Methods: 311 *de novo* MDS patients diagnosed between 2010 and 2016 under the 2016 WHO criteria were enrolled, with written informed consent. Studies were approved by the ethics committee of the First Affiliated Hospital of Soochow University (FAHSU) in accordance to the declaration of Helsinki protocol. FLT3 testing was applied only at initial diagnosis and at the first time of AML progression. Hazard ratios (HRs) with 95% confidence intervals (CIs) were estimated using Cox proportional hazards models, which were adjusted for possible confounding factors.
Results: The mutation patterns of FLT3-ITD seen in our patients were similar with their AML counterparts. With basic clinical characteristics well balanced, leukemia transformation rate was significantly different between FLT3-ITD and wild type groups, with 42.9% (3/7) and 10.2% (31/304) of each. Two groups also showed diverse prognosis. The progression free survival (PFS) was 43(16-310) days and 365(8-2208) days in ITD positive and negative group, respectively(P<0.001). And the overall survival (OS) was 218(16-334) days and 414(8-2208) days (P<0.001). In later univariate and multivariate analysis, five factors were found having independent impact on OS: bone marrow blast percentage, WBC count, cytogenetics subtype, treatment and FLT3-ITD mutation status. Here the treatment was graded into three parts, transplantation, chemotherapy or demethylation agents and supportive care only.
Summary/Conclusion: When observed at MDS stage, patients harboring FLT3-ITD mutations had higher AML-transformation rate, quicker disease progression and shorter survival than wild type patients among Chinese population, laying in accordance with data from previous studies.

DIAGNOSTIC POTENTIAL OF ALDEHYDE DEHYDROGENASES ISOENZYMES IN MDS AND AML

A.C. Gonçalves[1,2], B. Macedo[3], A. Barbosa Ribeiro[1,2,4], R. Alves[1,2], J. Jorge[1,2], G. Marques[5], L. Jorge[5], E. Cortesão[1,2,4], A.B. Sarmento Ribeiro[1,2,4,6,*]

[1]Coimbra Institute for Clinical and Biomedical Research (iCBR) - Group of Environment Genetics and Oncobiology (CIMAGO), FMUC, [2]Laboratory of Oncobiology and Hematology and University Clinic of Hematology, Faculty of Medicine, University of Coimbra (FMUC), Coimbra, [3]Chemistry Department, Aveiro University, Aveiro, [4]Clinical Hematology Department, [5]Clinical Pathology Department, Centro Hospitalar e Universitário de Coimbra (CHUC), [6]Center for Neuroscience and Cell Biology (CNC), University of Coimbra, Coimbra, Portugal

Background: Aldehyde dehydrogenases (ALDH) are critical to the protection against toxic aldehydes and have been associated with multiple diseases,

namely with cancer. Myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML) are two myeloid neoplasias with a complex multistep development involving abnormal differentiation, cellular proliferation, and apoptosis. Since ALDHs are involved in some of these biological processes, the deregulation of these enzymes may influence MDS and AML development.

Aims: This study aimed to evaluate the gene expression levels of ALDHs isoenzymes in patients with MDS and AML in order to verify their potential as a biomarker for the diagnosis and/or prognosis of these diseases.

Methods: To this end, we analyzed the gene expression levels of *ALDH1A1*, *ALDH1A2*, *ALDH1A3*, *ALDH1B1*, *ALDH1L1*, *ALDH1L2*, *ALDH2*, *ALDH3A1*, *ALDH3A2*, *ALDH3B1*, *ALDH3B2*, *ALDH4A1*, *ALDH5A1*, *ALDH7A1*, *ALDH16A1*, and *ALDH18A1*. The ALDH expression levels were analyzed using RT-PCR and the differentially expressed genes were quantified by qPCR. This study enrolled 34 MDS patients [median age of 72 years (ranging from 49 to 89 years) and 59% males], 20 AML [median age of 56 years (ranging from 26 to 92 years) and 45% males], and 34 healthy controls [median age of 70 years (ranging from 32 to 88 years) and 59% males]. According to the 2016 WHO classification, MDS group included: 4 MDS with single lineage dysplasia (MDS-SLD), 15 MDS with multilineage dysplasia (MDS-MD), 7 myelodysplastic syndrome/myeloproliferative neoplasm (MDS/MPN), 4 MDS with excess blasts (MDS-EB), 3 MDS with ring sideroblasts (MDS-RS), and 1 MDS associated with isolated del(5q). According to WPSS, 5 MDS patients have very low risk, 9 low risk, 6 intermediate risk, 2 high risk, 1 very high risk (4.4%), and 11 patients were unclassified. The AML group included 7 AML with minimal differentiation (AML-MD), 5 acute myelomonocytic leukemia, 4 acute promyelocytic leukemia with PML-RARA, and 4 AML with myelodysplasia-related changes (AML-MRD). The statistical analysis was carried out by uni- and multivariate tests. A value of $p<0.05$ was considered significant.

Results: The results indicate that *ALDH3A2*, *ALDH3B1*, *ALDH4A1*, and *ALDH18A1* had a differential expression among the study groups and were posteriorly quantified by real-time PCR. MDS and AML patients showed higher median expression levels of *ALDH3A2* [MDS: 1.93 interquartile range (IR) 1.28; $p<0.001$; AML: 1.51 IR 0.99; $p=0.008$)] and *ALDH4A1* (MDS: 0.18 IR 0.47; $p=0.011$; AML: 0.16 IR 0.78; $p=0.012$) in comparison with controls (*ALDH3A2*: 0.4624 IR 1.53 *ALDH4A1*: 0.0388 IR 0.12). The expression of *ALDH3B1* was higher in MDS patients (1.64 IR 1.39) than in AML patients (0.45 IR 0.47; $p<0.001$) and controls (0.35 IR 0.51; $p<0.001$). Moreover, this isoenzyme was significantly higher in MDS-SLD and in very low-risk patients (WPSS) comparatively with the others subgroups. Additionally, patients with MDS and AML with myelodysplasia-related changes (AML-MRC) did not express ALDH18A1. ROC curve analysis showed that *ALDH3A2* ($p=0.001$), *ALDH3B1* ($p<0.001$), and *ALDH4A1* ($p=0.012$) were able to discriminate MDS patients from controls. Moreover, *ALDH3A2* was the only isoform with diagnostic value for AML patients.

Summary/Conclusion: ALDH isoforms have differential expression patterns in MDS and AML patients when compared to controls and with each other, and can be good diagnostic biomarkers of these diseases. However, further studies are needed to prove the potential of these enzymes as diagnostic/prognostic biomarkers.

This work was supported by CIMAGO and by the FCT through the fellowship SFRH/BD/51994/2012.

RISK-MITIGATION PLANS TO REDUCE INCIDENCE OF URINARY ADVERSE EVENTS IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES (MDS) TREATED WITH ORAL RIGOSERTIB (RIGO) IN COMBINATION WITH AZACITIDINE (AZA)

S.C. Navada[1,*], G. Garcia-Manero[2], M.N. Rajeh[3], J.M. Shammo[4], E.L. Atallah[5], E.A. Griffiths[6], S.K. Khaled[7], P.S. Zbyszewski[8], M.E. Petrone[8], S.M. Fruchtman[8], L.R. Silverman[1]

[1]Mount Sinai Medical Center, New York, [2]University of Texas MD Anderson Cancer Center, Houston, [3]Saint Louis University, St. Louis, [4]Rush University Medical Center, Chicago, [5]Froedtert Hospital & the Medical College of Wisconsin, Milwaukee, [6]Roswell Park Cancer Institute, Buffalo, [7]City of Hope, Duarte, [8]Onconova Therapeutics, Inc., Newtown, United States

Background: MDS are a rare group of blood cancers that occur as a result of disordered development of blood cells within bone marrow. MDS occur most commonly in older adults, with a median age at dx of ≥65 yrs. Previous studies have shown oral RIGO at a dose of 560mg BID in Low-Risk MDS (LR-MDS) patients (pts) demonstrate a transfusion independence rate (IWG2006) of 44% (Raza *et al*., Blood 2017). Oral RIGO in combo with AZA in pts with MDS is being studied (Navada S, Blood 2016). In monotherapy & combination trials, oral RIGO has been associated with urinary adverse events (UAEs) of interest, shown to be dose & administration scheme dependent (Garcia-Manero G, Blood 2016).

Aims: Reported are initial results of a dose exploration study in MDS pts focusing on impact of risk-mitigation plans in reducing incidence of UAEs including hematuria.

Methods: Pts w MDS or leukemia (N=168) were given oral RIGO monotherapy in doses escalating from 70mg-1680mg 2x daily for either 14 consecutive days per 21-day cycle (intermittent schedule) or for 21 consecutive days per 21-day cycle (continuous schedule). In Part 1 of a trial of oral RIGO with AZA 75mg/m^2/d SC or IV (N=54) pts were administered RIGO 2x daily on Day 1-21 of a 28-day cycle in escalating cohorts, max dose of 560mg qAM & 280mg qPM (total 840mg) & AZA, administered for 7days/month starting on Day 8. In an ongoing Part 2 Study, oral RIGO at a total dose of 1120mg in 2 cohorts 560mg BID or 840mg/280mg is administered on Days 1-21 of a 28-day cycle in MDS pts with AZA; applying risk-mitigation plans to reduce UAEs: 1. Second RIGO dose must be taken at 3 PM (±1 hour) at least 2 hours after lunch to avoid a nocturnal bladder dwell time (Maniar M, *et al.* ASCO 2018 Sub for Pub); 2. Oral hydration of at least two liters of fluid per day is encouraged; 3. Mandatory bladder emptying prior to bedtime; 4. Urine pH approx. 2 hours after AM dose. Sodium bicarbonate suggested 650 TID if pH tests <7.5.

Results: The most frequent treatment emergent AEs observed in safety-evaluable pts in MDS studies w oral RIGO monotherapy (N = 168) were urinary. Higher frequency was identified for pts treated with continuous RIGO dosing *versus* intermittent dosing. Due to UAEs, continuous 560mg BID dosing is no longer being studied. Incidences of renal and urinary disorders have been identified with single agent AZA. In a trial of RIGO (total dose of 840mg) & AZA, incidence of UAEs, including hematuria, was 74%, w Gr ≥3 UAEs of 29%. In 37 pts studied w oral RIGO 1120mg & AZA, implementation of risk-mitigating plans to reduce UAEs, UAEs were 30%; Gr ≥3 5% have been seen to date (Table 1).

Table 1.

Table: UAEs Comparison Between RIGO Mono & Combo Therapy*

Patients on Monotherapy**	168
Patients with Urinary AEs	108 (64%)
Patients with hematuria	37 (22%)
Grade 1/2	35 (21%)
Grade ≥3	6 (3.5%)
Patients on Part I RIGO 840mg & AZA	42
Patients with Urinary AEs	31 (74%)
Patients with hematuria	20 (48%)
Grade 1/2	17 (40%)
Grade ≥3	5 (12%)
Patients on Part 2 RIGO (1120mg) & AZA with risk mitigation plan	37
Patients with Urinary AEs	11 (30%)
Patients with hematuria	4 (11%)
Grade 1/2	4 (11%)
Grade ≥3	0 (0%)

* preliminary analysis of platelet count to be presented
** AEs were Graded per National Cancer Institute's Common Toxicity Criteria ver4.0

Summary/Conclusion: Dose optimization & risk mitigation plans to reduce UAEs associated with oral RIGO in combination with AZA have resulted, to date, in a decrease in frequency of UAEs. This study is ongoing. Reduction of AEs permits pts to continue treatment to optimize benefit. Reduction in incidence of UAEs enables continued study of oral RIGO in LR-MDS based on promising transfusion independence rate previously reported (Raza *et al*., Blood 2017).

PB2089

THE HIDDEN IMPACT OF PATIENT GENERAL CONDITION ON THE OVERALL SURVIVAL OF MYELODYSPLASTIC SYNDROMES AND RELATED DISEASES (CHRONIC MYELOMONOCYTIC LEUKEMIA AND ACUTE MYELOID LEUKEMIA)

P. González Carmona[1,*], V. Martínez-Robles[1], S. Cerdá[1], J. Sánchez-del-Real[1], S. Jacoubi[1], F. Rondón[1], N. Bonache[2], M.L. Villalobos[1], J.A. Rodríguez-García[1], F. Ramos[1]

[1]Hematology, [2]Internal Medicine, Hospital Universitario de León, León, Spain

Background: Patient clinical situation at diagnosis (Dx) of MDS is a function of general condition (GC) *before Dx* and the impact of the new disease.

ECOG performance status probably depends on both of them, and consequently may be highly dependent on the very moment that it is measured. GC at baseline can be measured by Lee Index (LIx) for Older Adults (Lee SJ *et al.*, 2006), a 12-item validated scale that has been shown to predict 4-year mortality among community-dwelling adults in USA and also to predict overall survival (OS) in a prospective and molecularly annotated cohort of Spanish MDS patients (Ramos F *et al.*, 2017). To our knowledge, LIx has not been applied yet to MDS-related conditions (CMML and AML).
Aims: To analyze whether patient GC before Dx can be considered an independent determinant of OS in a heterogenous population of Pts diagnosed with MDS and related diseases.
Methods: We have reviewed the clinical charts of 132 pts (84 M, 48 F), median age 79y (IQR 73-82y), diagnosed in our center with MDS (n=88), CMML (17) or AML (27), whose GC had been evaluated by means of the LIx. The study was approved by our Institutional Review Board. All Pts were Dx and classified according to WHO 2008 and stratified prognostically (Px) according to disease-specific criteria (IPSS-R in MDS, CPSS in CMML and MRC/LRF scoring system in AML). ECOG was 0 in 23 Pts (17.4%), 1-2 in 93 (70.4%), 3-4 in 15 (11.4%) and NA in 1 (0.75%). Twenty-two Pts (16.7%) had received therapy known to prolong OS, while the rest had received only supportive care. After a median follow-up of 38.1 months (IQR 37.7-71.6), 70 Pts (53.0%) had died, 45 (34.1%) were alive, and 17 (12.9%) were lost to follow-up. The proportion of Pts that received disease-modifying therapy was similar across the Dx and Px groups. OS was evaluated by Log-rank tests (for trend, as appropriate) and Cox regression models.
Results: OS was longest for CMML Pts (median NR), intermediate for MDS (53.4 months, IQR 29.1-77.7) and shortest for AML (8.5, IQR 0-19.1), p<0.001 (Log-rank). As expected, it was also progressively shorter as the disease-specific Px categories were worse (p<0.001, Log-rank for trend). ECOG categories were strongly associated with both LIx and Px categories (Chi-Square for trend 10.84, p=0.001 and 7.94, p=0.006, respectively), but not to the Dx category (p=0.55). LIx score ranged 0-19 points (median 8, IQR 6-10). Fifty-three Pts (40.2%) were included in the Q1 (score 0-5), 45 Pts (34.1%) in Q2 (6-9), 25 (18.9%) in Q3 (10-13) and 9 (6.8%) in Q4 (score 14+). As expected, LIx categories were associated neither with the Dx nor with the Px categories (p=0.15 and p=0.36, respectively). At first sight, we observed a non-significant univariate trend towards a shorter OS as the LIx was higher: Q1 68.2 months (IQR 25.6-110.9), Q2+Q3 45.2 (IQR 14.9-75.4) and Q4 16.2 (IQR 0-41.8); p=0.211, Log-rank for trend. Interestingly, multivariate models disclosed that LIx score was an independent determinant of OS in this heterogeneous population, whether the type of treatment is included in the model (p=0.019) or not (p=0.034).
Summary/Conclusion: Patient general condition, as evaluated multidimensionally by the Lee Index for Older Adults, is an independent determinant of OS in patients with MDS, CMML and AML. This statement is now being evaluated in a larger and prospective patient cohort.

PB2090

SOLUBLE ADHESION MOLECULE LEVELS PREDICT RESPONSE TO AZACYTIDINE IN PATIENTS WITH HIGH RISK MYELO DYSPLASTIC SYNDROME – RESULTS OF A PIVOTAL TRIAL

T. Kupsa[1,2], P. Belohlavkova[2], L. Jebavy[1,2], P. Zak[2], J.M. Horacek[1,2,*]

[1]Department of Military Internal Medicine and Military Hygiene, University of Defence, Faculty of Military Health Sciences, [24]th department of Internal Medicine, Hematology, University Hospital and Charles University, Faculty of Medicine, Hradec Kralove, Hradec Kralove, Czech Republic

Background: Since introduction of azacytidine therapy for high risk myelodysplastic syndromes (MDS) several attempts have been made to define predicitive and prognostic factors in this patient cohort. Cytokines and adhesion molecules have been studied as markers of immune system activation in many diseases including MDS and acute myeloid leukemia (AML). Further knowledge gained from baseline cytokine levels assessment may help to improve treatment outcomes.
Aims: The aim of this study is to evaluate baseline levels of selected cytokines and soluble adhesion molecules and their relationship to azacytidine therapy response.
Methods: Baseline serum levels of 19 MDS patients, age 70.7±3.5 years, median 72 years, were collected prior to azacytidine therapy in the period 2015-2017. These patients were not candidates for intensive chemotherapy or allogeneic stem cell transplantation. All patients were treated with azacytidine 75mg/m^2 per day for 7 consecutive working days. Dose reduction was applied when necessary. Two subgroups were identified according to response to therapy within 6 cycles. Age, IPSS, normal karyotype, complex karyotype and bone marrow blast cell infiltration over 15% were variables included into analysis. We evaluated serum levels of the following 17 analytes: interleukins (IL-1α, IL-1β, IL-2, IL-4, IL-6, IL-8, IL-10), Epidermal Growth Factor (EGF), Interferon-γ, Monocyte Chemotactic Protein-1 (MCP-1), Tumor Necrosis Factor-α (TNF-α), Vascular Endothelial Growth Factor (VEGF), E-selectin (E-SEL), P-selectin (P-SEL), L-selectin (L-SEL), Intercellular Adhesion Molecule-1 (ICAM-1) and Vascular Cell Adhesion Molecule-1 (VCAM-1). All biomarkers were measured by biochip array technology on Evidence Investigator analyzer (Randox). Statistical analysis was performed in STATISTICA 2.0.
Results: Based on response to azacytidine therapy, the subgroups of responders (n=9, 47%) and non-responders (n=10, 53%) were identified. CR was achieved in 3 cases (16%). The subgroups have not differed in age, IPSS, bone marrow blast cell infiltration or frequency of normal karyotype or complex karyotype. The responders to azacytidine had lower levels of ICAM-1 (229.08±37.85 *vs* 290.97±45.3, *P*=0.0363), E-SEL (6.16±1.85 *vs* 16.38±9.89, *P*=0.0431) and L-SEL (759.84±206.74 *vs* 1166.16±359.83, *P*=0.0383).
Summary/Conclusion: The results indicate that high risk MDS patients can be further stratified according to cancer microenvironment, which is a sine qua non for development of new treatment approaches. We plan to analyse these cytokines and soluble adhesion molecules as possible prognostic markers in the future.
The work was supported by a long-term organisation development plan 1011 (FMHS).

MIR-16 IS ASSOCIATED WITH VEGF UPREGULATION IN HIGH-RISK MYELODYSPLASTIC SYNDROMES

Y. Nie[1,*], Y. Yu[2], S. Wang[3], Y. Jia[1], B. Xiong[2], X. Zuo[2]

[1]sino-us diagnostics, Tianjin, [2]Department of Hematology, Zhongnan Hospital of Wuhan University, Wuhan, [3]Institute of Hematology & Blood Disease Hospital, Tianjin, China

Background: Myelodysplastic syndromes (MDS) is a heterogeneous group of hematological disorders characterized by impaired hematopoiesis with a high risk of leukemic transformation. Recently, overexpression of Vascular endothelial growth factor (VEGF), a major angiogenic factor, has been found in MDS and showed different expression status in different risk of MDS.
Aims: Our aim is to investigate the possible role of miR-15a and miR-16 on regulation of VEGF expression and their effects on angiogenesis in different risk of MDS.

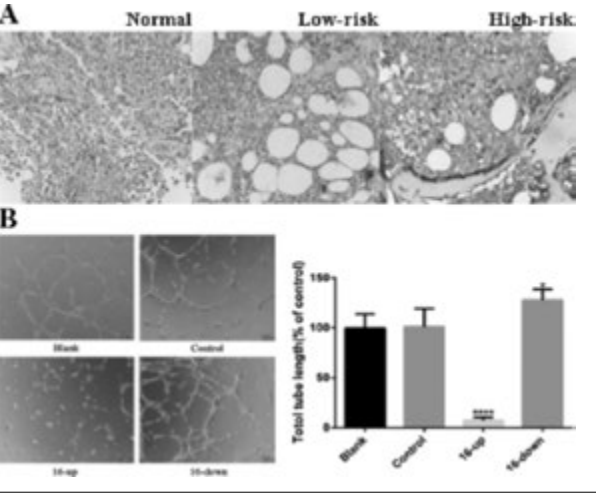

Figure 1.

Methods: ELISA, immunohistochemistry assay and immunofluorescence were used for detection of VEGF secretion in peripheral blood of MDS patients, protein expression in biopsies of MDS patients and several leukemia and MDS cell lines, repectively. qRT-PCR was performed to detect the expression of miR-15a and miR-16 in MDS bone marrow samples and cell lines. A human MDS SKM-1 cell line was transfected with pre-miR-16, anti-miR-16 and their respective negative control. ELISA and western blotting were performed to test the effect of miR-16 on the secretion and protein expression of VEGF. The luciferase reporter assays was conducted to confirm VEGF is a potential target of miR-16. The migration and tube formation of human umbilical vein endothelial cells were performed in miR-16 transfected SKM-1 condition medium (CM).

Results: Levels of miRNA-16 were significantly decreased in high-risk MDS patients as well as SKM-1 cell line, while the expression levels of VEGF were upregulated. Transfection of miR-16 in SKM-1 cells resulted in reduced secretion and protein expression of VEGF. The migration and tube formation of human umbilical vein endothelial cells were decreased in miR-16 transfected SKM-1 CM compared to CM from SKM-1 cells transfected with vector control. Direct binding of miR-16 to the 3' untranslated region of VEGF was confirmed by luciferase reporter assay.
Summary/Conclusion: These data suggest that miR-16 may play a role in disease progression of MDS partially by modulation of angiongenesis through targeting VEGF and that miR-16 might serve as a novel therapeutic target in MDS.

PB2092

ACCESS TO DIAGNOSTIC AND THERAPEUTIC TOOLS FOR MYELODYSPLASTIC SYNDROMES IN GENERAL PRACTICE: SURVEY AMONG LATIN-AMERICAN HEMATOLOGISTS

R. Crisp[1,2,3,*], G. Vidal-Senmache[3,4], J. Navarro Cabrera[3,4], F. Huaman-Garaicoa[3,5], B. Maldonado[3,5], M.S. Undurraga Sutton[3,6], X. Valladares[3,6], J. Reyes[3,7], V. Abello[3,7], M. Pimentel[3,8], A. Ayala[3,8], S. Grille[3,9], C. Guillermo[3,9], J. Choque[3,10], V. Salinas Viedma[3,11], M. Royg[3,11], M. Iastrebner[2,3], C. Belli[2,3]

[1]Clinical Hematology, Hospital Nacional Alejandro Posadas, [2]Sociedad Argentina de Hematología, Buenos Aires, Argentina, [3]Grupo Latinoamericano de Sindromes Mielodisplasicos (GLAM), Montevideo, Uruguay, [4]Sociedad Peruana de Hematología, Lima, Peru, [5]Sociedad Ecuatoriana de Hematología, Guayaquil, Ecuador, [6]Sociedad Chilena de Hematología y Hemoterapia, Santiago de Chile, Chile, [7]Asociación Colombiana de Hematología y Oncología, Bogota, Colombia, [8]Sociedad Dominicana de Hematología, Santo Domingo, Dominican Republic, [9]Sociedad de Hematología de Uruguay, Montevideo, Uruguay, [10]Sociedad Boliviana de Hematología y Hemoterapia, La Paz, Bolivia, Plurinational State Of, [11]Sociedad Paraguaya de Hematología, Asuncion, Paraguay

Background: MDS refers to a heterogeneous group of closely related clonal hematopoietic disorders. Among the diagnostic and prognostic tools, pathology, cytogenetics, immunophenotyping and, more recently, point mutations have been shown to identify patients at different risk for survival. Standard treatment options include supportive care, disease-modifying agents and allogeneic hematopoietic stem cell transplantation (HSCT).
Aims: To assess the real-world hematologist practice patterns within Latin-America (LA).
Methods: A printed 23-question survey consisting mainly of multiple-choice questions covering demographics of responders, diagnosis, therapy, evaluation of response, and cause of stopping treatments was collected since August 2015.
Results: Among the 458 respondents: 234 were from Argentine, 8 Bolivia, 47 Chile, 17 Colombia, 16 Dominican Republic, 36 Ecuador, 10 Paraguay, 64 Peru and 26 Uruguay. The response rate was 22-90% depending on their respective Hematology Societies. The majority of responders practiced hematology with a similar distribution within a 5-years range, except for Paraguay (<10: 70%) and Ecuador (>10: 92%). The practice setting was highly heterogeneous: public (0-90%), private/health insurance institution (0-59%) and combined (10-75%). The age-target practice was mostly split between adult and pediatric, however, restricted to adult patients in Paraguay/Uruguay, and mixed in 49% - Peru. Morphological description is a common practice. Additional tests include the histological examination of the BM (87-100%), being mostly done at the institution of attendance (except for Bolivia/Chile). The cytogenetic analysis (53-100%) and immunephenotyping by flow cytometry are heterogeneous (42% - 100%), being mostly referred. Physicians from Chile, Colombia, Ecuador and Peru selected to introduce MDS diagnosis as a pre-leukemia, cancer or neoplasia while others avoided these words. The IPSS and IPSS-R are preferred by most hematologists, however, age becomes the main factor for therapeutic decisions. Regarding therapies, most responders indicated transfusions of blood components and erythropoietin +/- other growth factor without differences. Chelation therapy ranged between 0% Bolivia and 100% Colombia/Ecuador. Azacytidine has been highly indicated in 89% Argentine and in 100% Colombia/Ecuador/Dominican Republic. The average for 5-aza-2'-deoxicytidine was lower (77% Colombia followed by 60% Argentine). Lenalidomide was less indicated in 23% Chile and 22% Uruguay. HSCT indication ranged among 33-94% and was not available in Paraguay/Bolivia/Dominican Republic. The access to clinical trials is significantly limited (8-0%). The suspension of treatment was mainly related to lack of response while chelation-therapy to side effects.
Summary/Conclusion: This is the first study that explores the real-world clinical practice for MDS in LA showing a heterogeneous access to complementary diagnostic tools, management and treatment in the surveyed countries.

PB2093

HEALTH IMPACT OF THE 5-AZACYTIDINE ADMINISTRATION IN THE DOMICILIARY CARE IN PATIENTS WITH MYELODYSPLASTIC SYNDROME

C. Alarcón-Payer[1,*], J.M. Puerta Puerta[2], A. Jiménez Morales[1], F. Hernández Mohedo[2], J. Badiola González[2], M.E. Clavero Sánchez[2], Z. Mesa Morales[2], P.A. González Sierra[2], E. López Fernández[2], R. Ríos Tamayo[2], A. Romero Aguilar[2], M. Jurado Chacón[2]

[1]Servicio de Farmacia, Hospital Universitario Virgen de las Nieves, [2]UGC Intercentro Hematología y Hemoterapia, Hospitales HUVN-PTS, Granada, Spain

Background: Most patients with intermediate-2 and high-risk myelodysplastic syndrome (MDS) have a median age of 75 years and 25% of them are diagnosed beyond 80 years of age. Therefore, many of them may have great difficulty to travel to the hospital during the 7 days of duration of each cycle of 5-azacytidine treatment.
Aims: To analyse the health impact of the administration of 5-azacytidine in the domiciliary care and to evaluate the therapeutic adherence.
Methods: 2-year prospective observational study on 20 MDS patients with a median of age of 75 years, with difficulty to travel to the day hospital to received treatment with 5-azacytidine during 7 days. The drug was prepared in the hospital pharmacy service, using the water reconstitution method for refrigerated injections and kept in refrigerator (2-8 ºC), resulting in both chemically and physically stable solutions for 22 hours. Once the inclusion of the patient in the study was confirmed by the haematologist, the prescribed treatment regime was informed to the pharmacy service and to the nurse to organize medication regime in the domiciliary care. The variables considered in this study were: beginning of treatment with 5-azacytidine, treatment duration, level of satisfaction of patients, treatment adherence and detected side effects.
Results: 20 MDS patients received treatment with 5-azacytidine in domiciliary care during a mean of 15 months of treatment. 70% of the patients showed great difficulty to travel to the day hospital because they required an accompanying person and 30% did not possess supporting infrastructure. 100% of the patients were highly satisfied with the service, therapeutic adherence improved in 95% and it was detected side effects in 15% of them (neutropenia, anaemia and gastrointestinal reactions).
Summary/Conclusion: The administration of 5-azacytidine in domiciliary care in MDS older patients with difficulty to travel to the day hospital has allowed to bring support to these patients, improving the day hospital logistics, increasing the satisfaction of the patients and its adherence to the treatment and offering a better quality healthcare.

STUDY ON QUALITY OF THE TRANSFUSION PROCESS IN OUTPATIENT CARE IN A TERTIARY HOSPITAL

B. Cidoncha Morcillo[1,*], L.J. Garcia Frade[2], E. Fernández Fernández[2], E. Bonis Izquierdo[2], A. Campano Garcia[2], N. Andres Hernandez[2]

[1]Hosp. Univ Del Rio Hortega, Valladolid, Spain, [2]Hematology and Hemotherapy, Hosp. Univ Del Rio Hortega, Valladolid, Spain

Background: The evidences in transfusional matter, are realized in patients admitted, reason why the established criteria so much for patients in the Units of Hospitalization as in the Day Hospital, are not the same There is currently enough evidence to affirm that the transfusion of blood products can be carried out effectively, safely and in accordance with the American Blood Bank Association guidelines in the HDD, which entails, among other benefits, a significant reduction in the number of revenues. We have no knowledge of publications of works with this content by hospital centers equivalent to ours in population area and / or number of beds in our country. Therefore, our study is focused on the care activity, developed mainly in the Day Hospital, in relation to the transnfusional activity.
Aims: The main one is the quantification of the percentage of transfusion episodes of packed red blood cells (CH) according to the criteria of the AABB.
Methods: Retrospective, open and unicentric study. The period 2012-2013 is compared with 2015-2016. The inclusion criteria cover all patients over 14 years of age, who were transfused in the HURH Day Hospital, regardless of the medical service prescribing the transfusion.The lists of patients and number of CH transfused were obtained from the Blood Bank management program (DELPHIN).The pretransfusional haemoglobins were obtained from the MODULAB laboratory program.The diagnoses of the patients

were extracted from the hospital records (SICLINICA).The data was collected anonymously in an Access ® database designed to preserve confidentiality.The statistical analysis has been performed using Stata program (StataCorp, Texas, USA).
Results: From 2012 to 2013, 203 patients were transfused in HDD. Among them, 41.38% were treated in haematology service. The pretransfusional haemoglobin was 7.7g/dl, with a range of 7.0-8.3g/dl. 319 transfusion episodes (63.55% of the total) were considered correctly indicated. Haematology service had the highest percentage of transfusions indicated, 230 (72.59%). The difference in adecuated indications between Haematology and the rest of services was 24.4%, which is statistically significant (p<0.001). From 2015 to 2016, 270 patients were transfused in HDD. Of those, 35% belonged to Haematology service. The pretransfusional haemoglobin was 7.9g/dl, with a range of 7.2-8.4g/dl. A total of 373 transfusion episodes (54.61% of the total) were considered correctly indicated. Haematology service had the highest percentage of transfusions indicated, 233 (61.97%). The difference in indications between Haematology and the rest of services was 16.4%, which statistically significant (p<0.001).

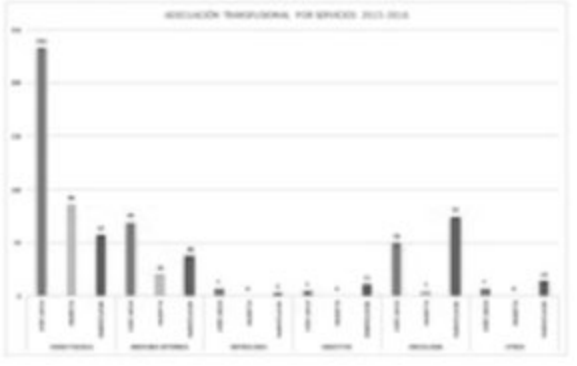

Figure 1.

Summary/Conclusion: The increase in transfusion in our center was 25% from the periods of 2012-13 to 2015-16. This finding is related to the increasing complexity of care and the chronification of several pathologies. The figures of pretransfusional Hb and infusion times were within the current recommendations, however, between 5.1%-6.4% of transfusions were performed without recent analysis. The comparison of adequate and inadequate transfusion, between haematology and the other services was statistically significant in the two periods of time studied (p<0.001), which can be considered reasonable given the greater involvement of haematology in the transfusion process.

PB2095

CHARACTERISTICS AND SURVIVAL OF DIABETIC AND NON-DIABETIC PATIENTS WITH MYELODYSPLATIC SYNDROMES

Y. Moshe[1,2,*], E. Joffe[2,3], G. Uri[4,5], M. Broitman[1], K. Filanovsky[6,7], G. Man-El[3], H. Oster[2,8], P. Raanani[2,3], I. Avivi[1,2], M. Mittelman[1,2,8]

[1]Hematology, Tel-Aviv Sourasky Medical Center, [2]Sackler Faculty of medicine, Tel Aviv University, Tel Aviv, [3]Hematology, Rabin Medical Center, Petah Tikva, [4]Hematology, Soroka Medical Center, [5]Faculty of Medicine, Beer Sheba and Ben-Gurion University, Beer Sheba, [6]Hematology, Kaplan Medical Center, Rehovot, [7]Hadassah Medical School, Hebrew University, Jerusalem, [8]Medicine, Tel-Aviv Sourasky Medical Center, Tel Aviv, Israel

Background: Diabetes mellitus (DM) is a common co-morbidity in patients with myelodysplastic syndromes (MDS). In the general population, DM is associated with a shorter life expectancy, greater risk for infection, and anemia even in the absence of severe renal disease. It would be reasonable to assume that these issues would have a considerable impact on the management and outcomes of patients with MDS and DM.
Aims: We aimed to determine differences in the clinical chracteristics and disease course of diabetic *vs* non-diabetic MDS patients.
Methods: We retrospectively analyzed the characteristics and survival of MDS patients from four medical centers in Israel. We compared disease parameters at presentation, co-morbidities and overall survival between diabetic MDS patients and non-diabetic MDS patients.
Results: We reviewed records of 700 patients diagnosed with MDS between 2004 and 2016. Of these, 185 MDS patients (26.4%) had DM prior to MDS. The median age (75 *vs* 76.5, p=0.322) and gender distribution (43.3% *vs* 40.5% females, p=0.581) were similar for MDS patients with and without DM, respectively. Diabetic patients had a higher median body mass index (27.7 *vs* 26.7, p=0.02). MDS patients with DM had more co-morbidities than non-diabetic patients: cardiovascular disease (32.9% *vs* 22.6%, p=0.018), chronic kidney disease (37.8% *vs* 19.2% p<0.001), and hypertension (89.6% *vs* 67.7% p<0.001). COPD and history of previous chemotherapy were not significantly different between the two groups. Among patients with sufficient data to assign an IPSS-R risk category (n=259) diabetic patients had a trend towards lower risk disease (IPSS-R very low/low in 76% of diabetics *vs* 66% non-diabetic, p=0.09). Survival data were available for 481 patients. Median follow-up time was 74 months (95% CI 64-87 months). We observed no significant difference in overall survival curves or median overall survival between diabetic and non-diabetic MDS patients (**Figure 1**) (median OS 67.7 months 95% CI 57-78.3 months *vs* 62.9 months 95% CI 48-77.8 months, p=0.778).

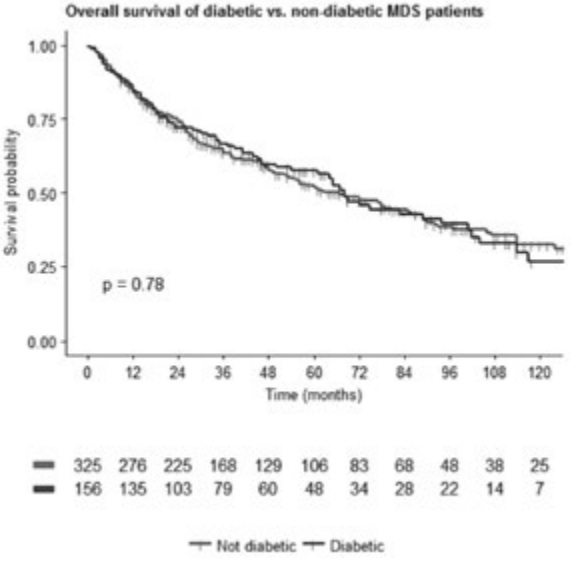

Figure 1.

Summary/Conclusion: MDS patients with DM have more co-morbidities than MDS patients who are non-diabetic. In contrast to expectations, in our series, diabetic and non-diabetic patients with MDS had similar overall survival. Additional studies are needed to confirm this finding, and to elucidate whether this is due to specific biological differences between diabetic and non-diabetic MDS patients or whether this is due to closer medical follow-up of diabetic patients, leading to diagnosis of MDS in earlier stages.

PB2096

CHRONIC MYELOMONOCYTIC LEUKEMIA AND AUTOIMMUNE DISORDERS

G.A. Pinto Solano*, M. Calbacho, J. López

Hematology, Hospital Ramon Y Cajal, Madrid, Spain

Background: Multiple autoimmune conditions have been described in the context of chronic myelomonocytic leukemia (CMML), but it is not clear if they could have an impact on clinical evolution.
Aims: We describe the subgroup of CMML related to autoimmune diseases (AD) and the main clinical features, compared to the patients who have other types of CMML.
Methods: We have studied 38 patients over 14 years (2003-2016), and compared the subgroup with autoimmune *versus* non-autoimmune disorders, in order to establish differences in some clinical parameters and the free progression survival (PFS) defined as the time from diagnosis to transformation to acute myeloid leukemia.
Results: We found a prevalence of AD of 23.6%, with the following autoimmune conditions: primary immune thrombocytopenia (22.2%), psoriasis (22.2%), adult-onset Still's disease (11.1%), giant cell arteritis (11.1%), ankylosing spondylitis (11.1%), rheumatic polymyalgia (11.1%) and unspecified arthropathy (11.1%). The main clinical features for both groups are described in table 1. The mean follow-up was 32.5 months. PFS at 2 years was 76.5% *versus* 47.2% in the AD group compared to non-AD group (p: 0.536), respectively.
Summary/Conclusion: The patients with CMML and AD represent a special subgroup that could have a better prognosis, as occur in other hematological

malignancies. This group of AD tend to have a normal karyotype and dysplastic subtype. More studies could be necessary to confirm the features and clinical evolution of this association.

Table 1.

Clinical features	Autoimmune disease (N=9)	Non-autoimmune Disease (N=29)
Mean age (years)	69.4	71.2
Gender (male/female %)	77/23	62/38
Normal karyotype (% patients)	77	51
CPSS (low or int-1/ int-2 or high %)	44/56	58/42
FAB subtype (dysplastic/proliferative)	33/67	51/49
WHO subtype (0/1/2 %)	75/6.8/17.2	78/11/11

PB2097

DEPLETION OF PROGENITORS B CELLS IN CHRONIC MYELOMONOCYTIC LEUKEMIA

G.A. Pinto Solano*, M. Calbacho, J. Lopez

[1]Hematology, Hospital Ramon y Cajal, Madrid, Spain

Background: Depletion of progenitors B cells (PBC) has been described as a frequent event in myelodysplastic syndromes and aplastic anemia, but we do not know if this event occurs in other related conditions as chronic myelomonocytic leukemia (CMML), and if it has any potential diagnostic or prognostic significance.
Aims: Describe the prevalence of depletion of PBC at bone marrow of CMML at diagnosis, and correlate if exists difference in the progression-free survival (PFS) compared to patients without this event.
Methods: We retrospectively reviewed the bone marrow flow cytometry of CMML patients at diagnosis during the period of 2008-2016. Depletion of PBC (CD34+CD19+CD10+) was defined as a value less than 0.05% of the total nucleated cell at the bone marrow. PFS was defined as the time from diagnosis to progression to acute myeloid leukemia.

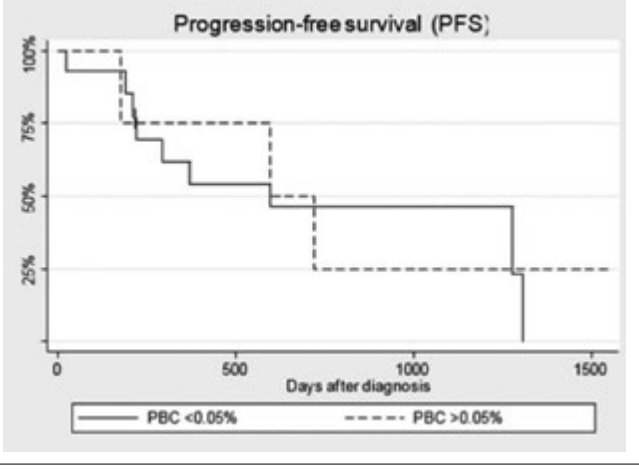

Figure 1.

Results: The studied group had a median age of 73.1 years, with a distribution by sex (male/female) of 61% and 49% respectively, and a mean follow-up of 24.2 months. According to WHO subtype (0, 1 and 2), the distribution was 66.7%, 11.1% and 22.2%, respectively. We found that 78% of the patients had depletion of PBC. The depleted patients had the CPSS prognostic scale (low/int-1/int-2/high) of 23%, 15.3%, 46.1% and 15.3%, and the non-depleted of 20%, 20%, 60%, 0%, respectively. By FAB subtype the proportion of dysplastic *versus* proliferative disease was 46% and. 54% in depleted patients, and 60% and 40% in non-depleted. The PFS to 2 years was 50% in non-depleted patients *versus* 46% in depleted patients (p: 0.816, see figure 1).

Summary/Conclusion: Based in our data, it is possible to consider that the depletion of PBC as a frequent event in CMML, and there is not a prognostic correlation with statistical significance in terms of PFS to 2 years in depleted or non-depleted patients. The depletion of PBC occurred without specific tendency in all subgroups by CPSS and FAB classification. Due to small sample size, further studies are necessary to clarify the relevance of this event.

Abstract withdrawn.

PB2099

ASIA-INCLUSIVE CLINICAL DEVELOPMENT OF PEVONEDISTAT IN COMBINATION WITH AZACITIDINE IN HIGHER RISK MYELODYSPLASTIC SYNDROMES, CHRONIC MYELO MONOCYTIC LEUKEMIA, OR LOW-BLAST ACUTE MYELOID LEUKEMIA

X. Zhou[1,*], S. Friedlander[1], F. Sedarati[1], S. Kuroda[2], Z. Hua[1], Y. Yamamoto[3], D.V. Faller[1], T. Takubo[2], S. Sugizaki[2], K. Nakai[2], E. Bedell[1], K. Venkatakrishnan[1]

[1]Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, United States, [2]Takeda Pharmaceutical Company Limited, Tokyo, [3]Takeda Pharmaceutical Company Limited, Osaka, Japan

Background: Pevonedistat (PEV), a first-in-class NEDD8-activating enzyme inhibitor, combined with azacitidine (AZA) has demonstrated clinical activity in Western patients (pts) with acute myeloid leukemia (AML). PEV is currently in global clinical development for higher risk myelodysplastic syndromes (HR MDS), chronic myelomonocytic leukemia (CMML), and low-blast AML in a global phase 3 pivotal trial PANTHER (P3001).
Aims: To enable timely enrollment of Study P3001 for pts in East Asia, we proposed to apply multi-regional clinical trial (MRCT) principles of the ICH E17 draft guidelines informed by ICH E5 principles from an exploratory point of view to define the dose and minimum required number of East Asian pts in the pooled East Asian region.
Methods: Disease epidemiology, cytogenetic and mutational profiles of MDS, CMML, and AML among Caucasian and East Asian populations, treatment landscape, and efficacy of AZA were investigated. PEV pharmacokinetics (PK) and safety data in East Asian pts were collected in Pevonedistat-1012 (P1012), a phase 1 dose-finding study of PEV in combination with AZA conducted in Japan, South Korea, and Taiwan. Informed consent was provided for Study P1012. Population PK analyses were conducted to compare PEV exposures between East Asian and Western pts. Statistical considerations were provided to estimate the probabilities of consistency in efficacy between East Asian pts and the overall study population to be enrolled in the P3001 phase 3 study.
Results: According to epidemiological data reported by US, EU, Japan, and South Korea, the incidence of MDS and AML are comparable across these regions. Comparison of the molecular alterations in AML, MDS, and CMML across Caucasian and East Asian populations as well as the frequencies of these alterations suggested that the cytogenetic and mutational landscape is generally similar across these ethnicities. Literature research indicated that AZA shows comparable efficacy (response rate and hematologic improvement) in pts from Japan and South Korea. Preliminary PEV PK data from 18 pts (including 8 from Japan, 7 from Taiwan, and 3 from South Korea in Study P1012) indicated similar PEV PK profiles in East Asian (37%) and Western pts (geometric mean dose-normalized AUC_{48h} of 1167 [CV of 37%] and 1065 h*ng/mL [CV of 32%], respectively). In addition, systemic PEV exposures were consistent across the major East Asian races (ie, Japanese, Korean, Chinese). The safety profile of PEV alone or in combination with AZA in East Asian pts was generally comparable to that observed in Western pts. Based on the assumption that the treatment effects in Japanese/East Asian pts are similar to those in the overall population, with a total of 30 East Asian pts, the estimated probabilities of achieving consistent efficacy outcomes (measured by event-free survival and overall survival) between East Asian pts and the overall 450 pts in the global pivotal trial P3001 are >80%.
Summary/Conclusion: Intrinsic and extrinsic factors relevant to disease (HR MDS, CMML, and low-blast AML) and PEV were inferred to be similar across the planned countries of enrollment in the pooled East Asian region (Japan, South Korea) and between East Asian and Western regions. Clinical efficacy and safety data from the P3001 phase 3 study are therefore applicable to inform benefit-risk assessment for the East Asian population and are additionally justified to be pooled across pts enrolled for purposes of assessing consistency in the benefit-risk profile in East Asian populations.

