain 'real-world' prognostic factors, treatment patterns and outcomes of DLBCL patients in the rituximab era in first-line, refractory and relapsed setting. Hereby, we aim to distinguish subgroups that may benefit most from new treatments.
Methods: An observational study was performed using the population-based 'HemoBase' registry from the province of Friesland, the Netherlands. All DLBCL patients diagnosed between 2005 and 2015 were included with a follow-up to early 2018. Patients had free access to health care. Fully detailed information of patient and disease characteristics and outcomes for all lines of treatment were collected. Survival analysis was performed by Kaplan-Meier and multivariate by Cox proportional hazard models.
Results: 568 patients (median age 70 years, 53,8% male) were included.

Median follow up was 6.3 years. Progression free survival (PFS) and overall survival (OS) at 4 years were 55% and 60%, respectively. The International Prognostic Index (IPI) score at diagnosis was calculated for 96% of patients and was 0 in 43 (8%), 1-2 in 278 (52%) and 3-5 in 214 patients (40%) with corresponding 4-year OS of 94%, 70% and 46%. 69 patients (12%) received no treatment or palliative treatment only. These patients were older (median age 83 years, p<0.01) and had a worse WHO performance status (84%≥2, p<0.01) compared to the 489 patients treated with curative intent. 314 patients (65%) achieved continuous complete remission after first-line chemo-immunotherapy. 61 patients (12%) did not complete treatment due to toxicity or death. In 61 patients (12%) refractory disease (primary refractory or early relapse <6 months after completing first-line therapy) and in 53 patients (11%) relapse was found. Second-line palliative therapy was offered to 45% of refractory (median OS 0.9 years) and to 59% of relapsed patients (median OS 2.9 years) and consisted of chemotherapy, radiotherapy, steroids or supportive care. Salvage therapy was initiated in 55% of refractory (median OS 1.3 years) and 41% of relapsed DLBCL (median OS 6.0 years). 17% of R/R patients underwent ASCT with a continuous curation rate of 63% and 4-year OS of 58%. Outcome in relapse was favorable over refractory disease (HR3.26, p<0.01). Multivariate survival analysis will be presented for age, sex, lower performance, Ann Arbor stage, B-symptoms, IPI score, LDH, Charlson Comorbidity Index and subtypes based on immunohistochemistry and histology (Figure 1).



Overall survival of patients with diffuse large B-cel lymphoma divided into four subgroups: 1) continuous complete remission after first line treatment; 2) relapse (>6 months) after first line treatment; 3) refractory disease or not completing first line treatment; 4) primary palliative or no treatment in first-line

Figure 1.

Summary and Conclusions: In this detailed population-based DLBCL cohort, primary palliative patients, patients unable to complete first-line treatment and patients with refractory disease were identified as subgroups with exceptional poor prognosis. This substantial group of 34% of all DLBCL patients had a lower performance and a higher age and might benefit from less toxic (up-front) novel therapies. In addition, given the response rates to palliative second-line therapy in patients with relapse, this group should be considered for participation in clinical trials investigating novel approaches.

PF288

LOW SUNLIGHT EXPOSURE AT TIME OF DLBCL DIAGNOSIS MAY BE ASSOCIATED WITH INFERIOR SURVIVAL IN ELDERLY WOMEN

A. Elinder Camburn[1,*], H. Chan[1]

[1]*Haematology, North Shore Hospital, Auckland, New Zealand*

Background: Data from RICOVER60 demonstrates that vitamin D deficiency is a risk factor for elderly patients with Diffuse Large B-cell Lymphoma (DLBCL) treated with R-CHOP chemotherapy due to postulated impaired rituximab-mediated cellular cytotoxicity. The primary source of vitamin D for most people is from sun exposure of epidermal tissue, and this varies with the amount of daylight hours in different seasons.
Aims: The purpose of this restrospective study was to analyse the long term survival of elderly patients with DLBCL diagnosed in different seasons of the year.
Methods: Cases were extracted from the New Zealand Cancer Registry, and all patients diagnosed with DLBCL between 1 January 2010 and 31 December 2016 were included. Overall survival was calculated from the date of diagnosis to the date of death by any cause. All cases that were not known to be dead at the time of analysis were presumed alive and censored. Southern hemispher summer season was defined as the months between November and February, and winter season was defined as the months between May and August.
Results: Between 1 January 2010 and 31 December 2016, a total of 2263 cases of DLBCL were reported in patients aged 18 or over. 755 were diagnosed in the winter months and 761 were diagnosed in the summer months. The remaining 747 patients were diagnosed between the two seasons. Female patients aged 50 or above, diagnosed in the winter months had a significant inferior survival compared to those diagnosed during the summer months (55.9 *vs* 87.6 months, p=0.039). For men aged 50 or above, a difference in overall survival relating to season at time of diagnosis was not observed (median OS 62.6 *vs* 48.8 months, p=0.297) (Figure 1).

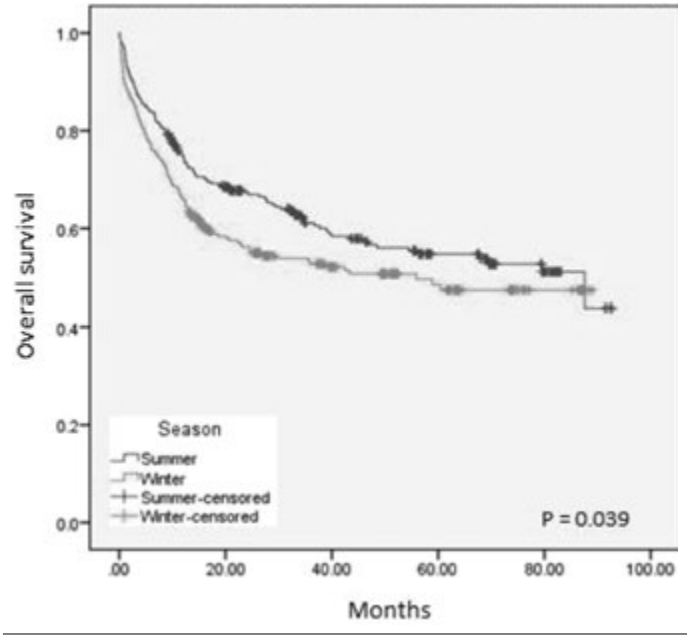


Figure 1.

Summary and Conclusions: Elderly female patients diagnosed with DLBCL in the winter months had inferior survival compared to those diagnosed in the summer months. This difference in survival may be partly due to the increased prevalence of vitamin D deficiency in elderly women relating to reduced sunlight exposure during the winter months.

PF289

THE PROGNOSTIC ROLE OF 18FDG-PET/TAC AT THE END OF FIRST LINE CHEMO-IMMUNOTHERAPY IN PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA: A MONOCENTRIC STUDY ON 308 PATIENTS

E. Maiolo[1,*], F. D'Alò[1], S. Bellesi[1], A. Cuccaro[1], E. Alma[1], V. Rufini[2], L. Leccisotti[2], S. Annunziata[2], A. Rizzo[2], G. Macis[3], L. Calandriello[3], M. Balducci[4], S. Chiesa[4], V. De Stefano[1], S. Hohaus[1]

[1]*Institute of Hematology, Policlinico Gemelli Foundation, Catholic University of the Sacred Heart,* [2]*Institute of Nuclear Medicine, Policlinico Gemelli Foundation, Catholic University of the Sacred Heart,* [3]*Institute of Radiology, Policlininico Gemelli Foundation, Catholic University of the Sacred Heart,* [4]*Radiation Therapy Department, Policlinico Gemelli Foundation, Catholic University of the Sacred Heart, Rome, Italy*

Background: Although ^{18}FDG-PET/TAC is the gold standard for definition of the final response to chemio-immunotherapy in patients with diffuse large B cell lymphoma (DLBCL), data about its prognostic role are few and sometimes conflicting. PET scan evaluation in DLBCL is often performed using either the International Harmonized Project (IHP) or Deauville score (DS) visual criteria.
Aims: Aim of our study was to retrospectively assess the prognostic role of PET scan evaluation in patients with DLBCL and to analyse for patient characteristics that associate with PET response.
Methods: ^{18}FDG-PET/CT performed at the end of first line chemo-immunotherapy were retrospectively but blindly evaluated using visual methods according to available literature (both IHP and DS) by a physician

with experience in nuclear medicine and lymphoproliferative disease. The prognostic power of visual scores was evaluated considering lack of complete remission, relapse or progression as adverse events. Progression-free survival (PFS) curves were estimated using the Kaplan-Meier method and compared to each other by the log-rank test.
Results: We analysed PET/CT scans of 308 patients with DLBCL treated with chemo-immunotherapy (rituximab+CHOP) between 2009 and January 2017 at our centre were included. Median follow up was 33 months. Scans were negative according to IHP criteria in 212 (69%) patients, positive in 96 (31%) patients. Deauville scoring classified scans as DS1 in 163 (53%) patients, DS2 in 44 (14%), DS3 in 36 (12%), DS4 in 43 (14%), and DS5 in 22 (7%) patients. Variables significantly associated with PET negativity were ECOG <2 *(p=0.004),* albumin>4 g/dL *(p<0.0001),* absence of bulky disease *(p<0.0001),* limited stage (*p<0.0001),* and the anthracycline dose *(p=0.012).* End of chemo-immunotherapy PET predicted for outcome. The 3-years PFS was 96% for patients with negative PET according to IHP and 69% for patients with a positive PET, respectively *(p<0.0001);* Deauville scoring was even more powerful to predict 3-year PFS: 95% for patients with DS 1-3 and 61% for patients with DS 4-5. The survival difference according to PET was confirmed also when analysing patients at low and high risk according to IPIaa (0-1 *vs* 2-3) separately. Anthracycline dose was the most important risk factor for disease recurrence in patients with DS 1-3 *(p=0.02).* In patients with DS4, consolidative radiotherapy appeared to be associated with better outcome *(p=0.02).*
Summary and Conclusions: ^{18}FDG-PET/CT is a prognostic factor in patients with DLBCL at the end of first line chemo-immunotherapy in a large monocentric cohort. Patients obtaining PET Deauville Score 1-3 had an very good prognosis. Still classical risk factors as IPI and dose-intensity of anthracyclines impacted on prognosis. Prognosis of patients with DS4 was significantly worse, and consolidation with radiotherapy might improve prognosis. We are currently evaluating semi-quantitative parameters in this cohort in a attempt to further improve the predictive power of end of chemo-immunotherapy PET.

PF290

CLINICAL CHARACTERISTICS AND OUTCOMES OF BURKITT LYMPHOMA IN A DEVELOPING COUNTRY

W. Fernandes Da Silva Junior[1,*], L. Inês da Rosa[1], L. A. de Pádua Covas Lage[1], V. Rocha[1], J. Pereira[1]

[1]Internal Medicine, Institute of Cancer of São Paulo (ICESP) / University of São Paulo (USP), São Paulo, Brazil

Background: Burkitt lymphoma (BL) is a highly aggressive but curable disease characterized by high proliferation rate and chromosomal translocation involving the oncogene c-MYC and an immunoglobulin locus. Despite its first description in a developing country, few studies have been performed in this world region, particularly in adults and in the Human Immunodeficiency Virus (HIV) infection setting. Likewise, in Brazil the data on adult BL are yet scarce.
Aims: To analyze clinical features and to evaluate response and survival of adults with BL in HIV(+) and HIV(-) patients treated in our institution.
Methods: Retrospective observational study involving patients older than 15 years diagnosed with BL treated in ICESP from 1999 to 2017. BL diagnosis was performed according to WHO criterion.
Results: Seventy patients met the eligibility criteria. Median age was 35 y (15–66 y), 48/70(69%) were men and 30/70(43%) HIV(+). Median serum lactate dehydrogenase (LDH) was 828 IU/L (range 135–9314), with abnormal level in 90%(62/70) patients. CNS involvement was found in 18/70(26%) and bone marrow (BM) and gastrointestinal tract (GIT) involvement was noticed in 19/70(27%) and 34/70 (49%), respectively. 59/70(84%) were in advanced stage. HIV-associated BL showed a higher rate of CNS involvement (15% *vs* 40%, p=0.027) and 9/30(32%) HIV(+) patients were using combined anti-retroviral therapy (cART). 17/30 (68%) HIV(+) patients showed CD4$^+$ lower than 200 cells/mL with a median of 123 cells/mL (15–800). Median HIV viral load was $10.2x10^3$ copies/mL (0–$6639.5x10^3$). Adapted LMB regimen and Hyper-CVAD were the most common regimen used for HIV(-) (n=35) and HIV(+) (n=23) patients, respectively, and 12 patients were treated with CHOP-like due to poor performance status (PS). When possible, all these regimens were adapted to outpatient setting. Only one HIV(-) patient was referred to autologous hematopoietic stem-cell transplantation in first partial remission. For HIV(+) patients, the cART was given along with chemotherapy. Rituximab was not used since it is not yet reimbursed for BL in our public health system. 50/70 (71.4%) patients achieved complete response (CR) and early death (during the first 30 days of the start of chemotherapy) occurred in 20/70(28%) patients, mostly HIV(+) patients (80%). Similarly to literature, CR was more frequent in HIV(-) than in HIV(+) (90 *vs* 47%, p<0.001). Age (>35 years) was also a statistically significant factor for CR (p=0.022) in both groups. In a median follow-up of 5.6 years (3.6–7.5 y) the relapse rate was 21.4% for HIV(+) *vs* 8.3% for HIV(-) (p=0.075). CNS infiltration was found as risk factor for relapse (p=0.002) and other factors as age, clinical stage, LDH, BM and GIT involvement, CD4+ cell and viral load were not significant. 5-year overall survival (OS) was 85% for HIV(-) and 34% for HIV(+) (p<0.001) (Figure 1).

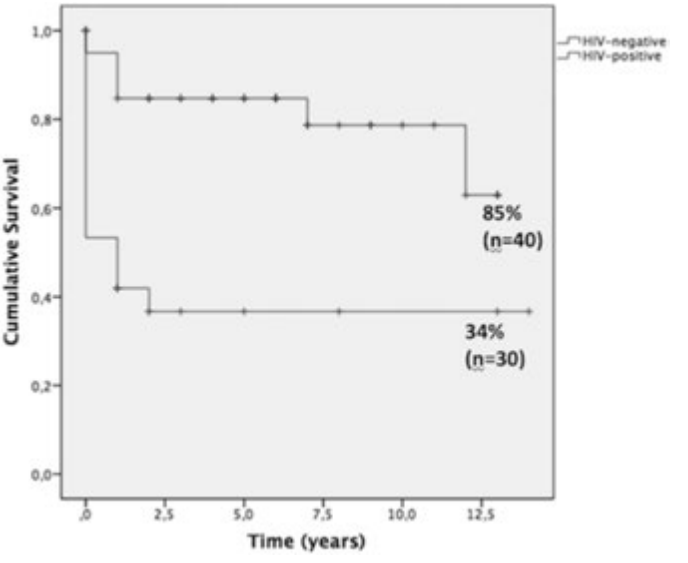

Figure 1.

Summary and Conclusions: In this study, results of HIV(-) BL patients were similar to the literature, despite of unavailability of rituximab. However, HIV(+) BL patients had a decreased PS, with a lower level of CD4$^+$ cells, advanced disease and higher CNS involvement in comparison to literature, that may explain the unsatisfactory outcome found in this group. It seems that, at least in developing countries, optimizing regimens for HIV(+) patients providing early access to treatment and improving supportive care are still an unmet need.

PF291

AN INCREASED RISK OF POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDER IN CHILDREN AFTER CARDIAC TRANSPLANTATION FOR CONGENITAL HEART DISEASE

U. Offor[1,*], S. Bomken[1], C. Bacon[1], A. Gennery[2], Z. Reinhardt[3]

[1]Northern Institute for Cancer Research, [2]Institute of Cellular Medicine, Newcastle University, [3]Department of Cardiopulmonary Transplantation, Newcastle Hospitals NHS Trust, Newcastle Upon Tyne, United Kingdom

Background: Patients subjected to lifelong immunosuppressant therapy for solid organ transplantation are at an increased risk of developing malignancies. Post-transplant lymphoproliferative disorder (PTLD) represents the most common cause of malignancy seen in children after cardiac transplantation. The significance of pre-transplant cardiac diagnosis as a risk factor for PTLD in this population has not been previously investigated in depth.
Aims: This study aimed to examine the risk factors for development of PTLD specific to children undergoing cardiac transplantation.
Methods: We retrospectively reviewed the demographics, clinical features and outcomes of all 203 children (<18 years), who received a heart transplant in our institution between January 2000 and December 2015. Kaplan-Meier method and Cox proportional hazards were used to assess the impact of prognostic factors including pre-transplant cardiac diagnosis on survival and freedom from PTLD.
Results: The study cohort consisted of 75 patients transplanted for congenital heart disease (CHD) and 128 patients for idiopathic cardiomyopathy (IC). The median follow up was 5.5 years. There was a significant difference in age at first invasive cardiac procedure via median sternotomy between children with CHD and IC (4 months *vs* 5 years, p <0.001) but no difference in the age at transplantation between both groups (p= 0.78). PTLD was diagnosed in 15 (7.4%) children transplanted for underlying CHD (10/15)

and IC (5/15) with a median age at diagnosis of 10.4 years (range; 6.6-14.0) and 11.5 years (range; 4.8-13.5) respectively. The median time to PTLD was 24 months (range; 10 - 50 months) with no significant difference in time to PTLD between patients with CHD and IC (p= 0.09). All tumour samples were Epstein Barr Virus (EBV) positive and of B-cell lineage. The histological subtypes consisted of 10 (67%) monomorphic lesions, 3 (20%) polymorphic, and 2 (13%) classical Hodgkin lymphoma. Early stage disease (stage I-II) was observed in 5 (33%) patients while advanced tumour (stage III-IV) was seen in the remaining 10 (67%) children. Overall freedom from PTLD was 96% at 1-year, 92% at 5-years and 90% at 10-years. The risk of PTLD was not significantly associated with age at transplantation, gender, ethnicity or type and number of immunosuppressants used (p >0.05). Recipient EBV seronegativity prior to transplantation increased the risk of PTLD (p= 0.04) on multivariate Cox regression, while children with CHD had a significantly higher risk of developing PTLD compared to those with IC (Hazard Ratio= 5.3; 95% Confidence Interval= 1.5–18.9).

Summary and Conclusions: The identification of congenital heart disease as an important risk factor in the development of PTLD after paediatric heart transplantation is a novel finding. We posit that the underlying diagnosis of CHD is a potential proxy marker for early dysregulation of T cell mediated immunity occuring as a consequence of earlier thymectomies during invasive cardiac procedures in these patients compared to children with IC, predisposing them to primary EBV infection and aberrant proliferation of lymphoid cells. This hypothesis is supported by our study finding of a significant age disparity at the time of first invasive cardiac procedure via median sternotomy between children with CHD and IC, which warrants further investigation.

Bleeding disorders (congenital and acquired)

PF292

IDENTIFICATION OF NOVEL MECHANISMS UNDERLYING FUNCTIONAL RESPONSE TO DRUG-INDUCED READTHROUGH OF HAEMOPHILIA B NONSENSE MUTATIONS

M. Ferrarese[1,*], F. Bernardi[1], M. Pinotti[1], A. Branchini[1]

[1]Department of Life Sciences and Biotechnology, University of Ferrara, Ferrara, Italy

Background: Drugs inducing ribosome readthrough over premature stop codons, with synthesis of full-length proteins, are proposed as potential therapy for genetic disorders caused by nonsense mutations. This is particularly relevant for coagulation disorders, in which even small increases in functional levels would significantly ameliorate patients bleeding phenotypes. However, the poor responses reported in several patients underlies high variability in the efficacy of readthrough-inducing drugs. The functional rescue results from the interplay between mRNA (nucleotide context) and protein (impact of the amino acid inserted at the nonsense codon) components.

Aims: To investigate the responsiveness to the readthrough-inducing drug geneticin of a wide panel of factor IX (FIX) nonsense mutations, accounting for ~80% of Haemophilia B patients with this mutation type.

Methods: Transient expression of FIX variants in HEK293 cells and evaluation of protein levels (ELISA), full-length/truncated forms (Western Blotting) and activity (chromogenic/coagulant assays).

Results: Among the 11 investigated nonsense mutations, only the p.W240X and p.R384X responded with a remarkable rescue of activity. The amount of rescued FIX protein and activity was comparable for the p.W240X. Strikingly, the activity for the p.R384X (7.5±0.7% of wt) remarkably exceeded secreted protein levels (2.0±0.3%). Data indicate specific favourable mechanisms underlying the observed response: i) re-insertion of the original residue (tryptophan) for the p.W240X and ii) hyperactive features for the p.R384X (Padua position), further confirmed by the 4-fold increased specific activity of the readthrough-deriving R384W missense variant. For most nonsense mutations, an impaired secretion/function prevented a significant functional rescue due to readthrough-mediated amino acid substitutions, as experimentally demonstrated by expression of the most probable missense variants arising from readthrough. We further hypothesized that mutations falling in regions such as pre-peptides would be favoured upon readthrough. Indeed, since these regions are poorly conserved and intracellularly removed, the impact of missense changes on the secreted protein could be vanished. Investigation on paradigmatic nonsense mutations of FIX pre-pro-peptide demonstrated that the p.G21X at the variable hydrophobic core appreciably responded (4±0.3%) to geneticin treatment and the position tolerated all the predicted readthrough-deriving missense changes (G21W/C/R). Specific activity of the secreted proteins was not affected, pointing towards the secretion of wild-type FIX upon pre-pro-peptide removal. As expected, induction of two mutations facing constraints of adjacent cleavage sites was virtually ineffective.

Summary and Conclusions: Data obtained from the optimized FIX expression platform help interpreting the variable response to induced readthrough and lead to the identification of mechanisms underlying a therapeutically-relevant output: i) re-insertion of the authentic residue; ii) rare gain-of-function effects; iii) favourable localization in regions removed during biosynthesis (*i.e.* pre-peptide, B-domain). Taken together, these data support a rational approach to identify a few nonsense mutations, and thus patients, potentially eligible for therapeutic options based on readthrough.

PF293

ASSESSMENT OF IMMUNE FUNCTION BEFORE AND AFTER TREATMENT WITH RECOMBINANT FACTOR VIII FUSED WITH FC FRAGMENTS

S. P'ng[1,*], C. Almeida[1]

[1]Haematology, Fiona Stanley Hospital, Perth, Australia

Background: Up to 30% of Haemophilia A patients develop of inhibitors or alloantibodies to Factor VIII. Modifications to the Factor VIII product to increase their half life are speculated affect their immunogenicity. In particular Elocate which contains the Fc fragment of immunoglobulin (FVIIIFc). This Fc fragment contains regulatory T cell (Treg) epitopes which protect the FVIII molecules from immune responses generated by T cells. There is

evidence in a mouse model that repeated administration of FVIIIFc resulted in significantly lower antibody responses to the rFVIII compared with standard recombinant products. The immune response was characterized by higher percentage of Treg cells, lower percentage of pro-inflammatory splenic T cells and upregulation of tolerogenic cytokines and markers compared with exposure to standard rFVIII.
Aims: This study examines the potential change in immune responses after repeated exposure to FVIIIFc in patients with severe haemophilia A.
Methods: Peripheral blood mononuclear cells (PBMCs) from two individuals were collected pre- and post-treatment with Eloctate and cultured *ex vivo* with both drugs. The frequency of various CD4 and CD8 T cell subsets was measured along with the activation and cytokine-producing capabilities of these subsets. Flow cytometry was used to measure the frequency of various CD4+ and CD8+ T cellular populations. Intracellular levels of TNF-α were measured by flow cytometry.IFNγ was measured by enzyme linked immunosorbent assays (ELISAs, BD) in culture supernatants. Inhibitor FVIII levels were measured in plasma samples collected at the three time-points using the Bethesda assay.
Results: The frequencies of CD4+ and CD8+ T cells were not significantly affected by treatment with Xyntha or Eloctate. The frequency of naïve CD4+ and CD8+ T cells was the highest at each time point, irrespective of drug treatment. Both the CD4+ and CD8+ terminally differentiated cells (CD45Ra+/CD27-) were present at higher frequencies in cells cultured with 100 U/mL of drug. The expression of PD-1 markedly increased in PBMCs collected at the three and six month time points and cultured in the presence of 100 U/mL of Xyntha. PD-1 expression on PBMCs collected at these same time points and cultured in the presence of Eloctate did not vary with drug concentration but were higher in comparison to cells collected before the two subjects' commenced treatment with Eloctate. The levels of TNFα and IFNγ did not vary with time or drug treatment. Neither did the expression of the activation marker CD137 and the frequency of CD4+TRegs.
Summary and Conclusions: Our study demonstrated increased levels of PD-1 expression after 6 months of Eloctate exposure.There was an increase in terminally differentiated T cells after this period suggesting a relative suppression of the immune response and development of T cell anergy. The lack of cytokine production and absence of T cell activation could potentially be attributed to the up-regulation of PD-1, which has previously been associated with T cell exhaustion. This was most noticeable at the 6 month mark suggesting exposure to the Fc fused FVIII product Eloctate may be contributory to a T cell anergy. This is the first human clinical study to support the theory that the Fc fused product maybe less immunogenic than unaltered recombinant FVIII. Further studies are required to support and expand this theory in the clinical setting.

FACTOR VIII RECOVERY TEST IN PERIOPERATIVE MANAGEMENT OF ORTHOPEDIC SURGERY IN ADULT PATIENTS WITH SEVERE HEMOPHILIA A

J.J. Han[1,*], J. Kong[1], G. Shin[1], Y.J. Cho[2], H.-J. Yoon[1]

[1]Internal Medicine, [2]Orthopaedic surgery, Kyung-Hee University Medical Center, Seoul, Korea, Republic Of

Background: Hemophilic arthropathy caused by recurrent bleeding inside joints has been the most serious complication of hemophilia. Outcome of orthopedic surgery in adult patients with severe hemophilia A may be influenced by many factors, including concentration of factor VIII (FVIII) and type of blood group. Perioperative dosing of FVIII concentrate is challenging and vary between individuals.
Aims: To evaluate clinical characteristics of adult patients with severe hemophilia A those who underwent orthopedic surgery and preoperative test of FVIII recovery in association with the outcome of surgery.
Methods: This retrospective analysis included adult patients with severe hemophilia A those who underwent orthopedic surgery at a single center from January 2000 to January 2018. Preoperative test of FVIII recovery was done before the surgery. FVIII recovery rate (%/IU^{-1}/kg^{-1}) was calculated using the following formula: [Post-test FVIII level (%) – Pre-test FVIII level (%)]/Test unit of FVIII concentrate (IU)/Body weight (kg). Blood sampling for post-test FVIII level was taken after 30 – 60 minutes from FVIII concentrate infusion. Patients with high titer inhibitors who received bypassing agents were excluded in this study. All patients received VIII concentrate replacement as intermittent bolus infusion during the perioperative hospital stay. Blood sampling for trough FVIII levels were collected during the hospital stay. Target range plasma levels of FVIII during postoperative day (POD) 1 to 3 were defined according to the WFH guideline on management of hemophilia. Complications were defined as reoperation, more than 2 units of red blood cell transfusion, and death.
Results: 98 severe hemophilia A patients with median age of 36 (range, 19 – 64) were included. 84 (86%) of them received surgery for hemophilic arthropathy, including knee (n=41), ankle (n=20), and hip joints (n=16). 69 patients received plasma derived FVIII concentrate and 29 patients received recombinant product during perioperative factor replacement. 20 patients (20%) had low titer inhibitors at the time of admission (median=0.7 BU/ml; range 0.6 – 1.69). The median FVIII recovery rate was 1.7%/IU^{-1}/kg^{-1} (range, 0.3 – 7.7). FVIII recovery rate of lower 25% and upper 25% was 1.3 and 2.1%/IU^{-1}/kg^{-1}, respectively. FVIII recovery rate were significantly lower in patients who received plasma derived product than those who received recombinant product (1.6 *vs* 2.1%/IU^{-1}/kg^{-1}, p=0.004). Patients with blood group O also showed lower FVIII recovery rate than those with other blood groups (1.3 *vs* 1.9%/IU^{-1}/kg^{-1}, p=0.002). FVIII recovery rate showed a significant positive correlation with body mass index (r=0.22, p=0.029). Patients who had complications were older than those without complications (mean age: 45 *vs* 34 years old, p<0.001). More patients in blood group O could not reached target FVIII levels during POD 1-3 than those in other blood groups (58% *vs* 28%, p=0.013). FVIII recovery rate was significantly lower in patients who could not reached target FVIII levels during POD 1-3 (1.4 *vs* 1.8%/IU^{-1}/kg^{-1}, p=0.029). Patients who had complications had significantly lower FVIII recovery rate than those without complications (1.4 *vs* 1.8%/IU^{-1}/kg^{-1}, p=0.044).
Summary and Conclusions: FVIII recovery rate, in addition to blood group O, could predict the achievement of postoperative target FVIII levels during POD 1-3 and complications after elective orthopedic surgery in adult patients with severe hemophilia A.

PF296

PREDICTION OF INHIBITORS IN HAEMOPHILIA PATIENTS BY SCORE IN ONE CENTER

O. Stasyshyn[1,*], V. Krasisvska[1]

[1]General and Haematological Surgery, SI "Institute of Blood Pathology and Transfusion Medicine of UNAMS, Lviv, Ukraine

Background: Replacement therapy in hemophilia patients is complicated by the formation of inhibitors among 30% of hemophilia A (HA) patients and 3–5% of hemophilia B (HB) patients. The treatment of bleeding and elimination of inhibitors is complicated, costly and not always successful.
Aims: To develop a simple score that stratifies patients with hemophilia according to their risk of developing inhibitory antibodies.to develop a simple score that stratifies patients with hemophilia according to their risk of developing inhibitory antibodies.
Methods: 135 patients with HA and HB divided into two groups: Group I – 74 patients with inhibitors and group II – 61patients without inhibitors. We analyzed 16 factors affecting the tendency to develop inhibitor: type of hemophilia (A or B), severity, age, age at diagnosis, hereditary or sporadic, family history of inhibitors, intensive treatment at initial treatment (ED/1 episode), age at first exposure to FVIII/IX, reason for first treatment with FVIII, FVIII/IX product type, prophylaxis or "on demand" treatment, clotting factor concentrate switching, significant and life-threatening bleeding localization; surgery: I – the urgency (urgent and selective); II – the type (large and small), and the presence of purulent complications. To examine the relationship between risk factors and the likelihood of inhibitor development, we used regression models of discrete choice. Specifically, we estimate the range of one factor binomial choice models to study the individual effects of each factor on the probability of inhibitor development. In addition, we analyze the joint impact of risk factors using multiple logit regression that allows exploring the effects and importance of each factor, controlling for the presence of other factors.
Results: To build a multivariate logit model we used stepwise forward regression with 1%, 5% and 10% significance levels. The first model includes the following factors: age, , switching, FVIII/IX product type, purulent complications and the number of (ED)/1 episode. At 5% significance level, the type of surgery (large and small) as well as positive "inhibitory" history are added. At the 10% significance level, the model additionally contains a variable characterizing the urgency of surgery (urgent or planned). The number ED/1 episode has the highest impact on the probability of inhibitor development: if it increases, the likelihood of

inhibitor development increases by 27%. For patients who switch the type of concentrates, the likelihood of inhibitor development increases by 23%. The effect of the FVIII/IX product type, the age and the type of the surgery - is negative and significant, while purulent complications and burdened "inhibitory" history result in the increase in the likelihood of inhibitor development by 21% and 12%, respectively.
Summary and Conclusions: The prediction based on the multiple logit regression allows to identificate patients at high risk of inhibitor development. According to our model, the factors associated with treatment have the highest impact on the probability of inhibitor development. Based on the results, reducing the frequency of inhibitor development can be achieved by changing the approaches to the treatment of patients with hemophilia.

PF297

REAL WORLD SWITCHING FROM CONVENTIONAL FVIII PRODUCTS TO RFVIIIFC IN FRANCE, GERMANY, ITALY AND THE UK

K.-J. Myren[1], M. van der Sluijs[1], P. Kritikou[1,*], S. Lethagen[1]

[1]Swedish Orphan Biovitrum AB, Stockholm, Sweden

Background: Recombinant factor VIII Fc (rFVIIIFc), an extended half-life product for the treatment of haemophilia A, was first approved by EMA in November 2015. Since then a growing number of patients have been treated with rFVIIIFc in the real world setting. However, limited data are available on physicians' switching behaviour from conventional FVIII products to rFVIIIFc in clinical practice.
Aims: The aim of this physician survey of patient records was to describe the characteristics of patients who switched to rFVIIIFc. The aim was further to analyse the impact of rFVIIIFc on factor consumption and injection frequency in prophylactically treated patients who had switched from conventional FVIII products.
Methods: A random sample of physicians in France, Germany, Italy and the UK, who had initiated treatment with rFVIIIFc during the last 12 months were asked to collect and review patient level information for up to 5 of their most recent rFVIIIFc patients and report the requested information in an on-line electronic survey. The patient record survey was performed during July to September 2017. Data on factor consumption, treatment regimen, duration on treatment, reason for switch and age were some of the key variables collected. Physicians excluded records of patients currently involved in a clinical trial or who currently had an inhibitor to FVIII. The results were reported as descriptive statistics.
Results: The physician survey of patient records included 139 patients who switched to or from rFVIIIFc during the last 12 months. The mean age was 33 years. 53% had severe, 37% moderate and 10% mild haemophilia A. 74% of the rFVIIIFc patients were on long term prophylaxis (LTP), whereas 26% were treated on-demand (OD) or with intermittent prophylaxis (IP). The most common reason for switch was to improve quality of life (40%). In the 87 patients who switched from conventional FVIII prophylactic treatment to rFVIIIFc prophylactic treatment the annualised mean factor consumption decreased from 515,610IU to 378,849IU (27%). Further, the mean number of injections per week was reduced from 3 to 2.1 per week (30% reduction). Patient switch trends to or from rFVIIIFc are outlined below to further describe survey results (Table 1).

Table 1.

	Patients switched to rFVIIIFc			Patients switched from rFVIIIFc		
Regimen before switch	Regimen after switch			Regimen after switch		
	LTP	OD	IP	LTP	OD	IP
LTP	87		1	5		
OD	13	26		3	8	
IP	4	1	7			2

Summary and Conclusions: Patients on prophylactic regimens reduced their mean factor consumption by 27% and their injection frequency by 30%. The most common reason for switching to rFVIIIFc was to improve patients' quality of life. These results are in line with current published real world prophylactic switching data on rFVIIIFc. Further studies are warranted to gather deeper insights into patients' rationale for switching in Haemophilia A, as only the physician perspective was captured in this study.

PF298

APPLICATION OF THE ISTH BLEEDING SCORE IN HEMOPHILIA

N. Fatima[1,*], M. Borhany[2], M. Abid[1], M. Othman[3], T. Shamsi[4]

[1]Research and Development, [2]Hematology, National Institute of Blood Diseases and Bone Marrow Transplantation, Karachi, Pakistan, [3]Biomedical and Molecular Sciences, Queen's University, Ontario, Canada, [4]Hematology, National Institute of Blood disease and Bone Marrow Transplantation, Karachi, Pakistan

Background: Hemophilia is an inherited bleeding disorder. With proper treatment and self-care, patients with hemophilia can maintain an active and productive lifestyle. Hemophilia can be mild, moderate, or severe, depending on the degree of plasma clotting factor deficiency. The ISTH/SSC joint committee established a bleeding assessment tool (BAT), to standardize the reporting of bleeding symptoms. To date, the majority of research on bleeding questionnaires has been focused on von Willebrand disease (VWD) and to a lesser extent on platelet disorders with very little if any on hemophilia.
Aims: The objective of this study was to evaluate the use of ISTH-BAT in hemophilia patients of varying severity at higher hemorrhagic risk, compare the bleeding score (BS) in adult and pediatric groups and to investigate its correlation with plasma factor levels. In developed countries, the diagnosis of hemophilia is usually made during childhood. Due to the limited healthcare resources hemophilia patients in Pakistan are often only recognized after childhood age. This provided the unique chance to compare the association of the BAT and factor levels obtained in previously unknown hemophilia patients (before the factor levels became available) with the BAT in known hemophilia patients within the study.
Methods: This cross sectional analytical study was conducted at the National Institute of Blood Disease & Bone Marrow Transplantation, Karachi, Pakistan after getting approval from institutional ethics committee. One hundred and fifteen patients of Hemophilia A (HA) and Hemophilia B (HB) and 100 healthy male controls comprised of relatives of patients and blood donors were included from 2014 to 2016. Written informed consent was obtained from all participating. A team of hematologist and a trained clinical research officer in the outpatient clinics conducted these assessments and administered the ISTH BAT. The data was analyzed by using SPSS version 23.
Results: A total of 115 patients including 78 HA and 37 HB patients and 100 healthy controls were investigated using the ISTH-BAT. The mean age was 11.8 years for HA patients, 18.1 years for HB patients. Bleeding scores were higher in hemophilia patients compared to controls (P-value= 0.001), but did not differentiate between HA and HB patients (P-value=0.738). BS was lower in the pediatric group compared to the adult group (P-value =0.02) in HA patients, while there was no difference in the BS of pediatric and adult HB patients (P-value=0.3). The BS was very similar in newly diagnosed compared to known hemophilia patients and higher in severe compared to mild HA patients (P-value= 0.004). Muscle hematoma and hemarthrosis were found to be the most common symptoms in HA and HB.
Summary and Conclusions: The ISTH BAT gives comparable results whether the factor levels are known or not. For the first time we generated data on the score in newly diagnosed adult hemophilia patients. Our ongoing study will show, whether the score can predict the risk for bleeding and pediatric and/or adult hemophilia patients.

PF299

MYPKFIT HEMOPHILIA EXPERIENCE IN PEDIATRIC CASES

S. Aytac[1,*], I. Yaman Bajin[1], M. Cetin[1], F. Gumruk[1]

[1]Pediatric Hematology, Hacettepe University, Ankara, Turkey

Background: Prophylaxis is the gold standart treatment of severe Hemophilia A. However prophylaxis regimens in patients with severe Hemophilia A can be individualized according to the age, bleeding phenotype, presence of hemophilic arthropathy, life-style, physical activity and PK. MyPKFIT hemophilia dosing tool let us to estimate indivudial half life with 2 sample using Bayesian method and based on the PK prophile it can easily help to determine dosing and dosing interval.
Aims: Our aim is to show MyPKFIT experince in a small group of patient with severe Hemophilia A.
Methods: 9 patient (FVIII<1% n=7, FVIII≤2% n=2) with a median age of 11 years (2-17 years) were analysed. All were on prophylaxis without inhibitor at the time of analysis. 3 blood samples were drawn at pre-infusion and post infusion (+4 hour and +24 hours) for each case. All were on prophylaxis without inhibitor at the time of analysis. They were receiving prophlylaxis with a 25-40IU/kg adminestered at a frequency of 2 days / a week so FVIII throgh levels were taken in between 48- 72 hours after the last injection. 3 patients had a history of annual 1/2/4 joint bleeding and

the rest no joint bleeding during the last year. 4 had a history of radionuclide synovectomy in 7 joints.
Results: The mean FVIII trough levels for the cases with an initial FVIII <1% and ≤2% were 2.48±0.97%(1.48-3.75%), 5.2±0.5%(4.8-5.6%) respectively. Mean t1/2 for the cases with an initial FVIII<1% and ≤2% were 8.7±1.1 hours(7.2-10.4h), 12±0.4(11.7-12.4h), respectively. Mean t1/2 was found to be longer in patients with an initial FVIII level≤2%. When we match the patients with a bleeding event during the last year and/or HJHS >4 point (n=4 patient) with the MyPKFIT recommendation of increase dose+decrease intervals(n=3) only one patient find to be present in both of these groups.On the other hand rest of these patients(n=5)(patients without any joint bleeding during the last year and/or HJHS<4 point(n=4 patients), patients without any bleeding during the last year and/or HJHS>4 points(n=1)) myPKFIT recommend to increase dose interval without changing dose or decrease dose +increase dose interval.
Summary and Conclusions: According to our experience with the help of MyPKFIT, clinic evaluation and HJHS we can easily find high risk of patients and individualize their dose and intervals in a proper manner in developping countries.

PF300

CHALLENGES OF MANAGEMENT OF REFUGEE CHILDREN WITH CONGENITAL FACTOR DEFICIENCIES

T.N. Güçer[1], Z. Şalcıoğlu[1], E. Türkkan[2], C. Bayram[1], E.P. Uysalol[1], N.N. Ozdemir[1,*]

[1]Pediatric Hematology Oncology, Kanuni Sultan Suleyman Education and Research Hospital, [2]Pediatric Hematology Oncology, Okmeydani Research and Training Hospital, Istanbul, Turkey

Background: Refugee patients with congenital factor deficiencies (CFD) are faced with problems such as delayed diagnosis, inability to access specialist care, inadequate treatment and associated joint damage, more often than other patients. Here, we present the demographic data, treatment, outcome and problems in management of refugee children in Istanbul, Turkey.
Aims: Hemophilia and rare factor deficiency patients from two centers caring refugee patients between 2011 and 2017 were included.
Methods: A retrospective review of patients' files was performed.
Results: Of a total 526 congenital factor deficiency patients, on follow-up, 20 refugee patients were included (18 male, 2 female). Mean age of the patients was 12±10.5 years (Range 1.3-40 yrs). Nineteen were from Syria and one was from Egypt. Fifteen had history of coagulation disorder in the family. Nine had HA, 5 had HB, 2 had FVII deficiency, 2 had afibrinogenemia and 2 had vWD. Two HA, 3 HB, 2 vWD and 2 afibrinogenemia patients were consanguineous. Three hemophilia patients were diagnosed due to excess bleeding at circumcision, 11 were diagnosed after joint bleeding or muscle haematoma. 6 (2 vWFD, 2 FVII, 2 afibrinogenemia) were diagnosed after mucocutaneous bleeding. Mean age of the diagnosis was 2.2 yrs (Range 2 days-17 yrs). Only one patient from Egypt was treated with specific factor concentrate on demand before migration. Rest of the patients were treated with fresh frozen plasma (FFP) on demand in their country. No information on exposure days was available. In Turkey, all patients were treated with factor concentrate after diagnosis if required. No inhibitor was detected in any of the patients. Six patients had target joints.
Summary and Conclusions: The number of refugees is increasing worldwide due to conflicts and war which affect many public health issues. Over 2 million refugees are estimated to migrate to Turkey in recent years. Chronic diseases in refugees cause a substantial burden to the health systems of the host countries. Patients are confronted with language barriers, problems in compliance to treatment, shelter and psychosocial problems. Medical records, factor exposure days, previous treatment, inhibitor history or viral infections are unknown to health care staff caring factor deficiency patients. Analysis of care of refugee patients with CFD is needed to inform future responses.

Bone marrow failure syndromes incl. PNH – Biology & Translational Research

PROTEIN EXPLORER IN THE CONTEXT OF OVERLAP OF BONE MARROW FAILURE DISORDERS

A. Alaiya[1,*], Z. Shinwari[1], H. Alzahrani[2], T. Owaidah[3], F. Al Mohareb[2], F. Al Sharif[2], R. Al Nounou[3], W. Rasheed[2], R. El Fakih[2], A. Hanbali[2], M. Shaheen[2], F. Alfraih[2], H. Shahrukh[2], M. Dasouki[4], N. Chaudhri[2], S.O. Ahmed [2], M. Aljurf[2]

[1]Stem Cell & Tissue Re-Engineering Program, Research Center, [2]2Adult Hematology/HSCT Section, Cancer Center, [3]Hematopathology Section, Department of Pathology & Laboratory Medicine, [4]Department of Genetics, King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia

Background: There is considerable overlap among BMFs entities impacting on accurate diagnostic pitfalls and caveats. The lack of surveillance tools for disease progression and possible cancer development poses significant implications on the management and care of these patients. It is therefore fundamental to understand the indications and limitations of the emerging number of analysis platforms that requires interdisciplinary interactions to overcome this difficulty.
Aims: We have aimed to identify and validate panels of disease specific/disease associated proteomics based biomarkers of potential clinical value in patients presenting with various forms of bone marrow failure syndromes including Severe Aplastic Anemia (SAA), Paroxysmal Nocturnal Hemoglobinuria (PNH) and Hypoplastic Myelodysplastic Syndrome (MDS). Others are Inherited BM Failure Syndromes (IBMFS), Fanconi Anemia (FA), Cytopenia-Severe Congenital Neutropenia (CSCN), and Thrombocytopenia (TCP).
Methods: Peripheral blood plasma (PBP) samples from 49 subjects diagnosed with bone marrow failure; including AA/ MDS/ PNH/FA/IBMFS/CSCN/TCP as well as PBP from 10 healthy subjects and 2 family unaffected family members of two affected subjects were analyzed using liquid chromatography tandem mass spectrometry (LC-MS/MS).
Results: Well over 400 unique protein species were identified from PBP of which 106 were significantly differentially expressed (≥2 to ∞ - fold change & p <0.05) between SAA/MDS/PNH/ Normal control subjects. These protein fingerprints independently discriminates all patients and control subjects into four distinct clusters using principal component analysis.
The expression changes of the 106 proteins were tested on four additional samples groups (Fanconi/CSCN/TCP/SAA+IBMF) and all samples were classified distinctively into 8 clusters using PCA. Furthermore, the diagnostic accuracy of the 106 protein signatures was tested on three additional samples without prior knowledge of their proven or presumptive diagnosis. Remarkably, these new samples stood out as outliers from the 8 other distinct cohorts. These samples ultimately turned out to be Dyskeratosis Congenita (DKC). Furthermore; analysis of two unaffected family members shares similar protein signatures as their corresponding affected siblings suggesting the likelihood of being carriers or having the risk of developing the disease. Some of our identified potential biomarker proteins were implicated in hematological diseases and multiple signaling networks associated with known bone marrow failure syndrome genes using Ingenuity Pathway Analysis (Figure 1).

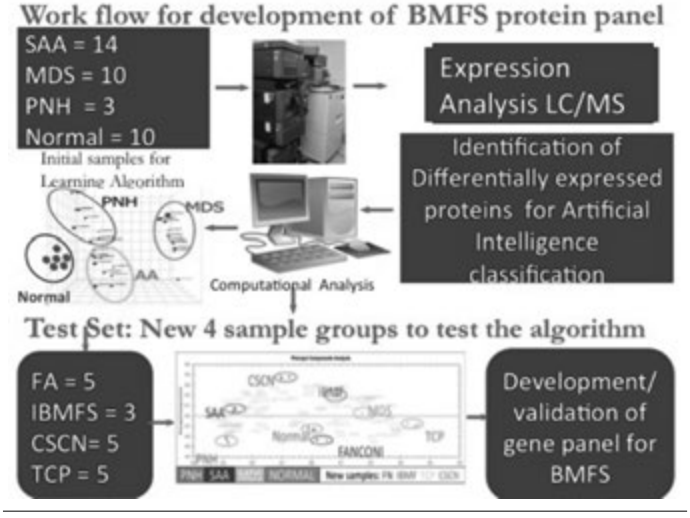

Figure 1.

Summary and Conclusions: We have identified 106 proteins panel as potential biomarker protein signatures capable for objective molecular diagnosis of bone marrow failure entities. It is anticipated that this study might reveal sets of proteins that are unique to each of the BMF entities. These proteins once validated, on a larger cohort of patients, might be valuable to complement the currently existing genetic alterations parameters for reliable and objective disease diagnosis, prognostic indicators in the management of and clinical outcome of bone marrow failure syndrome patients.

PF302

NOVEL MUTATIONS IN PATIENTS WITH TELOMEROPATHIES

M. Haubitz[1,*], I. Helsen[1], E. Oppliger Leibundgut[1,2], G.M. Baerlocher[1,2]

[1]Department for BioMedical Research, Bern University, [2]Department of Hematology, University Hospital Bern, Bern, Switzerland

Background: Telomeropathies are characterized by insufficient telomere maintenance resulting in short telomeres due to defects in the telomerase, shelterin, CST or Cajal body complex. The phenotypes of patients (pts) with such defects are very heterogeneous ranging from mild cytopenias to severe bone marrow failure (BMF), classical dyskeratosis congenita (DC, triad of leukoplakia, hyper- and hypopigmentation, nail dystrophy), lung or liver fibrosis and described are a shorter life span and predisposition of cancer. In part of the pts mutations are found in 12 genes involved in telomere maintenance, however, consequences of novel mutations are often unknown.
Aims: Our aims were to screen suspected individuals and pts for telomere length (TL) and in case of short telomeres to search for telomeropathy-relevant variants as well as functionally characterize novel mutations.
Methods: TL in leukocyte subsets was measured using combined fluorescence *in situ* hybridization and flow cytometry (flow FISH) and compared to percentiles (P) of reference ranges. Mutation detection was performed in 12 genes (*ACD*, *CTC1*, *DKC1*, *NHP2*, *NOP10*, *PARN*, *RTEL1*, *TCAB1*, *TERC*, *TERT*, *TINF2* and *USB1*) by high throughput sequencing. Enzyme activity and altered protein function are investigated by TRAP, Western blot, D-loop recombination assay and immunostaining.
Results: We assessed the TL in leukocyte subsets of 349 blood samples from 235 index pts (IP) (median age 17 years (y), range 0.1-77 y) and 114 relatives (RL) (median age 32 y, range 0.9-69 y) sent for the TL screening due to a suspected telomeropathy. 226/235 IP and 10/114 RL were described with a clinical phenotype; 2% had DC, 59% cytopenias and/or BMF of unknown origin, 11% myeloid neoplasia, 4% other organs involved and 25% suspected telomeropathies. 60% of IP and 38% of RL had TL <1st P and 27% of IP and 34% of RL between the 1st-10th P in all subsets of leukocytes. 82 IP and 42 RL had a mutation analysis. In this cohort 72% of IP, 75% of the 9 affected RL and 45% of non-affected RL had TL <1st P. 34% of IP, 33% of non-affected RL and 78% of affected RL had variants in the genes *TERT*, *TERC*, *DKC1*, *NPH2*, *TCAB1*, *TINF2*, *ACD*, *RTEL1* and *CTC1*. 18 novel and 6 known mutations were identified in IP; recurrent mutations included a known mutation in *TERT* in 3 IP and 2 novel variants in *RTEL1* and *CTC1* in 2 and 4 IP, respectively. In IP of 5 unrelated families with histories of bone marrow failure and with TL <1st P, but no signs for defects in other organs, we found novel heterozygous variants in *TERC* and *TERT* leading to reduced telomerase enzyme activity. Two novel heterozygous *RTEL1* variants, not affecting telomerase activity, but binding of the telomerase to telomeres, were detected in 3 unrelated families with histories of bone marrow failure, head and neck cancer and liver fibrosis and TL <10th P. In 5 IP with variable clinical signs and TL <10th P two or three heterozygous variants each in the genes *TERT*, *TERC*, *NHP2*, *ACD*, *CTC1* and *RTEL1* were detected.
Summary and Conclusions: We found mutations in 39% of IP and affected RL, a high proportion of novel variants and 2 recurrent in 6 families. 82% of IP or RL with mutations present TL values in leukocyte subsets <1st P but 13% fall in the range 1st-10th P. The investigation of the functional consequences of important mutations in genes of the telomerase, shelterin, CST or Cajal body complex either alone or in combination is ongoing. Since telomerase activity can be increased by hormonal stimulation as a treatment option, uncovering the pathophysiologic mechanisms of these mutations is of great importance.

PF303

LOW PROPORTION OF MYELOID DERIVED SUPPRESSOR CELL POPULATIONS IN THE PERIPHERAL BLOOD OF PATIENTS WITH CHRONIC IDIOPATHIC NEUTROPENIA

N. Bizymi[1,*], M. Velegraki[1], A. Damianaki[1], H. Koutala[1], V. Kaliafentaki[1], M. Ximeri[1], P. Kanellou[1], I. Mavroudi[1], C. Pontikoglou[1], H. Papadaki[1]

[1]Haemopoiesis Research Laboratory, School of Medicine, University of Crete and Department of Haematology, University Hospital of Heraklion, Heraklion, Greece

Background: Chronic Idiopathic Neutropenia (CIN) is a mild bone marrow (BM) failure syndrome characterized by presence of oligoclonal/monoclonal T-cell populations with myelosuppressive properties. The triggering event leading to T-cell activation remains unknown. The myeloid derived suppressor cells (MDSCs) are cells of myeloid origin capable of suppressing T-cell responses mainly through activation of arginase 1 and nitric oxide synthase 2 and production of reactive oxygen species, modulation of macrophage polarization and induction of T-regulatory cells. MDSCs are divided in two subpopulations, namely the polymorphonuclear (PMN)-MDSCs and monocytic (M)-MDSCs characterized by the immunophenotype HLA-DR$^{low/-}$CD11b^{+}CD33^{+}CD15^{+} and HLA-DR$^{low/-}$CD11b^{+}CD33^{+}CD14^{+}, respectively. The possible involvement of MDSCs in the aberrant T-cell responses associated with CIN has not been studied before.
Aims: The aim of the present study is to investigate the quantitative characteristics of MDSCs in the peripheral blood (PB) of CIN patients in comparison to healthy subjects.
Methods: We have studied 34 patients fulfilling the previously reported diagnostic criteria for CIN and 23 age- and sex-matched with the patients, healthy subjects. According to the criteria, CIN patients had absolute neutrophil counts (ANC) below 1800 x 10^6/L for a period at least 3 months, had no clinical, serological or ultrasonic evidence of any underlying disease associated with neutropenia, no history of exposure to irradiation, use of chemical compounds or intake of drugs to which neutropenia might be ascribed, normal BM karyotype and negative antineutrophil antibodies. Cyclic cases were excluded by serial neutrophil enumerations. The proportion of PB MDSCs was evaluated by flow cytometry. According to the current recommendations (*Bronte et al., Nature Communications 2016*), MDSCs should be studied in the fraction of PB mononuclear cells (PBMCs). Thus, we have changed our previously reported (EHA 2017) protocol that included staining of total PB and performed flow cytometric analysis of PMN-MDSCs and M-MDSCs in the PBMC fraction.
Results: Surprisingly, in contrast to our previous preliminary results (EHA 2017) from total PB, CIN patients displayed decreased proportion of M-MDSCs in the PBMC fraction (0.657±0.664) compared to the healthy controls (2.085±2.496; P=0.0228). No statistically significant difference was identified between CIN patients and controls in the proportion of PMN-MDSCs. The proportion of M-MDSCs correlated with the number of ANC (r=0.2976, P=0.0273) suggesting that patients with more severe neutropenia display lower M-MDSCs numbers. A positive correlation was also found between the proportion of M-MDSCs and the number of PB monocytes (r=0.2672, P=0.0486).
Summary and Conclusions: CIN patients display low proportions of M-MDSCs compared to the healthy subjects. These cells normally protect from uncontrolled immune responses; therefore the low number of these cells in CIN patients may contribute to the sustained chronic inflammation. The results of this study contribute to the better understanding of the pathogenesis of CIN and underlie the importance of the methodology used to study this population of cells.

Bone marrow failure syndromes incl. PNH – Clinical

PF304

CLINICAL SIGNIFICANCE OF PNH CLONES IN 3085 PATIENTS WITH CYTOPENIA: A LARGE SINGLE-CENTER EXPERIENCE

B. Fattizzo[1,*], A. Dunlop[1], R. Ireland[1], S. Kassam[1], D. Yallop[1], G. Mufti[1], J. Marsh[1], A. Kulasekararaj[1]

[1]Hematology, King's College Hospital, London, United Kingdom

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare clonal disorder due to GPI anchored proteins deficiency on blood cells surface, resulting in complement activation and chronic intravascular hemolysis. Along with classic one, PNH in the setting of bone marrow disorder [aplastic anemia (AA)/myelodysplastic syndrome (MDS)], and subclinical PNH, with a small PNH population and no evidence of hemolysis, have been described. The prevalence and clinical significance of PNH clones, especially small ones, detected by high sensitive FLAER are still under debate.
Aims: To evaluate the prevalence of PNH clone in 3085 patients with cytopenia tested at a single tertiary center, and to assess their relationship with disease severity and outcome.
Methods: We collected clinical (diagnosis, stage, therapy, complications and outcome) and laboratory features (complete blood counts, LDH, PNH clone) of 3085 patients tested from March 1998 till October 2017.
Results: Main baseline clinical and laboratory characteristics of patients, divided according to presence or absence of PNH clones, are shown in Table 1.

Table 1. Patients screened for PNH clones at our Institution.

N 3085	PNH neg	PNH pos
Study period	Mar 1998 to Oct 2017	
Number of patients, N (%)	2311 (75)	774 (25)
Male/Female ratio	1.17	1.05
median age years (range)	55 (0-91)	47 (1-89)*
	N=2160	N=744
MDS N(%)	693 (32)	176 (23.6)*
AA N(%)	204 (9.4)	327 (43.9)*
MDS/AA N(%)	5 (0.2)	22 (2.9)*
Acute leukemia N(%)	209 (9.6)	29 (3.9)*

*p≤0.0001, **p=0.01

PNH clone (PNH+) was found in 774 cases (25%), mostly AA (44%), MDS (24%), and florid hemolytic PNH (13%). Clone size, evaluated on granulocyte in 468 cases, was <1% in 224, 1-50% in 120, and >50% in 124, and correlated with LDH levels (p<0.0001). Considering diagnosis, PNH+ MDS displayed smaller clones compared to AA and haemolytic PNH ones (60% of cases with PNH clone size >50%). Serial PNH clone evaluation (n=230), showed mean clone size increase along time, particularly in haemolytic PNH cases treated with eculizumab. Among PNH- cases, the most frequent reason for testing were MDS (32%), idiopathic cytopenia (23.7%), and isolated thrombosis (13%). PNH+ cases were younger (p<0.0001), more frequently anaemic (p=0.01), thrombocytopenic (p=0.0003), or pancytopenic (p<0.0001), with higher LDH (p<0.0001). PNH+ patients also showed longer OS from first test [mean 14.24±0.35 years (95%CI 13.56-14.93) *versus* 8.16±0.26 years (7.64-8.68), p<0.0001]. PNH+ MDS patients (N=176, 20.3%) were significantly younger, more hypoplastic (p<0.001), and less frequently showed excess of blast (p=0.01); they also showed deeper cytopenias

(p=0.04 for Hb, and p<0.0001 for PLT), and had higher LDH levels (p<0.0001). Moreover, they had more frequently received cyclosporine and ATG (p=0.0001), less frequently chemotherapy or azacytidine (p<0.0001 and p=0.002), and 7 cases had been treated with eculizumab. PNH+ MDS showed lower rate of higher risk progression (p=0.003), AML evolution (p=0.01), and death (p<0.0001), but had higher incidence of thrombotic events (p=0.05). Survival analysis also showed a longer OS for PNH+ MDS [mean 11.9±0.7 years (10.5-13.3) *vs* 7.3±0.3 (6.6-7.9), p<0.0001] compared to PNH- ones. PNH+ AA (61%) showed deeper thrombocytopenia (p<0.0001), higher reticulocyte counts (p=0.0004) and LDH values (p<0.0001). PNH+ AA were more frequently treated (p<0.0001), and showed lower MDS progression and deaths (p=0.01 and p<0.0001), and longer OS [mean 15.8±0.43 years (14.9-16.7) *vs* 6.5±0.35 (5.8-7.21), p<0.0001].

Summary and Conclusions: Prevalence of PNH clones of any size is high in patients with bone marrow failure and carries prognostic significance. In this largest reported retrospective series, even the presence of small clones correlates with lower blood counts, increased LDH, and occurrence of thrombosis. Finally, PNH positivity seems to be more frequent in patients of younger age and to predict a better survival

PF305

RA101495, A SUBCUTANEOUSLY-ADMINISTERED PEPTIDE INHIBITOR OF COMPLEMENT COMPONENT C5, FOR THE TREATMENT OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA: PHASE 2 RESULTS

A. Hill[1,*], H. Schrezenmeier[2], P. Hillmen[1], J. Szer[3], H. Pullon[4], R. Spearing[5], C. Forsyth[6], E. Armstrong[7], C. Patriquin[8], I. Weitz[9], Y.-M. Shen[10], T. Munir[1], M. Griffin[1], M. Hoarty[11], A. Ricardo[11], R. Farzaneh-Far[11], A. Kulasekararaj[12]

[1]Department of Haematology, St. James' Institute of Oncology, Leeds, United Kingdom, [2]Center for Transfusion Medicine and Immunogenetics, Ulm University, Ulm, Germany, [3]Royal Melbourne Hospital, Melbourne, Australia, [4]Waikato Hospital, Hamilton, [5]Christchurch Hospital, Christchurch, New Zealand, [6]Jarrett Street Specialist Center, Gosford, Australia, [7]Helsinki University Cancer Hospital, Helsinki, Finland, [8]Toronto General Hospital, Toronto, Canada, [9]University of Southern California, Los Angeles, [10]University of Texas Southwestern Medical Center, Dallas, [11]Ra Pharmaceuticals, Inc., Cambridge, United States, [12]King's College School of Medicine, United Kingdom, United Kingdom

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare, clonal, hematopoietic stem cell disorder caused by a deficiency of glycosylphosphatidylinositol-anchored proteins (GPI-AP) on cell surfaces. Patients with acquired mutations in the phosphatidylinositol glycan class A gene lack functional complement-regulatory proteins, resulting in abnormal accumulation of complement fragments on the surface of erythrocytes, and subsequent intravascular hemolysis by the membrane attack complex (MAC). RA101495 is a synthetic macrocyclic peptide that binds with high affinity to C5 and prevents its cleavage into C5a and C5b, thereby preventing the assembly and cytolytic activity of MAC on GPI-AP-deficient erythrocytes. In a completed Phase 1 study in healthy volunteers, subcutaneously-administered RA101495 was safe and well-tolerated, and achieved rapid, complete, and sustained inhibition of complement activity.

Aims: Study RA101495-01.201 and RA101495-01.203 are international, multicenter, open-label, Phase 2 dose-finding studies designed to evaluate the safety, tolerability, and efficacy of RA101495 in patients with PNH.

Methods: Study RA101495-01.201 enrolled separate cohorts based on prior eculizumab treatment history: the treatment naïve cohort recruited 10 patients who had not previously received eculizumab; the eculizumab switch cohort recruited 16 patients who had received treatment with eculizumab for at least 6 months prior to Screening. Study RA101495-01.203 recruited 3 patients with an inadequate response to eculizumab. All patients received an initial loading dose of 0.3 mg/kg of RA101495 administered subcutaneously (SC) at the Day 1 visit. Thereafter, patients self-administered once daily SC doses of 0.1 mg/kg or, upon dose escalation, 0.3 mg/kg for 12 weeks. The primary endpoint was the change in lactate dehydrogenase (LDH) from baseline to the mean of the Week 6-12 values. Patients completing 12-weeks of dosing were eligible to enter a long-term extension study RA101495-01.202.

Results: In treatment naïve patients, the pre-specified primary endpoint was met for LDH reduction from baseline to the mean of Weeks 6-12 (p=0.002). All 10 treatment-naïve patients exhibited LDH reductions on RA101495, and all successfully completed 12 weeks of dosing. The reduction in LDH levels after initiation of RA101495 was rapid and robust, and has been sustained in the long-term extension study for up to 36 weeks of dosing (Figure 1). The effect of RA101495 to reduce LDH in treatment-naïve patients was accompanied by consistent and complete (95-98%) suppression of complement activity in an *ex-vivo* antibody-sensitized sheep red blood cell (sRBC) direct hemolysis assay. LDH reductions in treatment-naïve patients were associated with reductions in transfusion dependence and improvement in quality of life measures. In patients switching from eculizumab to RA101495 a divergent LDH response was observed, with prior transfusion-dependence on eculizumab associated with breakthrough hemolysis after switching. Overall, the majority (16/21, 76%) of patients completing the 12-week study continue to receive RA101495 in the longterm extension.

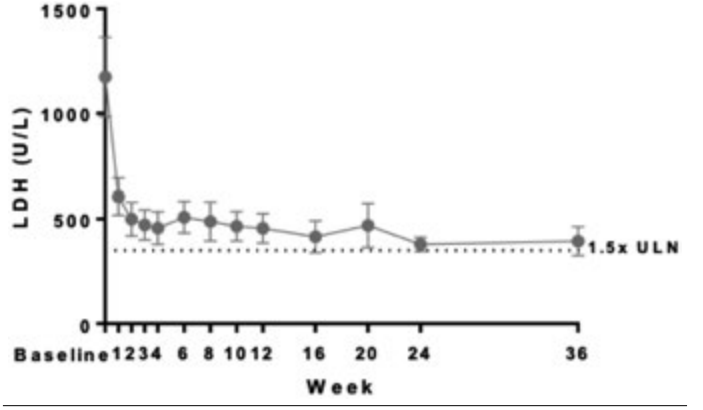

Figure 1.

Summary and Conclusions: RA10495, self-administered daily by subcutaneous injection, appears safe and well-tolerated in patients with PNH. RA101495 rapidly and robustly reduces LDH to the levels seen in patients receiving eculizumab, and which are associated with improved long-term outcomes in PNH. These Phase 2 findings support a phase 3 confirmatory study, and indicate that RA101495 may provide a more convenient and cost-effective treatment for PNH patients.

PF306

DIFFICULTIES IN DIAGNOSIS AND MANAGEMENT IN PATIENTS WITH CYCLIC NEUTROPENIA

S. Mellor-Heineke[1], F. Froemling[1], M. Klimiankou[2], J. Skokowa[2], K. Welte[3], C. Zeidler[1,*]

[1]Department of Hematology, Hemostasis,Oncology, Stem Cell Transplantation, Hannover Medical School, Hannover, [2]Department of Oncology,Hematology, Immunology, [3]Pediatric Hematology, Oncology, University of Tuebingen, Tuebingen, Germany

Background: Cyclic neutropenia (CyN) is a rare hematological condition in which underlying ELANE mutations can be detected in approximately 50% of patients. The Diagnosis of CyN is based on the cycling course of neutrophils which decreases to <0.5 x 109/L, at 21 day intervals. Patients suffer from recurrent bacterial infections during the neutrophil nadir. Typical infections include recurrent aphthae, tonsillitis or skin abscesses as well as early loss of teeth.

Aims: Depending on the time of the cycle bone marrow morphology can vary between normal or severe maturation arrest. Normal bone marrow morphology may be misleading towards autoimmune neutropenia. Therefore patients do not receive adequate therapy. Here we describe the difficulties of making the diagnosis already in the first months of life.

Methods: We analyzed the clinical data of 100 patients with CyN reported to the Severe Chronic Neutropenia International Registry (SCNIR) Europe.

Results: Out of the 100 patients with CyN 58/100 (28 female, 30 male) patients revealed a mutation in the ELANE gene, 9/100 patients have been tested negative and 33/100 patients have not been tested so far. The age at diagnosis ranges from 0 to 35.5 years in the 58 ELANE positive patients, including 11 families with 2 or more affected family members. 53/58 patients are receiving G-CSF treatment with a median dose of 2 µg/kg/day (range 0.15–17.86 µg/kg/d). Under G-CSF therapy infectious episodes are significantly reduced. Intriguingly, treatment with G-CSF in patients with CyN does not abrogate cycling, but increases the absolute neutrophil count, shortens the cycle periodicity from the usual 21 days to about 14 days and prevents serious infections. CyN has a lower risk of malignant evolution as compared to other patients with ELANE mutation positive congenital neutropenias. To document the difficulties of making the diagnosis already in the first months of life, we will present seven young adult patients who have been diagnosed with CyN at the age of 12-30 years. All 7 patients have a history of recurrent bacterial infections starting in early childhood. In 3 patients bone marrow aspirations showed normal maturation. 2 patients

presented with severe parodontitis and imminent loss of teeth. Complete blood counts (CBC) were performed sporadically before G-CSF treatment showing fluctuating absolute neutrophil counts ranging from 0-3400/µl. CyN diagnosis was finally established with the collection of CBC 2-3x/week over a period of 4-6 weeks. In all 7 patients genetic analysis revealed an ELANE mutation. G-CSF therapy was initiated on a daily basis and it is well tolerated. However the cycling of neutrophils is still present under G-CSF treatment.

Summary and Conclusions: Cyclic neutropenia still remains difficult to discriminate from other types of congenital neutropenia. The delay of diagnosis is mainly due to milder morbidity and insufficient number of blood counts available to document the cycle and the heterogeneity of bone marrow morphology. There might be a dark digit of undiagnosed patients suffering from severe infections who have not been diagnosed so far. ELANE-CyN Patients with affected family members are often diagnosed earlier than patients with *de-novo* mutations due to the awareness of the disease. To diagnose CyN it is most important to collect a sufficient number of CBCs (3x/week over a period of 6 weeks). The presence of ELANE mutations does not discriminate between CyN and other congenital neutropenias. G-CSF therapy given at an individual dose on a daily basis is beneficial to protect from infections.

PF307

CLINICAL AND MORPHOLOGIC PREDICTORS OF OUTCOME IN APLASTIC ANEMIA PATIENTS TREATED WITH ELTROMBOPAG

B. Fattizzo[1,*], N. Benson-Quarm[2], A. Hill[3], L. Arnold[4], K. Riley[5], T. Munir[4], M. Griffin[4], R. Ireland[2], H. De Lavallade[2], D. Mc Lornan[2], K. Raj[2], G. Mufti[2], J. Marsh[2], A. Kulasekararaj[2]

[1]Haematology, [2]Hematology, King's College Hospital, London, [3]Haematology, [4]Hematology, Leeds Teaching Hospital, [5]Hematology, St James's University Hospital, Leeds, United Kingdom

Background: Aplastic anemia (AA) is a rare autoimmune disease with high morbidity and mortality mainly due to bleeding and infections. Although immunosuppressive therapy (IST) is a highly effective first line treatment, up to 30-40% of cases would be refractory to or relapse after IST. TPO mimetic eltrombopag (EPAG) has demonstrated 40% response in refractory AA, however little is known about predictors of response.

Aims: To evaluate clinical/morphologic predictors of response and outcome in a cohort of EPAG treated patients.

Methods: 49 AA patients treated with EPAG in a compassionate use program from January 2012 to July 2017 were evaluated. Clinical and hematologic parameters including treatment response (PR=transfusion independence, CR=hematologic normalization) and marrow characteristics were collected.

Results: Table 1 shows baseline clinical and morphologic characteristics: all cases were transfusion dependent and 4 showed cytogenetic aberrations (+8, delY, and del13q in 2 cases). 43 cases had received a previous treatment (IST or androgen). Patients received EPAG for a median of 4 months (range 3.5-30), and 11 cases (22%) responded, of whom 4 PR and 7 CR. Median time to best response was 3 months. Compared to baseline, 21% of cases became RBC and 14% PLT transfusion independent. Hematologic improvement was observed in all three lineages (mean Hb, PLT and ANC increase was 34±12.4 g/L p<0.001, 80±53x10^3/mcL p<0.001, and 1.25±0.95x10^3/mcL, p=0.02, respectively). The presence of moderate disease was associated with a better response (73% in responders *vs* 24 in non-responders, p=0.004), together with a lower lymphoid marrow percentage (9.1 *vs* 18.1%, p=0.04), and with a smaller PNH clone (0.69±1.1% *versus* 11.22±24%, p=0.01). Patients who relapsed after IST showed a better response to EPAG (p=0.05). Marrow cellularity significantly improved after EPAG therapy in responders (p=0.004), whereas PNH clone dynamic changes did not show any relationship with response. 29% of cases experienced an adverse event including nausea (N=2, grade I and II), diarrhea (2, grade II and III), liver enzyme elevation (3, grade II), rash (grade II), muscle cramps (grade I), pneumonia (grade III), sepsis (grade III), and bone marrow fibrosis (2). Eleven patients (9 responders and 2 non-responders) are still on treatment, whereas 38 discontinued because of death (11), lack of response (21), loss of response (2), evolution to MDS (1), treatment intolerance (1), no response with increase in marrow fibrosis (1), and longstanding CR with bone marrow fibrosis (1). Three cases relapsed after 7, 15 and 34 months, respectively. One received danazol, another cyclosporin and tacrolimus, and the latter was re-challenged with EPAG with a new CR. Among non-responders, 10 cases received supportive care, 6 androgens, 1 ATG, 3 cyclosporin, and 7 underwent HSCT. One patient with large PNH clone was treated with eculizumab. Median overall survival (OS) calculated from the beginning of eltrombopag was 9 months (range 4-54 months), and was significantly longer in patients responding to eltrombopag therapy (34 *versus* 7 months, p=0.003), with 100% OS in responders *versus* 50% in non-responders at 12 months.

Table 1. Baseline clinical and laboratory characteristic of AA patients enrolled.

	Patients N=49
Age years mean±SD	62±16.4
Gender F/M	22/27
AA type	
acquired N(%)	48 (98)
inherited N(%)	1 (2)
AA severity	
moderate N(%)	22 (44)
severe N(%)	14 (29)
very severe N(%)	13 (27)
Overlapping MDS N(%)	6 (12)
EPO levels (N=32,65%) mean±SD	695.32±599
TPO levels (N=10,20%) mean±SD	1892.04±925.99
Hb g/L, mean±SD	89±16
PLT x10 ^{9}/L mean±SD	21±16*
ANC x10 ^{9}/L mean±SD	1±0.88*
Transfusion dependence	
RBC N(%)	43 (88)
PLT N(%)	42 (86)
BM features (N=46, 94%)	
cellularity % mean±SD	16.08±13.5
MGK	
absent N(%)	22 (48)
reduced N(%)	18 (39)
dysplastic N(%)	4 (9)
normal N(%)	2 (4)
Lymphoid infiltrate % mean±SD	16.15±19.19
PNH clones positivity N(%)	32 (65)
Cytogenetic abnormalities N(%)	4 (8)
Normal	37 (76)
Failed	8 (16)
Abnormal	4 (8)

*Mean PLT were 34±7x10^9/L and mean Hb 110±13 g/L in transfusion independent patients.

Summary and Conclusions: EPAG is effective and safe in the real world setting, although with a lower response rate (22%). Non-severe AA, relapsed disease rather than refractory AA, smaller PNH clone, and lower marrow lymphoid percentage seem to correlate with better response to treatment. Finally, response to treatment significantly predicts better survival.

PF308

A COMPARATIVE STUDY OF INTENSIVE IMMUNOSUPPRESSIVE THERAPY AND HAPLOIDENTICAL TRANSPLANTATION FOR YOUNG SEVERE APLASTIC ANEMIA

M. Chen[1,*], Y. Wu[2], W. Xiaoxiong[2], B. Han[1]

[1]Department of Hematology, Peking Union Medical College Hospital, Peking Union Medical College & Chinese Academy of Medical Sciences, [2]Department of Hematology, The First Affiliated Hospital, Chinese PLA General Hospital, Beijing, China

Background: Intensive immunosuppressive therapy of anti-thymocyte immunoglobulin(ATG) combined with CsA is the first choice for young severe aplastic anemia patients without matched sibling donor.Haploidendical donor hematopoietic stem cell transplantation (HID-HSCT) has been improved greatly and showed similar efficiency as matched sibling donor transplantation.

Aims: This study aimed to compare the differences of intensive immunosuppressive therapy(IST) and HID-HSCT for young patients with severe aplastic anemia.

Methods: A retrospective study of 55 severe aplastic anemia(SAA) patients aged 14-30 years old was done. They were treated with anti-thymocyte immunoglobulin(ATG) combined with CsA (29 cases) or HID-HSCT (26 cases). The efficacy, survival, side effects and costs of two groups were compared.

Results: The median follow-up of survival patients was 30 (12-71) months. Complete remission (CR) in IST group and HID-HSCT group were 58.6% *vs* 84.6% (P=0.034), and overall reaction (OR) was 86.2% *vs* 84.6%(P=1.000), respectively. There was no significant difference in estimated overall survival for 5 years (IST 77.9±11.7% *vs* HID-HSCT 82.1±8.4%) and event free survival (IST 67.6±11.7% *vs* HID-HSCT 69.2±9.1%). The relapse rate of IST group was 3.4% and the clonal transformation was 13.8%. In the HID-HSCT group, both relapse and clonal

transformation was 0, but the incidence of grade II-IV aGVHD and extensive and limited cGVHD was 19.2% and 15.4%. The hospitalization expense in IST group was significantly lower than that in HID-HSCT group (median $ 24 thousands *vs* $ 54 thousands, P=0.000) (Figure 1).

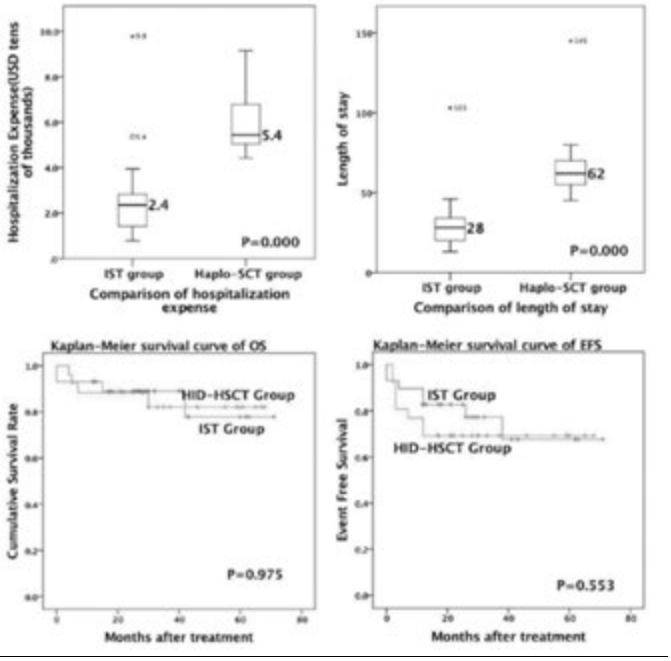

Figure 1.

Summary and Conclusions: IST should still be the first choice for young SAA without matched sibling donors. HID-HSCT can improve the outcome of patients who failed by IST, relapsed or clonal transformed.

PF309

EFFECTIVENESS OF ECULIZUMAB IN PNH PATIENTS RECEIVING CONCOMITANT IMMUNOSUPPRESSIVE THERAPY

A. Hill[1,*], R. Peffault de Latour[2], A.G. Kulasekararaj[3], M. Griffin[1], R.A. Brodsky[4], J.P. Maciejewski[5], A. Wilson[6], J.L. Marantz[6], H. Schrezenmeier[7]

[1]Leeds Teaching Hospitals, Leeds, United Kingdom, [2]Hôpital Saint-Louis AP-HP, Paris, France, [3]King's College Hospital, London, United Kingdom, [4]Johns Hopkins University School of Medicine, Baltimore, [5]Taussig Cancer Institute, Cleveland Clinic, Cleveland, [6]Alexion Pharmaceuticals, Inc., Lexington, United States, [7]Institute of Transfusion Medicine, University of Ulm and Institute of Clinical Transfusion Medicine and Immunogenetics, German Red Cross Blood Transfusion Service Baden-Württemberg-Hessen and University Hospital Ulm, Ulm, Germany

Background: Paroxysmal nocturnal hemoglobinuria (PNH) often occurs concurrently with aplastic anemia (AA), and immunosuppressive therapy (IST) is commonly used in the management of AA. Data regarding concomitant use of eculizumab and IST in patients with PNH and AA are limited. The International PNH Registry (NCT01374360) is a prospective, multinational, observational study to collect data on the long-term efficacy and safety of eculizumab treatment.
Aims: To evaluate real-world effectiveness of eculizumab in PNH patients receiving concomitant IST.
Methods: Patients enrolled in the PNH Registry on or before January 1, 2018, with known demographics and enrollment date, who (1) ever reported a diagnosis of AA, (2) were ever treated with eculizumab, and (3) were ever treated with IST (defined as cyclosporine and/or anti-thymocyte globulin). Patients were categorized into 3 cohorts: (I) IST before eculizumab, no overlap; (II) IST before eculizumab, with overlap; (III) eculizumab before IST, with overlap. Baseline was defined as initiation of eculizumab for all patients. The numbers of units of red blood cells (RBCs) during follow-up were calculated and summarized as rates with 95% confidence intervals (CIs) using Poisson regression for each cohort. Lactate dehydrogenase (LDH) ratios (LDH/LDH upper limit of normal) within 6 months of baseline and last follow-up were assessed, mean change was adjusted for baseline and cohort, and the following pairwise comparisons were made: cohort I *vs* cohort II; cohort I *vs* cohort III; and cohort II *vs* cohort III.
Results: Results of interest are shown in the Table 1. Patients receiving IST before eculizumab with no overlap (cohort I) had the highest platelet count at baseline (mean [SD], 141.3 [88.07] x 10^9/L) with slightly improved platelet count and the lowest rate (95% CI) of RBC transfusions during follow-up (2.1 [2.0, 2.2]). In contrast, patients receiving IST before concomitant eculizumab (cohort II) and those receiving eculizumab prior to concomitant IST (cohort III) had lower mean (SD) platelet counts at baseline (108.1 [75.32] x 10^9/L and 82.3 [71.26] x 10^9/L, respectively) with platelet count minimally improving or declining and higher transfusion rates (95% CI) during follow-up (3.9 [3.8, 4.1] and 7.3 [6.9, 7.7], respectively). Despite these differences, all 3 cohorts had elevated mean (SD) LDH ratio at baseline: 5.4 (3.23) in cohort I, 4.8 (3.33) in cohort II, and 4.2 (2.80) in cohort III. LDH ratios were reduced during follow-up to 1.5 (1.69), 1.4 (1.40), and 1.2 (0.85), respectively. No significant between-group differences were observed in pairwise comparisons of cohort I *vs* II, cohort I *vs* III, or cohort II *vs* III for adjusted mean change from baseline in LDH or PNH granulocyte clone size.

Table 1.

	Cohort I IST before ecu, no overlap of treatment n=199	Cohort II IST before ecu, with overlap of treatment n=182	Cohort III Ecu before IST, with overlap of treatment n=47
RBC transfusions between baseline and last follow-up	n=192	n=138	n=46

Baseline, mean (SD)	141.3 (88.07)	108.1 (75.32)	82.3 (71.26)
Last follow-up, mean (SD)	152.7 (75.76)	120.4 (69.90)	79.0 (74.72)
Change from baseline to last follow-up, adjusted mean (SE)	19.3 (5.28)	6.4 (6.14)	-30.5 (12.94)*

CI, confidence interval; ecu, eculizumab; eGFR, estimated glomerular filtration rate; GPI, glycosylphosphatidylinositol; IST, immunosuppressive therapy; LDH, lactate dehydrogenase; RBC, red blood cell; SD, standard deviation; SE, standard error; ULN, upper limit of normal.
*P=0.0004 vs cohort I; P=0.0105 vs cohort II.

Summary and Conclusions: This analysis of patients with PNH in a real-world setting confirms the effectiveness of eculizumab during concomitant treatment with IST, which did not differ with the sequence of use.

PF310

EFFECT OF ECULIZUMAB ON TRANSFUSION NEEDS IN PNH PATIENTS WITH AND WITHOUT TRANSFUSION HISTORY

A. Röth[1,*], D. Araten[2], L. Larratt[3], A. Kulasekararaj[4], J. Maciejewski[5], A. Wilson[6], P. Gustovic[7], Y. Kanakura[8]

[1]West German Cancer Center, University Hospital Essen, Essen, Germany, [2]NYU Langone Medical Center, New York, United States, [3]University of Alberta, Edmonton, Canada, [4]King's College Hospital, London, United Kingdom, [5]Taussig Cancer Institute, Cleveland Clinic, Cleveland, [6]Alexion Pharmaceuticals, Inc., Lexington, United States, [7]Alexion Pharma GmbH, Zürich, Switzerland, [8]Osaka University Graduate School of Medicine, Suita, Japan

Background: Eculizumab, a humanized monoclonal antibody that blocks terminal complement activation at C5, prevents complement-mediated hemolysis and reduces need for transfusions in paroxysmal nocturnal hemoglobinuria (PNH) patients who were transfusion-dependent before treatment initiation; it has also been shown to reduce lactate dehydrogenase (LDH) irrespective of transfusion history. The International PNH Registry (NCT01374360) is an ongoing prospective, multinational, observational study to record the natural history of PNH and evaluate the long-term efficacy and safety of eculizumab.
Aims: Evaluate, in a real-world setting, effectiveness of eculizumab on transfusion needs and other parameters in PNH patients with and without history of transfusion at initiation of eculizumab.
Methods: Patients enrolled in the PNH Registry on or before January 1, 2018, with known demographics and enrollment date, who (1) were treated with eculizumab, (2) had known red blood cell (RBC) transfusion status for 12 months before initiation of eculizumab, and (3) had ≥12 months of follow-up after initiation of eculizumab, were included. Numbers of units

of packed RBCs received in the year before initiation of eculizumab and during follow-up were calculated and summarized as rates (units/patient-year). Event rates for thromboembolism (TE) and all major adverse vascular events (MAVE; including TE) were calculated from disease start until eculizumab initiation and from eculizumab initiation to last follow-up. Transfusion rates were further stratified by history of bone marrow disease (BMD). LDH ratio (LDH/LDH upper limit of normal [ULN]) was assessed and change from initiation of eculizumab to last treated follow-up was analyzed using general linear mixed models, adjusted for baseline and subpopulation.

Results: 596/543 patients had/did not have history of RBC transfusion in the 12 months before initiation of eculizumab, and were included. Mean (SD) age at eculizumab initiation was 44 (17) years in both groups. Both cohorts had >2600 patient-years of follow-up. Results for outcomes of interest are in the Table 1. In patients with a history of transfusion, the transfusion rate (95% CI) decreased from 10.6 (10.3, 10.9) units/year in the year before initiation of eculizumab to 3.3 (3.3, 3.4) for a 70% reduction in transfusions (Table 1). This reduction was more pronounced in patients without history of BMD (80% reduction) *versus* those with history of BMD (60% reduction). In the overall group with no history of transfusions, the rate (95% CI) of transfusions during follow-up was 1.5 (1.4, 1.5) units/year; the rate in patients with a history of BMD was 2.2 (2.1, 2.3) units/year, as compared with the rate in patients with no history of BMD of 1.1 (1.1, 1.2) units/year. Patients with and without a history of transfusion at initiation of eculizumab showed a significant reduction in hemolysis after initiation of eculizumab (mean change in LDH ratio –5.4 [P<0.0001] and –3.9 [P<0.0001]), and mean LDH was <1.5 xULN in both groups. Rates of TE and MAVE declined by 70% after initiation of eculizumab regardless of transfusion history.

Table 1.

Outcomes Overall	History of RBC Transfusion n=596		No History of RBC Transfusion n=543	
RBC Transfusions				
During 12 months prior to initiation of ecu	n=592		N/A

Initiation of ecu to last treated follow-up				
Incidence rate/100 patient-years (95% CI)	1.5 (1.1, 2.0)		1.7 (1.3, 2.3)	
Incidence rate ratio (95% CI)	0.3 (0.2, 0.4)		0.3 (0.2, 0.4)	
RBC Transfusions Stratified by BMD‡ History	**BMD n=247**	**No BMD n=327**	**BMD n=198**	**No BMD n=331**
During 12 months prior to initiation of ecu	n=246	n=324	N/A	N/A
Transfusion rate/patient-years (95% CI)	12.1 (11.7, 12.6)	9.6 (9.3, 9.9)	N/A	N/A
Between initiation of ecu and last treated follow-up	n=246	n=324	n=195	n=331
Transfusion rate/patient-years (95% CI)	4.8 (4.7, 5.0)	2.3 (2.2, 2.4)	2.2 (2.1, 2.3)	1.1 (1.1, 1.2)
Transfusion rate ratio (95% CI)	0.4 (0.4, 0.4)	0.2 (0.2, 0.3)	N/A	N/A

BMD, bone marrow disease; CI, confidence interval; ecu, eculizumab; LDH, lactate dehydrogenase; MAVE, major adverse vascular event; N/A, not applicable; RBC, red blood cell; SD, standard deviation; TE, thromboembolism; ULN, upper limit of normal.
*TE includes thrombophlebitis/deep vein thrombosis, renal vein thrombosis, renal arterial thrombosis, mesenteric/visceral vein thrombosis, mesenteric/visceral arterial thrombosis, hepatic/portal vein thrombosis, dermal thrombosis, acute peripheral vascular disease occlusion, cerebral arterial occlusion/cerebrovascular accident, cerebral venous occlusion, and pulmonary embolus.
†MAVE includes TE (as defined above), amputation (nontraumatic, nondiabetic), myocardial infarction, transient ischemic attack, unstable angina, gangrene (nontraumatic, nondiabetic), and other MAVE.
‡BMD includes aplastic or hypoplastic anemia, acute myelogenous leukemia, myelodysplastic syndrome, myelofibrosis, and other bone marrow diseases.

Summary and Conclusions: In this analysis of real-world data from the International PNH Registry in patients with PNH, eculizumab was efficacious in reducing transfusion rates, complement-mediated hemolysis, TE, and MAVE, irrespective of prior transfusion history or BMD status. Transfusion rates in patients with no history of transfusion in the year before eculizumab initiation remained low after initiation of eculizumab, regardless of BMD status.

PF311

PROGNOSTIC SIGNIFICANCE OF RENAL DYSFUNCTION DURING THE CLINICAL COURSE IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA: A KOREAN MULTICENTER STUDY

Y.-C. Mun[1,*], J.S. Kim[2], J.H. Jang[3], D.-Y. Jo[4], J.W. Lee[5]

[1]Hematology and Oncology, Ewha Womans University Hospital, College of Medicine, Ewha Womans University, [2]Hematology, Severance Hospital, Yonsei University College of Medicine, [3]Hematology-Oncology, Samsung Medical Center, School of Medicine, Sungkyunkwan University, Seoul, [4]Internal Medicine, Chungnam National University Hospital, School of Medicine, Chungnam National University, Daejeon, [5]Hematology, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

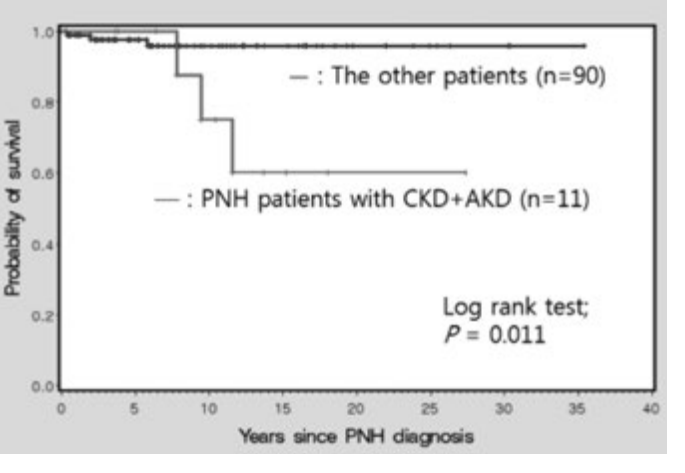
Background: Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired hematopoietic stem cell disease characterized by the intravascular lysis of red blood cells, thromboembolism (TE), and bone marrow failure. Previous study from Korean PNH registry reported that renal dysfunction defined as history of acute renal failure or reported glomerular filtration rate (GFR) <60 mL/min/1.73m^2 at the time of diagnosis of PNH was 16%. However, renal events may occur repeatedly during the clinical course of PNH. Therefore, the clinical characteristics and dynamics of renal dysfunction during PNH natural disease course should be systematically evaluated.

Aims: We investigated the clinical characteristics and dynamics of renal dysfunction during the natural course of PNH to affect the survival of PNH patients.

Methods: We conducted a multicenter, retrospective study of 101 Korean PNH patients with PNH granulocyte clone size >10% and serum LDH >1.5 fold of upper limit of normal at the time of PNH diagnosis for identifying an association between renal dysfunction and clinical outcomes during the disease course. Renal events such as acute kidney disease (AKD) or chronic kidney disease (CKD) were defined according to the definition of KDIGO (Kidney Disease Improving Global Outcomes). Medical records were reviewed until eculizumab was administered.

Results: During the 94.2 months of median follow up duration, the renal events were observed in 55 patients (55/101; 54.5%). Eleven patients (10.9%) experienced both AKD and CKD. Median time to first renal event from diagnosis of PNH was 79.3 months. The elevated levels of LDH at the time of first renal event were observed compared to the level of LDH at the time of diagnosis (Pearson correlation coefficient r=-0.58, P=0.022 in the patients with 1 renal event and r=-0.75, P=0.0002 in the patients with renal events ≥2). The rate of TE was a higher trend in the patients with renal events ≥2 (10/32, 31.3%) compared to those with renal events ≤1 (15/69, 21.7%). (P=0.303). The rate of recurrent TE was significantly higher in patients with renal events ≥2 (6/32, 18.8%) compared to those with renal events ≤1 (2/69, 2.9%) (P=0.012). The patients with renal events ≥2 showed a trend toward inferior overall survival (OS) compared to those with renal events ≤1 (86.4% *vs* 96.0% at 10 years OS; P=0.124). The rate of TE was a higher trend in the patients with the patients with CKD+AKD compared to the other patients (5/11, 45.5% *vs* 20/90, 22.2%, P=0.134). The rate of recurrent TE was significantly higher in patients with CKD+AKD (3/11, 27.3%) compared to the other patients (5/90, 5.6%) (P=0.040). Of note, the OS was significantly inferior in the patients with CKD+AKD compared to the other patients (75.0% *vs* 95.8% at 10 years OS; P=0.011) (Table 1).

Table 1.



Summary and Conclusions: These data indicate that the rate of recurrent TE was higher in PNH patients with recurrent renal events, especially in patients with CKD+AKD group. The OS of PNH patients with recurrent renal events including CKD+AKD group has been shown to be lower than those of other patients. Therefore, physician should pay attention to evaluate the renal events during follow-up period. The monitoring of renal function is essential for identifying the high risk patients and making a decision for appropriate management.

PF312

COMPLEMENT ACTIVATION AND EXACERBATION OF HAEMOLYSIS SECONDARY TO RESPIRATORY VIRAL INFECTIONS IN PAROXYSMAL NOCTURNAL HAEMOGLOBINURIA (PNH) PATIENTS TREATED WITH ECULIZUMAB

I. Lazana[1,*], S. Apap Mangion[1], S. Babiker[1], B. Fattizzo[1], K. Bell[1], J. Large[1], M. Sudhanva[1], J. Marsh[1], S. Gandhi[1], M. Zuckerman[2], A. Kulasekararaj[1]

[1]Haematology, [2]Virology, King's College Hospital, London, United Kingdom

Background: Paroxysmal Nocturnal Haemoglobinuria (PNH) is a clonal stem cell disorder disorder, with haemolysis being a major clinical and diagnostic feature. Precipitation or exacerbation of haemolysis can be induced by stress conditions, which activate the complement system, including infections, surgical procedures and vaccinations. Early diagnosis and treatment of an acute haemolytic process is critical, as it may lead to thrombosis and organ damage. Case reports have suggested that viral infections may have a role in inducing acute haemolysis. However, there are no studies investigating the possible role of respiratory virus infections in inducing/exacerbating haemolysis.
Aims: A retrospective study was performed, analysing PNH patients, presenting with coryzal symptoms during the influenza season, between September 2016 and April 2017, for acute haemolysis.
Methods: 33 of 110 patients presented with fever and coryzal symptoms and had a combined nose and throat swab (NTS) collected and tested for 10 respiratory virus infections, using a multiplex PCR. 10 of 33 NTS were positive (1 parainfluenza, 6 rhinovirus, 2 influenza B and 1 influenza A (H3N2) virus). The median age and the number of patients on prophylactic penicillin V and/or EPO, were similar between the two groups (NTS+ and NTS-).
Results: Patients in the NTS+ group had been on eculizumab treatment for a significantly longer period compared to NTS- patients (83.1 *vs* 52.7 months, p 0.023). A CRP rise was noted in 5/10 of NTS+ patients compared with only 8/23 NPA- patients. 5/10 of NTS+ patients required antibiotics and 4/10 received oseltamaivir and 1/10 patients required GCSF for neutropenia, in contrast to the NTS- group, where only 5/23 patients were given antibiotics and none of them required GCSF. Furthermore, 3/10 NTS+ patients required hospitalisation, compared with only 2/23 of NTS- patients. It is of note that two patients, suffered from recurrent viral infections (three and two episodes, respectively) and that in all cases a significant haemolysis, requiring red cell transfusion, was noted. In one case an extra dose of eculizumab had to be given to control the degree of haemolysis.
With regards to the haemolysis markers, a significantly higher increase in LDH and a significantly higher% increase in bilirubin was noted in the NTS+ group, compared to the NTS- group, (%LDH increase: 81.21 *vs* 51.6, p 0.03,%bilirubin increase: 73.1 *vs* 22.6, p 0.02, respectively). Similarly a significantly higher number of NTS+ patients exhibited a drop in their Hb, compared to the NTS- group (70 *vs* 34%), and again the% decrease in Hb was significantly higher in the NTS+ group. Furthermore, 3/10 NTS+ patients required urgent red cell transfusion. The reticulocyte count was increased (from baseline) in more patients in the NTS+ group, compared to the NTS- group, but this was not significant. None of the NTS- group required an extra dose of eculizumab, whereas 2/10 NTS+ patients did, to control haemolysis. The time from the last dose of eculizumab to a positive NTS, appeared longer in the NTS+ group (10.1 *vs* 2.8 days), but this difference was not significant. No difference in vaccination for seasonal influenza uptake was seen in the two groups, although the overall uptake was low.
Summary and Conclusions: Overall, our data indicate that respiratory virus infections may pose a significant risk of acute haemolysis to PNH patients, underlying the need for regular screening and close monitoring of symptomatic or high risk PNH patients.

PF313

RESULTS OF COBALT, A PHASE II CLINICAL TRIAL OF COVERSIN IN PNH

A. Hill[1,*], J. Windyga[2], T. Robak[3], A. Hellman[4], A. Kulasekararaj[5], W. Weston-Davies[6], M. Griffin[1], T. Munir[1], A. Szmigielska-Kaplon[3], A. Piekarska[4], M. Nunn[67]

[1]Haematology, St James's University Hospital, Leeds, United Kingdom, [2]Department of disorders of hemostasis and Internal Medicine, Institute of Hematology and Transfusology, Warsaw, [3]Haematology, Medical University of Lodz, Lodz, [4]Haematology and Transplantology, Medical University of Gdansk, Gdansk, Poland, [5]Haematology, Kings College Hospital, [6]Akari Therapeutics plc, [7]Haemostasis Research Unit, UCL, London, United Kingdom

Background: The advent of eculizumab, a monoclonal antibody which prevents the cleavage of C5 to C5a and C5b transformed the prognosis of patients with PNH and led to a marked improvement in their quality of life. However, eculizumab is administered by health care professionals by intravenous infusion which may interfere with the life-styles, occupations and personal privacy of patients. Interval dosing has led to concerns by some clinicians related to breakthrough haemolysis. Coversin is a protein suitable for small-volume subcutaneous (SC) injection and can be self-administered by patients.
Aims: The aims of this study were to assess the safety and tolerability of Coversin, the efficacy of the dosing regime and whether self-injection by patients is well-accepted.
Methods: In a Phase 2 single arm open label trial, PNH patients who had not previously had access to complement inhibitors were treated with Coversin for 90 days. The aim of the trial was to recruit 8 adult patients with a diagnosis of PNH confirmed by flow cytometry. For the first 5 patients, following an initial ablating regime (AR) of 60mg followed by 1 - 3 doses of 30mg q12 hours delivered by SC injection, a dose of 15 or 22.5mg q12 hours was given. On day 28, they switched to 30 or 45mg q24 hours for the remainder of the trial. All patients were encouraged to self-inject after suitable instruction.Those patients not satisfactorily controlled could be up dosed or switched to the same dose divided into 2 doses administered q12 hours. After admission of the first 5 patients an amendment to the protocol was made under which all patients were started on 22.5mg 12 hourly after the AR, switching to 45mg daily at day 28. Patients could revert to 22.5mg 12 hourly in the event of unsatisfactory control. All patients who completed the trial and wished to do so, could continue to receive Coversin under a long-term safety and efficacy protocol. The primary end point was LDH <1.8X ULN at the local laboratory at day 28. Secondary endpoints included LDH (xULN) at 60 and 90 days, terminal complement activity assessed by CH50 ELISA (Quidel®), haemoglobin stabilisation, reduction in requirement for blood transfusions, sheep erythrocyte haemolysis assay, PK (free and bound Coversin levels), anti-drug antibodies (ADA) and quality of life.
Results: Eight patients were enrolled in the trial in the UK and Poland. One patient was withdrawn at Day 43 because of a suspected co-morbidity unrelated to the study drug. Seven patients completed the study and all opted to continue to receive Coversin in the long-term follow-up study, CONSERVE. The trial met its primary endpoint with a median LDH at Day 28 of 1.5X ULN (n=8). At the conclusion of the trial 6 patients were on 45mg/day and 1 was on 30mg/day. There were no serious adverse events related to Coversin, patients tolerated the drug well, and for those experiencing them, the injection site reactions observed were mild to moderate, self-limiting and diminished with time. There has been no evidence of the formation of neutralising antibodies (Figure 1).

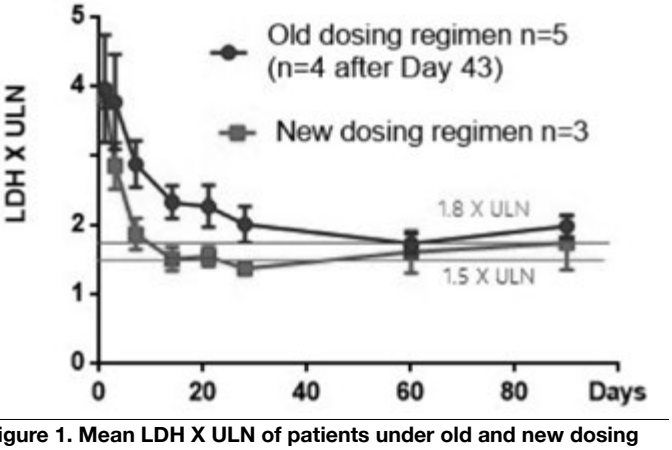


Figure 1. Mean LDH X ULN of patients under old and new dosing regimen.

Summary and Conclusions: Coversin may be an effective alternative for patients with PNH who prefer the independence of self- administration. The relatively short dose interval may also help to reduce breakthrough events.

PF314

THE INCIDENCE OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA CELL CLONES IN THE NORDIC COUNTRIES

E.-S. Korkama[1], U. Overgaard[2], E. Tjønnfjord[3], M. Vikman[4], A. Ahmadi[4], T.-T. Pelliniemi[5], H. Jarva[16], S. Meri[16], E. Armstrong[7], C. Kjellander[8,*]

[1]Department of Bacteriology and Immunology, University of Helsinki, Helsinki, Fin-

land, [2] Department of Hematology, Rigshospitalet, Copenhagen, Denmark, [3]Department of Hematology, Oslo University Hospital, Oslo, Norway, [4]Department of Clinical Pathology and Cytology, Karolinska University Hospital Huddinge, Stockholm, Sweden, [5]Tampere University Hospital, Fimlab, Tampere, [6]Helsinki University Hospital Laboratory (HUSLAB), [7]Coagulation Disorders Unit, Helsinki University Central Hospital Comprehensive Cancer Center, Helsinki, Finland, [8]Department of Hematology, Karolinska University Hospital Solna, Stockholm, Sweden

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare acquired hematopoietic stem cell disorder characterized by the triad of intravascular hemolysis, thrombosis and bone marrow failure. The symptoms are caused by complement-mediated damage of cells of hematopoietic origin. A mutation on the *PIG-A* gene leads to the lack of glycosylphosphatidylinositol (GPI) -anchored complement regulators, CD55 and CD59, on the cell surface, which allows the complement system to attack host cells. The detection of a PNH clone is made by analyzing GPI-anchored molecules on blood cells by flow cytometry. PNH is known to be a rare chronic disorder. Well conducted studies on prevalence and incidence are lacking. Probably the best estimates come from Yorkshire (UK) and Spain, reporting an incidence of 1.3/1 million/year (1991-2006) and 2.5/million/year (2011-2014), respectively. The development of modern flow cytometric techniques has improved the diagnostic accuracy and created possibilities for the follow-up of small clones.
Aims: The Nordic countries have unique systems of database records and centralization of diagnostics to a few centers, which allows accurate characterization of incidence and prevalence values. Our aim is to describe PNH clones detected over a period of 6 years by flow cytometry in Denmark (Den), Finland (Fin), Norway (Nor), and Sweden (Swe).
Methods: Data was collected from the Stockholm and Gotland regions in Sweden, Copenhagen region in Denmark, Oslo region in Norway and from the whole of Finland. The total population of the study regions is 13.2 millions. Diagnostics were done in six different laboratories. PNH clones were detected by flow cytometry. For gating and detection of GPI deficient cells CD45, CD15, CD64 (or CD157), CD24, CD14 antibodies, FLAER reagent and CD235a, CD59 antibodies were used in leukocytes (neutrophils and monocytes) and red blood cells, respectively. All laboratories used accredited methods. The study population included all patient samples referred to the laboratories for PNH testing between 2011 and 2016. We included all newly detected PNH clones in neutrophils between 0.1-100% in the study.
Results: The mean incidence of newly detected PNH clones between 0.1 and 100% was 2.33 per year and million inhabitants in the Nordic countries (Den 2.05/million, Fin 2.98/million, Nor 2.53/million, and Swe 1.74/million). Of all newly diagnosed PNH clones, 41% were <1% and 17% >50%. The mean age at detection of the clone was 52 years (range from 6 to 90 years). PNH clones were evenly distributed between age groups, and there was no gender difference.
Summary and Conclusions: This is the first study to report the annual incidence (2.33/million) and distribution of PNH clones in the Nordic countries. PNH clone incidence was similar to the reported Spanish data where PNH clone distribution was missing. In the Yorkshire data 18% of the PNH clones were ≤1% and 20% >50%, compared to 41% and 17% respectively in our material. This may reflect an increase in the testing for PNH clones in bone marrow failure syndromes or other conditions associated with PNH, or more sensitive modern laboratory methods. In the Finnish data 49% of the patients had a clone <1% compared to 28%, 38% and 39% in Denmark, Norway and Sweden, respectively. This may explain the seemingly higher incidence of PNH clones in Finland. Our study has given an estimate of PNH incidence in the Nordic countries and important information for further health economical studies.

Chronic lymphocytic leukemia and related disorders – Biology & Translational Research

USP28 LOCALIZED IN 11Q23 REGULATES C-MYC, NOTCH1 AND FBXW7 IN CLL

V. Meyer-Pannwitt[1,2,*], J. Bloehdorn[1], S. J. Kugler[1,2], F. Oswald[3], J. Edelmann[4], H. Döhner[1], S. Stilgenbauer[1], D. Mertens[1,2]

[1]Internal Medicine III, Ulm University, Ulm, [2]Department of Molecular Genetics (B061), Cooperation Unit "Mechanisms of Leukemogenesis" DKFZ, Heidelberg, [3]Internal Medicine I, Ulm University, Ulm, Germany, [4]Barts Cancer Institute, Queen Mary University of London, London, United Kingdom

Background: FBXW7, c-MYC and NOTCH1 are of central relevance in the pathomechanism of chronic lymphocytic leukemia (CLL). Mutations of *FBXW7* occur in 2.5-4% of CLL cases, dysregulation of c-MYC coincides with disease progression and CLL patients with a mutation of *NOTCH1* (4-13% of cases) do not respond appropriately to chemoimmunotherapy. FBXW7 regulates the stability of oncoproteins such as c-MYC and NOTCH1 via ubiquitination. FBXW7-mediated ubiquitination can be antagonized by the deubiquitinase USP28, which is frequently dysregulated in cancer. Interestingly, *USP28* is located in 11q23, a region commonly deleted in CLL. We speculate that c-MYC, NOTCH1 and FBXW7 are regulated via USP28 in CLL.
Aims: To delineate the function of USP28 in CLL with regard to c-MYC, NOTCH1 and FBXW7 stability and activity.
Methods: Our high-resolution SNP-array data (Edelmann, Blood 2012) allowed to assess the frequency of *USP28* deletion in 96 untreated CLL cases with del(11q) and to correlate deletion with *USP28* expression levels. The consequence of USP28 dysregulation on its direct substrates c-MYC, NOTCH1 and FBXW7, as well as NOTCH1 target gene expression was investigated in primary CLL cells with and without del(11q).
Results: In line with our hypothesis for a role of USP28 in the pathomechanism of CLL, we found that USP28 protein levels varied in CLL, strongly correlated with c-MYC and NOTCH1 and anti-correlated with FBXW7 levels. USP28 levels were independent of the del(11q) status. Monoallelic deletion of *USP28* was detectable in 90% (86/96) of untreated del(11q) CLL patients, which resulted in a significant decrease of *USP28* expression in comparison to non-del(11q) cases. In the same cohort, deletion of *ATM* was detectable in 100% of cases (96/96), while deletion of *BIRC3* occurred in only 61% (59/96) of cases. Low *USP28* expression in del(11q) patient cells correlated with reduced NOTCH1 target gene expression of *HES1*, *HEY1* and *HES2* in comparison to non-del(11q) patients, which is in line with reduced NOTCH1 activity in del(11q) patients. ATM has been shown to regulate USP28 by phosphorylation, and we postulate that this has an effect also on NOTCH1 target gene expression. To disentangle effects of ATM, we selected only non-del(11q) patient samples and separated them into groups with *USP28* high or low expression. Strikingly, in CLL cases with low *USP28* expression and no del(11q), 12/17 NOTCH1 target genes were significantly upregulated. In line with elevated NOTCH1 target gene expression, significantly reduced *MS4A1* (CD20) expression was detectable in *USP28*-low expressing CLL cells.
Summary and Conclusions: Deletion of *USP28* was detected in del(11q) CLL patients more commonly than *BIRC3* disruption and coincided with decreased *USP28* expression. Therefore, we propose *USP28* as a novel oncogenic candidate of relevance in CLL. In CLL, USP28 not only regulates levels of FBXW7 and NOTCH1, which are frequently mutated, but also stabilizes c-MYC. USP28 levels correlate with protein levels of c-MYC, NOTCH1 and FBXW7 and provide another mechanism of NOTCH1 dysregulation in CLL. Furthermore, low expression of *USP28* correlated with increased NOTCH1 target gene expression and reduced *MS4A1* (CD20) expression, which coincides with reduced response to anti-CD20 treatment.

PF316

INTERROGATION OF HAEMATOPOIETIC BONE MARRROW PROGENITORS FOR DRIVER MUTATIONS OF CHRONIC LYMPHOCYTIC LEUKAEMIA

D. Bruce[1,*], A. Burns[2], P. Robbe[2], N. Appleby[2], J. Klintmann[2], D.R.A. Silveira[3], A. Rodriguez-Meira[4], A.J. Mead[4], A. Schuh[2]

Paulo, Sao Paulo, Brazil, [4]Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom

Background: Chronic lymphocytic leukaemia (CLL) is generally considered a disease derived from mature B-cells. Novel agents targeting B-cell receptor signalling are highly effective in controlling the disease, but do not cure. One hypothesis is that leukaemia is maintained by cells that have not yet undergone immunoglobulin rearrangement.
Aims: To phenotypically and genotypically characterise pre and post-treatment sort-purified bone marrow derived progenitors from patients with CLL treated with either chemo-immunotherapy or with novel agents.
Methods: A flow cytometry panel was developed to assess populations of haematopoietic and lymphoid progenitors. Mutations in peripheral blood CLL were detected either from whole genomes generated as part of the Genomics England CLL Pilot or using a 21 gene NGS panel which covers all major driver genes in CLL. Ethical approval for the study was via the Oxford Radcliffe Biobank Haem-Subprotocol. Twenty-four bone marrow (BM) and peripheral blood (PB) samples from patients taking part in clinical trials involving the novel small molecule inhibitors ibrutinib and venetoclax in which pre- and post-treatment bone marrow collection was mandated were collected. FACS was used to isolate: CD34+38- haematopoietic stem cell compartment, CD34+38+10-19- multipotent progenitor compartment, Pro B-cells, CD34+38+10+19- lymphoid progenitors and CD5+CD19+ CLL. Sort purity was at least 98%. Whole genome amplification (WGA) was performed using Repli-G mini kit (Qiagen). We used a modified Nextera (Illumina) approach and performed PCR using mutation specific primers with Nextera tags. A second PCR added indexes before the library was sequenced on an Illumina MiSeq and aligned using BWA v2.1.0.
Results: Preliminary results of 6 patients (3 treated with FCR, 3 with ibrutinib-rituximab in treatment naïve patients) show stable levels of haematopoietic stem cell and multipotent progenitor compartments, but a trend in reduction in pro B-cells post-treatment compared to pre-treatment (p=0.06). We determined the sensitivity of our approach by FACS sorting a total of 500 cells made up of two patient samples of PB CLL, one of which had a clonal MYD88 p.L265P mutation, the other was wild-type. In this artificial mix clonal MYD88 mutant CLL was present at 0, 1, 2, 5, 10 and 20% in 4 replicates each except for the 0% level where 6 replicates were used to establish a baseline sequencing variability. Using this method we could reliably detect samples with 5% mutation and in 2/4 samples down to a level of 2%.FACS was performed on 6 pre-treatment samples carrying 8 driver mutations, seven of which were clonal in PB CLL (ATMx2, SF3B1, EGR2, RPS15, MYD88, FBXW7 and subclonal TP53). Samples were sorted and analysed as above. A control of DNA from another sample (processed in the same way) that lacked the driver mutation was used to establish the baseline sequencing variation rate at that individual base (median read depth 1676, range 533-6872).In one case a clonal ATM "mutation" was present in all fractions with a variant allele frequency of between 30-60%, and it is likely this is a private SNP. In five other samples, no clear evidence of mutation in any progenitor fraction was detected.
Summary and Conclusions: Using a stringent cell purification approach and internal controls to exclude sequencing errors or contamination by CLL cells, we have so far not identified any CLL driver mutations in bone marrow progenitors. Further experiments, including interrogation of early events (del13q; XPO1) and single cell analyses are on-going.

PF317

SMG1 LOSS ENHANCES MTOR SIGNALLING IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

P. Rebeiro[1], A. James[1], S. Ling[2], N. Caixeiro[1], T. Roberts[1,*]

[1]Ingham Institute for Applied Medical Research, Western Sydney University, [2]Haematology, Liverpool Hospital, Sydney, Australia

Background: SMG1 (suppressor of morphogenesis in genitalia) is a member of the PI-3 kinase like kinase (PIKK) family of proteins which includes ATM, ATR, DNA-PK and mTOR. Members of this family have well-characterised roles in responses to cellular stress including DNA damage and nutrient deprivation. SMG1 is central to nonsense-mediated decay (NMD), a process that degrades mRNA containing premature stop codons thus prevening the production of truncated proteins. NMD is particularly active in B and T cells to prevent expression of PTC containing B and T cell receptor transcripts as such B and T cells normally have high levels of SMG1 expression. In our mouse model loss of one SMG1 allele resulted in increased development of B cell cancers. mTOR is the kinase core of two complexes: mTOR complex (mTORC) 1 and 2. Signalling via these complexes is often enhanced in cancers including lymphomas and leukemias.
Aims: We aimed to understand how loss of SMG1 enhanced cancer cell growth and whether loss of SMG1 in patients alters their responses to therapy.
Methods: We combined the study of cell lines, animal models and isolated patient tumour cells to examine how loss of SMG1 altered cellular biology and to identify key dysregulated signaling pathways.
Results: Here we show that PIKK family member, SMG1, is a novel negative regulator of mTORC2 signalling. SMG1 constitutively interacts with the mTORC2. Immunoprecipitation experiments show that SMG1 interacts specifically with mTORC2 and not mTORC1. SMG1 knockdown in cell lines leads to increased activation of mTORC2 and increased phosphorylation of the mTORC2 substrates Akt and Protein kinase C. We examined patients with chronic lymphocytic leukaemia and showed that >30% of patients lack detectable SMG1 protein. Further, the level of SMG1 expression in CLL patients B cells inversely correlated with Akt phosphorylation indicating that in these tumours loss of SMG1 resulted in increased mTORC2 signalling. Preliminary *ex vivo* assays suggest that CLL patient cells lacking SMG1 have altered susceptibility to mTOR inhibitor.
Summary and Conclusions: SMG1 loss correlates with increased mTORC2 signalling in CLL patient cells and that SMG1 interacts with the mTORC2 complex to negatively regulate its activity. Loss of SMG1 may identify a sub-group of patients with altered susceptibility to mTOR inhibition.

PF318

TP53 CLONAL AND SUBCLONAL ARCHITECTURE IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS UNDER CHEMOIMMUNOTHERAPY AND IBRUTINIB

L.V. Cappelli[1,*], L. Cafforio[1], I. Del Giudice[1], C. Ilari[1], S. Raponi[1], P. Mariglia[1], M.S. De Propris[1], M. Filetti[1], F.R. Mauro[1], A. Guarini[2], R. Foà[1]

[1]Department of Cellular Biotechnologies and Hematology, [2]Department of Molecular Medicine, Hematology, Sapienza University, Rome, Italy

Background: In patients (pts) with chronic lymphocytic leukemia (CLL), analysis of *TP53* defects is mandatory before each line of treatment.
Aims: To analyze and compare the *TP53* clonal and subclonal architecture in CLL pts under multiple lines of chemoimmunotherapy (CIT) and ibrutinib (IBR).
Methods: Twenty-two pts (Table 1), undergoing a longitudinal *TP53* monitoring by Sanger sequencing (SS) before each line of CIT, developed a clonal *TP53* mutation over time; 8 pts also received IBR after a median of 2 CIT lines (range: 1-4) and were studied both before and after the drug intake (IBR exposition: 2.1 to 4 years in 7/8 pts). A total of 70 samples were retrospectively analyzed by ultra-deep sequencing. Libraries, prepared by TruSeq Custom Amplicon Low Input Library Prep kit (Illumina, Inc., San Diego, CA), were run on Illumina MiSeq sequencer (Illumina, Inc.) to obtain a ~5000x coverage/amplicon. For variant calling, the MiSeq Reporter software and an in-house bioinformatics pipeline were applied. Variants identified were checked on the IARC *TP53* database. The variant allele frequency (VAF) was corrected to cancer cell fraction (CCF) by the proportion of CD19+/CD5+ cells in each sample.
Results: Overall, 15/22 pts (68%) had at least 3 available time points. The mean number of clonal/subclonal *TP53* mutations per patient was 3.4 (range 1-11). In the 70 samples, 136 mutations were detected. According to SS sensibility, 41/136 (30%) mutations were clonal (mean VAF: 31.9%; range 10.3%>80.8%) and 95/136 (70%) were subclonal (mean VAF: 2.94%; 0.46%>9.89%). Of these, 83/95 (87%) showed a VAF≤5%. In the 22 pts receiving CIT, we identified 3 patterns of *TP53* mutation kinetics: 1) clonal mutations present from the first time point (n=2); 2) subclonal mutations evolving to clonal with or without additional minor subclones (n=10); 3) clonal mutations emerging with additional subclones not predicted by a previous subclone (n=10). In group 2, the mean CCF of the evolving *TP53* mutations increased from 5% to 43.5% (p<0.0001). In 14 pts with available pretreatment samples (n=21), 8 mutations (6 subclonal, 2 clonal) were detected, whilst the posttreatment samples (n=28) showed 71 mutations (41 subclonal, 30 clonal) (p<0.0001). The mean CCF was 5.1% (0.9%>17.2%) *vs* 16.8% (0.9%>80.7%) (p=0.002), respectively. Furthermore, we longitudinally followed the 8 IBR pts during the CIT and the subsequent IBR phases. During the CIT phase (mean duration: 3.1 years), 11 novel clonal/subclonal mutations developed, 2 subclonal evolved to clonal, 14 remained stable and none was lost. On the contrary, during the IBR phase (mean duration: 2.6 years), only 2 subclonal novel mutations emerged, one clonal decreased to subclonal, 17 remained stable and 9 -all subclonal- were lost (p<0.0001). Notably, the mean CCF of the existing clonal mutations remained stable before and after IBR treatment (CCF means: 32.2% *vs* 31.3%; p=NS), although the lymphocyte count significantly decreased (ly: 44.7 x 10^9/L *vs* 8 x 10^9/L; p=0.027).

Table 1.

Clinical and biological characteristics of 22 patients with *TP53* mutated CLL.	
Gender	16 M (73%) / 6 F (27%)
Median age (range)	55.5 years (38-71)
Median follow-up from diagnosis	10.8 years (3.5-22.2)
Median time from diagnosis to clonal *TP53* mutation	9.4 years (2.7-21.3)
Germline *IGHV*	15/21 (71.4%)
FISH del 17p	8/19 (42%)
TP53 mutations	59
	41/59 (69%): missense
	11/59 (19%): indels
	5/59 (8.5%): splicing
	2/59 (3.5%): nonsense
Mean lymphocyte count (x10^9/L):	
at first time point (n= 22 pts)	56.6 (1-207.5)
Pre-ibrutinib (n=8 pts)	44.7 (1.5-137.8)
Post-ibrutinib (n=8 pts)	8 (2.7-18.9)

Summary and Conclusions: Clonal *TP53* mutations emerging under CIT can be anticipated in at least half of the cases by subclones carrying the same mutation, according to the positive selection of resistant clones. The major clone can be accompanied by several other subclones which often remain under the SS detection limits, likely having a lower functional relevance. Contrariwise, IBR appears to lead to a decrease of the numerosity and complexity of *TP53* mutations. However, despite a marked reduction in lymphocytosis, the dominant clones survive the effect of the drug and may give rise to subsequent relapses.

PF319

PAPTP LEADS TO NEOPLASTIC CELL APOPTOSIS IN THE EM-TCL1 CHRONIC LYMPHOCYTIC LEUKEMIA MOUSE MODEL

Background: The potassium channel Kv1.3 is highly expressed in CLL cell mitochondria. We previously demonstrated that direct inhibition of Kv1.3 using mitochondria-targeted inhibitors alters mitochondrial function and leads to ROS mediated death of even chemoresistant cells. The inhibitor PAPTP killed 98% of *ex vivo* primary CLL cells while sparing healthy B cells. E -TCL1 CLL murine model is characterized by a high expression of TCL1 protein in B cells leading to the development of a CLL-like lymphoproliferative disease.
Aims: We were aimed to evaluate the toxicity and the efficacy in killing pathological B cells of PAPTP in the E -TCL1 mouse model.
Methods: Since the CLL phenotype is arising late in mouse age (around 10-18 months), we used only animals at that age presenting at least 50% of clonal expansion of CD19+/CD5+ in the peripheral blood. Furthermore, we isolated B CLL cells in order to confirm both surface antigen expression and clonality. Indeed, cells were stained with antibodies specific for murine CD45, CD5, CD19, Igk, Igl, CD3, CD4 and CD8 and evaluated by flow cytometry (FC). Once assessed the presence of disease, we cultured *ex-vivo* mouse leukemic lymphocytes from mice for 24h with or without PAPTP (10mmol/l) and evaluated cell viability by FC. 11 mice were treated with an injection of PAPTP 5 nmol/gbw diluted in DMSO and 8 control mice with only DMSO (5 days/week for 2 weeks). At the end of treatment, mice were sacrificed and blood, spleen, bone marrow and intraperitoneal wash were collected stained and evaluated either for the antigen distribution by FC as well as by histological stain with Hematoxylin and eosin. Splenomegaly was also assessed by spleen volume measurements.
Results: We confirmed the efficacy of PAPTP also in the murine neoplastic clone in *ex vivo* experiments: Kv1.3 protein is over-expressed in pathological B cells and its mitochondria targeted inhibitor was able to reduce E -TCL1 B CLL cell viability. Furthermore, we performed *in vivo* experiments. After 2 weeks of therapy, we observed an improvement of treated mice in term of appearance (posture and weight gain) with respect to controls. We also demonstrated a decrease in absolute total lymphocyte number after PAPTP administration and a higher reduction of pathological B cells (CD19+/CD5+) in spleen and bone marrow of treated, with respect to untreated, mice. Moreover, hematoxylin and eosin stain showned that untreated mice had enlarged spleen and liver, with evidence of CLL infiltration in both organs. Treated mice had smaller spleens and livers, with minimal (if any) CLL infiltration. In particular, the spleens disclosed well-preserved withe pulp architecture with clear-cut follicles and marginal zones.
Summary and Conclusions: The high selectivity of PAPTP and its capability to induce selectively apoptosis in B CLL cells also *in vivo* in E -TCL1 mouse model, may suggest the use of this inhibitor for designing new therapeutic strategies.

PF320

OVERTIME ASSESSMENT OF EPIGENETIC PROFILES IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS TREATED WITH CHEMOIMMUNOTHERAPY

Background: Aberrant DNA methylation is implicated in the pathogenesis of chronic lymphocytic leukemia (CLL), however its contribution to disease progression has not been conclusively defined.
Aims: The purpose of this study was to investigate the role of DNA methylation changes overtime in a group of CLL patients homogeneously treated with fludarabine, cyclophosphamide and rituximab (FCR).
Methods: Using 450K Illumina arrays, we determined methylation profiles in 34 CLL patients before treatment and at relapse; corresponding whole exome-seq data was available for 26/34 cases. We also analysed by 450K arrays 2 samples of memory B cells (MBC) from healthy donors. ChIP-seq data for histone modifications of MBC was also available.
Results: Differential methylation analysis did not identify reccurent changes at group level (all pre-treatment samples *vs* all relapse samples). However, analysis of each individual patient separately, in two axes, revealed significant differences in the number of differentially methylated CpGs (DMCpGs). More specifically, we compared: (i) MBC *vs* pre-treatment CLL sample, with the number of DMCpGs, referred as epigenetic burden (EB), ranging from 32,380 to 54,257; and, (ii) pre-treatment *vs* relapse sample, with the number of DMCpGs, referred as relapse changes (RC), ranging from 45 to 81,383. We found a correlation between EB and time to first treatment (TTFT) (rho=-0.41, p=0.01) and also between RC and time to relapse (TTR) (rho=0.39, p=0.02). Comparing low-EB (n=25, EB=32,380-45,372; median=40,669) *versus* high-EB cases (n=9, EB=45,383-60,526; median=50,443), the latter showed very early need for treatment (median TTFT=0.1 *vs* 2 years, p-value<0.001) and a higher frequency of *TP53* mutations after relapse (p=0.04). Focusing on the low-EB group, we found a strong negative correlation (rho=-0.58, p=0.002) between EB and RC, an association not observed amongst high-EB cases.

Despite the large heterogeneity between cases, DNA methylation changes were not fully stochastic since we found that hypomethylating events, regarding both EB and RC, mainly occurred within gene bodies, introns and 3' UTRs in heterochromatin and polycomb repressed regions. Hypermethylation events targeted enhancers, promoters and polycomb repressed regions, while at relapse these were mainly restricted to poised promoters and polycomb regions. In both analyses (EB and RC), we found enrichment for pathways common between patients (*e.g.* signaling pathways of Calcium, Rap1, cAMP) and strong association with binding sites of common transcription factors, mainly on hypermethylated CpGs (*e.g.* EB analysis:, MEF2A, POU2F1, ZIC2, AP-1, JUN -B/-D, c-Fos| RC analysis: MEF2A, POU2F1, E2F, p53). Additionally, using a machine learning approach, we identified an epigenetic signature of 10 CpG sites that was capable of accurately predicting the early relapse cases (TTR<2 years) (OOB error=10.53%, ROC-AUC= 0.978).
Summary and Conclusions: In conclusion, this study highlights the active role of DNA methylation changes in CLL evolution, particularly in response to chemoimmunotherapy, involving several transcription factors and pathways and displaying association with particular genetic events. Moreover, it raises the possibility of using the DNA methylation levels of specific CpGs as prognostic biomarkers.

PF321

JAK/SYK INHIBITION IS VITAL TO PREVENT B CELL RECEPTOR SIGNALING AND ITS REGULATION BY THE TUMOUR MICROENVIRONMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA

R. Dobson[1], M.D. Blunt[1], K.-R. Rogers Broadway[1], L.D. Smith[1], L. . Karydis[1], A. Minton[1], J.C. Strefford[1], F.K. Stevenson[1], M.S. Cragg[1], F. Forconi[1], G.P. Coffey[2], P.B. Conley[2], G. Packham[1], A.J. Steele[1,2,*]

[1]Cancer Sciences Unit, Somers Building (MP824), Tremona Rd, University of Southampton, Southampton, United Kingdom, [2]Portola Pharmaceuticals, Inc., South San Francisco, CA, United States

Background: Understanding the role of the B cell receptor (BCR) in chronic lymphocytic leukemia (CLL) pathology is critical for the identification of effective treatment strategies for this currently incurable disease. We previously demonstrated that the tumour microenvironment is pivotal to BCR signaling. Indeed, IL-4 treatment increased surface (s)IgM (but not sIgD) expression and augmented downstream signaling. These effects were restricted to IL-4 and observed down to 0.1ng/ml, with maximal effects seen between 4 and 10ng/ml IL-4 for all cases. Pivotally we demonstrated that IL-4 treatment reduced the effectiveness of ibrutinib and idelalisib to inhibit the BCR signaling pathway using calcium flux and phosphorylated ERK as readouts. IL-4 induced BCR signaling and resistance to BCR-kinase inhibitors was greater within CLL cases with progressive (U-CLL) compared to indolent (M-CLL) disease, suggesting that IL-4 effects may contribute to BCR induced tumour pathogenesis and therapy resistance.
Aims: To investigate the effect of SYK/JAK inhibition on BCR signaling and its regulation via IL-4 in CLL
Methods: Primary CLL cases were treated with anti-IgM in the presence or absence of IL-4 following pre-incubation with or without ibrutinib, idelalisib, tofacitinib, fostamatinib, PRT062607 or cerdulatinib (all 1μM). Drug effects on BCR-induced signaling was performed by calcium flux using flow cytometry or immunoblotting.
Results: Ibrutinib and idelalisib inhibited anti-IgM induced signaling at 1μM as previously demonstrated, however, this inhibition was variable and signaling was only inhibited 80-90% *in vitro*. The ability of ibrutinib and idelalisib to block BCR signaling was further reduced following IL-4 treatment (n=20). However importantly, the addition of the JAK1/3 inhibitor tofacitinib restored complete inhibition of the BCR pathway by ibrutinib and idelalisib (n=10). To determine whether these effects were restricted to BTK or PI3K, we subsequently treated the same CLL samples with the SYK inhibitors fostamatinib (R406), PRT062607 or the dual SYK/JAK inhibitor cerdulatinib. In contrast to ibrutinib and idelalisib, PRT062607, cerdulatinib or R406 alone completely inhibited anti-IgM induced signaling at equivalent concentrations in the absence of IL-4 in the majority of patient samples. However, in contrast to ibrutinib and idelalisib, IL-4 treatment did not reduce the effectiveness of PRT062607 or cerdulatinib to inhibit anti-IgM signaling, suggesting that SYK was involved in the IL-4 induced BCR signaling axis. Next we subsequently explored protein expression associated with positive BCR signaling (GAB1, FOXP1) and suppressors of cytokine (SOCS1, SOCS3) signaling following treatment with IL-4. IL-4 treatment significantly induced expression of FOXP1, GAB1, SOCS1 and SOCS3 within 24h. Interestingly these IL-4-mediated changes in protein expression were greater in U-CLL cases compared to M-CLL cases but were suppressed by the SYK/JAK inhibitor cerdulatinib. Cerdulatinib unlike PRT062607, R406, ibrutinib and idelalisib can simultaneously inhibit IL-4 and BCR signaling and may therefore have a dual role in reducing BCR signaling in CLL cases.
Summary and Conclusions: These data suggest that targeting SYK/JAK disrupts both BCR signaling directly as well as cross-talk via the IL-4 receptor. Therefore combined SYK/JAK inhibition appears to be a rational strategy to control important survival signals in CLL and potentially follicular lymphoma where the microenvironment plays a role in disease pathogenesis.

CLL-DERIVED EXOSOMES REPROGRAM THE PHOSPHOPRTEOMICS LANDSCAPE OF ENDOTHELIAL CELLS

L. Lipshtein[1,*], O. Uziel[1], E. Beery[1], P. Raanani[2], M. Lahav[1], U. Rozovski[2]

[1]FMRC, Rabin Medical Center and Tel Aviv University, Petah-Tikva, Israel, [2]Hematological Institute, FMRC, Rabin Medical Center and Tel Aviv University, Petah-Tikva, Israel

Background: CLL cells travel between blood, bone marrow and lymphatic tissues. In the lymph nodes CLL cells receive pro-survival signals coming from neighboring cells. For example, the interaction of CLL cells with vascular endothelial cells enhances the survival of the neoplastic cells. How endothelial cells provide CLL cells with a survival advantage is unknown. We hypothesized that CLL cells shape their own fate by sending "floating" massages that are taken up by endothelial cells. These massages subsequently reprogram the protein repertoire of the recipient cells to support the survival of the neoplastic cells. Exosomes are cellular-derived nano-sized particles, secreted by different type of cells including tumor cells, carrying a cargo of proteins and nucleic acids. They are up taken by other cells and alter their phenotype. Here we asked whether CLL derived exosomes are taken up by endothelial cells, modify their phenotype and transforming them to CLL-supportive cells.
Aims: 1) To quantify the uptake of CLL-exosomes by vascular endothelial cells. 2) To determine whether CLL-exosomes alter the phosphoproteomics makeup of recipient endothelial cells. 3) To determine whether and how exosomal-treated endothelial cells support the survival of CLL cells.
Methods: CLL cells were isolated from patients and cultured in exosome free medium for 72h. Thereafter, exosomes were isolated from the cultured media by ultracentrifugation and quantified by NanoSight tracking system. Human Umbilical Vein Endothelial Cells (HUVEC) were exposed to CLL-derived exosomes. The uptake of exosomes was quantified by flow cytometry and by fluorescent microscopy. The phosphoprotein profiling of exposed and unexposed cells was analyzed by Mass spectrometry. RT-PCR was conducted to validate the array results and Western blotting was employed to quantify levels of beta catenin protein. IL-6 levels in culture media were quantified by ELISA. To annotate the proteomics data we used DAVID (Database for Annotation, Visualization and Integrated Discovery) and ANAT (Advanced Network Analysis Tool).
Results: We found that HUVECs uptake exosomes in a dose and time dependent manner, the pick uptake being 24 h from exposure. 52 peptides were significantly more phosphorylated after the cells were exposed to CLL-derived exosomes. Intriguingly, none of the peptides tested had reduced phosphorylation status in exosomal-treated cells. The phosphoproteomics results were validated in 3 of 52 top altered peptides. These proteins are involved in "cell to cell adhesion", operative for trafficking and retention of CLL cells in the bone marrow and lymphoid organ, "mRNA splicing" and "phosphorylation of the PDZ motif" which facilitate the anchoring of receptor proteins to the actin cytoskeleton. Among these 52 proteins is beta catenin for which phosphorylation levels increased 3.5-fold after CLL exosomal exposure. It was shown to induce secretion of IL-6. Furthermore, IL-6 induces STAT3 phosphorylation, thus increasing CLL cells' viability. We confirmed that phosphor-beta catenin is several fold higher in exosomal-treated cells and these cells secrete IL-6 to the cultured media.
Summary and Conclusions: By secreting exosomes which carry a cargo of mRNAs and proteins CLL cells reprogram endothelial cells to activate various pathways. In this way the crosstalk between CLL cells and endothelial cells may contribute to CLL cells' survival at lymph nodes where CLL cells survive and proliferate.

PF323

DYNAMIC REGULATION OF THE HS1/CXCR4 AXIS IN CHRONIC LYMPHOCYTIC LEUKAEMIA CELLS

L. Pavesi[1,2,*], F. Barbaglio[1], L. Scarfò[12], E. Ferrero[1], D. Belloni[1], M. Ponzoni[2,3], L. Bongiovanni[3], D. Zambroni[4], V. Caiolfa[4,5], K. Stamatopoulos[6], F. Caligaris-Cappio[7], P. Ghia[1,2], C. Scielzo[1]

Background: Chronic Lymphocytic Leukaemia (CLL) cells traffic and home to specific hemato-lymphoid tissues where they interact with the surrounding microenvironment, proliferate and accumulate. We previously identified Hematopoietic Cell-Specific Lyn Substrate 1 (HS1) protein, a central cytoskeletal regulator, as a strong prognostic factor in CLL patients and found that HS1 activity and expression significantly impact on the migration, adhesion and bone marrow (BM) homing of CLL cells. We here report the identification of a novel HS1/CXCR4 axis that is heterogeneously expressed (in a dynamic fashion) in the leukemic clone especially in the BM and is possibly involved in the regulation of trafficking, homing and tissue retention of CLL cells.
Aims: The aim of the present study was to dissect: (1) HS1 and CXCR4 expression in different hemato-lymphoid tissues infiltrated by CLL cells; (2) CLL cell dynamics thanks to novel 3D models that better mimic the complexity of the *in vivo* microenvironment.
Methods: We utilized: (1) primary cells derived from CLL patients' peripheral blood (PB) or BM, (2) CLL cell lines (MEC1, Knocked-Down or WT for HS1 expression), (3) human BM derived stromal cells (HS-5) to perform co-cultures. To mimic the BM setting, we optimized a 3D co-culture model (CLL+HS-5 cells seeded on spongostan scaffolds) coupled with a dynamic growth in a bioreactor under microgravity, interestingly also suitable to analyse cell mobilization from the scaffold after kinase inhibitor treatment. We evaluated changes in HS1/CXCR4 axis expression by RT-qPCR and confocal microscopy. We concomitantly evaluated at single cell level the intra-clonal expression of HS1/CXCR4 by ImageStream analysis (capable to combine flow cytometry and imaging).
Results: By analysing BM and PB CLL cells isolated from 9 CLL patients we found that both *HS1* and *CXCR4* were significantly down-regulated in the BM (p=0,0498). At single cell level, HS1/CXCR4 expression appeared to be heterogeneous and we observed a population negative for HS1 expression mainly represented in the BM, as confirmed by ImageStream. Considering the possibility of microenvironmentally-mediated regulation of the *HS1/CXCR4* axis, we co-cultured in 2D CLL cells in the presence of HS-5 cells and observed significant down-regulation of *HS1* (p=0,0062) and *CXCR4* (p=0,0537) in the leukemic clones. Accordingly, our 3D model allowed to detect strong down-regulation of the *HS1/CXCR4 axis* in the scaffold, while the expression remained unchanged in the cells outside the scaffold, confirming the dynamic expression of the genes.
Taking advantage of our 3D model, we tested Ibrutinib effect on primary CLL cells and observed a strong mobilization effect on all patients analysed (n=8, p=0,0047), and that cells retained in the scaffold maintained HS1/CXCR4 axis downregulation.
Summary and Conclusions: The present findings support our hypothesis that tissue homing and migration of CLL cells *in vivo* are tightly regulated by a complex interplay between cytoskeleton regulators (HS1) and chemokine receptors (CXCR4), that changes over time. Our novel 3D *in vitro* model appears to closely mimic the *in vivo* setting, allowing to observe and follow dynamic changes occurring in tissues, especially in the BM, including the pharmacological effect of novel inhibitors that cannot be thoroughly explored in conventional 2D co-culture models.

PF324

CHRONIC LYMPHOCYTE LEUKEMIA CELLS SHARE A UNIQUE CIRCULAR RNA EXPRESSION PATTERN

O. Raz[1,*], G. Granot[1], M. Pasmanik-Chor[2], P. Raanani[3,4], U. Rozovski[3,4]

[1]Felsenstein Medical Research Center (FMRC), Beilinson Hospital, Rabin Medical Center, Petah Tikva, [2]Faculty of Life Sciences, Tel-Aviv University, Tel Aviv, [3]Institute of Hematology, Davidoff Cancer Center, Beilinson Hospital, Rabin Medical Center, Petah Tikva, [4]Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel

Background: MicroRNAs are known to be dysregulated in CLL and have been shown to be involved in the initiation and progression of the disease. The role of other non-coding RNAs in the pathobiology of CLL is less clear. Circular RNAs (circRNAs) are endogenous noncoding RNAs that represent approximately 10% of the human transcriptome. They result from noncanonical alternative splicing which generates a stable circular form through a covalent bond between their 3' and 5' ends. The expression profile of circRNAs has been shown to have a unique pattern in various pathological conditions. Yet, their expression has not been tested in CLL. Although the exact mechanism of action of circRNAs remains to be clarified, one suggested mode of action is regulation of gene expression via an interaction with miRNAs thus functioning as miRNA sponges. Other alternative modes of action include protein binding or regulation of transcription and post-transcriptional modifications. Through these functions, circRNAs may act as tumor suppressors or as oncogenes and contribute to the pathogenesis and/or progression of CLL
Aims: To decipher the circRNA expression profile in CLL cells and compare it to that of normal B-lymphocytes and to evaluate the potential impact of the CLL specific circRNA profile on the pathogenesis and/or progression of CLL.
Methods: Lymphocytes from 6 CLL patient and 3 healthy volunteers were separated on a ficoll gradient and B cells were sorted with the aid of magnetic anti-CD19+ microbeads. circRNA expression in CLL lymphocytes was identified and quantified using a microarray based platform, provided by Arraystar Inc. Real-time PCR was used to validate the microarray results. Extensive bioinformatics analysis was performed in order to construct circRNA-miRNA-mRNA-protein networks and to identify pathways that may be influenced by these differently expressed circRNAs.
Results: Of the 13,438 circRNAs transcripts that are represented in the array, 13,195 (98%) were present in at least 3 of 9 sample tested, indicating that circRNAs are abundant in both normal and neoplastic lymphocytes. Overall, 397 circRNAs were upregulated in CLL cells compared to normal B cells and 688 were downregulated. This downregulation of circRNA expression is 2 folds more than is expected by chance ($P<0.01$), suggesting a possible global downregulation of cirRNA transcription activity in CLL cells. Next, in an attempt to model a possible sponge effect, we constructed four circRNA-miRNA-mRNA networks. Two networks represent up regulated circRNAs (hsa_circRNA_104424, hsa_circRNA_100251) and two represent downregulated circRNAs (hsa_circRNA_102680, hsa_circRNA_001430). Each network consists of one circRNA, five miRNAs and over 1000 target genes. Deregulated expression of all of the circRNAs was verified by real-time PCR. Multiple fundamental biological processes that may be associated with the deregulated circRNAs including; apoptosis, cell cycle regulation, B cell activation and RNA transcription and processing were revealed by the DAVID and WebGestalt database resource and by GO enrichment analysis.
Summary and Conclusions: Our study demonstrates that the circRNA profiling of CLL cells is significantly different from that of normal B-cells and revealed that the deregulated circRNAs may have profound impact on the pathogenesis of CLL. This is the first study publishing circRNA profiling in CLL thus paving the way towards an understanding of whether a specific expression pattern is associated with prognosis and whether targeting circRNAs may have therapeutic benefit in CLL.

PF325

T CELL CLONAL DYNAMICS ARE ASSOCIATED WITH CLINICAL RESPONSE AFTER LENALIDOMIDE CONSOLIDATION TREATMENT IN CLL

A. Vardi[1], E. Vlachonikola[2], C. Galigalidou[2], K. Gemenetzi[2], K. Pasentsis[2], N.E. Kay[3], A. Anagnostopoulos[1], A.G. Ramsay[4], T.D. Shanafelt[5], K. Stamatopoulos[2], A. Hadzidimitriou[2,*]

[1]Hematology Department & HCT Unit, G. Papanikolaou Hospital, Thessaloniki, Greece, [2]Institute of Applied Biosciences, Centre for Research and Technology, Thessaloniki, Greece, [3]Division of Hematology, Department of Medicine, Mayo Clinic, Rochester, MN, United States, [4]Department of Haemato-Oncology, School of Cancer and Pharmaceutical Sciences, Faculty of Life Sciences and Medicine, King's College London, London, United Kingdom, [5]Division of Hematology, Stanford University School of Medicine, Stanford, CA, United States

Background: The T cell repertoire in chronic lymphocytic leukemia (CLL) is characterized by the existence of clones which persist and expand over time in untreated patients, appear to be disease-specific and may be shared by different cases, alluding to selection by CLL-related antigens. In preliminary NGS immunoprofiling studies investigating the impact of treatment on T cell repertoire dynamics in CLL, we suggested that while chemoimmunotherapy increases T cell clonality through an ablative mechanism, signaling inhibitors retain T cell clones that may have developed in response to tumor antigens. In order to further explore the differential impact of various treatment types, we evaluated the *in vivo* impact of an IMID (lenalidomide [len]) on T-cell dynamics. *Ex vivo* studies suggest len may repair the B-T cell immune synapse defect in CLL.
Aims: To investigate T cell dynamics overtime in a phase II trial for previously untreated CLL patients where len was administered as consolidation following pentostatin-cyclophospamide-rituximab (PCR).
Methods: We analyzed paired samples from 14 CLL patients (i) after com-

pleting 6 cycles of PCR (post-PCR, pre-len) and (ii) following 6 months of continuous lenalidomide administration (post-len). TRBV-TRBD-TRBJ gene rearrangements were PCR-amplified on DNA from PBMCs, subjected to paired-end NGS and characterized in detail by a standardized bioinformatics pipeline.

Results: Only productive TRBV-TRBD-TRBJ rearrangements were evaluated (n=2,916,367; median 99,468/sample). For repertoire analysis, clonotypes (*i.e.* rearrangements with identical TRBV gene usage and TRB CDR3 amino acid sequence) were considered (median: 7006 distinct clonotypes/sample). All cases displayed significant clonal expansions both pre- and post-len (clonality, measured as median cumulative frequency of the 10 most expanded T cell clonotypes/sample, 20.1% *vs* 27.0%, respectively), with post-PCR major T cell clones persisting over len treatment (median of 5/10 most expanded post-PCR clonotypes). However, there was no clear trend in clonal dynamics post len-treatment, with clonality increasing in 9 patients and decreasing in the remaining 5 patients (p=0.43). Therefore, we evaluated the association between clonality changes and clinical response among cases with available staging data (n=10). Deepening clinical response [from partial remission (PR) to complete remission (CR), n=2] and sustained CR status (n=2) were associated with decrease in T cell clonality (24.5% pre-len *versus* 14.3% post-len), while stable PR status (n=5) or progressive disease (n=2) were associated with increased T cell clonality (18.3% pre-len *versus* 31.2% post-len). Despite small sample size, the clonality fold-change difference between these two groups was statistically significant (median fold change 0.66 *versus* 1.48, respectively, p=0.004).

Summary and Conclusions: Differential T cell clonal dynamics were observed with respect to clinical response following len consolidation in treatment-naïve CLL patients who had received induction chemoimmunotherapy. Clonality increase in stable PR or progressive disease recalls previous findings of T cell clones expanding overtime in untreated CLL patients, possibly in response to CLL-related antigens, albeit unable to mount effective anti-tumor responses. On the other hand, eradication of the malignant clone in patients achieving sustained CR or deepening response may explain the decrease in T cell clonality in the context of gradual reconstitution of a "normal" T cell repertoire after the ablative effect of chemoimmunotherapy.

PF326

PREVALENCE AND PROGNOSTIC IMPACT OF THE IGLV3-21 G110R MUTATION IN CLL – A PATHOBIOLOGICAL REDEFINITION OF THE UNFAVORABLE CLL SUBTYPE II

R.S. Barendse[1], W. Ismailzada[1], M.T. Koning[1], E. Quinten[1], H. Jumaa[2], C. A. van Bergen[1], H. Veelken[1,*]

[1]Hematology, Leiden University Medical Center, Leiden, Netherlands, [2]Immunology, University of Ulm, Ulm, Germany

Background: One-third of CLL cases can be classified into stereotypes by sequence similarities of their B-cell receptors (BCR). CLL stereotypy has been interpreted as consequence of selection for antigen binding. Since antigen-independent, autonomous BCR signaling has been discovered as an indispensable, dominant oncogenic CLL driver, stereotypy likely reflects BCR sequences that structurally facilitate autonomous BCR signaling. CLL subtype II has a relatively poor prognosis and is conventionally defined by expression of a mutated IGHV3-21/IGHJ06-containing BCR heavy chain (HC) with a CDR3 of 9 amino acids and a D or E residue at position 3, and coexpression of an IGLV3-21-containing BCR light chain (LC). A recurrent G110R mutation of the IGLV3-21 allele causes autonomous BCR signaling in subtype II.

Aims: 1. To determine the prevalence of the IGLV3-21^{G110R} mutation in CLL. 2. To assess its impact on the natural CLL history, irrespective of its occurrence in conventionally defined subtype II.

Methods: BCR HC and LC sequences were determined by ARTISAN PCR on 132 cases of biobanked CLL (diagnosis confirmed by immunophenotyping). Time from diagnosis to first treatment (TTFT) and overall survival (OS) were obtained from patients' records and compared by log-rank test.

Results: Six CLL cases (4.5%) were conventional subtype II, all indeed expressing the mutated IGLV3-21^{G110R} allele. Four CLL (3.0%) expressed a LC containing wild-type IGLV3-21. Twenty-six CLL expressed IGLV3-21 that carried the G110R mutation (19.7%; 95% CI: 12.9-26.5%). In 122 CLL with sufficient clinical information, age, Rai stage, and chromosomal aberrations were not significantly different between IGLV3-21^{G110R}-expressing and remaining mutated CLL. Conventional subtype II cases had a non-significantly different TTFT (median: 22 months) from unmutated CLL (n=65; median 13 months; p=0.91) and an inferior TTFT compared to the remaining mutated CLL (n=51, median 121 months; p=0.016). TTFT of IGLV3-21^{G110R}-expressing CLL (median: 28 months) was similar to unmutated CLL (p=0.23) and strikingly inferior to the remaining mutated CLL (median: 147 months; p<0.0001). TTFT of IGLV3-21^{G110R}-expressing CLL not belonging to conventional subtype II (*i.e.* expressing a HC chain not containing IGHV3-21; n=20) likewise had an inferior TTFT (median: 28 months; p=0.001) than mutated CLL not expressing IGLV3-21^{G110R}. The median OS of patients with conventionally defined subtype II CLL (146 months) was not statistically different from the remaining mutated CLL (211 months) or unmutated CLL (102 months). Patients with a IGLV3-21^{G110R}-expressing CLL had inferior median OS (143 months) compared to mutated CLL (247 months; p=0.03); their survival was not significantly different form unmutated CLL (101 months; p=0.08). When conventional subtype II cases were excluded, OS of IGLV3-21^{G110R}-expressing CLL (132 months) remained inferior to mutated CLL (p=0.04) but was not significantly different from unmutated CLL (p=0.12) (Figure 1).

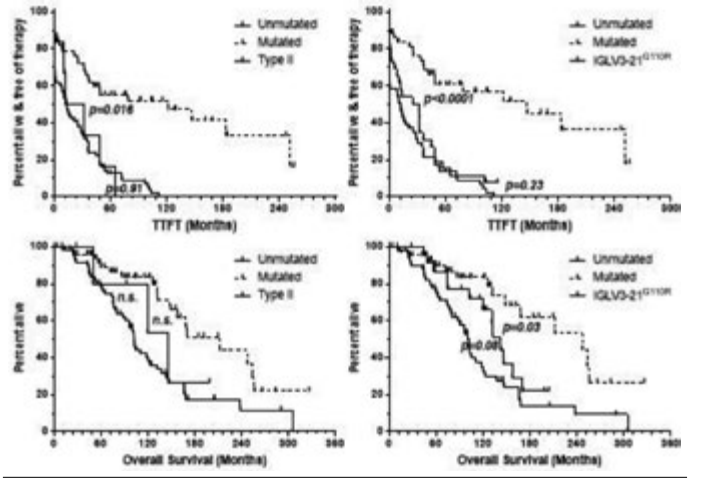

Figure 1.

Summary and Conclusions: The IGLV3-21^{G110R} mutation has an unfavorable prognostic impact in accordance with its role in causing antigen-independent, autonomously active BCR signaling. The IGLV3-21^{G110R} mutation rather than BCR HC criteria should serve as a new definition of the prognostically unfavorable CLL subtype II, thereby creating the largest (app. 20%) immunologically defined subgroup of CLL.

PF327

EVOLUTION OF GENOMIC ABNORMALITIES DURING CLL DISEASE COURSE IS ASSOCIATED WITH TELOMERE LENGTH CHANGES

H. Olbertova[1,2,*], K. Plevova[1,2], J. Malcikova[1], J. Kotaskova[2], S. Pavlova[1], M. Spunarova[2], M. Trbusek[2], V. Navrkalova[1], B. Kantorova[2], Y. Brychtova[2], A. Panovska[2], M. Doubek[2], S. Pospisilova[1,2]

[1]Central European Institute of Technology, Masaryk University, [2]Department of Internal Medicine – Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Czech Republic

Background: Telomeres are structures protecting the ends of chromosomes, which are getting shorter with each cell division. In CLL a telomere length is considered to be stable during disease course, even despite a treatment administration. It was also shown that short telomeres predict for an early need of treatment and reduced overall survival, and associate with the unmutated status of IGHV locus and higher genomic complexity.

Aims: To study telomere length in the context of genomic architecture of CLL clones and their evolution during disease course.

Methods: Telomere length was measured in 198 CLL patients using established qPCR protocol. Relative telomere length (RTL) was assessed by comparing to β-globin (HBB) as a single-copy gene and Human Genomic DNA (Promega) as a reference DNA. Genes recurrently mutated in CLL were sequenced by amplicon next-generation sequencing. Following mutation frequencies were found using 5% VAF cut-off: *TP53* (82/244; 33.6%), *ATM* (45/233; 19.3%), *NOTCH1* (36/242; 14.9%), *SF3B1* (59/238; 24.8%), *BIRC3* (26/232; 11.2%). In 36 patients with clonal evolution detected in relapse, samples from two (29 cases), or more than two (7 cases) timepoints were analyzed. Relative expression of hTERT telomerase subunit was assessed by reverse transcription TaqMan qPCR assay, using GAPDH as a housekeeping gene and RAMOS cell line as a positive control.

Results: In the cohort of 198 CLL patients, significant associations with time to first treatment, IGHV mutation status, 11q deletion, complex karyotype and mutations in *TP53* and *ATM* genes were found in concordance with published results. In 36 patients that manifested CLL cells clonal evolution, telomere length of the major leukemic clone was different between pre-therapy and corresponding relapse sample. This specific cohort consisted primarily of patients with therapy-driven *TP53* mutation expansion (26/36; 72.2%). Changes in other tested genes were less frequent in this subgroup, which precluded their more detailed evaluation. Thus, focusing only on the cases with *TP53* evolution, we observed that telomeres in relapse became shorter, remained stable, or became longer in 12/26 (46.1%), 8/26 (30.8%), and 5/26 (19.2%) of patients, respectively. Additionally, in 1/26 cases studied in three timepoints, telomeres initially lengthened and subsequently shortened following exchange of dominating TP53 mutation clone (Figure 1). Altogether, in 4/7 cases with TP53 mutation proportion change tested in >2 timepoints, telomere length changed according to alteration in TP53 mutation proportion. Since the observed changes of telomere length could potentially be caused by deregulated telomerase, we tested also the hTERT gene expression in all 36 patients who underwent clonal evolution. However, only weak or null hTERT expression was detected, showing no apparent correlation with telomere length or its change.

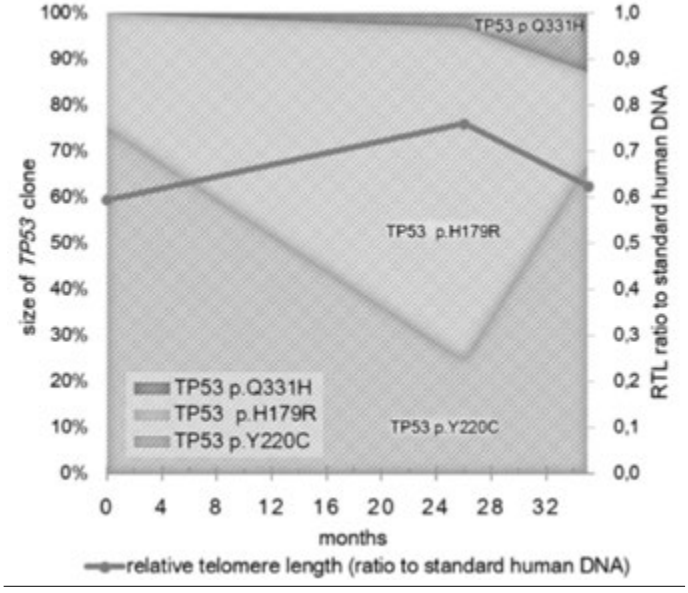

Figure 1. Example case for telomere length change associated with changing dominant clone of TP53.

Summary and Conclusions: Although telomere length is generally considered to be stable in CLL, our findings suggest that in patients undergoing clonal evolution significant changes may occur. This telomere length evolution can be likely attributed to selective pressure of therapy favoring some clones over the others. Our observation concerns primarily an acquisition of *TP53* defects, thus further investigation also in the context of other CLL-related genes is warranted.

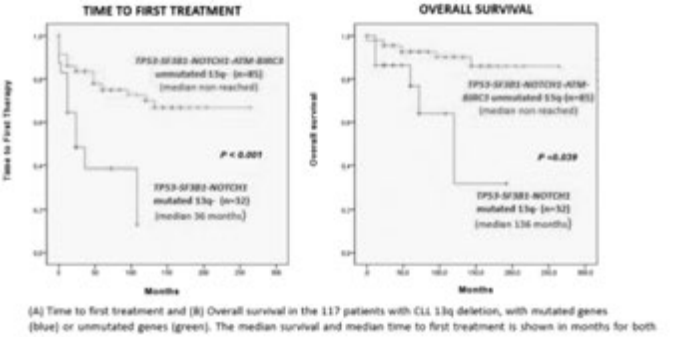
Background: 13q deletion (13q-) is the most common cytogenetic aberration in chronic lymphocytic leukemia (CLL) associated with a favorable prognosis. However, CLL patients showing 13q- can have a variable outcome. Although the use of next-generation sequencing (NGS) has expanded our knowledge of the genomic alterations in CLL, the mutational background of 13q- patients has not been analyzed in detail so far.

Aims: To analyze the mutational status of CLL patients with 13q- by NGS in order to improve our understanding of the genetic underpinnings of this subgroup of CLL.

Methods: A total of 213 untreated CLL patients were selected for the study. Clinical and biological data were recorded. CD19 positive B cells were isolated and DNA extracted to perform NGS. The mutational status of 54 genes (8,952 probes, 416 Mb) was evaluated using a custom-designed gene panel (MiSeq, Illumina) including recurrent mutated genes in CLL associated with CLL pathogenesis. 95% of regions were sufficiently covered (>100X) and a mean depth of 343 reads/base within the regions of interest was obtained, allowing us to identify variants at low allele frequencies (down to 3%).

Results: A total of 117 patients (54.9%) had 13q- as a sole abnormality. Most patients (82.9%) were in Binet's stage A. The median follow-up for the CLL patients was 60 months. A total of 172 mutations were detected in 39 genes in seventy-three 13q- CLL patients (13q- mut). The median of mutations detected per patient was 1 (0-7). 63% of the 13q- mut cases presented more than one mutation. Surprisingly, the most frequently mutated genes were *NOTCH1* (16.7%), *TP53* (14.3%), *SF3B1* (11.9%) *ATM* (7.1%) and *BIRC3* (4.7%), genes previously associated with bad prognosis. The presence of mutations was associated with Binet B/C (p<0.001), unmutated *IGHV* gene (p=0.001), CD38 positivity (p=0.05) and need for treatment (p=0.004). Of note, in 13q- patients with mutations in *NOTCH, TP53, SF3B1, ATM or BIRC3* (32 cases, 27.35%), OS was 136 months (CI95% 98–174) whereas in the group without any mutation, OS has not been reached (CI95% 216–254) (p=0.039). In the univariate analysis, Binet B/C (p<0.001), unmutated *IGHV* status (p<0.001), B symptoms (p=0.002), hepatomegaly (p<0.0001), splenomegaly (p=0.01), lymphocyte count>20·10^9/L (p<0.001) and b2M high levels (p=0.048) were significant associated with a short OS. In the multivariate analysis, only unmutated *IGVH* status resulted significant in predicting OS (HR 5.89, CI95% 1.15–30.13, p=0.033). Regarding TFT, in 13q- mut patients the median TFT was 36 months (CI95% 0–87.7), whereas in the group without any mutation TFT has not been reached (p<0.001). In the univariate analysis, significant variables were Binet B/C (p<0.001), unmutated *IGHV* status (p<0.001), b2M levels (p<0.001), splenomegaly (p=0.015), lymphocyte count>2020·10^9/L (p<0.001), the percentage of cells >80% with 13q- (p=0.008) and B symptoms (p<0.001). In the Cox analysis, Binet stage (HR 10.1, CI95% 2.83–26.89,p<0.0001), B symptoms (HR 0.17, CI95% 0.05–0.54, p=0.003), lymphocytes count >20·10^9/L (HR 0.38, CI95% 0.18–0.81,p=0.012) and the presence of mutations in *NOTCH, TP53, SF3B1, ATM or BIRC3* (HR 0.45, CI95% 0.21–0.96,p=0.039) resulted significant in predicting TFT (Figure 1).



(A) Time to first treatment and (B) Overall survival in the 117 patients with CLL 13q deletion, with mutated genes (blue) or unmutated genes (green). The median survival and median time to first treatment is shown in months for both groups.

Figure 1.

Summary and Conclusions: 13q- CLL patients with mutations in *NOTCH1, TP53, SF3B1, ATM* or *BIRC3* have shorter overall survival (OS) and time to first treatment (TFT).

PF329

CHARACTERIZATION OF A NOVEL ENTITY IN CLL: SYMPTOMATIC BRONCHIAL INVOLVEMENT; A STUDY OF THE FRENCH INNOVATIVE LEUKEMIA ORGANIZATION (FILO) GROUP

M. Nudel[1,*], F. Baran-Marszak[2], R. Dubois[3], H. Dapvril[4], J. Dupuis[5], K. Laribi[6], J.O. Bay[7], C. Tomowiak[8], B. Dreyfus[8], S. Lepretre[9], H. Demarquette[10], F. Wallyn[11], L. Wemeau[11], M. Wemeau[12], S. Poulain[13], F. Morschhauser[10], F. Cymbalista[14], C. Herbaux[10]

Background: Chronic lymphocytic leukemia (CLL) infiltration is mostly described in peripheral blood, lymph nodes and bone marrow. Large autopsy reviews revealed that other organs can be infiltrated by CLL. Nevertheless, extra-medullary infiltration is rarely responsible of symptoms. Leukemic pulmonary infiltration (LPI) is a well-known process with a development of the disease in the lung parenchyma. Bronchial involvement is a distinct infiltration that has been rarely described in few case reports.
Aims: The aim of this study is to better characterize symptomatic infiltration of the bronchial tree by CLL, using clinical, radiological, biological and therapeutic tools.
Methods: We retrospectively collected 19 cases of symptomatic bronchial involvement of CLL. A histological evidence of bronchial involvement by CLL lymphocytes was available for 17 patients (90%). We disposed of lung function tests for 13 patients. Airflow obstruction was defined by a ratio of Forced Expiratory Volume in one second on Forced Volume Capacity less than 0.7. A thoracic CT scan was performed for 18 patients. A central reanalysis of thoracic CT scan was performed for 13 patients. Molecular analysis by NGS was performed on 15 patients.

Figure 1. Example of chest CT scan: endobronchial nodules.

Results: During the course of the disease, all patients presented bronchial symptoms: cough, recurrent bronchitis, dyspnea. Bronchial spur biopsies showed a diffuse mucosal infiltration by small B lymphocytes with a cytoplasmic expression of CD79a, CD5 and CD23. In the remaining 2 patients, a body of evidence strongly suggested a bronchial involvement (symptoms, imaging and analysis of bronchoalveolar lavage fluid). Lung function tests revealed an airflow obstruction in 9/13 (69%) evaluated patients. The presence of bronchial involvement was not correlated with the importance of lymphocytosis. Karyotype or FISH were available for all patients. Of note, a high incidence of trisomy 12 was observed: 7/19 cases (36.8%) concordant with a low incidence of del13q (4/19: 21%). Molecular analysis found different mutations: 5 *TP53*, 4 *NOTCH1*, 2 *SF3B1*, 2 *RPS15*, 1 *FBXW7* and 1 *ATM* mutations. Thoracic CT scan analysis revealed a radiological anomaly of the bronchial tree for all patients. The presence of multiple endobronchial nodules was observed; these lesions are extremely rare and seem pathognomonic of the bronchial involvement by CLL. Symptomatic bronchial involvement had an impact on treatment initiation (first line or more) for 13 patients (76%). It was the only treatment criteria for 9 patients (53%). Other signs of CLL proliferation were not always noted. Indeed, Binet stage was A for 6 patients (32%), B for 11 (52%) and C for 2 patients (16%). Treatments included classic immunochemotherapy and BCR inhibitors. Twelve patients (66%) presented an improvement of bronchial symptoms (clinical, lung function test and/or CT improvement) after CLL treatment (Figure 1).
Summary and Conclusions: To our knowledge, this is the first extensive description of this type of extra medullary involvement in CLL. Symptomatic bronchial involvement by CLL may occur in the absence of other signs of progression. Airway obstruction symptoms in CLL should rapidly lead to an anatomopathologic analysis by bronchial spur biopsy if lung function tests and CT scan are compatible. In particular, the presence of multiple endobronchial nodules is very evocative. This study establishes a novel entity in CLL, the specific bronchial involvement. It should be suspected in case of unexplained bronchial symptoms and can indicate the initiation of CLL therapy, even in the absence of other classical treatment criteria.

PF330

GENETIC ABERRATIONS AND PROGRESSION-FREE SURVIVAL IN CLL PATIENTS TREATED WITH FRONT LINE RITUXIMAB-BASED CHEMOIMMUNOTHERAPY (FCR/BR): CLINICAL PRACTICE EXPERIENCE

M. Spunarova[1,*], J. Malcikova[1], N. Tom[2], M. Borsky[1], Y. Brychtova[1], M. Doubek[1], A. Panovska[1], H. Skuhrova Francova[1], K. Durechova[1], A. Brzobohata[1], A. Freibergerova[1], M. Jarosova[1], M. Mraz[1], S. Pospisilova[1], J. Mayer[1], M. Trbusek[1]

[1]University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, [2]CEITEC, Masaryk University, Brno, Czech Republic

Background: Fludarabine with cyclophosphamide and rituximab (FCR) constitute a front-line therapy for younger and fit chronic lymphocytic leukemia (CLL) patients. Elderly patients should be provided with alternative regimen consisting of bendamustine with rituximab (BR). Neither of these regimens is suitable for CLL patients harboring *TP53* defects. Inferior prognosis after FCR treatment has also been reported for patients with unmutated status of the immunoglobulin heavy chain variable region (*IGHV*), 11q deletion (11q-) or *NOTCH1* gene mutations.
Aims: To analyze progression-free survival (PFS) according to the presence of genetic defects in CLL patients treated with front line FCR or BR regimen in routine clinical practice at a large university hospital.
Methods: Mutation analysis of *ATM* (exons 2-63), *SF3B1* (exons 14-16), *NOTCH1* (part of exon 34 a 3 UTR), *BIRC3* (exons 7-10) and *TP53* (exons 2-11) genes was performed by the next-generation sequencing using MiSeq (Illumina) in pre-therapy samples. The cut-off was set at 10% VAF to consider clinicaly relevant mutated clones. *ATM* variants were verified by online tools (SIFT/PolyPhen), and by western blot (WB) of ATM level. Notch1 protein level (ICN domain) was assessed by WB in *NOTCH1*-mutated patients. Cytogenetic aberrations and *IGHV* status were determined by karyotyping, FISH and sequencing. Complex karyotype (CK) presence (analyzed at least 15 mitoses) was defined as three or more aberrations in two or more mitoses. The PFS analysis was done by log-rank (Mantel-Cox) test using interval from therapy initiation to clinical progression (according to the iwCLL recommendations) or the last follow up. Patients were provided with 2-6 cycles (median 4) of FCR (n=77 patients), FCR-Lite (reduced doses; n=30) or BR (n=43) according to clinical protocols.
Results: For PFS analysis, we included only patients with intact *TP53* gene (n=150). Further, 8 patients experienced progression or stable disease after the therapy and were also excluded from the PFS analysis; they did not manifest a predominant genetic trait. The PFS was assessed on the final cohort of 142 patients; 100 of them (70%) harbored unmutated *IGHV*. We observed the following outputs: (a) similar effect of FCR and BR regimens (median PFS 30 and 28 months (m), respectively); this justifies the pooling of the regimens to one analysis; (b) clear impact of *IGHV* mutation status (27 *vs* 52 m in unmut-*IGHV* and mut-*IGHV* patients; P 0.001); based on this result, we performed subsequent analyses separately according to the *IGHV* status; (c) clear negative impact of *ATM* mutations in patients with mut-*IGHV* (25 *vs* 56 m in *ATM*-wt patients; P=0.017); (d) no negative impact of *ATM* mutations in patients with unmut-*IGHV* (30 *vs* 24 m in *ATM*-wt patients); (e) very short PFS in patients with sole 11q- (other *ATM* allele intact) (15 m *vs* 28 m in *ATM*-wt patients and 30 m in *ATM*-mut

patients; P=0.052); the analysis was done in *IGHV*-unmut patients (f) no impact of *SF3B1* mutations; (g) no impact of *NOTCH1* mutations or high Notch1 protein level; (h) no impact of CK; (i) trend to shorter PFS in patients with *BIRC3* mutations (19 *vs* 28 m in *BIRC3*-wt patients; P=0.056). Note: analyses (g)–(i) were performed in *IGHV*-unmut patients.
Summary and Conclusions: We show predictive impact of *IGHV* status after the first-line FCR/BR. The shortest PFS was recorded for patients with unmutated *IGHV* and sole 11q-. We did not observe negative impact of Notch1 activation, *SF3B1* mutations or CK on the PFS. Supported by projects AZV 16-32743A, FNBr 65269705, MUNI/A/0968/2017.

CIRCULATING SEX HORMONES AND NUCLEAR HORMONE RECEPTOR EXPRESSION ARE ASSOCIATED WITH TREATMENT-FREE SURVIVAL IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

E.P. Allain[1], K. Venzl[2], P. Caron[1], V. Turcotte[1], D. Simonyan[3], M. Gruber[2], T. Le[2], E. Lévesque[1], C. Guillmette[1,4], K. Vanura[2,*]

[1]Laval University, Quebec, Canada, [2]Medical University of Vienna, Vienna, Austria, [3]CHU de Québec Research Center, [4]Canada Research Chair in Pharmacogenomics, Quebec, Canada

Background: CLL is the most prevalent adult leukemia in the western world. While it is not considered a hormone-regulated cancer, sex is a known risk factor with a male/female incidence ratio of 2:1 and male patients also developing progressive disease more frequently. In spite of these significant clinical observations, a detailed analysis of sex steroids and pituitary hormones, and hormone receptor expressions in CLL patients is still lacking.
Aims: This study aimed to provide a first insight into sex steroids in CLL and explore possible relationships between these hormones, their receptors and disease progression in CLL. We hypothesized that variable hormonal exposure may have a sexually dimorphic effect on CLL progression.
Methods: We quantified 15 circulating sex steroids (androgens, estrogens and progesterone) by sensitive and specific mass spectrometry and measured two pituitary hormones (luteinizing hormone (LH) and follicular secreting hormone (FSH)) by immunoassay in 156 samples from mostly early-stage, treatment-free CLL patients. Nuclear receptor expression levels were measured by RT-qPCR. Data were analyzed separately by sex and in relation to treatment-free survival (TFS). Univariate and multivariate analyses of TFS were performed using Cox's proportional hazard model.
Results: Median age of CLL patients was 59.8 and 62.9 years for men and postmenopausal women, respectively. Expression-based and cytogenetic CLL prognostic markers had very similar frequencies between male and female cases. Median TFS was shorter for male patients than for women (80.7 *vs* 135.0 months, P=0.033). Hormonal profiles of CLL patients differed significantly from those of healthy donors whereas male CLL cases had higher levels of circulating steroids than female CLL patients, confirming the relevance of analyzing them separately. In male CLL cases, no association was noted between steroid levels and TFS; however, higher LH levels were associated with shorter TFS in multivariate analyses with an adjusted hazard ratio (HRadj) of 2.11 (P=0.004). In female CLL cases, high levels of potent ligands of the androgen receptor (AR), testosterone (T) and dihydrotestosterone (DHT), were associated with improved TFS with HRadj values of 0.24 (P=0.007) and 0.53 (P=0.023), respectively. In line, in univariate analyses, high AR expression was associated with improved outcome in female CLL cases (HR=0.70, P=0.009). A trend for a similar association with AR expression in male patients was also noted (HR=0.84, P=0.081), along with a trend for improved survival with high estrogen receptor α expression (HR=0.76, P=0.056).
Summary and Conclusions: This study is the first to comprehensively profile steroids and pituitary hormones in CLL patients and to establish a link between outcome of CLL patients and circulating hormones. It reveals a sex-specific hormonal imbalance associated with disease progression, and suggests a possible role for nuclear steroid hormone receptor signaling in CLL cases.

DESIGN AND MINION TESTING OF A NANOPORE SEQUENCING SPECIFIC GENE PANEL FOR CHRONIC LYMPHOCYTIC LEUKEMIA

P. Orsini[1], C. Minervini[1], C. Cumbo[1], L. Anelli[1], A. Zagaria[1], A. Minervini[1], N. Coccaro[1], G. Tota[1], P. Casieri[1], L. Impera[1], C. Brunetti[1], E. Parciante[1], A. Giordano[1], G. Specchia[1], F. Albano[1,*]

[1]D.E.T.O. - Hematology Section, University of Bari, Bari - Italy, Bari, Italy

Background: MinION is a single-molecule nanopore sequencer from Oxford Nanopore Technologies connected to a laptop through a USB 3.0 interface. Sequencing is performed by the moving of individual DNA strands through biologic nanopores on a chip, where an electric field is applied and electrical signal variations are recorded. In the last years, next generation sequencing (NGS) methods have identified a wide range of gene mutations which have improved our knowledge about chronic lymphocytic leukemia (CLL) development, allowing to refine both the prognostic subgroups and better therapeutic strategies. Consequently, it is reasonable to assert that integration of the newly discovered genetic lesions into a comprehensive prognostic model based on both chromosomal abnormalities and gene mutations would help to improve prognostication of CLL patients.
Aims: In this study, we report a custom gene panel assay based on multiplex long-PCR followed by sequencing on MinION to identify single nucleotide variations (SNV) and insertions/deletions (indels) in 5 prognostically relevant genes in CLL: TP53, NOTCH1, BIRC3, SF3B1 and MYD88.
Methods: We designed a custom gene panel consisting of 7 primers pairs in 2 pools, with a total panel size of 15kb. Twelve patients were selected according to specific cytogenetic and molecular features significantly associated with the mutational status of these genes. For each DNA sample, 2 multiplex long-PCRs were prepared. MinION library preparation, sequencing and data analysis were performed. All cases included in the study were analyzed by Sanger Sequencing (SS) or other molecular assays for all the targets included in the gene panel, in blinded manner.
Results: Read depth analysis showed that the range of sequencing depth was inversely related to the amplicon size, with the smaller amplicons having a higher coverage (up to about 2100x). Anyway, the minimum coverage value was never below 50x. The error rate calculated was on average 6% and 2% for indels and SNV respectively. Except for the known mutation hotspots of NOTCH1 and MYD88 and the polymorphisms identified, considering the low chance to find a rare variant simultaneously in a small cohort, we decided to exclude the variants occurring in multiple samples from further validation analyses; excluding these critical positions from the analysis, the actual coverage of the custom panel was 94,7%. These data are closely related to the chemistry and basecalling algorithms used and are probably intended to improve with the progress of nanopore technology. Overall, 8 pathogenic mutations were detected in 6 patients, with 2 patients harboring concurrently 2 mutations: 6 SNV and 2 indels. The lowest mutation allelic ratio was around 10%. These mutations were simultaneously identified and confirmed with SS or other molecular assays.
Summary and Conclusions: Our assay allows a rapid analysis of the prognostically relevant genes in CLL, with just 2 PCRs per patient. This is the first report of targeted gene sequencing based on a custom panel of prepooled multiplexed primers on MinION. This approach offers a rapid, easy and affordable workflow of analysis compared to SS or the common NGS platforms, even if it is still not ready to substitute the other NGS platforms because of MinION error proneness. Anyway, the rapid and constant improvements of nanopore technology promise an exclusive and convenient use of MinION in the next future.

Background: B-cell receptor (BCR) signaling is a key determinant of variable clinical behavior and a target for therapeutic interventions in chronic lymphocytic leukemia (CLL). Endogenously produced H_2O_2 is thought to fine-tune the BCR signaling by reversibly inhibiting phosphatases. However, little is known about how CLL cells sense and respond to such redox cues and what impact they have on CLL.
Aims: In this study, we aimed at characterizing signaling sensitivity to exogenous H_2O_2 in prognostic subsets of leukemic cells and investigating possible mechanisms regulating response of leukemic cells to redox cues in CLL.
Methods: We analyzed peripheral blood mononuclear cell (PBMC) samples from 42 untreated CLL patients and from 9 age-matched healthy donors. To characterize signaling response of BCR proteins to exogenous H_2O_2, we used phospho-specific flow cytometry. Antioxidant enzymes were analyzed

at mRNA level using real-time PCR quantification and at a protein level using monoclonal antibodies and flow cytometry.
Results: CLL cells exhibit a specific redox sensitivity pattern with an overall higher and more heterogeneous redox response than healthy-donor B cells. Moreover, exogenous H_2O_2 in the absence of BCR engagement induced a signaling response of BCR proteins that was higher in CLL with favorable prognostic parameters (M-*IGHV*, CD38 and ZAP70 negative expression) and an indolent clinical course, measured as a longer time to first treatment (TTFT). We hypothesized that redox hypersensitivity could be due to an increased accumulation of exogenous H_2O_2 within the cells –possibly linked to a reduced antioxidant capacity- which would induce a higher inhibition of phosphatases with the consequent shift of the enzymatic balance towards phosphorylation. To test this hypothesis, we analyzed major cellular antioxidant systems -enzymatic and nonenzymatic- and compared them between the two CLL subsets characterized by different redox sensitivity. We identified low *catalase* expression as a possible mechanism accounting for redox signaling hypersensitivity: inhibiting catalase activity resulted in a further increase of protein phosphorylation whereas incubation of cells with exogenous catalase before addition of H_2O_2 completely reversed protein phosphorylation induced by H_2O_2. These findings establish a functional link between catalase and redox sensitivity and support the hypothesis that a lower catalase activity could cause an escalated accumulation of exogenous H_2O_2 in leukemic cells, with a consequent greater inhibition of phosphatases and an increase in redox signaling sensitivity. Moreover, lower levels of *catalase* were significantly associated with a slower progression of the disease. In leukemic cells characterized by redox hypersensitivity, we also documented an elevated accumulation of reactive oxygen species (ROS) and an increased mitochondrial amount.
Summary and Conclusions: In conclusion, this study shows that differential redox profiles in CLL are associated with divergent clinical behaviors and advances our understanding of the redox and signaling heterogeneity of CLL. Future challenges are to design therapeutic strategies targeting redox pathways that could implement the effectiveness of current therapies and overcome drug resistance in CLL.

PF334

STAT3 AND STAT5B MUTATIONS IN LARGE GRANULAR LYMPHOCYTES LYMPHOCYTOSIS/LEUKEMIAS: DIAGNOSTIC AND PROGNOSTIC VALUE

N. Muñoz-García[1,*], M. Jara-Acevedo[1], C. Caldas[1], P. Bárcena[1], A. López[1], N. Puig[2], M. Alcoceba[2], N. Villamor[3], P. Fernandez[4], M. González[2], A. Orfao[1], J. Almeida[1]

[1]Department of Medicine and Service of Cytometry, Cancer Research Center [IBMCC, CSIC-USAL], University of Salamanca, IBSAL & CIBERONC, Salamanca, Spain, [2]Department of Hematology, University Hospital & IBSAL, Salamanca, [3]Department of Pathology, Hematopathology Unit, Hospital Clínic, IDIBAPS, University of Barcelona, Barcelona, Spain, [4]Department of FACS/Stammzell, Institut für Labormedizin, Kantonsspital, Aarau, Switzerland

Background: T-cell large granular lymphocytic leukemia (T-LGLL) and chronic lymphoproliferative disorders of natural killer cells (CLPD-NK) are rare entities usually showing an indolent clinical course; despite this, these diseases are often associated with autoimmune disorders and even in some cases may evolve into aggressive forms of leukemia. Diagnosis is usually difficult, due to the absence of clear phenotypic clonality/malignant-related markers, the difficulty of distinguishing T clonal expansions from reactive oligoclonal process of T cells and, in CLPD-NK, the absence of a universal molecular marker of clonality. The presence of somatic *STAT3* and *STAT5b* mutations has recently been found in a subgroup of T-LGLL (particularly in CD8+ T-LGLL) and CLPD-NK; however, its systematic utility in clinical settings remains unknown.
Aims: The aim of this study was to analyze the frequency and type of somatic mutations in the *STAT3* and *STAT5b* genes in all subgroups of clonal large granular lymphocytes (LGL) expansions, and relate these findings with the phenotype of the expanded cells, as well as with the clinical characteristics of patients with T-LGLL and CLPD-NK, in order to better establish its diagnostic and prognostic utility.
Methods: *STAT3* and *STAT5b* genes were sequenced in a total of 132 populations of FACS sorted lymphoid cells (previously phenotyped by flow cytometry), from 78 patients with monoclonal LGL expansions (35 TabCD8$^+$, 12 TabCD4$^+$CD8$^{-/+d}$, 1 TabCD4$^+$CD8$^+$, 2 TabCD4$^-$CD8$^-$, 12 Tgd and 16 CLPD-NK), 6 patients with oligoclonal LGL expansions (4 TabCD8$^+$ and 2 Tgd), 13 patients with non-cytotoxic T-CLPD and 35 polyclonal T-cell populations.
Results: Somatic mutations in *STAT3* and *STAT5b* genes were detected in 25/78 populations from patients with clonal LGL expansions (32%), all but one in the *STAT3* gene (Y640F mutation was the most frequent, among others previously described). Furthermore, two mutations – not previously described - were found (K658F and Gly656_Tyr657insPhe). According to the cell lineage involved in the expansion, mutations were present in 37% of TabCD8$^+$-LGLL, 20% of CLPD-NK, 8% of TabCD4$^+$CD8$^{-/+d}$-LGLL, 100% of TabCD4$^+$CD8$^+$-LGLL, 50% of TabCD4$^-$CD8$^-$LGLL and 50% of Tgd-LGLL. *STAT3* mutations were not only found in T-LGLL and CLPD-NK cases, but also in 1/14 population from a patient with non-cytotoxic T-CLPD. None of the polyclonal cytotoxic T-cell populations showed *STAT3* or *STAT5b* mutations. Two patients who had two or more clonal LGL expansions from different cell lineages (*i.e.* one of them from NK cells and the other(s) from T cells) showed that at least two of them had *STAT3* mutations, which would support the monoclonal diagnosis. In 15 out of 22 mutated cases (68%) in which clinical information could be available, patients showed a significantly higher incidence of autoimmune disorders (*vs* non-mutated monoclonal LGL expansions), further supporting the prognostic interest.
Summary and Conclusions: Our results support the utility of the *STAT3* and *STAT5b* mutations study for clonality assessment and prognostic evaluation in T-LGLL and CLPD-NK; additionally, these findings suggest that in LGLL, similar or identical activation pathways would be involved in the pathogenesis of the disease, regardless of the cytotoxic cell lineage involved.

PF335

T-PLL CELLS RESEMBLE MEMORY-TYPE T-CELLS WITH ABERRANT EFFECTOR FUNCTIONS IMPLICATING A LEUKEMOGENIC COOPERATION OF TCL1A WITH TCR SIGNALING

Background: The pathogenesis of the rare and aggressive T-cell prolymphocytic leukemia (T-PLL) is poorly understood, which particularly applies to a mechanistic concept around its hallmark oncogene TCL1A. Existing data implicate TCL1A as a catalytic enhancer of the oncogenic kinase AKT, a central node in a T-cell's antigen receptor (TCR) signaling cascade, which mediates proliferation and differentiation. The levels and role of TCR activation in T-PLL's pathogenesis are not known.
Aims: The aim of our study was to describe the T-PLL cell phenotypically, by gene expression, and their effector functions compared to healthy donor T-cells. Furthermore, we wanted to dissect TCL1As impact on T-cell receptor signaling and its functional relevance in leukemia development.
Methods: We performed immunophenotyping and gene expression profiling of 79 T-PLL samples and compared these to healthy donor derived T-cells. In functional experiments we used T-cell lines with or without TCL1A overexpression. Different mouse models were used for the investigation of TCL1As impact on leukemia development with or without *in vivo* stimulation.
Results: To first clarify which physiological T-cell subset T-PLL cells most resemble, we performed comprehensive global gene expression profiling & immunophenotyping of primary T-PLL (n=79) in comparison to healthy-donor derived T-cell populations. Principle component analyses and gene signature alignments revealed a high similarity of T-PLL cells to (central) memory T-lymphocytes over naïve T-cells. Surface markers revealed a spectrum of memory-type differentiation (n=69/79; 87%) with predominant central-memory stages (n=35/79; 44%). The usually TCR and/or CD28-coreceptor positive T-PLL cells revealed no restrictions to genetic or surface TCR-clonotypes. The abnormally high basal activation

levels (surface CD25, CD38, CD69) correlated in their degree with inferior clinical outcomes (med. survival 20.8 *vs* 58.3 mo.). In parallel, T-PLL cells lost expression of negative-regulatory TCR-co-receptors (*e.g.* CTLA-4, LAG3). Fittingly, TCR engagement of primary T-PLL cells revealed a trend to hyperactive intracellular responses and interleukin(IL)-2 release alongside a prominent Th1-cytokine program. T-PLL cells also showed a robust resistance to stimulation-induced cell death and agonistic CD95 ligation. TCR-derived signals (phospho-kinase induction, IL-2 release) were enhanced *in vitro* by the modulated presence of TCL1A with kinetics indicative of a sensitizer relationship, mainly in the CD3 axis as opposed to the CD28 branch.

A mouse model with TCL1A-initiated protracted development of T-PLL (*Lck*^{pr}*-TCL1A*^{tg}) revealed congruent findings with the aberrant T-cell phenotype of human T-PLL. TCL1A expressing T-cells of this model, that were further equipped with monoclonal epitope-defined TCRs against ovalbumine or a chimeric-antigen-receptor (CAR) against carcinoembryonic antigen, gained a pre-leukemic growth advantage in scenarios of pulsed or continuous low-level receptor stimulation.

Summary and Conclusions: Overall, we establish that T-PLL cells resemble antigen-experienced memory T-cells. Retention of functional effector responses to TCR stimulation and loss of restricting activation regulators underlie a highly activated phenotype and a marked resistance to death-inducing signals. TCL1A proactively enhances TCR responses and we postulate that this leukemogenic cooperation drives accumulation of memory-type cells that utilize amplified, hence permissive, low-level cognate antigen input.

Background: T-cell prolymphocytic leukemia (T-PLL) is a rare disorder with an aggressive clinical course and a generally fatal outcome (median OS ~20-36 months). Limited therapeutic options warrant the need for more efficient approaches that address the specific biology of the transformed mature T-cell. The usually complex karyotypes of T-PLL most recurrently (80%) harbor rearrangements of the T-cell leukemia 1 (TCL1) locus at 14q32.1. Supporting the initiating capacity of TCL1 are transgenic mice (lck-TCL1), which develop T-PLL-like expansions. However, a refined mechanistic disease concept of T-PLL is not established.

Aims: Our aim was to genetically characterize a large T-PLL cohort and to drwa functional conclusions.

Methods: To address its incomplete molecular concept, we integrated large-scale profiling data of alterations in gene expression, allelic copy number (CN), and nucleotide sequences in 111 well-characterized patients.

Results: The dominant alteration of T-PLL's molecular make-up is a unique and functionally synergistic combination of TCL1-overexpression and damaging ATM lesions. We also identified novel tumor-specific hot-spots for CN variability, fusion molecules, transcript variants, and progression-associated dynamics. The overall lesional spectrum of T-PLL is mainly annotated to axes of DNA damage responses, of cytokine signaling, and histone modulation. The chromosomal complexity of T-PLL is determined by a specific phenotype of impaired proximal DNA damage processing, telomere attrition, and abrogated cell death execution. Despite frequently identified ATM mutations and genomic losses, specific targeting of factors in potentially synthetic lethal relationships to ATM through small molecule inhibitors did not affect T-PLL cell viability in the context of DNA damage.

Summary and Conclusions: Based on the most current lesions, we established a model of T-PLL evolution resolved for pivotal genetic alterations integrated with landmarks of cellular dysfunctions.

CG'806, A NON-COVALENT PAN-FLT3/PAN-BTK INHIBITOR, EXHIBITS UNIQUE BINDING TO WILD TYPE AND C481S MUTANT BTK AND GREATER POTENCY THAN IBRUTINIB AGAINST MALIGNANT B CELLS

H. Zhang[1,*], A. Local[1], K. Benbatoul[1], P. Folger[1], S. Sheng[1], S.E. Kurtz[2], J.W. Tyner[3], S.B. Howell[4], W.G. Rice[1]

[1]Aptose Biosciences, Inc, San Diego, CA, [2]Knight Cancer Institute, Division of Hematology and Medical Oncology, Oregon Health & Science University, [3]Department of Cell, Developmental & Cancer Biology, Oregon Health & Science University, Knight Cancer Institute, Portland, OR, [4]Moores Cancer Center, Department of Medicine, University of California, San Diego, La Jolla, United States

Background: Bruton's tyrosine kinase (BTK) is a validated drug target due to its role in B-cell malignancy development. Ibrutinib, an irreversible BTK inhibitor that covalently binds to cysteine residue 481 (C481) and is approved for chronic lymphocytic leukemia (CLL) and other B-cell malignancies, is limited by its adverse effects and resistance resulting from C481S or other mutations. A safe and potent inhibitor against all forms of BTK is needed for patients intolerant, refractory and resistant to ibrutinib. CG'806 is an oral small molecule pan-FLT3/pan-BTK inhibitor, designed to solve ibrutinib's shortcomings. It is in development for acute myeloid leukemia (AML) and B-cell malignancies.

Aims: We compared CG'806 and ibrutinib with respect to BTK binding mode, kinase inhibition profiles and cytotoxic activity against cultured and patient-derived malignant B-cells. CG'806 was also screened for potential safety issues using *in vitro* biomarkers.

Methods: CG'806 was co-crystallized with the kinase domain of wild type (WT) and C481S mutant forms of BTK. CG'806 was tested at 1 μM for biochemical inhibition of 583 kinases, and IC_{50}s were determined on the most sensitive kinases. The Safety44 panel (DiscoverX) was screened to identify potential off-target activities. CG'806 was evaluated in a cytotoxicity assay on cultured malignant B-cell lines or freshly isolated mononuclear cells from patients. The effect of CG'806 on cell signaling was assessed by Western blotting.

Results: The co-crystal complex of CG'806 bound to BTK-WT or -C481S at resolution of 1.84Å and 1.63Å, respectively, revealed a binding mode of an atypical type II inhibitor. The DFG motif occupies an atypical conformation whereby the Phe540 is rotated out of the ATP binding pocket and the Asp539 side chain is tilted to hydrogen bond with CG'806. Moreover, CG'806 interacts with the hinge region and the αC-helix is in a partial out position. No electron density interaction was observed between CG'806 and the C481 residue. Kinase profiling revealed that CG'806 most potently inhibits kinases from the BTK, FLT3, TRK, and AURK clusters with IC_{50}s <25 nM. CG'806 had similar potency against BTK-WT (IC_{50}=8.4 nM) and C481S mutant (IC_{50}=2.5 nM) as opposed to ibrutinib that was >60-fold less potent against the C481S mutant. Importantly, CG'806 did not inhibit TEC, EGFR or ERBB2/4, which are related to ibrutinib's side effects. CG'806 inhibited cell proliferation 50-6,000 times more potently than ibrutinib in 11 tested malignant B-cell lines; it also had greater activity on primary CLL samples than ibrutinib. CG'806 inhibited signaling from BCR, AKT/mTOR and NF B as demonstrated by decreasing phosphorylation of BTK, PLCγ2, AKT, PI3K and ERK in a cell line dependent manner. CG'806 demonstrated a desirable safety profile when tested against the hERG ion

channel (IC_{50} >10 μM) and CYP450 enzymes (IC_{50}s >50 μM on Cyp3A4, 2C19, 2D6, 1A2; IC_{50}=8.6 μM on Cyp2C9). At 10 μM, CG'806 had no significant effect on the 44 common side-effect related GPCRs, nuclear receptors, transporters or ion channels.
Summary and Conclusions: CG'806 is a potent, non-covalent, oral inhibitor of WT and C481S BTK with a favorable *in vitro* safety profile. CG'806 killed cultured and primary malignant B-cells more potently than ibrutinib and was equipotent against WT and C481S BTK without affecting TEC, EGFR, ERBB2/4 or other safety-related targets. The data support clinical development of CG'806 in patients with CLL and other B-cell malignancies intolerant, resistant, or refractory to ibrutinib.

PF338

EPIGENETIC DRUG SCREEN ON RITUXIMAB-RESISTANT CELLS REVEALED AN UNEXPECTED ROLE OF AURORA KINASE INHIBITORS IN CD20 EXPRESSION

V. Kozlova[1,*], A. Ledererova[1], M. Doubek[1,2], J. Mayer[1,2], S. Pospisilova[1,2], M. Smida[1,2]

[1]Molecular Medicine, CEITEC MU, [2]Department of Internal Medicine - Hematology and Oncology, Medical Faculty of Masaryk University and University Hospital Brno, Brno, Czech Republic

Background: CD20 antigen is the prime target of monoclonal antibody (mAb) therapy, a standard of care for B-lymphoid malignancies. Although effective at first, repeated cycles of anti-CD20 treatment (*e.g.* rituximab (RTX)) often result in the loss of CD20 from the surface of malignant B cells and consequently in therapy resistance and therapy failure. Interestingly, mechanisms regulating CD20 expression are largely unknown. Yet, the possibility to modulate CD20 levels seems an appealing strategy to enhance the efficacy of CD20 mAbs.
Aims: RTX was suggested to induce epigenetic changes within the CD20 promotor and few epigenetic inhibitors were proposed to increase CD20 expression in some lymphoma cell lines. Our aim was to use an unbiased screening approach with a broad panel of epigenetic inhibitors to search for drugs that are able to increase CD20 expression and thereby improve the effectiveness of CD20 mAbs.
Methods: We have generated RTX-resistant cells by chronic exposure of B-lymphoid cell lines to gradually increasing doses of rituximab in multiple cycles. Thereby we have created cell lines that have permanently strongly downregulated CD20 protein on the cell surface as well as reduced CD20 gene transcription. These cells are fully resistant to additional treatment with CD20 antibodies, which is maintained long-term. We then screened these cells against a library consisting of 182 small-molecule compounds targeting various epigenetic modifying and related enzymes (histone deacetylases, methyltransferases, etc.) to determine surface CD20 expression changes by flow cytometry.
Results: We have applied the epigenetic drug library on our resistant CD20-low cells to identify drugs enhancing CD20 expression. Surprisingly, the most significant increase in CD20 surface density was reproducibly detected using multiple diverse Aurora kinase inhibitors. We then modified the screen and added RTX with the human serum (source of complement) together with the epigenetic drug panel to assess which inhibitors are able to enhance the response to RTX in a viability assay. Multiple diverse targets were identified, among them also Aurora kinases. We then selected few of the most significant aurora kinase inhibitors to validate in follow-up experiments. By performing multiple-point dose-response curves on resistant CD20-low cells, we could confirm that these compounds are able to increase CD20 surface levels in a dose-dependent manner. Importantly, such increase was not observed when using wildtype cells. In addition, we could confirm these results on both MEC1 and Ramos cell lines and on cells rendered resistant by chronic exposures to another CD20 mAb Ofatumumab. Aurora kinase inhibitors triggered CD20 increase was sustained for extended time period. Finally, when we first pretreated resistant cells with the aurora kinase inhibitors and then added RTX with the human serum, we could observe a profound shift in a viability curve and hence a strong sensitization towards RTX.
Summary and Conclusions: Our results indicate an unexpected role of Aurora kinases in CD20 regulation and their possible use for combination with CD20 mAbs. Molecular analysis is underway in order to understand the mechanistic effect of Aurora kinase inhibitors upon CD20 expression, as their co-administration could lead to the improvement in the efficacy of CD20 mAbs.

DISTINCT IMMUNE SIGNATURES IN CHRONIC LYMPHOCYTIC LEUKEMIA AND RICHTER'S SYNDROME

Y. Wang[1,*], S. Sinha[1], H. Dong[1], C. Secreto[1], T. Call[1], S. Parikh[1], J. Leis[2], K. Rech[1], A. Feldman[1], S. Kenderian[1], N. Kay[1], S. Ansell[1], R. He[1], W. Ding[1]

[1]Mayo Clinic, Rochester, [2]Mayo Clinic, Phoenix, United States

Background: Immune checkpoint blockade with the anti-PD-1 monoclonal antibody pembrolizumab was effective in Richter's Syndrome (RS) but not Chronic Lymphocytic Leukemia (CLL) in a phase 2 clinical trial (NCT02332980). Analyzing the immune signatures including PD-L1 expression and T cell diversity is important for understanding the differential responses.
Aims: To compare the tissue PD-L1 expression and peripheral blood T cell diversity in CLL and RS patients enrolled in the NCT02332980 trial, and to correlate the results with clinical response to pembrolizumab.
Methods: 15 CLL and 14 RS patients in the NCT02332980 trial were included in this study. Expression of PD-L1 in the lymph node was analyzed by immunohistochemistry staining. Peripheral blood and lymph node T cell diversity was analyzed using the ImmunoSEQ platform (Adaptive Biotechnology), which quantifies the clonailty of T cells by deep sequencing of the CDR3 region of the T cell receptor (TCR). The calculated clonality ranges from 0 to 1, and a higher clonality indicates a more diverse T cell population. Data analysis (Student's t-test and Mann-Whiney U test) was done by GraphPad Prism (v7).
Results: PD-L1 expression was significantly lower in CLL (n=6) *vs* RS (n=12) patients (mean 5.5% *vs* 22.9%, *P*=0.003). A control CLL cohort (n=11, Mayo CLL tissue registry) also had lower PD-L1 expression compared with the RS cohort (7.7% *vs* 22.9%, *P*=0.002). RS Patients progressed on ibrutinib or chemotherapy had similar PD-L1 expression (25.3% *vs* 19.6%, *P*=0.416). Peripheral blood TCR clonality at trial baseline was significantly lower in RS (n=13) *vs* CLL (n=13) patients (median 0.098 *vs* 0.342, *P*=0.026). Patients progressed on ibrutinib or chemotherapy had similar TCR clonality (CLL: 0.34 *vs* 0.24, *P*=0.524; RS: 0.11 *vs* 0.09, *P*=0.534). Five RS patients achieved an objective response (1 complete response [CR], 2 partial response [PR], 1 complete metabolic response [CMR] and 1 partial metabolic response [PMR]), 4 of which were after progression on ibrutinib. For CLL patients, only 1 nodal reduction was seen. Four RS patients had prior CLL state samples available for TCR analysis. Two patients had a notable decrease of TCR clonality (0.21 to 0.04 and 0.17 to 0.03) from CLL (peripheral blood) to RS state (lymph node), and achieved CR and PR, respectively. Two other patients with stable clonality (0.04 to 0.05 and 0.03 to 0.08) had stable disease (SD) and PMR, respectively. Peripheral blood TCR clonality did not change significantly after treatment with pembrolizumab (CLL [n=11]: *P*=0.775; RS [n=11]: *P*=0.830; paired t-test).
Summary and Conclusions: RS patients had higher expression of PD-L1 and lower TCR clonality (more diverse T cells) compared with CLL patients. The distinct immune signatures may explain their differential responses to PD-1 blockade. The dynamic changes of TCR clonality during Richter's transformation may predict a response to PD-1 blockade.

Chronic lymphocytic leukemia and related disorders – Clinical

PF340

DURABILITY OF RESPONSE TO VENETOCLAX (VEN) IN PATIENTS WITH CLL RELAPSED/REFRACTORY TO IBRUTINIB AND/OR IDELALISIB

J.C. Byrd[1,*], W.G. Wierda[2], M.S. Davids[3], M. Choi[4], R.R. Furman[5], A. Mato[6], L. Zhou[7], M. Verdugo[7], J. Potluri[7], S. Coutre[8]

[1]The Ohio State University, Columbus, [2]University of Texas MD Anderson Cancer Center, Houston, [3]Dana-Farber Cancer Institute, Boston, [4]UCSD Moores Cancer Center, San Diego, [5]Weill Cornell Medicine, [6]Memorial Sloan Kettering Cancer Center, New York, [7]AbbVie, Inc., North Chicago, [8]Stanford Cancer Center, Stanford University School of Medicine, Stanford, United States

Background: Therapies are urgently needed for patients (pts) with CLL relapsed/refractory (R/R) to BCRi.
Aims: We report outcomes for the full trial population from an ongoing phase 2 trial with VEN monotherapy, including the impact on detectable minimal residual disease (MRD).
Methods: Pts with CLL R/R to ibrutinib and/or idelalisib received 400 mg daily VEN after initial dose ramp up. Results are from a data cut on 28 Nov 2017.
Results: Pts (N=127) had received a median of 4 prior therapies (1 – 15). Del(17p) was noted in 40% (50/126) and 28% (34/122) of pts had mutated *TP53*. After a median of 17 (.1 – 36) months on VEN, the best overall response rate was 66% (84/127; CR/CRi – 10%, nPR/PR – 56%) per investigators (INV) and 70% (89/127) by independent review committee (IRC). Per INV (median follow up, 16 [.03 – 33] months), estimated median progression-free survival (PFS) was 25 months (18-month rate, 66%); neither median duration of response (18-month rate: 75%) nor median overall survival (18-month rate: 88%) was reached. 36/77 pts assessed (47%; 28% [36/127] by intent to treat) had undetectable blood MRD, 9/26 assessed were also undetectable in marrow (2 CR/CRi, 7 PR). Median PFS was longer for pts with undetectable MRD in blood *vs* positive (not reached *vs* 21.9 months; HR, .148 [.04 – .49], *p*=.0019). 64 pts discontinued VEN, most commonly for CLL progression (n=35; median time, 10 months [.1 – 29]), AEs (n=8), and Richter's transformation (n=6; median time, 13 months [4 – 19]). Common any-grade AEs were GI AEs (diarrhea [50%], nausea [49%]) and cytopenias (anemia [43%], neutropenia [41%], thrombocytopenia [28%], decreased white blood cell count [28%]) (Table 1).

Table 1.

n (%)	Last prior BCRi				N=127	
	Ibrutinib n=91		Idelalisib n=36			
	INV	IRC	INV	IRC	INV	IRC
ORR	59 (65)	64 (70)	25 (69)	25 (69)	84 (66)	89 (70)
CR	5 (6)	0	2 (6)	0	7 (6)	0
CRi	4 (4)	1 (1)	2 (6)	0	6 (5)	1 (1)
nPR	3 (3)	0	0	0	3 (3)	0
PR	47 (52)	63 (69)	21 (58)	25 (69)	68 (54)	88 (69)
SD	21 (23)	27 (30)	9 (25)	11 (31)	30 (24)	38 (30)
PD	5 (6)		2 (6)		7 (6)	
Early discontinuation	6 (7)		0		6 (5)	

Summary and Conclusions: Based on longer follow up, VEN monotherapy demonstrates robust activity, with good tolerability in pts with CLL R/R to ibrutinib and/or idelalisib. Though most pts achieved PR, outcomes appear durable with undetectable MRD.

PF341

SALVAGE USE OF IBRUTINIB AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION FOR CHRONIC LYMPHOCYTIC LEUKEMIA OR MANTLE CELL LYMPHOMA: A STUDY ON BEHALF OF THE SFGM-TC AND THE EBMT

M. Michallet[1,*], P. Dreger[2], M. Sobh[1], J. Hoek[3], A. Boumendil[4], L. Muller[5], P. Corradini[6], W. Bethge[7], D. Russo[8], N. Durakovic[9], M. Van Gelder[10], N. Schaap[11], N. Kroger[12], J. Schetelig[13]

[1]Hematology, Centre Léon Bérard, Lyon, France, [2]Internal Medicine V, University of Heidelberg, Heidelberg, Germany, [3]EBMT Data Office, Leiden, Netherlands, [4]EBMT Data Office, Paris, France, [5]Hematology, Martin-Luther-Univeristy, Halle, Germany, [6]Hematology, University hospital of Milano, Milan, Italy, [7]Hematology, Eberhard Karls University Tuebingen, Tuebingen, Germany, [8]Hematology, University of Brescia, Brescia, Italy, [9]Hematology, Clinical Hospital Center Zagreb, Zagreb, Croatia, [10]Hematology, University Medical Center, Maastricht, [11]Hematology, Radboud University Medical Centre, Nijmegen, Netherlands, [12]Hematology, University Hospital Eppendorf, Hamburg, [13]Hematology, University Hospital Dresden, Dresden, Germany

Background: Allo-HSCT is an accepted treatment option for patients with relapsed and refractory mantle cell lymphoma (MCL) or high-risk chronic lymphocytic leukemia (CLL). This treatment option is currently reshaped by the introduction of pathway inhibitors (PWI). In case of disease relapse after transplantation, the outcome is a major concern and the prognosis is dismal. PWI could be very promising when used before and/or after transplantation.
Aims: The purpose of our study is to provide information on the safety and efficacy of ibrutinib when administered as salvage treatment after allo-HSCT for CLL or MCL.
Methods: A total of 62 patients (56 CLL and 6 MCL), were included, 41 (63%) males; median age at transplantation was 49 (range: 35-64) years and the median number of treatment lines prior to transplantation was 3 (1-10). Before transplantation, del17p was present in 30% of patients and del11q was present in 18% of other cases. Disease status at allo-HSCT was sensitive in 45/60 (75%) patients. Conditioning was reduced-intensity in 68% of patients.
Results: In all patients, Ibrutinib was initiated for disease progression after allo-HSCT. The median time between allo-HSCT and Ibrutinib administration was 30 months (range: 1-140) and the median time between post-allo-HSCT relapse and Ibrutinib initiation was 3 months. Overall, 44/62 (71%) patients responded to Ibrutinib; 24 (39%) patients with a PR, and 20 (32%) patients reached CR. Of these, 11 were evaluated for MRD by flow cytometry, 5 were MRD negative and 6 were MRD positive . All of the 44 responding patients were still on Ibrutinib at the last follow-up with a median exposure of 407 days (104-937). The 18 other patients failed to respond after Ibrutinib, 4 did not obtain any change in response while 14 patients progressed, among them 5 received idelalisib and failed to respond. At time of ibruinib initiation, 10 patients had still an active chronic GVHD, all of these patients had their GVHD resolved after receiving Ibrutinib. Ibrutinib was generally well tolerated, 14 (22%) patients discontinued ibrutinib, 4 because of toxicity and 10 because of disease progression. Overall, 16 patients relapsed (median PFS=24 months), 9 died (all CLL) only from disease progression. Two-year OS and PFS probabilities from start of ibrutinib were 72% and 49% respectively. OS and PFS after ibrutinib were not influenced by del17p/del11q while patients with late relapse after allo-HSCT (>24 months) had a better PFS after ibrutinib.
Summary and Conclusions: We showed in this largest series of patients described to date in this indication, that ibrutinib can be safely administered for CLL/MCL relapse after allo-HSCT, with an efficacy at least similar to non-transplanted patients with high-risk disease.

PF342

MANAGEMENT, ADVERSE EVENTS, AND OUTCOMES OF 282 CLL PATIENTS (PTS) TREATED WITH VENETOCLAX (VEN) IN THE REAL WORLD

C. Nabhan[1,*], A. Klink[2], J. Samp[3], J. Pauff[3], J. Nielsen[3], B. Meissner[3], H. Keim[3], K. Kennard[4], A. Mato[5]

[1]Cardinal Health, Dublin, [2]Cardinal Health, Dallas, [3]AbbVie, Chicago, [4]Hematology and Oncology, University of Pennsylvania, Philadelphia, [5]Memorial Sloan Kettering Cancer Center, New York, United States

Background: Ven is an oral bioavailable BCL-2 inhibitor with demonstrated activity in clinical trials for relapse/refractory (R/R) CLL pts including those with del17p or failing a kinase inhibitor (KI). Ven was initially approved in the US and EU in 2016. As expanded indications for Ven in CLL are under investigation, additional data are needed to understand use and outcomes in clinical practice.
Aims: Describe initiation, management and outcomes of Ven-treated CLL pts in the real world.
Methods: This is a retrospective cohort study of CLL pts initiating Ven. Investigators from 33 community centers provided pt-level data from medical records including demographics, clinical characteristics, ramp up management and outcomes. Tumor burden was assessed per FDA label, tumor lysis syndrome (TLS) was defined by Howard criteria and response was

based on iwCLL criteria. The primary endpoints were progression free survival (PFS) and overall survival (OS). The secondary endpoint was overall response rate (ORR: complete or partial response [CR or PR]). Characteristics and outcomes were summarized by descriptive statistics, and comparisons of ORR by subgroups were assessed on univariate analyses.

Results: 282 Ven pts were included, of whom 22% used Ven in combination with ibrutinib (7%) or an anti-CD20 (15%). Median age was 67 years (range 60-73); 83% had *TP53* interruption; 64% had 1 prior therapy and 23% had ≥2 prior therapies (median 1; range 0-6); 61% and 3% had prior use of 1 and 2 KIs, respectively. At baseline, 12%, 54% and 34% had low, medium and high tumor burden, respectively; 32% initiated Ven as inpatient. During ramp up, 9% had a dose interruption; 4 of 6 dose reductions were due to TLS or hematologic abnormalities. TLS events occurred in 8% of pts (n=22) with 5 pts experiencing clinical TLS. With a median follow up of 5.8 months, ORR was 82% (CR: 29%). Responses were not negatively affected by pt, disease or treatment factors that were assessed with the exception of TP53 status (Table 1; response not assessed in 27(9.6%) pts). The 12-month PFS and OS were 83% and 91%, respectively (Figure 1). Among 48 pts assessed for minimal residual disease (MRD) during Ven treatment, 27 (63%) were MRD negative. Resolution of baseline lymphadenopathy, lymphocytosis, or B symptoms were reported in 94%, 95% and 95%, respectively. Among 48 pts (17%) who discontinued Ven, median time to discontinuation was 6.1 months. Discontinuation was mainly due to response to therapy (n=12), refractoriness (n=11), pt request (n=10) or relapse (n=5).

Table 1.

	All Ven pts	Age		Prior lines			TP53 interruption		Prior KI use		Lymph node size		TLS during ramp-up		Max Ven dose	
		<65 years	≥65 years	0	1	≥2	Present	Absent	Yes	No	All LN <5cm	Any LN ≥5cm	Yes	No	400 mg	<400 mg
ORR, n (%)	208 (82%)	76 (83%)	132 (81%)	32 (91%)	130 (80%)	46 (81%)	176 (84%)	32 (70%)	117 (82%)	91 (81%)	95 (80%)	105 (83%)	16 (80%)	192 (82%)	108 (81%)	100 (83%)
CR, n (%)	73 (29%)	30 (33%)	43 (26%)	13 (37%)	44 (27%)	16 (28%)	61 (29%)	12 (26%)	38 (27%)	35 (31%)	28 (24%)	45 (36%)	8 (40%)	65 (28%)	41 (31%)	32 (26%)
ORR across subgroups, *p*-value	-	0.87		0.28			0.03		0.75		0.62		0.77		0.75	

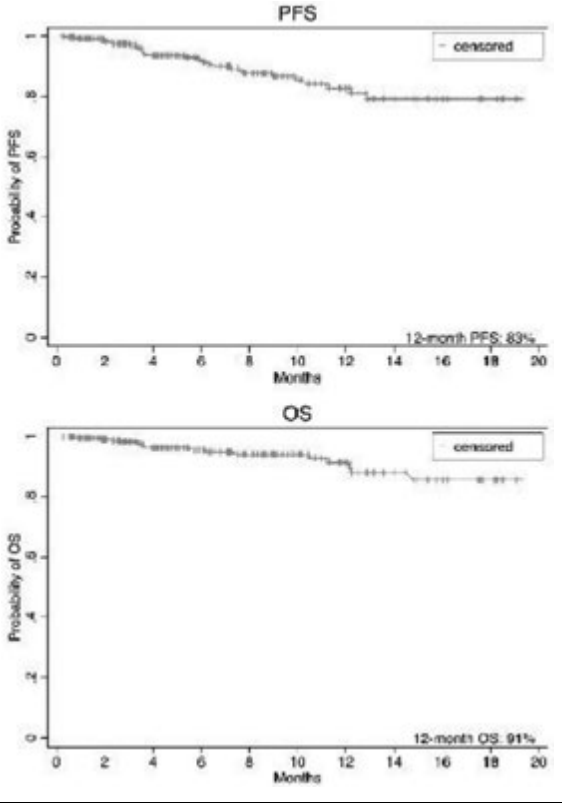

Figure 1.

Summary and Conclusions: In the largest study of Ven-treated CLL pts in community practice, PFS, OS and response rates were comparable to clinical trials with most clinical factors not impacting response to therapy. Ven was well tolerated and few experienced a TLS/ hematologic event. Taken together, these results support the generalizability of Ven use in community settings. Further analyses on ramp up management and outcomes will be presented.

PF343

IBRUTINIB FOR FIRST-LINE TREATMENT OF OLDER PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA/SMALL LYMPHOCYTIC LYMPHOMA (CLL/SLL): A 4-YEAR EXPERIENCE FROM THE RESONATE-2 STUDY

Background: Ibrutinib (ibr), a first-in-class, once-daily inhibitor of Bruton's tyrosine kinase, is approved in the EU and other regions for the initial treatment of CLL. RESONATE-2 is a phase 3 study designed to compare efficacy and safety of first-line ibr *vs* chlorambucil (clb) in patients (pts) with CLL/SLL. Primary results (assessed by independent review committee [IRC]) with a median follow-up of 18.4 mo demonstrated that ibr reduced the risk of progressive disease (PD) or death by 84% (P<0.001) (Burger, *N Engl J Med* 2015).

Aims: This extension study updates long-term ibr efficacy and safety from RESONATE-2.

Methods: Pts with treatment-naïve CLL/SLL aged ≥65 y (ITT n=269) were randomized 1:1 to receive 420 mg ibr once-daily continuously or clb for up to 12 cycles. Pt informed consent was obtained. The primary endpoint was PFS by IRC. Secondary endpoints included ORR, rate of hematologic improvement, and safety; long-term follow-up safety focused on ibr. Pt-reported outcomes included FACIT-Fatigue (F). Pts with PD on clb could crossover to ibr. IRC was discontinued after primary analysis. Long-term efficacy is reported per the investigator. Additional review for CR was undertaken by the sponsor to assure alignment with iwCLL criteria.

Results: With median follow-up of 4 yrs (max 55 mo), prolongation of PFS benefit for ibr *vs* clb was sustained (HR 0.137; 95% CI 0.090-0.210; Figure 1), including in high-risk subgroups (del11q: HR 0.034; 95% CI 0.011-0.110; unmutated (UM)-*IGHV*: HR 0.088; 95% CI 0.046-0.169). 48-mo PFS rates for ibr *vs* clb overall were 74% *vs* 16%, in pts with del11q were 79% *vs* 0% (72% with ibr in pts without del11q) and in UM-*IGHV* were 75% *vs* 4% (79% with ibr in pts with mutated *IGHV*). ORR was 91% with ibr *vs* 37% with clb; sponsor-confirmed CR with ibr was 18% (increased from 4% [IRC-confirmed] at primary analysis). Ibr led to sustained hematologic improvement in 80% of pts with baseline anemia *vs* 24% with clb (P<0.0001) and in 54% of pts with thrombocytopenia *vs* 25% with clb (P=0.0229). Ibr led to significantly greater improvements over time *vs* clb in FACIT-F (P=0.0014; repeated measure analysis). Grade (Gr) ≥3 adverse events (AEs) in ≥5% of pts over the 4-yr follow-up included neutropenia (13%), pneumonia (12%), anemia (7%), hypertension (HTN; 7%) and hyponatremia (5%) terms. Gr ≥3 hematologic and infectious toxicities were generally highest in the first yr and then decreased, while HTN remained stable. Of interest, Gr ≥3 atrial fibrillation occurred in 4% of ibr-treated pts and Gr ≥3 major hemorrhage in 7%. The most common reason for discontinuation in ibr-treated pts was AEs (19%, n=26), which decreased over time (yr 0-1, n=9; yr 1-2, n=7; yr 2-3, n=6; yr 3-4, n=4). AEs leading to discontinuation in >1 pt were atrial fibrillation (n=4), palpitations, and pneumonia (n=2 each). With a median ibr treatment duration of 46.9 mo (range 0.7-55.2), 89/136 (65%) pts remain on first-line ibr; 7/136 pts discontinued ibr due to PD. 11/136 pts received subsequent CLL therapy after stopping ibr (most commonly FCR [n=3], BR [n=2], acalabrutinib [n=2]).

Summary and Conclusions: With 4 yrs of follow-up, efficacy of single-agent ibr continues to endure with 86% risk reduction of PD or death. Ibr substantially improved PFS in pts with traditional high-risk features del11q or

UM-*IGHV* (risk reduction 97% and 91% *vs* clb, respectively). PFS with ibr was preserved in pts with or without del11q or UM-*IGHV*. CR rates improved with prolonged follow-up. Discontinuation due to AEs decreased over time, with 65% of ibr pts continuing daily treatment.

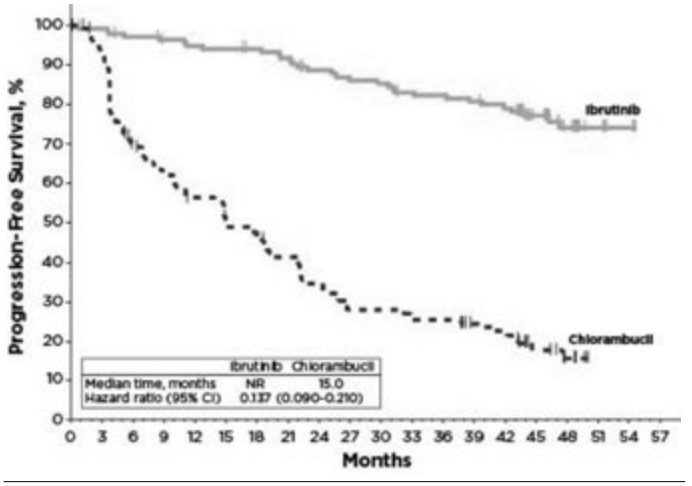

Figure 1.

PF344

IMPACT OF TP53-MUTATED CLONE SIZE ON OUTCOME OF RELAPSED/REFRACTORY (R/R) CLL PATIENTS TREATED WITH VENETOCLAX PLUS RITUXIMAB WITHIN THE PHASE 3 MURANO STUDY

Hoffmann–La Roche, Welwyn Garden City, United Kingdom, [16]Peter MacCallum Cancer Centre, Royal Melbourne Hospital, and University of Melbourne, Melbourne, Australia

Background: CLL pts with alterations in the *TP53* pathway (including del(17p) and *TP53* mutations) are a high-risk population in need of novel therapies. Retrospective studies suggest that pts with low clone size (subclones) of del(17p) and/or *TP53* mutations have similar poor survival as pts with high clone size following immunochemotherapy, but remains to be confirmed. We recently reported on improved efficacy with venetoclax plus rituximab (VenR) *vs* bendamustine plus rituximab (BR) in R/R CLL for ORR, PFS and MRD negativity (MRD–) (MURANO phase 3 study).
Aims: Assess the impact of clone size of *TP53* alterations on prognosis and MRD negativity with both regimens in MURANO.
Methods: *TP53* mutation status assessed centrally by targeted next-generation sequencing spanning exons 2–11 (entire *TP53* coding region). Cutoff was ≥5% allele frequencies (AF). del(17p) status was assessed centrally by Vysis CLL FISH probe kit, with cutoff of 7% del(17p) nuclei used to define abnormality. Low clone size *vs* high clone size was defined for del(17p) by 7%–≤20% del(17p) nuclei *vs* >20%; and *TP53* mutations by 5%–≤20% mutant AF *vs* >20% AF; definitions enabled subsets of adequate sample size to assess correlation with outcome.
Results: By central assessment 27% of pts had only del(17p), 26% only *TP53* mutations, and 13% del(17p) and *TP53* mutations; equally balanced between treatment arms. Among 92 pts with del(17p), clone size was highly variable (median=15%; range, 7.5%–94% of del(17p) nuclei). Among del(17p) pts, high del(17p) clone size (n=36, 10.5%) was associated with higher incidence of *TP53* mutations *vs* low clone size (69% *vs* 34%), and in pts treated with BR, high del(17p) clone size was also associated with inferior PFS. At median follow-up of 23.8 mo., median PFS for VenR *vs* BR was not reached (NR) *vs* 8 mo. (HR 0.1; 0.02–0.47) in high clone size del(17p) pts, NR *vs* 21 mo. (HR 0.14; 0.04–0.43) in low clone size, and NR *vs* 21 months (HR 0.19; 0.12–0.32) in non-deleted pts. MRD negativity in VenR *vs* BR was 60% *vs* 10% in high clone size del(17p) pts, 94% *vs* 28% in low clone size and 87% *vs* 26% in non-deleted pts. Similarly for *TP53* mutations, high clone size was associated with worse PFS *vs* low clone size in pts treated with BR. Patients with both del(17p) and *TP53* mutations, indicative of loss of TP53 on both alleles, had inferior outcomes to pts with either del(17p) or *TP53* mutation alone, with BR. Importantly, PFS was superior for VenR *vs* BR across subgroups with del(17p) and/or *TP53* mutations including high and low clone size (Table 1 and Figure 1). 2-year PFS rates between subsets by treatment arm will be presented.

Table 1.

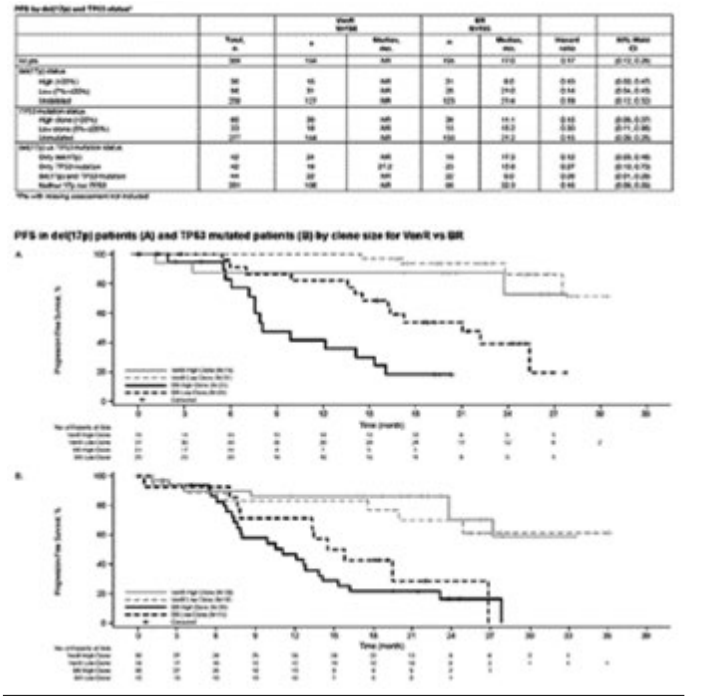

Figure 1.

Summary and Conclusions: A clear prognostic difference was found between low and high clone size with respect to chemoimmunotherapy. High-risk prognostication based on *TP53* alterations is minimized by treatment with VenR; VenR is superior to BR in these biological subsets.

PF345

B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL) IN CLL PATIENTS TREATED WITH LENALIDOMIDE

Città della Salute e della Scienza, University of Torino, Torino, Italy, [4]Onkologische Schwerpunktpraxis Esslingen, Esslingen, Germany, [5]Department of Hematology, Vall d'Hebron Institute of Oncology, Vall d'Hebron University Hospital, Universitat Autònoma de Barcelona, Barcelona, Spain, [6]3rd Department for Hematology and Oncology, Hanusch Hospital, Vienna, Austria, [7]Universita Vita-Salute San Raffaele and IRCCS Instituto Scientifico San Raffaele, Milano, Italy, [8]Department of Hematology, Academic Medical Center Amsterdam, University of Amsterdam, on behalf of the HOVON CLL Working Group, Amsterdam, Netherlands, [9]2nd Department of Internal Medicine, University of Schleswig-Holstein, Campus Kiel, Kiel, [10]Department of Internal Medicine III, University of Ulm, Ulm, Germany

Background: The immunomodulatory drug lenalidomide has shown clinical activity in CLL. It has been associated with an increased rate of second pri-

mary malignancies (SPM) in multiple myeloma (MM). In MM degradation of transcription factors Ikaros and Aiolos leads to its anti-tumor activity and T-cell activation; in CLL, its mechanism of action has not been determined yet. In our CLLM1 trial, 3 of 56 pts developed precursor B-ALL during or after lenalidomide maintenance while there were no cases in the placebo group.
Aims: To evaluate an association between exposure to lenalidomide and the occurrence of B-ALL in subjects with CLL receiving lenalidomide maintenance.
Methods: First, we screened all phase III trials using lenalidomide in CLL patients for reported ALL cases. Second, we obtained reports from the FDA Adverse Event Reporting System (FAERS) to identify additional cases of B-ALL in CLL patients treated with lenalidomide. Next, we analysed available data for B-ALL cases in five non-lenalidomide GCLLSG trials in order to estimate the occurrence of B-ALL in CLL patients not exposed to lenalidomide. Finally, in the 2 BCR-ABL positive B-ALL cases identified in CLLM1, RQ-PCR was performed for detection of BCR-ABL fusion transcripts at different time points before B-ALL diagnosis; NGS-based clonality testing of IGHV will be done to assess clonal relationships of B-ALL and underlying CLL.
Results: In 3 published phase III trials (CLLM1, CONTINUUM, ORIGIN) that evaluated the use of lenalidomide in CLL, a total of 846 patients were enrolled, with 438 receiving lenalidomide monotherapy. Six out of 438 patients (1.4%) developed B-ALL either during treatment (n=1) or after discontinuation (n=5). No B-ALL cases were reported in the control groups including 408 patients. Of the 6 patients (3M, 3F), 2 received lenalidomide as firstline treatment and 4 as maintenance after firstline therapy, median length of exposure was 33,5 months (range 15-47) and median age at B-ALL diagnosis was 70 years (range 60-82). All evaluable patients were categorized as either 'high risk' or 'very high risk' according to CLL-IPI, 1 patient featuring a TP53 mutation, 1 patient with a 17p-deletion, all patients showed unmutated IGHV. In the two BCR-ABL positive patients, BCR-ABL fusion transcripts could not be detected at any time point before B-ALL diagnosis. Clonal relationship of B-ALL and underlying CLL is currently being analysed. In order to estimate the occurrence of B-ALL in CLL patients not exposed to lenalidomide, data of patients treated in GCLLSG trials were evaluated. In 2015 patients evaluable for second primary malignancies, 2 cases of B-ALL were identified (0.1% of all patients). Cytogenetic abnormalities were del(17p) in one patient and del(11q) in the other, both patients exhibited unmutated IGHV. This rate of B-ALL occurrence in CLL patients is consistent with findings of other groupsand underscores the assumption that secondary B-ALL is usually a rare event in CLL.
Summary and Conclusions: According to a large GCLLSG cohort and in accordance with published data on second primary malignancies in CLL, B-ALL is a rare event in CLL patients. In CLL patients treated with lenalidomide as firstline therapy or maintenance following chemotherapy, an increased number of B-ALL was observed, the reason for this increase is unknown. Further investigation of the evolution of different lymphoid populations during treatment is warranted to better understand the aetiology of secondary B-ALL in CLL.

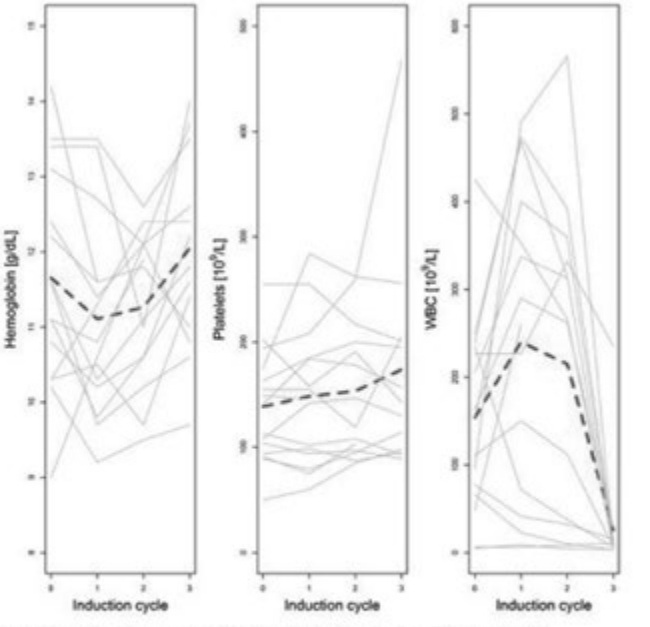
PF346

SAFETY ANALYSIS OF VENETOCLAX AND IBRUTINIB FOR PREVIOUSLY TREATED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): FIRST INTERIM ANALYSIS FROM THE PHASE II VISION HO141 TRIAL

C.U. Niemann[1,*], M.-D. Levin[2], K. Nasserinejad[3], A.M. Janssens[4], L. Enggaard[5], S. Kersting[6], G.J. Veldhuis[7], R. Mous[8], C.H. Melink[9], J.A. Dobber[9], I. Schjødt[1], E. Dompeling[10], C.B. Poulsen[11], H.T. Tran[12], T. Salmi[13], M. Mattsson[14], A.P. Kater[9]

[1]Department of Hematology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [2]Department of Internal Medicine, Albert Schweitzer ziekenhuis, Dordrecht, [3]HOVON Data Center, Rotterdam, [4]UZ Leuven, Leuven, Netherlands, [5]Herlev Hospital, Copenhagen, Denmark, [6]HagaZiekenhuis, van Den Haag, [7]Antonius Ziekenhuis, Sneek, [8]Universitair Medisch Centrum Utrecht, Utrecht, [9]AMC, Amsterdam, [10]Isala, Zwolle, Netherlands, [11]Roskilde Sygehus, Roskilde, Denmark, [12]Akershus, Oslo, Norway, [13]Turku University Hospital, Turku, Finland, [14]Uppsala University Hospital, Uppsala, Sweden

Background: Standard of care for patients with relapsed or refractory CLL (RR CLL) is rapidly changing. For patients with late relapse >2-3 years from 1st-line, repeated fixed duration therapy with chemoimmunotherapy may be used, while patients with early relapse or TP53 aberrations are treated with novel targeted agents until toxicity or progression. Thus, chemotherapy-free regimens with the option to safely stop treatment are warranted.
Aims: The aim of the VISION / HOVON 141 study is to evaluate whether combination treatment with venetoclax+ibrutinib in patients with RR CLL can lead to minimal residual disease (MRD) negativity, allowing MRD-guided treatment cessation. We here report on a preplanned safety interim analysis.
Methods: Patients were treated with ibrutinib monotherapy (420 mg daily) for the first two cycles of 28 days, in cycle 3 venetoclax was ramped up weekly from 20 mg to the final dosage of 400 mg daily from start of cycle 4. All patients are treated for 15 cycles; MRD negative patients (blood and bone marrow, by central flowcytometry, 10^{-4}level) are randomized 1:2 between maintenance ibrutinib or observation thereafter, MRD positive patients continue ibrutinib monotherapy. Patients in the observation arm are assessed for blood MRD every three months; venetoclax+ibrutinib is reinitiated upon MRD >10^{-2}. Enrollment is ongoing, 62 of 207 planned patients enrolled. This interim analysis includes data for the first 3 induction cycles of the first 15 eligible patients in the study with focus on safety including the incidence of adverse events (AEs) of special interest (atrial fibrillation, bleeding and tumor lysis) and initial response evaluation. Only grade 2 and above AEs were reported as per protocol. Registered at clinicaltrials.gov: NCT03226301.
Results: The median age for the first 15 patients was 59 years (range 40-79), eight (53%) were male, 11 (73%) showed WHO performance status 0, 14 (93%) were classified as Binet stage B/C, five (33%) as high and nine (60%) as medium risk of tumor lysis (one unknown), six (40%) had centrally assessed TP53 aberrations and nine (60%) were IGHV unmutated (one unknown). All patients completed the first two cycles of ibrutinib monotherapy and the third cycle of ibrutinib combined with venetoclax ramp up. Three and two patients had dose modifications of ibrutinib and venetoclax, respectively, no patients stopped treatment. Three (20%) patients experienced grade 2 AEs, three (20%) grade 3 and two (13%) grade 4 AEs, no grade 5 AEs were reported. Two (13%) patients experienced an SAE during ibrutinib monotherapy (febrile neutropenia, adenocarcinoma of the lung) while no SAEs were reported during cycle 3 venetoclax ramp up. No tumor lysis, atrial fibrillation or bleeding events reported. Eight (53%) patients achieved a clinical complete remission (CR) and six (40%) patients achieved a partial remission (PR) while one (7%) achieved PR with lymphocytosis as assessed by the local investigator at end of cycle 3 (the day before the ramp up to 400 mg venetoclax in the 4th cycle). Improvement in median hemoglobin and platelet count were seen while the median white blood cell count decreased from 260 to 8 x 10-E9 after an initial ibrutinib induced lymphocytosis. (Figure 1).



Preferred term for AEs reported for the first 15 patients within cycle 1-3:
(more than one type of AE per patient, each patient counts only once for -Any)

	grade 2	grade 3	grade 4
-Any	3 20%	3 20%	1 7%
General disorders and administration site conditions	3 20%	.	.
Respiratory, thoracic and mediastinal disorders	2 13%	1 7%	.
Infections and infestations	2 13%	.	.
Investigations	.	1 7%	1 7%
Musculoskeletal and connective tissue disorders	2 13%	.	.
Blood and lymphatic system disorders	.	1 7%	.
Hepatobiliary disorders	.	1 7%	.

Figure 1.

Summary and Conclusions: Treatment with ibrutinib and ramp up with venetoclax in the setting of RR CLL was manageable without any unexpected AEs; all patients responded, 53% had a clinical complete response within the first three cycles of treatment, before reaching the final dosage of venetoclax. The DSMB recommends continuing of the study.

PF347

EFFECT OF ADDING IDELALISIB TO FRONTLINE OFATUMUMAB PLUS EITHER CHLORAMBUCIL OR BENDAMUSTINE IN LESS FIT PATIENTS WITH CLL: UPDATED RESULTS FROM THE NCRI RIALTO TRIAL

Background: The Phase 3 RIAltO trial opened in December 2011 to compare ofatumumab plus chlorambucil (O+C) with ofatumumab plus bendamustine (O+B) in patients with previously untreated chronic lymphocytic leukaemia (CLL) considered unfit for FCR (fludarabine, cyclophosphamide, rituximab). A protocol amendment was introduced in September 2014 to investigate the addition of idelalisib (first-in-class inhibitor of the p110δ isoform of phosphoinositol-3 kinase) or placebo. Review of safety data in January 2016 revealed excessive toxicity due to idelalisib, and recruitment was suspended pending the implementation of additional safety measures including mandatory antimicrobial prophylaxis and CMV surveillance. However, all idelalisib/placebo treatment was withdrawn from the trial in March 2016 following safety analysis of idelalisib registration studies and recommendations from Gilead Sciences Ltd and regulatory authorities.
Aims: Here, we present an updated ad-hoc analysis of the cohort of patients in RIAltO who received idelalisib or placebo.
Methods: Patients were eligible for inclusion if they had previously untreated CLL requiring treatment by NCI/IWCLL criteria, were considered unfit for FCR and did not have any contraindications to the study drugs. Consenting patients underwent an unblinded 1:1 randomisation to ofatumumab (300mg iv day 1 and 1000mg iv day 8 of cycle 1; 1000mg iv day 1 of cycle 2 onwards) plus either chlorambucil (10mg/m^2 day 1-7, repeated every 28 days for 3-12 cycles) or bendamustine (70mg/m^2 iv day 1-2 for 3-6 cycles) and a double-blinded 1:1 randomisation to concurrently administered placebo or idelalisib (150mg bd for up to 3 years). Co-trimoxazole prophylaxis was recommended. Study drugs were discontinued in the event of disease progression or unacceptable toxicity. The primary endpoint was progression-free survival (PFS). The mandatory post-treatment reporting period for serious adverse events (SAEs) was 6 months for grade ≥3 infections and 28 days for other events.
Results: 145 patients received idelalisib (73) or placebo (72), with a median idelalisib exposure time of 2.5 months (IQR 1.7-5.5 months). The two arms were well balanced for age, gender, stage, co-morbidity, performance status and chemotherapy allocation. As of January 2018, SAEs were reported in 80% of idelalisib-treated patients (84 grade 3-4 and 7 grade 5) compared to 47% of the placebo arm (35 grade 3-4 and 3 grade 5). The frequency of SAEs in the idelalisib arm was similar in both chemotherapy arms. Grade 5 events in this arm were sepsis (1), lung infection (2), febrile neutropenia (2), myocardial infarction (1) and sudden death NOS (1). After a median follow-up of 25 months (range 0.1-38.1 months), 15 PFS events have been reported in the idelalisib arm compared with 28 in the placebo arm (P=0.061, log-rank test). Regarding OS, 7 deaths have been observed in the idelalisib arm compared to 15 in the placebo arm (P=0.093, log-rank test). 0 and 11 deaths in the respective arms occurred beyond 6 months, while 0 and 10 deaths were associated with CLL progression (Figure 1).
Summary and Conclusions: In less fit patients with CLL, the addition of idelalisib to frontline O+C or O+B resulted in an increased rate of early grade 3-5 toxicity, much of it due to infection and febrile neutropenia. However, despite a median drug exposure time of only 2.5 months, there was a non-significant trend for superior PFS and OS in the idelalisib arm. Longer follow-up is required to establish whether the efficacy of frontline O+C/B is improved by brief co-administration of idelalisib.

PF348

OBINUTUZUMAB PRE-INDUCTION ABROGATES HIGH TUMOR LYSIS RISK OF VENETOCLAX IN TREATMENT NAÏVE FCR-UNFIT PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA: A PLANNED INTERIM ANALYSIS

M.-D. Levin[1,*], S. Kersting[2], Y. van Norden[3], J. Dobber[4], C. Mellink[5], L. Evers[4], F. Croon - de Boer[6], J. Schreurs[7], E. van der Spek[8], H. Visser[9], C. Idink[10], S. Wittebol[11], M. Hoogendoorn[12], S. Tonino[13], A.P. Kater[13]

[1]Internal Medicine, Albert Schweitzer hospital, Dordrecht, [2]Internal Medicine, HAGA hospital, the Hague, [3]Statistics, Erasmus MC Institute HOVON data centre, Rotterdam, [4]Laboratory special hematology, [5]Laboratory of clinical genetics, Academic Medical Center, Amsterdam, [6]Internal Medicine, Ikazia hospital, Rotterdam, [7]Internal Medicine, Martini hospital, Groningen, [8]Internal Medicine, Rijnstate hospital, Arnhem, [9]Internal Medicine, Northwest Clinics, Alkmaar, [10]Internal Medicine, ZorgSaam hospital, Terneuzen, [11]Internal Medicine, Gelderland Valley hospital, Ede, [12]Internal Medicine, Medical Center Leeuwarden, Leeuwarden, [13]Hematology, Academic Medical Center, Amsterdam, Netherlands

Background: Combination of chlorambucil and obinutuzumab is currently the most effective treatment for CLL patients unfit for fludarabine or bendamustine containing regimens with 1/3 of patients reaching peripheral blood (PB) minimal residual disease negativity (MRD-). Early data on venetoclax containing regimens show promising results with deep remissions but are hampered by risk of tumor lysis syndrome (TLS). Whether optimal duration of venetoclax treatment can be guided by MRD- is currently unknown. We perform a randomized phase 2 study to address 1) whether TLS-risk can be mitigated in an unfit population by introducing pre-induction and 2) whether MRD-guided duration of venetoclax treatment is a feasible and efficacious approach.
Aims: Here we report on a planned interim safety analysis (especially TLS risk before and after obinutuzumab pre-induction) and MRD data of the first 30 patients in this HOVON 139 / GIVE trial.
Methods: Treatment regimen is as follows: Pre-induction (Figure 1): 2 cycles of obinutuzumab monotherapy (C1 d1:100 mg, d2: 900 mg, d8:1000 mg, d15: 1000mg and C2 d1: 1000 mg); Induction I: 6 cycles obinutuzumab (C3-8 d1: 1000 mg) in combination with venetoclax (C3: ramp-up weekly 20-50-100-200mg and 400mg daily thereafter); Induction II: 6 cycles venetoclax monotherapy (C9-14: 400 mg daily); MRD-guided maintenance: randomization of patients with at least partial remission (PR) after induction II: 12 additional cycles of venetoclax irrespective of MRD or venetoclax maintenance only in MRD+ patients. All cycles are 28 days. MRD–: <1 CLL cell/10^4 leukocytes (L) by flowcytometry. TLS risk groups according to Roberts.
Results: Until the 29th of January 2018, 46 patients were included in this trial. Thirty patients were followed for at least 3 cycles (median age 70, range 57-79 years) and are reported here, of whom 73% was male, 47% had RAI stage ≥3 and median CIRS-score was 3 (range 0-16). IGHV was mutated in 13 (43%) and unmutated in 13 (43%) patients (non-conclusive in 4 (13%). Deletion 17p was found in 3 (10%), 7 (24%) patients showed a TP53-mutation (≥10%) and 9 (30%) had complex karyotype. Baseline TLS risk scores are depicted in Table 1. Downgrading of TLS risk occurred in 25 patients (83%): 3 from high to medium, 3 from high to low and 19 from medium to low risk. Laboratory TLS grade 1 occurred in 4 times in 3

patients: 2 times during pre-induction with obinutuzumab, both with medium TLS risk and 2 times during venetoclax ramp-up with low TLS risk after pre-induction, of whom 1 with high and 1 with medium TLS risk at baseline. All TLS resolved with protocolled hydration, allopurinol +/- rasburicase. During pre-induction 9 patients (30%) experienced grade 3-4 toxicities, but none in the second pre-induction cycle. The intended dose of 3000 mg obinutuzumab in the first pre-induction cycle was reached in 28 patients (93%). During the first induction cycle 3 patients (10%) developed grade 3-4 toxicity. In addition, all patients received the total intended dose of venetoclax ramp-up. First PB MRD data showed 21 of 25 patients (84%) MRD-, 3 (12%) MRD intermediate (10^{-4}–$<10^{-2}$) and 1 (4%) MRD+ after 6 cycles of induction treatment and 4 of 4 (100%) MRD- after 12 cycles of induction treatment (see Table 2).

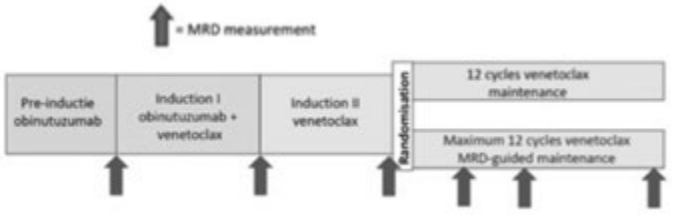

Figure 1.

Table 1.

TLS risk (%)	Baseline (n=30, %)	After pre-induction (n=28, %)*
Low	2 (7%)	24 (80%)
Medium	22 (73%)	4 (13%)
High	6 (20%)	0 (0%)

*Unknown in 2 patients

Table 2.

PB MRD	After 6 cycles induction (n=25, %)*	After 12 cycles induction (%) (n=4)**
$<10^{-4}$:	21 (84%)	4 (100%)
10^{-4}–$<10^{-2}$:	3 (12%)	0
$\geq 10^{-2}$:	1 (4%)	0

*in patients 5 MRD assessment after 6 cycles was not (yet) done
**only 4 patients complete 12 cycles of induction treatment

Summary and Conclusions: Obinutuzumab pre-induction is well tolerated in elderly patients and results in abrogating high TLS risk in all patients. MRD-negativity is seen in 84% of patients after 6 cycles and in all patients reaching 12 cycles of induction treatment with obinutuzumab and venetoclax.

PF349

CONTINUING REMISSIONS AFTER VENETOCLAX AND OBINUTUZUMAB IN PATIENTS WITH PREVIOUSLY UNTREATED CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) AND COEXISTING MEDICAL CONDITIONS

Background: The combination of venetoclax and obinutuzumab was reported to achieve excellent responses regarding overall responses rates (ORR), complete responses (CR) and MRD-negativitiy with manageable toxicity in previously untreated patients with chronic lymphocytic leukemia (CLL).
Aims: The CLL14 trial is a prospective, open-label, multicenter, randomized phase-III trial to compare the efficacy and safety of obinutuzumab and venetoclax with obinutuzumab and chlorambucil in patients with previously untreated CLL and coexisting medical conditions. Prior to the randomized phase, a safety run-in phase was conducted. Here we present long-term follow-up results for safety and efficacy for patients treated within the run-in phase.
Methods: Thirteen previously untreated patients with confirmed CLL and with coexisting medical conditions assessed by cumulative illness rating scale (CIRS) total score >6 and/or estimated creatinine clearance (CrCl) <70 mL/min requiring treatment according to iwCLL criteria were enrolled. Treatment consisted of 6 cycles obinutuzumab and venetoclax followed by 6 cycles of venetoclax. Risk assessment for tumor lysis syndrome (TLS) was performed before treatment. Adverse events were graded per NCI CTCAE v.4. MRD in peripheral blood was assessed by ASO-PCR, flow cytometry and NGS. Progression free survival (PFS) was defined as the time between enrollment and first disease progression or death and overall survival (OS) as the time between enrollment and death.
Results: Baseline characteristics, acute toxicity and ORR of 100% three months after the end of treatment, were previously reported. As of this analysis, 12 patients had completed treatment and had at least 18 months of follow-up. One patient discontinued treatment early due to a grade 4 infusion-related reaction following the first infusion of obinutuzumab. Median observation time was 29.6 months (range 20.7-35.0). A total of 264 adverse events were reported for all 12 patients that had received obinutuzumab and venetoclax. Of these, 226 occurred during the treatment period, 27 during the first and 11 during the second year of follow-up period. No prolonged neutropenia was observed. A total of 35 infections were reported. One basal cell carcinoma, but no further secondary malignancies were reported. A 90 year old patient who was in CR died of cardiac failure nine months after the end of treatment, which was assessed as non-related by the investigator. Median PFS and OS have not been reached. At month 30, 80.2% of the patients were progression-free and 92.3% were alive (Figure 1A,B). At follow-up month 3, 11 of 12 treated patients had no detectable (<10-4) minimal residual disease by ASO-PCR in peripheral blood and one patient was assessed positive (≥10-4). At follow-up month 18, seven patients remained MRD negative and four patients were assessed positive. MRD results assessed by flow cytometry are shown in Figure 1C.

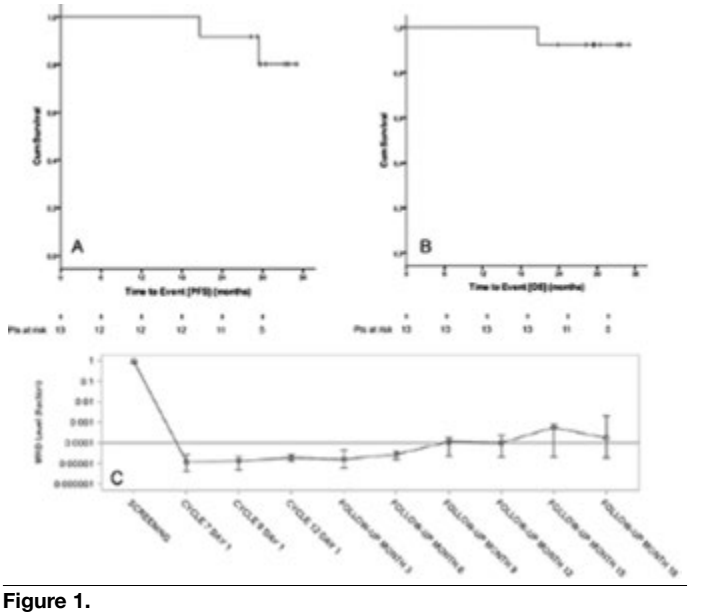

Figure 1.

Summary and Conclusions: The combination of venetoclax and obinutuzumab in previously untreated patients with CLL appears to induce long-lasting remissions. The trial population consists of 13 elderly patients (median age 75 years) with clinically meaningful comorbidities in addition to CLL including 2 patients with deletion 17p. After the fixed treatment duration of 12 cycles and with median follow-up of 30 months, 80.2% of patients are progression-free and 12 patients are still alive.

Background: Patients (pts) with relapsed or refractory (R/R) chronic lymphocytic leukaemia (CLL) who failed treatment with Bruton's Tyrosine Kinase inhibitor (BTKi) ibrutinib have a particularly dismal prognosis. A previous phase I study showed that the Fc-enhanced, humanized, anti-CD19 antibody MOR208 was well tolerated with encouraging single-agent activity in pts with R/R CLL. In preclinical studies, MOR208 showed synergistic potential in combination with idelalisib (IDE, PI3Kδ inhibitor) and venetoclax (VEN, BCL-2 inhibitor).
Aims: This ongoing phase II study assesses the safety and preliminary efficacy of MOR208+IDE (Cohort A) or MOR208+VEN (Cohort B) in pts with R/R CLL previously treated with a BTKi. Here we present the first results of Cohort A.
Methods: Adult pts with R/R CLL without transformation or Richter's syndrome, who progressed on BTKi therapy or were intolerant to a BTKi during last prior therapy, were eligible in case of having an ECOG status 0–2 and adequate organ function. In Cohort A pts were treated until progression or for up to 24 cycles (C; each C consists of 28 days) with MOR208 administered intravenously at a dose of 12 mg/kg body weight, weekly during C1-3 (with equivalent loading dose on day 4 of C1), every other week in C4-6, monthly in C7-24 and with IDE continuously administered orally at 150 mg BID. Primary endpoint is the incidence and severity of adverse events (AEs), secondary endpoints include overall response rate (ORR) as per IWCLL 2008.

Table 1.

Treatment Emergent Adverse Events in Cohort A

Preferred Term	n (%) , N=11			
	TEAEs (22 pts)		SAEs (Any)

Abbreviation: n.a= not applicable. Data cut-off 29-Jan-2018.
*As pancreatitis may be an immune-mediated AE caused by IDE, the study's Independent Data Monitoring Committee recommended early use of steroids in pts suspicious of developing pancreatitis based on laboratory results.

Results: Eleven pts had completed at least 1 cycle of study treatment in Cohort A. Median age: 69 years (51-79); Female 45%; Rai stage ≥3: 36%; Binet stage B/C: 28%/36%; ECOG 0/1: 55%/45%. Nine pts (82%) discontinued prior BTKi treatment due to progressive disease and 2 pts (18%) due to toxicity. The median number of prior treatment lines including ibrutinib was 5 (2-9). Pts experienced prior FCR chemoimmunotherapy (73%), anti-CD20 mAb (100%) and allogeneic/autologous stem cell transplantation (SCT) (9%/18%). Table 1. summarizes treatment-emergent adverse events (TEAEs). Ten treatment-emergent serious adverse events (SAEs) were reported in 5 pts (45%), none was fatal. All 5 pts recovered, 1 with sequelae after acute pancreatitis. Two pts (18%) permanently discontinued MOR208+IDE due to TEAE (Pt#1: amylase increased Gr4, lipase increased Gr4 and pancreatitis acute Gr4; Pt#2: transaminase increased Gr4). With a median observation time of 4.2 months, investigator assessed ORR was 82%: 1 CR (9%) confirmed by bone marrow biopsy and 8 PR (73%). Of note, 1 patient with "a very good PR" was taken off the study and received allogeneic SCT. Two pts had progressive disease, 1 of them resulted in fatal cardiorespiratory failure. Two patients who discontinued prior BTKi treatment due to toxicity reached PR, 1 of them discontinued study treatment due to AE. Treatment of 6 pts is ongoing.
Summary and Conclusions: The novel combination treatment of MOR208 with idelalisib showed acceptable safety and tolerability as well as promising antitumor activity in heavily pre-treated pts with R/R CLL who failed prior treatment with ibrutinib.

PF351

REAL-WORLD RESULTS ON IBRUTINIB IN RELAPSED/REFRACTORY CLL: 30-MONTH FOLLOW-UP OF 95 SWEDISH PATIENTS TREATED IN A COMPASSIONATE USE PROGRAM

M. Winqvist[1,*], P.-O. Andersson[2], A. Asklid[3], K. Karlsson[4], C. Karlsson[1], B. Lauri[5], J. Lundin[1], M. Mattsson[6], S. Norin[7], A. Sandstedt[8], R. Rosenquist[9], F. Späth[10], L. Hansson[1], A. Österborg[1]

[1]Department of Hematology, Karolinska University Hospital, Stockholm, [2]Department of Hematology, Borås Hospital, Borås, [3]Department of Oncology, Karolinska University Hospital, Stockholm, [4]Department of Hematology, Lund University Hospital, Lund, [5]Department of Hematology, Sunderbyn Hospital, Sunderbyn-Luleå, [6]Department of Hematology, Uppsala University Hospital, Uppsala, [7]Department of Internal Medicine, Karolinska Institutet, Stockholm, [8]Department of Hematology, Linköping University Hospital, Linköping, [9]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, [10]Department of Radiation Sciences, Oncology, Norrland University Hospital, Umeå, Sweden

Background: Ibrutinib is standard of care for patients with chemoimmunotherapy-refractory CLL. There is often a discrepancy between data obtained in pivotal clinical trials with strict inclusion criteria and those later obtained in routine health care. We have previously reported the 10-month follow-up of real-world results on ibrutinib in consecutive Swedish CLL patients treated in a compassionate use program (CUP) (Winqvist *et al.*, Haematologica 2016).
Aims: This 30-month follow-up reports long-term PFS, OS and safety as well as the impact of inclusion/exclusion criteria (obtained from RESONATE trial, Byrd *et al.*, NEJM 2014) on the outcome of patients treated in the Swedish CUP.
Methods: All patients treated in the CUP (n=95) were identified for long-term follow-up and in-depth analyses of their files were performed. All patients started at 420 mg/d.
Results: Median age was 69 years, 63% had del(17p)/*TP53* mutation, 27% had ECOG PS grade 2-3 and median no. of prior therapies was 3. Median treatment duration was 27 months (range 0.6-38) and 51% remained on ibrutinib at follow-up. ORR was 84% (CR not evaluable). Median PFS and OS were not yet reached. At a median follow-up time of 30 months (range 1-38) the OS rate was 63% and the PFS rate was 52% (Figure 1A and B). We analyzed the impact of the inclusion/exclusion criteria obtained from the RESONATE pivotal study (Byrd 2014): 44% of CUP patients had at least one exclusion criteria, supporting real-world representativity of our cohort. OS was significantly ($p<0.05$) shorter for CUP patients not matching these criteria (Figure 1C), there was no difference in PFS. 51% of patients had a grade 3-4 infection; 22% pneumonia, 13% febrile neutropenia/septicemia and 31% other infections. 13% had grade 3-5 opportunistic infections. 41% and 20% had grade 3-4 neutropenia or thrombocytopenia. Richter transformation (RT) occurred in 12 patients (13%) after a median time of 14 months (range 4-36); no clear-cut RT plateau was yet observed. 37% of the patients had died due to RT (n=12), CLL progression (n=6), second malignancy (n=5), infection (n=7), miscellaneous toxicity (n=4) and sudden death (n=1). Ibrutinib was permanently stopped in 47 patients (49%). The most common reasons were toxicity (n=18), RT (n=11), second malignancy (n=3), allogeneic SCT (n=4) and CLL progression (n=6). The drop-out rate of 49% at 30 month follow-up in our study is in contrast to the 42% discontinuation rate at 17 months follow-up in the recent real-world report by Mato et al (Haematologica 2018).

Four of 6 patients who progressed while on ibrutinib were tested for BTK mutations at PD; all carried a C481S mutation in >50% of the cells (Sanger sequencing); baseline tests (n=2) were negative. 19 patients had totally 21 treatment breaks >14 d (median 22d). In contrast to others (Barr *et al.*, Blood 2017, UK CLL Forum, Haematologica 2016) we found no impact on PFS or OS (Figure 1D). In contrast to our 10-month report (Winqvist 2016), the negative impact of del(17p) was not significant, but del(17p) patients who had ≥3 previous therapies had a short OS on ibrutinib (median 20.7 months). In multivariate analyses OS was associated with number of prior therapies and PFS was associated with baseline comorbidities (CIRS).

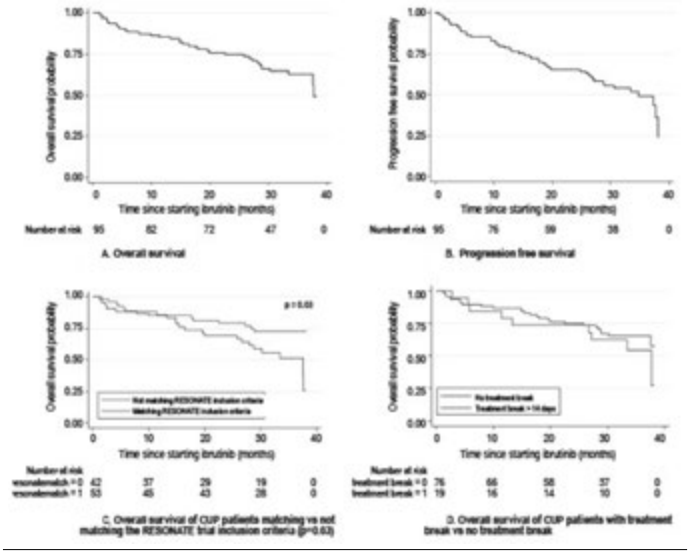

Figure 1.

Summary and Conclusions: The 30-month follow-up of the Swedish real-world cohort showed that 51% of CLL patients remained on ibrutinib. The impact of pivotal trial inclusion/exclusion criteria on the effects of new drugs in routine health care merits further investigations.

PF352

ANALYSIS OF SUSTAINED HEMATOLOGIC IMPROVEMENT WITH IBRUTINIB TREATMENT IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA/SMALL LYMPHOCYTIC LEUKEMIA

Background: Ibrutinib (ibr), a first-in-class, once-daily oral inhibitor of Bruton's tyrosine kinase. Ibrutinib as a single agent is indicated for treatment of patients (pts) with chronic lymphocytic leukemia (CLL) by EMEA and for CLL/small lymphocytic leukemia (SLL) by US FDA and allows for treatment without chemotherapy. Superior efficacy of ibr over comparator drugs was demonstrated in clinical studies with ibr in CLL/SLL (Byrd, *NEJM*, 2014; Burger, *NEJM*, 2015; Chanan-Khan, *Lancet Oncol*, 2016).
Aims: To assess sustained hematologic improvement (SHI) with a side-by-side presentation of three phase 3 clinical studies with ibr *vs* comparator arm as first line treatment in pts with CLL/SLL or in pts with relapsed/refractory (R/R) CLL/SLL.

Methods: Ibr 420 mg daily was given until progressive disease or unacceptable toxicity in the RESONATE (PCYC-1112) and RESONATE-2 (PCYC-1115/1116) studies and in combination with bendamustine plus rituximab (BR) in the HELIOS study (CLL3001). Comparator/combination agents were of fixed duration. In the RESONATE study, pts with R/R CLL/SLL received up to 6 cycles of ofatumumab (ofa; Byrd, *NEJM*, 2014). In RESONATE-2, treatment naïve pts aged ≥65 y with CLL/SLL received up to 12 cycles of chlorambucil (clb; Burger, *NEJM*, 2015). In the HELIOS study, pts with R/R CLL/SLL received up to 6 cycles of combined placebo and BR (Chanan-Khan, *Lancet Oncol*, 2016). All patients provided written informed consent. SHI was compared using Fisher's exact test and was defined as ≥56 days with: 1) platelet count >100 x 109/L if baseline ≤100 x 109/L or increase ≥50% over baseline; or 2) hemoglobin >11 g/dL if baseline ≤11 g/dL or increase ≥2 g/dL over baseline (in pts without blood transfusion or growth factor support).
Results: The analysis included a total of 1238 pts (391 RESONATE, 269 RESONATE-2, 578 HELIOS). Compared to respective comparator arms, ibr treatment resulted in sustained increase in hemoglobin for pts with baseline anemia (RESONATE: 80% *vs* 44%, *P*<0.0001; RESONATE-2: 90% *vs* 45%, *P*<0.0001; HELIOS: 74% *vs* 65%, *P*=0.2528) or sustained increase in platelets for pts with baseline thrombocytopenia (RESONATE: 85% *vs* 20%, *P*<0.0001; RESONATE-2: 83% *vs* 46%, *P*=0.0032; HELIOS: 69% *vs* 59%; *P*=0.1935) (Figure 1). The rates of SHI were improved with ibr treatment *vs* comparators across specified high-risk genomic subgroups (del11q, complex karyotype, unmutated *IGHV* and trisomy 12) in all three studies and in del17p pts, which were enrolled in the RESONATE study only. Pts with SHI had improved progression-free survival (PFS) with ibr *vs* comparators at 36 months in all studies (Figure 1, RESONATE: 68% *vs* 7%; RESONATE-2: 80% *vs* 32%; HELIOS: 77% *vs* 21%) as well as overall response rates (ORR; RESONATE: 97% *vs* 29%; RESONATE-2: 95% *vs* 50%; HELIOS: 95% *vs* 76%). Improvement in fatigue was observed for all patients who achieved SHI on RESONATE and RESONATE-2. In long term follow-up, grade 3-4 hematologic adverse event (AE) rates overall and in pts with SHI continued to appear favorable for ibr (median treatment and AE collection periods up to 8-fold longer in ibr *vs* comparator arms).

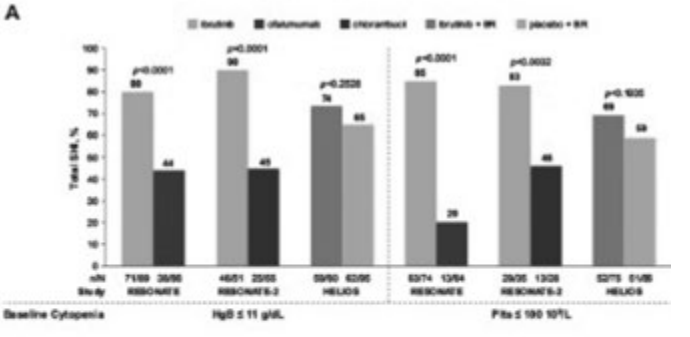

Figure 1.

Summary and Conclusions: Analyses showed that single-agent and combination treatment with ibr resulted in a high frequency of SHI in hemoglobin and platelet levels for both first-line and R/R pts *vs* comparators. ORR and PFS improvements with ibr, including in pts with SHI benefit, were maintained *vs* comparators. Over a median treatment duration of 34-41 months, the rates of severe hematologic AEs continue to remain low for patients treated with ibr.

PF353

REAL WORLD TREATMENT PERSISTENCE OF AUSTRALIAN IBRUTINIB PATIENTS IN A NAMED PATIENT PROGRAM

C. Tam[1,2,*], B. Kuss[3], S. Opat[4], A. Puig[5], M. Acar[5], C. Zhou[6], S. Mulligan[7,8]

[1]Peter MacCallum Cancer Centre Parkville, [2]Haematology, St. Vincent's Hospital, Melbourne, [3]Molecular Medicine and Pathology, Flinders University/Flinders Medical Centre, Bedford Park, [4]Monash Health, Monash University, Melbourne, [5]Health Economics, Pricing and Outcomes Research, [6]Medical and Scientific Affairs, Janssen-Cilag Pty Ltd, [7]Royal North Sydney Hospital, [8]University of Sydney, Sydney, Australia

Background: NPPs (Named Patient Programs) can provide controlled access to treatment in response to unsolicited requests by physicians for specific patients before medicines become commercially available. In 2014, a global ibrutinib NPP was opened for patients with relapsed or refractory Chronic Lymphocytic Leukemia (CLL) in multiple countries, including Australia. The program closed in Australia in November 2017.
Aims: To analyse duration on ibrutinib treatment for patients with relapsed/refractory CLL enrolled in a NPP in Australia.
Methods: A retrospective cohort analysis was conducted using baseline patient characteristics such as age, sex, received 3 or more prior lines of therapy, etc. (collected on a binary scale, *e.g.*, age <65 years *versus* >=65 years) entered by treating physicians when enrolling patients into the NPP via the Janssen Managed Access portal (MacWeb). Patients were considered to be on treatment until they were reported as discontinued. Treatment duration was estimated from the date of first supply to date of last resupply. This real-world estimate of treatment duration was compared to time to treatment discontinuation in the ibrutinib arm of the RESONATE trial, as reported in Brown et al Leukemia, 32, 83-91 (2018). Time on treatment was evaluated descriptively using Kaplan-Meier (KM) curves, and statistical testing was conducted using log-rank test.
Results: Of the 1,015 patients treated with ibrutinib in the NPP in Australia from 2014 to 2017, 68% were male, 73% were 65 years or older, and 43% of patients had received 3 or more prior lines of therapy before commencing in the NPP. While 226 patients (22%) discontinued treatment by the end of the NPP, 85% (95% CI: 0.82-0.87) remained on treatment for at least 12 months; median duration on treatment was not reached over the NPP period. Duration on treatment in NPP for this analysis ranged from 0 to 39 months. There was no difference in the time on treatment between the RESONATE trial and the NPP (p= 0.11, HR= 0.81, 95% CI= 0.63-1.05) (Figure 1).

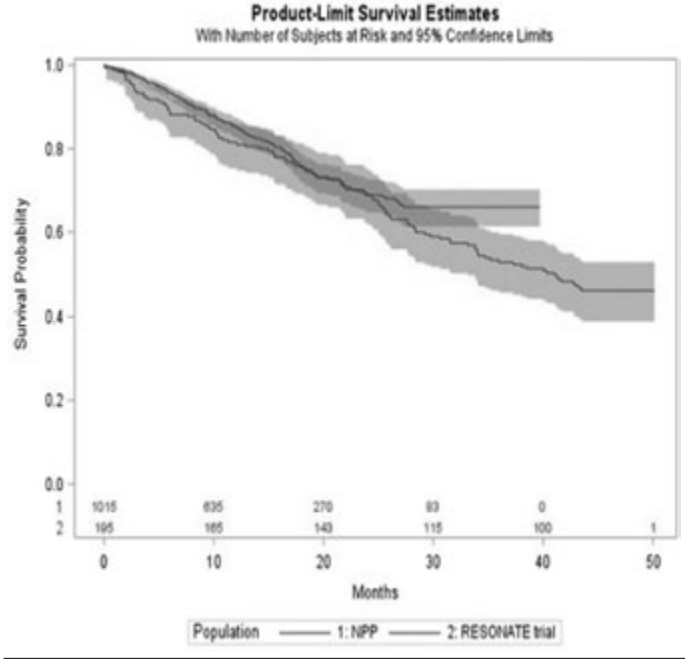

Figure 1.

Summary and Conclusions: The Australian NPP estimates of time on treatment closely tracks to the time on treatment observed in the pivotal Phase 3 trial for Ibrutinib in relapsed/refractory CLL, RESONATE, with caveats associated with the statistical comparability of these cohorts. While there are limitations to the NPP data given that it was based on unmonitored physician declarations, and the duration on treatment was estimated from resupply data, these findings provide a real-world estimate of time-on-treatment with ibrutinib that is similar to the time-on-treatment in the RESONATE trial.

PF354

THE EFFICACY OF DUVELISIB MONOTHERAPY FOLLOWING DISEASE PROGRESSION ON OFATUMUMAB MONOTHERAPY IN PATIENTS WITH RELAPSED/REFRACTORY CLL OR SLL IN A PHASE 3 CROSSOVER EXTENSION STUDY

P. Hillman[1,*], B. Kuss[2], C. Moreno[3], M. Davids[4], N. Lammana[5], Z. Nagy[6], J. Essell[7], P. Ghia[8], C. Tam[9], U. Jaeger[10], S. Stilgenbauer[11], J. Delgado[12], N. Le[13], B. Jeglinski [13], M. Montillo[14]

Background: Duvelisib, an oral dual inhibitor of PI3K-δ, γ, is being developed for the treatment of hematologic malignancies, including relapsed/refractory (RR) CLL/SLL. In the Phase 3 DUO study (NCT02004522) duvelisib monotherapy demonstrated significant improvement compared to ofatumumab monotherapy (PFS 13.3 *vs* 9.9 mo. p<0.0001; ORR 74% *vs* 45% p <0.0001) with a manageable safety profile (Flinn, ASH 2017). Study IPI-145-12 (NCT02049515) is an open-label, optional, crossover extension study where pts with confirmed progressive disease (PD) on DUO were given the option to receive the opposite treatment.
Aims: Herein we present data for the 89 pts who voluntarily rolled over following PD on ofatumumab on DUO and received duvelisib on Study IPI-145-12.
Methods: Eligible pts were enrolled within 3 months of PD on the DUO study (excluding Richter's transformation or prolymphocytic leukemia), and maintained adequate renal and hepatic function and an ECOG PS of 0-2. Duvelisib 25 mg BID was administered until PD, intolerance, death, or study withdrawal. Responses were determined by investigators per modified IWCLL/IWG criteria.
Results: Median age was 68 yrs (range: 39-89), 63% were male, and 90% Caucasian. Nearly half (49%) had Rai Stage III/IV or Binet Stage C, and 23% had del(17p) and/or *TP53* mutation. Median prior anticancer therapies was 3 (range: 2-8). Median exposure to duvelisib was 32 weeks on the extension study. The ORR for pts treated with duvelisib in the crossover was 73% (95% CI: 64, 82) (all PRs) compared to 28% (95% CI: 19, 37) (1% CR, 27% PR) when previously treated with ofatumumab in DUO. The median PFS for duvelisib was 15 mo. (95% CI: 10, 17) compared to 9 mo. (95% CI: 9, 11) for prior ofatumumab.
Summary and Conclusions: In an extension study, duvelisib monotherapy achieved robust and durable responses in 89 RR CLL/SLL pts with PD following ofatumumab treatment in the DUO study (ORR: duvelisib 73%; prior ofatumumab 28%), with a longer PFS with duvelisib than prior ofatumumab (PFS: duvelisib 15 mo.; prior ofatumumab 9 mo.). These data further support duvelisib monotherapy as an effective oral treatment option for pts with RR CLL/SLL.

PF355

A PHASE 1 DOSE ESCALATION STUDY OF ARQ 531 IN SELECTED PATIENS WITH RELAPSED OR REFRACTORY HEMATOLOGIC MALIGNANCIES

J. Woyach[1,*], I. Flinn[2], D. Stephens[3], F. Awan[1], R.E. Savage[4], F. Chai[4], S. Eathiraj[4], B. Schwartz[4], L. Szuszkiewicz[1], K. Tith[4], J.C. Byrd[1]

[1]Ohio State University, Nashville, [2]Sarah Cannon Research Institute, Columbus, [3]Huntsman Cancer Institute, Salt Lake City, [4]ArQule, Inc., Burlington, United States

Background: Bruton's tyrosine kinase (BTK) is a key regulator of the B cell receptor (BCR) signaling pathway that contributes to survival, proliferation and trafficking of malignant B cells. Despite impressive clinical response of ibrutinib in B-cell malignancies, cases of primary and secondary resistance have emerged with poor outcomes and no established treatment options. The underlying drug resistance mechanisms are complex and diverse, in ~80% of relapsing CLL patients develops resistance in association with BTK-C481S and PLCg mutations. ARQ 531 is a reversible ATP competitive inhibitor of BTK that does not require C481 residue for binding. With its distinct kinase selectivity profile, ARQ 531 targets multiple oncogenic signals of BCR signaling pathway and has demonstrated potent inhibitory activity in CLL and DLBCL mouse models.
Aims: The primary objectives of the study are to assess the safety and tolerability, and to determine the recommended Phase 2 dose and schedule of ARQ 531. The secondary objectives are to assess the pharmacokinetic (PK) profile, pharmacodynamics (PD) activity, and to generate preliminary evidence of anti-tumor activity of ARQ 531.
Methods: This is a first in human, phase 1 dose escalation study in patients

with relapsed or refractory CLL/SLL, WM, B-cell NHL who received at least 2 prior lines of systemic therapy including a BTK inhibitor approved for their diseae. Patients with DLBCL must have failed, refused, or be ineligible for autologous stem cell transplant. Patients with low grade lymphoma must be progressing and requiring treatment. Dose escalation was performed according to a 3+3 design. TEAEs were assessed per NCI CTCAE v.4.03. Tumor response were evaluated per disease specific guidelines. Blood samples were collected for PK and PD analysis.
Results: A total of 8 patients enrolled (2 DLBCL, 5 CLLs and 1 follicular lymphoma) and treated at dose levels of 5 mg QD, 10 mg QD, and 15 mg QD. All patients signed written informed consent prior to initiation of any study-specific procedures. No DLTs or drug-related AEs have been reported so far. Preliminary PK data show that increases in ARQ 531 exposure were close to dose proportional and that the estimated plasma half-life was ~24 hours. Sustained pBTK PD knockdown was observed. One patient treated at the dose of 5 mg QD has shown >30% tumor reduction after 8 weeks on treatment and is ongoing.
Summary and Conclusions: The study is actively enrolling patients. Updated data in safety, PK, PD and efficacy will be presented.

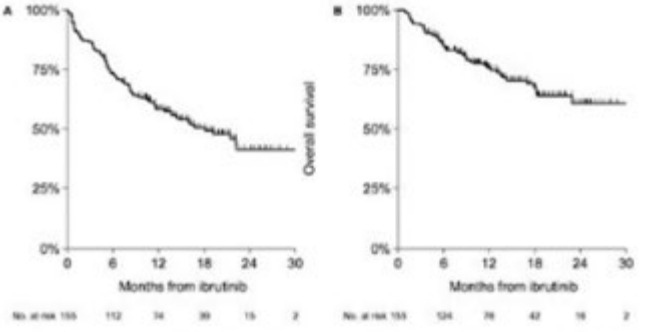
PF356

EFFECTIVENESS OF IBRUTINIB FOR THE TREATMENT OF CHRONIC LYMPHOCYTIC LEUKEMIA IN DAILY PRACTICE IN THE NETHERLANDS: A NATIONWIDE POPULATION-BASED COHORT STUDY

L. Van Der Straten[1,2,*], M.-D. Levin[2], O. Visser[3], N.M. Blijlevens[4], J.J. Cornelissen[5], J.K. Doorduijn[5], A.P. Kater[6], A.G. Dinmohamed[1,5,7]

[1]Research, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [2]Internal Medicine, Albert Schweitzer Hospital, Dordrecht, [3]Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [4]Hematology, Radboud University Medical Center, Nijmegen, [5]Hematology, Erasmus MC Cancer Institute, Rotterdam, [6]Hematology, Academic Medical Center, Amsterdam, [7]Public Health, Erasmus University Medical Center, Rotterdam, Netherlands

Background: In the late 2014, ibrutinib was approved in the Netherlands for patients with relapsed/refractory chronic lymphocytic leukemia (CLL) and for CLL patients with p53 dysfunction in any line of therapy. At present, most of our knowledge on the effectiveness of ibrutinib arrive from compassionate-use programs (CUPs), which to a certain degree are associated with patient selection as in randomized clinical trials (RCTs).
Aims: The aim of this nationwide, population-based study was to assess the effectiveness of ibrutinib in CLL patients in a post-approval setting in the Netherlands.
Methods: We identified all adult (≥18 years) CLL patients who were treated with ibrutinib in the Netherlands between January 1, 2015 and December 31, 2016 from Dutch Hospital Data. These patients were subsequently linked to the nationwide Netherlands Cancer Registry to allow for additional data collection on patient, disease, and treatment characteristics. The primary endpoint was progression-free survival (PFS; see Figure 1 for definition). The secondary endpoints included prescription pattern of ibrutinib according to the HOVON-endorsed indications (see Table 1 for indications) discontinuation rate, and overall survival (OS; see Figure 1 for definition). Multivariable logistic regression (MLR) and multivariable Cox regression (MCR) was used to assess covariates (listed in Table 1) associated with permanent ibrutinib discontinuation and outcome (*i.e.* PFS and OS), respectively. A $P<0.05$ indicates statistical significance.
Results: A total of 155 ibrutinib-treated CLL patients (median age, 70 years; range, 48-91 years) were included in this analysis, of whom 94% received ibrutinib as subsequent treatment and 55% according to the HOVON-endorsed indications. At ibrutinib initiation, the majority of patients were male (74%), had anemia (51%), had RAI stage ≥3 (67%), received ≥3 prior lines of therapy (62%), received ibrutinib within a non-university hospital (68%), and had ≥1 comorbidity (71%). Del(17p) and *TP53* mutation was found in 27/86 (31%) and 10/16 (63%) tested patients, respectively. At a median follow-up of 12.0 months (range, 0.9-30.9), 47% of the patients were still on ibrutinib. The median PFS and OS was 18.2 months (95% confidence interval [CI], 11.6-not reached [NR]; Figure 1A) and NR (95% CI, 22.9-NR; Figure 1B). At 1-year, PFS and OS was 58% (95% CI, 50%>66%) and 76% (95% CI, 68%>82%), respectively. Of note, median PFS for patients with anemia was 14.3 months (95%CI, 7.3-21.5), as compared with NR (95%CI, 13.7-NR) for non-anemic patients (P=0.004). Furthermore, patients with anemia experienced more toxicity, as compared with non-anemic patients (57% *vs* 38%%; P=0.021). MLR analysis showed that anemia was the sole covariate that was associated with permanent ibrutinib discontinuation (OR 2.33; 95% CI, 1.20-4.52; P=0.012). In the MCR analysis, anemia was associated with lower PFS (P=0.014) and OS (P=0.001; Table 1). Further, hepatosplenomegaly (P=0.033) and number of previous therapies (P=0.002) were associated with inferior OS (Table 1).