Background: Myelodysplastic syndromes (MDS) represent a complex group of myeloid clonal disorders. Decision making in MDS is complicated by advanced age of MDS-patients and a high prevalence of comorbidities. Moreover, development of treatment strategies is complicated by the inconsistent outcome reporting in MDS studies and by the resulting lack of comparability.
Aims: The aims of this research were (1) to provide an overview of accepted and implemented outcomes in studies in MDS patients, (2) to identify the most important outcomes for the treatment of MDS from the perspective of health care practitioners (HCPs) and (3) to initiate the development of an unified MDS-specific core outcome set (COS).
Methods: To identify potential MDS core outcomes we performed a comprehensive systematic literature review in the ClinicalTrials.gov database and four clinical trial registries (ISRCTN, ICTRP, EU-CTR and NCI). We included studies evaluating MDS patient-relevant outcomes registered between 2012 and 2016 and excluded studies focusing solely on pharmacokinetics, pharmacodynamics or molecular research. Data regarding the registration year, funding, intervention, study population characteristics, primary and secondary outcomes were extracted using a predefined data extraction form and summarized in a comprehensive evidence table. All studies were screened by at least two independent reviewers. After summarizing the data, researchers together with MDS clinical experts actively participated in the discussion and derived a consensus on the potential MDS core outcomes. The selection process included a three-round online Delphi survey among HCPs from 17 different countries as part of the MDS-RIGHT project. Each outcome was ranked using a scale from 1 to 9. Following recommended criteria, highly important outcomes were defined as those ranked 7-9 by at least 70% of participants and ranked 1-3 by not more than 15%. Outcomes were excluded if ranked 1-3 by at least 70% of the participants and 7-9 by not more than 15%. All outcomes proceeded to the next round and were presented together with the ratings of the previous round. The final, third round was intended for deriving consensus and defining the outcomes specifically for MDS.
Results: From 425 (observational and interventional) included studies, we extracted 1,341 patient and/or clinically relevant outcomes that were condensed into 26 potential MDS core outcomes. 56 responses (24% response rate) obtained in the first round resulted in 15 outcomes ranked as highly important, and one additional outcome, suggested by two participants. None of the outcomes could be excluded. 38 responses (17%) were analyzed in the following round, where six outcomes were ranked highly important. No outcomes fulfilled the exclusion criteria, leading to the overall selection of six MDS core outcomes (quality of life, treatment-related mortality, overall survival, performance status, safety, hematological improvements). Final consensus on the remaining outcomes and definition of all included outcomes is ongoing.
Summary/Conclusion: Our study succeeded in identifying six outcomes that experts agreed on being included in the MDS-COS. The selected outcomes show the experts' awareness of the importance of patient-reported outcomes in MDS. MDS-specific definition of the MDS core outcomes and inclusion of perspectives of different stakeholders, namely of patients and health-care providers are currently ongoing.

PB2101

THE PREDICTIVE VALUE OF FERRITIN, FOLIC ACID AND VITAMIN B12 AS BIOMARKERS FOR THE DEVELOPMENT OF LEUKEMIA IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES. A PILOT STUDY

D.L. Lighezan[1,*], S.O. Cismas[1], C. Sorica[1], O. Potre[1], B. Timar[2], H. Ionita[1], I. Ionita[1]

[1]Hematology, [2]Diabetes, Nutrition and Metabolic Diseases, University of Medicine "Victor Babes" Timisoara, Timisoara, Romania

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of hematologic disorders defined by ineffective hematopoiesis, manifesting in peripheral cytopenias. The progression of these clonal hematopoietic disorders is highly unpredictable and leukemic transformation is an often occurring hematological feature. No accurate prediction model has been so far established, due to the fact that no efficient prognostic markers have been identified.
Aims: The aim of this study was to evaluate whether the serum levels of ferritin, folic acid and vitamin B12 can be regarded as biomarkers of acute leukemic transformation in patients with MDS.
Methods: In this single-center, retrospective, registry-based study we included 128 patients diagnosed with primary MDS between 2012 and 2017. Data regarding serum levels of ferritin, folic acid, vitamin B12 were collected at the moment of diagnosis and during follow-ups. The initial medullary blast count and disease progression were also noted. The evaluated patients with MDS were divided into two groups: the patients with stable disease and those with leukemic progression.
Results: Out of the one hundred and twenty eight patients, 38.3% (n=49) suffered disease progression and ultimately acute leukemia transformation, with a gender ratio of 61% male to 39% female. At the moment of diagnosis mean ferritin levels were lower in patients with stable disease 409.8 ng/ml *vs* 504.5 ng/ml in patients with leukemic progression; whereas the opposite was observed for mean B12 and folate levels. The mean B12 levels were higher in stable disease patients 479.5 pg/ml vs, 455.2 pg/ml and the mean folate levels were 9.0 ng/ml *vs* 8.0 ng/ml in patients with leukemic progression. The blast count at diagnosis was significantly higher in patients with disease progression into acute leukemia (8.8 *vs* 4.3) with a p <0.001. Follow-up data revealed a significantly elevated Δferritin (ferritin last evaluation - ferritin diagnosis) in patients with subsequent acute leukemia transformation (1072.3ng/ml *vs* 680.4ng/ml), p=0.006, highlighting a continuous trend of increase. An elevation of Δfolate levels (3.7 ng/ml *vs* 4.7 ng/ml) and a decrease of ΔVitamin B12 levels (251.9 pg/ml *vs* 213.4 pg/ml), without statistical significance, were also observed.
Summary/Conclusion: Despite the small sample size which may lead to possible type 2 statistical errors, the results of this study may be regarded as triggers for further research. Our results are pointing to a possible use of ferritin as a predictor for disease progression in patients with MDS. In the same time, the results are pointing to a lack of association between serum vitamin B12 or folic acid and the disease progression.

PB2102

A SINGLE CENTRE EXPERIENCE OF RESPONSE RATES TO AZACITIDINE FOR MDS, AML AND CMML IN RELATION TO CYTOGENETICS RISK AND PERFORMANCE STATUS

V. Murthy*, N.D.G. Kapuge, E. Shereef, J. Suhr, C. Kartsios, E. Xenou, J. Ewing, E. Nikolousis

Haematology, Heart Of England NHS Foundation Trust, Birmingham, United Kingdom

Background: The advent of targeted therapy has increased the repertoire of therapeutic options. In particular the methyl transferase inhibitor 5 Azacytidine, that targets epigenetic changes in MDS and AML.The myelodysplas-

tic syndromes (MDS) are an acquired form of clonal stem cell disorders that manifest heterogeneously but are unified clinically by progressive bone marrow failure, susceptibility to life threatening infections, and a risk of transforming to leukemia.We report a single centre experience of using Azacitidine in the licensed NICE indications, comparing with the published data.
Aims: Aim of our study was to assess azacitidine response rates in different cytogenetic risk groups and varying performance status.
Methods: We retrospectively reviewed patients with MDS and AML who received Azacitidine at the Heart of England NHS Foundation Trust from Apr 2012- January 2018. Patient's demographic data, disease characteristics, treatment, outcome and follow up data were obtained and all patients were included irrespective of the number of the cycles.
Results: 57 patients were included in the analysis. Median age of treatment was 73.9 years. Median number of cycles was 6 (range from 1 to 43). There were 68% of MDS patients, 22.8% of AML and 8.8% of CMML2 patients in the cohort. Varying degree of performance stage was noted including ECOG 0,1 and 2 at 40.4%, 43.9% and 7.7% respectively. 42.1% had high risk cytogenetics depending upon the IPSS-R risk based classification. 19.3% patients had complex karyotype (3/>3). Median Hb was 9g/dl, Neutrophil count was $0.7x10^9$/l and platelet count was $41x10^9$/l in this population. Median bone marrow blast percentage was 10%. Responding patients showed reduced transfusion requirement. 10, 26 and 25 patient had not had any transfusions in first second and third quarters correspondently. Causes of death were mainly disease progression and sepsis. 42.2% died due to disease progression and 35.1% died due to sepsis. Overall, median progression free survival (PFS) was 19 monts while median overall survival (OS) was 12 months. Overall survival was not affected by age, Bone marrow median blast percentage and median neutrophil count, however, survival was affected by presenting peripheral blast percentage, IPSS-R, Haemoglobin and median platelet count that seemed to be statistically significant (P<0.05). There is no statistically significant PFS or OS for patients who had varying performance stage (p=0.78 and p0.65 respectively). Nevertheless, there is significance difference noted in the group of who had high risk cytogenetic *versus* other cytogenetic risks with PFS of 8 months and 15 months respectively (p=0.017), OS of 15 and 29 months respectively (p=0.09).

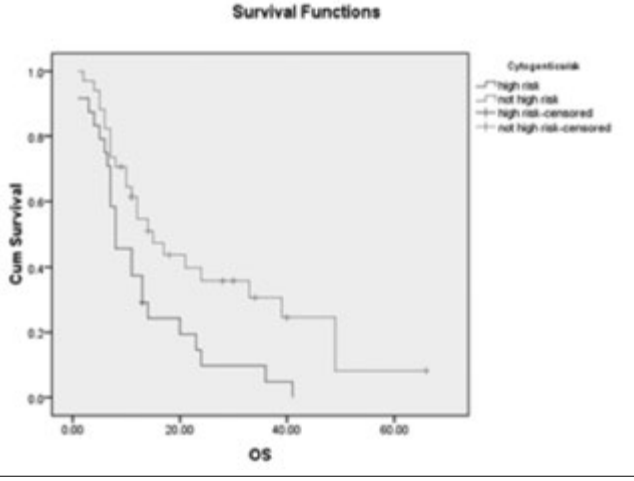

Figure 1.

Summary/Conclusion: Azacidine therapy has benefited for the patients who had advanced age AML CMML and MDS irrespective of their performance stage at ECOG 0-2 and patient who has non high risk cytogenetic based on IPSS-R risk categorization. However, the group of patients with high risk cytogenetic and poor performance considered historically very poor survival had considerable PFS and OS benefitting treatment rather than best supportive care.

PB2103

UNUSUAL FAVOURABLE CLINICAL COURSE IN A PATIENT WITH LOW-RISK MYELODYSPLASTIC SYNDROME WITH DEL (5Q) AND ACQUIRED TP53 MUTATION: CLINICAL, BIOLOGICAL AND MOLECULAR SEQUENTIAL STUDY

C. Finelli[1,*], E. Ottaviani[1], M. Follo[2], N. Testoni[1], M. Raffini[1], M.T. Bochicchio[1], S. Parisi[1], S. Mongiorgi[2], L. Cocco[2], M. Cavo[1]

[1]Ematologia, Policlinico S.Orsola-Malpighi, [2]Biomedical Sciences-Human Anatomy, University of Bologna, Bologna, Italy

Background: Lenalidomide (LEN) is the approved first line treatment for lower risk myelodysplastic syndromes (MDS) with del (5q) and transfusion-dependent anemia. However, the acquisition of a TP53 mutation in these patients is considered a high-risk factor, predictive of a poor clinical outcome, due to a high risk of evolution in acute myeloid leukemia (AML).
Aims: To present the clinical, biological and molecular data, sequentially assessed, of a patient with low-risk MDS with del(5q, who acquired a TP53 mutation during the course of the disease, but, nevertheless showed a particularly favourable clinical course.
Methods: The patient at the time of the first diagnosis, on November 1996, underwent a complete diagnostic work-up, with complete blood counts, bone marrow aspiration and cytogenetic study. Subsequently, starting from July 2009, when she started LEN, she also underwent biological and molecular studies, performed sequentially throughout the subsequent course, until now. Mutation analysis of TP53 exons 5-9 was performed on mononuclear cells by PCR and direct bidirectional Sanger sequencing. Each chromatogram was compared with wild-type sequence (GenBank; NM_001126114). Gene expression analyses were performed on mononuclear cells at diagnosis and during treatment by a TaqMan-based Real-Time approach (Follo, PNAS 2009).
Results: At diagnosis (November 1996) the patient, a 55-year-old female, showed transfusion-dependent anemia. Refractory anemia (according to FAB) with the presence of del (5q)(q13;q33) in 8/9 metaphases was diagnosed. IPSS risk was low, and IPSS-R risk was intermediate. The patient, refractory to erythropoietin, continuously received red cell transfusions, and also iron chelation, (subcutaneous deferoxamine from March 1998, and subsequently oral deferasirox, starting on July 2003), until July 2009, when LEN was started. At that time no mutation of TP53 was detected. The patient discontinued transfusions after 2 months of LEN, after 3 months the Hb level reached 12.2 g /dL, and after 6 months no del(5q) metaphases were detectable, while 3 metaphases with + 8 were observed. Complete cytogenetic remission was achieved after 12 months, and persisted after 24 months, on July 2011, when LEN was discontinued. Cytogenetic remission was maintained for another 6 months, and hematologic remission, in the absence of treatment, lasted for 55 months, until February 2016, when the patient showed hematologic relapse, with transfusion need, but without excess of marrow blasts or high-risk cytogenetic alterations. LEN was restarted on April 2016, and a quick second hematologic response was observed after 2 cycles (Hb 11.1 g/dL), with a partial cytogenetic response (14/30 normal metaphases) on November 2017, after 11 cycles. The patient is still continuing LEN, still maintaining complete hematologic remission. Starting from February 2015, a TP53 mutation was detected for the first time, and was confirmed on November 2015 and November 2017: a missense variant in exon 5 C135Y (c.404G>A), intron variant in intron 6-7 (rs1825895). As to biological studies, the patient showed an increased expression of Beta-Globin mRNA during response to LEN, that was associated with an induction of PI-PLCgamma1, therefore hinting at an activation of erythroid differentiation.
Summary/Conclusion: This case shows that the detection of a TP53 mutation is not necessarily associated with a poor clinical outcome in all cases, and that probably not all types of TP53 mutations might have a negative prognostic impact.

PB2104

NEXT GENERATION SEQUENCING IN PREDICTING OUTCOME IN MDS- DAWN OF NEW ERA IN PAKISTAN

N. Anwar[1,*], A. Arshad[1], S. Shahid[2], S. Ahmed[2], N. Fatima[3], T. Shamsi[1]

[1]Hematology, [2]Genomics, [3]Research and development, National Institute of blood diseases and bone marrow transplant karachi Pakistan, Karachi, Pakistan

Background: Myelodysplastic syndromes (MDS) are a heterogenous group of hematologic malignancies characterized by clonal expansion of bone marrow myeloid cells with impaired differentiation. Studies utilizing next-generation sequencing (NGS) have identified a core set of recurrently mutated genes in the majority of patients with AML and MDS. The identification of recurrent mutations in MDS has led to incipient insights into the pathophysiology of this disorder including those with mundane cytogenetics. DNA-level mutations in several of these genes including ASXL1, ETV6, EZH2, RUNX1 and TP53 in MDS contribute to disease pathogenesis, outcome and currently is an active area of research.
Aims: Our institution is first in the country to perform next generation sequencing analysis. This study is a beginning to the insight of genomics in this disorder with respect to racial difference as much limited has been done

on regional level with none reported nationally. With this aim the study was done to assess mutation analysis in MDS and correlate the data with the clinical outcome of the patient.
Methods: A total of 20 MDS diagnosed patients by bone marrow biopsy and cytogenetics were included. Informed consent and detailed history was taken from all patients. The next generation sequencing analysis for a panel of 54 genes including tumor suppressor and oncogenic hotspots associated with myeloid malignancies (AML, MDS, MPN, CMML and JMML) was performed using DNA samples.
Results: A total of 20 MDS patients (14 males and 6 females) meeting the criteria of WHO classification were included. The mean age of the patients was 42 years. Most common presenting complain was weakness in 13 (65%) patients followed by fever and lethargy in 6 (30%). The mean IPSS was 01. Cytogenetic analysis revealed 13(65%) patients with abnormal karyotype while 7(35%) with normal karyotype. Using next generation sequence analysis, 10 (50%) patients had mutations including 2 novel mutations {RUNX1 p.lle428Thr(het) and GATA2 p.Thr358Pro} and 8 reported mutations including p.Pro384Leu (het) RunX1,p. Pro75Leu CDKN2A,Tet-2 c5162 T>G mutation,p.Gln1039Ter (het) ASXL1,p.Gly12Ser, NRAS and DNMT3A NPM. Patients who carried mutations received blood transfusion, lenalidomide, hematinics and azacitidine for treatment. Out of these, 03 patients were transformed into acute myeloid leukemia and received chemotherapy. Mutations in MDS are associated with changes in patient outcomes and it was found statistically significant in our cohort. Numbers of expiry in patients identified with mutations were comparably higher than those who did not carry any mutation (P-value=0.017).
Summary/Conclusion: Sequencing studies suggest that multiple mutations are required for MDS initiation and progression to acute myeloid leukemia (AML). In addition to providing prognostic information, these gene mutations can be used to monitor patient disease burden through the use of ultrasensitive detection techniques like NGS. The past several years have yielded many incipient insights, but the consummate genetic landscape of MDS is not yet kenned. Additional studies will be required to understand the prognostic implications of these mutations for treatment, disease progression and survival.

PB2105

ASSEMENT OF TRANSFUSION FREQUENCY AS A MORTALITY INDICATOR IN MYELODYSPLASTIC SYNDROMES. A SINGLE CENTER DATA

S. Cismas[1,*], D. Lighezan[1], C. Sorica-Romanescu[1], M. Delamarian[2], O. Potre[1], I. Ionita[1]

[1]Hematology, University of Medicine "Victor Babes" Timisoara, [2]Hematology, Municipal Emergency Hospital Timisoara, Timisoara, Romania

Background: Myelodysplastic syndromes (MDS) are a heterogenous set of clonal stem cell neoplastic disorders defined by ineffective hematopoiesis which translates to peripheral cytopenia with one or more lineages being affected. According to WHO, MDS is classified into six distinct entities based on morphologic, quantative and qualitative evaluation of both peripheral blood and bone marrow. Flow cytometry immunophenotyping, bone marrow biopsy, cytogenetics and molecular biology offer further information relating to prognosis and treatment options. An independent prognostic factor in MDS is transfusion dependency. Higher mortality rates have, especially in low-risk patients, been related to higher transfusion frequency and consequential iron overload.
Aims: The aim of this study is to evaluate the prognostic value of transfusion requirement, anaemia severity at moment of diagnosis, chelation therapy and to estimate mortality as it relates to these factors.
Methods: We analysed data retrospectively from one hundred twenty eight patients with myelodysplastic syndrome diagnosed between January 2012 and February 2018 and we evaluated transfusion requirement, admission frequency, anaemia severity at diagnosis, chelation therapy and overall survival.
Results: Mortality rate was high, at 67% (n=86); for these patients, haemoglobin at diagnosis was 8.7, transfusion requirement median was 18, with an average of 10 admissions per patient, as opposed to a haemoglobin at diagnosis of 9.3, transfusion requirement of 19 and a number of admission of 15 for the 33% (n=42) of patients that survived. In cases where chelation therapy was needed, mortality was related to the number of transfusions administered with a median of 30 in the higher morality group and a median of 7 transfusions for the lower mortality group.
Summary/Conclusion: In conclusion, a lower haemoglobin level at diagnosis resulted in a higher mortality rate, the same as with patients with a higher transfusion requirement and post transfusion iron overload that required chelation therapy. This retrospective data supports the use of transfusion frequency as an negative prognostic indicator.

PB2106

AZACITIDINE CAN INDUCE LIFE-THREATENING SKIN LESIONS

C. Vo[1,*], A. Thoresen[1], I. Dybedal[2]

[1]Hematology, Innlandet Hospital, Gjoevik, [2]Hematology, Oslo University Hospital, Rikshospitalet, Oslo, Norway

Background: Azacitidine (AZA) was the first drug demonstrating survival benefit over conventional care in patients with high risk MDS, including AML with 20-30% blasts. It has been the standard of care in patients not eligible for allogeneic stem cell transplantation and is lately also used in elderly patients with AML. The medication is usually well tolerated. We will report two patients with cutaneous side effects of AZA, which turned into a life-threatening systemic affection in one of them.
Aims: By these cases, we want to demonstrate that AZA can cause life-threatening skin lesions. High-dose steroids can dramatically improve a nearly fatal clinical situation.
Methods: The two patients included in this report have both given written informed consents to this publication. We describe two patients who have been treated at a local and a university hospital. **Patient 1** was a 79-year-old woman with MDS-EB-2 treated with AZA 100 mg/m^2 subcutaneously (sc) days 1-5. She was admitted to hospital on day 5 because of dyspnea, coughing and high fever. Chest X-rays showed a consolidation. She was treated with broad-spectrum antibiotics. After 7 days she developed darkly red and swollen skin lesions on her right hand. This rapidly changed into necrotic tissues as demonstrated at the picture. In addition, 3 more necrotic skin lesions were observed, also affecting her other hand. Surgery was performed several times. She became critical ill and circulatory instable with low blood pressure. It was considered unlikely that she would survive. Since no bacteria were found and AZA can give necrotizing fasciitis, acute febrile dermatosis and lung infiltrations, we as a last try, started with high-dose steroids. Within a short time, her condition was dramatically improved. **Patient 2** was a 72-year-old man with relapse of AML. He was treated with AZA 100mg/m^2 sc day 1-5. Before cycle 4, he was admitted to hospital because of neutropenic fever and received empirically broad-spectrum antimicrobials. Feeling better after 4 days he started AZA cycle 4.The following day he rapidly developed darkly red and swollen skin lesions on both hands and forearms in addition to high fever. The similarity between his skin affection and the findings in patient 1, made us consider AZA-induced side effects likely. We chose to treat him with high-dose steroids. Already the next day his condition had improved.
Results: For patient 1 laboratory values revealed neutrophils 42.3x10^9/L. Microbiological samples from skin and blood were all negative. Biopsy of the skin lesions showed neutrophilic dermatosis as in Sweet syndrome.
For patient 2 a skin biopsy showed subacute inflammation with no signs of vasculitis or infection, but findings comparable with drug-induced changes.

Figure 1.

Summary/Conclusion: AZA-induced Sweet syndrome appears to be the cause of the progressing, necrotic skin lesions with the fulminant systemic affection and circulatory collapse in patient 1. High-dose steroids dramatically improved her situation. A similar development may have been prevented by introducing steroids to patient 2.

PB2107

CLINICAL IMPLICATION OF SERUM FERRITIN LEVEL AT DIAGNOSIS IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES

S. Osanai, M. Shiseki*, K. Yoshinaga, N. Mori, J. Tanaka

Department of Hematology, Tokyo Women's Medical University, Tokyo, Japan

Background: Iron overload due to an ineffective erythropoiesis and/or red cell transfusion is often observed in myelodysplastic syndrome (MDS) patients, resulting in damage of target organs including heart, liver, and pancreas. Several reports showed clinical impacts of iron overload in MDS.
Aims: In the present study, we retrospectively analyzed relationship between serum ferritin level at diagnosis and clinical features in MDS patients to evaluate clinical implication of serum ferritin level.
Methods: This retrospective observational study was conducted according to the Declaration of Helsinki, and approved by institutional ethics committee (No. 4301). We reviewed medical records and laboratory data base of the patients who were diagnosed as MDS between January 2003 and December 2016. Patients in whom serum ferritin level at the time of MDS diagnosis were available, were included this study. Patients with therapy-related MDS, with history of transfusion, any specific therapy for MDS were excluded from the study.
Results: A total of 98 patients (59 males and 39females, median age, 71 years, range, 20-91 years) were included into this study. Median follow-up period was 22.5 months (mean 39.0, range 0.4-165.7 months). We analyzed relationship between serum ferritin level and clinical parameters and laboratory data to evaluate clinical implication of serum ferritin level. Inverse correlation was observed between serum ferritin level and hemoglobin concentration (r=-0.4022, P<0.0001). Positive correlation was observed between serum ferritin level and ring-sideroblast percentage in bone marrow (r=0.4163, P=0.0002). No significant difference in serum ferritin level was observed among MDS subtypes, IPSS and IPSS-R risk categories. The Cox proportional hazards model was employed to evaluate prognostic significance of serum ferritin level, demonstrating that high serum ferritin level (more than 500 ng/ml) was associated with worse OS (hazard ratio=3.04, 95% CI, 1.58-5.70, P=0.0012). Patients were classified into two groups according to serum ferritin level, high (500ng/ml or more) ('H'), and low (less than 500 ng/ml) ('L') groups. Kaplan-Meier plots indicated that 'H' group showed shorter OS than 'L' group (log-rank test, P=0.0014). Estimated OS rates at 2 years, 5 years, and 10 years from diagnosis were 48.8%, 42.1%, and 12.0% in 'H' group, and 82.4%, 66.5%, and 50.4% in 'L' group, respectively. Subgroup analysis demonstrated that prognostic significance of serum ferritin level was obviously observed in patients with lower IPSS (Low and Int-1), but not in those with higher IPSS (High and Int-2). Among patients with lower IPSS, Kaplan-Meier plots demonstrated significant worse OS in 'H' group compared with 'L' group (log-rank test, P=0.0003); estimated 2-year, 5-year and 10-year OS rates were 44.0%, 30.8%, and 0% in 'H' group, and 73.2%, 62.5%, and 47.1% in 'L' group, respectively. In contrast, among patients with higher IPSS, no difference in OS was observed between 'H' and 'L' groups (log-rank test, P=0.9224).
Summary/Conclusion: Our present results showed correlation between serum ferritin level at diagnosis and degree of anemia, suggesting serum ferritin level reflects dyserythropoiesis. High serum ferritin level at diagnosis was associated with worse survival in low risk MDS patients, indicating clinical implication of serum ferritin level as a prognostic marker.

PB2108

IS MDS REALLY TREATABLE? EXPERIENCE FROM PAKISTAN

N. Anwar[1,*], A. Arshad[1], S. Sharif[2], N. Fatima[2], T. Shamsi[1]

[1]Hematology, [2]Research and development, National Institute of blood diseases and bone marrow transplant karachi Pakistan, Karachi, Pakistan

Background: Myelodysplastic syndromes (MDS) represent a diverse group of hematopoietic stem cell disorders characterizing ineffective hematopoiesis, morphological dysplasia and leukemic transformation. Although the international prognostic scoring system (IPSS) represents gold standard for risk assessment, it is still difficult to predict survival and median time to leukemic transformation in the majority. MDS being considered a relatively uncommon disorder in our region having no national registry for evaluation of disease burden is presumed to be an incurable disease with majority of patients conventionally being treated by only blood product support. Most of the patients are unable to avail standard treatment and those who are treated with recommended options are presumed to have hopeless outcomes. Hence, the study was planned to evaluate the fate of this disorder in our region with respect to various given treatment options.
Aims: The aim of the study was to assess disease outcome in the region with best available treatment option given and establish local data on it.
Methods: It was an analytical cross sectional study conducted at National Institute of Blood Diseases and Bone Marrow Transplantation, Karachi Pakistan from June 2010 to January 2018. Baseline investigations done including complete blood counts, bone marrow biopsy and cytogenetics. Clinical parameters of all patients were recorded. Patients were classified according to world health organization (WHO) 2008 classification and IPSS was calculated. Approval from the institutional ethics committee was obtained prior to the study. Differences in clinical measurements were evaluated using SPSS version 23. Moreover overall survival (OS) was also observed.
Results: A total of 186 patients were included in the study. The median age was 55 (range 3-90) years. There were 139 males and 47 females. In our patients the most common presenting complaint was loss of appetite 110(59%) followed by weakness and fever in 76(41%). The mean hemoglobin (Hb%) was 7.94±2.17g/dl, total leucocyte count (WBC) 7.51±13.3 × 10^9/l, platelet count 81±93.7 × 10^9/l. Cytogenetic data was available for 104 patients which revealed normal karyotype in 58 (56%) and abnormal karyotype in 46 (44%). The mean IPSS of the patients was 01. Out of total, supportive treatment was offered to (n=70,38%), hematinics (vitamin B12 and folic acid) (n=45,24%), recombinant erythropoietin (n=25,14%), lenalidomide (n=19,10%), thalidomide (n=11,06%), hypomethylating agents in (n=06,03%), steroids (n=06,03%) and growth factors (GCSF) in (n=04,02%). Death of 124 patients occurred during the study period. Cause of death was ascertained in 84 patients. Septicemia was the most common cause of death and found in (n=27, 32%) followed by shortness of breath (n=26, 31%), severe anemia (n=21, 25%) and intracranial bleeding in (n=10, 12%). The overall survival was 33% analyzed by using Kaplan meier curve. Risk of progression to AML was found in 06 patients with median time of 15 months.
Summary/Conclusion: Although MDS is considered as an uncommon disease yet the numbers of patients are increasing in Pakistan. There is a need to develop disease registry in our region to understand and approximate better measures which will help to treat patients with definitive treatment. Moreover, further studies with large sample size are needed to convince state's health department to finance treatment and research in the context so that better treatment options are made available.

PB2109

EVALUATION OF THE EFFICACY OF LENALIDOMIDE IN PATIENTS WITH HIGH-RISK MYELODYSPLASTIC SYNDROME (MDS) WHO ARE PARTIALLY RESISTANT TO HYPOMETHYLATING THERAPY

G. Dudina*

Hematology, Moscow Scientific&Clinical Center, Moscow, Russian Federation

Background: In Russia, there are no approved drugs for MDS patients who retain blood transfusion dependence despite the antineoplastic effect observed after hypomethylating therapy. The median survival rates in this cohort are significantly lower than those in the complete response group. The risk of relapse is significantly higher in these patients.
Aims: To assess the possibility of increasing the median survival rate and reducing blood transfusion dependence in patients partially resistant to hypomethylating therapy with azacitidine by administering second-line lenalidomide therapy.
Methods: 9 high-risk MDS patients (6 women, 3 men) were enrolled in the study. Cytogenetic analysis of bone marrow revealed no del(5q). The median age was 67 (52 to 84). Before enrollment patients received 4 to 12 cycles of azacitidine at a dose of 75 mg/m^2. All patients remained transfusion-dependent. The mean number of blast cells in the bone marrow was 2.8±0.3% (0.8±0.04%-5.2±0.2%). Lenalidomide was administered at a dose of 10 mg per day for 21 days. In cases when bone marrow relapse had been documented or when no decrease in the degree of blood transfusion dependence was observed for 3 cycles, the drug was discontinued. The average period from diagnosis to beginning lenalidomide therapy was 22 months. The median duration of lenalidomide therapy was 81 days (range: 42 to 168 days). The follow-up period was 18 months.
Results: 4 (44%) patients responded with a decrease in blood transfusion dependence. Three patients had complete response, one demonstrated a 50% reduction in need for transfusions (intervals between transfusions were increased up to 2 months, dose of packed RBCs reduced from 5–6 to 2–3 per month). All patients responded during the first three cycles of therapy. Five (56%) patients fully retained a need for blood transfusions. As for side effects, episodes of grade 3 or 4 neutropenia (neutrophil counts below 1,000 in 1 μl) occurred in 50% of patients during lenalidomide therapy. However, neutropenia was detected during Cycle 1 in one patient among those with a complete response, while in the non-responded group, 4 (80%) patients had neutropenia during 2-3 cycles of treatment. The treatment was discontinued after cycle 2 in 1 patient due to disease progression into acute leukemia. Four patients stopped taking the drug after cycle 3 due to a lack of effects. Blood transfusion therapy was continued for these patients. Within six months, all four patients underwent disease progression to acute myeloblastic leukemia. The mean duration of the response, characterized

by blood transfusion independence, was 8 months. The recurrence of blood transfusion dependence in all patients was accompanied by disease progression, which required third-line therapy with low-dose cytarabine at 15 mg/m2 for 14 days at 21- to 38-day intervals. A partial response was achieved in 5 (55%) patients. In terms of overall survival, in the general group, 7 (77%) patients were alive for 12 months. 3 patients (33%) were alive for 18 months.
Summary/Conclusion: Use of lenalidomide in MDS patients with a high risk of progression to acute leukemia with persistent blood transfusion dependence after hypomethylation therapy is clearly justified. The effect observed in the form of cessation/reduction of transfusion dependancy and prolongation of disease-free and overall survival, with satisfactory drug tolerance. This treatment can be recommended in elderly patients with a high comorbidity index when allogeneic stem cell transplantation cannot be performed.

PB2110

CHRONIC MYELOMONOCYTIC LEUKAEMIA A RETROSPECTIVE STUDY FROM A SINGLE CENTRE IN ROMANIA

N.A. Dobrete[1], C. Ghita[1], D. Coriu[1,2], A. Tatic[1,2,*]

[1]Hematology, Fundeni Clinical Institute, [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background: Chronic myelomonocytic leukaemia (CMML) represents a clonal hematopoietic disorder with myelodysplastic and myeloproliferative features. Some CMML cases are similar to a myelodysplastic syndrome with persistent blood monocytosis (MDS-CMML). Other cases present with leucocytosis, neutrophilia, persistent peripheral blood monocytosis and splenomegaly and are similar to a myeloproliferative syndrome (MPN-CMML). According to the 2016 WHO classification CMML is classified into 3 groups based on the peripheral/ bone marrow blast count: CMML-0, CMML-1, CMML-2.
Aims: The aim of this study was to analyse the features and treatment response in the CMML patients in our centre.
Methods: Between 2011- 2017, in our clinic, 38 patients met the criteria for CMML and were reclassified according to the 2016 WHO classification for the purpose of this retrospective study. The median monitoring time was 18 months.
Results: There were 25 (65.79%) men and 13 (34.21%) women, with a sex ratio ♂/♀= 1.9. Women presented a younger median age at diagnosis 62 years (47, 67) *vs* men 68 years (62, 75), (p=0,025), with an overall median age of 66 years (59, 75). The majority of patients were over 60 years old at diagnosis (73.68%). Half the patients presented multiple cardiovascular comorbidities at diagnosis. In this lot, 16 patients (42.1%) were categorized as MPN-CMML and 22 patients as MDS-CMML (57.9%). According to the WHO 2016 classification 13 patients (34.21%) were CMML-0, 11 patients (28.95%) CMML-1 and 14 patients (36.84%) CMML-2. There was a statistically significant difference between the median value for leukocytes (p<0,001), neutrophils (p<0,001) and monocytes (p<0,001) for MDS-CMML and MPL-CMML, but not regarding the median value for haemoglobin, platelets, bone marrow blast and LDH level. Between the 3 WHO groups no statistically significant difference was observed for the median value for leucocytes, neutrophils, monocytes platelets and haemoglobin. The difference between the median LDH levels for the three groups was statistically significant (p=0.038). The transformation rate to AML for this lot was 34.2%, with a median time to progression of 17 months and a survival time of 2.2 months afterwards. No difference regarding the transformation rate for the 2 groups (MDS-CMML, MPN-CMML) respectively the 3 groups (CMML-0, CMML-1, CMML-2) was observed. The median survival time for CMML-0 was 32 months, for CMML-1 25 months and for CMML-2 18 months with an overall median survival time of 32 months. Regarding the treatment, 8 patients (21.05%) received hypomethylating agents, 9 patients (23.68%) received Hydroxycarbamide and 2 patients (10.52%) received intensive chemotherapy including allogeneic stem cell transplant (1 patient ongoing at 47 months after allogeneic stem cell transplant, while another died 3 months after the same procedure). No statistically significant difference was found between these treatment groups for our study.
Summary/Conclusion: We conclude that CMML is a heterogeneous disease, mostly affecting the elderly with a reserved outcome. The only curative treatment with an impact on survival is allogeneic stem cell transplantation.

PB2111

NEUTROPHIL TO LYMPHOCYTE RATIO AND PLATELET COUNT AS PROGNOSTIC INDEX IN MYELODYSPLASTIC SYNDROME

I. Mandac Rogulj*, K. Mišura, N. Popović, B. Ačamović Stipinović·

A. Beganović, S. Ostojić Kolonić

Clinical Hospital Merkur, Zagreb, Zagreb, Croatia

Background: Inflammatory and immune response in tumor microenvironment is important in the pathophysiology of tumor progression, and has been studied so far in many solid tumors and haematological malignancies. In tumor microenvironment, neutrophils secrete different cytokines that stimulate tumor growth, while lymphocytes represent immune defense against tumor cells and mediate cytotoxic cell death. Absolute neutrophil to lymphocyte ratio (NLR) was previously analyzed as prognostic parameter in solid tumors and haematological disorders. Thrombocytopenia is a known hematologic parameter of poor survival in patients with myelodysplastic syndrome (MDS). In this work, we tried to determine the prognostic significance of NLR and platelet count in MDS patient group.
Aims: In the retrospective cohort of 58 untreated MDS patients, we analyzed clinical and laboratory data of MDS patients and the prognostic significance of the NLR and platelet count in correlation with well known prognostic indices (IPSS, IPSSR).
Methods: The study included 58 patients (24 women, 34 males), median age 73 years. Patients with IPSS <1.5 had significantly higher platelet count compared to those with IPSS>1.5 (138 *vs* 58, p<0.001), as well as in the R-IPSS group <4.5 *versus* those in the group with R-IPSS>4.5 (122 *vs* 68, p<0.01).
Results: No statistically significant difference in NLR (p<0.087 for IPSS or p<0.112 for R-IPSS) was found. The number of platelets showed a negative correlation with IPSS (rho=-0.500, p<0.001) and R-IPSS (rho=-0.456, p<0.001). Analyzing other parameters, statistically significant correlation of IPSS with LDH (p<0.008) and CRP (p<0.01) was observed. In the IPSS group <1.5 there was a significantly lower LDH level compared to patients with IPSS>1.5 (189 *vs* 233) as well as for CRP (3.25 *vs* 11.05) The same observation was for R-IPSS (for LDH 189.5 *vs* 227.5, p<0.01, for CRP 2.55 *vs* 12.1, p<0.002).
Summary/Conclusion: In a small number of our patients, we have shown that platelet count, LDH and CRP, have negative correlation with IPSS and R-IPSS prognostic index. NLR was not statistically significant, but this should be analyzed on a larger number of MDS patients.

PB2112

FLOW CYTOMETRIC CHARACTERIZATION OF THE CD4 AND CD8 T CELL IN MDS – IS IT CLINICALLY RELEVANT?

A. Arshad*, N. Anwar, M. Saud, S. Munzir, T. Shamsi

Hematology, National Institute of blood diseases and bone marrow transplatation, Karachi, Pakistan

Background: Myelodysplastic syndromes MDS is a hematopoietic disorder of clonal pluripotent stem cells, bone marrow failure, varying degree of pancytopenia and a propensity for conversion to Acute Myeloid Leukemia. The myeloid lineage is mostly involved but there is ongoing immune responses occurs in MDS involving B cell with or without T cell involvement. Studies suggests an increasing evidence of an autoimmune process in pathogenesis of the bone marrow failure that accompanies MDS. Analysis of CD4/CD8 subsets analysis shows abnormal expansion in MDS and could predict response to treatment.
Aims: The current has been done to evaluate the intimacy of t cells in the pathogenesis of MDS.
Methods: The study was done at National Institute of Blood Diseases and Bone Marrow Transplantation, Karachi Pakistan during the period of June 2017 to January 2018.A total of 12 MDS including (7 males and 5 females) confirmed patients meeting criteria of WHO classification were included.24 aged and sex matched were also part of study. Approval for the study was obtained from the Institutional Review Board of NIBD. Written informed consent of each participant was also obtained. However, the illiterate participants had the consent forms read and interpreted to them in their native languages and with their oral consents, literate family representatives of the illiterate participants signed the consent forms on behalf of each of them.In this cross-sectional study, using sterile disposable needles and syringes, 5 ml of blood was aseptically collected from each participant by venipuncture of the cubital vein. Samples were each placed in BD vacutainers containing anticoagulant, and conveyed to the Flow Cytometry and Hematology Departments.CBC was done utilizing XN-1000.CD3,CD4 and CD8 T cells were enumerated using BD FACScount flow cytometer (BD Biosciences, San Jose, CA, USA) according to the manufacturer's instructions.
Results: A total of 12 MDS patients with 24 aged and gender matched controls were included. The mean age of the patients was 43yrs ±18.4. The common presenting complain was weakness, fever in 8(66.6%) patient followed by abdominal pain and gums bleeding in 4(33.3%) patients. The mean Hb of patients was 8.71±2.05(g/dl), TLC 4.39±2.03*10^9/l and platelets count

132±168*10⁹/l with ipss of o.8 while in control group Hb 14.24±1.29(g/dl), TLC 7.18±1.87(*10⁹/l) and platelets counts were 231±68(*10⁹/l). In patient CD4 counts were 693±426 and elevated CD8 were 620±313.8 while in control group CD4 counts were 858±355 and CD8 counts 537±208.
Summary/Conclusion: MDS is although a disease of bone marrow failure but there is an strong evidence that autoimmune processes are involment in the pathogenesis of bone marrow failure mds..Further studies with large sample size are needed to determine whether CD4/CD8 T cells analysis could be useful in predicting responders to immunosuppressive treatment.

PB2113

CHILDHOOD SECONDARY MYELODYSPLASTIC SYNDROME CASE REPORT OF A RARE DIAGNOSIS

J. Medeiros[1,*], I. Oliveira[2], A. Ferrão[3], M.J. Palaré[3], A. Morais[3]

[1]Serviço de Hematologia e Transplantação de Medula, Centro Hospitalar Lisboa Norte, Hospital Santa Maria, [2]Serviço de Pediatria, Centro Hospitalar Setúbal, E.P.E., Hospital São Bernardo, [3]Unidade de Hematologia, Departamento de Pediatria, Centro Hospitalar Lisboa Norte, Hospital Santa Maria, Lisboa, Portugal

Background: Myelodysplastic syndrome (MDS) in children is rare and accounts for less than 5% of hematopoietic malignancies in childhood. Most are secondary to cytotoxic therapy, inherited bone marrow failure disorders or acquired severe aplastic anemia. Abnormalities in chromosome 7 are seen both in *de novo* and therapy-related MDS.
Aims: We aim to present a case of a child with a rare diagnosis of secondary MDS.
Methods: Clinical case presentation.
Results: A 4 year-old female child from Angola presented with pancytopenia in 2014. She was first treated with quinine and clindamycin due to an ongoing malaria endemic outbreak, although the diagnosis was not confirmed, and later with ceftriaxone, cloxacillin, meropenem and fluconazole for persistent fever and high inflammatory levels. In July 2014 she was transferred to Namibia, where she was diagnosed with aplastic anemia (AA) and treated with 2 cycles of cyclosporine and antithymocyte globulin (ATG), and subsequently becoming transfusion independent until April 2017. At that point, due to pancytopenia, a new bone marrow aspirate was performed, showing dysgranulopoiesis, dyserythropoiesis and dysplasia. She was then sent to Portugal for diagnostic and treatment purposes. Upon arrival she presented with normal growth and development. The complete blood count showed severe anemia (hemoglobin 4.5g/dL), mild neutropenia (1290 neutrophils/µL) and moderate thrombocytopenia (83000 platelets/µL). Infectious disease were excluded, including malaria, tuberculosis and viral serologic tests. The initial bone marrow aspirate showed less than 10% dysplastic erythroid cells and 5% myeloblasts. Since MDS was not confirmed, a second bone marrow aspirate was obtained, which revealed significant dyserythropoiesis and dysmegakaryopoiesis, as well as monosomy 7 in FISH analysis, compatible with a diagnosis of MDS. She is currently scheduled to undergo allogeneic hematopoietic stem cell transplantation.
Summary/Conclusion: We present a case of a patient with a probable diagnosis of acquired aplastic anemia and secondary MDS. We can only speculate about the underlying etiology of the AA. Quinine can be associate with the development of aplastic anemia. Patients treated with immunosuppressive therapy have an increased risk of developing clonal hematopoietic disorders, with MDS being one of the most frequent, although there's no conclusive evidence that cyclosporine and ATG increase the risk for secondary MDS. The underlying dyspoiesis of aplastic anemia is the most acceptable reason for MDS in the current literature. Monosomy 7 is the most frequent cytogenetic alteration in children with MDS and is associated with a poor outcome, making allogeneic hematopoietic stem cell transplantation the treatment of choice.

PB2114

THE 5 - AZACITIDINE THERAPY IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIA

H. Ionita[1,*], I. Ionita[1], M. Delamarian[2], D. Calamar[1], M. Ionita[3], M. Ifrose[2], I. Pascu[2], C. Ionita[4], M. Samfireag[2]

[1]Hematology, University of Medicine and Pharmacy Victor Babes Timisoara, [2]Hematology, Clinical County Hospital, [3]Internal Medicine, [4]Surgery, University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of neoplastic disorders, with variable clinical course, originated from a clonal disorder of hematopoietic cell. MDS affects most frequently old individuals, who usually have an increased prevalence of comorbidities. In intermediate-2 and high risk myelodysplastic syndromes (MDS), chronic myelomonocitic leukemia (CMML) with 10-29% marrow blasts, and acute myeloid leukemia (20% to 30% marrow blasts) 5-azicitidine induces hematologic responses and prolongs overall survival.
Aims: We retrospectively evaluated the efficacy and tolerability of azacitidine in patients with MDS, CMML and AML in our department of hematology.
Methods: From 2012-2017, 30 patients affected by int-2 and high risk MDS, CMML or AML with marrow blasts <30%, who were not candidates to aggressive therapy, have been treated with azacitidine at a dosage of 75 mg/m2/d subcutaneously 7 days, every 28 days. The diagnosis was established according to the 2008 WHO criteria, IPSS and WPSS prognostic scores were calculated. The WHO diagnoses were: 20 MDS with IPPS risk int-2 or high, 8 AML with blasts 20-30% and 2 CMML. The median age was 71 (range 45-78), male to female ratio was 0.8 and the median number of cycles received was 7 (range 1-20).
Results: The overall response rate (OPR) was 19/30 patients (59%). According to International Working Group (IWG) 2006 criteria, we detecte complete remission (CR) in eight patients (27%) after a median of 6 cycles (range 6-8), hematologic improvement with bone marrow complete remission in four patients (13%) after 8 and 13 cycles of therapy, hematologic improvement in 9 patients (30%) after 6 cycles (range 4-8), stable disease (SD) in 6 patients (20%), and progressive disease (PD) in 3 patients (10%) after 6 cycles (range 4-8). Median duration of response was 14 months (range 6-28); median overall survival, for all patients treated, from the beginning of azacitidine was 15.2 months (range 8-35). No differeces in response rate could be appreciated according to age, bone marrow fibrosis and transfusion requirements. Among the non-responding patients, five (17%) recquired several admisions to hospital because of infectious or hemorrhagic complications.
Summary/Conclusion: Besides a high rate of response (ORR 59%, CR 27%), azacitidine was well tolerated. In particular the low rate of serious adverse events and of hospital admissions despite severe cytopenias, improved quality of life and reduced utilization of standard medical resources. Azacitidine confirmed to be an active therapy in patients not candidate to high intensity treatment for age and/or comorbidities.

DETECTION OF MYD88 L265P MUTATION BY DIGITAL PCR IN PERIPHERAL BLOOD SAMPLES FROM IGM MONOCLONAL GAMMOPATHY PATIENTS

N. Garcia-Gisbert[1,*], E. Abella[2], C. Fernandez-Rodriguez[1,3], A. Ferrer[3], M.D.C. Vela[3], L. Camacho[1,3], X. Calvo[3], S. Montesdeoca[3], L. Arenillas[3], E. Gimeno[2], C. Besses[1,2], A. Salar[1,2], B. Bellosillo[1,3]

[1]Grup de Recerca Clínica Aplicada a Neoplàsies Hematològiques, IMIM, [2]Hematology Department, [3]Pathology Department, Hospital del Mar-IMIM, Barcelona, Spain

Background: Assessment of *MYD88* p.L265P mutation has been implemented in clinical routine as a diagnostic tool in IgM monoclonal gammopathy. Although bone marrow sample is usually available at diagnosis, the study of peripheral blood is useful for patient follow-up or in absence of bone marrow sample. However, the proportion of cells with the mutation in peripheral blood may be very low, which makes it difficult to detect them, leading to a false negative result. A strategy to overcome this situation is to enrich the target population and to use high sensitivity techniques. Enrichment of the sample in mutated cells can be done by depletion of CD3-positive lymphocytes (as the expression of CD19 is usually weak in the B-cell clonal population). Digital PCR is a technology that allows the detection and quantification of mutated DNA, even when it is present in a low proportion of total DNA.
Aims: To analyze the mutational status of *MYD88* p.L265P in peripheral blood samples by real-time allele-specific PCR (AS-qPCR) and digital PCR in a series of patients with IgM monoclonal gammopathy, as well as to determine the utility of the enrichment of the CD3-negative population for the detection of this mutation.
Methods: 41 peripheral blood samples were collected from 36 patients with IgM monoclonal gammopathy (28 with Waldenström macroglobulinemia (WM) and 8 with IgM monoclonal gammopathy of undetermined significance (IgM MGUS)). Depletion of CD3-positive lymphocytes was performed and DNA was obtained from the fraction of total mononuclear cells and from the CD3-negative subfraction. The *MYD88* p.L265P mutation was analyzed by AS-qPCR (7500Fast, Applied Biosystems) and digital PCR (QuantStudio 3D, Applied Biosystems).

Table 1.

Table 1. Number of positive samples for the *MYD88* p.L265P mutation according to the cell population studied and the technique used.

	AS-qPCR	digital PCR
PBMC	22/41 (53.7%)	31/41 (75.6%)
CD3- PBMC fraction	24/41 (58.5%)	33/41 (80.5%)

PBMC: peripheral blood mononuclear cells.

Results: When the total mononuclear cell fraction was analyzed, *MYD88* p.L265P was detected in 22 from the 41 samples studied (53.65%) using AS-qPCR and in 31/41 samples (75.6%) by digital PCR. The analysis of the CD3-negative fraction allowed the detection of the *MYD88* p.L265P in 24/41 samples (58.5%) by AS-qPCR and in 33/41 (80.5%) by digital PCR. These results are summarized in Table 1. In the CD3-negative fraction, the average mutational load was of 1.72% (range: 0.05%>16.75%), which was significantly higher than the observed in the total mononuclear cell population: mean 1.13% (range: 0.05% >11.21%), p=0.004. The negative cases by AS-qPCR corresponded to cases with low mutational load (<0.25%). No significant differences were observed in the allelic load between WM and IgM MGUS cases. As a whole, *MYD88* p.L265P was detected in 29 from the 36 cases studied, 6/8 (75%) IgM MGUS and 23/28 (82%) WM patients. This later percentage rose up to 91% (21/23) when only untreated WM patients were considered.
Summary/Conclusion: In patients with MW and IgM MGUS, the application of high sensitivity techniques such as digital PCR and, to a lesser extent, the enrichment of the sample in tumoral cells by T-cell depletion, improve the detection of *MYD88* p.L265P mutation.

CIRCULATING TUMOR DNA ANALYSIS OF KRAS, NRAS AND BRAF MUTATIONS USING MASS SPECTROMETRY IN MULTIPLE MYELOMA PATIENTS

L.-T. Hsiao[1,2,*], T.-J. Chiou[1,3], J.-P. Gau[1,2]

[1]School of Medicine, National Yang-Ming University, [2]Division of Hematology, Department of Medicine, [3]Division of Transfusion Medicine, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, Republic of China

Background: Multiple myeloma (MM) is an incurable malignancy of plasma cells and the incidence of Taiwan MM has markedly increased in recent decades. There were frequent mutations in KRAS (particularly in previously treated patients), NRAS, BRAF, FAM46C, TP53, and DIS3 genes.
Aims: The study is to examine the prevalence of hotspot gene mutations in Taiwan MM patients by using the DNA from MM bone marrow samples, and further develop so-called liquid biopsy and to detect several hotspot gene mutations in patients' plasma DNA.
Methods: BM DNA was extracted from 122 MM patients at diagnosis or relapse. In addition, cell-free DNA (ccfDNA) was collected from 24 of these patients at the comparable time of BM collected. Mass Spectrometry was used to simultaneously detect a panel of assay including 26 types of KRAS, 26 types of NRAS and 6 types of BRAF mutations.
Results: We found that total 45 (36.89% of 122) and 50 (40.98% of 122) patients had mutations in KRAS and NRAS genes in the BM, respectively. KRAS_A59T, NRAS_G12S and NRAS_A146T were the most frequent 3 mutations. For 24 ccfDNA, RAS/BRAF mutations were detected in 70.83% (17 of 24) of patients, including 41.67% (10/24), 41.67% (10/24), 4.17% (1/24) patients. The same mutations detected in the plasma of 6 patients could be also seen in the bone marrow. When compared the detection of RAS/BRAF mutations in plasma and bone marrow, 12 patients (50% of 24) had RAS/BRAF mutations detected in both plasma and bone marrow, and 3 patients (12.5% of 24) did not mutations in both specimens. Four patients (16.67%) had mutations only detected in BM, and 5 patients (20.83% of 24) had mutations only detected in the plasma. When RAS/BRAF mutations was detected in the plasma of MM patients by MassArray, the sensitivity and specificity of RAS/BRAF mutations in the bone marrow was 75% and 37.5%, respectively. The positive predictive value and negative predictive value were 70.59% and 42.86%, respectively.
Summary/Conclusion: Our study found a comparable mutation rate of RAS/BRAF gene in Taiwan MM patients, when comparing those in recent reports of Western countries. We further used Mass Spectrometry to detect circulating tumor DNA, and one fifth of patients (5 of 24, 20.83%) had mutations only detected in the plasma.

PB2119

MOGROL REPRESENTS A NOVEL ANTI-MYELOMA AGENT VIA ERK AND NF-KB INHIBITION

S. Mu*, L. Ai, Y. Hu

Hematology, Wuhan Union Hospital, Wuhan, China

Background: Multiple myeloma (MM) is the second most prevalent hematologic malignancy after non-Hodgkin's lymphoma. Drug resistance and relapse limit MM to be an incurable disease. Mogrosides are reported to represent a novel class of bioactive plant compounds with anti-cancer effects, which are digested to mogrol *in vivo.*
Aims: Here, we sought to verify the anti-myeloma effect of mogrol both *in vitro* and *in vivo*, and investigate the pharmacological mechanism to provide new therapeutic strategy for MM.
Methods: Inhibitory rates under different concentrations of mogrol between 0 and 50umol/L were measured via cell count kit-8 (CCK-8) to ascertain

the maximal inhibitory concentration (IC50). Peripheral blood mononuclear cells (PBMCs) from health donors was used to make sure the safety of mogrol. Next, 2 myeloma cell lines (ARH77 and U266) were exposed to mogrol at different concentrations of 0, 0.5×IC50 and IC50, and cell viability, apoptosis and cell cycle distribution were measured to verify the anticancer effects of mogrol on MM cells. Moreover, myeloma xenografted BALB/c nude mice model was established to validate the pharmacological effects of mogrol *in vivo*. The Raf/MEK/extracellular regulated kinase (ERK) and nuclear factor kappa-light-chain-enhancer of activated B cells (NF-κB) pathways were investigated through detecting related proteins expression by western blot.

Results: CCK-8 test showed that mogrol significant inhibited MM cell proliferation in a time- and dose-dependent manner. However, viability of PBMCs was not influenced by mogrol at any concentrations. And the inhibitory rate on MM cells changed from 7.73% to 78.9% at concentrations between 0.62 and 50umol/L, thus IC50 of mogrol on myeloma cells was 26.52±0.21umol/L. In addition, we also found that mogrol not only decreased MM cell viability, increased the total apoptosis rate, and caused G1/S arrest *in vitro*, but also reduced tumor volume and slowed down tumor growth *in vivo*, with an average size of tumors of 228.20±11.02mm^3 *vs* 422.90±50.07mm^3 after 4 weeks (p<0.05). Accordingly, western blot results displayed the dysregulation of relative proteins expression, such as up-regulated Bax and Cleaved caspase-3, and down-regulated Bcl-2. Moreover, ERK phosphorylation was inhibited in MM cells treated with mogrol, and NF-κB was also decreased in the mogrol-treated MM cells. Legends: A. Inhibitory effect of mogrol on ARH-77 cell proliferation after 24h. B. Apoptotic effects of mogrol on ARH-77 cells as determined by flow cytometry. C. Mogrol induced G1/S phase arrest in ARH-77 cells. D. Mogrol inhibited tumor growth in the myeloma xenografted BALB/c nude mice model. E. Effects of mogrol on the expression of p-NF-κB, p-ERK1/2, Bcl-2, Bax, and Cleaved caspase-3.

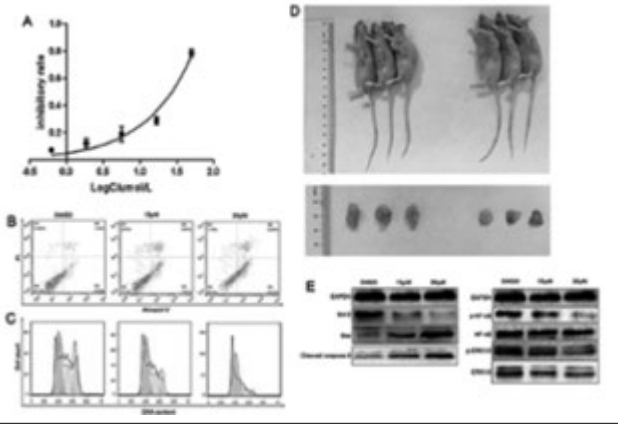

Figure 1.

Summary/Conclusion: Our results showed that mogrol not only inhibited MM cells growth *in vitro*, but also hampered MM development and progression *in vivo*. Besides, we found that ERK and NF-κB pathways was inhibited in the MM cells treated with mogrol. These findings suggested that mogrol, a novel ERK inhibiting agents, might grow to be a safe and promising anti-myeloma drug.

CIRCULATING EXOSOMAL LONG NON-CODING RNA PRINS FIRST FINDINGS IN MONOCLONAL GAMMOPATHIES

D. Vrábel[1,*], L. Sedlaříková[1], B. Bollová[1], L. Radová[2], L. Brožová[3], J. Jarkovský[3], M. Almáši[4], M. Penka[4], P. Kuglík[5], V. Sandecká[6], M. Štork[6], Z. Adam[6], L. Pour[6], M. Krejčí[6], S. Ševčíková[1,4]

[1]Babak Myeloma Group, Department of Pathological Physiology, Faculty of Medicine, [2]Central European Institute of Technology, [3]Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, [4]Department of Clinical Hematology, University Hospital Brno, [5]Department of Experimental Biology, Faculty of Science, Masaryk University, [6]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, Brno, Czech Republic

Background: Monoclonal gammopathies (MG) are heterogeneous diseases with focal lesions in the bone marrow (BM); therefore, analysis of biopsy specimen obtained from a single biopsy site in the BM may not always contain information about all pathological clones. In the case of MM, these subclones directly influence survival of patients and may not be present in the sampled BM. The so-called liquid biopsies (biopsies of peripheral blood) represent a real promise for these diseases since circulating molecules that are detectable in peripheral blood (PB) mirror the complex heterogeneity of MG and can serve as potential diagnostic, prognostic and predictive markers. So far, others and we showed that these molecules include cell-free DNA and non-coding RNA (ncRNA), especially microRNA (miRNA) and long non-coding RNA (lncRNA). LncRNA expression is tissue-specific and implicated in diverse biological functions, including physiological and pathological processes, including tumorigenesis. At the same time, it is known that these molecules circulate in body fluids but their potential as MG diagnostic markers has not been clarified yet.

Aims: We investigated lncRNA expression profiles in exosomal fraction of peripheral blood serum of newly diagnosed multiple myeloma (MM) patients, monoclonal gammopathy of undetermined significance (MGUS) patients in comparison to healthy donors (HD) to find out if circulating lncRNA may be used as diagnostic markers of MG.

Methods: We performed expression profiling of 84 lncRNA by a commercial lncRNA PCR Array, followed by validation of chosen lncRNA by quantitative real-time PCR on a cohort of 50 MM, 49 MGUS patients and 30 healthy donors.

Results: Our analysis revealed dysregulation of exosomal lncRNA PRINS in MM *vs* HD with sensitivity of 80.8% and specificity of 76.9%; for exosomal PRINS in MGUS *vs* HD, sensitivity was 83.3% and specificity 80.8%. Overall, expression of exosomal lncRNA PRINS distinguished MM and MGUS patients from HD with sensitivity of 84.9% and specificity of 83.3%.

Summary/Conclusion: Our study suggests a possible diagnostic role for exosomal lncRNA PRINS in monoclonal gammopathies patients.

PB2121

A ROLE OF LIGHT AS POTENTIAL BIOMARKER FOR PROGRESSION OF SMOLDERING TO SYMPTOMATIC MULTIPLE MYELOMA

R. Rizzi[1,*], B. Giacomina[2], A. Mestice[1], G. Storlino[3], S. Bortolotti[3], P. Sindaco[1], R. De Robertis[1], P. Curci[1], S.C. Colucci[2], G. Specchia[1], M. Grano[3]

[1]Hematology Section, Dept. of Emergencies and Organ Transplantation, Bari University Medical School, [2]Department of Basic and Medical Sciences, Neurosciences and Sense Organs, Section of Human Anatomy and Histology, University of Bari, [3]Section of Human Anatomy and Histology, Dept. of Emergencies and Organ Transplantation, Bari University Medical School, Bari, Italy

Background: In 2014 the definition of smoldering multiple myeloma (sMM) was updated by the International Myeloma Working Group (IMWG). Thus, at present, the detection of SLIM CRAB can be considered for treatment need. In addition, several clinical and biological predictors of progression to symptomatic MM can be used to discriminate sMM patients on the basis of their different degree of risk of progression. Beside to the validated criteria included in Mayo Clinic or Spanish models, several other potential biomarkers have been each time proposed. We previously demonstrated that LIGHT/TNFSF14, a TNF superfamily member, is over-expressed on CD14+ monocytes, CD8+ T-cells and neutrophils of patients with MM lytic bone disease.

Aims: Given lytic bone disease as the most frequent MM-defining event in symptomatic MM patients, here we aimed to test LIGHT as potential biomarker for progression of sMM to symptomatic MM.

Methods: PB samples were obtained from 58 patients (30 M/28 F, 63±10 years) newly diagnosed as having symptomatic MM with related-bone disease, 60 with sMM (36/24, M/F, 54±20 years) and 50 healthy controls. Patients and controls were age and sex matched. Patients were diagnosed as having symptomatic MM or sMM based on IMWG criteria. By means of multiparameter flow cytometry (MFC), we evaluated LIGHT expression on circulating CD14+-monocytes, CD16+-neutrophils, CD4+- and CD8+-T cells. The results were compared to those obtained in healthy controls.

Results: The levels of LIGHT measured on CD14+ monocytes of symptomatic MM, sMM patients, compared to those of healthy controls gave the following results: 47.1%±9.5% (range 30-90%), 14.75%±20% (range 0-88%) *vs* 2.1%±1.2 (range 0-4%), p<0.01. In addition, we found that in sMM patients, LIGHT levels positively correlated with high involved/uninvolved serum free light chain (FLC) ratio r=0.613 p<0.001.

Summary/Conclusion: Several clinical and biological biomarkers have recently been proposed to stratify sMM patients on their risk of progression to symptomatic disease. Based on the positive correlation between LIGHT expression levels on circulating monocytes, and involved/uninvolved serum FLC ratio, we could argue that LIGHT may be further assessed as a potential biological precursor of lytic bone-disease development in sMM patients. Reliable clinical and biological biomarkers for risk stratification of sMM

can allow to plan optimized follow-up as well as to identify further subgroups of patients, who could benefit from an early treatment. The high levels of LIGHT expressed by circulating monocytes and their correlation with FLC ratio, suggest a possible role of this cytokine as biological predictor of sMM progression to symptomatic MM.

PB2122

DIFFERENTIAL MIRNOME EXPRESSION PROFILE IN NON TUMOR LYMPHOMONOCYTES OF THE PERIPHERAL COMPARTMENT OF MGUS SUBJECTS

O. Bianco[1,*], A. Allegra[1], M. Mania[2], S. Campo[2], V. Innao[1], M. Scuruchi[3], D. Vaddinelli[1], A. Avenoso[2], A. D'Ascola[3], G.M. Campo[3], A.G. Allegra[1], C. Musolino[1]

[1]Division of hematology, Department of Patologia Umana dell'adulto e dell'età evolutiva, [2]Department of Biomedical and Dental Sciences and Morphofunctional Images, [3]Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy

Background: Monoclonal gammopathy of undetermined significance (MGUS) is a pre-malignant abnormality of plasma cells, with increased serum levels of immunoglobulins. Patients with MGUS may evolve to multiple myeloma (MM) through a multistep process, including also deregulation of gene expression.
Aims: We aimed to demonstrate that MGUS patients display a deregulation of miRNA gene expression (short non-coding RNAs, regulating gene expression at the translational level) in peripheral lymphomonocytes.
Methods: Utilizing reverse transcription quantitative polymerase chain reaction we independently measured MiRNome expression profile in healthy and MGUS subjects.
Results: We obtained a specific MGUS microRNAs signature. Furthermore, six different pathways involved in important cellular processes of lymphomonocytes were analysed using *in silico* analysis, in order to identify dysregulated miRNAs in MGUS compared to controls. IL6 pathway, intrinsic and extrinsic apoptosis pathways, G1/S transition of the cell cycle, AKT-dependent pathway and PI3K pathway were influenced by 141 dysregulated miRNAs, making lymphomonocytes anti-apoptotic, non-proliferative, metabolically altered and inhibiting activation of angiogenic and immune responses.
Summary/Conclusion: This study demonstrates that MGUS patients have a different microRNA profile in peripheral blood cells in comparison with healthy donors, and that these microRNAs may play a role in the immune response and in anti-apoptotic processes.

PB2123

PDCD1, PDL1 AND CTLA4 POLYMORPHISMS ASSOCIATED WITH THE SUSCEPTIBILITY TO AND CLINICAL FEATURES OF MULTIPLE MYELOMA

T. Kasamatsu[1,*], M. Awata[1], R. Ishihara[1], M. Ohata[1], Y. Kanai[1], Y. Murakami[1], K. Murata[1], S. Watanabe[1], N. Takahashi[1], N. Gotoh[1], M. Takizawa[2], A. Yokohama[3], N. Tsukamoto[4], H. Handa[2], T. Saitoh[1], H. Murakami[1]

[1]Department of Laboratory Sciences, [2]Department of Medicine and Clinical Science, Gunma University, [3]Blood Transfusion Service, [4]Oncology Center, Gunma University Hospital, Gunma, Japan

Background: Programmed cell death-1 (PD-1), PD-1 ligand 1 (PD-L1) and cytotoxic T lymphocyte-associated antigen-4 (CTLA-4) plays an important role in immune checkpoint pathways. Single nucleotide polymorphisms (SNPs) of *PDCD1*, *PDL1* and *CTLA4* have been reported to be associated with susceptibility to some cancers. However, the potential association between SNPs in these immune checkpoint genes and risk of multiple myeloma (MM) remain controversial and obscure.
Aims: The aims of this study were to clarify the influence of *PDCD1*, *PDL1* and *CTLA4* SNPs on the risk of developing MM and its clinical features.
Methods: We extracted the genomic DNA from 125 MM patients and 211 healthy controls, and determined 3 *PDCD1* SNPs (rs36084323, rs41386349, rs2227982), 2 *PDL1* SNPs (rs2297136, rs4143815) and 4 *CTLA4* (rs733618, rs1157131, rs231775, rs3087243) by using the PCR-restriction fragment length polymorphism or the TaqMan allelic discrimination real-time PCR method. Haplotypes were statistically inferred from *PDCD1*, *PDL1* and *CTLA4* genotype data using Haploview version 4.2 (www.broad.mit.edu/mpg/haploview). All statistical analyses were performed with the IBM SPSS software package ver. 24 (IBM, Armonk, NY, USA). This study was approved by the Institutional Review Board of Gunma University Hospital (Approval #160007).
Results: The patients with MM had a significantly higher frequency of the *PDCD1* GCC/GCC haplotype (rs36084323 high-expression type/rs41386349 high-expression type/rs2227982) compared with healthy controls (10.4% *vs* 4.3%, OR=2.61, p=0.028). However, no statistically significant differences were observed in the genotype and the haplotype of *PDL1* and *CTLA4* SNPs between MM patients and healthy controls. In MM patients, the *PDCD1* rs41386349 CT & TT genotypes (low-expression type) was associated with significantly higher frequency of patients with plasmacytoma at diagnosis than the CC genotype (high-expression type) (30.4% *vs* 14.5%, p=0.039). The *PDCD1* rs2227982 CC genotype was associated with significantly higher frequency of patients with bone lesion than the CT & TT genotypes (86.0% *vs* 68.3%, p=0.033). Moreover, the *PDL1* rs2297136 TT & TC genotypes (high expression type) was associated with significantly lower albumin level than the CC genotype (low expression type) (mean±SD 3.84±0.65 *vs* 4.36±0.54, p=0.038). The *CTLA4* rs733618 AG & GG genotypes (low-expression type) was associated with significantly higher frequency of patients with plasmacytoma at diagnosis than the AA genotype (high-expression type) (27.0% *vs* 9.8%, p=0.029). In addition, the *CTLA4* rs1157131 GG genotype had a higher frequency of patients with ISS stage III than the AA & AG genotypes (43.8% *vs* 26.2%, p=0.040). However, we observed no significant difference in OS of MM patients among *PDCD1*, *PDL1* and *CTLA4* SNPs.
Summary/Conclusion: Our findings indicate that *PDCD1* polymorphisms may contribute to susceptibility of MM. The polymorphisms in immune checkpoint gene is not associated with the prognosis of MM but *PDCD1*, *PDL1* and *CTLA4* SNPs may be associated with extra-medullary disease and severity of MM.

PB2124

NOVEL THERAPEUTICS FOR MULTIPLE MYELOMA TESTED IN A 3D BONE MARROW MODEL

M. Braham[1,*], A. Deshantri[2], M. Minnema[3], Z. Sebestyen[3,4], T. Straetemans[3,4], J. Kuball[3,4], C. Öner[1], R. Schiffelers[2], M. Fens[2,5], J. Alblas[1]

[1]Department of Orthopaedics, [2]Department of Clinical Chemistry and Hematology, [3]Department of Hematology, [4]Laboratory of Translational Immunology, University Medical Center Utrecht, [5]Department of Pharmaceutics, Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Utrecht, Netherlands

Background: Multiple myeloma is an incurable malignancy of plasma cells that develops in the bone marrow (BM). 2D cell line cultures are commonly used to assess the therapeutic potential of experimental anticancer treatments against myeloma *in vitro*. These 2D cultures do not mimic the dependency of primary myeloma cells on the surrounding BM, nor the BM itself. Since myeloma progression and resistance to therapy are dependent on the BM microenvironment, these essential characteristics need to be taken into account when assessing the therapeutic potential of experimental anticancer interventions.
Aims: Our first aim was to analyze the feasibility of testing novel therapeutics in a previously developed 3D BM myeloma model. For this, both a cellular immunotherapy (αβT cells engineered to express a defined γδTCR; TEGs) and a nanomedicine delivery system (VLA4 targeted liposomal drug delivery) were tested. Secondly, the effect of the therapies on both the cultured myeloma cells and the surrounding BM was analyzed.
Methods: The 3D BM myeloma model components are mesenchymal stromal cells, endothelial progenitor cells and (primary) myeloma cells co-cultured in hydrogel. The 3D BM myeloma model allows non-invasive time-lapse imaging, following the (primary) myeloma cells in the culture system before and after treatment. After 7 or 14 days of pre-culture (allowing myeloma outgrowth), the novel therapeutics were added. The delivery, migration and effect of the therapy were followed for 48 hours. The targeted VLA4 liposomes were loaded with doxorubicin and compared to standard doxorubicin treatment.
Results: The TEGs, when added to the 3D BM myeloma model, were capable of migrating through the 3D model, exerting a killing response towards the primary myeloma cells in 6 out of 8 donor samples after both 24 and 48 hours. This was not observed when adding non-functional control T cells. The supporting stromal microenvironment was unaffected in all conditions after 48 hours. The VLA4 targeted liposomes of different sizes (70 nm, 100 nm and 200 nm) were injected in the 3D BM myeloma model. Only the 70 nm and 100 nm liposomes were capable of passively diffusing through the 3D model. Cellular uptake of the liposomes was observed throughout the model, displaying a concentration gradient after injection. When comparing standard doxorubicin therapy to liposomal doxorubicin

therapy, similar killing effects towards myeloma cells were observed. However, the targeted liposomal drug therapy induced significantly less unwanted stromal and endothelial cell death compared to the standard doxorubicin therapy.

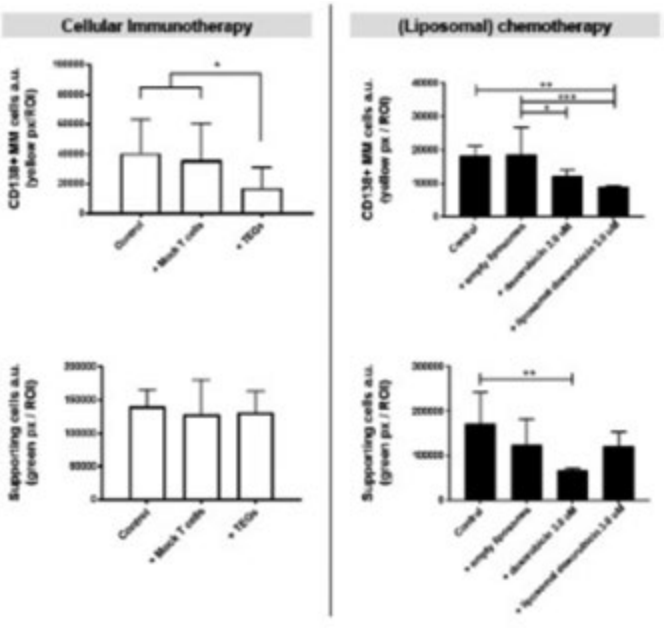

Figure 1.

Summary/Conclusion: The previously developed 3D BM myeloma model allows the *in vitro* study of both cellular immunotherapy and a nanomedicine delivery system on (primary) myeloma cells. Equally important, this model allows testing within an engineered BM environment, analyzing treatment effects on the BM environment as well. The model can thus be used to study cellular targeting throughout the model and general effectiveness of the added therapy by analysis of both on- and off-target effects.

FEATURES OF STROMAL BONE MARROW MICROENVIRONMENT IN PATIENTS WITH MULTIPLE MYELOMA WITH INEFFECTIVE TRANSPLANTATION OF PERIPHERAL HEMATOPOIETIC STEM CELLS

N. Semenova*, I. Kostroma, S. Gritsaev, S. Bessmeltsev, V. Rugal

Russian research institute hematology and transfusiology, Saint-Petersburg, Russian Federation

Background: High-dose chemotherapy and subsequent Autologous hematopoietic stem cell transplantation (AutoHSCT) are widely used at the stage of remission consolidation in patients with multiple myeloma (MM). AutoHSCT is not equally effective for all patients. The ineffective AutoHSCT group includes patients undergone unsuccessful mobilization and ones with early relapse after AutoHSCT. AutoHSCT success depends on many factors, including the patient's age, general status and the status of comorbidity, the intensity and duration of prior therapy, etc. No less important is the state of the niche of HSC, which has been subjected to toxic effects of aggressive treatment, as well as the success of homing and fixing poured HSC in niches, which is largely determined by the morphological and functional characteristics of the main stromal components of the niche.
Aims: To investigate the morphological and functional characteristics of the main stromal components of the niche HSC in patients with multiple myeloma and inefficient AutoHSCT.
Methods: 12 trepanobiopsy of bone marrow from patients diagnosed with progressive MM (5 men and 7 women) were used in the study. The age of the patients ranged from 52 to 68 (median 57 years). Inefficient mobilization of HSC was noted for 7 patients and early relapse (*i.e.* within 12 months after AutoHSCT) for five. The study applied histological, immunohistochemical (IHC) and morphometric methods (VideoTest®).
Results: Assessment of the amount of infiltration of the bone marrow plasma cells is one of the main criteria for diagnosis of MM. Histological examination of trepanobiopsies of patients with MM showed non-uniform cellular infiltration of myeloma cells in the bone marrow. All types of bone marrow infiltration were identified in the group studied: focal (2 cases), interstitial 5-10% lesions (4 cases), interstitial 20-30% lesions (4 cases), diffuse (2 cases). Bone marrow damage did not exceed 10% for half of the cases (6 patients). We carried out a histomorphometric analysis of niche-forming structures of bone marrow microenvironment: vessels, endosteal cells, proteins of extracellular and intratrabecular matrix (collagen I, III, IV). Following trends were revealed during analysis. An increase of microcirculation vessels number especially in 8 patients It comprises 15.2±2.8% and 9.1±1.2% for experimental and control (bone marrow donors) respectively($p<0.05$). A marked increase in cell per unit length of bone trabecular was observed for endost of 2.7±0.5 compared with 1.4±0.2 in the control ($p<0.05$). Pronounced expression of CD56 tumor cells in subendosteal area was revealed in case of damage to the bone marrow exceeded 30%. Osteolysis was observed by the type of smooth resorption. Increased expression of collagen type IV was observed around all blood vessels of microcirculation, venules, arterioles. A typical feature was the appearance of focal network of reticulin fiber in subendosteal and perivascular spaces. Despite the treatment, microenvironment of the bone marrow retained the features of the tumor-associated environment.
Summary/Conclusion: Discovered key features of stromal elements of the bone marrow niche HSC evidence of serious violation of their morphological status, which is directly reflected in the results AutoHSCT. Studies of the stromal component of bone marrow can give clinicians additional information for successful training of patients with MM to AutoHSCT.

PB2126

MYELOMA CELL DEATH INDUCED BY ZEBULARINE LEADS TO CMYC DOWNREGULATION AND IS DECREASED BY CYTIDINE DEAMINASE OVEREXPRESSION

P. Krzeminski[1,*], R. García-Sanz[2], N. Gutiérrez[2]

[1]Centro de Investigacion del Cancer, [2]Hematologia, Hospital Universitario. IBSAL, IBMCC (USAL-CSIC), Salamanca, Spain

Background: A significant progress has been made in the treatment strategies for multiple myeloma (MM) over the last decade. However, the genetic complexity is hindering the cure of the disease. Epigenetic therapies have shown clinical efficacy in several hematological malignancies. The most investigated drugs modulating DNA methylation are 5-azacitidine and decitabine, which are approved by FDA for treatment of myelodysplastic syndromes. Although both agents have been investigated in MM, their therapeutic benefit is rather marginal. Other compounds like zebularine, which is considered a second generation DNA methylation inhibitor, has not been well explored in MM. In contrast to 5-azacitidine and decitabine, zebularine is stable, less toxic and inhibits not only DNA methylation but also cytidine deaminase (CDA), an enzyme responsible for a resistance to nucleoside analogs.
Aims: To investigate the cytotoxic effect of zebularine on MM and to elucidate it potential mechanisms of action.
Methods: The KMS12BM, KMS12PE, MM1s/r, OPM2, H929, RPMI and U266 human MM cell lines were obtained from ATCC, and JJN3 was obtained from DSMZ. Zebularine was bought from Santa Cruz Biotech and decitabine was obtained from Sigma Aldrich. The following antibodies were purchased and used as recommended by the manufacturer: GAPDH and cMyc (Abcam), DNMT3a, DNMT3b, E2F1 and PSME1 (Santa Cruz Biotech), pH2Ax was bought from (Novius). Total DNA methylation was estimated by ELISA kit and Anexin/PI kit was used to analyze apoptosis by FacsScalibur.
Results: DNA methylation evaluated by ELISA showed that zebularine treatment induced DNA demethylation in a panel of 6 MM cell lines and this effect was similar to demethylation induced by decitabine. DNA demethylation was associated with DNMT3a/b decrease and was accompanied by the reduction in cell viability tested by MTT and Anexin V experiments in 8 out of 9 MM cell lines. Interestingly, zebularine reduced cell viability more than decitabine in H929, KMS12BM, MM1s and RPMI cells. The cytotoxic effect of zebularine was associated with the induction of DNA damage and the decrease of cMyc protein in 4 cell lines, regardless of *TP53* mutation status. Moreover, zebularine potentiated the effect of bortezomib by decreasing PSME1 protein involved in bortezomib resistance. Surprisingly, overexpression of CDA enzyme that can be inhibited by zebularine, reduced cytotoxic effect of the compound and abrogated DNA damage and cMyc protein decrease.
Summary/Conclusion: Zebularine induces cytotoxicity in MM cell lines resistant to decitabine and sensitizes myeloma cells to bortezomib treatment. The anti-myeloma activity of zebularine is associated with the decrease of cMyc protein.

PODOCYTURIA IN MULTIPLE MYELOMA PATIENTS HAS A TENDENCY TO INCREASE WİTH TREATMENT

T. Kuzu[1], S. Paydaş[2], E. Gurkan[3,*], S. Paydas[4], A.H. Uğuz[5]

[1]Dept of Internal Medicine, [2]Dept of Nephrology, [3]Dept of Hematology, [4]Dept of Oncology, [5]Dept of Pathology, Çukurova University Medical School, Adana, Turkey

Background: Multiple myeloma (MM) is a clonal B-cell disease of proliferating plasma cells. Renal disease is a common complication of MM that occurs in 20-25% of newly diagnosed patients. Cast nephropathy, amyloid light chain amyloidosis and monoclonal Ig deposition disease are the most common causes of chronic kidney disease in MM patients. Podocytes are unique cells with complex interdigitating foot processes that cover the outer surface of the glomerular basement membrane and thereby form an important layer of the glomerular filtration barrier. Podocyte injury is the hallmark of many glomerular diseases.
Aims: We have performed this study in order to investigate whether podocyte injury contributes to the pathogenesis of renal disease in MM patients and tried to detect correlations with treatment outcomes.
Methods: A total of 27 patients with newly diagnosed multiple myeloma and 20 healthy subjects were enrolled in the study and assessed concerning urinary podocytes and podocyte-associated molecules at bbaseline and end of the 6th month. Seven of the patients were lost due to death before the end of the study period. All the patients received bortezomib-based treatment. Determination of urine protein and creatinine (Cr) concentrations and quantitative analyses of Podocyn-mRNA (Pod), nephrin mRNA (Nep), and VEGF-A mRNA expression were performed using RT-PCR in pelleted urine samples. Levels of mRNA expression of podocyte proteins were also corrected by urine Cr concentration., cDNA was produced and PCR was processed. Podocytes were identified by PCR tagging nephrin, podocyn and VEGF-A which are biomarkers of podocyte, was detected.
Results: Proteinuria was found in 74% and renal failure in 33% of the cases at diagnosis. Median proteinuria levels were significantly higher compared to controls (725 mg *vs* 45 mg, (P<0.001). Proteinuria significantly decreased at the end of sixth months of treatment (P=0.002). Podocyturia monitored by Pod-mRNA, VEGF-A mRNA and Nep-mRNA expression was unremarkable compared to healthy controls in newly diagnosed MM patients. However, although was insignificant, there was a tendency towards an increase in urinary podocyte proteins concomittantly with a significant increase in urinary podocyte proteins, Pod-mRNA:/Cr, Nep mRNA/Cr and VEGF-A mRNA/ Cr ratios after treatment as compared with the pretreatment levels (P=0.001; P:0.039 and P=0.001 respectively).
Summary/Conclusion: Podocyturia as a marker of glomerular injury is unremarkable in MM patients at diagnosis. However, increase in podocyturia and related proteins during treatment might indicate glomerular injury as a consequence of therapeutic drugs especially bortezomib which is known as an nonnephrotoxic agent except causing thrombotic angiopathy. Further studies with more patients and longer observation period are needed in order to understand the extent of glomerular injury in MM patients while on treatment with different and new agents.

PB2128

HUMAN MONOCLONAL IGG DERIVED FROM PATIENTS WITH MULTIPLE MYELOMA ARE ABLE TO PENETRATE LIVING NEOPLASTIC CELLS AND EXHIBIT INTRACELLULAR BIOLOGICAL FUNCTIONS

I. Sarrigeorgiou[1], E. Terpos[2,*], T. Stivarou[1], P. Chalas[1], E. Kastritis[2], M.A. Dimopoulos[2], P. Lymberi[1]

[1]Immunology Laboratory, Department of Immunology, Hellenic Pasteur Institute, [2]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

Background: Our group has previously described that high frequency of serum monoclonal immunoglobulins (M-Igs) of G and A class (M-IgG, M-IgA) from patients with Multiple Myeloma (MM) exhibit polyreactivity, which is a common feature with Natural Antibodies (NAbs) (*Abs present in the serum of healthy subjects, able to recognize self- and non self- antigens*). This and other findings support the view that in MM, certain clones producing M-Igs originate from NAb-producing clones occurring under normal conditions. Antibodies able to penetrate living cells (CPAbs) have been detected and well characterized in patients with systemic lupus erythematosus and in mouse models; recognize DNA and accumulate in the nucleus. Their penetration ability seems to be directly related to their polyreactivity. Our laboratory has recently described the existence of Cell-Penetrating Antibodies (CPAbs) in healthy conditions, derived either from BALB/c mice (monoclonal CPAbs), or from intravenous immunoglobulin (IVIg) (polyclonal human IgG). The development of human monoclonal IgG-CPAbs is of major importance in drug delivery and in cancer therapy.
Aims: The aim of the present study was to investigate the cell-penetrating ability of M-IgG exhibiting NAb–like activity, as well as their intracellular biological functions in neoplastic cells.
Methods: Seventy-one sera of patients with IgG-MM (IgG M-peak >5 g/l: 42 IgGκ/29 IgGλ) were studied by in-house ELISAs against a panel of self and non-self antigens (actin, tubulin, myosin, carbonic anhydrase, thyroglobulin, DNA and the hapten trinitrophenyl (TNP). We selected and purified five polyreactive IgG and one non-polyreactive IgG (negative control) by protein-G affinity chromatography. We then established the optimum conditions in terms of concentration, temperature and time-course in order to examine their ability to: 1) penetrate FcγR$^+$ (Raji & MDA-MB-231) and FcγR$^-$ (NIH-3T3 & HeLa) cells by immunofluorescence, 2) induce apoptosis on the aforementioned cells by flow cytometry (FACS), and 3) hydrolyze plasmic and genomic DNA.
Results: The five purified M-IgGs tested (3 IgGκ and 2 IgGλ) were able to penetrate all cell types, either FcγR$^+$ or FcγR$^-$, at 37^{o}C in a dose- and time-dependent mode of entry, while three of them were able to also penetrate cells at 4^{o}C (energy-independent mode of entry); optimum conditions of cell-penetration: 300 μg/ml, 2h-incubation. All M-IgGs: 1) were polyreactive, exhibiting a unique polyreactivity profile with the antigens of the panel used, 2) accumulated in the cytoplasm, 3) induced apoptosis especially in MDA-MB-231 cells, and 4) were able to hydrolyze plasmid DNA isoforms, while one of them also hydrolyzed genomic DNA.
Summary/Conclusion: We demonstrate herein that the sera of MM-patients with M-IgG represent an excellent source of human monoclonal IgGs exhibiting cell-penetrating ability and intracellular functionality. These human monoclonals can be exploited as a potential therapeutic tool in several disorders including malignant diseases, using them either *per se*, or as carriers for intracellular drug delivery, or even both.

HIGH-RISK YOUNG MULTIPLE MYELOMA PATIENTS TREATED UP-FRONT WITH LENALIDOMIDE: IMPACT OF KIR 3DL1-EDU AND KIR HAPLOTYPES ON CLINICAL OUTCOME

F. Puglisi[1,*], A. Romano[1], C. Conticello[1], S. Toscano[2], M.P. Azzaro[2], M. Parisi[1], V. Calafiore[1], E. Martino[1], G. Sapienza[1], S. Leotta[1], G. Milone[1], G. Sortino[2], F. Di Raimondo[1]

[1]Division of Hematology and Bone Marrow Transplantation Units – Policlinico Hospital, [2]Tissue Typing Laboratory - Division of Hematology and Bone Marrow Transplantation Units – Policlinico Hospital, University of Catania, Catania, Italy

Background: Natural killer (NKs) cells provide rapid responses to viral-infected and malignant cells, including Multiple Myeloma (MM) cells. The balance among inhibitory and activating signals, delivered by multiple interactions between ligands (NKRL) on target cells and NK receptors (KIR), determines the posture of the NK cell response to either one of target cell elimination or tolerance. Despite novel therapeutic options, 15% to 20% of newly-diagnosed MM patients experience early death and rapid relapse following or even during initial induction therapy, the majority of them carrying high-risk cytogenetics (HRC) features, such as del (17p), del (1p), t(4;14) or t(14;16), as detected by FISH.
Aims: The aim of this work was to study the influence of the differential expression of activating or inhibitory KIR and the inhibitory HLA class I ligands on clinical outcome of HRY-MM patients treated up-front with regimens followed or not by lenalidomide maintenance.
Methods: KIR expression, KIR haplotype AA/Bx, and their HLA ligands were determined in 31 healthy subjects (controls) and 69 MM patients using the Genotyping SSP and SSO kit. In 50 HRY-MM patients (median age 54.1 years, 30 males), carrying at diagnosis del (17p), t(4;14) or t(14;16) and who were randomly assigned to lenalidomide maintenance until progression or observation after one autologous stem cell transplantation, we evaluated the role of KIR expression, KIR haplotype AA/Bx, and their HLA ligands on progression free survival (PFS).
Results: We observed that presence of KIR3DL1-edu was significantly more prevalent among controls as compared to MM patients (76,7% *vs* 43,5, 9%, p<0,0023). After median follow-up of 45 months, HRY-MM-patients carrying on KIR3DL1-edu had longer PFS than those without it (53.8 *versus* 41.5 months, p=0.08), without significant impact on overall survival (OS). In MM patients the AA and Bx genotype frequencies were 24,6% (AA) and 74,4% (B/x) with an A:B ratio of 1:3.05. Among the healthy controls, the AA and B/x genotype frequencies were 33% and 67% with an A:B ratio of 1:2. There was no significant difference in KIR haplotype AA/Bx frequencies in MM *versus* healthy subjects, however, in HRY-MM-patients, B/x haplotype was associated to longer PFS (56.4 *versus* 27.8 months, p=0.06). In

multivariate analysis, only complete remission achievement after induction and consolidation treatment were predictors of outcome, independently from KIR and haplotype genetics.
Summary/Conclusion: Our data show that 3DL1-edu and B/x haplotype are associated to clinical outcome in HRY-MM-patients receiving a lenalidomide based approach, implying a role of NK cytotoxicity against MM residual cells. These data will be confirmed in larger prospective series.