- Progression-free survival was defined as the time from start of ibrutinib to progression/relapse, start of subsequent therapy, death resulting from any cause, or last follow-up (October 27, 2017), whichever occurred first. Seven patients who received an allogeneic hematopoietic stem cell transplantation (alloHSCT) after having responded to ibrutinib were censored at the date of alloHSCT.
- Overall survival was defined as the time from start of ibrutinib until death resulting from any cause or until the last date the patient was known to be alive (October 27, 2017), whichever occurred first.

Figure 1.

Table 1.

Results of the multivariable Cox regression

Covariate	Progression-free survival HR	95% CI	P	Overall survival HR	95% CI	P
Age, years (per one unit increase)	1.00	0.97 - 1.04	0.858	0.99	0.95 - 1.03	0.532
Female sex	0.73	0.41 - 1.31	0.293	0.66	0.30 - 1.43	0.288
No. of comorbidities (per one unit increase)	1.09	0.92 - 1.30	0.311	1.07	0.85 - 1.36	0.558
Lymphadenopathy (as per RAI stage)	1.21	0.42 - 3.45	0.720	1.00	0.22 - 4.47	0.999
Hepato- and/or splenomegaly (as per RAI stage)	1.45	0.76 - 2.76	0.254	**3.09**	**1.09 - 8.72**	**0.033**
Anemia (as per RAI stage)	**1.90**	**1.15 - 3.34**	**0.014**	**3.56**	**1.67 - 7.60**	**0.001**
Thrombocytopenia (as per RAI stage)	1.67	0.64 - 1.79	0.798	0.97	0.49 - 1.90	0.926
Treatment as per HOVON-endorsed indication[a]	1.48	0.91 - 2.40	0.112	1.85	0.96 - 3.57	0.065
No. of previous therapies (per one unit increase)	1.18	0.98 - 1.41	0.080	**1.46**	**1.16 - 1.85**	**0.002**
Prior therapy with purine analogue and/or bendamustine	0.83	0.47 - 1.47	0.529	0.87	0.39 - 1.94	0.731

[a]The current ibrutinib label in the Netherlands is defined by HOVON as follows: (i) salvage treatment for patients with CLL in need for treatment within 2 years after FCR or BR treatment, (ii) or within 6 months after chlorambucil in combination with an anti-CD20 agent, (iii) or as first-line treatment in the presence of del(17p) and/or a *TP53* mutation.

Summary and Conclusions: In this nationwide population-based study, we demonstrated that PFS among ibrutinib-treated CLL patients was substantially lower than reported in RCTs and CUPs. This might be explained by differences in patient characteristics and provision of care between patients treated in the real-world, as compared to those enrolled into RCTs and CUPs. The impact of anemia on ibrutinib discontinuation and outcome calls for confirmation in future RCTs and population-based studies.

PF357

RAPID DOSE ESCALATION OF VENETOCLAX IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA PREVIOUSLY TREATED WITH B-CELL RECEPTOR INHIBITOR THERAPY

K. Koenig[1,*], D. Konstantinou[2], A. Rogers[3], T. Wiczer[4], K. Rogers[3], J. Woyach[3], J. Byrd[3], F. Awan[3]

[1]Department of Internal Medicine, The Ohio State University Wexner Medical Center, [2]The Ohio State University College of Medicine, [3]Division of Hematology, [4]Department of Pharmacy, The James Cancer Hospital and Solove Research Institute at The Ohio State University, Columbus, United States

Background: Despite the remarkable disease control observed with B-cell receptor pathway inhibitors (BCRi), patients with chronic lymphocytic leukemia (CLL) who relapse after these agents frequently tend to have rapidly progressive, symptomatic disease that requires immediate intervention and disease control. Venetoclax selectively inhibits anti-apoptotic protein B-cell lymphoma 2 (BCL-2), and is the only agent that has demonstrated remarkable efficacy after BCRi therapy. However, its use requires a slow, weekly dosing ramp-up from 20mg to 400mg goal dose over 5 weeks, to reduce the risk of tumor lysis syndrome (TLS). Herein, we report our experience with a rapid dose escalation protocol for venetoclax that attains prompt disease control.
Aims: Given the need to promptly attain goal venetoclax dose, we aim to demonstrate the feasibility, safety/tolerability, and efficacy of a "rapid dose escalation" of venetoclax in relapsed/refractory CLL pts previously treated with BCRi in a properly equipped university institution.
Methods: With permission from an IRB approved protocol, data was retrospectively compiled from medical records of patients who received rapid venetoclax (dosing ramp up <5 weeks to goal dose). Patient demographics, treatment, disease, and survival outcomes were collected. Detailed safety and efficacy measures were also assessed.

Results: Fifteen patients received rapid venetoclax dose escalation as inpatients with close laboratory and clinical monitoring and aggressive supportive care for laboratory and clinical TLS. Median age was 65 years (range 48-77) and 80% were men with ECOG 0-1 in 93% of patients. Patients had received a median of 5 previous treatments (range 3-7). Most recent prior treatment was a BCRi alone in 10 patients, BCRi in combination with chemotherapy in 3 and high dose steroids in 2 patients. The BCRi treatments overlapped with venetoclax in 6 patients. High risk cytogenetics were present in the majority of patients including: complex karyotype in 60%, del17p in 67% and unmutated IGHV in 80%. Three patients had high tumor burden disease (per venetolax package insert and NCCN Guidelines) and 73% had confirmed BTK/PLCG2 mutations. The mean time to goal venetoclax dose was 12 days (range 5-21), and all patients reached goal dose. Seven (46.7%) pts developed tumor lysis syndrome (TLS) by lab criteria at doses ranging from 20-200 mg (1 patient at 20 mg, 2 patients each at the 50 mg, 100 mg and 200 mg dose); but only 2 patients developed TLS by clinical criteria, of grade 0 or 1 severity (per Cairo-Bishop definition). No patients required renal replacement; 53.3% had an elevated uric acid requiring rasburicase and 40% had hyperphosphatemia requiring phosphate binders. Twelve patients (80%) achieved a partial response, 2 had progressive disease and 1 patient died within 30 days from progressive disease. Mean time to best response was 71 days (range 13-428), and to subsequent treatment was 298 days (range 204-430).
Summary and Conclusions: Rapid dose escalation of venetoclax with close inpatient monitoring in experienced centers could be a feasible approach in patients with disease relapse after BCRi in patients who require urgent disease control. Further trials in these patients utilizing a consistent rapid dose escalation protocol are warranted.

PF358

INDIRECT TREATMENT COMPARISON OF VENETOCLAX PLUS RITUXIMAB WITH B-CELL RECEPTOR INHIBITORS IN PATIENTS WITH RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA

A. Mato[1,*], G. Follows[2], K. Sail[3], I. Diakite[4], D. Nicoloso[4], B. Dietz[5], J. Maher[3], D. Alexiou[3], V. Chirikov[4]

[1]CLL program, Leukemia Service, Division of Hematological Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, United States, [2]Department of Hematology, Cambridge University Hospitals NHS Foundation Trust Addenbrooke's Hospital, Cambridge, United Kingdom, [3]AbbVie, Inc., North Chicago, IL, [4]Pharmerit International, Bethesda, MD, United States, [5]AbbVie Deutschland GmbH & Ko KG, Ludwigshafen, Germany

Background: The primary analysis of the MURANO (median follow up 23.8 months) Phase 3 trial (NCT02005471) in patients with relapsed/refractory chronic lymphocytic leukemia (CLL) demonstrated improvement in progression-free survival (PFS IRC: HR=0.19 [95% CI: 0.13-0.28], p<0.001) and strong pattern of clinically meaningful improvement in the secondary endpoint overall survival (OS: HR=0.48 [95% CI: 0.25-0.90], descriptive p=0.02) for venetoclax plus rituximab (V+R) compared to bendamustine plus rituximab (BR). Recent randomized trials HELIOS (NCT01611090) for ibrutinib+BR and Study 115 (NCT01569295) for idelalisib+BR have also showed improved efficacy *versus* BR. However, there is absence of head-to-head clinical evidence on the comparative efficacy of novel targeted therapies.
Aims: This study aimed to indirectly compare PFS and OS relative efficacy of V+R *versus* B-cell receptor inhibitor therapies.
Methods: Published survival data from HELIOS (median follow up 17 months) and Study 115 (median follow up 14 months) on PFS as assessed by independent review committee (IRC) and OS was used to conduct indirect treatment comparisons (ITC) *versus* V+R. Consistent with the exclusion criteria for HELIOS, MURANO patients with 17p deletion were excluded for V+R to ibrutinib+BR comparisons. Given the availability of a common comparator, the ITC for V+R *versus* ibrutinib+BR and V+R *versus* idelalisib+BR were anchored by accounting for cross-trial differences in Kaplan-Meier curves for the BR arms. Based on literature review and analysis of the patient-level MURANO data, it was determined that the efficacy of novel CLL selective inhibitors would not be significantly modified by differences in patient populations and the anchored ITC was conducted without further adjustment for baseline characteristics.
Results: PFS and OS relative efficacy estimates in MURANO patients without 17p deletion for V+R (N=123) compared with BR (N=119) were consistent with those reported for the general trial population. In the ITC analysis using BR as a common comparator, V+R was similar in efficacy to ibrutinib+BR with respect to PFS (HR=0.90 [95% CI: 0.50-1.64]) and OS (HR=0.70 [95% CI: 0.27-1.83]). Compared to idelalisib+BR, V+R had improved PFS (HR=0.57 [95% CI: 0.35-0.93]) but similar OS (HR=0.71 [95% CI: 0.33-1.51]) (Figure 1).

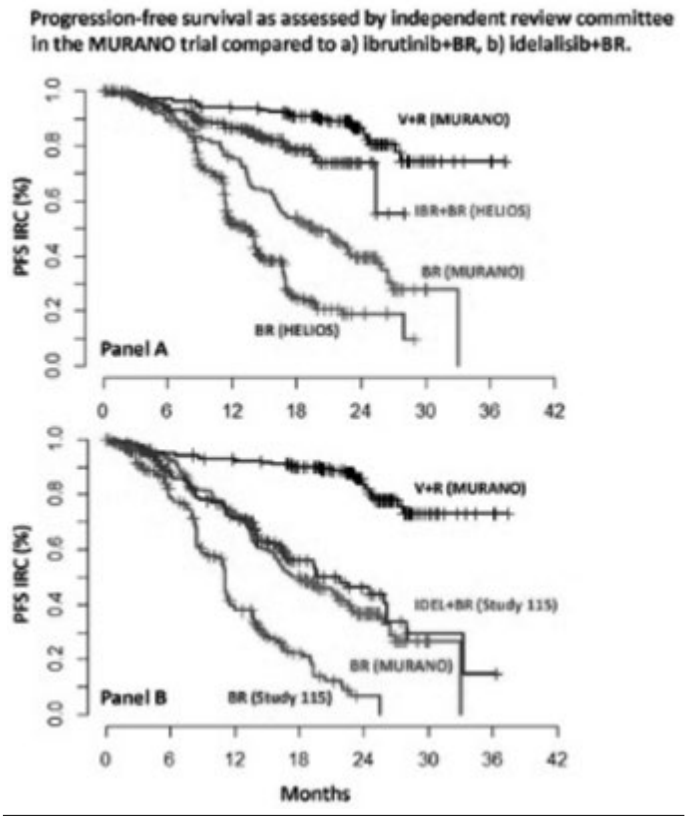


Figure 1.

Summary and Conclusions: V+R is an effective therapy for patients with relapsed/refractory CLL. Indirect comparisons suggest V+R to have improved PFS *versus* idelalisib+BR and similar PFS and OS compared to ibrutinib+BR. Future comparisons as data mature across trials will provide more robust estimates of OS comparisons.

Chronic myeloid leukemia – Biology & Translational Research

INHIBITION OF NUCLEOCYTOPLASMIC EXPORT ENHANCES SELECTIVE ELIMINATION OF LEUKEMIC STEM CELLS IN CHRONIC MYELOID LEUKEMIA

M. Deininger[1,2,*], H. Than[2,3], A. Pomicter[2], C. Mason[4], A. Eiring[2], W. Heaton[2], D. Yan[2], A. Senina[2], P. Clair[2], T. Holyoake[5], T. O'Hare[1,2]

[1]Division of Hematology and Hematologic Malignancies, University of Utah / Huntsman Cancer Institute, [2]Huntsman Cancer Institute, University Of Utah, Salt Lake City, United States, [3]Department of Hematology, Singapore General Hospital, Singapore, Singapore, [4]Division of Pediatric Hematology/Oncology, University of Utah, Salt Lake City, United States, [5]Paul O'Gorman Leukaemia Research Centre, Institute of Cancer Sciences, University of Glasgow, Glasgow, Ukraine

Background: Chronic myeloid leukemia (CML) is a hematopoietic stem cell malignancy driven by BCR-ABL1 tyrosine kinase and effectively managed with tyrosine kinase inhibitors (TKIs) such as imatinib. Reactivation of BCR-ABL1 through mutations in the kinase is a common mechanism of resistance, but fails to explain clinical resistance in a significant proportion of cases, a situation referred to as BCR-ABL1-independent resistance. Additionally, most patients require continuous TKI therapy to avoid recurrence of active leukemia, suggesting that primitive, fully leukemogenic CML stem cells (LSCs) are BCR-ABL1-independent. We have previously demonstrated that BCR-ABL1-independent CML cells from patients with overt resistance require functional nucleocytoplasmic export (NCE) and are sensitive to knockdown of the NCE regulator RAN and selective inhibitors of NCE (SINEs) such as KPT-330 (selinexor, Karyopharm) [Khorashad *et al.* Blood. 2015].
Aims: Test whether reliance on NCE extends to LSCs, the reservoir for persistent CML.
Methods: LSCs ($CD34^+CD38^-$) and leukemic progenitor cells (LPCs, $CD34^+CD38^+$) isolated from newly diagnosed chronic phase CML patients and their normal (cord blood, CB) equivalents were analyzed with colony forming assays +/- KPT-330 and/or imatinib. Cells were cultured for 72h in +/- KPT-330 and/or imatinib and analyzed for apoptosis, plated in LTC-IC assays or injected into NSG mice. LTC-IC colonies and human $CD45^+$ cells isolated from the NSG mice were genotyped for BCR-ABL1 by FISH. In a separate set of experiments, we assessed drug effects on cell division using CSFE.
Results: Treatment with KPT-330 reduced colony formation by LPCs and LSCs to 42% and 55% of controls (Table 1). When combined with imatinib, KPT-330 dramatically reduced colony formation by LPCs and LSCs to 8% and 2% of controls. Single agent KPT-330 had modest effects on apoptosis, but the combination increased apoptosis in LPCs and LSCs by 280% and 940%, compared to 180% and 270% respectively for CB. These data suggest that combining KPT-330 with imatinib has the most profound effects on LSCs, with a large differential compared to normal hematopoietic stem cells.

Table 1.

% Control		CML		CB		p(CML vs. CB)	
		LPC	LSC	HPC	HSC	PC	SC
CFU-GM Colony formation	Imatinib (2.5μM)	13%	8%	77%	63%	<0.01	<0.01
	KPT-330 (50nM)	42%	55%	78%	96%	<0.05	<0.01
	Combination treatment	8%	2%	66%	43%	<0.01	<0.01
Apoptosis	Imatinib (2.5μM)	200%	410%	130%	160%	ns	ns
	KPT-330 (50nM)	100%	200%	110%	80%	ns	ns
	Combination treatment	280%	940%	180%	270%	ns	<0.01

While no reduction in colonies was seen in LTC-IC experiments with either single agent, a 64% reduction in LTC-IC colonies was observed with combination. Genotyping of LTC-IC colonies by FISH revealed that *BCR-ABL1*$^+$ colonies were reduced by 11% and 22%, when treated with KPT-330 or imatinib respectively, while combination treatment reduced *BCR-ABL1*$^+$colonies by 38%, significantly lower than either single agent. Similarly, neither imatinib nor KPT-330 monotherapy reduced the proportion of *BCR-ABL1*$^+$cells, but combination treatment reduced *BCR-ABL*$^+$cells by 42%. CFSE staining showed that imatinib monotherapy promoted accumulation of undivided $CD34^+$CML cells, with little effect on CB, as previously reported. In contrast, KPT-330 promoted cell division and this effect overrode imatinib effects when the two drugs were combined. These data suggest that the efficacy of the KPT-330/imatinib combination may be due to KPT-330-enforced cell division, with subsequent killing of cycling cells by imatinib.
Summary and Conclusions: Our data illustrates that interrupting NCE by SINEs preferentially eliminates CML LSCs and enhances their sensitivity to TKIs, suggesting that combinations of TKI and SINEs represent a clinical strategy to target BCR-ABL1 independent resistance, as well as persistent residual CML. Mechanistic studies exploring the effects of nuclear entrapment of certain NCE cargo proteins of biological significance in CML LSCs are ongoing and will be reported.

PF360

IMMUNOMODULATORY EFFECTS OF IFN-ALPHA ON T AND NK CELLS IN CHRONIC MYELOID LEUKEMIA PATIENTS IN DEEP MOLECULAR RESPONSE IDENTIFY POTENTIAL CANDIDATES FOR TREATMENT DISCONTINUATION

M. Breccia[1,*], M.C. Puzzolo[1], P. Mariglia[1], M. Molica[1], G. Colafigli[1], S. Pepe[1], A. Guarini[2], R. Foà[1]

[1]Department of Cellular Biotechnologies and Hematology, [2]Department of Molecular Medicine, Hematology, Sapienza University, Rome, Italy, ROMA, Italy

Background: Recent studies indicate that about 40% of chronic myeloid leukemia (CML) patients are able to discontinue tyrosine kinase inhibitor (TKI) treatment without molecular recurrence, defined as the loss of major molecular response (MMR). Novel strategies aimed at increasing the cure rates are thus warranted. In this context, adoption of combined treatments capable of activating the immune system to control residual leukemic cells may represent a promising approach to improve the rates of treatment-free remission.
Aims: In order to better identify potential candidates of successful treatment discontinuation, we have examined the phenotypic and functional host immune compartment - in particular T cells, NK and NK cell subsets - by comparing patients who had received INFα prior to TKI treatment (IFNα+TKI) with patients treated only with TKIs (TKI-only).
Methods: CML patients in deep molecular response (DMR) eligible to TKI discontinuation according to recent NCCN and ESMO guidelines (stable MR4 for more than 2 years) were evaluated for the T/NK-cell subset distribution, NK and T-cell cytokine production, activation, maturation markers and cytotoxic NK activity. We compared 10 patients treated with IFNα+TKI with 19 samples from TKI-only treated patients. Patients included in the study had discontinued IFNα for 15 years on average. T and NK cells have been evaluated for the surface expression of CD3, CD4, CD8, CD16, CD56, NKp30, NKp44, NKp46, NKG2C, NKG2D, DNAM-1, CD25, CD69, CD62L, CD57 and, after activation and permeabilization, for intracytoplasmic IFNγ and TNFα production (BD Biosciences, San Jose, CA and R&D System, Minneapolis, MN).
Results: We observed an increased number of lymphocytes capable of producing IFNγ and TNFα in INFα+TKI patients compared to TKI-only. In particular, the cytokine production by $CD3^+CD4^+$cells was: IFNγ=36.9±16.8 *vs* 23.0±9.7% (p=0.01), TNFα=70.4±11.0 *vs* 62.3±21.1% (ns) and by $CD3^+CD8^+$: IFNγ=75.2 ±17.4 *vs* 63.5±18.9% (ns), TNFα=71.3±17.1 *vs* 63.6±22.4% (ns). We found no differences in the percentage of $CD4^+$ and $CD8^+$T cells, and of the $CD4^+/CD8^+$ ratio between the two groups of patients. No differences were also observed in the percentage of NK and NK-T cells in the two groups of patients, nor in the NK cell subpopulations ($CD56^{bright}$/CD16, $CD56^{bright}/CD16^{dim}$, $CD56^{dim}/CD16^+$), as well in the activation, maturation markers and activating receptors (NKp30, NKp44, NKp46 and NKG2D) for NK cell subsets. In INFα+TKI patients, the NKG2C mean fluorescence intensity (MFI) was significantly higher compared to the TKI-only group in the $CD56^{bright}/CD16^{dim}$ and $CD56^{dim}/CD16^+$ NK cell subsets (p=0.01 and p=0.005, respectively). Furthermore, we observed a significant increase of DNAM-1 MFI in the $CD56^{bright}/CD16^-$ NK cell subset (p=0.03).
Summary and Conclusions: Our data indicate that in CML patients treated with INFα+TKI, IFNα appears to induce substantial modifications in the immune system, in particular in memory T lymphocytes, differentiated $NKG2C^+$ "long-lived" NK cells and $DNAM\text{-}1^+$ "adaptive" NK cell responses, even after a long time period (12-17 years) from the last IFNα contact. Our results confirm that IFNα modulates and potentiates the host immunologic compartment and pave the way to design and carry out immunotherapeutic strategies aimed at maintaining a DMR after TKI discontinuation in CML patients.

Background: Chronic myeloid leukemia (CML) is a clonal myeloproliferative disorder with heterogeneous biological and clinical features. The biomolecular mechanisms of CML response to tyrosine-kinase inhibitors (TKI) are not fully defined. Despite the TKI nilotinib being a very effective drug for the treatment of CML, drug resistance can emerge.
Aims: In the contest of the REL-PhilosoPhi34 study (EudraCT: 2012-005062-34) on behalf of the Rete Ematologica Lombarda, we undertook gene expression profiling (GEP) of selected bone marrow (BM) CD34+/lin- cells of 30 patients with CP-CML at diagnosis *vs* the same patients after 12 months of nilotinib treatment to investigate molecular signatures characterizing both conditions.
Methods: MNCs and CD34+/lin- cells of 30 CML patients were counted at diagnosis and after 3, 6 and 12 months of nilotinib, respectively. We performed GEP of BM CD34+/lin- cells of 30 patients at diagnosis *vs* the same patients after 12 months of nilotinib.
Results: BM CD34+/lin- cells decreased between the diagnosis and after 3 as well as 6 months of nilotinib while the BM CD34+/lin- cells slightly increased between 6 and 12 months of nilotinib (Table 1 and Figure 1). FISH analysis detected CD34+/lin- Ph+ cells in 30 CML patients at diagnosis. No positive Ph+ nuclei were found in CD34+/lin- cells after 12 months of treatment. We identified 264 statistically significant differentially expressed genes at diagnosis *vs* 12 months of nilotinib. Functional enrichment analysis revealed groups of genes belonging to 14 pathways differentially active during nilotinib. CD34+/lin- cells after 12 months of nilotinib showed altered expression of genes involved in metabolic processes: *AGPAT4, LPCAT3, MBOAT2* (lipid metabolism), *HK1, PDK3, UGGT1* (glycaemia), *PRKAR2A, PRKAR2B, PTPN1* (insulin resistance), *CR1, HBB, HBBP1* (coagulation cascade), and *TLN1, FCGR2A, ITGA2B* (platelet activation). Several pathways involved in cell proliferation, RAS pathway, cell adhesion, B cell differentiation were up regulated whereas sphingolipid metabolism (*SGMS2* and *SGPP1*) and apoptosis (*CCNG1, GAS2, SPTA1, CDH*) were down regulated in CML CD34+/lin- cells at diagnosis, respectively. In addition, genes involved in the mechanisms of transport across extra- and intra-cellular membranes were overexpressed (*ABCC5, SLC25A33, SLC25A37, SLC25A38, SLC27A2, SLC43A3, SLC4A4, ABCC5)* in CD34+/lin- cells at diagnosis, providing a rationale for investigating this phenomenon in patients undergoing nilotinib treatment.
Summary and Conclusions: GEP analyses of CD34+/lin- cells of CP-CML patients at diagnosis *vs* 12 months of nilotinib demonstrated that 264 genes belonging to 14 pathways were significantly differently regulated. We can speculate that nilotinib might interfere with biologic mechanisms (lipid and glycemic metabolism, insulin resistance, coagulation cascade and platelet activation) that are relevant in CML patients as previously determined by several studies in literature. The alteration of pathways regarding apoptosis in CML CD34+/lin- cells at diagnosis may underlie the increased cell proliferation playing a significant role in recognizing resistance mechanisms of leukemic stem cells treated with TKI. Future GEP studies on a larger cohort of CML patients at diagnosis *vs* 12 months of nilotinib are ongoing. We believe that BM CD34+/lin- cells from CML patients at diagnosis and after nilotinib harbor differences in certain biologic and genetic properties, that may predict how well they will respond to nilotinib and we will test this hypothesis.

Table 1.

Range, average and standard deviation of the number of BM MNCs as well as the number of the BM CD34+/lin- cells among the 30 CML patients at diagnosis and after 3, 6 and 12 months of nilotinib.

	BM MNC at diagnosis ($x10^6$)	BM MNC at 3 months ($x10^6$)	BM MNC at 6 months ($x10^6$)	BM MNC at 12 months ($x10^6$)
Range (min-max)	36-3450	12-166	9-257	8-187
Average	974	61	57	51
Standard deviation	800	41	46	41

[1]Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Translocation t(9;22) in hematopoietic cells is the origin of chronic myeloid leukemia (CML). T(9;22) leads to BCR-ABL1 tyrosine kinase, which speeds up cells division and cause genomic instability. Tyrosine kinase inhibitors (TKI) such as imatinib and nilotinib specifically inhibit BCR-ABL1 activity and can induce complete remission in CML patients. Monitoring of residual disease in CML is carried out by quantitative real time PCR of BCR-ABL1. Over the last few years consequences of the cancellation of TKI have been actively studied. After prolonged use of the TKI and achievement of complete molecular remission, some patients develop an early molecular relapse (MR, *BCR-ABL1* level >0.1%) within six months after the cancellation of the TKI. Identification of factors predicting MR development could possibly allow optimization of TKI-discontinuation protocols.
Aims: The aim of the study is to estimate relations between different NK-cell subsets and *BCR-ABL* level in CML patients after TKI discontinuation.
Methods: The study included 66 CML patients with deep molecular response (DMR, *BCR-ABL1* <0.01%) for TKI therapy. 103 peripheral blood samples were studied: 28 on day of TKI discontinuation, 30, 19, 14 samples - after 3, 6, 12 months and 12 studies - on another time-points. First line therapy includ-

ed imatinib (46 patients) and nilotinib (7 patients) and 12 patients received nilotinib as the second line therapy. We used monoclonal antibodies anti-CD3, CD16, CD56 and CD45 to evaluate proportion of NK-cells and two distinct subsets (CD56bright/CD16- and CD56+/CD16+ NK cells) by flow cytometry. *BCR-ABL1* level was evaluated by RT-PCR by standard protocol. Frequencies of MR were compared by Fisher test, means were compared with Mann-Whitney test due to non-normal distribution of data.

Results: Analysis of MR frequency showed same MR rate for patients received imatinib (as 1st line therapy) and nilotinib as 2nd line (34% *vs* 30%, p=0.7). MR was not detected in patients received nilotib as 1st line therapy (n=7), but no significant differences compared to other therapy were found (p=0.1). All studies were divided into 3 groups: 1st group had no detectable level of *BCR-ABL1* (n=63), 2nd had *BCR-ABL1* level below 0.1% (n=33) and 3rd group had *BCR-ABL1* level above 0.1% (n=7). 3rd group showed significantly higher percentage of CD56bright+/CD16- NK-cells than other two groups (p<0.0094) (Figure 1). Differences in proportion of NK-Cell and CD16+/CD56+ subsets were not found.

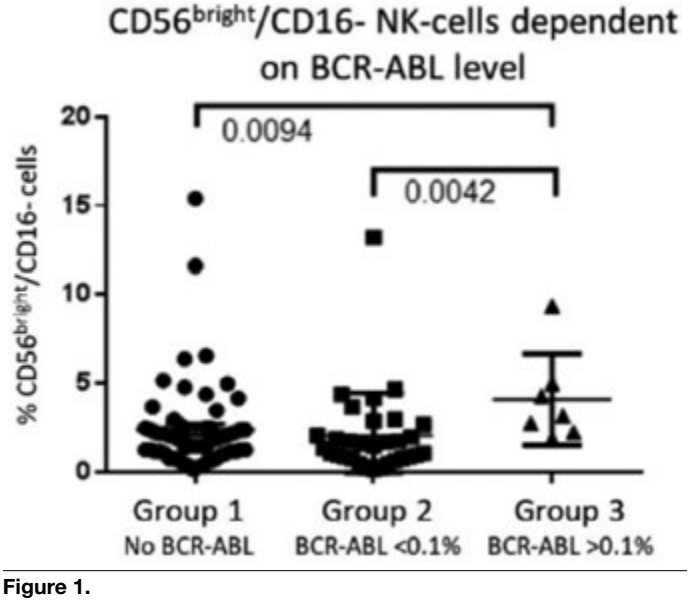

Figure 1.

Summary and Conclusions: These results show correlation between cytokine-producing NK cells and *BCR-ABL1* level, which potentially could be the evidence of participation of NK cells in the development of molecular relapse after TKI therapy discontinuation.

LMC-TRIO, A REAL LIFE STUDY OF CHRONIC MYELOID LEUKEMIA CARE IN FRANCE BETWEEN 2006 AND 2013: FACTORS OF FAILURE FROM TREATMENT-FREE REMISSION

C. Jim[1,2,*], L.G.-P. Sandra[1,2], C.-M. Pascale[3], E. Gabriel[4], G.-B. Stéphanie[5], M. Marc[5], P. Jean-Marc[6], T. Xavier[6], O. Sébastien[1,2], M. Alain[1,2]

[1]Registre des hémopathies de Gironde, Institut Bergonié, [2]Team EPICENE, University of Bordeaux, INSERM, Bordeaux Population Health Research Center, UMR 1219, Bordeaux, [3]Service d'Hématologie, C.H. Annecy Genevois, Pringy, [4]Service d'hématologie, Institut Bergonié, Bordeaux, [5]Registre des hémopathies Malignes de Côte d'Or, Faculté des Sciences de Santé de Dijon, Dijon, [6]Registre régional des hémopathies malignes de Basse-Normandie (RRHMBN), CHU Caen, Caen, France

Background: With the occurrence of Tyrosine Kinase Inhibitor (TKI) in the beginning of 2000, Chronic Myeloid Leukemia (CML) survival has dramatically improved. To maintain CML under control, patients have to take daily dose of TKI. To reduce this burden, several clinical studies introduced treatment discontinuation exclusively proposed to patients with a deep molecular response. In case of loss of deep molecular response patients in Treatment-Free Remission (TFR) will have to start again daily treatment with TKI. Various clinical studies identified specific factors linked to TFR continuation such as TKI treatment duration before TFR or Sokal score. However, few data from real-life studies explored such factors.

Aims: In this study, we aim to investigate in a real life setting the factors influencing the failure of patients in TFR during its establishment. Population characteristics and care have been described according to their TFR status. In addition, we will describe the nature and the effect of factors leading to failure of TFR.

Methods: *Study design* retrospective cohort using data from three French haematological malignancies population based registries. *Population* patients with CML bcr-abl+ (ICD-O-3: 9875/3) diagnosed between 2006 and 2013. Atypical CML (ICD-O-3: 9876/3) and CML « without precision » (ICD-O-3: 9863/3) were excluded. *Analysis* End-point was set on 1st January 2017. Characteristics were described by TFR status: "failure" or "ongoing". Factors linked to failure were estimated with a logistic regression. Patients who have received an allograft before the establishment of TFR were excluded from the analysis.

Results: Between January 1st 2006 and December 31st 2013, 363 new patients with CML has been diagnosed in the regions covered by the registries. Median age at diagnostic was 61.6 years old (Q1 – Q3: 48.5 – 72.6 years old). Median of follow-up was 5.3 years (Q1 – Q3: 3.7 – 7.9 years). At end-point, 78 (21.5%) patients have been (at least once) in TFR, 41 (52.3%) patients failed after a median of 4.8 months (Q1 – Q3: 3.6 – 7.2 months) and treatment was restarted for all of them whereas six of them had a second TFR. At the end of follow-up, when counting the six patients who had already been in TFR once, ,43 patients were still in TFR after a median follow-up of 1.6 years (Q1 – Q3: 0.4 – 2.6 years). Eight of the 78 patients died during follow up (10%), two had stopped their TFR previously and were currently treated, four were still in TFR and two died after experiencing two TFR. Compared to patients still in TFR, patients who experienced a failure of the first TFR were mostly men (58.5% *versus* 39.5%), were less included in clinical trials (22.0% *versus* 30.2%), had poorer performance status at diagnosis (ECOG >0: 31.7% *versus* 20.9%) and were more frequently treated in non teaching hospital (general hospital or private clinic) (31.7% *versus* 16.3%). We estimated using a logistical regression that the following factors would statistically decrease the probability of leaving TFR: a longer TKI treatment duration before TFR, the absence of splenomegaly at diagnosis and to be treated in a teaching hospital (regional hospital or comprehensive cancer center). Table 1 presents the adjusted odds-ratios.

Table 1. Result for the logistical regression on the probabilities of failure of TFR (n=77).

Characteristics	$\widehat{OR}$	$CI_{95\%}$	*p-value*
TKI treatment duration to TFR (years)	0.78	[0.20 ; 0.82]	0.03
Care facility			0.02
Non-teaching hospitals	1		
Teaching hospitals	0.24	[0.06 ; 0.89]	
Splenomegaly at diagnosis			0.02
Yes	1		
No	0.23	[0.03 ; 0.47]	

Summary and Conclusions: Despite the low numbers, our study shows that factors influencing the failure of TFR in a real life setting are comparable to those identified in clinical studies. In addition, our study points out the eventual role of the care facility that need further investigations.

PF364

POLYMORPHISMS IN MULTIDRUG RESISTANCE TRANSPORTER GENES AFFECT THE DURATION OF MOLECULAR RESPONSE TO NILOTINIB IN CHRONIC MYELOID LEUKEMIA PATIENTS

F. Loscocco[1,*], G. Visani[1], S. Galimberti[2], A. Ruzzo[3], I. Bagaloni[3], F. Stagno[4], P. Pregno[5], M. Annunziata[6], A. Gozzini[7], S. Barulli[1], M. Magnani[3], A. Isidori[1]

[1]AORMN, Hematology and Stem Cell Transplant Center, Pesaro, [2]Department of clinical and experimental medicine, University of Pisa, Pisa, [3]Department of biomolecular sciences, University of Urbino Carlo Bo, Urbino, [4]AOU Policlinico Vittorio Emanuele, Divisioni clinicizzata di ematologia con trapianto di midollo osseo, Catania, [5]AOU Città della scienza e della Salute di Torino, Hematology, Torino, [6]Hematology, Cardarelli Hospital, Napoli, [7]AOU Careggi, Unità funzionale di Ematologia, Firenze, Italy

Background: Despite the high efficacy of Nilotinib in chronic myeloid leukemia (CML), there is still a significant proportion of patients who fail to maintain a major molecular response (MMR, MR3). For those patients, treatment-free remission once in deep molecular response (DMR), which is the final goal of nilotinib treatment, will never be an achievable endpoint. Little is known about the impact of pharmacogenetic variability in influencing MMR/DMR. It has been reported that ABC multidrug transporters, responsible for multi-drug resistance, interact with tyrosine kinase inhibitors (TKIs). However, data are missing about how genetic variants in ABC genes may modify pharmacological proprieties of second generations TKIs.

Aims: We investigated the impact of 5 single nucleotide polymorphisms (SNP) in three ABC transporter genes, namely *ABCC1*, *ABCC2*, and *ABCB1*, on achieving and maintaining molecular response (MMR, DMR) in CML patients treated with nilotinib.
Methods: We prospectively genotyped 71 CML patients treated at 5 Italian sites. The following SNPs in ABC multi-drug transporter genes were studied: ABCC1rs212090, ABCC2rs3740066, ABCC2rs4148386, ABCC2rs1885301, and ABCB1rs13435. Genomic DNA was analyzed by High Resolution Melting assay and pyrosequencing. All patients gave informed consent before entering the study, that was approved by Institutional Ethical Committees. Hardy-Weinberg equilibrium was verified for all examined SNPs. Difference in genotype and allele's distributions among the patients and the associations of the various genotype with response, resistance o lost of response to Nilotinib were determined using the Fisher's exact test. The associations between SNPs status and progression free survival (PFS) were assessed using Kaplan-Meier method and Log-rank test.
Results: The characteristics of patients are listed in Table 1. MR3, MR4 and MR 4.5 were achieved by 90%, 59% and 48% of patients, respectively. Analysis of the difference in genotype distribution and alleles frequencies in responders and non-responders to Nilotinib showed that ABCC2 3972C>T SNPs (rs3740066) significantly impact on the loss of MR3, in dominant and codominant model (P=0.02 and P=0.01 respectively). Multivariate analysis in ongoing.

Table 1.

Clinical characteristic	CML patients
Gender	
Male	40
Female	31
Age at diagnosis	
median age (range)	50 (18-75)
18-50 years	37
=50-74 years	34
Nilotinib Treatment	
I line	34
II line	37
Sokal Score	
Low	37
Intermediate	28
High	6
Hasford score	
Low	37
Intermediate	28
High	6
Eutos score	
0	1
1	66
2	4
Best Molecular Response To Nilotinib	
MR3	90%
MR4	59%
MR4.5	48%

Summary and Conclusions: Our study hypothesizes, for the first time, that genetic variants in ABC genes may increase the number of patients not able to maintain a sustained MR3 with Nilotinib, thus limiting the number of patients able to achieve treatment-free remission. Further studies in lager series are warranted to confirm our preliminary experience.
Acknowledgements: The study was supported in part by AIL Pesaro Onlus.

MYELOID CELL POPULATION DYNAMICS IN TKI-TREATED CML

S. Sopper[1,*], B. Hofer[1], S. Mustjoki[2], K. Porkka[2], J. Janssen[3], G. Ossenkoppele[3], B. Gjertsen[4], D. Wolf[5]

[1]Hematology and Oncology, Medical University Innsbruck, Innsbruck, Austria, [2]Hematology, Helsinki University Hospital, Helsinki, Finland, [3]Hematology, VU University Medical Center, Amsterdam, Netherlands, [4]Institute of Medicine, Hematology Section, University of Bergen, Bergen, Norway, [5]Hematology, Oncology and Rheumatology, University Hospital of Bonn, Bonn, Germany

Background: Immune mechanisms may impact treatment response of CML patients to TKI therapy and the success of therapy cessation. Myeloid populations such as classical and non-classical monocytes and different types of myeloid-derived suppressor cells (MDSCs) are important immune-mediators but their role in CML has not been systematically investigated. Therefore, we comprehensively characterized these population in 52 chronic phase CML (CML-CP) patients as a substudy to the ENEST1st study (NCT01061177).
Aims: Determination of myeloid cell populations in plasma of newly diagnosed CML-CP patients in the course of tyrosine kinase inhibitor therapy and definition of immunological surrogates for response prediction in CML-CP patients.
Methods: Whole blood was collected prior to and after 6 and 12 months of nilotinib therapy for immune-phenotyping by 9-color flow cytometry employing 6 antibody panels. Levels of circulating soluble factors were measured by immunoassays in plasma samples. Molecular response was quantified in central EUTOS reference laboratories. Changes in immune parameters were correlated to clinical and molecular endpoints.
Results: At diagnosis, the relative proportion of monocytes was lower ($p<0.0001$) whereas the absolute number was higher ($p<0.0001$) when compared to follow up samples at months 6 and 12 of therapy. Both, the CD16+CD14hi "intermediate" ($p<0.01$) and the CD56+ subset ($p<0.0001$) of monocytes were higher at baseline. $CD15^+$ polymorphnuclear and $CD15^-$ early stage MDSC, defined as Lin^-, $CD11b^+$ and $CD33^+$ cells according to recently published protocols (Bronte V *et al.*, Nat Comm 2016) were strongly increased at diagnosis ($p<0.0001$). However, a more detailed flow cytometric analysis revealed that these cells are identical to neutrophils and basophils, respectively. Monocytic MDSC are defined as CD14+ cells with low to negative HLA-DR expression. We therefore quantified HLA-DR expression levels on CD14+ monocytes, which increased ($p<0.05$) after initiation of therapy. Interestingly, HLA-DR expression at diagnosis negatively correlated with $BCR\text{-}ABL^{IS}$ levels throughout therapy ($p<0.05$). Cumulative response rates for MMR were higher in patients with high HLA-DR expression ($p<0.001$). HLA-DR expression negatively correlated with plasma levels of sCD62L, a predictive marker recently defined (Sopper *et al.*, J Clin Oncol 2017), but not with Arginase, a key enzyme for MDSC function.
Summary and Conclusions: Our comprehensive study demonstrates that several myeloid cell populations are substantially altered in CML patients. Specifically, a low HLA-DR expression on monocytes, associated with immunosuppressive functions, may have a negative impact on anti-leukemic immune response and may constitute a biomarker for response prediction to TKI therapy.

PF366

THE EFFECT OF PREGNANE X RECEPTOR SNP AND TKI TROUGH CONCENTRATION ON CLINIC RESPONSE AND TOXICITY AMONG CHINESE CML PATIENTS

Z. Jiang[1,*], P. Xu[2], X. Zhao[1], Y. Zhu[2], Q. Wang[2], J. Zeng[2], Q. He[1]

[1]Department of Hematology, Central South University, Xiangya Hospital, [2]Department of Pharmacy, Central South Univeristy, the Second Xiangya Hospital, Changsha, China

Background: Imatinib mesylate (IM) has dramatically improved the outcomes of Chronic myeloid leukemia (CML) patients, with a significant effect on both quality of life and long-term survival rate. However, many patients still suffered from suboptimal response leading to treatment failure. Several mechanisms that lead to IM resistance have been investigated, including the suggestion that pharmacogenetic variability influences the pharmacokinetics of IM. On the other hands, trough concentration (C_0) of IM might play a role in the different outcomes of imatinib therapy and could serve as predictive markers but the results of different studies remain controversy. We had performed a early meta-analysis that revealed that the patients who achieved MMR have significantly higher C_0 of imatinib than those who failed to achieve MMR. We also found the patients achieved CCyR have significantly higher C_0 of imatinib than those not achieved CCyR (Figure 1). However, the reason behind the pharmacokinetic inter-individual variation is still unknown.
Aims: 1. To study the correlation between trough concentration and drug effect including toxicity and clinic response among Chinese CML patients. 2. To investigate the possible pharmacogenetic variation that could affect the IM metabolism then influence the clinic response or drug toxicity.
Methods: A total of 171 chinese chronic phase CML patients (97 males and 74 males) were enrolled in this study. All patients were initially orally administrated 400 mg per day and dose reduction was allowed for patients with severe adverse events. The steady-state trough concentrations of imatinib were determined by ultra performance liquid chromatography-mass spectrometry. Clinic response including CCyR, MMR and CMR was evaluated according to NCCN guidelines. Hematological toxicity was recorded and graded. Total genomic DNA was extraced and genotyping of CYP3A4, ABCB1, ABCG2, *SLCO1B3* and PXR was determined by using polymerase Chain Reaction (PCR) and then Sanger sequencing.
Results: The mean trough concentrations of the study population (109 patients available) was 1287.21±652.59 ng/mL, widely ranging from 318.83 to 3433.58 ng/mL. Association between imatinib trough concentrations and response was analyzed in patients orally administrated 400mg/day.

Patients with CCyR, MMR and CMR achieved significantly higher trough concentrations than those without these corresponding efficacy (1478.18±659.83 *vs* 984.89±454.06 ng/mL; 1486.40±703.38 *vs* 1121.17±527.14 ng/mL; 1528.00±709.98 *vs* 1112.67±518.35ng/mL, respectively Figure 1). This study also revealed patients with thrombocytopenia had significantly lower trough concentrations than those without thrombocytopenia (910.47±568.75 *vs* 1585.47±757.47 ng/mL, *p*=0.002 Figure 1).This result confirmed the relationship between metabolism of TKIs and effect of treatment as well as toxicity. We failed to find clinical significant results between CYP3A4, ABCB1, ABCG2, *SLCO1B3* genotype and trough concentrations and clinic response. However, we found rs3814055, a SNP of pregnane X receptor (**PXR**, **NR1I2**), showed significant higher trough concentration of imatinib (P=0.015) and dose-adjusted trough concentration of imatinib (P=0.039) than the wild-type. It was also showed the mutation group of PXR has significant more patients who achieved MMR(p=0.025) and CMR(P=0.022, Figure 1).

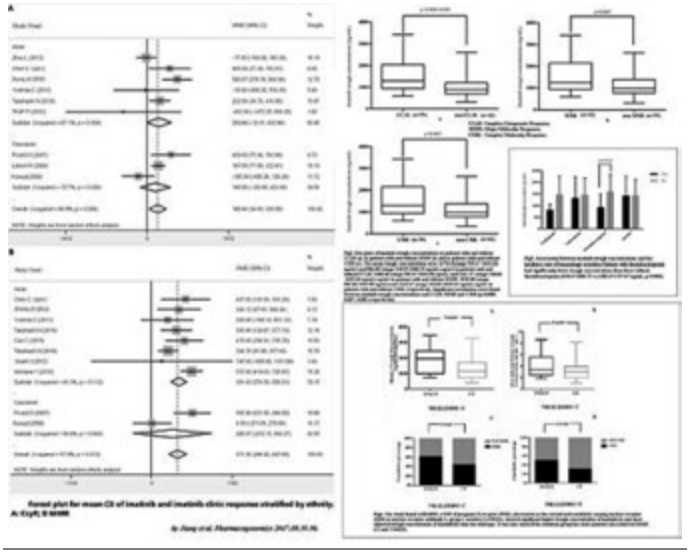

Figure 1.

Summary and Conclusions: This finding suggests nuclear receptors affect clinic response of imatinib by interfering drug metabolism and highlights the importance of investigation on the effect of nuclear receptors on TKI response among large cohort of CML patients.

PF367

WT1 EXPRESSION PREDICTS THE RESPONSIVENESS OF CHRONIC MYELOID LEUKEMIA TO FIRST LINE THERAPY OF TYROSINE KINASE INHIBITOR

E. Toffoletti[1,*], G. Maccari[1], M. Tiribelli[1], A. Chiarvesio[2], S. Di Giusto[2], L. Floreani[1], D. Damiani[1], R. Fanin[1]

[1]Department of Experimental and Clinical Medical Sciences, Division of Hematology and BMT, University of Udine, [2]Hematological Division of Udine, Azienda Sanitaria Universitaria Integrata di Udine, Udine, Italy

Background: The prognosis of Chronic Myelogenous Leukemia (CML) profoundly changed by the advent of Tyrosine Kinase Inhibitors (TKIs). Unfortunately, the biological factors affecting therapeutic response at the first line of TKIs remain under investigation and not all cases respond optimally to the therapy. BCR-ABL oncoprotein supports malignant hematopoiesis by multiple effects, mainly by promoting cell proliferation, abnormal cell adhesion and resistance to many anti-apoptotic stimuli. BCR-ABL induces WT1 expression and it is known that increasing levels of WT1 correlate with an advanced phase of disease. Recent evidence demonstrates that the anti-apoptotic effect of BCR-ABL is driven by a WT1-mediated pathway.
Aims: The aim of our study was to investigate the WT1 expression levels at onset and the response to first line TKI, in CML patients.
Methods: We studied WT1 expression levels retrospectively in 59 consecutive CML patients, followed-up from our Division from 2012 to 2016. For each patients, clinical scores, BCR-ABL type transcript, BCR-ABL IS levels and WT1 gene expression were collected on peripheral blood, at onset. Response to therapy was defined as European Leukemia Net reccomendations.
Results: We observed optimal response in 60% (35/58) of cases and warning/failure in 40% (23/58) of cases. The median age was 56 years (range 17-81 years). The majority of patients had a low EUTOS score (94% of patients) and 83% of cases had low/intermediate Sokal score. The optimal responding group showed a median expression level of WT1 equal to 94 copies/10000 ABL copies, significantly lower than the WT1 expression level of the warning/failure group (271 copies/10000 ABL copies, p=0,0024). B2a2 rearrangement was detected in 50% of cases in the warning/failure group, and in only 33% in optimal responder group. The BCR-ABL levels at onset were similar in optimal and warning/failure group (73,99%IS *versus* 63,86%IS) with no significant difference. In both groups the frequency of second generation administered TKI as first treatment was similar (respectively 40% *versus* 43% of cases). Moreover, all patients with WT1 expression level, at onset, lower than 100 copies/10000ABL copies turned out to be optimal responders. In low expressing WT1 samples, the b2a2 rearrangement was less frequent than in high expressing WT1 group (33% *versus* 44%). Finally, cases receiving a second generation TKI at onset were 23% in low expressing WT1 patients and 48% in high expressing WT1 patients.
Summary and Conclusions: In our cohort, WT1 expression levels, at onset, were shown to be correlated with the response to TKIs. Moreover, our data confirm the correlation between b2a2 rearrangement and the unfavorable response. Finally, the level of 100 copies of WT1 on 10000 ABL copies seems to be a crucial cut-off to guide the physician in therapy administration and CML monitoring.

Background: ENESTfreedom (NCT01784068) is the first dedicated study evaluating pts with sustained deep molecular response (DMR) on 1L NIL for achievement of TFR, a new treatment goal in CML. Previous results from ENESTnd showed that more pts achieved sustained DMR (per ENESTfreedom criteria) by 6 y with 1L NIL (37.9% [300 mg BID]) *vs* 1L imatinib (IM; 21.6%), suggesting that more newly diagnosed pts may reach TFR eligibility with NIL.
Aims: In ENESTfreedom, TFR rates of 51.6% at 48 wk and 48.9% at 96 wk have been reported; here we present a long-term (144-wk) analysis of the durability and safety of TFR.
Methods: Pts with ≥2 y of 1L NIL who achieved $MR^{4.5}$ (*BCR-ABL1* ≤0.0032% on the International Scale [$BCR\text{-}ABL1^{IS}$]) entered a 1-y NIL consolidation phase; those with sustained DMR could enter the main TFR phase. Pts not eligible to enter the main TFR phase received another 1 y of NIL and, if sustained DMR was achieved, they could enter the TFR-2 phase. Pts in either TFR phase restarted NIL after loss of major molecular response (MMR; $BCR\text{-}ABL1^{IS}$ ≤0.1%). Data cutoff was Oct 11, 2017, by which all pts who entered the main TFR phase had completed ≥144 wk of TFR, restarted NIL, or discontinued the study. All pts gave informed consent.
Results: At the data cutoff, 89/190 pts in the main TFR phase remained in TFR (46.8%; 95% CI, 39.6%>54.2%); 94 pts (49.5%) lost MMR (91 restarted NIL) and 7 (3.7%) discontinued TFR for other reasons. Only 4/93 pts in TFR at 96 wk were no longer in TFR at 144 wk; 3 of these first lost $MR^{4.5}$ within the first 8 wk of TFR. Of 91 pts who restarted NIL, 90 (98.9%) regained MMR and 84 (92.3%) regained $MR^{4.5}$ (1 discontinued study without MMR, 5 discontinued with MMR but not $MR^{4.5}$, 1 remained in reinitiation phase with MMR but not $MR^{4.5}$). Of 84 pts who regained $MR^{4.5}$, 70 (83.3%) had stable $MR^{4.5}$ 48 wk later, 11 (13.1%) discontinued the study <48 wk after regaining $MR^{4.5}$, and 3 (3.6%) remained on NIL with <48 wk of follow-up after regaining $MR^{4.5}$. At the data cutoff, 5/10 pts (50%) who entered the TFR-2 phase remained in that phase; the other 5 lost MMR and restarted NIL (4 regained $MR^{4.5}$, 1 regained MR^{4}). TFR rate among these 10 pts was 40% at both 48 wk (1 pt had missing 48-wk data) and 96 wk (1 pt had <96 wk of follow-up). Including all pts who attempted TFR (after 1 or 2 y of consolidation), the overall TFR rate was 51% (102/200) at 48 wk and 48.5% (97/200) at 96 wk. No pt had disease progression. There were 10 deaths: 2 during consolidation (1 cardiac arrest, 1 suicide), 1 during TFR (unknown cause), 4 during reinitiation (1 acute myocardial infarction, 1 respiratory failure, 1 hepatobiliary cancer, 1 unknown cause), 3 >30 d after discontinuing study in the TFR phase (1 mesothelioma) or reinitiation phase (1 transitional cell cancer of renal pelvis and ureter, 1 unknown cause). 144-wk treatment-free survival (TFS) rate (based on main TFR phase) was 48.7% (95% CI, 41.4%>55.6%; Figure 1). Among 94 pts remaining in TFR for >96 wk, any-grade AE rates were 85.1%, 76.6%, 69.1%, and 45.7% in consolidation and the first, second, and third 48 wk of TFR, respectively; any-grade musculoskeletal pain–related AE rates were 16.0%, 40.4%, 9.6%, and 4.3%. Cardiovascular event rates were low across these periods.

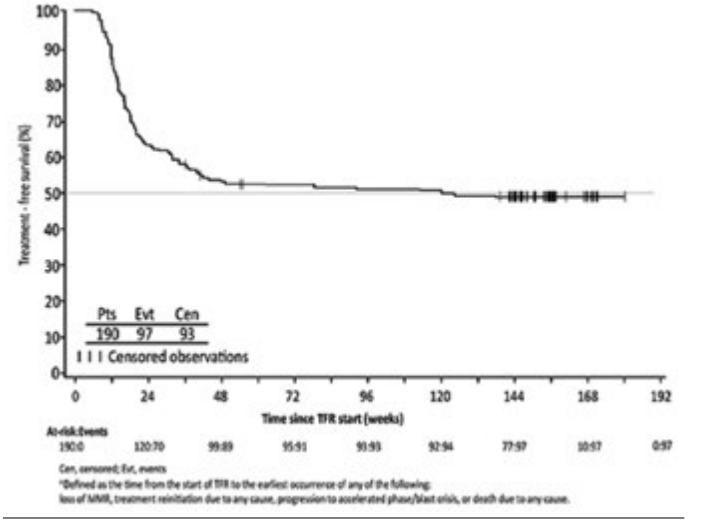

Figure 1. Treatment-free survival*.

Summary and Conclusions: These results support the long-term durability and safety of TFR following 1L NIL, with no disease progressions or deaths attributable to CML. Together with ENESTnd data showing higher sustained DMR rates with 1L NIL *vs* IM, these findings suggest more pts may be able to attempt and achieve TFR with 1L NIL.

PF369

BOSUTINIB *VERSUS* IMATINIB FOR NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA IN THE BFORE TRIAL: 24-MONTH FOLLOW-UP

Background: Bosutinib is a dual Src/Abl tyrosine kinase inhibitor approved for the treatment of newly diagnosed chronic phase (CP) chronic myeloid leukemia (CML) and CML resistant/intolerant to prior therapy.
Aims: Here we compare efficacy of first-line bosutinib and imatinib after ≥24 months (median: 27 months) of follow-up.
Methods: In the ongoing, open-label, phase 3 BFORE trial (NCT02130557), 536 patients were randomized 1:1 to bosutinib (n=268) or imatinib (n=268 [3 untreated]).
Results: Higher molecular and complete cytogenetic response (MR and CCyR) rates were observed for bosutinib *vs* imatinib at 12 months; these differences continued after ≥24 months (Table 1). The between-arm difference in major MR (MMR) rate was retained at 24 months; however, differences in rates of deeper MRs (MR^{4} and $MR^{4.5}$) were smaller. Times to MR and CCyR were shorter for bosutinib *vs* imatinib, consistent with 12-month data. In an analysis of event-free survival, 14 patients in the bosutinib arm and 17 in the imatinib arm had on-treatment events, with some patients experiencing multiple events. Events for bosutinib *vs* imatinib included death (1 *vs* 4), transformation to accelerated/blast phase (6 *vs* 7), loss of CCyR (3 *vs* 5), loss of complete hematologic response (CHR; 1 *vs* 3), and doubling of white blood cell count (confirmed by 2 values >20 × 10^9/L at least 1 month apart) for patients not achieving a CHR (4 *vs* 0). 71% *vs* 66% remained on bosutinib *vs* imatinib treatment.
Summary and Conclusions: At 24 months, a higher MMR rate was main-

tained with bosutinib *vs* imatinib, confirming the superior efficacy of bosutinib. The results continue to support the use of bosutinib as first-line therapy for CP CML.

Table 1.

* 2-sided *P* values not adjusted for multiple comparisons; *P* value for overall survival not provided until 5-year analysis

† Modified intent-to-treat population (bosutinib n=246; imatinib n=241); includes Philadelphia chromosome-positive patients with e13a2/e14a2 transcripts

‡ Bosutinib vs imatinib; hazard ratio >1 indicates shorter time to response for bosutinib

§ 3 and 9 deaths in the bosutinib and imatinib arm, respectively, due to adverse event related (0 vs 1) or unrelated (2 vs 2) to study drug, disease progression (1 vs 3), and other causes (0 vs 3)

PF370

PREVALENCE AND OUTCOMES OF UNCOMMON BCR-ABL FUSION TRANSCRIPTS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA: DATA FROM A SINGLE CENTER

Y.-Z. Qin[1,*], Q. Jiang[1], H. Jiang[1], Y.-Y. Lai[1], H.-X. Shi[1], X.-J. Huang[1]

[1]Peking University People's Hospital, Peking University Institute of Hematology, Beijing, China

Background: Uncommon BCR-ABL junctions are observed in very few patients with chronic myeloid leukemia (CML). The data on the prevalence of uncommon BCR-ABL transcripts are limited. Moreover, response and outcomes have not been well-established in the era of tyrosine kinase inhibitors (TKIs).
Aims: To explore the types, prevalence and outcomes in CML patients with uncommon BCR-ABL transcripts receiving TKI therapy.
Methods: Data for 4750 CML patients were retrospectively reviewed. The patients were screened for uncommon BCR-ABL transcripts by multiplex polymerase chain reaction (PCR), fusion types were identified by Sanger sequencing, and type-specific real-time quantitative PCR was performed for molecular monitoring. Responses and outcomes were compared between newly diagnosed patients in chronic phase (CP) with uncommon BCR-ABL transcripts and patients with the common e13a2/e14a2 transcript receiving frontline imatinib therapy during the same period.
Results: A total of 19 uncommon BCR-ABL transcripts, including e1a2, e1a3, e6a2, e8a2, e12a2, unusual e13a2, e13a3, unusual e14a2, e14a3 and e19a2, were identified in 83 (1.7%) patients. The most frequent type was e19a2 (39.7%), followed by e13a3/e14a3 (20.5%) and e1a2 (16.9%). These transcripts accounted for three-quarters of cases with uncommon transcripts. Compared with the 571 newly diagnosed CP patients with common transcripts receiving frontline imatinib therapy, patients with the e19a2 (n=16) and e1a2 (n=11) transcripts had significantly reduced probabilities of 1-year complete cytogenetic response (CCyR, 44.4% *versus* 87.9%, p=0.0004 and 58.0% *versus* 87.9%, p=0.016, respectively, Figure 1A) and major molecular response (MMR, defined as a 3 log reduction of BCR-ABL from individual baseline level for patients with uncommon transcripts, 6.3% *versus* 48.6%, p=0.0018 and 0% *versus* 48.6%, p=0.0035, respectively, Figure 1B), and patients with the e13a3/e14a3 transcript (n=10) had significantly increased probabilities of 1-year CCyR (100% *versus* 87.9%, p=0.0072, Figure 1A) and MMR (83.3% *versus* 48.6%, p=0.0073, Figure 1B). With a median follow-up of 23 (range, 3-115) months, patients with the e19a2 transcript had low probabilities of 2-year event-free survival (EFS, 69.1% *versus* 94.4%, p=0.0004, Figure 1C) and progression-free survival (PFS, 76.6% *versus* 95.7%, p=0.0067, Figure 1D), and patients with the e1a2 transcript had low probability of 2-year EFS (30.3% *versus* 94.4%, p<0.0001, Figure 1C). However, patients with the e13a3/e14a3 transcript had similar outcomes as patients with common transcripts (Figure 1C and D).

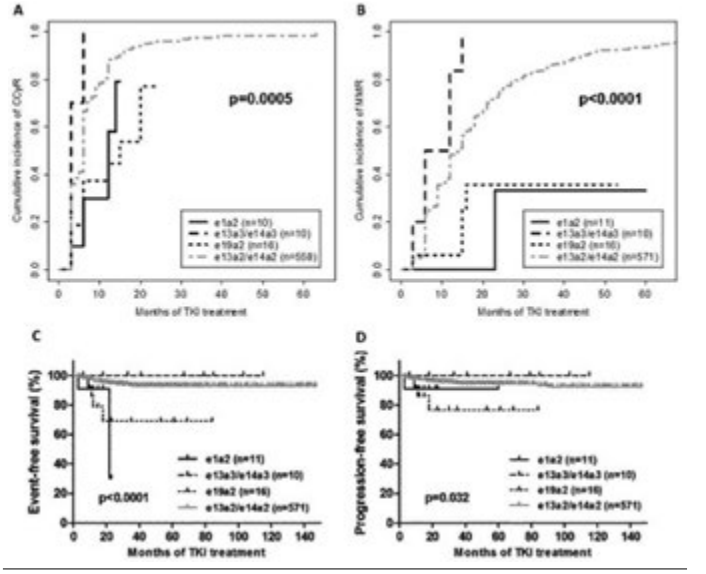

Figure 1.

Summary and Conclusions: Uncommon BCR-ABL fusion transcripts are rare and diverse in patients with CML and may be relevant for TKI therapy outcomes. Our data suggested that the identification uncommon BCR-ABL transcripts is essential at presentation to aid in diagnosing, appropriate monitoring and guiding treatment choices for patients with CML.

PF371

UPDATED RESULTS FROM THE ONGOING PHASE I STUDY OFPF-114 MESYLATE IN PATIENTS WITH CML WITH FAILURE OF PRIOR TKI THERAPY

A. Turkina[1,*], O. Shukhov[1], E. Chelysheva[1], I. Nemchenko[1], A. Petrova[1], A. Bykova[1], A. Zaritskey[2], E. Lomaia[2], N. Siordiya[2], O. Vinogradova[3], V. Shuvaev[4], E. Shatokhina[5], F. Novikov[6], V. Shulgina[6], G. Chilov[6]

[1]National Research Center for Hematology, Moscow, [2]Almazov Medical Research Centre, Saint-Petersburg, [3]Botkin Hospital, Moscow, [4]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, [5]Federal State Budget Institution of Additional Postgraduate Education "Central State Medical Academy" Department for Presidential Affairs of the Russian Federation, [6]Fusion Pharma, Moscow, Russian Federation

Background: PF-114 is a third-generation oral tyrosine kinase inhibitor (TKI), which, according to pre-clinical studies, blocks native and mutated *Bcr-Abl* forms, including the T315I mutant. Currently PF-114 undergoes phase I clinical trial in patients with chronic or accelerated phase Ph+ CML who are resistant to at least one of the 2nd generation TKIs or intolerant to previous treatment with TKIs or who have T315I mutation (NCT02885766).
Aims: The primary objective of the current Phase I is to study the dose-limiting toxicities (DLTs) occurring in 1-st 28-day cycle of treatment and determine the maximum tolerated dose (MTD). Secondary objectives include safety, pharmacokinetics, anti-CML activity (based on hematologic, cytogenetic, and molecular assessments).
Methods: The trial design is a classical 3+3 dose escalation till the MTD followed by expanded cohorts planned for dose(s) below the MTD. The total expected enrollment is 65 patients. Treatment on a continuous QD regimen is being continued until disease progression, unacceptable toxicity, consent withdrawal, or death. Adverse events (AEs) are assessed and graded according to NCI-CTCAE v4.03.
Results: At data cut-off on January 24th, 2018, six dose-cohorts – 50mg, 100mg, 200mg, 400mg, 500mg and 600mg have completed cycle 1 and 750mg cohort had been opened for enrollment. Overall 27 patients (11 males) had been initially enrolled at the following doses: 50mg (n=3), 100mg (n=3), 200mg (n=3), 400mg (n=12), 500mg (n=3), 600mg (n=3), and the MTD has not yet been reached. A total of 13 patients with T315I mutation

were included into the trial thus far. Median age was 50 years (range, 30-66 years). Median time from diagnosis to treatment was 11 years (range, 20-1 years). All patients had baseline ECOG performance status 0-1. Patients were heavily pretreated: 14 (51,9%) had received ≥3 prior TKIs, 8 (29,6%) had received 2 prior TKIs and 5 (18,5%) patients with T315I had received 1 prior TKI. Intra-patient dose escalations occurred during the study in case the starting dose was well tolerated for at least 1 cycle and dose escalation seemed appropriate from the curative perspective. Median duration of treatment at each dose (including intra-patient dose escalations) comprised: 3 cycles for 50mg, 4 cycles for 100mg, 9 cycles for 200mg, 4 cycles for 400mg; 2 cycles for 500mg; 3 cycles for 600mg. In 10 patients the treatment is ongoing at doses 200-600mg, and 17 patients discontinued: lack of efficacy n=8, AEs n=4, patients' decision n=5. The pharmacokinetics of PF-114 was dose-proportional. So far, a single case of DLT was observed at the dose of 400mg – grade 3 erythematous rash. No non-hematologic AEs of grade≥3 occurred on doses below 400mg. Most common grade 3 AE on dose≥400mg was dermatologic toxicity (6/20). Other cases of grade 3 toxicities were presented by toxic hepatitis (n=1), neutropenia (n=2) and thrombocytopenia (n=2). No deterioration of the ankle-brachial index, which is being prospectively assessed during the trial, or vascular occlusive events were observed. The major cytogenetic response (MCyR) was obtained in 4 of 12 patients who completed 3 cycles and were not in MCyR at enrollment: 2 cases of complete CyR and 2 – partial CyR; 3 of responders had a T315I mutation

Summary and Conclusions: PF-114 exhibits antitumor activity in heavily pretreated patients with resistant forms of CML. The evaluation of the safety profile and efficacy continues. The dose escalation stage of the trial continues, while the enrollment of patients into expanded cohorts at doses below MTD has already started

PF372

VARIATION IN LIMIT OF BLANK FOR BCR-ABL1 DETECTION BETWEEN LABORATORIES IMPACTS ON SCORING OF DEEP MOLECULAR RESPONSE

Background: Accurate and reproducible scoring of deep molecular response (DMR) is critical for selection and monitoring of CML patients who may be eligible to stop tyrosine kinase inhibitor treatment. The current *BCR-ABL1* RT-qPCR molecular response guidelines assume that all laboratories are able to detect *BCR-ABL1* with maximal efficiency. However varying limits of blank (LoB) and limits of detection (LoD) between centers may result in variation in the way that DMR is scored. In particular, efforts by labs to increase the sensitivity of their tests could increase the false positive rate leading to detection of *BCR-ABL1* in samples that are negative (variation in LoB). Laboratory LoBs have not been examined systematically to date because of a lack of suitable control reagents and agreed methodology.
Aims: The aim of the project was to determine the LoB for *BCR-ABL1* RT-qPCR assays carried out in experienced EUTOS laboratories (n=12). The LoB is defined as the highest measurement result that is likely to be observed for a negative sample *i.e.* the likelihood of reporting a false positive *BCR-ABL1* result at a defined probability (α).
Methods: To determine the LoB the Clinical and Laboratory Standards Institute guidelines [EP17-A2; 2012] recommend the following minimum requirements: test 4 negative samples, using 2 reagent lots of RT-qPCR master mix, on 1 instrument, on 3 independent days, analysing 2 replicates per sample, generating 60 blank replicate results per reagent lot. Prior to the study, a questionnaire was sent to all labs to determine sample requirements (lysis type and volume). Fresh (<48hrs), 4ml non-leukaemic peripheral blood samples (n=360) were processed and pooled to generate 8x *BCR-ABL1* negative lysates with *ABL1* copy numbers comparable to clinical samples (Trizol n=4, RLT n=4). These samples (n=4) were provided to each lab and were used to generate RNA and cDNA to perform 18 RT-qPCR replicates (15x *BCR-ABL1*, 3x *ABL1*) per sample, per reagent lot using their standard protocols.
Results: *BCR-ABL1* copy number results of all samples from each lab were ranked in order from lowest to highest (n=60). The rank position corresponding to the chosen probability of α (0.05) was calculated as 57.5. The LoB was defined as the highest measurement value of the sample at the given rank position across both lots. The results are summarised in the Table 1. For 75% of labs (n=9) the likelihood of a true negative sample giving a result greater than zero was ≤5%, i.e acceptable. However, for 25% of labs (n=3: labs 5, 8 and 11) the likelihood of a true negative sample giving a result greater than zero ranged from 10-50%.

Table 1.

Summary and Conclusions: Defining the LoB (and LoD) of quantitative assays is important for assay validation and is necessary for accreditation of a diagnostic test to ISO 15189 (2012). This study provides a practical recommended protocol for determining the LoB for *BCR-ABL1* RT-qPCR assays. A major challenge of the study was the production of *BCR-ABL1* negative samples. Initially material was prepared from several '*BCR-ABL1* negative' human cell lines from independent sources but these showed very low level but reproducible amplification of *BCR-ABL1*. Therefore the use of cell line derived material for LoB studies is not recommended. Preparation of pools of blood samples from non-leukaemic patients was time consuming but provided good quality material for the study. The study showed that 25% of labs had a LoB greater than zero which may compromise the scoring of DMR and demonstrates the importance of establishing a LoB.

Background: Treatment of CML with TKIs aims to achieve a major molecular response and to possibly obtain a Deep Molecular Response (DMR), to gain the opportunity for treatment discontinuation. Due to its intrinsic limitations qPCR cannot be considered the optimal tool for monitoring the DMR. The digital PCR (dPCR) has emerged as a more sensitive and accurate method to detect and monitor MRD.
Aims: This study aims to comparatively monitor the DMR of CML patients treated with TKIs by qPCR and dPCR to evaluate the suitability and reliability of the dPCR for an improved recognition of "stable" DMR and for a better selection of the best candidates for TFR.
Methods: Using qPCR and dPCR (QuantStudio 3D Digital PCR System by Life Technologies), we comparatively analyzed 495 peripheral blood samples from 130 CML patients with DMR. qPCR analyses were performed according to the last International Guidelines and absolute quantifications of BCR-ABL1 transcript obtained by dPCR were expressed as number of BCR-ABL1 copies/ul of reaction. Out of 130 cases, 62 (48%) with a minimum of 12 months of observation were analyzed for evaluation of the"stable"DMR. 25 out of 62 (40%) discontinued the TKIs treatment and were also monitored by q/dPCR until the DMR was lost. 68 cases were analyzed for evaluating the positive predictive value (PPV) of q/d PCR for TFR. They included the above reported 25 patients who were monitored for the "stable" DMR and discontinued the TKI treatment and other 43 cases who had only one q/d PCR evaluation before the discontinuation of TKI and the q/d PCR at the time of DMR loss.
Results: At the time of enrollment 52/130 (40%) and 78/130 (60%) patients belonged to MR 4.0 and MR 4.5-5.0, respectively. According to the cut-off value determined by the previous dPCR curve ROC analysis, the patients were divided in 2 groups, based on the first dPCR evaluation: group 1 (dPCR BCR-ABL1 >0.468 copies/ul) and group 2 (dPCR BCR-ABL1 <0.468 copies/ul). 72% and 75% of the patients with MR 4.0 and MR 4.5-5.0 falled in group 2, respectively. Patients belonging to the same MR class, as determined by qPCR, at the time of enrollment showed variable transcript levels of dPCR BCR-ABL1 copies/ul. While qPCR did not allow the identification of the patients with "stable" DMR, dPCR BCR-ABL1 <0.468 copies/ul helped to discriminate the patients with deeper and more stable DMR. Furthermore, the dPCR evaluation made in the 68 patients before the TKIs discontinuation, resulted highly predictive for TFR. Indeed, 17 out of 68 patients had a dPCR BCR-ABL1 >0.468 copies/ul and 9/17 (53%) lost DMR. 51 out of 68 had a dPCR BCR-ABL1 <0.468 copies/ul and 9/51 (17%) lost the DMR. Conversely, the PPV, meaning the probability to maintain the TFR, was 47% in the cases with dPCR BCR-ABL1 >0.468 copies/ul and 83% in the cases with dPCR BCR-ABL1 <0.468 copies/ul, respectively.
Summary and Conclusions: The results suggest that dPCR would be more accurate than qPCR in order to recognize the CML patients with stable DMR and the best candidates for TKI discontinuation.
Acknowledgments: Reseach supported by DPT of Clinical and Experimental Sciences founds and by Lions Association Bassa Bresciana, and BTL Foundation.

PF374

FIRST INTERIM ANALYSIS OF THE RUSSIAN MULTICENTER PROSPECTIVE STUDY RU-SKI: DISCONTINUATION OF TYROSINE KINASE INHIBITORS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA AND DEEP MOLECULAR RESPONSE

E. Chelysheva[1,*], A. Petrova[1], O. Shukhov[1], A. Bykova[1], I. Nemchenko[1], G. Gusarova[1], L. Gavrilova[2], G. Miliutina[3], L. Vysotskaia[4], A. Abdullaev[1], A. Sudarikov[1], I. Martynkevich[5], A. Golenkov[4], N. Tsyba[1], S. Kulikov[1], A. Turkina[1]

[1]National Research Center for Hematology, Moscow, [2]Mordovian Republican clinical hospital № 4, Saransk, [3]Bryansk Regional Hospital №1, Bryansk, [4]Moscow Regional Research and Clinical Institute n.a. M.F.Vladimirsky, Moscow, [5]Russuan Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Treatment-free remission (TFR) is becoming a new goal for patents (pts) with chronic myeloid leukemia (CML). Discontinuation of tyrosine kinase inhibitors (TKI) in CML pts with stable deep molecular response (DMR) requires a careful molecular monitoring. A limited financial support of molecular tests and a limited number of the standardized molecular laboratories in Russia are the main obstacles to apply the TFR approach into routine practice. Russian Healthcare Ministry has approved the TFR approach in CML patients within the Clinical Approbation (ID 18-10) based on the protocol of the prospective multicenter study RU-SKI.
Aims: To describe the CML pts enrollment into prospective study of TKI discontinuation in Russia and to evaluate the first results of survival without loss of major molecular response (MMR).
Methods: CML pts with chronic phase (CP), TKI therapy for at least 3 years and a stable DMR (MR4 or BCR-ABL<0,01%) for at least 2 years were enrolled. Pts with previous imatinib failure were eligible for trial inclusion. The BCR-ABL level was evaluated by RQ-PCR within international scale (IS). The molecular tests were done monthly during first 6 months (mo) after TKI cessation, every 2 mo from 6 to 12 mo and every 3 mo thereafter. Treatment by the same TKI was resumed in case of MMR loss (BCR-ABL>0,1%). The survival without MMR loss after TKI cessation was the primary endpoint. The analysis was performed by Kaplan–Meier method.
Results: During a period from Aug.2015 till Dec.2017 151 eligible CML pts were evaluated as candidates for inclusion into the RU-SKI trial. Of those 151 candidates 51 (33%) pts were declined and 100 (67%) pts were enrolled which fulfilled the expected number of the trial participants. The reasons of inclusion failure were refusal from trial due to fear of relapse in 39 (26%) pts, lack of molecular monitoring or insufficient duration of DMR in 10 (6,6%) pts, non confirmed DMR at screening in 2 (1,3%) pts. The baseline characteristics of the enrolled 100 pts were as follows: male: 48%; age at TKI cessation 46 years (range 22-80); Me duration of TKI therapy 8,3 years (range 3-16,2); Me duration of DMR 3,2 years (range 2-10,7). Social characteristics: graduate degree n=72 (72%), non-smokers n=78 (78%). Therapy before treatment stop: imatinib in 69(69%) pts, second-generation (2G) TKI in 31(31%) pts including nilotinib in 29 pts and dasatinib in 2 pts. In 10 of 31 pts 2G TKI were used as 1st line; in 21 pts as 2nd line. Nine pts received 2G TKI after imatinib failure, 12 pts after imatinib intolerance. Pretreatment by interferon was in 16 (16%) pts. Me follow-up time after TKI stop was 14 mo (range 1-31). Loss of MMR after TKI cessation occurred in 46 (46%) pts. Me time to MMR loss was 3 mo (range 1-15). TKI therapy was resumed in all 46 patients. The survival without MMR loss at 6, 12 and 24 months after TKI discontinuation was 56%, 51% and 48% respectively (Figure 1).

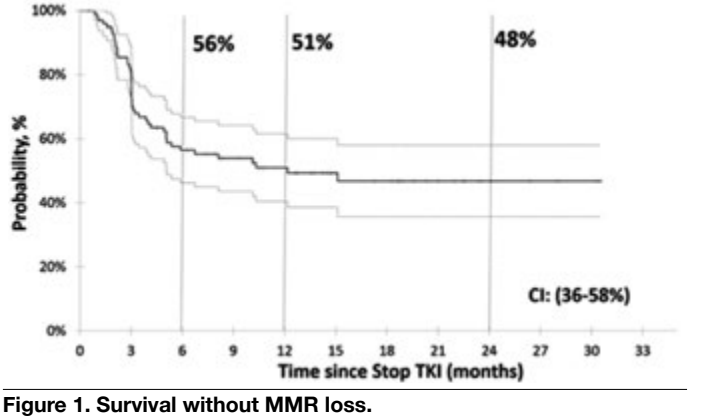

Figure 1. Survival without MMR loss.

Summary and Conclusions: The enrollment of CML pts with DMR into the first prospective trial evaluating the TFR approach in Russia was successful though a significant proportion of trial candidates was declined. The preliminary analysis of survival without MMR loss showed the results comparable to large international trials in a cohort of pts which was heterogeneous in terms of duration and lines of TKI therapy, icluding pts with previous resistance to imatinib. The results will be updated within a longer follow-up.

PF375

RESULTS OF TREATMENT OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA AND PREGNANCY IN ACCORDANCE WITH THE LEUKEMIC BURDEN AND TERM OF PREGNANCY (THE LET SCHEME)

E. Chelysheva[1,*], A. Turkina[1], E. Polushkina[2], R. Shmakov[2]

[1]National Research Center for Hematology, [2]FSBI National Research Center of Obstetrics, Gynecology and Perinatology of the Healthcare Ministry named after V.I. Kulakov, Moscow, Russian Federation

Background: Planning pregnancy in patients (pts) with chronic myeloid leukemia (CML) is safe when a stable deep molecular response (DMR) is achieved and a treatment free observation is possible in order to avoid the potential teratogenicity of tyrosine kinase inhibitors (TKI). However, unplanned pregnancies with high leukemic burden force to develop the treatment schemes with the possibility to use TKIs.
Aims: To evaluate the results of treatment scheme in CML pts with pregnancy considering the Leukemic burden and Term of pregnancy (LET).
Methods: The LET scheme has been developed in collaboration with obste-

tricians and used in years 2012-2017. The main principles were as follows: 1) to avoid TKI at early pregnancy till 15th week (organogenesis, no placental barrier) and to stop TKI immediately after pregnancy confirmation; to use interferon (IFN) before 15th week if there is no complete hematologic response (CHR); 2) after 15th week (at late pregnancy) to allow the use of imatinib (IM) or nilotinib (NIL) in case of no CHR or MR2 loss (BCR-ABL >1%) as these TKI have a moderate placental transfer; 3) if at least MR2 remains (BCR-ABL<1%) to observe without treatment or to use (IFN) at any pregnancy stage. The results were collected within CML Pregnancy Registry together with data of other treatment schemes.

Results: The data about 125 pregnancy cases in women with CML from Russia were gathered. The outcomes were as follows: labor n=83(66%), artificial abortion n= 34(27%), miscarriage n=8 (7%). The LET scheme was used in 45 pts with chronic phase CML including 49 subsequent pregnancy cases which ended in labor. Median (Me) age of pts at pregnancy onset was 29 years (range 20-43). A DMR (at least MR4 or BCR-ABL<0,01%) at pregnancy onset was observed only in 14 (29%) of pts, a spectrum of BCR-ABL levels was in other cases (Table 1a). No CHR in 1st trimester was in 13(27%) cases. At early pregnancy (till 15thweek) observation without treatment or IFN was used in 41(84%) and 7(14%) cases respectively; in 1(2%) case IM was used because a woman did not know about pregnancy. At late pregnancy (after 15th week) observation without treatment, IFN, IM at dose 400 mg and NIL at dose 400 mg QD were used in 16(38%), 3(6%), 26(53%) and 4(8%) of cases respectively (Table 1b). Me time of TKI cessation was 4thweek (range 3-17). Me time of TKI restart was 19th week (range 15-35). The newborns were healthy including 30 infants who underwent TKI exposure at late pregnancy. In 7 of these 30 infants a low birth weight (<2500 g) was observed. Hypospadia which is frequently seen in common population (1:150-180 cases) was found in 1(2%) infant. There was no association of this abnormality with TKI use as the mother had only IFN therapy throughout pregnancy. The follow-up of pts within 1 year after labor showed that CHR was in 47(96%) of cases; DMR, major molecular response (MMR or BCR-ABL≤0,1%) and no MMR were in 17(35%), 15(30%) and 17(35%) cases respectively. One woman with CML diagnosed during pregnancy unfortunately died after labor from blast crisis. She had no CHR on IFN therapy and was switched to IM at late pregnancy (3rd trimester); the subsequent dasatinib therapy after labor and allogenic bone marrow transplantation were insufficient. Three pts with DMR continued treatment free observation after labor for >24 months.

Table 1.

Molecular response	cases, n (%)
BCR-ABL >10%	10 (20%)
BCR-ABL 1% - 10%	7 (14%)
MR2 BCR-ABL 0,1 -1%	6 (12%)
MR3 BCR-ABL 0,01 -0,1%	5 (11%)
MR4 BCR-ABL <0,01%	14 (29%)
No molecular/cytogenetic data	7 (14%)
Total number	49 (100%)

a. Molecular response at pregnancy onset

Therapy	Period		
	conception	at 15th week	after 15th week
	cases, n (%)		
imatinib	28 (57%)	1 (2%)	26 (53%)
nilotinib	4 (8%)	0 (0%)	4 (8%)
dasatinib	1 (2%)	0 (0%)	0 (0%)
IFN	2 (4%)	7 (14%)	3 (6%)
no therapy	14 (29%)	41 (84%)	16 (33%)
Total number	49 (100%)	49 (100%)	49 (100%)

b. Therapy during pregnancy according to LET scheme

Summary and Conclusions: The LET scheme which considers a pregnancy stage and a leukemic burden may support a successful childbirth in different clinical situations for CML pts. Further analysis of treatment schemes at pregnancy may help to find a balance of risks both mother and baby.

Background: The majority of patients with chronic myeloid leukemia (CML) in chronic phase (CP), will reach a near normal life expectancy under treatment with tyrosine kinase inhibitors (TKI). Nevertheless, about 400 patients with CML undergo allogeneic hematopoietic stem cell transplantation (allo-HSCT) in Europe each year, of which a sizeable number in first chronic phase.

Aims: We aimed to evaluate patients undergoing allo-HSCT regarding indication, phase of disease at transplantation and outcome in a population-based manner. Furthermore, data concerning relapse rate and management of relapse in different patient groups as well as post-transplant TKI treatment were analyzed.

Methods: From the in the Swedish CML registry, covering 98% of CML cases in the country, 119 patients diagnosed with CML between 2002 and 2016 that underwent allo-HSCT between 2002 and august 2017 were identified. Additional information was collected by systematic review of patient records.

Results: Patients diagnosed with CML at age <65 years had a cumulative probability to undergo allo-HSCT within 5 years of 12.4%. In patients transplanted in CP1 (N=57, 47.9%), indications for allo-HSCT were TKI resistance (57.9%); high risk disease/ T315I mutation (21.1%); TKI intolerance (8.8%); other causes (12.3%). Of patients, transplanted in >CP1 (n=47, 39.5%), 61.7% were initially diagnosed in accelerated phase (AP) or blast crisis (BC). Of 15 patients transplanted in AP/BC, 12 were diagnosed in CP initially. When transplanted in CP1, >CP1 or AP/BC, an unrelated donor was used in 68.4%, 70.2% and 93.3% of patients. Myeloablative conditioning was used in 45.6% of patients transplanted in CP1, 76.6% in >CP1 and 53.3% in AP/BC. Median follow-up for patients alive at last control was 7.2 years. 5-year overall survival (OS) for patients transplanted in CP1, >CP1 and AP/BC was 96.3% (95% CI 91.4-100%), 69.3% (95% CI 56.5-85.1%) and 34.3% (95% CI 16.2-72.4%). (Figure 1) In total, 37 of 119 patients had relapsed and 81% of relapses occurred within 2 years. Characteristics of relapse were linked to the disease phase at allo-HSCT with mainly molecular relapses in patients transplanted in CP1. In 10 of 12 relapsed patients in this group, MR3 was achieved by treatment with DLI and/or TKI. Hematological relapse occurred in 7 of 8 patients transplanted in AP/BC and 5 of these patients died due to relapse. The probability to develop GvHD of any grade was 63.9% for all patients, 50.9% when transplanted in CP1 and 80.9% in >CP1. Risk factors for death were AP/BC at time of allo-HSCT (p=<0,001) and EBMT score >2 (p=0.008). These factors were also associated with risk for relapse with p=0.007 and p=0.013. Sokal risk score, age at transplantation, time to transplantation, conditioning regimen, type of donor or time period of allo-HSCT were not significantly associated with death or relapse. At most recent follow up 29 of all 119 patients had died. Cumulative probability for non-relapse mortality (NRM)) for patients transplanted in CP1 or >CP1 compared to patients with AP/BC at time point of allo-HSCT was 11.6% and 21.4%.

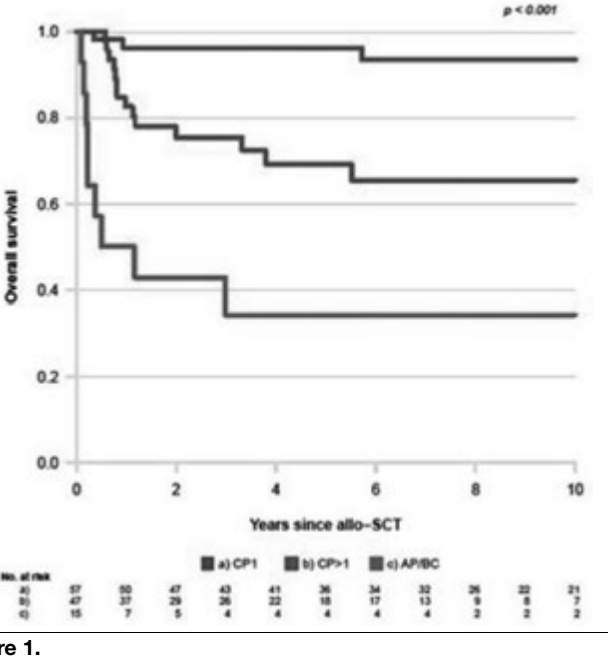

Figure 1.

Summary and Conclusions: Our population-based study demonstrates that there is still a considerable number of patients with CML in CP undergoing allo-HSCT each year. Patients transplanted in CP1 have an excellent OS, low NRM and respond to TKI and/or DLI treatment in case of relapse. We found a relatively low NRM even for patients transplanted in AP/BC but a high number of relapses, underlying the dismal OS in this group.

Background: The ENESTop study (NCT01698905) is assessing pts with CML-CP who achieved a sustained deep molecular response after switching from imatinib (IM) to NIL for achievement of TFR, a new treatment goal in CML. TFR rates of 57.9% at 48 wk (primary endpoint) and 53.2% at 96 wk were previously reported.
Aims: Assess long-term TFR durability and safety at 144 wk after stopping 2L NIL.
Methods: Pts treated with tyrosine kinase inhibitors for ≥3 y (IM for >4 wk followed by NIL for ≥2 y) and achieving $MR^{4.5}$ (*BCR-ABL1* ≤0.0032% on the International Scale [*BCR-ABL1*^{IS}]) on NIL were eligible to enroll and enter a 1-y consolidation (CS) phase; those with no confirmed loss of $MR^{4.5}$ could enter the main TFR phase. Pts who did not have stable $MR^{4.5}$ received another 1 y of treatment; those with stable $MR^{4.5}$ could then enter the TFR-2 phase. Pts with loss of major molecular response (MMR; *BCR-ABL1*^{IS} ≤0.1%) or confirmed loss of MR^4 (*BCR-ABL1*^{IS} ≤0.01%) during either TFR phase restarted NIL. Data cutoff for this analysis was Oct 18, 2017, when all pts in the main TFR phase had completed ≥144 wk of TFR, restarted NIL, or discontinued the study. All pts gave informed consent.
Results: By the data cutoff, 61/126 pts in the main TFR phase remained in TFR (48.4% [95% CI, 39.4%>57.5%]), 7 permanently discontinued the study while in this phase, and 58 reinitiated NIL (loss of MMR, 34; confirmed loss of MR^4, 24). 6/67 pts in TFR at 96 wk were no longer in TFR at 144 wk: 3 had confirmed loss of MR^4 (at 108, 120, and 144 wk of TFR), 2 died, and 1 discontinued the study due to pt decision. Of 34 pts who restarted NIL due to loss of MMR, 33 (97.1%) and 31 (91.2%) regained MMR and $MR^{4.5}$, respectively. The pt who did not regain MMR had been retreated with NIL for 19.7 wk. Of 24 pts who restarted NIL due to confirmed loss of MR^4, 23 (95.8%) regained $MR^{4.5}$; the remaining pt had only 1.1 wk of follow-up at the data cutoff. Of 54 total pts who regained $MR^{4.5}$ after restarting NIL, 42 (77.8%) had stable $MR^{4.5}$ 48 wk later. Of 26 pts who did not have stable $MR^{4.5}$ during the 1-y CS phase and received another 1 y of treatment, 7 achieved stable $MR^{4.5}$ and entered the TFR-2 phase. TFR rate among these pts was 71.4% (5/7 pts) at both 48 and 96 wk. The remaining 2 pts restarted NIL and discontinued the study due to AEs: arterial occlusive disease in 1 pt (last *BCR-ABL1*^{IS} 0.003%), cardiovascular disorder in 1 pt (last *BCR-ABL1*^{IS} 0.004%). Among all pts who attempted TFR (after 1 or 2 y of CS), TFR rate was 58.6% (78/133 pts) at 48 wk and 54.1% (72/133 pts) at 96 wk. No disease progressions were reported. Five pts died; 1 during CS (arterial hemorrhage), 2 during TFR (respiratory failure and arthritis bacterial, respectively; both after 96 wk of TFR), and 2 >30 d after discontinuing the reinitiation phase (1 cardiopulmonary failure, 1 adenocarcinoma). Based on pts who entered the main TFR phase, the 144-wk treatment-free survival (TFS) rate was 52.0% (95% CI, 42.9%>60.4%; Figure 1); median TFS was not reached. Of 68 pts remaining in TFR for >96 wk, any-grade AE rates were 77.9%, 83.8%, 67.6%, and 50.0% in the CS phase and first, second, and third 48 wk of TFR, respectively; any-grade musculoskeletal pain–related AE rates were 10.3%, 51.5%, 19.1%, and 11.8%. Any-grade cardiovascular-related AEs were low across these periods (CS, 1 pt; TFR, 2 pts during the second 48 wk).

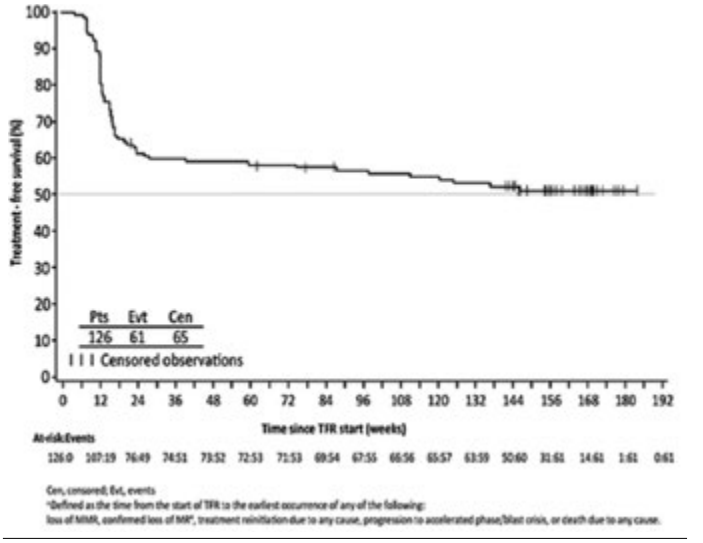

Figure 1. Treatment-free survival*.

Summary and Conclusions: These results show that following 2L nilotinib, long-term durable TFR is achievable in many pts, and pts should be monitored for potential late loss of response. Most pts restarting NIL regained stable $MR^{4.5}$.

Background: Nilotinib (NIL)+Pegylated IFN-a2a (Peg-IFN) are able to induce high deep molecular response (DMR) rates in chronic phase CML (CP CML) patients (pts), as first-line therapy (Nicolini FE., Lancet Haematol. 2015).
Aims: Comparison of DMR rates of NIL+Peg-IFN *vs* NIL alone, prospectively, in newly diagnosed CP-CML. (EudraCT 2013-004974-82).
Methods: Pts ≤65 yrs with no arterial history were randomized 1:1 to get

NIL 300 mg BID (Month (M) 0 to M72, arm A) *vs* Peg-IFN alone 30 days (M-1 to M0) 30 mg/wk as priming, prior to NIL 300 mg BID+Peg-IFN 30 mg/wk 2 wks, upgraded to 45 mg/wk thereafter, for up to 2 yrs (M0 to M24, arm B) followed by NIL alone for 4 more yrs. The primary endpoint is the rate of MR4.5 at M12.

Results: 201 pts were randomized (100 arm A, 101 arm B), 65 males in both arms, 35 females in arm A, 36 in arm B. The median follow-up was 25 (13.4–39) months. Results were analysed in ITT. Sokal was high in 25%, interm. in 35% and low in 39% pts; Eutos LTS was high in 2%, interm. in 17%, and 81% low; equally balanced. Median age was 46 (18-66) yr, equally balanced; 8 pts had a cryptic Ph, 12 a variant Ph, and 15 ACAs, all pts had a "Major" BCR transcript. CHR was obtained in 9.6% pts at M0 (arm B) and in 88% pts in arm A and 90.4% pts in arm B at M1. The rates of CCyR at M3 were 72.5% *vs* 76% in arm A *vs* B. At M12, the MR4.5 rates were 15.22% *vs* 24.21 (p=0.018) in arm A *vs* B respectively. By M12, the CI of MMR were 68.54% *vs* 90.79% (p=0.066), MR4 were 34.80% *vs* 48.89% (p=0.046), MR4.5 were 17.03% *vs* 24.11% (p=0.048), MR5 11.68% *vs* 36.13% (p=0.025), in arm A *vs* arm B respectively (Figure 1). Only 1 pt progressed toward accelerated phase in arm A with a Y253H mutation, to date. Fourty-two pts were withdrawn from study, 23 in arm A [toxicity 7, other cancer 2, resistance 14 (4 Y253H, 1 E255K, 1 F317L mutations), lost for follow-up 1] and 18 pts in arm B [toxicity 11, resistance 7 (T315I mutation 1)], no pt died. The median dose of Peg-IFN delivered in arm B during the first month was 30 (0-30)mg/wk, 45 (0-45)mg/wk at M2, 45 (0-45)mg/wk at M3, 30 (0-30)mg/wk M0-M12. The median daily doses of NIL were 600 mg in both arms M0-M12. The NIL doses delivered were not different between the 2 arms until M9 (p=0.053). Multivariate analysis demonstrated that female gender favourably impacted, but high Sokal and low cumulated doses of Peg-IFN (0-540 mg) negatively impacted on the M12 rate of MR4.5. The overall rate of grade 4 hematologic toxicities was 9.5%, with no anemia, 0.5% and 1.5% thrombocytopenia, 1.5% and 1% neutropenia, 0% and 0.5% leucopenia, and 0.5% and 0.5% pancytopenia in arm A *vs* B respectively. Grade ¾ non-hematologic toxicities consisted in 2% of cardiac disorders in arm A *vs* 2.5% in B, 0% vascular disorders in arm A *vs* 2% in B, 1.5% gastro-intestinal disorders in arm A *vs* 0.5% in B; 1% auto-immune disorders in arm B (1 recurrent pericarditis, 1 hemolytic anemia); 3 and 6 pregnancies (of the female partner except 2) were observed in arm A and B respectively, despite recommended contraceptive methods. We observed 8% lipase elevations in arm A *vs* 3% in B, 1% cholestatic episodes in arm A *vs* 0.5% in B. There were 1% depressive episodes in arm B; 2% infections in arm B and 1 before randomisation. Finally 3 intercurrent cancers were detected in arm A (cervix, breast, thyroid).

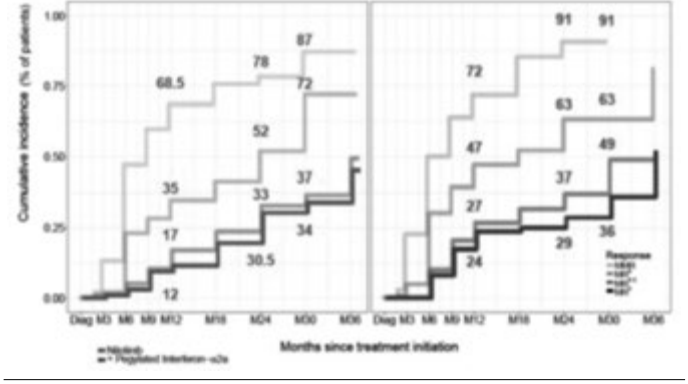

Figure 1. Cumulative incidence of molecular responses at definite time points.

Summary and Conclusions: The combination of NIL+Peg-IFN provides significantly higher rates of DMR rates by M12, in newly diagnosed CP CML pts without increasing the rate of early SAEs in such setting. M30 updated results will be presented during the meeting.

PF379

THE VALUE OF BCR-ABL1 QPCR LEVEL AND DOUBLING TIME (DT) TO PREDICT SUCCESSFUL TREATMENT-FREE REMISSION AFTER IMATINIB DISCONTINUATION: TREATMENT-FREE REMISSION ACCOMPLISHED BY DASATINIB (TRAD) TRIAL

D. Kim[1,*], D. Forrest[2], L. Savoie[3], I. Bence-Bruckler[4], S. Couban[5], L. Busque[6], P. Laneuville[7], R. Delage[8], A. Xenocostas[9], E. Liew[10], K. Paulson[11], J. Lipton[1], S. Kamel-Reid[12], B. Leber[13]

[1]Princess Margaret Cancer Centre, Toronto, [2]British Columbia Cancer Agency, Vancouver, [3]Tom Baker Cancer Centre, Calgary, [4]Ottawa Hopsital, Ottawa, [5]Queen Elizabeth II Health Sciences Centre, Halifax, [6]Hopital Maisonneuve-Rosemont, [7]McGill University Medical Centre, Montreal, [8]Laval University, Quebec, [9]London Health Science Centre, London, [10]University of Alberta, Edmonton, [11]Cancer Care Manitoba, Winnipeg, [12]Toronto General Hospital, Toronto, [13]Juravinski Cancer Centre, Hamilton, Canada

Background: The ongoing Canadian tyrosine kinase inhibitor (TKI) discontinuation trial is designed to determine if a second generation TKI (dasatinib) can be used for successful attaining treatment-free remission (TFR) after an initially unsuccessful attempt of TFR with imatinib discontinuation (IM). Our preliminary result indicates that: 1) The 6-month relapse-free survival (RFS) rate after IM discontinuation is estimated as 58.0%; 2) Dasatinib re-treatment leads to rapid re-achievement of MMR and MR4.

Aims: One aim of our trial is to identify early surrogates that predict successful TFR by using serial measures of BCR-ABL1 qPCR and doubling time (DT).

Methods: This prospective clinical trial (BMS CA180-543, Clinicaltrial.gov NCT#02268370) has 3 phases: 1) IM discontinuation 2) dasatinib rechallenge 3) dasatinib discontinuation. Serial measures of BCR-ABL1 qPCR test and the DT of the transcript were evaluated monthly for the first 6 months. For the latter the baseline qPCR level prior to IM discontinuation or the qPCR level from the prior month was used and DT was calculated as x=ln(2)/K (x is the DT, and k is the fold change in BCR-ABL1 from the previous value divided by the number of days between measurements). To define cut-off levels for BCR-ABL1 qPCR and DT, a binary recursive partitioning method was applied for RFS and a decision tree analysis was performed incorporating the variables BCR-ABL1 monthly, and DTs.

Results: As of Feb 11 2018, 53/131 patients (40.4%) lost molecular response; the 12-month relapse-free survival (RFS) rate was estimated as 58.0% (42.1-71.0%). 51/53 patients who lost response received dasatinib. The incidence of MMR, MR4 and MR4.5 at 3 months was 97.7%, 89.9%, and 84.6%, respectively. 22/51 patients have currently attained MR4.5 for 12 months or longer and have discontinued dasatinib for a second TFR attempt. 11/22 patients (50.0%) have lost molecular response, with an estimated TFR2 rate of 39.3% at 6 months, and a median of 5.5 month to loss of molecular response. BCR-ABL1 qPCR kinetics after IM discontinuation showed rapid rise of BCR-ABL1 transcript level in first 3 months, followed by gradual rise after the 3 months. We have analyzed the monthly level of BCR-ABL1 qPCR at 0-6 months. Recursive partitioning suggested 2 months' BCR-ABL1 qPCR as strong predictive for successful TFR. The RFS rate at 12 months was 89.3%, 26.5% and 0% with BCR-ABL1 qPCR 5 log or deeper (n=71), 4-5 log (n=28), and less than 4 log level (n=24) at 2 months (p<0.001). The DT of BCR-ABL1 transcript was evaluated at each month for the first 6 months using qPCR level at screening or at the previous month as a baseline. The DT between 0 (baseline) and 2 months was very predictive of successful TFR after IM discontinuation. The RFS rate at 12 months was 0% with DT less than 14 days (n=26) *vs* 34.2% with DT 14 days or longer (n=23) *vs* 84.1% with DT equal to or below zero (n=80; p<0.001). The result of the DT at 2 months calculated based on the qPCR levels of the present and previous month (+/- 8 days) was also highly predictive (p<0.001). When combined qPCR level and DT at 2 months, three prognostic groups were identified as shown in the Figure 1.

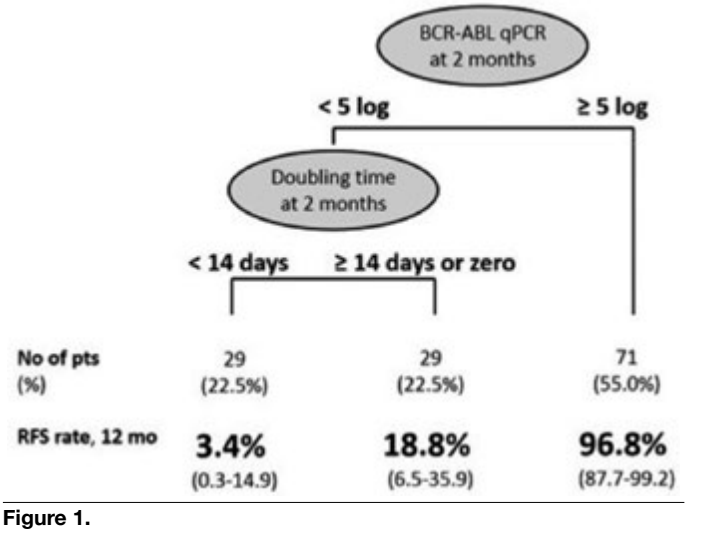

Figure 1.

Summary and Conclusions: BCR-ABL1 qPCR level at 2 months was very predictive of TFR success with a molecular cutoff of 5.0 logs.

Enzymopathies, membranopathies and other anemias

PF380

ADDRESSING THE DIAGNOSTIC GAPS IN PYRUVATE KINASE (PK) DEFICIENCY. CONSENSUS RECOMMENDATIONS ON THE DIAGNOSIS OF PK DEFICIENCY

Background: Pyruvate kinase deficiency (PKD) is the most common enzyme defect of glcolysis, causing hereditary non-spherocytic hemolytic anemia. PKD is an autosomal recessive disease, caused by homozygosity or compound heterozygosity for mutations in *PKLR* gene. The disease has a worldwide geographical distribution but there are no exact and verified data regarding its frequency. Difficulties in the diagnostic workflow and interpretation of PK enzyme assay likely play a role.
Aims: We studied the current gaps in the diagnosis of PKD in order to establish diagnostic guidelines that will improve diagnosis and increase awareness of the disease.
Methods: A global PKD Advisory Board Committee was established in 2016, involving 24 experts from 20 Centers of Expertise (CE). By means of a detailed survey and subsequent forum discussions, multiple aspects on the diagnosis of PKD were evaluated and discussed by 13 members of CEs from Europe (7), USA (5), and Asia (1). The outcomes were compiled and presented as recommendations.
Results: Broad consensus was reached on many clinical and technical aspects of the diagnosis of PKD. In particular: PKD should be suspected in: a) patients with a variable degree of chronic anemia and/or splenomegaly, and/or jaundice, with normal or near-normal red cell morphology; b) transfusion-dependent cases of unknown etiology; c) patients with severe neonatal indirect hyperbilirubinemia and hemolysis (mean degree of agreement: 95%). Clinical information, family history, and the time of last blood transfusion is essential and should be provided along with patient blood samples (98.5%). Similarly, laboratory parameters such as complete blood count, RBC morphology and markers of hemolysis (reticulocyte count, LDH, haptoglobin, unconjugated bilirubin) are considered mandatory upon sample acceptance (97%). Spectrophotometric PK activity assay (Beutler, A Manual of Biochemical Methods, 1984) is performed by all CEs and considered the reference assay (98.7%). >95% of agreement was reached on several technical aspects: sample is stable up to 21 days at 4°C or 15 days if the PK assay is performed together with hexokinase activity to evaluate the influence of high reticulocyte count or sample aging; anticoagulant (ACD/EDTA); sample purification by alpha-cellulose/microcrystalline cellulose column (buffy-coat removal may be considered as an alternative); interference of reticulocyte number and recent transfusion must to be taken into account when interpreting results of PK enzyme assay. Different positions were expressed on the need to confirm a PK enzyme deficiency by molecular testing (88%); two Centers consider this necessary only for atypical cases. Different approaches among Centers may be due to different levels of reimbursement for testing by national insurances. The use of Next Generation Sequencing panels is an alternative reliable method for PKD diagnosis, in particular in neonates (when parents are not available), in transfusion dependent, or recently transfused patients, or on samples with prolonged shipping times (91% degree of agreement).
Summary and Conclusions: A wide consensus on diagnosis of PKD was reached among 13 ECs worldwide. The results of this study will be presented as recommendations for the diagnosis of PK deficiency and will be useful in preparing a diagnostic algorithm. Since no external quality control program exists for PK testing, this information might be helpful for other centers to deliver timely and appropriate diagnosis and to increase awareness in PKD.

Indus., University Federico II, Napoli, Italy

Background: Mutations in more than 70 genes cause hereditary anemias (HA), a highly heterogeneous group of rare/low frequency disorders in which we included: hyporegenerative anemias, as congenital dyserythropoietic anemias (CDA) and Diamond-Blackfan anemia; erythrocyte membrane defects, as hereditary spherocytosis and stomatocytosis; hemolytic anemias due to enzymatic defects, as pyruvate kinase (PK) deficiency. The classification and the distinction among different types of HA is often difficult. The variety of unspecific and overlapping syndromic and non-syndromic phenotypes somewhat hampers a clear clinical diagnosis and prevents straightforward genetic testing. The diagnosis of these conditions may require several lines of lines of investigation.Due to the failure of the current diagnostic workflow to find a definitive and correct diagnosis of HA, next-generation sequencing (NGS) is making its way on this field. The major current application of NGS in diagnostics is through targeted (t)-NGS, in which a selected fraction of genes is analyzed (custom gene panels).
Aims: We propose a new diagnostic workflow for HA based on t-NGS.
Methods: We have developed two consecutive versions of a t-NGS panel, including 34 and 71 genes, respectively. Seventy-four probands from 62 unrelated families were investigated. The probe design was performed by web-based tool SureDesign (Agilent Technologies, USA). Sample preparation was performed following the instruction's manufacturer for HaloPlex Target Enrichment kit for Illumina Sequencing (Agilent Technologies). High-throughput sequencing was performed by Illumina NextSeq 500. Agilent SureCall software (v 3.0.3.1, Agilent Technologies) was used for bioinformatic and computational analyses. The pathogenicity of each variant was evaluated by gathering evidence from various sources, according to the guidelines of ACMG.
Results: We obtained an overall diagnostic yield of 64.9%. Despite 54.2% of cases showed conclusive diagnosis fitting well to the clinical suspicion, the multi-gene analysis modified the original clinical diagnosis in 45.8% of patients (non-matched phenotype-genotype). Of note, 81.8% of non-matched patients were clinically suspected to suffer from CDA. Particularly, 45.5% of the probands originally classified as CDA exhibited a conclusive diagnosis of chronic anemia due to enzymatic defects, mainly due to mutations in *PKLR* gene. Interestingly, we also identified a syndromic CDA patient with mild anemia and epilepsy, showing a homozygous mutation in *CAD* gene, recently associated to early infantile epileptic encephalopathy-50 and CDA-like anemia. Multi-target diagnosis also allowed us identifying polygenic conditions, in which the phenotypic variability could be explained by the co-inheritance of multiple disease mutations. This was the case of a *PIEZO1* patient that also exhibited the E109K-SEC23B genotype, causative of CDAII. The co-inheritance of *PIEZO1* and *SEC23B* mutations accounts for marked iron overload in this patient.
Summary and Conclusions: We herein described the diagnostic workflow that we established for molecular diagnosis of HA, based on the development of two consecutive versions of a t-NGS panel, including 34 and 71 genes, respectively. We showed the results obtained by the analysis of 74

probands. This is the largest cohort of patients and the most comprehensive gene set for this subset of anemias described so far. We also demonstrated that the multi-gene approach is valuable not only for achieving a correct and definitive diagnosis, but also for guiding treatment.

PF382

GENETIC MARKERS AND NEW TARGET GENES IN THE DIAGNOSIS OF RARE ANAEMIAS

J.-L. Vives-Corrons[1,*], E. Llaudet Planas[1], V. Rizzuto[1], E. Krishnevskaya[1], J. Iraola[1], M.D.M. Mañú Pereira [1]

[1]*Erythropathology, Institute for Leukaemia Research Josep Carreras, Barcelona, Spain*

Background: In spite of the use of different phenotypic, clinical and laboratory markers, between 15 and 20% of rare anaemias (RA), rare diseases with a prevalence of less than 5 cases per 10,000 individuals, remain undiagnosed. In all these cases, the final diagnosis requires the use of genetic markers, where the approach will depend on the presence of suggestive phenotypic characteristics of congenital haemolysis or hereditary erythropoietic failure.
Aims: The main objective of our task is to provide a fast and efficient diagnosis of rare anaemias (RA) using New Generation Sequencing (NGS) and two panels of genes. One panel for analysing known gene mutations leading to hereditary haemolytic anaemia, and a second panel for analysing other genes related with erythropoiesis, or modulators of clinical expression
Methods: 166 patients from 117 unrelated families have been studied by Next Generation Sequencing (NGS) including a panel of 35 genes responsible of membranopathy (ANK1, EPB41, EPB42, SLC4A1, SPTA1 (HBA1, HBA2), haemoglobinopathy (HBA1, HBA2), enzymopathy (ADA, AK1, ALDOA, BPGM, CYB5A, G6PD, GCLC, GPI, GSR, GSS, HK1, NT5C3A, PFKM, PGK1, , HBB) and CDA (CDAN1, C15orf41, SEC23B, KLF1, GATA1, KIF23). In a second panel, additional 33 genes, potential modulators of clinical expression have been also analysed. The diagnosis of patients studied was: 1. Haemoglobinopathy (7 patients): alpha thalassemia (3), beta thalassemia (2), unstable haemoglobin (1) and high affinity haemoglobin (1), 2. Enzymopathy (33 patients): G6PD deficiency (6), Pyruvate kinase deficiency (17), Glucose phosphate isomerase (1),Phosphofructokinase (2) and cytochrome b5 reductase (7), 3. Membranopathy (75 patients): Hereditary spherocytosis (63) and elliptocytosis (9) Congenital Xerocytosis (3), 4. Haemolytic anaemia of unknown origin but suspected to be a hereditary membranopathy (24 patients), 5- CDA type I (1) and 6- Haemolytic anaemia of unknown origin but without clinical orientation (26 patients)
Results: The mutation has been identified in 1.Haemoglobinopathies: 5 of 6 patients, since NGS does not detect major deletions such as the 3.7KB HBA, 2. Enzymopathies: 24 of 33 patients (72.7%) 3-Membranopathies: 73 of 76 patients (96%). 49% of the variants identified (36/73) were missense, most in the SPTB gene (11 variants), and the remaining (37/73), nonsense or Frameshift, most in the ANK1 gene (12 variants) and SPTB (9 variants) 4. Haemolytic anaemia suspected to be a membranopathy: 17 of 22 patients (77%), 5- CDA type I (1 case), and 6. Haemolytic anaemia of unknown origin: 8 of the 26 patients (31%)
Summary and Conclusions: Using the NGS panel of genes causing anaemia, it was possible to identify the mutation in 142 of the 166 patients studied (86%), leaving 24 unidentified cases (14%); 5 with suspected membranopathy, and 19 without diagnostic orientation (unknown aetiology) . The next step is to carry out the NGS analysis with additional 33 genes candidates to be modulators of clinical expressivity. If after all the studies, some RA remain unidentified, we will participate in the H-2020 RD-Solve project with the cooperation of EuroBloodNet consortium

PF383

ACTIVATE: A PHASE 3, RANDOMIZED, MULTICENTER, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY OF AG-348 IN ADULTS WITH PYRUVATE KINASE DEFICIENCY WHO ARE NOT REGULARLY TRANSFUSED

M.-H. Jouvin[1,*], C. Bowden[1]

[1]*Agios Pharmaceuticals, Inc., Cambridge, United States*

Background: Pyruvate kinase (PK) deficiency is an under-recognized hereditary disease resulting in lifelong hemolytic anemia. PK deficiency is caused by mutations in the *PKLR* gene that lead to reduced red cell PK (PK-R) enzyme activity, resulting in defective glycolysis and decreased lifespan of red blood cells. AG-348 is a novel, first-in-class, oral, small molecule allosteric activator of PK-R under clinical testing as the first targeted disease-altering therapy for PK deficiency. In the DRIVE PK study (NCT02476916; a phase 2, open-label, dose-ranging trial in adults with PK deficiency who are not regularly transfused) twice-daily (BID) dosing with AG-348 for >6 months was well tolerated and induced rapid, durable responses (Grace RF *et al.* ASH 2017). As of July 14, 2017, 26 (50%) of 52 enrolled subjects had a maximum hemoglobin (Hb) increase of >1 g/dL. Among these 26 subjects, the mean maximum Hb increase was 3.4 g/dL and 25 (96%) had at least one missense *PKLR* mutation.
Aims: To report the design of the planned ACTIVATE study of AG-348.
Methods: ACTIVATE is a phase 3, multicenter, randomized, double-blind, placebo-controlled study to evaluate the efficacy and safety of AG-348 in adult subjects with PK deficiency who are not regularly transfused. The study will consist of a screening period of up to 42 days, a 12-week dose optimization period, and a 12-week fixed-dose period (Figure 1). During the dose optimization period, AG-348 or matched placebo will be titrated up to each subject's individually optimized dose, with an initial dose of 5 mg BID for all subjects and two potential sequential dose increases (from 5 to 20 mg BID and from 20 to 50 mg BID), depending on safety and Hb change. Approximately 76 adults with PK deficiency who are not regularly transfused will be randomized in a 1:1 ratio to AG-348 (administered orally, BID) or matched placebo. Key inclusion criteria include: written informed consent; not regularly transfused (≤4 transfusion episodes in previous year and no transfusions in the 3 prior months); baseline Hb ≤10 g/dL; adequate organ function. Subjects who are homozygous for the R479H mutation or have two non-missense mutations (without the presence of another missense mutation) in *PKLR* will be excluded. The primary endpoint is the Hb response, defined as the proportion of subjects who achieve a ≥1.5 g/dL increase in Hb sustained over at least two of the last three visits in the fixed-dose period. Key secondary endpoints include change in Hb, markers of hemolysis, hematopoietic activity, health-related quality of life, and safety. An independent data monitoring committee will review the study data periodically and provide safety oversight. The ACTIVATE study will be initiated globally in the first half of 2018.
Results: Not yet available.

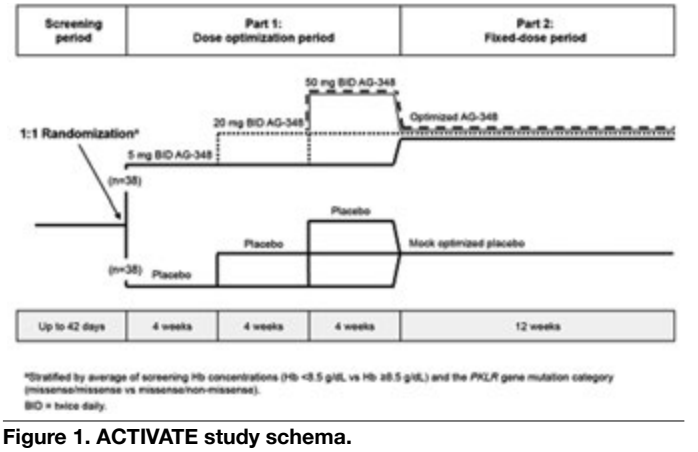

Figure 1. ACTIVATE study schema.

Summary and Conclusions: AG-348 is a novel, first-in-class PK-R activator undergoing clinical testing in subjects with PK deficiency. The ACTIVATE study of AG-348 in subjects with PK deficiency who are not regularly transfused will start enrollment in 2018.

PF384

PYRUVATE KINASE DEFICIENCY IN JAPAN: A SUMMARY OF CLINICAL FEATURE, LABORATORY DATA AND ENZYMATIC DIAGNOSIS

T. Iwasaki[1,*], T. Utsugisawa[1], T. Yamamoto[2], H. Ogura[1], T. Aoki[1], Y. Okamoto[1], T. Kawakami[1], S. Ohga[3], A. Ohara[4], E. Ito[5], H. Kanno[1]

[1]*Transfusion Medicine and Cell Processing,* [2]*Institute of Medical Genetics, Tokyo Women's Medical University, Tokyo,* [3]*Pediatrics, Graduate School of Medical Sciences, Kyushu University, Fukuoka,* [4]*Pediatrics, Toho University, Tokyo,* [5]*Pediatrics, Hirosaki University, Aomori, Japan*

Background: Pyruvate kinase deficiency (PKD) is the most prevalent congenital hemolytic anemia due to a glycolytic enzyme defect, and inherited in an autosomal recessive manner. We have been working on the differential diagnosis of congenital hemolytic anemia and related disorders by the biochemical, physiological and genetic tests.

Aims: In this study, we aim to clarify the clinical entity of PKD in Japan: Clinical features, laboratory data, red cell enzyme analysis and genotypes of the Japanese PKD cases are summarized.
Methods: All PKD cases are enzymatically diagnosed by using the leukocyte-depleted erythrocytes. To exclude possible inactivation of the mutant enzymes, patients' blood samples are always transported to our laboratory with normal controls simultaneously sampled.
Results: We diagnosed 120 PKD cases since 1972 through 2017. The median age of diagnosis as PKD is 10 (min 0 - max 72), and gender of PKD showed 52 male and 68 female cases. The parents of 34.7% of PKD patients had consanguinity; 63.6% of patients experienced exchange transfusion at the neonatal period; 64.8% experienced RBC transfusion; 47.7% had acute hemolytic crisis; 53.1% were noticed as having splenomegaly and 58.6% were splenectomized. Mean values of Hb, reticulocytes, indirect bilirubin, serum LDH, transferrin saturation, and ferritin were 8.8g/dL, 13.0%, 3.7mg/dL, 587 IU/L, 57% and 497 ng/mL, respectively. We confirmed that 36 PKD cases harbored two *PKLR* mutations, and 42 family members were heterozygous by genetic testing. The relative erythrocyte PK activity of the PKD cases was 38.5±3.7% (mean±SE) of controls, whereas that of heterozygotes was 58.5±3.3%(mean±SE). By using a receiver operator characteristic (ROC) curve, we identified the cut-off limit as 79.8% (Figure 1 left) and 85.9% (Figure 1 right) to discriminate PKD patients from heterozygotes and heterozygotes from normal subjects, respectively.

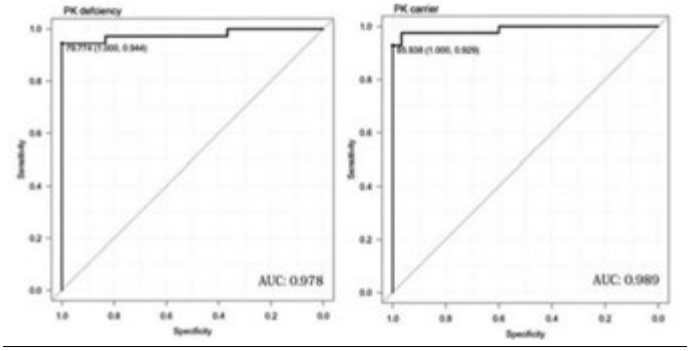

Figure 1.

Summary and Conclusions: According to the diagnostic guidelines of PKD currently being promoted as the international collaborative research, it is recommended that confirmation of mutation of both PK alleles by genetic testing be desirable for definite diagnosis of PKD. It is obvious that both next generation sequencing analysis or conventional PCR resequencing is more complicated, time consuming and more costly than enzyme assay. It is expected that a erythrocyte PK activity threshold that can be used for rapid and accurate clinical diagnosis can be determined by association analysis of the results of measurement of erythrocyte PK activity and genotype by a method standardized between PKD diagnostic facilities.

PF385

ACTIVATE-T: A PHASE 3, OPEN-LABEL STUDY TO EVALUATE THE EFFICACY AND SAFETY OF AG-348 IN REGULARLY TRANSFUSED ADULTS WITH PYRUVATE KINASE DEFICIENCY

M.-H. Jouvin[1,*], C. Bowden[1]

[1]Agios Pharmaceuticals, Inc., Cambridge, United States

Background: Pyruvate kinase (PK) deficiency is an under-recognized hereditary disease resulting in lifelong hemolytic anemia. PK deficiency is caused by mutations in the *PKLR* gene that lead to reduced red cell PK (PK-R) enzyme activity, resulting in defective glycolysis and decreased lifespan of red blood cells. AG-348 is a novel, first-in-class, oral, small molecule allosteric activator of PK-R under clinical testing as the first targeted disease-altering therapy for PK deficiency. In the DRIVE PK study (NCT02476916; a phase 2, open-label, dose-ranging trial in adults with PK deficiency who are not regularly transfused) twice-daily (BID) dosing with AG-348 for >6 months was well tolerated and induced rapid, durable responses (Grace RF *et al.* ASH 2017). As of July 14, 2017, 26 (50%) of 52 enrolled subjects had a maximum hemoglobin (Hb) increase of >1 g/dL. Among these 26 subjects, the mean maximum Hb increase was 3.4 g/dL and 25 (96%) had at least one missense *PKLR* mutation. The ACTIVATE-T study is designed to assess the efficacy and safety of AG-348 for the first time in regularly transfused subjects with PK deficiency.
Aims: To report the design of the planned ACTIVATE-T study.
Methods: ACTIVATE-T is a global, multicenter, open-label study to evaluate the efficacy and safety of AG-348 in regularly transfused adults with PK deficiency. Approximately 15–20 adults with PK deficiency who are regularly transfused will be enrolled and treated with AG-348. The study will comprise an 8-week screening period, in which each subject's complete transfusion history from the prior 52 weeks will be documented, followed by a 16- to 24-week dose optimization period, and a 24-week fixed-dose period (Figure 1). During the dose optimization period, each subject will undergo individualized AG-348 dose optimization. All subjects will start on a dose of 5 mg BID, which may be increased twice over the course of 16–14 weeks (from 5 to 20 mg BID and from 20 to 50 mg BID). In the fixed-dose period, each subject will receive AG-348 at their optimized dose for 24 weeks. Key inclusion criteria include written informed consent, regular transfusion (≥6 transfusion episodes in the previous year), and adequate organ function. Subjects who are homozygous for the R479H mutation or have two nonmissense mutations (without the presence of another missense mutation) in *PKLR* will be excluded. An additional key exclusion criterion is an average transfusion frequency of more than once every 3 weeks in the previous year. During the study, subjects will be transfused when their Hb reaches their individual transfusion trigger calculated from their transfusion history. The primary endpoint is the proportion of subjects who achieve a reduction in transfusion burden, defined as a reduction of ≥33% in the number of red blood cell units transfused during the 24 weeks of the fixed-dose period compared with the historical transfusion burden standardized to 24 weeks. Secondary endpoints include safety. An independent data monitoring committee will meet at least once to review the study data. The ACTIVATE-T study will be initiated globally in the first half of 2018.
Results: Not yet available.

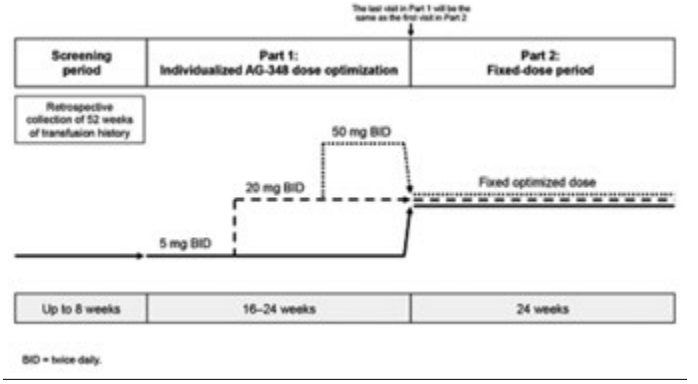

Figure 1. ACTIVATE-T study schema.

Summary and Conclusions: AG-348 is a novel, first-in-class PK-R activator undergoing clinical testing in subjects with PK deficiency. The ACTIVATE-T study of AG-348 in regularly transfused subjects with PK deficiency will start enrollment in 2018.

PF386

CLASSIFYING, SHARING AND REVIEWING GENETIC VARIANTS ASSOCIATED WITH RED CELL DISORDERS

D. Philip[1], F. Smith[2], R. Mayhew[3], D. Brawand[4], S. Allouni[2], N. Parkin[3], B. Clark[4,5,*]

[1]SW Thames Regional Genetics, St Georges Hospital, [2]Molecular Diagnostics, [3]Molecular Pathology, Viapath LLP at Kings College Hospital, [4]Precision Medicine, Kings College Hospital, [5]Molecular Haematology, Kings College London, London, United Kingdom

Background: Having sequenced 212 genes in over a thousand individuals with a suspected red cell disorder we have amassed 1594 common genetic variants (allele frequency >10%) and classified 3408 unique variants, using a five class classification system. It is important to be able to share this genetic variation with other laboratories carrying out similar investigations to ensure patients receive an equitable service no matter which laboratory undertakes the testing. The Variant Scoring Assistant (VASA) that we have developed is a software tool that enables laboratories to upload variants in batch, as a VCF, or individually. This allows users to see how other laboratories have classified the same variant and gives them the opportunity to classify their own genetic variants and store any associated evidence. VASA scores variants according to the American College of Medical Genetics (ACMG) guidelines and automatically assigns a pathogenicity score. This score can be overridden by a user allowing scientists to exercise their scien-

tific judgment. By using VASA it is hoped that different laboratories will consistently score variants using the ACMG guidelines and will build their own institution specific dataset. Being able to see scores from other institutions should make pathogenicity classifications quicker and easier and reducing reporting times and improving patient care.
Aims: To develop a cloud based software tool that enables different laboratories to share genetic variant pathogenicity classifications.
Methods: Developed a SQL database that permits automated ACMG classification of genetic variants.
Results: Confirmed that the database scores variants using the ACMG guidlines by comparing manually scored variants to automatically scored variants. This indicated that the database rules and underlying code is functioning correctly. We have confirmed that variants can be uploaded in batch, as a VCF, or individually. When working from a VCF variants can be scored and the associated evidence stored using the VCF as a worklist. The VCF is not stored and therefore variants from the same individual are not linked. We have built an API allowing VASA to be linked to other databases.
Summary and Conclusions: By comparing scores submitted from different groups VASA can serve as a tool to identify genetic variants where there are differences in scores between groups. These variants could then be reviewed with the patient's haematology to understand the differences of opinion. If there is agreement on classification between multiple groups then laboratories can have greater confidence in these variant classifications. In this way VASA may work as a framework for collaboration on variant interpretation for red cell disorders. We aim to have the system hosted on a public cloud by June 2018.

Background: Most patients with anemia are diagnosed through clinical phenotype and basic laboratory testing, including a peripheral blood smear, iron body status, and hemoglobin electrophoresis. Nonetheless, in cases of rare congenital anemias, some patients remain undiagnosed despite undergoing an exhaustive workup. The diagnosis of those rare disorders often requires specialized analyses available in only a few dedicated laboratories. However, an accurate diagnosis in many of those disorders is crucial for optimal clinical management and for genetic counseling.
Genetic testing is complicated by the large number of genes involved in rare anemias and the similarities in the clinical presentation of the different syndromes. The advent of targeted gene capture technique followed by next generation sequencing (NGS) offers a rapid, accurate and cost-effective approach in these difficult cases.
Aims: We aimed to enhance the diagnosis of patients with congenital anemias by using targeted next generation sequencing.
Methods: Genetic diagnosis was performed by gene-capture followed by next generation sequencing of 78 genes known to cause anemia syndromes, including congenital dyserythropoietic anemia (CDA), red blood cell enzymopathies and membranopathies, sideroblastic anemia, and Diamond-Blackfan anemia (DBA).
Results: Genetic diagnosis was achieved in 13 out of 21 patients (62%). Six patients were diagnosed with pyruvate kinase deficiency, four with dehydrated hereditary stomatocytosis, two with sideroblastic anemia and one with CDA type IV. The mean lag-time from presentation to diagnosis was over 12 years. Overall, eight novel mutations were found. In seven patients the genetic diagnosis differed from the pre-test presumed diagnosis. One patient, who passed away due to recurrent pulmonary embolism post splenectomy, was eventually diagnosed with dehydrated hereditary stomatocytosis, a condition in which splenectomy is contra-indicated.
Summary and Conclusions: In our study, targeted next generation sequencing led to an accurate diagnosis in over 60% of patients with rare anemias. Earlier incorporation of this method into the workup of patients with congenital anemia may improve patients' care and enable genetic counseling.

Background: Hereditary chronic hemolytic anemias (CHAs) are heterogeneous rare disorders including defects of red cell membrane structure or cation permeability, defects of metabolism, hemoglobinopathies, and disorders of erythropoiesis. All these diseases are complex and frequently difficult to diagnose. The diagnostic laboratory tools include routine tests and more specialized analyses, available only in few dedicated laboratories. In our experience, a conclusive diagnosis is not reached in about 15-20% of cases despite detailed and exhaustive investigations. The advent of next generation sequencing (NGS) tools has made diagnosing complex genetic disorders feasible.
Aims: We developed and applied a NGS targeted panel to identify the underlying genetic cause in a selected series of patients with undiagnosed CHAs.
Methods: A total of 52 cases with CHAs from 40 families were studied. In 33 subjects no definitive diagnosis was previously done despite extensive investigation, in 12 the conventional diagnostic workup was unreliable due to transfusions or sample shipping. In addition three HS/HE families with intra-family clinical variability were studied to elucidate the molecular basis of the atypical phenotype. Using SureDesign software (Agilent) we created a NGS based panel containing 40 genes associated with RBC membrane disorders (13 genes), enzymopathies (20), CDAs (7), and 9 other candidate or modifier genes. Libraries were obtained by HaloPlexHS Target Enrichment System Kit and sequenced on a MiSeq platform (Illumina). The panel was validated on previously characterized patients. Mutations were confirmed by Sanger.
Results: We identified pathogenic variants that enabled a definitive diagnosis in 24 cases (17 families). Results are reported in Table 1. 15 mutations were novel and considered pathogenetic. Notably, we identified a PK deficient case with normal activity in absence of transfusions. Moreover, we found a TPI deficiency in a 7 month child with anemia but no neuromuscular manifestations at the time of the study, thus permitting an early diagnosis. A new pathogenic variant in *ALAS2* gene was detected in a female with macrocytic anemia, suggesting a diagnosis of congenital sideroblastic anemia; HUMARA analysis showed a skewed X-Chr inactivation pattern. Seven cases carried pathogenic variants in *PIEZO1* gene, associated with hereditary xerocytosis, five of them displaying p.R2456H mutation. We identified a new patient with a *de novo* R352H mutation in KCNN4 gene (Gardos Channellopathy) and one with a mutation in *ABCG8* gene associated with congenital sitosterolemia. Complex genotypes were identified in 3 families with HS/HE: case F11-817 (mixed HS/HE phenotype) carried two pathogenic variants in *SPTA1* and *SLC4A1*, whereas the brother with typical HE

had only the *SPTA1* variant; case F12-73 with combined 68% spectrin and 56% ankyrin deficiency, had two different *in trans* mutations in *SPTA1*, one of them associated with the alpha-LELY allele. Finally, 3 different pathogenetic *SLC4A1* variants were detected in case F13-723 with severe HS and 50% Band 3 deficiency, the father presenting only one missense mutation, thus justifying intra-family clinical variability.

Summary and Conclusions: NGS platform is a powerful tool to elucidate the molecular causes in patients with CHAs where traditional hematologic testing failed. However, in this selected series we attributed pathogenetic variants in 40% of the examined families. Different approaches need to be considered to investigate the cause of hemolysis in the remaining cases.

PF389

NEXT GENERATION SEQUENCING FOR DIAGNOSIS OF INHERITED HEMOLYTIC ANEMIAS

J. Nieto[1,*], C. Cuéllar PA[2], B. Prieto[1], F.A. Gonzalez[1], A. Villegas[1], A. Velasco[1], R. Trelles[1], A. Bobes[1], C. Vicente[1], A. Gonzalez[1], M. Ibarra[1], R. Martinez[1], P. Ropero[1]

[1]Hematology, Hospital Clínico San Carlos, [2]Hematology, Hospital Universitario La Princesa, Madrid, Spain

Background: Inherited hemolytic anemias (IHAs) are a group of congenital disorders with multiple etiologies, such as intrinsic erythrocyte enzyme deficiencies or membrane protein alterations. The typical clinical presentation is usually unspecific, with anemia, pallor, jaundice and often splenomegaly. Morphological and biochemical differential diagnosis between IHAs is challenging due to the limited availability of all the necessary techniques in one single centre. Mutations in many different genes can cause an IHA, thus, genetic analysis by Sanger sequencing become expensive and very time consuming. Of note, treatment options could be different based on the etiology of the IHA. In this scenario, we wonder if a Next Generation Sequencing (NGS) approach would be useful in the differential diagnosis between IHAs.
Aims: To define pros and cons of genetic analysis by NGS in patients with an IHA (with known or unknown cause).
Methods: Biological samples of 44 patients with IHA were sent to our hospital for genetic analysis to confirm or to find out a specific diagnosis. We have developed a custom sequencing panel (TruSeq Custom Amplicon, Illumina) for sequencing 40 genes (exons and intron-exon boundaries) previously associated to IHAs. Studied diseases encompass membranopathies (spherocytosis, stomatocytosis, etc.) and enzimopathies (deficiency in PK, G6PD, GPI, etc.). Genes causing congenital dyserythropoietic anemias were included in the panel. Hemoglobinopathies are studied in our hospital with other techniques. Only results concerning to variants classified as pathogenic, likely pathogenic and those with unknown significance are shown in this abstract. We have followed ACMG standards for variant classification.
Results: 34 out of 44 patients had an initial suspicion of a specific IHA. Eighty eight percent of them (n=30) have shown genetic variations that are likely causing the disease. In the other hand, 8 out of the remaining 10 patients with initial unknown cause for the IHA have genetic alterations. No significant alterations were found in 6 patients (14%).
Remarkably, NGS analysis helps us to identify 2 patients (#29 and #30) in which a spherocytosis was initially suspected but they actually have a PK deficiency. In this study we have found 17 new or novel genetic alterations. These results are summarized in Table 1.

Table 1. NGS results in 44 patients with suspected IHA.

* Cation permeability studies required
# Sanger sequencing
LELY: SPTA1 low expression allele; DHS: Dehydrated Stomatocytosis, DHS: Overhydrated Stomatocytosis, CDA: Congenital Dyserythropoietic Anemia; (P): Pathogenic, (LP): Likely Pathogenic; (US): Unknown significance. Novel mutations are indicated in bold.

Summary and Conclusions: Overall, there is a high percentage (86.4%) of patients with a recognizable genetic variant that is likely causing the IHA. In 6 cases we obtain no significant genetic results; 2 patients with no initial proposed cause for the IHA, 3 with low suspicion for spherocytosis and 1 with xerocytosis that could be caused by mutations in KCNN4 (not included in our panel). In some patients, biological significance of genetic variants is difficult to assess, especially when a gain of function variant is expected to cause the disease (*i.e.* PIEZO1 mutations in xerocytosis). Without complementing this information with functional analyses, many of the novel findings have to be classified as unknown significance variations. Therefore, it remains some degree of uncertainty in the diagnosis of a number of patients. In 10 cases (#29 to #38), NGS enabled us to better identify genetic variations that can cause IHAs. 8 of them had an unknown cause. Of special interest, there were 2 cases labeled as spherocytosis where NGS had a huge added value, since final diagnosis turned into PK deficiency (the former disease have new promising pharmacologic options in clinical trials).