PB2130

THE INVOLVEMENT OF MESANGIOGENIC PROGENITOR CELLS IN MULTIPLE MYELOMA PATHOGENESIS

C.P. Schifone[1,*], S. Pacini[1], M. Montali[1], S. Barachini[1], F.M. Panvini[2], G. Buda[1], F. Mazziotta[1], F. Martini[1], M. Petrini[1]

[1]Hematology, University of Pisa, [2]Scuola Superiore Sant'Anna, Pisa, Italy

Background: Mesangiogenic Progenitor Cells (MPCs) are a bone marrow (BM) cell population isolated in humans able to differentiate into mesenchymal stromal cells (MSCs) and retaining an angiogenic potential. These two differentiation fates are mutually-exclusive, MPC-derived MSCs are not able to take part in angiogenic process but they can differentiate into adipocytes, chondroblasts or osteoblasts. The MPC differentiation toward the mesengenic lineage has been demonstrated to activate the non-canonical Wnt pathway, not involved during angiogenesis. More specifically, the MSCs differentiation takes place toward two hierarchical steps: a first differentiation into "early MSCs" (also called P1-MSCs) with the activation of Wnt-5/calmodulin pathway, then a terminal differentiation into "late MSCs" (also called P2-MSCs) independent from this pathway. Indeed, it has been demonstrated that Calmidazolium Chloride (CLMDZ), a potent calmodulin inhibitor, blocks the MPC mesengenic differentiation acting on the early phase. Previous studies, conducted on BM samples of non-hematological patients, demonstrated that the MPC angiogenic differentiation is, instead, inhibited by Bortezomib. For these peculiar characteristics, MPCs can be thought to be involved in the pathogenesis and progression of Multiple Myeloma (MM). The same *in vitro* experiments performed on BM samples from newly diagnosed MM patients, surprisingly showed that both mesengenic and angiogenic differentiations were impaired by Bortezomib while CLMDZ did not affect any differentiation. This data suggests that possibly MPCs would be restricted to an angiogenic fate, losing the mesengenic potential in the pathological setting.
Aims: To evaluate a possible involvement of MPCs in MM pathogenesis, we assessed the angiogenic potential of P1-MSCs applying sprouting tests.
Methods: After written consent, BM samples were obtained from 11 newly diagnosed MM patients. We isolated MPCs, as previously described, from each sample and performed mesengenic differentiation applying a specific medium for MSC expansion. After six days of culture, P1-MSCs were detached and two 3D-spheroids were produced by the hanging drop method. The spheroids were then plated on Matrigel thick gel and cultured in EGM-2 endothelial growth medium for one week. Sprouting distance was then measured by image analysis software and the mean values obtained from three different observers were recorded and analyzed by t-test.
Results: Six of eleven patients have a mean sprouting value of 41.2±16.1μm while the other five have a mean value of 206.7±15.2μm, the statistical analysis demonstrates a significative difference ($p<0.01$) between these two groups (figure 1). Surprisingly, higher sprouting values have been detected into patients with a more aggressive stage of disease and reporting osteolytic lesions, instead, a reduced sprouting has been detected in patients without osteolytic lesions or affected by smoldering MM.

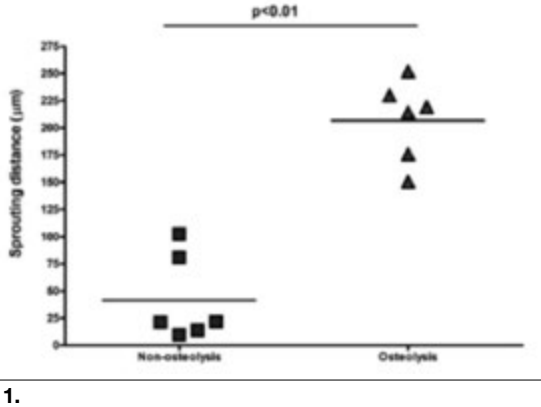

Figure 1.

Summary/Conclusion: Multiple Myeloma as a BM niche disease, affects the microenvironment. Particularly, our results suggest that disease in advanced stage (characterized by osteolytic lesions) probably forces MPCs toward an angiogenic differentiation regardless of the culture conditions. Thus, MPCs could be involved in the transition from a sub-clinical and "non-vascular" stage of disease to the advanced stages. Moreover, this MPCs restriction to the angiogenic fate could correlate *in vivo* with a reduced mesengenesis which cooperates to osteolytic lesions.

MYELOID AND LYMPHOID DENDRITIC CELLS IN PATIENTS WITH MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE - POSSIBLE LINK WITH DISEASE PROGRESSION

E. Grywalska[1,*], M. Pasiarski[2], A. Stelmach-Goldys[3], B. Sosnowska-Pasiarska[4], P. Steckiewicz[2], A. Kowalska[1], K. Gosik[1], B. Garus[2], S. Gozdz[5], J. Rolinski[1]

[1]Department of Clinical Immunology and Immunotherapy, Medical University of Lublin, Lublin, [2]Department of Hematology, Holycross Cancer Center, [3]Department of Hematology, Holycross Cancer Center, [4]Department of Oncocardiology, [5]Department of Clinical Oncology, Holycross Cancer Center, Kielce, Poland

Background: Monoclonal gammopathy of undetermined significance (MGUS) is a premalignant, clonal plasma cell disorder, characterized by the presence of a monoclonal (M) protein, <10% clonal plasma cells in the bone marrow, and absence of multiple myeloma or related lymphoplasmacytic malignancies. MGUS is present in 3% of the general population ≥50 years old. Dendritic cells (DCs) are a heterogeneous population of leukocytes defined as professional antigen presenting cells playing a key role in anticancer immunity.
Aims: The purpose of this study was to evaluate subpopulations of myeloid and lymphoid DCs in the peripheral blood (PB) and bone marrow (BM) of patients with MGUS in correlation with known prognostic factors.
Methods: The study involved 40 patients diagnosed with MGUS and 20 individuals belonging to the control group. The mean percentage of myeloid and lymphoid DCs was determined using flow cytometry.
Results: In the present study, we demonstrated a significant reduction in the percentages of both myeloid and lymphoid DCs in MGUS patients, more pronounced in those with the worse prognosis as determined by the high levels of M protein and low concentration of hemoglobin. Accordingly, a marked decrease in the proportions of both myeloid and lymphoid DCs in the BM of patients with MGUS in comparison with healthy controls was also found. The frequencies of both myeloid and lymphoid DCs correlated negatively with the percentages of plasmocytes in the BM.
Summary/Conclusion: Our results suggest that the degree of DC subpopulations deficit could be related to the MGUS progression, which in consequence may contribute to the MGUS-related impairment of the immune responses. This work was supported by research grants no. DS460 of the Medical University of Lublin and no. UMO-2016/21/B/NZ6/02279 of the Polish National Science Centre.

QUANTIFICATION AND CHARACTERIZATION OF BONE MARROW MESENCHYMAL STROMAL CELLS IN MONOCLONAL GAMMOPATHIES

R. Leite[1], J. Barradas[2,*], B. Paiva[3], I. Silva[4], P. Rocha[2], H. Silva[2], C. Geraldes[5], A. Paiva[1,4]

[1]College of Health Technology of Coimbra, Coimbra, [2]Clinical Hematology Department, Centro Hospitalar Tondela-Viseu, Viseu, Portugal, [3]Center for Applied Medical Research University of Navarra, Navarra, Spain, [4]Flow Cytometry Unit – Clinical Pathology Service, [5]Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Monoclonal Gammopathies (MG) are plasma cell (PC) dyscrasias caused by clonal accumulation of PC in the bone marrow (BM). The BM microenvironment plays a crucial role in disease development. BM Mesenchymal Stromal Cells (MSC) are able to interact with clonal PC contributing for a microenvironment suitable for disease progression.
Aims: To evaluate the relationship between PC dyscrasias progression with the frequency and phenotype of BM MSC.
Methods: Clinical process consultation and BM aspirates were proceded in patients diagnosed with MGUS (n=32), smoldering Multiple Myeloma (sMM) (n=5) and MM (n=24), and in a control group (n=10) of normal BM samples. Multidimensional flow cytometry was used to identify, quan-

tify and characterize BM MSC (based on the expression of CD13, CD24, CD29, CD49e, CD73, CD90, CD105, CD106 and CD271).
Results: After frequency normalization, by removing clonal PCs from all BM nucleated cells, a significantly increased in the frequency of MSC (0,137%) was observed in symptomatic MM patients when compared with sMM (0,027%), MGUS (0,027%) and normal BM (0,034%). We also found that the higher frequency of BM MSC was associated with lower hemoglobin concentrations, higher frequency of BM PC and higher ISS staging. In MM patients, a higher MSC frequency was observed in the cases whereas clonal PC didn t express CD56. Moreover, a lower expression of CD73 and a higher of CD90 by MSC, was observed through disease progression, from MGUS to MM.
Summary/Conclusion: The higher frequency of MSC and the altered phenotype observed in BM samples from patients with PC dyscrasias, could play an important role in MM pathogenesis.

PB2133

ANALYZING BONE AND EXTRAMEDULLARY PLASMACYTOMA SUBSTRATES IN PATIENTS WITH MULTIPLE MYELOMA

M. Firsova*, L. Mendeleeva, A. Kovrigina, N. Deineko, M. Solovev, V. Savchenko

National Research Center for Hematology, Moscow, Russian Federation

Background: At the time of the diagnosis of multiple myeloma (MM) the incidence of plasmacytomas varies from 3,5 to 18%. We defined plasmacytomas as bone (plasma cell tumor extending from the intramedullary spaces of the bone marrow through the cortical bone) and extramedullary (spread to organs distant from bone). The presence of extramedullary plasmacytoma at the time of the diagnosis of MM has a negative impact on the disease prognosis, while bone plasmacytomas in patients with MM are treatable. The pathogenesis of extramedullary disease has not been thoroughly analyzed, thought cell adhesion molecules and chemokine receptors are assumed to participate in this process. Study of tumor plasmacytoma substrate is great interest due to the rarity of this pathology.
Aims: Analyzing CD56, CD166, CXCR4, Ki-67 and c-MYC expression in the tumor substrate of bone and extramedullary plasmacytomas in patients with MM.

Table 1.

Marker	MM patients with:	Expression values (%)		p
		M	± m	
CD56	bone plasmacytoma (n=14)	54.29	10.18	0.165
	extramedullary plasmacytoma (n=7)	28.57	14.86	
CD166	bone plasmacytoma (n=14)	36.29	7.61	**0.044**
	extramedullary plasmacytoma (n=7)	9.57	8.46	
CXCR4	bone plasmacytoma (n=14)	45.50	9.35	0.413
	extramedullary plasmacytoma (n=7)	31.71	13.91	
Ki-67	bone plasmacytoma (n=14)	25.36	5.63	**0.004**
	extramedullary plasmacytoma (n=7)	61.43	10.50	
c-MYC	bone plasmacytoma (n=14)	33.29	8.37	0.748
	extramedullary plasmacytoma (n=7)	37.86	10.57	

Table 1. Markers expression values of bone and extramedullary plasmacytomas in patients with MM

Methods: From October 2013 to April 2017 21 patients with newly diagnosed MM (10 males and 11 females) 23-77 years old (mean value: 52 y.o.) were included in the study. The disease was diagnosed in accordance to IMWG criteria (2014). 14 patients were diagnosed with bone plasmacytoma associated with skeleton bones (vertebrae, ribs, skull and pelvis) and 7 patients were diagnosed with extramedullary plasmacytoma distant from bone (liver, pancreas, stomach, soft tissues, muscles and skin). In all cases a tumour biopsy was taken which confirmed the presence of plasma cell infiltration. Paraffin block slices from tumour biopsy material were used to perform an immunohistochemistry analysis with an antibody panel to CD56, Ki67, CXCR4, CD166, c-MYC. Marker expression level was analyzed with Leica DM4000B microscope by viewing 10 fields of view at 400-fold magnification. Marker expression assessment was carried out by means of semi-quantitative method. The percentage of cells expressing the protein in question against the total number of tumor substrate cells was calculated. To assess statistical differences between the mean values we applied Student's *t*-test (including preliminary assessment using Levene's test for equality of variances).
Results: Analyzing mean values of marker expression in bone and extramedullary plasmacytomas resulted in revealing significant differences in CD166 and i-67 (Table 1), while no significant differences between expressions of other markers in question were found. A higher Ki-67 index (p=0.004) was reported for extramedullary plasmacytoma cells, comparing to that of bone plasmacytoma cells, with their mean values of 61.43±10.50% and 25.36±5.63% respectively. The expression of cell adhesion molecule CD166 in bone plasmacytoma cells was significantly higher than that of extramedullary plasmacytoma cells (36.29±7.61% and 9.57±8.46% respectively, p=0.044).
Summary/Conclusion: Aggressive course of MM complicated with extramedullary plasmacytoma may be caused by significantly higher proliferative activity of extramedullary plasmacytoma cells, comparing to that of bone plasmacytoma cells. Low expression of adhesion molecule CD166 in extramedullary plasmacytoma cells may be the reason behind weakening bond between myeloma cell and bone marrow microenvironment, which leads to the occurrence of hematogenic dissemination of plasma cells in various organs and tissues. In the same time, high expression of CD166 in bone plasmacytoma cells may point to this marker's participation in modelling osteogenesis and forming osteodestructions.

PB2134

ASSOCIATION OF HLA-SPECIFICITIES OF CLASSES I, II WITH IMMUNOCHEMICAL VARIANTS OF MULTIPLE MYELOMA

E. Poponina[1,*], E. Butina[1], G. Zaytseva[1], N. Minaeva[2], I. Paramonov[3]

[1]Immunohematology, [2]Hematology, [3]Director, Federal State Institute of Science "Kirov research Institute of Hematology and Blood Transfusion of the Federal Medical and Biological Agency of Russia", Kirov, Russian Federation

Background: The main histocompatibility complex plays an important biological role, participating in the regulation of the immune response. There is some information in the literature about the relationship of specific HLA-specificities to various diseases, including oncohematological ones. In multiple myeloma (MM) the malignant clone develops from B-lymphocyte precursor cells, retaining the ability to produce pathological monoclonal immunoglobulins (the most common immunochemical variants are IgG, IgA) or light chains of immunoglobulins (the Bence-Jones variant). It is of interest to investigate the dependence of the onset of MM and its immunochemical variants on the specificity of the genes of the HLA system.
Aims: Identify the dependence of the occurrence of MM variants on the characteristics of patients HLA-genotypes.
Methods: The results of typing the HLA-genes of loci A, B, DRB1, DQA1, DQB1 by the SSP method were analyzed in 134 MM patients: 78 (58.2%) with variant G, 26 (19.4%) with A, 26 (19,4%) - with Bence-Jones. The frequency of occurrence of HLA-genes in patients with various forms of MM was compared with the frequency of these genes in healthy residents of the region – donors of blood components.
Results: It was found that in the general group of patients with MM this alleles were revealed significantly more often than in a healthy population: A*19 (21.6% *vs* 13.1% in healthy persons, p<0.05, RR=2.0), B*16 (13.4% *vs* 7.7% in healthy subjects, p<0.05, RR=2.0) and the DRB1*09 (10.9% *vs* 1.5%, p<0.01; RR=8.4). The HLA-B*05 gene, on the contrary, was less common than in healthy individuals (5.2% *vs* 11.6%, p<0.05, RR=0.3), which indicates its preventive effect. A detailed analysis of the distribution of HLA-genes revealed specific genes for each immunochemical variant of MM. The HLA-A*19 gene (23.1% *vs* 13.1% in healthy p<0.05, RR=2.1) and B*16 (17.9% *vs* 7, 7%, p<0.01, RR=2.5) predisposed to the immunochemical variant with IgG secretion. In the variant with the secretion of pathological IgA, the specificity of HLA-A*03 was detected 3 times less frequently than in healthy individuals (11.6% *vs* 33.7%, p<0.05, RR=0.3). For Bence-Jones myeloma, there was an increase in the occurrence of HLA-A*10 and B*18, often heritarily linked (HLA-A*10 - 38.5% *vs* 16.3%, p<0.01, RR=3.7; HLA-B*18-30.8% *vs* 11.3%, p<0.01, RR=3.9). The DRB1 * 09 gene was detected in 1.5% of a healthy population, while in the variant with IgA secretion - in 4.8%, IgG - in 7.5% of patients (the differences did not reach statistical significance). In patients with the Bence-Jones variant, the DRB1 * 09 frequency was 28.0% (p<0.001, RR=22.7).
Summary/Conclusion: To the development of MM predispose the genes A*19, B *16, DRB1*09; to the variant G - A*19, B*16; to the light chain variant - A*10, B*18, DRB*09. Protective to the development of MM is the gene B*05, to the development of variant IgA - A*03.

RECONSIDERING JAK2 IN AN INTER-TUMOUR HETEROGENEITY OF MULTIPLE MYELOMA

S. Sommaluan[1], B. Rerkamnuaychoke[1], T. Puavilai[2], S. Chuncharunee[2], T. Chareonsirisuthigul[1], P. Pornsarayuth[1], T. Siriboonpiputtana[1,*]

[1]Pathology, [2]Medicine, Mahidol University, Bangkok, Thailand

Background: Multiple myeloma is a hematological malignancy characterized by abnormal accumulation of clonal plasma cells in the bone marrow. Beside the complexity and heterogeneity of the disease, we and others attempt to molecularly identify the biomarkers of multiple myeloma aiming for early detection, risk-assessment, monitoring, and importantly, the potential therapeutic markers.
Aims: We molecularly identify the biomarkers of multiple myeloma aiming for early detection, risk-assessment, monitoring, and for the development of potential therapeutic markers.
Methods: We combined our routinely genetic testings including the conventional cytogenetic analysis, iFISH for CD138 enriched samples, MLPA analysis, and a pan-screening array CGH to identify genetic alterations in 35 newly diagnosed myeloma patients.
Results: While several recurrent genetic alterations in multiple myeloma such as translocation involving immunoglobulin gene rearrangements, Del(17p), Del(13q), and Amp(1q) were observed in similar frequency as compared to previous publications, the amplification of short arm of chromosome 9 (JAK2) by MLPA analysis was predominantly observed (10/35; 29%) in our tested samples. Consistency results were observed by using array CGH technique. Moreover, our preliminary data in the transcriptional analysis of multiple myeloma patients using expression microarray was able to identify the dysregulation of JAK2 in all multiple myeloma subgroups.
Summary/Conclusion: Our findings further highlight the inter-tumour heterogeneity of multiple myeloma between populations and the alteration of JAK2 may play a role as a key driving mutation in multiple myeloma which mainly positive in our tested population.

TARGETING SIGLEC-7: A NOVEL IMMUNOTHERAPEUTIC APPROACH TO POTENTIATE THE CYTOTOXIC FUNCTIONS OF NATURAL KILLER CELLS AGAINST MULTIPLE MYELOMA

J. Daly*, S. Sarkar, A. Natoni, J. Hu, S. Chauhan, R. Henderson, T. Duggan, L. Kirkham, C. McEllistrim, M. O'Dwyer

Medicine, National University of Ireland, Galway, Galway, Ireland

Background: Multiple Myeloma (MM) is a malignant plasma cell disorder, accounting for 10% of all haematological malignancies. The immune-suppressive functions of sialylated glycans, abundant on the surface of myeloma cells, has not previously been addressed. We hypothesize that hypersialylation of MM enables evasion of Natural Killer (NK) cells within the bone-marrow niche. Disrupting the interactions between these sialylated glycans and their cognate sialic acid-binding lectin (Siglec) receptors on NK cells could lead to the development of novel immunotherapeutic strategies for treating MM.
Aims: Determine the expression of Siglec-7 ligands on a panel of MM cell lines and primary MM cells and determine the expression of Siglec-7 on primary bone marrow-derived NK cells. Determine the effect de-sialylating MM cell lines has on their sensitivity to NK-mediated cytotoxicity using both a sialidase and sialyltransferase inhibitor and the effect blocking Siglec-7/Ligand interactions has on NK-mediated cytotoxicty.
Methods: Siglec-7 ligand expression was measured by staining with a recombinant Siglec-7 Fc chimera (1.25µg/ml, R&D systems) and flow cytometry was used to determine Siglec-7 ligand positive cells. Siglec-7 expression was measured using an anti-Siglec-7 antibody (Miltenyi) and flow cytometry.
In order to desialylate MM both the sialidase Neuraminidase (Sigma-Aldrich) and sialyltransferase inhibitor P-3Fax-Neu5Ac (Merck) were used. Cells were either treated with 1X neuraminidase for 45mins prior to co-culture, or with 200µM 3Fax for 5 days. To block Siglec-7 interacting with its concomitant ligands, RPMI8226 myeloma cells were treated with recombinant Siglec-7 Fc chimera (10µg/ml, R&D systems) for 30mins prior to co-culture with KHYG-1 NK cells.
Results: We observed that Siglec-7 ligands (Siglec-7L) are highly expressed across a panel of MM cell lines. Furthermore, Siglec-7L expression was also observed on CD38+/CD138+ primary MM cells isolated from BM aspirates of newly diagnosed and relapsed MM patients (N=3,N=2 respectively). Immunophenotyping analysis revealed that the BM-derived NK cells of MM patients have significant cell surface expression of the cognate Siglec-7 receptor (Siglec-7R)(82±25%, n=5). Cytotoxicity assays and flow cytometry analysis revealed that abolishing sialylated glycans from the cell surface of MM cells using a sialyltransferase inhibitor results in a 1.3-1.6 fold increase ($p<0.05$) in NK cell induced cell death in MM cell lines RPMI8226 and H929, but not MM1S. (Fig.1, n=3). Furthermore, to validate our observations we pre-treated RPMI8226 cells with 10µg/ml of recombinant Siglec-7 Fc chimera to block Siglec-7 ligands on the cell surface. We observed statistically significant enhancements of NK cytotoxicity against the Siglec-7 Fc chimera treated RPMI 8226 *versus* an isotype Fc control and at all E:T ratios (P=0.003 1:1, P=0.001 2.5:1, P=0.03 5:1).

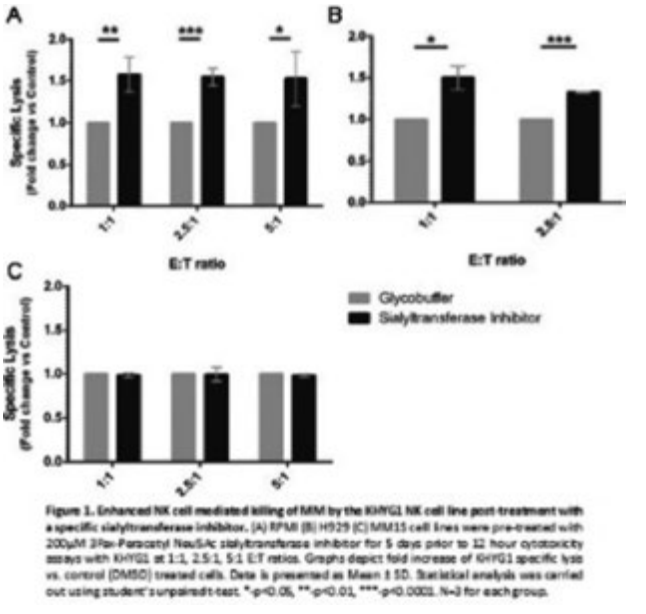

Figure 1. Enhanced NK cell mediated killing of MM by the KHYG1 NK cell line post-treatment with a specific sialyltransferase inhibitor. (A) RPMI (B) H929 (C) MM1S cell lines were pre-treated with 200µM 3Fax-Peracetyl Neu5Ac sialyltransferase inhibitor for 5 days prior to 32 hour cytotoxicity assays with KHYG1 at 1:1, 2.5:1, 5:1 E:T ratios. Graphs depict fold increase of KHYG1 specific lysis vs. control (DMSO) treated cells. Data is presented as Mean ± SD. Statistical analysis was carried out using student's unpaired t-test. *-p<0.05, **-p<0.01, ***-p<0.0001. N=3 for each group.

Figure 1.

Summary/Conclusion: We observed that Siglec-7 and it's cognate ligands are abundantly expressed on the surface of NK and MM cell lines respectively. Additionally, Siglec-7 is significantly expressed on primary NK cells circulating within the BM of MM patients. Functional assays revealed that Siglec-7L and Siglec-7R receptor interactions have significant immune suppressive effects on the cytotoxicity of NK cells towards MM cell lines. Thus, we can leverage the findings of this study to develop NK cell based cellular therapies to target Siglec-7 ligand- receptor interactions in MM.

BONE MARROW MESENCHYMAL STROMAL CELLS FROM HEALTHY DONORS SECRETE ANTI-ANGIOGENIC EXTRACELLULAR VESICLES AS WELL AS SOLUBLE FACTORS HAVING GROWTH INHIBITORY EFFECT IN MULTIPLE MYELOMA

T. Umezu[1,*], S. Imanishi[2], N. Gladkova[3], K. Ohyashiki[1], J. Ohyashiki[4]

[1]Department of Hematology, [2]Institute of Medical Science, Tokyo Medical University, Shinjyuku, [3]Kintaro Cells Power Corrporation, Shinagawa, [4]Department of Advanced Cellar Therapy, Tokyo Medical University, Shinjyuku, Japan

Background: The bone marrow mesenchymal stromal cells (BM-MSCs) from healthy donor is one of the most promising sources of cell therapy. We have previously shown that extracellular vesicles (EVs) secreted from BM-MSCs had anti-angiogenic effect rather than direct growth inhibition in multiple myeloma (MM) (Umezu *et al.* Blood Adv 2017).
Aims: To elucidate the molecular mechanism of BM-MSCs administration in cancer patients, we investigated both EVs and soluble factor mediated effect on multiple myeloma cells using a freshly obtained BM-MSC specimens.
Methods: BMSCs from Russian healthy volunterrs (KNT_D_170714, KNT_L_170714, KNT_80_170825 and KNT_86_170825: KNT cells) are kindly provided by Kintaro cells power Co. (Tokyo, Japan). Fresh bone marrow specimens were collected at Federal Research and Clinical Center of Federal Biomedical Agency of Russia (FRCC FMBA, Moskva, Russia) after obtaining approval of institutional ethical committee. Spectral karyotyping (SKY), immunophnotyping was done to validate KNT cells. In addition, KNT cells was evaluated after induction using MSC differentiation media, according to the manufacuture's protocol (PromoCell). To analyze the factors secreted by the KNT cells, 90% confluent, passage 2-4 KNT cells in T25 tissue culture flask, were transferred to a serum-free AIM-V

medium (Invitrogen) during 48 h. The EVs were isolated from conditioned medium (CM) using a Exoquick-TC (SBI). The size of EVs was confirmed using a NanoSight LM10 (Malvren). CM was fractionated using 3-kDa, 10-kDa and 50-kDa MW cut-off filter units (Millipore). To determine the effect of secretion from KNT cells, we used a MM cell line, RPMI8226. Endothelial tube formation assay was used for validating function of MM cell-endothelial cell (HUVECs) communication.
Results: We first validated KNT cells as follows. The KNT cells had a fibroblast-like morphology in culture regardless of donor's age. Immunophenotyping and karyotyping showed a normal karyotypes. The cells were positive for all MSC markers (CD90, CD73, CD105), but negative for hematopoietic markers (CD34 and CD45). When cultured in appropriate culture conditions KNT cells showed adipogenic or osteogenic potential. The nanoparticle size distribution of EVs secreted from KNT cells (KNT-EVs) were approximately 50 nm. We found that the donor's age involved the properties of KNT-EVs, We found that KNT-EVs derived from young healthy donors significantly reduced tube formation of HUVECs co-cultured with a MM cell line (RPMI8226), but did not affect the survival of RPMI8226 *in vitro*. We also found KNT cell-derived CM (KNT-CM) derived from young healthy donors markedly inhibited the growth of RPMI8226 as well as the tube formation of HUVECs. Especially the MM cell growth inhibitory effect was remarkable in the CM fractionated by 50-kDa MW cut-off filter.
Summary/Conclusion: In the current study, we used freshly obtained BM-MSCs (KNT cells) instead of commercially avairable BM-MSCs, such as widely used BM-MSCs from LONZA co. Our results indicates that the young healthy donor-derived KNT cell secretome including EVs and other soluble factors have the ability to inhibit MM-induced angiogenesis. In contrast, growth inhibitory effect was only seen at the molecules up to a MW of 50-kDa in KNT-CM. These findings indicated the limitation of EV-based therapy, however, analysis of EVs and fractionated CM may shed light on the complex molecular mechanism of BM-MSC-based therapy.

IMPACT OF THE EXPRESSION OF LRP GENE ON THE SENSITIVITY OF TUMOR PLASMA CELLS TO BORTEZOMIB *IN VIVO* AND *IN VITRO*

Y. Chernykh[1,*], A. Golenkov[1], E. Rybalkina[2], S. Shushanov[2], T. Mitina[1], E. Kataeva[1], E. Trifonova[1], E. Klinushkina[1], S. Zakharov[1], L. Vysotskaya[1], K. Belousov[1]

[1]Clinical haematology, Moscow Regional Research and Clinical Institute, [2]N.N.Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: The impact of the expression of Lung Resistance Protein (LRP) gene on the development of drug resistance to the first generation proteasome inhibitor Bortezomib is currently under active study.
Aims: To study the impact of LRP gene expression on the sensitivity of tumor plasma cells of bone marrow aspirate of patients with stage III multiple myeloma (MM) and tumor plasma cells of human MM cell lines to Bortezomib.
Methods: The LRP gene expression was assessed in bone marrow mononuclear cell fraction containing plasmocytes of 15 patients with newly diagnosed multiple myeloma Durie-Salmon stage III and in the human MM cell lines RPMI8226 and IM9. The assessment of LRP gene expression was measured by reverse transcription polymerase chain reaction test. The sensitivity of tumor plasmocytes to Bortezomib-action *in vivo* was assessed by the percentage reduction in the absolute level of paraprotein after 6 courses of Bortezomib-containing treatment, as well as in the overall survival (OS) index. OS were analyzed by the Kaplan-Meier method using the Cox-Mantel criterion. Differences were considered statistically significant at $p < 0.05$. The expression of the LRP gene in MM cell lines was examined before and after prolonged cells culture on a medium with Bortezomib.
Results: The LRP gene expression was found in 10 of 15 patients (67%) before start of cytostatic therapy. The intensity of gene expression was different. Were show 2 subgroups of patients: a subgroup with high LRP gene expression and a subgroup with low intensity of gene expression. After 6 cycles of induction with Bortezomib, there was not a significant decrease of paraprotein levels in the subgroups. Overall survival was negatively associated with high LRP gene expression only (median of overall survival in patients with high LRP gene expression was 17 months and in those with low expression –62 months, $p<0.05$). *in vitro* IM9-cells with low LRP expression were more sensitive to Bortezomib- action than RPMI8226-cells with high LRP expression (IC50 were 0.8±0.3x10-8 M and 2.7±0.6x10-8 M respectively). Cultivation of the cell lines on the Bortezomib containing medium for 90 days was leads to increase of IC50 of Bortezomib, as well as to increase of LRP expression in both human MM cell lines.
Summary/Conclusion: The high LRP gene expression can impact on the development of tumor plasma cell`s resistance to Bortezomib.

EFFECT OF AUTOLOGOUS STEM CELLS TRANSPLANTATION OF PATIENTS WITH MULTIPLE MYELOMA ON THE CALORIMETRIC MARKERS OF THE SERUM PROTEOME. CORRELATION WITH THE IMMUNOLOGICAL MARKERS

L. Gartcheva[1,*], A. Danailova[2], S. Todinova[2], K. Dimitrova[1], V. Petkova[1], S. Krumova[2], M.G. Guenova[1], S. Taneva[2], B. Spassov[3]

[1]Laboratory haematopathology and immunology, University National Specialised Hospital for Active Treatment of Haematological Diseases, [2]Institute of Biophysics and Biomedical Engineering, Bulgarian Academy of Sciences, [3]University National Specialised Hospital for Active Treatment of Haematological Diseases, Sofia, Bulgaria

Background: The thermodynamic stability of biofluids is currently extensively studied by means of differential scanning calorimetry (DSC), a biophysical technique that measures thermally induced conformational transitions of biomolecules in solution.
Aims: With the aim to develop a novel strategy for monitoring of patients with multiple myeloma (MM) that underwent autologous stem cells transplantation (ASCT) we have explored the potential of differential scanning calorimetry (DSC).
Methods: Blood sera were derived from 11 patients, defined as eligible for ASCT – 8 secretory, 2 non secretory(NS) and 1 with Free Light Chain (FLC) MM before and at 1; 2; 3; 6; 9; 12;16 months after the ASCT. In addition, 21 age matched control samples were studied. The quantification of immunoglobulin heavy/light chains (HLC) and the ratio FLC (rFLC) was performed by "Hevylite immunoassay" and "Freelite" R test, with SPAPLUS (Binding Site, UK) analyzer. Blood sera were heated with constant scanning rate (1 °C/min) in the range 20–95 °C by means of highly sensitive DASM 4 (Privalov, BioPribor)-built-in calorimeter. Origin software package was used to evaluate the calorimetric parameters: transition temperature (T_m) and excess heat capacity (C_p^{ex}) of the successive thermal transitions; temperature of the major peak (T_m^{mp}) and weighted average center of the thermogram, T_{FM} ($T_{FM}=^{T1}\int_{T2} T\, C_p^{ex}(T)\, dT / C_p^{ex}(T)\, dT$), where T_1 and T_2 are the initial and final temperatures of the thermogram. We applied linear correlation in the thermogram's shape (Pearson's correlation coefficient) and non-parametric statistical test.
Results: Before and after ASCT however the M protein concentration, rFLC and HLC varied in very large intervals. The calorimetric profiles and the thermodynamic parameters before the ASCT derived from the thermograms deviated strongly from the control thermogram. The excess heat capacity at and above 70 °C was clearly larger in the MM cases than in the control samples. The T_m^{mp} shifts from 61.9 °C in the control samples to 72.6–76. 3 °C and the T_{FM}, shifts from 64 to 68.0–74.5 °C, for all MM samples before ASCT. These changes in the C_p^{ex} and the denaturation temperatures of the individual transitions resulted in greatly reduced values of the shape similarity parameter, r, (0.09–0.9) as compared to those typical for healthy thermograms (0.97). Before the ASCT the Cp^{HSA} value is ca. 1.5–2.0 times, lower than that of the control. For NS MM and FLC MM cases before ASCT, Cp^{HSA} is lower by 1.5–2.3 times than the control, r was 0.74–0.90 and T_m^{mp} was 62–64 °C. After ASCT there was a trend for strong reduction in the M protein content and the HLC for all secretory cases. There was also an inverse correlation between the changes in the M protein level and in the thermogram's shape similarity parameter, r. The decrease in M protein concentration was also related to strong reduction in T_m^{mp} from 78 °C to 62 °C as well as in T_{FM}, but less pronounced – from 76 °C to 68 °C; those correlations are less strong than that between the M protein level and r. The calorimetric scans recorded for the two NS MM cases both before and after ASCT deviated strongly from those of healthy controls.
Summary/Conclusion: We established that the change in the paraprotein level and thus the patient's clinical status is clearly reflected in the serum thermogram. Hence, DSC can be used as complementary bioanalytical tool for the monitoring of MM remission/progression in a fast and cheap way.

STUDY OF MULTIPLE MYELOMA CHROMOSOMAL ABNORMALITIES BY MULTIPLEX LIGATION-DEPENDENT PROBE AMPLIFICATION: CORRELATIONS WITH FLUORESCENCE IN SITU HYBRIDIZATION

F. Carbone[1,*], F. Nozza[2], G. Vona[2], A. Dell'Acqua[1], S. Oronzo[3], C. Mannarella[4], A. Ciancio[4], B. Daraia[4], G. Pietrantuono[5], I. Attolico[6], R. Nuccorini[6], S. Pascale[6], P. Musto[7], M. Pizzuti[6], A. Fragasso[4]

[1]Hematology Unit, Madonna delle Grazie Hospital (Laboratory "Muscas"), Matera, [2]"Carla Alagia" Laboratory of Clinical Research and Advanced Diagnostics, IRCCS-CROB, Rionero in Vulture, [3]Genetics, [4]Hematology Unit, Madonna delle Grazie

Hospital, Matera, [5]Department of Onco-Hematology, IRCCS-CROB, Rionero in Vulture, [6]Hematology Unit, San Carlo Hospital, Potenza, [7]Scientific Direction, IRCCS- CROB, Rionero in Vulture, Italy

Background: Chromosomal abnormalities play an important role in prognostic stratification of Multiple Myeloma (MM). Current technology used to evaluate such genetic abnormalities is Fluorescence *In Situ* Hybridization (FISH). Nevertheless, it is difficult for FISH to screen all lesions simultaneously, due to high costs and technique limitations. Multiplex Ligation-dependent Probe Amplification (MLPA) is a polymerase chain reaction that permits the amplification of multiple targets by a single reaction. This technique is useful to detect Copy Number Variations (CNVs), but it is unable to find out balanced translocations. Furthermore, MLPA analysis detects abnormalities only if they are present in 30-40% of pathological cells.
Aims: In this study we evaluated the MLPA technique in the identification of chromosomal abnormalities occurring in MM patients, comparing the results with those obtained by FISH.
Methods: Cohort study included 24 MM patients (male to female ratio 15/9, median age 69 years, range 53-85 years). Bone marrow samples were taken in line with good medical practice. After evaluating the presence and percentage of plasma cells with optical microscopy, a sample part of bone marrow was used for the FISH assay. MLPA analysis (SALSA MLPA P425-B1 MM probemix, MRC-Holland, Amsterdam, Netherlands) was conducted on DNA extracted from marrow aspirates with commercially kits. PCs were purified from MM samples using CD138 microbeads and magnet-assisted cell sorting (MiltenyiBiotec).We enriched 7/24 (29%) samples. The PCR products were initially analyzed using ABI 3130 Genetic analyzer (Applied Biosystems), later using SeqStudio Genetic Analyzer (Applied Biosystems).
Results: FISH analysis detected genetic alterations in 20 of 24 patients tested for assay: 13q deletion was the most frequently genetic aberration (9/20) followed by 17p deletion (3/20) and 1q amplification (3/20). Other genetic alterations included 1p deletion in 1patient and a deletion of Y chromosome in another one. Out of these 20 patients, 16 were positive for IGH rearrangements. Overall, out of 24 patients, 12 cases were positive for CNVs. We could identify genetic alteration in 10/24 multiple samples by using MLPA. The most frequently genetic aberrations included 13q deletion (6/10) followed by 1q amplification (4/10). There was 1 positive case for chromosome 1p deletion, while the chromosome 17p deletion was positive in 1 patient. Interestingly, we also found 2 patients with chromosome 5q amplification, 2 with 15q amplification, 1 with 12p deletion and 1 with Y chromosome deletion. Overall, concordant results were detected in 18/24 (75%) cases. The discordant results were 6/24 (25%). Out of these 6 cases, MLPA analysis were conducted on DNA isolated from CD138-enriched plasma cells in 2 patients, while MLPA tests were made on DNA isolated from whole bone marrow mononuclear cells in 4 patients.
Summary/Conclusion: In this study there was a consistent concordance between FISH and MLPA for detection of CNVs. However, some discrepancies emerged, which were probably attributable to the non-isolation of CD138+ cells in some samples. MLPA can't detect balanced aberrations, but identified some additional cytogenetic abnormalities that are not usually investigated by a standard FISH approach; therefore, taken together, MLPA and FISH represent complementary techniques, both useful to find cytogenetic aberrations in MM patients. The study is still recruiting new patients.

PB2141

ACTIVIN A: A NOVEL URINARY BIOMARKER REFLECTING EARLY RENAL IMPAIRMENT IN MULTIPLE MYELOMA

H. Iriuchishima[1,*], A. Maeshima[2], S. Takahashi[2], T. Ishizaki[1], A. Yokohama[3], N. Tsukamoto[4], T. Saitoh[5], H. Murakami[5], H. Handa[1]

[1]Hematology, [2]Nephrology and Rheumatology, [3]Blood Transfusion, [4]Oncology Center, [5]Laboratory Sciences, Gunma University, Maebashi city, Gunma, Japan

Background: Renal impairment (RI) is a common complication of multiple myeloma (MM), which significantly affects not only treatment efficacy but also patient mortality. The conventional parameters defining RI in MM (the level of serum creatinine (Cr) >2.00 mg/dl or Ccr <40 ml/min) are not sensitive, resulting in the delay of diagnosis and treatment of RI. Recently, it is reported that monoclonal gammopathy of renal significance (MGRS), which represents all renal disorders caused by a monoclonal immunoglobulin secreted by a B-cell or plasma cell clone, is associated with high morbidity. Therefore, sensitive reliable parameters for early diagnosis of RI in MM are required. Activin A, a multifunctional cytokine belonging to the TGF-β superfamily, has been reported to be involved in kidney development, tubular repair after injury and fibrotic process of the kidney. However, it is unclear whether activin A plays a role in renal damages in MM.
Aims: To clarify the involvement of activin A in renal damages in MM, we examined whether activin A can be detectable in the urine from patients with newly diagnosed MM (NDMM), asymptomatic (smoldering) (SMM), and MGUS including MGRS.

	control	MGUS	SMM	NDMM
U-Act/Cr (ng/gCr)	0	25.0	6.61	97.3

Figure 1.

Methods: We investigated the data of patients with NDMM (n=41), SMM (n=10), and MGUS (n=28) diagnosed in our department between October 2012 and September 2017. Along with common blood and urine chemistry determinations, serum and urinary activin A were measured by ELISA. In some cases, renal histological evaluation was performed using renal biopsy samples. This study was approved by the local institutional review board, and written informed consent was obtained from all patients.
Results: Urinary activin A, which was undetectable in healthy controls (HC), significantly increased in NDMM (97.3±36.0 ng/gCr, p<0.05 *vs* HC), but not in MGUS (25.0±9.4 ng/gCr) and SMM (6.61±3.9 ng/gCr). There were no significant differences in serum activin A level among these subgroups. Urinary activin A level was significantly reduced after initial treatment in NDMM (73.9 *vs* 12.0 ng/gCr, $p<0.01$). Improvement rate of urinary activin A from baseline after treatment was much higher than that of serum Cr or eGFR (84%, 30%, 12%, respectively). There was a significant correlation of urinary activin A with urinary protein level (p<0.001), but not with eGFR, serum Cr, and N-acetyl-glucosaminidase. Interestingly, there was no significant correlation between serum and urinary activin A level. Immunohistochemical analysis revealed that activin A, which was absent in normal kidney, was present at the tubulointerstitial area of the kidneys from patients with MGRS.
Summary/Conclusion: These data suggest that urinary activin A is a novel urinary biomarker detecting renal damages in MM. Measurement of urinary activin A might be an useful tool to perform early diagnosis of RI or to predict the severity of renal damages in MM.

RAMAN SPECTROSCOPY IS ABLE TO DISCRIMINATE BETWEEN CD138-/CD138+ PLASMA CELLS OF MULTIPLE MYELOMA PATIENTS

A. Allegra[1,*], O. Bianco[1], E. Fazio[2], M. Bonsignore[2], F. Neri[2], G. Ferlazzo[3], S. Trusso[4], D. Franco[2], L.M. De Plano[5], M.G. Rizzo[5], S. Crea[5], S.P.P. Guglielmino[5], C. Musolino[1]

[1]Division of Hematology, Department of Patologia Umana dell'Adulto e dell'Età Evolutiva, [2]Dep. of Mathematical and Computational Sciences, Physical Science and Earth Science, [3]Laboratory of Immunology and Biotherapy, Department of Human Pathology, University of Messina, [4] Institute of Chemical-Physical Processes (IPCF)-CNR, CNR-Messina, [5]Department of Chemical Sciences, Biological, Pharmaceutical and Environmental, University of Messina, Messina, Italy

Background: Multiple myeloma is a B cell neoplastic disorder characterized by clonal proliferation of malignant plasma cells in the bone marrow. CD138 is a marker of plasma cells and MM cells. The expression of CD138 highly correlates with that of VEGFR3. However, a low CD138 expression is frequently observed in MM patients and several studies have reported how a decreased CD138 expression can affect the prognosis and the treatment response.

Aims: We proposed Micro-Raman spectroscopy as an easily accurate and non invasive method to discriminate plasma cell immune-phenotype.

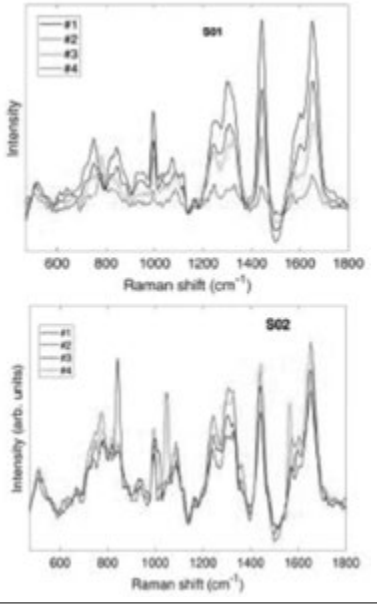

Figure 1.

Methods: two distinct cell subtypes for antigen expression pattern: i) subtype 2 CD45-/CD56-/CD38+ (namely, S01); ii) subtype 3 CD45+/CD38+/CD138+ (namely, S02) separated by the conventional flow cytometry approach and then fixed on CaF2 substrate, were analyzed carrying out Raman mapping analyses. Raman contributions were observed in selected spectral regions where markers of specific functional groups, useful to characterize the cell state, are present. Hence, comparing Raman spectra, the investigated cell subtypes can be distinguished, analyzing several spectra for each sample. So, intracellular variability, repeatability and sensitivity of the analyses for each sample was evaluated.
Results: - Regarding S01cells: the spectra acquired in the #3 and #4 points are characterized by DNA and PO-P vibrational modes in the 637-665 and 776-827 cm-1, respectively. In addition, RNA features at 725 cm-1 and in the 1560-1580 cm-1 regions are more evident. C-C or C-O vibrational modes, ascribed to membrane phospholipids, are envisaged in the 1075-1116 cm-1 region. Regarding S02 cells: The main spectral differences respect to S01 cells are referred: 1) to the nucleic acids contributions (DNA/RNA) and 2) to the protein features (1255-1670 cm-1 region) more pronounced and defined in the S02 cells in comparison to the S01 ones. Furthermore, cells S01 show an high internal variability respect to S02, suggesting a high metabolic activity.
Summary/Conclusion: Plasma cells are a eterogenous population in Multiple Myeloma patients. A different rate of CD138+ cells is able to modify the prognosis. Raman Spectroscopy could increase our knowledge of the structure and problably the function of these cells contribuiting to a better awereness of the mechanisms of Multiple Myeloma progression.

PB2143

PDGFR-B AND CXCR4 IN MULTIPLE MYELOMA DISEASE STAGES: PRELIMINARY RESULTS

L. Correia[1,*], M.M. Tenreiro[1], M. Silveira[2], M.A. Brito[1], R. Malhó[3]

[1]DBBH, FFUL, [2]IPOFG, [3]FCUL, Lisboa, Portugal

Background: Multiple myeloma (MM) is characterized by the clonal expansion of plasma cells (PCs) in the bone marrow (BM) that leads to bone destruction, anaemia and renal failure. The evolution from the asymptomatic stage of monoclonal gammopathy of undetermined significance (MGUS) to MM and the progression of the disease itself are related with cellular and molecular alterations in the BM microenvironment, including the development of the vasculature. Many factors are involved in the mobilization of endothelial progenitors, including C-X-C motif chemokine ligand 12 (CXCL12) that stimulates the motility of cells and its receptors, namely the C-X-C motif chemokine receptor 4 (CXCR4). Another factor is platelet-derived growth factor receptor (PDGFR)-β, a marker of pericytes, mural cells recruited to stabilize newly formed blood vessels. Despite the increasing knowledge about the disease, there is still no effective cure and the standard survival is up to 4 years. Therefore a better understanding of the disease evolution at cellular and molecular levels is needed.
Aims: To evaluate the changes in PDGFR-β and CXCR4 positive cells, and their relation with PCs, in the bone marrow, along the several disease stages.
Methods: We performed a longitudinal study, using BM smears archived at the Hematology Service of Instituto Português de Oncologia Dr. Francisco Gentil, Lisbon. BM smears from patients evolving from MGUS to MM and from MM to remission (MMr) were used (n=3). Smears were May-Gr nwald-Giemsa stained for PCs analysis, and were subjected to immunofluorescence analysis of PDGFR-β and CXCR4.
Results: As expected, the evolution of MGUS to MM was characterized by a significant increase in PCs levels, from 5.8% to 23.4% ($p<0.01$), and by a decrease from 39.0 to 2.9% from MM to MMr ($p<0.001$). Analysis of PDGFR-β+ cells revealed no significant difference from MGUS to MM but a significant increase from 14.5% in MM to 39.0% in MMr ($p<0.001$). The results for CXCR4 showed that the patients who evolved from MGUS to MM with PCs>20% in MM, presented a decrease in CXCR4+ cells from 55.1% to 27% ($p<0.05$), whereas the group of patients with less severe disease (PCs ≤20% in MM) showed no statistical significance. To establish if the levels of PDGFR-β and CXCR4 were correlated with those of plasma cells, we analysed the results obtained in MM patients as fold change from those of the same patients in MGUS and determined the correlation coefficients between PCs, and PDGFR-β or CXCR4. PCs were 4-fold higher in MM than in MGUS, whereas the levels of PDGFR-β+ and CXCR4+ cells were nearly 0.8-fold of those of MGUS. Analysis of the correlation coefficients revealed that PCs were negatively correlated with CXCR4+ cells ($r=-0.825$, $p<0.05$). In contrast, no significant correlation was observed concerning PDGFR-β+ cells, or between CXCR4+ and PDGFR-β+ cells, probably due to the limited study population.
Summary/Conclusion: Although preliminary, these results point to variations in PDGFR-β+ and CXCR4+ cells along different stages of the disease that deserve to be further studied in larger groups of patients. Moreover, they indicate that CXCR4 and PDGFR-β are involved in the BM microenvironement alterations along MM disease stages.

PB2144

INTRODUCTION OF A EUROPEAN QUALITY ASSESSMENT SCHEME FOR GENETIC TESTING IN MYELOMA: PROGRESS AND UPDATE

P. Talley[1,*], A. Chantry[2], A. Cox[2], K. Rack[3], R. Hastings[3]

[1]Haematological Malignancy Diagnostic Service (HMDS), St James's University Hospital, Leeds, [2]Department of Oncology and Metabolism, University of Sheffield, Sheffield, [3]GenQA, John Radcliffe Hospital, Oxford, United Kingdom

Background: Recent guidelines have highlighted the importance of genetic analysis in plasma cell myeloma (PCM) patients. GenQA (Genomics Quality Assessment) are a branch of UKNEQAS (UK National External Quality Assessment Schemes) and offer external quality assessment (EQA) schemes covering a range of haematological disease. In 2014, a pilot EQA scheme for PCM was launched. The scheme was aimed at all laboratories offering genetic testing for PCM patients, and included a questionnaire assessing the current status of PCM genetic testing. As well as providing a method to evaluate and assess laboratories analytical and interpretative skill and ability, the scheme aimed to provide an education component with the idea of creating a more equitable and consistent diagnostic genetic service. We present an update on the progress of the EQA scheme to date.
Aims: To introduce an EQA scheme for PCM to evaluate analytical and interpretative ability. To assess the status of PCM genetic testing at scheme introduction. To influence equity and consistency of genetic testing through educational components of scheme participation and production of best practice guidelines for genetic laboratories.
Methods: The pilot GenQA scheme involved analysis of two known abnormal cases; the first case involved analysis of online FISH images, the second was presented as fixed patient cells for internal FISH processing and analysis. For each case, the participating laboratory produced a report that mirrored their standard reports. A panel of four experts, as well as the GenQA scheme organiser/deputy, assessed the analytical ability and the interpretative components presented in the report. This methodology has been followed in subsequent years. A questionnaire interrogating the laboratories referral patterns, sample numbers, turnaround times, techniques employed and gene regions examined was also issued in the inaugural year.
Results: At scheme introduction, 39 laboratories participated; of those, 33 produced satisfactory reports. Participation rates have shown an overall increase and plateau over the period of four years, 56 laboratories in year 2, 65 in year 3 and 61 in year 4. The number of poor performance laboratories demonstrated a decrease over the first three years with an upward

spike in year 4; 15.4%, 10.7%, 3.1% and 14.8% over 2014, 2015, 2016 and 2017 respectively. This peak in poor performance was due to a change in testing strategy employed by some laboratories, with penalities being applied to the use of specific probes in an inappropriate context. Case 2, the wet sample, results in more poor performance, but also involves increased assessment of the testing strategy, technical and analytical ability of laboratories. The inaugural scheme survey, provided evidence for the *ad hoc* nature of genetic testing in PCM, although the majority of laboratories did carry out the essential tests.
Summary/Conclusion: In summary, we present the successful implementation of an EQA for genetic diagnosis in myeloma, which is now entering its fifth year. We have seen an increase and plateau of participants over this period, and a positive effect of the educational component provided by the scheme. Although the essential tests are being provided by the majority of laboratories, an inequitable service is provided. This highlights the need, not only for the educational component of the EQA scheme, but for the production of best practice guidelines (BPG) in this area. BPG are currently in progress, to address this shortfall.

PB2145

Abstract withdrawn.

PB2146

MOLECULAR CYTOGENETIC ANALYSIS IN MULTIPLE MYELOMA/ PLASMA CELL LEUKEMIA PATIENTS WITH CIRCULATING PLASMA CELLS

J. Balcárková*, M. Mlynárčiková, J. Minařík, T. Pika, P. Krhovská, H. Urbánková, T. Papajík

Hemato-oncology, University hospital Olomouc, Czech republic, Olomouc, Czech Republic

Background: The common feature shared by primary plasma cell leukemia (pPCL) and multiple myeloma (MM) with circulating plasma cells (CPCs) is the expansion of plasma cells independent of bone marrow (BM). The presence of CPCs is considered as a marker of highly proliferative disease and an adverse independent prognostic factor. The diagnosis of pPCL is based upon absolute number (≥2x10^9/L) and/or the percentage (≥20%) of CPCs in peripheral blood (PB). Cytogenetic studies showed that CPCs have a variety of genetic abnormalities. Majority of cytogenetic abnormalities in patients with CPCs are non-hyperdiploid with higher frequency of major IgH translocations, *i.e.* t(11;14)(q13;q32), t(4;14)(p16;q32) and t(14;16) (q32;q23). The most common abnormalities are deletion of 13q/ monosomy 13, deletion of 17p and abnormalities of chromosome 1 (1q21 gain/ deletion 1p21).
Aims: The aims of the present study were to analyze cytogenetic changes in a cohort of 7 patients (3 with pPCL and 4 MM with CPCs).
Methods: We used array comparative genomic hybdridization (arrayCGH) and FICTION method (fluorescence immunophenotyping and interphase fluorescence *in situ* hybridization) with commercially available probes specific for RB1/c15, IgH, 1q21/1p32, TP53/c17, to assess clonal evolution in BM and CPCs and to evaluate the prognostic importance.
Results: We detected translocation of *IgH* gene in 4 out of 7 patients- t(11;14) in 3 patients, t(4;14) in one patient. In one patient we delineated der(4)t(4;7)(p16;q?)ins(4;7)(p16;q?) including FGFR3/MMSET. Gain of 1q21 was found in 5/7 patients. Deletion of RB1 gene was detected only in 2/7 patients and TP53 deletion in one patient. Abnormalities identified in BM were also found in CPCs. ArrayCGH found common deletions of 1p, 6q, 13q, 16q and gain of 1q, chromosome X abnormalities (monosomy/Xq gain). Chromotripsis of chromosome 8 and hyperdiploidy with trisomies of chromosomes 3, 5, 7, 9, 11, 15 and 19 was found in 2 other patients.
Summary/Conclusion: In summary, genetic aberrations were recorded in all 7 analyzed cases with PCL and MM with CPCs. We found numerical changes as well as structural aberrations similarly as in MM patients. Our findings underline that genetic abnormalities are more frequent in PCL/MM with CPCs than in MM patients and they tend to be more complex.

ALTERED MICRORNA EXPRESSION PROFILE IN THE PERIPHERAL LYMPHOMONOCYTES OF MULTIPLE MYELOMA PATIENTS WITH BISPHOSPHONATE-INDUCED OSTEONECROSIS OF THE JAW

V. Innao[1,*], A. Allegra[1], G. Oteri[2], M. Mania[2], A. D'Ascola[2], O. Bianco[1], A. Avenoso[2], D. Vaddinelli[1], A.G. Allegra[1], S. Campo[2], C. Musolino[1]

[1]Division of Hematology, Department of Patologia Umana dell'Adulto e dell'Età Evolutiva, [2]Department of Biomedical, Dental Science and Morphological and Functional Images, University of Messina, Messina, Italy

Background: Bisphosphonates are formidable inhibitors of osteoclast-mediated bone resorption employed for therapy of multiple myeloma (MM) subjects with osteolytic lesions. Osteonecrosis of the jaw (ONJ) is an uncommon drug-induced adverse event of these agents. MicroRNAs (miRNAs) are a group of small, noncoding RNAs nucleotides, which are essential post-transcriptional controllers of gene expression. They have a central role in the normal bone development.
Aims: The goal of our study was to investigate 18 miRNAs, whose targets were previously validated and described in MM subjects without ONJ, in peripheral lymphomonocytes of MM subjects with bisphosphonate-induced ONJ.
Methods: Utilizing reverse transcription quantitative polymerase chain reaction we evaluated miRNAs in five healthy subjects and in five MM patients with ONJ.
Results: Our experimental data revealed that a diverse miRNA signature for ONJ subjects emerged respect to control subjects. Using the filter for *in silico* analysis, among 18 miRNAs we recognized 14 dysregulated miRNAs. All of these miRNAs were significantly over-expressed in patients *vs* controls (MIR-16-1, MIR-21, MIR-23A, MIR-28, MIR-101-1, MIR-124-1, MIR-129, MIR-139, MIR-145, MIR-149, MIR-202, MIR-221, MIR-424, MIR-520). Among them, six were strongly up-regulated (4-fold up-regulated and more). These miRNAs target numerous pathways and genes implicated in calcium ion binding, bone resorption, mineralization of bone matrix, differentiation and maintenance of bone tissue.
Summary/Conclusion: A modified microRNA expression profile after zoledronate therapy could participate to the onset of ONJ. Targeting these miRNAs could provide a new treatment for the prevention or treatment of ONJ.

PB2148

RELATIONSHIP OF MOLECULAR PECULIARITIES WITH CYTOGENETIC ABERRATIONS IN MULTIPLE MYELOMA

E. Nazarova*, M. Sarpova, N. Minaeva, J. Suhorukova, I. Paramonov, E. Zotina, I. Dokshina, V. Shardakov

Kirov Research Institute of Hematology and Blood Transfusion, Kirov, Russian Federation

Background: Multiple myeloma (MM) is characterized by pronounced genomic heterogeneity due to a complex combination of numerical and structural changes in chromosomes that play a key role in oncogenesis. In studies of malignant plasma cells using fluorescence *in situ* hybridization (FISH) and flow cytometry, karyotype abnormalities are detected in more than 90% of MM patients, frequency and severity of which correlates with the stage of the disease, the prognosis and response to therapy. Genetic mutations also play an important role in the pathogenesis of MM.
Aims: To study the relationship between the mutational status of a number of immune response genes and cytogenetic aberrations in MM patients.
Methods: 39 patients with MM aged from 33 to 75 years (median - 57 years) in the onset of the disease were evaluated, 14 men (35.9%), 25 women (64.1%). FISH-method of the bone marrow cells interphase nuclei is performed with Kreatech FISH Probe DNA probes. Genotyping of 20 polymorphic locus of the 13 immune response genes of genomic DNA from peripheral blood leukocytes was carried out by polymerase chain reaction with allele-specific primers (single nucleotide polymorphism - SNP).
Results: The patients were divided into two groups. The first group included 24 (61.5%) patients with MM who had no chromosomal abnormalities in the FISH analysis. The second group consisted of 15 (38.5%) patients with different cytogenetic aberrations in the form of monosomy 13, trisomy 4, 11, 13, 14, 17, 20 chromosomes, amplification of 1q21, del DLEU1 (13q14), del IGH (14q32), del TP53 (q13;q32), t(4;14) (p16;q32) and t(14;16) (q32;q23). When comparing the obtained cytogenetic data with the results of SNP genotyping, it was found that the presence of the mutant allele G in the haplotypes (CG+GG) of the interleukin-6 (*IL6*) gene at the locus-174 by four times (p=0.04), and the presence of the «wild» type G allele in the homozygous state at the mutation point -915 of the transforming growth factor-β (*TGF-β*) gene, it reduces the detection rate of cytogenetic aberrations in MM by 33 times (p=0.02). The conducted studies confirmed the generally recognized molecular heterogeneity of MM. The genes *IL6* and *TGF-β* are localized in 7 and 19 chromosomes, respectively. Aberrations in these chromosomes are detected in MM with hyperdiploid karyotype, which has a favorable prognosis. Proteins synthesized by these genes play a particular role in MM. IL-6 is one of the growth and survival factors of malignant plasma cells, inhibiting their apoptosis. In addition, IL-6 is able

to interact with other factors involved in the pathogenesis of MM, such as adhesion molecules, tumor suppressor genes and oncogenes. The transforming growth factor-β (TGF-β) refers to a transcription factors family that are involved in cell proliferation, differentiation, and apoptosis. In MM, TGF-β can act as a suppressor and a tumor growth promoter.
Summary/Conclusion: Cytogenetic studies in MM are used to predict the course of the disease. The detection of genetic characteristics of malignant disorders creates prerequisites for the development of targeted therapy. Given the important role of IL-6 and TGF-β in this disease, it is advisable to use the mutation status of the *IL6* and *TGF-β* genes to predict the course of MM and personalized treatment. Thus, the complex determination of chromosomal changes, the spectrum of mutations and the evolution of subclones in MM requires further research in this direction.

PB2149

EPIDEMIOLOGY OF MULTIPLE MYELOMA IN A LARGE METROPOLITAN AREA OF RUSSIA (NOVOSIBIRSK)

N. Skvortsova*, T. Pospelova, I. Kovynev

Novosibirsk State Medical University, Novosibirsk, Russian Federation

Background: Morbidity and prevalence of MM in some regions of Russia have not been studied enough and are characterized by a significant spread of indicators reflecting the large territory of the country, the heterogeneity of its geographical and climatic conditions, migration processes and the level of diagnostic capabilities of each region. Novosibirsk is the largest commercial, business, cultural, industrial, transport and scientific center of Western Siberia and the third city of Russia with a population of 2 million 84.4 thousand people. The obtained data will allow to reveal the peculiarities of MM epidemiology in this region of Russia and will help in the development and implementation of regional and national programs for the provision of timely and qualified medical care to patients with this disease.
Aims: Analysis of the dynamics of the main epidemiological indicators of MM in a large metropolitan area of Russia (Novosibirsk).
Methods: The study included 335 patients with newly diagnosed MM who were observed at the City Hematology Center in Novosibirsk between 2006 and 2016. The median age of the patients was 67 years (range from 30 to 89 years). The dynamics of intensive morbidity, prevalence, lethality and survival of MM patients in Novosibirsk for the analyzed period was retrospectively studied. Statistical processing of data was carried out using the statistical software STATISTIKA (version 7.0) and SPSS (version 23.0). Overall survival was calculated using the Kaplan-Meier method. Reliability of differences in survival in the study groups was calculated using a log-rank test, the differences were considered reliable at $p<0.05$.
Results: The average intensive morbidity of MM in Novosibirsk over the past 10 years has increased 1.6 times and amounted to 2.4 cases per 100 000 population per year, which corresponds to the incidence in Russia as a whole and lower than in Europe and The United States. The prevalence of MM for the period under review increased from 2.8 to 13.8 per 100,000 people per year, indicating an increase in the number of newly diagnosed patients with MM and prolonging their life span. Among women, MM morbidity and prevalence is statistically significantly higher than among men, which is associated with better survival rates for women and fewer males in the region according to regional statistics. The annual mortality of MM patients decreased from 28.3 to 8.2 with a negative linear trend throughout the analyzed period, which is most likely due to the high efficacy of bortezomib and lenalidomide-containing regimens introduced since 2006. The median overall survival (OS) of patients with MM for the study period was 70 months. In patients younger than 65 years, the median OS was 79.1 months, in the 65-75 year-old group, 54.3 months, and in patients over the age of 75, 36.1 months, respectively.
Summary/Conclusion: Thus, the epidemiological data obtained by us indicate an increase in the incidence of MM during the analyzed period. An increase in the prevalence of MM along with a decrease in mortality indicates an increase in the life of patients due to the rather high efficiency of modern chemotherapy programs based on new medicinal agents. The overall survival of MM patients in different age groups corresponds to international literature data.

PB2150

THE MOLECULAR SIGNATURES OF HIGH RISK MULTIPLE MYELOMA IN THAI POPULATION

P. Kamseng[1,*], T. Siriboonpiputtana[1], T. Puavilai[2], K. Paisooksantivatana[1], T. Chareonsirisuthigul[1], S. Chuncharunee[2], B. Rerkamnuaychoke[1]

[1]Department of Pathology, [2]Department of Medicine, Faculty of Medicine Ramathibodi hospital, Mahidol university, Bangkok, Thailand

Background: Multiple myeloma (MM) is recognized as a hematological malignancy characterized by the accumulation of abnormal plasma cell clones in bone marrow. MM is a heterogeneous disease in which clinical representation, cell morphology, immunophenotype, prognosis, disease progression as well as treatment outcome, harbors specific genetic alterations. Advanced genomic techniques including microarray have been currently used to study the heterogeneity/complexity of the disease which could help further identify biomarkers as well as develop the new effective therapy.
Aims: In this work, we aimed to primarily explore the transcriptional signature of different subgroups of myeloma patients in Thai population.
Methods: We performed gene expression profile analysis using microarray to analyze a total of seventeen CD138-enriched samples from newly diagnosed MM patients. The risk-assessment was based on the Mayo Stratification of Myeloma and Risk-Adapted Therapy. Finally, gene set enrichment analysis (GSEA) was performed by using Hallmark gene set version 4.0 MSigDB collections as a gene set database.
Results: We could categorize individual patients in to different subgroups as following: 2 patients with high-risk (11.8%), 7 patients with intermediate-risk (41.2%), and 8 patients with standard-risk (47.1%). Markedly, 2 patients with high-risk group shared both del(13q) and del(17p). Additionally, we found that several genes are differentially expressed in different subgroups of multiple myeloma. Moreover, GSEA analysis revealed that TNFA signaling via NFKB, TGF beta signaling, and KRAS signaling are differentially expressed in high-risk group when compared with the standard-group (FDR<25% and nominal p-value <0.05).
Summary/Conclusion: We provide the preliminary data of a transcriptional signature in different subgroups of MM in Thai patients. The results from GSEA reveal and highlight several molecular pathways that are critical for the development of high-risk MM phenotype in Thai population.

PB2151

THE NOVEL TRANSLOCATION OF T(1;21) IN MULTIPLE MYELOMA WITH COMPLEX KARYOTYPE

M. Okay*, R. Ciftciler, E. aladag, H. Goker

Hematology, Hacettepe University, Ankara, Turkey

Background: Multiple myelomas (MM) is characterized as the neoplastic proliferation of plasma cells producing a monoclonal immunoglobulin. Multiple myeloma is a heterogeneous disease. The prognosis of patients with MM is dependent on four factors: staging, patient factors, disease biology and response to therapy. The cytogenetic anomalies of patients have prognostic significance.
Aims: The cytogenetic anomalies of patients have prognostic significance. Accurate identification of high-risk and low-risk cytogenetic abnormalities plays a crucial role in predicting the response or resistance to the treatment. The aim of this paper is to report complex karyotype with novel translocation leading to a fatal clinical course in a patient with MM.

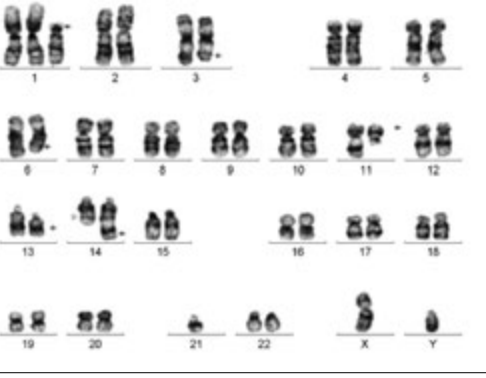

Figure 1.

Methods: We report the case of a 48-year-old man presenting with black stool, bicytopenia, high creatinine level and hypercalcemia. The bone marrow aspiration of the patient showed diffuse neoplastic plasma cell infiltration and complex karyotype was detected in all of 20 metaphases on cytogenetic analyses. The karyotype of the patient was 46,XY,dic(1;21)(p11;p11), del(3)(q25;q29), del(6)(q24;q26), t(11;14)(q13;q32), del(13)(q14q21). The anomaly of t (1; 21) (p11; p11), which we detected in this

case and which has not been detected between these breaking points in any malignancies before, was detected in a case with MM for the first time.
Results: The anomaly of t (1; 21) (p11; p11), which we detected in this case and which has not been detected between these breaking points in any malignancies before, was detected in a case with MM for the first time. Although the prognostic impact of this unique anomaly may be unclear. Regarding the very aggressive clinical presentation of the MM, cytogenetic abnormalities could be linked to poor prognosis.
Summary/Conclusion: Multiple myeloma is a heterogeneous disease. The cytogenetic anomalies of patients have prognostic significance. We report the case of complex karyotype was detected in all of 20 metaphases on cytogenetic analyses. The karyotype of the patient was 46,XY,dic(1;21)(p11;p11), del(3) (q25;q29), del(6) (q24;q26), t(11;14) (q13;q32), del(13) (q14q21). The anomaly of t (1; 21) (p11; p11), which we detected in this case and which has not been detected between these breaking points in any malignancies before, was detected in a case with MM for the first time.

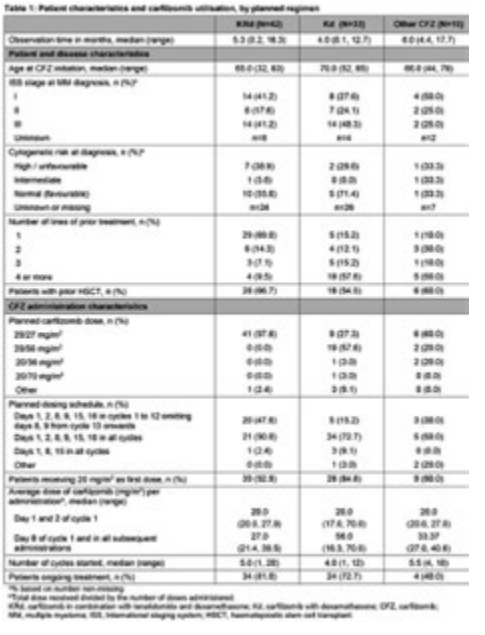
REAL-WORLD EVIDENCE OF THE USE OF CARFILZOMIB AMONG PATIENTS WITH RELAPSED MULTIPLE MYELOMA IN EUROPE: AN INTERIM ANALYSIS FROM A PROSPECTIVE OBSERVATIONAL STUDY

E. Terpos[1,*], J. Caers[2], M. Sohne[3], F. Suzan[4], M. Schoonen[5], S. Wetten[5], C. Turkington[6], M. Ladetto[7], D. Lechner[8]

[1]Department of Clinical Therapeutics, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, [2]Department of Hematology, CHU de Liège, Liège, Belgium, [3]St. Antonius Hospital, Nieuwegein, Netherlands, [4]Amgen (Europe) GmbH, Zug, Switzerland, [5]Centre for Observational Research, Amgen Ltd., [6]Global Biostatistical Science, Amgen Ltd., Uxbridge, United Kingdom, [7]Hematology Division, Azienda Ospedaliera Santi Antonio e Biagio e Cesare Arrigo, Alessandria, Italy, [8]Department of Hematology and Medical Oncology, Ordensklinikum Linz Elisabethinen, Linz, Austria

Background: Carfilzomib (CFZ) is a next-generation proteasome inhibitor currently approved in combination with lenalidomide and dexamethasone (KRd) or with dexamethasone alone (Kd) for treatment (Tx) of adult multiple myeloma (MM) patients (pts) with at least one prior Tx in the European Union (EU). Access to CFZ is ongoing throughout the EU. Real-world evidence is crucial to understand how CFZ based regimens are used in practice and in relation to EU prescribing information (PI).
Aims: To describe CFZ utilisation in routine clinical practice as well as the pt population, safety profile, response to Tx and selected healthcare resource utilisation. Results from a first planned interim analysis are reported.
Methods: This prospective cohort study (NCT03091127) recruited adults who at the time of CFZ initiation had experienced a relapse, received ≥1 prior line of MM Tx and ≥1 dose of CFZ in a combination regimen in routine clinical practice. Medical history and pt characteristics prior to CFZ initiation are collected as well as further data during pt observation until 30 days after final CFZ administration or until 18 months after initiation, whichever is earlier. All adverse events of grade 3 or above (Gr3+, including serious adverse events [SAE]) are collected.

Table 1.



Results: First pt was enrolled on 14th March 2017. As of 30 October 2017, 85 pts have been included from 4 countries participating so far: Austria

(22), Belgium (23), Greece (26), and the Netherlands (14). The reported regimens planned to be prescribed were KRd (49%), Kd (39%), and other CFZ regimen combinations (12%) which included triplets with cyclophosphamide (n=5), pomalidomide (n=3), methylprednisolone (n=1), and elotuzumab (n=1). Overall, 34.1% of pts reported a history of hypertension, 15.3% of cardiac disorders, 15.3% of diabetes and 5.9% of pulmonary embolism prior to CFZ. On average, pts with planned KRd were younger than pts with planned Kd and 69% of KRd pts had received 1 prior line of Tx compared with 15% of Kd pts. For nearly all KRd pts (97.6%) and over half of Kd pts (57.6%), the planned CFZ dose was per EU PI, 20/27 mg/m^2 and 20/56 mg/m^2 respectively. For all remaining Kd pts physicians planned a dose lower than the recommended biweekly dose of 112 mg/m^2. For nearly half of KRd pts (47.6%) and around three quarters of Kd pts (72.7%), the planned administration schedule was per EU PI. Regardless of regimen, most pts received the starting dose, 20 mg/m^2. The average dose for administrations from day 8 of cycle 1 onwards was largely in line with the EU PI. After a median observation time of 4.6 months, 81% and 73% of KRd and Kd pts, respectively, are still ongoing CFZ Tx. Treatment-emergent adverse events Gr3+ were reported in 26.2% of KRd (16.7% SAEs), 21.2% of Kd (18.2% SAEs) and 60% of other combinations (10.0% SAEs) and one fatal event of cardio-respiratory arrest occurred in the Kd group. The most frequent events were neutropenia (n=4), pneumonia (n=4), anaemia (n=3), decreased platelet count (n=3) and sepsis (n=2) and one pt experienced cardiac failure. Only 3 pts discontinued CFZ Tx due to an AE.

Summary/Conclusion: These first results suggest that KRd may be preferably used as second-line Tx and Kd may be deferred to later Tx lines, however, KRd was generally available before Kd in participating countries. The planned CFZ dose reduction among Kd pts may reflect a real-life approach to manage frail and heavily pretreated pts. Further observation of increasing number of pts in routine practice with further follow up is ongoing to assess longer-term pt management and response.

PB2154

ASSESSMENT OF PNEUMOCOCCAL VACCINATION RESPONSE IN MULTIPLE MYELOMA

M. Ellis[1,2,*], N. Runnegar[1], P. Hogan[1], P. Mollee[1,2]

[1]Princess Alexandra Hospital, [2]University of Queensland, Brisbane, Australia

Background: Patients with myeloma are at increased risk of infective complications and current international guidelines recommend the use of immunization against S. pneumoniae, H. influenzae and influenza A and B. Prior studies assessing response to influenza vaccine have demonstrated poor rates of seroconversion. Modern myeloma therapy is based around combinations of immunosuppressive proteasome inhibitors (PI) and immunomodulatory (IMiD) agents.

Aims: We sought to assess the rate of seroconversion in patients with myeloma receiving different treatment regimens.

Methods: This study was conducted as a pilot study. Patients had serological assessment for the pneumococcal serotypes 4, 6B, 9V, 14, 18C, 19F and 23F prior to vaccination with the 23-valent purified polysaccharide vaccine Prevenar 23 using an ELISA platform. Repeat serology was taken approximately six weeks following vaccine administration. Patients were stratified in to three groups based on whether they were newly diagnosed (vaccinated prior to any therapy), or currently on (or within three months of ceasing) either PI or IMiD based therapy. An appropriate response was defined as a four-fold increase in antibody concentrations or an absolute value increase of >1.3 ug/mL. An optimal response was defined as an appropriate response in >75% of tested serotypes (>5 of the 7 tested serotypes).

Results: A total of 63 patients were vaccinated and had baseline serology, 51 follow-up serology samples were available for analysis. Median age was 67 (range 43-89), and 42 (67%) patients were male. Median ages did not differ between treatment groups. There was a significant difference between weekly dexamethasone dose (49mg *vs* 17.5mg *vs* 30.7mg, p<0.001), prior lines of therapy (0 *vs* 1.9 *vs* 0.89, p=0.002), paraprotein size (32 *vs* 5.5 *vs* 14.6g/L p<0.001) and level of residual gamma globulins (3 *vs* 5.4 *vs* 4.1g/L, p=0.003). Baseline pre-vaccination anti-Pneumococcal IgG antibody geometric mean concentrations (GMCs) were 0.12, 0.21, 0.16, 0.47, 0.20, 0.34 and 0.20 respectively for serotypes 4, 6B, 9V, 14, 18C, 19F and 23F. Post vaccination GMCs were 0.34, 0.61, 0.56, 2.25, 1.26, 1.05 and 0.55. One-way ANOVA demonstrated significant increases in antibody concentration (P<0.001) however with differences only seen with serotypes 14 and 18. 41 (80%) patients responded to at least one serotype. Median number of seroconverted serotypes was 3 (IQR=4). 18 (35%) had an optimal response to vaccination. There was one case of documented Pneumococcal infection following vaccination. Two-way ANOVA demonstrated a difference in response between serotypes (p<0.001) but not treatment group (p=0.36).

Summary/Conclusion: Baseline levels of pneumococcal immunity in this population are low. Although most patients are capable of seroconverting to at least one serotype, the rates of protective post-vaccination antibody concentrations remain low. Choice of therapy does not appear to influence seroconversion rates however this may be confounded by other clinical and disease related factors.

Background: Pomalidomide is a 2nd generation immunomodulatory drug that has been approved for the treatment of patients who progress after prior treatment with proteasome inhibitor and lenalidomide. Experience with pomalidomide in Asian patients is very limited to date.

Aims: We aim to study the efficacy and toxicity of Pd in Asian patients with relapse or refractory myeloma and if the additional of cyclophosphamide can elevate response in suboptimal responders to Pd.

Methods: We conducted a prospective Phase 2 trial of pomalidomide (4mg daily for 21 days every 4 weeks) plus dexamethasone (40mg once weekly) in myeloma patients who have relapsed after prior bortezomib and are refractory to lenalidomide Asia (NCT02158702). If there was less than a minimal response after three cycles of Pd, including progression within three cycles, cyclophosphamide 300mg/m^2 (day 1, 8, 15) can be added. This report presents data available up till the data cut-off date of 17 Jan 2018.

Results: One hundred and thirty patients have available base line information and safety data. At the cut-off date, 51% of the patients have either progressed or died. Cohort has typical disease characteristics of relapse MM. Median prior line of treatment is 3. 81% of patients experienced adverse events (AEs) of any grade (27% of episodes grade 3 or higher), with 67% of these episodes related to the study drugs. 71.5% of patients experienced serious AEs (SAEs) of any grade (72% of episodes grade 3 or higher), with 32% of these episodes related to the study drugs. Almost all grade 3 or higher events were related to cytopenias and infections. Only 1 patient experienced each of the following AEs: grade 3 peripheral neuropathy, venous thromboembolism or grade 3 renal impairment. 45 patients have died, 22 from disease progression, 10 from sepsis or pneumonia, and 4 from cardiac events.The median follow-up of the whole group is 9.2 months. The median progression free survival (PFS) (N=119) was 10.2 months. Those treated with only Pd (n=81) have a median PFS of 9.2 months. Patients on Pcd (n= 38) had a median PFS of 11.37 months. Achievement of a partial response (PR) or better was significantly associated with improved PFS. There was no significant difference in PFS by age, number of prior lines of treatment, or the presence of high-risk genetics. Overall median OS was 18.4 months. For those treated with Pd, the median OS was 18.4 months whereas it is not yet reached for those on Pcd. One hundred and two patients have data for response assessment. Fifty-three (52%) achieved a ≥PR response with 1 achieving CR and 1 stringent CR. The median duration of response was 11.7 months for those who had achieved a ≥PR. If minimal response was included, the response rates would be 87%. For those on Pd (N=64), 58% achieve ≥PR. Thirty-eight patients had cyclophosphamide added due to suboptimal response after three cycles of Pd, 16 (42%) of these achieve ≥PR. In these patients the median duration of response is 13.5 months.

Summary/Conclusion: This is the first prospective report of the efficacy and safety of Pd in Asian patients with RRMM. Our results compare favorably with previously published data from the US and Europe. In patients with suboptimal response, the addition of cyclophosphamide upgraded responses,

rendering survivals comparable to those Pd-responsive patients. A randomized Phase 3 study conducted by the AMN comparing Pcd to Pd has commenced enrolment recently.

PB2156

EVALUATION OF PULMONARY FUNCTION TESTS IN PATIENTS WITH MYELOMA REVEALS THAT PULMONARY ABNORMALITIES ARE COMMON AND ARE INDEPENDENTLY ASSOCIATED WITH WORSE OUTCOME

E. Kastritis*, D. Fotiou, G. Trakada, M. Gavriatopoulou, I. Panagiotidis, D.C. Ziogas, E. Eleutherakis-Papaiakovou, M. Roussou, M. Migkou, N. Kanellias, I. Ntanasis-Stathopoulos, L. Velentza, A. Kallianos, E. Terpos, M.A. Dimopoulos

Department of Clinical Therapeutics, National and Kapodistrian University of Athens, Athens, Greece

Background: Pre-existing pulmonary disease may affect the treatment choices, toxicity and the survival of patients with Multiple Myeloma (MM). However, data on the prognostic value of Pulmonary Function Tests (PFTs) in myeloma patients' outcome, at the time of initial assessment of newly-diagnosed patients, are scarce.
Aims: To evaluate the incidence and prognostics importance of lung function abnormalities in patients with symptomatic myeloma
Methods: We prospectively performed PFTs in 121 consecutive newly-diagnosed MM patients, before initiation of treatment and we evaluated possible associations of baseline lung function with their outcomes.

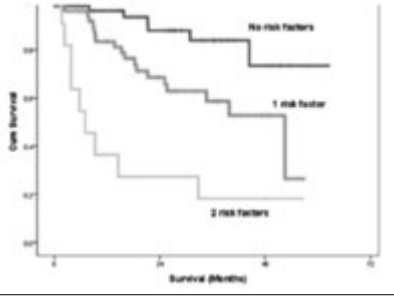

Figure 1.

Results: Pulmonary function evaluation with PFTs revealed that 54 patients (44.63%) had either obstructive or restrictive pulmonary function defects, even among patients that did not report a history of lung disease. The survival was significantly worse in patients with obstructive pulmonary defect (median OS: 32.8 months) *vs* those with restrictive (median OS: 52.5 months) or normal lung function (median not reached, 3-years survival 76%) (p=0.013). In the univariate analysis specific indices of lung function that were associated with survival included Forced Vital Capacity (FVC)(lt)(p=0.012), FVC(%)(p=0.006), Forced Expiratory Volume in 1 sec (FEV1)(lt)(p=0.018), FEV1(%)(p=0.013), Peak Expiratory Flow (PEF)(lt/min)(p=0.008), PEF(%)(p=0.005), carbon monoxide diffusion capacity corrected for hemoglobin (DL_{CO})(p=0.012), maximal expiratory (Pe)(kPa)(p=0.032) and Pe(%)(p=0.024) and inspiratory pressures (Pi)(kPa)(p=0.023) and Pi(%)(p=0.027). Other baseline factors associated with survival included ISS stage (p=0.008), hypercalcemia (p=0.064), and the presence of high risk cytogenetics (any of t(4;14), t(14;16) or del17p) (p=0.004). Abnormal PFTs were associated with early mortality (<1 year from initiation of therapy). Low PEF was strongly associated with early death (p<0.001); other indices included FVC (p=0.001), FEV1 (p=0.001) and DL_{CO} (p=0.005). Abnormal breathing pattern was also associated with early death, especially obstructive pattern (HR:8, 95%CI 2.1-30, p<0.001) and less restrictive (HR:2.2, 95%CI 0.9-9.7, p=0.068), compared to normal pattern. We identified that PEF <65% of predicted (33 months *vs* not reached at 3 years, HR:2.8, 95%CI 1.47-5.5, p=0.001) and a DL_{CO} <65% (median OS of 33 months *vs* not reached, HR:2.54, 95%CI 1.3-5.1, p=0.005) were associated with worse survival. There was a strong association of the two indices (p<0.001): 21% of patients had both, 19% only PEF <65%, 6% only DL_{CO} <65% and 53% none of the two. Multivariate analysis indicated that R-ISS-3 and the presence of either or both PEF(%)<65% and DL_{CO}<65% of predicted were the strongest prognostic factors for survival. Thus, we formulated a prognostic score encompassing myeloma-related and myeloma-independent factors that discriminates 3 groups with different survival: 3 year survival was 85% and 59% for patients with none or either of the risk factors and 18% (median survival of 7 months) if they had both (p<0.001) (see figure). Importantly, the prognostic significance of this score was independent of the age of the patients.
Summary/Conclusion: We conclude that PEF and DL_{CO} could be useful in the initial assessment of newly-diagnosed MM patients as significant predictors of survival. Respiratory screening should be included in the routine initial evaluation of myeloma patients, despite the presence or absence of respiratory symptoms or abnormal clinical respiratory examination.

PB2157

EARLY PARAPROTEIN REDUCTION AND RESPONSE TO FIRST-LINE TREATMENT IN MULTIPLE MYELOMA

M. Binder*, S.V. Rajkumar, M.Q. Lacy, M.A. Gertz, F.K. Buadi, A. Dispenzieri, Y.L. Hwa, A. Fonder, M. Hobbs, S.R. Hayman, S.R. Zeldenrust, J.A. Lust, S.J. Russell, N. Leung, P. Kapoor, R.S. Go, W.I. Gonsalves, T. Kourelis, R. Warsame, R.A. Kyle, S.K. Kumar

Division of Hematology, Mayo Clinic, Rochester, United States

Background: The introduction of novel agents including immunomodulators and proteasome inhibitors has led to an improvement in response rates and survival outcomes in patients with newly diagnosed multiple myeloma. Despite these therapeutic advances a subset of patients do not respond to first-line treatment and biomarkers are needed to identify those at risk.
Aims: To evaluate whether early paraprotein reassessments can predict response to first-line treatment and identify patients at risk for treatment failure.
Methods: We studied 419 patients with newly diagnosed multiple myeloma who were treated in routine clinical practice (n=225, training cohort) or on prospective clinical trial protocols (n=194, validation cohort) between 12/2003 and 12/2015 at Mayo Clinic. All patients had serum M-spike and free light chain (FLC) measurements performed before and after the first treatment cycle. Response to first-line treatment was evaluated using the International Myeloma Working Group Uniform Response Criteria. The biomarkers of interest were the relative decrease in M-spike and absolute FLC difference (ΔFLC). The measurements were standardized to a 28-day interval (divided by the number of days between reassessments and multiplied by 28). Three milestones were defined: Achieving neither a 25% reduction in M-spike nor a 25% reduction in ΔFLC within one treatment cycle (M0), achieving a 25% or greater reduction in at least one of the two biomarkers (M1), and achieving a 25% or greater reduction in both biomarkers (M2). Receiver operator characteristics (ROC) analysis was performed to determine the performance characteristics of these milestones in regards to predicting the best response to first-line treatment.

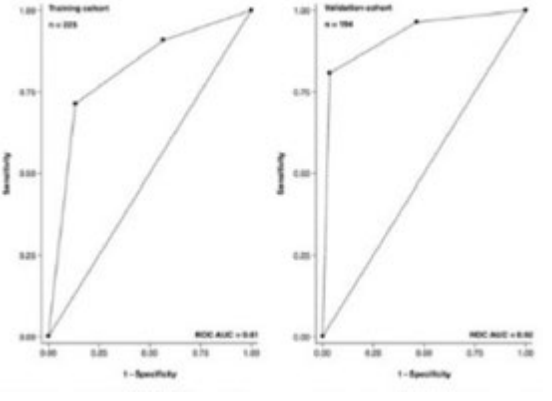

Figure 1.

Results: The median age at diagnosis in the training and the validation cohort was 66 (32-94) and 66 years (38-85), respectively. One hundred forty-nine (61%) and 103 patients (53%) were male, respectively. The three most common regimens in the training cohort were lenalidomide + dexamethasone, bortezomib + cyclophosphamide + dexamethasone, and bortezomib + lenalidomide + dexamethasone. The three most common regimens in the validation cohort were carfilzomib + thalidomide + cyclophosphamide, lenalidomide + cyclophosphamide + dexamethasone, and ixazomib + cyclophosphamide + dexamethasone. One hundred ninety-five patients in the training (87%) and 166 patients in the validation cohort (86%) achieved a partial response or better to first-line treatment (PR+). One hundred thirty-nine of the 143 patients (97%) in the training cohort and 134 of the 135 patients (99%) in validation cohort who reached M2

achieved PR+ later on. Thirty-eight of the 51 patients (75%) and 26 of the 38 patients (68%) who reached M1 achieved PR+ later on. Eighteen of the 31 patients (58%) and 6 of the 21 patients (29%) who reached M0 achieved PR+ later on. The ROC curves for the milestones in regards to achieving PR+ are shown in **Figure 1**. Reaching M2 was fairly sensitive (71%, 95% CI 64-78 and 81%, 95% CI 74-86) and highly specific (87%, 95% CI 69-96 and 96%, 95% CI 82-100) for achieving PR+, translating into a high positive predictive value (97%, 95% CI 93-99 and 99%, 95% CI 96-100).
Summary/Conclusion: Patients with newly diagnosed multiple myeloma treated in routine clinical practice and on clinical trial protocols were highly likely to respond to treatment if they experienced at least a 25% decrease in serum M-spike and ΔFLC during the first treatment cycle. Biomarker reassessment after the first treatment cycle may help to identify patients at risk for treatment failure early on.

Inst. Hematol. Infectol., Budapest, Hungary, [11]Dana-Farber Cancer Institute at St. Elisabeth`s, Boston, MA, [12]Division of Hematology, Mayo Clinic, Rochester, MN, United States

Background: IgE multiple myeloma (MM) is an uncommon hematologic malignancy, which represents <0.01% of all diagnosed MM cases. In the current literature, there are only several dozen cases described. The clinical features and treatment outcomes of IgE MM patients have not been compared to other MM isotypes.
Aims: To describe the clinical characteristics and outcomes of patients with IgE MM.
Methods: We completed a retrospective chart review using a standardized protocol from 50 clinical centers specializing in MM management and treatment. We describe the clinical presentation, diagnostic results, management and treatment outcomes of patients with IgE MM. Clinical and pathological features are presented using descriptive statistics. Response was assessed using IMWG criteria. Overall survival was estimated using the Kaplan-Meier method.

Table 1.