PF390

REPORT OF THE FIRST CASE OF HEREDITARY SPHEROCYTOSIS DUE TO A LARGE DELETION OF THE SPTA1 GENE

J. Russello[1], I. Bertchansky[2], C. Guittard[1], O. Guillot[1], V. Cacheux[1], M. Giansily-Blaizot[1], P. Aguilar-Martinez[1,*]

[1]biological hematology, [2]addictology, CHU Montpellier, Montpellier, France

Background: Hereditary spherocytosis (HS), is caused by a defect in proteins forming the red cell membrane cytoskeleton, therefore leading to a progressive modification of the red cell shape and ultimately to red cell destruction by spleen macrophages. The typical clinical presentation is chronic haemolytic anaemia. Causative mutations are generally located in the *ANK1*,

SPTB, SLC4A1, EPB42 or *SPTA1* genes, which encode ankyrin, spectrin beta chain, the anion exchanger 1 (band 3) protein, protein 4.2 and spectrin alpha-chain, respectively.
Aims: Here, we report the first case of a large deletion of the *SPTA1* gene associated with HS.
Methods: The *proposita* is a18year-old girl who underwent a DAT negative haemolytic episode with anaemia (Hb 67 g/l) and hepatic cytolysis due to an acute cytomegalovirus infection. After recovery from the infection, haemoglobin levels spontaneously returned to normal (146 g/L) as well as LDH and bilirubin levels, but haptoglobin levels remained below 0.1g/L and the reticulocyte count ranged between normal and high values. A membrane defect was suspected because of increased osmotic fragility (positive pink test). The EMA test was in the normal range and osmotic gradient ektacytométrie displayed an atypical profile. Informed consent for genetic studies was obtained and analysis of a panel of eleven genes involved in HS was performed by next generation sequencing, using the Custom SureSelectQXT® Target Enrichment system (Agilent) on a MiSeq platform (Illumina). Each deleterious variation was independently checked using conventional Sanger sequencing. The large rearrangements were confirmed by Array-CGH using Sure Print G3 Human CGH Microarray 2x400K (Agilent).
Results: We did not identify any likely pathogenic (class 4) or pathogenic (class 5) variants among the eleven studied genes. The α^{LELY} allele (rs28525570; c.6531-12CNT) was present, apparently at the homozygous state. However, all *SPTA1* sequence variations were surprisinglyat the homozygous state, which may correspond to a loss of heterozygosity. Subsequent copy number variation (CNV) analysis revealed a large deletion of the *SPTA1* gene at the heterozygous state. The 392Kb deletion, confirmed by array-CGH, involved the following genes: *SPTA1, MNDA, OR6Y1, OR6P1, OR10X1,OR10Z1, OR6K2, OR6K3, OR6K6, OR6N1, OR6N2* on chromosome 1 (1q24.2) from 158496074 to 158888723. This is the first report of a complete deletion of the *SPTA1* gene, associated with hemizygozity of the α^{LELY} allele *in trans*. An interstitial deletion of the *SPTA1* gene leading to an expressed abnormal protein and associated with the α^{LELY} polymorphism *in trans* has been reported in a splenectomised patient with mild symptomatic elliptopoikilocytosis (Iolascon et al 2011).
Summary and Conclusions: SPTA1-related disorders have marked clinical, biochemical and genetic heterogeneity. In the reported case, despite the complete deletion of one *SPTA1* gene, the patients had a mild compensated haemolysis at the basic level and the disease was revealed by an acute episode triggered by viral infection. A possible explanation is that, when the α^{LELY} allele, which results in 50% reduction of alpha chains, is inherited *in trans* to a pathogenic *SPTA1* allele, a greater proportion of the defective α-spectrin is recruited by spectrin β-chains. This leads to a higher percentage of defective αβ dimers, resulting in a higher percentage of abnormal tetramers leading to a more severe clinical phenotype. In our case, the absence of abnormal alpha spectrin chains due the entire gene deletion may have impaired this phenomenon thus producing a milder phenotype.

PF391

CONGENITAL ERYTHROPOIETIC PORPHYRIA AS A MIMICKER OF CHRONIC HEMOLYTIC ANEMIAS IN INFANTS

Y. El Chazli[1,*], A. Elsharkawy[1], A. Salama[2], S. Hasan[3], B. Shanash[4], W. Shoman[5]

[1]Pediatric Hematology/Oncology, Faculty of Medicine, Alexandria University, [2]Pediatric hematology specialist, Alexandria University Hospitals, [3]Pediatric intensive care unit, [4]Pediatric clinical genetics, [5]Immunology/Rheumatology unit, Faculty of Medicine, Alexandria University, Alexandria, Egypt

Background: Congenital erythropoietic porphyria (CEP) is rare, with only approximately 200 cases reported in the literature. Cutaneous phototoxicity and hemolytic anemia are the predominant findings in CEP. The paucity of the reported cases makes an accurate description of the disease presentation and its diagnosis a real challenge, especially in resource-limited countries.
Aims: To report the experience of a single institution in the diagnosis of CEP and highlight the importance of considering this rare disease as a differential diagnosis of chronic hemolytic anemia in infants.
Methods: A descriptive study from the Hematology-Oncology clinic at Alexandria University Children's Hospital. After taking an informed consent, the patients have been subjected to history taking, clinical examination; Wood's light urine examination, urine and stool porphyrin quantification. Sanger sequencing to confirm Uroporphyrinogen III synthase (UROS) gene was done.
Results: Three patients (2 males and a female) have been diagnosed as CEP during 2016 spring season. All were born at term to consanguineous parents (first-degree cousins) and have presented to our clinic after several months of investigations. All three infants have been symptomatizing since birth, showing anemia requiring transfusions early in life. Two of them had received phototherapy for hyperbilirubinemia and have developed skin lesions that were thought to be incidental or due to neonatal sepsis. They had intermittently red urine and all have developed progressive hepatosplenomegaly during first months of life. They have undergone investigations for diagnosis of chronic hemolytic anemia and have been misdiagnosed as unclassified hemolytic anemia (patient 1) and as Evans syndrome (patient 2). It is only with exposure to the sun during the spring, that skin blisters appeared raising suspicion of CEP in the first two cases with an interval of several months between first presentation and final diagnosis. Patient '3' has been diagnosed earlier (at the age of 3.5 months) as awareness has been raised to CEP in our center. A positive Wood's light examination of urine strongly supported the diagnosis of CEP in the three cases. Confirmatory testing was done in collaboration with Triemli hospital in Zurich and revealed elevated urinary and fecal porphyrin and sequencing of exon 4 of UROS gene revealed a p.C73R mutation in the homozygote state in the three patients and in the heterozygote state in their parents (Figure 1).

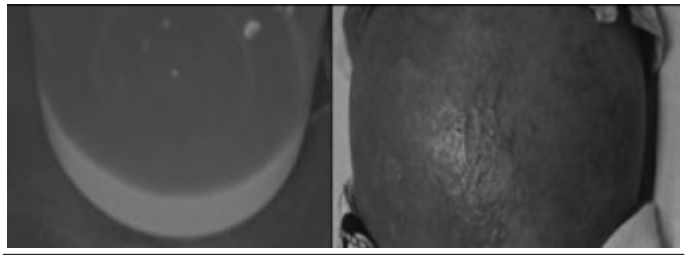

Figure 1.

Summary and Conclusions: Raising awareness about rare diseases like CEP is essential to prevent delayed diagnosis and increased complications. Manifestations of phototoxicity can be delayed and might not appear except during spring/summer months. The Wood's light examination is an easy and cheap way of supporting the diagnosis of CEP in resource-limited countries. Finally, although it is too early to determine the most common mutations causing CEP in Egyptian infants, this early report suggests testing for exon 4 mutations could be done as the first step of genetic testing in suspected cases.

PF392

CLINICAL CHARACTERISTICS OF PATIENTS WITH RED CELL PYRUVATE KINASE DEFICIENCY IN GERMANY

P. Klothaki[1,*], R. Grace[2], S. Eber[3], M. Wlodarski[4], J. Kunz[5], P. Bianchi[6], E. Fermo[7], S. Burdach[8], O. Andres[9], M. Nathrath[1], N. Kollmar[1]

[1]Pädiatrische Hämatologie und Onkologie, Klinikum Kassel, Kassel, Germany, [2]Dana-Farber Boston Children´s Cancer and Blood Disorder Center, Boston, United States, [3]Praxis für Kinder und Jugendmedizin, Munich, [4]Pädiatrische Hämatologie und Onkologie, Universitätsklinik Freiburg, Freiburg, [5]Pädiatrische Hämatologie und Onkologie, Universität Heidelberg, Heidelberg, Germany, [6]Fondazione IRCCS Ca´Granda, Ospedale Maggiore Policlinico, [7]Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Milan, Italy, [8]Medizinische Fakultät, Technische Universität München, Munich, [9]Erythrozytenlabor Universitäts-Kinderklinik Würzburg, Universitäts-Kinderklinik Würzburg, Würzburg, Germany

Background: Pyruvate kinase deficiency (PKD) is the most common enzymopathy of anaerobic glycolysis in erythrocytes. PKD is a rare autosomal recessive disease caused by mutations in the *PKLR* gene causing a hereditary non-spherocytic hemolytic anemia. There is a lack of research concerning clinical characteristics and molecular findings of patients with PKD in Germany.
Aims: This study describes clinical and molecular findings of patients with red cell PKD in Germany.
Methods: 28 patients (11 female, 17 male) with compound heterozygous or homozygous PKD who participated in Germany in the PKD Natural History Study (Bianchi et al 2017) were included in the analysis. Medical and laboratory data of the patients were retrospectively collected.
Results: 36% (n=10) of the patients were adult and 64% (n=18) children. The median age at diagnosis was 6.9 years (range: 0-48 years) and the median residual pyruvate kinase activity was 49% (range: 13- 100%). 57% of the patients (n=16) had severe anemia (Hb<8 g/dl), 11% (n=3) moderate anemia (Hb 8-10 g/dl) and 29% (n=8) mild anemia (Hb 10-12 g/dl). There was no correlation between the residual enzyme activity and the hemoglobin level. 39% (n=11) were homozygous and 61% (n=17) compound heterozygous for mutations in the *PKLR* gene. 23 different mutations were found.

The most common mutation was c. 1529 G>A (39% of the patients, n=11). 71% (n=20) of the patients had newborn hyperbilirubinemia and were treated with phototherapy (80%) and/or exchange transfusions (45%). 64% (n=18) needed at least 1 transfusion in the newborn time and 86% (n=24) of the patients needed at least 1 lifetime transfusion. 57% (n=16) received regular transfusions (≥6 transfusions over a 12 month period) after the newborn period. Chelation therapy for transfusion-associated iron overload was necessary in 36% (n=10) of the patients. Gallstones are common complication reported in 36% (n=10) of the patients. Liver cirrhosis was reported in 7% (n=2) of the patients. Splenectomy was reported in 29% (n=8) and cholecystectomy in 25% (n=7) of the patients with median age at splenectomy of 11.5 years (SD 11.9 years) and at cholecystectomy of 20.3 years (SD 12.7 years). The splenectomy led to a decrease in the transfusion burden and to an increase of median hemoglobin in 63% (n=5) of these patients but led to no change in hemoglobin or transfusion burden in 25% (n=2) of these patients. The median rise of the hemoglobin level was 1.7 g/dl (range: 0.9-3.3). In 12% (n=1) of these patients remained the effects of splenectomy unknown. 25% (n=2) of the patients developed a thrombosis after splenectomy.

Summary and Conclusions: This study suggests that patients with PKD living in Germany have wide clinical and molecular heterogeneity. Most patients have severe anemia and receive regular transfusions. Splenectomy leads to a decrease in the transfusion burden in the majority of patients. Careful monitoring for complications, such as iron overload, cholelithiasis and liver cirrhosis is essential.

ANTITUMOR ACTIVITY BY TEGS: ALPHA/BETA T CELLS ENGINEERED TO EXPRESS A DEFINED GAMMA/DELTA TCR IN A 3D BONE MARROW NICHE MODEL OF MULTIPLE MYELOMA

T. Straetemans[1], M. Braham[2], T. Aarts-Riemens[1], J. Alblas[2], M. Minnema[3], Z. Sebestyen[1], J. Kuball[3,*]

[1]Department of Hematology / Laboratory of Translational Immunology, [2]Department of Orthopaedics, [3]Department of Hematology, University Medical Center Utrecht, Utrecht, Netherlands

Background: γδT cells mediate cancer immune surveillance by sensing metabolic changes of malignant cells via their γδT cell receptor (TCR). Activation of the γδTCR is independent of MHC molecules, making them a valuable treatment strategie. Moreover, γδTCR are able to differentiate between healthy and leukemic stem cells (Sebestyen *et al.* Cell Reports 2016). This concept led to the development of next generation CAR T cells, so-called TEGs: aβT cells Engineered to express a defined γδTCR. A particular γ9δ2TCR, isolated from "clone 5", has been selected as the candidate for clinical testing (TEG001). TEG001 cells showed a strong and broad recognition of hematological malignancies (Straetemans *et al.* Clin Can Res 2015, Marcu-Malina *et al.* Blood 2011, Gruender *et al.* Blood 2012).

Aims: Important for the therapeutic success of TEGs is a better understanding of the cross-talk between malignant, stromal and immune cells present in the bone marrow, as well as investigation of the changes in the microenvironment during immune-therapy.

Methods: A 3D bone marrow niche model was established that allowed engraftment of multiple myeloma (MM) cell lines and primary MM cells within a humanized bone marrow niche consisting of mesenchymal stroma cells and endothelial progenitor cells (Braham *et al.*, Oncoimmunology 2018). TEG001 cells were engineered from both healthy donor and multiple myeloma patients' T cells and added when MM growth was established. Homing, efficacy and toxicity of TEG001 cell treatment was evaluated using a combination of confocal microscopy and luminex technology.

Results: TEG001 cells, but not mock engineered T cells, migrated into the 3D structure and exerted a killing response towards the tumor cells but not towards the supportive stroma cells. Importantly, this cognate recognition was associated with the differential production of chemokines, cytokines and inhibitory molecules. Amongst others, TEG001 cells induced CCL1 secretion, but also the secretion of IL-6 and GM-CSF, reported to be involved in cytokine release syndrome. Soluble Galectin-9, the proposed ligand for inhibitory receptor TIM-3, was reduced in the supernatant.

Summary and Conclusions: These findings demonstrate that TEGs are a promising addition to the currently available immune therapeutic strategies as they target cancer as a metabolic disorder. Moreover, we show that 3D-bioprinted bone marrow model allows the interplay between malignant, stromal cells and tumor-targeting TEG001 cells and enables studying of immune therapy in a complex tissue environment. In addition to tumor targeting, this system is able to model treatment-related immune escape mechanisms of bone marrow derived cancers and may be of great value to improve the chance to successfully translate novel immune therapy concepts, such as TEGs, into patients.

PF394

DUAL TARGETING STRATEGY OF ACUTE MYELOID LEUKEMIA BY ENGINEERED CYTOKINE-INDUCED KILLER CELLS COEXPRESSING AN INTERLEUKIN 3 CHIMERIC ANTIGEN RECEPTOR (CAR) AND AN ANTI-CD33 COSTIMULATORY RECEPTOR

V.M. Perriello[1,2,*], M.C. Rotiroti[2], M.P. Martelli[1], B. Falini[1], S. Tettamanti[2], A. Biondi[2]

[1]CREO, University of Perugia, Perugia, [2]Department of Pediatrics, University of Milano-Bicocca, Tettamanti Research Center, Monza, Italy

Background: Acute myeloid leukemia (AML) is the most common acute leukemia in adults. Chemotherapeutic regimens are initially effective in most patients but only a minority achieves long-term survival (about 25% 5-year survival). Adoptive cell therapy with chimeric antigen receptor (CAR) engineered T cells could represent a promising approach to prevent relapse by targeting chemoresistant quiescent leukemic stem cells (AML-LSCs). CD123 (known as IL-3 receptor alfa) and CD33 are myeloid surface markers co-

expressed in up to 70% AML, commonly upregulated in AML-LSCs and in both NPM1 and FLT-ITD mutant AML. Anti-CD123 CAR redirected Cytokine Induced Killer (CIK) cells demonstrated a better safety profile against normal hematopoietic stem/myeloid progenitor cells (HSPCs) compared to anti-CD33 CAR CIK cells in preclinical studies, probably related to the lower CD123 expression by normal HSPCs. Despite that, CD123 expression in healthy tissues such as endothelial cells represents a possible on-target off-tumor effect. Here, we probe a dual targeting model to improve selectivity for CD123+/CD33+ cells through a first generation anti-CD123 IL-3 cytokine CAR and an anti-CD33 without activation signalling domains.

Aims: The aim of the present study is to explore the anti-leukemic efficacy of genetically-modified CIK cells coexpressing anti-CD123 IL-3 cytokine CAR and anti-CD33 costimulatory receptor.

Methods: We evaluated the *in vitro* efficacy profile of dual targeting IL.3(z).CAR/CD33(CD28-41BB).CCR CIK cells together with single targeting first generation IL-3.CAR CIK cells and third generation (CD28-4.1 BB) anti-CD33.CAR CIK cells. IL-3.CAR and anti-CD33.CAR were generated in separate SFG-retroviral vectors while, for the dual targeting model, the IL-3.CAR and CD33.CCR constructs were cloned between a self-cleavage 2A peptide in a unique retroviral construct. Fresh and frozen peripheral blood mononuclear cells were transduced with retroviral vectors at day 4 and 5 of the CIK cell differentiation process. The anti-AML activity of all CAR-CIK cell conditions was assessed by means of cytotoxicity (4 hours at 5:1 E/T ratio), proliferation (72 hours at 1:1 E/T ratio) and cytokine production (5 hours at 1:3 E/T ratio) assays upon challenge with highly CD123/CD33 positive THP1 AML cell line, the CD123/CD33 negative MHH-CALL4 cell line was used as control.

Results: Dual targeting IL-3.CAR/CD33.CCR CIK cells display a potent and specific *in vitro* anti-leukemic efficacy against THP1 cells as compared to non-transduced CIK cells. The killing efficiency of the dual targeting model was up to 90%, analogous to third generation anti-CD33.CAR+CIK cells. In addition, IL-3.CAR/CD33.CCR CIK cells proliferate (up to 30%) and secrete IL-2 (up to 15% of IL-2 producing CAR-CIK cells) and IFNγ (up to 80% of IFNγ producing CAR-CIK cells), almost equally to anti-CD33.CAR, when stimulated with THP-1 cells. IL-3.CAR alone display also a similar activity, suggesting a high binding affinity for the CD123 target.

Summary and Conclusions: These data demonstrate a potent antitumor efficacy mediated by dual targeting IL-3.CAR/CD33.CCR CIK cells and single targeting IL-3.CAR- and anti-CD33.CAR CIK cells.The absence of a truly AML-restricted antigen supports the use of a double targeting approach in order to increase the selectivity of CAR-redirected T cells towards the leukemic target. Considering the power of the anti-CD123 IL-3.CAR, we next aim to find strategies that could retain efficacy and at the same time minimize toxicity by lowering the IL-3.CAR affinity.

PF395

SYNERGISTIC T CELL SIGNALING BY CD79A/CD40 COSTIMULATORY ENDODOMAIN ENHANCES CD19 CHIMERIC ANTIGEN RECEPTOR T CELL PROLIFERATION AND SURVIVAL

J. Julamanee[1,2,*], S. Terakura[1], K. Miyao[1], S. Okuno[1], S. Kamoshita[1], E. Takagi[1], T. Sakai[1], S. Okazaki[1], D. Koyama[1], T. Goto[1], T. Nishida[1], M. Murata[1], H. Kiyoi[1]

[1]Department of Hematology and Oncology, Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]Department of Internal Medicine, Prince of Songkla University, Songkhla, Thailand

Background: Adoptive transfer of CD19 chimeric antigen receptor (CAR) T cell unveiled promising clinical outcomes, particularly in acute B-cell lymphoblastic leukemia (B-ALL). Among several studies, CAR-T cell persistence *in vivo* correlated with long-term clinical efficacy. Consequently, various costimulatory domains have been developed to improve T cell signaling, ultimately enhanced T-cell function and persistence. However, no novel signaling domains have been recently reported to be useful.

Aims: We adopted B-cell signal moiety, CD79A, and dendritic signal moiety, CD40, and generated the composite costimulatory domain of CD79A/CD40 to synergize T cell signaling in order to improve T cell proliferation and persistence.

Methods: The CD79A/CD40 costimulatory domain was developed and fused into anti-CD19scFv-CD28TM-CD3z-tEGFR construct. The CD19.79a.40z CAR gene was subsequently cloned into retroviral vector and transduced into human $CD3^+$ cells. The anti-EGFR mAb was used to assess CAR expression and purify, which resulted in achieving greater than 90% purity. We then expanded CD19 CAR-T cell by coculture with irradiated EBV-LCL. The expanded CD19.79a.40z CAR-T cells were further used for downstream experiments in order to compare with conventional CD19.28z CAR-T cells. In addition, CD19 CAR-transduced Jurkat-Dual luciferase reporter cells were also generated and used for NF- B signaling assay.

Results: The CD19 CAR genes were successfully transduced with similar transduction efficacy between the costimulatory domains. We next examined the NF- B activity and found significant higher NF- B signaling in CD19.79a.40z compared to CD19.28z upon $CD19^+$ target cells stimulation. Regarding cytokine production, the intracellular cytokine staining showed comparable proportions of IFN-γ^+ and IL-2^+ responders between CD19.79a.40z and CD19.28z CAR-T cells after stimulated with CD19-K562. The equal amounts of IFN-γ, IL-2, and TNF-α, produced by CD19.79a.40z and CD19.28z CAR-T cells, were also confirmed using ELISA. We next assessed T cell proliferation by coculturing CD19 CAR-T cells with CD19-K562 without exogenous IL-2. Surprisingly, the novel CD19.79a.40z exhibited robust T cell proliferation and persistence throughout 2 weeks of culture compared to CD19.28z (Figure 1). To analyze anti-tumor efficacy *in vitro*, we first performed a standard ^{51}Cr release assay and found similar cytotoxicity against CD19-K562 and two primary B-ALL samples between the costimulatory domains. We therefore did the coculture assay to examine the integrated activities of cytotoxicity as well as T cell expansion. Although CD19.28z CAR-T cells rapidly killed target cells in first few days, however, the target cell regrowth was observed after one week of culture. In contrast, CD19.79a.40z CAR-T cells could suppress target cell growth throughout the end of culture. To determine the plausible factors owing to T-cell survival advantage, we assessed T cell differentiation and exhaustion phenotypes upon antigen encounter and found no difference among the costimulatory domains. Lastly, we examined anti-tumor efficacy *in vivo* that a small survival advantage was observed in NALM-6 bearing mice treated with CD19.79a.40z CAR-T cells.

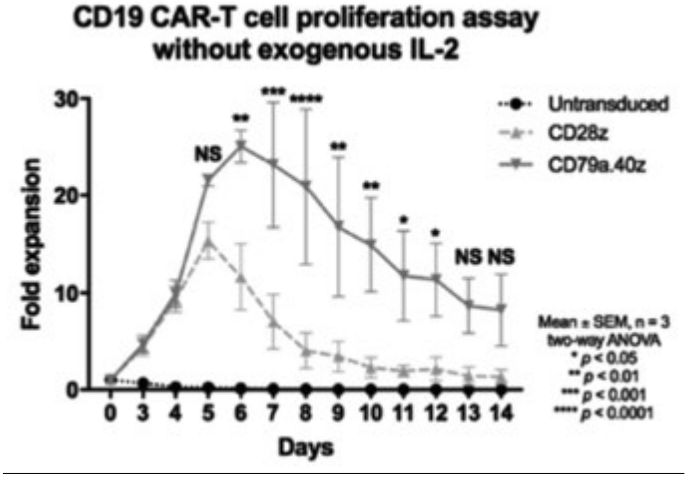

Figure 1.

Summary and Conclusions: The novel CD79A/CD40 costimulatory domain enhanced CD19 CAR-T cell proliferation and persistence, which improved anti-tumor efficacy. In addition, our construct exhibited higher NF- B activity upon antigen exposure, which possibly synergized to T-cell signaling and led to a proliferation advantage.

PF396

LENALIDOMIDE AND PROGRAMMED DEATH-1 BLOCKADE SYNERGISTICALLY ENHANCES THE EFFECTS OF DENDRITIC CELL VACCINATION IN A MODEL OF MURINE MYELOMA

S.-H. Jung[1], J.-J. Lee[1,2,*], M.-C. Vo[1], T.-H. Chu[1], H.-J. Lee[2], T.J. Lakshmi[1], H.-S. Park[1], H.-J. Kim[1], J.H. Rhee[2,3]

[1]Chonnam National University Hwasun Hospital, [2]VaxCell-Bio Therapeutics, [3]Chonnam National University Medical School, Hwasun-Eup, Korea, Republic Of

Background: The therapeutic efficacy of dendritic cell (DC)–based immunotherapy may be realized in combination with other anticancer therapies that enhance DC function by modulating immune responses and the tumor microenvironment.

Aims: In this study, we investigated the efficacy of DC vaccination in combination with lenalidomide and programmed death (PD)-1 blockade in a model of murine myeloma.

Methods: MOPC-315 cell lines were injected subcutaneously to establish myeloma-bearing mice and following five test groups were established: PBS

control, DCs, DCs+lenalidomide, DCs+PD-1 blockade, and DCs+lenalidomide+PD-1 blockade.
Results: The combination of DCs plus lenalidomide and PD-1 blockade strongly inhibited tumor growth compared to the other groups. This effect was associated with a reduction in immune suppressor cells (such as myeloid-derived suppressor cells, M2 macrophages, and regulatory T cells) and an increase in immune effector cells (such as $CD4^+$ and $CD8^+$ T cells, natural killer [NK] cells, and M1 macrophages) in the spleen. Functional activities of cytotoxic T lymphocytes and NK cells were also enhanced by the triple combination. Levels of immunosuppressive cytokines, such as TGF-β and IL-10, were significantly reduced in the tumor microenvironment.
Summary and Conclusions: These findings suggest that the combination of DCs plus lenalidomide and PD-1 blockade synergistically establishes a robust anti-myeloma immunity through a two-way mechanism, which inhibits immunosuppressive cells while activating effector cells with superior polarization of the Th1/Th2 balance in favor of the tumor immune response. This result would provide an experimental ground for incorporating check point inhibitors to existing immunotherapeutic modalities against multiple myeloma.

PF397

RNAI-MEDIATED SILENCING OF ENDOGENOUS TCR ENHANCES TUMOR KILLING ACTIVITY OF TCR-ENGINEERED WT1-SPECIFIC T CELLS

D. Campillo[1,*], F. Fujiki[2], J.M. Van den Bergh[1], H. De Reu[1], E.L. Smits[1,3,4], H. Goossens[1,5], H. Sugiyama[2], E. Lion[1,3], Z.N. Berneman[1,3,6], V.F. Van Tendeloo[1]

[1]Laboratory of Experimental Hematology, University of Antwerp, Edegem, Belgium, [2]Department of Cancer Immunology, Osaka University Graduate School of Medicine, Osaka, Japan, [3]Center for Cell Therapy & Regenerative Medicine, Antwerp University Hospital, [4]Center for Oncological Research (CORE), University of Antwerp, [5]Division of Clinical Biology, [6]Division of Hematology, Antwerp University Hospital, Edegem, Belgium

Background: The major bottleneck with standard cancer therapies is treatment failure leading to progressive disease or clinical relapse. The specificity of T cells for their cognate antigen turns them into an attractive and targeted cancer therapeutic. Unfortunately, the scarcity of tumor-reactive T cells and the difficulty of their isolation in sufficient numbers for adoptive cellular immunotherapy have hindered their clinical application. Gene transfer of a T cell receptor (TCR) specific for a tumor-associated antigen into T cells would confer redirected anti-tumor specificity to effector T cells for adoptive T-cell therapy. However, mispairing between transgenic and endogenous TCR alpha and beta chains results in reduction of transgenic TCR expression and potentially harmful reactivities.
Aims: Here, we sought to develop a novel non-viral, rapid and clinically safe strategy to promote transgenic expression of a Wilms' tumor 1 (WT1)-specific TCR by electroporation of Dicer-substrate small interfering RNA (DsiRNA) and codon optimized *TCR* mRNA electroporation.
Methods: First, we isolated and cloned an HLA-A*02:01-restricted WT1 peptide-specific TCR derived from a leukemia patient who demonstrated clinical benefit after receiving a WT1-targeted DC vaccine. Next, we produced a codon optimized *TCR* (WT1 *TCR*-co) sequence from the wild-type *TCR* construct (WT1 *TCR*-wt) and both *TCR* mRNAs were generated by *in vitro* transcription. In order to suppress the translation of endogenous *TCR* mRNA in $CD8^+$ T cells, DsiRNA duplexes were designed to specifically target the constant regions of endogenous TCR alpha (*TRAC*) and beta (*TRBC*) mRNAs, but not the codon optimized *TCR* mRNA. We further developed a sequential double electroporation protocol in which DsiRNA electroporation was performed 24 hours prior to transgenic *TCR* mRNA electroporation. To determine the epitope-specific activation and functionality of DsiRNA/TCR-engineered resting $CD8^+$ T cells, we analyzed the expression of CD69 and CD137, secretion of cytokines and cytotoxicity activity against epitope-bearing tumor cells.
Results: Our results show more than 2-fold increase in WT1 *TCR*-co TCR expression by HLA-A2/WT1 tetramer staining after DsiRNA treatment as compared to transgenic *TCR* mRNA electroporation only. Transgenic TCR expression was present at least 5 days after transgenic *TCR* mRNA electroporation in resting peripheral blood $CD8^+$ lymphocytes from healthy donors. The enhanced transgenic TCR expression in DsiRNA-transfected $CD8^+$T cells was also correlated with an increase of epitope recognition as shown by interferon (IFN)-γ ELISpot, higher levels of activation markers CD69 and CD137 and secretion of IFN-γ and granzyme B upon TCR triggering as compared to the non-DsiRNA treated T cells. Cytotoxicity, which was already present in WT1 *TCR*-wt and WT1 *TCR*-co mRNA-transfected cells, was significantly enhanced in WT1 *TCR*-co mRNA-electroporated T cells after suppression of the endogenous *TCR* by DsiRNA treatment.
Summary and Conclusions: In summary, we show a marked enhancement of transgenic codon optimized WT1-specific TCR expression upon silencing of the endogenous *TCR* using DsiRNA electroporation prior to *TCR* mRNA electroporation. Importantly, this enhancement in transgenic TCR expression was correlated with a significant increase in WT1-specific $CD8^+$ T-cell killing activity, expression of CD69 and CD137 and cytokine secretion after recognition of WT1 peptide-bearing target cells. These results pave the way for developing a clinically safer strategy for T-cell-based adoptive immunotherapy of patients with WT1-expressing malignancies.

ANTI-CD19 CAR T-CELL THERAPY IN ADULTS WITH RELAPSED/REFRACTORY AGGRESSIVE B-CELL MALIGNANCIES AS A BRIDGE TO ALLOGENEIC TRANSPLANTATION – THE EXPEIENCE OF A SINGLE CENTER

A. Avigdor[1,*], R. Shoval[1], A. Shimoni[1], O. Itzhaki[2], J. Schachter[2], A. Toren[3], E. Jacoby[3], M. Besser[4], A. Nagler[1]

[1]Division of Hematology and Bone Marrow Transplantation, Chaim Sheba Medical Center and Sackler School of Medicine, Tel Aviv University, [2]Ella Lemelbaum Institute for Immuno Oncology, Chaim Sheba Medical Center, Tel Hashomer and Sackler School of Medicine, Tel Aviv University, [3]Department of Pediatric Hematology-Oncology, Safra Children's Hospital, Chaim Sheba Medical Center and Sackler School of Medicine, [4]Ella Lemelbaum Institute for Immuno Oncology, Chaim Sheba Medical Center and Department of Clinical Microbiology and Immunology, Sackler School of Medicine, Tel Aviv University, Tel Hashomer, Israel

Background: Early encouraging results on treatment with T-cells expressing anti-CD19 chimeric antigen receptor (CAR) in relapsed/refractory (R/R) aggressive B non-Hodgkin lymphomas (B-NHL) have been recently published. The reported overall response rates (ORRs) compare favorably with historical data for patients treated with current standards of care. However, progression occurs in approximately 50% of responding patients in the first year. The impact of allogeneic stem cell transplantation (alloSCT) on outcome following CAR T-cell treatment is unknown.
Aims: We report the early results on the outcomes of adult patients (age 18-55) with R/R aggressive B-NHL, treated with locally produced CAR T-cells followed by consolidation with alloSCT.
Methods: This interim analysis is a part of a single center, phase 1b/2 study of CAR T-cell therapy in B-cell malignancies (NCT02772198) that is now underway in our center. Patients with R/R B-NHL and adequate organ function are eligible. The approach uses a CAR construct that is composed of an anti CD19 single-chain Fv, CD28 co-stimulatory and CD3-zeta intracellular domains. The CAR is transfected by retrovirus into bulk-stimulated autologous peripheral blood (PBL) cells. Treatment includes lymphodepletion with fludarabine and cyclophosphamide followed by infusion of fresh transduced T-cells. Responders proceed to an alloSCT. The primary end-points are safety and best ORRs 28 days after infusion.

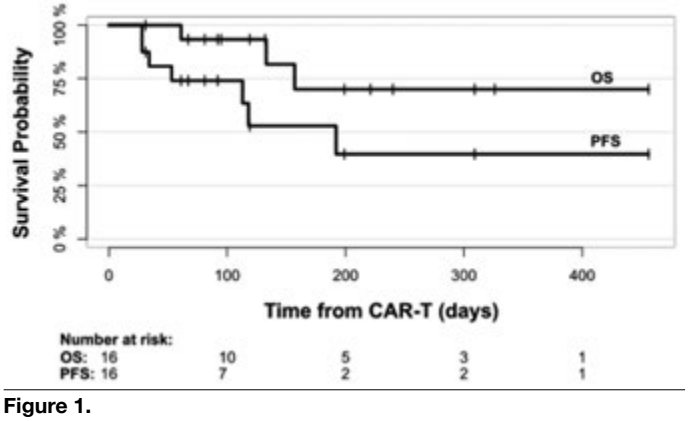

Figure 1.

Results: As of November 2016, 16 adult patients were enrolled. Thirteen patients were male. Median age was 36 years (range 23-52). Eleven patients were diagnosed with diffuse large B cell lymphoma (DLBCL, 8 – *de novo*, 2 - transformed and 1- primary mediastinal B cell lymphoma), 3 patients with B acute lymphoblastic leukemia and 2 with Burkitt lymphoma. Median number of prior therapies was 3 (range 2-5). Thirteen patients (81%) were refractory to their last therapy. Eight had a prior HSCT (4 - allogeneic and 4 - autologous). Ten days following apheresis patients received CAR T-cells at a median dose of 1 x 10^6/kg. Cells reached maximal expansion in PBL 7-14 days after infusion. Cytokine release syndrome occurred in 13 patients (83%), and was severe in one. Three patients (19%) experienced neurotoxicity (2 - grade 2, 1 - grade 3); one patient received tocilizumab and dexamethasone. No deaths were attributed to CAR T-cell therapy. alloSCT was performed in 11/16 patients (69%) at a median time of 59 days (range 48-126) after CAR T-cell infusion. Related toxicities were severe acute graft-*versus* host disease (2 patients) and sinusoidal obstruction syndrome (2 patients). At day 28 after infusion of CAR T-cells the ORs for the entire cohort and DLBCL group were 73% (47% CR) and 66% (33% CR), respectively. With a median follow-up of 7 months, 56% of patients continued to have a response. Median duration of response was 4 months (range 1-16). Three patients have died: 2 due to disease progression and one from transplant-related toxicity. Median progression free survival was 7 months and median overall survival was not reached (Figure 1).
Summary and Conclusions: Our interim results show that treatment patients with R/R B-cell malignancies with in-house produced CAR T-cells followed by consolidation with alloSCT is feasible. Our findings corroborate those from previous phase 2 studies, showing high ORRs. However, the durability of responses remains a major concern. Longer-term follow-up is needed to clarify the role of alloSCT in maintaining those responses.

PF399

EARLY MRD NEGATIVITY PREDICTS DEEPENING MYELOMA RESPONSE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM) PATIENTS TREATED WITH BB2121 ANTI-BCMA CAR T CELLS

N. Munshi[1,*], J. Berdeja[2], Y. Lin[3], J.M. Kochenderfer[4], N. Raje[5], M. Liedtke[6], S. Jagannath[7], D. Madduri[7], J. Rosenblatt[8], M. Maus[5], A. Turka[9], L.P. Lam[9], K. Hege[10], T. Campbell[10], M. Massaro[9], F. Petrocca[9], D. Siegel[11]

[1]Dana-Farber Cancer Institute, Boston, [2]Sarah Cannon Research Institute and Tennessee Oncology, Nashville, [3]Mayo Clinic, Rochester, [4]Experimental Transplantation and Immunology Branch, National Cancer Institute/Institutes of Health, Bethesda, [5]Massachusetts General Hospital Cancer Center, Boston, [6]Stanford University Medical Center, Palo Alto, [7]Mount Sinai Medical Center, New York, [8]Beth Israel Deaconess Medical Center, Boston, [9]Bluebird Bio Inc., Cambridge, [10]Celgene Corporation, San Francisco, [11]Hackensack University Medical Center, Hackensack, United States

Background: A high frequency of rapid minimal residual disease-negative (MRD-negative) responses has been seen in CRB-401, a phase I trial of bb2121 chimeric antigen receptor (CAR) T cell therapy for relapsed/refractory multiple myeloma (RRMM) (Kochenderfer, ASH 2017).
Aims: We report responses based on International Myeloma Working Group (IMWG) Uniform Response Criteria for Multiple Myeloma in MRD-negative patients and associated factors.
Methods: Patients treated with ≥150 × 10^6 anti-B-cell maturation antigen (BCMA) CAR+ T cells in the dose-escalation phase of CRB-401 and evaluable for MRD by Adaptive NGS-based MRD Assay (Adaptive Biotechnologies) were included in this analysis (n=10 as of 02 Oct 2017; median follow-up: 34 wks; min, max: 7, 67).
Results: Nine of 10 evaluable patients were MRD-negative with a sensitivity of 1 in 10^{-4} nucleated cells (1 patient), 1 in 10^{-5} (6 patients), and 1 in 10^{-6} (2 patients). Achievement of MRD negativity was independent of depth of response at first MRD-negative assessment; 2 patients had stable disease, 3 had partial response (PR), 2 had very good PR (VGPR), and 2 had complete response (CR)/stringent CR. Of 8 evaluable MRD-negative patients, all showed ≥85% and ≥97% decline in serum BCMA and involved free light-chain levels, respectively, at month (M) 1. Two of 9 MRD-evaluable patients were in CR at MRD-negative assessment and the remaining 7 achieved deeper response over time, 4 with CR or stringent CR, 2 with VGPR and 1 with PR between M1 and M15. One MRD-negative patient became MRD-positive at M12, and 1 MRD-negative patient had progressed as of data cut-off. Achievement of MRD negativity was independent of occurrence of cytokine release syndrome. MRD-negative status was observed across all active bb2121 doses (150 [n=3], 450 [n=5], and 800 x 10^6 [n=1] CAR+ T cells). Of 9 MRD-negative patients, 7 had at least 6 months follow-up and 1 had IMWG progression (at M6); 3 had at least 12 months follow-up, 1 had become MRD-positive, and none had IMWG progression. Attainment of MRD-negative status was independent of peak CAR T expansion (vector copy min, max: 93,744, 1,457,070 copies/µg gDNA; n=9) and was observed in high (>50%) bone marrow plasma cells (BMPC; n=6) and low BMPC (n=3) tumor burden patients. Eight of 9 MRD-negative patients had cytogenetic abnormalities including del(17), del(13), amp(1q21), or t(11:14).
Summary and Conclusions: bb2121 induced a high frequency of rapid MRD-negative responses, independent of IMWG MM responses. These early MRD-negative responses starting at M1 offer insights into bb2121 kinetics and may portend achievement of deeper responses.

PF400

FIRST-LINE THERAPY WITH DONOR DERIVED HCMV-SPECIFIC T CELLS PROMOTES ANTIVIRAL IMMUNITY BY RESTORING THE QUANTITY AND FUNCTION OF RECIPIENT'S ENDOGENOUS HCMV-SPECIFIC T CELLS AFTER ALLO-HSCT

X. Zhao[1,*], X. Pei[1], Y. Chang[1], Y. Wang[1], L. Xu[1], X. Huang[1,2]

[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking-Tsinghua Center for Life Sciences, Beijing, China

Background: Our previous trial had demonstrated that adoptive transfer with donor HCMV-specific T cells is a promising therapeutic option for the treatment of persistent human cytomegalovirus (HCMV) infection after allogeneic stem cell transplantation (allo-SCT). However, the safety and antiviral activity of adoptive transfer with donor HCMV-specific T cells as for first-line therapy for HCMV have yet to be established. In addition, the mechanisms driving the sustained antiviral immunity induced by adoptive T cell transfer remain undetermined. Previous studies reported that adoptive therapy with donor HCMV-specific T cells can enhance antiviral immunity concomitantly with the reduction of HCMV viremia. However, whether the recovery of HCMV-specific T cells is delivered by adoptive infused T cells, recipient's endogenous immune recovery after stimulation, or both, remains unknown.
Aims: i) To evaluate the safety and efficacy of first-line therapy with HCMV-specific T cells for HCMV infection. ii) To explore where the adoptive transferred cells trafficked and persisted, and identify whether adoptive T cell therapy could promote HCMV-specific immunity. iii) To investigate the recovery of HCMV-specific immunity were from the *in vivo* expansion of adoptive T cells or the recovery of recipient's endogenous T cells.
Methods: i) We conducted a prospective study of 21 allo-SCT patients who had a high risk developing refractory HCMV infection, and treated with donor HCMV-specific T cells together with antiviral drugs as first-line therapy when HCMV infection was diagnosed. Another group of 21 matched patients only treated with antiviral drugs were selected as controls. The quantitative and functional recovery of HCMV-specific T cells were monitored in both cohorts. ii) We transferred HCMV-specific T cells labeled with both of BrdU and CFSE to HCMV infected humanized mice, and explored the recovery of HCMV-specific antiviral immunity in transferred mice and control mice.
Results: i) First-line therapy with HCMV-specific T cells promoted the quantitative and functional recovery of HCMV-specific T cells, and showed a trend to reduce the persistent HCMV reaction rate (4.8% *vs* 28.6%, *P*=0.038) and HCMV disease rate (0% *vs* 4.8%, *P*=0.311) compared to control group. There were no significant side effects attributable to adoptive T cell infusion. ii) Adoptive transferred HCMV-specific T cells had the ability homing to the bone marrow, spleen and liver, and diminished HCMV pathology in humanized mice. A preferential *in vivo* proliferation of HCMV-specific T cells were observed, and peak of HCMV-specific T cells were on day 14 after adoptive therapy. However, rate of the transferred HCMV-specific T cells was reduced over time, and on day 21 post infusion all of the proliferated HCMV-specific T cells were recipient's endogenous T cells. These observations indicated that adoptive T cell therapy most likely contributed to endogenous HCMV-specific T cell reconstitution.
Summary and Conclusions: First-line therapy for HCMV infection with donor HCMV-specific T cells showed prolonged benefit which promoted the quantitative and functional recovery of HCMV-specific T cells and decreased the rate of refractory CMV infection. However, the long-term recovery of the HCMV-specific immunity mainly developed from the restoring of recipient's endogenous T cells, not the expansion of transferred cells.

PF401

LONG TERM OUTCOMES OF TABELECLEUCEL (ALLOGENEIC THIRD-PARTY EBV-TARGETED CYTOTOXIC T LYMPHOCYTES) FOR RITUXIMAB-REFRACTORY POST-TRANSPLANT EBV+ LYMPHOMAS: A SINGLE CENTER EXPERIENCE

S. Prockop[1,*], E. Doubrovina[1], A. Feng[2], G. Koehne[3], P. Dahi[4], E. Papadopoulos[4], C. Sauter[4], S. Suser[1], W. Navarro[2], A. Sudhindra[2], R. O'Reilly[1]

[1]Pediatric BMT, Memorial Sloan Kettering Cancer Center, New York, [2]Clinical Development, Atara Biotherapeutics, Westlake Village, [3]BMT and Hematologic Oncology, Miami Cancer Institute, Miami, [4]Adult BMT, Memorial Sloan Kettering Cancer Center, New York, United States

Background: Monoclonal EBV+ post-transplant lymphoma disorders (PTLD) following solid organ transplant (SOT) or hematopoietic cell transplant (HCT) are life-threatening. Patients (pts) who fail rituximab(R)-based therapy have limited treatment options. R failure in EBV+ PTLD following HCT portends a dismal prognosis with a median overall survival (OS) in the range of 16-56 days (d). Pts with EBV+ PTLD following SOT tolerate anthracycline-based chemotherapy more poorly than non-immunocompromised lymphoma pts. Effective therapy with lower toxicity is needed. We have previously shown that treatment with tabelecleucel (tab-cel™) results in durable responses and a 1-year OS rate of 50-67% in R-refractory EBV+ PTLD pts after HCT (Prockop AACR 2015). Here we report longer-term study results of tabelecleucel for pts with EBV+PTLD following HCT or SOT.
Aims: Report updated long-term survival results of tabelecleucel in pts with EBV+ PTLD following HCT or SOT
Methods: Protocols 11-130 and 95-024 were single-center, open-label studies enrolling pts with EBV+ PTLD following HCT or SOT and other EBV-driven malignancies with measurable disease and adequate organ function and performance status. Pts providing signed informed consent were treated with tabelecleucel sharing ≥2/10 HLA alleles with the disease, including ≥1 HLA allele through which tabelecleucel exerts cytotoxicity (HLA restriction). Tabelecleucel was given at 2 x 10^6 cells/kg/dose (Protocol 11-130) or 1-2 x 10^6 cells/kg/dose (Protocol 95-024) on d1, 8, and 15 of every 4-6 week cycle with imaging at ~d35 of each cycle. Pts could receive multiple cycles of tabelecleucel.
Results: Across both studies from 1995-2017, 50 (35 HCT; 14 SOT) pts with PTLD after R-based failure received tabelecleucel (Table 1).

Table 1.

Median (range)	HCT-Associated PTLD (N=35)	SOT-Associated PTLD (N=14)
Age: yrs	28 (5-74)	18 (6-77)
Karnofsky Score—adults (Protocol 11-130 only)	70 (30-100, n=23)	60 (40-90, n=7)
Time from Diagnosis to Start of Tab-cel: months (mos)	1.2 (0.2-14.6)	13.3 (1.2-139)
Cell Dose: cells/kg/dose	2 x 10^6 (0.9-2.4)	1.9 x 10^6 (1.6-2.4)
Number of Cycles	2 (1-5)	2 (1-6)
Duration of Treatment: mos	1.4 (0.4-25.5)	1.4 (0.05-14.5)
Duration of Follow-Up: mos	23.3 (0.5-88.9)	21.3 (0.3-115)

The 1-yr Kaplan-Meier (KM) estimated OS for pts with PTLD following HCT and SOT is 68 and 64%, respectively. Median OS for HCT PTLD pts has not been reached after a median follow-up of 23.3 mos; median follow-up for SOT pts was 21.3 mos and median OS is 21.3 mos. Treatment-related serious adverse events (SAEs) were reported in 1 and 1 pts with PTLD following HCT and SOT, respectively.
Summary and Conclusions: Long term follow-up of pts with R-refractory PTLD following HCT or SOT treated with tabelecleucel shows durable responses and low incidence of related SAEs. Median OS for HCT pts with PTLD was not reached with a median follow-up time of 23.3 mos; recognizing limitations of cross-study comparisons, this represents a marked improvement compared to reports for this pt population prior to tabelecleucel. Phase 3 studies of tabelecleucel in pts with R relapsed/refractory PTLD after HCT or SOT are underway.

PF402

THE EFFICACY AND SAFETY OF HUMANIZED CD19 CAR-T CELLS FOR RELAPSED OR REFRACTORY B-CELL NON-HODGKIN LYMPHOMA (NHL): A PRELIMINARY REPORT

H. Huang[1,*], J. Cai[1], F. Xiao[1], X. Han[1], B. Ni[1], T. Yin[1], Z. Li[2], F. Chen[1], J. Hou[1]

[1]Department of Hematology, Ren Ji Hospital, School of Medicine, Shanghai Jiaotong University, Shanghai, China, [2]State Key Laboratory of Oncogenes and Related Genes, Shanghai Cancer Institute, Ren Ji Hospital, School of Medicine, Shanghai Jiaotong University, Shanghai, China

Background: Chemo-resistant, advanced B cell lymphomas are difficult to treat and often fatal. Recent studies have shown that chimeric antigen receptor (CAR) T cells have shown promising results in patients with B cell malignancy. However, CAR-T therapy-associated adverse systemic responses can be life-threatening. Therefore, how to optimizing CAR-T therapy regimen is key to the success of such innovative treatment.
Aims: The safety and efficacy of administering autologous humanized CD19 CAR-T cells to patients with relapsed or refractory (R/R) CD19(+) B-cell non-Hodgkin lymphoma (NHL) were assessed. Herein we report preliminary results from the single institute using CD19 CAR-T cells to treat R/R B-cell NHL. This study is registered at www.clinicaltrials.gov as #NCT02933775.
Methods: Patients with relapsed or refractory CD19+ B-cell NHL were eligible, provided there was no curative treatment available. Autologous CAR-T cells were manufactured by CARsgen Therapeutics. Patients received a conditioning chemotherapy regimen of cyclophosphamide and fludarabine

followed by infusion of CD19 CAR-T cells. Cyclophosphamide (400mg/m^2) was given from d-6 to d-5 and fludarabine (20mg/m^2) from d-6 to -4 or -3. The primary objective of the trial is to evaluate the safety of humanized CD19 CAR-T Cells as determined by the incidence of dose-limiting toxicities. Key secondary objectives include evaluating the overall response rate, duration of response, levels of CAR-T cells in the blood, and levels of serum cytokines. Cytokine release syndrome (CRS) was graded per revised criteria (Lee *et al.* Blood 2014).

Results: Three patients were enrolled into this prospective cohort until March 2018. Patient 1 was diagnosed as mantle cell lymphoma (MCL) in 2015, obtained complete remission (CR) after 6 cycles of R-CHOP and relapsed after 12-month follow-up. Patient 2 had diffuse large-B cell lymphoma (DLBCL) diagnosed in 2016 and she never achieved CR after several lines of immune-chemotherapy regimens. Patient 3 had DLBCL (double-expressor lymphoma) diagnosed in 2017, obtained partial remission (PR) after 3 cycles of R-CHOP and progressed after additional 3 cycles of same regimen. The patients received infusion of CAR-T cells (1x10^7 cells patient#1; 3x10^7 patient#2; 6x10^{7}patient#3). One month after CAR-T cells infusion, the PET-CT or CT scan showed all of the three patients responded to treatment (1/3 CR; 2/3 PR) without any symptoms of CRS. Laboratory test indicated the cytokines were dramatically increased in the peripheral blood 3 days after infusion and began to decrease gradually, especially serum IL-8 levels. The circulating CAR transgene can still be detected after 1 month and remained in high level. All patients had neutropenia (grade II adverse events) and lymphocytopenia (grade III to IV adverse events). No other adverse events were found during the treatment. Up to submission of this abstract, patient#1 and #3 remained in remission after 9 and 5 months post CAR-T infusion respectively. Patient#2 progressed after 3 months and was still alive after 8 months post CAR-T infusion.

Summary and Conclusions: This is the first report of successful treatment of R/R B-cell NHL with humanized CD19 CAR-T cells. The efficacy and safety demonstrated by these preliminary results provides strong support for further study of this approach.

PF403

THE STUDY OF LYMPHOCYTES SUBPOPULATIONS IN PERIPHERAL BLOOD OF PATIENTS WITH AND WITHOUT GVHD PROPHYLAXIS BY MEANS OF MULTIPOTENT MESENCHYMAL STROMAL CELLS AFTER ALLOGENEIC BMT

Y. Davydova[1,*], N. Kapranov[1], I. Galtseva[1], N. Petinati[1], N. Drize[1], L. Kuzmina[1], E. Parovichnikova[1], V. Savchenko[1]

[1]*National Research Center for Hematology, Moscow, Russian Federation*

Background: Multipotent mesenchymal stromal cells (MSCs) are increasingly used to modulate immune responses in conditions related to auto-alloimmunity, including graft *versus* host disease (GVHD). The mechanisms that possibly underlie the capacity of MSCs to treat and prevent GVHD are still obscure. Most studies involve extensive characterization of the heterogeneity within and between different MSC preparations. Patient monitoring can help to identify the *in vivo* mechanisms of action in the treatment of GVHD.

Aims: The aim of the study is to analyze the alterations in lymphocytes subpopulations in patients soon after the injection of MSCs and a month later.

Methods: The study included 28 patients received allo-BMT from related donors after informed consent. The patients were randomized into 2 groups: first received standard prophylaxis of GVHD (n=13) and the second (n=15) were additionally infused with MSCs from the bone marrow of corresponding hematopoietic stem cells donor. MSCs were administered intravenously when the blood counts indicated recovery (WBC ≥1x10^9/l). Lymphocytes markers CD25, HLA-DR, PD-1 as well as distribution of naïve and effector cells were studied by flow cytometry on day 0 just before MSCs injection, day 3 and day 30 after MSCs injection. Differences between treatments groups were analyzed using Student's t-test for normally distributed data and the Mann–Whitney test for non-normal distributions.

Results: The Table 1 shows the composition of lymphocyte population. On day 0 before MSCs injection there were no significant differences between the groups. The absolute number of CD4+ transitional memory (TM) cells increased 3 times (p=0.029), CD8+ terminal effectors (TE) 8 times (p=0.05), CD4+PD-1+ 4 times (p=0.019) on 3rd day after MSCs injection in comparison with the control group. The subpopulations of CD4+ central memory (CM) increased 2.3 times (p=0.007); CD4+TM - 2.8 times (p=0.05); CD4+TE - 3.5 times (p=0.01); CD8+TE - 2.7 times (p=0.03); CD4+CD25+ - 2.8 times (p=0.02) and T reg 2.3 times (p=0.007) on 30th day after MSCs injection in comparison with the control group. The remaining subpopulations of lymphocytes did not differ significantly between the groups either 3 or 30 days after the MSCs administration. A significant increase in the number of central memory and effector memory cells, as well as CD4+CD25+ in the peripheral blood of patients after MSCs administration, in the absence of changes in the number of naive T cells, indicates the activation of cells participating in the adaptive immune response. The incidence of infections was lower in the group of patients with MSCs (27% *vs* 50%, non-significant). The number of CD8+TE was 4 times lower in patients with infections (p=0.004). The increase in the T-reg subset confirms the possibility of MSCs modulating immune response in the development of acute GVHD.

Table 1.

Cells number	Day 0		Day 3		Day 30

Summary and Conclusions: The alterations in lymphocytes subpopulations caused by MSCs may contribute to prevention of infectious complications and GVHD.

PF404

LIVE ATTENUATED VARICELLA ZOSTER VIRUS VACCINATION TO ADULT T-CELL LEUKEMIA/LYMPHOMA PATIENTS CAN INDUCE TUMOR SPECIFIC CELLULAR IMMUNITY

T. Jo[1,*], K. Horio[1], J. Taguchi[1]

[1]*Hematology, Japanese Red Cross Nagasaki Genbaku Hospital, Nagasaki, Japan*

Background: Adult T-cell leukemia/lymphoma (ATLL) is caused by human T lymphotropic virus type I (HTLV-I). ATLL is still quite difficult to be cured despite lots of researchers and clinicians have struggled for this entirely refractory hematologic malignancy for more than 40 years. Up-regulation of cellular immunity such as HTLV-I Tax-specific cytotoxic T cells (CTLs) has been proved to be important to win long time survival through knowledge of previous experiments and clinical experiences. However, no efficacious method to activate ATLL specific cellular immune response is available at present.

Aims: We planned this clinical study to investigate if Live Attenuated Varicella Zoster Virus (VZV) vaccination to ATLL patients can activate HTLV-I Tax specific cellular immune response. We also examined TCR V beta repertoire pre- and post-VZV vaccination. The primary objective is whether the percentage of Tax-specific CTLs after VZV vaccination increases.

Methods: It was planned that 3 indolent (smoldering or favorable chronic) type ATLL and 3 to 5 aggressive (acute, lymphoma, and unfavorable chronic) type ATLL patients to be enrolled in this study. VZV vaccination was conducted twice with at least 12 weeks interval between 2 doses. VZV vaccination method was changed for patients enrolled after May 2017 to 2 courses. Each course included up to 5 doses of vaccine with 1 to 4 weeks intervals.

Results: The enrollment of patients started from May 2016. Three indolent type (smoldering) patients and 2 aggressive type ATLL (1 acute, 1 lymphoma) patients were enrolled in this study. The aggressive type ATLL (lym-

phoma) patient was enrolled after May 2017 and subjected to the changed VZV vaccination protocol. The aggressive (1 acute and 1 lymphoma) type patients had VZV vaccination after the end of whole courses of anti-ATLL therapy including mogamulizumab (Moga, an anti-CCR4 monoclonal antibody) and combination chemotherapy including EPOCH therapy and VCAP-AMP-VECP therapy. Treatment effect after finishing Moga plus chemotherapy was complete remission in both patients. On the other hand 3 indolent type patients had VZV vaccination without any anti-tumor treatment. In all enrolled patients, no grade 3/4 adverse event due to VZV vaccination has been observed up to the present. Figure 1 shows the results of Tax-specific CTLs using tetramer assay in 1 smoldering and 2 aggressive type patients. There was no significant change in 2 indolent type patients (data not shown). However, moderate elevation from 0.15% (pre-vaccination) to 0.27% (post vaccination) was observed in 1 indolent type patient (Figure 1A). Obvious elevation of Tax-specific CTLs was observed in 2 aggressive type patients. The percentages changed from 0% to 0.07% in the acute type patient (Figure 1B) and from 0.02% to 0.75% in the lymphoma type patients (Figure 1C) after VZV vaccination. No disease progression has been observed in 3 indolent type patients, and complete remission has been maintained for more than 750 days in the acute type patient and 460 days in the lymphoma patient since the beginning of immunochemotherapy at present.

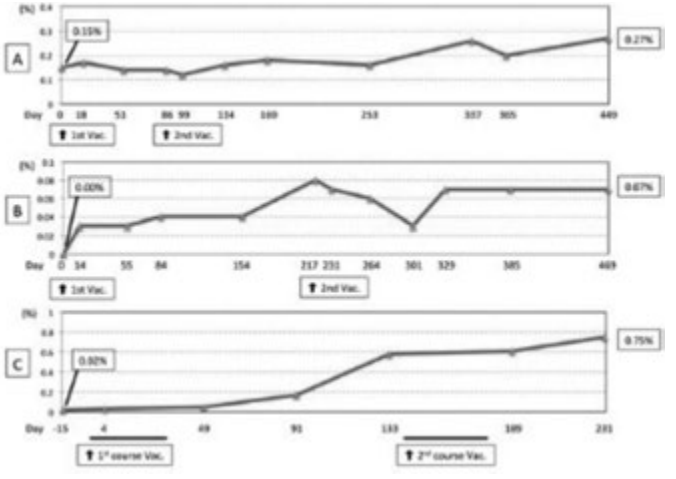

Figure 1. Tax-specific CTL/CD8+ T cell (tetramer assay).

Summary and Conclusions: These data suggest that VZV vaccination to aggressive type ATLL patients after Moga plus chemotherapy can up-regulate HTLV-I Tax-specific CTLs without any problematic adverse events. Enrollment for aggressive type ATLL patients is on going at present.

PF405

PRODUCTION OF ARI-0001 CELLS (A3B1:CD8:4-1BB:CD3Z CAR19 CELLS) IN PATIENTS WITH CD19+ RELAPSED/REFRACTORY B-CELL MALIGNANCIES USING THE CLINIMACS PRODIGY SYSTEM

M. Caballero-Baños[1], J. Delgado[2,*], S. Rives[3], M. Castella[1], V. Ortiz-Maldonado[2], A. Boronat[1], E. Garcia-Rey[4], J. Cid[5], M. Lozano[5], B. Marzal[1], J.M. Canals[6], A. Vilarrodona[4], J. Tabera[4], E. Trias[4], A. Urbano-Ispizua[2], J. Yagüe[1], M. Juan[1]

[1]Immunology, [2]Hematology, Hospital Clinic, [3]Hematology, Hospital Sant Joan de Deu, [4]Banc de Sang i Teixits, [5]Apheresis Unit, Hospital Clinic, [6]University of Barcelona, Barcelona, Spain

Background: The prognosis of relapsed or refractory (R/R) B-cell malignancies is very poor, particularly in patients relapsing after, or ineligible to, allogeneic hematopoietic cell transplantation (alloHCT). In the last decade, several chimeric antigen receptor targeting CD19 (CAR19) constructs have been developed. One of them (tisagenlecleucel) was approved by the FDA for pediatric or young adults with R/R ALL. The other construct (axicabtagene ciloleucel) was approved by the FDA for R/R diffuse large B-cell lymphoma after two or more lines of systemic therapy.
Aims: To produce our own CAR19 (ARI-0001) cells for clinical use in patients with R/R CD19-positive B-cell malignancies recruited into the CART19-BE-01 clinical trial
Methods: We selected the anti-CD19 A3B1 hybridoma licensed by our institution, identified the scFv sequence and incorporated the CD8, 4-1BB and CD3z modules next to it. We cloned it into a 3rd generation lentiviral vector and transduced PBMCs from buffy coats after activation with CD3 and CD28 TransACT polymeric nanomatrix (ARI-0001 cells). Once cytotoxicity and specificity were confirmed *in vitro* and *in vivo* (in NALM6-xenograft NSG murine models), we scaled-up both lentiviral and cell production, the latter using the CliniMACS Prodigy System (Miltenyi). After reaching all pre-specified acceptance criteria in lymphoaphereses from 3 healthy donors, the Spanish Agency of Medicines approved our IND and also our first pilot clinical trial (clinicaltrials.gov NCT03144583) on May/2017. Eligibility criteria included R/R ALL (adult and pediatric), non-Hodgkin's lymphoma and chronic lymphocytic leukemia (CLL) who had failed all standard available therapy.
Results: As of February 2018, we have recruited 14 patients with R/R CD19+ B-cell malignancies, 10 patients with ALL, three patients with DLBCL and one patient with CLL. Patients with ALL (with one exception) had relapsed after alloHCT. Median age was 22.5 years (range 3-54) and 42% were female. Six out of 10 patients with ALL had active disease at the time of study inclusion, while all 4 patients with DLBCL/CLL had progressive disease upon inclusion. We successfully prepared ARI-0001 cells in all but two patients, who required two procedures each (2/16 [12.5%] production failure rate). Causes of production failure were bacterial contamination (1 patient) and insufficient viral transduction (1 patient). The median total number of cells harvested after 8-10 days of culture was 1350 $x10^6$(range, 230-3400 $x10^6$). The median percentage of CD3+ cells was 97.5% (median of CD4+ cells 56%; median of CD8+ cells 42%). The median percentage of ARI-0001 cells in the cell product was 30.15% (range, 20.4-72.3). After fludarabine (90 mg/m^2) and cyclophosphamide (900 mg/m^2) chemotherapy, we have infused 0.5-5 $x10^6$ ARI-0001 cells/kg to 11 patients. In one patient, the infusion was delayed due to pneumonitis and the other two patients are awaiting quality control results. In all infused patients, ARI-0001 cells were detected in peripheral blood together with B-cell aplasia.
Summary and Conclusions: It is feasible to prepare CART19 (ARI-0001) cells in a purely academic setting using the automated CliniMACS Prodigy System and home-made lentiviral vectors. The production failure rate was 12.5% and yet enough cells were produced in all patients (two required two procedures).

Hematopoiesis, stem cells and microenvironment

BLOOD-CIRCULATING BILE ACIDS SUPPORT EXPANDING HEMATOPOIETIC STEM AND PROGENITOR CELLS AND IMPROVE RECOVERY FROM MYELOSUPPRESSIVE CHEMOTHERAPY

V. Sigurdsson[1,*], Y. Haga[2], V. Radulovic[1], H. Takei[3], M. Suzuki[1], C. Okamatsu-Haga[4], M. Van Der Garde[1], E. Mansell[1], S. Koide[1], H. Nittono[3], A. Ohara[2], K. Miharada[1]

[1]Dep. Molecular Medicine and Gene Therapy, Lund University, Lund, Sweden, [2]Department of Pediatrics, Toho University Omori Medical Center, [3]Junshin Clinic Bile Acid Institute, Tokyo, [4]Department of Pathology, Tokai University School of Medicine, Kanagawa, Japan

Background: Chemotherapeutic agents and irradiation can damage hematopoietic stem and progenitor cells (HSPCs) in bone marrow and cause prolonged myelosuppression or myeloablation in the worst cases. These side effects are among the most common life-threatening complications of cancer treatment. It is hard to predict in which patients this will be problematic but will limit the tolerability of the therapy, result in a delay and/or discontinuation of the treatment protocol and can impact cancer free survival of patients. Previously, we discovered a novel role for bile acids (BAs) as key components in the expansion of HSPCs in fetal development and that BAs suppress the activation of the unfolded protein response (*Sigurdsson et al., Cell Stem Cell, 2016*). Recently we have seen that BAs are upregulated in plasma of pediatric cancer patients undergoing chemotherapy.
Aims: The aim of the project was to explore if bile acids supported recovery of the hematopoietic system and HSPCs after chemotherapy.
Methods: To study the role of bile acids during hematopoietic recovery we used pediatric patient material, mouse models of altered BA levels and composition and BA supplementation to 5-Fluorouracil treated mice.
Results: We have discovered that BAs are highly increased in systemic circulation, specifically during recovery from myelosuppression and that this is correlated to improved clinical outcome in pediatric patients. Mice treated with 5-Fluorouracil (5-FU) showed a similar upregulation of BAs, during recovery. Using a mouse model of altered bile acid composition, *Cyp8b1* KO mice, we see that a subset of mice recover poorly after 5-FU chemotherapy. The poor recovery was connected to low expression levels of key BA production enzymes in liver and subsequent low levels and changed composition of total BAs in systemic circulation. In line with this, BA supplementation, using TUDCA, in 5-FU treated WT mice resulted in significantly improved recovery (Figure 1).

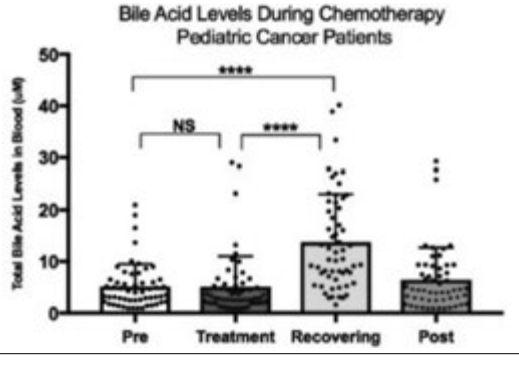

Figure 1.

Summary and Conclusions: Our results indicate that bile acids are a part of the recovery system in hematopoietic regeneration, and a potential supportive factor for rapid and efficient recovery from myelosuppression.

PF407

EARLY GROWTH RESPONSE (EGR)-1 IS A KEY REGULATOR OF HUMAN PRIMARY BONE MARROW STROMA CELLS WITH A DUAL ROLE IN PROLIFERATION AND HEMATOPOIETIC STROMA SUPPORT FUNCTION

H. Li[1], R. Ghazanfari[1], H. C. Lim[1], J. Hansson[1], D. Zacharaki[1], S. Scheding[2,*]

[1]Molecular Hematology, University of Lund, [2]Hematology, University Hospital Lund, Lund, Sweden

Background: Bone marrow mesenchymal stem cells (BMSCs) are essential constituents of the hematopoietic stem cell (HSC) niche with potent hematopoietic stroma function and multilineage differentiation capacity. Despite considerable progress in the identification of the bona fide MSC in human bone marrow, little is known about how BMSCs are regulated. Our previous gene expression profiling data demonstrated that the expression level of early growth response 1 (EGR1) in primary colony-initiating bone marrow MSCs was substantially higher compared to the non-colony-forming cells and cultured stromal cells, respectively.
Aims: The regulatory role of EGR1 in human BMSC has thus far not been investigated. In this study, we therefore studied the functional role of EGR1 for BMSC proliferation and hematopoietic supporting function.
Methods: EGR1 expression and function in human bone marrow stroma cells were evaluated by gene expression analysis, proteomics, gain-of-function and loss-of function approaches, and CD34 expansion and transplantation assays.
Results: EGR1 expression was 126.9±9.1-fold and 2.8±0.2-fold higher in highly fibroblast colony-forming cells (CFU-F) enriched human primary $lin^-/CD45^+/CD271^+/CD140a^-$ bone marrow cells compared to the non-colony forming $CD45^-/CD271^-$ cell population and $CD45^-/CD271^+/CD140a^+$ cells, which contains minimum CFU-F activity.
The hematopoietic supporting function of EGR1 was evaluated by co-culturing cord blood (CB) $CD34^+$ cells with EGR1 knockdown or EGR1 overexpressing stromal cells. HSC function of the expanded $CD34^+$ CB cells was evaluated by *in-vivo* transplantation into NSG mice. Both the percentage and absolute number of transplantable $CD34^+CD90^+$ hematopoietic stem cells (HSCs) were reduced in co-cultures with EGR1 knockdown cells as supporting stroma, while HSC production was significantly increased in co-cultures with EGR1 overexpressing cells. *Ex vivo* CB $CD34^+$ expansion experiments using transwell assays and stroma cell-conditional medium demonstrated that the EGR-1 mediated hematopoietic support was mediated by both soluble factors and direct cell-cell contact. Array-based gene expression profiling demonstrated upregulation of multiple hematopoietic supporting genes in EGR1 overexpressing stromal cells. Of these, a functional role was demonstrated for CCL28 (soluble factor) and for surface expressed VCAM1, which is mediating cell-cell contact.
EGR1 knockdown, on the other hand, resulted in enhanced colony-forming capacity and reduced population doubling times compared to controls. In contrast, CFU-F activity was virtually absent in EGR1 overexpressing cells. Proteomic profiling of EGR1 knockdown stromal cells identified a group of downregulated proteins related to oxidative-reduction processes, and reactive oxygen species (ROS) levels were indeed elevated in EGR1 knockdown cells, which explained the increased cell proliferation of these cells
Summary and Conclusions: In summary, EGR1 is highly expressed by primary BM-MSC compared with non-colony forming cells. EGR1 expression negatively regulates BMSC proliferation while positively regulating hematopoietic stroma support function. Increased proliferation of EGR1 knockdown cells is (at least in part) mediated by elevated ROS levels, while the enhanced hematopoietic support of EGR1 overexpressing cells is mediated by upregulation of a number of hematopoietic supporting genes. Our data thus indicate that EGR1 is an important MSC regulator coordinating the specific functions of BMSC in their different biological contexts.

PF408

A SINGLE-CELL RNA-SEQUENCING ATLAS OF THE MOUSE SPLEEN

R. Chawla[1,2,3,*], M. Wray-Dutra[4,5], D. Jackson[3], D. Rawlings[4,5,6], R. James[5,6,7], C. Trapnell[3,8]

[1]Department of Pediatric Hematology & Oncology, University of Basel Children's Hospital, [2]Department of Biomedicine, University of Basel, Basel, Switzerland, [3]Department of Genome Sciences, [4]Department of Immunology, University of Washington, [5]Center for Immunity and Immunotherapies, Seattle Children's Research Institute, [6]Department of Pediatrics, [7]Department of Pharmacology, [8]Molecular & Cellular Biology Program, University of Washington, Seattle, United States

Background: B cells constitute a principal component of humoral immunity and their dysregulation leads to numerous human diseases. Following activation, B cells undergo terminal differentiation within secondary lymphoid organs such as the spleen, giving rise to antibody-secreting plasma cells. Much effort has been devoted towards the classification and characterization of B-cell subsets. Yet, most studies to date are biased in that the subsets are classified on the basis of cell surface marker expression and characterized in bulk.
Aims: We set out to dissect the cellular components of the murine spleen in a completely unbiased manner using single-cell RNA-sequencing and to study their dynamics upon immunization with a T cell-dependent antigenic

stimulus. By comparing the cellular and molecular dynamics in wildtype mice *vs* different transgenic mouse models, we also aimed to shed light on mechanisms underlying lymphomagenesis.
Methods: We immunized wildtype and transgenic mice with degenerating sheep red blood cells and prepared single-cell suspensions from spleens harvested at different time points post-immunization. Following immunomagnetic B-cell enrichment, single-cell cDNA libraries were generated using a commercially available, droplet-based platform and sequenced using standard next-generation sequencing pipelines. Established computational methods were used for the processing of sequencing reads, as well as for the subsequent, in-depth analysis.
Results: We have thus far generated single-cell expression profiles of nearly 40,000 murine spleen cells across different conditions. Using unsupervised clustering, we were able to classify not only broad cell types but also many cellular subtypes and define their expression signatures in a completely unbiased manner. Besides validating the known splenic B-cell subsets, including transitional, follicular, marginal zone, B1a, germinal center (GC) B cells, and differentiated plasma cells, we found a previously uncharacterized follicular B-cell population with a strong type I interferon response signature. Differential gene expression analysis demonstrated that naïve B cells exhibit a much lower total mRNA abundance than activated B or plasma cells, revealed both known and new markers for the identified B-cell subsets, and uncovered novel insights into the patterns of immunoglobulin expression. Moreover, we were able to generate branched developmental trajectories which suggest that early B-cell maturation into plasma cells occurs primarily via an extrafollicular pathway rather than via the GC. Finally, we found that expression of a constitutively activate version of CARD11 in B cells promoted skewing of GC B cells towards a dark zone phenotype, along with enhanced class switching of both GC B and plasma cells.
Summary and Conclusions: In conclusion, we used single-cell RNA-sequencing to dissect the cellular components of the murine spleen, thereby defining the transcriptional signatures of multiple B-cell subtypes and maturational stages, and gain novel insights into the kinetics of B-cell maturation, both in wildtype and transgenic settings. Importantly, this dataset is the first to offer an unbiased classification of virtually all splenocytes, and we are hopeful that it will serve as a reference to immunologists and genomicists alike.

PF409

BONE MARROW ERYTHROPOIETIC DEFECT ACCOMPANYING EXTRAMEDULLARY HEMATOPOIESIS IS MIMICKED BY DOWNREGULATION OF NOTCH SIGNALING IN SPECIFIC MICROENVIRONMENT

T. Sakamoto[1,2,*], N. Obara[1], H. Nishikii[1], T. Kato[1], R. Fujimura[3], L. Cao Sy[4], M. Sakata-Yanagimoto[1], S. Takahashi[5], S. Chiba[1]

[1]Department of Hematology, Faculty of Medicine, University of Tsukuba, [2]Transfusion Medicine, University of Tsukuba Hospital, [3]School of Medical Sciences, [4]Department of Hematology, Graduate School of Comprehensive Human Sciences, [5]Department of Anatomy and Embryology, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan

Background: Nestin-expressing cells (NeC) have been characterized as one of many types of bone marrow (BM) stromal cells, including endothelial cells, osteoblasts, CXCL12-abundant reticular cells, etc. Recent studies have gradually provided information about anatomy and functions of each of these cells. Nevertheless, subcellular signaling and transcriptional regulations in individual stromal cells remains unclear. Several previous studies showed that Notch signaling in BM microenvironmental cells developed myeloproliferative phenotypes. Despite this, information is limited whether Notch signaling plays a role in NeC. Nestin was originally identified in neural stem cells (NSCs), in which Notch signaling is known to play a pivotal role in the NSCs. This linkage urged us to investigate whether and how downregulation of Notch signaling in BM NeC affects hematopoiesis.
Aims: To investigate whether and how downregulation of Notch signaling in BM NeC affects hematopoiesis.
Methods: Mice with an *Rbpj*-flox allele were crossed with mice with a *CreERT2/ Z/EG* transgene under the nestin promoter (*Nestin-CreERT2;Z/EG;Rbpj$^{f/f}$* mice). Tamoxifen was intraperitoneally injected 5 times/week for 4 weeks to delete the *Rbpj* gene only in NeC (*Rbpj* cKO mice), with once a week maintenance injection for up to 8 weeks until the analysis. In this experimental system, GFP is expectedly expressed as a surrogate marker for the *Rbpj* gene deletion. Then, transplantation assays were performed using *Rbpj* cKO BM cells as a donor to reconstitute hematopoiesis in the wild-type (WT) mice, or using *Rbpj* cKO mice as recipients to see reconstitution of hematopoiesis from WT BM cells. To investigate the mechanism of impairment of erythroid differentiation in the BM, the erythroid-island reconstitution assay was performed, using BM macrophages from *Rbpj* cKO and littermate control mice and BM Ter119$^+$ erythroid cells prepared from WT mice. The littermate *Rbpj*$^{null/wt}$or*Rbpj*$^{wt/wt}$ mice were used as controls.
Results: GFP was detected by flow cytometry in approximately 0.5% of CD45(-)Ter119(-)CD31(-) cells only after tamoxifen injection. Deletion of *Rbpj* was specifically confirmed in CD45(-)Ter119(-)CD31(-)GFP(+) BM cells. *Rbpj* and *Hes1* mRNA level was decreased in BM CD45(-)Ter119(-)CD31(-)GFP(+) cells of *Rbpj* cKO mice. BM of *Rbpj* cKO mice demonstrated marked decrease in the CD71(+)Ter119(+) mature erythroid cells without obvious anemia and without changes in the hematopoietic stem/progenitor cells. In contrast, mild splenomegaly was observed in *Rbpj* cKO mice. In transplantation analysis, the *Rbpj* cKO recipients transplanted with BM cells from WT mice also showed the maturation arrest in erythroid cells and mild splenomegaly. The WT recipients transplanted with BM cells from *Rbpj* cKO mice did not show any phenotypes. The erythroid island reconstitution capacity of macrophages from cKO BM showed the reduction compared with that of the macrophages from control mice. Additionally, mRNA level of *interleukin-6*, which is reported as the regulator of erythroid island formation, was decreased only in the macrophages forming erythroid islands.
Summary and Conclusions: *Rbpj* cKO in NeC induced impaired erythroid differentiation in BM together with mild splenomegaly, accompanied by the damaged erythroid island forming capacity of BM macrophages in *Rbpj* cKO mice, through the IL-6 hyperproduction of the macrophages. The *Rbpj* cKO mice may model a part of inflammation-induced disorder of erythropoiesis accompanying mild splenomegaly.

PF410

HIERARCHICALLY RELATED LINEAGE-RESTRICTED FATES BY MULTIPOTENT HEMATOPOIETIC STEM CELLS

P. Woll[1,*], J. Carrelha[2,3], Y. Meng[2,3], L.M. Kettyle[1], T.C. Luis[2,3], R. Norfo[2,3], V. Alcolea[2,3], H. Boukarabila[2,3], A. Gambardella[3], A. Grover[3], K. Högstrand[1], A. Lord[1], A. Sanjuan-Pla[3], C. Nerlov[3], S.E.W. Jacobsen[1,2,3]

[1]Dept. of Medicine, Huddinge and Dept. of Cell and Molecular Biology, Karolinska Institutet, Stockholm, Sweden, [2]HSC Laboratory, Weatherall Inst. of Molecular Medicine, [3]MRC Molecular Hematology Unit, Weatherall Inst. of Molecular Medicine, University of Oxford, Oxford, United Kingdom

Background: Rare multipotent hematopoietic stem cells (HSCs) in adult bone marrow (BM) with extensive self-renewal potential possess the ability to efficiently replenish all myeloid and lymphoid blood cells, securing long-term multilineage reconstitution following physiological and clinical challenges, including chemotherapy and hematopoietic transplantations. HSC-transplantation remains the only curative treatment for many hematological malignancies, but inefficient blood-lineage replenishment remains a major cause of morbidity and mortality. Single cell transplantation has uncovered considerable heterogeneity among reconstituting HSCs, supported by findings in unperturbed hematopoiesis and suggested to reflect different propensities for lineage-fate decisions by distinct myeloid-, lymphoid- and platelet-biased HSCs. However, other studies suggested that such lineage-bias might rather reflect generation within the phenotypic HSC compartment of unipotent or oligopotent self-renewing progenitors, and implicated uncoupling of the defining HSC properties of self-renewal and multipotency.
Aims: To monitor the long-term contribution to all mature blood lineages, by transplanted single long-term self-renewing HSCs
Methods: Kinetic monitoring of blood lineage replenishment from single HSCs transplanted into lethally irradiated mice, as well as genetic fate-mapping of the lineage contribution of platelet-biased HSCs.
Results: Highly sensitive tracking of progenitors and mature cells of the megakaryocyte/platelet, erythroid, myeloid, B and T cell lineages produced from singly transplanted HSCs revealed a highly organized, predictable and stable framework for lineage-restricted fates of long-term self-renewing HSCs. Most notably, a distinct class of HSCs adopts a fate towards effective and stable replenishment of a megakaryocyte/platelet-lineage tree but not other blood cell lineages, despite sustained multipotency, whereas no HSCs contribute exclusively to any other single blood-cell lineage. Single multipotent HSCs can also fully restrict towards simultaneous replenishment of megakaryocyte, erythroid and myeloid lineages without executing their sustained lymphoid lineage potential. Unpublished data will be presented with regard to the further characterization and significance of these distinct classes of multipotent HSC adopting lineage-restricted fates *in vivo* following transplantation and through genetic fate-mapping.
Summary and Conclusions: These findings uncover a limited repertoire of distinct HSC subsets, defined by a predictable and hierarchical propensity to stably adopt a fate towards replenishment of a restricted set of blood cell lineages, prior to loss of self-renewal and multipotency.

PF411

GATA2 DIRECTLY REPRESSES CARDIAC FATES TO PROMOTE HEMATOPOIETIC SPECIFICATION OF HUMAN MESODERM

A. Giorgetti[1,*], J. Castaño Cardoso[1], S. Aranda[2], C. Bueno[3], F.J. Calero-Nieto[4], E. Mejia-Ramirez[1], E. Blanco[2], X. Wang[4], C. Prieto[3], L. Zabaleta[5], M. Rovira[1], B. Göttgens[4], L. Di Croce[2], P. Menendez[3], A. Raya[1]

[1]Center of Regenerative Medicine, [2]Center for Genomic Regulation (CRG), [3]Josep Carreras Leukemia Institute and Department of Biomedicine, Barcelona, Spain, [4]Wellcome and MRC Cambridge Stem Cell Institute and Cambridge Institute for Medical Research, Cambridge, United Kingdom, [5] Fundación Inbiomed, Donostia, Spain

Background: In vertebrates, GATA2 transcription factor is a master regulator of hematopoiesis, repeatedly used throughout embryo development and the adult life. Studies in the mouse system have suggested an early key role of GATA2 promoting mesoderm specification toward hematopoietic lineages, at the expense of cardiac fates. However, investigating the function of GATA2 during early human hematopoietic development remains elusive.
Aims: We took advantage of the model of induced pluripotent stem cells (hiPSCs) differentiation to study the early GATA2 functions in this process.
Methods: To determine the developmental impact of GATA2 in early human hematopoiesis, we established transgenic hiPSCs in which the expression of transgenic GATA2 could be temporally controlled and specifically induced by doxycycline (Dox) administration.
Results: Here we show that transient induction of *GATA2* during mesoderm patterning robustly promotes hemogenic progenitor (HEP) cell specification and their further differentiation into hematopoietic progenitor cells (HPCs). Remarkably, *GATA2* knockout impaired hematopoietic development while simultaneously enhancing cardiac potential of mesodermal progenitors. Surprisingly, genome-wide transcriptional (RNA-Seq) and chromatin immunoprecipitation (ChIP-seq) analyses showed that GATA2 bound preferentially to regulatory regions, and repressed expression, of cardiac development-related genes. In contrast, gene important for hematopoietic differentiation were upregulated by GATA2 in human mesoderm precursors in a mostly indirect manner.
Summary and Conclusions: Collectively, our data reveal a previously unsuspected role of GATA2 as a direct repressor of cardiac fates, and highlight the importance of coordinating the specification and repression of alternative cell fates.

PF412

NORADRENALINE STIMULATES MITOCHONDRIAL REALLOCATION AND HAEMATOPOIETIC MIGRATION TO THE SPLEEN

A. Morfakis[1,*], C. Marlein[1], C. Hellmich[1], R. Horton[1], J. Mistry[1], K. Bowles[1], S. Rushworth[1]

[1]Norwich Medical School, UEA, Norwich, United Kingdom

Background: During a stressed state, catecholamines are released, leading to widespread changes, including altered haematopoiesis in the bone marrow (BM). Increased levels of catecholamines such as Noradrenaline (NA) have been previously shown to facilitate haematopoietic cell egress from the bone marrow, commonly seen in burn and trauma patients. These patients often have erythropoietin-resistant anaemia, independent of any blood loss, persisting after the initial injury has been treated. The length of anaemia is associated with the increased levels of circulating catecholamines and circulating primitive haematopoietic cells. This process requires energy resources that could not be made *de-novo* in such a short timeframe.
Aims: The aim of our study was to determine if mitochondrial content was reallocated in haematopoietic progenitor cells when stimulated with NA.
Methods: Animal experiments were conducted with approval from the UK Home Office and University of East Anglia Animal Welfare and Ethical Review Board. Mitochondrial content was quantified *in vitro* using C57/BL6 mouse BM stroma using MitoTracker Green FM and flow cytometry. MitoTracker content and cell population changes in C57/BL6 mice were quantified *ex vivo* using flow cytometry after NA intraperitoneal injections, or sham phosphate buffered solution (PBS) injection, and euthanised after 2 hours.
Results: We first quantified mitochondrial content of mature erythroid-lineage cells *in vitro* under different conditions. We found that culturing with noradrenaline (NA) at stressed levels *in vitro* led to decreased mitochondrial content compared to control. Moreover, culturing with atenolol (a beta-blocker which counters NA's actions) led to an increase in mitochondrial content of erythroid-lineage cells. Next, we found that intraperitoneal injection of NA led to a significant efflux of haematopoietic cells from the BM within 2 hours as well as a reduction in their mitochondrial content compared to control. This corresponded with an increased number of erythroid and myeloid lineage cells in the spleen, with an increased mitochondrial content. Finally, we investigated the effect of NA on haematopoietic progenitor cells (HPCs) in the BM. This revealed fewer progenitors (granulocyte-macrophage, common myeloid and megakaryocyte-erythroblast progenitors) in the BM with a decreased mitochondrial content in common myeloid progenitors. There was also an increase in the multipotent progenitor population.
Summary and Conclusions: NA is a major driver of mitochondrial reallocation and cell-lineage bias under stressed haematopoiesis. Migration of cells to the spleen, a major lymphatic organ, prepares the body to combat infection, but potentially at the expense of normal haematopoiesis in the bone marrow, slowing long-term recovery. This pathway has multiple therapeutic applications including stem cell transplant and post-trauma recovery.

PF413

CELLULAR AND MOLECULAR MAPPING OF HUMAN EARLY LYMPHOID PROGENITOR CELLS SUBMITTED TO LOW OXYGEN DOSES

S. Chabi[1,*], B. Uzan[1], I. Naguibneva[1], J. Rucci[1], L. Fahy[1], M.-L. Arcangeli[1], J. Calvo[1], S. Rahming[2], C. Waskow[2], F. Mazurier[3], F. Pflumio[1], R. Haddad[1]

[1]Cea/UMR967, Fontenay-aux-Roses, France, [2]T U Dresden, Dresden, Germany, [3]UMR7292, TOURS, France

Background: *In vitro* studies of human lymphoid development are routinely conducted in normoxic/hyperoxic conditions, however physiologic *in vivo* O_2 levels are lower. Indeed adult hematopoietic stem/progenitor cells (HSPC) are maintained in bone marrow (BM) within a microenvironment characterized by low oxygen (O_2) tension (pO_2: 1-6% O_2) commonly called hypoxia. Conventional *in vitro* cell culture thus appears not suitable for studying human lymphoid differentiation since it does not faithfully reproduce the *in vivo* tissue niches especially as it is related to *in vivo* oxygen tension.
Aims: In this study we aimed at measuring how low O_2 levels impact the biological characteristics of early lymphoid progenitors.
Methods: We addressed the functional, developmental and molecular consequences of direct exposure to hypoxia in distinct umbilical cord blood (UCB)-derived HPC more or less polarized towards the lymphoid lineage. HSPC, multipotent progenitors (MPP), lymphoid-primed multipotent progenitors (LMPP), Pro-T/NK and Pro-B cells were isolated and short-term co-cultured with BM derived stromal MS-5 cells in hypoxia (3.5% O_2) comparatively to normoxia (21% O_2) prior to *in vitro* analysis of cell cycle, metabolic profile, lymphoid cell differentiation in bulk and limiting dilution, *in vivo* hematopoietic reconstitution of NSGW41 immune-deficient mice, and to molecular profile of early lymphopoiesis related genes.
Results: Incubation of human hematopoietic progenitor cells in hypoxia enhanced cell quiescence, reduced autophagy and protected cells from mitochondrial activation. Functionally hypoxia empowered NK-cell development capability from MPP, LMPP and Pro-T/NK cells and B and T cell generation capacity from LMPP and Pro-T/NK respectively while it preserved LMPP and Pro-T/NK intrinsic lymphoid-cell generation capacity as compared to the original sorted cells. Furthermore, higher human hematopoietic chimerism was obtained in BM of NSGW41 immune-deficient mice injected with LMPP-derived cells from hypoxic cultures in comparison to normoxia. *In vivo* B cell production was enhanced from LMPP-derived cells maintained in hypoxia compared to normoxia. As expected, HIF-1α is highly expressed, is efficiently stabilized and robustly localizes in the nucleus under hypoxia in LMPP- and Pro-T/NK-derived cells. Accordingly, *VEGF*, *CXCR4* and *GLUT3* HIF-1α target genes are upregulated under hypoxia. Interestingly, hypoxia promoted lymphoid molecular identity of LMPP and Pro-T/NK cells in comparison to normoxia allowing the expression of early lymphoid genes such as *FLT3*, *SOX4*, *BCL11A*, *E2A*, *NOTCH1*, *IL15RA*, *IL7RA*, *RAG1*. Interplay of HIF-1/2α in hypoxia-related LMPP and Pro-T/NK lymphoid behavior is being investigated.
Summary and Conclusions: Our results indicate that hypoxia acts differentially in human hematopoietic progenitor cell populations and especially enhances lymphoid development from LMPP and Pro-T/NK with HIF-1/2α factors being important players. This study provides new insights into the contribution of O_2 levels in the lymphoid development of human hemato-lymphoid progenitors, thereby establishing valuable tools to explore the cellular and molecular events that direct the initiation of normal and pathological lymphoid cell fate. The work may enable to generate therapeutically useful cell types.

PF414

AGE-RELATED CLONAL HEMATOPOIESIS (ARCH) IN CENTENARIANS AND CARDIOVASCULAR DISEASE PATIENTS: A SURVIVAL BIAS HYPOTHESIS

L. Bertamini[1,2,*], C. Sala[3], N. Martinelli[1], C. Papayannidis[2], C. Giuliani[4], G. Malerba[5], M. Cavo[2], A. Curti[2], P. Garagnani[6], O. Olivieri[1], G. Martinelli[7], C. Franceschi[6], D. Girelli[1]

Seràgnoli", Univeristy of Bologna, [3]DIFA and Galvani center for Bioinformatics, University of Bologna, [4]BIGeA, Laboratory of Molecular Anthropology & Centre for Genome Biology, Univeristy of Bologna, Bologna, [5]Department of Neurosciences, Section of Medical Genetics, University of Verona, Verona, [6]DIMES, Univeristy of Bologna, Bologna, [7]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST), IRCSS, Meldola, Italy

Background: Accumulation of somatic DNA mutations is an unavoidable result of ageing, due to a lot of cell cycles and exposure to exogenous genotoxic agents (Tomasetti C, Science 2017). Hematopoietic tissue is particularly exposed to this somatic variation. Some mutations can give an advantage to a hematopoietic stem cell, leading to its clonal expansion. This condition, known as age-related clonal hematopoiesis (ARCH), has been linked to an increased risk of hematological malignancies, and of overall cardiovascular mortality (Jaiswal S, NEJM 2014). Noteworthy, in the elderly population suffering from cardiovascular diseases (CVD) there is a relatively low prevalence of classical cardiovascular risk factors (Baber U, JACC 2015), and ARCH could represent a novel entity explaining at least part of the still unknown "residual risk".
Aims: To estimate the prevalence and importance of ARCH as cardiovascular risk factor in patients with Coronary Artery Disease (CAD) and in a group of "super-controls" centenarians, free of atherosclerosis related diseases (Garagnani P, Aging 2013).
Methods: We performed whole-exome sequencing (WES) from peripheral-blood cells DNA in 99 patients with angiographically proven severe CAD from the Verona Heart Study (Girelli D, *NEJM* 2000), and 79 centenarians (of which 58 semi-supercentenarians, aged >105 years). The mean data coverage was between 30x and 100x (maximum in centenarians). After eliminating germline variants, we defined ARCH carriers as those subjects having at least 1 somatic mutations predicted to alter the protein function in a list of 6 key genes (*TET2*, *ASXL1*, *DNMT3A*, *JAK2*, *PPM1D*, *TP53)*, previously associated to ARCH (Jaiswal S, *NEJM* 2014).
Results: The prevalence of ARCH in CAD patients was 18.2%, a result that is comparable to the increased prevalence recently described in other CAD populations (Jaiswal S, NEJM 2017). Intriguingly, we found an extremely low prevalence (2.5%) of ARCH in centenarians, contradicting the expected exponential increase of this condition in subjects aged over 80. This counterintuitive result could be explained by a "survival bias" model, in which ARCH increases with ageing but, in the meantime, contributes to an higher risk of mortality. Of note, the majority (85%) of the driver mutations in CAD patients occurred in *TET2*, at variance with other studies where *DNMT3A* was the most recurring driver gene.
Summary and Conclusions: Our outcomes add further insights to the recent hypothesis that links ARCH to an increased cardiovascular risk and its possible role in elderly population with CVD. Our results raise the question over a possible multi-faceted clinical and biological significance of ARCH that might depend on the driver mutation. In particular, *TET2*-driven ARCH may be the most important driver of an higher cardiovascular risk, consistently with the pro-atherosclerotic and heart remodeling role of this gene in mouse models (Fuster JJ, *Science* 2017, Jaiswal S, *NEJM* 2017, Sano S, *JACC* 2018).

HUMAN ADULT HSCS CAN BE DISCRIMINATED FROM LINEAGE-COMMITTED HPCS BY THE EXPRESSION OF ENDOMUCIN

K. Reckzeh[1,*], H. Kizilkaya[1], A. Søgaard Helbo[1], M. Estruch Alrich[1], K. Theilgaard-Mönch[1]

[1]Novo Nordisk Foundation Center for Stem Cell Biology, DanStem, The Finsen Laboratory, Rigshospitalet & Biotech Research and Innovation Centre, University of Copenhagen, Denmark, Copenhagen, Denmark

Background: Hematopoietic stem cells (HSCs) promote the lifelong production of all mature blood cell lineages through their unique ability of durable self-renewal and multi-lineage differentiation. Given the extensive regenerative property of HSCs, various types of stem cell products including bone marrow (BM), cord blood (CB), and mobilized peripheral stem cells (PBSC) have been successfully utilized in the clinic for stem cell transplantation (SCT) of patients with hematological malignancies and monogenic diseases. Despite the clinical success of HSC therapies, much of our knowledge on HSC biology is based on either mouse studies, or studies on cord blood-derived HSCs of limited purity. Hence, identification of novel human HSC markers to refine the human HSC immunophenotype is instrumental to gain new insights into human HSC biology and advance HSC-based therapies in the clinic setting.
Aims: The goal of this study is to identify novel cell surface markers of human adult HSCs in order to refine their immunophenotype. In addition, this study aims at identifying HSC-exclusive markers allowing for tumor-free autologous stem cell grafts from patient-derived PBSC products.
Methods: To identify novel human HSC surface markers, we screened of microarray gene expression profiles of BM populations with the "classic" immunophenotypes of HSCs, MPPs, HPCs, and mature blood cells. Candidate markers were screened against AML gene expression data sets (HemaExplorer) and subsequently validated in sorted BM by qRT-PCR. To test enrichment for functional HSCs BM cells positive for the cell surface marker were transplanted into immune-deficient NOG mice. Assessment of long-term, multi-lineage engraftment was performed 20 weeks after transplantation.
Results: The screen identified Endomucin (EMCN) as a candidate HSC marker highly expressed by human HSCs and progressively down-regulated as HSCs differentiate via MPPs, CMPs, GMPs, MEPs, and mature monocytes and neutrophils. Flow cytometry analysis of adult BM samples from healthy subjects combining EMCN with current standard markers for the identification of lineage-committed HPCs, LMPPs, MPPs, and HSCs, demonstrated that EMCN is highly expressed on the surface of HSCs and to some extent on MPPs, but almost entirely absent on LMPPs and HPCs. Transplantation of 50,000 L-EMCN- or 2,000 L-EMCN+ highly purified BM cells into sublethally irradiated NOG mice demonstrated significant multi-lineage engraftment in BM and spleen including B-cells and myeloid cells only in L-EMCN+ transplanted mice.
Summary and Conclusions: These findings establish EMCN as a marker expressed by the majority, if not all, bona fide functional human adult HSCs. This study further highlights the use of EMCN in future studies in combination with "classic" HSC markers for refinement of the human HSC immunophenotype and purification of HSCs in order to gain new insights into human HSC biology. EMCN also represents a potential marker for simplified HSC purification strategies including two-color flow cytometry-based or two-step immunomagnetic cell sorting protocols that could be adapted in the clinical setting allowing for production of highly pure stem cell products for patients undergoing allogeneic or autologous SCT, respectively. In summary, our study identifies EMCN as novel HSC marker, which holds great potential to advance future studies on human HSC biology and improve HSC-based therapies.

PF416

ROS-DEPENDENT SELF-RENEWAL DEFECTS OF HUMAN HEMATOPOIETIC STEM CELLS AFTER EXPOSURE TO LOW DOSE OF IONIZING RADIATIONS

I. Souissi-Sahraoui[1], M. Deynoux[1], E. Henry[1], A. Lefèvre[1], V. Barroca[1], J. Calvo[1], F. Pflumio[1], M.-L. Arcangeli[1,*]

[1]iRCM-CEA, INSERM U967, Fontenay-aux-Roses, France

Background: Hematopoietic stem cells (HSC) are responsible for life-long blood cell regeneration. In the adult, HSC quiescence, self-renewal and differentiation capacities are tightly regulated. Nowadays, HSC endure more and more genotoxic stresses that can alter their self-renewal properties. Indeed, people are increasingly exposed to low doses of ionizing radiation (LDIR, <100mGy) due to the recurrent usage of medical imaging. Moreover, studies have shown that combination of several CT scans (thoracic or cranial) can have an incidence in cancer development risk. Up to 5 CT scans (corresponding to a cumulative dose of 30 mGy) can increase up to 3 times the risk to develop pediatric leukemia.
Aims: Therefore, it is crucial to study the consequences of LDIR exposure in human cells in particular in human HSC. We aim also to understand how LDIR can affect human HSC fundamental properties such as self-renewal potential and multipotency.
Methods: We studied the consequences of a single *ex vivo* or *in vivo* acute 20mGy LDIR on differentiation and self-renewal capacities of human cord blood-derived HSC using xenograft models, functional *in vitro* tests such as CFU-C and LTC-IC assays and flow cytometry.
Results: We showed that exposure of human HSC to a single 20mGy LDIR has an impact on long-term HSC self-renewal properties. No alteration in HSC differentiation potential can be detected after exposure to LDIR when tested in primary assays (transplantation, CFU-C assay or cultures). However, when HSPC were irradiated *in vivo* in the NSG mouse bone marrow, a defect

in human hematopoietic reconstitution was observed; deleterious effects observed in HSPC after *ex vivo* LDIR exposure were detected after the tertiary transplantation in NSG mice, strongly arguing for a HSC self-renewal defect. In addition, in serial CFU-C assay, HSPC exposure to 20mGy induced loss of secondary CFU-C potential as well as a loss in secondary LTC-IC frequency. Single 20mGy LDIR does not induce DNA double strand breaks in HSC, suggesting no major defect in DNA repair, but results in a fast and transient increase in ROS production resulting in the activation of p38MAPK pathway. Importantly *ex vivo* treatment of HSC with ROS or p38MAPK inhibitors prior to radiation allows rescuing the 20 mGy-induced-HSC defects.
Summary and Conclusions: Altogether our results indicate that exposure to a single 20 mGy LDRI induces HSC self-renewal defect through a ROS/p38MAPK pathway. P38MAPK activation as well as ROS increased levels are associated with decreased efficiency of HSC to transplant upon serial transplantation and aging. Thus, it is tempting to speculate that exposure to LDIR may induce early/accelerated aging of the young CB-derived HSC albeit not to the extent of biased myelopoiesis. Since radiation sensitivity as well as transplantation efficiency highly depends on HSPC origin, aged HSPC may have been more sensitive to LDIR. Moreover, another feature of HSC aging is higher risk of leukemic transformation, especially in presence of an oncogenic initiating event such as a mutation of the epigenetic modifier dnmt3a, as it is observed in blood cells from aged people. The next question will be thus to determine if aged HSC exposed to LDIR are more prone to (pre)leukemic transformation, especially in aged cells containing primary oncogenic mutations.

PF417

THE HISTONE CHAPERONE NAP1L3 IS REQUIRED FOR HEMATOPOIETIC STEM CELL MAINTENANCE AND DIFFERENTIATION

Y. Heshmati[1], S. Kharazi[2], G. Turköz[1,*], D. Chang[1], E. Kamali Dolatabadi[1], J. Boström[2], A. Krstic[3], T. Boukoura[1], E. Wagner[1], N. Kadri[1], R. Månsson[3], M. Altun[3], H. Qian[1], J. Walfridsson[1]

[1]Department of Medicine, Center for Haematology and Regenerative Medicine, Karolinska University Hospital, [2]Department of Medical Biochemistry and Biophysics, Research Division of Translational Medicine and Chemical Biology, [3]Department of Laboratory Medicine, Center for Haematology and Regenerative Medicine, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden

Background: Hematopoietic stem cells (HSCs) are rare cell populations, which possess multipotent activities and self-renewal capacities. Nucleosome assembly proteins (NAPs) are histone chaperones with an important role in chromatin structure and epigenetic regulation of gene expression. *NAP1L3* has previously been shown to be expressed predominantly in HSCs, indicative of a potential functional role in primitive hematopoietic cells.
Aims: The purpose of this study is to determine the *in vitro* and *in vivo* role of *NAP1L3* in HSC activities and hematopoietic differentiation.
Methods: The gene expression profile of *NAP1L3* in various hematopoietic cells was studied with quantitative real time PCR (qPCR) analysis. The functional importance of *NAP1L3* in HSCs, cell differentiation and hematopoiesis both *in vitro* and *in vivo* was investigated using a combination of shRNA, CRISPR-Cas9 and over expression approaches. The cellular and molecular mechanisms of NAP1L3 in hematopoiesis were delineated with a combination of cell cycle analysis, apoptosis studies and expression profiling.
Results: We find that high gene expression levels of murine *NAP1L3* are restricted to HSCs in mice. Importantly, with shRNA or CRISPR-Cas9 mediated loss of function of mouse *Nap1l3* and with overexpression of the gene, the number of colony-forming cells and myeloid progenitor cells *in vitro* are reduced. This manifests as a striking decrease in the number of HSCs, which reduces their reconstituting activities *in vivo*. Inhibition of human *NAP1L3* in umbilical cord blood (UCB) HSCs impairs the maintenance and proliferation of HSCs both *in vitro* and *in vivo*. *NAP1L3* inhibition in UCB HSCs causes an arrest in the G0 phase of cell cycle progression and induces gene expression signatures that significantly correlate with downregulation of gene sets involved in cell cycle regulation, including E2F and MYC target genes. Moreover, we demonstrate that *HOXA3*, *HOXA5*, *HOXA6*, and *HOXA9* genes are markedly upregulated when *NAP1L3* is suppressed in UCB HSCs.
Summary and Conclusions: Histone chaperones constitute a family of chromatin regulators that have an important function in epigenetic gene regulation. Our studies identified a novel role of the histone chaperone *NAP1L3* in hematopoiesis. Moreover, we found *NAP1L3* to be highly expressed in HSCs, and showed that loss of function of *NAP1L3* in primitive human UCB HSCs had a remarkable impact on the survival and proliferation of HSCs and cell differentiation *in vivo*. Taken together, our findings establish an important role for *NAP1L3* in HSC homeostasis and hematopoietic differentiation.

PF418

THE *IN VIVO* EFFECT OF CHEMOTHERAPY AND CXCR4 ANTAGONISM ON AML AND T-ALL CELL MIGRATION IN THE BONE MARROW

D. Duarte[1,2,3,*], S. Amarteifio[4], H. Ang[1], N. Ruivo[1], G. Pruessner[4], E. Hawkins[5], C. Lo Celso[1]

[1]Department of Life Sciences, Imperial College London, London, United Kingdom, [2]Department of Haematology, IPO-Porto / Porto Comprehensive Cancer Centre, [3]i3S - Instituto de Investigação e Inovação em Saúde / University of Porto, Porto, Portugal, [4]Department of Mathematics, Imperial College London, London, United Kingdom, [5]The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia

Background: The majority of acute myeloid leukemia (AML) patients and a significant number of relapsed T-cell lymphoblastic leukemia (T-ALL) patients have a dismal prognosis with poor response to conventional chemotherapy. Leukemia-bone marrow (BM) microenvironment interactions are emerging as potential therapeutic targets, which could be shared across multiple diseases. Inhibition of CXCR4, a known regulator of cell migration, was shown to induce blast mobilization and improve disease outcomes of both AML and T-ALL in pre-clinical models. We recently showed that treatment-naïve and chemoresistant T-ALL cells are highly motile in the BM. In contrast, the features of AML cell migration *in situ* remain unexplored.
Aims: Characterize in detail the impact of (1) chemotherapy and (2) CXCR4 antagonism on the *in vivo* migratory behavior of T-ALL and AML within the BM.
Methods: In this study, we use the well-established Notch1-driven T-ALL and MLL-AF9-driven AML pre-clinical disease models combined with 2-photon and confocal intravital microscopy (IVM) of calvarium BM, which allows imaging at the single-cell level with high temporal resolution.
To model chemoresistance, drugs commonly administered in the treatment regimens of T-ALL and AML patients were used in our mouse models. For CXCR4 inhibition experiments, mice were i.v. injected with AMD3100.
We analyzed leukemic cells during disease establishment, when cells were either isolated or grouped in small clusters, and following treatment with chemotherapy, once chemoresistant populations had been selected. To understand the short-term effect of CXCR4 inhibition, we time-lapsed the same BM areas before and after administration of AMD3100. We used image and mathematical analysis to study the migratory behaviour of leukemic cells.
Results: AML cells migrated unexpectedly rapidly and faster than T-ALL cells in the BM at early stages of disease. These findings suggest that migration is an important trait of malignant cells of both lymphoid and myeloid origin. In contrast with chemoresistant T-ALL cells, AML cells surviving induction chemotherapy were less migratory than seeding AML cells.
We next investigated the effect of CXCR4 antagonism on non-mobilized, parenchymal T-ALL and AML cell migration. AMD3100 strikingly decreased T-ALL cell speed at both seeding and post-chemotherapy stages. However, we show that CXCR4 inhibition on AML cells elicits mobilization, but not significant changes in migration. Time-averaged mean-squared displacement (MSD) analysis revealed that in contrast with the typical leukemic diffusive/sub-diffusive cell movement, chemo-resistant T-ALL cells uniquely shifted to a super-diffusive and ballistic-like movement when exposed to AMD3100.
Furthermore, the size of T-ALL cell clusters diminished following AMD3100 treatment, as a result of combined intravasation and cell death. In contrast, AML cell clusters were maintained after AMD3100 injection.
Summary and Conclusions: We show that motility is a baseline feature of both AML and T-ALL cells. However, we demonstrate that increased cell migration following chemotherapy is specific to T-ALL cells. We also demonstrate that CXCR4 promotes residence of T-ALL and AML cells in the BM and regulates migration of T-ALL cells inside the BM. Our study suggests that migration is a feature of acute leukemias that can be targeted through CXCR4 inhibition in T-ALL but not in AML.

PF419

PROSPECTIVELY ISOLATED BONE MARROW STROMAL CELLS FROM PATIENTS WITH HEMATOLOGICAL MALIGNANCIES DIFFER PHENOTYPICALLY AND RELATE TO DISEASE STAGE IN MGUS/MYELOMA

D. Zacharaki[1], R. Ghazanfari[1], H. Li[1], H. C. Lim[1], S. von Palffy[2], S. Soneji[1], T. Fioretos[2], S. Scheding[1,3,*]

[1]Molecular Hematology, [2]Clinical Genetics, University of Lund, [3]Hematology, University Hospital Lund, Lund, Sweden

Background: Bone marrow (BM) mesenchymal stromal cells (MSCs) are important elements of the hematopoietic stem cell (HSC) niche contributing to the tight regulation of hematopoiesis under homeostasis. MSCs have also been implicated in disease progression and even in disease initiation in hematologic malignancies. Studies of human bone marrow primary *bone-fide* MSCs – in contrast to cultured stroma cells which do not necessarily reflect the properties of their *in vivo* counterparts (Ghazanfari *et al.*, Stem Cells Development 2017) – have become possible by recent progress in the identification of the BM-MSC phenotype as reported by us and others (Li at al., Stem Cell Reports 2014).
Aims: Therefore, the current study aimed to characterize phenotypical and functional properties of primary MSC from patients with hematological malignancies.
Methods: BM samples were collected from patients and healthy age-matched controls. Surface marker expression of primary MSC was measured by flow-cytometry. RNAseq analysis was performed on FACS-sorted primary MSC using the Illumina NextSeq500 platform.
Results: We collected a total of 85 diagnostic BM aspirates from patients that were under investigation for suspected hematological diseases and 9 samples from healthy age-matched donors (HC). FACS analysis of primary MSC identified as lin$^-$CD45$^-$CD31$^-$CD71$^-$CD235a$^-$CD271$^+$cells was performed to investigate the co-expression of known and recently reported MSC markers (CD105, CD106, CD140, CD146, CD230, CD51, CD73, CD90, W5C5). These data formed the basis to generate a surface maker expression heat-map (% median frequency of each marker) that clearly showed disease-cluster-specific differences in several of the markers, *e.g.* lower CD146 expression in MSC from patients with monoclonal gammopathy of undetermined significance (MGUS) compared to multiple myeloma (MM) patients. CD105 expression was lower in MM-MSCs compared to MGUS-MSCs and age-matched controls. MSCs from myelodysplastic syndrome (MDS) patients expressed lower levels of CD105, CD106 and CD51 compared to age-matched controls. MSCs from patients with myeloproliferative diseases (MPDs) showed a low expression of most of the markers.
Intrigued by the differences between MGUS, MM and HC-MSCs we performed RNAseq on prospectively-sorted primary lin$^-$CD45$^-$CD71$^-$CD235a$^-$CD31$^-$CD271$^+$ stromal cells. Unsupervised clustering of the RNAseq data showed that MGUS-MSC clustered partly with HC-, but also with MM-MSC. When restricting the analysis to those MSC samples that clustered separately, a total of 3,758 genes was found to be differentially expressed between the three groups. Pre-ranked gene set enrichment analyses (GSEA) showed a strong enrichment of inflammatory response/oncogenic pathways in MM-MSC compared to HC-MSC. Venn diagram analysis identified commonly expressed genes among MM- and MGUS-MSC *versus* HC-MSC. Furthermore, a total of 17 genes was identified that were highly deregulated in MM- and intermediately deregulated in MGUS-MSC when compared to controls.
Summary and Conclusions: Taken together, phenotypical analysis of primary MSC from patients revealed disease-specific surface marker expression patterns. High throughput transcriptome analysis of primary MSC from HC, MGUS and MM identified genes that were specifically upregulated/suppressed in MM-MSC compared to MGUS-MSC and control-MSC. These genes thus represent potential candidates that might be related to the progression of MGUS to MM and studies investigating a possible functional role of these genes are ongoing.

Hodgkin lymphoma – Biology & Translational Research

PF420

CD83 IS A NEW POTENTIAL BIOMARKER AND THERAPEUTIC TARGET FOR HODGKIN LYMPHOMA

Z. Li[1,2,*], X. Ju[1,2], K. Lee[2,3], C. Clarke[3], J. Hsu[1,2], E. Abadir[1,2], C. Bryant[1,4], S. Pears[5], N. Sunderland[5], S. Heffernan[5], A. Hennessy[5], T.-H. Lo[1], G. Pietersz[6], F. Kupresanin[1], P. Fromm[1,2], P. Silveira[1,7], C. Tsonis[1], W. Cooper[2,8], I. Cunngingham[9], C. Brown[4], G. Clark[1,2], D. Hart[1,2]

[1]Dendritic Cell Research, ANZAC Research Institute, [2]Sydney Medical School, University of Sydney, [3]Anatomical Pathology Department, Concord Repatriation General Hospital, [4]Institute of Haematology, [5]Animal Facility, Royal Prince Alfred Hopspital, Sydney, [6]Burnet Institute, Melbourne, [7]Anatomical Pathology Department, University of Sydney, [8]Tissue Pathology and Diagnostic Oncology, Royal Prince Alfred Hopspital, [9]Haematology Department, Concord Repatriation General Hospital, Sydney, Australia

Background: Hodgkin lymphoma (HL) is a B cell neoplasm that is defined by the presence of Hodgkin and Reed-Sternberg (HRS) cells. New targeted therapies for HL are warranted, especially for refractory/relapsed patients and elderly patients where limiting treatment toxicity is essential. CD83 is a member of the Ig superfamily that is expressed as a membrane molecule (mCD83) and as a membrane cleaved soluble molecule (sCD83). Our group reported that Hodgkin lymphoma tumor cells expressed mCD83 and sCD83 can be detected in serum in lymphoma patients. CD83 was identified as one of the four classifiers to distinguish HL with ALK- anaplastic large cell lymphoma. Despite its potential as a relatively specific target and potential biomarker, CD83 has not been investigated as a therapeutic target on HL.
Aims: The aim of this study is to assess whether CD83 is a potential biomarker and therapeutic target in HL patients. We developed a therapeutic human anti-human CD83 mAb, 3C12C, and its toxin conjugate, 3C12C-MMAE. We will test the killing efficiency of 3C12C and 3C12C-MMAE on HL cell lines. To "de-risk" the antibodies before advancing 3C12C into a clinical trial, we performed dose-escalation studies of 3C12C in non-human primates (NHP).
Methods: Immunohistochemical (IHC) staining of CD83 was performed on formalin fixed paraffin embedded (FFPE) lymph node biopsies of 35 HL patients. Serum samples were collected from HL patients at diagnosis and during sequential standard chemotherapy. Human sCD83 was analyzed by human sCD83 ELISA. Antibody-dependent cell-mediated cytotoxicity (ADCC) was tested on HL lines using 3C12C mAb. 3C12C-toxin conjugate was prepared and tested for killing effect *in vitro*. For dose-escalation studies, five NHP received intravenous human-IgG (10mg/kg) or 3C12C mAb (1, 5, 10, 10 mg/kg) at days 0, 7, 14 and 21. PBMC were collected and analyzed for immune cell populations including DC, T and B cells on flow cytometer. Liver and kidney function were assessed by measuring alkaline phosphatase, aspartate transaminase & creatinine in serum samples.
Results: IHC staining of HL patient FFPE biopsy samples showed 8/35 expressed high levels (10-90% positive) of CD83 on the HRS cells (>90% positive), 21/35 expressed middle level and 6/35 expressed low levels (<10% positive) of CD83 (Figure 1A).

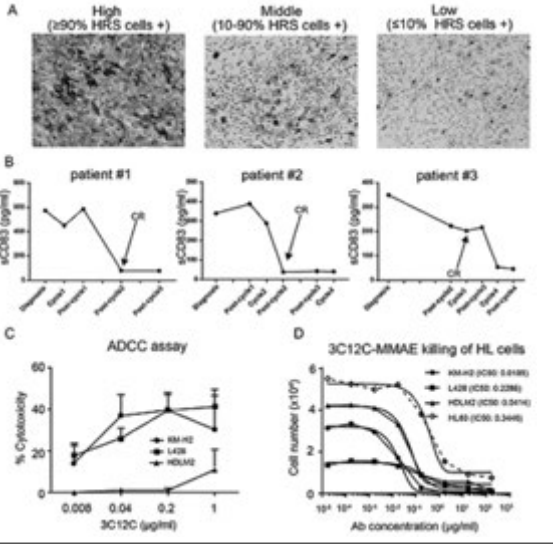

Figure 1.

HL patients had significantly higher serum sCD83 (360.5±54.82 pg/ml, n=10) at diagnosis than healthy donors (52.6±9.5 pg/ml). High levels of sCD83 returned to normal in patients who had good clinical responses to chemotherapy confirmed by positron emission tomography scans (Figure 1B). The ADCC activity of 3C12C was tested on the three HL lines: KM-H2, L428 and HDLM2. Whilst 3C12C killed KM-H2 and L428 efficiently, HDLM2 was relatively resistant to it (Figure 1C). To investigate further potential therapeutic applications, we generated a 3C12C toxin conjugate 3C12C-MMAE. 3C12C-MMAE killed CD83+ KM-H2 cells most efficiently, followed by HDLM2 and L428, while CD83- HL-60 cells were least sensitive to 3C12C-MMAE (Figure 1D). In NHP trial, no toxicity was observed but there was evidence of CD83 positive target cell depletion in lymph node in the 3C12C treated animals (10mg/kg) compared to the control animals. In addition, reductions in blood B cells were noted by flow cytometry.

Summary and Conclusions: Most HRS in HL LN biopsies were CD83+ and sCD83 may be a useful blood biomarker to monitor disease. Anti-CD83 mAb, 3C12C and its toxin conjugate, kill CD83+ HL cells *in vitro*. No toxicity was observed in 3C12C dose-escalation NHP study. These data establish CD83 as a potential biomarker and therapeutic target in HL.

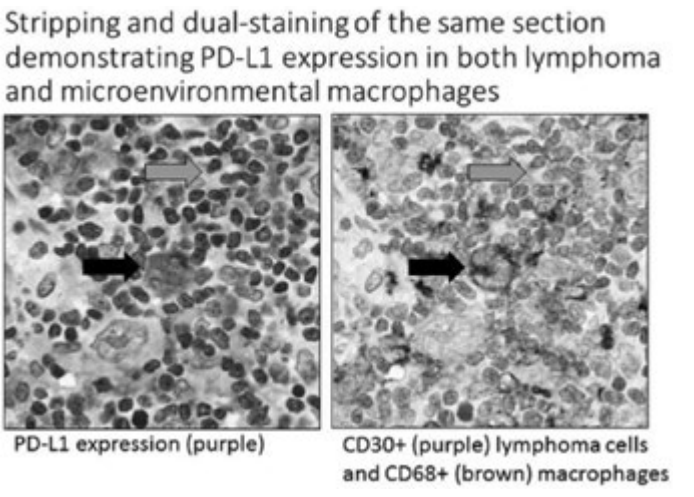

Figure 1.

PROGRAMMED DEATH LIGAND 1 EXPRESSION IN THE MICROENVIRONMENT OF CLASSICAL HODGKIN LYMPHOMA IS INDUCED BY LYMPHOMA CELLS VIA AN IL27-DEPENDENT MECHANISM

J. Taylor[1,2,*], A. Clear[1], M. Poynton[1], M. Caporale[1], M. Calaminici[1], J. Gribben[1]

[1]Centre for Haemato-Oncology, Barts Cancer Institute, [2]Haematology, St Barts Hospital, London, United Kingdom

Background: Tumor-associated macrophages (TAM) in Classical Hodgkin Lymphoma (CHL) are associated with relapse and inferior survival. TAM express immunosuppressive molecules including Programmed Death Ligand 1 (PDL1). The responses seen in CHL with PD1 inhibition highlight the importance of this axis. Mechanisms of lymphoma PDL1 upregulation are known in CHL but mechanisms of TAM PDL1 upregulation are unknown. IL27 is a heterodimeric cytokine made up of a and β subunits (IL27p28 and EBI3). It has immunosuppressive effects in the myeloid compartment including PDL1 upregulation. Isolated EBI3 expression by CHL lymphoma cells is known but its relevance was previously unclear.

Aims: To evaluate mechanisms contributing to TAM PDL1 upregulation in the CHL.

Methods: Immunohistochemistry (IHC) was used to assess lymphoma cells, TAM, PDL1 and IL27 subunit expression. Co-expression was assessed by IHC followed by antibody stripping and re-staining of the same section. *In vitro*, monocytes from healthy donors were differentiated into monocyte-derived macrophages (MdMφ). Conditioned media (CM) was harvested from the KMH2 CHL cell line. Western blotting was performed on supernatants and MdMφ lysates. PDL1 expression was determined by flow cytometry.

Results: IHC staining of PDL1 followed by stripping and re-staining with CD30 and CD68 (see Figure 1) demonstrated PDL1 expression on both lymphoma cells and TAM. Lymphoma-involved areas were enriched for PDL1+TAM. TAM were responsible for the majority of PDL1 expression. We assessed the role of IL27 in PDL1 upregulation. Lymphoma cells stained positive for EBI3 (IL27 subunit β) in 85% (47/55) of cases whilst TAM stained universally negative. TAM stained positive for IL27p28 (IL27 subunit a) in 76% of cases with positive staining in lymphoma cells in 14% of cases. EBI3 H score (incorporating intensity and area stained) correlated positively with TAM markers including CD68 (p=0.004) and CD163 (p=0.001) and with Il27p28 intensity (p=0.006). This suggeststhat higher EBI3 production coincides with increased TAM infiltration and higher IL27p28 production. Finally, EBI3 H Score correlated positively with PD-L1 expression (p=<0.001). This is consistent with EBI3 and IL27p28 formation of IL27 within the microenvironment promoting PDL1 upregulation. We modelled this process *in vitro*, treating healthy donor derived MdMφ with KMH2 CHL cell line conditioned media (CM). We demonstrated by western blotting that EBI3 but not IL27p28 was present in the KMH2 CM and that IL27p28 was upregulated in a dose-dependent manner in CM-treated MdMφ but was not expressed in lysates of RPMI control MdMφ. PDL1 was upregulated on CM-treated MdMφ compared to control (p=0.009). Finally, to assess the impact of IL27 on PDL1 expression we treated with neutralising doses of anti-IL27 antibody, partially abrogating PDL1 upregulation.

Summary and Conclusions: These data suggest that TAM PDL1 upregulation in CHL is promoted by IL27. EBI3 is secreted by the lymphoma and TAM are stimulated to express IL27p28 by lymphoma-secreted factors. These data support that IL27 is responsible, at least in part, for subsequent PDL1 upregulation. These findings are important as they provide a mechanism connecting TAM PDL1 expression with the lymphoma cell and identify an immunosuppressive role for monomeric EBI3 secretion. A similar mechanism is described in other lymphoma cell lines and monomeric EBI3 secretion is described in lung cancer demonstrating broader relevance. To date, monomeric EBI3 secretion is only described in the context of malignancy raising the possibility of its use as a therapeutic target.

PF422

TARGETING ROR1 RECEPTOR IN CLASSICAL HODGKIN LYMPHOMA: EFFECTS ON APOPTOSIS AND PROLIFERATION AND ITS EMERGING THERAPEUTIC IMPLICATIONS

L. Velentza[1,*], I. Zerdes[1], A. H. Daneshmanesh[1], N. Tsesmetzis[1], M. Hojjat-Farsangi[1], A. Ghaderi[1], E. Drakos[2], M. Palma[1], A. Österborg[1], H. Mellstedt[1], G. Rassidakis[1]

[1]Oncology-Pathology, Karolinska Institute, Stockholm, Sweden, [2]Pathology, University of Crete, Heraklion Crete, Greece

Background: Receptor tyrosine kinase-like orphan receptor 1 (ROR1) is a member of the ROR family consisting of ROR1 and ROR2. RORs have been involved in physiologic embryonic patterning and neurogenesis and, in addition, ROR1 is only detectable in embryonic tissue and generally absent in normal adult tissues. Accumulating evidence has established ROR1 as a marker for chronic lymphocytic leukemia and possibly other hematologic malignancies. ROR1 seems to be critically involved in the progression of these diseases. However, the potential role of ROR1 receptor signaling in the pathogenesis of classical Hodgkin lymphoma (cHL) is yet unknown. Wnt5a, a member of the Wnt family, binds as a ligand to ROR1 and activates ROR1 signaling in various *in vitro* models. Recent evidence suggests that non-canonical Wnt5a pathway activity is involved in the mutual interactions between cHL cells and microenvironment. Therefore, the Wnt5a/ROR1 signaling merits further investigation in cHL.

Aims: To investigate the potential role of ROR1 receptor in tumor cell survival and proliferation in cHL and assess the effects of a novel ROR1 inhibitor in an vitro model of cHL.

Methods: Five cHL cell lines including L428, L1236, HDML2, HDMyZ and MDA-V were used. Expression, and localization (surface *vs* cytoplasmic) of ROR1 protein in the cell lines were assessed by Western blot and flow cytometry, respectively. Standard cell viability, apoptosis, proliferation and cytotoxicity assays were performed to assess the biologic effects after pharmacologic inhibition of ROR1 using the novel inhibitor, KAN00440571-C alone or in combination with ibrutinib. Silencing of ROR1 gene was performed using specific si-RNA constructs and the Nucleofector transfection system (Amaxa). The levels of critical cell cycle and apoptosis regulators were assessed by Western blot analysis. In a cohort of 110 previously untreated patients with cHL (University of Crete), ROR1 protein expression was assessed by immunohistochemistry performed on a tissue microarray (TMA) that included duplicate tumor cores from each case.

Results: ROR1 was differentially expressed among cHL cell lines with L1236, HDML2 and MDA-V expressing the highest protein levels in the cytoplasm or the surface of the cells. Similarly, ROR1 receptor was detected in the Hodgkin and Reed-Sternberg cells (HRS) of cHL in the cohort of 110 patients at a variable level (number of positive HRS, staining intensity). Selective inhibition of ROR1 using the novel inhibitor KAN571-C in HDML2 and MDA-V cells resulted in significantly increased cytotoxicity (MTT assay), which was associated with increased apoptosis and cell death as well as decreased cell proliferation. The efficiency of KAN571-C was substantially higher as compared with a previous ROR1 inhibitor (KAN0493834). Combination of KAN0440571-C with ibrutinib resulted demonstrated additive effects in the same *in vitro* model of cHL. These effects were linked to decreased levels of critical regulators of both the intrinsic (*i.e.* BAX, MCL-1) and extrinsic (*i.e.* cFLIP) apoptotic pathways. Knocking -down of the ROR1 gene by specific siRNA constructs resulted in decreased cell viability and proliferation as well as induction of apoptosis (up to 61% of the cHL cells), which was associated with changes in the protein levels of apoptosis regulators including BAX and cFLIP.
Summary and Conclusions: Taken together, these findings show for the first time that ROR1 receptor-mediated signaling may contribute to cell survival and proliferation in cHL *in vitro* and thus, it represents a promising target for investigational therapy using ROR1 inhibitors in cHL.

Hodgkin lymphoma – Clinical

PF423

TREATMENT RELATED INCIDENCE OF DISEASES OF THE CIRCULATORY SYSTEM IN PATIENTS DIAGNOSED WITH HODGKIN LYMPHOMA

C. Weibull[1,*], M. Björkholm[2], I. Glimelius[3,4], P. Lambert[5], T. Andersson[1], K. Ekström Smedby[3], P. Dickman[1], S. Eloranta[3]

[1]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, [2]Division of Haematology, Department of Medicine, Karolinska University Hospital Solna, [3]Clinical Epidemiology Unit, Department of Medicine Solna, Karolinska Institutet, Stockholm, [4]Department of Immunology, Genetics and Pathology, Uppsala Academic Hospital, Uppsala, Sweden, [5]Biostatistics Research Group, Department of Health Sciences, University of Leicester, Leicester, United Kingdom

Background: With excellent cure rates for patients diagnosed with Hodgkin lymphoma (HL), focus has shifted towards reducing long-term treatment related morbidity and mortality. The two major sequelae, with risk of fatal outcome, are secondary cancers and diseases of the circulatory system (DCS). In Sweden, a reduction in excess mortality due to DCS (that is, the DCS mortality attributable to the HL and its treatment) has been observed among long-term survivors since the mid-1980s. This is likely explained by less cardiotoxic HL treatment, improved risk communication and prevention, and better prognosis for individuals diagnosed with DCS.
Aims: We present temporal trends in excess DCS incidence among HL patients diagnosed in Sweden between 1985 and 2013. By characterizing the incidence of treatment related DCS we aim to enhance the understanding of the overall disease burden of DCS, and to provide data that may serve as a basis for further improvements of existing DCS prevention and treatment strategies in HL survivors.
Methods: We identified 4,479 patients (aged 18-80 years) with an HL diagnosis recorded in the Swedish Cancer Register during the study period. Patients were followed from diagnosis until the first diagnosis of DCS (ICD-10 codes I00-I99, or equivalent in earlier versions). Excess incidence was defined as the difference between the observed DCS incidence in the patient population and the incidence in the general population (assumed free from HL) matched on age, sex and year. Excess incidence rate ratios (EIRRs) with 95% confidence intervals (CIs) were estimated using flexible parametric relative survival models. As a measure of absolute risk, cumulative excess DCS incidence in the presence of competing risks (*i.e.*, deaths due to a non-DCS cause) was further calculated based on these models.
Results: Among all HL patients, 945 (21%) had a diagnosis of DCS during follow-up and another 978 (22%) died (due to causes unrelated to DCS). The five- and ten-year excess incidence of DCS decreased slightly between 1985 and the late 1990s among young (25-year olds: $EIRR_{5\text{-year}}$=0.36, 95% CI: 0.15-0.83, and $EIRR_{10\text{-year}}$=0.28, 95% CI: 0.11-0.72 comparing 1999 to 1985) and middle-aged patients (60-year olds: $EIRR_{5\text{-year}}$=0.52, 95% CI: 0.29-0.91, and $EIRR_{10\text{-year}}$=0.40, 95% CI: 0.21-0.80 comparing 1999 to 1985). No improvements were observed among elderly patients. The cumulative probability of excess DCS within the first five years after diagnosis remained stable throughout the study period. For patients treated in 2009, the treatment related risk of DCS within five years of diagnosis was 3.5% (95% CI: 1.6-5.4) for 25-year olds, 15.0% (95% CI: 10.3-19.6) for 60-year olds, and 17.0% (95% CI: 9.0-24.9) for patient aged 75 years.
Summary and Conclusions: Although excess incidence of DCS has decreased since the mid-1980s, at least for young- and middle-aged HL patients, treatment related DCS morbidity still persists. Further efforts towards reducing cardiotoxicity from first- and second line HL therapy are needed, and this study can thus serve as a basis for future analysis on DCS incidence among contemporarily treated HL patients.

PF424

ACTIVATED CASPASE-3 EXPRESSION BY HODGKIN AND REED-STERNBERG CELLS (HRS) IS A POWERFUL PROGNOSTIC FACTOR IN CLASSICAL HODGKIN LYMPHOMA (CHL) TREATED WITH ABVD OR EQUIVALENT REGIMENS

T. Vassilakopoulos[1,*], G. Rassidakis[2], E. Drakos[3], L.J. Medeiros[2], S. Viviani[4], G. Nadali[5], B. Thakral[2], M. Herling[6], R. Giardini[4], M. Chilosi[5], A. Kanta[3], C. Kittas[7], A. Gianni[4], G. Pizzolo[5], J. Khoury[2], G. Pangalis[1], F. Cabanillas[6], A. Sarris[6]

[1]Department of Haematology and Bone Morrow Transplantation, Laikon General Hospital, National and Kapodistrian University of Athens, Athens, Greece, [2]Depart-

ment of Hematopathology, The University of Texas M.D. Anderson Cancer Center, Texas, United States, [3]Department of Haematology, EUROCLINIC, Athens, Greece, [4]Department of Haematology, Istituto Nationale Tumori, Milano, [5]Department of Haematology, University of Verona, Verona, Italy, [6]Lymphoma Service, The University of Texas M.D. Anderson Cancer Center, Texas, United States, [7]Department of Histology-Embryology, National and Kapodistrian University of Athens, Athens, Greece

Background: Most HRS cells are derived from B-cells that lack surface B-cell receptor due to transcriptional defects or rearranged immunoglobulin genes bearing crippling mutations. Although this should normally lead to apoptosis, HRS cells escape apoptosis via several mechanisms. Caspase-3 is the executioner pro-apoptotic protease and its activation by cleavage leads to irreversible cell death irrespective of the upstream activated apoptotic pathways.
Aims: To investigate the expression of active caspase-3 (aC3) in HRS cells of cHL and correlate them with aC3 levels with BCL2 expression, presenting features and clinical outcome.
Methods: Eligible patients had biopsy-proven cHL treated with ABVD or equivalent regimens, pretreatment archival tumor tissue available and no HIV infection. Expression of aC3 (clone C92-605, BD Pharmingen) and BCL2 (clone 124, DAKO) were assessed by immunohistochemistry. A cutoff of 1% was used to define high *vs* low aC3 expression ($aC3^{high}$ *vs* $aC3^{low}$). Any BCL2 expression was considered positive (Rassidakis, Blood. 2002;100:3935-41).
Results: This study included 260 patients from 4 Centers, with baseline features consistent with an unselected series of non-pediatric cHL population: Median age 30 years, males 50%, B-symptoms 47%, Ann Arbor Stage (AAS) I 14%, II 46%, III 20%, and IV 20%. Histology was nodular sclerosis (NS) in 76%, mixed cellularity (MC) in 17% and other cHL 7%. Low (<1% of HRS cells) aC3 expression was observed in 156/260 patients (60%) (range, 0-5.5%). aC3 expression did not differ significantly between NS and MC, with $aC3^{high}$ in 39% of NS *vs* 43% of MC cases. There was absolutely no correlation between aC3 expression and any baseline feature reflecting demographics, tumor burden or disease aggressiveness. However, $aC3^{high}$ was observed in 52% *vs* 34% of $BCL2^{neg}$ and $BCL2^{pos}$ cases [U1] respectively (p=0.008). After a median follow-up of 17.5 years, the 20-year freedom from progression (FFP) was 90% *vs* 65% for $aC3^{high}$ *vs* $aC3^{low}$ patients (p<0.0001). The corresponding 20-year overall survival was 76% *vs* 64% (p=0.056). $aC3^{low}$ was an adverse prognostic factor for PFS within AAS I/II (91% *vs* 74%, p=0.02) and III/IV as well (89% *vs* 50%, p<0.0001). As previously published, BCL2 expression also correlated with inferior FFP (p=0.004). In multivariate analysis, $aC3^{low}$ and $BCL2^{pos}$ were independent adverse prognostic factors for FFP [hazard ratio (HR) 3.6 (95% CI 1.7-7.3), p=0.001 and HR 2.2 (1.1-4.3), p=0.02 respectively]. The 20-year FFP for patients whose tumors were $aC3^{high}/BCL2^{neg}$, either $aC3^{low}$ or $BCL2^{pos}$, and $aC3^{low}/BCL2^{pos}$ was 91% *vs* 84% *vs* 60% (p<0.0001). Within stages I/II, the 20-year PFS for these groups was 89% *vs* 86% *vs* 74% (p=0.15). Within stages III/IV, it was 91% *vs* 80% *vs* 43% (p<0.0001), with 25/97 (26%) and 42/97 patients (43%) falling into the low- and the high-risk group. Other established prognostic factors, such as stage IV, low albumin, anemia and high LDH could add independent prognostic information to the aC3/BCL2 model (data to be presented at the Meeting).
Summary and Conclusions: In a large study with extremely long follow-up, $aC3^{high}$ HRS cell expression was associated with superior FFP after ABVD or equivalent regimens. The combination $aC3^{low}/BCL2^{pos}$ defined a sizeable (~43% of patients) subgroup of advanced cHL with very poor outcome reflected by PFS<50%. Similarly, a very low risk subgroup can be defined as $aC3^{high}/BCL2^{neg}$ for both early and advanced cHL, with 5- and 20-year failure rates of <5% and ~10%.

PF425

RISK OF SECOND MALIGNANCIES IN HODGKIN LYMPHOMA PATIENTS IN THE NEW MILLENNIUM: REAL WORLD EVIDENCE FROM THE SEER DATABASE

V. Shivarov[1,*], M. Ivanova[2]

[1]Laboratory of Clinical Immunology and Department of Clinical Hematology, Sofiamed University Hospital, [2]Laboratory of Clinical Immunology, Alexandrovska University Hospital, Sofia, Bulgaria

Background: The risk of long-term toxicity in patients treated for Hodgkin lymphoma (HL) including development of second solid cancer (SSC) and hematological malignancies (SHM) has been recognized early on during the development of curative approaches in this lymphoma subtype.
Aims: We decided to complement the existing data with an analysis of the risk of second cancers in adult patients diagnosed with HL after 2000 using the data from a population based cancer registry – The Surveillance, Epidemiology, and End Results (SEER) program of the NCI with its latest release from April 2017.
Methods: To numerically assess the incidence of second malignancies in HL patients we used the standardized incidence ratio (SIR). We estimated the 99% confidence intervals (CIs) for the calculated SIRs based on the exact method. The cumulative incidence (CumIn) of second hematological and solid neoplasms was calculated with a competing risk survival methodology. Fine and Gray model was used to model the effect of different variables on the CumIn.
Results: We identified a total of 28450 adult (≥18 years) patients with HL reported in the SEER registry between 2000 and 2014. A total of 1432 cases with second cancers were identified, conferring overall statistically increased risk – SIR: 1.75 (99% CI: 1.63-1.87). The risk was increased for both SSC (SIR: 1.32 (99% CI: 1.21-1.43)) and SHM (SIR: 6.34 (99% CI: 5.59-7.17)). The risk was increased irrespective of gender, race, periods of diagnosis, stages, histological subtypes, for use of chemotherapy and radiotherapy. All age groups also showed increased risk except for the elderly patients. The SIR for all solid cancers was 1.32 (99% CI: 1.21-1.43). The incidence of radiation exposure related cancers such as thyroid cancer (SIR: 3.07 (99% CI: 2.27-4.06)) and lung cancer (SIR: 1.71 (99% CI: 1.4-2.08)). However, the incidence of female breast cancer was not increased (SIR: 0.74 (99% CI: 0.54-0.98)). The SIR for all SHMs was 6.34 (99% CI: 5.59-7.17) with significant increase for NHLs (SIR: 9.17 (99% CI: 7.92-10.56)) and acute non-lymphocytic leukemia (SIR: 8.71 (99% CI: 6.2-11.87)). However, there was no significantly increased risk of ALL (SIR: 3.26 (99% CI: 0.7-9.23)) and multiple myeloma (SIR: 1.36 (99% CI: 0.62-2.55)). SSCs occurred later than SHMs with median latency of 53.03 and 41.18 months, respectively ($p<10^{-5}$). The 10-year CumIn for SSC and SHM was 4.69% and 1.96%, respectively. In univariate Fine and Grey models of death, SSCs and SHMs as competing risks, chemotherapy and radiotherapy alone were not significant risk factors for SSC for SHM (p=0.076 and p=0.106, respectively), whereas only radiotherapy was significant risk factor for any type of SHM (p<0.0001). Combined modality treatment (CMT), however, was significant risk factor for both SSC and SHM (p=0.002 and p<0.0001, respectively).
Summary and Conclusions: Our analysis based on the SEER database shows no significant decrease of the risk for second solid and hematological malignancies in HL survivors diagnosed in USA after 2000. Interestingly, the incidence of female breast cancer was not increased, which might be attributed to the shorter follow-up and the inclusion of only adult patients. Repeated analysis at a later time point would address this issue more adequately. In spite of the efforts for optimization of CMT for HL in the last decades it seems that consistent mitigation of risk for second cancer would be eventually achieved only with the bringing of immunotherapy to the forefront of HL management.