Patients' characteristics at diagnosis

Characteristic		n/n$_{miss}$	
Age	median (range), years	18/0	60 (35 - 85)
Gender	male, n (%)	18/0	9 (50%)
Serum IgE	median (range), IU/ml	10/8	2 158 (810 – 50 000)
Hemoglobin	median (range), g/dl	16/2	11 (8 - 14)
Glomerular filtration rate	median (range), ml/min	9/9	45 (9 – 99)
Serum calcium	median (range), g/dl	15/1	10 (9 – 12)
Albumin	median (range), g/dl	16/2	3.6 (2.6 – 4.9)
β2 microglobulin	median (range), g/dl	12/6	3.2 (1.7 – 17.8)
ISS I	n (%)	10/8	8 (80%)
ISS II			1 (10%)
ISS III			1 (10%)
Bone lesions present	n (%)	12/6	10 (83%)

n/n$_{miss}$ – number of patients with data available/missing

Results: We report data on 18 patients with IgE MM diagnosed between 1982 and 2016 from 9 centers from Hungary, Italy, Israel, Poland and the United States. The table summarizes patient characteristics at diagnosis. The most common symptoms reported were available in 14 patients, and included bone pain (n=12, 86%), constitutional symptoms (n=5, 36%), anemia (n=3, 21%), renal failure and paresthesia (n=1 each). Flow cytometry data were available in only 6 patients. CD38 and CD138 expression was positive while CD20 expression was negative in all patients. CD56 expression was positive in 3 patients (50%). Cytogenetic testing was available in 10 patients: 2 (20%) with t(11;14), 2 (20%) with del13q, 2 (20%) with del17p, and 1 (10%) with t(4;14). First line treatment included the following: 6 (38%) received an immunomodulatory drug, 10 (63%) received a proteasome inhibitor, 11 (69%) received conventional chemotherapy, and 7 (44%) subsequently underwent autologous stem cell transplantation. Response to first line treatment was available in 10 patients: 4 (40%) complete response, 3 (30%) very good partial response and 3 (30%) partial response, for an overall response rate of 100%. At a median follow-up of 8.1 years, the 5-year and 10-year overall survival (OS) rates were 63% (95% CI: 35 - 82%) and 54% (95% CI: 26 - 76%), respectively. The median OS was not reached. The cause of death was known in 3 patients and included disease progression, amyloidosis and secondary plasma cell leukemia.
Summary/Conclusion: The present case series is the largest reported to date of this rare type of MM. The clinical, pathological features and responses of patients with IgE MM appear similar to other isotypes. The OS time was longer than previously reported in this small series. However, it should be noted that most previously published cases came pre-date the availability of novel agents. Most of the patients reported in this study were exposed to novel agents, which could have impacted on the longer survival observed here.

PB2159

GOOD OUTCOMES USING ACTIVE TREATMENT WITH NOVEL AGENTS IN ELDERLY MYELOMA PATIENTS

N. Ediriwickrama*, T. Oyebamiji, S. Munisamy, S. Bowcock

Haematology Department, King's College Hospital, London, United Kingdom

Background: Despite recent improved survival with the use of novel agents in myeloma, elderly patients have benefited less than younger patients. The median survival for patients age >75 in previous studies is 24-27 months and patients who were untreated survived only 2 months median. Our unit pursues an active policy of offering anti-myeloma treatment with novel agents to all patients regardless of age, performance status (PS) and comorbidity, provided some reversibility is likely. Treatment doses are reduced for those age >75 for the first 1-2 cycles and dosage subsequently escalated if tolerated. We audited the outcome.
Aims: This study aims at evaluating the outcome of the elderly myeloma cohort who were mainly treated with novel agents
Methods: All patients age ≥75 years with symptomatic myeloma presenting to a general hospital from January 2011-June 2017 were included. The following were collected: baseline demographics, ECOG PS, age-adjusted Charlson comorbidity index (aCCI), International Staging System (ISS). Data were analysed using SPSS 20 software and Kaplan-Meier survival curves plotted.

Table 1.

Key baseline characteristics for all 52 patients (above) Responses to treatment for 50 treated patients (below)				
Age median=79 (range 75-99) (N=52)	ISS stage II=31% ISS stage III=42% (N=45)		PS ≥2=56% PS 3+4=23% (N=45)	aCCI ≥5=64% (N=50)
Response rate to treatment in all patients who started 1st and 2nd line therapies				
	1st line treatment (n=50)	Overall response rate to 1st line (CR+VGPR+PR)	2nd line treatment (n=30)	Overall response rate to 2nd line (CR+VGPR+PR)
Complete response (CR)	9(19%)	72%	2(8%)	58%
Very good partial response (VGPR)	9(19%)		2(8%)	
Partial response (PR)	16(34%)		10(42%)	
Stable disease (SD)	8(17%)		8(33%)	
Progressive disease (PD)	5(11%)		2(8%)	
Died before response assessment	3		6	

Results: 52 patients were found age 75-99 (median 79 years) PS ≥2=56%, aCCI 3-8 (median 5), ISS 3=42%. 50 (96%) patients received therapy and only 2 patients were not treated (1 declined, 1 severe dementia). Of the 50 patients who received first line therapy, 49 were treated with novel agents (bortezomib based=36(72%), thalidomide based=12(24%), lenalidomide based=1(2%)) and 1(2%) with dexamethasone only. 72% achieved a partial response (PR) or better. 8 patients died during treatment (toxicity 1, disease

progression 4, unrelated causes 3). 30 patients received second line treatment and the mean time to commence second line treatment (from the commencement of first line treatment) was 16.3 months. All patients were treated with novel agents (43% proteasome inhibitor based, 30% thalidomide based, 26% lenalidomide based). 13 patients underwent third line treatment or more. At the data cut-off date 24/11/2017 62% (32) patients were still alive. The median overall survival (OS) for the cohort was 45.4 months (95% CI 37-57). Of the 20 patients who died during the study period, the majority (16, 80%) died of disease progression while only 2 died due to treatment related toxicity (the other 2 patients died of unrelated causes). The 3 patients with advanced dementia fared poorly and did not complete treatment. Mild dementia (6) was manageable with support.
Summary/Conclusion: Our OS for this group aged ≥75 is better than that reported from the Mayo clinic at 27 months. They reported a similar study from 1999-2008 where only 39% patients received novel agents. Our more recent cohort was treated almost exclusively with novel agents and this may have contributed to better OS. Our patients were a poor prognosis group in view of their age, PS, ISS and aCCI. Treatment was therefore dose reduced from the start and this may have contributed to the small number of toxic deaths (2) and the overall tolerability of treatment with few discontinuations. Despite the dose reductions, patients gained useful responses and OS was encouraging. Although significant numbers of patients had poor prognostic factors (PS, aCCI, ISS stage) in this group, we have shown that the majority of patients tolerated treatment and had a positive response. We observed more than double the OS in our cohort compared to those published in the literature (45.4 months *vs* 22 months). In conclusion, an active treatment strategy regardless of age and comorbidity can benefit elderly patients.

PB2160

MONTELUKAST COMBINED WITH THE LIPID LOWERING DRUG GEMFIBROZIL REVERSES RESISTANCE TO COMBINATION CHEMOTHERAPY IN PATIENTS WITH MULTIPLE MYELOMA RESULTS OF PROSPECTIVE PHASE 1/2 CLINICAL TRIAL

S. O'Mara[1,2,3,*]

[1]New England Northwest Haematology, [2]Tamara Hospital, [3]Haematology, Laverty Pathology, Tamworth, Australia

Background: The asthma drug Montelukast has been shown to have many inhibitory physiological effects at an *in vitro* level that could be used to inhibit malignant processes. There is also no known maximal tolerated dose of this drug. It was thus proposed that that montelukast could be repurposed for use in malignancy. A solitary patient who had rapidly progressive lambda light chain myeloma while on Thalidomide based combination chemotherapy was treated with Montelukast in addition to Bortezomib based chemotherapy. This patient achieved a strict Complete response measured at 12 weeks despite the dire prognosis. A small phase 1 /2 longnitudinal cross over clinical trial was conducted in relapsed and refractory multiple myeloma patients to determine whether this benefit was due to montelukast and to establish whether the treatment is safe.
Aims: To determine whether montelukast combined with bortezomib based therapy is safe.To determine whether montelukast would reverse resistance to chemotherapy in high risk relapsed/refractory/resistant multiple myeloma patients.
Methods: Subjects had previously received a median of five treatments including stem cell transplant. Three of the patients had lambda light chain myeloma. The patients would have been excluded from clinical trials based on refractoriness. Patients were given CyBorD chemotherapy on a 4 week cycle. They received a minimum of two cycles. Paraproteins were measured at the end of each four week cycle. If there had been an increase in the paraprotein from the previous treatment cycle montelukast and gemfibrozil was added to their drug regimen. Five of the six patients had enough measurements and were eligible for review. The paraprotein levels were again measured following each 4 week cycle following montelukast administration. The patients were seen weekly to determine toxicity. The response in paraprotein was compared using a paired t-test as each patient acted as their own control.
Results: The patients had a median of five previous forms of therapy for myeloma including stem cell transplant. The increase in paraprotein on CyBorD was statically significant prior to the addition of montelukast. Three patients received two cycles of montelukast/ CyBorD. Two patients received a solitary cycle. There was no toxicity up to a dose level of montelukast 60mg a day, Gemfibrozil 600mg per day. Addition of these two agents lead to an improvement in the response to combination chemotherapy in all five patients. p<0.01 Student's T test. Four of the five patients achieved a partial response including a VGPR following the addition of montelukast and gemfibrozil. The other had a partial response in bone marrow alone. The five patients are alive at a median of 15 months post treatment despite having highly advanced and refractory disease. Median progression free survival has not been reached and is over 8 months.
Summary/Conclusion: The addition of montelukast and gemfibrozil to standard chemotherapy leads to deeper responses in multiple myeloma patients resistant/refractory to chemotherapy including patients that have progressed following stem cell transplant. The treatment appears extremely effective, is safe and has few to no side effects.

PB2161

AUTOLOGOUS TRANSPLANTATION WITH REDUCED PRE-TRANSPLANT CONDITIONING IN PATIENTS WITH MULTIPLE MYELOMA AT A HIGHER AGE - TOXICITY VERSUS EFFICACY

A. Jungova[1,*], E. Havlova[2], T. Zabranska[1], D. Lysak[1], P. Jindra[1]

[1]Hemato-oncology department, [2]Institute of Biochemistry and Hematolog, Charles University Hospital Pilsen, Pilsen, Czech Republic

Background: Multiple myeloma (MM) is a relatively usual hemato-oncological disease the incidence of which has been increasing. Despite a significant progress in drug development, autologous transplantation (Tx) of peripheral hematopoietic stem cells remains the fundamental pillar of the treatment. The standard administration consists in a dose of melphalan 200mg/m^2, and this regimen is preferably used with younger patients due to the toxicity risk of the preparation regimen. The dose of melphalan can be reduced to 100-180mg/m^2 in older patients depending on the overall patient's condition.
Aims: The objective of our work was to compare the length of hospitalization, event. infection and GIT complications and also the influence on PFS and OS in a group divided by age.
Methods: Retrospective analysis in 179 patients with MM transplanted consecutively in the Department of Hematology and Oncology, University Hospital in Pilsen, between 2013-2017. The data evaluation was performed after the first Tx. In all patients, melphalan was only administered as a part of conditioning.

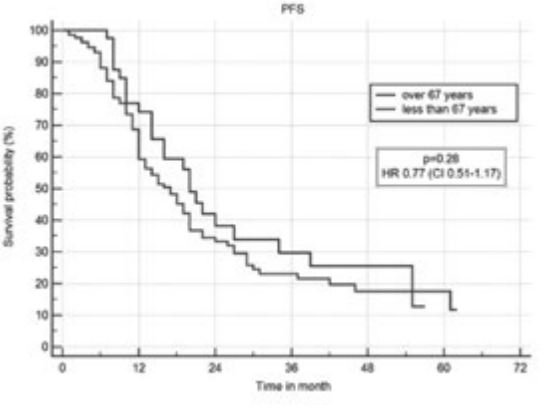

Figure 1.

Results: The group of 179 patients was divided by age. In the group of patients >67 years of age, there were a total of 47 patients with median age 70 (67-75), while the group of patients <67 years of age at the time of Tx (B) was represented by 133 patients with median age 59 (41-66). Besides age, there was no statistical difference between the basic parameters. In group A, the average dose of melphalan was 154mg/m^2, in group B, it was 188mg/m^2. The total hospitalization time showed median of 15 days (14-28) in group A and 16 days (13-63) in group B. The engraftment was the same in both groups. Gastrointestinal toxicity was completely comparable in both groups, the median showed grade I (0-IV), in group A, there was no more serious complication than grade III, in group B there was grade III+IV just in 2%. Infective complications in group A were relatively rare, the median was grade 0 (0-II) with no occurrence of more serious infective complications, in group B, just 1% of very serious infections (gr. III+IV), median of grade I (0-IV). Our analysis did not even show any apparent influence of the lower dose of melphalan on PFS or OS. Median PFS in group A was 20 months and 15 months in group B (p=0.28, HR 0.77, CI 0.51-1.17). Median OS in group A was not reached and in group B, it was 40 months (p=0.23, HR 0.66, CI 0.36-1.22).

Summary/Conclusion: Autologous transplantation is an integral part of the treatment in patients having the diagnosis of multiple myeloma. So far, it has been standardly used in younger patients, however, our data show that even older patients may be transplant eligible and that it is possible to get the same results as in younger patients including PFS and OS while the toxicity risk remains the same. Take message home: Autologous Tx with a reduced dose in patients up to 70 years of age is more convenient than regimens based on 'new drugs'.

THE PROSPECTIVE INTERSECTORAL NATIONAL COHORT STUDY MYRIAM TO STUDY CHARACTERISTICS, TREATMENT AND OUTCOME OF PATIENTS WITH MULTIPLE MYELOMA IN GERMANY

W. Knauf[1,*], M. Engelhardt[2], C. Losem[3], J. Lipke[4], C. Kasper[5], L. Houet[6], C. Vannier[6], M. Jänicke[6], N. Marschner[7], T. Dechow[8], H. Einsele[9]

[1]Centrum für Hämatologie und Onkologie Bethanien, Frankfurt a.M., [2]Universitätsklinikum Freiburg, Freiburg i. Br., [3]MVZ für Onkologie und Hämatologie im Rhein-Kreis Neuss, Neuss, [4]Gemeinschaftspraxis für Hämatologie und Onkologie, Dortmund, [5]Onkologische Schwerpunktpraxis Hof - Medizinisches Versorgungszentrum, Hof, [6]iOMEDICO, [7]Praxis für interdisziplinäre Onkologie & Hämatologie, Freiburg i. Br., [8]Gemeinschaftspraxis für Hämatologie und Onkologie, Ravensburg, [9]Universitätsklinikum Würzburg, Würzburg, Germany

Background: In Germany, multiple myeloma (MM) represents the third most common hematologic malignancy and is still considered incurable with standard treatment regimens. Therapeutic options have markedly increased over the last decade and a number of new treatments that showed promising results in clinical trials may be approved in the near future. However, few so called "real world" data is available regarding the implementation of these new treatments into routine care and their impact on the prognosis of patients with MM treated outside of clinical trials.
Aims: The purpose of MYRIAM is to create a prospective, intersectoral, national, longitudinal, multicenter cohort study to document patient and disease characteristics, treatments, course of disease, including clinical and patient-reported outcomes and consent to perform translational research.
Methods: Between 2017 and 2021 about 2.000 patients with MM giving informed consent at the start of their first or second systemic treatment will be prospectively recruited in 150 different sites, including university hospitals, community hospitals and outpatient clinics (office-based practices) and will be followed until death or for a maximum of 5 years. Data will be collected in electronic case report forms with implemented completeness and plausibility checks, regularly examined by data managers and randomly monitored. Patient-reported outcomes will be assessed at the time of recruitment, every 3 months for the first 24 months and every 6 months thereafter, for a maximum of 5 years altogether using the EORTC-QLQ-C30+MY20 and the Brief Pain Inventory. Patients will be asked to give informed consent for future translational research of their unused tumor samples. Annual interim analysis will be performed. The study was approved by local ethics committees and is registered under clinicaltrials.gov (identifier: NCT03308474).
Results: The first patient was recruited in September 2017. At the time of abstract submission (February 2018), 138 patients had been recruited in 43 sites, and a further 63 sites had already agreed to participate. Data cut for the first planned interim analysis will be April 30th 2018. First results on patient and disease characteristics and initial treatments will be presented.
Summary/Conclusion: MYRIAM will for the first time present prospective, intersectoral, longitudinal data on patient characteristics, treatment and outcome of MM patients across all health care sectors in Germany. Data will shed light to the current state of care outside of clinical trails, allow identification of unmet medical needs that can be used to create recommendations to improve care, and will facilitate generation of hypothesis for clinical trials to improve current best practice.

PB2163

URINARY RETINAL BINDING PROTEIN IN UNTREATED SYSTEMIC IMMUNOGLOBULIN LIGHT CHAIN AMYLOIDOSIS AT BASELINE

T. Rezk[1,*], J. Gilbertson[1], S. Packer[2], R. Salota[3], H. Lachmann[1], S. Walsh[4], P. Hawkins[1], J. Gillmore[1]

[1]UCL Division of Medicine, National Amyloidosis Centre, London, [2]BBI Solutions, BBI, Kent, [3]Epsom and St Helier University Hospitals, Biochemistry Departement, Carshalton, [4]UCL Division of Medicine, Centre for Nephrology, London, United Kingdom

Background: Renal involvement causing progressive proteinuric chronic kidney disease is present in 70% of patients with systemic AL amyloidosis at diagnosis. Patient and renal survival are dependent upon both successful free light chain suppression and degree of renal dysfunction at the time of diagnosis[1]. Urinary excretion of retinal binding protein (RBP), an indicator of renal tubular injury, has been used in detecting early renal involvement in multiple myeloma[2,3] Free light chains (FLC) are known to be toxic to the proximal tubule which contributes to a range of pathologies including cast nephropathy and Fanconi's syndrome.[4] Furthermore, treatment with systemic chemotherapy (often proteasome inhibitor based) to suppress FLC production can be associated with acute kidney injury (AKI).
Aims: We hypothesized that a significant proportion of patients with newly diagnosed renal AL amyloidosis have proximal tubular dysfunction and sought to determine whether this may predict renal outcomes.
Methods: All patients (n=158) who attended the National Amyloidosis Centre (NAC) from September 2016 to October 2017 and were enrolled into 'ALchemy', the centre's prospective observational study for newly diagnosed patients with AL amyloidosis, underwent measurement of urinary RBP (uRBP) excretion in conjunction with routine clinical, biochemical and scintigraphy assessments.
Results: Median age was 69 yrs (44-90) with median serum creatinine of 89 umol/L and eGFR of 67 ml/min/1.73m^2. Median urinary protein creatinine ratio (uPCR) was 311 mg/mmol. Median uRBP was 285µg/L. There was a significant correlation between uRBP and serum creatinine (Pearson correlation p<0.0001, R 0.6440) and uRBP and uPCR (Pearson correlation p<0.0001, R 0.5247) with a weaker correlation with uACR (Pearson correlation p<0.0001, R 0.3039). Despite this however, a markedly elevated uRBP/Creatinine (>1000mg/mmol) was detected in 35 patients including 9 who had an eGFR >30ml/min/1.7m^2, and 8 who had uPCR <300mg/mmol and ACR <50mg/mmol. There was a strong correlation between altered fractional excretion of both phosphate and urate with uRBP (Pearson correlation, p<0.0001, R 0.6181).
Summary/Conclusion: Although there is a significant correlation between low molecular weight protein excretion indicating proximal tubular dysfunction with both serum creatinine and uPCR, there is a cohort of patients with both preserved renal excretory function and absence of significant proteinuria who have elevated uRBP excretion,. The association with fractional excretion of both phosphate and urate demonstrate that elevated uRBP excretion in patients with newly diagnosed untreated renal AL amyloidosis specifically indicates proximal tubular dysfunction. The analysis of whether uRBP predicts renal outcomes is underway and may be of relevance to other renal pathological lesions.

FIRST-LINE THERAPY WITH BENDAMUSTINE/PREDNISONE/BORTEZOMIB (BPV) FOR NON-TRANSPLANT ELIGIBLE SYMPTOMATIC MULTIPLE MYELOMA PATIENTS

W. Knauf[1,*], G. Dingeldein[2], R. Schlag[3], M. Welslau[4], C. Kunz[5], T. Moehler[6], C. Habermehl[5], H. Goldschmidt[7], M.S. Raab[7], T.G. BPV[1]

Background: Elderly patients with multiple myeloma (MM) frequently are ineligible for intensive therapies including autologous stem cell transplantation and require an individualized therapy.
Aims: This study investigated efficacy and safety of the 3-drug-combination bendamustine/prednisone/bortezomib (BPV regimen) as first-line therapy for elderly patients with multiple myeloma (MM).

Methods: Elderly patients with symptomatic MM not eligible for intensive therapy and autologous stem cell transplantation were enrolled in this phase IIb study for first-line treatment with the bendamustine/prednisone/bortezomib regimen. All 46 patients were included in the safety and intention-to-treat (ITT) analysis for the secondary objectives. 34 patients were eligible for the primary efficacy analysis of overall response rate (ORR) defined as CR and PR in the per protocol (PP) population, which consisted of all patients who completed at least 3 cycles of BPV therapy and were evaluable for response. For evidence of superiority compared to historical MPV (melphalan, prednisone, bortezomib) data we postulated the lower confidence boundary for the primary endpoint of ORR to be at least 67%. The study was conducted as a multicenter, single-arm, open-label clinical trial. The treatment regimen consisted of bendamustine 90mg/m^2 iv: d1, 2; prednisone 60mg/m^2 po: d1-4; bortezomib 1.3mg/m^2 iv: cycle 1 [d1-d42]): d1, 4, 8, 11, 22, 25, 29, 32; cycle 2-9 [d1-28]: d1, 8, 11, 22. Treatment was scheduled for 9 cycles with 42 d for cycle 1 and 28 d for cycle 2-9.
Results: From November 2014 to October 2016, 46 patients were included into the trial. Patients had the following key baseline characteristics: median age 76 years, female: 61%, median glomerulofiltration rate (GFR) of 64ml/min. The ORR was 76.5% with a lower 95% confidence bound of 62.7%. The clinical benefit rate (CBR) including MR was 91.2%. 19 patients with renal impairment at baseline had a median GFR of 42.6 ml/min [range 12.9-49.7]. A renal response (defined as improvement of renal function by IMWG criteria, Dimopoulos *et al.* J Clin Oncol 2010) was observed in 11 pts.. 6 pts. achieved a complete recovery of the renal function. The BPV regimen was well tolerated. 33 of 46 pts. (71.7%) experienced AEs of CTC grade 3 and 4. The most common grade 3/4 AEs were neutropenia (26%), infections (26%), and thrombocytopenia (19.5%). Pneumonia was documented in 4 patients. Cardiac grade 3 and 4 complications were atrial fibrillation (3 events) and hypertension (2 events). No new safety signals for the study drugs were observed. 46% of patients developed at least 1 SAE.
Summary/Conclusion: BPV may serve as a well tolerated first-line regimen for transplant ineligible elderly MM patients with an encouraging ORR of 76%. BPV can be also considered, if a fast renal response is required in patients with myeloma induced renal impairment. However, the study did not provide statistical evidence of superiority compared to historical MPV response data.

PB2165

LENALIDOMIDE MAINTENANCE CHEMOTHERAPY; AN ANALYSIS OF REAL WORLD SURVIVAL DATA IN MULTIPLE MYELOMA PATIENTS TREATED WITH AUTOLOGOUS STEM CELL TRANSPLANT AND BORTEZOMIB-BASED INDUCTION

H. Cherniawsky[1,*], I. Sandhu[2], M. Chu[2], J. Hewitt[2], I. Ismail[2], A. Belch[2], L. Pilarski[2], T. Nikitina[2], C. Venner[2]

[1]Internal Medicine, University of Alberta, [2]Cross Cancer Institute, Edmonton, Canada

Background: Multiple myeloma (MM) is an incurable plasma cell malignancy. The primary goal of therapy is to obtain a deep and durable response to improve disease control and survival. In the post-transplant setting, large phase 3 trials suggest daily low-dose lenalidomide has a positive impact on progression free survival (PFS) and overall survival (OS).
Aims: We sought to evaluate the impact of lenalidomide maintenance in a real world setting in patients treated with bortezomib based induction chemotherapy and autologous stem cell transplant (ASCT) at our centre.
Methods: We evaluated all patients with MM from the Cross Cancer Institute who received frontline bortezomib-based induction chemotherapy and ASCT between December 2004 and January 2016 to ensure a minimum of 2 years follow-up. Patients were analyzed as receiving or not receiving maintenance based on intention-to-treat. Maintenance therapy involved lenalidomide monotherapy or in combination with bortezomib, an option at our center for patients with high risk cytogenetics. OS was measured from treatment initiation to death or last follow-up. PFS was measured from treatment initiation to relapse, death or last follow-up. Maximal response to treatment was assessed according to the International Myeloma Working Group criteria with an additional endpoint of near complete response (nCR) where CR was not confirmed by immunofixation or bone marrow biopsy.
Results: 207 patients were included. 131 received lenalidomide based maintenance and 76 did not. Median ISS score was 2 in both groups (p=0.14). A mean of 28 cycles of lenalidomide (0.5-89) was given. 18% patients discontinued therapy prior to relapse. In the maintenance arm, 96% obtained a VGPR or greater compared to 76% in the no maintenance group (p<0.01). The median follow-up is 70 months in the non-maintenance cohort and 47 months in the maintenance cohort likely due to more recent adoption of lenalidomide use and therefore less time for follow-up in this cohort. The estimated 4-year OS was 87.1% in the maintenance group and 70.7% in the non-maintenance group (p<0.01, figure 1a). To date 105 patients have relapsed (47 in the maintenance and 58 in the non-maintenance cohort). The estimated 4-year PFS was 61.5% in the maintenance group and 34.6% in the non-maintenance group (p<0.01, figure 1b). The incidence of thromboembolism (TE) (3.1% *vs* 1.3% (p=0.43)) and second primary malignancies (SPMs) (2.3% *vs* 6.6% (p=0.12)) were low in the maintenance and non-maintenance groups respectively. 37.4% of patients in the maintenance group required dose adjustments. When first adopted, lenalidomide maintenance was given in a 28/28 day schedule and was pursued in 92 patients. Of these, 74.0% received all cycles at the intended dose. The current standard is a 21/28 day dosing schedule and was used in 38 patients. Of these, 77.6% received all cycles at the intended dose. In all, 18.3% of patients discontinued medication for reasons other than relapse.

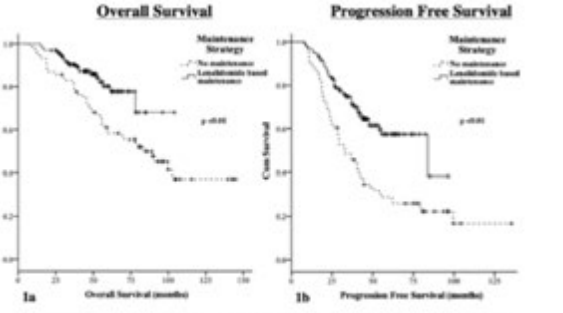

Figure 1. OS (1a), PFS (1b) in patients treated with and without lenalidomide based maintenance following bortezomib based induction and autologous stem cell transplant.

Figure 1.

Summary/Conclusion: Our data illustrates the positive impact of lenalidomide on depth of response, PFS and OS. Treatment was well tolerated with the majority of patients receiving the intended dose regimen. Few patients discontinued treatment prior to relapse. The rates of TEs and SPMs and consistent with previous reports. This data supports the ongoing use of lenalidomide maintenance in myeloma patients post-ASCT as a standard of care.

CARFILZOMIB AND DEXAMETHASONE VERSUS 8 CYCLES OF BORTEZOMIB AND DEXAMETHASONE: AN INDIRECT COMPARISON AND EXPLORATORY ANALYSIS OF THE EFFICACY AND SAFETY OF THE RANDOMIZED, PHASE 3 ENDEAVOR TRIAL

K. Weisel[1,*], I. Majer[2], L. DeCosta[3], A. Oriol[4], H. Goldschmidt[5], H. Ludwig[6], M. Campioni[2], Z. Szabo[7], M. Dimopoulos[8]

[1]Medical Clinic II, Department of. Hematology, Oncology, Immunology, Rheumatology and Pulmonology, Tuebingen, Germany, [2]Global Health Economics, Amgen (Europe) GmbH, Zug, Switzerland, [3]Global Biostatistical Science, Amgen Ltd., Uxbridge, United Kingdom, [4]Institut Català d'Oncologia, Institut Josep Carreras, Hospital Germans Trias i Pujol, Barcelona, Spain, [5]Department of Internal Medicine V, University Hospital Heidelberg, and National Center for Tumor Diseases (NCT), Heidelberg, Germany, [6]Wilhelminen Cancer Research Institute, Wilhelminenspital, Vienna, Austria, [7]Amgen (Europe) GmbH, Zug, Switzerland, [8]School of Medicine, National and Kapodistrian University of Athens, Athens, Greece

Background: In patients with relapsed and/or refractory multiple myeloma, carfilzomib and dexamethasone (Kd56) was superior to bortezomib and dexamethasone (Vd) in the randomized, phase 3 ENDEAVOR trial for progression-free survival (PFS) (hazard ratio [HR] 0.53; 95% confidence interval [CI] 0.44–0.65; P<0.0001). In ENDEAVOR, both Kd56 and Vd were planned to be administered until disease progression, while in other clinical trials, e.g., the randomized, phase 3 CASTOR trial comparing Vd with or without daratumumab, Vd was administered for up to 8 cycles (6 months) according to its EU label.
Aims: To estimate how efficacy and safety results for Kd56 *vs* Vd would have differed if Vd had been given for up to 8 cycles only.
Methods: For the efficacy analysis, published PFS data from the ENDEAVOR (Dimopoulos *et al.*, *Lancet Oncol* 2017) and CASTOR (Spencer *et al.*, ASH 2017) trials were used in three steps. First, ENDEAVOR Vd patients were matched to average characteristics of CASTOR Vd patients using matching-adjusted indirect comparison methodology. Then, a piecewise Cox regression model was fitted to the matched ENDEAVOR Vd data and

re-constructed virtual patient-level CASTOR Vd data that allowed assessing the increased PFS risk due to stopping Vd treatment after 8 cycles *vs* continuing Vd treatment beyond 8 cycles till progression. Finally, the PFS HR for Kd56 *vs* Vd from ENDEAVOR was adjusted according to the increased PFS risk for the period beyond 8 cycles. The presented modeling approach has been previously accepted by the National Institute for Health and Care Excellence in the UK (Technology Appraisal Guidance TA457, 2017). For the safety analyses, using most recent data on file, only adverse events (AEs) that occurred during the first 8 cycles plus 30 days of follow-up after the last dose were considered for patients in the Vd arm of the ENDEAVOR trial. Besides the incidence of treatment-emergent adverse events (TEAEs) of grade 3 or more (Gr3+) for Vd 8 cycles, Kd56/Vd 8 cycles exposure-adjusted risk ratios were estimated for Gr3+ TEAEs.

Results: During the first 8 cycles, the risk reduction in PFS for Kd56 *vs* Vd 8 cycles was equal to that estimated for Kd56 *vs* Vd in ENDEAVOR. For Vd patients, the increase in PFS risk associated with stopping Vd beyond 8 cycles was estimated to be 32% (HR: 1.32, 95% CI 0.89-1.96, P=0.17). This corresponds to a 60% risk reduction in PFS for Kd56 *vs* Vd (HR: 0.40; 95% CI 0.26-0.63; P<0.0001) beyond 8 cycles (Figure). The frequency of Gr3+ TEAEs was 81.9% for Kd56, 71.1% for Vd, and was estimated to be 64.5% for Vd 8 cycles. Incidence of Gr3+ peripheral neuropathy was 2.4%, 9.6%, and 8.6% for Kd56, Vd, and Vd 8 cycles, respectively. The exposure-adjusted risk ratios of Kd56 *vs* Vd 8 cycles were estimated to be 0.61 (95% CI 0.53-0.71) for all Gr3+ TEAEs and 0.08 (95% CI 0.04-0.17) for Gr3+ peripheral neuropathy.

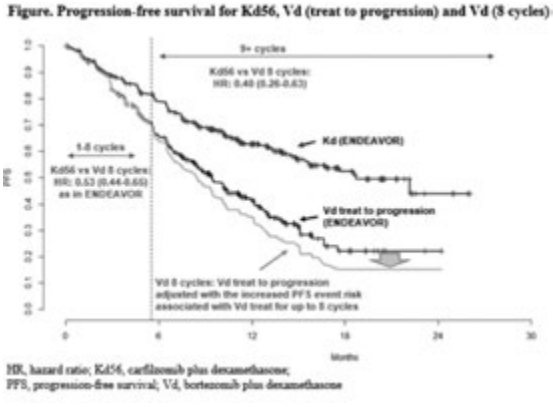

Figure 1.

Summary/Conclusion: Results from the matched-efficacy analysis indicated that the duration of Vd treatment has a significant impact. If Vd had been given for 8 cycles, the relative decrease in PFS risk with Kd56 would have been larger than that observed in ENDEAVOR where Vd treatment was continued beyond 8 cycles till progression. The approach used in this study adjusts for differences in trial design such as Vd treatment duration, allows to reduce bias, and is a robust methodology. In contrast, indirect treatment comparisons including network meta-analyses that do not adjust for differences in trial design and/or patient populations are susceptible to greater bias.

PB2167

MYC REARRANGEMENT IN COHORT OF NEWLY DIAGNOSED SLOVENIAN MM PATIENTS

H. Podgornik*, N. Zima, J. Nussdorfer, H. Čibej, A. Doplihar Kebe, S. Zver

Department of Haematology, University Medical Centre, Ljubljana, Slovenia

Background: *MYC* rearrangements (*MYC*r) are late progression events in multiple myeloma (MM). Reported frequency differs considerably among studies ranging from 15% and up to 50% of MM patients. Increased *c-MYC* expression was found to be involved in MM progression, is associated with it's aggressive nature, short remissions and overall survival.

Aims: We determined the frequency and type of *MYCr* in newly diagnosed MM patients in Slovenija and analysed correlation with concomitant cytogenetic aberrations as well as with some clinical parameters.

Methods: 69 patients were included, aged 45 to 93 (median 68) years. Observation time was 0-8.3 years with (median 1.1 year). *MYC* was analysed in all but one patient before the induction MM treatment. *MYC* rearrangement was determined on CD-138 isolated plasma cells by FISH which was also used to detect other MM specific cytogenetic abnormalities: del(13q), del(17p), *IGH* rearrangements, amp(1q), del(1p), and hyperdiploidy. Poseidon DNA probe MYC TC with established cut-off value 2.5% was used not only to detect *MYC*r but trough the co-localization patterns of signals also to distinguish different breakpoints in *MYC* gene. Differences between categorical variables were determined by Fisher's exact test using Medcalc software.

Results: *MYCr* was found in 17% (12/69) of patients. The clone size ranged from 5 - 99% of plasma cells. We observed all three breakpoints: distal and proximal to *MYC* gene and in the *MYC* gene. Dominant breakage variant in 7/12 pts was distal. The later was commonly observed as a sole subtype as well as a prevailing clone. Besides typical signals also proximal and distal breakage accompanied by deletion of the corresponding chromosomal region was observed. Considering other routinely determined chromosomal rearrangements, *MYC* was more frequently rearranged in patients with del(13q) (P=0.004), amp(1q) (P=0.035), and hyperdiploidy (P=0.012). *MYCr* was found in 2/12 patients as a sole abnormality. MYCr was accompanied with secondary cytogenetic changes In 9/10 patients and only in 1/10 patients with primary change (hyperdiploidy). The difference between groups was significant (P=0.0011). When we focused on cytogenetic risk groups 25% (7/28) of patients in high risk group was MYC positive, while only 19% (4/21) and 6% (1/17) of patients were positive in standard and low risk group respectively. Difference among groups was however, not statistically significant. For 52 patients clinical data were available. We couldn't find difference between *MYC* positive and negative groups for ISS score and due to the short observation time neither for non-responsiveness to induction MM treatment and survival.

Summary/Conclusion: The observed frequency of *MYCr* in our cohort of almost exclusively newly diagnosed MM patients is consistent with previous literature reports. We observed strong correlation between *MYCr* and secondary chromosomal aberrations as well as with overall high risk cytogenetic group. This confirms not only that *MYCr* itself is a secondary genetic event but also the need for its early recognition and more effective/specific therapeutic approaches in *MYCr* patients. The short observation time is a limitation of the current analysis but will enable us to obtain valuable data in the future work. Namely, majority of MM patients were treated with the same therapeutic regimen.

PB2168

SUPERVISED AND HOME-BASED EXERCISE IN PATIENTS NEWLY DIAGNOSED WITH MULTIPLE MYELOMA – A RANDOMIZED CONTROLLED FEASIBILITY STUDY

R.F. Larsen[1,*], M. Jarden[2], L.R. Minet[3], U.C. Frølund[4], N. Abildgaard[5]

[1]Department of physiotherapy and occupational theray, Zealand University Hospital, Roskilde, [2]Department of Hematology Finsen Center, Copenhagen University Hospital Rigshospitalet, Copenhagen, [3]Department of Rehabilitation, Odense University Hospital, Odense, [4]Department of Hematology, Zealand University Hospital, Roskilde, [5]Department of Hematology, Odense University Hospital, Odense, Denmark

Background: Exercise is considered to be feasible, safe and beneficial for patients with haematological cancer. However, patients with Multiple Myeloma (MM) are not only underrepresented in exercise studies (3 RCT, 1 pilot), the studies also primarily include younger patients with MM prior to, undergoing and after autologous stem cell transplantation. Due to the bone disease in MM, exercise can be challenging. Our ongoing RCT examines the effect of an individualized, early initiated exercise intervention (EI) in newly diagnosed patients with MM, irrespective of age.

Aims: The aim of the present study is to report the interim analysis of feasibility and safety of the EI.

Methods: This is a two-center RCT with blinded outcome assessors. Informed consent is obtained. Exclusion criteria include radiology assessed risk of fractures according to scoring system. Baseline tests are carried out within 4 days after starting anti-myeloma treatment, followed by randomization to control group (CG) or intervention group (IG). Randomization is stratified according to planned treatment (high dose chemotherapy with autologous stem cell transplantation or non-intensive treatment), WHO performance status (0-1 or ≥2) and study site. The EI starts within one week and is a 10-week supervised and home-based exercise program comprising aerobic and strengthening exercises and physical activity in accordance with international guidelines. Both groups (CG and IG) receive written information about physical activity and transfer techniques (usual care). Main objectives are muscle strength (knee extensor strength and grip strength), physical function (6 minutes walk test and 30 seconds sit to stand test) and physical activity (monitored by use of ActivPal 3 micro). Feasibility outcome measures were eligibility, acceptance and drop-out rates. Further, adherence, tolerability and safety (adverse events (AEs)) of the supervised exercise sessions (SES) were obtained.

Results: Of 49 patients screened, 40 (82%) were eligible for inclusion; 30 (75%) accepted participation and were randomized (IG n=17, CG n=13). The participants (n=30) age in years (median (range)) was 69 (38-90). Of the 17 IG participants, 14 (82%) started intervention. Withdrawals prior to start of EI (n=3) was caused by no surplus energy (n=1), wish for treatment closer to home (n=1), and sudden impairment (n=1). Two withdrew during the EI period due to stroke (n=1) and because exercise was found too hard (n=1). One CG participant dropped out after receiving usual care because of no surplus energy. In the total period from baseline to end of the intervention 12 participants (71%) completed the intervention, and in the total period five IG participants dropped out (29%). Of those starting EI (n=14) the adherence to SES was 94%, and the tolerability was 98%; two patients discontinued one SES each due to non-serious AEs (symptoms of pain, and dyspnea and dizziness). No serious AEs were reported, and importantly, no patients had pathological fractures during the EI.
Summary/Conclusion: Early initiated exercise in newly diagnosed patients with MM, regardless of age and intensity of anti-myeloma treatment, is feasible, safe and tolerable. Early initiated exercise may be important in preventing physical decline during treatment for MM.

Background: Whole body MRI is emerging as the most sensitive imaging technique for patients with multiple myeloma (MM) and as such is recommended by the IMWG for all patients with an apparent diagnosis of asymptomatic myeloma. In the UK whole body MRI is first line imaging for all patients with a suspected diagnosis of myeloma, follow up, response assessments and restaging at relapse. MRI is also the most sensitive imaging test for detection of avascular necrosis (AVN) of the femoral heads, a complication of corticosteroid use in MM patients.
Aims: To assess the prevalence and outcome of MM patients with features of AVN on whole body MRI.
Methods: We conducted a retrospective analysis of all whole body MRIs between1st January 2010 to 1st May 2017 for MM patients at the Royal Marsden Hospital. All scans were reported by consultant radiologists with a special interest in myeloma for whom review for skeletal complications of myeloma is routine practice. These radiological reports were searched for the following terms "AVN" and "avascular necrosis". Images of the patients with AVN were interrogated and correlating clinical information documented.
Results: Out of 650 whole body MRI scans performed in 226 patients, 15 patients (6.6%)(10 male, 5 female, median age 66.5 years [range 31-74]) were identified to have typical MRI features of AVN which included subchondral serpiginous lines and oedema. 2/15 had femoral head collapse and 4/15 had bilateral AVN. 10/15 patients had active disease according to IMWG criteria and 8/15 were being treated with steroid-combination regimens. Indications for scanning included disease assessment post-induction therapy (6/15), biochemical progression (5/15) and bony pains at other sites (1/15). Only 3/15 (20%) patients had reported hip/pelvic pain at the time of AVN detection. Patients with AVN had received a median cumulative dexamethasone dose of 540mg (range 80-5040mg), while 3/15 patients had had prior femoral radiotherapy. None of the patients had known diabetes. All patients were receiving bisphosphonates on a monthly to 2-monthly basis. During surveillance, 8/15 patients had scans demonstrating progressive AVN, including worsening femoral head oedema and increasing effusions. Of these, 4/8 reported worsening symptoms in the affected hip(s) and subsequently required surgical intervention with total hip replacements. All other patients were managed conservatively and are continuing to be reviewed by the orthopaedic team.
Summary/Conclusion: In keeping with previous published data which has shown a 9% incidence of AVN, the incidence of AVN in MM patients imaged with routine whole body MRI was low (6.6%). However we have shown that asymptomatic AVN can be detected early on whole body MRI before femoral head collapse. Early orthopaedic referral provides an opportunity for interventions to preserve the joint before femoral head collapse and the requirement for total hip replacement. Additionally, when early signs of AVN are identified, rapid de-escalation of steroid dosing should be considered once the patient's myeloma is well controlled. We recommend that whole body MRI scans in patients with MM should always be interrogated for early signs of AVN.

PB2170

ASSOCIATION OF CLINICAL RESPONSE WITH SURVIVAL AND QUALITY OF LIFE (QOL) AFTER CARFILZOMIB AND DEXAMETHASONE (KD56) TREATMENT IN THE PHASE 3 ENDEAVOR TRIAL

D. Siegel[1,*], H. Ludwig[2], P. Moreau[3], M.-V. Mateos[4], R. Niesvizky[5], W.J. Chng[6], K. Mezzi[7], Z. Yang[7], S. Panjabi[7], M. Dimopoulos[8]

[1]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, United States, [2]Wilhelminen Cancer Research Institute, Wilhelminenspital, Vienna, Austria, [3]University Hospital Hotel-Dieu, Nantes, France, [4]Hematology Service, University Hospital Salamanca, Salamanca, Spain, [5]Center for Myeloma, New York Presbyterian Hospital-Weill Cornell Medical Center, New York, United States, [6]National University of Singapore, Singapore, Singapore, [7]Amgen Inc., Thousand Oaks, United States, [8]University Athens School of Medicine, Athens, Greece

Background: ENDEAVOR demonstrated superior response rates, depth of response, PFS, and OS with Kd56 *vs* Vd (bortezomib-dexamethasone).
Aims: Here, we assessed post-hoc the association between response and clinical outcomes/QoL.
Methods: PFS and OS were assessed for responders (≥partial response [PR]) *vs* non-responders (<PR; a 2-mo Simon-Makuch landmark analysis was conducted; Kaplan-Meier [KM] estimates conditioned at the landmark) and by response status (KM estimates; medians not adjusted for responder bias). QoL was assessed by the EORTC Global Health Status/QoL (GHS/QoL) subscale with higher scores indicating better QoL. Changes from baseline in GHS/QoL scores by response status were explored using mixed models for repeated measures. PFS and OS were assessed for responders (≥partial response [PR]) *vs* non-responders (<PR; a 2-mo Simon-Makuchlandmark analysis was conducted; Kaplan-Meier [KM] estimates conditioned at the landmark) and by response status (KM estimates;medians not adjusted for responder bias). QoL was assessed by the EORTC Global Health Status/QoL (GHS/QoL) subscale withhigher scores indicating better QoL. Changes from baseline in GHS/QoL scores by response status were explored using mixed modelsfor repeated measures.
Results: In the Kd56 arm, 77% of patients (pts) had a response: 13% ≥complete response (CR), 42% very good partial response (VGPR), and 22% PR. In pts at risk at the 2-mo landmark, median PFS beyond the landmark was not estimable (NE; 95% CI: 20.2, NE) in responders *vs* 10.9 mos (95% CI: 7.6, NE) in non-responders. Median OS beyond the landmark was 49.3 mos (95% CI: 45.6, NE) in responders *vs* 25.8 mos (95% CI: 19.8, 32.9) in non-responders. Simon-Makuch analysis indicated a significant difference in PFS and OS between responders and non-responders ($p<0.001$). For ≥CR, VGPR, or PR, median PFS (95% CI) was NE (NE, NE), 22.2 (18.7, NE), and 10.3 (8.8, 14.9) mos, respectively. Median OS (95% CI) was NE (NE, NE) for ≥CR, 51.3 (NE, NE) for VGPR, and 42.5 (33.6, 47.6) mos for PR. Kd56 responders had improved GHS/QoL scores *vs* Kd56 non-responders (difference in mean change [diff]: 7.22 [95% CI: −0.68, 15.12]). Among Kd56 responders, changes were similar by response depth (diff for ≥CR *vs* VGPR: 0.35; ≥CR *vs* PR: 1.59).
Summary/Conclusion: In the Kd56 arm, 77% of pts had a response and OS beyond the 2-mo landmark improved by 24 mos *vs* non-responders. Responders also had better GHS/QoL scores *vs* non-responders.

PB2171

EFFECT OF COMPOUND KUSHEN INJECTION ON IMMUNE FUNCTION FOR PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA UNDERGOING CHEMOTHERAPY

H. Tu[1,*], L. Zhang[2], L. Ding[1], Y. Jin[1], F. Zhou[1,3]

[1]Department of Hematology, Zhongnan Hospital of Wuhan University, Wuhan, [2]Department of Traditional Chinese medicine, Inspection test center of Xiaogan Food and Drug, Xiaogan, [3]Department of Hematology, Second Affiliated Hospital, Medical School of Xi'an Jiaotong University, Xi'an, China

Background: Therapy integrating traditional Chinese and Western medicine has been the most distinctive method for treating malignant tumors in China. As a representative of traditional Chinese medicine (TCM), compound Kushen injection (CKI, also known as Yanshu injection) is extracted from the Kushen (*Radix sophorae flavescentis*) and Baituling (*Rhizoma smilacis glabrae*) herbs, using modern standardized Good Manufacturing Processes (GMP). There have been numerous clinical reports demonstrating the anti-

cancer effect of CKI, including the use of CKI to treat gastric cancer, liver cancer, lung cancer, breast cancer, ovarian cancer, colorectal cancer and additional cancer types.However, the literature contains little experimental data involving CKI in MM, and the underlying complex mechanisms of its anti-cancer effects are not fully understood.
Aims: The aim of the present study was to assess the clinical effectiveness and safety of compound Kushen injection (CKI) plus (vincristine, doxorubicin and dexamethasone) VAD regimen chemotherapy for the treatment of newly diagnosed multiple myeloma (MM).
Methods: A total of 142 newly-diagnosed MM patients were randomly assigned to the treatment group (n=72), and were treated with CKI plus chemotherapy, or the control group (chemotherapy only; n=70). After four treatment cycles, the treatment effect was evaluated including, overall response rate (ORR), quality of life (QoL), lymph cellular immunity function, secretion of cytokines and toxicity reactions.
Results: Before treatment, the peripheral blood $CD3^+CD4^+$, $CD3^+CD8^+$, NK cells and cytokine (IL-2, IFN-γ) levels of MM patients were significantly decreased compared with health volunteers (p<0.05). In addition, TNF-α levels were significantly increased in MM patients (p<0.05) compared with healthy volunteers. Post-treatment, patients in the treatment group showed significantly higher levels of $CD3^+CD4^+$, $CD3^+CD8^+$, NK cells, IL-2 and IFN-γ than the control group (p <0.05). Furthermore, TNF-α levels were significantly lower in the treatment group compared with the control group (p<0.05). ORR and QoL improvement rate in the treatment group was significantly higher than the control (87.5% *vs* 71.4%, p<0. 05; 65.3% *vs* 54.3%, p<0. 05, respectively), as was bone pain relief 3 months later for chemotherapy (p<0.05). In addition, the control group had more incidences of hematologic and nonhematologic toxicity compared with the treatment group (p<0.05).
Summary/Conclusion: In conclusion, CKI plus standard chemotherapy appears to have enhanced short-term efficacy and lower toxicity compared with standard chemotherapy alone, which may depend on increasing the patient's immunological function and improving the QoL.

PB2172

ANALYTICAL CRITICALITIES ASSOCIATED TO DIFFERENT METHODS FOR SERUM FREE LIGHT CHAIN DETECTION: IMPACT ON THE INTERNATIONAL MYELOMA WORKING GROUP (IMWG) CRITERIA DEFINING SYMPTOMATIC MULTIPLE MYELOMA

K. Weisel[1,*], H. Salwender[2], M. Ums[3], L. Kanz[3], R. Klein[3], A. Peter[1]

[1]Hematology and Oncology, University Hospital of Tuebingen, Tuebingen, [2]Asklepios Clinic, Hamburg, [3]University Hospital of Tuebingen, Tuebingen, Germany

Background: Current criteria differentiating between monoclonal gammopathy of unknown significance (MGUS), smoldering multiple myeloma (SMM) and multiple myeloma (MM) are included in the IMWG guidelines published in 2003. Recently in 2014, the IMWG updated the criteria and revised the definition of multiple myeloma by adding a serum free light chain ratio (sFLC) of >100 as a definition for multiple myeloma requiring treatment. At present, two commercial assays for sFLC quantification are available: The TBS Freelite assay and the Siemens N Latex FLC assay. The first is based on polyclonal antibodies directed against a variety of FLC epitopes. It may be run on a wide range of nephelometers as well as turbidimeters. The second method uses a probe mixture of monoclonal antibodies and runs exclusively on Siemens nephelometers.
Aims: Here, we present a prospective monocentric trial evaluating sFLC measurement and calculated kappa/lambda ratio with the N Latex FLC and the Freelite assays in patients with MGUS, SMM and MM either newly diagnosed (NDMM), or relapsed and refractory (RRMM).
Methods: Between Apr. and Aug. 2016, 40 patients were included into the clinical trial. Patients underwent routine clinical analysis for sFLC. The trial included 5 patients with MGUS and 35 patients with MM. 8 had SMM, 33 NDMM and 2 RRMM. The involved light chain was kappa in 23 and lambda in 17 cases. sFLC analysis was performed at study entry and for a maximum of 6 analyses during follow-up. All samples were analyzed for sFLC on a single Siemens BN II analyzer with Freelite reagents (The Binding Site) and with N Latex reagents (Siemens Healthcare Diagnostics). Clinical diagnoses matching submitted serum samples were retrieved from the patients' medical file. For method comparison Passing Bablok correlation analysis after log/log transformation was performed.
Results: Based on their established reference ranges, sFLC results were classified in different groups to perform an interrater agreement analysis. Values for concordance between the N Latex FLC and the Freelite test for kappa FLC, lambda FLC and kappa/lambda ratio in the total patient population were 0.85, 0.73 and 0.93 showing a very good concordance above 0.81 for FLC kappa and FLC ratio and still a good concordance for FLC lambda. In the regression analysis, the Pearson correlation coefficient (r) showed an overall good correlation with r=0.977 for kappa, r=0.900 for lambda and r=0.975 for kappa/lambda ratio, respectively.In 35 patients with NDMM either smoldering or symptomatic, 17 (49%) patients showed sFLC ratio >100 and involved FLC >100mg/L in the Freelite test. 7/17 of those identified patients had a sFLC ratio >100 in the N Latex FLC assay plus one further patient. Applying a cutoff of 50 for N Latex FLC ratio identified 4 additional patients.
Summary/Conclusion: sFLC analysis requires continuous awareness of analytical limitations. Concordance between the Freelite and N Latex FLC assays show overall good concordance, however in single cases large differences are observed especially in measurement of lambda FLC. As the sFLC ratio >100 is implemented in the IMWG criteria defining MM disease requiring treatment physicians should be aware that this criterion might be solely rely on the method or the analyzer used for determination of sFLC values. This might lead to discrepant decisions in a proportion of NDMM patients. Therefore, IMWG guidelines for treatment of NDMM including patients solely showing sFLC ratio >100 should be carefully revised.

PB2173

ELIGIBILITY CRITERIA FOR CLINICAL TRIALS AND COMORBIDITY AS PREDICTORS OF CHEMOTHERAPY DOSE ADJUSTMENT IN PATIENTS WITH MULTIPLE MYELOMA

E. Pérez Persona*, A. Unamunzaga, I. Oiartzabal Ormategui, A. Vega Gonzalez de Viñaspre, R. Diez Angulo, A. Santamaría Lopez, L. Cuevas Palomares, C. de Miguel Sanchez, D. Robles de Castro, A. Pereda Vicandi, M. Gabilondo Jalon, J.M. Guinea de Castro

Hematology, Hospital Universitario de Araba-Sección Txagorritxu, Vitoria, Spain

Background: Approval of new standards of treatment in cancer is usually preceded by phase III clinical trials to demonstrate whether or not a product offers a treatment benefit to a specific population, providing information on safety and efficacy data. There is important selection bias on clinical trials. Strict eligibility criteria could compromise extrapolation of results to the general population.
Aims: Asses if comorbidity by Cumulative Illness rating score for geriatrics (CIRS) score or the possibility of been eligible to participate in clinical trials is associated with dose drug reduction for unsuitable-transplant patients with newly diagnosed multiple myeloma in real setting
Methods: CIRS score, and dose adjustment was assessed retrospectively for transplant-ineligible multiple myeloma patients diagnosed at Hospital Universitario de Araba (Spain). Eligibility criteria of 5 clinical trials: 3 commercial (VISTA, FIRST, ALCIONE) and 2 academic (GEM05MAS65 and GEM10MAS65) were verified for all the patients.
Results: From feb/10 to dec/17, 143 multiple myeloma patients were diagnosed in Hospital Universitario de Araba. 64% of them (92 patients) were transplant-ineligible. Median age was 77 years old, higher than published trials (median age VISTA: 71, FIRST: 73, ALCIONE: 71, GEM05: 73, GEM10: 75). CIRS score identify different prognostic groups in overall survival: CIRS <4: 52.3 months; CIRS 4 to 8: 57 months and CIRS>8: 13.5 months (p: 0.017). There was a high proportion of patients ineligible for participating in clinical trials: VISTA: 75% FIRST: 70%; ALCIONE 75%; GEM05: 75%; GEM10: 77%. 72% of the patients were treated with bortezomib, melphalan and prednisone scheme, and 28% with bortezomib/dexamethasone +/- ciclophosphamide. In general, tolerance to treatment was good, no deaths attributed to treatment were observed. 47.3% of the patients need to reduce any of the drugs prescribed, and 11% withdrawn treatment due to toxicity. By drugs, melphalan need to be reduce or withdrawn in 57% of patients, bortezomib in 29%, and corticoids in 18% of the patients. Interestingly, we could not observe correlation between the CIRS score and the possibility of been eligible for any of the selected clinical trials. Neither CIRS score nor eligibility for clinical trials was associated with the possibility of reduce of withdrawn chemotherapy.
Summary/Conclusion: Clinical trials are excessively restrictive. There is no apparent correlation between the possibility of been eligible for participating in clinical trials, comorbidities and chemotherapy s adjustment. Eligibility criteria of clinical phase 3 trials compromised extrapolation of security and efficacy of results to real setting patients.

PB2174

A COMPARATIVE ANALYSIS OF FREE LIGHT CHAIN CONCENTRATIONS IN SERUM AND CEREBROSPINAL FLUID FOR PATIENTS WITH MULTIPLE MYELOMA COMPLICATED BY MYELORADICULOPATHY

?. Трифонова [1,*], ?. Голенков [1], ?. Митина [1], ?. Москалец [1], ?. Когарко [2], ?. Белоусов [1], ?. Катаева [1], ?. Кедров [1]

[1]ГБУЗ МО МОНИКИ им. М.Ф. Владимир, [2]Институт химической физики им. Н.Н. Семенова, Москва, Russian Federation

Background: To formulate the concept of intrathecal tumor growth in patients with multiple myeloma (MM), complicated by myeloradiculopathy based on model concentration gradients of free light chains in serum (sFLC) and the free light chain in cerebrospinal fluid (FLC CSF).
Aims: To formulate the concept of intrathecal tumor growth in patients with multiple myeloma (MM), complicated by myeloradiculopathy based on model concentration gradients of free light chains in serum (sFLC) and the free light chain in cerebrospinal fluid (FLC CSF).
Methods: 12 patients with MM complicated by myeloradiculopathy were included in this study. Paraprotein (PIg) G was determined in 6 patients (κ- at 3; λ - in 3), PIg M/κ – in 1 patient, an isolated BJ disease - in 5 patients (λ-5). A newly diagnosed MM was present in 5 patients, a resistant MM - in 4 patients; 3 patients were receiving maintenance treatment during the study. All patients received chemotherapy treatment, including bortezomib, melphalan (cyclophosphamide) and prednisone (dexamethasone), lenalidomide administered when tumor resistance occurred. Concentrations of sFLCand FLC CSF were measured by ELISA method on a spectrophotometer (Kenstar, USA).
Results: The average concentrations of κ- sFLC was 15,9±4 mg/l, which was greater than this value for healthy individuals (7,3 mg/l). Distribution of values for concentrations reached 6,7±2 and 28,9±7 mg/l. The average value of κ- FLC CSF was 0,03±0,01 mg/l with a distribution of 0,02±0,05 and 0,05±0,02 mg/l. The average concentration of λ- sFLC was 54,3±16,4 mg/l (values for healthy individuals - 12.7 mg/l), with distribution of 12,6 and 98,7 mg/l. Concentration of λ -FLC CSF was 0.5±0.18 mg/l with a distribution of 0.17 and 0.83 mg/l. To determine the concentration gradient for sFLC and FLC CSF the concentrations of κ- and λ – FLC were determined in serum and in cerebrospinal fluid. The ratios for FLC concentration in serum *vs* FLC concentration in cerebrospinal fluid were calculated for κ-FLC and for λ – FLC, which was 1,7 and 1,6 respectively. Comparison of this model with the performance of each patient showed that 6 out of 12 results were below the 1.7 or 1.6, indicating an intrathecal growth. Tumor cytosis in cerebrospinal fluid was determined in one case.
Summary/Conclusion: Results of this study could serve as indicators for intrathecal chemotherapy for MM complicated by tumor myeloradiculopathy.

PB2175

THE CLINICAL SIGNIFICANCE OF THE IMMUNOPHENOTYPIC PROFILE OF TUMOR PLASMA CELLS IN THE BONE MARROW AND PERIPHERAL BLOOD IN MULTIPLE MYELOMA COMPLICATED BY PLASMACYTOMAS

K. Belousov [1,*], ?. Митина [1], ?. Чуксина [1], ?. Голенков [1], ?. Трифонова [1], ?. Катаева [1], ?. Черных [1], ?. Высоцкая [1], ?. Захаров [1], ?. Клинушкина [1], ?. Митин [2], ?. Караулов [3]

[1]ГБУЗ МО МОНИКИ им. М.Ф. Владимир, [2]ФГБУ «ГНЦ институт иммунологии» ФМБА России, [3]Первый Московский государственный медицинский университет имени И. М. Сеченова, Москва, Russian Federation

Background: the study of the immunophenotype of tumor plasma cells of the bone marrow (PC BM) and circulating tumor cells (CTC MM) can reveal new mechanisms of metastasis and generalization of the disease in multiple myeloma (MM) complicated by plasmacytomas.
Aims: the study of the immunophenotypic profile of bone marrow tumor cells and circulating tumor cells in patients with multiple myeloma complicated by plasmacytomas, depending on the clinical course of the disease.
Methods: 18 patients with MM (9 women, 9 men), from 41 to 85 years (median 59 years) were examined. All patients had 3 stages of the disease according to Salmon-Durie, and plasmacytomas of different localization. The average level of plasma cells in CM according to the myelogram is 19.3% (0.4-69.0%). The first detected MM was in 9 patients, 9 previously received therapy (VCP, VMP, RVP). In 13 (72.2%) patients there were bone plasmocytomas, in 5 (27.8%) - extramedullary plasmacytomas. In 14 (77.8%) patients, the plasmacytomas were more than 7 cm in diameter (bulky disease). Differences between PC KM and COCMM in patients with primary and pre-treated, with solitary bone and extramedullary plasmacytomas, in patients with plasmacytomas more than 7 cm were assessed.
Results: in primary and treated patients a significantly higher level of CD138 + on PC KM is determined in comparison with COC MM. In both groups, the detectability of CD138 cells was significantly higher at CIC MM. There was no significant difference in the detection of CD56, CD11c, CD117, CD81, CD33, CD27, CD28, CD19, CD20, CD79b in both groups. Patients with bone plasmacytomas have a higher detectability of CD138 + on PC KM compared to COCMM. Detectability of CD138- was higher at COC MM. In the group of patients with extramedullary plasmacytomas, there was no significant difference in the detection of CD138 + and CD138- between CM of PC and COC of MM, there were no other antigens. When comparing the detectability of plasmocyte antigens *versus* the size of the plasmacytoma - more than 7 and less than 7 cm in both groups, a significant predominance of CD138 + cells in the CM KM and a higher detection of CD138 cells at COC MM were revealed.
Summary/Conclusion: immunophenotypically CTCs of MM are less mature cells compared to PC KM, losing the antigen CD138 + and the connection with the bone marrow stroma. These results were noted in both primary and treated patients, as well as when comparing patients with plasmacytomas more than 7 cm and less than 7 cm. In this connection, the loss of surface CD138 + by the plasma cell can be regarded as one of the mechanisms of metastasis and progression of MM. In the group of extramedullary plasmocytes, there were no significant differences between PC BM and CTC MM, which allows us to conclude that the immunophenotypic identity of these cells is medullar. However, these data require further study due to the small sample of patients in this group.

PB2176

THE OCCURRENCE AND ECONOMIC BURDEN OF TREATMENT INDUCED PERIPHERAL NEUROPATHY IN PATIENTS WITH MULTIPLE MYELOMA IN SWEDEN

H. Nahi[1,*], G. Walinder[1], F. Gatta[2], H. Beydogan[3], A. Levine[3], C. Lourdudoss[3], I. Majer[2], S. Gonzalez-McQuire[2], M. Hansson[4,5]

[1]Department of Medicine, Huddinge, Karolinska University Hospital, Stockholm, Sweden, [2]Amgen (Europe) GmbH, Zug, Switzerland, [3]IQVIA, Solna, Stockholm, [4]Wallenberg Center for Molecular Medicine, Lund University, [5]Hematology clinic, Skåne University Hospital, Lund, Sweden

Background: Approval of novel regimens for multiple myeloma (MM) in Europe have improved the efficacy and safety of treating patients with MM. Peripheral neuropathy (PN) is both a MM complication and a toxicity that can occur from some anti-myeloma treatments. Treatment-induced peripheral neuropathy (TIPN) impairs quality of life of patients; however, the economic burden of TIPN is not well known.
Aims: The primary aim of the study was to understand the treatment patterns in patients with MM. This analysis focused on secondary and exploratory objectives assessing the occurrence and economic burden of TIPN in a real-world setting in Sweden.
Methods: This retrospective cohort study used data from electronic medical records (EMR) from three large haematology clinics in Stockholm, Sweden that were linked to national health registries. Eligible patients were those with a diagnosis of MM (ICD-10:CD90.0) in the Swedish Cancer Registry between 2006–2015 and had initiated MM treatment during the same period. Follow-up was until last EMR visit, death or study end (March 2017). For this analysis, patients who had no record of PN or TIPN for the past two years before the initiation of the analysed treatment line were included. Diagnosis of TIPN was retrieved from the National Patient Register (ICD-10:G62.0) and EMR case notes. An index matching method with replacement was used to match patients with TIPN and those without for baseline characteristics, MM treatment that induced TIPN and line of therapy. For patients with TIPN, the time from treatment initiation to the TIPN diagnosis date was estimated (TIPN lag days). For patients without TIPN, a pseudo TIPN diagnosis date was set according to the TIPN lag days of the related case, after the initiation of the matched treatment. Cost calculations were based on 2015 DRG tariffs. Statistical analyses were descriptive in nature.
Results: In total, 1298 MM patients were identified from EMRs; of which 550 were eligible for the overall study. Of these patients, 385 met this analysis criterion (135 received stem cell transplantation [SCT] and 250 did not [non-SCT]). Overall, 26% of patients were diagnosed with TIPN. At first line (1L), most patients with TIPN had received a bortezomib-based regimen (81%) while at second line (2L), most patients with TIPN had received a lenalidomide-based regimen (55%) (Table 1). Median TIPN lag days was similar in both SCT and non-SCT patients (4.3 and 4.4 months respectively, for 1L bortezomib-based treatment and 1.3 months each, for 2L lenalidomide-based treatment). Matched patients (n=73) were well balanced on all matching variables. Median follow-up from TIPN date and pseudo date was 1.7 and 1.8 years, respectively. Overall, patients with TIPN had increased healthcare resource utilisation (HRU) compared with those without TIPN: mean hospital inpatient visits (3.5 *vs* 2.3 visits), median total length of stay (7.2 *vs* 1.2 days) and mean hospital outpatient visits (17.8 *vs* 12.6 visits). Similarly, patients with TIPN showed significant increased total cost of HRU per patient-year than those without TIPN (mean €52,353 *vs* €31,194, respectively), mainly driven by outpatient prescription drugs costs (mean €27,399 *vs* €18,808).

Table 1.

Table 1. Number of MM patients experiencing occurrence of TIPN by MM treatment and line of therapy

Treatment regimens	Number of MM patients experiencing TIPN occurrrence 1L (n = 57)	2L (n = 31)	3L (n = 12)	4L (n = 2)
Bortezomib-based[a]	46 (81%)	11 (35%)	5 (42%)	0 (0%)
Bortezomib + thalidomide-based[b]	2 (3%)	1 (3%)	0 (0%)	1 (50%)
Lenalidomide-based[c]	4 (7%)	17 (55%)	7 (58%)	1 (50%)
Thalidomide-based[d]	5 (9%)	2 (6%)	0 (0%)	0 (0%)

1L, first line; 2L, second line; 3L, third line; 4L, fourth line; MM, multiple myeloma; TIPN, treatment-induced peripheral neuropathy

[a]Total number of bortezomib-treated patients included in this analysis: 259 in 1L; 66 in 2L; 30 in 3L; 7 in 4L
[b]Total number of bortezomib + thalidomide-treated patients included in this analysis: 10 in 1L; 9 in 2L; 2 in 3L; 3 in 4L
[c]Total number of lenalidomide-treated patients included in this analysis: 46 in 1L; 102 in 2L; 35 in 3L; 7 in 4L
[d]Total number of thalidomide-treated patients included in this analysis: 67 in 1L; 21 in 2L; 11 in 3L; 1 in 4L

Summary/Conclusion: Findings showed that most patients with TIPN had received bortezomib-based treatments. Patients with TIPN had increased HRU and ~70% higher cost per patient-year *versus* those without TIPN. There is a need for effective MM treatments which reduce the occurrence of TIPN in order to ensure benefit to patients and decrease healthcare expenditure.

PB2177

OUTCOMES OF TREATMENT OF MULTIPLE MYELOMA IN PATIENTS REQUIRING RENAL REPLACEMENT THERAPY: "REAL WORLD" SINGLE CENTRE EXPERIENCE OVER AN 11 YEAR PERIOD

A. Ratnayake[1,*], M. Srikantharajah[2], D. Makanjuola[1], S. Stern[2]

[1]Renal, [2]Haematology, Epsom & St Helier University Hospital NHS Trust, Carshalton, United Kingdom

Background: Renal impairment is a recognised complication of multiple myeloma (MM), ranging from mild chronic kidney disease to end-stage renal failure. The incidence of renal impairment at diagnosis of myeloma is between 20-50%; of these, approximately 10% present with severe acute kidney injury (AKI) requiring dialysis. Treatment regimens including both the proteasome inhibitor Bortezomib and Dexamethasone are now most commonly used as first line therapy in such patients. These regimens have improved the overall prognosis of these patients, where successful therapy can also result in partial or full recovery of renal function. However, these treatments also cause side effects such as peripheral neuropathy, infection and cytopenias.
Aims: We reviewed patients managed at our centre to determine whether the treatment of myeloma patients requiring renal replacement therapy (RRT) was associated with a high incidence of the above side effects, and to look for an improvement in outcomes over an 11 year period.
Methods: Patients diagnosed with MM with associated renal impairment between January 2007- December 2017 were identified. Only patients who required RRT were included in the analysis. Patient data including demographics, type of myeloma, chemotherapy regimens, associated complications, response to treatment and survival rates were obtained from electronic patient records.
Results: 29 patients were identified who met the above inclusion criteria. Median age was 64 years (range 45-86). 59% patients were male; 72% were Caucasian. Median follow up time was 33 months (range 8-96 months). 65% (N=19) patients were treated with first line chemotherapy regimens which included Bortezomib; of these 84% showed a complete (21%) or partial (63%) response to therapy. 1 year survival was 89% (N=19), 5 year survival was 71% (N=14). Complications of therapy included thrombosis (11%), neuropathy (53%), and infection requiring hospital admission (42%). 37% of patients to-date recovered enough renal function to come off RRT. 35% (N=10) patients did not have Bortezomib as part of initial chemotherapy regimen. 50% of these patients responded to therapy; all with partial response, none with a complete response. 1 year survival was 90% (N=10), 5 year survival was 50% (N=10). Thrombosis (20%) and infection requiring hospital admission (20%) were also recognised complications. None of these patients were recorded to have experienced neuropathy. Only 10% of patients recovered renal function sufficiently to stop RRT.
Summary/Conclusion: Advances in therapies for MM have improved prognosis and quality of life for patients. The time frame of our study coincides with the introduction in this centre of Bortezomib as first-line treatment for MM in patients with renal impairment in 2010. In our cohort of patients who required RRT, Bortezomib treatment resulted in an increased likelihood of response to first line therapy, sufficient improvement of renal function to cease RRT, and improved overall survival. However, our cohort also demonstrates a larger side effect profile with Bortezomib-containing regimens, notably peripheral neuropathy and infection, thereby increasing overall morbidity for some of these patients.

PB2178

PROGNOSTIC ROLE OF NEUTROPHIL-LYMPHOCYTE RATIO IN PATIENTS WITH MULTIPLE MYELOMA

A. Luchinin[1,*], N. Minaeva[1], S. Semochkin[2]

[1]Kirov Scientific Research Institute of Hematology and Blood Transfusion of the Medical-Biological Agency, Kirov, [2]Pirogov Russian National Research Medical University, Moscow, Russian Federation

Background: The neutrophil-lymphocyte ratio (NLR) has been recently identified for multiple myeloma (MM) as prognostic factor. There are several trials and one meta-analysis confirm it. The NLR is neutrophil count (cells/μL) divided by lymphocyte count (cells/μL) in common blood count.
Aims: In our research we studied the NLR prognostic significance for overall survival (OS) and for distribution by Durie-Salmon stages of patients with MM. We checked hypothesis that NLR can serve as a negative prognostic immune biomarker in newly diagnosed MM.
Methods: Our study included 314 patients with newly diagnosed MM at the Kirov Research Institute of Hematology and Blood Transfusion from 1990–2015. All patients fulfilled the IMWG criteria for symptomatic MM. The correlation of NLR with various parameters was assessed with ANOVA corrected by Turkey HSD test for multiple comparisons. For assessment categorical parameters we used Kruskal-Wallis rank test. The Cox proportional hazards model, Wilcoxon and log-rank tests for comparison survival curves was used to evaluate NLR at diagnosis as a prognostic factor for OS. Statistical analysis was performed using R language (v 3.4.3). A p-value of <0.05 was considered statistically significant.
Results: In our group, the median age was 64 years old (range: 29–90) and 190 patients (60%) were female. Overall, 179 patients (57%) had IgG type, 74 (23%) had IgA type, 43 (14%) had light chain disease and 15 (5%) had non-secretory MM. The MM type of 3 (1%) patients was unknown. The median NLR at diagnosis was 1.6. The cutoff point of NLR 2.6 that yielded the greatest differential to segregate cohorts, was based on the analyzed at different cutoff points from the long-rank test. At the time of this study, 256 (82%) patients had died. The median of OS in all group was 35 months, 5-year OS – 30%. We found that patients with stage IIB and IIIB by Durie-Salmon had more superior average NLR level *versus* patients with stage IA, IIA and IIIA (ANOVA test, $p<0.0001$). During multiple comparative analysis patients with A and B subclasses differed among themselves by NLR level (Turkey HSD test, $p<0.05$). In this regard we compare medians in this group because they did not have normal distribution. The median of NLR level in patients in B stages by Durie-Salmon was higher than among patients with A stages (2.45 *versus* 1.45, Kruskal-Wallis test, $p<0.0001$). Also, patients with baseline NLR 2.6 had shorter median OS (28 months *versus* 40 months, respectively; HR=1.38, 95% CI: 1.05–1.8, p-value=0.023; Wilcoxon test, p=0.008).
Summary/Conclusion: The MM patients with higher NLR (≥2.6) are more likely to have poorer prognosis by OS than those with lower NLR. Also, in patients with B stages (IIB or IIIB) by Durie-Salmon with high creatinine level (≥2mg/dL) the average NRO level is higher than those, who don't have myeloma nephropathy.

PB2179

BLEEDING AND THROMBOTIC COMPLICATIONS IN PLASMA CELL DISORDERS IN THE "NOVEL AGENTS ERA": RISK FACTORS, OUTCOME ,PROGRESSION AND STRATEGIES OF PREVENTION A REAL-LIFE MONOCENTRIC RETROSPECTIVE ANALYSIS

L. Torti[1,*], A.M. Morelli[1], F. Bacci[2], P. Di Bartolomeo[1]

[1]Clinical Hematology, Department of Hematology, Transfusion Medicine and Biotechnology, "Spirito Santo" Civic Hospital, Pescara, [2]Section of Hematopathology, Department of Hematology and Oncological Sciences, S.Orsola Malpighi Hospital, Bologna, Italy

Background: "Thrombosis is often reported in cancer" Trousseau wrote in 1865. Multiple myeloma(MM) is associated with venous-thromboembolism. Moreover bleeding-complications are possible in plasma-cell-disorders and are cause of early mortality. Data available in this setting are rare.
Aims: We'd like to share our experience regarding 138 patients with these events retrospectively analysed.
Methods: We reviewed 20 bleeding and 118 thrombotic events consecutively diagnosed and managed between 1999 to 2018 in the median-time of 18 years, median follow up 12,5 years (10,2-19).

Results: We reported 4 bleeding events in amyloidosis patients:3 periorbital hemorrhages related to X-factor-deficiency and one intestinal-bleeding. We described 15 hemorragic events in MM patients under treatment: one of them was lifethreatening (an extensive brain hemorrhage)and 4 gastrointestinal-bleeding. 11 events were minor mucocutaneous-haemorrhages. Among risk-factors we have high monoclonal-component at diagnosis (13). A 49-year old female died during induction-therapy of a fatal brain hemorrhage. On CT an extended intracranial hemorrhage developed in right parietal region (Fig.2c-e). Platelet and coagulation-exams were normal. Hypothesized mechanisms are an acquired platelet disfunction o an amyloidotic deposition of fibrils. We had 5 events after osteomedullary-biopsies:we recommend a good post-procedure-compression. Within thrombotic manifestations we have 69-events in MGUS(59 venous, 10 arterial), 29 events in MM (22 venous,7 arterial) and 20 events in SMM patients (18 venous, 2 arterial). Thrombophilic screening was negative.Venous thromboses described were at diagnosis not at relapse(75/99). We had one case of massive lethal pulmonary embolism. We have described 7 thrombotic manifestations in MM-patients at the time of diagnosis before the start of therapy, highlighting how the disease is associated with a thrombogenic condition. Among risk factors of disease we have ISS score (III 39, II 7 and I 3), elevated serum-FLC(40/49). Therapy-consisted-of dexamethasone(29), chemotherapy(9), lenalidomide(8), KRD(2),doxorubicin(3), thalidomide(5), pomalidomide(2 patients). We chose low molecular heparin for prophylaxis. Among MGUS patients 48 evolved with median TTP of 56 months(14-90). We compared TTP with an homogeneous group of 48 patients (69 months,51-110) matched by age and risk-profile, with evidence of a shorter progression-time in patients with MGUS and thrombosis (Fig1a, Longrank-test-95% IC 2, 9-9, HR5). M-protein level is a risk factor. Moreover in our study 14 SMM-patients evolved with medium time of 34 months (11-53). We have compared TTP with an age and risk-profile-matched-SMM-patients-group (14-patients), median-time-69-months,range-29-75(Fig1d). L-Rtest, 95%CI, HR3,4), showing a shorter time for SMM-series with thrombosis. Crosstalk between microenvironment and clone can facilitate progression. Finally we compared OS and PFS among our 44 MM patients under therapy and thrombosis and a similar group regarding age and ISS score,demonstrating how outcome and PFS are worse in patients with thrombosis (Fig 1b-c). For first series median OS is of 36 months(20-60)and PFS of 18,5 months (range 7-29) and for second-series without thrombosis median OS of 69 months (35-110) and PFS of 31 months (6-39), L-R test, 95%CI, HR 4,7 for OS and HR4,2 PFS).

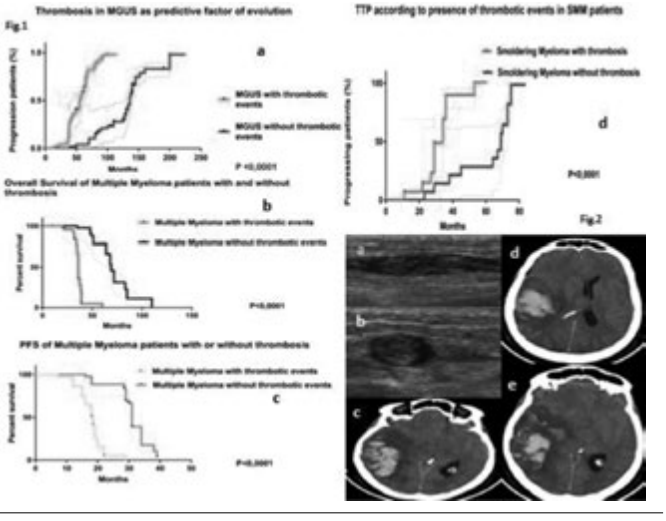

Figure 1.

Summary/Conclusion: Our study is limited:heterogeneity of population and no information about cytogenetics. Cancer protrombogenicity may promote angiogenesis, metastasis and poorer prognosis. Prospective studies are needed to verify our conclusions and to investigate exact pathogenesis.

PB2180

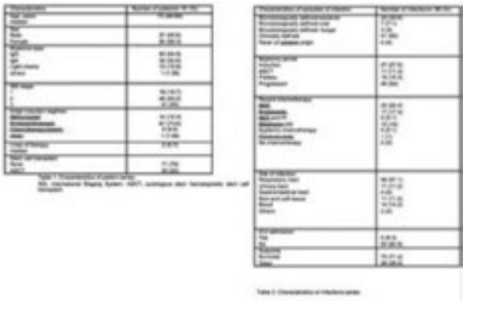
MULTIPLE MYELOMA AND INFECTIONS IN THE "NOVEL AGENTS ERA": A REAL-LIFE RETROSPECTIVE UNICENTRIC EXPERIENCE

M.S. Infante*, I. Gonzalez, C. Muñoz, M.A. Foncillas, C. Heras, K. Marin, J.A. Hernandez-Rivas

Hospital Infanta Leonor Madrid, madrid, Spain

Background: Multiple myeloma (MM) is a clonal plasma cell malignancy that is increasing in prevalence as the population ages and the survival improves. Infection is a leading cause of morbidity and mortality, contributing to nearly 50% of early deaths (Augustson *et al.*, 2005). Infection risk is increased due to patient-, disease- and treatment-related factors. New treatment options in the last decades have improve survival in MM patients but their effect on the risk of infections remains to be established yet.
Aims: To describe retrospectively the development of infections requiring hospitalization in 91 MM patients diagnosed in our institution between 2008 and 2017.
Methods: Median age 73 years (46-89), 54 females. There were 51 patients with 1 or 2 infections and 9 patients with >3 infections. 31 patients had no infection. Characteristics of the studied patients are detailed in Table 1.
Results: 98 episodes of infection were identified. Of these, 43 (43.8%) were microbiologically identified, 51 (52%) clinically defined and 4 (4%) were fever of unknown origin. Of the 43 microbiologically defined infections, 77% (33) were bacterial, 7% (3) fungal and 16.2% (7) viral. Of the 33 bacterial infections, 18 (54.5%) were caused by gram negative and 15 (45.4%) gram positive microorganisms. *Escherichia Coli* was the most frequently isolated organism (21%). Vaccine-preventable encapsulated bacteria *Str.pneumoniae* was isolated in 18% of all bacterial infections. The 7 viral infections were due to influenza virus (57%), respiratory syncytial virus (28%) and herpes simplex reactivation (14%).There were 3 fungal infections: 2 candidemias and 1 *Pneumocystis Jiroveci* pneumonia. Respiratory tract (57,1%) and blood (14.2%) were the most common sites of infection. Bacterial infections occurred more frequently in relapse phases (84%), during neutropenia (53%) or in hypogammaglobulinemic patients (62%).All the patients with viral-infections had previous PIs (Proteosome Inhibitors) based therapies. All the patients with fungal-infections had previous IMiDs (Immunomodulatory drugs) therapies and were receiving HD (high dose) steroids.Infections occurred more frequently at disease progression (50%) and during induction (27.5%) and the majority of patients were older than 65 (74%). 11/16 infections occurring during plateau were of low severity and had good outcome.Most recent therapies administered before infection development were IMiDs (22,4%) and Bortezomib (17.3%). Admission to the intensive care unit (ICU) was required in 8.3% infection episodes. 28 infections resulted in death (28.5%): 22/28 occurring during disease progression, 2/28 during induction (1 patient with herpetic encephalitis and 1 multiorganic failure MOF), 1 in ASCT and 3 deaths during plateau (1 heart failure in VGPR, 1 MOF after prolonged hospitalization for toxicity in PR, 1 pneumococcal pneumonia in CR). Overall Survival (OS) was 63 months. More details of infections are shown in table 2.

Table 1.



Summary/Conclusion: Our study identifies a high risk patient group for infections: older age, late disease, advanced ISS, multiple treatments, HD corticoids treatments. Infections represent a significant-comorbidity factor especially during induction and in refractory/relapsed-patients, with 28.5% infection related mortality in our population. Immunoglobulin replacement therapy, vaccination for encapsulated bacteria or antibiotic-prophylaxis may have a role in older patients with high ISS stage. Trials are needed to target new approaches for prevention, early detection and treatment of infection in MM patients.

PB2181

OUTCOME OF RELAPSED OR REFRACTORY MULTIPLE MYELOMA PATIENTS TREATED WITH PCCD (POMALIDOMIDE - CYCLOPHOSPHAMIDE-CLARITHROMYCIN - LOW DOSE DEXAMETHASONE) IN THE REAL-LIFE SETTING

R. Ríos-Tamayo[1,*], A. Martín[2], D. Sánchez-Rodríguez[3], M.E. Clavero[1],

A.B. Rivera[1], T. Rodríguez[4], M.J. Olivares[4], R. Sánchez[5], C. Alarcón[6], A. Jiménez[6], J. Badiola[7], E. Morente[7], P. Garrido[7], J. Sainz[7], M. Jurado[7]

[1]Monoclonal Gammopathies Unit, University Hospital Virgen de las Nieves, [2]Clinical Trials Unit, [3]Monoclonal Gammopathies Unit, FIBAO, [4]Immunology, [5]Nuclear Medicine, [6]Pharmacy, [7]Hematology, University Hospital Virgen de las Nieves, Granada, Spain

Background: Multiple myeloma (MM) is a complex and heterogeneous malignancy. Despite the widespread use of new agents and the use of less toxic and more efficient regimens, the treatment of relapsed and/or refractory MM (RRMM) is challenging, with poor outcome in most patients. Pomalidomide and low-dose Dexamethasone (Pd) is considered a standard of care in RRMM. To further improve its results, Pd has been associated with Cyclophosphamide (PCd)(Baz RC *et al.* 2016; Chari A *et al.*2016) achieving an impressive 64.7% and 67% overall response rate (ORR) respectively. Many other combinations have been used (Ríos-Tamayo R *et al.* 2017) without showing clear advantage over PCd. However, to our knowledge, the baseline addition of clarithromycin (c) to PCd (PCcd) has not been previously explored.
Aims: To assess in a preliminary way if the addition of c to PCd add clinical value to the triplet
Methods: Patients included in our MM population-based registry fulfilling RRMM status according with IMWG criteria, were prospectively treated with P 4 mg/day/21 days, C 50 mg/day/21 days, c 500mmg/12h/continous and d 40 mg/weekly, in cycles of 28 days. We estimated efficacy in terms of overall response rate (ORR), progression free survival (PFS) and overall survival (OS), as well as the main grade 3-4 toxicity.
Results: Since 2015, 24 RRMM patients have been treated with P-based regimens, and 19 of them received complete (not scaled) PCcd, 9 men and 10 women, median age at diagnosis 63 years (48-81). The ISS was I 47%, II 32% and III 21%. 5 patients (26.3%) had light chain MM. PCcd was used as third line of therapy (LT) in 8 patients (42%), fourth LT in 3 (16%), fifth in 4 (21%) and subsequent LT in 3 (21%). Median of cycles administered was 5 (1-25). 12/17 patients achieved at least PR, with 70.5% ORR (11.8% CR). Median PFS and OS were 6.7 and 11 months, respectively. 4 patients have died (3 with progressive disease, 1 renal failure) whereas 11 remain ongoing in follow-up. No patient died due to infection. 5 patients (26.3%) are long-term responders, receiving 12 or more cycles. Neutropenia (grade 3-4) was documented in 57.9%. Infection (grade 3-4) was present in 26.3%. Thrombocytopenia (grade 3-4) was shown in 21.1%.
Summary/Conclusion: PCcd seems to be a convenient and optimized way to use P in real-life RRMM patients. This is an all-oral four-drug regimen with a remarkable ORR and a manageable safety profile. If PCcd is able to improve the outcome of PCd must be confirmed in a clinical trial.

PB2182

SURVIVAL OF RELAPSED MYELOMA PATIENTS WITH A SECOND AUTOGRAFT: LOCAL EXPERIENCE

C. Hendry[1,*], R. Soutar[2]

[1]University of Glasgow, [2]Haematology, Beatson Oncology Centre, Glasgow, United Kingdom

Background: In the UK five year overall survival in myeloma is estimated to be 47%, with 10 year overall survival (32.5%) ranking 6th lowest of the 20 most common cancers. The Beatson Oncology Centre serves the west of Scotland, encompassing some of the most deprived areas in Europe. Male life expectancy in Glasgow city is 73.4 years, while the average for Scotland is 77.1. Female life expectancy is 81.1 years in Glasgow (78.7 in Scotland). For comparison male and female life expectancy is 7 years greater in Sweden than Glasgow (male life expectancy 80.56 years and female life expectancy 84.09 years). Poor life expectancy is reflected in cancer survival rated.
Aims: In light of this, we were interested to see how this impacted on the overall survival of a group of unselected patients who were treated for relapsed multiple myeloma with a second autologous stem cell transplant (ASCT) at the Beatson Oncology Centre, Glasgow. Second autologous stem cell transplantation is 'standard of care' for our myeloma patients.
Methods: Patients were identified from data registration for EBMT. Electronic case records were retrospectively analysed for data retrieval for patients who underwent a second autograft between 1 January 2005 and 31 December 2015. Survival analysis was carried out by *IBM SPSS Analytics.*
Results: Of the 40 patients analysed 65% were male, 35% female. The average age was 59 (range 50-71). 57.5% of patients were diagnosed with IgG disease, 20% light chain, 15% IgA, 2.5% IgE, 2.5% non-secretory and 2.5% unrecorded. The mean average time from diagnosis until first transplant was 12 months (range 5-61 months, median =8). Average hospital stay for the first transplant was 22.1 days (range 11-54, median =18). The average time until time to next treatment (TNT) from the first ASCT was 45.5 months (range 6-199, median =35.5). The mean average time until next second transplant was 55.65 months (range 20-208, median =46.5). Average hospital stay for the second transplant was 21.2 days (range 14-53, median =18). The average time until next treatment from second transplant was 23.1 months (median =18, range 2-51). To date, 25% of patients have not required treatment post-transplant. Patients who did require treatment were generally retreated with a Lenalidomide based regimen (n=30) as per national Scottish guidance. 13 (32.5%) patients have died since their second treatment, the majority of progressive myeloma. Median overall survival post second transplant is 80.3%.

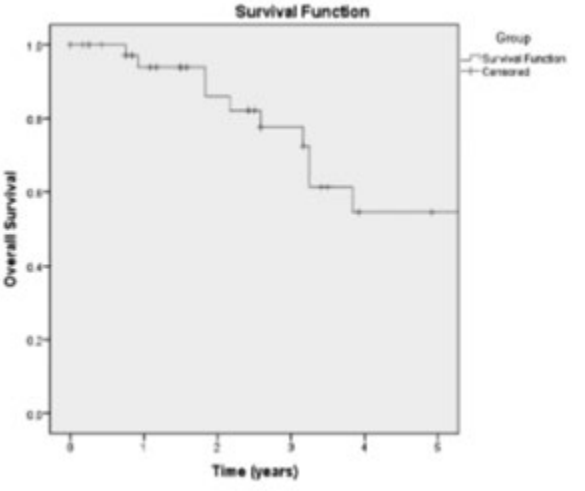


Figure 1.

Summary/Conclusion: The 'NCRI Myeloma X Relapse' trial demonstrated the benefit of a second autologous stem cell transplant with three year overall survival as 80.3%. In our cohort, three year survival compared favourably at 81.9% (95% Confidence Interval [CI] 64.9-97.5). Projected five year survival is calculated to 59.4% (CI 42.8-47.5). Our data confirms the good outcome associated with a second autologous transplant in a non-trial unselected population despite background adverse life expectancy. It is therefore likely that our data can be extrapolated to our European populations with poor survival demographics.