PF426

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION AFTER NIVOLUMAB TREATMENT IN RELAPSED/REFRACTORY HODGKIN LYMPHOMA

J.-B. Mear[1,*], E. Nicolas-Virelizier[2], J.-M. Schiano[3], B. Bareau[4], B. Deau[5], H. Lanic[6], A. Schmitt[7], L. Molina[8], K. Bouabdallah[9], A. Tempescul[10], W. Lescaut[11], T. Marchand[12], G. Manson[12], R. Houot[12]

[1]Hematology, CHU Rennes, Rennes, [2]Centre Léon Berard, Lyon, [3]Institut Paoli Calmette, Marseille, [4]Clinique Sévigné, Rennes, [5]Hematology, APHP (Cochin), Paris, [6]Hematology, Centre Henri Becquerel, Rouen, [7]Institut Bergonié, Bordeaux, [8]CHU Grenoble, Grenoble, [9]CHU Bordeaux, Bordeaux, [10]CHU Brest, Brest, France, [11]Centre Hospitalier Princesse Grace, Monaco, Monaco, [12]CHU Rennes, Rennes, France

Background: Anti-PD1 antibodies have been approved for the treatment of relapse/refractory (R/R) Hodgkin lymphoma (HL). Responders are likely to be candidates for allogeneic hematopoietic stem cell transplantation (alloHSCT). However, preliminary results (Merryman *et al.*, Blood 2017, N=39 HL) suggest that alloHSCT after PD-1 blockade may be associated with increased immune toxicity.
Aims: To evaluate the safety and efficacy of alloHSCT in patients with R/R Hodgkin lymphoma previously treated with nivolumab.
Methods: We retrospectively analyzed 14 patients with R/R HL who were treated with nivolumab in the French early access program (EAP) between March and August 2015 and underwent alloHSCT thereafter.
Results: The median age was 31 (19-44) and the median number of prior treatment lines was 6 (3-11). Ten (71.4%) patients had received prior autologous HSCT and all of them had received Brentuximab-Vedotin. Patients

had received a median of 7.5 (4-23) cycles of Nivolumab before transplantation. Median time between the last infusion of nivolumab and alloHSCT was 32 days (15-115). Graft source was haplo-identical donor in 7 (50%) patients. At the time of alloHSCT, 8 (57.1%) patients were in complete remission (CR), 4 (28.6%) were in partial remission, one patient had progressive disease (PD) and one patient was not evaluated. After a median follow up of 17.5 month (9-27), 12 (85.7%) patients were still alive, 1 patient died of hemoptysis and 1 patient died of acute Graft *versus* host disease (GvHD). Ten (71.4%) patients remained in CR (the two other patients were not evaluated). All evaluated patients converted to CR. Median PFS and OS have not been reached. Three patients (21,2%) developed grade 3-4 acute GVHD and 3 patients developed chronic GVHD (one mild, one moderate and one severe). The six patients not in CR before AlloHSCT were in CR at post-transplant evaluation (Figure 1).

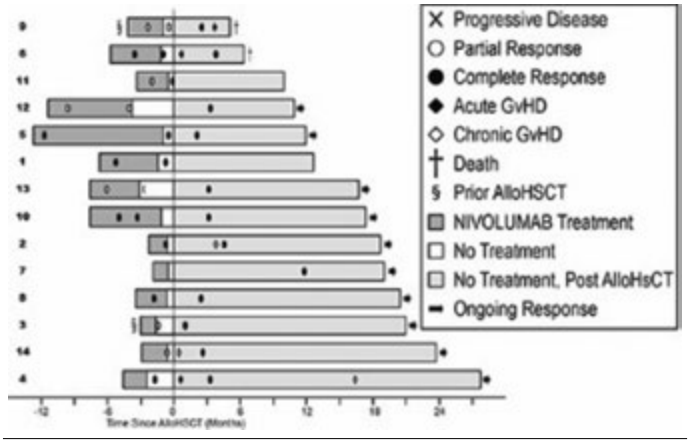

Figure 1.

Summary and Conclusions: AlloHSCT after Nivolumab treatment appears feasible and is associated with prolonged remissions in patients with R/R Hodgkin lymphoma. Updated results will be presented at the meeting.

PF427

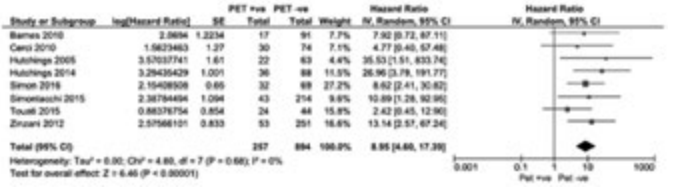
INTERIM- PET RESULTS FOR PROGNOSIS IN ADULTS WITH HODGKIN LYMPHOMA: A PROGNOSTIC FACTOR EXEMPLAR REVIEW (PRELIMINARY RESULTS)

A. Aldin[1,*], G. Collins[2], K. Moons[3], L.J. Estcourt[4], A. Engert[5], C. Kobe[6], B. von Tresckow[5], M. Trivella[7], N. Skoetz[1]

[1]Cochrane Haematological Malignancies, Department I of Internal Medicine, University Hospital of Cologne, Cologne, Germany, [2]Centre for Statistics in Medicine, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, [3]Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands, [4]Haematology/Transfusion Medicine, NHS Blood and Transplant, Oxford, United Kingdom, [5]Department I of Internal Medicine, [6]Department for Nuclear Medicine, University Hospital of Cologne, Cologne, Germany, [7]Centre for Statistics in Medicine, University of Oxford, Oxford, United Kingdom

Background: [18F]-fluorodeoxy-D-glucose (FDG)-positron emission tomography (PET) has been increasingly used for staging, potential prognosis and treatment planning in patients with Hodgkin Lymphoma (HL). Particularly an interim FDG-PET scan identifies the state of disease after a few cycles of chemotherapy and it has been suggested to be a good predictor of prognosis, aiding the distinction between patients with poor prognosis from those with a better prognosis.
Aims: To identify all studies evaluating interim-PET scan results as a prognostic factor, and where treatment was not modified due to the interim-PET result. Further, to describe the characteristics and risk of bias of included studies and if possible, meta-analyse results on the association between PET scan results and overall survival (OS), progression-free survival (PFS) and adverse events (AE).
Methods: Based on a-priori Cochrane protocol, we developed sensitive search strategies for Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, databases of ongoing trials and conference proceedings (search date 07/2017). Two authors independently assessed studies for eligibility using pre-defined inclusion and exclusion criteria. Data were extracted using a self-developed data extraction form for prognostic factor studies. Methodological quality of studies was assessed using the Quality in Prognosis Studies (QUIPS) checklist. The primary outcome was OS and secondary outcomes were PFS and AE. We used hazard ratios (HR) as an effect measure. Where values were not available, we attempted to estimate it using available data according to the methods suggested by Tierney and colleagues. We included studies which evaluated interim-PET as a prognostic factor after a few cycles of first-line chemotherapy in adult patients with HL. We excluded studies which modified treatment based on interim-PET results. This project was funded by the German Federal Ministry of Education and Research, grant number 01KG1709.
Results: A total of 28 eligible studies were identified, including 6328 patients diagnosed with HL. However, during data extraction four studies were excluded as they did not present any results for our outcomes of interest. One additional study was excluded during data extraction because it included patients with additional disease. All studies reported values for OS and/or PFS, but no study reported values for AE. Here, we present the **preliminary results** of a meta-analysis of the primary outcome OS, including eight studies with 1151 patients. All patients received first-line chemotherapy with ABVD (doxorubicin, bleomycin, vinblastine and darcarbacine), with or without radiotherapy, and interim-PET was conducted after two cycles of chemotherapy. Meta-analysis shows a higher OS of PET-negative patients than PET-positive patients, with a HR of 8.95 [95% Confidence Interval (CI) 4.60, 17.39] (Table 1).

Table 1.



Summary and Conclusions: Despite the wide CI, we seem to have positive results that interim-PET can be considered a prognostic factor for OS in univariate analysis. As a next step, we need to examine other concurrent factors in order to identify the prognostic ability of interim-PET. However, the lack of standard reporting of prognostic studies, and the consequential poor quality and reliability of reported data in the primary studies makes it difficult to give final conclusions at this stage. We are currently in the process of contacting authors in order to receive more information and data in order to update our data set and analysis accordingly.

PF428

DOWNREGULATION OF STATS DETERMINE POOR PROGNOSIS IN HODGKIN'S LYMPHOMA

A. Zargari[1], K. D. Cummins[2], A. Pham[3], P. Hosking[4], E. Hawkes[5], S. Ting[1,2,*]

[1]Haematology, Eastern Health, Box Hill, [2]Haematology, [3]Anatomical Pathology, Alfred Health, Melbourne, [4]Anatomical Pathology, [5]Oncology, Eastern Health, Box Hill, Australia

Background: Patients with Hodgkin Lymphoma (HL) have a long term overall survival (OS) of approximately 85%. Despite prognostication tools, with the IPS-7 being the most commonly used, a small subset of patients deemed "favourable" unpredictably relapse and progress despite autologous stem cell transplant and novel salvage therapies. To investigate the mechanisms driving treatment-refractory HL, we hypothesised that upregulation of the JAK-STAT pathway within pathognomonic Hodgkin-Reed-Sternberg (HRS) cells may act as both biomarker of poor prognosis and a potential targeted pathway for therapy.
Aims: To stain diagnostic HL tissue with candidate biomarkers, pSTAT3, STAT1, p53, CD68 and PD1 by immunohistochemistry (IHC) and correlate these with clinical outcome.
Methods: An initial retrospective test cohort (n=29) from one institution with known OS was chosen for staining with pSTAT3 and PTP1B. Cohort A (n=18) had durable complete remission (100% 5-year OS) whilst cohort B (n=11) had relapsed/refractory (R/R) disease (54.5% 5-year OS). We sought to validate this with retrospective analysis of a separate cohort of HL patients at our institution whose clinical outcome was unknown; of the 98 patients assessed for diagnostic tissue availability, 53 patients were eligible for tissue staining with pSTAT3, STAT1, p53, CD68 and PD1.
In both the test and validation cohorts, anatomical pathologists were blinded to the patients' identity and scored HRS cells (based on a combination of morphology and CD15/30 staining; using previously published cut-offs) for:

(i) STAT intensity (low or high) and overall percentage of positive STAT stained HRS cells; (ii) p53 wild-type (weak positive) or dysregulated (absent or strongly positive) and surrounding (non-HRS) cells for CD68 and PD1. Kaplan-Meier OS and progression free survival (PFS) analyses were performed on this validation cohort based on each candidate biomarker assessment.

Results: The experimental design to assess the initial cohort was based on the hypothesis that upregulated JAK-STAT would correlate with worse prognosis; however, the reverse was found to be true with both low intensity (p=0.003) and reduced percentage (p=0.008) of pSTAT3 staining in HRS cells was seen in patients with poor outcomes. This loss of STAT signalling was further evaluated in the validation cohort.

The diagnostic samples from our validation cohort (n=53) showed different staining intensities of p53 in HRS cells and both CD68 and PD1 in surrounding "inflammatory" cells, but there were no differences in either 5-year OS or PFS between cohorts whose samples were stained for p53, CD68 or PD1. In contrast, as with the test cohort, low (n=23) *versus* high (n=30) intensity staining of pSTAT3 in HRS cells correlated with both inferior 5-year OS (73% *vs* 93%, p=0.0148) and PFS (47% *vs* 72%, p=0.113), shown in Figure 1. A similar pattern was demonstrated with STAT1 staining, with low (n=19) *versus* high (n=34) staining correlating with a 5-year OS of 69% *vs* 93% (p=0.0050) and PFS 54% *vs* 66% (p=0.4165). Demographics including: sex, age, stage at diagnosis and treatment received were similarly represented in the low and high staining groups for both pSTAT3 and STAT1.

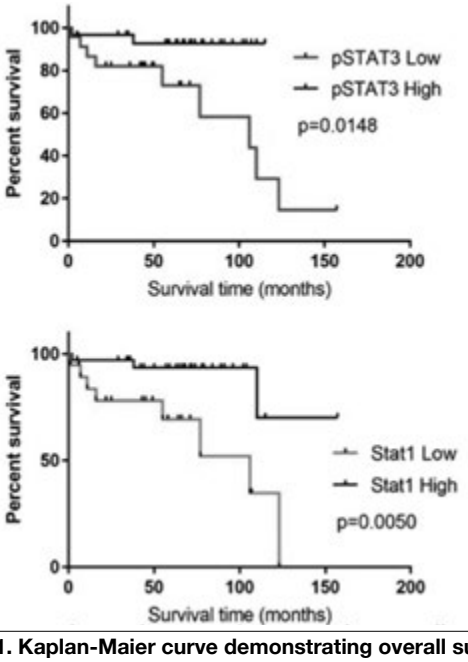


Figure 1. Kaplan-Maier curve demonstrating overall survival of low *vs* high intensity staining HRS cells for pSTAT3 and STAT1.

Summary and Conclusions: Contrary to our hypothesis of an upregulated JAK-STAT pathway portending poor prognosis in HL patients, these retrospective analyses in fact correlate down-regulation of pSTAT3/STAT1 (by IHC) with statistically significant inferior OS in both a targeted R/R and an independent validation cohort. These results suggest novel insights into HL biology where STAT transcription may function as a tumour suppressor.

PF429

A PHASE 1 STUDY INVESTIGATING THE COMBINATION OF AFM13 AND PEMBROLIZUMAB IN PATIENTS WITH RELAPSED/ REFRACTORY HODGKIN LYMPHOMA AFTER BRENTUXIMAB VEDOTIN FAILURE: UPDATED SAFETY AND EFFICACY DATA

N.L. Bartlett[1], R.W. Chen[2], A. Forero-Torres[3], P. Armand[4], I.S. Lossos[5], C.B. Reeder[6], A. Strassz[7,*], C. Choe-Juliak[8], S.M. Ansell[9]

[1]Washington University in St. Louis, St. Louis, MO, [2]City of Hope, Duarte, CA, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Dana-Farber Cancer Institute, Boston, MA, [5]Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Miami, FL, [6]Mayo Clinic, Scottsdale, AZ, United States, [7]Affimed GmbH, Heidelberg, Germany, [8]Affimed, Inc., New York, NY, [9]Mayo Clinic, Rochester, MN, United States

Background: AFM13 is a bispecific, tetravalent NK cell-engaging antibody construct binding to CD30 on Hodgkin Lymphoma (HL) cells and CD16A on NK cells. By engaging CD16A-positive NK cells, AFM13 leads to NK-cell mediated killing of CD30-positive lymphoma cells (Reusch *et al.*, 2014). Pembrolizumab is a PD-1 blocking antibody that prevents tumor immune evasion and has shown to induce high single-agent response rates in patients (pts) with relapsed or refractory (R/R) HL (Armand *et al.*, 2016). AFM13 has shown first signs of clinical activity in R/R HL as single agent in a preceding Phase 1 study (Rothe *et al.*, 2015). Preclinical *in vivo* data of the combination of AFM13 with PD-1 inhibition suggest potential synergistic activity and the potential for induction of cross-talk between innate and adaptive immunity (Zhao *et al.*, 2016). The combination of the two agents could potentially improve outcomes in pts with R/R HL.

Aims: A Phase 1b study is ongoing to evaluate the safety and tolerability of the combination of AFM13 with pembrolizumab (Keytruda) as salvage therapy after failure of standard therapies including brentuximab vedotin in HL (NCT02665650).

Methods: Patients (pts) receive escalating doses of AFM13 (Table 1) in combination with pembrolizumab at a dose of 200 mg flat administered every 3 weeks following the classical 3+3 design. Upon completion, recruitment continues into an extension cohort. Response assessment is performed every 12 weeks by PET/CT according to the Lugano Classification Revised Staging System for malignant lymphoma (Cheson *et al.*, 2014).

Results: As of January 31st 2017, 12 pts have been enrolled into the dose escalation part of the study and 3 pts have been enrolled into the extension part of the study. All pts have relapsed disease and have failed standard treatments including brentuximab vedotin. Preliminary data presented earlier showed that the combination of AFM13 and pembrolizumab is well-tolerated and that the 3-month ORR of the combination compares favorably to historical ORR of pembrolizumab alone. 3-month response data from the dose-escalation and extension cohorts will be reported at the 23rd Congress of EHA.

Table 1. Dose escalation and extension of AFM13.

	Weeks 2 & 3	Weeks 4, 5, 6, 7, 8, 9	Weeks 10, 13, 16, 19, 22 & 25
Cohort 1	0.1 mg/kg x 3	0.5 mg/kg	0.5 mg/kg
Cohort 2	0.5 mg/kg x 3	1.5 mg/kg	1.5 mg/kg
Cohort 3/ Extension	3 mg/kg x 3	7.0 mg/kg	7.0 mg/kg

Summary and Conclusions: Early data suggest that the combination of AFM13 and pembrolizumab is a well-tolerated salvage therapy in pts with R/R HL. While IRRs were observed frequently, most of these events were of mild or moderate severity. Moreover, the combination showed promising signs of antitumor activity which will be further analyzed in the extension cohort.

PF430

PAEDIATRIC HODGKIN LYMPHOMA IN VERY YOUNG PATIENTS: THE ITALIAN EXPERIENCE

Background: Many studies described a more favorable outcome in younger patients affected by paediatric Hodgkin's Lymphoma (HL).
Aims: The first aim of this study was to find an appropriate age cut-off able to detect low risk children. After having identified the most reliable cut-off, the next step was to describe the natural history in a large group of very young HL patients.
Methods: By using the database of patients enrolled in in 3 following national A.I.E.O.P. (Associazione Italiana di Emato-Oncologia Pediatrica) trials MH89, MH96 and LH2004 for paediatric HL, we have evaluated data of 1584 patients, applied a ROC curve based procedure, identified a reliable age cut-off and described the natural history of 148 very young patients treated from 1.1.1989 to 1.4.2016. We considered the following data at diagnosis: age, sex, stage, symptoms A *vs* B, TG, date of relapse/progression, date of second malignant neoplasm (SMN), date of last follow-up (FUP) and FUP status.
Results: The ROC analysis to set an appropriate cut-off for age showed that, while age seemed to behave as a weak prognostic factor (AUC=0.532), using Youden's index as a parameter the best cut-offs were found in the range of 7 – 11 years ; we chose to use, among the values in that range, the 7 year age value, which is the one with highest sensitivity, because, in the perspective of using it as a cut-off to identify patients with a better prognosis, it is definitely preferable to have a low number of false negatives. Table 1 shows sex, stage, symptoms (A *vs* B) and Therapeutic Group (TG) distribution in the 2 age groups (≤7 years and >7 years of age): male sex, stage I, A symptoms and TG1 were much more frequent in the younger cohort. Significant difference between the two age groups are present also in terms of EFS (p=0.0267), PFS (p=0.0056) and OS (p=0.0378). Then we verified how sex, protocol, A - B symptoms, stage and TG influenced the EFS and PFS of the whole case study: sex was not relevant (p=0.16 for EFS and 0.3 for PFS), protocol showed borderline significance (p = 0.0424 and 0.0667), whereas symptoms A *vs* B (p=1.49e-09 and 5.31e-11), stage (I-II *vs* III-IV) (p=1.77e-05 and 0.0001) and TG (1-2 *vs* 3) (p=1.21e-10 and 9.89e-11) were extremely significant.. So, in order to verify if the better prognosis of younger patients could be attributed to the different risk factors, we carried out a multiple Cox model analysis of EFS and PFS over the entire case study, including as prognostic variables age (≤7 years), A - B symptoms, stage (I-II *vs* III-IV) and TG (1-2 *vs* 3). This analysis showed that age group was not independently associated to prognosis. More specifically for both EFS and PFS the only independently significant prognostic factors are TG (p=0.003 for EFS and 0.0012 for PFS) and A - B symptoms (p=0.0008 for EFS and 0.0002 for PFS).

Table 1.

Sex, stage, A - B symptoms and TG distribution in the 2 age groups

Sex distribution by age					
	F	%	M	%	p
≤ 7y	29	19.6	119	80.4	1.17e-09
> 7y	655	45.6	781	54.4	

Stage distribution by age									
	I	%	II	%	III	%	IV	%	p
≤ 7y	39	26.4	61	41.2	32	21.6	16	10.8	7.602e-13
> 7y	107	7.5	715	49.8	336	23.4	278	19.4	

A - B symptoms distribution by age					
	A	%	B	%	p
≤7y	122	82.4	26	17.6	2.518e-07
>7y	875	60.9	561	39.1	

TG distribution by age							
	1	%	2	%	3	%	p
≤7y	79	53.4	35	23.6	34	23.0	2.2e-16
>7y	279	19.5	328	22.8	829	57.7	

y: years; TG: therapeutic group

Summary and Conclusions: Children affected by HL older than 7 years of age present a higher rate of primary treatment failures and mortality, but the better prognosis in younger patients seems to be related to a different presentation of the disease.

PF431

NIVOLUMAB IN COMBINATION WITH BRENTUXIMAB VEDOTIN IN PATIENTS WITH RELAPSED OR REFRACTORY HODGKIN'S LYMPHOMA AFTER FAILURE OF NIVOLUMAB MONOTHERAPY

L. Tsvetkova[1,*], K. Lepik[1], A. Kozlov[1], E. Kondakova[1], Y. Zalyalov[1], E. Borzenkova[1], V. Baykov[1], N. Mikhailova[1], B. Afanasyev[1]

[1]Raisa Gorbacheva Memorial Institute of Children Oncology Hematology and Transplantation, Saint-Petersburg, Russian Federation

Background: Nowadays chemotherapy induces durable remission rates of 60% to 80% of newly diagnosed patients with Hodgkin's lymphoma. High-dose chemotherapy followed by autologous hematopoietic stem cell transplantation (auto-HSCT) induce responses in 50% of patients with relapsed or refractory Hodgkin's lymphoma (r/r HL), but some of the patients remain to be resistant. Brentuximab vedotin (BV) is a highly efficient agent for HL relapses after auto-HSCT. Immunotherapy with PD-1 blocking monoclonal antibody nivolumab demonstrated significant activity in patients with r/r HL after auto-HSCT and BV. However, the relapses still occur. There are data, that nivolumab and BV may have synergistic effects and improve outcomes of treatment r/r HL.
Aims: The goal of this analysis was to evaluate the safety and the efficacy of combination nivolumab+BV in patients with relapsed or refractory Hodgkin's lymphoma after failure of nivolumab in monotherapy.
Methods: The current analysis included 10 patients (6 male,4 female) with the median age of 28 (range, 23-35 years). All patients received nivolumab in monotherapy previously with the median number of infusions 18 (12-27). During previous therapy 40% of patients had undergone auto-HSCT, 70% had prior treatment with BV. The progression of disease was observed in 80% of patients at initiation of nivolumab+BV therapy and two patients had indeterminate response by LYRIC (LYmphoma Response to Immunomodulatory therapy Criteria). Patients were treated in 21-day cycles for up to 4 (range, 3-6) cycles. BV (1.8 mg/kg) and nivolumab (3 mg/kg) was given on day 1. Toxicity was graded according to the NCI CTC for Adverse Events (AEs) (version 5.0). After completion of treatment, the responses were evaluated by PET-CT scan and assessed by investigators according to the LYRIC.
Results: Median follow-up time was 10.8 months from first dose (range; 7,4–13). The objective response rate among all treated patients was 70% with the CR rate of 30%; 2 (20%) patients had indeterminate response and 1 patient - stable disease. A decrease of SPD was observed in 90% of patients. Relapse with an increase in tumor volume and metabolic activity occurred in one patient after achieving of CR. Six patients received subsequent salvage combination therapy nivloumab+bendamustine after nivolumab+BV treatment. One patient proceeded to allogeneic hematopoietic stem cell transplantation in the CR. Nine patients (90%) experienced treatment adverse events (AEs). Among the most common were nausea (40%) and peripheral neuropathy (30%). Grade 3 adverse events developed in one patient (10%) as a maculopapular rash. Combined treatment was discontinued in cases of severe adverse events. Rash was resolved using systemic glucocorticosteroids. At the time of analysis 9 (90%) were alive at the time of analysis. One patient died due to the secondary myelodysplastic syndrome, which preceded nivolumab therapy, with transformation to chemoresistant acute myeloid leukemia.
Summary and Conclusions: The conducted study suggests that nivolumab+BV combination may represent highly active salvage regimen for patients with r/r HL after failure of nivolumab monotherapy. The toxicity profile was favorable with manageable adverse events. Nivolumab and BV combination probably demonstrated synergism of action and it can be effective even in patients who had resistance to monotherapy of this agents.

PF432

THE COMBINATION OF ALISERTIB AND ROMIDEPSIN IS A SAFE AND EFFECTIVE REGIMEN FOR RELAPSED/REFRACTORY AGGRESSIVE HODGKIN AND T-CELL LYMPHOMAS: A PHASE 1 STUDY

P. Strati[1,*], Y. Oki[1], L. Fayad[1], L. Nastoupil[1], N. Fowler[1], F. Hagemeister[1], L. Kwak[2], H. Lee[1], M. Wang[1], J. Westin[1], C. Ruben[1], E. Wesson[1], M. Fanale[1]

[1]MD Anderson Cancer Center, HOUSTON, [2]City of Hope, Duarte, United States

Background: In preclinical studies, aurora A kinase inhibitors have shown to enhance lymphoma cell death to histone deacetylase inhibitor through repression of C-Myc and C-Myc-responsive micro RNAs, exhibiting highly synergistic effects in lymphoma cell lines through cytokine modulation.
Aims: Therefore, we initiated a phase I trial (NCT01897012) combining alisertib with romidepsin in patients with multiple lymphoma subtypes.
Methods: Patients with PTCL, Hodgkin lymphoma (HL) or aggressive BCL, relapsed or refractory to at least 1 line of therapy, were eligible for the study. Eight dose levels were defined and a standard 3+3 design used for dose escalation; cycles were repeated every 21 days for levels 1-4, amended to every 28 days for levels 5-8, for a maximum of 8 cycles. Dose limiting toxicity (DLT) was assessed during cycle 1 and defined as grade 4 neutropenia or thrombocytopenia lasting longer than 14 days and/or uncontrollable grade 3 or 4 non-hematological toxicity.
Results: Twenty-five patients have been enrolled in the study between 08/2013 and 10/2017. Median age was 56 (range, 23-77 years) and 21 (84%) were male; 12 (48%) patients had aggressive diffuse large B-cell lymphoma (DLBCL), 7 (28%) HL, 4 (16%) PTCL, and 2 (8%) Burkitt lymphoma (BL); median number or previous regimens was 4 (range, 1-10), 9 (36%) patients had received autologous stem cell transplant (SCT) and 7 (28%) allogeneic SCT; overall response rate (ORR) to latest regimen was 24% and 23 (92%) patients had relapsed within 6 months. One additional patient was enrolled at dose level 6, because of 1 withdrawal before DLT assessment. Median number of cycles delivered was 2 (range, 1-8) and 24 (96%) patients have discontinued treatment to date; reasons for study discontinuation were: progression in 19 (79%) patients, completion of treatment in 2 (9%), indication for SCT in 1 (5%), patient's choice in 1 (4%) and toxicity in 1 (4%). No DLTs have been observed to date. The most common (>10%) grade 3-4 toxicities were thrombocytopenia (40%), anemia (28%), neutropenia (24%), infections (24%) and fatigue (16%). Twenty-one patients were evaluable for response by PET/CT; among 12 patients who had a decrease in tumor burden, median reduction was 49% (range, 7-89%), and among 9 patients who had an increase in tumor burden, median increase was 49% (range, 4-300%). Three patients (12%) achieved complete remission (2 patients with HL, 1 with PTCL), 2 (8%) partial remission (1 with DLBCL and 1 with PTCL), and 7 (28%) stable disease, and ORR rate was 20%. Only 1 (5%) patient proceeded to SCT (allogeneic) after 3 months of treatment. After a median follow-up of 5 months (range, 1-46 months), median progression-free survival (PFS) was 2 months (range, 1-21 months), and the longest PFS (>6 months) was observed in 2 patients with heavily pretreated HL (lymphocyte depleted) and 3 patients with PTCL. At most recent follow-up, 24 (96%) patients have progressed, 1 after SCT. Median OS was 12 months (range, 1-46 months), and at most recent follow-up, 11 (44%) patients have died, all of disease progression.
Summary and Conclusions: The combination of romidepsin and alisertib can be safely used as salvage therapy in patients with relapsed or refractory aggressive Hodgkin lymphoma and T cell lymphoma. As the majority of patients developed disease progression during follow-up, further investigation is needed about the role of maintenance therapy, identification of predictive factors of response, and evaluation of other targeted therapy doublets or triplets.

PF433

ΔSUVMAX AND ΔSUVPEAK IMPROVE THE NEGATIVE PREDICTIVE VALUE OF INTERIM PET SCAN IN HODGKIN LYMPHOMA

T. Ribeiro[1,*], G. Ferreira[2], A.I. Marques[1], M. Tavares[1], C. Castro[3], J. Lobo[4], B. Loureiro[1], D. Pereira[1], S. Chacim[1], N. Domingues[1], A. Espírito Santo[1], Â. Martins[1], I. Moreira[1], I. Oliveira[1], L. Viterbo[1], C. Moreira[1], M. Mariz[1]

[1]Onco-hematology, [2]Nuclear Medicina, [3]Epidemiology, [4]Pathological Anatomy, Instituto Português de Oncologia - Porto, Porto, Portugal

Background: Current therapies for Hodgkin Lymphoma (HL) achieve high complete response rates and overall survival. Limiting therapy-associated toxicity is now one of the main goals. Early positron emission tomography (PET) scan, performed after 2-4 cycles of chemotherapy (interim PET, PETi), may represent an important tool for early recognition of good response to first-line therapy and to guide de-escalation of therapy. PET interpretation is usually performed according to the 5-point scale (5-PS), a qualitative visual scale. Although having shown a higher predictive value for patient outcome compared to the currently available prognostic scores, it has limitations related to the reproducibility between observers. Therefore, alternative semiquantitative strategies based on the standardized uptake value (SUV) have been developed. The maximum SUV (SUVmax) is widely used, although it is significantly influenced by some technical details and tumoral heterogeneity. On the other hand, peak SUV (SUVpeak) relates to greater intra-patient reproducibility, being the proposed measure in PET Response Criteria in Solid Tumors. It is still to be determined which strategy would be best in evaluating PET results in HL patients and how PETi results correlate with patient outcome.
Aims: To compare the interpretation of the PETi scan result according to the 5-PS with ΔSUVmax or ΔSUVpeak between staging PET scan and PETi scan, in predicting outcome in HL patients.
Methods: Retrospective single-center analysis of 99 HL patients diagnosed according to the WHO classification criteria between 2012 and 2016 in our Institution, with median follow-up of 46.5 months. Fifty-eight patients with available staging and interim PET scans were analysed. In order to define PETi result as positive or negative according to ΔSUVmax or ΔSUVpeak, we used receiver-operating-characteristics curves and Youden index to determine best cut-off values.
Results: A positive PETi result consisted of a score of 4 or 5 in the 5-PS, or ΔSUVmax below 93.5% or ΔSUVpeak below 88.4%, according to our results. Of the 58 patients in our analysis, 2 had a positive PETi[5-PS] result (only one had persistent disease) and 56 had a negative PETi[5-PS] result (9 of these had persistent or relapsed disease). Considering PETi[ΔSUVmax] and PETi[ΔSUVpeak], 18 and 17 patients respectively had a positive result (7 of these patients had persistent or relapsed disease). The interpretation of PETi result according to ΔSUVmax and ΔSUVpeak showed higher sensitivity (70% in both cases) compared to the 5-PS (sensitivity of 10%), but lower specificity (77% and 79% for ΔSUVmax and ΔSUVpeak respectively, with 98% for the 5-PS). Therefore, ΔSUVmax and ΔSUVpeak have a very high negative predictive value (93% and 98% respectively; *vs* 85% for the 5-PS), but a lower positive predictive value than the 5-PS (39% and 41% respectively; *vs* 50% for the 5-PS). There is statistically significant difference between the progression free survival (PFS) curves at 60 months of follow-up of patients with positive and negative PETi[ΔSUVmax] (56.9% and 88.0%, respectively, $p<0.05$) and PETi[ΔSUVpeak] results (55.9% and 88.1%, respectively, $p<0.05$). The PFS of patients with negative PETi[5-PS] at 60 months of follow-up was 73.8% (Table 1).

Table 1.

	VISUAL ANALYSIS (1,2,3, vs. 4,5)	ΔSUVmax (93≤ % VS. > 93%)	ΔSUVpeak (88≤ % VS. > 88%)
SENSITIVITY	10% IC 95%(0.25-44.5)	**70%** IC 95%(34.8-93.3)	**70%** IC 95%(34.8-93.3)
SPECIFICITY	**98%** IC 95%(89.5-99.9)	77% IC 95%(62.7-88.0)	79% IC 95%(65.0-89.5)
NEGATIVE PREDICTIVE VALUE	85% IC 95%(81.3-87.3)	93% IC 95%(82.5-97.0)	**98%** IC 95%(82.9-97.0)
POSITIVE PREDICTIVE VALUE	**50%** IC 95%(6.37-93.6)	39% IC 95%(24.8-55.2)	41% IC 95%(86.0-58.3)

Summary and Conclusions: ΔSUVmax and ΔSUVpeak appear to discriminate better between patients who respond well to therapy, so that a negative result could support de-escalating therapy intensity, and those with persistent or relapsed disease, which would otherwise go unnoticed. More studies are needed to address these questions and confirm these results.

PF434

OUTCOME OF ELDERLY PATIENTS WITH CLASSICAL HODGKIN LYMPHOMA IN CENTRAL SCOTLAND, UK

M. Rafferty[1,*], A. Ivanos[1], K. Leighton[2], F. Scott[2], P. McKay[1]

[1]Haematology, NHS Greater Glasgow and Clyde, Glasgow, [2]Haematology, NHS Lothian, Edinburgh, United Kingdom

Background: Survival of patients with Hodgkin lymphoma (HL) has improved in recent years due to more effective use of chemo-radiotherapy. HL in the young is generally associated with a good overall prognosis. Despite these advances in treatment, management of the older patient with HL remains challenging. 5-year overall survival in the UK is less than 50% in patients aged over 60 years. Reported outcome rates vary across Europe with location and regimen used. Observational Swedish data from Sjoberg *et al* in 2012 shows a 59% 5-year overall survival. The presence of co-morbidities and excess treatment related toxicities make delivery of combination chemotherapy in this age group difficult.
Aims: The aim of this study was to evaluate the outcome of older patients diagnosed with classical HL treated in Edinburgh and Glasgow, Scotland, UK.
Methods: Departmental records were used to retrospectively identify patients aged over 60 years with classical HL diagnosed between 2009 and 2014. The Cumulative Illness Rating Scale for Geriatrics was calculated in a subset of patients as a measure of elderly 'comorbid burden'. Statistical analysis was performed using GraphPad Prism statistical software ©.

Results: 71 consecutive patients were reviewed. Median age at diagnosis was 72 (range 60-85) years. 43 patients (61%) were male. 14 patients had early stage disease (EORTC: 100% unfavourable); 56 patients had advanced stage disease (median Hasenclever 4; 2-6); staging information was unavailable for 1 patient. CIRS-G score was available for 25 patients; median total CIR-G score was 7 (0-16); median CIRS-G severity index was 1.7 (0-2.3). 59 patients (83%) received intensive chemotherapy: 46 (65%) received ABVD (bleomycin omitted at outset in 10 patients); 7 (10%) received ChLVPP; 4 (6%) received VEPEMB; 2 (3%) received P-VACE-BOP. Consistency was seen within the 60-69 year old cohort where 85% of patients received ABVD chemotherapy. 2 patients (3%) received palliative radiotherapy and 10 patients (14%) were palliated supportively. Successful delivery of planned chemotherapy was achieved in 53% of patients receiving intensive treatment (59% ABVD, 29% ChLVPP, 25% VEPEMB, 50% P-VACE-BOP). Bleomycin was discontinued in 6 patients (17%) treated with full ABVD due to clinical or radiological concerns of pulmonary toxicity. 5-year overall survival within our patient cohort was 42%. Median overall survival (OS) and progression free survival (PFS) were 40 and 36 months for all patients, 56 and 52 months for patients receiving intensive therapy, and 1.5 and 1.5 months for those receiving non-intensive measures. OS and PFS in the 60-69 year cohort (47% of those treated intensively) were 75 and 75 months *versus* 20 and 14 months in the 70-85 year cohort (53% of those treated intensively. Of those patients treated with ABVD/AVD chemotherapy (n=46), median OS was 85 months in those achieving successful full delivery of planned chemotherapy. Total CIRS-G score was inversely associated with overall survival (p=0.0033).
Summary and Conclusions: The high overall survival rates seen in the young are not reproducible in older patients with current combination chemotherapy regimens. Older patients are more likely to require de-escalation of therapy due to toxicities although those elderly patients who receive the planned dose of chemotherapy have much improved outcome. Overall survival in our cohort was lower than that seen in large European cohorts which may reflect the inclusion of frail patients within our analysis. Alternative treatments must be explored, especially in frail patients >70 years, in the context of clinical trials.

Indolent Non-Hodgkin lymphoma – Clinical

PF435

LONG-TERM FOLLOW-UP OF VEMURAFENIB IN BRAF MUTANT HAIRY CELL LEUKEMIA SHOWS DURABLE REMISSIONS AND HIGH RESPONSE RATES WITH REPEATED TREATMENT WITH VEMURAFENIB AT RELAPSE

J. Park[1,*], S. Vemuri[1], S. Chung[1], O. Abdel-Wahab[1], M. Tallman[1]

[1]Memorial Sloan-Kettering Cancer Center, New York, United States

Background: We have previously reported high response rates of the BRAF inhibitor, vemurafenib, in 26 U.S. patients with BRAF mutant relapsed or refractory (R/R) hairy cell leukemia (HCL) (Tiacci and Park *et al.* N Engl J Med 2015). However, follow-up duration of the study was short (median 11.7 months), and outcomes of the patients who relapse after vemurafenib remain largely unknown.
Aims: We analyzed the rates and timing of relapse with a longer follow-up duration for a total of 36 patients in the completed trial with an emphasis on responses to retreatment with vemurafenib at relapse.
Methods: Adult patients with R/R HCL were enrolled to the phase II clinical trial (NCT01711632), and received vemurafenib 960mg bid for 3-6 months. The trial enrollment has now been completed. During subsequent follow-up, patients with relapsed disease were allowed to be re-treated with vemurafenib until disease progression or development of unacceptable toxicity. Vemurafenib dose could be adjusted to as low as 240mg bid.
Results: Among the 36 enrolled patients, 31 patients completed at least 1 month of therapy and were evaluable for response; 5 patients discontinued therapy before response assessment due to drug-related toxicities (n=3), patient desire (n=1) and infection (n=1). Of the 31 evaluable patients, 8 patients (26%) achieved complete response (CR), 22 patients (71%) achieved partial response (PR), and 1 patient achieved no response with an overall response rate of 97%. With a median follow-up of 24 months (range, 1-61 months), 17 of 31 patients (55%) experienced relapse. The median time to relapse from treatment initiation was 18 months (range, 6.7-47 months). All 17 patients with relapse had retained BRAF V600E mutation, and 11 patients (65%) received retreatment with vemurafenib, 4 patients (24%) received alternative treatment, and 2 patients (12%) were observed. With retreatment of vemurafenib at relapse, 9 of 11 patients (82%) achieved PR with complete hematologic recovery; 1 patient developed acquired resistance to vemurafenib with KRAS mutation; and 1 patient discontinued therapy after 1 week due to drug-related toxicity (photosensitivity). Vemurafenib retreatment was well-tolerated with a median duration of therapy of 7 months (range, 0.3-39 months) but all patients received a lower dose of 240-480mg bid due to prior toxicity experience from initial treatment.
Summary and Conclusions: With a longer follow-up duration of up to 61 months, we confirm the high anti-tumor efficacy and safety of vemurafenib monotherapy in patients with R/R HCL. While relapses were common, retreatment with vemurafenib, even at a lower dose of 240mg bid, was highly effective (82% response rate) and acquired resistance to vemurafenib was rare. However, optimal duration of vemurafenib at retreatment remains unknown, and an addition of anti-CD20 monoclonal antibody may improve the CR rate and remission duration.

PF436

METABOLIC (PET) AND MRD RESPONSE CONFER REDUCED RISK OF PROGRESSION OR DEATH IN PATIENTS TREATED WITHIN THE PHASE III GALLIUM STUDY

C. Pott[1,*], A. Davies[2], W. Hiddemann[3], E. Hoster[3], R. Marcus[4], C. Schmidt[3], C. Harbron[5], K. Mundt[6], T. Nielsen[6], J. Trotman[7]

[1]University Hospital Schleswig-Holstein, Kiel, Germany, [2]Cancer Research UK Centre, University of Southampton, Southampton, United Kingdom, [3]Department of Medicine III, University Hospital Munich, Munich, Germany, [4]Kings College Hospital, London, [5]Roche Products Ltd, Welwyn, United Kingdom, [6]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [7]Concord Repatriation General Hospital, University of Sydney, Sydney, Australia

Background: In the randomised GALLIUM (NCT01332968) trial of 1202 previously untreated follicular lymphoma (FL) patients (pts), the primary endpoint of investigator (INV)-assessed progression-free survival (PFS) was significantly prolonged with obinutuzumab (GA101; G)-based *vs* rituximab (R)-based immunochemotherapy and maintenance (Marcus *et al.* NEJM

2017). Lymphoma metabolic activity by ^{18}F-FDG PET-CT (PET) (Lugano 2014 criteria) showed complete metabolic response (CMR) at end of induction (EOI) to be prognostic for prolonged PFS and overall survival (Trotman *et al.* Haematologica 2017); minimal residual disease (MRD)-negative status in peripheral blood (PB) and/or bone marrow (BM) was prognostic for prolonged PFS (Pott *et al.* Blood 2016). MRD is a sensitive molecular measure of disease in PB and/or BM, and may add to PET prognostic information.
Aims: We assessed the relationship between EOI MRD and PET responses in GALLIUM and prognostic implications for PFS in previously untreated pts with FL.
Methods: Pts in GALLIUM received induction with G or R plus bendamustine, CHOP or CVP chemotherapy followed by maintenance with the same antibody in responders. PET scans were performed at baseline and EOI (6–8 weeks after Day 1 of the last cycle of induction) and assessed by an Independent Review Committee (IRC). PET images were assessed according to the Lugano 2014 criteria, with CMR defined as a score of 1, 2 or 3 on the 5-Point Scale. For MRD assessment, diagnostic PB and BM samples were screened by consensus PCR to detect a clonal t(14;18) translocation and/or Ig variable domain rearrangement. In pts with a detectable clonal marker, standardised allele- or translocation-specific real-time quantitative (RQ)-PCR assays with a sensitivity of $\leq 10^{-4}$ were performed and evaluated by European Study Group criteria (van der Velden *et al.* Leukemia 2007). MRD at EOI was defined as positive if RQ-PCR or subsequent qualitative nested PCR were positive in PB or BM.
Results: At baseline, 595/609 (98%) pts with PET scans had detectable lesions and 815/1101 (74%) pts with MRD evaluable samples had an MRD marker meeting the predefined quality criteria; 298 pts were evaluable for both measures at EOI. These pts were slightly younger, and had more advanced disease and fewer Asian pts than the non-evaluable intent-to-treat population (n=904). CMR was achieved by 266/298 evaluable pts (89%); 250 (94%) were MRD-negative. Median follow-up in the evaluable group was 44 months. In 250 CMR pts with MRD-negativity, 2.5-year PFS from EOI was 85% (95% CI: 80–89; Figure 1). In Cox proportional hazards modelling, this group had better INV-assessed PFS than the other groups: hazard ratio (HR)=0.39 (95% CI: 0.17–0.93; p=0.03) *vs* pts with CMR and MRD-positive response (n=16); and HR=0.39 (95% CI: 0.19–0.81; p=0.01) *vs* pts without CMR who were MRD-negative (n=24). Too few pts without CMR but with MRD-positive response (n=6) were available for Cox analysis. Results for IRC-assessed PFS were similar to those for INV-assessed PFS.

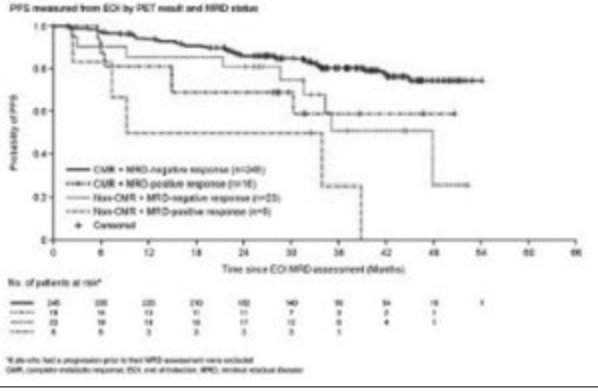

Figure 1.

Summary and Conclusions: Most evaluable pts achieved CMR and MRD-negativity, with a minority progressing despite a favorable prognosis. Risk of progression or death in pts achieving only CMR or MRD-negativity was 2.5-fold greater than that in pts who achieved both, suggesting that EOI PET and MRD responses could provide complementary information. Further evaluation of quantitative PET indices and molecular markers, and of early progressors, may help to identify additional prognostic markers.

Background: Subsets of B cell malignancies depend on tonic B cell antigen receptor (BCR) signaling for survival. SYK is a key regulator of BCR signaling (upstream of BTK and PI3K), and its inhibition using entospletinib has demonstrated clinical activity in B cell malignancies. SYK is also expressed in peripheral T cell lymphomas (PTCL), and pre-clinical evidence suggests it may be an oncogenic driver in this disease. Importantly, tumor growth may additionally be supported by autocrine or paracrine derived cytokines. IL2, IL4, and IFN alpha are all known to promote basal survival and protect against drug-induced cell death in chronic lymphocytic leukemia (CLL) *in vitro*. Furthermore compared to control tissues, lymph nodes from patients with follicular lymphoma (FL) have greater numbers of T follicular helper (T_{FH}) cells that express high levels of IL-4 which appears to drive tumor progression. Of particular interest, subsets of PTCL express either wild type SYK or overexpress SYK following an ITK-SYK translocation. Genetic or pharmacological inhibition of SYK expressing PTCL cell lines results in reduced growth and increased cell death. In contrast transgenic expression of ITK-SYK in mice CD4+ T cells generates a lethal T cell lymphoproliferative disease. Activating mutations in JAK/STAT pathways in PTCL are also frequently observed. These data suggest that combined SYK/JAK inhibition may have therapeutic activity in B and T cell malignancies. Cerdulatinib is a selective and potent inhibitor of SYK, JAK1, JAK3 and TYK2. A phase 1 dose escalation study of cerdulatinib in 43 patients with r/r CLL and B cell NHL was completed in 2016 (Hamlin *et al.*, EHA Congress 2016). Inhibition of SYK and JAK was well tolerated and consistent anti-tumor activity was seen in CLL and FL.
Aims: Here, we report the interim results on the efficacy and safety of cerdulatinib in an ongoing phase 2a study in patients with r/r B- and T-cell lymphoma.
Methods: An ongoing phase 2a study is to assess the antitumor activity of cerdulatinib in patients with specific subtypes of B cell or T cell NHL or CLL/SLL (ClinicalTrials.gov ID: NCT01994382). In this interim analysis, the safety and efficacy of cerdulatinib dosed 30 mg orally BID in patients with r/r B- and T-cell lymphoma was investigated. Response was assessed by Lugano Classification criteria.
Results: Ninety-nine patients were enrolled, 36 with FL, 28 with CLL/SLL, 18 with PTCL, 8 with MZL, 4 with WM, and 5 with aggressive NHL. Median age was 68 (42-93) and median number of prior therapies was 3 (1–13). 30 patients had prior BTK, PI3K or BCL-2 inhibitor therapy. The most common AEs of any grade were diarrhea (42%), fatigue (36%), and nausea (32%). Grade 3+ AEs occurring in ≥5% patients were neutropenia (18%), lipase increase (15%), pneumonia (12%), diarrhea (10%), and fatigue (7%). Five patients have had grade 5 infections considered potentially related to study drug, primarily in advanced stage CLL patients. The target PK range has been achieved with an average SSCmin of ~0.8 µM. Broad clinical activity has been observed, including: 61% ORR in CLL/SLL, 50% in FL, and 43% in PTCL (4 CRs, 2 PRs in 14 patients). The first PTCL patient enrolled achieved a CR and remains on drug at 12 months. Durable PRs have occurred in patients who relapsed on BTK inhibitor (CLL, 5+ months, WM, 7+ months, FL, 12 months), venetoclax (SLL, 18+ months).
Summary and Conclusions: The cerdulatinib phase 2a dose of 30 mg BID demonstrated good tolerability and efficacy in patients with heavily pretreated r/r B and T cell NHL.

PF438

ACALABRUTINIB ALONE OR IN COMBINATION WITH RITUXIMAB IN FOLLICULAR LYMPHOMA

N.H. Fowler[1,*], M. Coleman[2], D. Stevens[3], S. Smith[4], P. Venugopal[5], P. Martin[2], T. Phillips[6], R. Agajanian[7], D.M. Stephens[8], R. Izumi[9], J. Cheung[9], J.G. Slatter[9], M. Yin[9], M. Hiremath[9], N. Hunder[9], B. Christian[10]

[1]The University of Texas MD Anderson Cancer Center, Houston, [2]Weill Cornell Med-

icine, New York, [3]Norton Cancer Institute, Louisville, [4]University of Chicago, [5]Rush University Cancer Center, Chicago, [6]University of Michigan, Ann Arbor, [7]The Oncology Institute of Hope & Innovation, Downey, [8]University of Utah Huntsman Cancer Institute, Salt Lake City, [9]Acerta Pharma, Redwood City, [10]The Ohio State University Comprehensive Cancer Center, Columbus, United States

Background: Bruton tyrosine kinase (BTK) inhibition has shown clinical benefit in follicular lymphoma (FL). Acalabrutinib is a highly selective, potent, covalent inhibitor of BTK.
Aims: This Phase 1b study evaluated acalabrutinib±rituximab in patients with treatment-naive (TN) or relapsed/refractory (R/R) FL.
Methods: Patients with R/R FL (≥1 prior treatment) were randomized to acalabrutinib (mono) or acalabrutinib+rituximab (combo); TN patients received the combo. In 28-day cycles, rituximab (375 mg/m^2 IV) was given weekly in Cycle 1 and on Day 1 of Cycles 2-6; acalabrutinib (100 mg PO bid [2 patients received 200 mg qd]) was given until progressive disease (PD) or intolerance. The primary endpoint was safety. Secondary endpoints included overall response rate (ORR), duration of response (DOR), pharmacokinetics (PK) and pharmacodynamics.
Results: Thirteen TN and 27 R/R patients were treated. In all patients, the median age was 66 years (range 32-83), 98% of patients had ECOG PS ≤1, and 88% had stage III/IV disease. R/R patients received a median of 2 prior therapies (range 1-5). At a median follow-up of 22 and 7.6 months, 62% of TN patients and 26% of R/R patients, respectively, were still on treatment. Discontinuations were primarily due to PD (TN 15%; R/R 56%) and adverse events (AEs; TN 8%; R/R 11%). BTK occupancy and PK parameters were consistent with previous acalabrutinib studies. In all patients, the most common AEs of any grade were fatigue (48%), headache (43%), diarrhea (40%), nausea (30%) and sinusitis (25%). The most common Grade 3/4 AEs were hypertension (8%), increased alanine aminotransferase, increased aspartate aminotransferase, and cellulitis (all 5%), with no Grade 5 events. There were no cases of atrial fibrillation or Grade ≥3 hemorrhage. Efficacy outcomes are reported in the Table 1.

Table 1.

	TN combo (n=13)	R/R combo (n=13)	R/R mono (n=12)[a]
ORR[b] (≥ partial response), n (%)	12 (92)	5 (39)	4 (33)
95% CI	64, 100	14, 68	10, 65
Complete response	4 (31)	1 (8)	1 (8)
Median DOR, mo	NR	NR	NR
Range[c]	12.1 to 20.5+	10.8+ to 20.5+	0.03+ to 18.7+

NR: not reached.
[a]The 2 patients dosed at 200 mg qd are not included (1 stable disease, 1 PD).
[b]Investigator assessed using Cheson 2014 criteria.
[c]"+" indicates ongoing response.

Summary and Conclusions: Acalabrutinib, alone and combined with rituximab, was well-tolerated and yielded promising response rates in FL. These results support further evaluation of acalabrutinib in FL.

PF439

RESPONSE RATE TO LENALIDOMIDE PLUS RITUXIMAB (R2) IS INDEPENDENT OF RITUXIMAB-REFRACTORY STATUS: INITIAL INTERIM ANALYSIS OF MAGNIFY PHASE IIIB STUDY OF R2 FOLLOWED BY MAINTENANCE IN R/R INDOLENT NHL

M.J. Rummel[1,*], D.J. Andorsky[2,3], M. Coleman[4], A. Yacoub[5], J. Melear[3,6], H. Brooks[3,7], S. Fanning[3,8], K. Kolibaba[3,9], F. Lansigan[10], C. Reynolds[11], J. Li[12], D. Liu[12], M. Llorente[12], J.L. Ricker[12], J. Sharman[3,13]

[1]Justus-Liebig Universität, Giessen, Germany, [2]Rocky Mountain Cancer Centers, Boulder, [3]The US Oncology Network, The Woodlands, [4]Clinical Research Alliance Inc, Weill Cornell Medicine, New York, [5]The University of Kansas Cancer Center, Westwood, [6]Texas Oncology-Austin, Austin, [7]Oncology and Hematology Associates, Roanoke, [8]Greenville Health System, Greenville, [9]Compass Oncology, Vancouver, [10]Dartmouth-Hitchcock Medical Center, Lebanon, [11]IHA Hematology Oncology Consultants - Ann Arbor, Ypsilanti, [12]Celgene Corporation, Summit, [13]Willamette Valley Cancer Institute and Research Center, Eugene, United States

Background: Relapsed/refractory indolent non-Hodgkin lymphoma (iNHL) is generally considered incurable at advanced stages. Patients refractory to their last prior treatment, including rituximab, have poor prognosis with limited treatment options. Combination immunotherapy lenalidomide with rituximab (R^2) has shown promising efficacy and tolerability in multiple NHL studies.
Aims: This report explores the association between rituximab-refractory baseline status and response to R^2.
Methods: MAGNIFY (NCT01996865) is a phase IIIb, multicenter, open-label study of relapsed/refractory NHL patients, including follicular lymphoma (FL) grade 1-3a and marginal zone lymphoma (MZL). Upon informed consent, patients receive 12 cycles of R^2 (lenalidomide 20 mg/d, d1-21/28+standard rituximab). Patients with stable disease or better are randomized 1:1 to maintenance with R^2 or rituximab alone for a total of 18 cycles. This analysis focuses on the initial period prior to randomization (12 cycles R^2) comparing patients who were rituximab-refractory, defined as experiencing a best response of ≤SD or ≥PR lasting <6 months following patient's last prior rituximab dose, or rituximab-sensitive prior to enrollment.
Results: As of May 1, 2017, 232 patients have been enrolled in the initial treatment period, including 186 patients with FL grade 1-3a and 46 patients with MZL (n=26 nodal MZL, n=10 each MALT lymphoma and splenic MZL). Overall, median age was 66 years (range, 35-91), 54% were male, most had ECOG PS 0-1 (96%) and stage III/IV disease at study entry (89%). Analyzed subgroups included 138 (59%) rituximab-sensitive and 94 (41%) rituximab-refractory patients. Baseline characteristics were generally similar for these subgroups, including a median number of 2 prior systemic therapies for both groups. Rituximab-sensitive and rituximab-refractory patients have been on the study for a median follow-up time of 11.2 and 12.3 months, respectively. In efficacy-evaluable patients, the overall response rates (ORR) in the rituximab-sensitive and rituximab-refractory groups were 75% and 58%, respectively (Table 1). Median time to response (mTTR) was 2.8 months (range, 2-12) for both groups. For rituximab-sensitive and rituximab-refractory groups, 1-year rates for progression-free survival (PFS; 95% CI) were 76% (67% - 83%) and 60% (50% - 68%), and for DOR were 82% (68% - 91%) and 73% (51% - 87%), respectively. The most common grade ≥3 treatment-emergent adverse events for rituximab-sensitive and rituximab-refractory patients, respectively, were neutropenia (29%; 40%), thrombocytopenia (8%; 8%), anemia (6%; 2%), and leukopenia (5%; 7%).

Table 1. Efficacy of R^2 in efficacy-evaluable patients according to rituximab-refractory status.

	Rituximab-Sensitive (n=110)	Rituximab-Refractory (n=77)
ORR	75%	58%
CR/CRu	47%	35%
Median TTR, months (range)	2.8 (2-12)	2.8 (2-12)

Summary and Conclusions: In patients with relapsed/refractory FL grade 1-3a and MZL, initial treatment with R^2 showed clinically significant activity and tolerable safety profiles for patients, regardless of their prior response to a rituximab-containing regimen. Enrollment in MAGNIFY is ongoing in the USA and Europe.

PF440

AUTOLOGOUS STEM CELL TRANSPLANTATION MAY CURE FOLLICULAR LYMPHOMA PATIENTS WITH EARLY THERAPY FAILURE WHO REACH COMPLETE RESPONSE AFTER RESCUE TREATMENT IRRESPECTIVE OF PREVIOUS RITUXIAMB EXPOSURE.

A. Jiménez Ubieto[1,*], C. Grande [1], D. Caballero[2], L. Yañez[3], A. López-Guillermo[4], A. Salar[5], J.J. Lahuerta[1]

[1]Hematología, Hospital 12 de Octubre, Madrid, [2]Hematología, Hospital Universitario de Salamanca, Salamanca, [3]Hematología, Hospital Universitario Marqués de Valdecilla, Santander, [4]Hematología, Hospital Clinic de Barcelona, Barcelona, [5]Hematología, Hospital San Pau, Barcelona, Spain

Background: Patients with follicular lymphoma (FL) experiencing early therapy failure (ETF) within two years of frontline chemotherapy/immunochemotherapy have poor overall survival (OS) and lack of standard therapeutic options.
Aims: To analyse data from the GELTAMO registry to determine whether ASCT is an effective option in this high-risk subgroup of FL patients.
Methods: ETF was defined as failure to achieve at least PR after first line chemotherapy/immunochemotherapy (primary refractoriness) or relapse/progression within 2 years of starting first line chemotherapy/

immunochemotherapy. We identified two groups: the EFT cohort (n=155: 15 primary refractory patients, 95 transplanted in CR2 and 45 in PR2] and the non-EFT cohort [FL patients who received ASCT in either CR2 or PR2 but who did not experience ETF following first-line therapy (n=62: 50 transplanted in CR2 and 12 in PR2]. We additionally analyzed outcome of patients who need >1 therapy lines to reach CR1/PR1 and underwent ASCT in first response (n=152; CR1=85 and PR1=67).

Results: In the ETF cohort and non-ETF cohort, a total of 54 (35%) and of 16 (31%) patients were exposed to rituximab before ASCT. Median follow-up from ASCT was 12 years .In the ETF group a total of 74% of the patients received ASCT within the first year after treatment failure. Patient/disease characteristics were well balanced between the EFT and non–EFT except for: a) status of the disease at the moment of ASCT (CR2 60% *vs* 80%; *P*=.005, PR2 30% *vs* 22%; *P*=.005 and resistant/refractory 10% *vs* 0%; *P*=.01), b) median time from FL diagnosis to ASCT (28 months *vs* 67 months; *P*<.00001) and c) the number of therapy lines to reach first response (28% *vs* 8%; *P*=.01), respectively. In the ETF group a total of 74% of the patients received ASCT within the first year after treatment failure. There was a significant difference in PFS (*P*=0·016) between the ETF and non-ETF cohorts, with 5-year PFS from ASCT of 45% and 58%, respectively. Nevertheless, in patients experimenting EFT with an interval from first relapse after primary treatment to ASCT <1 year, the 5-year PFS was 55%; similar to that of the non-EFT cohort (*P*=0·5).There was no significant difference in OS (*P*=0·27) between the ETF and non-ETF cohorts, with 5-year OS of 70% and 77% respectively (Figure 1). In the EFT cohort, on multivariate analysis, the factors associated with inferior OS were age >46 years (HR=1.85; 95% CI=1.08-3.18; P=-02), male sex (HR=1.89; 95% CI=1.15-3.2; P=.01), a status of disease different to CR at ASCT (HR=2.24; 95% CI=1.44-3.56; P=.0005) and the use of bone marrow as stem cell source (HR=2.56; 95% CI=1.42-4.64; P=-.0002). In the ETF group, in patients transplanted in CR (n=95), there was a plateau in the PFS and OS curves beyond 12.7 years of follow-up at 40%. Finally; 5-year PFS and OS of patients needing >1 therapy line to reach CR1/PR1 (n=152; 33% of them exposed to rituximab before ASCT) and undergoing ASCT in first response presented a 5-year PFS and OS of 60% and 77%, respectively.

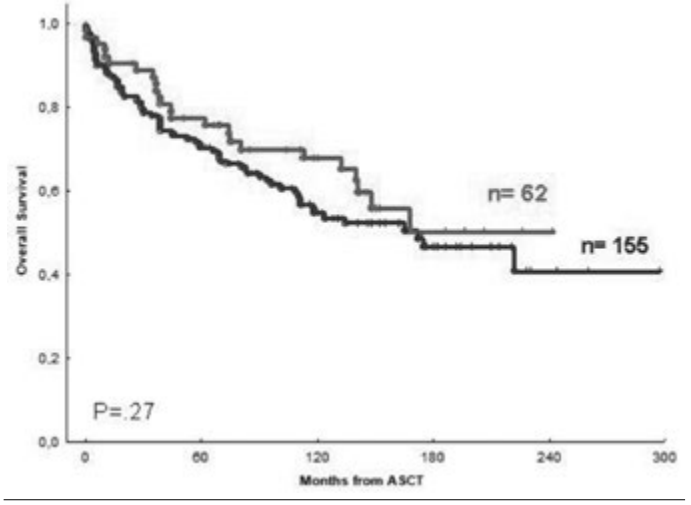

Figure 1.

Summary and Conclusions: ASCT can be a curative and cost-effectiveness option in ETF who respond to rescue treatments, irrespective of previous rituximab use. However, the value of ASCT in primary refractory patients remains to be elucidated. Additionally, patients requiring more the one line to reach CR1/PR1 are good candidates to consolation with ASCT. Nevertheless, large randomized trails focus on high risk patients and biological research are urgently needed.

PF441

RESULTS OF A DOSE ESCALATION STUDY OF ME-401, A SELECTIVE PI3KΔ INHIBITOR, IN RELAPSED/REFRACTORY (R/R) FOLLICULAR LYMPHOMA (FL) AND CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)/SMALL LYMPHOCYTIC LYMPHOMA (SLL)

Background: PI3Kδ mediates B-cell receptor signaling and microenvironmental support signals that promote the proliferation and survival of malignant B lymphocytes. ME-401 is a potent, structurally differentiated, second generation oral tyrosine kinase inhibitor highly selective for PI3Kδ. Pharmacokinetic (PK) and pharmacodynamic data from a prior study in healthy volunteers informed the starting dose for this first-in-patients trial.

Aims: This phase 1b study evaluated the safety, tolerability, dose limiting toxicities (DLT), maximum tolerated dose (MTD), efficacy, and PK of ME-401 in patients (pts) with R/R FL or CLL/SLL.

Methods: Eligible pts ≥18 years of age had FL or CLL/SLL, relapsed disease after ≥1 prior therapy, ECOG performance status ≤2, no prior PI3K therapy, and no prior progression of disease (POD) on BTK therapy. ME-401 was given once daily on days 1-28 of 28-day cycle until POD or unacceptable toxicity. All pts received PJP prophylaxis, and CMV monitoring was mandatory. Dose escalation was guided by a continuous reassessment model (CRM) design to identify the MTD. At least 6 evaluable pts were treated at each dose level, with option to expand to 12 pts for further efficacy assessment. DLT were assessed in the first 56 days window. Response was assessed after Cycles 2 and 6, and then every 6 months or as clinically indicated, using the IWCLL 2008 and Lugano 2014 criteria.

Results: 31 pts (21 FL, 10 CLL/SLL) received ME-401 and 30 were evaluable for DLT: 12 at 60 mg, 12 at 120 mg, and 6 at 180 mg. Median age was 65 years (range: 47-79), 12/30 (40%) pts received ≥2 prior therapies, and 9/21 (43%) pts with FL had POD <24 months after initial chemoimmunotherapy (POD24). Of 29 pts evaluable for response, the overall objective response rate (ORR) was 83% (24/29), including 21% (6/29) with a complete nodal response. An objective response was noted by Cycle 2 in 21/24 (88%) responders. In FL, the ORR was 75% (15/20), including 9/9 (100%) who had POD24. In CLL/SLL, the ORR was 100% (9/9). No DLTs were reported and dose escalation above 180 mg was closed given frequent responses across lower dose levels. With a median follow-up of 23 weeks (range: 5-55 weeks), 3 pts had POD at Weeks 8, 14 and 17. Five pts discontinued ME-401 due to adverse events (AEs): rash (n=3), colitis (n=1), and cardiomyopathy (n=1), and 2 pts discontinued for personal reasons at Weeks 4 and 21. Most common AEs (all grades/grade ≥3) were diarrhea (32%/16%), fatigue (29%/0%), cough (29%/0%), rash (29%/10%), and nasal congestion (26%/0%). All grade ≥3 AEs were reported in Cycle 3 or later. Dosing was interrupted in 9/31 pts (29%) to manage toxicities. PK parameters were dose proportional, and steady state pre-dose plasma concentrations exceeded the EC90 of the basophil activation test (BAT) at all 3 doses.

Summary and Conclusions: ME-401 resulted in frequent early responses among pts with R/R FL, including POD24, and CLL/SLL. No DLTs were reported in the first 56 days, and the MTD was not identified. Dose escalation was closed due to high ORR across lower dose levels. Toxicities were manageable, albeit still with limited follow-up. An alternative dosing (ME-401 given on days 1-7 of 28-day cycle starting with Cycle 3) is being evaluated, including dosing ME-401 at 45 mg and at 60 mg in combination with rituximab with various B-cell malignancies.

PF442

SHORT DIAGNOSIS TO TREATMENT INTERVAL IS ASSOCIATED WITH POOR OUTCOMES IN PATIENTS WITH FOLLICULAR LYMPHOMA TREATED WITH IMMUNOCHEMOTHERAPY

M.R. Clausen[1,*], B.K. Link[2], C. Madsen[1], G. Nowakowski[3], T.E. Witzig[3], A. Feldman[4], S.L. Slager[5], T.M. Habermann[3], S.M. Ansel[3], F. d'Amore[1], J.R. Cerhan[5], M. Maurer[5]

[1]Department of Hematology, Aarhus University Hospital, Aarhus, Denmark, [2]Division of Hematology, Oncology and Blood & Marrow Transplantation, University of Iowa Hospitals and Clinics, Iowa City, [3]Division of Hematology, [4]Department of Laboratory Medicine and Pathology, [5]Department of Health Sciences Research, Mayo Clinic, Rochester, United States

Background: The time interval from diagnosis to treatment initiation (DTI) has prognostic implications in diffuse large B-cell lymphoma. Patients who

initiate therapy urgently (shorter DTI) have more adverse prognostic features and poor outcomes compared to patients with longer DTI.
Aims: To evaluate whether this also applies to patients with follicular lymphoma (FL) initially managed with immunochemotherapy (IC).
Methods: Discovery was performed in patients prospectively enrolled from Iowa/Mayo Lymphoma SPORE Molecular Epidemiology Resource (MER) with validation in the Danish Lymphoma Registry (LYFO). Patients had newly diagnosed FL grades 1 to 3a, were treated with rituximab(R)-CVP, R-CHOP or R-bendamustine based therapy and had treatment initiated within 90 days of biopsy leading to the diagnosis. We excluded patients who had CNS-lymphoma or had a discordant lymphoma including DLBCL at diagnosis. DTI was defined as days from the initial biopsy containing lymphoma to first day of treatment. We analyzed DTI both on a continuous scale and dichotomized in 0-14 days *vs* >14 days based on functional form assessment. Kaplan-Meier curves and Cox regression (adjusted for FLIPI and treatment) were used to assess the association of DTI with event free survival (EFS) and overall survival (OS) from initiation of therapy.
Results: 447 patients from the MER diagnosed from 2002-2015 and 918 from the LYFO diagnosed from 2001-2012 were included. In the MER, median age was 59 years (IQR: 49, 68), 56% were male, and FLIPI was 0-1 in 28%, 2 in 33% and 3-5 in 39%. At a median follow-up of 75 months (range: 1-168) 178 (40%) had events and 92 (21%) had died. In the LYFO, median age was 62 years (IQR: 54, 69), 52% were male, and FLIPI was 0-1 in 16%, 2 in 26%, and 3-5 in 58%. Median follow-up was 52 months (range: 2-173) with 331 (36%) events and 205 (22%) deaths. Median DTI was 22 days (IQR: 13, 35) in the MER with 29% initiating therapy within 14 days of diagnosis; median DTI in the LYFO was 24 days (IQR: 13, 41) with (30%) initiating therapy within 14 days. For both cohorts early DTI (0-14 days) was significantly associated with elevated LDH, anemia, and poor performance status; however, association between DTI and FLIPI did not reach significance (MER p=0.12, LYFO p=0.07). Early DTI was strongly associated with inferior EFS and OS (see Figure 1). Event-free survival at 24 months from treatment initiation was 63% (95%CI: 55-72%) (MER) and 70% (95%CI: 64-75%) (LYFO) for patients with early DTI *vs* 80% (95%CI: 76-85%) and 84% (95%CI: 81-86%) in MER and LYFO patients with DTI >14 days, respectively. Associations between early DTI and outcome remained significant in both the MER and LYFO cohorts after adjusting for FLIPI and type of therapy: EFS (MER: HR=1.98, 95%CI: 1.44-2.72; LYFO: HR=2.15, 95%CI: 1.59-2.90) and OS (MER: HR=2.23, 95%CI: 1.44-3.46; LYFO: HR=2.40, 95%CI: 1.56-3.69). Associations were consistent when analyzing DTI as a continuous variable.

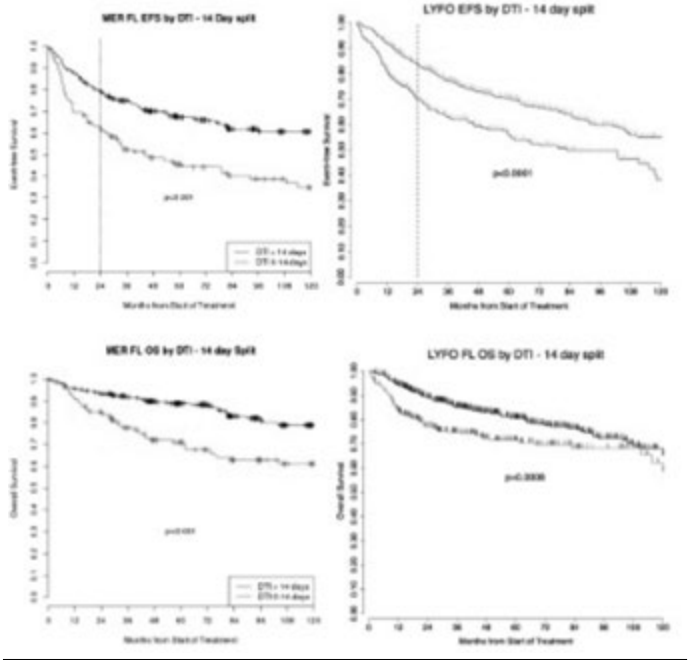

Figure 1.

Summary and Conclusions: We found that shorter DTI was strongly associated with inferior outcomes in IC treated FL in two independent cohorts. This association was independent of the FLIPI and type of therapy regimen. This finding has implications for clinical trials illustrating a potential selection bias since patients with urgent need of treatment are less likely to be enrolled in clinical trials.

PF443

NEW ASSESSMENT INDEX OF CLINICAL TRANSFORMATION FROM FOLLICULAR LYMPHOMA (FL) TO DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) IN THE RITUXIMAB ERA

T. Shichijo[1,*], D. Maruyama[1], N. Yamauchi[2], A. Miyagi Maeshima[3], M. Sugano[4], K. Tajima[1], S. Yuda[1], T. Suzuki[1], K. Toyoda[1], S. Makita[1], S. Fukuhara[1], W. Munakata[1], T. Suzuki[1], Y. Kobayashi[1], H. Taniguchi[3], Y. Minami[2], K. Izutsu[1], K. Tobinai[1]

[1]Hematology, National Cancer Center Hospital, Tokyo, [2]Hematology, National Cancer Center Hospital East, Kashiwa, [3]Pathology and Clinical Laboratory, National Cancer Center Hospital, Tokyo, [4]Pathology and Clinical Laboratory, National Cancer Center Hospital East, Kashiwa, Japan

Background: Histological transformation (HT) is still a critical event because the prognosis of FL patients (pts) with HT is poorer than that of FL pts without HT even in the rituximab era. Although the histological diagnosis of HT by biopsy is the gold standard, it is not always possible to obtain a biopsy specimen. Indeed, more than half of the pts have been diagnosed with HT based on clinical criteria without histological confirmation according to the doctor's discretion in several previous reports. Hence, estimates of the true incidence of HT have wavered because the definition of clinical transformation has never been standardized. Thus, we proposed an assessment index for clinical transformation, which was retrospectively analyzed in a derivation cohort [Hematol Oncol. 2017; 35: 367]. Here, we further validated our assessment index in an independent cohort.
Aims: To propose a new assessment index for clinical transformation of FL that is easy to use in both daily practice and clinical trials in the rituximab era, we conducted a multicenter retrospective analysis.
Methods: In the derivation set, we retrospectively analyzed pts who were initially diagnosed with FL and underwent biopsy at the time of disease progression at the National Cancer Center Hospital (NCCH) from 2000 to 2016. We compared the clinical factors at disease progression and constructed an assessment index based on clinical covariates obtained with a multivariate logistic regression model. In the validation set, to confirm the accuracy of our assessment index, we retrospectively analyzed pts who were diagnosed at the NCCH East (NCCHE) from 2003 to 2014 based on the same criteria.
Results: In the derivation set, 459 pts were diagnosed with FL (grade 1-3a) at the NCCH with a median follow-up duration of 9 (range: 0.7-16) years. Disease progression was observed in 184 pts, 80 (43%) of whom had histological documentation (FL in 42, HT with DLBCL in 34, HT other than DLBCL in 4). Finally, we identified 76 pts with biopsy-proven FL or HT with DLBCL as subjects for the derivation analysis. HT occurred at a median of 5.5 (range: 0.2-16) years from the initial FL diagnosis and the 5-year overall survival rate from HT was 62%. In the multivariate analysis, rapid nodal growth, bulky disease ≥6 cm, elevated serum lactate dehydrogenase (LDH) level and hemoglobin level (Hgb) <12 g/dL at disease progression were associated with HT. The weights of variables were decided based on the regression coefficients, and we then constructed the final assessment index consisting of the above four factors (score 1 each) (Figure 1).

Risk factor	Regression coefficient	Odds ratio (95% CI)	P-value	Score
Rapid nodal growth	2.3419	10.4 (2.24–48.3)	0.003	1
Bulky disease (≥ 6 cm)	2.4996	12.2 (1.45–102)	0.021	1
Hgb < 12 g/dL	2.1521	8.6 (1.69–43.9)	0.010	1
LDH > normal upper limit	2.3567	10.6 (2.4–46.4)	0.002	1

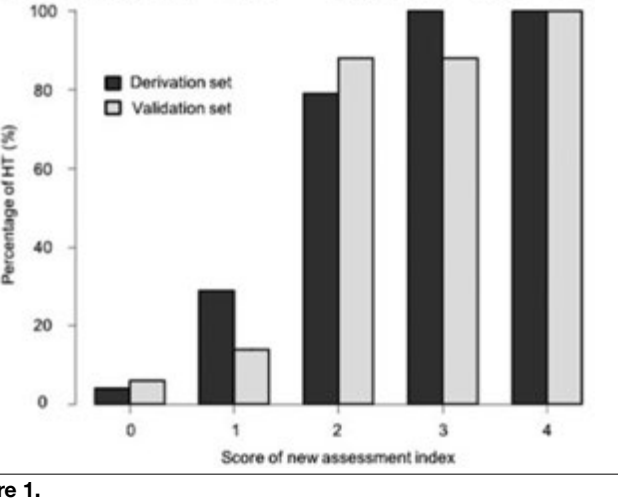

Figure 1.

The percentage of HT was score 0: 4%, score 1: 29%, score 2: 79%, score 3: 100% and score 4: 100% (Figure 1). In the validation set, 243 pts were diagnosed with FL (grade 1-3a) at NCCHE. Disease progression was observed in 95 pts, 50 (53%) of whom had histological documentation (FL in 30, HT with DLBCL in 20). Finally, our assessment index was applied to 50 pts with biopsy-proven FL or HT with DLBCL, and the percentage of HT was score 0: 6%, score 1: 14%, score 2: 88%, score 3: 88% and score 4: 100% (Figure 1). The probability of HT was high when the score was 2 or higher.

Summary and Conclusions: We developed a new assessment index for clinical transformation of FL that was confirmed by validation analysis. It is likely to be a simple and valuable tool for the diagnosis of HT, especially for pts from whom it is difficult to obtain a biopsy specimen. Further investigation is warranted in prospective studies on a large number of pts.

PF444

LONG TERM INTEGRATED SAFETY ANALYSIS OF UMBRALISIB (TGR-1202), A PI3K-DELTA/CK1-EPSILON INHIBITOR WITH A DIFFERENTIATED SAFETY PROFILE, IN PATIENTS WITH RELAPSED/REFRACTORY LYMPHOID MALIGNANCIES

Seràgnoli", University of Bologna, Bologna, Italy, [26]TG Therapeutics, Inc., New York, [27]University of California Irvine, Chao Family Comprehensive Cancer Center, Orange, United States

Background: First generation PI3Kδ inhibitors such as idelalisib and duvelisib are active in patients (pts) with lymphoid malignancies, but are often associated with significant immune-mediated adverse events (AEs), including transaminitis, diarrhea/colitis, and pneumonitis. These toxicities can be severe, and frequently lead to treatment discontinuation; moreover, these toxicities may arise only after pts have been on drug for several months. Umbralisib (TGR-1202) is a next generation, once-daily, oral PI3Kδ/CK1 inhibitor, that is active in pts with relapsed/refractory (R/R) lymphoid malignancies (Burris *et al.*, 2018). We previously have presented data suggesting that umbralisib has a favorable safety profile, though follow-up in the prior analysis was short, and the crucial information about the rate of late immune-mediated AEs with umbralisib was not available due to short follow-up.

Aims: We performed an integrated safety analysis focusing on key immune-mediated AEs with long term follow-up of pts on umbralisib.

Methods: Safety data were pooled from 5 completed or ongoing Phase 1 or 2 studies with umbralisib alone or in combination with other agents. All studies shared similar key eligibility criteria: pts had R/R lymphoid malignancies w/out limit to # of prior therapies. Umbralisib was dosed daily until PD or toxicity, while dosing of combination agents varied.

Results: A total of 347 pts were included in the analysis. Patients received the following regimens: umbralisib as monotherapy (146 pts) or umbralisib in combination with: the glycoengineered anti-CD20 mAb ublituximab ("U2", 98 pts), ibrutinib (32 pts), ublituximab+ibrutinib (38 pts), or ublituximab+bendamustine (33 pts). Among the 347 pts, 34% had CLL/SLL, 33% DLBCL, 21% indolent NHL, and 12% other lymphomas. Pts had a median 3 prior therapies. Median duration of exposure to umbralisib was 6.5 months, with the longest patient on daily umbralisib for 4+ years. The most common all-grade non-hematologic toxicities were: diarrhea (44% All – 29% GR1, 11% GR2, 4% GR3), nausea (39% All – 25% GR1, 13% GR2, 1% GR3), and fatigue (35% All – 19% GR1, 14% GR2, 2% GR3). The median time to onset for diarrhea events was early (32 days) and resolved in a median of 7 days. All-grade hematologic toxicities included neutropenia (22%), anemia (20%), and thrombocytopenia (18%). Grade 3/4 adverse events are described in Table 1. Key adverse events prevalent in prior generation PI3Kδ inhibitors were infrequent: transaminitis (8.6% All; G3/4 2.3%), colitis (1.4% All; G3/4 0.9%), and pneumonitis (1.4% All; G3/4 0.3%). Discontinuations due to treatment related adverse events were rare at under 10% for all studies. A total of 167 pts treated with umbralisib for a minimum duration of 6 months were included in a sub-analysis of long term safety. The median duration of exposure amongst these pts was 15.6 months (range 6.4 – 60.6 months). A summary of AEs occurring after 6 months on therapy is presented in Table 2.

Table 1.

Table 2.

All Grades, All Causality AEs Occurring After 6 Months on Umbralisib (N=167)

Adverse Event	All Grades		Grade ¾	
	N	%	N	%
Diarrhea	41	25%	12	7%
Nausea	25	15%	3	2%
Cough	21	13%	-	-
Neutropenia	20	12%	17	10%
Fatigue	20	12%	1	1%
Vomiting	18	11%	2	1%
Sinusitis	18	11%	-	-
Insomnia	15	9%	-	-
Abdominal pain	14	8%	3	2%
Pyrexia	14	8%	2	1%
Hypokalemia	13	8%	3	2%
Upper respiratory infection	13	8%	-	-
Thrombocytopenia	12	7%	5	3%
Anemia	12	7%	3	2%
Headache	12	7%	2	1%
Arthralgia	12	7%	-	-
Hypophosphatemia	10	6%	3	2%
Blood creatinine increased	10	6%	1	1%
Rash	10	6%	1	1%
Dizziness	10	6%	-	-

Summary and Conclusions: In this integrated analysis with long term follow-up, once-daily umbralisib exhibited a differentiated safety profile compared to prior generation PI3Kδ inhibitors. In particular, late onset diarrhea or colitis commonly associated with first-generation PI3Kδ inhibitors was infrequent. Umbralisib can be safely combined with a diverse array of other agents active in lymphoid malignancies, and is currently being studied in the global registration directed UNITY-CLL Phase 3 randomized trial (NCT02612311) and UNITY-NHL Phase 2b randomized trial (NCT02793583).

Ltd., Beijing, China, [14]Beigene (Beijing) Co. Ltd., Emeryville, CA, United States, [15]Royal Melbourne Hospital, Parkville, Victoria, [16]Monash University, Clayton, Victoria, [17]Sir Charles Gairdner Hospital, Perth, Western Australia, [18]University of Western Australia, Perth, Australia

Background: Bruton's tyrosine kinase (BTK) plays a critical role in B-cell receptor signaling, which mediates B-cell proliferation, migration and adhesion. Zanubrutinib is a potent, selective and irreversible BTK inhibitor. It has demonstrated profound BTK inhibition with minimal inhibition of off-target kinases such as EGFR, ITK, JAK3, HER2, and TEC, providing a good scientific rationale for a reduced toxicity profile.
Aims: To demonstrate the safety profile of zanubrutinib.
Methods: Safety data from patients (pts) in 6 ongoing zanubrutinib monotherapy studies were analyzed. All pts have been treated with ≥1 dose of oral (po) zanubrutinib at 40 mg once-daily to 160 mg twice-daily (bid). The analysis included frequency and severity of adverse events (AEs), AEs of special interest, and AEs leading to treatment discontinuation.
Results: A total of 424 pts were included in the pooled analysis, with a data cutoff date of September 15, 2017. The median age was 64 years (range 20-87) and 71.9% were males. The median follow-up duration was 4.8 months (range 0.03-36.0). The most common (occurring in ≥10% of pts) AEs were upper respiratory tract infection (23.8%), contusion (17.5%), diarrhea (14.2%), cough (13.0%), rash (12.7%), anemia (11.8%), and neutrophil count decreased (11.6%). Serious AEs (SAEs) were reported in 24.3%, including 7.5% that were assessed as related to zanubrutinib. The most common SAEs included pneumonia (3.5%), lung infection (1.7%) and febrile neutropenia (1.2%). AEs of special interest are shown in the Table 1. The most common bleeding events included contusion (17.5%) and hematuria (8.3%). Major hemorrhage, defined as serious or Grade ≥3 bleeding of any site, or central nervous system bleeding of any grade included gastrointestinal hemorrhage, purpura (0.5% each), melena, hemorrhagic cystitis, hematuria, renal hematoma, cerebral hemorrhage and hemothorax (0.2% each). The median time to first major hemorrhage was 23 days (range 3-262). The fatal event of cerebral hemorrhage was reported in a 70 year old male pt with mantle cell lymphoma who developed left occipital lobe hemorrhage after treatment with zanubrutinib 160 mg bid for 6 days. Amongst pts with atrial fibrillation/flutter (8 pts) a majority had known risk factors including hypertension (2 pts), pre-existing cardiovascular disease (2 pts) and concurrent infection (1 pt). The rates of Grade ≥3 infections were 10.1 events/100 pts in the first 3 months, 3.1 in months 3 to 6, and 5.5 after 6 months. The most common second primary malignancies included basal cell carcinoma (3.5%) and squamous cell carcinoma of skin (2.8%) with 2.1% of pts having a prior history of skin cancer. AEs led to treatment discontinuation in 5.9% of pts with 2.4% related to zanubrutinib.

Table 1.

AEs of Special Interest	All Patients (N=424)	
	All Grades, %	Grade ≥ 3, %
Hemorrhage	38.0	2.1
Major hemorrhage	2.1	2.1
Atrial fibrillation/flutter	1.9	0.2
Hypertension	4.2	1.4
Diarrhea	14.4	0.7
Infections	51.9	12.0
Second primary malignancies	7.1	2.4

Summary and Conclusions: Zanubrutinib has shown a favorable safety and tolerability profile in pts with various B-cell malignancies. In zanubrutinib's cumulative safety experience, events of interest with BTK inhibitors, such as atrial fibrillation (1.9%), major hemorrhage (2.1%), and severe diarrhea (0.7%) have been infrequent. Additionally, treatment discontinuation due to zanubrutinib-related adverse events was uncommon (2.4% of pts). These data suggest that exposure levels of zanubrutinib resulting in complete and sustained BTK inhibition can be safely achieved, resulting in low tolerability-related treatment failure rates.

PF446

R-ESHAP IS NOT EFFECTIVE AS SALVAGE THERAPY IN REFRACTORY FOLLICULAR LYMPHOMA: RESULTS OF A RETROSPECTIVE MULTICENTRE STUDY ON BEHALF OF GELCAB GROUP

ICO Hospitalet, Barcelona, [7]Hematology, Hospital Joan XXIII, Tarragona, [8]Hematology, Hospital Parc Taulí, Sabadell, [9]Hematology, Hospital Arnau de Vilanova, Lleida, Spain

Background: Follicular lymphoma (FL) is an incurable disease with a clinical course of successive relapses. However, there is no standard treatment for relapsed and refractory patients. Even though platinum-based chemotherapy combinations are one of the most widely used treatment schemes, few data have been reported in this setting.
Aims: The aim of our study was to analyse the efficacy of R-ESHAP chemotherapy in relapsed or refractory FL patients who had previously received at least one containing-Rituximab regimen. These data have particular interest nowadays when new targeted drugs are available.
Methods: We retrospectively collected data from 80 FL patients diagnosed between January 2000 and December 2016 in 9 different centres belonging to GELCAB group. Patients must have been treated with R-ESHAP in the first or successive relapses. R-ESHAP cycles were administered every 4 weeks. The number of total cycles that each patient received was determined based on physician criteria. The use of G-CSF was allowed, and histologically transformed patients were also included in the study. Autologous or allogeneic stem cell transplantation performed following R-ESHAP salvage treatment was permitted.
Results: Median age of the whole series (n=80) was 50 years, 79% (n=63) were male. At the time of R-ESHAP initiation, 85% of the patients (54/65) were in advanced stage, 28% had bulky disease (18/65) and 40% had increased LDH (26/65). FLIPI was low, intermediate or high in 28%, 33% and 39% of the patients, respectively. R-ESHAP was administered as salvage treatment for the first relapse in 45 patients (56%), for the second relapse in 23 (29%) and for the third or successive relapses in 15% of the cases. At the moment of R-ESHAP initiation, 17 patients had histological transformation to DLBCL. These transformed cases were excluded from the former analysis of response. Among the 63 remaining patients, 47 were considered as early relapsed to first-line treatment (defined as refractoriness or progression within the 24 months after diagnosis, POD24). Excluding transformed patients, ORR was 77% (47/63), with 46% of CR (28/63). None of the clinical characteristics at the time of R-ESHAP was associated with the sort of response. There were no statistically significant differences between POD24 and non-POD24 patients in terms of response to R-ESHAP (ORR of 72% *vs* 93%, p=0.109 and CR rate of 43% *vs* 57%, p=0.336, respectively). Median OS was 3.8 years and median PFS was 1.5 years (calculated from the time of R-ESHAP). When analysing R-ESHAP efficacy according to the response to the immediately previous line of treatment, we found that patients achieving CR or PR to previous line chemotherapy (n=45) had better CR rates to R-ESHAP than those who did not respond (n=14) (CR rates of 57% *vs* 15%, respectively, p=0.009) and a trend to better ORR (84% *vs*, 54%, p=0.054), as well as differences in OS (median of 7.2 years *vs* 1.4 years, p<0.0001), and in PFS (median of 2.1 years *vs* 0.3,p<0.0001) (Figure 1). Finally, in the subgroup of transformed FL (n=17) R-ESHAP provided an ORR of 47% (CR in 24%), with a median (95% CI) of OS and PFS of 1.3 (0.5, 2.1) years and 0.3 (0.1, 0.5) years, respectively.

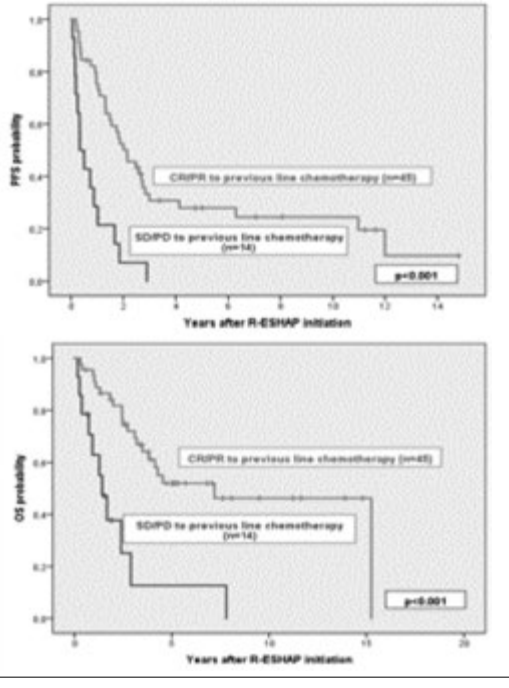

Figure 1.

Summary and Conclusions: In our series, R-ESHAP is not an effective salvage treatment in previously refractory FL patients, independently of response to first line treatment and clinical characteristics, nor in transformed FL. Our results support the use of new recently approved treatments (such as obinutuzumab or idelalisib) in these especially poor prognosis patients.

PF447

CHALLENGES IN DELIVERY OF MAINTENANCE ANTI-CD20 THERAPY IN ADVANCED FOLLICULAR LYMPHOMA: 5-YEAR EXPERIENCE AT THE ROYAL MARSDEN HOSPITAL

H. Kayhanian[1,*], A. Pender[1], M. Gleeson[1], N. Joharatnam[1], R. Taylor[1], J. Clark[1], T. Murray[1], M. Harris[1], L. Whiteman[1], C. Dearden[1], S. Iyengar[1], M. Ethell[1], M. Potter[1], D. Cunningham[1], I. Chau[1]

[1]Department of medicine, The Royal Marsden Hospital, London, United Kingdom

Background: The anti-CD20 monoclonal antibody rituximab (R) with chemotherapy followed by R-maintenance is standard of care for patients with symptomatic stage III/IV follicular lymphoma (FL). However, R is associated with potential complications such as hypogammaglobulinaemia (HG) and prolonged neutropenia. Furthermore, symptomatic HG may require intravenous immunoglobulin (IVIG).
Aims: 1. To benchmark the real-world occurence of infectious complications associated with anti-CD20 therapy 2. To measure the incidence of HG, infectious complications and need for IVIG in this population 3. To determine whether choice of induction regimen influences incidence of HG
Methods: All patients with stage III/IV histologically-confirmed FL (grade 1-3a) receiving at least 1 cycle of systemic therapy between January 2010 and December 2015 were identified from hospital and pharmacy records. Data were collated from electronic patient records.
Results: 68% (84/123) of patients received first-line chemo-immunotherapy: R-bendamustine (RB) in 40% (34/84), RCVP in 29% (24/84) and RCHOP in 24% (20/84).70% (59/84) of patients subsequently received MT. The reasons for MT not being administered are listed in Figure 1. Anti-CD20 therapy was with R in all patients except for one who received obinutuzumab within a clinical trial. Following induction the median time to starting MT was 9.1 weeks (range 3-19.7), with a delay of >8 weeks occurring in 31% (18/59); due to patient choice (n=8), prolonged neutropenia (n=3), recurrent infection (n=1) and other/unknown (n=6). The median number of MT cycles received was 12 (range 1-12). 42% (25/59) did not complete the planned 12 cycles and reasons for this are listed in Figure 1. Baseline Ig levels prior to commencing induction were available for 51% (43/84) and serum IgG, IgA and IgM were below normal range in 4% (2/43), 7% (3/43) and 21% (9/43) respectively. Post-induction 19% (16/84) had serum Igs tested and 81% (13/16) had a low level of at least one serum Ig. Following MT, 20% (12/59) had serum Igs tested and 92% (11/12) of those tested had a low level of at least one serum Ig. A total of 21% of patients (18/84) developed HG during follow-up and 94% (17/18) had received MT. For the two commonest induction regimens, RB and RCVP, there was no significant difference in rate of HG occurrence (71% *vs* 67%; Fisher's exact p=0.99). The proportion receiving MT was similar for these two groups (82% *vs* 72%; Fisher's exact p=0.36), however Ig testing was inconsistent with only 41%(14/34) of RB and 24%(6/25) of RCVP treated tested post-baseline. 12% (10/84) had recurrent infections and all had received MT, with respiratory infections seen most frequently (n=7). The majority (n=6/10) had received R-bendamustine induction. 6 (7%) cases of recurrent infection had concurrent HG diagnosed and 4 required IVIG (5%). The median duration of IVIG therapy was 8 months (range 4-30).

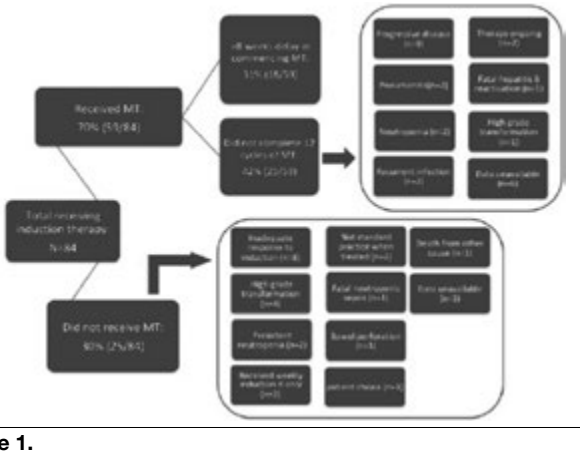

Figure 1.

Summary and Conclusions: The majority of delays to starting MT were due to patient choice, although delays due to recurrent infections or prolonged neutropenia were also observed. The incidence of recurrent infections was 12% overall and all occured in patients who had received MT; concurrent HG was diagnosed in 7%, consistent with published data on the incidence of symptomatic HG. Following systemic therapy Ig testing was only performed if clinically indicated so the frequency of asymptomatic HG may have been underestimated.

PF448

OUTCOMES FOR DIABETIC PATIENTS FROM THE CHRONOS-1 STUDY WITH RELAPSED OR REFRACTORY INDOLENT B-CELL LYMPHOMA TREATED WITH COPANLISIB

M. Dreyling[1,*], S. Leppä[2], T. Comeau[3], M. Kosinova[4], G. Lenz[5], D.S. Heo[6], S.Y. Oh[7], L. Huang[8], A. Miriyala[8], J. Garcia-Vargas[8], B.H. Childs[8], P.L. Zinzani[9]

[1]Medizinische Klinik und Poliklinik III, Klinikum der Universität München LMU, Munich, Germany, [2]Department of Oncology, Helsinki University Central Hospital Cancer Center, Helsinki, Finland, [3]Saint John Regional Hospital, New Brunswick, Canada, [4]Kemerovo Regional Hospital, Kemerovo, Russian Federation, [5]Translational Oncology, University Hospital Münster, Münster, Germany, [6]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, [7]Dong-A University Hospital, Busan, Korea, Republic Of, [8]Bayer HealthCare Pharmaceuticals Inc, Whippany, United States, [9]Department of Hematology, Institute of Hematology "L. e A. Seràgnoli"- University of Bologna, Bologna, Italy

Background: Copanlisib is a pan-Class I phosphatidylinositol 3-kinase (PI3K) inhibitor with predominant PI3K-α and PI3K-δ activity recently approved in the US for treatment of relapsed follicular lymphoma. In the CHRONOS-1 trial, treatment of patients with relapsed or refractory indolent lymphoma resulted in an objective response rate of 59% (*JCO* 35:2169-2178, 2017). The most common adverse event following intravenous administration of copanlisib is transient hyperglycemia, thought to be due to impaired glucose uptake associated with PI3K-α isoform inhibition.
Aims: We focus here on the efficacy and safety of copanlisib treatment in indolent lymphoma patients with a medical history of diabetes mellitus (DM).
Methods: Indolent B-cell lymphoma patients with well-controlled DM were eligible and required to have fasting glucose <160 mg/dL prior to each infusion. Patients received copanlisib 60 mg as a 1-hour infusion on days 1, 8, and 15 of a 28-day cycle. On C1D1, glucose was measured at pre-dose, and 3, 5, 6 and 8 hours after infusion. DM patients were instructed to check blood glucose at home 3x per day for 72 hrs after infusion until fasting glucose was <160 mg/dL or non-fasting glucose was <200 mg/dL.
Results: Twenty patients with DM out of a total of 142 patients were enrolled; 17 patients with a history of DM, 1 with history of impaired glucose tolerance, and 2 diagnosed at screening. Comparing non-DM patients (n=122) to DM patients, all-grade (G) hyperglycemia was 43% *vs* 85%, G3 31% *vs* 40%, and G4 2% *vs* 35%. In routine laboratory glucose assessments, G3 events were reported in 39% *vs* 70% and G4 in 2% *vs* 30%, non-DM *vs* DM respectively. Dose reductions due to any drug-related adverse event (AE) were higher in DM patients (40%) compared to non-DM patients (20%), as were permanent discontinuations due to AEs (30% *vs* 14%, respectively). Three patients overall discontinued treatment due to hyperglycemia, 2 of whom were DM patients. Objective responses were observed in 9 of 20 patients (45%; 2 non-evaluable), including one complete response and stable disease in 8 patients (40%). Of note, 6 responders were on treatment >300 days (or >30 infusions), with 5 of these patients remaining on treatment at data cut-off.
Summary and Conclusions: These results strongly suggest that the transient hyperglycemia seen with IV administration of copanlisib is manageable and should not preclude treatment of indolent lymphoma patients with DM. With appropriate management such patients can derive long-term clinical benefit.

COMPARATIVE EFFICACY AND SAFETY OF DIFFERENT ANTIVIRAL AGENTS FOR CYTOMEGALOVIRUS PROPHYLAXIS AFTER HEMATOPOIETIC-CELL TRANSPLANTATION: A SYSTEMATIC REVIEW AND META-ANALYSES

N. Gagelmann[1,*], P. Ljungman[2], J. Styczynski[3], N. Kröger[4]

[1]Stem Cell Transplantation, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Karolinska Institutet, Stockholm, Sweden, [3]Nicolaus Copernicus University Torun, Bydgoszcz, Poland, [4]University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: No evidence synthesis available to date assessed the role of newly studied antiviral agents on cytomegalovirus (CMV) after transplantation.
Aims: We conducted a systematic review, conventional meta-analysis and network meta-analysis of all randomized controlled trials (RCTs) to examine the role of antiviral prophylaxis on CMV after allogeneic hematopoietic-cell transplantation, and to compare each agent's relative efficacy.
Methods: We performed a systematic literature review using MEDLINE®, MEDLINE® in-process, the Cochrane Library and the website www.clinical-trials.gov. In addition, meeting abstracts (ASH, ASCO, EBMT, EHA, BMT Tandem) were screened to include the most recent evidence. Primary objectives were CMV disease and infection. Survival and serious adverse events were considered as secondary end points. The analysis consisted of two steps, the first step being the computation of the conventional meta-analysis while the second step was the actual network meta-analysis. Pooled relative risks (RRs) with corresponding confidence intervals (CIs) were generated using a random-effects model in R (package meta). The GRADE approach was used to assess quality of evidence.
Results: Fifteen trials used seven different treatment options reporting on a total of 3924 patients: (1) acyclovir, (2) ganciclovir, (3) maribavir, (4) brincidofovir, (5) letermovir, (6) vaccine, and (7) valacyclovir. Twelve trials compared antiviral prophylaxis *versus* placebo while three trials compared different antiviral agents. Antiviral prophylaxis compared with control significantly prevented CMV disease (RR, 0.66; 95% CI, 0.48 to 0.90) in the conventional meta-analysis. Overall, antiviral prophylaxis reduced the risk for CMV disease with 34%. Ganciclovir was the only agent which significantly reduced the risk for CMV disease showing the most favorable RR of 0.35 (95% CI, 0.20 to 0.62). The use of ganciclovir provided the probability of 92% of being the best treatment option (high quality of evidence). Regarding CMV infection, antiviral prophylaxis compared with control significantly reduced the incidence of infection (RR, 0.63; 95% CI, 0.50 to 0.79). Ganciclovir and letermovir significantly prevented CMV infection showing the most favorable RRs of 0.34 (95% CI, 0.12 to 0.91) and 0.44 (95% CI, 0.21 to 0.93). The use of either ganciclovir or letermovir provided probabilities of 83% and 73% of being the best options (low quality of evidence). Regarding survival and safety, antiviral treatment appeared to reduce the risk for death (RR, 0.88; 95% CI, 0.73 to 1.06) while prophylaxis showed no impact on the risk for serious adverse events compared with any control condition with a RR of 1.09 (95% CI, 0.94 to 1.27). Across the network, the risk for death at 24 weeks was significantly reduced by letermovir (RR, 0.58; 95% CI, 0.34 to 0.98) as well as acyclovir (RR, 0.62; 95% CI, 0.40 to 0.95) leading to probabilities of 82% (letermovir) and 80% (acyclovir) of being the best treatment options. In terms of safety, letermovir showed the best relative efficacy compared with all other antiviral agents with a RR of 0.85 (95% CI, 0.54 to 1.32) and was thus at least similar in comparison with placebo with the probability being 76% that letermovir shows the best risk-benefit profile (moderate quality of evidence).
Summary and Conclusions: Cytomegalovirus disease and infection could be significantly reduced by antiviral prophylaxis in hematopoietic-cell transplantation. While ganciclovir and letermovir appeared to be the best options for CMV prophylaxis, only letermovir showed the best risk-benefit ratio.

CANDIDA-REACTIVE T CELLS FOR THE DIAGNOSIS OF INVASIVE CANDIDA INFECTION

F. Koehler[1,*], O. Cornely[1,2,3], H. Wisplinghoff[4,5,6], A. Schauss[1], J. Salmanton-Garcia[2], H. Ostermann[7], M. Ziegler[4], P. Bacher[8], A. Scheffold[8,9,10], R. Alex[11], A. Richter[11], P. Koehler[12]

[1]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), [2]Department I of Internal Medicine, ECMM Diamond Center of Excellence in Medical Mycology, German Centre for Infection Research (DZIF), [3]Clinical Trials Centre Cologne (ZKS Köln), University of Cologne, [4]Labor Dr. Wisplinghoff, [5]Institute for Medical Microbiology, Immunology and Hygiene, University of Cologne, Cologne, [6]Institute for Clinical Microbiology, University Witten/Herdecke, Witten, [7]Department of Internal Medicine III, University of Munich, Munich, [8]Department of Cellular Immunology, Clinic for Rheumatology and Clinical Immunology, Charité – University Medicine Berlin, [9]German Rheumatism Research Centre (DRFZ), [10]Leibniz Association, Berlin, [11]Miltenyi Biotec GmbH, Bergisch Gladbach, Germany

Background: Invasive *Candida* infection (ICI) is the most common fungal bloodstream infection. Blood and tissue cultures are the current gold standard diagnostic methods, however false-negatives remain a clinical challenge.
Aims: *Candida*-reactive T cells were quantitated based on the upregulation of CD69/CD154 (CD40L) from peripheral blood as new diagnostic readout for ICI. In a pilot study, we examined healthy donors and three patient cohorts with either proven ICI, suspected ICI, or high risk of ICI
Methods: *Candida* cells were lysed mechanically by gentleMACS® dissociator (Miltenyi Biotec GmbH, Germany). Peripheral blood mononuclear cells (PBMC) of patients and healthy donors were isolated by density gravitation. Cultured cells were stimulated with CD28 and CD40 pure antibodies and co-incubated with lysate of either *C. albicans*, *C. glabrata*, *C. parapsilosis*, *C. tropicalis* or *C. krusei* for 5h in 5% CO_2. Missing challenge with fungal lysate served as negative control, Staphylococcal Enterotoxin B as positive control. PBMCs were stained with CD4FITC, CD8PerCP, CD14PerCP, CD20PerCP, CD69APC, CD154PE (all Miltenyi Biotec GmbH, Germany) and 7AAD (Miltenyi Biotec GmbH, Germany and eBioscience, USA) and measured on a MACSQuant® flow cytometer (Miltenyi Biotec GmbH, Germany). *Candida*-reactive $CD4^+$ T cells were detected based on the upregulation of CD69and CD154 (CD40L). Cut-off values discriminating between healthy donors, disease control and patients with proven ICI were calculated by receiver operating characteristic analysis using IBM SPSS Statistics software (Version 23, IBM Corporation, Armonk, NY, USA).
Results: In a prospective pilot study, we determined the performance of the *Candida*-reactive lymphocyte assay in 26 patients, including 16 proven ICI and one patient with probable hepatosplenic candidiasis. Nine hematological high-risk patients served as disease control and 14 healthy donors as negative control. To examine the mean frequency of *C. albicans*-reactive T cells in healthy individuals we included an additional cohort of 96 healthy blood donors. Thirteen of 16 patients with proven ICI and one patient with probable ICI had elevated levels of *Candida*-reactive $CD4^+$ T cells. Due to autofluorescence of cells we excluded 3 candidemia patients from analysis. In 10 of 12 proven ICI, T cell reaction matched the *Candida* spp. identified by conventional diagnostics. One histology proven ICI patient had no species identification by standard diagnostics. Disease and healthy control patients of the pilot study cohort had no elevated *Candida*-directed T cells counts. The sensitivity and specificity of the *Candida*-reactive lymphocyte assay identifying ICI and causing *Candida* spp. among evaluable ICI patients were 83.3% and 100%, respectively.
Summary and Conclusions: The *Candida*-reactive lymphocyte assay correctly identified the majority of ICI patients by species level. Autofluorescence of cells and insufficient cell count of T cells are limiting factors. The *Candida*-reactive lymphocyte assay has the potential to complement current diagnostic assays for invasive *Candida* infection.

PF451

TENOFOVIR *VERSUS* LAMIVUDINE FOR PREVENTION OF HEPATITIS B VIRUS REACTIVATION AMONG PATIENTS WITH AGGRESSIVE LYMPHOMAS UNDERGOING FRONT-LINE ANTHRACYCLINE-CONTAINING CHEMOTHERAPY

I. Zacheo[1,*], R. Della Pepa[1], C. Giordano[1], A. Giordano[1], C. Mortaruolo[1], M. Raimondo[1], M. Di Perna[1], F. Trastulli[1], M. Picardi[2], F. Pane[1]

[1]Hematology, [2]Advanced Biomedical Science, Federico II, University of Naples, Naples, Italy

Background: Primary antiviral prophylaxis (PAP) is essential for patients seropositive for hepatitis B surface antigen (HBsAg) who undergo intensive cytotoxic chemotherapy for lymphoma. Lamivudine (LAM) is the most commonly used drug, but alternative nucleos(t)ide analogs such as entecavir and tenofovir disoproxil fumarate (TDF) may provide a better efficacy.
Aims: We compared the efficacy and safety of LAM (systematically administered from July 2004 to June 2009; LAM-cohort) and TDF (systematically administered from February 2009 to June 2015; TDF-group) in preventing HBV reactivation in HBsAg-positive patients with advanced-stage diffuse large B cell (DLBC) non-Hodgkin lymphoma (NHL) or classic Hodgkin lymphoma (HL).
Methods: All patients were scheduled to receive full-course of anthracy-

cline-containing chemotherapy, according to R-CHOP or ABVD regimen.During the study period, of the 64 HBsAg-positive patients who received PAP with either LAM or TDF, 20 were excluded due to liver dysfunction and/or high serum HBV-DNA levels at baseline, chemotherapy reduction or delay for acute toxicity not due to HBV infection, or because lost to follow-up. Twenty-one patients received LAM and 23 received TDF.
Results: The rate was significantly lower in the TDF-group compared with the LAM-cohort for HBV reactivation (0% *vs* 52.3%, respectively; *p*=.0002), HBV-related hepatitis (0% *vs* 19%, respectively; *p*=.04) and chemotherapy disruptions (0% *vs* 23.8%, respectively; *p*=.02). No difference was observed between the two groups in terms of incidence of PAP-related adverse events (4.3% [TDF-group] *vs* 19% [LAM-cohort]; *p*=.17). Furthermore, at a median follow-up of 34 months there was no significant difference between the TDF-group and LAM-cohort in terms of lymphoma progression free survival (94.7% *vs* 84.8%; *p*= .37). In a multivariate analysis, TDF prophylaxis and serum HBV-DNA ≤73 IU/mL were associated with a lower risk for HBV reactivation (*p* values, <.0001 and =.03, respectively) (Table 1).

Table 1. Patients characteristics.

	No (%) of Patients[a]		P value

Seronegative	4 (17.4)	2 (9.5)	
Serum HBV-DNA level			n.a.
Median (range) IU/mL	200 (10-948)	192 (21-877)	
Cycles of R-CHOP			n.a.
median	6	6	
Cycles of ABVD			n.a.
median	6	6	

Abbreviation:
RCHOP, rituximab, cyclophosphamide, doxorubicin, vincristine and prednisolone.
ABVD, doxorubicin, bleomycin, vinblastine and dacarbazine.

Summary and Conclusions: Therefore, TDF should be suggested for frontline prophylaxis in HBsAg-positive patients receiving induction chemotherapy for aggressive lymphomas to prevent HBV reactivation and evolution in HBV-related hepatitis, which could lead to chemotherapy disruption. Further studies are warranted to confirm these findings.

PF452

SWITCHING FROM POSACONAZOLE ORAL SUSPENSION TO TABLETS INCREASES SERUM LEVELS, PRESERVES SAFETY AND IMPROVES TREATMENT SATISFACTION: A PROSPECTIVE CLINICAL TRIAL IN PATIENTS WITH ACUTE LEUKEMIA

R.F. Duarte[1,*], I. Sánchez-Ortega[2], I. Salcedo[1], C. de Miguel[1], A. Lerma[1], B. Pérez de Camino[1], M.E. Martínez-Muñoz[1], C. Fernández-Maqueda[1], A. de Laiglesia[1], G. Bautista[1], H. Pomares[2], A. Sureda[2], J.R. Cabrera[1], M. Cuenca-Estrella[3], A. Gómez-López[3]

[1]Hospital Universitario Puerta de Hierro Majadahonda, Madrid, [2]Catalan Institute of Oncology, Barcelona, [3]National Microbiology Centre - ISCiii, Madrid, Spain

Background: Posaconazole (POSA) is the standard anti-mold prophylaxis agent for high-risk hematology patients with acute myeloid leukemia and myelodysplastic syndromes (AML/MDS). Compared with the original oral suspension (OS), gastro-resistant POSA tablets (TAB) have shown improved pharmacokinetics (PK) in registration trials. However, there is only anecdotal retrospective data comparing both formulations in the same subjects [DS Jung, *et al.* 2014].
Aims: Here we present a prospective clinical trial on sequential administration of POSA OS and TAB in AML/MDS patients to assess the relative impact of the new formulation on PK and safety.
Methods: A phase IV, multicenter, open-label clinical trial in adult patients undergoing induction chemotherapy for AML/MDS, to receive primary antifungal prophylaxis with POSA sequentially, first as OS (200mg TDS) until steady state concentration, and then (day 10-14) switch to TAB (300mg OD) for two additional weeks until day 28. Endpoints included the comparative PO *vs* TAB PK profile (primary), clinical and laboratory safety, as well as patient satisfaction with both formulations. EudraCT# 2015-003940-38.
Results: Twenty-one patients were successfully screened and received at least one dose of POSA (May 2016 - July 2017). Of these, 5 patients stopped POSA prophylaxis (23.8%) for chemotherapy-induced mucositis and diarrhea (2; 9.5%) or to receive antifungal treatment (3; 14.3%). There were no cases of breakthrough invasive fungal infection. Sixteen cases (76.2%) completed sequential treatment with both POSA formulations and are the study population for PK endpoint analysis. As described in Table 1, POSA serum levels significantly increased in these patients with the shift from OS to TAB formulation. Although 9 subjects (56%) had steady-state average concentration (Cavg) <0.5 mg/L with the OS, all 16 subjects (100%) achieved the recommended steady-state Cavg >0.5 (and >0.7) mg/L after switching to POSA TAB (note: all differences P<0.001). Three patients experienced grade 3 adverse events (CTCAE version 4) including supraventricular tachycardia, increased GGT and acute cholecystitis. They were all considered unlikely to be related to the study drug and all resolved within the treatment period without discontinuation of POSA. No other patients experienced changes in the electrocardiogram or prolongation of the QT interval. All patients experienced grade 3 and 4 cytopenias as a result of intensive chemotherapy and not related to the study drug (data not shown). Other than in the two cases mentioned above, liver function tests including bilirubin, alanine aminotransferase and gamma-glutamyl transferase remained stable through the switch from OS to TAB POSA. All 21 patients survived the course of induction chemotherapy (measured at 1 week after neutrophil recovery and end of treatment). Finally, subjects completed a questionnaire of patient satisfaction at the end of treatment with both formulations. A large majority of >80% patients preferred the TAB formulation of POSA, with a significantly higher level of overall satisfaction (P=0.037) and better experience of interference with activities of daily life (P=0.012) with TAB POSA compared to OS.

Table 1.

Pharmacokinetics and Liver Function Test Results.

	OS day 1	OS day 8	TAB day 1	TAB day 8
AUC				
Mean +/- SD	2.674 +/- 1.818	11.041 +/- 9.323	23.811 +/- 12.793	55.072 +/- 37.412
Median	2.236	7.648	20.000	38.832
Range	0.552 - 6.810	1.660 - 33.238	4.277 - 49.105	19.838 - 126.768
Cavg				
Mean +/- SD	0.092 +/- 0.088	0.454 +/- 0.379	0.905 +/- 0.532	2.638 +/- 1.579
Median	0.059	0.330	0.788	2.352
Range	0.012 - 0.354	0.066 - 1.345	0.141 - 1.884	0.750 - 5.242
Bilirubin (mean +/- SD)	0.690 +/- 0.345	0.830 +/- 0.712	0.800 +/- 0.976	0.611 +/- 0.569
ALT (mean +/- SD)	23.6 +/- 7.3	35.7 +/- 37.3	40.2 +/- 20.9	48.2 +/- 28.7
GGT (mean +/- SD)	42.3 +/- 22.7	85.5 +/- 113.8	124.8 +/- 127.7	97.2 +/- 68.9

ALT: alanine aminotransferase (IU/mL); AUC: area under the curve (mcg/mL*h); bilirubin: mg/dL; Cavg: average concentration (mg/L); GGT: gamma-glutamyl transferase (IU/mL); OS: oral suspension; SD: standard deviation; TAB: gastro-resistant tablets.

Summary and Conclusions: This is the first clinical trial to evaluate prospectively the sequential use of POSA OS and TAB for primary antifungal prophylaxis. Our data show that in patients with AML/MDS receiving intensive chemotherapy, the switch from POSA OS to TAB increases drug serum levels, preserves its safety profile and improves patient tolerance and treatment experience.

PF453

MURCORMYCOSIS AND ASPERGILLOSIS IN ONCOHEMATOLOGICAL PATIENTS: WHAT'S THE DIFFERENCE?

O. Shadrivova[1], S. Khostelidi[1], Y. Borzova[2], E. Desyatik[2], A. Volkova[3], M. Popova[3], I. Markova[3], O. Uspenskaya[4], T. Bogomolova[2], S. Ignatyeva[2], L. Zubarovskaya[3], B. Afanasyev[3], N. Klimko[1,*]

[1]Department of Clinical Mycology, Allergy and Immunology, [2]I. Mechnikov North-Western State Medical University, [3]I.Pavlov First Saint Petersburg State Medical University, [4]Leningrad Regional Clinical Hospital, St. Petersburg, Russian Federation

Background: Invasive aspergillosis (IA) and mucormycosis (M) are the main mold invasive fungal diseases in oncohematological patients.
Aims: We compare M and IA in oncohematological patients from our registries.
Methods: In the study were included 59 M patients (males – 56%, age – 3-74 y, median – 27) and 541 IA patients (males – 57%, age – 1-78 y, median – 38). We used EORTS/MSG, 2008 criteria for M and IA diagnosis.
Results: The main underlying diseases in M and IA patients were leukemia (64% *vs* 51%), p= 0,03. M patients were more immunosuppressed: severe neutropenia was in 88% *vs* 82%, duration of neutropenia (median) - 30 d *vs* 14 d (p=0,0001), lymphocytopenia – 77% *vs* 65%, duration of lymphocytopenia – 25 d *vs* 14 d (p= 0,001), allogeneic hematopoietic stem cells transplantation – 44% *vs* 28% (p=0,01), and GVHD was observed in 42% *vs* 22% (0,0001). In 52% patients M was diagnosed in 1–225 days after IA. The main M etiological agents were *Rhizopus* spp. (47%), *Rhizomucor* spp. (28%) and *Lichtheimia cor mbifera* (17%), IA – *A. fumigatus* (43%), *A. niger* (33%) and *A. flavus* (17%). The main sites of infection were lungs (73% *vs* 96%), in M patients more frequently was identified disseminated process (42% *vs* 8%, p=0,001) and paranasal sinuses involvement (15% *vs* 6%, p=0,04). Typical clinical feature of M was hemoptysis (32% *vs* 6%), lung CT signs – hydrothorax (53% *vs* 7%), lesions with destruction (38% *vs* 8%, p=0,0001) and a "reverse halo" symptom (17% *vs* 3%). Antifungal therapy received 78% *vs* 99% (p=0,001) patients, surgery – 47% *vs* 3% (p=0,0001). Overall 12 weeks survival was significantly lower in M patients (49% *vs* 81%, p=0,0001). Unfavorable prognosis factors in M and IA patients were ≥2 organs involvement (p=0,0009), concomitant bacterial or viral infection (p=0,001; p=0,008, respectively). Unfavorable prognosis factor in M patients was unresolved hemoptysis (p=0,002), favorable – remission of underlying disease (p=0,006). Favorable prognosis factors in IA patients were early bronchoscopy (p=0,003), voriconazole use (p=0,0007) and secondary antifungal prophylaxis (p=0,0001).
Summary and Conclusions: In patients with mucormycosis more often observed agranulocytosis, lymphocytopenia, GVHD. The main sites of mucor and aspergillosis infection were lungs. Overall 12 weeks survival was significantly lower in M patients (49% *vs* 81%, p=0,0001). Unfavorable prognosis factors in M and IA patients were ≥2 organs involvement and concomitant bacterial or viral infection. Favorable prognosis factor in M patients – remission of underlying disease, in IA patients - early bronchoscopy, voriconazole use and secondary antifungal prophylaxis.

PF454

INVASIVE FUNGAL DISEASES CAUSED BY RARE PATHOGENS IN CHILDREN WITH HEMATOLOGICAL DISEASES AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION AND CHEMOTHERAPY

M.O. Popova[1,*], I. Markova[1], Y. Rogacheva[1], A. Volkova[1], I. Nikolaev[1], K. Ekushov[1], O. Paina[1], T. Bykova[1], O. Pinegina[1], S. Ignatieva[2], T. Bogomolova[2], O. Pirogova[1], E. Darskaya[1], M. Vladovskaya[1], I. Moiseev[1], S. Bondarenko[1], L. Zubarovskaya[1], N. Klimko[1], B. Afanasiev[1]

[1]Raisa Gorbacheva Memorial Institute of Children Oncology, Hematology and Transplantation, First Pavlov State Medical University, Saint-Petersburg, [2]Dept. of Clinical Mycology, I.I. Mechnikov North-Western State Medical University, Saint-Petersburg, Russian Federation

Background: Introducing a new antifungals and diagnostic procedures has improved prognosis of the invasive fungal diseases (IFD) in hematological patients. The number of publications on epidemiology of IFD caused by rare pathogens in children with hematological diseases after hematopoietic stem cell transplantation (HSCT) and chemotherapy (CT) is limited.
Aims: Our study focused on epidemiology of IFD caused by rare pathogens in children with hematological diseases.
Methods: Between 2009 and 2016 More than 3000 patients was observed and treated, 1337 allogeneic hematopoietic stem cell transplantation (allo-HSCT) and 617 autologous hematopoietic stem cell transplantation (auto-HSCT) were performed in our center. A retrospective study includes 30 cases of rare IFD in the period of time in patients with hematological malignances and non-malignant hematological diseases after CT and HSCT. The study group consist of children (n=11). Patients >18 y.o. with rare IFD (n=19) were used for the outcome analysis. EORTC/MSG 2008 criteria were used for the diagnosis of proven and probable IFD as well as to evaluate response to therapy.
Results: The incidence of rare IFD in children after allo-HSCT was 1,5% (n=7/461), auto-HSCT – 0,4% (n=1/232). Rare IFDs developed more often in patients with acute leukemia (45,4%). The etiological structure of confirmed rare IFD in children were *Mucorales* at six patients (54.5%), two cases of IFD caused by *Fusarium spp.* (18.2%), one – *Trichosporon asahii*(9.1%), one – *Scedosporium apiosperium* (9.1%), and combination of *Fusarium spp.* and*Paecilomyces spp.* were diagnosed in one patient (9.1%). In 36% of cases, IFD caused by rare pathogens develops after or in combination with invasive aspergillosis. The median day of onset of IFD was 92 days after allo-HSCT and 138 after auto-HSCT, 134 days after start of CT. Febrile fever was the main clinical symptom of IFD (100%). Main organ of defeat were lungs (87%). Antifungals were prescribed in 100% of cases of IFD caused by rare pathogens. All pediatric patients with mucormycosis had combination therapy. Overall survival at 12 weeks and 1 year from the diagnosis of IFD was 46,2% and 36,4% and was not differ in age groups. Combination antifungal therapy improves 1 year survival in children and adult with mucormycosis (n=30) (40% *vs* 10%, p=0,05).
Summary and Conclusions: The incidence of rare IFD in children after allo-HSCT was 1,5%, auto-HSCT – 0,4%. The main etiology agents of rare IFD were mucorales. Rare IFD were late complications after CT and HSCT. Rare IFD develops after or in combination with invasive aspergillosis. Combination antifungal therapy improves 1 year survival in patients with mucormycosis.

PF455

INVASIVE ASPERGILLOSIS IN HAEMATOLOGICAL PATIENTS: A REVIEW OF 625 CASES

C. Duval[1], M.-P. Ledoux[1], F. Danion[1], G. Morel[1], B. Guffroy[1], C. Simand[1], E. Toussaint[1], A. Cazes[1], M. Lamothe[2], J. Denis[3], V. Letscher-Bru[3], L.-M. Fornecker[1,4], R. Herbrecht[1,4,*]

[1]Oncology and Hematology, [2]Pharmacy, [3]Parasitology and Medical Mycology, Hôpitaux Universitaires de Strasbourg, [4]Université de Strasbourg, INSERM UMR-S1113/IRFAC, Strasbourg, France

Background: Invasive aspergillosis (IA) remains a frequent infection in haematological patients and diagnosis and treatment are still difficult despite significant progresses over the last two decades.
Aims: To review the cases of IA observed in our center in patients with an underlying haematological disease and to describe the characteristics of the disease and the evolution of outcome over time.
Methods: A retrospective review of consecutive cases of IA in a single haematology center over 20 years (1997 – 2016). IA episode were classified into possible, probable or proven according to EORTC/MSG criteria.
Results: We have identified 625 episodes of IA (possible: 137, 22%; probable: 429, 69%; proven: 59, 9%) in 585 different patients. Median age is 57 years (range: 5.5 – 90). Most frequent primary underlying condition is acute myeloblastic leukemia (AML) (227, 36%), allogeneic haematopoietic stem cell transplantation (HSCT) (119, 19%), aggressive lymphoma (85, 14%), low-grade lymphoma (42, 7%), acute lymphoblastic leukemia (ALL) (37, 6%), autologous HSCT (29, 5%), myeloma (22, 4%), and myelodysplastic syndrome (17, 3%). Neutropenia is present in 416 (67%) cases. Potential additional risk factors are recent chemotherapy in 484 (77%), T-cell suppressor including nucleoside analogues in 356 (57%) cases, active or prior use of tobacco in 280 (45%), prior respiratory disease in 157 (25%), systemic and/or aerosolized steroids in 273 (44%), diabetes in 90 (14%). Thirteen patients have also a history of solid organ transplantation prior to the onset of the haematological malignancy. Most frequent primary therapies are voriconazole (340, 54%), amphotericin B deoxycholate (AmBd) (104, 17%), liposomal amphotericin B (L-AmB) (40, 6%). Isavuconazole was given to 10 (2%), primary combination therapy to 52 (8%) and 16 (3%) patients did not receive any therapy. Overall 12-week survival is 58.0%. Long-term survival is 21.0% at 5 years and 16.2% at 10 years. Survival at week 12 is higher for possible IA (73.7%), than for probable (55.0%) and proven (42.4%) (p value: <0.001). Twelve-week survival is highest for isavuconazole (70.0%) and voriconazole (65.6%) treated patients compared to liposomal AmB (45.0%) and AmB deoxycholate (48.1%) treated patients (p value: 0.0003) (Figure 1A). Survival is similar for acute leukemia patients (64.8%) and alloHSCT recipients (58.8%), and is lower for patients with lymphoma, chronic lymphocytic leukemia and multiple myeloma (45.9%) (p value: 0.0019) (Figure 1B). Sur-

vival improved over time (p value: 0.034). This improvement over time correlates with availability of voriconazole in 2002.

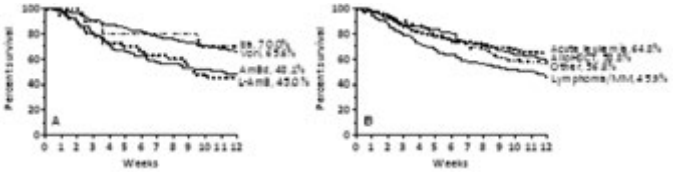

Figure 1.

Summary and Conclusions: This real-life study demonstrates that IA is still associated with a high mortality rate, greater than 30%, despite the significant improvement over time. Outcome is especially poor in patients with lymphoproliferations.

PF456

DIAGNOSIS OF INVASIVE ASPERGILLOSIS IN HIGH RISK HEMATOLOGICAL MALIGNANCY PATIENTS: PERFORMANCE OF BIOMARKERS AND CYTOKINES IN SAME DAY BLOOD AND BRONCHOALVEOLAR LAVAGE FLUID SAMPLES

S. Heldt[1], J. Prattes[1], S. Eigl[1], B. Spiess[2], J. Rabensteiner[1], F. Prueller[1], A. Wolfler[1], P. Neumeister[1], H. Strohmaier[1], R. Krause[1], D. Buchhheidt[2], H. Martin[1,*]

[1]Medizinische Universitaet Graz, Graz, Austria, [2]Mannheim University Hospital, Heidelberg University, Mannheim, Germany

Background: *Aspergillus* spp. and other molds have been shown to induce elevated levels of several cytokines. It remains unknown whether these cytokines hold value for clinical routine and enhance diagnostic performances of established and novel biomarkers/molecular tests for invasive aspergillosis (IA) and other invasive mold infection (IMI).
Aims: To determine the diagnostic potential of a number of cytokines, as well as established and emerging tests for IA and IMI in patients with underlying hematological malignancies in a setting that uses mold-active prophylaxis.
Methods: This cohort study included 106 prospectively enrolled (2014-2017) adult cases with underlying hematological malignancies and suspected pulmonary infection undergoing bronchoscopy. Serum samples were collected within 24 hours of bronchoalveolar lavage fluid (BALF) sampling. Both, serum and BALF samples were used to evaluate diagnostic performances of the *Aspergillus*-specific lateral-flow device test (LFD), *Aspergillus* PCR, galactomannan, β-D-glucan, and a bundle of cytokines for IA and IMI, classified according to the revised EORTC/MSG criteria.
Results: Among the 106 cases, 11 had probable IA, 32 possible IA (of which 7 had probable IMI), and 63 no evidence for IMI. Combinations of serum IL-8 with either BALF LFD (sensitivity 100%, specificity 94%) or BALF PCR (sensitivity 91%, specificity 97%) were highly sensitive and specific for differentiating probable IA from no IA. Serum IL-8 showed also potential for differentiating patients with possible/probable IMI from those without IMI, while serum and BALF GM and BDG did not.
Summary and Conclusions: Our study indicates that serum IL-8 testing may be a valuable addition to clinical routine for diagnosing IA and IMI in high risk patients who receive mold-active antifungals.

PF457

NEUTROPHIL EXTRACELLULAR TRAPS IMPAIR FUNGAL CLEARANCE IN A MOUSE MODEL OF INVASIVE PULMONARY ASPERGILLOSIS

A. Alflen[1,*], P. Aranda Lopez[1], A.-K. Hartmann[2], J. Maxeiner[3], M. Bosmann[4,5], H. Beckert[6], W. Ruf[4], M. Radsak[1]

[1]3rd medical department, [2]Institute for Immunology, [3]Asthma Core Facility, [4]Center for Thrombosis and Hemostasis, University Medical Center, Mainz, Germany, [5]Pulmonary Center, Department of Medicine, University Medical Center, Boston, United States, [6]Ruhrland Clinic, West German Lung Clinic of the University Medical Center, Essen, Germany

Background: Invasive pulmonary aspergillosis (IPA) is a major threat to patients with hematologic neoplasms or patients receiving immunosuppressive drugs after organ or hematopoietic stem cell transplantation. In this setting polymorphonuclear neutrophils (PMN) play a critical role in the immune response against fungal pathogens since they are rapidly recruited to sites of infection and kill microbes through a combination of cytotoxic mechanisms. Besides phagocytosis and the production of reactive oxygen species, they can expulse their nuclear contents to form neutrophil extracellular traps (NETs). Thereby they trap and kill microbes by forming highly decondensed chromatin structures that correlates with histone hypercitrullination catalyzed by peptidylarginine deiminase 4 (PAD4). Besides their ability to clear bacterial infections, the impact of NETs on fungal clearance is controversial. Furthermore, the toxicity of free DNA and histones is associated with organ damage.
Aims: Hence we asked whether NETs contribute to fungal clearance and outcome in a mouse model of IPA where PMN are essential for the survival.
Methods: IPA was induced by intratracheal application of *Aspergillus fumigatus* conidia in wildtype (C57BL/6J) or PAD4 deficient (*Pad4*$^{-/-}$) mice. After 24 h fungal load was assessed as colony forming units after plating and culturing lung homogenates on agar. Broncho alveolar lavage fluid (BALF) was analyzed for cell count, ELISA was performed for albumin amount and citrullinated Histone H3 (citH3), and cytokines were analyzed by a multiplex assay. One week after infection mice were anesthetized and invasive lung functions were performed. Afterwards, mice were sacrificed and blood, BALF and lungs were analyzed as described above. PMN functions (oxidative burst, phagocytosis, degranulation, CD62L shedding) from mice were analyzed by flow cytometry after lysis of whole blood and activation of cells. Human PMN were isolated from the blood of healthy donors by density gradient centrifugation. PMN were preincubated with a PAD4 inhibitor (GSK 484), activated and functions were analyzed by flow cytometry (see above) and viability by MTS assay.
Results: 24 hours after induction of IPA *Pad4*$^{-/-}$ mice revealed lower fungal burden in the lungs, which was accompanied by a significantly lower amount of albumin in the BALF, indicating lower acute lung injury. However, *Pad4*$^{-/-}$ and wildtype mice showed similar PMN recruitment in the blood and into the BALF. As expected, *Pad4*$^{-/-}$ mice showed significantly lower amounts of citH3 in the BALF of infected animals and also a lower amount of TNFa accompanied by a differential cytokine profile compared to wildtype mice. While GROa and IL-17A were also lower in BALF of *Pad4*$^{-/-}$ animals, MCP-1 was elevated in these mice and eotaxine, G-CSF and IL-18 showed only minor differences in the two mice strains. Invasive lung function tests one week after infection did not detect any significant differences in airway resistance in wildtype and *Pad4*$^{-/-}$ mice demonstrating no permanent lung damage. Furthermore, PMN functions from *Pad4*$^{-/-}$ and wildtype mice revealed no relevant differences when analysing them *ex vivo e.g.* for degranulation or phagocytosis and also pretreatment of human PMN with a PAD4 inhibitor did not results in differentially regulated PMN functions.
Summary and Conclusions: NETs impair fungal clearance in a mouse model of IPA and contribute to acute lunge injury. Inhibition of NET formation might therefore be a useful strategy to reduce fungal dissemination and to avoid lung damage in immunocompromised patients.

PF458

HEMOPHAGOCYTIC LIMPHOHISTIOCYTOSIS ASSOCIATED WITH LEISHMANIASIS: A HIDDEN PASSENGER IN ENDEMIC AREAS?

J. Badiola[1,*], J. M. Puerta-Puerta[1], P. González-Sierra[1], J. Sainz[2], L. Cabo-Zabala[3], F. Hernández-Mohedo[1], A. Romero-Aguilar[1], F. Ruiz-Cabello[3], R. Ríos-Tamayo[1], M. Jurado-Chacón[1]

[1]Hematology, Hospital Virgen de las Nieves, [2]GENYO. Centre for Genomics and Oncological Research, [3]Immunology, Hospital Virgen de las Nieves, Granada, Spain

Background: Hemophagocytic lymphohistiocytosis (HLH) is a rare and devastating heterogeneous disorder causing an uncontrolled immune inflammatory response and cytokine storm triggering tissue damage and leading to organ failure. The number of reported HLH cases in the adult population has increased dramatically in the last several years, probably due to the rise in recognition of the syndrome. In HLH the identification of the trigger is mandatory because it's elimination could remove the stimuli that prompts the abnormal immune system activation. Although the predominant causes differ in each country and age, infectious diseases and neoplasms are the most frequent triggers worldwide. An association between visceral leishmaniasis and HLH is well-described in the literature, especially in children. In adults, leishmaniasis is a rare cause of HLH, with less than 30 documented cases, being the trigger in less than 1% of adult HLH cases.
Aims: After identifying a few cases of HLH triggered by Leishmania, the objective of our study was to analyze the presentation, diagnosis and prognosis of this association in our area.
Methods: Retrospectively, we collected clinical and analytical data of adult patients diagnosed with HLH in the province of Granada (Spain), in the last 10 years (2008-2017).

Results: 21 patients were diagnosed of HLH in this period with the clinical and analytical characteristics that are shown in Table 1. Infectious diseases were the most common triggers, with 8 cases (5 leishmaniasis, 2 HIV and 1 CMV), followed by oncohematological triggers, 4 cases (1 T lymphoma, 1 B lymphoma, 1 acute lymphoblastic leukemia and 1 colorectal cancer), autoimmune triggers, 4 cases (2 systemic lupus erythematosus, 1 inflammatory bowel disease and 1 antiphospholipid syndrome), idiopathic, 4 cases, and HSCT, 1 case. It should be noted that no statistically significant differences were found in the characteristics or in the clinical-analytical presentation between HLH triggered by Leishmania and those that were not. In the cases of leishmaniasis, the PCR in the bone marrow was positive in 100% of the patients, the detection of Leishmania antigen in urine in 40% and the visualization of Leishmania in bone marrow analysis and the culture only in 20%. The mortality of the Leishmania group has been lower, (Figure 1) although it has not reached statistical significance (p=0.09).

Table 1. Clinical-analytical characteristics of the presentation (average).

Male sex, age, previous immunosuppression and temperature	52.4%, 44, 52.4% and 39.1ºC
Splenomegaly, hepatomegaly and adenopathies	100%, 70% and 25%
Hemoglobin, leukocytes and platelets	7.4 g/dL, 1978 x 10^3/L and 37100 x 10^3/L
Ferritin, triglycerides and fibrinogen	11199 ng/ml, 411 mg/dl and 202 mg/dl
ALT, AST, bilirubin, CRP and LDH	126 U/l, 159 U/l 5.4 mg/dl, 172 mg/L and 1357 U/l

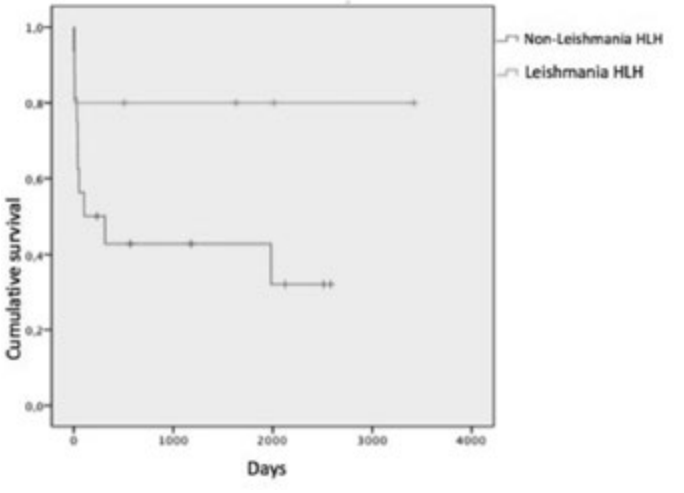

Figure 1.

Summary and Conclusions: Leishmania, far from being an infrequent cause of HLH, is the predominant trigger of adult HLH in our area. HLH triggered by Leishmania is indistinguishable from those not triggered by them, with an identical clinical and analytical presentation. Intense search of Leishmania is mandatory in every case of HLH using PCR. The rest of the techniques have low sensitivity in these cases, probably because of the paucimicrobial nature of the disorder. Diagnosis and adequate treatment of leishmaniasis could improve the prognosis of HLH in these patients.

PF459

ANALYSIS OF THE BURDEN OF CYTOMEGALOVIRUS REACTIVATION IN PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION

C. Tham[1,*], S. Monsalvo[1], S. Lozano[1], D. Avenoso[1], B. Sevillano[1], F. Fernando[1], N. Farah[1], C. Paliompeis[1], D. Milojkovic[1], R. Palanicawandar[1], E. Olavarria[1]

[1]Haematology, Imperial College London, London, United Kingdom

Background: CMV reactivation can be managed with pre-emptive antiviral therapy but this strategy is associated with significant morbidities and subsequent economic burden.
Aims: To analyse the incidence of CMV infection and the healthcare resource utilisation by estimating length of inpatient stay and recurrent hospitalisation rates.
Methods: We have analysed 385 consecutive patients undergoing allogeneic stem cell transplantation (AlloSCT) that were at risk of CMV infection (patient and/or donor CMV seropositive).
Results: Median age was 47 years (18-72). There were 229 (59%) males. CMV serology (Recipient/Donor) distinguished 3 groups: Pos/Pos 238 (62%); Pos/Neg 103 (27%); Neg/Pos 44 (11%). Transplant conditioning was myeloablative in 189 (49%) and reduced intensity in 196 (51%). Donor types were 178 (46%) HLA-identical sibling, 116 (30%) matched unrelated, 37 (10%) mismatched unrelated and 54 (14%) haploidentical donors. T-cell depletion with Alemtuzumab was performed in 194 (50%). All patients were managed with pre-emptive therapy after CMV reactivation was confirmed in 2 consecutive PCR samples. CMV reactivation occurred in 171 (44%) patients at a median of 35 (6-331) days post SCT. In 59 (34%) cases, CMV reactivated a median of 19 (2-314) days before the diagnosis of GVHD. Acute GVHD developed in 34 patients before CMV reactivation after a median of 25 (1-103) days post AlloSCT. Systemic steroids were started in 54(31%) patients a median of 9 (1-82) days before CMV reactivation. A total of 167 (98%) patients received antiviral therapy as per pre-emptive protocol. Intravenous Ganciclovir was given as first line antiviral therapy to 86 (50%) patients while Foscarnet was given to 39, oral Valganciclovir to 39 and Cidofovir to 2 patients. Four patients did not receive anti-CMV therapy. The median time between CMV reactivation and starting antiviral therapy was 1.5 days (0-26) with >96% of patients starting antivirals within 72 hours of reactivation. The median duration of antiviral therapy was 29 (3-130) days. The overall response to antiviral therapies was 83% complete remission (negative CMV PCR) and 10% partial response (reduction in CMV PCR copies). 13 (7%) patients died before their response could be evaluated (9 on Ganciclovir and 4 on Foscarnet). The respective response rates according with the different initial treatments was: Ganciclovir 75% CR and 11% PR, Foscarnet 75% CR and 10% PR and Valganciclovir 92% CR and 10% PR. A total of 92 (53%) patients required second-line antiviral therapy: 28 patients after a partial response and 64 patients (45% of CR patients) because of a second CMV reactivation (CMV relapse). In addition, 68 (41%) patients changed their initial antiviral for different reasons: renal toxicity (13%), intolerance (15%) and de-escalation to oral Valganciclovir (13%). A total of 63 patients required re-hospitalisation for their treatment (37% of CMV reactivations, 16% of all patients at risk of CMV reactivation). The median number of days in hospital was 21 (3-133).
Summary and Conclusions: CMV infection occurs in over 40% of patients at risk. Responses to first line antivirals are satisfactory, although there is a significant risk of relapse. Anti-CMV therapies impact on healthcare resources with a high rate of re-hospitalisation.

PF460

ANTIGFUNGAL DRUGS MODULATE HUMAN NEUTROPHIL ACTIVITIES *IN VITRO* AND *IN VIVO* IN PATIENTS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

F. Ries[1], A. Alflen[1], P. Aranda Lopez[1], E.-M. Wagner-Drouet[1], M. Theobald[1], H. Schild[2], M. Radsak[1], D. Teschner[1,*]

[1]Department of Hematology, Medical Oncology, & Pneumology, [2]Institute of Immunology, University Medical Center of the Johannes Gutenberg University, Mainz, Germany

Background: In high risk patients antifungal agents substantially contribute to reduced morbidity and improved survival. However, besides their well-known antifungal activity there is a growing body of evidence for their immunomodulatory side effects on different immune effector cells.
Aims: The aim of our study is to clarify the impact of antifungal drugs on the effector functions of human polymorphonuclear neutrophils (PMN) *in vitro* and *ex vivo* and on the clinical course of invasive pulmonary aspergillosis (IPA).
Methods: Isolated PMN from healthy donors were preincubated with different antifungals (fluconazole [FLU], voriconazole [VOR], posaconazole [POS], isavuconazole [ISA], caspofungin [CAS], micafungin [MIC], conventional [AmB], and liposomal amphotericin b [LAmB]) and stimulated with lipopolysaccharides (LPS) or zymosan *in vitro*. Afterwards, PMN were analyzed by flow cytometry regarding shedding of CD62L, degranulation of CD66b/CD11b, and phagocytosis or by dichlorofluorescein assay to detect reactive oxygen species (ROS). Furthermore, the influence of MIC and POS on IPA was investigated *in vivo*. Therefore, mice treated with antifungals were inoculated with *A. fumigatus* conidia and lungs were analyzed by fungal culture assays, histopathologic staining, and pulmonary damage (albumin ELISA). Afterwards, blood samples of patients after allogeneic hematopoietic stem cell transplantation (HSCT) under treatment with antifungal drugs were analyzed *ex vivo* as described above with PMN from untreated HSCT patients serving as controls.
Results: *In vitro*, POS led to enhanced PMN activation (CD62L: 44% +/- 8 *vs* 13% +/- 2, *; mean +/- SEM; p-value ≤0.05 [*]), increased degranulation, and intensified generation of ROS. In contrast, ISA pretreatment resulted in impaired activation, degranulation, and generation of ROS (6980 rfu +/- 1338 *vs* 28730 +/- 6893, LPS, *). MIC led to enhanced expression of acti-

vation marker CD62L but reduced expression of CD11b, and decreased degranulation. Phagocytosis (27% +/- 4 *vs* 44 +/- 1, LPS, *) as well as generation of ROS were substantially impaired. CAS showed an increased phagocytosis (75% +/- 6 *vs* 44 +/- 5, LPS, *), whereas degranulation and generation of ROS were reduced by trend. Pretreatment with AmB resulted in generally enhanced effector functions besides impaired phagocytosis (43% +/- 3 *vs* 59 +/- 3, LPS, *). In contrast, LAmB did not significantly alter any effector functions. Regarding IPA, treatment with POS resulted in generally reduced fungal burden but led to decreased pulmonary damage (111 ng/ml +/- 46 *vs* 380 +/- 31, *). Despite similar fungal culture assays, MIC resulted in reduced fungal load in histopathologic staining compared to neutropenic controls. As expected from our *in vitro* experiments, PMN isolated from a patient after HSCT treated with ISA displayed relevantly impaired generation of ROS especially after additional LPS stimulation (12365 rfu [ISA] *vs* 41605 [control]) compared to PMN taken from a HSCT patient without antifungal medication. Other PMN effector functions were affected by trend through ISA treatment *ex vivo* but not as pronounced as seen in the *in vitro* assays.

Summary and Conclusions: Independent from substance class, antifungals drugs show variable modification on PMN effector functions *in vitro*, *in vivo*, and *ex vivo*. These interactions are obviously multidimensional and potentially derive from involvement of different pathways. Further experiments regarding PMN taken from HSCT patients under treatment with various antifungal compounds are ongoing to clarify the impact of our findings in daily patients care.

PF461

(1-3)-β-D-GLUCAN ASSAY AND AIRWAY-INVASIVE RADIOLOGICAL FINDINGS AS EARLY SIGNS OF PULMONARY ASPERGILLOSIS IN HIGH-RISK HEMATOLOGIC PATIENTS IN THE POSACONAZOLE ERA: PRELIMINARY OBSERVATIONS

C. Giordano[1,*], R. Della Pepa[2], I. Zacheo[3], C. Mortaruolo[3], A. Giordano[3], F. Trastulli[3], M. Raimondo[1], M. Lucignano[1], M. Di Perna[1], M. Picardi[3], F. Pane[4]

[1]Hematology, Federico II University, [2]Hematology, Federico II, [3]Hematology, [4]Advance Biomedical Science, Federico II, University of Naples, Naples, Italy

Background: Invasive pulmonary aspergillosis (IPA) is a severe complication in immuno-compromised patients with neutropenia, due to chemotherapy for acute myeloid leukemia (AML) remission induction. The Serum Aspergillus galactomannan index (s-GMI) test is helpful in early diagnosing IPA, with excellent performance and the halo sign detected at the high resolution chest computed tomography (HRCT) may suggest early IPA. However, microbiological and radiological findings may vary according to several factors, including antifungal prophylaxis.

Aims: With the intention of optimizing the mycological and radiological diagnostic yield, we wondered whether the diagnostic criteria of EORTC 2008 for IPA diagnosis could be adapted based on the type of drug used as primary antifungal prophylaxis (PAFP).

Methods: In this prospective study, of the Hematology of the Federico II University of Naples (Italy), we analyzed the results of IPA diagnostic work-up of AML patients, neutropenic with persistent fever in prophylaxis with posaconazole or itraconazole. From 2009 to 2012 patients obtained itraconazole, from 2013 to 2016 patients received posaconazole as PAFP. In the event of febrile neutropenia, they underwent a baseline diagnostic work-up based on blood cultures and conventional radiological examinations. Patients with persisting fever after 96h unresponsive to broad-spectrum antibiotics (77 cases), underwent an intensive diagnostic work-up that included s-GMI and serum (1-3)-β-D-GLUCAN (s-BDG) assay twice a week, and HRCT. These results were compared in the two groups (Student *t* test and square test).

Results: Median value of s-BDG was 168 pg/ml (17-352) in the posa-group and 85 pg/ml (23-330) in the itra-group; s-GMI median result was 0.5 (0.1-0.8) in the posa-group and 0.8 (0.1-2) in the itra-group. Most frequent HRCT findings for the posa-group were aspecific whether, in the itra-group, frequent findings were included in the EORTC 2008 diagnostic criteria. During the study period, 11% of the patients in the posa-group had a proven or probable fungal infection, *vs* the 45% patients of the itra-group (*P*<.001). Patients with positive s-BDG value and a HRCT scan aspecific result, were classified in a new category of IPA called "probable invasive aspergillosis with positive s-BDG and aspecific radiological findings" (14 cases in the posa-group and 2 in the itra-group; *P*<.001). This new category of patients that are febrile, neutropenic and unresponsive to broad- spectrum antibiotics, but positive to indirect mycological tests with HRCT aspecific lesions during posaconazole prophylaxis can be considered as having a probable IPA in an airway bronchogenic phase (Figure 1).

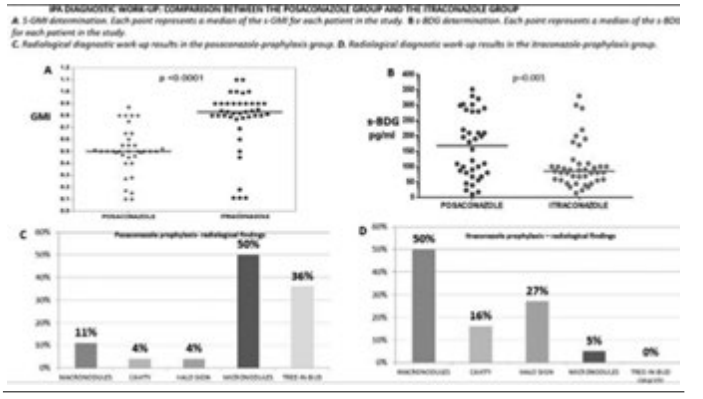

Figure 1.

Summary and Conclusions: Considering our data, the fungal dissemination and consequent radiologic and microbiologic signs are tightly related to the prophylaxis. Posaconazole seems to limit the angioinvasive disease while *Aspergillus* can disseminate through bronchi giving lesser expression in classical radiological findings and s-GMI results, thus supporting the hypothesis it's fungicide. More patients from the posa-group received an earlier systemic antifungal therapy (day 5 of work-up) in contrast with the itra-group (treated more frequently from day 7), thus affecting the 30-day OS (6 deaths *vs* 3). These results suggest the possibility of revising EORTC 2008 criteria by extending the suspicion of IPA to less specific HRCT features and a positive s-BDG value in patients with posaconazole prophylaxis, with regard to acting a pre-emptive therapeutic approach in an early stage of IPA.

PF462

COMPARATIVE ANALYSIS OF DETECTION OF EBV SMALL NON-CODING RNA (EBER) AND MARKERS OF ACUTE EBV INFECTION AT THE ONSET OF ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA

N. Chernova[1,*], D. Tikhomirov[2], M. Sinitcina[3], Y. Sidorova[4], A. Kovrigina[3], S. Kulikov[5], T. Tupoleva[2], E. Zvonkov[1]

[1]Department Chemotherapy of Lymphomas, [2]Laboratory of Virology, [3]Department of Pathology, [4]Department of Molecular Hematology, [5]Laboratory of Biostatistic, National Research Center for Hematology, Moscow, Russian Federation

Background: Angioimmunoblastic T-cell lymphoma (AITL) is associated with Epstein-Barr virus approximately in 70% of cases, which is proved by detection of EBV small non-coding RNA (EBER) in lymph node biopsies by *in situ* hybridization. At the same time, it is not known whether this is a sign of acute EBV infection or a tumor feature. The frequency of acute EBV infection markers at the onset of AITL is also unknown. A possible link between detection of EBER and the markers of acute EBV infection is uninvestigated.

Aims: The aim of the study was to perform a comparative analysis of detection EBER in lymph node biopsies and markers of acute EBV infection in primary patients with AITL.

Methods: 38 primary AITL patients were enrolled in the study. Male/female ratio was 20/18; a median age was 61 (29-81) years. Diagnosis was based on standard WHO criteria. EBV DNA concentration were screened by real-time PCR in peripheral blood (PB, n=38), bone marrow (BM, n=16), lymph node biopsies (LN, n=14) and bronco-alveolar aspirates (BAA, n=6). IgM against viral capsid antigen (IgM VCA EBV), IgG against early antigen (IgG EA EBV) and IgG against nuclear antigen type 1 (IgG ENBA-1 EBV) were tested by ELISA in all cases. Detection of DNA in low concentration (like less than 500 copies in 10^5 mononuclear cells of PB, BM and LN or in 1 ml of BAA) was regarded as latent infection. Detection of EBV DNA in concentration above 500 copies and/or of IgM VCA and/or IgG EA was regarded as acute infection. Discovery of markers of acute infection in absence of IgG ENBA-1 was referred to as primary infection. EBV small non-coding RNA (EBER) was tested by *in situ* hybridization in all lymph node samples.

Results: Laboratory markers of acute EBV infection were determined in 24 (63.2%) of 38 patients. EBV replication in PB were detected of 21 (55.3%) out of 38 patients, including 7 (18,4%) cases of primary infection. Serological markers of acute EBV infection (IgM VCA and/or IgG EA) were positive in 9 (23.7%) patients. EBV DNA in concentration relevant to active replication was detected in 14 (36,8%) cases. Comparison of viral DNA load in PB and/or BM and/or LN and/or BAA samples of a single patient showed that the highest level of viral load was determined in LN (up to

4.0x10^{6}copies/10^{5}cells) and BAA (up to 5.7x10^5/ml). EBV small non-coding RNA (EBER) was positive in 27 (71,1%) of 38 cases. Comparison of detection of EBER and acute markers of EBV infection showed good correlation (p<0,001). Patients with EBER-negative lymph node samples (n=11) didn't have any markers of acute EBV infection. Conversely, 24 of 27 (88,9%) EBER-positive cases accompanied by markers of acute EBV infection: 7 (25,9%) of them held markers of primary infection and 17 (63.0%) – reactivation. A pattern of markers of latent EBV was observed in the rest 3 (11.1%) EBER-positive cases. The results of detection of EBER and markers of acute EBV infection are summarized in the Table 1.

Table 1.

Comparison of detection of EBER in lymph nodes samples and patterns EBV markers in primary AITL patients

Pattern of EBV-markers		EBER-positive, n=27		EBER-negative, n=11	
		n	%	n	%
Acute EBV infection	Primary infection, n=7	7	25,9	0	0,0
	Reactivation, n=17	17	63,0	0	0,0
	TOTAL, n=24	24	88,9	0	0,0
No EBV replication	Latent infection, n=13	3	11,1	10	90,9
	Absence of infection, n=1	0	0,0	1	9,1
	TOTAL, n=14	3	11,1	11	100,0

Summary and Conclusions: The manifestation of AITL was accompanied by acute EBV infection (reactivation or primary infection) in almost half of enrolled patients. Markers of acute EBV infection were identified in most EBER-positive cases. Patients with EBER-negative lymph node samples didn't have any markers of acute EBV infection. Thus, screening for markers of acute EBV infection is strongly recommended at the onset of AITL.

PF463

THE ROLE OF SERUM GALACTOMANNAN ASSAY IN THE MANAGEMENT OF INVASIVE MOLD INFECTIONS IN AUTOLOGOUS HEMATOPOIETIC CELL TRANSPLANTATION.

M.E. Martinez-Muñoz[1,*], F. Portero[2], E. Ojeda[1], G. Bautista[1], R. Forés[1], I. Krsnik[1], A. de Laiglesia[1], B. Navarro[1], A. Ramos[3], J.R. Cabrera[1], R. Duarte[1]

[1]Hematology, [2]Microbiology, [3]Infectious Diseases, Hospital Universitario Puerta de Hierro Majadahonda (Madrid), Majadahonda, Spain

Background: Serum galactomannan (sGM)-based preemptive strategies are used for the management of invasive mold infections (IMI) in hematology patients. We have previously shown that effective anti-mold prophylaxis in high-risk patients makes sGM surveillance unreliable [RF Duarte, et al; Clin Infect Dis 2014]. Thus, these strategies would be particularly suited for patients not receiving anti-mold prophylaxis.
Aims: It remains to be tested wether they would be useful to manage patients for whom anti-mold prophylaxis is usually not recommended for an intermediate or low risk of IMI, such as autologous HCT recipients.
Methods: We present a single-center study on the use of sGM as part of a preemptive strategy to diagnose IMI in 86 consecutive episodes of autologous HCT (2009-2015) in 84 patients: 43 men; median age 52, range 16-69; 38 multiple myelomas, 28 non-Hodgkin lymphomas, 13 Hodgkin lymphomas, 2 systemic amyloidosis, 2 acute promyelocytic leukemias, 1 Crohn's disease. Patients received itraconazole prophylaxis up until 2011 (25; 30%) and fluconazole thereafter (61; 70%), and underwent twice weekly sGM surveillance throughout the risk episode.
Results: A total of 677 sGM tests were performed in this series, median 8 tests per risk episode (2-12). There were no cases of IMI according to EORTC/MSG criteria. One patient in the series (1.2%) died from septicemia with a single sGM positive test result (optical index [OI]: 0.9), no other features of IMI, and no necropsy (EORTC/MSG unclassified episode). A vast majority of 648 sGM tests (95.7%) and 72 episodes (83.7%) were all negative. Fourteen episodes (16.3%) had positive sGM test results (median 1, range 1-6) with a median OI of 0.9 (0.5-5.3). Five of these were false positive sGM episodes (5.8% of total, 35.7% of sGM positive episodes), as despite having positive sGM results (median OI 1.1, 0.7-1.6) patients remained afebrile, did not receive antifungal treatment and recovered from neutropenia with no other features of IMI (Table 1). The remaining nine episodes, with a median of 2 positive sGM results (range 1-6; OI 0.9, 0.5-5.3) were not evaluable to assess sGM performance, as test results led to the initiation of antifungal treatment (10.5% of total, 64.3.4% of positive episodes). All these non-evaluable episodes occurred in patients who survived and developed no other features of IMI, in five of them as antifungal surveillance in the absence of persistent fever. Despite the low incidence of IMI, positive sGM episodes were more likely to receive antifungal treatment (64.3% *vs* 23.6%; *p*<0.01). Of note, there were no differences in the occurrence of false positive or non-evaluable sGM episodes between patients on itraconazole or fluconazole prophylaxis (Table 1).

Table 1. Episode distribution according to serum galactomannan results.

Episode Type	No. (%)	Prophylaxis	
		Itra	Fluco
True positive	0	-	-
True negative	55 (64%)	15	40
False positive	5 (6%)	2	3
Non-evaluable	26 (30%)	8	18
• *sGM pos*	*9 (10%)*	*1*	*8*
• *sGM neg*	*17 (20%)*	*7*	*10*

Abbreviations: Fluco: fluconazole, Itra: itraconazole, sGM: serum galactomannan.

Summary and Conclusions: This study reproduces a very low incidence of IMI in recipients of autologous HCT. In keeping with our previous findings in high-risk patients on effective antifungal prophylaxis, our data show that sGM-based preemptive strategies are not reliable to manage IMI in this setting of low prevalence of infection, regardless of the use of mold-active prophylaxis. The vast majority of sGM tests are negative, and beyond confirmed false positive GM episodes, the remaining positive sGM test results can mislead diagnostic and therapeutic efforts, in particular when used as surveillance in patients without persistent fever.

PF464

CYTOMEGALOVIRUS (CMV) IMPACT ON CLINICAL OUTCOMES AND RESOURCE USE AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION: THE INFLUENCE OF RECURRENT EPISODES OF CMV INFECTION

C. de Miguel[1,*], A. Royuela[2], M.F. Portero[3], J.L. Cruz[4], M.E. Martínez-Muñoz[1], M.I. Sánchez-Romero[3], G. Bautista[1], R. Cabrera[1], R.F. Duarte[1]

[1]Hematology, Hospital Universitario Puerta de Hierro Majadahonda, [2]Clinical Biostatistics Unit, Biomedical Sciences Research Institute Puerta de Hierro-Segovia de Arana, [3]Microbiology, Hospital Universitario Puerta de Hierro Majadahonda, [4]IT Department, Hospital Universitario Puerta de Hierro Majadahonda - Universidad Politécnica de Madrid, Majadahonda, Spain

Background: Despite pre-emptive therapy (PET), Cytomegalovirus infection (CMVi) poses a negative impact on the outcome of allogeneic HCT recipients, and potentially on the use of resources for patient management.
Aims: The objective of this study is to analyse the impact of CMV infection on clinical outcomes and resource use in a tertiary hospital.
Methods: This retrospective study analyses the impact of CMVi on clinical outcomes and resource use including hospital length of stay (LOS) in consecutive allogeneic HCT recipients (2009-2016), with a particular focus on recurrent CMVi episodes.
Results: 183 allogeneic HCT in 172 recipients were included: 101 men (58.7%); median age 44 years (16-68); 51% AML/MDS, 16% ALL, 16% chronic lymphoproliferative disorders, 8% myeloma and 9% other; 45% matched related, 30% cord-blood, 20% unrelated and 5% haploidentical donors; 52% myeloablative conditioning; 161 (88%) at risk of CMVi (donor and/or recipient positive serology); 61 (33%) had acute GvHD grades II-IV. CMV disease occurred in only 4 cases (2%). CMVi occurred in 56% of patients (60% of patients at risk), at a median day +35 post-HCT (15-58), and had an impact on overall survival (44% *vs* 60% at 2 years; p=0.027). Patients above median age had higher CMV serology at risk (97% *vs* 80%; p<0.001) and CMVi rates (65% *vs* 48%; p=0.005). Compared to matched-related HCT, cord-blood and haploidentical HCT-recipients had higher CMVi rates (68% *vs* 49%; p=0.009, respectively) and earlier onset (70% *vs* 32% within day +35 post-HCT; p<0.001). Acute GVHD also increased CMVi rates (87% *vs* 43%; p<0.001). Among patients with a first CMVi, 57% had ≥2 and 20% had ≥4 recurrent CMVi episodes. CMVi recurrence

≥2 was also higher in cord-blood and haploidentical *versus* matched related HCT (HR 2.38; 95%CI 1.61-3.52; p<0.001), age at the time of HCT (+1.6% per year OR HR 1.02 (1.016); 95%CI 1-1.03; p=0.024) and acute GVHD (HR 2.3; 95%CI 1.62-3.26; p<0.001). In terms of clinical burden, hospital LOS throughout the first year post-HCT was overall >30 days longer in patients with CMVi (*vs* without, p<0.001; Table 1). This increase in LOS was >40 additional days in patients with ≥2 recurrent CMVi, significantly higher than in those with only one CMVi episode (19 days; p<0.001). In terms of treatment, 73.7% of CMV reactivations responded to 1st line of treatment, 60% to 2nd line and only 30% to 3rd line. The rate of adverse effects with PET was 31% after 1st line of treatment, and increased with usual drugs to 60% after 2nd line.

Table 1. Impact of CMV infection and recurrent infections on hospital admission length of stay.

Hospital LOS	No CMV infection	p	CMV infection (Any)	Number of CMV infection episodes		p
				Only 1	>=2	
1st HCT Hospital Admission	44.59 +/- 21.7	0.029	53.98 +/- 33.9			
1st Discharge to d +100	11.90 +/- 28.4	0.864	12.59 +/- 26.5	12.32 +/- 26.8	12.89 +/- 26.8	0.976
1st Discharge to d +365	24.75 +/- 39.1	0.002	47.30 +/- 56.5	35.93 +/- 46.2	54.59 +/- 62.1	0.004
d +100 to d +365	12.86 +/- 24.1	<0.001	34.65 +/- 52.3	23.59 +/- 37.9	41.69 +/- 59.7	0.001
HCT Admission to d +365	69.34 +/- 43.9	<0.001	101.28 +/- 63.2	88.49 +/- 52.5	109.7 +/- 69.2	<0.001

Abbreviations: CMV: Cytomegalovirus; HCT: Hematopoietic Cell Transplantation; LOS: Length of stay (expressed in days, d).

Summary and Conclusions: Despite preemptive therapy, CMVi remains a hurdle to the success of allogeneic HCT, with a significant impact on patients' outcome and use of resources. Recurrent CMVi episodes are very frequent, in particular in high-risk HCT-groups such as cord-blood, haploidentical and acute GVHD, pose a significant impact on outcomes and are a strong driver of hospital LOS and resource burden for the HCT program.

PF465

EPIDEMIOLOGY AND TREATMENT APPROACHES OF INVASIVE FUNGAL INFECTIONS MANAGEMENT IN HEMATOLOGICAL MALIGNANCIES: RESULTS FROM A SINGLE-CENTRE STUDY

N.S. Fracchiolla[1,*], M. Sciumè[1], N. Orofino[1], F. Guidotti[1], A. Grancini[2], F. Cavalca[1], A. Freyrie[1], M.C. Goldaniga[1], D. Consonni[3], A. Cortelezzi[1]

[1]Oncohematology Division, IRCCS Ca' Granda - Maggiore Policlinico Hospital Foundation and University of Milan, [2]UOS Microbiology, Central Laboratory, I.R.C.C.S. Foundation, Cà Granda Ospedale Maggiore Policlinico, [3]Unit of Epidemiology, Fondazione IRCCS Ca' Granda-Ospedale Maggiore Policlinico, Milan, Italy

Background: Invasive fungal infections (IFI) are a leading cause of morbidity and attributable mortality in oncohematologic patients (pts), particularly after intensive chemotherapy or hematopoietic stem cell transplant. Timely diagnosis is essential but challenging.
Aims: To describe the epidemiology and treatment of IFIs in a large, monocentric real-life cohort of hematological malignancies.
Methods: Oncohematologic pts treated with anti-fungal therapy (AFT) at our Hematology Department between January 2010 and July 2017 were identified from institutional databases. Clinical data, diagnostic work-up, treatment modalities, and outcomes were extracted. Diagnosis of IFI was carried out according to the revised definitions of European Organization for Research and Treatment of Cancer/Mycoses Study Group (EORTC/MSG, 2008).
Results: Among 1719 consecutive hospitalizations, 221 AFT in 196 pts were recorded: the most represented disease was acute myeloid leukemia (103 pts) (p<0,001). Median age was 61 years (18-85) and male/female ratio was 58/42%. At fever onset 177 (80%) pts had a neutrophil count <0.5x10^9/L. Twenty-nine (13%) pts were receiving antifungal prophylaxis (26 posaconazole, 2 fluconazole, 1 itraconazole). The incidence of AFT was 13%. Serum galactomannan antigen (GM) was positive in 20% of the tested cases, while 85% of the pts had a CT scans suggestive for IFI, but only 23% of these cases had a GM positivity (p=.02). Only one case with a negative CT scan had a positive GM. Yeasts and moulds were identified in 42 (19%) and 22 (10%) pts, respectively. Four (2%) pts presented multiple positivity. Moulds were isolated from the respiratory tract, except for a case of hepatic mycoses at liver biopsy and a fungemia (Fusarium spp). Yeasts were isolated from peripheral blood (15 cases) and respiratory tract in the remaining cases. According to EORTC/MSG criteria, 22 (10%) cases were proven IFIs, 61 (28%) probable and 81 (36%) possible, but 57 (26%) cases could not be classified. Fifty-nine percent of the patients were treated with single agent AFT, 37% with sequential AFT, 8% with a combination regimen. Caspofungin (Caspo) was used in 100 cases, liposomal amphotericin B (L-AmB) in 123 and voriconazole (VCZ) in 93. The most used sequences were L-AmB and VCZ (20 cases), L-AmB and Caspo (17 cases), VCZ and Caspo (13 cases), L-AmB and Caspo (4 cases). Most frequent combination therapies were L-AmB plus VCZ (6 cases), Caspo plus L-AmB (6 cases), and Caspo plus VCZ (4 cases). IFI attributable mortality was 20%. At multivariate analysis, age, Caspo and L-AmB use were associated with increased mortality (p 0.007, p 0.002, p 0.008).
Summary and Conclusions: We described IFI epidemiology and treatment in a large monocentric cohort of consecutive oncohematologic pts, and correlated it with EORTC/MSG criteria, evidencing their potential weakness (high incidence of unclassifiable cases). This epidemiologic survey evidenced a persistent significant necessity of AFT, with high frequency of sequential and combination therapy. Interestingly, we failed to demonstrate an impact on outcome of diagnosis, GM or CT scan positivity, suggesting that the timely and aggressive therapeutic strategy applied seems to be efficacious in hematological diseases with different degree of immunosuppression and for IFI with different aggressiveness.

PF466

HERPES VIRUSES AT THE ONSET OF ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA. IS THERE AN ASSOCIATION?

D. Tikhomirov[1,*], N. Chernova[2], N. Yaroslavtseva[1], T. Romanova[1], F. Filatov[3], E. Zvonkov[2], T. Tupoleva[1]

[1]Laboratory of Virology, [2]Department Chemotherapy of Lymphomas, National Research Center for Hematology, [3]Laboratory of Molecular Biotechnology, Research Institute of Vaccines and Sera. named after I.I. Mechnikov, Moscow, Russian Federation

Background: Angioimmunoblastic T-cell lymphoma (AITL) is traditionally thought to be associated with Epstein-Barr virus (EBV) or rarer with Human Herpes Virus type 6 (HHV 6). It has been speculated that these viruses could directly or indirectly trigger AITL. However, data on association with other human herpes viruses and on frequency of detection of herpes viruses' markers in primary patients with AITL are scarce.
Aims: The aim of the study was to analyze the patterns of herpes viruses' markers at the onset of AITL.
Methods: 40 primary AITL patients were enrolled in the study. Male/female ratio was 22/18; a median age was 61.5 (29-81) years. Diagnosis was established based on standard WHO criteria. Markers of EBV, HHV 6, Cytomegalovirus (HCMV) and Herpes simplex virus types 1 and 2 (HSV 1, 2) were investigated. Antiviral IgM and IgG were tested in serum (40 samples) via ELISA. IgM detection was considered a marker of acute infection. Viral DNAs concentration were screened by real-time PCR in peripheral blood (PB, 40 samples), bone marrow (BM, 16 samples), lymph node biopsies (LN, 14 samples) and bronco-alveolar aspirates (BAA, 6 samples). Because of tropism to lymphoid cells and pathogenesis features of EBV and HHV 6, detection of EBV DNA or HHV 6 DNA in low concentration (like less than 500 copies in 10^5 mononuclear cells of PB, BM, LN or in 1 ml of BAA) was considered as marker of latent infection. HSV 1,2 DNA was tested only in LN and BAA due to absence of permissive cells for viral replication in PB and BM. Detection of HCMV DNA or HSV 1,2 DNA in any sample was regarded as markers of acute infection. Discovery of markers of acute infection in absence of IgG was considered as primary infection otherwise – reactivation
Results: Laboratory markers of acute herpes virus infection were detected in PB of 29 (72.0%) out of 40 patients, including 10 cases of primary infection (7 – EBV, 2 – HCMV, 1 – EBV and HCMV simultaneously). The data are presented in Table 1. The most frequent acute infection as expected was EBV. It's markers were detected in PB of 21 (52.5%) out of 40 patients. Markers of acute HSV 1,2 (IgM) and HCMV (IgM and DNA) infection in PB were rarer (15 (37.5%) and 14 (35.0%) respectively). Surprisingly high frequency was observed for anti-HSV 1,2 IgM detection (15 (37.5%) of 40 patients). Comparison of viral DNAs load in PB and/or BM and/or LN and/or BAA samples of single patient showed that the highest level of viral load was determined in LN (up to 4.0x10^{6}copies/10^{5}cells) and BAA (up to 5.7x10^5/ml). Marker of acute HHV 6 (HHV 6 DNA in BAA in concentration 700 copies/ml) was detected only in 1 patient
Summary and Conclusions: AITL during the onset appears to be associated

with acute herpetic infections (reactivation of endogenous virus or primary infection). Their markers, mainly markers of acute EBV, were observed in 29 (72.0%) out of 40 patients. High frequency of HSV 1, 2 IgM in primary AITL patients' needs further investigation. The highest level of viral load was determined in LN and BAA.

Table 1.

Virus	Viral DNA in concentration, relevant to acute infection	Antiviral IgM detection	Total	Primary infection among them
EBV	14 (35,0%)	9 (22.5%)	21 (52.5%)	8 (20.0%)
HCMV	9 (23,1%)	4 (10.0%)	14 (35.0%)	3 (7.5%)
HHV 6	0 (0%)	n/a*	0 (0.0%)	n/a*
HSV 1, 2	n/a*	15 (37.5%)	15 (37.5%)	0 (0.0 %)
Markers of any acute infection	19 (47,5%)	21 (52.5%)	29 (72.5%)	10 (25.0%)

POST-TRANSPLANT EBSTEIN-BARR VIRAL LOAD MONITORING EXPERIENCE IN A HEMATOPOIETIC STEM CELL TRANSPLANTATION CENTER

M.S. Aydın[1,*], A.C. Inkaya[2], E. Karakulak[1], R. Çiftçiler[1], M. Turgut[3], H. Goker[1], E. Kelkitli[3], H. Demiroglu[1], Y. Buyukasik[1], N. Sayinalp[1]

[1]Hematology, [2]Infectious Diseases, Hacettepe University Faculty of Medicine, Ankara, [3]Hematology, 19 Mayıs University Faculty of Medicine, Samsun, Turkey

Background: Ebstein-Barr virus (EBV) viremia is a cause of post-transplant lymphoproliferative disorder (PTLD) and a significant cause of morbidity and mortality in hematopoietic stem cell transplant (HSCT) recipients. Risk of EBV viremia differs between different donor sources and T- cell depletion status. Prolonged immunosuppression increases EBV viremia risk. Most of the EBV viremias are asymptomatic and do not require treatment. Higher viral loads may require decreasing the grade of immunosuppression and pre-emptive use of rituximab.
Aims: To evaluate EBV viral load monitoring attitudes and clinical correlations of EBV viremia in HSCT patients
Methods: Retrospective data from a total of 565 hematopoietic stem cell transplant patients were analyzed who were transplanted between 01.01.2001 and 01.02.2018. EBV viral loads, dates, types of transplantation procedure and donor sources were recorded. Univariate analyses were done by Chi-square test for categorical and by t-test for numerical variables, respectively. Multivariate analyses were done by Cox regression analysis.
Results: There were 96 patients with post-transplantation EBV viral load test at least once. Median age was 43 (range, 16-75). There were 8 patients with EBV viremia. Four patients had acute leukemia, 1 had chronic myeloid leukemia (CML), 2 had non-Hodgkin lymphoma and 1 had multiple myeloma. Three of them were autologous and there was no difference between autologous and allogeneic HSCTs (p=1.000) and also there was no difference between myeloablative, reduced-intensity-conditioning and haploidentical HSCTs (p=0.898) in viral load positive and negative groups. EBV viral loads range between 73-14234 copies/mL. Only 1 patient who was transplanted (matched-related) for CML had EBV viral load >1000 copies/mL and had chronic graft *versus* host disease (GVHD) with severe thrombocytopenia. Rituximab 375 mg/m^2 was given for 2 times (3 week intervals) and after re-checking it was negative and thrombocytopenia was resolved. Three more patients with EBV viremia also had GVHD and 2 of them were negative when re-checked. All EBV viral loads were ordered incidentally with no suspicion of PTLD also neither patient had PTLD or second other malignancy with a median follow-up of 31 months. Also overall survival was not different in EBV viral load positive patients with respect to viral load negative patients (p=0.881).
Summary and Conclusions: As EBV viremia is mainly a problem of mismatched- or matched-unrelated donor and umbilical cord source for transplants. Our center mainly uses matched-related peripheral blood stem cell source and also T-cell depletion is not a generally issue. Our data shows, in low risk patients there may be no need for EBV viral load monitoring; it may be ordered in whom PTLD was suspected.

Clinical Trials Centre Cologne (ZKS Köln), University of Cologne, Cologne, Germany

Background: Isavuconazole is a novel antifungal drug, approved by both, the US as well as the European regulatory agencies in 2016 for treatment of adults with invasive aspergillosis and mucormycosis. While azoles as a class effect are known to prolong QTc interval, clinical trials have shown that isavuconazole administration may shorten QTc interval in a dose-related manner. Here, we assessed the effects of isavuconazole on the length of QTc interval.
Aims: To evaluate the effect of isavuconazole on QTc.
Methods: A total of 26 adult patients from seven hospitals were included. Patients received isavuconazole for treatment of invasive fungal disease and, in one case, for prophylaxis due to QTc prolongation under fluconazole. 12-channel electrocardiograms (ECG) were performed before and during treatment.
Results: 24 out of 26 patients showed shortening of QTc interval, while no changes were found in two patients. In those patients with QTc shortening, QTc during isavuconazole treatment showed a mean decrease of 7.4±5.8% (36.5±38.8 ms, range 7 to 202; p=0.004), compared to pre-isavuconazole ECG. One patient, with available long-term follow-up showed further decrease in QTc on day 55 and day 110.
Summary and Conclusions: Apart from one case report, these are the first data outside controlled clinical trials showing QTc shortening. Knowledge about cardiac effects of isavuconazole will serve to better manage the use of concomitant medications.

Iron metabolism, deficiency and overload

PF469

ALPHA LIPOIC ACID REDUCES THE TOXIC EFFECTS INDUCED BY IRON OVERLOAD TREATMENT: *IN VITRO* AND *IN VIVO* MODELS

G. Camiolo[1,2,*], D. Tibullo[1,2], C. Giallongo[1], N.L. Parrinello[1], P. La Cava[1], A. Romano[1], F. Puglisi[1], G. Li Volti[2], R. Avola[2], G.A. Palumbo[1], F. Di Raimondo[1]

[1]Division of Hematology - Policlinico Hospital "Vittorio Emanuele" (CT), [2]Biometec, University of Catania, Catania, Italy

Background: Secondary iron overload syndromes are due to hematological diseases such as thalassemias, transfusion-dependent anemias and myelodysplastic disorders. Several organs are affected by iron overload including liver, heart and endocrine glands. A comprehensive approach including tailored transfusion protocols, monitoring and assessment of total body iron levels and iron chelation is currently the mainstay in hindering iron overload.
Aims: Numerous studies suggest that iron chelation improves survival of trasfusion-dependent patients. The aim of the present study was to investigate whether alpha- Lipoic Acid (ALA), a naturally occurring substance, reduces cellular damage induced by iron overload focusing on its antioxidant and chelating properties *in vitro*, on a stromal cell line and *in vivo*, using an adult zebrafish model.
Methods: HS-5 cell line (stromal cells) was treated with Ferric Citrate Ammonium (FAC) 25µg/mL alone and in combination with ALA 20µg/ml. Oxidative stress was evaluated by flow-cytometry, western blot, immunofluorescence, autophagy induction by AVO-test and Fe3+ stores using the Perls staining. Concerning *in vivo* model, adults zebrafish were treated with FAC 120µg/ml alone and in combination with ALA 20µg/ml up to 48h. Specimens were fixed in formaldehyde 4% and Hematoxilin-Eosin and Perls staining were performed. Gene expression analysis of oxidative stress markers (HMOX1b, mtSOD and FPN1) was carried out by real time quantitative RT-PCR.
Results: The co-treatment of HS5 cells with FAC plus ALA was able to reduce the oxidative stress, measured by all the different methods, induced by FAC alone ($p<0.001$). After 24h of FAC treatment, iron overload induced the upregulation of oxidative stress marker genes and proteins HO-1 (heme oxygenase1) and SOD (superoxide dismutase). Interestingly, ALA co-treatment was able to induce glutathione synthesis ($p<0.0001$) and to restore the mitochondrial membrane potential ($p<0.001$) after mitochondrial damage induced by iron accumulation ($p<0.001$). In addition, co-treatment improves both mitochondrial integrity, increasing EF-Tu protein levels, and cellular homeostasis, decreasing the autophagolysosomes formation ($p<0.001$) compared to iron alone treatment. Looking at *in vivo* results, ALA protects zebrafish intestine, liver, heart and gills from iron overload showing its ability to prevent histological alterations and to reduce both the oxidative stress expression markers (HMOX1b, mtSOD; $p<0.001$) and Ferroportin1 (FPN1; $p<0.001$).
Summary and Conclusions: Both *in vitro* and *in vivo* model data suggest that ALA protects against iron overload mediated damages through suppression of oxidative stress induced by iron overload, reduction of cell autophagy, restoring mitochondrial integrity and preventing iron overolad-induced organ damages. Our findings back up the novel idea that ALA supplementation could be of help in countering secondary iron overload related diseases.

PF470

A PHASE 1, PLACEBO-CONTROLLED STUDY TO DETERMINE THE SAFETY, TOLERABILITY, AND PHARMACOKINETICS OF ESCALATING SUBCUTANEOUS DOSES OF LJPC-401 (SYNTHETIC HUMAN HEPCIDIN) IN HEALTHY ADULTS

D. Yaeger[1], A. Piga[2], A. Lal[3], A. Kattamis[4,*], S. Salman [5], B. Byrnes[1], G. Tidmarsh[1], L. Chawla[1]

[1]La Jolla Pharmaceutical Company, San Diego, United States, [2]Università degli Studi di Torino, Turin, Italy, [3]University of California San Francisco Benioff Children's Hospital, Oakland, United States, [4]National and Kapodistrian University of Athens, Athens, Greece, [5]Linear Clinical Research, Nedlands, Australia

Background: LJPC-401, synthetic human hepcidin, is being developed as a therapeutic treatment for various conditions of iron overload, including transfusion-dependent anemia and hemolytic anemia.
Aims: To determine the safety, tolerability, and pharmacokinetics (PK) and pharmacodynamics (PD) of escalating doses of LJPC-401 in healthy adults.
Methods: This was a phase 1, placebo-controlled, double-blind, randomized, single-center study. Healthy adult subjects (aged 18-65 years) were assigned to 1 of 4 dose cohorts (5, 10, 20, and 30 mg) with 6 subjects per cohort receiving LJPC-401 and 2 receiving volume-matched placebo. A single-dose subcutaneous injection was administered on day 1, and dose cohort escalations occurred only after the final subject at each dose level had been observed for ≥3 days with no evidence of study drug–related toxicity. Safety assessments included treatment-emergent adverse events (TEAEs), physical and laboratory evaluations, and immunogenicity. PK parameters of baseline-corrected serum LJPC-401 were obtained by noncompartmental analysis, with blood samples collected at predose, and at 0.5, 2, 4,8, 24, 48, and 168 hours postdose. PD endpoints included effects on serum iron, ferritin, transferrin, and iron-binding capacity.
Results: Overall, 32 subjects (mean age 29.1 years; 53.1% female; 93.8% white) were enrolled, completed the study, and were included in all analyses. All subjects (100%) in the LJPC-401 dose groups (n=24) and 2 subjects (25%) in the placebo group (n=8) experienced at least 1 TEAE. All TEAEs were mild in severity, and there were no serious AEs, TEAEs leading to early discontinuation, or deaths reported during the study. The most frequently occurring TEAEs were injection site reactions (ISRs; LJPC-401 100% *vs* placebo 12.5%), catheter site phlebitis (12.5% *vs* 0%), and headache (8.3% *vs* 0%). ISRs did not generally require treatment, and all but one resolved before study end. No serum samples were confirmed positive for anti-LJPC-401 antibodies, and there were no trends or changes in physical or laboratory test results with LJPC-401. PK results indicated that LJPC-401 maximum serum concentration (C_{max}) and area under the serum concentration-time curve from time 0 to 24 hours postdose (AUC_{0-24}) increased with dose over the tested dose levels; increases were generally linear between 5 and 20 mg. Peak concentrations of LJPC-401 occurred ~2 hours postdose for all doses with a return to baseline hepcidin levels by ~24-48 hours postdose. The mean (standard deviation [SD]) baseline serum iron value was 88.46 (22.70) g/dL, and all 4 doses of LJPC-401 significantly decreased serum iron levels compared with baseline ($P<0.0001$ overall); the mean maximum reduction was 33% to 65% at 8 hours postdose. A larger reduction in serum iron was generally associated with an increase in dose up to 20 mg. There was no apparent difference in the maximum reduction of serum iron between the 20- and 30-mg dose levels.
Summary and Conclusions: LJPC-401 was well tolerated at doses between 5 and 30 mg in healthy adults and showed decreased serum iron levels that returned to baseline levels within 48 hours. In patients at risk for iron overload (abstract submission by Lal et al) serum iron reductions were sustained up to day 8 in most patients.

PF471

REPEATABILITY OF LIVER IRON CONCENTRATION MEASUREMENTS WITH MRI AND AN ARTIFICIAL NEURAL NETWORK DATA ANALYSIS SYSTEM

T. St Pierre[1,*], Y. Aydinok[2], A. El-Beshlawy[3], S. Bayraktaroglu[2], A. Ibrahim[4], M. Hamdy[3], W. Pang[5], S. Khorshid[6]

[1]The University of Western Australia, Crawley, Australia, [2]Ege University Hospital, Izmir, Turkey, [3]Cairo University, [4]Ain Shams University, Cairo, Egypt, [5]Resonance Health Ltd, Burswood, [6]Three Springs Technology, Perth, Australia

Background: Recent studies have shown that artificial neural networks (ANNs) can be trained to estimate liver iron concentration (LIC) from raw magnetic resonance image (MRI) data. Such ANNs open up the possibility of MRI data analysis without the need for special expertise or training in image data analysis.
Aims: The aim of this study was to determine the repeatability of measurements of LIC using an ANN for data analysis and compare with the repeatability of a well established R2-MRI method of data analysis.
Methods: Patients at risk of transfusional iron overload (N=50) and healthy control subjects (N=10) were recruited (age range 12 to 67 years, 44 with thalassemia major, 4 with sickle cell disease, 1 with non-transfusion-dependent thalassemia, 1 with myelodysplastic syndrome). Each subject was scanned twice using a standard R2-MRI data acquisition protocol. The median period between the two scans was 1.9 hours with the minimum time between scans being 1.0 hours. Subjects were scanned on either a 1.5T Siemens Symphony Vision (N=45) or a 1.5T Philips Intera (N=15). Image data were analysed by an analyst (with no formal training in MRI, physiology, or MRI data analysis) using an ANN (mse184ssw2). The image data were also analysed by highly trained and experienced MR data analysts using spin-density projection assisted (SDPA) R2-MRI analysis. Bland-Altman statistics were used to assess the repeatability of the measurements by both methods.

Results: Image data upload, analysis, and report production using the ANN took about 1 minute. Image data upload, analysis, and report production by SDPA R2-MRI took about 30 minutes per dataset. The 120 LIC results obtained from the ANN were compared with the corresponding 120 LIC results obtained from the SDPA R2-MRI method, each pair of values resulting from image datasets from visit 1 and visit 2 with one dataset analysed by the ANN and the other by SDPA R2-MRI. The results are plotted in Figure 1 together with the line of equivalence (solid line). Bland-Altman analysis of the logarithmically transformed LIC results indicated non-uniform variance of the differences between the logarithmic values of LIC across the range of LIC encountered, with the variance being significantly larger below 3 mg Fe/g dw. Bland Altman analysis indicated a mean ratio of the ANN LIC to R2-MRI LIC of 1.04 and 0.87 below and above 3 mg Fe/g dw respectively. The upper and lower 95% limits of agreement for ratios of ANN LIC to R2-MRI LIC were 1.80 and 0.60 (<3 mg Fe/g dw) and 1.20 and 0.63 (>3 mg Fe/g dw). The repeatability tests for the ANN LIC yielded 95% of pairs of repeat measurements having ratios between 0.65 and 1.54 (<3 mg Fe/g dw) and between 0.80 and 1.26 (>3 mg Fe/g dw). The repeatability tests for the R2-MRI LIC yielded 95% of pairs of repeat measurements having ratios between 0.63 and 1.59 (<3 mg Fe/g dw) and between 0.86 and 1.16 (>3 mg Fe/g dw).

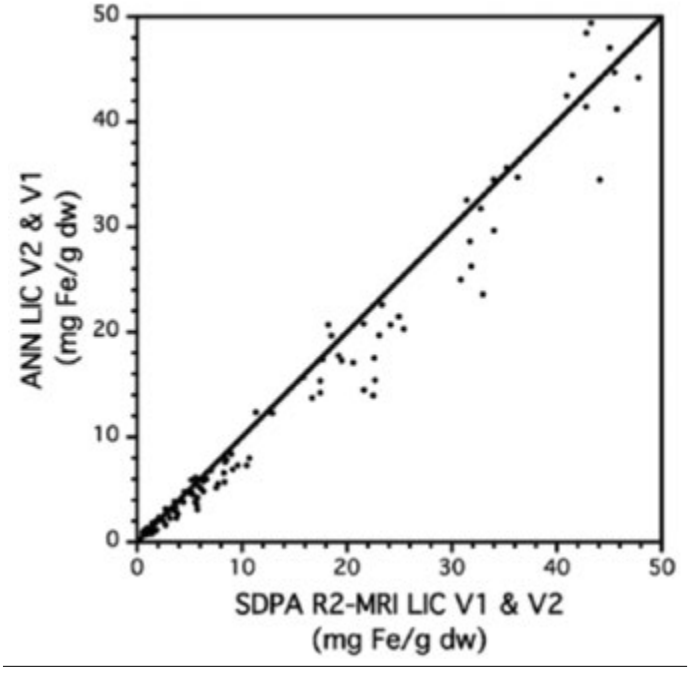

Figure 1.

Summary and Conclusions: Use of the ANN for data analysis eliminates the need for image analysis expertise and speeds up data analysis to an extent that point-of-care analysis could be performed and costs associated with analysis greatly reduced. The limits of agreement between the ANN analysis method and the SDPA R2-MRI method, together with the repeatability coefficients of each method, suggest that the ANN analysis method could be used in place of the SDPA R2-MRI method with good agreement and repeatability below 3 mg Fe/g dw but with a small but measurable bias and slightly decreased repeatability above 3 mg Fe/g dw.

PF472

IRON OVERLOAD FOLLOWING ALLOGENEIC HEMATOPOIETIC TRANSPLANTS: LONG-TERM OUTCOMES

G. Obi[1,*], A. Mukherjee[2], A. Scholoff[1], N. Vu[1], G. Carrum[1], R. Kamble[1]

[1]Bone Marrow Transplant, Center for Cell and Gene therapy, Baylor College of Medicine and Houston Methodist Hospital, [2]Hematology Oncology, Houston Methodist Hospital, Houston, United States

Background: Iron overload (IOL) is associated with increased transplant related morbidity and mortality related to oxidative damages from the free iron. Lack of prospective studies and variable definition of IOL in retrospective analyses precludes our understanding of IOL incidence and its long-term outcomes in patients receiving allogeneic hematopoietic transplantation (AHT).
Aims: To determine, incidence, IOL related morbidity and mortality in AHT.
Methods: Patient, disease and transplant related variables were retrospectively analyzed in 238 patients receiving AHT from January 2005- February 2017. Clinically significant IOL was defined as excess iron leading to organ dysfunction with SF of at least 1000 ug/dl along with abnormal transferrin saturation. Therapeutic intervention for IOL comprised of phlebotomy in all 25 patients with 2 receiving concurrent oral chelation. Phlebotomy program comprised of removing 250-500 ml of blood every 1-4 weeks when hemoglobin >11.5 gm/dl.
Results: Of the 238 patients receiving AHT, 37 (15.54%) were found to have post-transplant serum ferritin (SF) of >1000 ug/dl. Of these, a total of 25 (10.5%) developed clinically significant IOL. The median age of 19 males and 6 females was 55 years (24-70). Primary diagnosis for AHT included, AML/MDS (n=16), ALL (n=3), SAA (n=4) and others (n=2). Patients received median of 21 (7-66) life-time cumulative PRBCs transfusions.
The median pre-transplant SF and that at IOL was 1848 ug/dl (590-4658) and 3625 ug/l (1263-10696) respectively. IOL developed at median of 8.5 months (2-26) post AHT. All but 2 patients had cGvHD (limited skin=17, extensive=6). Liver dysfunctions (median AST=149 u/l (32-775), ALT=230 u/l (33-802) and alkaline phosphatase=249 u/l (48-841) was thought to be potentially IOL related. With a median of 9 (1-115) phlebotomies, SF <1000 ensued in 9 (2-30) months with corresponding improvement in transferrin saturation. Liver functions normalized at median of 3 months (1- 29) months. HFE analyses of both donor and recipients available in 11 patients had no impact on IOL occurrence of its response to treatment.
Interestingly, we noted improvement in hematopoiesis with iron chelation. Hemoglobin of 13 gm/dl and platelets count of 147 ug/L at initiation of phlebotomy rose to 13.9 and 178; a rise of 7% and 21% respectively. At the median follow-up of 45 (11-97) months, 18/25 (72%) patients are alive with median survival of 68 months (60- not reached). Cause of death included fungal infections in 2 patients, septic shock in 2 patients and relapse in 4 patients.
Summary and Conclusions: Phlebotomy for IOL in AHT produces predictable and safe iron reduction in patients with post AHT IOL with modest improvement in hematopoiesis.

PF473

IRON OVERLOAD IN RARE HEREDITARY HEMOLYTIC ANEMIA

S. van Straaten[1,2,*], J.-L. Kerkhoffs[3], J. Gitz-Francois[1], B.J. Biemond[4], R. van Wijk[1], E.J. van Beers[2]

[1]Laboratory of Clinical Chemistry & Haematology, [2]Van Creveldkliniek, University Medical Center Utrecht, Utrecht, [3]Haga Hospital, The Hague, [4]Department of Hematology, Academic Medical Hospital, Amsterdam, Netherlands

Background: Iron overload is an important, yet often overlooked complication in rare hereditary hemolytic anemia. Untreated, it may impair quality of life and shorten life expectancy. Currently, guidelines are mainly based on experience in the field of β-thalassemia. There are significant gaps in our knowledge with regard to prevalence and monitoring of iron overload in other forms of rare hereditary hemolytic anemia.
Aims: The aim of this study is to evaluate the prevalence of iron overload in non-transfused and transfused patients with different types of hereditary hemolytic anemia and to evaluate the predictive value of ferritin levels for liver iron overload.
Methods: This is a cross sectional analysis of iron overload in all patients with rare hereditary hemolytic anemia, from three expert centers for rare anemias in the Netherlands, who had MRI data on iron overload available.
Results: A total of 130 patients were included. Main disease categories were disorders of hemoglobin (*e.g.* sickle cell disease, β-thalassemia, HbH disease, unstable hemoglobins), disorders of red cell metabolism (*e.g.* pyruvate kinase deficiency, G6PD deficiency) and red cell membrane and hydration disorders (*e.g.* hereditary spherocytosis and hereditary xerocytosis). Mild liver iron overload (LIC≥3 mg Fe/g dry weight liver (DW) on MRI) was present in 82/130 of patients with MRI data available. Moderate/severe liver iron overload (LIC≥7mg/gDW) was present in 52/130 of patients and occurred in all forms of hemolytic anemia included. Importantly, 14/28 of patients who never received red cell transfusions did have mild or moderate/severe liver iron overload. Two of these 14 patients were diagnosed with sickle cell disease. Within the group of patients that had a plasma ferritin level below 1000 ng/mL at time of MRI (n=81), 20 (25%) patients had moderate/severe iron overload. Two of these patients had never received red cell transfusions. 7/100 patients had cardiac iron overload on MRI. Cardiac iron overload did not occur in patients with LIC<7mg FE/g DW and did not occur in patients without transfusion history (Figure 1).
Summary and Conclusions: We show that iron overload occurs in all forms of hereditary hemolytic anemia, even in patients without transfusion history. The currently used threshold of plasma ferritin ≥1000ng/ml is therefore a

poor predictor for iron overload. Diagnostic algorithms in current guidelines for patients with hereditary hemolytic anemia do not identify all patients with iron overload and we propose that these guidelines should be adapted.

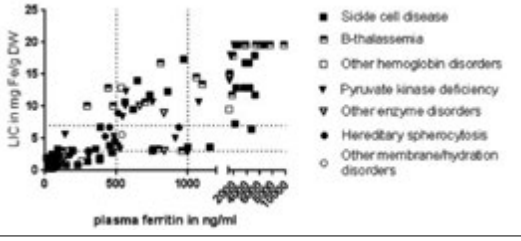

Figure 1. Ferritin *versus* LIC per disease category.

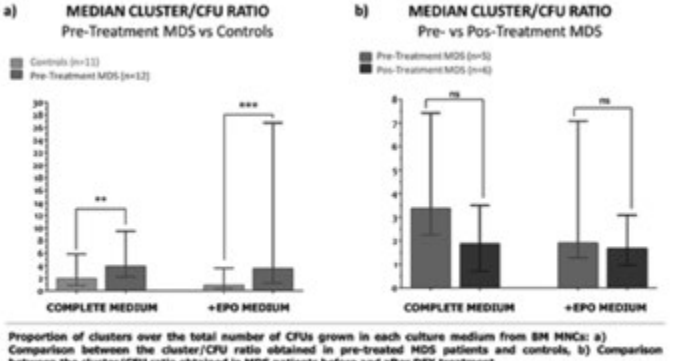
PF474

IRON OVERLOAD INCREASES OXIDATIVE STRESS AND DECREASES CLONOGENIC CAPACITY OF CELLS IN MDS PATIENTS: CAN BE RESTORED AFTER DEFERASIROX TREATMENT?

T. Jiménez Solas[1,2,*], F. López Cadenas[1,2], I. Aires Mejía[1,2], J.C. Caballero Berrocal[1], R. Ortega[1,2], A. Redondo Guijo[1,2], F. Sánchez-Guijo Martín[1,2], S. Muntión Olave[1,2], L. García Martín[1], B. Albarrán Severo[3], J.M. Alonso Alonso[3], C. Del Cañizo Férnandez-Roldán[1], Á. Hernández Hernández[2,4], M. Díez Campelo[1,2]

[1]Servicio de Hematología, Hospital Universitario de Salamanca, [2]Instituto de Investigación Biomédica de Salamanca (IBSAL), Salamanca, [3]Servicio de Hematología, Complejo Asistencial Universitario de Palencia, Palencia, [4]Departamento de Bioquímica y Biología Molecular, Universidad de Salamanca, Salamanca, Spain

Background: Low-risk myelodysplastic syndromes (MDS) patients usually presents iron overload due to the transfusion therapy they receive to ameliorate the effects of severe anemia. This overload may lead to a high level of oxidative stress in bone marrow (BM) cells, as free non-transferrin bound iron (LPI) catalyzes the production of reactive oxygen species (ROS).
We hypothesized that iron overload involved in ROS level rise in BM, may increase the hematopoietic cells (HPCs) and mesenchymal stromal cells (MSCs) dysfunction.
Aims: Our main objective is to analyze whether chelation therapy with deferasirox (DFX) could have a positive influence on the oxidative state of BM cells, on DNA damage and on clonogenic capacity of HPCs.
Methods: We analyzed samples from 13 iron-overloaded MDS patients before and 5-10 months after they were treated with DFX, and compared them with healthy donors (controls, n=20). We measured 3 oxidative stress parameters (intracellular ROS levels, DNA oxidation and DNA double strand breaks) in different BM populations by multiparametric flow cytometry analysis, and *in vitro* differentiation capacity of BM mononucleated cells (MNCs) by colony forming unit (CFU) assays.
Results: Comparing samples from pre-treated MDS patients with controls, our results showed a higher oxidative stress level in most patients HPCs, as well as greater DNA oxidative damage. After DFX treatment, the oxidative damage in DNA trends to decrease in HPCs populations: both for oxidation and for double strand breakage. Besides, the clonogenic assays carried out before treatment point to impairment in patients MNCs-derived CFU growth compared with controls (Figure 1a). This capacity trends to improve after DFX treatment, when the ratio cluster/CFU decreases and even approximates to control values (Figure 1b).



Proportion of clusters over the total number of CFUs grown in each culture medium from BM MNCs: a) Comparison between the cluster/CFU ratio obtained in pre-treated MDS patients and controls, b) Comparison between the cluster/CFU ratio obtained in MDS patients before and after DFX treatment.
Data expressed as the median ± range of the n indicated in each case. U from Mann-Whitney test: * = p < 0,05; ** = p < 0,01; *** = p < 0,001; ns: not statistically significant.

Figure 1.

Summary and Conclusions: We can conclude that BM cells in pre-treated MDS patients are subjected to higher oxidative stress conditions and present poor hematopoietic differentiation *in vitro*. These adverse features seem to be partially restored after DFX treatment *in vitro*.

PF475

RISK OF OVERTREATMENT OF HAEMOCHROMATOSIS DUE TO CO-INHERITED HYPERFERRITINAEMIA-CATARACT SYNDROME

H. Cutts[1,*], R. Farnell[1], H. Dreau[1], W. Atoyebi[1], J. Ryan[2], R. Aitchison[3], J. Porter[4], P. Bignell[1], E. Wilson[1]

[1]Haematology, [2]Gastroenterology, Oxford University Hospitals NHS Foundation Trust, Oxford, [3]Haematology, Buckinghamshire Healthcare NHS Trust, High Wycombe, [4]Haematology, University College London Hospitals NHS Foundation Trust, London, United Kingdom

Background: Haemochromatosis is a common genetic disorder most frequently caused by mutations in the HFE gene which can lead to progressive iron overload and eventually organ damage. These mutations however have variable penetrance and not all patients will progress to clinical iron overload or require therapy. Body iron stores in these patients are most commonly assessed by measuring serum ferritin and this is used to help determine the need to initiate therapy with phlebotomy and then to monitor the response to treatment and guide the frequency of venesections.
Aims: We present a series of three patients (ages 29, 50 and 70) who were found to have an elevated transferrin saturation and serum ferritin during investigation for lethargy, cardiac failure and abnormal liver function tests respectively.
Methods: All three patients were diagnosed with type one genetic haemochromatosis (one patient was homozygous for the C282Y HFE mutation and the other two were compound heterozygous for the C282Y and H63D mutations) and subsequently started on therapy with venesections for clinically significant iron overload, as assessed by elevated serum ferritin. They all however developed a microcytic anaemia during their venesection therapy (Hb 83-106g/L) despite the serum ferritin remaining elevated (Ferritin 160-1370mcg/L) above the treatment target of 50mcg/L. This is not consistent with the response of a haemochromatosis patient to venesection and specialist investigation was undertaken with an in-house NGS panel (TSCA v1.5, run on the MiSeq platform) comprising of sixteen genes involved in iron metabolism.
Results: In all three cases the HFE variants were confirmed but an additional variant (c.-160A>G, c.-160A>G and c.-162A>G) was detected in the iron regulatory element of FTL consistent with a diagnosis of the Hyperferritinaemia-cataract syndrome. This is a rare autosomal dominant genetic disorder resulting in an elevation of serum ferritin disproportionate to body iron stores but does not lead to pathological iron overload and early cataract is the only clinical consequence.
Summary and Conclusions: Hyperferritinaemia-cataract is well known as a cause of potential diagnostic confusion with haemochromatosis in patients being investigated for an elevated serum ferritin however these two conditions can usually be distinguished by the transferrin saturation which is elevated in haemochromatosis but not in the hyperferritinaemia-cataract syndrome. The co-inheritance of both conditions however leads to loss of the usefulness of ferritin as a marker of response to therapy in haemochromatosis and the potential for over treatment as occurred in our patients described above. Although there have been a couple of previous case reports of this association it is not widely recognised and our case series may imply that it is a more common occurrence than previously thought.

PF476

TISSUE IRON OVERLOAD ASSESSMENT IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

K. Lukina[1,*], N. Tsvetaeva[1], O. Nikulina[1], E. Sysoeva[1], E. Mershina[2], E. Lukina[1]

[1]Department of Orphan Diseases, National Research Center for Hematology, [2]Radiology Department, Federal Center of Treatment and Rehabilitation, Moscow, Russian Federation

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare acquired clonal non-malignant hematological disorder characterized by complement-mediated intravascular hemolysis and a prothrombotic state. PNH is characterized by diverse changes in iron metabolism. Chronic hemolysis leads to massive iron loss due to hemoglobinuria and hemosiderinuria, whereas chronic transfusions in severely anemic, transfusion-depen-

dent patients (pts) might cause the development of iron overload (IO).
Aims: To assess iron metabolism in PNH pts based on both laboratory parameters and MRI data.
Methods: The study group included 21 PNH patient followed up in our Center between 2015 and 2017. Laboratory parameters including hemoglobin (Hb), reticulocytes (RET), PNH clone size and LDH levels were analyzed. Chronic kidney disease (CKD) stage was assessed based on the estimated GFR. Iron metabolism was characterized by measurement of serum ferritin (SF), transferrin, iron concentration, total iron binding capacity (TIBC), transferrin saturation (TS). Multiecho gradient-echo T2* magnetic resonance imaging (T2* MRI) was performed in all pts to assess both liver and kidney IO. All pts were divided into 2 cohorts: 1 – eculizumab-naïve pts and 2 – pts treated with eculizumab.
Results: Cohort 1 included 14 eculizumab-naïve pts (12 men and 2 women aged from 29 to 58 yrs, median age 35 yrs). The median Hb level was 8,6 g/dl, median RET count – 9,1%. LDH levels ranged from 1322 to 8322 U/l (median 4721 U/l). The median erythrocyte PNH clone size was 52%. Median granulocyte and monocyte PNH clone sizes were 94% each. CKD Stages 1-3 were diagnosed in 8 (57%) pts. *Iron metabolism indices:* the median SF was 34 ng/ml, median TIBC – 60 umol/l, median TS – 28%. Laboratory signs of IO were detected in 1 (7%) patient. T2* MRI revealed signs of hepatic IO in 2 (14%) pts. One of these pts had laboratory signs of IO. Kidney IO was revealed in 100% pts. Cohort 2 consisted of 7 pts (2 men and 5 women aged from 31 to 64 yrs, median age 38 yrs). The median duration of eculizumab treatment in these pts was 1,5 yrs. The data of 6 pts was obtained in a period of 0,5 – 2 yrs after treatment termination due to administrative reasons. One patient continued to receive eculizumab at the time of analysis. The median Hb level was 7,7 g/dl, median RET count – 8,3%. LDH levels ranged from 567 to 7444 U/l (median 2623 U/l). The median erythrocyte PNH clone size was 35%. Median granulocyte and monocyte PNH clone sizes were 98% each. CKD Stages 1-2 were diagnosed in 3 (43%) pts. *Iron metabolism indices:* the median SF was 1118 ng/ml, median TIBC – 47 umol/l, median TS – 53%. T2* MRI revealed signs of hepatic IO in 6 (86%) pts which also had laboratory signs of IO. Signs of kidney IO were detected in 6 (86%) pts. The only patient with no signs of kidney IO was treated with eculizumab at the time of analysis (1,2 yrs).
Summary and Conclusions: Our findings prove that laboratory parameters of iron metabolism are not sufficient to identify tissue iron overload in PNH pts. T2* MRI is a noninvasive and reproducible technique that plays an impotrant role in the assessment of tissue iron overload. Our study revealed significant differences in iron metabolism parameters in the cohorts of eculizumab-treated and untreated pts. Hyperferritinemia was associated with the MR signs of liver iron overload in 86% of treated pts. On the other hand, 93% of untreated pts had either normal iron indices or signs of iron deficiency, MRI revealed signs of liver iron overload in 14% and signs of kidney overload – in 100% of untreated pts.

PF477

AN OPEN-LABEL, MULTICENTER, SINGLE-ARM, PHASE II STUDY ASSESSING PATIENT PREFERENCE FOR THE DEFERASIROX FILM-COATED TABLET COMPARED TO THE REFERENCE DISPERSIBLE TABLET FORMULATION: THE JUPITER STUDY

V. Viprakasit[1,*], R. Merad-Boudia[2], A. Das Gupta[3], A. T. Taher[4]

[1]Faculty of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [2]Novartis Pharma AG, Basel, Switzerland, [3]Novartis Healthcare Pvt Ltd, Hyderabad, India, [4]American University of Beirut Medical Center, Beirut, Lebanon

Background: Compliance with iron chelation therapy (ICT) influences the frequency and severity of iron overload-related complications.[1] Once-daily deferasirox (DFX) dispersible tablets (DT) have a well-defined safety and efficacy profile and, compared with parenteral deferoxamine, provide greater adherence, patient (pt) satisfaction, and quality of life.[2] However, barriers to optimal adherence remain, including gastrointestinal (GI) tolerability and palatability, leading to development of film-coated tablets (FCT) that contain the same active substance (strength adjusted to maintain comparable exposure to DT), can be taken with a light meal, and offer ease of administration. Results of the 24-week, randomized, open-label Phase II ECLIPSE trial (NCT02125877) indicated that the DFX FCT had a comparable safety profile to the DT with fewer severe GI-related adverse events (AEs) and more favorable pt-reported outcomes, including preference in favor of FCT.[3] However, preference was compared between two pt groups. A Phase II, open-label, multicenter, single-arm study has been initiated (currently enrolling pts) to evaluate preference in a broader pt population, including pediatrics, over a longer time period using one pt population that will cross over from DFX DT to FCT.
Aims: To evaluate pt preference for DFX FCT over DT in transfusion-dependent thalassemia (TDT) or non-transfusion-dependent thalassemia (NTDT) pts.
Methods: ICT-naïve or pre-treated (≥6 mths with ICT other than DFX) pts aged ≥2 yrs with TDT or NTDT, and serum ferritin (SF) >1000 ng/mL [≥800 ng/mL for NTDT] and, if available, LIC >3 mg Fe/g dw [≥5 mg Fe/g dw for NTDT] until 6 mths prior to screening will be included from 11 countries: Thailand, Lebanon, Malaysia, Iran, Saudi Arabia, Turkey, Oman, Vietnam, Algeria, Morocco and Egypt. Key exclusion criteria: creatinine clearance <60 mL/min or <40 mL/min per local label, serum creatinine >1.5x upper limit of normal (ULN), alanine aminotransferase >5xULN (unless LIC <10 mg Fe/g dw), urine protein/urine creatinine ratio >0.5 mg/mg, or impaired GI function. All pts/representatives will provide written consent for participation. 170 pts are planned to be enrolled in the study, consisting of two phases (Figure 1): Phase 1 (day 1 to week 24), pts to receive DFX DT starting at 20 mg/kg/day (10 mg/kg/day for NTDT) max 40 mg/kg/day (20 mg/kg/day for NTDT); Phase 2 (week 25–48), pts to receive DFX FCT starting at 14 mg/kg/day (7 mg/kg/day for NTDT) max 28 mg/kg/day (14 mg/kg/day for NTDT). An extension phase is planned for a max of 48 weeks with DFX FCT. Pts with difficulty swallowing the FCT could crush tablets. At the investigators discretion, pts can switch DFX formulation at any time. The primary objective is to evaluate preference at week 48, by Patient Preference questionnaire. Preference will also be evaluated at weeks 4, 24, and 28, alongside questionnaires to evaluate palatability, GI symptoms, and satisfaction conducted at screening, weeks 4, 24, 28, and 48. SF, pill counts, and the frequency/severity of AEs and changes in laboratory values will be monitored.
Results: -

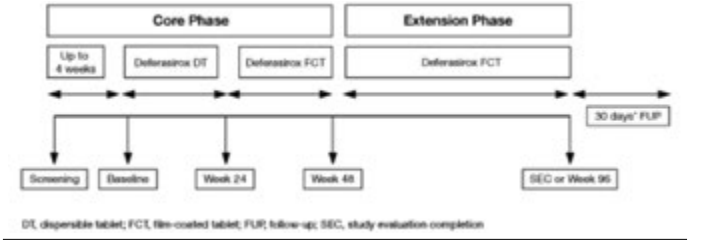


Figure 1. Study design.

Summary and Conclusions: This multicenter study will evaluate pt preference for DFX FCT compared to DT in pts with TDT or NTDT, providing valuable insight into the utility of DFX FCT to improve pt experience with ICT, as well as further evaluate the overall safety, tolerability, and efficacy profile.

A RARE CAUSE OF HEREDITARY HEMOCHROMATOSIS: COMPOUND HETEROZYGOSITY ASSOCIATING THE C282Y VARIATION WITH A PRIVATE HFE MUTATION - TWO CASES COMBINING NEW NONSENSE MUTATIONS

S. Cunat[1,*], C. Serrier[2], F. Danton[1], O. Guillot[1], M. Giansily-Blaizot[1], P. Aguilar-Martinez[1]

[1]Département d'Hématologie biologique, CHU de Montpellier Hôpital Saint Eloi, Montpellier, [2]Service d'Hématologie clinique, CH de Perpignan, Perpignan, France

Background: Homozygosity for the *HFE* p.C282Y mutation (C282Y) is the most common genotype associated with adult forms of genetic hemochromatosis (GH). The association of the C282Y mutation with the H63D variant in *trans* is also involved in milder forms of GH. Much rarer forms, combining another *HFE* private variant with the C282Y mutation, have been reported in GH patients (ref 1.2).
Aims: Here we describe two novel nonsense mutations in the *HFE* gene co-inherited with C282Y in 2 patients with iron overload.
Methods: After exclusion of acquired causes, genetic analysis of 40 patients with unexplained iron overload was undertaken by using next generation sequencing (Agilent SureSelectQXT®, Miseq® Illumina). A diagnostic panel, including the six most common genes involved in rare forms of iron overload, namely *HAMP, HFE, HJV, SLC40A1, TFR2* and *BMP6* was analyzed. Each identified pathogenic variant was subsequently checked by Sanger sequencing.
Results: Two unrelated C282Y carriers, a 39-year-old man and a 22-year-old woman, with a liver iron concentration of 250 and 100 mol/g respec-

tively, were found to be compound heterozygotes with a rare *HFE* variant. Both had hyperferritinemia >800 g/L and transferrin saturation >80%. The two nonsense mutations associated with C282Y were HFE:c.308G>A (p.W103*) and HFE:c.1004C>G (p.S335*), respectively. The *HFE* W103* and S335* mutations are not referenced in literature or in databases. Both generate a stop codon, truncating the synthesized protein at exon 2 and exon 5, respectively. Their combination in *trans* with the C282Y mutation could be responsible for the severe (man) or early (woman) iron overload presented by the two patients. These two mutations extend the small number of private *HFE* variants co-inherited with C282Y, described so far in literature. The majority of these rare *HFE* variants are missense mutations, seven are frameshifts and only four generate a stop codon.
Summary and Conclusions: This report confirms the importance of searching for a private *HFE* mutation in *HFE* C282Y heterozygotes with mild to severe iron overload (ref. 2). As exemplified here, the association of the C282Y mutation to a nonsense *HFE* mutation result in clinical forms of iron overload as severe as C282Y homozygosity.

THE RETICULOCYTE PARAMETERS: A NEW TOOL FOR ASSESSING AND MONITORING IRON HOMEOSTASIS

M.J. Teles[1,*], M. Coutinho[2], G. Melo[2], G. Porto[2,3,4,5]

[1]Clinical Pathology, Sao Joao Hospital Centre, [2]Clinical Hemathology Department, Porto Hospital Center, [3]Instituto de Ciências Biomédicas de Abel Salazar, University of Porto, [4]Instituto de Investigação e Inovação em Saúde, i3S, [5]Institute for Molecular and Cell Biology, University of Porto, Porto, Portugal

Background: Complete blood counts(CBC), serum ferritin(Ft) and transferrin saturation(TfSat) are useful markers to assess systemic iron homeostasis but their specificity is hampered by confounding effects of infection, chronic diseases or inflammatory states. Modern haematology equipments give additional RBC and reticulocyte(RET) parameters better reflecting iron acquisition and utilization for erythropoiesis. The hemoglobin content of RET (RET-He) is recognized as a marker of functional iron deficiency, used in the anemia of inflammation. The immature RET fraction(IRF) and RET counts(RC) offer a good picture of RET maturation and production used to evaluate erythroid response. To our knowledge, these parameters have never been described in the context of iron overload(IO) nor during iron depletion treatment. Phlebotomy is the standard therapy for hereditary hemochromatosis(HH), but its use in other acquired IO conditions, such as alcoholic or dysmetabolic liver diseases, is still debated.
Aims: 1.To test the discriminatory values of RET-He, IRF and RC in IO disorders, with or without inflammation; 2.To test the value of RET-He to monitor iron depletion therapy in patients with IO.
Methods: CBC, RET-He, IRF and RC were determined in Sysmex XE-5000 equipment in 127 adult patients who presented some form of IO, classified in 5 categories: 77 genetically confirmed HH; 9 secondary IO due to compensated chronic hemolysis(CCH), 25 hyperferritinemias associated with alchool abuse (AA), and 16 dysmetabolic hyperferritinemias (DHFt). For comparisons, 26 additional cases were included: 13 with absolute iron deficiency (ID) (TfSat <20%,Ft <20 ng/ml), 8 with non-ID inflammation (normal TfSat,Ft>400,CRP>3,0 ng/ml) and 8 controls (normal TfSat, Ft and CBC). Iron parameters, GGT and CRP were determined by routine standard methods. HH patients were analyzed at different stages: 9 at diagnosis (8 also followed during weakly intensive phlebotomy treatment) and 68 during maintenance treatment (every 3-4 months). Severity of IO in HH was estimated retrospectively by the total amount of iron removed by intensive phlebotomies (TBIS): 10 had<2g, 19 had 2-4g, 17 had 4-8g, 20 had>8g. Differences among groups were tested by ANOVA. A multiple regression analysis was performed to test the relative impact of sex, age, TfSat, AA and HH on RET-He values.
Results: The average RET-He values (controls 32,4+/-1,7) was significantly decreased in ID (23,4+/-3,6) and significantly increased in CCH (35,3+/-2,2), AA (35,3+/-2,0) and HH (34,4+/-1,6) but not in DHFt (33,7+/-1,4). RET-He in HH was significantly lower in patients who presented at diagnosis with TBIS<2g (33,8+/-0,6) than those who presented with TBIS>8g (35,0+/-1,1). Both in HH and AA (but not in CCH) neither RC nor IRF were increased, suggesting a limited/blunted erythroid response in the presence of excessive iron content. The major component influencing RET-He is TfSat (P<0,00001), but this relationship is affected by the presence of AA (P<0,00001) or HH (P=0,0280), evidenced by higher values under ID conditions. But while HH patients consistently maintain (or even increase) hemoglobin levels during intensive phlebotomy treatment, this was not observed in acquired IO (illustrative case reports will be shown).
Summary and Conclusions: The innovative RET parameters offer a new valuable and inexpensive tool to assess and monitor IO disorders. We speculate that HH patients have more effective iron avalilability/incorporation resulting in resistance to ID while patients with AA associated IO do not respond effectively, thus questioning the indication for phlebotomy treatment.

SOMATIC MUTATIONS AS MARKERS OF OUTCOME AFTER AZACITIDINE TREATMENT FOLLOWED BY ALLOGENEIC STEM CELL TRANSPLANTION (HSCT) IN HIGHER-RISK (HR) MDS AND LOW-BLAST COUNT ACUTE MYELOID LEUKEMIA (LBC-AML)

G. Falconi[1,*], E. Fabiani[1], A. Piciocchi[2], M. Criscuolo[3], L. Fianchi[3], C. Finelli[4], E. Cerqui[5], E.L. Lindfors Rossi[1], L. Iaccarino[1], T. Ottone[1], A. Molteni[6], M. Parma[7], S. Santarone[8], A. Candoni[9], S. Sica[3], F. Lo-Coco[1,10], M.T. Voso[1]

Orsola-Malpighi Hospital, Bologna, [5]Department of Hematology, A.O. Spedali Civili, Brescia, [6]Department of Hematology, Ospedale Niguarda, Milan, [7]Department of Hematology, San Gerardo Hospital, Monza, [8]Department of Hematology, Centro Trapianti Midollo Osseo, Pescara, [9]Department of Experimental and Clinical Medical Sciences, Azienda Ospedaliero-Universitaria di Udine, Udine, [10]Laboratorio di Neuro-Oncoematologia, Fondazione Santa Lucia, Rome, Italy

Background: The outcome of patients with HR-MDS has improved after the introduction of hypomethylating treatment, in particular azacitidine (AZA), which is considered the standard treatment. However, HSCT remains the only curative option in eligible patients. Somatic mutations play a pathogenic role in MDS/AML, and may predict clinical outcome.
Aims: Our aim was to evaluate the association between specific somatic mutations, response to AZA treatment and HSCT outcome in HR-MDS and LBC-AML.
Methods: Sixty-five patients (57 *de novo* HR-MDS and 8 LBC AML) with median age 59 years (range 21-66 years) enrolled in BMT-AZA multicenter trial, were studied. All patients were homogeneously treated with a standard AZA regimen (75 mg/sqm/day sc for 7 days every 28 days), for at least 4 cycles, followed by HSCT in 44 patients. Patients were considered responders to azacitidine, if they achieved complete remission (CR), partial remission (PR) or haematological improvement (HI). Patients exhibiting stable disease (SD) or progressive disease (PD) were considered resistant. Ultra-deep NGS (Myeloid Solution panel by Sophia Genetics on an Illumina platform) was performed on DNA extracted from BM mononuclear cell samples obtained before starting AZA treatment. Thirty genes known to be involved in MDS and AML pathogenesis were studied. Analysis of variant allele frequency (VAF) was performed using a standardized approach and the SOPHiA DDM® software. Changes in mutation burden were studied in selected cases after 4 cycles of AZA, using specific pyrosequencing assays.
Results: At diagnosis, we identified at least 1 mutation, at VAF greater than 1%, in 62 out of 65 patients (95.4%). The median number of mutations per sample was 3 (range, 0-6) and 57 patients (88%) carried more than 3 mutations. The most commonly mutated genes were: *ASXL1* (37%), *RUNX1* (29%), *SETBP1* (25%), *DNMT3A* (21%), and *TET2* (21%). Thirty-one of 62 patients (50%) had more than 1 mutation in the same gene (Figure 1). Response to AZA was documented in 30 patients (12 CR, 12 PR and 6 HI), while SD and PD were observed in 23 and 12 patients, respectively. Univariate analyses revealed that mutations in *DNMT3A* (VAF greater than 10%) were associated with lower response rate as compared to wild type cases (p=0.051). In particular, *DNMT3A* mutations localized in the methyltransferase domain were found in 11 of 65 patients (16.9%): only 1 patient in this subgroup achieved HI, whereas the remaining 10 patients were unresponsive (5 SD and 5 PD). The R882 mutation, present in 50% of DNMT3A-mutated patients (7 of 14), was identified only in unresponsive patients (4 SD and 3 PD). Allelic frequency of most mutations did not change upon AZA treatment, while in four AZA-responsive patients (2 CR and 2 PR) clearance of *TP53*-mutations was observed after 4 cycles. However, at the multivariable analysis, *TP53* mutations retained its unfavourable prognostic significance in terms of either PFS or OS (p=0.0013 and p=0.0008, respectively), together with AZA response (p=0.0003 and 0.0068, for PFS and OS). Moreover, mutations in *SETBP1* were associated to decreased OS (p=0.0241), whereas *TET2* mutations were a favourable prognostic factor (p=0.0237). When restricting the analysis to patients who underwent HSCT, *TP53, ZRSF2* or *PTPN11* mutations were negative prognostic factors for survival.
Summary and Conclusions: Our data show that mutational screening of HR-MDS and LBC-AML using a standardized NGS approach may predict response to AZA treatment and survival after HSCT.

SYNERGISTIC EFFECTS OF PRIMA-1MET (APR-246) AND AZACITIDINE (AZA) IN TP53-MUTATED MYELODYSPLASTIC SYNDROMES

N. Maslah[1,*], E. Verger[1], N. Partouche[2], P. Ly[3], P. Aubin[3], N. Naoui[3], M.-H. Schlageter[3], C. Bally[3], A. Wisniewska[3], R. Rahmé[3], J. Lehmann-Che[3], L. Adès[3], P. Fenaux[3], B. Cassinat[1], S. Giraudier[1]

[1]Hôpital Saint-Louis, INSERM, [2]Hôpital Henri Mondor, [3]Hôpital Saint-Louis, APHP, Paris, France

Background: Myelodysplastic syndromes (MDS) mutated for the *TP53* gene form a subgroup characterized by frequent relapses, poor survival and poor response to current therapies such as 5-azacitidine (AZA). PRIMA-1^{Met} (APR-246, APR) is a methylated derivative of the compound PRIMA-1 that induces apoptosis in human tumor cells through restoration of the transcriptional transactivation function of mutant *TP53*. We show here that low doses of APR reactivates P53 pathway and induces an apoptosis program alone and in combination with AZA.
Aims: - Testing the effect of APR-246 alone and in combination with AZA in TP53-mutated MDS cells *in vitro* and *in vivo*. - Look for a synergy between APR and AZA in MDS cells. - Decipher the mechanism of the synergy between the two drugs.
Methods: Myeloid cell lines SKM1, UT-7 / JAK2V617F and K562 were selected because each exhibiting different *TP53* mutations. Proliferation and viability of cells in the presence of APR-246, 5-Azacytidine (AZA) or simultaneous or sequential combination of the two drugs were evaluated. In parallel, bone marrow samples from MDS patients with a high frequency of TP53 mutations (complex karyotypes, 5q deletion, or known to be mutated for TP53) were evaluated for their clonogenicity with or without AZA. APR-246. The efficacy of the treatments was also evaluated *in vivo* in nude immunocompromised mice (n=30) after subcutaneous xenograft of SKM1 cells. Finally, a transcriptomic analysis was performed on SKM1 cells treated or not with APR, AZA or both.
Results: Functionally, we demonstrated that APRshows efficacy alone and synergize with AZA in *TP53* mutated MDS/AML cell lines and in *TP53* mutated primary cells from MDS/AML patients. *In vivo*, low doses of APR alone or in combination with AZA also induced major efficacy. Lastly, using transcriptomic analysis, the AZA+APR synergy was demonstrated as mediated by downregulation of the FLT3 pathway in treated cells. The overstimulation of the FLT3 pathway by FLT3 ligand (FLT3-L) rescues APR+AZA treated cells from apoptosis, thus demonstrating the involvement of this pathway in the survival of myelodysplastic cells.
Summary and Conclusions: These data therefore may open a whole new avenue to TP53-mutated MDS/AML treatment using combination therapies in this subgroup of poor prognosis.

PF482

GENE PANEL ANALYSIS BY NEXT GENERATION SEQUENCING FOR THE DETECTION OF CLONAL HAEMATOPOIESIS IN IDIOPATHIC CYTOPENIA OF UNDETERMINED SIGNIFICANCE (ICUS) AND MYELODYSPLASTIC SYNDROME (MDS)

Y. Wouters[1,*], F. Nollet[1], B. Cauwelier[1], J. Emmerechts[1], H. Devos[1]

[1]Laboratory medicine, AZ Sint-Jan Hospital, Brugge, Belgium

Background: According to the WHO 2016 definition, patients showing different degrees of cytopenia can only be classified as myelodysplastic syn-

drome (MDS) when concurrent bone marrow dysplasia, excess blasts or typical cytogenetic abnormalities are present. Cases lacking these major criteria but having persistent cytopenia are now classified as idiopathic cytopenia of undetermined significance (ICUS). It was reported that a fraction of these patients carry somatic mutations and are potentially at risk of progression to MDS or leukemia.
Aims: Aim of this study was to determine the frequency of gene mutations in patients with ICUS and overt MDS in our hospital using a custom next generation sequencing (NGS) based 19-gene panel analysis.
Methods: Bone marrow aspirates were collected from patients investigated for cytopenia. Samples were found eligible for testing when cytopenia was below the thresholds established by the original international prognostic scoring system (Haemoglobin <10 g/dL, Platelet count <100 $*10^9$/L, Absolute neutrophil count <1.8 $*10^9$/L). A total of 95 bone marrow aspirates were included: 61 patients were diagnosed with MDS because of morphological evidence of dysplasia, excess blasts or presence of a specific cytogenetic abnormality, whereas 34 patients were categorised as ICUS. A Qiagen GeneRead DNAseq custom panel was used to detect mutations in 19 genes associated with myeloid malignancies (ASXL1, CALR, CSF3R, DNMT3A, FLT3, IDH1, IDH2, JAK2, KIT, MPL, NPM1, RUNX1, SETBP1, SF3B1, SRSF2, TET2, TP53, U2AF1, WT1) and analysed on a MiSeq NGS sequencer (Illumina Inc., San Diego, CA, USA). A minimal read coverage of 300 reads was required, resulting in a sensitivity of the assay of 5% variant allele frequency (VAF). Statistical differences were calculated with the Mann-Whitney U test using Medcalc® version 18.2 (Medcalc Software, Mariakerke, Belgium).
Results: Out of 34 ICUS samples 6 (18%) bone marrow aspirates showed evidence of clonality by detection of at least one somatic mutations in either DNMT3A, SRSF2, TET2 or TP53. A higher mutation frequency was observed in MDS patients where 37 (61%) out of 61 samples carried at least one somatic mutation in a spectrum of 15 genes. No mutations were found in FLT3, JAK2, KIT or NPM1. Both groups showed an average of 2 mutated genes per sample in case of clonality. The overall average mutated gene per subject was however significantly lower in the total ICUS group compared to the total MDS group (p=0.0007). A lower mean VAF of 24% was also observed in ICUS subjects compared to a mean VAF of 36% in MDS patients (p=0.0029). An overview of the 4 most frequent mutated genes is shown in the following Table 1.

Table 1.

ICUS			MDS		
Gene	# samples	Mean VAF	Gene	# samples	Mean VAF
TET2	8	24%	TET2	31	39%
TP53	3	20%	ASXL1	13	35%
SRSF2	2	32%	TP53	11	36%
DNMT3A	1	16%	SF3B1	8	35%

Summary and Conclusions: Gene panel analysis by next generation sequencing revealed the presence of somatic mutations in bone marrow aspirates of 18% patients with ICUS compared to 61% patients with MDS. Both a significant higher number of mutated genes per subject and a higher mean VAF was observed in the MDS group.

PF483

IMPACT OF SOMATIC MUTATIONAL TESTING BY NEXT-GENERATION SEQUENCING (NGS) FOR SUSPECTED MYELODYSPLASIA OR MYELODYSPLASTIC/MYELOPROLIFERATIVE SYNDROMES IN "REAL-LIFE"

S. Vanthyghem [1], A. Ménard[1], C. Debord[1], T. Guillaume[2], O. Theisen[1], A. Garnier[2], M. Eveillard[1], S. Thepot[3], S. Wuilleme[1], A. Lebourgeois[2], C. Godon[1], M. Loirat[4], E. Lestang[4], M. Voldoire[5], M. Tiab[5], R. Boutault[1], F. Subiger[6], H. Maisonneuve[5], J. Delaunay[7], P. Chevallier[2], V. Ugo[8], M.C. Béné[1], P. Peterlin[2], Y. Le Bris[1,*]

[1]Hematology Biology, [2]Hematology, CHU Nantes, Nantes, [3]Hematology, CHU Angers, Angers, [4]Hematology, CH Saint Nazaire, Saint Nazaire, [5]Hematology, [6]Hematology Biology, CHD Vendee, La Roche Sur Yon, [7]Hematology, Le Confluent, Nantes, [8]Hematology Biology, CHU Angers, Angers, France

Background: Recurrent genomic alterations that could contribute to an integrated diagnosis have been identified in such myeloid disorders as myelodysplasia (MDS). Such somatic mutations (SM) can be screened by next-generation sequencing (NGS) but their impact on clinical decision is still ill-known.
Aims: The aim of this study was to evaluate the impact of NGS on diagnosis (group A) and prognosis assessment (group B) of myeloid disorders in 90 patients. Group A (n=48) included patients with idiopathic cytopenia of undetermined significance (ICUS), with (ICUSwtd, n=13) or without dysplasia (ICUSwod, n=18) (Bejar *et al.* 2015), suspected chronic myelomonocytic leukemia without evidence of dysplasia (sCMML, n=4) or ambiguous diagnosis between aplastic anemia (AA) and hypoplasic MDS (n=13). Group B included patients with MDS [n=26, no del(5q)], CMML (n=10) or mixed MDS/myeloproliferative syndrome (MMS, n=6).
Methods: A custom targeted panel of 35 genes (145kbp) was applied on DNA extracted from peripheral blood or bone marrow. The DNA libraries, built with a Haloplex® target enrichment protocol were sequenced by an Illumina MiSeq®. Data analysis used an in-house pipeline, public databases and *in silico* predictors. Variants of Undetermined Significance (VUS) had no clear association to disease. Final diagnoses consolidated by NGS were evaluated in group A. Group B allowed to assess patients whose prognosis and/or therapy were modified by the identification of high risk SM for MDS(Bejar *et al.* 2012) or CMML (Itzykson *et al.* 2013) (*TP53, EZH2, ETV6, RUNX1, ASXL1*).
Results: The cohort included 52 men and 39 women (median 59 yo [10-86]) with a median follow up after NGS of 10 months (0-36). Among the 48 group A patients, none of the 46 informative karyotypes was conclusive for MDS. SM were detected for 40% of group A patients (average 1 [0-5]). These mutated patients were significantly older (63 yo *vs* 46 yo p<0.001). The most frequent mutated genes were *DNMT3A* (17%), *ASXL1* (12%) and *TET2* (10%). Identification of at least 1 SM changed the final diagnosis from ICUSwtd to MDS (3/13), from ICUSwod to CCUS (7/18), and from sCMML to cCMML (2/4). *DNMT3A* and *ASXL1* mutations were found in 7/13 AA. *PIGA* and *BCOR* were both mutated in 11% of this subgroup. SM-negative NGS allowed to definitely exclude MDS in 21/48 cases with no dysplasia nor cytogenetic abnormalities. VUS were found in 21% of group A patients and 8% displayed non-contributive SM. Among the 42 group B patients, R-IPSS identified the 5 categories of risk from very low to very high as follows (%): 23-47-23-3-3. CMML patients were 70% low risk and 30% intermediate risk[2]. NGS results modified therapy for 5 group B patients (12%). SM of *ASXL1* (n=4), *EZH2* (n=2) and *RUNX1* (n=2) were found in 7 patients, who thus switched from low (6) or intermediate (1) standard risk to high molecular risk. This prompted allogeneic-stem cell transplantation (Allo-SCT) for 3 of them (MDS). Conversely 8 patients had a favourable *SF3B1* SM, which led to cancel Allo-SCT for one intermediate standard risk MDS. VUS were found in 24% of group B patients and 7% of VUS+ were detected in the high risk gene *RUNX1* but with no treatment impact.
Summary and Conclusions: NGS was confirmed here to be contributive in an integrated diagnosis of CCUS, MDS, CMML or AA for 40/48 patients. The benefit in terms of prognosis and therapeutic impact is interesting and could have even more weight if international recommendations emerge in the future through more comprehensive biological/clinical analyses of the type reported here.

Background: In the 1980s, pathologists identified the presence of irregular islands of CD123-positive cells in the bone marrow of a fraction of patients with a chronic or acute myeloid malignancy, with a strong predominance in chronic myelomonocytic leukemia (CMML). These cells were initially described as plasmacytoid T cells because of their plasma cell-like morphology and the expression of CD4, then as plasmacytoid monocytes because of the expression of myelomonocytic markers. They share somatic chromosomal

abnormalities with leukemic cells, indicating their common clonal origins. However, the mechanisms promoting the generation of these tumor nodules and their impact on disease evolution have not been explored thus far.
Aims: The present study was initiated to characterize CD123-positive cells infiltrating the bone marrow of CMML patients and their impact on disease outcome.
Methods: We set up a multiparametric flow cytometry assay to detect lineage-negative mononucleated cells expressing CD45, CD123, HLA-DR, BDCA-2, BDCA-4 and CD4 in the bone marrow of 161 CMML patients compared to 24 samples collected from age-matched healthy donors. Conventional and electron microscopy, additional cell surface markers, gene expression analyses in sorted cells (RNA sequencing) and cytokine production in response to Toll-like receptor (TLR) agonists were used to further characterize these cells. Whole exome sequencing of sorted cell populations, *ex vivo* differentiation of patient and cord blood CD34$^+$cells in the absence and presence of FMS-like tyrosine kinase 3-ligand (FLT-3L) and co-culture experiments with CD34$^+$ cells explored the origin and impact of these cells. Finally, we explored the relationship between these cells and CMML patient outcome.
Results: An increased fraction of CD45, CD123, HLA-DR, BDCA-2, BDCA-4 and CD4-positive cells was detected in mononucleated cells collected from the bone marrow of 39/161 (24%) CMML patients. All analyses converged to demonstrate that these cells were *bona fide*, interferon type I producing, plasmacytoid dendritic cells (pDCs) whose accumulation was associated with an expansion of bone marrow Tregs. A signature of 74 differentially expressed genes distinguished pDCs collected from pDC-poor and pDC-rich CMMLs. Whole exome sequencing of sorted monocytes and pDCs suggested that pDC generation may occur through the emergence of a Ras pathway activating mutation-containing sub-clone. CD34$^+$ cells from pDC-rich CMML patients produced a greater number of pDCs in culture than cord blood CD34$^+$ cells or CD34$^+$ cells from pDC-poor CMML patients, even in the absence of FLT-3L. Proliferation of CD34$^+$cells from pDC-rich CMML patients and cord blood CD34$^+$ cells were both decreased when CD34$^+$ cells were cultured with pDCs sorted from pDC-rich CMML patients, and this decrease was more important in the presence of TLR 9 agonists. Finally, retrospective immunohistopathological analysis of 216 CMML bone marrow biopsies associated pDC islands with a higher risk of leukemic transformation.
Summary and Conclusions: About one fourth of CMML patients demonstrate bone marrow enrichment in clonal pDCs through Ras-mediated hypersensivity of myeloid progenitors to FLT-3L. Therapeutic targeting of these cells, whose presence correlates with an increased risk of acute transformation, may deserve to be explored in these patients.

PF485

ASXL1 IS A MOLECULAR PREDICTOR IN IDIOPATHIC CYTOPENIA OF UNDETERMINED SIGNIFICANCE

D.-Y. Shin[1,2,*], J.-K. Park[1], S.-M. Kim[3], K. Im[3], J.-A. Kim[4], S.Y. Kim[5], S.M. Hwang[6], S.-S. Yoon[13], D.-S. Lee[34]

Background: Idiopathic cytopenia of undetermined significance (ICUS) is a challenging disease for clinical hematologist.
Aims: We studied to investigate the prognostic factors for survival of patients with ICUS in the context of genetic mutations.
Methods: Patients who were diagnosed as ICUS in a single institution were enrolled in our study. Patients with myelodysplastic syndrome (MDS) were also included for the comparison of mutational profiles. Targeted sequencing of 88 genes which have been reported to be associated with myeloid malignancies were performed from bone marrow mononuclear cells of each patient. The presence of mutation as well as clinical variables were analyzed for event-free survival (EFS) and overall survival (OS).
Results: A total of 40 patients with ICUS and 128 patients with MDS were included in this study. Median age of ICUS patients was 67 yrs (range, 31 – 83), and 23 pts were female (57.5%). A total of 28 mutations in these 16 genes were detected in patients with ICUS. The median mutational burden was 0.7 mutation/person in ICUS and 2.2 mutation/person in MDS, respectively. The most frequently mutated gene in ICUS was ASXL1 (7 pts). Every patient with ICUS and mutated ASXL1 showed cytopenia of bilineage or trilineage, while only half of patients (57.6%) without ASXL1 mutation harbored cytopenia of more than one lineage (p=0.033). ASXL1 mutation was enriched in elderly population (>60 years in all 7 ASXL mutants). ASXL1 was a significant prognostic factor for EFS in univariate and multivariate analysis (HR=12.8 and 10.07, 95% CI 3.08-53.17 and 2.13-47.72, p <0.001 and 0.004, respectively). In the multivariate analysis for OS, the presence of ASXL1 mutation was an independent significant prognostic factor for OS (HR=30.63, 95% CI 3.15 – 297.71, p=0.003) (Figure 1).

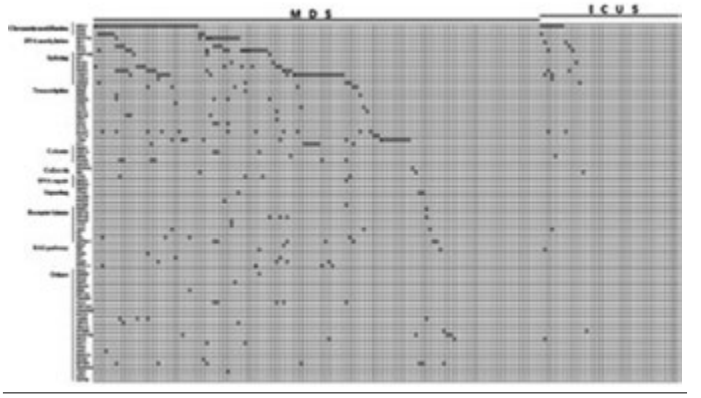

Figure 1.

Summary and Conclusions: ASXL1 mutation which is frequently detected in elderly patients is a molecular predictor for pancytopenia and survival in ICUS. A larger prospective study is warranted to validate the role of genetic mutation on the prognosis of ICUS.

PF486

MUTATIONAL PROFILE IN LOW RISK MDS WITHOUT RING SIDEROBLASTS

Background: The molecular pattern of low risk MDS patients without ring sideroblasts (RS) have not been addressed as occurs in RS MDS patients.
Aims: The study of somatic mutations in low-risk MDS patients without ring sideroblasts (RS) could help to better define the clinical and prognostic characteristics of the disease and identify potential mutational targets to personalized medicine.
Methods: The study cohort comprised a selected group of 135 **low-risk MDS** patients (IPSS: low or int-1; IPSS-R: very low, low or int) **without ring sideroblasts** (RS<5%) recovered in our institution. Sequencing was carried out in all patients by using a targeted custom capture enrichment panel (*Nextera Rapid Capture Custom Enrichment*) consisting of 117 myeloid-related genes on an Illumina MiSeq/NextSeq instrument. Data analysis was performed with an *in-house* pipeline for quality assessment, alignment, PCR duplicates removal, and variants detection and annotation. Funding PI17/01741, GRS1349/A/16, GRS1179/A/15, FEHH 2015-16 and CM17/00171.
Results: Median age was 77.3 years (p10-p90 62.2 – 85.1) and 58.5% of the patients were males. According to the WHO 2008 classification diagnoses were as follows: RCUD (11.1%), RCMD (58.5%) y MDS with del(5q) (17%), MDS-U (5.2%) and RAEB-1 (8.2%). Ring sideroblasts (RS) count was below 5% in all of patients (p10-p90 0.0%>3.4%). Conventional cytogenetic studies (according to IPSS-R, revealed that the majority of the patients (89.6%) had normal cytogenetics or very good/good clonal abnormalities, while a 6.7% and 2.2% carried intermediate and poor/very poor clonal

lesions, respectively. Regarding prognostic classification, all patients were considered as low risk MDS, most of the patients belonged to IPSS-R categories very low (32.6%) and low (48.1%), and only 17% had an intermediate IPSS-R. During disease evolution, 49.6% of patients died and 17% progressed to a higher risk entity (3 to RAEB and 20 to sAML). A total of 287 mutations were identified in the exonic regions of 70 genes. Among them, 41 genes were recurrently mutated (≥2 patients), with *TET2* (30.4%), *SRSF2* (14%), *DNMT3A* (11%), *RUNX1* (10.4%) and *ZRSR2* (8%) the most frequently mutated ones. Of note, 55 variants were found in *TET2*, affecting 41 patients, and interestingly, 13 of these had double mutations (32%), highlighting that one of them had 3 different mutations. The remaining genes were mutated with a lower incidence, below 6% of patients. In this selected cohort a median of 2 mutations per patient was found (p10-p90 0-4), with an 80% of cases having at least one mutation in one of the studied genes. Of these, 23.7% had one mutation, 16.3% had two mutations, while 15.6%, 15.6%, 6.6%, 1.5% and 0.7% of patients had 3, 4, 5, 6 and 7 mutations, respectively and 20% did not carry any mutation. Additionally, in relation to the pathways affected by these mutations, 65% of the patients presented mutations in epigenetic regulators (*i.e.* DNA methylation, 46%; chromatin modification, 19%), 25% in transcriptional regulators and 37% in components of the RNA splicing machinery. After a median follor up of 4.66 years, median OS was 5.13 years (95CI 3.636-6.709). Mutated genes with significnatly adverse influence on OS were *EZH2* (0.012), *IDH2* (p=0.04) or *U2AF1* (p=0.011). In this sense, the number of mutations detected, >2 *vs* ≤2 also decreased survival (p=0.049, Figure 1).

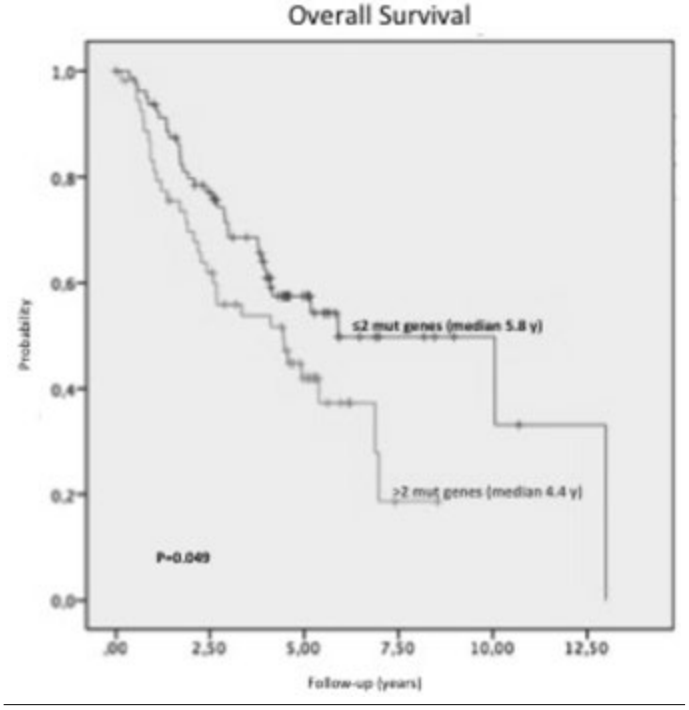

Figure 1.

Summary and Conclusions: Mutational profile in this subset of patients could help us to identify poor prognostic patients candidates to novel drugs that directly target the mutated gene and could improve prognosis in this subset of patients.

PF487

COMPARISON OF MUTATION DYNAMICS IN HIGHER RISK MYELODYSPLASTIC SYNDROME PATIENTS TREATED WITH AZACITIDINE AND DECITABINE

J. H. Moon[1,*], T. Kim[2], J.-S. Ahn[3], S.-S. Lee[3], S.-Y. Ahn[4], S.-H. Jung[5], D.-H. Yang[4], J.-J. Lee[4], S.H. Choi[6], D.W. Baek[1], Y.J. Lee[1], S.K. Sohn[1], H.-J. Kim[5], Z. Zhang[7], D.D.H. Kim[8]

[1]Hematology/Oncology, Kyungpook National University Hospital, Daegu, Korea, Republic Of, [2]Computer Science, University of Toronto, Toronto, Canada, [3]Chonnam National University Hwasun Hospital, Hwasun, Korea, Republic Of, [4]Hematology/Oncology, Chonnam National University Hwasun Hospital, [5]Hematology/Oncology, Chonnam National University Hospital, [6]Genomic Research Center for Hematopoietic Diseases, Chonnam National University Hwasun Hospital, Hwasun, Korea, Republic Of, [7]Molecular Genetics, University of Toronto, [8]Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, Canada

Background: Hypomethylating agents (HMAs) such as azacitidine (AZA) and decitabine (DEC) are used to treat higher risk myelodysplastic syndrome (HR-MDS). However, underlying genetics and mutational dynamics upon treatments with AZA and DEC have not been compared longitudinally.
Aims: To assess mutational dynamics on treatments between AZA and DEC, and to investigate the clinical relevance of these mutational allelic burdens using serial samples.
Methods: This study included bone marrow samples from 64 patients (34 AZA and 30 DEC) taken at diagnosis and follow-up after median 4 cycles. Targeted deep sequencing on a custom myeloid gene panel of 84 genes (Agilent SureSelect) was performed on trios of T-cell, pre-HMA, and post-HMA samples on 64 HR-MDS patients.
Results: At diagnosis, we detected 135 mutations from 54 patients. Most frequently mutated genes were *TP53* (n=9), *DNMT3A* (n=7), *ASXL1* (n=7), DDX41 (n=7) and *U2AF1* (n=6). HMAs were administered median 4 cycles (range 1-14). At follow-up, allelic burdens were decreased from mean 19.4% to 5.8%, where from 14.6% to 2.3% in patients treated with AZA (p<0.001) and from 23.4% to 10.6% in those treated with DEC (p=0.005). Nevertheless, 2-year overall survival (OS) rate did not differ between AZA and DEC groups (66.6±12.1% *vs* 60.6±13.4%, p=0.875) with median follow-up duration of 583 days (range 4-3012 days). TP53 mutations were detected in 9 patients including 4 with AZA and 5 with DEC group. CR/mCR was not achieved in the patients with TP53 mutation treated with AZA (n=0/4), while 2 patients (40%) achieved CR/mCR when treated with DEC (p=0.132). The presence of TP53 mutations did not affect the achievement of CR/mCR (p=0.379). In both groups, 2-year OS rates were lower in patients with TP53 mutations than those without: 25.0 ± 16.7% *vs* 59.7±9.3% in AZA group (p=0.057) and 20.0±17.9% *vs* 52.1±11.1% in DEC group (p=0.004). Cumulative incidence of leukemia transformation was associated with the presence of mutations in activated signaling pathway in AZA group but not in DEC group.
Summary and Conclusions: This study showed that allelic burden is decreased after treatment with both azacitidine and decitabine in HR-MDS patients. However, the mutation dynamics are independent to long-term survival. Presence of TP53 mutation remained independent prognostic factor in HR-MDS patients treated with HMAs, even with decreased allelic burden.

PF488

USING PU.1 AND JUN DIMERIZATION PROTEIN 2 TRANSCRIPTION FACTOR EXPRESSION IN MYELODYSPLASTIC SYNDROMES TO PREDICT TREATMENT RESPONSE AND LEUKEMIA TRANSFORMATION

K. Boasman[1], M. Simmonds [1], Y. Sauntharajah[2], C. Rinaldi[1,*]

[1]Life Science, University of Lincoln, Lincoln, United Kingdom, [2]Hematologic Oncology and Blood Disorders, Cleveland Clinic, Cleveland, United States

Background: Myelodysplastic syndromes (MDS) are malignant disorders of the myeloid progenitor leading to acute leukaemia (AML). Altered DNA methylation, and associated abnormal gene expression, results in aberrant cell growth and cytopenia seen in MDS. Demethylating agents are used to treat intermediate and high risk MDS with variable success. Recent breakthroughs identified significant down-regulation of transcription factor PU.1 in high risk MDS and AML patients, with work within NPM1 mutated AML cells showing PU.1 relocates in the cytoplasm causing cell differentiation arrest. In PU.1 overexpressing cell line model, microarray analysis revealed that Jun Dimerization Protein 2 (JDP2), a downstream of PU.1 which represses acetylation of core histones *in vitro* and *in vivo*, was significantly suppressed.
Aims: In this study, we show consistent and progressive reduction of PU.1 and JDP2 during MDS progression, with upregulated PU.1 and JDP2 levels only seen in patients achieving a clinically significant response to Azacitidine.
Methods: We investigated the gene expression of PU.1 and JDP2, in total bone marrow and selected CD34+ cells, from 12 newly diagnosed MDS patients stratified according to IPSS-R score (6-low, 3-intermediate, 3-high risk), 2 AML patient and 10 normal controls. Samples were enriched for the mononuclear fraction by Ficoll separation. Total RNA was extracted and analysed by Real Time PCR for PU.1 and JDP2 expression using the 2-ΔΔCT method. Protein expression was analysed by western blot. Results obtained were also compared with data from Bloodspot. PU.1-knockdown was performed in K562 using PU.1 short interfering RNAs.
Results: We revealed both PU.1 and JDP2 are down regulated in MDS patients. In addition, our data suggests that PU.1 and JDP2 expression

inversely correlates with disease, with expression of these genes consistently reducing according to IPSS-R groups. Furthermore, a positive correlation of PU.1 and JDP2 expression <R=O.9333, s=0.0004 >, provides additional evidence that suppression of JDP2 by PU.1 could contribute to the pathogenesis of AML. Investigating PU.1, and JDP2 expression data in MDS *vs* normal samples from the Bloodspot expression data showed they were significantly downregulated in MDS patients compared with normal controls, further confirming their potential role in predicting MDS progression. To confirm that JDP2 suppression is a direct result of reduced PU.1 we performed PU.1-knockdown in K562 cells stably expressing PU.1 short interfering RNAs *versus* control cells. Interestingly, these analyses reveal only a partial reduction in JDP2 expression when analysed by RT-PCR and Western blot, suggesting a more complex regulatory mechanism. During AML evolution, the expression level of both PU.1 and JDP2 in CD34+ cells, significantly and progressively reduces, suggesting their role in AML transformation but also highlight the possibility to early detection of AML transformation in MDS patient. This can allow a better stratification of MDS patients and help us in identifying the ones who might benefit sooner from a therapy change. Furthermore, in patients achieving a clinically significant response to Azacitidine, we demonstrated a significant upregulation in PU.1 and JDP2 expression compared with non-responders. This suggests that PU.1/JDP2 could be targets of the drug and their expression during treatment.

Summary and Conclusions: PU.1 and JDP2 expression correlates with patient's prognosis and leukaemia transformation in MDS, highlighting a potential role as new diagnostic and prognostic markers in MDS.

PF489

ASSOCIATION OF EMERGENT PTPN11 MUTATIONS WITH CLINICAL RESISTANCE TO THE COMBINATION OF AZACTIDINE AND RIGOSERTIB IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROME

L. Silverman[1,*], S. Navada[1], S. Melana[1], G. Garcia-Manero[2], R. Odchimar-Reissig[1], E.P. Demakos[1], M.E. Petrone[3], P. Zbyszewski[3], N. Azarnia[3], S.M. Fruchtman[3], E.P. Reddy[1]

[1]ICAHN School of Medicine, Mount Sinai, New York, [2]MD Anderson, MD Anderson, Houston, [3]Onconova Therapeutics, Onconova Therapeutics, Newton, United States

Background: The treatment of patients with MDS with Azacitidine (AZA) is associated with hematologic responses, and a significant increase in overall survival. AZA has become the standard of care for patients with higher-risk disease. However, all pts ultimately fail treatment due to either primary or secondary resistance. MDS, a hematopoietic stem cell disorder, is characterized by intricate complexities at the molecular, genetic and epigenetic levels contributing to the therapeutic challenge. Rigosertib (RIG) is a small molecule Ras mimetic that interferes with cellular signaling. This is believed to be mediated by the binding of RIG to the Ras-binding domain (RBD) and may inhibit multiple Ras-driven signaling pathways including RAS-RAF-MEK and the PI3K. *In vitro*, we demonstrated that the combination of RIG with AZA synergistically inhibits growth and induces apoptosis of leukemic cells in a sequence-dependent manner (Skidan *et al.*, AACR 2006). RIG combined with AZA in a phase I/II study in MDS pts demonstrated an overall response rate of 77%; 84% in pts that were HMA naïve and 64% in pts following HMA failure (Navada EHA 2017). Reversal of the clinical resistance phenotype represents a novel observation. Recently, we observed that RIG appears to act as a chromatin modifying agent and is associated with histone post-translational modifications (Silverman EHA 2017). Mutations that activate Ras signaling such as mutations in Ras genes or Ras regulators (NF1, PTPN11, or CBL) have been found in 30% of AML patients (Papaemmnanuil, 2016). Exploring the Ras pathway in patients treated with these agents can inform on potential mechanisms associated with clinical resistance.

Aims: Identify potential mechanisms of resistance

Methods: Patients participating in a clinical trial of the combination of RIG in combination with AZA had gene mutation analyses conducted serially at one of the participating institutions (Mount Sinai) while on the study. RIG was administered on day 1 -21 orally and AZA was administered parenterally on day 8 – 15. The cycle was repeated every 28 days. Serial samples were obtained from bone marrow and/or peripheral blood for NGS mutation analysis in conjunction with scheduled bone marrow samples. Data from the patients on this study were compared to a broad data set of patients in the MDS program at Mount Sinai.

Results: Comparison of changes in mutational analysis of pts treated with RIG/AZA revealed an emergence of PTPN11 mutations in a higher percentage of patients compared to the larger MDS population not treated with the combination. PTPN11 mutations were present at baseline in a total of 9 (2.7%) of 333 MDS patients studied; 4/300 (1.3%) comparator group (CG) *vs* 5/33 (15%) RIG/AZA group (P=0.0002). Of note the mutation emerged in 3 of the responding patients to RIG/AZA who had received treatment for >6 months, and the appearance of the mutation correlated with the onset of clinical resistance to the combination. The emergence of the mutation in 3 (10%) patients compares to 1 (0.03%) in the CG, P=0.0036. The appearance of the mutation was associated with progressive marrow failure and transformation to AML.

Summary and Conclusions: PTPN11 mutations occur much less frequently than other mutations in MDS. The appearance of these mutations in patients treated with the RIG/AZA combination in a disproportionately higher rate than the CG suggests that the dysregulation of the Ras pathway may lead to a clinical resistance phenotype to this combination. Further correlative studies of the Ras pathway are underway.

PF490

A NOVEL CULTURE MODEL FOR STUDYING TERMINAL ERYTHROID DIFFERENTIATION IN PATIENTS WITH SF3B1 MUTATED MYELODYSPLASTIC SYNDROMES

E.M. Elvarsdóttir[1,*], T. Mortera-Blanco[1], M. Dimitrou[1], T. Bouderlique[2], M. Jansson[1], S. Conte[1], I. Hofman[1], M. Creignou[1], M. Karimi Arzenani[1], B. Sander[2], I. Douagi[1], P. Woll[1], E. Hellström-Lindberg[1]

[1]Medicine, [2]Laboratory Medicine, Karolinska, Stockholm, Sweden

Background: Myelodysplastic syndrome with ring sideroblasts (MDS-RS) is characterized by recurrent mutations in the splicing factor gene *SF3B1* and terminal erythroid failure associated with formation of ring sideroblasts (RS). Previously established *in vitro* models used to study MDS-RS are based on CD34-enriched (CD34+) primary cells cultured in suspension, which facilitate production of erythroid progenitors and accumulation of aberrant mitochondrial ferritin. However, these models fail to support terminal erythropoiesis, including efficient production of erythroid islands and RS. Recently we demonstrated that RS can be generated in mouse bone marrow by transplanting HSCs from *SF3B1* mutated MDS-RS patients into immune-deficient mice (Mortera-Blanco, Blood 2017). We hypothesized that the bone marrow microenvironment and/or 3D structure plays a significant role in generating the MDS-RS phenotype.

Aims: The aim was to establish an erythroid culture model that simulates the human bone marrow and could be used to study terminal erythropoiesis in healthy individuals and MDS-RS patients.

Methods: Mononuclear cells (MNCs) and CD34+ cells isolated from 10 healthy individuals (NBM) and 9 MDS-RS patients were cultured for 4 weeks in scaffolds made out of collagen-coated polyurethane (3D culture), or in previously reported suspension cultures. Cells extracted before seeding and during week 2, 3 and 4 of culture were evaluated for proliferation via MTS assay, erythroid maturation by flow cytometry and self-renewal potential was assessed with long-term colony forming cell (LTC-CFC) assays. Cells were stained with Perl s Prussian blue for morphological assessment and quantification of RS and the allelic burden of *SF3B1* mutations were measured using pyrosequencing. Erythroid islands were counted after May-Grünwald Giemsa staining and visualized *in situ* with fluorescent staining of cryosectioned scaffolds.

Results: The proliferative capacity of MNCs and CD34+ cells isolated from NBM and MDS-RS patients was maintained for 4 weeks of 3D culture. In suspension however, only the MNCs grew beyond 2 weeks of culture. Cells extracted during the fourth week of NBM cultures, other than CD34+ cells in suspension, gave rise to colonies following LTC-CFC assays, indicating retained self-renewal potential. CD34+ cells cultured in 3D showed superior proliferation and generated the highest percentage of erythroid cells including enucleated erythrocytes. Importantly, *SF3B1* mutation allele frequency was maintained in all MDS-RS cultures. The RS seeded from MNCs disappeared after 2 weeks of culture followed by re-generation from the third week, coinciding with their appearance when CD34+ cells were cultured in 3D. Erythroid islands were identified in all cultures except for the CD34+ suspension.

Summary and Conclusions: We report a novel culture model able to mimic the terminal erythropoiesis of NBM and MDS-RS with ample *in vitro* generation of RS. Although we could induce terminal erythropoiesis, erythroid island formation and RS generation by seeding either MNCs or CD34+ cells, the latter produced a higher number of cells with the highest percentage of enucleated erythrocytes. Interestingly when seeding the same CD34+ cells in suspension the cells could only survive for two weeks without inducing erythroid maturation or RS generation, suggesting that the 3D simulation of the human bone marrow is important to model the disease. This culture system could be used for studying new treatment options for MDS-RS and to study other malignancies with erythroid maturation defects *in vitro*.

PF491

PROGNOSTIC SIGNIFICANCE OF THE ASXL1 GENE ALTERATION IN PATIENTS WITH ISOLATED 20Q DELETION

J. Brezinova[1,*], I. Sarova[1], K. Svobodova[2], H. Lhotska[2], S. Ransdorfova[1], S. Izakova[2], L. Pavlistova[2], L. Lizcova[2], K. Skipalova[2], L. Hodanova[2], J. Markova[3], Z. Zemanova[2], J. Cermak[3], A. Jonasova[4], K. Michalova[2]

[1]Cytogenetic Department, Institute of Hematology and Blood Transfusion, [2]Center of Oncocytogenetics, Institute of Medical Biochemistry and Laboratory Diagnostics, General University Hospital and First Faculty of Medicine, Charles University, [3]Clinical Department, Institute of Hematology and Blood Transfusion, [4]1st Medical Department, General University Hospital and First Faculty of Medicine, Charles University, Prague, Czech Republic

Background: In bone marrow cells of patients with myelodysplastic syndromes (MDSs), acute myeloid leukemia (AML) or myeloproliferative neoplasms (MPNs) the isolated deletion of 20q [del(20q)] is the common chromosomal abnormality associated with a favourable outcome. On contrary, alterations of the *ASXL1* gene, which maps to 20q11.21 region, generally represent a poor prognosis across the spectrum of hematologic malignancies.
Aims: Our objective was to determine the frequency of *ASXL1* alterations in deletion 20q cases, to characterize breakpoints in the *ASXL1* gene using microarray techniques [array comparative genomic hybridization (aCGH)] and to evaluate the difference in survival between patients with and those without *ASXL1* alterations.
Methods: FISH with locus specific probes for 20q11, 20q12 and 20q13.12 regions (Abbott, Kreatech Diagnostics, MetaSystems) confirmed the cytogenetically observed deletions of 20q in a cohort of 39 patients (29 male, 10 female, median age at diagnosis 68 years) with hematologic disorders: MDSs (n=24), MPNs (n=10), non-Hodgkin lymphomas (n=2), AML (n=1), thrombocytopenia (n=1), anemia (n=1). In all patients, deletion of 20q was the sole aberration; however, in 3 patients, a variant of del(20q), an isochromosome of deleted 20q, was detected. Metaphase FISH mapping using a set of 5 bacterial artificial chromosome (BAC) probes (RP11-600A9, RP1-316I5, RP11-358N2, RP4-669H2 and RP5-823G15, BlueGnome, Empire Genomics) that target sequences in 20q11.21 and 20q13.2, along with a chromosome-20-specific centromeric probe (Kreatech Diagnostics) as a control, were used for determination of the breakpoints. aCGH [CytoChip Cancer 4x180K, CytoChip Cancer SNP 4x180K (Illumina); SurePrint G3 Cancer CGH+SNP Microarray 4x180K (Agilent)] was done on DNA samples of bone marrow cells of 9 patients with suspected partial deletion in *ASXL1* to characterize the breakpoints.
Results: According to the FISH results, three groups of patients were established: (1) 9 patients (23%) had a proximal breakpoint in *ASXL1* with partial deletion of the gene; (2) 11 patients (28%) had complete deletion of *ASXL1*; and (3) 19 patients (49%) had no alterations in either copy of *ASXL1*, with the proximal breakpoint of the deletion located downstream of this gene. In summary, *ASXL1* gene was altered (partially or completely deleted) in 20 out of 39 patients (51%). aCGH confirmed the high heterogeneity of the breakpoints in the *ASXL1* with the most common frequency in/downstream of the exon 4 and with partial deletion of the 3 end of the gene. Kaplan-Meier survival curves for the patients groups with and without *ASXL1* gene alterations showed significant difference (overall survival 48.6 months and 119.0 months, respectively; p=0.05).
Summary and Conclusions: Alterations of the *ASXL1* gene have a prognostic impact in patients with hematologic malignancies. In our cohort of patients with isolated del(20q), FISH with specific BAC probes revealed the *ASXL1* partial/total deletions in 51% of cases with significantly shorter overall survival. aCGH confirmed all findings implied by FISH. We consider FISH using specific BAC probes to be a reliable and robust technique, that can readily detect *ASXL1* alterations in routine analyses of del (20q) patients and that may identify those patients who need to be monitored more carefully and more frequently than those without this alteration.

PARP1 EXPRESSION PROFILE AND DIVERGENT CLINICAL IMPACT IN MYELODYSPLASTIC SYNDROMES AND CHRONIC MYELOMONOCYTIC LEUKEMIA

A.M. Hurtado López[1,*], T.H. Chen-Liang[1], L. Palomo[2], E. Lumbreras[3], M. Díez-Campelo[4], L. Zamora[2], F.J. Ortuño[5], V. Vicente[1], C. del Cañizo[4], F. Solé[2], A. Jerez[1]

[1]Hematology and Medical Oncology Department, Hospital Morales Meseguer, IMIB, Murcia, [2]Josep Carreras Leukaemia Research Institute, ICO-Hospital Germans Trias i Pujol, Universitat Autònoma de Barcelona, Badalona, [3]Hematology, Hospital Universitario de Salamanca, [4]Hematology, Hospital Universitario de Salamanca, Salamanca, [5]Hematology and Medical Oncology Department, Hospital Morales Meseguer, IMIB, Murcia, Spain

Background: Clinical, pathological, and genomics disparities with MDS suggest that specific underlying biological mechanisms exist within CMML that might confer differential sensitivity to treatment. Independent studies have shown that neoplastic cells with homologous recombination-defective lesions are notably sensitive to *PARP1* inhibition.Recently, it has been reported in MDS patients, that mRNA PARP1 levels distinguish a subgroup with significant survival disadvantage, but there is a lack of information about *PARP1* in CMML.
Aims: To characterize mRNA *PARP1* expression in bone marrow at diagnoses in a large series of patient with MDS and CMML, assessing its potential clinical impact.
Methods: We measured by RT-qPCR, using TaqMan gene expression assays, mRNA *PARP1* in 82 CMML and 101 MDS bone marrow samples collected at diagnosis and 15 bone marrow samples from healthy donors. To validate our findings in the common cell of origin of myeloid neoplasms, CD34+ cells were enriched from thawed BM of 15 CMML patients, 15 MDS cases, and 15 controls and studied by RT-qPCR.We used Receiver Operating Curves (ROC) to determine the best *PARP1* expression cut-off point to discriminate prognoses, both in MDS and CMML. We performed univariate COX for overall survival and time to AML transformation. In case significant results were obtained, a multivariate analysis confronting IPSS-R or CPSS was planned.
Results: The MDS cohort included one hundred and one cases: 53% were male and median age was 69 y.o. (30-90). At a median follow-up of 20 months, 12% of patients experienced leukemic transformation. Compared with BM samples from 15 controls, we found a significant downregulation of *PARP1* in CMML (0.6 FC, p=0.04), and a statistical trend for downregulation in MDS cases (0.8 FC, p=0.09). We obtained similar results when assessing *PARP1* expression in bone marrow CD34+ cells from CMML (0.45 FC, p=0.08), MDS (0.25 FC, p=0.06), when comparing whit healthy donors. Those MDS patients with higher *PARP1* mRNA level (best sensitivity and specificity ROC cut-off point >0.00175) had a median time of survival of 22 months compared with 84 months in those cases with lower levels of *PARP1* mRNA (*P*=0.009; RR=2.3;95%CI[1.2-4.5]). When we performed a multivariate analysis including mRNA *PARP1* levels and IPSS-R (dichotomized as high risk-very high and high- *versus* low risk-intermediate, low and very low) both of them reached a statistical significance (*P*=0.016; RR=2.2;95%CI[1.1-4.3]) and (*P*=0.009; RR=7.5;95%CI[2.82-19]) respectively.The CMML cohort included eighty-two patients: 63% were male and median age was 74 y.o. (44-91). Conversely, no significant differences in survival were observed between those CMML patients with higher PARP1 mRNA levels, with a median survival of 36 months, compared to 39 months in patients with lower levels (cut-off point >0.00175; P=0.9;RR=0.9;95%CI[0.5-1.8]). Even when recalculating the best sensitivity and specificity ROC cut-off point for the CMML cohort (>0.00143), no significant differences in survival were found (P=0.66;RR=0.8;95%CI[0.4-1.6]).
Summary and Conclusions: In conclusion, we have identified important disease-specific differences for *PARP1* mRNA expression and its prognostic relevance comparing MDS and CMML cases, with potential translational ramifications for the positioning of novel therapeutic strategies. Our findings suggest that the promise of *PARP1* inhibition appears less pertinent to CMML than for other myeloid diseases. These differences might also shed insights into their distinctive biology.

PF493

CHROMATIN REGULATORS AS RESPONSE-PREDICTING BIOMARKERS OF AZACITIDINE THERAPY IN MDS PATIENTS

J. Diesch[1,*], K. Götze[2], J. Zuber[3], L. Zamora[4], M. Buschbeck[1]

[1]Josep Carreras Leukaemia Research Institute, Badalona, Spain, [2]Department of Medicine III, Klinikum rechts der Isar, Technische Universität München, München, Germany, [3]Research Institute of Molecular Pathology (IMP), Vienna, Austria, [4]Hematology Laboratory, ICO, Josep Carreras Leukaemia Research Institute, Badalona, Spain

Background: Myelodysplastic syndrome (MDS) is one of the most common bone marrow disorders in the elderly characterized by an ineffective hematopoiesis and strong predisposition to acute myeloid leukemia (AML). MDS is associated with a variety of genetic modification, many of which affect epigenetic regulators, however their biological and prognostic significance is not well understood. Currently the demethylating agent azacitidine (AZA) and its analogs are the major treatments given to high-risk MDS

patients. Nevertheless, only 40% to 50% of treated patients show hematological improvements and 10% to 15% can achieve complete response. However, even in responding patients, the drug is not curative and response is lost over time leading to disease relapse. Therefore, response-predicting biomarkers and new treatment options are urgently needed.
Aims: The goal of this project is to identify response-predicting biomarkers for AZA therpy and new treatment options to improve the clinical management of MDS patients.
Methods: To identify genes affecting AZA sensitivity and resistance we performed two loss-of-function short-hairpin high-throughput screens targeting 912 chromatin regulators in the AML/MDS cell line SKK1. The first shRNA screen was set out as resistance screen using a high AZA concentration only allowing the survival of resistant cell clones. Additionally, we performed a sensitivity shRNA screen using lower AZA concentrations and thus focusing on genes affecting drug sensitivity rather than resistance. In parallel, we are performing a longitudinal study of AZA treatment in MDS patients. Therefore, we are collecting samples at diagnosis, during treatment and, if occurring, at relapse and will determine gene expression changes as well as the mutational status in disease relevant genes.
Results: Since AZA is a chromatin-modifying agent, this project is focused on chromatin and transcriptional regulators. Performing loss-of-function shRNA screens targeting 912 chromatin regulators led to the identification of several genes conferring resistance and differential responses to AZA treatment. While some of these genes have already been implicated in hematological diseases, others have never been mentioned in this context and thus are currently being examined in greater detail. Furthermore, the expression of selected top hits is currently being assessed in a cohort of patient samples and correlated to treatment response, thus allowing to identify potential markers of treatment success or failure. In addition, we identified genes whose knockdown causes greater sensitivity towards AZA treatment. Hence, targeting these genes could potentially be employed to improve AZA response, and thus treatment success. This is currently being assessed in drug combination studies.
Summary and Conclusions: The combination and cross-validation of the results of our clinical and experimental approaches will help to identify markers of AZA response as well as dissect the molecular mechanisms underlying AZA action. This will not only improve patient stratification but also enable us to establish novel strategies for therapeutic intervention.

PF494

MECHANISTIC CHARACTERIZATION OF HDACI MEDIATED KIT DOWNREGULATION IN SYSTEMIC MASTOCYTOSIS

K. Lyberg[1,*], H. Abdulkadir Ali[1], J. Ungerstedt[2]

[1]Medicine Huddinge, Karolinska Institutet, Huddinge, [2]Institutionen för medicin, Huddinge (MedH), H7, Enheten för hematologi, M 54, Karolinska Universitetssjukhuset Huddinge, Karolinska Institutet, Stockholm, Sweden

Background: In systemic mastocytosis, there is an accumulation of mast cells in various tissues due to a point mutation in the tyrosine kinase receptor KIT rendering it continuously active. We have previously shown that histone deacetylase inhibitors (HDACi) induce apoptosis selectively in KIT mutated SM mast cells by downregulation of KIT at both mRNA and protein level.
Aims: The aim of this project is to elucidate the mechanism of action of HDACi induced mast cell apoptosis.
Methods: To further understand the mechanism of action of HDACi in SM, we have used the KIT mutated SM cell line (HMC-1.2). Following treatment with HDACi we have performed RNA seq to investigate alterations of the transcriptome, ATAC seq for whole genome nucleosome positioning and ChIP seq to assess repressive (H3K27me3) and active (H3K27ac, H3K4me3) chromatin marks.
Results: Already at 24h of HDACi treatment, there was a profound decrease in H3K4me3 in the KIT promoter region, and gene ontology analysis shows that the most silenced pathways (decreased H3K4me3) all are downstream pathways of KIT (*e.g.* MAPK cascade, phosphorylation). This is also evident when studying the RNA seq data, already at 6 hours but more profoundly at 24 hours of treatment with HDACi several regulators in KIT downstream pathways are significantly downregulated, *e.g.* STAT5, AKT, MAPK and FYN. Gene ontology analysis of RNA seq data shows upregulation of genes involved in negative regulation of phosphorylation and kinase activity, and downregulation of genes involved in heterochromatin formation processes.
Summary and Conclusions: Combining these results demonstrate that HDACi treatment silences not only KIT but also directly targets KIT downstream signaling pathways. We are now further analyzing the ChIP seq data from the additional active, repressive chromatin marks, and the ATAC seq data to understand the HDACi mechanism of action and selectivity for KIT mutated mast cells, to understand how we can use HDACi in the clinic for systemic mastocytosis, a disease that currently has limited treatment options.

Background: Myelodysplastic syndromes (MDS) may be characterized by hypocellular marrow, irrespective of their WHO classification or molecular characteristics. The prognostic weight of this specific feature must still be completely evaluated. MDS with hypocellular marrow tend to be considered an aplastic anemia "overlap syndrome" or a pre-aplastic anemia stage. There are no strong specific therapy recommendations, and large studies analyzing the outcome of hypocellular MDS are lacking. While selective sensitivity to immunosuppressive therapy is suggested, evidence in this sense is controversial.
Aims: We wanted to evaluate the clinical characteristics,outcome and choice of therapy of patients with hypocellular MDS, and compare them with normocellular MDS.
Methods: We analyzed 2559 consecutive MDS cases with complete clinical annotations and with evaluable bone trephine biopsy, enrolled in our Italian National Registry FISMonlus. In this cohort of patients, 438 had a bone marrow cellularity <= 30%,and 2121 cellularity above 30%. We proceeded by comparing these two groups in terms of age, gender, WHO classification, IPSS-R categories,overall survival and choice of first line therapies.
Results: Median age was 72.5 yrs in the hypocellular group and 72,3 yrs in the normocellulare group; M/F were 53.2%/46.8% for hypocellular MDS *vs* 62.6%/37.4% in normocellular MDS. IPSS-R risk categories were distributed as follows: Hypocellular MDS Very Low risk 15.5%,Low 35.1%, Intermediate 30.1%, High 11.3%, Very high 8%; Normocellular MDS Very Low risk 12.8%, Low 37.2%, intermediate 23.7%, High 15.5%, Very High 11.4%. Global median overall survival (OS) was 77 months for hypocellular MDS and 56 months for normocellular MDS. When OS was evaluated in the different IPSS-R risk groups, Lower risk MDS cases with hypocellular BM had a median OS of 125 mos while normocellular had a median OS of 74 mos (p<.001). Higher risk MDS with hypocellular BM had 19 mos median OS *vs* 20 mos OS in normocellular MDS. Regarding the choice of firts line therapy, the comparison of hypocellular MDS with normocellular ones yielded the following: watch and wait 33.8% *vs* 31.6% for IPSS-R lower risk, 12.1% *vs* 16% for higher risk cases; AML like chemotherapy and HSCT were chosen for<1% of lower risk cases overall, and in 1.7% of higher risk hypocellular MDS, while higher risk MDS with normocellular marrow received it in 6.2% of the cases. Azacitidine was first line treatment of choice for 36.2% of the higher risk MDS patients with hypocellular BM and 25% of normocellular BM. Immunosuppressive treatments were emploied for <1% and 1.5% respectively in lower risk cases only. Erythroid stimulating agents were administered in 42.6% and 41.2% MDS IPSS-R lower risk, hypo- and normocellular, respectively.
Summary and Conclusions: Our results are based on an unbiased analysis

of "real life" MDS patients with hypocellular BM compared to normocellular ones.Clinical characteristics between the two groups were not significantly different in terms of age, gender, and distribution in the various IPSS-R risk categories.The outcome of the hypocellular marrow-MDS cases was better in comparison with that of normocellular MDS, with significantly longer OS in IPSS-R lower risk cases. Such advantage in OS for hypoplastic MDS was not present for IPSS-R higher risk cases. Finally, the choice of first line therapy dose not seem to be influenced at all by the BM cellularity, with a surprising very low proportion of patients receiving immunosuppressive agents, despite several guideline recommend of this treatment for hypoplastic MDS.

PF496

DESCRIPTION OF MUTATIONAL PROFILE IN PATIENTS WITH LOWER-RISK MYELODYSPLASTIC SYNDROMES AT THE TIME OF LEUKEMIC PROGRESSION

B. Pedrote[1,*], J.F. Falantes[1], E. Carrillo[1], C. Calderon-Cabrera[1], F.J. Marquez-Malaver[1], I. Espigado[1], J.A. Pérez-Simón[1]

[1]Hospital Universitario Virgen del Rocio, Seville, Spain

Background: Despite refinement on prognostic stratification in myelodysplastic syndromes (MDS), clinical heterogeneity, particularly in the group of lower risk disease (LR-MDS), characterizes these disorders. Recent progress in mutational analysis supports the prognostic value of certain somatic mutations not only with regard to overall survival but also with response to azacitidine (AZA) [1-3]. By contrast, mutational profile at the time of leukemic progression remains poorly characterized.
Aims: A recent analysis from Chronic Myeloid working group of the International Cancer Genome Consortium detected *ASXL1* and *RUNX1* as most frequent mutations in 3 out 7 LR-MDS patients with mutational data available at progression [4].
Methods: Retrospective analysis of a large cohort (N=409) of patients with primary LR-MDS [defined as either an IPSS score of low/intermediate-1 and/or favorable cytogenetic categories (good/intermediate by IPSS or very good/good/intermediate by IPSS-R)] followed until progression to acute myeloid leukemia (AML) with mutational analysis available at the time of leukemic progression. The Ion AmpliSeq™ AML Cancer Research Panel targeting 19 genes implicated in AML (entire coding regions: *CEPBA, DNMT3A, GATA2, TET2, TP53; hotspot regions: ASXL1, BRAF, CBL, FLT3, IDH1, IDH2, JAK2, KIT, KRAS, NPM1, NRAS, PTPN11, RUNX1, WT1*) was used to detect driver mutations in an "Ion S5™ Sequencer". Nonsense, frameshift and splicing mutations with frequency >3% were considered for analysis. Somatic confirmed mutations in COSMIC database were considered pathogenic and mutations not described in COSMIC but with a pathogenic prediction, were considered probably pathogenic.
Results: After 103 months median follow-up for the entire cohort (95% CI: 81-123), 66 patients (16%) progressed to AML. Data on somatic mutations at the time of leukemic progression was available in 17 patients (25%). Median time from diagnosis of MDS to leukemic progression was 10.2 months (range: 2-98 months). Mean number of somatic mutations detected per patient was 2 (range: 1-5), being *RUNX1* (5 pts; 29,4%) and *TET2* (5 pts; 29,4%) the most frequently mutated, followed by *CBL* and *GATA2* (found in 4 pts each; 23,5%) and *TP53, DNMT3A,CEBPA, ASXL1, BRAF, IDH2, JAK2, KRAS, NPM1 and WT1* (detected in 3 pts, each; 17.6%). According to WHO classification, refractory cytopenia with multilineage dysplasia was the most frequent MDS subtype. Karyotype was diploid in 12/17 cases at MDS diagnosis. Four pts acquired additional cytogenetic abnormalities at AML progression (pts#2, 10, 14 and 15 in Table 1). Interestingly, 3 out of those 4 had *TP53* mutation at progression, all of them with complex karyotype at AML evolution, with 1 remaining pt presenting *TET2, ASXL1* and *CBL* mutation. Ten pts received AZA at AML progression. Among AZA treated pts, 3/10 experienced long lasting and complete responses (2 pts with *TET2* and *CBL* and 1 pt with *TP53* mutations) while pts with remaining mutations identified at leukemic progression did not or lost response promptly.
Summary and Conclusions: This study shows a heterogeneous mutational landscape in MDS at progression to AML, some of them displaying a higher frequency than expected at MDS diagnosis (>29% pts had *RUNX* and 23,5% pts had *CBL* mutation at progression compared to 10-20% and 1% reported in MDS, respectively). Whether these represents ancestral mutations or were present as small subclones and expanded over time needs to be clarified in larger studies. Risk models including mutation data should evaluate this information, not only predicting survival, but also, the probability of leukemic progression.

CLONAL EVOLUTION IS MUCH MORE FREQUENT IN MDS AS KNOWN AS YET

C. Ganster[1,*], K. Shirneshan[1], S. Dierks[1], R. Martin[1], B. Glass[2], H.K. Al-Ali[3], M. Metz[4], U. Germing[5], U. Platzbecker[6], C. Müller-Thomas[7], K. Götze[7], N. Kröger[8], F. Braulke[1], J. Schanz[1], L. Trümper[1], D. Haase[1]

[1]Clinics of Hematology and Medical Oncology, University Medicine Göttingen, Göttingen, [2]Clinic for Hematology, Oncology, Tumor Immunology and Palliative Care, Helios Clinic Berlin Buch, Berlin, [3]Universitätsklinikum Halle, Halle (Saale), [4]Joint Practice Göttingen, Göttingen, [5]Department of Hematology, Oncology and Clinical Immunology, Heinrich Heine University Düsseldorf, Düsseldorf, [6]Department of Internal Medicine I, University Hospital Carl Gustav Carus Dresden, Dresden, [7]III. Department of Medicine, Technical University of Munich, Munich, [8]Department of Stem Cell Transplantation, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: The acquisition of genetic aberrations during the course of the disease (clonal evolution, CE), is known to be associated with poor outcome in MDS. Considering only cytogenetic aberrations (CA), up to almost 30% of MDS patients are affected by CE. Little is known about the additional impact of cryptic CA, that cannot be detected by chromosomal banding analysis (CBA), and molecular mutations (MM, *e.g.* point mutations, indels) on the incidence of CE.
Aims: We aimed to identify the true incidence of CE in MDS by including obvious CA, cryptic CA, and MM in our study.
Methods: To accomplish this goal we retrospectively reviewed 108 pts with proven MDS (35x MDS MLD, 19x MDS EB2, 12x MDS SLD, 13x sAML, 12x MDS EB1, 6x CMML, 3x MDS del(5q), 3x MDS U, 2x hypoplastic MDS, 2x ICUS, 1x MDS/MPN-RS-T). The karyotype from CBA, and the molecular karyotype from SNP-array analysis (SNP-A) were available for all pts. Cryptic CA were detected by SNP-A and fluorescence *in situ* hybridization (FISH) analyses. Results from mutational analysis were included for 73 pts. Genetic follow-up by bone marrow and/or frequent sequential genetic monitoring of CD34+ peripheral blood cells was available for 61 pts.
Results: By CBA CA were detected in 59/108 pts (55%, at any time during the course of the disease). In 36 pts we detected cryptic CA which increased the number of informative cases to 65/108 (60%). Included were cryptic copy number (CN) variations in 12 pts and CN neutral losses of heterozygosity (CN-LOH) in 24 pts. We identified a homozygous MM or a cryptic deletion in the region of the CN-LOH in 17 pts. Affected were *EZH2* (7q36.1, 5 pts), *DNMT3A* (2p23.3, 3 pts), *RUNX1* (21q22.12, 3 pts), *CBL* (11q23.3, 2 pts), *TET2* (4q24), *IKZF1* (7p12.2), *TP53* (17p13.1),

and *SRSF2* (17q25.1). CE by the stepwise formation of a "double hit" aberration from a heterozygous MM to a homozygous MM due to a cryptic CN-LOH was observed in consecutive samples of 3 pts. Regarding the pts with genetic follow-up data and taking obvious CA, cryptic CA and MM into account, CE was detected in 35/61 (57%) pts. The median observation time was 42 months. Although 31/61 pts were genetically analyzed under treatment with disease modifying therapies, the first CE event was observed before treatment in 26/35 pts. Furthermore, 19/35 pts had <5% bone marrow blasts at first CE. Median time from first diagnosis to first CE was 13 months (range 0-176 months). Manifestation of antecedent CE at first diagnosis was observed in 8 pts (2x sub-clones; 6x homozygous MM in CN-LOHs). In 27 pts first observation of CE was after first diagnosis. There was no significant difference in median survival from time of detection of CE between these two groups (25 *vs* 18 months, P=0.92, n.s.). However, for pts without CE median survival from first diagnosis was significantly longer (78 months, P=0.04 and 0.01). While just 7/27 (26%) pts with first detection of CE after first diagnosis showed further CE events, subsequent CE events were observed in 7/8 (88%) of pts with patterns of CE at diagnosis.

Summary and Conclusions: There is a clear tendency that cytogenetic LOH preferentially affects regions with MM, resulting in homozygous MM. The development of these patterns seems to be an important step towards progression. Since we considered obvious CA, cryptic CA, and MM, the incidence of CE was much higher in our cohort of MDS pts than observed ever before in MDS. The occurrence of CE is important for therapy management of MDS patients, especially if targeted therapies are used in future and the target is moving over time.

Background: Serious hematologic conditions such as MDS are associated with an erythroid maturation defect leading to anemia and other clinical sequelae. Luspatercept (ACE-536) is being developed as an erythroid-maturation agent (EMA) for treatment of anemia in lower-risk MDS. Luspatercept binds to select TGF-β superfamily ligands reducing aberrant Smad2/3 signaling and promoting late-stage erythroid maturation and increased hemoglobin (Hgb) levels (Suragani R, Nat Med, 2014; Platzbecker U, Lancet Oncol, 2017).

Aims: This ongoing, phase 2, multicenter, open-label study followed by a long-term extension (ext) study evaluates the effects of luspatercept in pts with lower-risk MDS. Endpoints include long-term safety and tolerability, erythroid response (IWG HI-E), RBC transfusion independence (RBC-TI, ≥8 weeks), duration of HI-E, pharmacodynamic and iron metabolism biomarkers, and pt-reported quality of life (QoL). New analyses focus on mutational and bone marrow characteristics of luspatercept responders.

Methods: Inclusion criteria: MDS IPSS low or int-1, age ≥18 yr, Hgb <10 g/dL (if <4U RBC/8 weeks), no prior HMA, and no current lenalidomide or erythropoiesis-stimulating agent (ESA). Pts are treated every 3 weeks subcutaneously for up to 5 doses (titration up to 1.75 mg/kg) in the base study (NCT01749514) and are then eligible for long-term treatment up to 5 additional years (NCT02268383). Baseline bone marrow and blood samples were analyzed by central morphology and flow cytometry according to ELN guidelines for evaluation of erythroid precursors and soluble transferrin receptor.

Results: Data (as of 08Sept2017) were available for 88 pts treated at dose levels ≥0.75 mg/kg with evaluable mutational data at baseline. All 88 pts were evaluable for IWG HI-E. Increased response rates were seen in pts with EPO <500 IU/L. Response rates were also increased in the SF3B1 mutated group *vs* the non-SF3B1 mutated group. Responders in both the SF3B1 mutated and non-SF3B1 mutated groups had lower M/E ratios at baseline than non-responders with a parallel increase in erythroid precursors (Table 1).

Table 1.

	SF3B1 mutated N=46		non-SF3B1 mutated N=42*	
HI-E Response Rate, n/N (%)	33/46 (72%)		15/42 (36%)	
EPO < 500 IU/L	29/40 (73%)		14/29 (48%)	
EPO ≥ 500 IU/L	4/6 (67%)		1/13 (8%)	
	R	NR	R	NR
n	33	13	15	27
Erythroid cells and precursors (%, bone marrow morphology)	50	38	34	17
M/E ratio (bone marrow morphology)	1.00	1.63	1.98	4.00
Erythroid precursors (%, flow cytometry)	13.07	8.43	8.39	4.05
Soluble transferrin receptor (nmol/L)	63.6	57.8	42.4	34.9

Data presented as median
NR=non-responder; R=responder
*Non-SF3B1 group includes RS+ patients without an SF3B1 mutation

Summary and Conclusions: Increased response rates in patients with lower M/E ratios suggest that an expanded erythroid population at baseline may be associated with response to luspatercept, supporting the concept that luspatercept is acting as an erythroid-maturation agent (EMA). Patients with and without the SF3B1 mutation with EPO <500 IU/L experienced substantial response rates, consistent with earlier results. Additional analyses are ongoing to understand the role of other biomarkers such as mutation status and how they may impact the biology and influence response. As there is not one distinct profile of responder characteristics, this may suggest the possibility that luspatercept may work in a broad range of genotypes and phenotypes.

PF499

ROLE OF SOMATIC MUTATIONS IN PATIENTS WITH LOW-RISK MYELODYSPLASTIC SYNDROMES TREATED WITH ERYTHROPOIESIS STIMULATING AGENTS

J.C. Caballero[1,*], J.M. Hernández Sánchez[2], M. Abáigar[2], F. Ramos[3], J. Cervera[4], E. Such[4], E. Luño[5], B. Navarro[6], M. Tormo[6], C. Chillón[7], M. Martín Izquierdo[2], K. Janusz[2], C. Robledo[2], E. Lumbreras[2], M. Cabrero[1], F. López Cadenas[1], A. Redondo Guijo[1], J.M. Hernández Rivas[2,8], C. Del Cañizo[1], M. Díez Campelo[1]

[1]Hematology Department, Hospital Universitario de Salamanca, [2]Centro de Investigación del Cáncer (CIC), IBSAL, Salamanca, [3]Hematology Department, Hospital Universitario de León, León, [4]Hematology Department, Hospital Universitario La Fe, Valencia, [5]Hematology Department, Hospital Universitario Central de Asturias, Oviedo, [6]Hematology Department, Hospital Clínico Universitario de Valencia, Valencia, [7]Molecular Biology Department, [8]Hematology, Hospital Universitario de Salamanca, Salamanca, Spain

Background: Up to 90% of patients with Low-Risk Myelodysplastic Syndromes (LR-MDS) have somatic mutations in driver genes by Next Generation Sequencing (NGS). Erythropoiesis Stimulating Agents (ESAs) are the most frequently used therapy for anemia in these patients.

Aims: To evaluate the impact of somatic mutations in patients with LR-MDS receiving ESA.

Methods: The results of HSCT in 65 MDS patients from five centres in Spain were retrospectively analyzed. DNA from bone marrow samples from diagnosis was screened for somatic mutations by NGS, using a MiSeq platform (Illumina) and a 117 myeloid genes panel. This project has received the following funds: PI17/01741; GRS 1349/A/16; GRS 1179/A/15; CM17/00171.

Results: We selected 24 patients (36.9%) with a prolonged erythroid response (>1 year) and 41 (63.1%) without response (no statistical differences between both groups). Median age was 76 years (p25-p75 78-80) and 50.8% were male. According to WHO 2008 classification 4 (6.5%) were RCUD, 18 (29%) RARS, 25 (40.3%) RCMD, 1 (1.6%) RAEB-1, 1 (1.6%) RAEB-2, 5 (8.1%) 5q- syndrome, 3 (4.8%) Unclassifiable MDS, 4 (6.5%) CMML and 1 (1.6%) was other MDS/MPL. Among patients with calculated IPSS (IPSS) (63 of 65 patients) 45 (71.4%) had low risk and 18 (28.6%) were intermediate-1 risk. Regarding R-IPSS (62 of 65) 17 (27.4%) were very low risk, 38 (61.3%) low risk and 7 (11.3%) were intermediate risk. Forty five patients (69.2%) were RBC transfusion dependent, 25 (67.9%) had EPO levels <100 U/L and 36 (67.9%) had ferritin levels <500 mg/dL. Regarding mutational status, median number of mutated genes per patient was 2, with a mean VAF of 32.5%. Only 8 patients (12.3%) did not presented mutations; 20 patients (30.8%) had 1 mutated gene, 19 (29.2%) had 2, 6 (9.2%) had 3, 7 (10.8%) had 4, 5 (7.7%) and 5 (7.7%) had 5 mutated genes. The most frequently mutated genes were: *SF3B1* in 34 patients

(52.3%), *DNMT3A* in 11 (16.9%), *TET2* in 9 (13.9%) and *SRSF2* in 7 (10.8%); the other mutated genes were presented with a frequency <10%. Most of the patients had mutations in the splicing gene family (47, 72.3%). We observed a trend to a better erythroid response among patients with ≤2 or less mutated genes (42.6% *vs* 22.2% in those with >2; p=0.159). No significant association was found between erythroid response and specific mutated genes, but a trend toward to a best response was observed in patients with *TET2* mutations (66.7% responses; p=0.066). The only significant variable related with erythroid response was transfusion dependency (p=0.001). After a median of follow up for survivors of 3.30 years, median Overall Survival (OS) was 5.04 years. Univariate analysis determined that age as a continuous variable, sex, WHO 2008 diagnosis, IPSS, R-IPSS, erythroid response, number of mutated genes (≤2 *vs* >2) and somatic mutations in *SRSF2*, *GNAS* and *STAG2* genes significantly influenced on OS. We did not found differences in OS among patients with mutations in *SF3B1* alone or in association with mutations in other genes. In the multivariate analysis variables that significantly influenced on OS were age, sex, IPSS, erythroid response and number of mutated genes (≤2 *vs* >2) (Table 1).

Table 1. Multivariate analysis.

	Sig.	HR	95,0% IC Low	95,0% IC Upper
Sex (ref. women)	,007	**3,520**	1,412	8,770
Age (continous)	,000	**1,137**	1,073	1,206
IPSS (ref. low)	,000	**4,885**	2,161	11,040
Erythroid response (ref. No R)	,009	**,286**	,113	,728
Number of mutated genes (≤2 vs. >2) (ref. ≤2 mut.)	,011	**3,146**	1,303	7,594

Summary and Conclusions: We conclude that the number of mutated genes in patients with LR-MDS receiving ESAs have a significant impact on OS and could be related with the erythroid responses.

PF500

MOLECULAR SCORING SYSTEM INTEGRATED WITH IPSS-R IN KOREAN MYELODYSPLASTIC SYNDROME

H.S. Park[1,*], J. Park[2], K. Im[3], S.-M. Kim[3], J. Yun[1], D. Jeong[1], S.M. Hwang[4], D.S. Lee[1]

[1]Department of Laboratory Medicine, Seoul National University, Seoul, Korea, Republic Of, [2]The Webb schools, Claremont, United States, [3]Seoul National University, Seoul, [4]Department of Laboratory Medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of

Background: Revised International Prognostic Scoring System (IPSS-R) is global prognostic system in myelodysplastic syndrome (MDS). Recently, multi-gene target sequencing is widely performed for the purpose of prognostic prediction and application of targeted therapy. In spite of many reports on the prognostic implication of somatic mutation, combined implication with conventional IPSS-R have not been reported yet.
Aims: Here we proposed a new scoring system that encompass gene variations and IPSS-R together.
Methods: In 153 patients diagnosed with MDS in Seoul National University Hospital, G-banding, fluorescence *in situ* hybridization (FISH), targeted capture sequencing for 88 hematopoiesis-related genes, and measurement of telomere length (TL) were performed. Kaplan-Meier survival analysis with the log-rank test and Cox proportional hazards regression analysis were used to develop a new prognostic system using Mathematica.
Results: We developed new model including targeted capture sequencing and telomere length addition to IPSS-R scoring. Overall, 128 of the 153 patients (83.7%) harbored at least one mutation. We calculated prognostic implication of genes with frequency over 5% or more (*ASL1, U2AF1, TP53, RUNX1, TET2, DNMT3A, SRSF2, BCOR, EZH2, SF3B1, STAG2*, and *WT1*) and prognostic implication of TL. Patients with telomere length <5.58 showed an adverse survival. In univariate analysis, age, IPSS-R score, mutation in *ASXL1, EZH2, TP53* and telomere length were significantly associated with OS. We developed a new scoring model incorporating the weighted coefficients of these variables: age 0.017+IPSS-R score 0.220+*ASXL1*mutation 0.375+ *EZH2* 0.706+*TP53* 0.897+Telomere length 3.376. The age and IPSS-R score were used as a continuous variable. The presence of gene mutations and TL below 5.58 was scored as 1. According to this new scoring system, patients were divided into *four* groups: low score cutoff (≤5.44), intermediate-1 (5.44-5.98), intermediate-2 (5.98-7.30), high (>7.30). The median OS was 100.0, 49.7, 33.5, 10.6 months for low, intermediate-1, intermediate-2, and high, retrospectively (p<0.001). Meanwhile, according to conventional IPSS-R scoring system, the median OS was 97.2, 78.2, 79.1, 62.8, 33.7 months for very low, low, intermediate, high and very high, retrospectively (p <0.001).
Summary and Conclusions: The newly developed model incorporating molecular variations and TL yielded more clear separations of the survival curves. By adding the presence of gene mutation and telomere length to the existing IPSS-R, its predictive ability can be further improved in MDS.

PF501

PROGNOSTIC IMPACT OF ASXL1 MUTATIONS IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND MULTILINEAGE DYSPLASIA WITH OR WITHOUT RING SIDEROBLASTS

A. Mangaonkar[1,*], T. Lasho[1], C. Finke[1], N. Gangat[1], A. Al-Kali[1], M. Elliott[1], K. Begna[1], C. Hanson[2], R. Ketterling[2], A. Wolanskyj[1], W. Hogan[1], M. Litzow[1], A. Pardanani[1], A. Tefferi[1], M. Patnaik[1]

[1]Hematology, [2]Pathology, Mayo Clinic, Rochester, United States

Background: The 2016 iteration of World Health Organization (WHO) classification of myeloid neoplasms removed the sub-category of 'refractory cytopenia with multilineage dysplasia' and reclassified patients with myelodysplastic syndromes (MDS) and multilineage dysplasia (MLD) into either myelodysplastic syndromes, ring sideroblasts with multilineage dysplasia (MDS-RS-MLD) or myelodysplastic syndromes with multilineage dysplasia (MDS-MLD); primarily based on the presence or absence of RS &/or *SF3B1* mutations (Arber *et al. Blood* 2016).
Aims: We sought to validate this morphology-based distinction in classification, in the context of myeloid relevant genomic alterations.
Methods: Consecutive cases of WHO-defined MDS-RS-MLD & MDS-MLD, meeting the 2016 WHO criteria were identified from our institutional database. Bone marrow (BM) biopsy reports & cytogenetics were re-reviewed. A targeted exome sequencing for myeloid-relevant genes was performed on BM specimens obtained at diagnosis.
Results: Ninety-eight patients were included in the study (Table 1); 59 with MDS-MLD & 39 with MDS-RS-MLD. Median age of the entire cohort was 73 years (range: 34-96) with 71 (72%) males. Fifty-five (56%) patients had an abnormal karyotype; while 9 patients (9%) had a monosomal karyotype. Targeted exome sequencing in 95 patients demonstrated the following mutational frequencies; *ASXL1* 32%, *SF3B1* 25%, *TET2* 21%, SRSF2 16%, *U2AF1* 12%, *TP53* 8%, *IDH2* 4%, *DNMT3A* 3%, 2% each for *IDH1*, *RUNX1* & *EZH2* and 1% each for *CALR, JAK2 & CBL*.
Among the significantly different variables; median platelet counts (p=0.03), percentage of patients with abnormal karyotypes (p=0.03) and as expected, BM ring sideroblast% (p<0.001) & frequency of *SF3B1* mutations (p<0.0001) were higher in the MDS-RS-MLD group; while *TET2* mutations were more frequent in the MDS-MLD group (31% *vs* 6%, p=0.002) (Table 1). At last follow up (median 95 months), 85 (87%) deaths & 11 (11%) leukemic transformations were documented. Median overall survival (OS) for the entire cohort was 25 months (Range: 1-102); with no significant difference between MDS-MLD 25 (0.5-100) and MDS-RS-MLD 25 (1-102) groups respectively (p=0.6, Figure 1A). In univariate survival analysis that included the aforementioned clinical, cytogenetic & molecular parameters; only older age (age>75 years, p=0.02), lower (<10 g/dL) Hb (p=0.009), lower (<100 x 10^9/L) platelet count (p=0.01), higher risk IPSS (p=0.007) and R-IPSS (p=0.017) cytogenetic categories (p=0.007), lack of *SF3B1* mutations (p=0.024), presence of *ASXL1* (p=0.007) & *TP53* (p=0.03) mutations adversely impacted OS. Presence of ring sideroblasts did not affect OS (p=0.98). In a multivariate model that included the variables significant on univariate analysis, only lower (<100 x 10^9/L) platelet count (HR 2.1, 95% CI 1.25-3.44, p=0.004) & presence of *ASXL1* mutation (HR 2.4, 95% CI 1.35-4.1, p=0.003) retained independent prognostic significance (Figure 1B). Further, in the context of IPSS & R-IPSS stratification, presence of *ASXL1* mutations retained prognostic relevance (p=0.003). Given the small number of events, leukemia free survival analysis was not performed.
Summary and Conclusions: While the 2016 iteration of the WHO classification of myeloid neoplasms has favored the re-introduction of sub-classifying MDS-MLD into cases with and without RS, in the context of genomic data this segregation is prognostically irrelevant. With this study, we once again, demonstrate the adverse prognostic impact of *ASXL1* mutations in MDS patients with multilineage dysplasia.

Table 1.

Variable; Median value (range or %)	*Cohort (n=98)*	*MDS-MLD (n=59)*	*MDS-RS-MLD (n=39)*	*P value*

CLINICAL OUTCOMES OF PATIENTS WITH MDS/MPN OVERLAP SYNDROMES

S. Kavanagh[1,*], C. McNamara[1], S. Chan[1], D. Maze[1], M. Minden[1], A. Schimmer[1], A. Schuh[1], H. Sibai[1], V. Gupta[1], K. Yee[1]

[1]Department of Medical Oncology and Haematology, Princess Margaret Cancer Centre, Toronto, Canada

Background: The myelodysplastic/myeloproliferative overlap syndromes (MDS/MPN) are a group of rare myeloid malignancies. They are a clinically diverse group with highly variable prognosis, often limited by transformation to acute myeloid leukaemia (AML), and have limited treatment options.
Aims: To examine the clinical outcomes, particularly following disease progression, in patients with MDS/MPN.

Methods: Patients with newly diagnosed MDS/MPN, treated at Princess Margaret Cancer Centre between January 2008 and December 2016, were identified through PMCC databases. Charts were reviewed. Diagnoses were classified as per the WHO (2016) schema. MDS/MPN treatment responses were classified under the 2015 Working Group proposal; AML responses were classified by 2017 ELN guidelines. DNA sequencing, using a 54-gene myeloid panel, was performed at diagnosis since February 2015.
Results: We identified 149 patients with a diagnosis of MDS/MPN. The median age was 67 years (28-99). Ten (6.7%) patients had atypical CML, 96 (64.4%) CMML, 10 (6.7%) MDS-MPN-RS-T and 33 (22.1%) MDS-MPN-unclassifiable. Twenty-three (15.4%) had previously received cytotoxic chemo- and/or radiation therapy and were diagnosed with therapy-related disease. Patients with CMML had low (37), intermediate-1 (20), intermediate-2 (29) or high risk (4) disease as per CPSS classification. Patients with other MDS-MPN syndromes had low (27), intermediate-1 (15), intermediate-2 (4) and high-risk (1) disease according to IPSS classification. Six patients with CMML and six with other MDS/MPN could not be classified in the absence of cytogenetic results. Molecular data was available in 44 patients and will be presented at EHA. Sixty-one patients (40.9%) experienced disease progression, 43 (70.5%) to AML, 5 (8.2%) isolated myeloid sarcoma and 13 (21.3%) accelerated phase, defined as 10-19% blasts in peripheral blood or bone marrow. The median time to progression from diagnosis was 226 days (range 21 – 1636). Twenty-six received induction chemotherapy, 12 of whom achieved CR. The remaining patients received low-intensity therapy or supportive care; 2 achieved CR on clinical trial and 1 achieved CR with azacitidine. Nine patients received allogeneic bone marrow transplant following progression (6 in CR; 2 after reversion to chronic phase; 1 unknown). Overall survival of the cohort is shown in Figure 1A. Median survival was not reached in patients with MDS-MPN-RS-T and was significantly longer than survival in aCML (938 days), CMML (779 days) and MDS-MPN-u (491 days) ($p<0.05$ for all). There was no difference in survival between other MDS-MPN subgroups. OS was significantly shorter in patients who had disease progression compared to those patients who did not (538 *vs* 1005 days; p=0.012). No difference in survival, calculated from time of progression, was seen between those receiving intensive chemotherapy or less-intense therapy/supportive care for disease progression. In those achieving CR following treatment for disease progression, bone marrow transplantation was associated with superior OS (Figure 1B; 1866 *vs* 486 days, p=0.01).

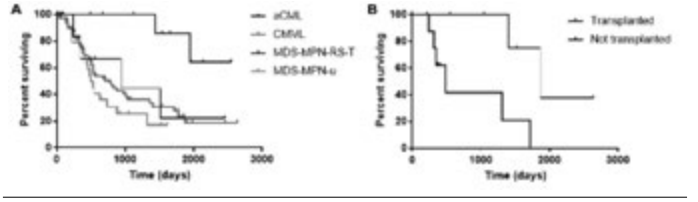

Figure 1.

Summary and Conclusions: In conclusion, survival is poor in MDS-MPN patients who progress. Allogeneic bone marrow transplantation remains the only option for long-term disease control in this situation. There is an unmet need to better characterise, prognosticate and develop appropriate treatment strategies for patients with these neoplasms.

PF503

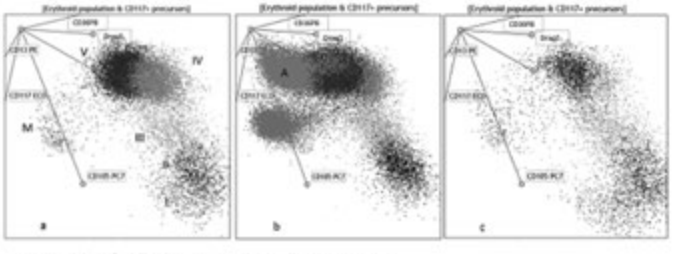
FLOW CYTOMETRY ANALYSIS OF ERYTHROPOIETIC MATURATION PATTERNS HELP TO DIAGNOSE AND FOLLOW-UP ERYTHROPOIETIC DYSPLASIA IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES

A. Porwit[1], D. Violidaki[1,*], O. Axler[1], M. Ehinger[1], K. Jafari[2], K. Navred[3], L. Nilsson[4]

[1]Clinical Sciences, Division Oncology and Pathology, Lund University, Lund, Sweden, [2]Pathology, Cross Cancer Institute, Edmonton, Canada, [3]Laboratory Medicine, Blekinge Hospital, Karlskrona, [4]Hematology, Lund University, Lund, Sweden

Background: Anemia, erythropoietic dysplasia and morphological signs of disturbance in erythropoietic maturation in the bone marrow (BM) are seen in most patients with myelodysplastic syndromes (MDS). By flow cytometry (FC), the reported changes in the erythropoietic compartment in MDS are increased CD36 CV, CD71 CV, MFI of CD71 and increased fraction of CD117+ erythroid cells.
Aims: To evaluate the recently developed single tube FC panel (ERY) and radar plot analysis protocol that facilitate adequate estimation of various BM cell compartments and assessment of erythropoietic differentiation pattern.
Methods: 250x10^3 BM cells were incubated with ERY panel: CD71FITC, CD13PE, CD117ECD, CD105PC7, CD36PB and CD45KO and 10 ml of 0.5

mM DRAQ5 (10 resp. 15 min in the dark). $10x10^5$ $DRAQ5^+$ events were acquired with a Navios flow cytometer and analyzed using Kaluza software. Myeloid compartment was evaluated by Ogata score using 10-color, 14 antibody screening tube (SC). The results were compared with cytological evaluation of BM smears by 500 cell differential count. Dysplasia was evaluated as high (>30% of erythropoietic cells), low (10-30%) and absent (<10%).
Results: BM Samples included 19 normal BM, 35 BM samples from patients with anemia but no dysplasia (hospital controls, HC) and 66 BM samples from patients with MDS (30% MDS-MLD, 17% MDS-RS-MLD, 21% MDS-EB1, 23% MDS-EB2 and 9% MDS 5q, according to WHO 2016). The frequency of erythropoietic cells derived from ERY tube showed better correlation with morphological differential count (R^2=0.7759) than counts obtained by the SC tube. The frequency of erythropoietic cells in SC was significantly lower, which could lead to overestimation of CD34+ cell counts. In normal BM, CD117+ myeloid cells were 0.4% (range 0.1-1.1%). Erythroid cluster was gated as CD71+/CD45- (mean 19%, range 3.4-29.5%) and we could confirm that CD36 and CD71 CV in erythroid compartment were higher in MDS patients than in control groups (p<0.05). The following subpopulations could be recognized using Radar plots analysis: the earliest precursors (CD117+/CD105+, mean 1.8% of erythropoiesis) followed by CD117-/CD105++ (mean 4.5%), CD117-/CD105dim (mean 6.6%), CD105-/CD36++ (mean 25.8%), and CD105-/CD36dim (mean 60.9%). These subpopulations created a reproducible pattern of maturation in all normal BM (Figure1a). Deviations from this normal pattern could be seen in 68% of MDS patients. In 45% of MDS patients, an aberrant cluster of CD105- erythroids with low expression of CD71 and CD36 (2-48% of erythroids) was noted (Figure 1b). This cluster was seen in 16% HC patients (0.5%>12% of erythroids). In patients showing this cluster, the fractions of early and proliferating erythroids were decreased. In 23% of MDS patients and 12% of HC, fractions of immature CD105+ erythroids were high and later stages were decreased (Figure 1c). 58% of MDS patients showed an increased cluster of CD117+ myeloid blasts (mean 3.6%, range 0.2-16%). In 8 MDS patients, follow-up samples were available. Changes in erythropoietic maturation patterns could be observed after VIDAZA treatment and normalization was seen after BM transplantation.



Radar analysis of erythroid maturation pattern and CD117+ precursors.
1a.Normal pattern, 1b.Aberrant pattern 1 with aberrant CD71dim/CD36dim population (A, light brown).
1c. Aberrant pattern 2 with high fraction of CD105+ immature erythroids.

Figure 1.

Summary and Conclusions: The developed panel allows adequate assessment of erythroid cell compartment, which could be of use in diagnosis of erythroid dysplasia and help in evaluation of treatment response.

PF504

MUTATIONS AND KARYOTYPE PREDICT TREATMENT RESPONSE IN MYELODYSPLASTIC SYNDROMES

D. Idossa[1,*], T. Lasho[2], M. Mudireddy[2], C. Finke[2], K. Rhett[3], M. Patnaik[2], A. Pardanani[2], N. Gangat[2], A. Tefferi[2]

[1]Internal Medicine, [2]Division of Hematology, [3]Laboratory Medicine, Mayo Clinic Rochester, Rochester, United States

Background: Myelodysplastic syndromes (MDS) comprise a heterogeneous group of malignant hematopoietic stem cell disorders that result in dysplastic and ineffective hematopoiesis, with variable risk of death and transformation to acute myeloid leukemia. Thus, treatment options also vary from watchful waiting and supportive care to disease modifying therapy and allogeneic stem cell transplant. With the advent of next generation sequencing (NGS), a number of prognostically-relevant mutations and karyotype have now been described in MDS.
Aims: To examined the influence of mutations and karyotype on conventional treatment response in myelodysplastic syndromes (MDS).
Methods: Cytogenetic and NGS-derived mutation information and treatment details were available for 159 patients evaluated and followed at our institution for MDS. A retrospective chart review was conducted for these patients to obtain information regarding treatments received and their response.
Results: 159 patients (median age 72 years; 68% males) were included in the analysis. IPSS-R risk distribution was very high in 11%, high 18%, intermediate 17%, low 38% and very low 16%. At least one mutation was detected in 83% of the patients; most frequent were *ASXL1* (27%), *TET2* (25%), *SF3B1* (21%), *SRSF2* (16%), *U2AF1* (14%), *TP53* (13%), *RUNX1* (11%) and *DNMT3A* (10%). At median follow-up of 30 months, treatment with hypomethylating agents (HMAs) was documented in 65 (41%) patients, immunomodulatory drugs (IMiDs) in 31 (19%) and erythropoiesis stimulating agents (ESAs) in 68 (43%). Genetic markers predicted treatment response to HMAs and IMiDs, but not to ESAs. HMA treatment response was positively affected by *IDH1* mutations (100% *vs* 47%; p=0.04) and negatively by *TP53* mutations (11% *vs* 55%; p=0.03) and monosomal karyotype (MK) or trisomy 8 (13%, 13% *vs* 71% for normal karyotype; p=0.007). IMiD response was unlikely in patients with *U2AF1* mutations (0% *vs* 46%; p=0.02) and in those with MK (0%). Multivariate logistic regression confirmed HMA treatment response effect from *TP53* and *IDH1* and IMiD response effect from *U2AF1* mutations. Absence of red cell transfusion need was the only other clinical variable with additional value in predicting response to HMAs or ESAs.
Summary and Conclusions: We conclude that MDS patients with *TP53* mutations are unlikely to respond to HMAs and those with *U2AF1* to IMiDs.

PF505

GENDER AND THE PATTERN OF RECURRENT MYELOID MUTATIONS ARE STRONGLY AND INDEPENDENTLY ASSOCIATED TO BLOOD TRANSFUSION INTENSITY IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES

J. Rydén[1,2,*], G. Edgren[3,4], M. Karimi[1], G. Walldin[1,2], M. Tobiasson[1,2], A. Wikman[5,6], E. Hellström-Lindberg[1,2], P. Höglund[1,5]

[1]Department of Medicine, Karolinska Institutet, Huddinge, Stockholm, [2]Department of Hematology, Karolinska University Hospital, [3]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, [4]Department of Cardiology, Stockholm South Hospital, [5]Department of Clinical Immunology and Transfusion Medicine, [6]Department of Laboratory Medicine, Karolinska University Hospital, Stockholm, Sweden

Background: Patients with myelodysplastic syndromes (MDS) frequently receive large numbers of blood transfusions over the course of the disease, but little is known about the clinical and disease-specific factors that drive the transfusion need and intensity in these patients.
Aims: This study aimed to identify clinical and disease-specific factors associated to transfusion need and to study the association between transfusion intensity and patient survival.
Methods: We established a retrospective cohort of MDS patients from the Karolinska University Hospital, Stockholm, Sweden, with detailed clinical information, complete transfusion data, and the pattern of recurrent myeloid mutations. Variables associated to transfusion intensity were estimated using a time-dependent Poisson regression and the association between transfusion intensity and risk of death was estimated using a time-dependent Cox regression.
Results: In addition to very high-risk disease according to the revised International Prognostic Scoring System (IPSS-R), male sex and mutational patterns were independently and significantly associated to high red cell and platelet transfusion requirements. Specifically, mutations involved in histone modulation, signaling and transcriptional regulation were independently associated with a higher transfusion need. Transfusion intensity during the past year was strongly associated with poor survival, when accounting for this variable, IPSS-R lost significance and only mutations in histone modulators were independently linked to survival.
Summary and Conclusions: The mutational profile in MDS is strongly associated to transfusion intensity, which indicates the involvement of specific gene pathways in ineffective hematopoiesis. Moreover, transfusion intensity has a stronger association to poor survival than previously recognized, which warrants further investigation.

PF506

DIFFERENCES IN MUTATIONAL PROFILE AND CLONAL ARCHITECTURE OF MYELODYSPLASTIC SYNDROMES WITH ISOLATED DELETION OF 5Q, HYPERPLASTIC AND HYPOPLASTIC MYELODYSPLASTIC SYNDROMES

F. Hernández Mohedo[1,*], J. Badiola[1], E. Cornejo[1], M. Bernal[2], P. Montes[2], F. Ruiz Cabello[2], A.R. Gonzalez[3], M. Jurado Chacón[1]

[1]Hematology, [2]Inmunology, [3]Investigation FIBAO, Complejo Hospitalario Universitario de Granada, Granada, Spain

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of hematologic malignancies. Although most MDS patients have normal or increased cellularity (NH- MDS), approximately 10-20% of them have hypocellular bone marrow (h-MDS). The reports concerning the differences in genetic alterations between them are limited, but h-MDS seems to be a different clinical-biological entity with a different molecular profile, and a better overall survival.
Aims: Our aim has been to investigate the molecular profile in MDS, in the sense of number of driver mutations, the dominant molecular pathway altered and the incidence of high risk mutation (HRM) between three categories of MDS: h-MDS, NH-MDS and MDS with islolated del(5q).
Methods: We performed a prospective analysis from January 2016 to December 2017, in 69 patients with MDS diagnostic divided in 3 groups: (A) NH-MDS, (B) h-MDS (≤25% bone marrow cellularity) and (C) MDS with isolated del(5q). The molecular profile was analyzed by next-generation gene sequencing technology (NGS Sophia Genetics-Illumina Sequencing analysis v.1.8.37). We analyze the number of driver mutations by molecular pathway (Splicing, Cohesin, DNA Metylation, Transcription, Chromatin modification, tumor suppressor,etc) and we categorize as High Risk molecular score if at least one of these conditions is present: (1) ≥1 High risk mutations (HRM) TP53, RUNX1, ASXL1, EZH2, and ETV6 (Bejar, *et al.* N Engl J Med 2011), (2) ≥2 driver HRM mutations or ≥1 HRM plus TP53 and (3) High variant allele frequency in HRM mutations (VAF ≥40%). The statistical analysis was performed with software IBM SPSS.21. Categorical variables were compared using a Chi-squared test, while continuous variables were compared using a Wilcoxon rank-sum test. P-values are two-sided and considered significant at the <0.01 level.
Results: In the 69 MDS, diagnostic classification was: 47 NH-MDS, 11 h-MDS and 11 MDS with isolated del(5q). The analysis by molecular pathway don't show differences between the 3 subtypes of MDS patients. By contrast, MDS with isolated del(5q) had lower mutational score than NH-MDS(HRM 0,5 *vs* 2;p=0.01), lower variant allele frequency HMR than NH-MDS(VAF ≥40%:1,7% *vs* 39,7%;p=0.019) and NH-MDS had higher bone marrow blast than h-MDS(4% *vs* 2%;p=0,006). The IPSS-R risk category don't show differences between the 3 subtypes of MDS patients.
Summary and Conclusions: In patients with MDS with isolated del(5q), we observe a lower incidence HMR driver mutations, lower score of HRM and VAF than NH-MDS, and don't seam to be depended on IPSS-R score. The analysis of driver mutations by molecular pathway, don't show diferences by disease subtypee. Our results suggest that MDS with isolated del(5q) have a different clonal architecture with lower risk molecular score, and this can explain the better overall survival previously described in this disease. In the majority of patients with MDS-h we olso observe a lower incidence of HMR driver mutations compared with MDS-NH, but the differences were not statistically significant. In the near future, integration of the somatic mutation with IPSS-R score could better stratifie the risk group and the therapeutic plan on Hypopplastic MDS and MDS with isolated del(5q).

PF507

CLINICAL SIGNIFICANCE OF REDUCED EXPRESSION OF THE GENES LOCATED WITHIN COMMON DELETED REGION OF DEL(20Q) IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES

M. Shiseki[1,*], M. Ishii[1], M. Ohwashi[1], Y.-H. Wang[1], K. Yoshinaga[1], N. Mori[1], J. Tanaka[1]

[1]Department of Hematology, Tokyo Women's Medical University, Tokyo, Japan

Background: Deletion of long arm of chromosome 20 (del(20q)) is observed in 5 to 10% of patients with myelodysplastic syndromes (MDS). Although biological significance of del(20q) in MDS pathogenesis has not been fully elucidated, it has been considered that common deleted regions (CDRs) of del(20q) contain target genes involved in molecular pathogenesis of MDS. Previously, we determined a CDR of del(20q) in MDS patients by an array comparative genomic hybridization analysis. The CDR contains more than 150 genes.
Aims: We examined expression of selected 28 genes within the CDR, including candidate tumor suppressor genes, and/or the genes involved in cell growth, death, and differentiation,in order to investigate clinical significance of each gene expression level.
Methods: Bone marrow samples of the patients with MDS at the time of diagnosis and those of control subjects were used for analysis. RQ-PCR was carried out to examine expression of 28 genes by the TaqMan probe method. To compare expression level of each gene between MDS patients and control subjects, a non-parametric test was used. Kaplan-Meier plots were used for estimation of survival. The COX proportional hazards model was employed to analyze impact of expression of each gene examined on overall survival (OS). The study was conducted according to the Declaration of Helsinki, and the protocol was reviewed by institutional ethics committee.
Results: We examined expression of the 28 genes in 48 MDS patients with (n=28) or without (n=20) chromosome 20 abnormalities, and control subjects (n=15). A total of 15 genes examined showed significant reduced expression in MDS patients with chromosome 20 abnormalities, compared to control subjects. In addition, expression of *BCAS4, ADA, and YWHAB* genes was significantly reduced in MDS patients without chromosome 20 abnormalities. We analyzed impact of expression level of each gene on OS to evaluate clinical significance of reduced expression, by employing the Cox proportional hazards model. Univariable analysis indicated association between inferior survival and reduced expression of five genes, *MMP9 BCAS4, BGALT5, SULF2,* and *ZNF335.* Multivariable analysis indicated that reduced *BCAS4* expression showed trend toward for association with inferior OS (P=0.0509). According to *BCAS4* expression level, we divided 48 MDS patients into two groups, low expression (less than median value) and high expression group (median or higher). Patients with high BCAS4 expression (median or higher) (H-group) showed superior survival to those with low BCAS4 expression (less than median) (L-group) (log-rank test, P=0.0022). Estimated median OS times were 67 months (H-group) and 32 months (L-group).
Summary and Conclusions: In conclusion, we analyzed expression of 28 genes located within CDR of del(20q), and expression of 15 genes was significantly reduced in MDS patients with chromosome 20 abnormalities, compared to control subjects. In addition, expression of *BCAS4, ADA,* and *YWHAB* genes was significantly reduced in MDS patients without chromosome 20 abnormalities. Five genes (*MMP9, BCAS4, B4GALT5, SULF2,* and *ZNF335*) showed clinical significance.

PF508

HIGH WT1 EXPRESSION LEVELS AT DIAGNOSIS PREDICTED POOR OUTCOMES OF PATIENTS PRESENTING ISOLATED THROMBOCYTOPENIA AT ONSET OF MYELODYSPLASTIC SYNDROME

Q.-S. Huang[1,*], X. Liu[1,2,3], R.-Y. Gui[1], J. Wu[1], X. Cai[1], Q. Jiang[1,2,3], H. Jiang[1,2,3], J. Lu[1,2,3], H.-X. Liu[4], X.-Y. Zhao[1,2,3], Y.-J. Chang[1,2,3], Y.-Z. Qin[1], Y.-R. Liu[1], L.-P. Xu[1,2,3], K.-Y. Liu[1,2,3], X.-J. Huang[1,2,3], X.-H. Zhang[1,2,3]

[1]Peking University Institute of Hematology, Peking University People's Hospital, [2]Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, [3]Collaborative Innovation Center of Hematology, Peking University, [4]Department of Clinical Epidemiology, Peking University People's Hospital, Beijing, China

Background: Myelodysplastic syndromes (MDS) comprise a heterogeneous group of clonal disorders of hematopoietic stem cell origin. Isolated thrombocytopenia is rare as the first presentation of patients with MDS. There is no information available on clinical characteristics, appropriate treatment, and prognosis of isolated thrombocytopenia MDS.Our findings demonstrate that haploidentical stem cell transplantation (haplo-SCT) is a reliable therapy for patients with MDS. WT1 is a transcription factor overexpressed in diverse neoplasms, including MDS. Accumulating evidence has suggested that WT1 expression levels increased in accordance with the aggressiveness of the disease in MDS. Therefore, whether WT1 expression could predict responses to specific interventions, including chemotherapy alone and haplo-SCT in patients with MDS presenting with isolated thrombocytopenia is unclear.
Aims: The aim of this study was to determine the WT1 expression level, morphologic, cytogenetic and the prognostic features of MDS presenting with isolated thrombocytopenia, to investigate the prognostic effect of WT1 expression level and to explore proper treatment methods.
Methods: We performed a retrospective nested case-control study in patients presenting with isolated thrombocytopenia at the onset of MDS. Patients were reviewed retrospectively from all the patients who were diagnosed with MDS between July 2007 and February 2018 at Peking University People's Hospital. WT1>1.0% was defined high-level expression according to our previous study(Zhao XS, 2012). In total, 280 patients with isolated thrombocytopenia as the first presentation (group A), 300 patients with two cytopenias (group B), and 300 patients with three cytopenias (group C) were enrolled in this study.
Results: During the 11-year period, 8100 patients were diagnosed with MDS. A total of 280 patients had isolated thrombocytopenia as the first presentation of MDS. Median cell counts at the time of first presentation were Hb 129.5g/L, ANC 3.6X10^9/L, and PLT 46.5X10^9/L. The most common cytogenetic profile, IPSS-R risk score, and WHO classification were normal karyotype, low, and MDS-SLD, respectively. Leukemia transformation occurred in 42 patients (15%). At the time of diagnosis with MDS, WT1 expression >1.0% was identified in 70.6%, 74.7%, and 78.5% of group A, group B, and group C, respectively. Median duration of isolated thrombocytopenia before diagnosis of MDS was 14.6 months (range 0-105

months). Median follow-up of the whole 280 patient cohort was 120 months, and the overall survival(OS) of group A was significantly longer than that of group B and group C, reflecting the favorable prognosis of isolated thrombocytopenia. In group A, WT1 high-expressing patients had a shorter OS than that of the WT1 low-expressing patients. Among the 280 patients, 69 patients underwent haplo-SCT, and 152 patients underwent chemotherapy. Patients undergoing haplo-SCT had a longer OS and progression-free survival(PFS) than that of chemotherapy patients. For patients undergoing haplo-SCT, in uni-variable and multi-variable analysis, WT1>1.0% was associated with shorter OS and PFS. Three-year OS in patients with WT1≤1.0% was longer than patients with WT1>1.0%.
Summary and Conclusions: Isolated thrombocytopenia as the first presentation of MDS had a low WT1 expression level and favorable outcome, compared to two cytopenias and three cytopenias. Haplo-SCT is superior to chemotherapy for these patients, after which the WT1 expression level could predict clinical outcomes and provide a potential way for suitable interventions.

PF509

ROLE OF DNA METHYLATION GENE AND TP53 MUTATIONS IN PREDICTING THE CLINICAL EFFICACY OF EPIGENETIC THERAPY IN MYELOID NEOPLASM PATIENTS - META ANALYSIS

L. Cai[1,*], H. Wang[1], Q. Chen[1]

[1]Hematology, Huazhong University of Science and Technology, Wuhan, China, Wuhan, China

Background: Myelodysplastic syndromes and acute myeloid leukemia (MDS and AML) are both heterogeneous myeloid disorders. Numerous genetic and epigenetic gene mutations are now identified in these patients such as mutation of TET2, DNMT3A, IDH1/2 and TP53. Hypomethylating agents (HMAs, azacitidine and decitabine), which results in overall response rates (ORR) of up to 50% and overall survival(OS) improvement, are now routinely used in MDS/AML patients. However, patients who do not response to HMAs get very poor outcome with a median OS of less than 6 months. Therefore, reliable markers predicting the clinical efficacy of HMAs to assist better selection of patients who really benefit from the HMAs are urgently needed in clinic.
Aims: This study is aim to assess the predictive role of mutations($TET2^{MUT}$, $DNMT3A^{MUT}$, $IDH1/2^{MUT}$ and $TP53^{MUT}$) on clinical efficacy of HMAs in MDS/AML patients.
Methods: We performed a Meta-analysis to summarize the existing evidences. We systematically searched PubMed, Embase, Cochrane and the Wan Fang database until 01 October 2017. Studies including MDS/AML patients treated with HMAs and providing available response and survival data were eligible. All data were analyzed within Revman 5.3 software.
Results: 317 papers were initially searched. Finally, 20 studies(participants, N=1710 patients) focusing on one or more genes mutations were included. Especially, 10 studies focus on $DNMT3A^{MUT}$,11 on $TET2^{MUT}$, 8 on $IDH1/2^{MUT}$, and 11 on $TP53^{MUT}$. For ORR, the pooled ORs (odds ratio, MUT *vs* WT) were calculated, only $TET2^{MUT}$ and $IDH1/2^{MUT}$ are significant factors ($TET2^{MUT}$OR=1.44, P=0.03; $IDH1/2^{MUT}$ OR=0.50, P=0.001; $DNMT3A^{MUT}$ OR=1.14, P= 0.53; $TP53^{MUT}$ OR=1.25, P=0.44). $TET2^{MUT}$ which acquires a slightly improvement of ORR(MUT *vs* WT:52.7% *vs* 46.7%) are further identified as having no significant impact on ORR. The combined mutations of $TET2^{MUT}$, $ASXL1^{MUT}$, $SF3B1^{MUT}$ and $RUNX1^{MUT}$, have no additional influence on treatment effect ($TET2^{MUT}$ $ASXL1^{WT}$*vs* others, OR=1.13, P= 0.78; $ASXL1^{MUT}$, OR=1.09, P= 0.59; $RUNX1^{MUT}$ OR=0.92, P= 0.73; $SF3B1^{MUT}$ OR=0.91, P= 0.77). For OS, the pooled HRs(hazard ratio) were calculated, $TP53^{MUT}$ and $DNMT3A^{MUT}$ turn to be poor factors ($DNMT3A^{MUT}$ HR=1.60, P=0.007; $TP53^{MUT}$ HR=2.53, P<0.00001; $TET2^{MUT}$ HR=1.12, P=0.34), the pooled HR was not assessed for $IDH1/2^{MUT}$ owing to limited studies.
Summary and Conclusions: Our results show that, in MDS/AML patients, $TP53^{MUT}$ patients who are resistant to conventional chemotherapy would benefit form HMAs, while $IDH1/2^{MUT}$ patients who proved to be resistant to HMAs should explore other new agents. $TET2^{MUT}$ and $DNMT3A^{MUT}$ patients do not get additional benefits from HMAs. In a word, these mutations can be used together to better select patients who really benefit form the epigenetic treatment.

PF510

THE EVALUATION OF OXIDATIVE STRESS AND IRON METABOLISM MARKERS IN MYELODYSPLASTIC SYNDROMES

M.-A. Gaman[1,*], C. Horescu[2], A.M. Gaman[2,3]

[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Bucharest, [2]Pathophysiology, University of Medicine and Pharmacy of Craiova, [3]Hematology, Filantropia City Hospital of Craiova, Craiova, Romania

Background: Myelodysplastic syndromes are clonal hematopoietic disorders characterized by hypercellular bone marrow with dysmyelopoiesis and peripheral blood cytopenias. Oxidative stress is involved in the aging process and in a manifold of hematological disorders (essential thrombocythemia, chronic lymphocytic leukemia or immune thrombocytopenia). Studies hypothesize that oxidative stress may be involved in the clonal expansion and transformation to AML of MDS, with prior studies reporting elevated levels of reactive oxygen species and a reduced total antioxidant capacity in plasma of MDS patients[1-8].
Aims: To evaluate the level of reactive oxygen species and the antioxidant capacity in MDS patients and healthy volunteers in relation to the iron metabolism.
Methods: We evaluated 30 patients with MDS hospitalized in the Clinic of Hematology, Filantropia City Hospital Craiova, Romania. Informed consent was obtained from all patients and healthy controls enrolled in the study. Oxidative stress was evaluated using a CR3000 analyzer from a single drop of capillary blood. Reactive oxygen species were evaluated by FORT (Free Oxygen Radicals Testing) and the total antioxidant capacity by the FORD (Free Oxygen Radicals Defense) assays. The normal range for the assays is: FORT <2.3 mmol/L H_2O_2 and FORD=1.07 – 1.53 mmol/L. Hemoglobin and parameters of iron metabolism (ferritin and serum iron) were also evaluated. The statistical analysis was performed using the student T-test. A p value ≤0.05 was considered significant.
Results: The male/female ratio was 1.5/1 (mean age=68 years). The distribution on MDS type was: refractory anemia (RA) – 14 patients, refractory anemia with ringed sideroblasts – 2 patients, refractory cytopenia with multi-lineage dysplasia – 4 patients, refractory anemia with excess blasts type 1 (RAEB1) – 3 patients, refractory anemia with excess blasts type 2 (RAEB2) – 5 patients, 5q deletion syndrome – 1 patient, and unclassified MDS – 1 patient. We registered medium high FORT levels in all MDS patients compared to controls (p≤0.05), but higher in patients with RAEB1 and RAEB2, and especially in patients with AML transformation (p≤0.05). FORD levels were lower in patients with MDS compared to controls (p≤0.05), and even lower in patients with RAEB2 transformed in AML (p≤0.05). MDS patients had high levels of ferritin compared to controls (p≤0.05), with significant differences in patients with RAEB2 and blastic transformation. We found a positive correlation between FORT and ferritin levels (Pearson correlation coefficient=0.774) and a weak negative correlation between FORT and hemoglobin values (Pearson correlation coefficient=-0.498) (Table 1).

Table 1.

	RA	RAEB1	RAEB2	RAEB2 → AML
Hemoglobin [g/dL]	8.57	8.3	7	6.87
Serum iron [μg/dL]	152.5	194.33	247.5	279.33
Ferritin [ng/mL]	370.3	1074.67	1923	3090
FORT [mmol/L H_2O_2]	2.51	3.03	3.45	3.95
FORD [mmol/L]	0.88	0.42	0.37	0.23

Summary and Conclusions: In our study, increased markers of oxidative stress and of iron metabolism were found in MDS patients compared to healthy controls. We may hypothesize that the level of oxidative stress and iron markers may be linked to the clonal expansion in MDS and possibly in the transformation to AML.

MUTATIONS IN 19S PROTEASOME SUBUNITS REPRESENT A NOVEL MECHANISM OF ACQUIRED RESISTANCE TO PROTEASOME INHIBITORS IN MULTIPLE MYELOMA PATIENTS

S. Barrio[1,*], M. Simicek[2,3], M. DaVia[1], K. Growkova[2,3], M. Bittrich[1], H. Einsele[1], R. Hajek[2,3], K. M. Kortüm[1]

[1]Medizin II, Universitätsklinikum Würzburg, Würzburg, Germany, [2]Haematology, Ostrava University Hospital, [3]Faculty of Medizine, Ostrava University, Ostrava, Czech Republic

Background: The 26S proteasome is a large multiprotein complex responsible for protein degradation. It is composed of two parts: the regulatory complex (19S) and the catalytical core (20S). Inhibition of this molecular machine is a backbone in the treatment of multiple myeloma (MM). Mutations in *PSMB5* (20S subunit, a direct target of proteasomal inhibitors (PIs)) have been described *in vitro and in vivo*. Recently, down-regulation of genes encoding 19S subunits was related to PIs resistance (Tsvetkov, *et al* eLife 2017).
Aims: Through a meta-analysis of published MM genomic data, we aimed to explore the impact of proteasome mutations in MM patients before and after the PI therapy, and define their potential role in the PI resistance.
Methods: We have analyzed publically available genomic data from 1.714 MM patient samples. From these, 1.219 come from Whole Exome Sequencing (WES) dataset and includes 910 patient samples at diagnosis and 309 from patients previously exposed to the PI therapy. We have combined this data with 495 patient samples analyzed by targeted sequencing (M3P sequencing panel containing *PSMA1*, *PSMD1*, *PSMB5*, *PSMB8* and *PSMB9* subunits). Additionally, we included our WES data from 7 MM patients with minimal residual disease.
Results: We have found mutations in 27 proteasome subunits. The mutational rate at the time of diagnosis was low (<0.5%) for all the 26S subunits, suggesting on any or little importance in the development of MM. However, we observed a significant increase in the mutational rate in the proteasomal subunits after the therapy. In total, 50 out of 910 (5,5%) newly diagnosed patients and 30 out of 316 (9,5%) of pretreated patients have mutations in at least one proteasome subunit. Besides *PSMB5*, most of these alterations occurred in the 19S subunits. Mutations were detected mainly in the subunits responsible for binding of ubiquitinated proteins (PSMD1 and PSMD2) and in the enzymes forming the hexameric AAA ATPase (PSMC1-6). For the ubiquitin receptor *PSMD1* the mutational rate increased from 0,24% at diagnosis to 2,3% after therapy (Z score 4,3. p<0.001), and 5 out of the 11 mutations detected in *PSMD1* clustered in the PSMD2 binding region. From the ATPase subunits, the two mutations detected in PSMC2 were not present at diagnosis (p.R284C 0% *vs* 28% and p.Y429S 0% *vs* 44%) and were located in close proximity to the ATP binding site. Indeed most of the ATPase subunits mutations (9 out of 10) were located directly or in close proximity of the ATP binding suggesting that mechanisms of the PI resistance could be related to the compromised functions of the 19S proteasome regulatory complex (Figure 1).

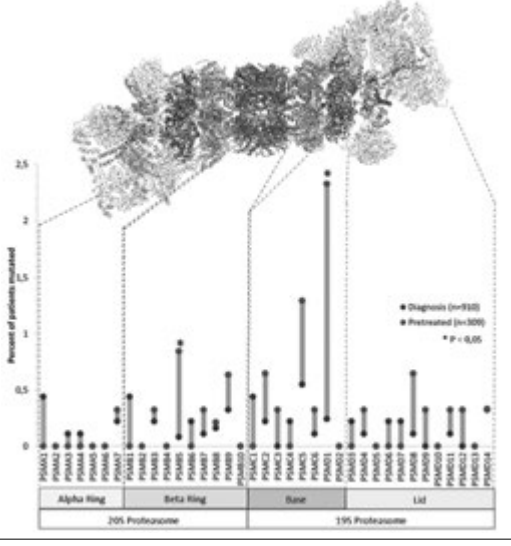

Figure 1.

Summary and Conclusions: The mechanisms of resistance to PIs are not fully understood. We and others have identified mutations in the PI binding subunit *PSMB5* after PI treatment. However, this proteasomal subunit is affected only very rarely in MM patients. Recently, downregulation of the 19S proteasome subunits was proposed as an alternative mechanism of PIs resistance due to the increase in the 20S/26S ratio and changes in transcription. Here, we present an analysis of a large cohort of MM patients with mutations in the 19S subunits, which were significantly enriched after treatment. Identified mutations in 19S will likely affect recognition of the ubiquitinated proteins by proteasome as well as protein unfolding and 20S gate opening. The patient-derived mutations indicate on novel mechanisms in the development of PI resistance in MM. Functional analysis of the mutations is ongoing and results will be presented at the meeting.

PF512

EXPRESSION OF P53 ISOFORMS AT MRNA LEVEL IN MULTIPLE MYELOMA: IMPLICATIONS FOR CLINICAL OUTCOME

Background: Loss and/or mutation of the *TP53* gene are associated with short survival in multiple myeloma (MM). Although both genetic abnormalities are routinely explored in the clinical practice, the p53 landscape goes far beyond the *TP53* deletion or mutation. At least 9 p53 mRNA isoforms have been found to be expressed by the *TP53* gene, due the combination of alternative splicing, usage of alternative promoter and/or alternative transcription site start: p53α, p53β, p53γ, Δ40p53α, Δ40p53β, Δ40p53γ, Δ133p53α, Δ133p53β and Δ133p53γ. They can be grouped depending on the molecular mechanisms that lead to their formation as α, β, γ, TA (full length), Δ40 and Δ133 subclasses. Although the deregulation of p53 isoform expression has been described in several cancers, to date, there are no studies evaluating their expression in MM.
Aims: To analyze the relative expression of p53 mRNA isoforms in MM and to evaluate the impact on MM treatment response and survival.
Methods: A total of 89 CD138-selected cell samples from newly diagnosed MM patients enrolled in the clinical trial of the Spanish Myeloma Group, VRD-GEM followed by ASCT conditioned with Mel-200 *versus* BuMel, were included in the study. The quantification of *TP53* gene and the subclasses of p53 mRNA isoforms were carried out by Taqman Real-Time PCR assays. Specific primers were used to quantify TA/∅40, ∅133, α, β, and γ subclasses. The gene/isoforms that had a Ct value ≥35 were considered as not expressed in that sample. The relative expression of the p53 gene and isoforms was normalized to 18S rRNA (ΔCt) and expressed as the fold change (FC) calculated using the $2^{\Delta\Delta Ct}$ method. The statistical analysis was carried out with IBM SPSS Statistics 22.0 and the Simfit package. Progression free survival (PFS) and overall survival (OS) were calculated for each isoform subclass. Survival curves were plotted by means of the Kaplan-Meier method and statistical significance was tested using the log-rank test. The Cutoff Finder software was used to obtain the optimal cutoff.
Results: The α and TA/∅40 p53 subclasses were expressed in all MM samples analyzed, while β, ∅133 and γ subclasses were expressed in 87% (77/89), 71% (63/89), and 48% (43/89) of MM samples, respectively. *TP53* gene was also expressed in all MM samples analyzed. At the time of study, the median follow-up for survivors was 25.3 months (range, 16-41), 76 patients remained free from disease progression and 80 remained alive. After induction treatment, 45% of patients achieved CR or sCR. There was no association between the p53 isoform subclasses expression and response to treatment. Kaplan-Meier log-rank analyses revealed that patients with higher expression of TA/∅40, ∅133, α, β and γ subclasses showed a significantly shorter PFS compared with the patients displaying lower expression of those isoforms (2-years PFS rate was 78% *vs* 93% for TA/∅40, 82% *vs* 88% for ∅133, 78% *vs* 96% for α, 78% *vs* 94% for β, and 77% *vs* 94% for γ; *p*-values <0.05). In addition, high expression levels of TA/∅40 and α subclasses were associated with inferior OS (TA/∅40, *p*-value=0.03 and α, *p*-value=0.04). The expression of β, γ and ∅133 subclasses did not influence OS (Figure 1).

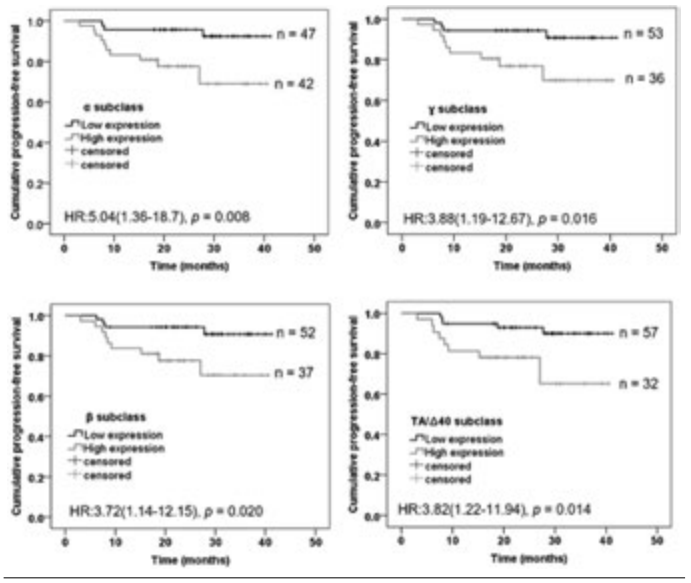

Figure 1.

Summary and Conclusions: The different expression of p53 isoforms at mRNA level is associated with prognosis of MM. The quantification of p53 isoforms in a larger number of patients as well as the analysis of mutation status of *TP53* is ongoing.

Background: Intensive chemotherapy combined with immunomodulatory drugs or proteasome inhibitors is the standard treatment for patients with newly diagnosed multiple myeloma. The clinical outcome varies substantially among patients with a given treatment what may be due to genetic alterations in the multiple myeloma cells.
Aims: We performed targeted sequencing in order to determine the impact of gene mutations on outcome in newly diagnosed multiple myeloma patients treated with an intensive treatment protocol comprising lenalidomide.
Methods: Targeted sequencing using the HaloPlex™ Target Enrichment System (Agilent) for 28 genes frequently mutated in multiple myeloma was performed in CD138+ enriched baseline bone marrow samples from 76 patients treated in the DSMM XII clinical trial. Patients received four cycles lenalidomide/ adriamycin/ dexamethasone followed by two cycles of high-dose melphalan with autologous stem cell transplantation or sequential autologous/ allogeneic stem cell transplantation for cytogenetically defined high-risk patients. All patients received lenalidomide maintenance for 12 months.
Results: In total, we found 68 mutations in 76 patients. The median number of mutations per patient was 1 (range, 0-3) and 62% of the patients had at least one mutation. The most frequently mutated genes were *NRAS* (N=17/ 22%), *KRAS* (N=13/ 17%), *TP53* (N=5/ 7%), *FAM46C* (N=4/ 5%), *DIS3* (N=3/ 4%), *CCND1* (N=3/ 4%), and *CYLD* (N=3/ 4%). With regard to genes involved in lenalidomide activity, we found one mutation in *IRF4*, but no mutations in *IKZF1* or *IKZF3*. Four of the 5 patients with *TP53* mutations had a concurrent del17p13. *TP53* mutations had an adverse impact on progression-free survival (PFS) and overall survival (OS) but had no additional negative impact in patients with del17p13. *RAS* mutations were more prevalent in patients without t(4;14) and/or t(14;16) and/or del17p13 than in those with these abnormalities (53% *vs* 9%, P=0.0003) and in patients with +9q31 as a marker for hyperdiploidy (83% *vs* 46%, P=0.002). Consistent with previous studies, *NRAS* mutations affected mainly codon Q61 when compared to codon G12, while both codons were equally affected by mutations in *KRAS*. None of the patients had a *BRAF* mutation. The majority of *KRAS* (median VAF 0.21, range 0.07-0.46) and *NRAS* (median VAF 0.25, range 0.07-0.45) mutations were subclonal. Response rates were similar between patients with *NRAS* mutations, *KRAS* mutations or no *RAS* mutations. The type of *RAS* mutation had also no impact on PFS. In contrast, patients with a *KRAS* mutation had an OS of 100% after 4 years *versus* 70% in *NRAS*-mutated patients and 63% in patients without *RAS* mutations (P=0.04 for *KRAS vs NRAS* mutation; P=0.02 for *KRAS vs* no *RAS* mutation).
Summary and Conclusions: The type of (mostly subclonal) *RAS* mutations has no impact on response or PFS in patients treated with intensive therapy and lenalidomide. The superior OS of *KRAS versus NRAS*-mutated patients suggests that subsequent treatment lines were less effective in *NRAS*-mutated patients. *NRAS*-mutated patients were shown to be less sensitive to bortezomib comprising therapies (Mulligan *et al.*, Blood 2014; Bolli *et al.*, Leukemia 2017). Data on 2nd line treatment (*i.e.*, bortezomib) in our DSMM XII patients will be presented.

ADAR1-MEDIATED-A-TO-I-EDITING IS BIOLOGICALLY AND CLINICALLY RELEVANT IN MULTIPLE MYELOMA

P.J. Teoh[1,*], O. An [1], T.-H. Chung[1], J.Y. Chooi[1], S. Toh[1], S. Fan[2,3], L. Chen[1,4], S.B. Ng[2,3], H. Yang[1], W. J. Chng[1,5,6,7]

Background: While alterations at the DNA level have been extensively studied in multiple myeloma (MM), the genomic changes including mutations, indels and translocations cannot yet fully explain all its biological and molecular abnormalities, which remains till this day an incurable disease with eventual emergence of refractory disease. In recent years, it has been shown that abnormalities at the RNA levels may have biological relevance in cancers. The role of microRNAs has been implicated in MM but the significance of other phenomenon such as RNA editing has been relatively underexplored. ADAR1-mediated-A-to-I-editing is a physiologically important post-transcriptional mechanism, its abnormality of which has emerged as a driver for carcinogenesis. Chromosome 1q21 consisting of the ADAR1 locus is amplified in more than 35% of MM, and this abnormality is a poor prognostic marker. Considering co-occupancy of other genes in 1q21, it is unknown if ADAR1 is an important driver gene.
Aims: We aimed to elucidate the RNA editome landscape of MM and to characterize the critical function of a disrupted editome in driving myelomagenesis. We would also like to delineate if ADAR1 is a critical gene in 1q21.
Methods: We analysed several publicly available MM datasets, including CoMMpass RNA-seq dataset from the MMRF and performed a systematic whole transcriptome sequencing on normal CD138+ cells and some primary patient samples (n=17) to identify the ADAR1 expression trend. For the elucidation of ADAR1 protein expression, immunofluorosence was conducted on patient's tissue microarray (TMA, n=200). The functional importance of ADAR1 in MM was investigated by modulating its expression level through the lentivirus system and the phenotypes were examined through cell viability (CTG), cell cycle (PI staining) and colony formation (Methocult semi-solid medium) assays.
Results: Our analyses on the gene expression datasets, RNA seq datasets and TMA identified that ADAR1 was overexpressed in MM. Its expression was gradually increasing along the disease progression route (Normal to MGUS to SMM to MM to Relapsed) and was higher in the high-risk TC classes, namely the 4p16 and MAF- translocation groups, signifying the role of ADAR1 in disease progression and in conferring disease aggressiveness. RNA sequencing revealed that A-to-G editing was the most common form of RNA modification. Critically, relative to the normal CD138+ cells, MM transcriptome was found to be aberrantly hyper-edited, with the highest frequency detected at the intronic and intergenic regions. Level of global editing events was closely correlated with ADAR1 expression. Additionally, artificial manipulation of ADAR1 expression could confer differential level of A-to-G editing, indicating that ADAR1 is a critical player of editing in MM. Importantly, high ADAR1 expression with the

consequent hyperediteme were closely associated with patients' survival. Although there was a close correlation between 1q21 copy number and ADAR1 expression, we found that ADAR1 was actually a poor prognostic factor independent of 1q21 amplification. ADAR1 level could also influence patients' responsiveness to different treatment regimes, including proteasome inhibitors. Physiologically, our functional assays established ADAR1 to be potentially oncogenic, driving growth and proliferation of MM cells.

Summary and Conclusions: Collectively, our data demonstrated that ADAR1- mediated-A-to-I editing is both clinically and biologically relevant in MM. These data unraveled novel insights into MM molecular pathogenesis, the current knowledge of which is deemed unsatisfactory.

PF515

MOLECULAR MECHANISMS OF THE ACTIVITY OF THE NOVEL C-MYC TARGETED-COMPOUND IDP-501 IN MM

[1]Hematology, Hospital Universitario de Salamanca (IBSAL). Centro de Investigación del Cáncer (IBMCC-CSIC-USAL), Salamanca, [2]IDP Discovery Pharma, Barcelona, Spain

Background: c-Myc is a well know player in the pathogenesis of cancer, and particularly in MM. The reduction of c-Myc protein level or inhibition of its binding to Max protein can lead to cell-cycle arrest, apoptosis and tumor regression, representing an appealing anticancer strategy. However, despite the existence of a large number of compounds targeting c-Myc, none of them is currently being effectively used in the clinics. IDP-501 is a new chemical entity specifically designed to target c-Myc protein.

Aims: To evaluate the antimyeloma activity and the underlying mechanisms of the novel cMyc inhibitor IDP-501

Methods: The experiments were performed in several MM cell lines (MM1S, MM1R, U266, NCI-H929, RPMI-8226 and OPM-2). Cell viability of myeloma cells was evaluated by the MTT method and potential synergy was quantitated using the Chou-Talalay Method with the Calcusyn Software. For mechanistic experiments, Western blot, flow cytometry and immunoprecipitation were employed. Förster resonance energy transfer (FRET) experiments were performed with MM1S and RPMI cell lines transiently transfected with plasmids coding GFP-cMYC and dsRED Express2-Max. FRET efficiency was measured by photobleaching method. For *in vivo* studies, MM1S cells were injected subcutaneously into 6-week-old female CB17-SCID mice and tumor development after treatment with IDP-501 ip at 6 mg/Kg was monitored.

Results: IDP-501 reduced the viability of all MM cell lines in a concentration and time dependent manner, with IC50s in the micromolar range. No correlation was found between the sensitivity and the levels of cMyc or p^{Ser62}-cMyc in the different cell lines tested. Interestingly, the effect of the compound was really quick as 3 hours of exposure were sufficient to exert its anti-myeloma effect. Similar reduction of cell viability was observed in primary samples *ex vivo* incubated with the compound. These results were further confirmed *in vivo* as IDP-501 inhibited tumor growth in mice bearing a subcutaneous plasmacytoma with a 75% reduction in tumor volume at day +38 of treatment. These results are particularly compelling since the previously investigated cMyc inhibitors failed to have any effect in animal models of MM. Regarding the mechanism of this anti-myeloma action, the cytotoxic effect revealed by MTT was confirmed by Annexin-V/PI assay what indicated an apoptotic mechanism of action; furthermore, experiments with caspase inhibitors suggested the presence of caspase-independent apoptosis. IDP-501 treatment resulted in an increase of DNA damage with marked by H2Ax phosphorylation and reduction of the mitochondrial potential. Unlike other cMyc inhibitors, IDP-501 did not induce phosphorylation of AMPK in MM, but, interestingly, nuclear fraction of cMyc and Max was reduced, and immunoprecipitation and FRET experiments demonstrated a dissociation of Myc-Max complexes caused by the inhibitor, pointing out at this mechanism as the main potential target of IDP-501. Finally, and importantly, IDP-501 potentiated the activity of bortezomib and dexamethasone and cyclophosphamide and dexamethasone, with combination indexes below 0.1.

Summary and Conclusions: The results here presented suggest that IDP-501 could be the first effective strategy able to inhibit the activity of cMyc in MM, and its preclinical activity (both *in vitro* and *in vivo*) prompts its clinical evaluation for the treatment of relapsed MM patients.

This project was supported by IDP-Discovery Pharma and by the Spanish National Projects RTC-2016-5056-1 and FIS PI15/00067.

Background: The genomic heterogeneity that characterizes all MM patients (pts) is the consequence of an evolutionary process operating during the pre-neoplastic phase of the disease. Among the MM genomic heterogeneity, several lesions are recurrent and their presence significantly impacts the prognosis.

Aims: To deeply characterize the MM clone of newly diagnosed MM pts by means of a genomic approach, aimed to identify CNAs affecting clinical outcomes.

Methods: 471 pts were included in the present study: 329 and 74 were treated in the context of the EMN02/HO95 or the BO2005 study, respectively. Overall, 286 pts received an autologous stem cell transplantation (ASCT). Genomic data were obtained by SNPs array on BM-CD138+ cells. At a median follow-up of 43 months (m), the estimated PFS and OS was 55% and 71%, respectively.

Results: We first dissected the genomic complexity observed in the overall population: as expected, most pts had a complex genomic background, while occasionally few of them (27/397, 7%) carried only one of the following alterations: CN losses (L) on chr. 13q, CN gains (G) on chr.1q, hyperdiploidy and any IgH translocations. Remarkably, these 4 alterations were also the most frequently observed across the overall pts population, and their combination identified 16 subgroups harboring a progressively more complex genomic profile. This suggests that these 4 alterations – either combined or alone - are both necessary and sufficient to describe the genomic background of the whole population. Analysis of clinical outcomes showed that inferior outcomes correlated with the presence of both CN-L on chr.13q and CN-G on chr.1q, regardless of others genomic lesions. Based on this, we re-stratified pts according to the absence or presence of 1 or both of these lesions, to define the following 3 groups: group 1 (125 pts), carrying both CN-L on chr.13q and CN-G on chr.1q; group 2 (160 pts), carrying either CN-L on chr.13q or CN-G on chr.1q; group 3 (186 pts), lacking both these lesions. We observed that the 43-m estimates of PFS was significantly shorter in group 1 (48%, 61% and 72% respectively; p=0.0021). OS rates were 72% in group 1 *vs* 88% in group 2 and 91% in group 3 (p=0.0001). PFS hazard ratio (HR) of pts in group 1 (HR=2,51, 95%CI: 1.48-4.25, p=0.0006) was comparable to that of pts carrying either del(17p) (HR=2.09, 95%CI: 1.20-3.65) or t(4;14) (HR=1.84, 95%CI: 1.14-2.99), resulting as an independent factor in predicting PFS in a Cox multivariate analysis (both from del(17p) and t(4;14), p=0.01). PFS benefit correlated with ASCT was statistically significant in groups 2 and 3, while only a trend was observed in group 1. The genomic background of pts belonging to group 1 was characterized by the presence of several genomic aberrations, which overall severely compromise genes involved in the control of cell cycle progression (Rb1, CKS1B, MDM4, MCL1, genes coding for the DREAM-complex components, YAP1, MYC, FANCA).

Summary and Conclusions: Based on an evolutionary rationale, we proposed a simply, CNAs-based risk-classifier, which was able to segregate our cohort of pts with newly diagnosed MM into 3 well-populated groups, thus recapitulating most of the genomic aberrations commonly described in MM. The 3 groups have different clinical outcomes and PFS benefit imparted from ASCT. According to the observed genomic background, a strong de-regulation of cell cycle control might be responsible of the dismal outcome of pts carrying both CN-L on chr.13 and CN-G on chr. 1q.

PF517

PEPTIDE STIMULATION OF PD-L1 SPECIFIC T CELLS NATURALLY OCCURING IN MYELOMA PATIENTS AUGMENT THE ADCC ACTIVITY OF DARATUMUMAB

N.G. Jørgensen[1,*], *S.M.* Ahmad[1], *S.K.* Bendtsen[1], *E.* Martinenaite[1], *M.O.* Holmström[1], *P.* Andersen[2], *Ö.* Met[134], *M.H.* Andersen[13]

[1]Center for Cancer Immune Therapy (CCIT), Department of Hematology, [2]Stem Cell Center, University Hospital Herlev, Herlev, [3]Department of Immunology and Microbiology, University of Copenhagen, Copenhagen, [4]Department of Oncology, University Hospital Herlev, Herlev, Denmark

Background: Daratumumab, an anti-CD38 IgG1k monoclonal antibody, represents a resent major advance in the treatment of patients with multiple myeloma (MM). One of the mechanisms of action of daratumumab is antibody-dependent cell-mediated cytotoxicity (ADCC) via interaction with Fcγ-receptors on natural killer (NK) cells. We have identified naturally occurring T cells specific to programmed death ligand 1 (PD-L1). These PD-L1 specific T cells are naturally present in healthy donors as well as cancer patients. We have previously shown that stimulation of PD-L1 specific T cells has a boosting effect on anti-viral immunity (Ahmad *et al., Leukemia* 2013) and enhances the immunogenicity of an antineoplastic dendritic cell vaccine (Munir *et al., Oncoimmunology*, 2016). Thus, PD-L1 specific T cells seem to have a broad immune-enhancing effect which might also boost the effect of antineoplastic antibodies.
Aims: The purpose of this study was to assess the presence of PD-L1 specific T cells in MM. In case of their presence in MM patients, we hypothesized that stimulation with PD-L1 peptide can boost the ADCC effect of daratumumab against MM cells.
Methods: To test the presence of PD-L1 specific T cells, leukapheresis products were assayed by interferon-γ (IFN-γ) enzyme-linked immunospot (ELISPOT) against a 19-amino acid peptide from the signal peptide of PD-L1. ^{51}Cr-release cytotoxic assays were used to assess the cytotoxic capacity of a PD-L1 specific T cell culture, leukapheresis products and healthy donor peripheral blood mononuclear cells (HD PBMCs). Target cells in the cytotoxic assays were the myeloma cell lines U266 and RPMI-8226. ADCC was assessed in ^{51}Cr-release cytotoxic assays +/- daratumumab, when HLA-types of effector and target cells were not matching.
Results: PD-L1 specific T-cells were present and responded to stimulation with PD-L1 peptide in INF-γ ELISPOT assays in 13 of 19 leukapheresis products. Furthermore, an HLA-A2 restricted PD-L1 specific T cell culture showed dose-dependent lysis of the HLA-matched PD-L1 positive myeloma cell line U266. This lysis was enhanced when PD-L1 expression on the myeloma cell line was increased by treatment with INF-γ. Finally, both HD PBMCs and leukapheresis products from myeloma patients lysed the CD38-positive myeloma cell line RPMI-8226, when the cell line was treated with daratumumab. Importantly, this lysis was frequently increased when the leukapheresis products or HD PBMCs were stimulated with PD-L1 peptide. Since the leukapheresis products and myeloma cell line did not have matching HLA-types, the boosting effect was not directly T-cell mediated but more likely due to an increased cytotoxicity by NK-cells, *i.e.* ADCC. Interestingly, the PD-L1 peptide mediated enhancement of the activity of daratumumab was only seen in patient samples showing presence and activity of PD-L1 specific T cells, as evidenced by IFN-γ ELISPOT responses against the PD-L1 peptide.
Summary and Conclusions: PD-L1 specific T cells are present in patients with MM, and myeloma cells can be lysed by PD-L1 specific T cells. Stimulation with a PD-L1 peptide augments the daratumumab mediated ADCC against myeloma cells. We have an ongoing phase I trial of PD-L1 peptide vaccination as monotherapy as consolidation after high dose chemotherapy and stem cell support for patients with MM. These findings are to our knowledge the first evidence that a peptide vaccine can boost the activity of a monoclonal antibody. The data support a clinical trial combining daratumumab with PD-L1 peptide vaccination.

PF518

NOVEL KINASE INHIBITORS AFURESERTIB AND PIM447 ARE ACTIVE IN A PREDICTIVE MYELOMA *IN VIVO* MODEL, AND A CRISPR GENOME-WIDE SCREENING APPROACH IDENTIFIES BIOMARKERS DETERMINING SUSCEPTIBILITY

N. Keane[1,*], M. Sharik[2], A. Natoni[1], M. Chesi[2], L. Bergsagel[2], O. Michael[1]

[1]Haematology, National University of Ireland Galway, Galway, Ireland, [2]Research, Mayo Clinic, Scottsdale, United States

Background: Novel therapies for advanced Multiple Myeloma (MM) constitute an unmet clinical need and increasing knowledge of the molecular abnormalities driving MM places an onus on clinicians to tailor treatment to the individual. The overlapping Pim and PI3K/AKT/mTOR pathways play a key role in MM pathogenesis. Our group reported potent synergy with Pim inhibitor pim447 and Akt inhibitor afuresertib in combination in MM however investigation of this combination in a murine MM model failed to identify a therapeutic window.
Aims: We hypothesise that these inhibitors will complement current standard therapies proteasome inhibitors (PIs) and Immunomodulatory drugs(Imids) without significant toxicity given their non-overlapping mechanisms of action, and that use of a CRISPR screen will identify molecular signature of patients likely to benefit from these novel combination strategies.
Methods: The CoMMpass dataset was analysed for patterns of expression of Akt and Pim kinases in MM. Cell viability was determined using MTS assay. pAKT was measured by immunoblotting and Pim-2 levels by RNA sequencing. *In vivo* studies were performed in the VK*MYC *de novo* (for single drug treatments) or transplantable (for combination treatment) models. Cas9-expressing KMS11 cells were transfected with TKO CRISPR knockout library. Cells were treated with concentrations that induce >90% cell death. gDNA was extracted from surviving cells, gRNAs amplified and sequencing performed on Illumina HiSeq2500. Differential gene expression was determined between combinations and controls, and pathways identified using Ingenuity™ pathway analysis.
Results: Pim-2 expression is highest in MM featuring Ig translocations, while Akt expression increases with advancing disease across all subtypes. Afuresertib and pim447 activity increases with greater pAkt and Pim-2 expression, respectively. Combination of each inhibitor with PIs/Imids is synergistic in MM cell lines. *In vivo* investigation of combinations with bortezomib in VK*MYC12598 model reveals synergy with bortezomib/pim447, with significant reduction in M-Spike in the combination arm. CRISPR screening identifies Ras pathway activation as the key determinant of sensitivity to this combination. By contrast we observed no synergy *in vivo* with the bortezomib/afuresertib combination, although we did observe improved survival in the afuresertib-only arm in this highly resistant model unexpectedly. Furthermore, afuresertib was inactive in the *de novo* VK*MYC model, indicating that afuresertib will likely find a niche in treatment of advanced, highly proliferative MM. Though Imid combinations cannot be tested in this model we establish that synergy in combining Imids with afuresertib/pim447 results from additive degradation of Ikaros and Aiolos followed by downstream synergistic depletion of MYC and IRF4. CRISPR screening of these promising combinations suggest that the Ras signaling pathway is also important in determining sensitivity to combined Imid/AKT inhibiton and that upregulation of NF B signaling may predict resistance to combined Imid/Pim inhibition.
Summary and Conclusions: We identify novel therapeutic strategies to exploit kinase signaling in MM. Combination of bortezomib with pim447 is synergistic in a clinically-predictive *in vivo* model. Afuresertib is identified as a therapeutic option for advanced MM. MM subtypes with Ras pathway activation and suppression of NF B pathway may be more likely to benefit from combinations incorporating Pim- or Akt-inhibition with standard therapies.

PF519

CD26 IS A POTENTIAL THERAPEUTIC TARGET BY HUMANIZED MONOCLONAL ANTIBODY IN MULTIPLE MYELOMA

H. Nishida[1,*], M. Hayashi[1], H. Suzuki[1], M. Sakamoto[1], T. Yamada[1]

[1]Department of Pathology, Keio University, School of Medicine, Tokyo, Japan

Background: CD26, a 110-kDa transmembrane glycoprotein which is expressed on several tumor cells including malignant lymphoma, has been implicated in tumorigenesis, whereas little is known about its role in plasma cell malignancies. More recently, we have identified CD26 expression on human osteoclasts (OCs) in MM. *In vitro* studies showed that although CD26 expression was low or absent on MM cell lines cultured alone, it was intensely and uniformly expressed on MM cell lines co-cultured with OCs.
Aims: In the present study, we examine the therapeutic impact of huCD26mAb, a humanized monoclonal IgG_1 antibody specifically targeting CD26 on MM cell growth and clarify CD26 could be a target for the treatment of MM.
Methods: Antibody-dependent cellular cytotoxicity (ADCC) assay and complement-dependent cytotoxicity (CDC) assay by huCD26mAb were conducted against MM cell lines, cultured alone or co-cultured with OCs. *In vivo* effect of huCD26mAb was also analyzed using xenograft murine model.
Results: Immunostaining on bone marrow biopsy specimens showed that CD26 is expressed on plasma cells in several MM patients. First, we inves-

tigated the impact of huCD26mAb on growth of MM cell lines (KMS18, KMS26, KMS27, KMS28, KMS34, U266). huCD26mAb had no direct effect on viability of tested CD26- MM cell lines cultured alone, but it inhibited growth of CD26+ MM cell lines co-cultured with OCs, chiefly at higher concentrations (>10 g/ml) (p<.05). Next, we conducted calcein-AM release assay to analyze the ability of huCD26mAb to lyse MM cell lines via ADCC. huCD26mAb triggered ADCC against CD26+ MM cell lines co-cultured with OCs in the presence of natural killer (NK) cells in a dose-dependent manner with lytic activity by huCD26mAb starting at 0.0001 g/ml and maximum lysis at 10 g/ml (p<.05) and in an E/T ratio-dependent manner. In contrast, huCD26mAb did not exhibit dose-dependent ADCC against CD26-MM cell lines cultured alone. Furthermore, CD26+ KMS18, KMS26 and KMS28 after co-culture with OCs were pretreated with dexamethasone (Dexa, 25nM) or bortezomib (BTZ, 3nM). Then, subsequent MM cell lysis triggered by huCD26mAb (10 g/ml) was significantly increased by NK cell-dependent ADCC at the E/T ratio of 20 (p<.05). huCD26mAb revealed synergistic ADCC against CD26+ MM.1R, pretreated with lenalidomide (Lena, 0.05, 0.5 M) (p<.05, <.01). Pretreatment of NK cells with Lena also potentiated subsequent huCD26mAb-induced lysis of CD26+ MM.1R cells in a dose-dependent fashion (p<.05, <.01). Next, the effect of CDC by huCD26mAb against CD26+ MM cells was tested. However, in the presence of human serum as a source of complement, huCD26mAb exerted low or absent potential to confer CDC against CD26+ MM cell lines. Moreover, we examined ADCC activity by huCD26mAb against SP fractions in MM cells. Interestingly, although Lena alone did not decrease SP ratio in CD26+ RPMI8226 or KMS11, huCD26mAb substantially reduced its ratio and its further reduction was observed with both in combination (p<.01). Lastly, *in vivo* effect of huCD26mAb using NOD/SCID-hu mice by direct intrabone injection of MM cells into subcutaneously implanted human bone grafts showed that huCD26mAb significantly reduced CD26+ MM tumor burden and TRAP+ OC formation (p<.05).

Summary and Conclusions: huCD26mAb elicited significant anti-MM efficacy by impairing both CD26+ MM cell growth and OC formation. Our results suggest that CD26 could be a potential therapeutic target of antibody-based therapy in MM.

PF520

DNA REPAIR PROCESSES TARGET TRANSCRIBED REGION IN MULTIPLE MYELOMA

M. Samur[1], R. Szalat[2], M. Lawlor[3], F. Maura[4], C. Ott[3], N. Bolli[5], K. Anderson[2], S. Minvielle[6], P. Campbell[4], H. Avet-Loiseau[7], N. Munshi[2,*]

[1]Biostatistics and Computational Biology, [2]Dana Farber Cancer Institute, [3]Massachusetts General Hospital, Boston, United States, [4]Wellcome Trust Sanger Institute, Cambridge, United Kingdom, [5]University of Milan, Milan, Italy, [6]CRCINA, INSERM, CNRS, Université de Nantes, Nantes, [7]L'Institut Universitaire du Cancer Oncopole, Toulouse, France

Background: Multiple myeloma (MM) is a plasma cells malignancy characterized by a complex and heterogeneous genomic landscape. Using whole-exome and targeted sequencing, two main active mutational processes have been identified in MM provide initial insight into both initial pathogenic mechanisms and the processes affecting disease progression. However, limited numbers of mutations identified using WES does not allow interrogation of question whether different parts of the genome are targeted by different mutational processes.

Aims: Here we interrogate various genomic regions and mutation types such as non-coding regions and protein coding regions with missense mutations, to understand activated processes that cause DNA alteration in MM.

Methods: We have processed 39 purified CD138+ MM cells samples with Whole Genome Sequencing; ten samples also have RNA and ATAC sequencing. Public WES data from 999 samples were collected from dbGaP and CoMMpass study. Mutational processes were analyzed using non-negative matrix factorization and multiple linear regression model.

Results: We identified an average >5000 SNVs per patient sample with a total of over 200K SNVs from WGS and additional >170K SNVs from public WES data. Overall C>T mutations constituted 30% of all detected mutations across the genome, including a small fraction of C>T mutations within CpG islands. Majority of the mutations were observed in the intergenic (IGR), introns and non-coding RNAs regions (lincRNAs and ncRNA). Transcribed strand of the genome showed enrichment in C>A and C>T mutations. With non-negative matrix factorization we were able to identify 8 mutational processes in MM genome six of which were not described before. Although APOBEC/AID processes were the majority for the non coding genome, DNA repair related processes were highly active in the coding genome. We have integrated WGS, ATACseq and RNAseq data from same patients and identified that DNA damage activity increased in the expressed genes and sub clonal populations. We have confirmed our results using publicly available WES data from 999 samples.

Summary and Conclusions: C>A and C>T enrichment on the transcribed strand has been connected to high transcriptional activities and different mechanisms such as single *versus* double-strand DNA repair functions. Targeting of non-coding regions by APOBEC/AID could be part of ongoing somatic hypermutation in MM. However, missense mutations may be driven by DNA double-strand break-repair by homologous recombination and DNA mismatch repair processes. Increased intensity for DNA repair signatures in subclonal missense mutations may indicate that these processes may occur late during the MM progression. Future studies that can compare paired samples from early stage to relapsed and refractory myeloma can help us understand if DNA repair processes become dominant during the MM development.

PF521

EFFECT OF DARATUMUMAB ON NORMAL PLASMA CELLS, POLYCLONAL IMMUNOGLOBULINS AND VACCINATION RESPONSES IN EXTENSIVELY PRETREATED MYELOMA PATIENTS

K. Frerichs[1,*], P. Bosman[1], J. van Velzen[2], I. Nijhof[1], A. Bloem[2], T. Mutis[1], S. Zweegman[1], N. van de Donk[1]

[1]Hematology, VU University Medical Center, Amsterdam, [2]Laboratory of Translational Immunology, University Medical Center, Utrecht, Netherlands

Background: Daratumumab (DARA) is a CD38-targeting monoclonal antibody, which induces multiple myeloma (MM) cell death via several immune-mediated mechanisms. DARA is approved as monotherapy and in combination with standards of care in relapsed/refractory MM, but the effect of DARA on normal plasma cells (PCs) is still unknown.

Aims: We studied the effect of DARA on frequency of normal PCs, polyclonal immunoglobulin levels and antibody responses upon vaccination in MM patients.

Methods: We analyzed baseline CD38 expression levels (median fluorescence intensity, MFI) on PCs from relapsed/refractory (RR) MM patients treated with DARA monotherapy (GEN501 or DARA-ATRA trial), and from healthy controls (HC). The frequency of normal PCs in bone marrow (BM) samples from these MM patients was analyzed before and during DARA treatment. We also measured serial levels of polyclonal immunoglobulins (IgG, IgA, IgM and IgE). Additionally, in accordance with (inter)national guidelines, these patients received *Haemophilus influenzae type B (HiB)* and *Streptococcus pneumoniae* vaccination. Specific serum antibody titers (IgG) against Hib and pneumococcal serotypes were measured before, and 4, 8, 12 and 16 weeks after the first vaccination.

Results: CD38 expression on normal PCs from HCs (n=5) was significantly higher (median MFI: 141288; range: 112426-164626) compared to MM PCs (n=25; median MFI: 36174; range: 6997-160005; *P<0.0001*). As a consequence, DARA monotherapy significantly reduced the frequency of normal PCs in serial BM samples after the initiation of DARA treatment (baseline: n=17, 0.03% normal PC; 3 months: n=10, 0.0007%, *P=0.0078*; disease progression: n=15, 0.001%, *P=0.002*). Surviving normal PCs had reduced CD38 expression levels, as well as a decrease in CD19 levels. Such phenotypic changes are similar to what we previously observed on MM cells. This reduction in normal PCs resulted in a decrease in polyclonal IgA, IgM and IgE in 30 patients treated with DARA monotherapy, while polyclonal IgG levels remained unchanged. Furthermore, antibody responses upon vaccination were assessed in these heavily pretreated RR MM patients (median 4 prior lines of therapy [range 2-9]). Seventeen patients received HiB (Act-HiB) and pneumococcal vaccination (PCV-13, followed 8 weeks later by PPV-23). At this moment, antibody responses for HiB are available in 14 of these patients. Twelve patients (86%) showed a good response, either by obtaining a protective titer ≥1.0µg/mL (if baseline levels <0.15µg/mL) or by a 4-fold increase in antibody titer (if baseline titers were ≥0.15µg/mL, Figure 1A). Pneumococcal antibody responses are currently available in 9 of these vaccinated patients. 7 patients (78%) achieved a ≥2 fold increase in antibody titer for at least 6 out of 9 analyzed subtypes (6B, 8, 9, 14, 15B, 19F, 20, 23F and 33F, Figure 1B). None of the vaccinated patients suffered from pneumococcal or HiB infections thusfar.

Summary and Conclusions: Normal PCs have higher CD38 expression compared to MM cells. We found that the frequency of normal PCs in BM is reduced upon DARA treatment in MM patients. The surviving normal PCs showed reduced CD38 cell surface expression. We also observed reduced levels of polyclonal IgA, IgM, and IgE in these patients, while polyclonal IgG levels remained stable. Furthermore, a majority of heavily pretreated MM patients was able to produce protective antibodies in response to vaccination, even during DARA treatment. Given the high incidence of respi-

ratory infections, we recommend to vaccinate patients also during CD38-targeted therapy.

Notarfranchi[2], I. Manfra[2], F. De Luca[1], L. Craviotto[1,2], F. Aversa[1,2], A. Neri[3,4], N. Giuliani[1,2]

[1]Medicine and Surgery, University of Parma, [2]Hematology and BMT Center, Azienda Ospedaliera Universitaria di Parma, PARMA, [3]Onocology and Hemato-oncology, University of Milan, [4]Hematology Unit, Fondazione IRCCS Ospedale Maggiore Policlinico, Milan, [5]Biopathology and Medical Biotechnologies, Biology and Genetic Section, University of Palermo, Palermo, Italy

Background: The molecular mechanisms involved in the progression of smoldering (SMM) to active multiple myeloma (MM) are not completely understood. Several genomic data indicate that genetic alterations that characterized MM patients are already present in SMM ones. However, few data are available on the transcriptional profiles of SMM patients in relationship to the progression to active MM.
Aims: In order to address this aim, in this study, we firstly compared plasma cells (PCs) from paired samples (SMM evolved in MM), then we investigated transcriptional differences between progressed and not progressed SMM patients.
Methods: All the SMM patients included in this study were defined according to the IMWG revised diagnostic criteria and stratified by known risk factors of progression. Median age at diagnosis was 72 years (range 58-84) in progressed patients and 74 years (range 38-86) in non-progressed patients. The median percentage of bone marrow plasma cells (BMPCs) at diagnosis in the 8 subsequently progressed SMM was 30% (range 13-40). High-risk FISH features (either del(17p), t(4;14) or t(14;16)) was detected in 3 out of 8 patients. The median time to progression was 14 months and all patients progressed with onset of CRAB features. The 12 non-progressed SMM patients had a median percentage of BMPCs of 14% (range 10-25%); high-risk FISH features was detected in 3 out of the 5 patients with enough BMPCs to allow examination. 55% of the patients were classified as intermediate-risk by Mayo score, whereas the remaining were low-risk. Median follow up in this cohort of patients was 49 months. Primary CD138$^+$ PCs were purified by magnetic beads from bone marrow (BM) aspirate of 8 paired SMM and MM samples and from 12 non-progressed SMM. Global expression profiles of 19.012 protein-coding and 13.972 non-coding genes were obtained on GeneChip® ClariomD arrays using annotations from Gencode v26. Hierarchical clustering was applied on the most variable coding/non-coding genes across the entire dataset. Rank Product and Gene Set Enrichment Analysis were used for differential and functional analyses.
Results: Hierarchical clustering analysis evidenced paired groupings of the 8 progressed SMM with the corresponding MM samples, whereas no markedly agglomerative similarities have been found with/between the non-progressed SMM cases. No significant differentially expressed coding/non-coding genes were observed between paired SMM and MM cases. Conversely, progressed SMM compared to non-progressed SMM down-regulated antigen processing and presentation and natural killer mediated cytotoxicity gene sets, whereas genes associated with proliferation and hyperdiploidy were positively modulated. Specifically, among the 28 most significantly deregulated genes, the Wnt inhibitors *FRZB* and *DKK1*, the TGF-beta targeting gene *SMAD1* and the pro-angiogenic one *CTGF* were found up-regulated in relation to progression to MM. This agrees with the recent finding that BM DKK-1 protein level is a new independent factor for progression in SMM (Dalla Palma B et al Br J Haematol 2017). Finally, 45 non-coding genes, mostly down-regulated (69%), were found modulated in the comparison between progressed and non-progressed SMM cases.
Summary and Conclusions: Our data indicate that the transcriptome of the PCs of SMM patients who progressed to MM did not significantly change throughout the progression; conversely, the upregulation of inhibitors of canonical Wnt signaling in PCs differentiated progressed from non progressed SMM patients.

PF523

GENOMIC CHARACTERIZATION OF HEMATOPOIETIC STEM AND PROGENITOR CELLS IN MULTIPLE MYELOMA REVEALS DISTINCT PATTERNS OF DISEASE EVOLUTION

A.-M. Leppä[1,*], S. Eldfors[1], P. Anttila[2], C. Heckman[1]

[1]Institute for Molecular Medicine Finland, [2]Helsinki University Hospital Comprehensive Cancer Center, Helsinki, Finland

Background: The expected overall survival of multiple myeloma (MM) patients has remarkably improved over the recent decades, but as a result, cases of secondary myelodysplastic syndrome and secondary acute myeloid leukemia (sMDS/sAML) have increasingly been recognized. Even though pathogenic alterations in MM have been well characterized in the malignant plasma cell fraction, little is known about the mechanisms leading to secondary myeloid disease. Also, it is unknown if molecular-level alterations can be detected in the hematopoietic stem and progenitor cells (HSPCs) of MM patients, that may be used to identify those patients predisposed to develop sMDS/sAML, as well as to better understand the clonal evolution of MM.
Aims: The aim of this study was to investigate if the HSPC fraction of MM patients harbor mutations associated with MDS/AML, potentially predisposing the patients to development of secondary disease, and to study the clonal evolution of MM.
Methods: Bone marrow (BM) aspirates were collected from 45 MM patients. For 6 patients, more than one sample was collected, thus, 51 samples were used in total. 30 samples were collected at the time of diagnosis and 21 at relapse. BM mononuclear cells (BM-MNCs) were isolated by gradient centrifugation, and processed by immunomagnetic bead selection to enrich for CD138+ cells. The CD138- fraction was further processed to isolate CD34+ HSPCs. DNA was prepared from the isolated cell fractions as well as matching skin biopsies. Whole exome sequence analysis was performed using the CD138+ and skin DNA, while targeted gene capture was performed using the TruSight Myeloid Sequencing Panel (Illumina, San Diego, CA, USA) using the CD34+ cell and skin DNA. High confidence somatic mutations were called for each CD34 and CD138-enriched sample.
Results: In 20 of the 51 HSPC-enriched MM samples, we detected a total of 42 mutations in 23 genes (39.2%) (Figure 1). The most commonly mutated gene was DNMT3A with 7 mutations observed. We compared the measured variant allele frequency (VAF) in the mutated samples and noticed substantial variance between the patients. Most of the mutations observed had a low VAF, more specifically 29/42 (69%) mutations had a VAF below 10%. The highest VAF was detected in TET2 (33.8% VAF, R1282H), SRSF2 (33.1% VAF, P95H) and IDH1 (28.5% VAF, R132H). Moreover, the first two were detected in the only patient in this cohort who proceeded to develop MDS, while the IDH1 hotspot mutation is considered an early driver event in leukemogenesis. Notably, exposure to alkylating agents and relapse-status were significantly associated with a higher VAF (both, P<0.01), which is an indication of clonal expansion.

The majority of the mutations we detected in the HSPC enriched samples were not observed in the CD138+ plasma cells. Intriguingly, four patients did, however, share mutations specific for MDS/AML in both cell fractions. Thus, MM patients with detectable MDS/AML associated mutations in HSPCs seem to present two different clonal evolution patterns during MM development: the malignant plasma cell population may arise from a genetically distinct subpopulation as well as from the genetically normal cell population.

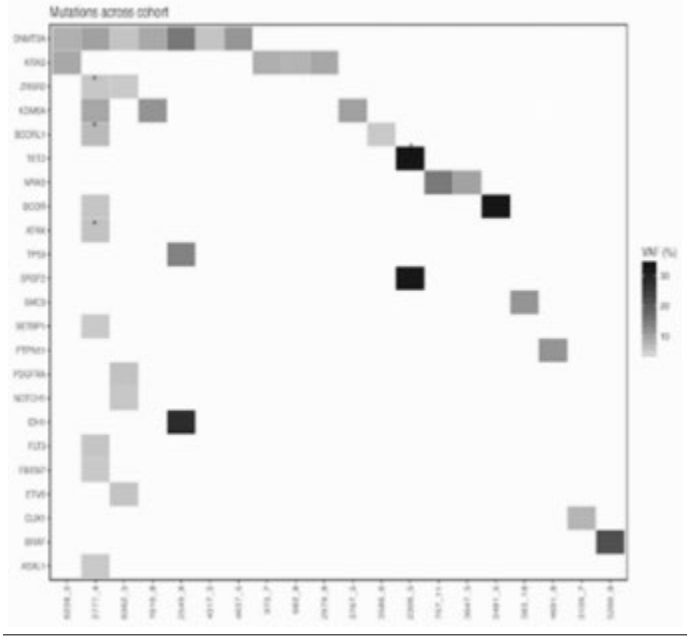

Figure 1.

Summary and Conclusions: Mutations in genes associated with MDS/AML are fairly frequent in HSPCs of MM patients, and exposure to alkylating agents is significantly associated with clonal expansion. For some patients, the mutations detected in the HSPCs were also observed in the malignant plasma cells, suggesting that MM can arise from a mutation-bearing, pre-malignant stem cell progenitor.

PF524

LONGITUDINAL CHROMOSOMAL ABNORMALITIES ANALYSIS IN MULTIPLE MYELOMA DISEASE PROGRESSION REVEALS CLONAL EVOLUTION AFTER THERAPY

S. Oliva[1,*], C. Simona[1], M. Ruggeri[1], G. Cetani[1], S. Spada[1], D. Oddolo[1], R. Troia[1], E. Marzanati[1], G. Gazzera[1], M. Gilestro[1], E. Saraci[1], C. Pautasso[1], V. Muccio[1], S. Bringhen[1], M. Boccadoro[1], P. Omedé[1]

[1]Myeloma Unit, Division of Hematology, University of Torino, A.O.U. Città della Salute e della Scienza di Torino, Torino, Italy

Background: Multiple myeloma (MM) is a very heterogeneous disease and prognosis is influenced by the presence of cytogenetic abnormalities (CA), such as del(17p), t(4;14) and/or t(14;16). In some cases, these mutations might change after receiving chemotherapy. However, it is unclear whether CA changes at disease progression have an impact on the prognosis of MM patients, as at diagnosis.
Aims: We investigated CA changes in bone marrow plasma cells (BMPC) from Monoclonal Gammopathy of Undetermined Significance (MGUS)/Smouldering Myeloma (SM) to Multiple Myeloma (MM)/Plasma Cell Leukemia (PCL) and from diagnostic samples to progressive disease.
Methods: Samples were collected from 2002 to 2018 at several timepoints for FISH analyses: MGUS/SMM phase, MM/PCL diagnosis and MM relapses (first and/or subsequent relapses). FISH analysis was performed on purified BMPC using anti-CD138-coated magnetic beads. Nuclei from fixed BMPC were prepared for interphase FISH using standard methods. DNA probes were used to detect Rb1 and TP53 deletions, t(11;14)(q13;q32), t(4;14)(p16;q32) and t(14;16)(q32;q23). 1p/1q detection was subsequently added to the standard FISH panel in 2012, thus it was not available for all patients. High risk (HR) was defined by the presence of at least one CA among del(17p), t(4;14) and t(14;16). In the absence of the aforementioned cytogenetic anomalies, patients were considered at standard risk.
Results: A total of 103 patients were analysed with a median follow up of 60 months (IQR 37-88 months). Median age was 64 years (IQR 56-72), and male patients were 54 (53%). According to the International Staging System (ISS), 36% had ISS-I,, 41% ISS-II, and 19% ISS-III (4% had no ISS data available). Twenty-two patients had both MGUS/SMM and MM/PCL diagnostic samples, 55 had MM diagnostic and first relapse samples, all the other patients had at least one subsequent relapse sample. Forty-three (42%) patients received front-line proteasome inhibitor (PI)-based therapy, 56 (54%) lenalidomide-based therapy, 3 (3%) melphalan-prednisone-thalidomide (MPT)/cyclophosphamide, whereas 1 patient did not start any therapy. Finally, 32 (31%) patients received autologous stem cell transplantation (ASCT). Twenty-eight/103 (27%) patients presented high risk CA at diagnosis: 17 had del(17p), 11 had t(4;14) (4 patients had both CA), no one had t(14;16). Almost one third of patients (33/103, 32%) showed changes in terms of FISH results during disease progression. Three different patient populations were identified: 25/33 patients (76%) with gain of new CA among Rb1, TP53 deletions, t(4;14), t(14;16) and 1q CA (group 1 – CA acquisition); 7/33 patients (21%) with loss of previously detected CA (group 2 – CA loss); the other 70 patients with no changes (group 3 – CA unchanged); only 1 patient had gain of t(11;14). The worst survival was observed in patients with gain of new CA during disease evolution (group 1): median OS was 66 months (95% CI, 58-89 months) in this group, 82 months (95% CI 68-NR months) in group 2 and 87 months (95% CI 78-NR) in group 3 (group 1 *vs* 3, P=0.002; group 2 *vs* 3, p=0.79) (Figure 1).

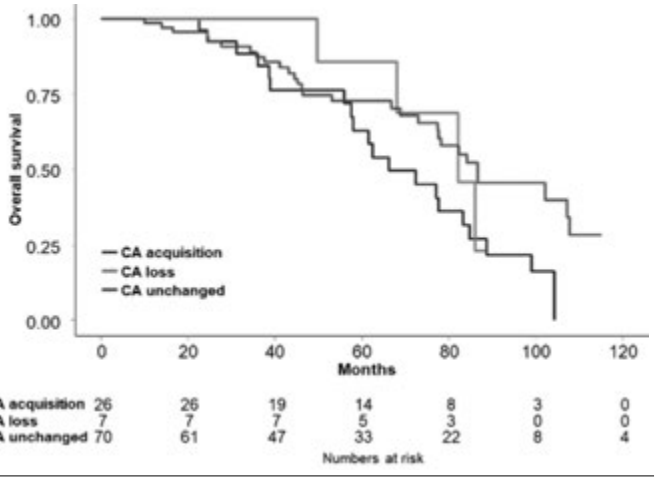

Figure 1.

Summary and Conclusions: Our results confirm that clonal evolution occurs as disease progresses after different chemotherapy lines, and patients who acquired high risk CA had the poorest prognosis. This could be explained by the fact that some clones might have existed at the diagnosis as a minor population, and became predominant during treatment, turning into resistant clones. Our findings also confirm the importance of performing FISH analysis both at diagnosis and relapse.

PF525

MYTYPE TARGETED NEXT GENERATION SEQUENCING ASSAY FOR DETECTION OF IGH TRANSLOCATIONS AND COPY NUMBER ALTERATIONS IN MULTIPLE MYELOMA

Background: Multiple myeloma is a genetically complex disease where early

hits include chromosome 14 (IGH) translocations or hyperdiploidy. Later events are additional copy number alterations (CNAs), *e.g.* gain 1q, deletion 13q or 17p as well as somatic mutations. Currently, translocations and CNAs are commonly assessed via fluorescent *in situ* hybridization (FISH) in the clinical setting. Recently, targeted DNA assays have been evaluated in myeloma cell lines and showed correlation with conventional methods.
Aims: To interrogate genomic aberrations in primary samples from patients with multiple myeloma and we developed a targeted next generation sequencing panel, called myTYPE, and compared detection rates to those from FISH.
Methods: In the myTYPE assay, baits were designed to capture the entire IGH locus where the vast majority of the chromosome 14 breakpoints occur, genome wide single nucleotide polymorphisms (SNPs) for hyperdiploidy and other CNAs, as well as exons of 120 frequently mutated somatic genes in multiple myeloma.
To validate the capture of IGH translocations and CNAs using myTYPE, 46 samples from 22 patients with multiple myeloma as well as bone marrow samples from 16 healthy individuals were analyzed. All samples were sequenced using 126 bp paired end reads using Illumina HiSeq with a mean target depth of ~600x. All patient samples contained a high percentage of plasma cells. After sequencing, CNAs and translocations were identified using validated bioinformatic algorithms such as CNVkit, Brass and Delly.
Results: We found that the targeted sequencing assay myTYPE was equally good or better for detecting IGH translocations and CNAs compared to FISH. Using myTYPE, a higher number of t(4;14) and t(11;14) and equally many t(14;16) were captured using myTYPE in relation to FISH. (Table 1) Hyperdiploidy was detected in 14% and 22% with FISH and myTYPE, respectively. Greater numbers of 1q gains and 13/13q deletions were found using myTYPE while the number of 17p deletions were similar. Since myTYPE covers genome-wide SNPs, this assay was able to detect additional CNAs such as 6q deletion, 8p deletion, 16q gain, and trisomy 8 that were not targeted by FISH. In 4 multiple myeloma patients enrolled on a study protocol allowing for several parallel bone marrow/extramedullary disease biopsies in the same patient, the same IGH translocations and CNAs were detected across all sites of extramedullary disease except in two samples where a 6q deletion and 8p deletion were not detected in one sample each. This is likely explained by clonal heterogeneity, *i.e.* that the CNA was not present since we have no reason to suspect sequencing failure in these samples.

Table 1.

IGH Translocations and Copy Number Alterations	FISH	myTYPE
t(4;14)	9%	14%
t(11;14)	23%	36%
t(14;16)	9%	9%
Hyperdiploidy	14%	23%
Gain 1q	32%	32%
Deletion 13/13q	32%	59%
Deletion 17p	14%	14%

FISH=fluorescent in situ hybridization. myTYPE=targeted next generation sequencing panel designed to capture IGH translocations, copy number alterations, as well as exons of 120 frequently mutated genes in multiple myeloma

Summary and Conclusions: In this analysis, based on the targeted DNA capture assay myTYPE used head-to-head with FISH on primary samples from patients with plasma cell myeloma, we found that the sensitivity for detecting IGH translocations and CNAs was higher using the targeted sequencing approach as compared to FISH. Furthermore, using myTYPE, we found additional CNAs not covered by FISH, as FISH detects only the probe-specific alterations. Translocations and CNAs can be detected with high sensitivity also using whole genome sequencing, however, targeted sequencing is less complex and more cost-effective. In summary, targeted sequencing using myTYPE is an effective and sensitive approach to assess IGH translocations and chromosomal gains and losses in multiple myeloma and there are ongoing efforts to implement sequencing-based assays to replace FISH in the clinical setting.

PF526

RAPID AND SCALABLE GENOME-WIDE PROFILING OF CLINICALLY RELEVANT GENETIC ABERRATIONS IN MULTIPLE MYELOMA

D. Alpar[1,*], L. Atanesyan[2], S. Kosztolanyi[3], R. Kiss[1], A. Gango[1], K. de Groot[2], M. Steenkamer[2], P. Jakso[4], A. Matolcsy[1], B. Kajtar[4], L. Pajor[4], K. Szuhai[5], S. Savola[2], C. Bodor[1]

[1]1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary, [2]MRC-Holland, Amsterdam, Netherlands, [3]1st Department of Internal Medicine, [4]Department of Pathology, University of Pecs, Clinical Center, Pecs, Hungary, [5]Department of Cell and Chemical Biology, Leiden University Medical Center, Leiden, Netherlands

Background: Multiple myeloma (MM) has a heterogeneous genomic landscape coupled with diverse clinical outcome. Copy number aberrations (CNAs) including whole chromosome and subchromosomal gains and losses are common contributors of the pathogenesis and progression of MM. Genome-wide analysis of recurrently altered regions with short turn-around time is therefore highly warranted in order to stratify patients into risk groups and predict their responses to various treatment strategies.
Aims: Comprehensive, high-resolution and high-throughput profiling of all disease-relevant CNAs in MM.
Methods: A novel digital multiplex ligation-dependent probe amplification (digitalMLPA) assay has been developed for the molecular characterization of MM by combining conventional MLPA and next-generation sequencing (NGS). The probemix contains 500 probes and allows for screening for all chromosomal and focal CNAs recurrently occurring in MM as well as for specific detection of BRAF V600E mutation. Diagnostic bone marrow samples from 56 patients were analyzed, copy number status of each target locus was assessed by relative sequencing read count quantification. Plasma cell purity as measured by flow cytometry was considered at the interpretation of copy number changes. Results were compared to conventional MLPA, fluorescence *in situ* hybridization (FISH), pyrosequencing and droplet digital PCR data (ddPCR).
Results: CNAs indicating focal or whole chromosome aberrations were detected in all but one patient. Aneusomies were identified in 47 patients (84%), with predominant occurrence of monosomy 13 and trisomies of odd-number chromosomes, characteristic features of MM. The number of detected recurrent subchromosomal aberrations specifically affecting putative driver genes/regions varied between 0 and 13 (mean: 4.4) per patient. Gain(1q) was the most common lesion among the 53 patients harboring focal CNAs, followed by loss(1p), loss(8p), loss(16q), loss(12p), loss(14q), gain(8q), gain(Xq), loss(13q), loss(6q), gain(14q), loss(17p), loss(20p), loss(22q), loss(5q), gain(6p) and gain(9q). Biallelic deletions reported to be associated with disease progression were observed in *CDKN2C*, *FAF1*, *BIRC3*, *TRAF3*, *CYLD* and *TP53* genes. Investigating the location, allelic burden and extension of CNAs along chromosome 1, a high variability with 24 distinct patterns was observed across 38 patients. FISH, MLPA and digitalMLPA results at genomic loci investigated by multiple methods showed a congruency of 95%. The vast majority of whole chromosome changes and 63% of focal CNAs revealed by digitalMLPA were not detected by MLPA or FISH. BRAF V600E mutation was observed in two patients and the results were successfully validated by pyrosequencing and ddPCR
Summary and Conclusions: digitalMLPA has successfully been tested and validated for comprehensive, high-resolution profiling of disease-related unbalanced genetic aberrations and for screening a specific point mutation in MM. The whole protocol can be completed within 48 hours, thus, the method could represent a valuable addition to the diagnostic pipeline of MM by replacing more tedious procedures. Due to its targeted approach, data processing and evaluation are computationally less demanding as compared to most NGS methods. Owing to its specific probe composition, digitalMLPA allows both genome-wide aneusomy and large CNA detection as well as targeted interrogation of genomic driver regions in a single reaction, thus facilitating an efficient patient stratification to improve personalized treatment strategies.

Croce Carle, Cuneo, Italy, Cuneo, [6]Department of Medical Sciences, Laboratory of Immunogenetics and CeRMS, University of Torino, Turin, Italy

Background: CD38 is a pleiotropic cell surface glycoprotein with receptorial

and enzymatic functions. The molecule is highly expressed in plasma cells which score the highest surface levels of CD38 among mature lymphoid cells, therefore CD38 has become the target of therapeutic antibodies in multiple myeloma (MM). Daratumumab (Dara) has been approved as monotherapy or in combination. The results obtained are good in patients refractory to standard myeloma therapies. Dara mechanisms of action comprehend: complement- and antibody-dependent cell cytotoxicity, antibody-dependent phagocytosis, programmed cell death, modulation of enzymatic activities and immunomodulation (in addition to its direct effects on cytotoxicity).
Aims: The aim of this study is to investigate the nature of the structural and functional modifications occurring in MM cells and in immune effectors after Dara treatment. Such modifications and effects could partially clarify the ways through which Dara acts on MM cells and even possible mechanisms of resistance.
Methods: Cell lines were cultured in IMDM supplemented with 10% FCS and MV were isolated from the culture supernatant through differential centrifugation steps. The phenotype of MV was analyzed by flow cytometry, using appropriate conjugated mAbs. MV internalization was evaluated by confocal microscopy with Alexa-conjugated mAbs and Vybrant Did-labelled MV. NK proliferation, viability and cytotoxicity after MV exposure was assessed by flow cytometry using conventional assays (CFSE, Annexin V/PI). Analyses of gene modulation were performed with NGS.
Results: CD38 engagement by Dara on MM cells is followed by a selective polar aggregation of the target molecule in myeloma membranes, with subsequent release into the extracellular space of microvesicles (MV) of 100–1,000 nm in diameter. We validated the hypothesis that MV released by MM in the bone marrow (BM) niche express functional ectoenzymes (CD38, CD39, CD73, and CD203a), potentially capable of metabolizing both ATP and NAD+ and to produce adenosine (ADO), a potent immunosuppressive molecule. Results indicate that MV obtained after Dara treatment tend to be internalized in NK cells, monocytes, dendritic cells and MDSC, cells all expressing Fc Receptors (FcR). Since NK cells apparently disappear in patients during Dara treatment, they were selected for testing MV-mediated effects. Comparative analysis of mRNA and small RNA modulated after exposing NK cells to the MV/Dara complex were followed by functional *in vitro* experiments. Both sets of results confirmed reduced proliferative ability and enhanced NK cell-mediated killing of MM cells. A further support to the immune modulatory roles exerted by Dara comes from the observation that MV surface represents not only a clustering of the expected CD38/Dara complex (flanked by a set of ectoenzymes involved in the generation of ADO), but also of inhibitory complement receptors such as CD55 and CD59, which impair the ability of the complement to exert *in situ* a cytolytic activity. Another set of observations indicate that PD-L1 tends to accumulate on the surface of MV after Dara treatment, anticipating a role in the modulation of immune checkpoint pathways (PD-1/PD-L1).
Summary and Conclusions: Results of the observations collected during the present work indicate that MV obtained from MM cells treated with Dara may be a particulate system to influence both the BM niche (local modulation) and at distance the immune response against the malignancy. Therefore, MV could also be partially responsible for Dara resistance.

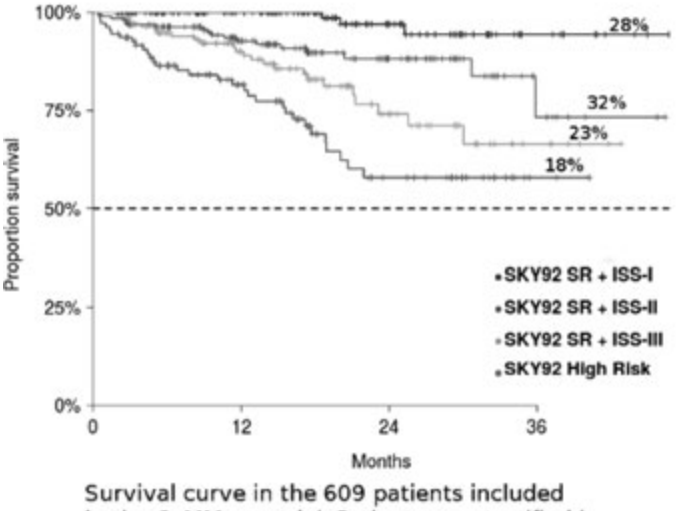
PF528

RNA-SEQ BASED RISK STRATIFICATION IN MULTIPLE MYELOMA PATIENTS VALIDATES SKY92 AS A HIGH RISK MARKER IN THE COMMPASS TRIAL

R. Kuiper[1,2,*], M.H. van Vliet[2], M. van Duin[1], E.H. van Beers[2], P. Sonneveld[1]

[1]Department of Hematology, Erasmus MC Cancer Institute, [2]SkylineDx, Rotterdam, Netherlands

Background: Multiple myeloma (MM) is a plasma cell cancer characterized by large variation in survival between patients; in this disease prognostic markers include gene expression (GEP) classifiers and FISH. Currently, GEP is mostly measured by microarray approaches (predominantly Affymetrix U133 Plus 2.0). Alternative technologies for GEP exist, such as RNA-Seq. Although measuring the same – *i.e.* relative mRNA abundance per gene specific sequence – the approach of both methods is entirely different. This raises the question how well RNA-Seq can be applied to microarray based markers.
Aims: Here we describe the conversion of the SKY92 classifier, from microarray to RNA-seq, and its validation in an independent cohort of MM patients.
Methods: The CoMMpass trial (NCT145429) is a longitudinal observational study in MM patients, performed by the Multiple Myeloma Research Foundation (MMRF). Each patient received a treatment regimen containing a proteasome inhibitor, IMiD or both. Preprocessed paired-end RNA-Seq and corresponding patient annotations were downloaded from the MMRF Researcher Gateway. In short, RNA-Seq (Illumina TruSeqRNA library kit; >60M 86 bp read pairs) was performed on purified plasma cells (>80% CD138+) obtained at diagnosis. The sequenced reads were mapped against the GRCh37 reference genome and resulting counts were converted to TPM (transcripts per million) values using SALMON v0.5.1.
The 92 Affymetrix probeset identifiers that define the SKY92 classifier were matched with Ensembl genes. In case of multiple matches, the corresponding TPM values were averaged. Five of 92 probesets were excluded: four probesets could not be matched and one had no expression in the RNA-Seq data in any of the patients. The weights of the linear SKY92 model as reported previously (Kuiper *et al.* Leukemia 2012) were adjusted using independent microarray data to correct for the missing probesets. This RNA-Seq classifier will be indicated as SKY92r and is applied to the $\log_2(1+TPM)$ values.
Results: For 632 patients from the CoMMpass trial, overall survival and corresponding RNA-Seq data was available. These patients were risk classified by the SKY92r gene classifier. In accordance with previous results, the patients with the 18% highest SKY92r scores were classified as high-risk (HR). In a Cox proportional hazards survival analysis, SKY92r HR classified patients had a hazard ratio of 3.3 (95%CI:[2.1 – 5.2]; p=1.4x10^{-7}) relative to the standard-risk (SR) patients. As shown previously, the SKY92 classification is further refined by addition of the international staging system (ISS), resulting in a low risk group, two intermediate and a high-risk group (Figure 1). The 3-yr overall survival rates are 94% (SKY92r SR with ISS-I), 73% (SKY92r SR with ISS-II), 66% (SKY92r SR with ISS-III) and 58% (SKY92r HR).



Survival curve in the 609 patients included in the CoMMpass trial. Patients are stratified by SKY92r and ISS.

Figure 1.

Summary and Conclusions: These results are in line with previous results published in Kuiper *et al.* (Blood 2015) using microarray data. This is a strong indication that the SKY92 classifier can effectively be converted from a microarray to an RNA-Seq platform. Further validation of the SKY92r in independent RNA-Seq datasets is required for future use.

PF529

MDSCS CONTRIBUTE TO CANCER STEM CELLS ACCUMULATION VIA PIRNA 823 UPREGULATION AND *DE NOVO* DNA METHYLATION IN MULTIPLE MYELOMA

L. Ai[1,*], S. Mu[1,1], Y. Hu[1]

[1]Hematology, Wuhan Union Hospital, Wuhan, China

Background: MDSCs (myeloid derived suppressor cells) promote tumor growth and invasion, exert immunosuppression and host immune evasion by suppressing lymphocyte activation and antigen recognition. A small population of cells, cancer stem cells (CSCs), are reported to persist in myeloma bone marrow, with unlimited self-renewal capacity to initiate tumor formation and disease relapse. Piwi-interacting RNAs (piRNAs) are non-coding RNAs (ncRNAs) of 26–31 nucleotides in length, which plays important role of epigenetic regulation in multiple myeloma (MM) via *de novo* DNA methylation.
Aims: Here, we sought to demonstrate the promoting effects of MDSCs on MM-CSCs accumulation, and investigate the involvement of piRNA-823 in the crosstalk between MDSCs and myeloma cells, thus providing theoretic basis of therapeutic strategy for MM patients.

Methods: CD11b^{+}HLA-DR$^{low/-}$MDSCs were isolated from BM via magnetic activated cell sorting (MACS). And Co-cultures of MDSCs with MM cell lines (RPMI8226 and NIH929) were performed in a non-contacted transwell system. Side population (SP) cells detection, cell colony formation, and stemness related genes expression were measured to validate the MDSCs' promoting effects on MM-CSCs accumulation. Besides, Expression of piRNA 823 and its target DNMT 3B were measured by qRT-PCR and Western blot, and total genome DNA methylation level was measured by 5-mC ELISA test according to the manufacturer's instructions. Specific antagomir for piRNA 823 was added to the co-culture system to investigate the regulating mechanisms in the crosstalk between MDSCs and MM cells.
Results: SP cells percentage in MM cells co-cultured with MDSCs was much higher than that in MM cells clone, and the experiment group showed greater sphere formation, with elevated expression of stemness related genes, such as Oct-4, Sox2, and Nanog. In addition, MDSCs co-culture induced the expression of piRNA 823 and its target DNMT 3B in MM cells, and the results of 5-mC ELISA test showed elevated DNA methylation level in MM cells co-cultured with MDSCs. Moreover, the promoting effects were almost abolished by the specific antagomir of piRNA 823. Adding antagomir-823 to the MDSCs/MM co-culture system not only decreased SP percentages in MM cells, hampered sphere formation, but also inhibited the CSC genes expression. That is to say, piRNA 823 is involved in the mechanisms about MDSCs' promoting effects on MM-CSCs accumulation (Figure 1).

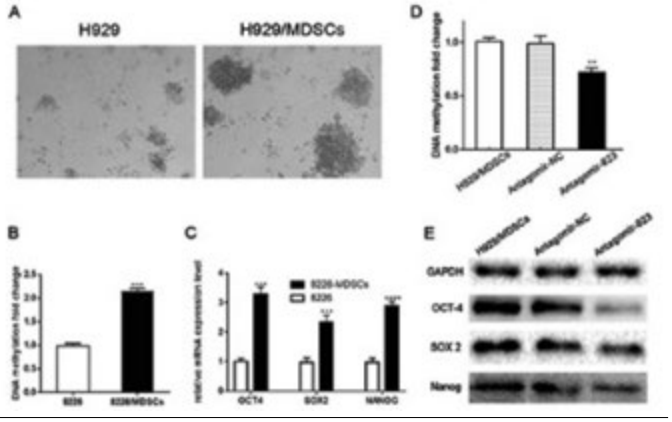


Figure 1.

Summary and Conclusions: Our results demonstrated that MDSCs worked as an important contributor to MM-CSCs accumulation *in vitro*. piRNA 823 and relevant *de novo* DNA methylation were involved in the regulatory mechanisms on MDSCs-MM interactions. These findings suggested that targeting MDSCs or other demethylating agents may become a new therapeutic strategy to improve the prognosis of MM patients.

PF530

MESENCHYMAL STROMAL CELL SIALYATION ENHANCES IMMUNE SUPPRESSION: IMPLICATIONS IN MULTIPLE MYELOMA

K. Lynch[1,2,*], K. De Veirman[3], G. O'Malley[1,2], K. Vanderkerken[3], A. Ryan[1,2,4], M. O'Dwyer[1,5], T. Ritter[1,2]

[1]College of Medicine, National University of Galway, [2]Regenerative Medicine Institute (REMEDI), Galway, Ireland, [3]Labo Hematology and Immunology, Vrije Universiteit Brussel, Brussels, Netherlands, [4]Discipline of Pharmacology and Therapeutics National University of Ireland, [5]Haematology Services, Galway University Hospital, Saolta University Health Group, Galway, Ireland

Background: Multiple myeloma (MM) is a plasma cell malignancy involving the bone marrow (BM) where the tumour microenvironment plays an important role in mediating survival, proliferation, resistance to therapy as well as disease evolution. Signals in the MM microenvironment are known to influence bone marrow mesenchymal stromal cells (BM-MSCs) facilitating MM progression and drug resistance. Little is known about the mechanisms of immune modulation mediated by BM-MSCs in MM. Aberrant glycosylation is a hallmark of cancer cells, playing an important role in tumour progression. In this study we investigate if regulation of BM-MSC sialylation alters their ability to inhibit effector T-cell function in an inflammatory microenvironment and if BM-MSCs isolated from MM mice have elevated levels of sialic acid and if this correlates with T-cell modulation.
Aims: 1. Characterise inflammatory mesenchymal stromal cells. 2. Profile sialic acid changes on inflammatory mesenchymal stromal cells and MM-MSCs. 3. Investigate if regulation of MSC sialylation alters their ability to inhibit effector T-cell function in an inflammatory microenvironment.
Methods: MM-MSCs and BM-MSC were isolated from mice and extensively characterized *in vitro*. BM-MSC were treated with both tumour necrosis factor alpha (TNF-α) and interleukin 1 beta (IL-1β) (i-MSC) for 72 hours and the sialic acid levels were analysed by flow cytometry. MM-MSCs, BM-MSC and i-MSC were co-cultured in mixed lymphocyte reactions (MLRs) for 96 hours. T-cell proliferation and activation were determined by flow cytometry. To assess the role of increased sialylation in lymphocyte suppression, both BM-MSC and i-MSC were pre-treated with the sialyltransferase inhibitor (SI) 3Fax-Neu5Ac for 72 hours prior to TNF-α and IL-1β stimulation.
Results: i-MSC displayed significant phenotypical changes with CD73 and CD44 increasing significantly. MM-MSCs and i-MSCs have significantly increased levels of both α2-3 and α2-6 linked sialic acid when compared to BM-MSC. *In vitro*, both MM-MSCs and i-MSCs displayed an enhanced ability to inhibit the proliferation of lymphocytes when compared to BM-MSC alone. Both MM-MSCs and i-MSC inhibited the proliferation of stimulated CD3^{+}CD4^{+} and CD3^{+}CD8^{+} lymphocytes significantly. SI BM-MSC and i-MSC displayed no significant changes in phenotype, viability, proliferation and cell size. However, following SI treatment, i-MSC lost the ability to suppress both CD3^{+}CD4^{+} and CD3^{+}CD8^{+}lymphocytes resulting in significant restoration of lymphocyte proliferation. Sialic acid expression on the cell surface correlated with both CD3^{+}CD4^{+} and CD3^{+}CD8^{+} lymphocyte suppression.

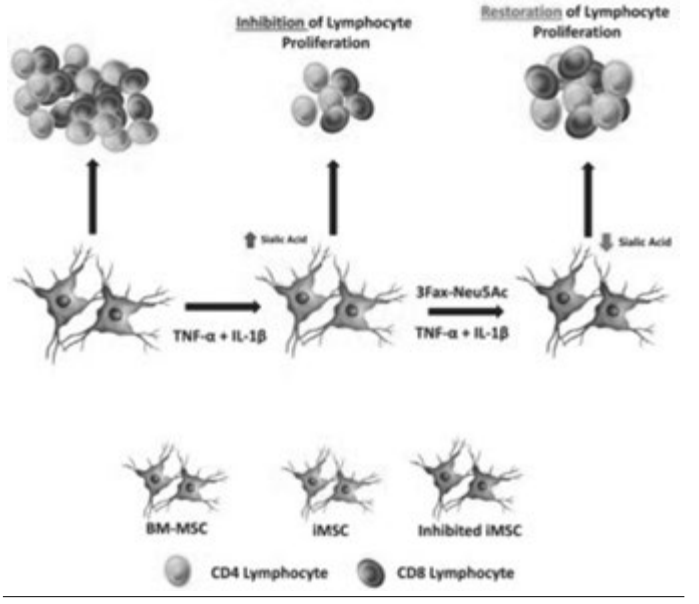

Figure 1.

Summary and Conclusions: Our findings confirm that inflammation, characteristic of the MM TME, induces BM-MSC sialylation and enhances their ability to suppress activated adaptive and innate immune effectors. Understanding the potential utility of targeting BM-MSC sialylation and consequently their immunomodulatory potential, may enhance immune cell activation in the MM microenvironment, providing further rationale to targeting BM-MSC sialylation in the context of MM. We suggest that understanding the functional importance of the BM stroma and its interaction with MM and immune cells is likely to lead to the identification of sialylation, as a new molecular target.

PF531

LOW-PASS SEQUENCING OF PLASMA CELL DNA AND OF CIRCULATING CELL-FREE DNA FOR THE DETECTION OF COPY NUMBER ABERRATIONS AND EARLY RESPONSE MONITORING IN MULTIPLE MYELOMA

B. Dewaele[1,*], S. Smits[1], L. Michaux[1], M. Delforge[2], G. Ameye[1], L. Dehaspe[1], N. Brison[1], J. Ding[1], S. Lehnert[1], N. Boeckx[3], J. Van Houdt[1], J. Vermeesch[1], P. Vandenberghe[2]

[1]Center for Human Genetics, [2]Hematology, [3]Department of Laboratory Medicine, University Hospitals Leuven, Leuven, Belgium

Background: Cytogenetic abnormalities are powerful prognosticators in multiple myeloma (MM). Presently, FISH on bone marrow (BM) plasma cells (PLCs) is the gold standard in diagnostics. Recently, array-CGH has been introduced as an alternative method for the detection of somatic copy number aberrations (CNAs) in PLCs, which allows to reduce the number of FISH tests needed per case, and yields genome-wide information. Next generation sequencing (NGS) technologies offer new perspectives for the diagnostic work-up of malignant disorders.
Aims: In this study, we compared low-pass sequencing with array-CGH for the detection of somatic CNAs in PLCs from BM aspirates in patients with MM at diagnosis and/or relapse. In addition, we explored whether low-pass sequencing of circulating cell-free DNA (ccfDNA) in plasma can reveal CNAs at diagnosis and can be used to monitor early response, as a non-invasive method.
Methods: BM aspirates were obtained from 31 cases with MM. All 31 cases were analyzed by FISH either on CD138+ cell-sorted samples or combined with cytoplasmic immunoglobulin (cIg) staining. When sufficient material was available, DNA was extracted from purified PLCs or from whole BM and subjected to array-CGH and/or low-pass sequencing. Array and genome-wide sequencing data were analyzed by the Cytosure Interpret Software (OGT) and our in-house pipeline, respectively. Paired samples of ccfDNA obtained at diagnosis and at early time points after therapy initiation were analyzed by low-pass sequencing.
Results: Low-pass sequencing of purified PLC (n=16) or whole BM cells (n=1) revealed CNAs in all cases. The CNAs identified by low-pass sequencing were confirmed by array CGH for each of these 17 cases. For 14 of the latter cases, paired ccfDNA samples were available. In 7 of these, sequencing of ccfDNA yielded a genomic representation profile compatible with the DNA profile on BM PLC. The 7 remaining cases had normal ccfDNA profiles despite abnormal profiles from BM aspirates. This could be due to a lower myeloma burden in these cases (mean 20,3% PLC in BM aspirates, range 10-30%) in comparison to those with abnormal ccfDNA profiles (mean 37,7% PLC, range 10-97%). Twelve patients with an aberrant ccfDNA profile at diagnosis were treated during the course of this study. The ccfDNA profiles of 11 of these patients returned to normal within 3 to 10 weeks after treatment initiation. The 12th patient is clinically not responding well, consistent with persistence of the abnormal ccfDNA profile under treatment.
Summary and Conclusions: Low-pass sequencing of PLCs DNA yields identical CNAs profiles in comparison with array-CGH: this validates low-pass sequencing as a novel and cost-efficient tool for the detection of CNAs in MM at diagnosis and relapse. In addition, we provide proof-of-principle that ccfDNA contains ctDNA from MM PLCs in a substantial fraction of patients. Therefore, analysis of ccfDNA in MM could be developed as a novel and non-invasive approach for monitoring of early disease response in a dynamic fashion.

PF532

RNA-SEQ ANALYSIS UNRAVELS SPECIFIC LONG NON-CODING RNA TRANSCRIPTIONAL FINGERPRINTS IN MULTIPLE MYELOMA SUBTYPES

E. Taina[1,2,*], C. Vinci[1,2], V. Ferla[1], D. Ronchetti[1,2], A. Pompa[1], K. Todoerti[1,2], M. Manzoni [1,2], L. Nobili[1,2], V. Favasuli[1,2], A. Cortelezzi[1,2], L. Baldini[1,2], A. Neri[1,2], L. Agnelli[1,2]

[1]Hematology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, [2]Department of Oncology and Hemato-oncology, University of Milan, Milano, Italy

Background: Long non-coding RNA (lncRNAs) represents the largest class of non-protein coding genes in the human genome. The increasing studies on lncRNAs have been changing the landscape of cancer biology. In multiple myeloma (MM), they are promising candidate to provide further insights into the molecular mechanism of the pathology.
Aims: The present study was aimed at characterizing lncRNAs expression in MM by next-generation sequencing, and unraveling their putative transcriptional relationships with the different molecular subtypes and biochemical-clinical parameters.
Methods: The study was performed in a cohort of 30 MM patients admitted to our hematology unit from 2000 to 2014. Cytogenetic and mutational data of TP53, KRAS, NRAS, BRAF, FAM46C, DIS3 were available for all patients. RNA-sequencing (RNA-seq) of lncRNA was performed using TruSeq® RNA Sample kit (Illumina) and HiSeq2000 (Illumina) platform. Fragments were aligned to the human genome using *STAR* and Gencode v25 annotations based on Ensembl database version 87. Transcript abundance was estimated using featureCounts. FPKM (Fragments Per Kilobase Million) quantification was performed using *cufflinks*. Differentially expressed lncRNAs were identified using DeSeq. Array analysis was run under manufacturer's standard procedure on GeneChip® Human Gene 2.0ST platform.
Results: The natural grouping of the transcriptional profiles of the most variable lncRNA across the dataset generated by RNA-seq could be associated with the main MM molecular subgroups, characterized by the presence of t(11;14), t(4;14), MAF-related translocations or hyperdiploid status (P<0.0001). Then, a differential analysis revealed 391 unique lncRNAs differentially expressed between the four cytogenetics subgroups of MM with prognostic impact. As a validation, we assessed the transcriptional signature of 391 lncRNAs differentiating MM subgroups in the same cohort of patients evaluated on microarrays (that contain specific probes for 262/391 transcripts), gaining full reproducibility. In addition, this analysis demonstrated that a robust transcriptional signature distinguish the tumor samples from 4 available healthy donors. Finally, to select lncRNA with a possible role in MM, we considered the levels of lncRNAs expression together with their proximity to genes that, based on literature, are relevant in MM, according to the reported evidence of cis-regulatory relationships between the transcription of proximal mRNA and lncRNA transcripts. For this purpose, a list of 707 genes described as associated to MM was downloaded from the NCBI database and studied in the genomic context. For 409 of them we found at least one of the 9540 lncRNAs detected in our dataset in at least one sample that mapped at upstream or downstream distance lower than 4 Mbps. Next, for each pair of lncRNA / MM genes, the correlation of the expression level was evaluated and unraveled 43 significantly correlated pairs (r>|0.4| and p-value <0.01) constituted by the combination of 39 genes with 35 lncRNA with significant co-expression.
Summary and Conclusions: In the present study, we have investigated the lncRNA expression profiling in MM patients by RNA-seq, with the aim of providing an exhaustive catalogue of lncRNAs specifically associated with the main molecular subgroups and genetic alterations in MM. Furthermore, we defined a *repertoire* of lncRNAs and genes linked by putative cis-regulatory relationship with a potential involvement in MM.

PF533

COMBINATION TARGETING OF SIALYLATION AND THE PROTEASOME INHIBITS TUMOR GROWTH AND INCREASES SURVIVAL IN A HUMANIZED MOUSE MULTIPLE MYELOMA MODEL

M. Reagan[1,*], M. Farrell[1], M. Macauley[2], A. Natoni[3], H. Fairfield[1], M. O'Dwyer[3]

[1]Center for Molecular Medicine, Maine Medical Center Research Institute, Scarborough, United States, [2]Faculty of Science, University of Alberta, Alberta, Canada, [3]Dept. of Medicine/Haematology, National University of Ireland Galway, Galway, Ireland

Background: Multiple myeloma (MM) is a cancer of clonal plasma cells that hijack the bone marrow (BM) to create a drug resistant, incurable malignancy. Aberrant sialic acid glycosylation, sialylation, has been linked to immune cell evasion, drug resistance, and metastasis in cancer. In several cancers, sialyltransferases, including ST3GAL1, ST3GAL4 and ST3GAL6 (1), are aberrantly expressed.
Aims: We have previously shown that inhibiting sialylation of BM-homing cells by targeting ST3GAL6 inhibits the ability of MM cells to extravasate and colonize the BM in mouse models (1,2). Based off these findings, we herein investigated changes in BM homing, growth, and bortezomib response of MM cells treated with 3Fax-Neu5Ac, a small molecule sialyltransferase inhibitor. We hypothesized that inhibiting homing of MM cells to the BM will improve survival and that co-treatment with bortezomib and 3Fax-Neu5Ac will have a synergistic effect.
Methods: We first enriched human GFP$^+$/Luciferase$^+$ MM1S MM cells for a sialofucosylated cell population using the HECA-452 antibody to select for cells expressing sialofucosylated E-selectin ligands, using FACS. We then determined the 3Fax-Neu5Ac dose and exposure times needed to decrease sialylation on these MM cells without causing toxicity. HECA-452 -enriched MM1S cells were pretreated with 3Fax-Neu5Ac or vehicle for 7 days before being injected into SCID-beige mice and then treated with vehicle or bortezomib (0.3 mg/kg twice a week). Mice were analyzed via bioluminescence imaging to monitor tumor progression and euthanized when they began to show paralysis under our IACUC protocol.
Results: We successfully identified and enriched for a sialofucosylated subclone of MM1S using HECA-452 sorting. Treatment with 3Fax-Neu5Ac, at 300 M for 7 days significantly reduced sialylation on these cells. Importantly, reducing sialylation with 3Fax-Neu5AC reduced tumor burden and increased survival, although this did not reach significance for survival (Figure 1). Both vehicle- and 3Fax-Neu5Ac-treated cells significantly responded to bortezomib

in the first 5 weeks of the *in vivo* study (Figure 1). However, unlike 3Fax-Neu5Ac-treated cells, HECA-452-enriched cells did now show increased survival when treated with bortezomib, suggesting that their aggressive nature overrode the inhibitory effects of bortezomib that were seen in the earlier on with BLI and indicating a form of drug resistance (Figure 1). Overall, the lowest tumor burden and best survival outcomes were observed in the combination group of bortezomib plus 3Fax-Neu5Ac.

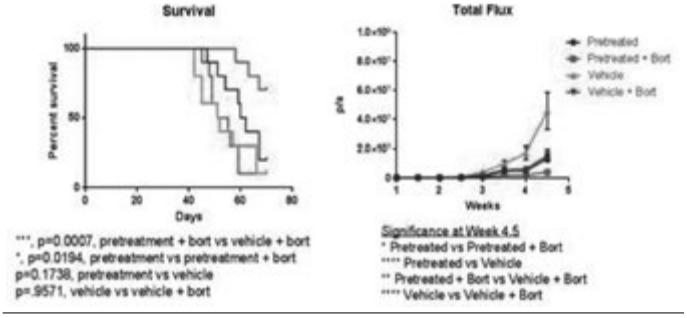

Figure 1.

Summary and Conclusions: In conclusion, sialylation plays an instrumental role in bone homing, BM colonization, and drug resistance of MM cells. Our data indicates that drug resistance can be overcome in HECA-452-enriched MM cells through the combination of 2 drugs: bortezomib and 3Fax-Neu5Ac which decreases sialylation. This is likely because 3Fax-Neu5Ac pretreatment increased MM circulation and reduced BM homing and bortezomib resistance, but it is possible that decreased sialylation also affected immune cell activity. This study supports prior work showing the importance of targeting sialylation in MM and demonstrates the feasibility and efficacy of targeting sialylation therapeutically, providing a strong rationale for further clinical translation of this novel approach.

ACTIVATION OF NFAT (NUCLEAR FACTOR OF ACTIVATED T CELLS) SIGNALING AND INDUCTION OF AUTOPHAGY CONFER BORTEZOMIB RESITSTANCE IN MULTIPLE MYELOMA

M. Ng[1,*], K.-M. Lau[1], C.-K. Cheng[1], N. Chan[1], J. Xia[1]

[1]Anatomical & Cellular Pathology, The Chinese University of Hong Kong, HKSAR, China

Background: Bortezomib (BTZ) is a proteasome inhibitor. It suppresses multiple myeloma (MM) cell growth by inducing apoptosis through endoplasmic reticulum (ER) stress. However, drug resistance remains an issue. Of note is a recent study demonstrating that BTZ conflictingly could promote MM cell proliferation and aggressiveness. Besides apoptosis, ER stress also stimulates pro-survival signals, particularly nuclear factor of activated T cells (NFAT) signaling. Whether BTZ could activate NFAT signaling, thereby counteracting its own growth inhibitory effects in MM deserves further studies.
Aims: We investigated the effects of BTZ on NFAT signaling in MM cells and determined how the signaling activation could enhance MM cell survivals. The potential therapeutic values of the chemical inhibitors blocking NFAT signaling in potentiation of BTZ induced MM cell growth inhibition were also evaluated.
Methods: Cellular calcineurin phosphatase (the upstream regulator of NFAT) activity was measured and NFAT luciferase reporter assay was used. Nuclear localization (activation) of NFAT proteins were studied by immunofluorescence staining and Western blot. RT-qPCR was performed to study the effects of BTZ on gene expressions and LC3 conversion assay for studying autophagy. MM cell growth and survival were studied by AccuCheck bead counting and Annexin V apoptotic assays respectively.
Results: We found that BTZ increased cellular calcineurin activity and NFAT transcriptional activity together with nuclear translocation of NFATc1 in MM1s myeloma cells. The BTZ-induced NFAT transcriptional activity was also confirmed in another MM cell line, ARH77. Mechanistically, BTZ up-regulated expressions of NFAT-related anti-apoptotic *BAG3* and *DDIT4* in both MM cell lines. Because these genes are also involved in autophagy as an adaptation strategy to deal with ER stress, concordantly we observed BTZ-induced autophagy in these MM cells. Further, we demonstrated that co-treatment with cyclosporin A or FK506, which inhibit calcineurin activity thereby blocking NFAT signaling, dramatically enhanced BTZ-mediated MM growth inhibition through intensification of BTZ-triggered ER stress-induced apoptosis as reflected by the concomitant up-regulation of fatal ER stress markers and down-regulation of anti-apoptotic *BCL2* expression in MM1s and ARH77 cells. The intensified BTZ-triggered apoptosis was also observed in CD138+ immunosorted MM cells from clinical bone marrow samples of the patients with MM (n=15, p=0.017).
Summary and Conclusions: These findings indicated that BTZ activates NFAT signaling, which induces pro-survival and adaptation signals to confer BTZ-resistance in MM. For clinical application, inhibition of NFAT signaling potentiates the therapeutic efficacy of BTZ treatment by circumventing the chemo-resistance in MM.

PF535

THE CONICAL AGAROSE MICROWELL ARRAY (CAMA) ENABLES 3D LONG-TERM CULTIVATION OF PRIMARY SAMPLES AND ENHANCED HIGH THROUGHPUT SCREENING FOR RATIONAL EPIGENTIC/ANTIBODY COMBINATION IN MULTIPLE MYELOMA

S.J. Mueller[1,*], D. Wider[1], M. Follo[1], S.M. Dold[1], C. Miething[1], G. Ihorst[2], J.M. Waldschmidt[1], J. Felthaus[1], J. Schueler[3], A.R. Thomsen[4], A.K. Azab[5], J. Duyster[1], M.J. Hug[6], M. Jung[7], R. Waesch[1], M. Engelhardt[1]

[1]Hematology, Oncology and Stem Cell Transplantation, [2]Clinical Trials Unit, Medical Center, [3]Oncotest GmbH, [4]Radiation Oncology, Medical Center, Freiburg, Germany, [5]Radiation Oncology, Cancer Biology Division, Washington University School of Medicine, St. Louis, United States, [6]Pharmacy, Medical Center, [7]Pharmaceutical Sciences, University of Freiburg, Freiburg, Germany

Background: Over the past decade, numerous small molecules and monoclonal antibodies have substantially improved the median survival of multiple myeloma (MM) patients (pts). However, the variety of anti-MM agents also constitutes a challenge to establish rational and best possible drug combinations to furthermore enhance long-term efficacy and tolerability.
Aims: For this purpose we here screened 33 primarily subclass selective epigenetic modifying agents for their anti-MM activity, to subsequently assess their influence on antigen expression levels (CD138, CD38, SLAMF7, PD-L1, and CXCR4) and to finally derive best antibody drug combinations using our 3D *ex vivo* high throughput screening platform.
Methods: Initially, our screening approach included 4 inhibitors for epigenetic reader proteins as well as 8 compounds impeding writer enzymes and 21 drugs inhibiting epigenetic erasers. Their anti-MM cytotoxicity was assessed after 48h, 120h and/or 168h using ATP-dependent viability assay. Multiple myeloma cell lines (MMCLs) as well as primary bone marrow samples were seeded into 2 mm deep conical agarose-based microcavities of the CAMA platform (Figure 1) and cluster growth or treatment response were analyzed via confocal imaging and non-destructive transmitted light scanner analysis. For antigen quantification the aggregates were harvested on days 2 and 4 with or without epigenetic treatment and measured via FACS.

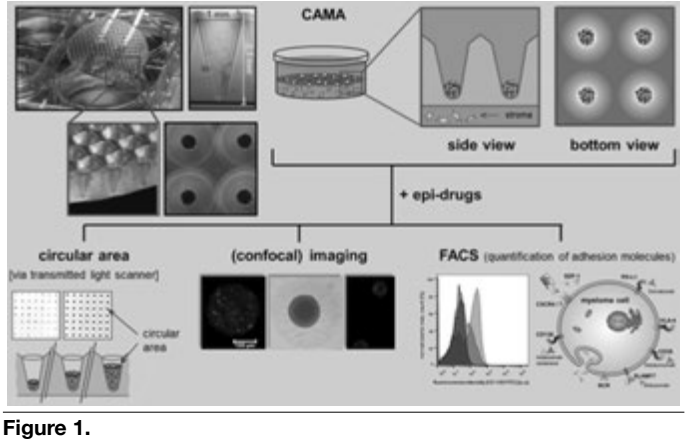

Figure 1.

Results: The well-defined, steep microwells of our CAMA enabled semi-adherent plasma cells (PCs) to form 3D-aggregates and furthermore mediate drug resistance to proteasome-inhibitors and epi-drug treatment. In this context qualitative confocal analysis of mCherry-transduced RPMI 8226 cells and fluorescent dye staining excluded uneven drug distribution within the CAMA. Moreover, PCs seeded into the microcavities showed prolonged

sigmoidal cluster growth in accordance to intratibial MM engraftment in our *in vivo* NOD/SCID mouse model. Using our established transmitted light scanner technique, stable *in vivo*-like proliferation of primary MM cells could be monitored for at least 2 weeks in a non-destructive manner and correlated to ATP concentrations and microscopic imaging. The evaluation of the epigenetic library identified 12 out of 33 compounds with potent anti-MM activity, including G9a, EZH2, panKDM and KDM5-selective inhibitors, but also 1 highly selective HDAC6 (JS28) and 2 HDAC10 selective inhibitors (HDACi: TH95 and TB76). For JS28, we could demonstrate a more than 200-fold selectivity for HDAC6 over HDAC1 or 8 via enzymatic *in vitro* assay. Consistently, we also assessed the selectivity on target via western blot as well as the functional synergism with bortezomib in 2 MMCLs. Our subsequent antigen analysis showed a dose-dependent increase of CD38, up to 140% in the presence of the class I selective HDACi entinostat as compared to persisting or decreased CD38 expression levels with vorinostat or panobinostat and JS28, respectively.
Summary and Conclusions: Our CAMA provides various advantages in MM, namely 1.) solid cluster formation of semi-adherent PCs including more *in vivo*-like proliferation and drug resistance, 2.) simultaneous, non-destructive observation of approx. 880 spheroids per matrix over time and 3.) cultivation of proliferating and viable primary MM-pt samples for at least 2 weeks. By using our investigated epigentic toolbox for subclass selective functional analysis, we found class I HDACis to upregulate CD38 expresion levels, which indicates that specific HDACi are promising and rationally-tested combination partner for daratumumab.

PF536

ENHANCED CYTOTOXICITY OF MULTIPLE MYELOMA CELLS USING DARATUMUMAB IN COMBINATION WITH NK CELLS ENGINEERED TO EXPRESS HIGH-AFFINITY CD16 (F158V)

S. Chauhan[1,2], S. Sarkar[1,2], T. Duggan[1], J. Daly[1], M. O'Dwyer[1,2,*]

[1]Apoptosis Research Centre, National University of Ireland, [2]Onkimmune Ltd., Galway, Ireland

Background: Multiple Myeloma (MM) is a clonal plasma B-cell malignancy, associated with strong expression of the CD38 antigen. Recent clinical trials with the anti-CD38 monoclonal Antibody (moAb) Daratumumab (Dara) have shown promising results. NK cells are important immune effectors of moAb therapy, mediating ADCC via FcγRIII (CD16). 15% of the population expresses a higher affinity (HA) form of CD16, due to a single point polymorphism (F158V) and this has been linked to higher responsiveness to therapeutic moAbs in the clinic. Therefore, we hypothesize that the combination of Dara with "off-the-shelf" NK cells, engineered to express high affinity (HA) CD16, could offer a new therapeutic strategy for treating MM patients.
Aims: In the current study, we investigated a "safer" m-RNA-based approach to develop high-affinity CD16 expressing NK cells for application as an off the shelf therapeutic.
Methods: CD38 expression was determined on a panel of *n=5* MM cell lines RPMI-8226, H929, MM.1S, U266 and JJN3. m-RNA transcripts coding for high-affinity CD16 protein was synthesized using *in-vitro* transcription (IVT), and KHYG1 NK cells were subsequently nucleofected using AMAXA Nucleofector II. 24 hours post-nucleofection cells were analyzed for surface expression of CD16, and further co-cultured with MM cell lines either alone or in combination with Dara. NK cell-induced cytotoxicity was measured by FACS-based methods. Experimental assays were performed with *n=5* MM cell lines at E:T ratios of 0.25:1, 0.5:1, 1:1 and 2:1. Cytotoxicity assays with each cell line were performed in *n=4* independent experiments.
Results: Immunophenotyping revealed that MM cell lines have a broad-spectrum cell surface expression of CD38, and therefore we classified them as $CD38^{hi}$ (RPMI 8226, H929), $CD38^{mod}$ (MM.1S), and $CD38^{lo}$ (U266, JJN3). Thereafter, ADCC assay was set-up against a panel of *n=5* MM cell lines (JJN3, H929, RPMI 8226, U266 and MM.1S) with HA-CD16 nucleofected KHYG1 either alone or in combination with Dara. HA-CD16 nucleofected KHYG1 in combination with Dara was significantly more cytotoxic towards NK resistant MM cell line H929 at E:T 0.5:1, 1:1, and 2:1, as compared to HA-CD16 KHYG1 alone. Furthermore, the combination was also significantly cytotoxic against $CD38^{lo}$ JJN3. Although RPMI 8226 cells and MM.1S cells are sensitive towards NK mediated killing, we found significant increase in cytotoxicity at multiple E:T ratios. Correlation plot analyzing sensitivity towards NK cells and change in cytotoxicity revealed than MM cells which are intrinsically resistant towards NK cells may benefit significantly more from this combination therapy (r^2=0.79).
Summary and Conclusions: This study provides the proof-of-concept for combination therapy of Dara and an "off-the-shelf" m-RNA approach based HA-CD16 expressing NK cells for treating MM patients.

PF537

IMMUNOLOGICAL PROFILING BY MASS CYTOMETRY REVEALS THAT TIM3 EXPRESSION IS REDUCED ON NK CELL SUBSETS IN NEWLY DIAGNOSED MYELOMA AND IS ASSOCIATED WITH LOSS OF NK FUNCTION AND DECREASED SURVIVAL

F. Seymour[1,*], J. Cavenagh[1], J. Gribben[1]

[1]Haematology, Barts Cancer Insititute, London, United Kingdom

Background: Natural killer (NK) cells have the potential to target malignant plasma cells and contribute to immunological control of myeloma. NK cells lose CD56 expression as they mature allowing the identification of bright and dim subsets with distinct functional roles.
Malignant plasma cells are known to have a range of immune modifying effects including the expression of PDL1 and the induction of a pro-tumour bone marrow environment. It is hypothesised that this downregulates the NK cell response, however the consequences for the function of NK subsets and its clinical significance is poorly understood.
Aims: To assess the phenotype and function of NK subsets in newly diagnosed myeloma (NDMM)
Methods: Bone marrow samples were interrogated by mass cytometry using a 36 parameter antibody panel to assess expression of 9 immune checkpoint regulators in addition to markers of cytotoxicity, cytokine production and proliferation.
Results: Total NK cell numbers were well preserved in NDMM with no numerical differences identified between control and disease. NK cell proliferation, as assessed by Ki67 expression, was reduced in myeloma (p=0.034). There was a marked reduction in proliferation within the NK CD56 dim subset while proliferation within the NK CD56 bright subset was well preserved. A reduction in TIM3 expression was seen in both NK cell subsets in myeloma compared to control (p=0.0018) suggesting loss of NK cell activation. Furthermore the NK CD56 bright subset had reduced expression of the NK cell activating receptor DNAM1 (p=0.0168), reduced production of IL10 (p=0.0077) and increased levels of the pro-tumour cytokine TGFb (p=<0.0001). The NK CD56 dim subset demonstrated reduced expression of IFNy (p=0.0103) and TNFa (p=0.0426) with increased levels of TGFb (p=0.0048). Perforin and granzyme production was preserved. PD1 expression was increased in the CD56 dim subset (p=0.0417). In addition to TIM3 and PD1, NK cells in myeloma also express the receptors DNAM1 (24%), NKG2D (19%) and 2B4 (69%) which may offer therapeutic targets to improve NK cell function. Expression of PD1 was of moderate, not high, intensity and was lower than that seen on CD8 cells in myeloma. Individuals with PD1 expression above the mean also had higher expression of Granzyme (p=0.0196), Perforin (p=0.0427) and DNAM1 (p=0.0152) suggesting that moderate NK cell PD1 expression may be a marker of activation rather than exhaustion. Total NK cell expression of TIM3 (p=0.0234) but not PD1 (p=0.0667) positively correlated with survival with individuals surviving more than 36 months having a 2.5 fold increase in NK cell TIM3 at diagnosis. NK cell TIM3 expression may therefore have prognostic value.
Summary and Conclusions: This data demonstrates that NK cell activation is reduced in NDMM with an associated reduction in proliferation and anti-tumour cytokine production. The functional deficits are most marked in the more mature NK CD56 dim subset and are likely to contribute to a pro-tumour microenvironment. Given that NK cells express a range of activatory receptors is may be possible to therapeutically target these in order to reverse the functional deficits. PD1 or TIM3 blockade may also produce beneficial functional responses. Interestingly those individuals with higher levels of NK TIM3 expression at myeloma diagnosis had a longer duration of survival, suggesting that the presence of activated NK cells is playing a key role in disease control. NK cell TIM3 levels at diagnosis may be a useful prognostic biomarker.

PF538

AUTOLOGOUS STEM CELL TRANSPLANTATION AS A MODEL FOR ACCELERATED T-CELL AGING

F. Lucas[1,*], J. Woyach[1], S. Zhang[2], X. Guan[2], C. Burd[3], D. Benson[1], Y. Efebera[1], A. Rosko[1]

[1]Department of Medicine, [2]Comprehensive Cancer Center, [3]Cancer Biology & Genetics, The Ohio State University, Columbus, United States

Background: Physiological aging is characterized by T-cell cellular senescence, immunosenescence and exhaustion. Cellular senescence results in permanent cell cycle arrest generally characterized by increased p16INK4a (p16) expression, which has been shown to be a robust marker of physiological age. Hall-

marks of T-cell immunosenescence include subset changes, declining effector function, reduced receptor diversity, and changes in transcriptome and epigenome. T-cell exhaustion occurs in the context of chronic antigen stimulation and is association with the upregulation of inhibitory molecules. In patients with multiple myeloma (MM), high-dose chemotherapy (HD-CHT) followed by autologous stem cell transplantation (ASCT) increases T-cell p16 to levels equivalent of 30 years of aging (Rosko *et al*., BMT 2015), indicating that ASCT is a useful model to study accelerated aging.
Aims: We hypothesized that ASCT in MM is a suitable model of accelerated T-cell cellular- and immunosenescence. Our aims were to: (1) confirm acceleration of T-cell cellular senescence in an expanded cohort of MM patients; (2) characterize T-cell immunosenescence before and after ASCT.
Methods: 100 patients with plasma cell dyscrasias were enrolled on OSU13135 to receive standard-of-care induction treatment, followed by high-dose melphalan (HD-M) with ASCT rescue, and standard-of-care maintenance therapy (proteasome inhibitor or IMiD). T-cell p16 was measured by Nanostring before treatment, before ASCT, 90 days after ASCT, and 1 year following transplant. T-cell subsets were characterized by flow cytometry before and after ASCT in 20 representative trial patients and 10 age matched controls.
Results: Induction and maintenance therapy did not significantly alter T-cell p16 levels. However HD-M followed by ASCT increased these levels at least 2-fold ($p<0.01$), confirming this regimen as a model of accelerated T-cell senescence. Similarly, an inversion in the CD4:CD8 ratio, reduced CD28 expression, and increased levels of CD4+ T-regulatory cells confirmed immunosenescent phenotypes in transplanted patients. ASCT also altered T cell subset compositions: central memory (CM) and effector memory (EM) cell populations were increased in CD4 T cells, whereas naïve T cells were lost. In CD8 T cells, EM and terminally differentiated EM (TEMRA) cells were expanded at the expense of CM and naïve T cells. After ASCT, immune senescent CD57+PD1- cells were significantly enriched in CD8 EM and EMRA cells. By contrast, both anergic and exhausted CD4 T cells were preferentially expanded after ASCT.
Summary and Conclusions: Phenotypic hallmarks of accelerated T cell cellular- and immunosenescence are replicated in MM patients undergoing ASCT. This suggests that transplant serves as a model to study mechanisms and biomarkers of age-related T-cell impairment. Additional studies assessing T-cell function and transcriptional and epigenetic signatures, and a direct correlation between the immune senescent phenotype and T-cell p16, are needed. A comprehensive immune assessment might serve as a modifiable clinical predictor of outcome of treatment and frailty in older cancer patients.

PF539

GENE EXPRESSION PROFILING OF PROSPECTIVE SERIES IN PRIMARY PLASMA CELL LEUKEMIA REVEALED GENE SIGNATURE ASSOCIATED WITH SURVIVAL

M. Naudot[1,*], M. Diouf[2], S. Minvielle[3,4], A. Caulier[1,5], H. Avet-Loiseau[6], J.-P. Marolleau[1,5], B. Royer[7]

[1]LNPC - EA4666, Université de Picardie Jules Verne, [2]Direction de la Recherche Clinique et Innovation, CHU Amiens, Amiens, [3]Service d'hématologie, CHU de Nantes, [4]CRCINA, INSERM, CNRS, Université de Nantes, Nantes, [5]Service d'Hématologie, CHU Amiens, Amiens, [6]Unité Génomique du Myélome, IUCT, IUCT, Toulouse, [7]Service Immuno-Hématologie, Hôpital Saint Louis, Paris, France

Background: Primary plasma cell leukemia (pPCL) is a rare, yet aggressive form of *de novo* plasma cell tumor, distinct from secondary PCL which represents a leukemic transformation of pre-existing multiple myeloma (MM). The prognosis of pPCL is poor, with median survival less than 1 year. The recent therapeutic progress in MM treatment offers novel agents (lenalidomide and bortezomib) to treat pPCL. A prospective phase II clinical trial of forty patients newly diagnosed pPCL combined novel agents and transplantation procedures (Royer *et al*., 2016). Patients received induction therapy composed of bortezomib, doxorubicine, cyclophosphamide and dexamethasone, followed by either a double autograft and long consolidation or an auto-allo-graft tandem. Overall response rate was 69% and median overall survival of 36 months.
Aims: pPCL shows complex and heterogeneous molecular patterns: the aim is to investigated the transcriptome of pPCLs and characterized gene signature correlated with PFS and/or OS.
Methods: Samples were available for 29 patients from the prospective phase II clinical trial and were analized with nCounter PanCancer pathways panel (nanostring). 770 genes from 13 cancer-associated canonical pathways were screened. Dataset was analyzed with nCounter advanced analysis software. To define statistically significant genes, p-value were adjusted with Benjamini-Yekutieli (BY) method.
Results: We found some upregulated genes CCND1, WHSC1 and FGFR3 in patients corresponding to genomic alterations, respectively t(11-14) and t(4-14), already characterized by FISH. nCounter advanced analysis software allocated patients into 4 groups according to the similarity of gene expression. This distribution is proved to be independent of the major cytogenetic alterations. These groups have strong expression characteristics and are correlated with PFS and OS. Group 3 overexpresses a large number of genes compared to all patients and has the more favorable outcome (PFS and OS). We investigated the dataset for differentially expressed genes in patients who failed to respond to induction therapy. No significant genes signatures were identified. Next, we assessed the relationship between each of the 770 genes across the pPCL dataset and OS. 2 genes: WNT5B and CD40, reached a highly significant correlation (BY. P value <0,05) with OS (Figure 1).

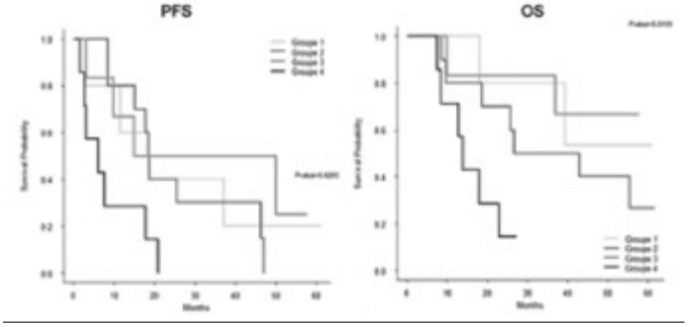

Figure 1.

Summary and Conclusions: This analysis, performed in a homogeneously treated population for a pPCL, allowed us to find 2 genes predictive of survival, whereas not predictive of the response to induction therapy. However the low number of patients in the non-responder group makes identification of gene signature less powerfull. These first hopeful results need to be confirmed with more patients.

PF540

MDSCS PROMOTED TUMORIGENESIS OF MULTIPLE MYELOMA BOTH *IN VITRO* AND *IN VIVO*

L. Ai[1,*], S. Mu[1], Y. Hu[1]

[1]Hematology, Wuhan Union Hospital, Wuhan, China

Background: Multiple myeloma (MM) is a clone malignancy of plasma cells, whose progression largely relies on support from the bone marrow (BM) microenvironment. MDSCs (myeloid derived suppressor cells) are heterogeneous population of myeloid lineage cells, which are highly increased in cancer patients as well as tumor bearing animal models.
Aims: Here, we sought to evaluate the clinical significance of MDSCs in MM development and progression, and validate the promoting effect of MDSCs on MM both *in vitro* and *in vivo*.
Methods: MDSCs frequency in the BM of MM patients or health donors (HDs) was detected by the multicolor flow cytometry (FCM), and other related clinicopathological parameters, such as age, gender, ISS staging, etc. were collected to analyze the clinicopathological significance of MDSCs in MM. Primary MDSCs were isolated from BM cells after removing red blood cells, using CD11b and HLA-DR microbeads selection according to the manufacturer's instructions. And Co-cultures of MDSCs with MM cell lines (RPMI8226 and NIH929) were performed in a non-contacted transwell system, and cell proliferation, apoptosis, cell cycle distribution were measured to validate the MDSCs' promoting effects on MM cell growth. BALB/c nude mice xenograft model was established to test the MDSCs' promoting capacity of tumorigenesis and progression *in vivo*.
Results: MDSCs frequency in the BM from MM patients was much higher than that in the HDs, and there existed positive association between MDSCs levels and the ISS staging for MM patients. Besides, MDSCs co-culture increased MM cells viability in a time-dependent manner, and the promoting effect was the strongest when MM cells were co-cultured with MDSCs for 48h *in vitro*. In addition, MM cells' apoptosis was inhibited by co-culturing with MDSCs, and much more MM cells co-cultured with MDSCs were at S phase in the cell cycle. thus contributing to MM growth *in vitro*. Accordingly, related proteins such as Bcl-2 and Cyclin D1 were up-regulated in MM cells co-cultured with MDSCs. Moreover, the study *in vivo* showed that pre-treatment with MDSCs to MM cells led to modest increase in tumor incidence and volume growth rate compared to MM cells-xenograft-

ed mice, with an average size of tumors of 530.03±69.91 $mm^{3 vs. 301.41 \pm 51.25 mm^3 after 4 weeks (}p<0.05$). Besides, immunohistochemistry and Western blot results showed that pre-treatment with MDSCs increased Ki-67, Bcl-2 and Cyclin D1 expression in MM cells (Figure 1).

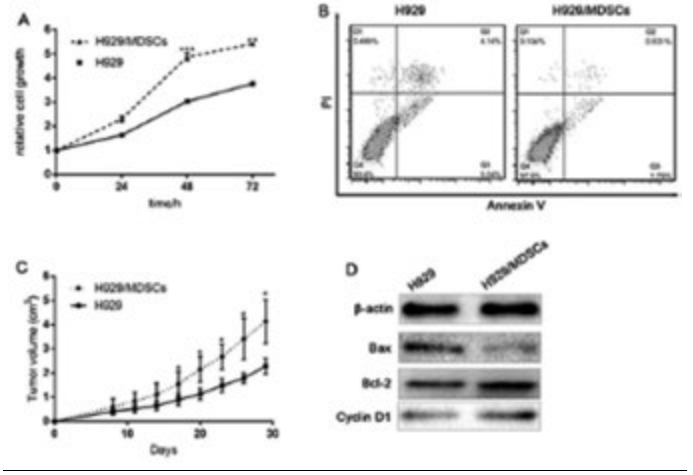

Figure 1. A. Promoting effect of MDSCs on NIH929 cells proliferation after 24h co-culture. B. Apoptotic effects of MDSCs on NIH929 cells as determined by flow cytometry. C. MDSCs co-culture accumulated tumor growth in the myeloma xenografted BALB/c nude mice model. D. Effects of mogrol on the expression of Bax, Bcl-2, and Cyclin D1.

Summary and Conclusions: Our results showed elevated MDSCs levels in MM patients and revealed the positive association between MDSCs and ISS staging in MM. Thus, we concluded that MDSCs might grow to be an important biomarker for MM diagnosis and prognosis. Furthermore, the study *in vitro* and *in vivo* both validate the promoting effects of MDSCs on MM proliferation and progression. These findings suggested that targeting MDSCs may become a new therapeutic strategy to improve MM patients' survival.

PF541

TARGETING THE INTERACTION OF MULTIPLE MYELOMA AND THE BONE MARROW MICROENVIRONMENT THROUGH NOVEL SMALL MOLECULES DIRECTED TO NOTCH PATHWAY

N. Platonova[1,*], C. Parravicini[2], L. Palazzolo[2], A. Paoli[1], S. Saporiti [2], M. Colombo[1], V. Vallelonga[1], D. Giannandrea[1], A. Neri[3,4], I. Eberini[2], R. Chiaramonte[3]

[1]Department of Health Sciences, [2]Department of Pharmacological and Biomolecular Sciences, [3]Department of Oncology and Hemato-oncology, Università degli Studi di Milano, [4]Hematology Unit, Fondazione Cà Granda, IRCCS Policlinico, Milan, Italy

Background: Multiple myeloma (MM) is an incurable hematological cancer characterized by plasma cells accumulation in the bone marrow (BM), where they shape the nearby BM milieu, inducing it to support tumor progression and acquisition of drug resistance. Despite recent advances, poor clinical response and relapse remain major problems. The oncogenic Notch pathway consists of 4 receptors (Notch1-4) activated upon binding to two families of ligands, Jag (Jag1 and 2) and Dll (Dll1, 3 and 4) and plays a crucial role in the pathological interaction between MM and BM cells. In MM the aberrant expression of Notch receptors and ligands on tumor cell results in homotypical interactions, which affect myeloma cell biology and heterotypical interactions with the BM cells, that favor tumor progression, osteoclastogenesis and drug resistance. In particular, aberrant Notch2 activation and overexpression of Jag2 ligand in MM cells play an important role in MM progression by stimulating osteoclast differentiation, release of pro-tumor cytokines by BM cells and MM cell self-renewal. Therefore uncoupling the interaction between Notch2 and Jag2 is critical to affect MM cell growth along with their pathological interaction with the BM niche. Currently, indirect approaches to inhibit Notch signaling are mainly based on inhibition of γ-Secretase, an enzyme that catalyzes Notch activation and the cleavage of several other γ-Secretase substrates. Moreover, γ-Secretase-mediated inhibition of all four Notch receptors is associated with gut toxicity, that might be avoided by selectively blocking of Notch signaling triggered by only one of the two family of ligands, Jag or Dll.
Aims: These lines of evidence prompted us to develop a therapeutic tool to selectively inhibit Notch2 signaling triggered by Jag2 using an unprecedented approach based on drug-like small molecules.
Methods: To select the small molecules, we performed *in silico* a protein-protein docking and virtual high-throughput screening (HTS) of an Asinex chemoteque of small molecules. The biological efficacy was validated through Notch responsive gene reporter and viability assays.
Results: We have set-up a strategy to exclusively uncouple Notch2::Jag2, leaving unaltered the interaction with Dll. The lack of crystallographic structures for Notch2::Jag2 was overcome by exploiting the differences in the surfaces of the Notch2::Jag2 and Notch2::Dll4 complexes, modeled by protein::protein docking on the bases of the crystallographic structures of Notch1::Jag1 and Notch1::Dll4, respectively. It allowed us to select *in silico* 100 top-scoring compounds supposed to be exclusively directed to Notch2::Jag2 surface by HTS of the small molecules chemoteque . Initially, 2 of 100 compounds were validated *in vitro*. A Notch responsive reporter assay on HEK293T cells showed that the compounds were able to significantly reduce Notch transcriptional activity. A viability assay of MM cell lines showed a dose-dependent cell growth inhibition in the presence of the compounds. Finally a Notch responsive reporter assay on co-culture systems allowed us to measure Notch2 activation triggered either by Dll4 or Jag2 ligands and to demonstrate that one of the two tested compounds specifically inhibited Notch2::Jag2 but not Notch2::Dll4 interactions.
Summary and Conclusions: Our integrated pipeline represents a successful strategy to identify compounds that directly and selectively antagonize Notch activation and lays a basis for the development of an entirely novel class of drugs to inhibit Notch signaling in cancer.

PF542

EXPRESSION LEVELS OF THE THREE GENES CRBN, IKZF1, AND IKZF3 IN PRIMARY MULTIPLE MYELOMA CELLS AT PRE- AND POST- LENALIDOMIDE TREATMENT

S. Kinoshita[1,*], M. Ri[1], T. Kanamori[1], S. Aoki[1], T. Yoshida[1], T. Narita[1], H. Totani[1], A. Ito[1], S. Kusumoto[1], H. Komatsu[1], S. Iida[1]

[1]Department of Hematology and Oncology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan

Background: Lenalidomide (Len) binds to cereblon and alters its substrate specificity, which results in immunomodulatory and anti-tumor effects. Among the substrates ubiquitinated by cereblon by Len exposure, the degradation of the two transcription factors IKZF1 and IKZF3 is considered critical in anti-tumor effect of Len. Although expression levels of *CRBN* and its related genes have been analyzed in association with treatment outcome of Len, their results are still controversial. In addition, the expression levels of these genes after Len treatment have not been fully investigated.
Aims: This study was conducted to explore if expression levels of *CRBN*, *IKZF1* and *IKZF3* mRNAs before treatment with Len plus dexamethasone (Ld) in primary multiple myeloma (MM) cells were associated with its treatment outcome and to investigate their alteration at post-Ld treatment.
Methods: A total of 83 patients with relapsed MM were treated with Ld therapy in our hospital between July 2010 and May 2017 and their samples and data were retrospectively analyzed. Forty-eight bone marrow (BM) specimens were collected just prior to Ld therapy. Among these, 25 paired BM samples were obtained at pre- and post- Ld therapy. After purification of CD138 positive cells from mononuclear cell fraction, mRNA levels of *CRBN*, *IKZF1* and *IKZF3* were quantified using real-time RT-PCR. Next, their expression levels were analyzed in association with the following outcomes such as response levels, progression-free survival (PFS) and overall survival (OS). Alteration of the expression levels of these genes in primary MM cells were compared between pre- and post-Ld treatment.
Results: Out of 48 patients who provided BM specimens with their informed consents, 47 patients were evaluated for the efficacy of Ld therapy. Expression levels of any of the three genes, *CRBN*, *IKZF1* and *IKZF3*, were not significantly associated with the PFS or OS. When tested using the ratio of *IKZF1* divided by *CRBN* expression, poor responders (SD+PD, n=15) to Ld therapy showed a significantly lower ratio than good responders (CR+VGPR+PR, n=32) (P=0.01). In addition, when the median value of the ratio of *IKZF1/CRBN* was set as a cut-off value, the patients with lower ratio of *IKZF1/CRBN* showed a significantly shorter OS than those with higher ratio (Figure 1a, median OS: 17 *vs* 38 months, P=0.034). There was no association of the ratio of *IKZF3* to *CRBN* with the efficacy of the Ld therapy. Of the 25 paired BM samples collected at both pre- and post-Ld therapy, 22 post-Ld samples were obtained when the patients became refractory to Ld. The expression levels of *CRBN* were reduced in 17 patients (17/25, 68%) and increased in 8 patients (8/25, 32%) at post-Ld compared to pre-Ld (Figure 1b). In the analysis of 22 refractory MM

cases to Ld, most of them (16/22, 73%), showed reduced expression of *CRBN* and two of them lacked *CRBN* expression after Ld therapy. In terms of *IKZF1* and *IKZF3* genes, 19 patients (19/25, 76%) showed increased expression of *IKZF1* and 16 patients (16/25, 64%) showed reduction of *IKZF3 mRNAs*.

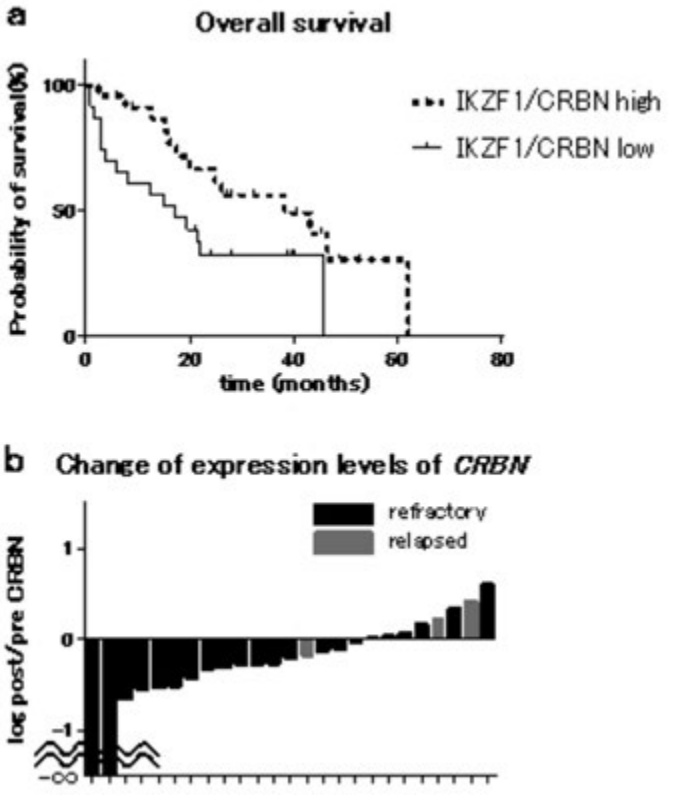

Figure 1.

Summary and Conclusions: A low ratio of *IKZF1/CRBN* may predict for the poor efficacy to Ld therapy and may serve as a biomarker in Len treatment. Reduced or lack of *CRBN* expression was observed in most refractory patients to Ld, suggesting an existence of lower dependence on cereblon and related pathways during development of Len resistance in primary MM cells.

MYC INVOLVES MULTIPLE MYELOMA PROGRESSION BY ATTENUATING TUMOR SUPPRESSIVE FUNCTION OF TP53-MICRO RNA 34 AXIS

H. Handa[1], Y. Murakami[2,*], K. Masuda[2], T. Oda[3], Y. Masuda[2], H. Hattori[4], R. Ishihara[2], K. Honma[2], S. Watanabe[2], Y. Kuroda[2], N. Kobayashi[1], T. Ishizaki[1], H. Shimizu[1], H. Koiso[1], Y. Osaki[1], A. Yokohama[5], N. Tsukamoto[6], T. Kasamatsu[2], T. Saitoh[2], H. Murakami[2]

[1]Department of Hematology, [2]Graduate School of Health Science, [3]Institute for Molecular and Cellular Regulation, Gunma University, Maebashi, [4]Graduate School of Medicine, Nagoya University, Nagoya, [5]Blood Transfusion Service, [6]Oncology Center, Gunma University, Maebashi, Japan

Background: Micro RNAs (miRs) are small non-coding RNAs of 19-25 bases in length having ability to modulate gene expression. Many miRs act as tumor suppressor genes (TSG) via degrading their target mRNA and/or inhibiting translation. MiR-34 is a transcriptional downstream and mediator of tumor suppressive function of TP53 by targeting MYC and CDK6. MiR29 acts as a tumor suppressor targeting DNA methyltransferase (DNMT). Those miRs cooperatively play a role in MM progression, however precise mechanism underlying miR dysregulation has not been elucidated yet. MYC simultaneously activates and silences many genes transcription including miR29.
Aims: In this study, we try to clarify mechanism of miR dysregulation in MM in the context of interaction between MYC and TP53-miR34 axis.
Methods: Purified bone marrow plasma cells by using anti-CD138 antibody and magnetic beads obtained from 123 MM patients, 57 MGUS patients 20 control subjects and 9 myeloma cell lines are subjected to the study after informed consent. This study was approved by IRB of Gunma University under the declaration of Helsinki. MiRs and their target gene mRNA values were determined by RQ-PCR. DNA methylation status was determined by methylation specific PCR. DNA demethylating agent decitabine, MDM2 inhibitor nutlin-3, MYC inhibitor 10058-F4, and miRNA-mimic™ and siRNA *in vitro* were used. U2OS/MYC-ER and KMS27/MYC-ER cell lines whose MYC are activated by incubation with 4-OHT were used.
Results: We found significantly reduced expression of miR 29a, 29b, 29c, 34a, 34b, and 34c in MM patients than in MGUS patients and control subjects (all: p<0.001). DNMT1 and 3A, 3B were elevated in MM patients than in MGUS patients and control subjects (p<0.001, p<0.001, p=0.01). The promoter of miR-34a and miR-34b/c were methylated with higher rate in MM (45.4%, 70.2%) than in MGUS patients (15.8%, 26.3%) (p<0.001). Significant positive correlations among miRs expressions were found: 29a-34a r=0.448, p<0.001; 29a-34b r=0.309, p=0.001; 29b-34a r=0.500, p<0.001; 29b-34b r=0.297, p=0.002). Unexpectedly, TP53 and its downstream p21 was rather higher in MM patients than MGUS and control subject (p=0.004, p<0.001), however TP53 level was not correlated with miR-34a, b, c. TP53 accumulation by nutlin-3 increased miR34a, b in U2OS, KMS28PE and KMS27 with wild type (wt) TP53, but did not increase miR34s in TP53 null KMS11 and TP53 mutated KMS18, KMS12PE, KMS28BM with wt TP53 and methylated miR34. Upregulation of miR34a by nutlin-3 was abrogated by MYC activation in U2OS/MYC-ER and KMS27-ER. MYC inhibitor increased pri-miR-29a/b-1 and miR-29a,b, pri-miR-34a and miR34a, b, c, however, knockdown by siRNAs did not show increase of miR29s and miR34s, probably because of insufficient suppression of MYC. Si-RNA-MAX showed slight increase of miR29b in KMS12PE. Decitabine increased miR34a, b and pri-miR-34a in, suggesting that miR-34s were suppressed by methylation. Transfection of miR-29a or 29b reduced DNMT3A and 3B and increased pri-miR-34s, and miR-34 transfection reduced CDK6 expression.
Summary and Conclusions: We found significantly reduced miR29 and 34 expression in MM discordant with higher TP53 expression. Escape from normal regulation of TP53-miR34 is promoted by MYC and promoter methylation. Correlations in between miRs in patients and *in vitro* study suggest that MYC involves multiple myeloma progression by attenuating tumor suppressive function of TP53-micro RNA 34 axis via abrogating micro RNA-29-DNA methyltransferase axis.

PF544

PREVENTING AND REPAIRING MYELOMA BONE DISEASE BY COMBINING CONVENTIONAL ANTI-RESORPTIVE TREATMENT WITH A NOVEL BONE ANABOLIC TREATMENT

A. Chantry[1,*], J. Paton-Hough[1], S. Tazzyman[1], H. Evans[1], L. Darren[1], J. Down[1], G. Alanna[1], S. John[1], M. Lawson[1]

[1]Oncology and Metabolism, University of Sheffield, Sheffield, United Kingdom

Background: Multiple myeloma is a plasma cell malignancy, which develops in the bone marrow and frequently leads to severe bone destruction. Current anti-resorptive therapies to treat the bone disease do little to repair damaged bone; therefore, new treatment strategies incorporating bone anabolic therapies are urgently required.
Aims: We hypothesised that combination therapy using the standard of care anti-resorptive zoledronic acid (Zol) with a bone anabolic (anti-TGFβ/1D11) would be more effective at treating myeloma-induced bone disease than Zol therapy alone.
Methods: JJN3-bearing mice (n=8/group) were treated with vehicle, Zol or 1D11 alone or Zol and 1D11 combined. Bone loss was analysed at the end stage of disease by *ex vivo* micro-CT and histomorphometry. U266-bearing mice (n=8/group) with established lytic bone lesions were treated with vehicle, Zol or Zol and 1D11 combined. Bone changes were monitored overtime by *in vivo* micro-CT, serum bone markers and dynamic histomorphometry. JJN3 myeloma-bearing mice treated with combined Zol and 1D11 resulted in a 48% increase (P≤0.001) in trabecular bone volume compared to Zol alone and a 65% (P≤0.0001) increase compared to 1D11 alone.
Results: The most significant finding was the substantial repair of U266-induced lytic bone lesions with combination therapy, which resulted in a significant reduction in lesion area compared to vehicle (P≤0.01) or Zol alone (P≤0.01). These results reveal a novel finding and demonstrate that combined anti-resorptive and bone anabolic therapy are significantly more effective at treating established myeloma-induced bone disease than Zol alone.
Summary and Conclusions: This is a highly translational strategy which could significantly improve bone outcomes and quality of life in myeloma patients.

PF545

TRYPTOPHAN SHORTAGE DUE TO IDO-1 EXPRESSED BY HIGH-DENSITY NEUTROPHILS INDUCE IMMUNE-SUPPRESSION AND PLASMA CELL FITNESS IN MULTIPLE MYELOMA

A. Romano[1,*], P. La Cava[1], N.L. Parrinello[1], C. Giallongo[1], D. Tibullo[2], G. Camiolo[2], F. Puglisi[1], V. Calafiore[1], M. Parisi[1], V. Del Fabro[1], C. Bellofiore[1], G. Sapienza[1], F. Cremasco[3], C. Conticello[1], G.A. Palumbo[2], S. Cenci[3], F. Di Raimondo[1]

[1]CHIRMED- Dipartimento Chirurgia Generale e Specialità Medico-Chirurgiche-Hematology Section, [2]Università degli Studi di Catania, Catania, [3]Age and Disease Related Unit, Fondazione Centro San Raffaele, Milano, Italy

Background: There is an increasing interest about the role of amino acid degrading enzymes in cancer immunotherapy. In multiple myeloma (MM), several groups including ours showed that immune-suppression due to arginine starvation is clinically relevant. However, Arginase inhibition or arginine supplementation cannot recover completely T-cell immune dysfunction.
Aims: In the attempt to investigate the role of amino acid deprivation in MM progression, we tested if availability of tryptophan could hamper immune function in the progression from MGUS through MM.
Methods: We first measured the amount of tryptophan and its degrading enzyme 2,3-indoleamine deoxygenase (IDO-1) in sera obtained from bone marrow and peripheral blood of 15 MGUS, 10 smoldering MM (sMM), 15 newly diagnosed and 10 relapsed MM. Second, we evaluated the main cellular source of circulating IDO by western blot and immune fluorescence of high- and low-density neutrophils (LDN), monocytes and neoplastic plasma cells. Third, we explored if the immune-suppressive activity of MM-LDN could be recovered by treatment *in-vitro* with 200 nM epacadostat, an IDO-1 inhibitor currently under investigation in phase I-II trials of immunotherapy in solid cancers. Fourth, we explored if tryptophan shortage could induce an adaptive response to MM cells MM1.s, OPM2 and U266 *in vitro* and mediate refractoriness to bortezomib, melphalan and lenalidomide.
Results: IDO-1 was increased in both bone marrow and peripheral blood of MM patients compared to MGUS and healthy subjects (p=0.002). Conversely, tryptophan was reduced (more in peripheral blood than in bone marrow) in MM *versus* MGUS patients and kynurenine (a product of tryptophan degradation) increased (p=0.001). T- cell function, evaluated as expression of HLA-DR and CFSE expression upon stimulation with 5ng/mL phytohaemagglutinin (PHA) for 72 hours, was hampered by co-colture at ratio 1:4 with MM-derived HDN, and only partially reverted by treatment with epacadostat.
MM cells expressed IDO-1 but their viability was not affected by exposure to epacadostat up to 72 hours. Tryptophan shortage (1000-10nM) did not affect cell proliferation and cell cycle of MM cell lines tested either, while induced T-cell apoptosis within 48 hours. In two human myeloma cell lines MM1.s and U266, progressive tryptophan shortage induced an adaptive response through increased expression, time and dose-dependent, of ATF4-ASNS-CHOP-GADD34, part of GCN2 signaling, followed by autophagy induction and fitness marker IRF4 and Blimp1 upon 96 hours of starvation. *In-vitro*, sub-toxic treatment with 5nM bortezomib, 10uM lenalidomide or 10uM melphalan for 24 hours showed synergic effect only between melphalan and epacadostat.
Summary and Conclusions: IDO-1 and tryptophan shortage are associated to MM progression. HDN are IDO-1 positive and mediate immune-suppression that can be reverted only partially by treatment with 200nM epacadostat. Epacadostat has synergic effect with melphalan *in vitro*. Experiments *in vivo* are ongoing to understand the contribute of IDO-1 in MM establishment in immune competent models of disease.

PF546

CHARACTERIZATION OF ST3GAL6-AS1, A NOVEL LNCRNA DEREGULATED IN MULTIPLE MYELOMA

C. Vinci[1,2,*], E. Taiana[1,2], V. Favasuli[1,2], D. Ronchetti[1,2], L. Agnelli[1,2], S. Galletti[1], M. Manzoni[2], F. Pelizzoni[2], M. Lionetti[1,2], K. Todoerti[1], A. Neri[1,2]

[1]Oncology and Hemato-Oncology, University of Milano, [2]Hematology Unit, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy

Background: During the last two decades, long non-coding RNAs (lncRNAs) relevance has been highlighted by a large number of studies. LncRNAs are non-protein-coding transcripts, longer than 200 nucleotides, which can act to regulate gene expression and be involved in cancer. More recently, some groups evidenced the impact of deregulated lncRNAs in Multiple Myeloma (MM). In previous report, we demonstrated that deregulated patterns of lncRNAs expression are associated with distinct MM molecular subtypes (Ronchetti *et al.*, Oncotarget, 2016).
Aims: (i) Confirming and extending data on lncRNA expression in MM (ii) Characterizing the RNA structure and explore the functional role in MM human cell lines (HMCLs) of ST3GAL6-AS1, the unique up-modulated lncRNA in MM patients compared with healthy donors.
Methods: A custom annotation pipeline was used to investigate lncRNA profiles on GeneChip® Human Gene 2.0 ST microarray in highly purified bone marrow PCs from 50 MM primary tumors and 4 normal donors. Real-time PCR (QT-PCR) was performed to confirm array data. Predicted splicing of ST3GAL6-AS1 transcripts were examined by qualitative PCR and Sanger sequencing in HMCLs and primary tumors. lncRNAs subcellular localization was evaluated by fractionated HMCLs nuclear and cytoplasmic RNA. HMCLs were treated with actinomycin D to determine the half-life of the lncRNAs. siRNA silencing of ST3GAL6 on HMCLs was performed by Neon Transfection system.
Results: We analyzed the long non-coding RNA fraction of the transcriptome of 50 MM patients using arrays that investigate more than unique 10000 sequences. First, we confirmed that the expression of the 5% most variable lncRNAs across the dataset grouped MM samples based on the main cytogenetics prognostic alterations (p<0.0001). One-hundred sixty-four lncRNAs showed significant differential expression in hyperdiploid, 11q14, 4p16 and MAF translocations groups. Importantly, we found ST3GAL6-AS1 as the unique significant overexpress lncRNA in MM samples compared to healthy donors. ST3GAL6-AS1 maps to 3q12.1 and is antisense to ST3GAL6, a protein involved in homing and *in vivo* engraftment of HMCLs and correlated with shorter overall survival in MM patients (Glavey *et al.*, Blood, 2014). The validation of array data by QT-PCR confirmed the overexpression of ST3GAL6-AS1 in MM sample. Analysis on HMCLs revealed that ST3GAL6-AS1 was overexpressed and equally localised in nuclear and cytoplasmic fractions. Furthermore, molecular analysis of the lncRNA in HMCLs and primary tumors showed the presence of a polymorphic splicing nucleotide variant (rs13065271) with the retention of a 128bp intron in the transcript. In homozygous mutated HMCLs we observed a prevalent nuclear localization of ST3GAL6-AS1, as well as a lower expression and reduced half-life of its transcripts. Moreover, ST3GAL6-AS1 and ST3GAL6 displayed a significant correlation in their expression levels. siRNA silencing of ST3GAL6 in HMCLs caused down-regulation of ST3GAL6-AS1, suggesting a possible co-regulation mechanism.
Summary and Conclusions: Our data indicate that ST3GAL6-AS1 is significantly deregulated in MM patients. Furthermore, the occurrence of a polymorphic variant leading to an alternative splicing in ST3GAL6-AS1 may have potential relevance in the transcript stability and its functional role.

PF547

MULTIPLE MYELOMA RELATED ANGIOGENESIS: ROLE OF NOTCH-JAG AXIS IN MODULATING ENDOTHELIAL CELLS BEHAVIOR

M.T. Palano[1,*], M. Colombo[1], N. Platonova[1], A. Neri[2], R. Chiaramonte[1]

[1]Department of Health Sciences, [2]Department of Oncology and Hemato-oncology, Università degli Studi di Milano, Milan, Italy

Background: Multiple myeloma (MM) is an incurable malignancy characterized by plasma cells accumulation in the bone marrow (BM). MM cells are able to shape the BM niche, inducing BM resident cells to support malignant cells survival and proliferation. In this process, a key role is played by alterations of Notch pathway. Indeed, the overexpression of Notch1/2 receptors and Jag1/2 ligands by MM cells promotes Notch hyperactivation not only in tumor cells, but also in the surrounding normal cells, stimulating different processes aimed to sustain MM cell progression. One of the mechanisms that promotes MM growth and contribute to its fatal outcome is the increased level of angiogenesis within BM. Interestingly, even if the link between MM progression and the angiogenic switch is well known, the contribution of Notch activity in this process still needs to be clarified.
Aims: This study aims to investigate the role of Notch-Jag axis in MM-associated angiogenesis evaluating the contribution of MM cells and of BMSCs.
Methods: We used 3 different cell lines, RPMI8226, U266 and OPM2 in which the Notch ligands, Jag1/2, were silenced ($MM^{KDJAG1/2}$) using specific siRNAs to study the role of Notch-Jag axis in promoting angiogenesis. The human pulmonary artery endothelial cells (HPAECs) were used to mimic the endothelial compartment while BMSCs were represented by the GFP^{+}HS5 cell line. The outcome of Jag1/2 silencing on MM-ECs interaction or on MM cells ability to secrete pro-angiogenic factors was analyzed using three assays that allowed us to evaluate different biological processes involved in tumor angiogenesis: motility (wound healing assays), adhesion on ECM-like substrate (adhesion assay) and EC tube formation assay. Finally, we analyzed MM capability to activate Notch signaling in BMSCs and induce the secretion of VEGF by qRT-PCR and flow cytometry. To investi-

gate the biological outcome of these variations, the above-mentioned assays were performed using CM collected from MM-BMSCs co-culture system.
Results: Our results indicate that MM cells promote tube formation both through direct contact and by releasing soluble factors. This effect is significantly reduced in the absence of Jag1/2 ligands, sustaining the hypothesis of a key role of Notch signaling in ECs stimulation. Comparable results were obtained in wound healing and in adhesion assays. Experiments performed on MM-BMSCs co-culture system showed that MM cells are able to boost BMSCs ability to produce the angiogenic factor VEGF. Interestingly, this effect is reverted by Jag1/2 silencing. As expected, MM-driven modulation of stromal-derived VEGF impacts on EC motility, adhesion and tube formation.
Summary and Conclusions: These findings indicate a novel role for the Notch-Jag axis in MM ability to promote angiogenesis in the BM microenvironment. Tumor-associated angiogenesis is supported by MM-ECs direct interaction and by the action of Notch-dependent MM-derived soluble factors. Moreover, Notch-Jag axis is involved in promoting stromal-derived VEGF production that further stimulates angiogenesis.

PF548

ADIPORON, THE FIRST ORAL ADIPONECTIN RECEPTOR AGONIST, INHIBITS THE PROLIFERATION OF MYELOMA CELLS VIA THE AMPK / MTOR /AUTOPHAGY SIGNALING PATHWAY

S. Wang[1,*], Y. Liu[1]

[1]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

Background: Multiple myeloma (MM) is the second most common hematological malignancies. New agent therapy and hematopoietic stem cell transplantation have significantly improved the survival of MM, but patients will eventually progress to death. To develop new drugs with different mechanisms of action is the fundamental ways to overcome this problem. Adiponectin has been reported to play an important role in the pathogenesis of MM and is a potential therapeutic target. However, it's difficult to directly use adiponectin in clinical practice. AdipoRon, the first oral adiponectin receptor agonist, plays a similar role as adiponectin in improving glycolipid metabolism while the role of AdipoRon in hematological malignancies remains blank.
Aims: The aim of this study was to investigate the inhibitory effects of AdipoRon on proliferation of myeloma cells and to explore the underlying mechanisms.
Methods: RT-PCR was used to quantify the AdipoR1 and AdipoR2 mRNA copy number in the bone marrow cells from 21 patients with MM. 23 normal marrow samples were served as control. Informed consent was obtained for every marrow sample. The cell proliferation was detected by CCK-8 and cell apoptosis was analyzed by flow cytometry. Western blot was used to determine the protein level of the signaling pathway.
Results: We found that the expression of AdipoR1 in MM was significantly higher than that in normal controls, while the expression of AdipoR2 in MM was significantly lower than that in normal controls, suggesting that adiponectin receptors are differentially expressed between MM patients and normal individuals. AdipoRon significantly inhibited the proliferation of MM cell lines Sp2 and MPC-11 in a concentration-dependent and time-dependent manner without affecting the proliferation of normal mesenchymal stem cell. Flow cytometry showed that AdipoRon induced apoptosis of MPC-11 cells in a concentration-dependent manner; Western blot showed that AdipoRon increased the expression of apoptosis-related proteins cleaved caspase-3 and cleaved PARP. AdipoRon upregulated p-AMPK and its downstream p-ACC and down-regulated p-mTOR in MPC-11. In addition, AdipoRon upregulated LC3- II / LC3-I level and down-regulated the protein level of p62, suggesting the activation of autophagy.
Summary and Conclusions: AdipoRon, the first adiponectin receptor agonist, could inhibit the proliferation and induce the apoptosis of myeloma cells, activate AMPK, inhibit the mTOR signaling pathway and activate autophagy in myeloma cells, suggesting that AdipoRon might play an important role in anti-proliferation of myeloma cells via the AMPK/mTOR/autophagy signaling pathway. The results need to be further verified *in vivo*.

PF549

CLINICAL RELEVANCE OF LONG NON CODING RNA IN MULTIPLE MYELOMA: RETROSPECTIVE MONOCENTRIC STUDY

V. Ferla[1,*], A. Pompa[1], L. Agnelli[1,2], F. Rossi[1], F. Guidotti[1,2], A.I. Gregorini[1], S. Fabris[1,2], M. Barbieri[1,2], M. Lionetti[1,2], K. Todoerti[1,2], M. Manzoni[1,2], A. Cortelezzi[1,2], A. Neri[1,2], L. Baldini[1,2]

[1]Hematology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, [2]Department of Oncology and Hemato-Oncology, University of Milan, Milano, Italy

Background: Multiple myeloma (MM) is a malignant proliferation of bone marrow plasma cells (BMPC) characterized by highly heterogeneous genetic background and clinical course. Long non-coding (lnc)-RNA represents the largest class of non-protein coding genes in the human genome. LncRNAs deregulation has been reported to promote tumor formation, progression and metastasis in many types of cancer. Their role in MM is progressively expanding. In previous report, specific lncRNA transcriptional profile has been described in subgroups characterized by molecular/cytogenetics alteration or progressive stages of the disease (Ronchetti *et al.,* 2016).
Aims: This study was aimed at evaluating the correlation between lncRNA expression profiles and clinical variables in MM at diagnosis.
Methods: We retrospectively collected the clinical and laboratory data of 80 MM patients (pts), who have been admitted to our Hematology unit from 2000 to 2014. Complete clinical data were available together with FISH/cytogenetics information and transcriptional profiles generated on GeneChip® Human Gene 1.0st arrays.
Results: The median age at diagnosis was 67 years, 38% of pts had anemia, 11% renal failure, only 4% was hypercalcemic, and 57% showed bone damage. BMPC infiltrate was greater than 60% in half of the cases, while extramedullary localizations occurred in only 2 pts. Del(13) was present in 51% of pts; del(17) in 10.1%; t(4; 14) translocation in 10%; t(11;14) in 25%; t(14;16) or t(14;20) in 7.5%; t(6;14) in 6.3%; 36.6% pts were hyperdiploid, 52.7% had 1q gain and 19% had 1p loss. Fit pts underwent autologous stem cells transplantation (ASCT), whereas others were treated with chemiotherapy, immunomodulatory drugs or Bortezomib. The median overall survival (OS) was 77 months and the time to next treatment (TNT) was 22 months. According to ISS), pts in stage I were 25, in stage II 30, in stage III 23. According to R-ISS, pts in stage I were 14, in stage II 52, and in stage III 12. R-ISS increased the number of patients in category II and effectively stratified pts in term of OS e TNT (p=0.005 and p=0.0003, respectively). We evaluated the association between lncRNA expression, assessed as a continuous variable, and outcome using *globaltest* package in R software, and identified 12 and 1 lncRNAs whose expression showed respectively negative and positive association with OS. Considering TNT, 15 lncRNAs were positively and 1 negatively correlated. In particular, the most significant correlation with poor outcome, in terms of both time to therapy and survival, was found for LIN00599, a lncRNA that was described to regulate the transcription through endogenous competition with microRNAs (specifically miR-4306, miR-185-5p, miR-4644). No correlation was found between lncRNA expression and response to therapy, independently of the type of treatment and the number of previous therapies. Additionally, our data indicated absence of relationship between lncRNA expression and ASCT therapy. Finally, the expression of each of the 13 lncRNAs associated with OS and the 16 associated with TNT was then tested as dichotomic variable in association with ISS and R-ISS. Our analysis revealed that none of the tested lncRNA improved ISS models.
Summary and Conclusions: In our retrospective cohort, representative of the main molecular alterations in MM, we unraveled lncRNA transcripts whose expression could be associated with outcome. However, lncRNA expression did not improve R-ISS staging model, which in our cohort retained the highest prognostic value.

PF550

DRUG SENSITIVITY SCREENING IN MULTIPLE MYELOMA (MM) FOR PRECISION CANCER THERAPY

D.B. Thimiri Govinda Raj[1,*], M. Giliberto[2], A. Cremaschi[2], S.S Skånland[2], A. Gade[3], D. Wang[2], G.E. Tjønnfjord[4], F. Schjesvold[4], L.A. Munthe[2], K. Tasken[1]

[1]Centre for Molecular Medicine Norway (NCMM), Nordic EMBL Partnership, University of Oslo and Oslo University Hospital, [2]Centre for Molecular Medicine Norway (NCMM), Nordic EMBL Partnership, University of Oslo and Oslo University Hospital, [3]NCMM UIO, [4]Department of Haematology, Oslo University Hospital, Oslo, Norway

Background: Chronic Lymphocytic Leukemia (CLL) and Multiple Myeloma (MM) are considered incurable. Although modern treatment regimens prolong survival, CLL and MM eventually relapse. Current challenges include design of optimal treatment for individual patients based on characterization of the tumor and its intratumor heterogeneity as observed by whole genome sequencing. Efficient therapies require a personalized approach that combines targeting malignant plasma cells as well as the support malignant plasma cells receive from the tumor microenvironment. Another major limitation is that there exists no efficient approach to identify the most efficient drugs for each patient and also for different cancer stage. Using our drug sensitivity screening platform, we aim to address the limitation in identifying the efficient drugs for individual patients.

Aims: We aim to establish a drug sensitivity screening platform for MM. We aim to perform drug sensitivity screening with 32 drugs at 5 concentrations to select drug candidates and pathway inhibitors for each patient sample. Selected drug candidates will be further analyzed by bioassays and flow cytometry to assess effects on intracellular signaling (phosphoflow-based approach). We aim to select efficient drug combinations for synergistic effects. We propose to use the drug sensitivity screening platform to identify and validate drug candidates for xenografting and precision medicine clinical trials.
Methods: We have established culture settings that mimic the tumor microenvironment for MM (Wang D. et al Leukemia 2017). MM cells were co-cultured with autologous bone marrow Th cells (wherein CD8+ T cells are depleted) directly in the presence of anti-CD3/28 beads and 100U/ml human IL2 for 2 days. Stimulated MM cells were then isolated using Miltenyi MACS CD138 positive selection. CD138+ MM cells were cultured in 384 well formats with 32 drugs at 5 concentrations for 72 hours (3 days). To define drugs that inhibit malignant plasma cell growth, we use the cell-based assays CellTiter-Glo® luminescent cell viability assay and CellTox™ green cytotoxicity assay as readout. As a quality control, DNA replication was tested by BrdU incorporation and also appropriate cell surface marker staining.
Results: Previous work from our group reported the experimental setting that mimic the tumor microenvironment for MM (Wang D. et al Leukemia 2017). We have performed drug screening on 10 patient samples. We have observed inhibitory effect of proteasome inhibitors on CD138+ MM cells in our drug screening experiment. We have also performed preliminary experiments with drugs that are in clinical trial. We performed drug screening on M2 cell line (patient derived cell line) for 527 drugs at 5 concentrations (Figure 1).

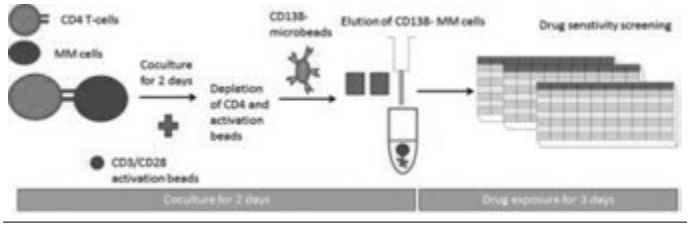

Figure 1.

Summary and Conclusions: Using our established MM drug sensitivity screening approach, we aim to perform drug screening on several patient samples. We aim to use statistical approach to identify synergistic drug effects and validate the drug combinations experimentally. As a future perspective, we would combine machine learning strategies with the experimental drug screening strategies for the precision medicine clinical trials.

ASSESSMENT OF SELECTED TOLL-LIKE RECEPTORS EXPRESSION ONT AND B LYMPHOCYTES IN PATIENTS WITH MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE

E. Grywalska[1,*], M. Pasiarski[2], P. Steckiewicz[2], A. Stelmach-Goldys[3], B. Sosnowska-Pasiarska[4], K. Gosik[1], A. Kowalska[1], B. Garus[2], S. Gozdz[5], J. Rolinski[1]

[1]Department of Clinical Immunology and Immunotherapy, Medical University of Lublin, Lublin, [2]Department of Hematology, Holycross Cancer Center, [3]Department of Hematology, Holycross Cancer Center, [4]Department of Oncocardiology, [5]Department of Clinical Oncology, Holycross Cancer Center, Kielce, Poland

Background: Monoclonal gammopathy of undetermined significance (MGUS) is an asymptomatic plasma cell dyscrasia that is present in more than 3% of the general white population older than age 50 and has an average multiple myeloma progression risk of 1% per year. Toll-like receptors (TLRs) play a protective role against infections, the leading cause of morbidity and mortality in MGUS patients, by recognizing a wide variety of pathogen-associated molecular patterns.
Aims: The aim of this study was to determine the percentages and absolute numbers of lymphocytes B and T with expression of TLR2, TLR4, and TLR9 in peripheral blood of MGUS patients. We analysed relationship between the number of TLR-positive lymphocytes and established prognostic factors in MGUS.
Methods: The study included 40 untreated patients with MGUS. The control group comprised 20 healthy subjects. After isolation of peripheral blood mononuclear cells, the viable cells underwent labeling with fluorochrome-conjugated monoclonal antibodies, and analyzed by flow cytometer.
Results: Compared to healthy individuals, patients with MGUS showed lower frequencies of lymphocytes B with phenotypes CD19+TLR2+ (p=0.000016), CD19+TLR4+ (p=0.0003), and CD19+TLR9+ (p=0.00053), as well as lower frequencies of CD3+TLR2+ (p=0.0034), CD3+TLR4+ (p=0.0021), and CD3+TLR9+ (p=0.00154) lymphocytes T. Lower percentages of TLR+ lymphocytes were associated with higher monoclonal (M) protein levels and decreased concentration of hemoglobin. Moreover, the number of plasmocytes correlated negatively with the number of CD19+TLR9+ (r=-0.654, p=0.002) B cells and CD3+TLR4+ (r=-0.680, p=0.003) T cells.
Summary and Conclusions: This study demonstrates that expression of TLR might represent hallmarks of immunosuppression in MGUS patients, and confirmed the association between negative prognosis and low expression of TLR in MGUS patients. Determination of TLR-positive T and B lymphocytes constitutes valuable diagnostic tool, completing cytometric evaluation of MGUS.
This work was supported by research grants no. DS460 of the Medical University of Lublin and no. UMO-2016/21/B/NZ6/02279 of the Polish National Science Centre.

PF552

DISCOVERY BLOOD PLASMA PROTEOMICS IN ELUCIDATING BIOMARKERS TO DISTINGUISH ONSET OF LETHAL MULTIPLE MYELOMA IN PREMALIGNANT MGUS

L.Y. Moreno[1,*], N.J. Weston-Bell[1], K. Vandyke[2], D. Hewett[2], A. Zannettino[2], S. Garbis[3], S. Sahota[1]

[1]Tumour Immunogenetics Group, Cancer Sciences Academic Unit, University of Southampton, Southampton, United Kingdom, [2]Myeloma Research Laboratory, Faculty of Health and Medical Sciences, The University of Adelaide, Adelaide, Australia, [3]Proteomics Group, Cancer Sciences Academic Unit, University of Southampton, Southampton, United Kingdom

Background: Multiple myeloma (MM) is characterized by accumulation of malignant plasma cells in the bone marrow, and is almost invariably preceded by asymptomatic monoclonal gammopathy of undetermined significance (MGUS). In symptomatic MM, clinical diagnosis is generally based on evidence for hypercalcemia, renal failure, anemia, and bone lesions (CRAB features). Despite global efforts to achieve early detection of malignancy, MM disease is still diagnosed at a late stage with onset of organ failure. Biomarkers that can identify early malignant transformation to MM in MGUS will overcome a major drawback, and allow immediate therapeutic intervention to improve disease outcomes in the absence of morbidity associated with CRAB features. In this, liquid biopsy biomarkers based on blood analysis directly will allow an ease of detection with minimal intervention.
Aims: To address this challenge, we have examined and compared the plasma proteome of 5 IgG MGUS patients, 5 IgG MM patients and 5 Healthy age-matched donors to interrogate potential biomarkers able to distinguish disease states.
Methods: We used multiplex isobaric labelling and three-dimensional liquid chromatography tandem mass spectrometry (TMT-3DLC-MS/MS) based quantitative proteomic analysis of non-depleted plasma. A total of 1095 proteins were commonly detected and fully quantified in all samples using high confidence ($q<0.01$) and 50% of isolation interference in Proteome Discoverer 1.4 software. The differential expression analysis was conducted using Limma.
Results: The expression analysis identified 478 proteins differentially expressed between MM and Healthy, 514 proteins between MGUS and Healthy and 82 proteins between MGUS and MM. 333 dysregulated proteins were commonly identified in MGUS and MM patients compared to Healthy donors. The differentially expressed proteins common to MGUS and MM revealed roles in bone cell and osteoclast development and bone remodelling (ATP6AP1, SPP1, SPP2, CTHRC1, MEPE), immune response and cytokine production (CD97, CFH, CFB, CFD, CCL5, CCL6, CXC16, CD14), cell adhesion (HSPB1, FBN1, FBLN5, SPON2, THBS1, FN1, FGA, POSTN, CD97, DAG1, FSTL3, ICAM1, MSLN), extracellular matrix and structural organization (SPINT1, LTBP2, TIMP1, COL1A2, BMP1, ICAM1, PRSS3, CST3) and cell migration (EFEMP1, CCL18, CCL14, PFN1, CFL1). Moreover, a number of these proteins have been previously identified in diseases with MM-related symptoms, including amyloidosis, kidney failure and secondary malignant neoplasms of the lymph node. Additionally, 31 proteins were found dysregulated *exclusively* in MM compared to MGUS and Healthy, including ECM1, BCHE, HPR, FCN2, FCN3, SLAMF1, C4BPA and C4BPB. These proteins are mainly associated with immune response, vesicle-mediated transport and proteolysis. b2-microglobulin was also identified as upregulated in MM. For MGUS, 26 proteins were identified dysregulated *solely* in the asymptomatic stage, including LGALS3, AMBP, PRDX1 and LCN2. These proteins are related to lymphocyte and

leukocyte aggregation. Importantly, a number of proteins identified as dysregulated in MM and MGUS in this study have been previously reported, including VCAM1, OSTP, extracellular matrix proteins and insulin-like factor binding proteins.

Summary and Conclusions: Our study of the plasma proteome has thus identified a compendium of biomarkers that can now be interrogated further on a more targeted basis to elucidate which specific or combination of plasma proteins demarcate onset of malignant MM. Such biomarkers have enormous potential to progress early detection and management of this lethal disease.

Myeloma and other monoclonal gammopathies – Clinical

PF553

VARIABLES PREDCITVE OF POOR PROGNOSIS IN PATIENTS WITH MAYO STAGE 1 SYSTEMIC LIGHT CHAIN AMYLOIDOSIS

F. Sharpley[1,*], R. Manwani[1], D. Foard[1], S. Mahmood[1], S. Sachchithanantham[1], C. Whelan[1], H. Lachmann[1], J. Gilmore[1], P. Hawkins[1], A. Wechalekar[1]

[1]*National Amyloidosis Centre, UCLH, London, United Kingdom*

Background: Cardiac involvement is the most reliable determinant of prognosis in light chain amyloidosis (AL). Mayo stage 1 patients, defined by normal cardiac biomarkers (N-terminal pro b-type natriuretic peptide (NT-proBNP) <332 ng/L, high-sensitive cardiac troponin T (cTnT) <55 ng/L, and a difference between involved and uninvolved free light chains (dFLC) of <180 mg/L) are still a very variable group with a prognosis ranging from 60-154 months.

Aims: This retrospective analysis of 405 Mayo Stage 1 patients at the National Amyloid Centre, London (UK-NAC) hopes to identify prognostic markers to help further stratify patients.

Methods: The Alchemy database at the UK-NAC was searched for all Mayo Stage 1 systemic AL patients, defined by normal cardiac biomarkers (NT-proBNP <332 ng/L, cTnT 55 ng/L). All Mayo Stage 1 patients assessed at the UK-NAC between 2009-2017 were eligible. Patients with cardiac involvement were excluded. A diagnosis of amyloidosis was confirmed by histology and typing by immunohistochemistry. Baseline assessment of organ function, imaging and biomarker assessments was performed and data collected on treatment regimen. Overall survival (OS) was calculated from date of diagnosis to death or last follow-up and organ involvement was defined according to the international amyloidosis consensus criteria. Survival was calculated by method of Kaplan-Meier and variables predictive of survival by logistic regression analysis. Median values were used to dichotomise continuous variables.

Results: A total of 365 Mayo Stage 1 patients were eligible for analysis. The median patient age was 68 years. The median number of organs involved was 2 (range 1-7); the majority of patients having renal involvement (n=272, 74.5%). Median NT-proBNP at presentation was 152ng/L (range 8-330ng/L), median cTNT 10ng/L (range 3-51ng/L) and median dFLC 61mg/L (range 0.5-3822mg/L). At baseline 36 patients (9.9%) had liver involvement, as defined by ALP 1.5 x upper limit of normal. The median number of treatment lines was one (range 0-5). The most common treatment was bortezomib, (n=236, 64.7%), 48 patients had an autologous stem cell transplant (ASCT) (n=48, 13.2%) and no treatment was given in 25 patients (6.8%). With a median follow up of 34 months (0-105 months), there were 57 deaths. Median OS was not reached. The only variables predictive of early death were troponin (HR 2.340, CI 1.211-4.523, p-0.011) and NT-pro-BNP (HR-2.469, CI 1.399-4.357, p=0.002). Liver involvement using ALP increase above the upper reference limit was significant, (HR-1.1395, 95% CI 1.011-1.284, p=0.032), but not when using the standard definition of liver involvement at ALP 1.5x upper limit. Treatment type had no significant impact on survival, including ASCT (Figure 1).

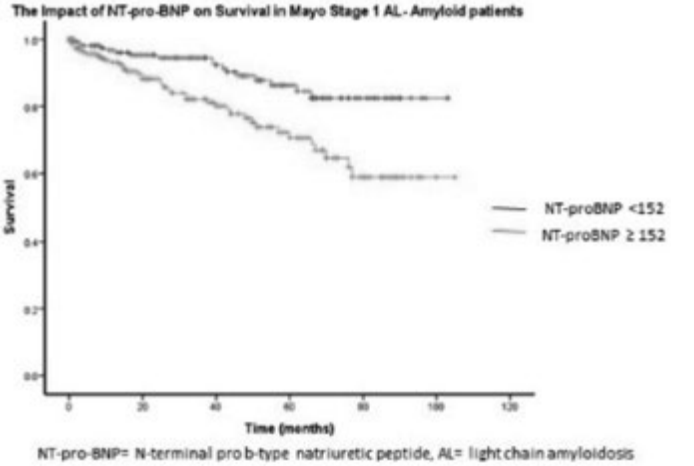

Figure 1.

Summary and Conclusions: In conclusion, this large dataset of Mayo Stage 1 patients adds to data from the Italian/German groups supporting that Mayo Stage 1 amyloid patients are characterised by predominate renal involvement and have a prolonged overall survival. Variables predictive of poor survival in our analysis included: an ALP above the upper limit of normal, NT-pro-BNP and troponin. Cardiac biomarkers appear to offer a prognostic significance even in patients without cardiac involvement by current established criteria. This may reflect early cardiac involvement and potentially offer some insight into the heterogeneity in survival of Mayo Stage 1 patients.

PF554

SINGLE AGENT CARFILZOMIB PROLONGSPFS FOLLOWING TRIPLET THERAPY WITH CYCLOPHOSPHAMIDE & DEXAMETHASONE FOR FIRST RELAPSE/PRIMARY REFRACTORY MULTIPLE MYELOMA: PHASE 2 MUKFIVE STUDY, SECOND ANALYSIS

K. Yong[1,*], S. Hinsley[2], D. Sherratt[2], S. Brown[2], L. Flanagan[2], C. Williams[3], J. Cavenagh[4], M. Kaiser[5], N. Rabin[6], K. Ramasamy[7], M. Garg[8], H. Auner[9], S. Hawkins[10], C. Bygrave[11], R. De Tute[12], G. Morgan[13], F. Davies[13], R. Owen[14]

[1]Haematology, University College London, London, [2]Clinical Trials Research Unit, Leeds University, Leeds, [3]Haematology, Nottingham University Hospitals, Nottingham, [4]Haematology, St. Bartholomew's Hospital, [5]Molecular Pathology, Institute of Cancer Research, [6]Haematology, University College London Hospitals, London, [7]Haematology, University of Oxford, Oxford, [8]Haematology, Leicester Royal Infirmary, Leicester, [9]Haematology, Imperial College London, London, [10]Cancer Centre, Royal Liverpool University Hospital, Liverpool, [11]Haematology, University Hospital Wales, Cardiff, [12]Haematology Malignancy Diagnostic Service, Leeds University Hospital, Leeds, United Kingdom, [13]Myeloma Institute, University of Arkansas, Little Rock, United States, [14]Haematology Malignancy Diagnostic Service, University of Leeds, Leeds, United Kingdom

Background: Carfilzomib (CFZ) is licensed for use in relapsed/refractory (RR) multiple myeloma (MM). In the ENDEAVOR study, carfilzomib was combined with dexamethasone for extended therapy, leading to superior progression-free and overall survival (PFS, OS) when compared with bortezomib and dexamethasone. Today, triplet regimens are standard of care, but administering a triplet regimen indefinitely may be challenging.
Aims: The MUK*five* phase 2 study compared safety and activity of KCD to bortezomib, cyclophosphamide and dexamethasone (VCD), as fixed duration therapy for patients at first relapse, or refractory to one prior line. The study also compared activity and safety of maintenance CFZ *vs* observation after KCD.
Methods: Patients were randomized (R1) in a 2:1 ratio in favor of KCD. Patients in the KCD arm with ≥SD after 6 cycles of KCD were randomized (R2) 1:1 to receive maintenance CFZ or observation. Minimisation factors were response to initial treatment (PR,MR,SD *vs* VGPR,CR) and prior ASCT. There was no maintenance in the VCD arm. See Figure 1 for regimens. Co-primary endpoints were ≥VGPR rate at 24 weeks post R1 (non-inferiority (NI)), and PFS from R2.
Results: 300 patients were randomized, 201 KCD and 99 VCD. Patient and disease features were balanced between arms. First primary endpoint, ≥VGPR at 24 weeks was KCD 40.2%, VCD 31.9% (NI), ORR 84.0% and 68.1% (p=0.0014, superior). 141 patients were eligible for R2, 69 allocated to maintenance CFZ. Arms were balanced for response (≥VGPR:CFZ 58.0%,observation 54.2%,) ECOG, ISS, MRD status (MRD-neg: CFZ 11.6%, observation 13.9%) at end of initial treatment. Median follow-up for patients from R2 was 10.5m (0.9-31.3): 44.3% of patients completed 6 cycles CFZ maintenance, 18% completed 18 cycles. 82.1% of patients had a dose modification, but 88.7% of all cycles were received on time. Median PFS from R2 for CFZ was 11.9m *vs* 5.6m observation (HR 0.59, p=0.009). Safety was as in Table 1. AE's were mild, most were <G3, mainly thrombocytopenia, anaemia, nausea and fatigue. Median follow-up for patients from R1 was 14.0m (0.0-49.4). In PFS analysis of KCD *vs* VCD induction, patients who received maintenance were censored at R2. Median PFS was 11.9 m (80%CI 11.6-12.7) for KCD and 10.2m (9.3-11.3) for VCD; HR=0.89 (80% CI 0.72-1.10).
Summary and Conclusions: Maintenance with single agent CFZ prolongs PFS after triplet therapy with cyclophosphamide and dexamethasone for MM at first relapse or primary refractory to one line. PFS for patients receiving KCD triplet for 6 cycles followed by maintenance CFZ for up to 18 months approximates 18 months, indicating that it is possible to attenuate regimen intensity following initial treatment with triplet regimen while maintaining disease control when using CFZ in the relapse setting.

	KCD: 6 x 28 day cycles	VCD: 8 x 21 day cycles
Carfilzomib	20/36mg/m² IV days 1, 2, 8, 9, 15, 16	
Bortezomib		1.3mg/m² SC days 1, 4, 8, 11
Cyclophosphamide	500mg days 1, 8, 15	500mg days 1, 8, 15
Dexamethasone	40mg weekly	40mg weekly

	Maintenance: 28 day cycles
Carfilzomib	36 mg/m²: Days 1, 2, 15, 16 for 6 months Days 1, 2 for a further 12 months

Background: Intravenous (IV) administration of daratumumab (DARA) 16 mg/kg is approved as monotherapy and in combination with standard of care regimens for patients with relapsed or refractory multiple myeloma. The phase 1b PAVO study (NCT02519452) demonstrated that delivery of DARA with recombinant human hyaluronidase enzyme (rHuPH20) by subcutaneous (SC) infusion through a syringe pump (Part 1) or by manual SC injection (Part 2) was well tolerated with an efficacy profile consistent with IV DARA (Chari A, *et al.* ASH 2017; abstract 838).
Aims: We present updated efficacy and safety data from Part 2.
Methods: Eligible patients received ≥2 prior lines of therapy including a proteasome inhibitor and an immunomodulatory drug. In Part 2, patients received a concentrated co-formulation of DARA (DARA SC; 1,800 mg in 15 mL) and rHuPH20 (30,000 U) dose in a single, pre-mixed vial, which was administered in 3 to 5 minutes by manual SC injection. Primary endpoints were C_{trough} of DARA at the end of weekly dosing on Cycle 3 Day 1 and safety. Secondary endpoints included overall response rate, rate of complete response, time to response, and duration of response.
Results: Patients in Part 2 (n=25) had a median age of 68 years and received a median of 3 prior lines of therapy. At a median follow-up of 4.6 months, none discontinued due to treatment-emergent adverse events. Pharmacokinetic analyses indicated that DARA SC had a T_{max} of approximately 72 hours and achieved similar or greater C_{trough} on Cycle 3 Day 1 compared to what has been observed with DARA IV. Most common Grade 3/4 treatment-emergent adverse events (>1 patient) were lymphopenia (16%), thrombocytopenia (8%), and neutropenia (8%). Infusion-related reactions (IRRs) were reported in 3 (12%) patients, all occurring within 6 hours of the first injection. No Grade 4 IRRs or discontinuations due to IRRs occurred. DARA SC injections in the periumbilical area were well tolerated

with reversible erythema observed in 20% of patients. DARA SC achieved an overall response rate of 44%, including 28% of patients achieving a very good partial response or better.
Summary and Conclusions: DARA SC, which enables dosing in 3-5 minutes, was well tolerated with low IRR rates, had an acceptable pharmacokinetic profile, and demonstrated clinical response rates similar to DARA IV. Updated data based on longer follow-up will be presented at the meeting.

PF556

LEVOFLOXACIN PROPHYLAXIS IN NEWLY DIAGNOSED MYELOMA REDUCES FEBRILE EPISODES AND DEATH WITHOUT INCREASING HEALTHCARE ASSOCIATED INFECTIONS: RESULTS FROM THE TEAMM TRIAL

S. Bowcock[1,*], T. Planche[2], G. Iqbal[3], G. Pratt[4], K. Yong[5], J. Wood[3], K. Raynes[3], P. Hawkey [6], J. Dunn[3], M. Drayson[6]

[1]Haematological medicine, King's college hospital, [2]Microbiology, St George's Hospital, London, [3]Warwick Clinical Trials Unit, University of Warwick, Coventry, [4]Haematology, University hospital Birmingham, Birmingham, [5]Haematology, University college London, London, [6]University of Birmingham, Birmingham, United Kingdom

Background: Infection is the biggest single cause of the high early death rate in myeloma. Levofloxacin is effective against the common bacterial infections in myeloma but there is concern about the development of healthcare associated infection (HCAI).
Aims: TEAMM (Tackling EArly Morbidity and Mortality in Myeloma) was a randomised, double-blind, placebo-controlled multi-centre phase III clinical trial assessing the benefits of levofloxacin prophylaxis *versus* the risk of HCAI. Patients were randomised to levofloxacin or placebo for 12 weeks to see if levofloxacin reduced febrile episodes and death. Subjects were regularly screened for carriage of resistant organisms.
Methods: Patients were age>21 years with newly diagnosed myeloma, intention to treat myeloma actively, and were +/- 14 days into anti-myeloma treatment. Patients received 500 mg levofloxacin or placebo tablets once daily for 12 weeks, dose adjusted for renal function. Patients were permitted to continue routine non-bacterial anti-infective prophylaxis, including 3x weekly Co-trimoxazole(CoT) for pneumocystis. Faecal and throat samples were taken 4 weekly to detect carriage of *Clostridium difficile(C diff)*, MRSA and faecal ESBL+ Gram-negative bacteria (ESBLGnB). The primary endpoint was the number of febrile episodes (defined as a temperature of ≥38°C treated with anti-infectives) and or death by any cause in the first 12 weeks using Kaplan-Meier methods with censoring at 12 weeks. Secondary outcomes included site of infection, severe septic episodes and non-febrile infections (treated with anti-infectives). Analysis was on an intention to treat basis.
Results: 977 patients were recruited from 93 UK centres from August 2012-April 2016. Median age 67 years, 63% male, 76% eGFR>50 ml/min, 54% planned autologous stem cell transplantation, 93% ECOG performance status ≤2, 71% with bone disease. The primary endpoint showed a significant benefit for the use of levofloxacin with 95 primary events in 489 (19%) Levofloxacin patients *versus* 134 in 488 (27%) placebo patients: Hazard ratio (HR)=0.66 (95%CI=0.51-0.86, p 0.002). Primary events (febrile episodes, deaths, febrile episodes with death) in Levofloxacin *vs* placebo arms were (87, 4, 4 *vs* 112, 15, 7) respectively. Of the 586 total infections (febrile and non-febrile) there were 257 in 189 Levofloxacin patients *vs* 329 in 214 placebo patients (^{2}=7.55,P-trend=0.006). There was a survival benefit for Levofloxacin *vs* placebo at 12 weeks (^{2}=5.84 p=0.02) but there was no benefit at 52 weeks (p=0.94). *C.diff* carriage at baseline was uncommon (7 of 785 subjects). There was no significant difference between the 2 arms for carriage or infection with *C. diff*, MRSA and ESBLGnB. There was 1 case of invasive *C.diff* (placebo arm) and no *pneumocystis*. Levofloxacin significantly reduced invasive gram-negative infections (6 *vs* 25) but not Gram positive infections (Table 1). CoT (315 patients, determined by centre) significantly reduced the number of febrile episodes and deaths and was additive with the effects of levofloxacin. Cox regression adjusting for baseline factors showed levofloxacin treatment HR 0.66(95%CI 0.51-0.86, p=0.002) and prophylactic CoT HR 0.59(95%CI=0.44-0.81, p=0.0008) to be independent predictors for reduction of febrile episodes and death. Other pre-specified subgroup data will be presented.
Summary and Conclusions: Prophylactic use of 12 weeks levofloxacin in patients with newly diagnosed myeloma significantly reduces febrile episodes and deaths without increasing key HCAI organism carriage or infection. Optimal duration of antibiotic prophylaxis remains to be determined.

Table 1.

Bacteriology of infections			
Species	Levofloxacin	Placebo	Total
Total all organisms isolated	41	68	109
Total gram negative bacteria	6 (19%)	25 (81%)	31

PROGNOSTIC SIGNIFICANCE OF MAGNETIC RESONANCE IMAGING BEFORE AND AFTER UPFRONT AUTOLOGOUS TRANSPLANTATION FOR NEWLY DIAGNOSED MULTIPLE MYELOMA – A SUBGROUP ANALYSIS FROM THE GMMG MM5 PHASE III TRIAL

M. Merz[1,*], T. Hielscher[2], A. Seckinger[1], A. Jauch[1], E. K. Mai[1], U. Bertsch[1], M.S. Raab[1], K. Neben[3], H. Salwender[4], I.W. Blau[5], H.-W. Lindemann[6], J. Dürig[7], C. Scheid[8], M. Haenel[9], K. Weisel[10], S. Delorme[2], H.U. Kauczor[1], D. Hose[1], H. Goldschmidt[1], J. Hillengass[11]

[1]University Hospital of Heidelberg, [2]German Cancer Research Center, Heidelberg, [3]Klinikum Mittelbaden, Baden-Baden, [4]Asklepios Klinikum Hamburg-Altona, Hamburg, [5]Charite, Berlin, [6]Krankenhaus Hagen, Hagen, [7]Uniklinikum Essen, Essen, [8]Uniklinikum Köln, Köln, [9]Klinikum Chemnitz, Chemnitz, [10]Uniklinikum Tübingen, Tübingen, Germany, [11]Roswell Park Comprehensive Cancer Center, Buffalo, United States

Background: We analyzed prognostic significance of magnetic resonance imaging (MRI) before and after autologous transplantation for newly diagnosed patients with multiple myeloma enrolled in the prospective, multicenter MM5 phase III trial from the German Speaking Myeloma Multicenter Group (GMMG).
Aims: Identify baseline MRI patterns associated with adverse outcome and imaging minimal radiological disease with MRI after transplantation.
Methods: From July 2010 to October 2012, 502 patients were randomly assigned to a bortezomib-based induction therapy (either PAd or VCD) followed by high dose melphalan and autologous stem cell transplantation (ASCT). After ASCT, patients were treated with a lenalidomide consolidation and maintenance therapy either for 2 years or until complete response (CR). Hundred and sixty-seven patients were recruited at the University Hospital of Heidelberg with 83 patients receiving an MRI before ASCT. A second MRI was performed in 77 patients after ASCT and before lenalidomide consolidation/maintenance therapy (median: 98 days, interquartile range: 20 days). We analyzed prognostic significance of initial bone marrow MRI lesions as well as impact of changes in MRI signal after ASCT. MRI findings were also correlated to baseline characteristics and treatment response.
Results: MRI detected a pathological bone marrow signal either depicted by focal lesions and/or diffuse infiltration in all analyzed patients at baseline. Patients with extramedullary disease (EMD, 25.3% of patients) had a significantly shorter overall survival (OS) than patients without EMD at primary diagnosis (5 year OS 59%, 95% confidence interval (CI) [40%;87%] *vs* 83% [73%;93%], p log-rank: 0.03). Residual focal lesions or diffuse marrow infiltration was detected in 81% (n=62) and 61% (n=47) of patients after ASCT, respectively. A residual diffuse marrow infiltration was associated with shorter progressions-free survival (PFS) in patients without CR (n=55) after ASCT (Median PFS: 26 months 95%CI [24;34] *vs* 54 months [32, not reached], p log-rank: 0.03). In 36% of patients (n=28) residual focal lesions underwent T2 hyperintense signal transformation after ASCT. Patients with T2 hyperintense focal lesions achieved more frequently a (near) complete response (75% *vs* 41%, p=0.005) but had a shorter PFS compared to patients without T2 hyperintense lesions after ASCT (Median PFS: 17 months 95%CI [14;34] *vs* 45 months [29, not reached], p log-rank: 0.014). Patients with T2 hyperintense lesions after ASCT harbored more frequently deletion 13p (62% *vs* 33%, p=0.03) as well as EMD (48% *vs* 7%, p<0.001) and showed more often a medium/high proliferation index as assessed by gene expression profiling (92% *vs* 67%, p=0.03). Even after adjustment for treatment arm, baseline International Staging System stage, tandem ASCT as well as response to treatment, presence of cystic T2 hyperintense

lesions after ASCT remained to have an negative impact on PFS (Hazard Ratio, 95% CI: 2.47 [1.25;4.91], p=0.0097).
Summary and Conclusions: Changes of MRI signal after ASCT are of major prognostic significance in newly diagnosed patients with multiple myeloma treated within the GMMG MM5 trial.

PF558

PHASE 2 STUDY OF VENETOCLAX PLUS CARFILZOMIB AND DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

L.J. Costa[1,*], E. Stadtmauer[2], G. Morgan[3], G. Monohan[4], T. Kovacsovics[5], N. Burwick[6], A. Jakubowiak[7], M. Mobasher[8], K. Freise[9], J.A. Ross[9], J. Pesko[9], W. Munasinghe[9], J. Cordero[9], L. Morris[9], P. Maciag[9], O.F. Bueno[9], S. Kumar[10]

[1]University of Alabama at Birmingham, Birmingham, [2]University of Pennsylvania, Philadelphia, [3]University of Arkansas for Medical Sciences, Little Rock, [4]University of Kentucky, Lexington, [5]Huntsman Cancer Institute, University of Utah, Salt Lake City, [6]VA Puget Sound Health Care System, University of Washington, Seattle, [7]The University of Chicago Medicine, Chicago, [8]Genentech Inc., South San Francisco, [9]AbbVie, Inc., North Chicago, [10]Mayo Clinic, Rochester, United States

Background: The BCL-2 inhibitor venetoclax (VEN) has demonstrated efficacy, as monotherapy and combined with PI bortezomib, in relapsed/refractory (R/R) multiple myeloma (MM).
Aims: We report preliminary data for VEN combined with second generation PI carfilzomib and dexamethasone (VENKd) in R/R MM.
Methods: In this ongoing phase 2, dose escalation study (NCT02899052), pts with R/R MM received VENKd on 28-d cycles: VEN 400 mg/day+K 27 mg/m^2 d1,2,8,9,15,16+ dex 40 mg d1,8,15,22 (Cohort 1), same regimen but with VEN 800 mg/day (Cohort 2), VEN 800 mg/day+K 70 mg/m^2 d1,8,15+dex 40 mg d1,8,15, 22 (Cohort 3/expansion cohort), or VEN 800 mg+K 56 mg/m^2 d1,2,8,9,15,16+dex 40 mg d1,2,8,9,15,16,22,23 (optional Cohort 4; no data available at cutoff). Treatment continued until progressive disease (PD) or unacceptable toxicity.
Results: As of 01Dec2017, 26 pts were enrolled. Median age was 67.5 years (40 – 79), 68% had ISS II/III disease, and 23% had t(11;14). Pts received a median of 1 prior therapy (1 – 3); no pts had prior K exposure, 96% had received prior PI (54% refractory), 62% were IMiD refractory, and 35% double refractory. At data cut off, 23 pts were on therapy for 0.3 – 10 months and 3 pts discontinued the study for PD, physician decision, and death. 85% of pts had an AE, grade 3/4 AEs were neutropenia (15%), hypertension (12%), thrombocytopenia (8%), decreased white blood cells (8%), and nausea (4%). 7 serious AEs occurred, but no dose-limiting toxicities were reported. Maximum tolerated dose was not reached and Cohort 3 is being expanded. VEN pharmacokinetics with Kd were comparable to VEN plus bortezomib and dexamethasone. Of 17 pts evaluated after completing ≥2 cycles, 3 had complete response (CR), 2 very good partial response (VGPR), 3 partial response (PR), 3 stable disease, and 2 PD (awaiting response data for 4 pts). Median time to first response was 1 month. Of 5 evaluable pts with t(11;14) MM, 1 achieved CR, 1 VGPR, 3 PR.
Summary and Conclusions: VENkd is well tolerated with promising preliminary efficacy that supports study in pts with R/R MM. Accrual continues with 34 pts enrolled to date. Updated safety and efficacy results will be available for presentation.

PF559

A NOVEL RISK-STRATIFICATION ALGORITHM FOR RELAPSED MULTIPLE MYELOMA (RMM): ASSESSMENT OF PERFORMANCE AND VALIDATION USING REAL-WORLD PATIENT DATA FROM FRANCE, GERMANY AND THE UNITED KINGDOM

R. Hájek[1,*], M. Delforge[2], M. S. Raab[3], A. Briggs[4], M. Campioni[5], L. DeCosta[6], Z. Szabo[5], S. Kroep[7], W. Bouwmeester[7], S. Gonzalez-Mcquire[5]

[1]Department of Haematooncology, University Hospital Ostrava, Ostrava, Czech Republic, [2]Department of Haematology, University Hospital Leuven, Leuven, Belgium, [3]Department of Internal Medicine, University Hospital Heidelberg, Heidelberg, Germany, [4]Institute of Health and Wellbeing, University of Glasgow, Glasgow, United Kingdom, [5]Amgen (Europe) GmbH, Zug, Switzerland, [6]Amgen Ltd., Uxbridge, United Kingdom, [7]Pharmerit International, Rotterdam, Netherlands

Background: There are no validated tools for risk assessment in RMM. The International Staging System (ISS) and revised ISS (R-ISS) were developed in the setting of newly diagnosed MM. Both tools include parameters that are often not monitored in RMM, and neglect data used define disease severity at first relapse, such as clinical outcomes and safety of first-line (1L) treatment. Therefore, a novel risk-stratification algorithm (RSA) was recently designed to predict risk of death in patients with RMM starting second-line (2L) treatment. The algorithm uses 16 predictors to stratify patients into four risk groups with different survival expectations (group 1: lowest risk–group 4: highest risk), and was the first to combine both frailty assessment and disease aggressiveness into a single score. It was developed using multivariable Cox regression using real-world data on MM from the Czech Registry of Monoclonal Gammopathies (RMG).
Aims: To provide insight into the predictive value of this new RSA and its suitability for use in clinical practice, we validated the RSA and assessed its performance using real-world data from three European countries.
Methods: Patient characteristics and outcomes data from bespoke retrospective chart audits in France, Germany and the United Kingdom (UK) were pooled for this real-world validation dataset. Physicians collected data from all patients with MM who began 2L anti-myeloma treatment in 2013, ensuring sufficient follow-up. The predictive performance of the Cox regression model was assessed using Harrell's concordance index (C-index; the RSA's ability to distinguish patients who died from those who did not); a value in the range 0.7–0.8 indicated accurate discriminative power. The ability of the RSA to discriminate by overall survival (OS) across four risk groups was evaluated using Kaplan–Meier curves and hazard ratios (HRs). The prognostic value of the total, frailty and aggressiveness scores was assessed by fitting three univariate Cox models with OS as dependent and each of the scores as predictor.
Results: Chart data were collected from 998 patients (France, 386; Germany, 344; UK, 268). Half (49.8%) received lenalidomide at 2L, 33.1% received bortezomib, and 3.7% received both agents. The validation dataset had lower mean β2 microglobulin and albumin levels, higher lactate dehydrogenase levels and bone marrow plasma cell count, and less 1L toxicity than the RMG cohort. Nonetheless, assessment of the stratification performance of the novel RSA by means of Kaplan–Meier analysis (Figure 1A) and HR data (Table 1) demonstrated clear discrimination in OS between the four risk groups, with a clear distribution of patients across groups in terms of both frailty and disease aggressiveness (Figure 1B). Mean risk scores were 2.3, 4.6, 9.8 and 27.4 in groups 1–4. The C-index was 0.715 (95% confidence interval: 0.690–0.734). Univariate Cox models showed that the hazards for risk of death associated with each unit increase in the total risk, aggressiveness and frailty scores were 1.018, 1.101 and 1.341, respectively; these results were consistent across the countries.

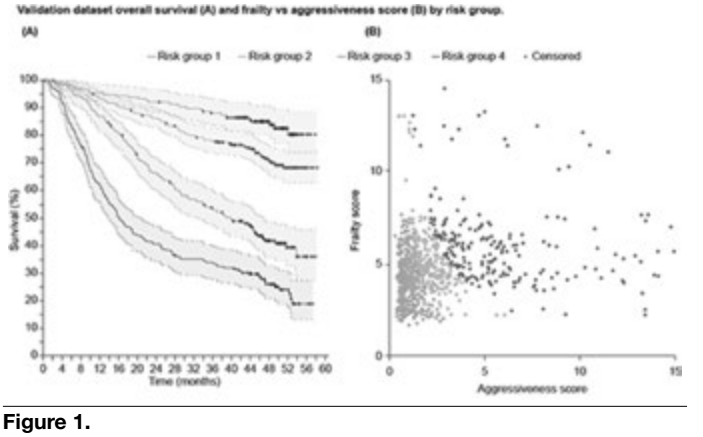

Figure 1.

Table 1.

Overall survival in pooled validation dataset and in Czech dataset.

	Validation dataset			Czech RMG		
Risk group	N (%)	Median OS (95% CI), months	HR (95% CI)	N (%)	Median OS (95% CI), months	HR (95% CI)
Group 1	178 (18%)	NA	Reference	351 (25%)	61.6 (51.7–71.4)	Reference
Group 2	345 (35%)	NA	1.87 (1.23–2.83)	596 (42%)	29.6 (26.6–32.6)	2.24 (1.78–2.83)
Group 3	249 (25%)	39.8 (32.7–46.7)	4.61 (3.09–6.88)	318 (22%)	14.2 (11.3–17.1)	4.30 (3.38–5.49)
Group 4	226 (23%)	16.2 (13.7–21.0)	8.51 (5.73–12.64)	153 (11%)	5.9 (4.4–7.5)	10.88 (8.32–14.23)

2L, second line; CI, confidence interval; HR, hazard ratio; NA, not available; OS, overall survival; RMG, Registry of Monoclonal Gammopathies.

Summary and Conclusions: Validation of the novel RSA in three independent real-world datasets proves it stratifies patients by risk of death. Despite patient-level differences between the development and validation cohorts, the RSA maintained discriminative ability in quantifying risk and stratifying

patients with RMM. This is the first tool that combines frailty and aggressiveness to provide a systematic approach to measuring risk and drivers of risk, which can support treatment decisions in RMM.

PF560

CARFILZOMIB IN COMBINATION WITH BENDAMUSTINE AND DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA: A MULTICENTER PHASE IB/II TRIAL OF THE EUROPEAN MYELOMA NETWORK TRIALIST GROUP (EMNTG)

F. Gay[1,*], M. Offidani[2], A. Günther[3], M. Salvini[1], M. Engelhardt[4], W. Poenisch[5], S. Spada[1], R. Wäsch[4], V. Montefusco[2], F. Patriarca[2], N. Schub[3], S. Gentili[2], E. Angelucci[2], P. Corradini[2], H. Einsele[6], M. Boccadoro[1], P. Sonneveld[7], M. Gramatzki[3]

[1]Myeloma Unit, Division of Hematology, University of Torino, A.O.U. Città della Salute e della Scienza di Torino, Torino, [2]Italian Multiple Myeloma Network, GIMEMA, Italy, [3]Division of Stem Cell Transplantation and Immunotherapy, University of Kiel, Kiel, [4]Department for Hematology and Oncology, University of Freiburg, Freiburg, [5]Department of Hematology, University of Leipzig, Leipzig, [6]Department of Medicine 2, University Hospital of Würzburg, Würzburg, Germany, [7]Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: The prognosis of refractory or relapsed multiple myeloma (RRMM) patients remains poor. The proteasome inhibitor (PI) carfilzomib (K) in combination with dexamethasone (d) showed high activity and an acceptable toxicity profile in heavily pre-treated multiple myeloma (MM) patients. Bendamustine (B) is an active and safe alkylating agent for patients with MM. There is evidence that PIs act synergistically with alkylating agents.
Aims: To evaluate the safety and efficacy of KBd combination, followed by Kd maintenance in RRMM patients.
Methods: Patients ≥18 years of age, with RRMM after failure of ≥2 treatment regimens were included. Phase IB was designed to determine the maximum tolerated dose (MTD) with a 3+3 dose escalation scheme. Treatment consisted of 28-day cycles of Bendamustine 70 mg/m^2 on day 1 and 8, Carfilzomib (escalating dose) on day 1,2,8,9,15,16 and dexamethasone 20 mg/m^2 on day 1,2,8,9,15,16,22,23. After receiving 8 cycles, responding patients continued with maintenance with Kd only on two consecutive days every 14 days until progression. Based on the safety/efficacy profile of the phase I portion of the trial, recommended phase II dose was 27 mg/m2 (Gramatzki M, *et al.* ASH 2016). Primary endpoint of the Phase II portion of the study was the rate of at least very good partial response (VGPR). For the present interim analysis, data cut-off was December 11, 2017.
Results: A total of 63 pts were evaluated (phase I: 13 patients; phase II: 50 patients). Median age (IQR) was 66 years (61-70), median number of prior lines was 4 (range 2-9), 87% of patients were previously exposed to bortezomib and 86% to immunomodulatory drugs; 75% had previously received autologous stem-cell transplantation; 48% of 46 patients evaluable for FISH had high-risk cytogenetic abnormalities (del17 and/or t(4;14) and/or t(14;16)). At data cut-off, 11 patients were still on treatment. The main reason for treatment discontinuation was progressive disease (27 patients). 51% of patients achieved at least a partial response and 32% at least VGPR, including 18% of patients achieving at least a near complete response; 41% achieved a stable disease, with a clinical benefit rate of 92%. After median follow-up of 12.8 months, median progression-free survival (PFS) was 11.6 months, median overall survival (OS) was 24 months. One-year PFS was 35% *vs* 72% for patients with high *vs* standard-risk FISH (HR 2.3; P=0.04). The main grade (G) ≥3 adverse events (AEs) were hematologic: lymphopenia (29%), neutropenia (25%) and thrombocytopenia (22%). The more frequent non-hematologic G≥3 AEs were: pneumonia (13%) and thromboembolic events (10%). Heart failure and acute coronary syndrome were reported in 3% of patients each, hypertension in 2%.
Summary and Conclusions: KBd followed by Kd maintenance was effective in RRMM. Cardiac and vascular AEs need attention and infection prophylaxis is mandatory in this immunosuppressed heavily pretreated population. *The trial is registered at Clinicaltrials.gov: NCT02056756*

PF561

CARFILZOMIB AND DEXAMETHASONE (KD56) *VS* BORTEZOMIB AND DEXAMETHASONE (VD) IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA (RRMM): UPDATED OVERALL SURVIVAL (OS), SAFETY, AND SUBGROUP ANALYSIS OF ENDEAVOR

R.Z. Orlowski[1,*], P. Moreau[2], H. Ludwig[3], A. Oriol Rocafiguera[4], W.J. Chng[5], H. Goldschmidt[6], Z. Yang[7], A.S. Kimball[7], M. Dimopoulos[8]

[1]The University of Texas MD Anderson Cancer Center, Houston, United States, [2]University Hospital Hotel-Dieu, Nantes, France, [3]Wilhelminen Cancer Research Institute, Wilhelminenspital, Vienna, Austria, [4]Institut Catala d'Oncologia, Hospital Germans Trias i Pujol, Barcelona, Spain, [5]National University Cancer Institute, Singapore, Singapore, [6]Heidlberg University, Heidlberg, Germany, [7]Amgen Inc., Thousand Oaks, United States, [8]University Athens School of Medicine, Athens, Greece

Background: The phase 3 ENDEAVOR trial demonstrated significantly improved PFS and OS with Kd56 *vs* Vd in RRMM patients (pts; Dimopoulos *Lancet Oncol* 2016 and 2017).
Aims: We report updated data after additional follow-up.
Methods: Hazard ratios (HRs) and 95% CIs were estimated using stratified or unstratified Cox proportional hazards models for primary and subgroup OS analyses, respectively.
Results: 929 pts were randomized (Kd56, n=464; Vd, n=465). As of 19-Jul-17, median OS was 47.8 (Kd56) *vs* 38.8 (Vd) months (mos; HR, 0.76 [95% CI, 0.633–0.915]; median follow-up, 44.3 *vs* 43.7 mos). OS was longer with Kd56 *vs* Vd within age subgroups (<65 years [yrs]: median, 47.8 *vs* 42.2 mos; HR, 0.79 [95% CI, 0.598–1.031]; 65–74 yrs: median, 49.0 *vs* 36.2 mos; HR, 0.71 [95% CI, 0.520–0.958]; ≥75 yrs: median, 36.1 *vs* 23.9 mos; HR, 0.78 [95% CI, 0.506–1.199]). OS was longer with Kd56 *vs* Vd by prior lines of therapy (1 line: median, 51.3 *vs* 43.7 mos; HR, 0.77 [95% CI, 0.583–1.018]; 2–3 lines: median, 39.5 *vs* 28.4 mos; HR, 0.75 [95% CI, 0.589–0.959]) and prior bortezomib (btz) exposure (prior btz: median, 41.8 *vs* 32.7 mos; HR, 0.85 [95% CI, 0.669–1.082; no prior btz: median, not estimable [NE] *vs* 42.2 mos; HR, 0.66 [95% CI, 0.496–0.875]). OS was longer with Kd56 *vs* Vd for high-risk (median, 28.0 *vs* 22.7 mos; HR, 0.81 [95% CI, 0.580–1.136]) and standard-risk (median, NE *vs* 43.5 mos; HR, 0.79 [95% CI, 0.618–1.009]) cytogenetics pts. 457 (98.7%, Kd56) and 451 (98.9%, Vd) pts had an adverse event (AE); 379 (81.9%, Kd56) and 324 (71.1%, Vd) had a grade ≥3 AE. Exposure-adjusted pt incidences per 100 pt-yrs (95% CI) of AEs were 1352.07 (1233.62–1481.89) for Kd56 and 1754.86 (1600.15–1924.53) for Vd; for grade ≥3 AEs, these values were 162.31 (146.77–179.50) and 175.90 (157.75–196.13). The most common AEs in the Kd arm (≥30% of subjects) were anemia (43.6%), diarrhea (36.7%), pyrexia (32.6%), hypertension (32.4%), fatigue (32.2%) and dyspnea (32.2%).
Summary and Conclusions: With median follow-up of ~44 mos, clinically meaningful OS improvements were observed with Kd56 *vs* Vd, including in all subgroups examined. The Kd56 safety profile was consistent with previous analyses.

PF562

MAINTENANCE AFTER LENALIDOMIDE, BORTEZOMIB, AND DEXAMETHASONE INDUCTION AND TRANSPLANT IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA AND HIGH-RISK CYTOGENETICS: AN ENHANCED MEDICAL RECORD ANALYSIS

R. Fonseca[1,*], K. Parikh[2], B. Ung[2], Q. Ni[2], A. Agarwal[2]

[1]Mayo Clinic, Phoenix, [2]Celgene Corporation, Summit, United States

Background: In the United States and Europe, lenalidomide (LEN or R) was the first drug approved for post–stem cell transplant (SCT) maintenance therapy (MT) in multiple myeloma (MM). Induction with lenalidomide, bortezomib, and dexamethasone (RVD) is common in newly diagnosed MM (NDMM), but real-world evidence of MT with LEN (R-MT) after RVD and SCT is limited, particularly in patients with high-risk cytogenetic abnormalities. Here, we report results of a retrospective observational analysis comparing R-MT *vs* no MT (No-MT) in this setting.
Aims: To compare post-SCT R-MT *vs* No-MT in patients with NDMM treated with RVD induction in a real-word setting.
Methods: This analysis used electronic health records from the Flatiron Health database. Eligible patients diagnosed with MM between Jan 2011 and Dec 2017 and who had ≥2 documented clinical visits were included. NDMM was defined as no anti-myeloma treatment for >14 days before diagnosis. The Index date was defined as the earlier of either the date of SCT+90 days or the start of R-MT. Patients were identified as high risk by fluorescence *in situ* hybridization at diagnosis using international standards (Table 1). Time to next treatment (TTNT), defined as the duration from the index date to the start of a new line of treatment, was analyzed by the Kaplan-Meier method and Cox proportional hazards model.
Results: Among 340 patients who received RVD induction and SCT, 85 had high-risk cytogenetic abnormalities. Of those patients, 41 (48%) received R-MT and 44 (52%) did not (No-MT). Patients in the R-MT group were older than those in the No-MT group (mean age, 62 *vs* 58 yrs; P=.0285), and a higher proportion had an ECOG performance status of 0 (80% *vs*

41%, respectively; P=.0399). More patients receiving R-MT had chromosome 1 abnormalities than did those receiving No-MT, but fewer had del17p13. Median follow-up was 21.9 *vs* 9.7 months. A smaller proportion of patients in the R-MT group advanced to second-line treatment than in the No-MT group (24% *vs* 59%, respectively); these patients had a significantly longer median TTNT than those receiving No-MT (38.8 *vs* 2.8 months, respectively; hazard ratio=3.5 [95% CI, 2.25-5.58]; P <.001).

Table 1.

Genetic Abnormality, %	R-MT (n = 41)	No-MT (n = 44)
Chromosome 1 abnormality	83	64
Del17p13	20	39
t(14;16)	12	9
t(4;14)	10	23
t(14;20)	0	2

No-MT, no maintenance therapy; R-MT, lenalidomide maintenance therapy.

Summary and Conclusions: This analysis demonstrated that patients with NDMM and high-risk cytogenetic abnormalities who received R-MT were less likely to progress to second-line treatment and had a significantly longer TTNT than were patients who received No-MT. These real-world outcomes align with reported clinical trial outcomes, which showed improved progression-free survival with R-MT *vs* placebo or observation in high-risk patients. Although patients with high-risk cytogenetic abnormalities may benefit from the addition of a proteasome inhibitor (PI) to MT, this study showed the benefit of LEN monotherapy. Future studies are needed to determine the impact of adding a PI to MT on tolerability, quality of life, and healthcare costs.

PF563

EUROPEAN POST-APPROVAL SAFETY STUDY IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA: SAFETY IN PATIENTS TREATED WITH POMALIDOMIDE IN A REAL-WORLD SETTING

M. Schmidt-Hieber[1,*], N. Abildgaard[2], B. Gamberi[3], F. Di Raimondo[4], A. Ramirez Payer[5], C. Kyriakou[6], H. Froen[7], A. Izarra[8], E. Kueenburg[9], A. Di Micco[9], B. Rosettani[9], P. Bacon[9], M. Atiba-Davies[9], T. Plesner[10]

[1]Helios Clinic Berlin-Buch, Berlin, Germany, [2]BD Odense University Hospital, Odense, Denmark, [3]Arcispedale Santa Maria Nuova, Reggio Emilia, [4]Department of Hematology, University of Catania, Catania, Italy, [5]H.U. Central de Asturias, Calle Carretera de Rubín, Oviedo, Spain, [6]University College London and Northwick Park Hospitals, London, United Kingdom, [7]Vestre Viken, Drammen, Norway, [8]Norrlands University Hospital, Umea, Sweden, [9]Celgene International, Boudry, Switzerland, [10]Department of Hematology, University of Southern Denmark, Center Little Belt, Vejle Hospital, Vejle, Denmark

Background: The combination of pomalidomide (POM) and dexamethasone (DEX) for the treatment (Tx) of relapsed or refractory multiple myeloma (RRMM) in patients (pts) who have received ≥2 prior Tx regimens, including lenalidomide and bortezomib, was approved in Europe in August 2013. POM+DEX is now a standard Tx for pts with RRMM. These pts are at an increased risk for adverse events (AEs) due to prior exposure to multiple lines of Tx and a high disease burden. The European post-approval safety study (EU PASS; NCT02164955) is an observational, non-interventional registry designed to characterize the safety profile of POM-based Tx in pts with RRMM in a real-world setting.
Aims: To report the incidence of important AEs with POM-based Tx, such as neutropenia, thrombocytopenia, venous thromboembolism (VTE), peripheral neuropathy (PN), and second primary malignancies (SPMs), in pts with RRMM treated with POM according to current clinical practice in a post-marketing setting.
Methods: Pts with symptomatic RRMM initiating POM-based Tx were enrolled and treated at the investigator's discretion. Thromboprophylaxis was administered per local standard practice. AEs were graded according to the National Cancer Institute Common Terminology Criteria for Adverse Events (v4.0). The study is ongoing and open for recruitment in centers across Europe. Participating pts provided informed consent.
Results: As of January 30, 2018, 530 pts across 100 institutions in 8 European countries were included in the safety population. At the time of this abstract, Tx was ongoing in 260 pts (49.1%). Median age was 70 (range, 37-92) yrs, with 29.4% of pts aged <65 yrs, 42.1% between 65 and 75 yrs of age, and 28.5% aged >75 yrs; 54.5% were male. Median time from diagnosis was 4.7 (range, 0.4-26.0) yrs. Median number of prior Txs was 3 (range, 0-13); 72.8% of pts had ≥3 prior lines. Most pts received prior lenalidomide (98.7%), and 98.1% received prior bortezomib. In 303 pts assessed for Eastern Cooperative Oncology Group performance status, 242 (79.9%) had a good performance status (0 or 1). In this analysis, median Tx duration was 17.7 (range, 0.0-134.6) wks and 3.6% of pts (n=19) discontinued Tx due to AEs. AEs (all grades) occurred in 499 pts (94.2%). PN (all grades) was observed in 21 pts (4.0%), VTE in 8 pts (1.5%), and pulmonary embolism in 3 pts (0.6%). Overall, 346 pts (65.3%) had grade 3/4 AEs, including neutropenia (n=110 [20.8%]), anemia (n=43 [8.1%]), thrombocytopenia (n=40 [7.5%]), and febrile neutropenia (n=18 [3.4%]). Grade 3/4 infections occurred in 127 pts (24.0%); of those, 40.9% were pneumonia. Grade 3/4 acute myocardial infarction occurred in 1 pt (0.2%). Incidence of AEs in pts aged >75 yrs was similar to that in the overall population. The following 20 SPMs were observed in 16 pts (3.0%): 11 nonmelanoma skin cancers (including 7 basal cell carcinomas, 3 squamous cell carcinomas, and 1 Bowen disease), 8 solid tumors (including 3 colorectal cancers, 2 carcinomas of unknown primary [liver and peritoneal metastases], 1 breast cancer, 1 soft tissue carcinoma, and 1 transitional cell carcinoma), and 1 hematologic SPM (myelodysplastic syndrome).
Summary and Conclusions: This ongoing, prospective, non-interventional study in pts with RRMM continues to demonstrate that POM-based Tx is generally well tolerated in the real-world setting, and its overall safety profile is similar to that seen in pivotal trials (Moreau P, *et al.* Eur J Haematol. 2017). Updated data will be presented at the meeting.

PF564

IMPACT OF PRIOR MALIGNANCIES ON THE DEVELOPMENT OF SUBSEQUENT MALIGNANCIES AND SURVIVAL IN MULTIPLE MYELOMA: A NATIONWIDE POPULATION-BASED STUDY IN THE NETHERLANDS

M. Brink[1,*], M.C. Minnema[2], O. Visser[3], A. Broijl[4], N.W. van de Donk[5], P. Sonneveld[4], S. Zweegman[5], A.G. Dinmohamed[1,4,6]

[1]Research, Netherlands Comprehensive Cancer Organisation, [2]Hematology, Cancer Center UMC Utrecht, [3]Registration, Netherlands Comprehensive Cancer Organisation, Utrecht, [4]Hematology, Erasmus MC Cancer Institute, Rotterdam, [5]Hematology, VU University Medical Center, Amsterdam, [6]Public Health, Erasmus University Medical Center, Rotterdam, Netherlands

Background: Following advances in treatment and supportive care, multiple myeloma (MM) survivors are an increasing group of individuals, whom, in turn, are at increased risk of developing subsequent malignancies. Prior malignancies might influence the risk on development of subsequent malignancies and survival in MM patients. Information is limited, only recently a Swedish population-based study (Jonsdottir, *Blood Adv*, 2017) reported on this topic.
Aims: In this nationwide population-based study, the impact of prior malignancies for developing a subsequent malignancy or survival in MM patients in the Netherlands was evaluated.
Methods: We identified all newly diagnosed MM patients between 1994-2012 from the nationwide population-based Netherlands Cancer Registry (NCR). Prior and subsequent malignancies (excluding basal cell carcinoma) relative to MM were identified from the NCR and classified into subgroups according to the third edition of the International Classification of Diseases for Oncology (Figure 1A). Synchronous malignancies diagnosed within a time-interval of 6 months prior to or after MM diagnosis, and malignancies diagnosed from autopsies were excluded. Cox regression models were constructed to calculate hazard ratios (HRs) and associated 95% confidence intervals (CIs). The first and second model assessed the risk of the development of a subsequent malignancy and the risk of death in MM patients with either a prior malignancy diagnosis or not, respectively. We adjusted for sex, age at and year of MM diagnosis. For the first model, all MM patients were followed from the time of MM diagnosis to subsequent malignancy development, death, or end of follow-up (February 1, 2017), whichever came first. For the second model, survival time was defined as the time from MM diagnosis to death or end of follow-up (February 1, 2017), whichever came first. A $P<0.05$ indicated statistical significance.
Results: Our analytic cohort included 17,196 MM patients (median age 70 years; range 22-99; 55% males), of whom 1,619 (9.4%) and 247 (1.4%) had 1 and ≥2 prior malignancies, respectively. Patients with a prior malignancy were younger at MM diagnosis, as compared to those without (median age 67 *vs* 70; $P<0.001$). A total of 196 (10.5%) of 1,866 MM patients with a prior malignancy developed a subsequent malignancy, as compared with 1,393 (9.1%) of 15,330 MM patients without ($P=0.04$). The types of prior and subsequent malignancies are presented in Figure 1A. MM patients with a prior malignancy diagnosis had a 47% increased risk of developing a subsequent malignancy, as compared with MM patients without (HR,

1.47; 95% CI, 1.40-1.55; *P*<0.001). Overall survival of MM patients according to the number of prior malignancies is shown in Fig 1B. MM patients with 1 and ≥2 prior malignancies had, respectively, a 42% (HR, 1.42; 95% CI, 1.34-1.50; *P*<0.001) and 68% (HR, 1.68; 95% CI, 1.47-1.92; *P*<0.001) increased risk of death, as compared with MM patients without.

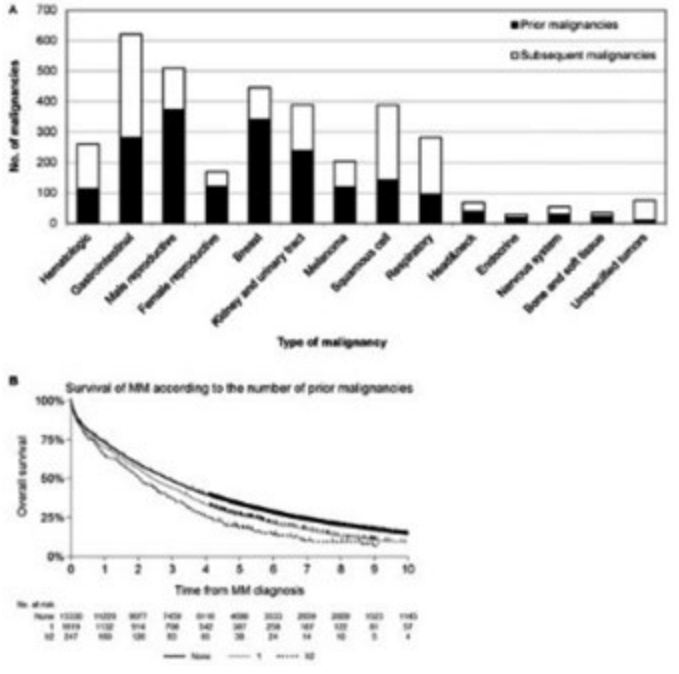

Figure 1.

Summary and Conclusions: We demonstrated that a prior malignancy diagnosis among MM patients increased the risk of developing a subsequent malignancy and negatively influences survival and this was in line with the Swedish study. An explanation for these findings could suggest a role for genetic susceptibility to cancer; however, this usually is associated with young age and observed in ~5% of all cancers only. Another explanation could be the effects of prior cytotoxic treatment. As MM survivorship is expected to increase, these findings may be important to augment cancer surveillance for early detection and appropriate management of subsequent malignancies.

PF565

A PHASE IB STUDY OF ATEZOLIZUMAB (ATEZO) ALONE OR IN COMBINATION WITH LENALIDOMIDE (LEN) IN PATIENTS (PTS) WITH MULTIPLE MYELOMA (MM)

H. Cho[1,*], C. Cole[2], T. Martin[3], J. Zonder[4], J. Fay[5], J. Byon[6], A. Teterina[7], C. Green[6], J. Adamkewicz[6], J.M. Venstrom[6], M. Dhodapkar[6]

[1]Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, [2]Division of Hematology/Oncology, University of Michigan School of Medicine, Ann Arbor, [3]Helen Diller Family Comprehensive Cancer Center, University of California San Francisco, San Francisco, [4]Barbara Ann Karmanos Cancer Institute, Wayne State University, Detroit, [5]Baylor Research Institute, Dallas, [6]Genentech, Inc., South San Francisco, United States, [7]Hoffmann-La Roche Ltd., Mississauga, Canada

Background: Despite treatment (tx) advances, most MM pts relapse, and relapsed/refractory (R/R) disease remains a challenge. Immunomodulatory agent len is approved for MM, and its immune-activating effects make it a candidate for combination with immune checkpoint (PD-L1/PD-1) inhibitors. PD-L1 supports tumor survival via immunosuppression and is expressed on MM and accessory cells in the tumor microenvironment. To date, minimal activity has been seen with anti–PD-1 monotherapy.
Aims: To evaluate the safety and activity of atezo (anti–PD-L1) alone and with len as part of an open-label Ph Ib study of MM pts (NCT02431208).
Methods: R/R MM pts with ≤3 prior therapies were enrolled in Cohorts A and B; Cohort C enrolled pts with measurable disease after ASCT. Pts received atezo 1200 mg IV Q3W (single agent, Cohort A). Cohort B and C pts also received len PO 2 wk on/1 wk off at 10, 15 or 25 mg starting C1D1 (Cohort B) or at 10 mg starting C4D1 (Cohort C). Primary endpoints were safety, ORR and the RP2D of len with atezo. Secondary endpoints included PFS and other efficacy measures. T-cell subsets were measured pre- and post-tx by flow cytometry; IFNγ, IL-2, -6 and -10 were measured in blood and bone marrow aspirate plasma by singleplex immunoassays.