PB2183

NORWEGIAN REAL-LIFE EXPERIENCE OF PREAPPROVAL CARFILZOMIB THROUGH COMPASSIONATE USE NAMED PATIENT PROGRAM (NPP) FOR RELAPSING/REFRACTORY MYELOMA (RRMM)

I. Haarstad[1,*], A. Lysén[2], F. Schjesvold[2]

[1]Faculty of Medicine at University og Oslo, [2]Oslo Myeloma Center, Oslo, Norway

Background: The proteasome inhibitor carfilzomib was recently approved for treatment of RRMM. In the period before approval, drugs can be provided to critically ill patients with few treatment options, through expanded access programs.
Aims: This retrospective study of patients who received carfilzomib before marketing, was designed to describe the patients' characteristics and their corresponding treatment responses. An additional intention was to use the real-life experience to highlight a possible benefit of making new drugs available before marketing approval.
Methods: 33 Norwegian patients received carfilzomib through an NPP in the period from March 2015 to January 2016, for RRMM within 10 different Norwegian hospitals. The patient journals were printed and sent from the respective hospitals to Oslo Myeloma Center. Baseline values and treatment responses was assessed and entered into our myeloma database. Statistical analysis was done to determine response rates and time to event outcomes.
Results: The participants had received a median of 6 (1-11) previous lines of therapy, frequently including bortezomib (100%) and thalidomide and/or lenalidomide (97%), which was refractory in respectively 63,5% and 65,6% of the exposed. The most frequently used regimen was carfilzomib and dexamethasone (Kd). Response rates showed a median overall response rate (ORR) of 25% and a clinical benefit rate (CBR) of 44,4%. The median progression free survival (PFS) was 3.0 months, with a median overall survival

(OS) of 7.0 months. Patients who achieved at least partial response (PR) showed a significantly longer progression free survival with a median PFS of 8,5 months, and patients who received lenalidomide in addition to carfilzomib (KRd) showed a significantly better response with an ORR of 55,6%. Among the patients refractory to bortezomib, ORR was 10,7% and CBR 28,6%; among the patients refractory to thalidomide/lenalidomide ORR was 14,8% and CBR 29%. The patients refractory to both bortezomib and thalidomide/lenalidomide demonstrated ORR of 10,5% and CBR of 31,6%. Adverse events occurred in 90,6% of the patients, with 59,4% experiencing one or more cytopenias, 25% fatigue, 21,9% dyspnea, 18,8% cardiovascular complication and 18,8% kidney failure. 3/32 (9,4%) of patients discontinued treatment owing to adverse events. 2/33 died before ending carfilzomib, and 25/33 (75%) was dead by the time of the end of study. Carfilzomib was not considered as a direct cause of death in any patient.
Summary/Conclusion: MM is incurable in most cases, and the response is inversely correlated with the number of treatment lines. The majority of our real-life patients had advanced MM and where heavily treated prior to carfilzomib. Still a significant part of the patients benefited from the treatment in terms of prolonged PFS (3 months) and OS (7 months), with significantly increased PFS of 8,5 months, among those who experienced PR or better. A superior response was shown by those treated with lenalidomid in addition to carfilzomib (KRd). The results confirms the advantage of access to medicines prior to marketing authorization.

PB2184

PHASE III (IKEMA) STUDY DESIGN: ISATUXIMAB PLUS CARFILZOMIB AND DEXAMETHASONE (KD) VS KD IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM)

P. Moreau[1], M.-A. Dimopoulos[2], K. Yong[3], J. Mikhael[4,5], M.-L. Risse[6], G. Asset[7], T. Martin[8,*]

[1]University Hospital, Nantes, France, [2]National and Kapodistrian University of Athens, Athens, Greece, [3]University College London, London, United Kingdom, [4]Mayo Clinic, Phoenix, [5]International Myeloma Foundation, Los Angeles, United States, [6]Sanofi, Vitry-Alfortville, [7]Sanofi, Chilly-Mazarin, France, [8]University of California, San Francisco, United States

Background: Multiple myeloma remains an incurable disease requiring multiple lines of therapy, in which carfilzomib-based treatments are a standard of care. Isatuximab (ISA), an anti-CD38 monoclonal antibody with antitumor and immunomodulatory activities in preclinical models of MM, has shown clinical activity as monotherapy and in combination with current standard of care in patients with RRMM.
Aims: This Phase III, prospective, randomized, open-label study (NCT03275285; IKEMA) will evaluate the clinical benefit of ISA in combination with Kd *vs* Kd alone in patients with RRMM.
Methods: Patients with RRMM who have received 1–3 prior lines of therapy will be enrolled. Patients who have received prior carfilzomib therapy, have primary refractory disease, or have free light chain measurable disease only will be excluded. Approximately 300 patients will be randomized according to 2 stratification factors (prior lines of therapy: 1 *vs* >1; revised International Staging System [R-ISS] criteria at baseline: I or II *vs* III *vs* unknown) in a 3:2 ratio to receive either ISA (10 mg/kg weekly in Cycle 1 then once every 2 weeks thereafter) in combination with Kd (carfilzomib [56 mg/m^2 on Days 1, 2, 8, 9, 15, and 16; 20 mg/m^2 on Days 1 and 2 of Cycle 1] and dexamethasone [20 mg on Days 1, 2, 8, 9, 15, 16, 22, and 23]) or Kd in 28-day cycles until disease progression (PD), patient choice, or unacceptable toxicity. Patients will provide written, informed consent before participation in the trial. The primary endpoint is progression-free survival (PFS), defined as the time from the date of randomization to the date of first documentation of PD (according to International Myeloma Working Group Criteria) or death. Comparison between arms will be conducted through a log-rank test procedure stratified by number of previous lines of therapy and R-ISS. Key secondary endpoints include overall response rate, rate of very good partial response or greater, minimal residual disease negativity rate, complete response rate, and overall survival. Other secondary endpoints include safety, duration of response, time to progression, PFS2 (defined as the time from randomization to the time of second PD or death), pharmacokinetics, and quality of life. Safety evaluations will include adverse events and laboratory parameters, vital signs, and physical examination.
Results: The IKEMA study is currently enrolling patients; recruitment is planned in 16 countries worldwide.
Summary/Conclusion: This Phase III, randomized, multicenter study will provide an evaluation of the efficacy and safety of ISA added to Kd standard of care in patients with RRMM.
Funding: Sanofi

PB2185

PHASE III (IMROZ) STUDY DESIGN: ISATUXIMAB PLUS BORTEZOMIB, LENALIDOMIDE, AND DEXAMETHASONE (VRD) VERSUS VRD IN TRANSPLANT-INELIGIBLE PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

T. Facon[1,*], H. Goldschmidt[2], M. Cavo[3], T. Martin[4], G. Paux[5], C. Oprea[5], R. Orlowski[6]

[1]Hôpital Claude Huriez, Lille, France, [2]University of Heidelberg, Heidelberg, Germany, [3]University of Bologna, Bologna, Italy, [4]University of California, San Francisco, United States, [5]Sanofi, Vitry-sur-Seine, France, [6]University Texas MD Anderson Cancer Center, Houston, United States

Background: Patients with transplant-ineligible, newly diagnosed multiple myeloma (NDMM) require therapies which prolong survival and improve quality of life. The combination of bortezomib (V), lenalidomide (R), and dexamethasone (d) significantly improves progression-free (PFS) and overall survival compared with Rd in NDMM, and has an acceptable safety profile. Combining VRd with a monoclonal antibody (mAb) may further improve efficacy. Isatuximab (ISA) is an anti-CD38 mAb that demonstrates antitumor and immunomodulatory activities with strong potentiation when combined with V and R in MM xenograft models.
Aims: This Phase III, randomized, open-label, multicenter study (NCT03319667; IMROZ), is being conducted to evaluate the clinical benefit of ISA plus VRd *versus* VRd alone in the treatment of adult patients with transplant-ineligible NDMM.

Table 1.

Table. Dosing schedule during the induction and continuous phases

Induction phase: Cycles 1–4 (6-week cycles)																			
Day	1	2	4	5	8	9	11	12	14	15	21	22	23	25	26	29	30	32	33	42
ISA (10 mg/kg)	x				x[a]					x		x[a]				x				
Bortezomib (1.3 mg/m^2)	x		x		x		x					x		x		x		x		
Lenalidomide (25 mg)	Days 1–14											Days 22–35								
Dexamethasone (20 mg)	x[b]	x	x[b]	x	x[b]	x	x[b]	x		x[b]		x[b]	x	x[b]	x	x[b]	x	x[b]	x	
Continuous phase: Cycle 4 onwards (4-week cycles)																				
ISA (10 mg/kg)	x									x										
Lenalidomide (25 mg)	Days 1–21																			
Dexamethasone (20 mg)	x				x					x		x								

[a]: Cycle 1 only; [b]: Patients ≥75 years receive dexamethasone only on these days

Methods: All enrolled patients will provide written informed consent. Approximately 440 patients with symptomatic MM (International Myeloma Working Group [IMWG] criteria) will be randomly assigned, according to Revised International Staging System criteria (I or II *vs* III *vs* unknown) and age (<70 *vs* ≥70 years), in a 3:2 ratio to ISA 10 mg/kg plus VRd or VRd alone for four 6-week cycles (induction phase) (Table). After Cycle 4, patients will receive Rd with or without ISA in 4-week cycles until disease progression, unacceptable adverse events (AEs), or patient decision to discontinue (Table) (continuous phase). ISA will be reduced to monthly dosing from Cycle 18. Patients in VRd arm who progress during the continuous phase could be eligible for cross-over to ISA plus Rd. The primary endpoint is PFS, which is defined as the time from randomization to the date of disease progression (assessed by a blinded independent review committee according to IMWG criteria) or death, and will be compared between the two arms with a 1-sided stratified log-rank test. Key secondary endpoints will include rate of very good partial response or better, minimal residual disease negativity rate, and complete response rate. Safety evaluations include AEs, laboratory parameters, vital signs, and physical examination.
Results: The IMROZ study is currently enrolling patients; recruitment is planned in approximately 100 sites worldwide, including Japan and China.
Summary/Conclusion: This Phase III, randomized, multicenter study will provide an evaluation of the efficacy and safety of ISA plus VRd in patients with transplant-ineligible NDMM.

A MULTI-CENTER RETROSPECTIVE STUDY OF BONE DESTRUCTION ASSOCIATED WITH 419 NEWLY DIAGNOSED MULTIPLE MYELOMA

Y. Jin[1,*], H. Liu[2], L. Ding[3], X. Tong[4], H. Tu[3], P. Liu[3], H. Shen[5], F. Zhou[1]

[1]Department of Hematology, Zhongnan Hospital of Wuhan University, Wuhan,

[2]Department of Hematology, Second Affiliated Hospital, Medical School of Xi'an Jiaotong University, Xi'an, [3]Department of Hematology, Zhongnan Hospital, Wuhan University, [4]Department of Hematology, hongnan Hospital, Wuhan University, Wuhan, [5]Department of Hematology, Zhongnan Hospital of Wuhan University, Wuhan, China

Background: Multiple Myeloma (MM) patients with bone destruction is difficult to restore, so deeply explore the factors affected the bone destruction associated with MM will be important in clinic. This study retrospectively analyzed 419 cases with multiple myeloma.
Aims: In this study, the factors correlated with bone destruction and factors affecting survival and prognosis of myeloma bone destruction were analyzed by a retrospective study.
Methods: Comparison between categorical variables was made by the chi-square analysis with pearson test. The parametric t test with independent samples was used to compare the mean of variables between without bone destruction and with bone destruction patients. Correlation was analyzed using bivariate correlation analysis by pearson test (r). The multivariate analysis that factors associated with bone destruction were determined by binary logistic regression model with forward stepwise. The survival analysis was evaluated according to the Kaplan-Meier method with the two-sided log-rank test
Results: Multiple linear regression analysis showed that those MM patients with higher concentration of Ca^{2+} in serum, higher positive rate of CD138 immuno-phenotype and advanced in stage with 13q34 deletion in cytogenetics would more prone to bone destruction, while total bile acid (TBA) and Kappa chain isotope negatively correlated with bone destruction in MM patients. The Kaplan-Meier analysis indicated that Ca^{2+}, serum β2-microglobulin (β2-MG), hemoglobin (HGB), creatinine (CREA), uric acid (UA) and age correlated with the survival of bone destruction in MM patients. Cox regression analysis further showed that the independent prognostic factors of β2-MG and CREA had higher risk for early mortality in bone destruction patients. Moreover, a novel index based on β2-MG and globulin (GLB) to white blood cell (WBC) ratio were associated with high-risk and predicted poor survival of bone destruction patients, which will be a novel index predicts prognosis of myeloma patients using routine examination method instead of bone marrow aspiration and has an important significance for clinical guide.
Summary/Conclusion: In a conclusion, for MM patients, those with higher concentration of Ca^{2+} in serum, higher positive rate of CD138 immunophenotype and advanced in Stage with 13q34 deletion in cytogenetics would more prone to bone destruction. Hypercalcaemia, elevated serum β2-MG, anemia, renal insufficiency, elevated UA and advanced in years were correlated with poor survival and high risk in bone destruction of multiple myeloma. Combined β2-MG, GLB and WBC significantly predicts prognosis of bone destruction patients, which will be an important significance for clinical guide.

PB2187

MONTELUKAST AND GEMFIBROZIL WHEN ADDED TO BORTEZOMIB BASED THERAPY INDUCES RAPID RESPONSE IN PATIENTS WITH REFRACTORY AND HIGH RISK DISEASE

S. O'Mara[1,2,3,*]

[1]Tamara Hospital, [2]Haematology, Laverty pathology, [3]New England Northwest Haematology, Tamworth, Australia

Background: The CyBorD drug regimen when administered to patients with multiple myeloma results in a complete response rate of 40% in previously untreated multiple myeloma and a complete response rate of 8% in relapsed or refractory myeloma. It has been found that Montelukast and Gemfibrozil when used in poor prognosis multiple myeloma deepens the response and reverses resistance to Bortezomib based treatment (MOM trial). The response was demonstrable within 1 cycle of CyBorD (28 days) and there was no additional toxicity. The question arises as to whether these agents when used up front earlier in the disease process leads to deeper and more rapid response.
Aims: To determine whether montelukast and gemfibrozil when added to bortezomib chemotherapy from the first cycle leads to an increase in complete responses over expected responses and whether the time taken to reach response is faster and deeper.
Methods: Three patients with relapsed/refractory Multiple Myeloma and two patients with high risk *de novo* disease have been given Montelukast 30mg orally twice daily with Gemfibrozil 600mg orally twice daily in combination with CyBorD regimen. Patient 1 and 2 had progressive disease while on CTD treatment including a patient with multiple soft tissue plasmacytomas and 17p deletion. The third patient had dialysis dependent renal failure for a period of 3 months prior to receiving treatment. The Fourth patient had recurrent nephrotic syndrome on the basis of AL Amyloid previously treated 6 years earlier with CTD. The fifth patient had Multiple Myeloma with suspected cardiac amyloid causing cardiac failure. The expected number of complete responders in this cohort was 1/5 and an expected ORR of 60%.
Results: 4/5 patients achieved a complete haematological resonse in paraprotein with a mean time to complete response of less than 35 days. 80% CR. 1/5 patient has achieved a haematological partial response. ORR 100% Expected 2= 40% chi^2 =14. df =2 p<0.01. Treatment is continuing and it is anticipated that all four patients in complete remission will undergo bone marrow biopsy and minimal residual disease assessment at the completion of four cycles of treatment. The soft tissue plasmacytomas resolved in 10 days, The symptoms signs of nephrotic syndrome improved markedly in 10 days. The renal failure appears to be improving (lower creatinine, more urine output) in 3 weeks. One patient was also found to have stage II co-existing breast cancer which partially responded to non breast cancer chemotherapy. There has been a partial response with post mastectomy histology to be reported at the congress. Patient 1 has been in complete remission for a period of two years.
Summary/Conclusion: The addition of Montelukast to standard CyBorD chemotherapy in high risk patients leads to an extremely rapid and much deeper response in most patients treated with CyBorD chemotherapy. There is little toxicity. The ORR is 100% with a haematological CR rate of of 80%. The rate of sCR will be published following further bone marrow studies when all four cycles of CyBorD are completed.

PB2188

EFFICACY, SAFETY AND TOLERABILITY OF CARFILZOMIB LENALIDOMIDE-DEXAMETHASONE (KRD) REGIMEN IN RR/MM

V. Calafiore*, E. Martino, M. Parisi, G. Sapienza, V. Del Fabro, S. Leotta, A. Romano, C. Conticello, F. Di Raimondo

Division of Hematology, Azienda Policlinico-OVE, University of Catania. Via Santa Sofia n.[78], [95100], Catania, Italy, CATANIA, Italy

Background: Carfilzomib, Lenalidomide and Dexamethazone (KRd) is currently utilized in relapsed/refractory multiple myeloma (RRMM) patients (pts) that have experienced almost one line of treatment. Improved progression free survival and overall survival was detected in this setting of pts treated with this combination in clinical trials. Although the onset of new cardiovascular events (CV) or worsening of pre-existing CV events have been described in less than 10% of pts, the regimen has an accettable safety and tolerability. Since its approval in Italy, data on real life KRd use are still lacking.
Aims: We conducted an analysis of RRMM pts treated with KRd out of clinical trials to provide further insights on efficacy, tolerability and safety.
Methods: From November 2016 up to now 35 RRMM pts were exposed to KRd. Median number of prior therapies was 2 (range 1-6); 16 (45%) was classified as high risk pts (r-ISS) and 17 (48%) were previously autotransplanted.
Results: We report results of the first 12-months safety interim analysis on KRD treatment of RRMM. Data cut-off was January 2018. 35 pts with a median age of 65 years (range 50-79) were evaluated. All the pts received almost 2 cycles, 1 pts 16 cycles, 2 pts 15 cycles, 3 pts 14 cycles, 2 pts 13 cycles, 2 pts 12 cycles, 3 pts 11 cycles, 2 pts 10 and 9 cycles, 5 pts 8 cycles, 2 pts 7, 6, 5 and 4, 2 pts only 3 cycles, 3 pts only 2 cycles, At least 5 KRD treatment cycles were given to 28 (80%) pts. All pts had a response to treatment at the first/second cycle. At the end of the second cycle 26 (74%) pts obtained a response. Overall response rate with KRD was nearly 80% among the 28 pts that have completed 5 cycles.The majority of the pts(n=26, 96%) responded after at least 1 cycle of chemotherapy. Partial response were observed in 6 pts(21%). Rate of very good PR was 32% (9 pts); 3 pts(10%) achieved complete response (CR), 1 patient minimal response (MR), 6 pts obtained a stable disease, 6 pts obtained a stable response and then progressed. To identify pts that could obtain the most advantage by KRd treatment, we distinguished pts that have completed almost three cycles in two groups, based on previous exposure or not to lenalidomide (Table1). The 13 pts previously treated with lenalidomide (group A), compared to 15 pts not exposed to lenalidomide (group B), showed a worst profile: in the group A there was a higher% of refractory pts(25% *vs* 11%, p=0.0007) who received more prior treatments, despite the duration of the last treatment was similar in both groups. The regimen was well tolerated. with grade 3-4 haematological and non-haematological AEs on 10 (35%) and 15 (53%) pts respectively. Grade 3-4 non- haematological AEs occurred in 53% of patients, the most common being pneumonia/fever (3/2, 10/7%), hypertension (8, 28%) hiperglicemia (1, 3%), and cardiac failure (2, 7%). Cardiac

AEs were 35% (10 pts). Pts with ≥1 CV risk factor at enrolment had a an increased risk of developing a CV AE during treatment as compared to pts with no CV risk factors.1 pt died of infection (not treatment-related). In pts who developed serious AE, KRD dose reduction (2, 7%) and discontinuation (3, 10%) were applied. Onset of CV events significantly increased the rate of dose reductions and treatment discontinuation. CV AEs may significantly impact treatment compliance and survival.

Table 1.

	Previous exposure to lenalidomide (n = 13) Group A	No previous exposure to lenalidomide (n = 13) Group B	p-value
Median age, years (range)	65 (49-77)	66 (51-78)	0.2
Males, n (%)	10 (77%)	8 (66%)	0.2
Paraproteins (isotype), n (%)			
Immunoglobulin G	10	7	0.13
Immunoglobulin A	1	3	0.6
Light chain only	2	3	0.39
Cytogenetics			
del13q	2	2	>0.99
t4,14 or t 11,14	3	4	>0.99
del17p	1	1	>0.99
normal	7	8	>0.99
Stage ISS			
I	7	6	0.7
II	2	4	0.65
III	4	5	>0.99
Prior treatments			
Single autologous SCT	4 (14%)	1 (3.5%)	0.15
Double autologous SCT	4 (14%)	7 (25%)	0.46
Median of prior treatments	5	2	0.46
Status disease			
Relapse	6 (21%)	12 (43%)	0.0007
Refractory	7 (25%)	3 (11%)	
PFS from the last treatment			
< 6 months	5 (18%)	5 (18%)	0.12
6-12 months	4 (14%)	6 (21%)	0.11
> 12 months	4 (14%)	4 (14%)	0.12
Response after two cycles			
At least PR	5 (18%)	11 (39%)	0.0005
Less than PR	8 (29%)	4 (14%)	
Best response			
At least PR	6 (22%)	12 (43%)	0.0004
Less than PR	7 (25%)	3 (10%)	

Summary/Conclusion: Rate of VGPR obtained with KRd combination was high with an overall response of about 80%. Safety profile was acceptable with a 35% of CV events. Additional analyses are needed to evaluate the impact of these patterns on efficacy outcomes.

AUTOLOGOUS STEM CELL TRANSPLANT IN PATIENTS WITH MULTIPLE MYELOMA AND RENAL FAILURE

L. Foster[1,*], S. Rassool[1], Y. Li[1], F. Dignan[2], D. Osborne[3], J. Norman[2], C. Barnes[4], R. Brown[5], C. Lobetti-Bodoni[2], S. Roberts[6], C. Gregory[7], R. Beezley[2], M. Waller[2], S. Choudhuri[3], H. Osman[7], E. Abu-Rashed[2], S. Raj[5], R. Thomas-Dewing[4], M. Rowlands[3], K. Brice[2], J. Sudhir[2], E. Tholouli[2], A. Rocci[2,8]

[1]Medical School, The University of Manchester, [2]Haematology, Manchester Royal Infirmary, Manchester University NHS Foundation Trust, [3]Haematology, Royal Oldham Hospital, The Pennine Acute Hospitals NHS Trust, [4]Haematology, Salford Royal Hospital, Salford Royal NHS Foundation Trust, [5]Haematology, Trafford General Hospital, Manchester University NHS Foundation Trust, [6]Haematology, Royal Bolton Hospital, Bolton NHS Foundation Trust, [7]Haematology, Royal Albert Edward Infirmary, Wrightington Wigan and Leigh NHS Foundation Trust, [8]Faculty of Biology, Medicine and Health, Division of Cancer Science, The University of Manchester, Manchester, United Kingdom

Background: Different degrees of renal impairment are commonly observed in patients with multiple myeloma (MM) due to direct or indirect damage to the kidneys by plasma cells or light chains. Most of the patients do partially recover kidney function, but for those with permanent kidney impairment the treatment options can be limited, particularly in regard to the autologous stem cell transplant (ASCT).
Aims: To retrospectively review the outcome of a cohort of patients with varying degrees of renal failure, treated with ASCT.
Methods: A representative group of patients with MM, treated in the Greater Manchester area and referred to Manchester Royal Infirmary for ASCT between 1/1/2010 and 31/12/2016 have been included in this study. They have been randomly selected from over 300 patients treated with ASCT. Patients received Melphalan 200mg/m^2 or 140mg/m^2 if creatinine clearance (CrCl) <30 ml/min or serum creatinine >200µmol/L. Time To Next Treatment (TTNT) and Overall Survival (OS) curves have been compared using log-rank test.
Results: A cohort of 158 patients was analysed. At the time of ASCT, 71 patients had CrCl ≥90ml/min (normal), 51 patients had CrCl of 60-89 ml/min (Chronic Kidney Disease (CKD) 2), 22 patients had CrCl of 30-59 ml/min (CKD 3) and 14 patients had CrCl of ≤30ml/min (CKD4, including 3 patients on dialysis). As expected, induction treatment differed according to CrCl: 70% patients with CKD1+2 received a Thalidomide-containing induction compared to 44% of those with CKD3+4, whilst a Bortezomib-based regimen was used in 26% *vs* 55%, respectively. The response after induction was similar: in the patients with CrCl ≥60 the CR was 32% (38% in patients with CrCl <60), VGPR was 48% (vs 49%), PR 18% (vs 13%), MR 1% (vs 0%) and PD 1% (vs 0%). Three months after ASCT, both groups' responses improved: CR 43% in patients with CrCl ≥60 (vs 62%), VGPR 47% (vs 25%), PR 9% (vs 10%) and 1 patient had PD in the CrCl<60 group. These translated into a 5-year TTNT of 65.6% for the patients with CrCl ≥60 *vs* 50.6% for patients with CrCl <60 (HR 0.526, CI 0.255-1.086, p=0.0824). The 5-year OS was the same at 81.6% for both groups (HR 0.848, CI 0.365-1.969, p=0.701). The toxicity profile in the 2 groups was largely similar: in patients with CKD1+2 the median days of hospitalisation for ASCT was 19, compared to 20 for patients with CKD3 and 23 for those with CKD4, and the median number of days with CRP >50mg/L was 5 and 7, respectively. Median time to engraftment showed no differences between the CKD1+2 and CKD3+4: Absolute Neutrophil Count >1x10^9/L in 13 *vs* 12.5 days, platelets >100x10^9/L in 19 *vs* 22 days and haemoglobin >10g/L after 28 *vs* 29 days, respectively. Rates of readmission to hospital were lower in the CKD1+2 group at 11.5% compared to 19.4% in CKD 3+4. Moreover, median days of readmission per patient were lower in CKD1+2 groups: 6.7 *vs* 10. Of note, sequential eGFR measurements in patients with CKD3+4 showed an improvement in kidney function over time: in patients with CKD 3 (and CKD 4) the median eGFR at diagnosis was 35 (and 12.5), pre-ASCT was 46 (and 20), 3 months after ASCT was 45.5 (and 20.5) and 12 months after ASCT was 42.0 (and 25).
Summary/Conclusion: Patients with MM and kidney impairment seem to benefit from ASCT to a similar level to patients with normal kidney function in terms of quality of response and long term survival. Patients with poorer kidney function show greater improvement in eGFR following ASCT. A higher rate of readmission has been observed in patients with kidney impairment, suggesting the need for closer follow-up in this particular population.

KRD TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS: A REAL LIFE EXPERIENCE

G. Barilà[1,2,*], V. Meneghini[1,3], A. Bonalumi[1,3], A. Furlan[1,4], F. Patriarca[1,5], F. Colasante[1,5], F. Scognamiglio[1,6], R. Sartori[1,7], M. Rupolo[1,8], M. Tinelli[1,9], N. Pescosta[1,10], C. Minotto[1,11], A. Liço[1,2], T. Berno[1,2], G. Semenzato[1,2], R. Zambello[1,2]

[1]Multiple Myeloma Triveneto Network, Triveneto, [2]Department of Medicine, Hematology and Clinical Immunology section, Padua University School of Medicine, Padua, [3]Department of Medicine, Section of Hematology, University Hospital of Verona, Verona, [4]Hematology Unit, Santa Maria di Ca' Foncello Hospital, Treviso, [5]Clinica Ematologica, Azienda sanitaria Universitaria Integrata, DAMe, Università di Udine, Udine, [6]Department of Hematology, San Bortolo Hospital, Vicenza, [7]Department of Medicine, Section of Hematology, Hospital of Castelfranco Veneto, Castelfranco Veneto, [8]Department of High Dose and Cellular therapy, C.R.O. Aviano hospital, Aviano, [9]U.O.C. Internal Medicine, San Bonifacio hospital, San Bonifacio, [10]Ematologia e Centro TMO, Ospedale Centrale Bolzano, Bolzano, [11] UOC di Oncologia ed Ematologia Oncologica, Mirano hospital, Mirano, Italy

Background: Multiple Myeloma (MM) is a hematologic neoplasm characterized by the proliferation of malignant clonal plasmacells in the bone marrow. The outcome of MM patients has significantly improved in the last years with the introduction of proteasome inhibitors (PI) and immunomodulatory (IMIDs) drugs as bortezomib and lenalidomide respectively. Besides, triplet regimens containing IMIDs with PI or monoclonal antibodies represent nowadays the backbone treatment for relapsed patients treatment. In detail, in the ASPIRE trial, the combination of second generation PI carfilzomib with lenalidomide and dexamethasone (KRD) led to a unprecedented results in term of high quality responses and progression free survival (PFS) with respect to lenalidomide-dexamethasone standard treatment. These results led to the approval in 2016 in Italy of KRD treatment for relapsed MM patients.
Aims: Here we report a multicentric real life experience of treatment with KRD in relapsed MM patients on behalf of the Gruppo Mieloma Triveneto.
Methods: A cohort of 80 patients affected by relapsed MM patients according to IMWG criteria was treated with KRD, in 10 hematological unit of Triveneto, Italy. Clinical characteristics, including response to treatment and toxicities, were collected.
Results: Median patient's age was 62 years (42-76) with 32/80 patients (40%) with >65 years. Patients previously received a median of 2 lines of

therapy (1-7), with 25/80 (31%) underwent to at least 3 regimens. Most patients (54/80, 68%) were treated due to clinical relapse, with 9/54 (17%) developing extramedullary disease, while only 26 patients (32%) received KRD due to biochemical relapse. With a median number of 5 cycles (1-17) of KRD received, the overall response rate (ORR) was 76% (61/80), including 40% of high quality response (21% Very Good Partial Response [VGPR] and 19% Complete Response [CR]). ORR and high quality response rate were higher although not significantly different among patients who previously received 1-2 lines of therapy towards patients who received >2 regimens (80% *vs* 65%, p=0.16 and 53% *vs* 35%, p=0.15). Eight patients (10%) during KRD treatment underwent to peripheral blood stem cells (PBSC) apheresis, 7 using high dose cyclophosphamide, and one using lenograstim with plerixafor. Almost all patients (7/8, 88%) completed PBSC collection, with a mean 7.39x10^6/Kg PBSC harvested. Besides, 7 patients already received stem cell transplantation, 5 using autologous PBSC and 2 using allogenic PBSC. Hematological toxicities were mild with neutropenia present in 27% of patients, thrombocytopenia in 26% and anemia in 11%; grade 3 toxicities were even lower (11%, 9% and 4% respectively). Non hematological toxicities were mostly infective, with 22 patients (28%) involved (with 8% of grade 3 events). Cardiovascular events including hypertension and heart failure were mild, with 8% of any grade events and only 5% grade 3 events. With a median follow up of 5 months, median PFS not reached; moreover, median PFS of patients who received at least 2 lines of therapy is already significantly higher than in patients who received >2 lines of therapy (17 months *vs* undefined, p=0.03).

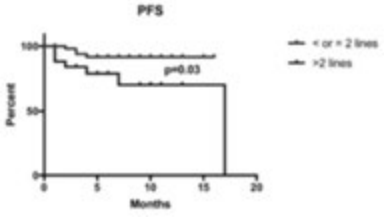

Figure 1.

Summary/Conclusion: In our experience, KRD treatment is feasible and effective in a non selected cohort of relapsed MM patients. The safety profile was acceptable, with main toxicities being represented by hematological and infective events, while cardiovascular side effects were fewer and less serious. Although our results need to be confirmed with a longer follow up, we point to the worst outcome in term of PFS of heavily treated patients.

ORAL CYCLOPHOSPHAMIDE'S ADDITION IN RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS WITH BIOCHEMICAL PROGRESSION DURING LENALIDOMIDE-DEXAMETHASONE TREATMENT

L. Cesini[1,*], A. Siniscalchi[2], S. Grammatico[1], A. Andriani[3], A. Fiorini[4], L. De Rosa[5], T. Za[6], A. Rago[7], T. Caravita[2], M.T. Petrucci[1]

[1]Department of Cellular Biotechnologies and Haematology, Sapienza University of Rome, [2]Institute of Haematology, S. Eugenio Hospital, [3]Department of Haematology, Nuovo Regina Margherita Hospital, Rome, [4]Department of Hematology, Belcolle Hospital, Viterbo, [5]Department of Haematology, S. Camillo Hospital, [6]Institute of Haematology, Catholic University, Rome, [7]Department of Cellular Biotechnologies and Haematology, Sapienza University of Rome, Polo Pontino, Latina, Italy

Background: Multiple Myeloma (MM) remains an incurable disease despite recent advances in therapy and supportive care. Retreatment for relapsed-refractory multiple myeloma (RRMM) represents one of the therapeutic challenge as well as the change of family drugs. Alkylating drugs have been the standard of care for MM patients (pts) for many years, with melphalan and prednisone (MP) being considered the standard approach for pts not eligible for autologous transplantation. Lenalidomide combined with dexamethasone (Rd) is one of the current standards for treatment of RRMM. However the majority of pts become resistant during the treatment.
Aims: We evaluated the addiction of cyclophosphamide (CRd) in RRMM pts who experienced biochemical relapse during Rd treatment, to slow down the progression in active relapse.
Methods: This analyses included 31 pts with RRMM treated with Rd who received cyclophosphamide at biochemical relapse. Data were collected in 7 Italian Centers of the Multiple Myeloma GIMEMA-Latium Region Working Group. The median age of pts was 70 years (range: 50-86); 15 males and 16 females. The median line of previous treatments was 1 (range: 1-4). Median time from diagnosis to the first CRd cycle was 32.4 months (range: 8.5-187). The CRd regimen was continued in responding pts or in stable disease (SD) until disease progression (PD).
Results: All pts received Rd with a median of 15 cycles (range: 1-52). Responses to Rd were observed in 18 pts (58%), particularly 12 partial responses (PR), 3 very good partial responses (VGPR) and 3 complete rsponses (CR). Three pts maintained a SD. Grade 3/4 side effects were neutropenia (19%), anemia (9.7%), muscle cramps (9.7%), polyneuropathy (9.7%), diarrhea (6.5%), infections (6.5%), esophagitis (3.2%) and rash (3.2%). One patient experienced pulmonary embolism (3.2%). All 31 pts developed a biochemical relapse during Rd treatment, with a median time of 18.5 months (range: 1-49) and received cyclophosphamide without lenalidomide dose modification. The median number of CRd cycles administered was 8 (range: 1-35) and the median time to response after CRd was 2.5 months. A response was observed in 9 (29%) pts, particularly 3 VGPR and 6 PR. Ten patients obtained a SD and 12 a PD. Among the responding pts, 3 are still in therapy with CRd. No correlation between Rd and CRd responses was observed. After a median observation time of 40 months, the median OS from the diagnosis of MM was 78.8 months, while the median OS from the beginning of CRd was 17.7 months. No significant difference in OS was observed between pts treated with 1 or >1 prior antimyeloma regimen (OS 22.9 months *vs* 13.5 months, p=0.65). The age at diagnosis (≥ or <70 years) was not predictive of outcome, with a median OS of 17.7 and 13.8 months for patients ≥ of 70 or <70 years, respectively (p=0.94). In addition median time to progression (TTP) was 7.6 months (range: 1-33) and the median PFS from the beginning of CRd was 13.1 months. No additional adverse events were observed by adding cyclophosphamide to Rd. After a median follow up of 11 months (range: 1.3-50.9), there were no treatment-related deaths, but 17 pts (55%) died for progressive myeloma, with a median time of 9.1 months (range: 1-38).
Summary/Conclusion: We confirm that Rd is an effective and well tolerated regimen for RRMM pts, inducing a high response rate. However, the addition of oral cyclophosphamide delays the progression in few pts, who present a biochemical relapse during Rd treatment.

PB2192

EARLY RELAPSE AFTER AUTOLOGOUS BONE MARROW TRANSPLANTATION IS A MAJOR PREDICTIVE FACTOR OF LOWER OVERALL SURVIVAL IN MULTIPLE MYELOMA PATIENTS

A. Roque[1,2,*], M.C. Afonso[2], E. Cortesão[1,2], A.I. Espadana[2], A.B. Sarmento-Ribeiro[1,2], C. Geraldes[1,2], M.L. Ribeiro[2]

[1]Faculty of Medicine, University of Coimbra, [2]Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: The new generation drugs and consolidation of response with high-dose chemotherapy and autologous hematopoietic stem cell transplantation (aHSCT) have revolutionized the prognosis of multiple myeloma (MM) patients (pts). However, MM remains a not curable disease and ultimately all pts will relapse, with different studies indicating 16-20% of relapse in the first year after aHSCT. Nevertheless, the relevance of early relapse after aHSCT in prognosis remains unclarified in the era of more and more effective and diversified treatments.
Aims: We aimed to evaluate the characteristics of pts that early relapse after aHSCT as well as its impact in overall survival (OS).
Methods: We analyzed 207 consecutive aHSCT performed in MM pts in our centre between January/2007 and December/2016. Pts were divided into two groups: R1 (relapse ≤12 months from aHSCT) and R2 (either relapsed >12 months after aHSCT or are disease free at the last follow up). The assessment of response was based on the International MM Working Group consensus criteria (2016).
Results: The median age of the cohort was 59 (27-70) years, 59.4% were male, which was similar between the two groups (p=NS). Thirty-two pts (15.5%) relapsed in the first year post-aHSCT (R1), while 175 (84.5%) relapsed after 1 year or maintain response at the time of the last follow-up (R2). Considering the pts with follow up over 3 years in group R2 (n=127), 30 (23.6%) relapsed between 12-36 months post-aHSCT, 27 (21.3%) relapsed after 3 years and 70 (55.1%) did not relapse after a median follow up of 54.6 months. Clinical and laboratorial characteristics such as International Staging System score, bone involvement, extramedullary disease and cytogenetic alterations were similar between the two groups. The percentage of pts treated with IMIDs was higher in R1 group (34.4 *vs* 16.6%; p=0.02), while the number of pts treated with proteasome inhibitor, the number of previous therapeutic lines, and the time between diagnosis and aHSCT were similar (p=NS). The percentage of patients with complete response (CR) criteria before aHSCT was similar between R1 e R2 (p=NS). However, there was a significant difference when we considered the achieve-

ment of CR 100 days after aHSCT, that was higher in group R2 (9.7 *vs* 13.8%; p<0.001). The early relapse group presented lower OS after diagnosis (36.3 months *vs* not reached [NR]; *Hazard ratio* [HR]=0.18; p<0.001) as well as after aHSCT (15.4 months *vs* NR; HR=0.14; p<0.001). Considering the group of pts that relapsed during the follow-up (n=89), the OS after relapse was significantly higher in those who relapse after the first year (11.3 *vs* 79.9 months; HR=0.43; p=0.015).
Summary/Conclusion: This study corroborates the concept that early relapse after aHSCT is a major negative prognostic factor, in the era of novel agents, with the sustainability of response being a very important variable. No clinical or analytical variables analyzed seemed to influence relapse timing.
Relapse at the first year correlated inversely with the depth of response at day 100 after aHSCT, in a more relevant way compared with the previous response. These results, conjoining with the absence of correlation between the time diagnosis-aHSCT and the time of relapse, suggest that aHSCT should not be delayed in order to obtain a prior deeper response.

LIGHT-CHAIN DEPOSITION DISEASE: DIAGNOSIS AND TREATMENT CHALLENGES. A SINGLE CENTER EXPERIENCE

S. Badelita[1,*], A. Jercan[1], R. Irimia[1], M. Popescu[1], D. Vasilache[1], C. Pantoc[2], D. Coriu[3]

[1]Hematology and Bone Marrow Transplant Department, Fundeni Clinical Institute, [2]Nephrology, Carol Davila, [3]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background: Light-chain deposition disease is characterized by deposition of nonamyloid monoclonal light chains in multiple organs. It is a rare disease caused by overproduction of kappa chains and very rarely lambda chains by a single clone of plasma cells. LCDD can occur in any organ but kidneys are always involved as a rapidly progressive glomerulonephritis or acute tubulointerstitial nephritis. A mandatory step in LCDD diagnosis is identifying the monoclonal pathological light chain in serum or urine. LCDD should be distinguished from other monoclonal proteins associated diseases like cryoglobulinemia, myeloma cast nephropathy, amyloidosis and Fanconi syndrome.
Aims: Large multicenter series of patients are needed to develop an optimal standardized treatment strategy.
Methods: We present a single center experience with twelve cases of LCDD diagnosed betweed 2015 and 2017. We assessed the patients with the same panel of investigations used in the case of amyloidosis, including serum electrophoresis and immunofixation, free light chain assay, proteinuria, fibroscan, echocardiogram, electromyography and whole body-low dose CT. Renal biopsy, bone marrow aspirate and biopsy, abdominal fat biopsy and salivary gland biopsy were performed on every patient. All diagnosis were confirmed following renal biopsy (electronic microscopy and immunofluorescence) that presented glomeruli with dense linear subendothelial deposits in capillary loops; patchy dense deposits ; mezangiosclerosis areas; multiple endothelial detachments; disorganised tubular basal membrane with spidery, linear dense deposits.In our group of patients all abdominal fat biopsies were Congo red stain negative under polarized light.
Results: Eleven of them had kappa LCDD and one presented lambda LCDD. All the patients had a bone marrow plasmacytic infiltrate of under 10%. None of them had osteolytic bone lesions. Three patients had hepatic involvement (Fibroscan >8,6 kPa) and one patient presented restrictive cardiomiopathy.Two patients had Sicca Syndrome. Electromyography showed sensitive neuropathy in one patient, chronic motor-sensitive axonal polyneuropathy in one patient and chronic demyelinating polyneuropathy in one patient. Renal involvement was present in six patients as stage 3 CKD, two had CKD stage 4 and the other four stage 5 CKD. Four patients required hemodyalisis initiation. Three patients presented with nephrotic syndrome and seven patients had subnephrotic range proteinuria. Three had microscopic haematuria. Nine patients presented with secondary hypertension.
Ten patients received Bortezomib-based therapy and two patients received Melphalan based therapy. Two of them underwent autologous bone marrow transplant without complications and without additional renal function reduction. After the completion of the treatment, in 2018 all twelve patients are alive with controlled disease. None of them required therapy resumption. Four patients had CR/VGPR and three of them showed renal function improvement. ASCT was performed even in advanced CKD stages.
Summary/Conclusion: LCDD should be considered in patients with MGUS and CKD. Bortezomib based therapy followed by ASCT showed promising results.

PB2196

EFFECTIVENESS OF BENDAMUSTINE IN RELAPSED OR REFRACTORY AL AMYLOIDOSIS

N. Forgeard[1,*], S. Harel[1], A. Talbot[1], B. Royer[1], I. Madelaine[2], M. Vignon[1], M. Baron[1], J. Verine[3], J.-P. Fermand[1], B. Arnulf[1]

[1]Immuno-hematology, [2]Pharmacy & Chemotherapy preparation Unit, [3]Anatomopathology, Hôpital St-Louis, Paris, France

Background: Treatment of AL amyloidosis (non IgM) currently aims at suppressing amyloidogen free light chains by targeting the underlying pathological plasmocyte clone. First line therapy relies on melphalan or bortezomib-cyclophosphamide with dexamethasone. However, there is no standardized treatment for relapsed or refractory patients. Bendamustine is an alkylating agent already used in multiple myeloma, with low cardiac, nephrologic or neurologic toxicities, and has already been studied in two series (one prospective and the other retrospective) without available data concerning organ response.
Aims: Our aim was to assess efficacy and tolerance of bendamustine as a salvage therapy in relapsed of refractory non IgM AL amyloidosis.
Methods: We retrospectively studied the data of 22 patients who received bendamustine for relapsed or refractory amyloidosis (IgA, IgG, kappa or lambda free light chain), treated in our center between 2012 and 2016. Patients had to receive at least 3 courses to be included. IgM amyloidosis were excluded. Bendamustine was administered in 28 days cycles, in association with high dose steroids. Associated treatments were determined by physicians on a case-by-case basis. Immunochemical and organ responses were assessed according to the First Roundtable on Clinical Research in Immunoglobulin Light-Chain Amyloidosis guidelines.
Results: The 22 patients (13 men, 9 women, median age 58 years) in this study had previously received a median number of 2 lines of therapy (melphalan 59%, bortezomib 86%, ASCT 9%). Organ involvement prior to therapy was as follows: heart 64%, renal 68%, liver 23%, GI tract 23%, neurologic 45%. Five patients (23%) had associated smoldering multiple myeloma. All patients received associated treatment with high dose steroids, 5 (23%) received bortezomib and 2 (9%) received thalidomide. Twelve patients (55%) achieved haematologic response, with complete response in 1 case (5%) and VGPR in 4 cases (18%). Among patients with hematologic response, 5/12 (42%) experienced organ response. The median overall survival was 31 months. Among patients who received ulterior treatment, the median time to next treatment was 5.2 months. Severe adverse events (grade 3 or 4) occurred in 6 patients (27%), among whom 5 experienced febrile neutropenias. One patient previously treated with melphalan, cyclophosphamide and lenalidomide developed secondary AML with complex caryotype, 3 years after 8 courses of bendamustine, of fatal evolution.
Summary/Conclusion: These results concur with those previously reported, and confirm bendamustine's efficacy from an immunochemical point of view, resulting in organ response in 42% of cases. Immediate tolerance is good, but the potential delayed occurrence of secondary myeloid hemopathies should be taken into account, as is the case with all alkylating agents.

PB2197

FACTORS ASSOCIATED WITH RENAL FAILURE AND RENAL FUNCTION RECOVERY IN MULTIPLE MYELOMA

A. Senturk Yikilmaz[1,*], S.M. Bakanay[1], S. Akinci[2], M. Gündüz[2], S. Küçükyurt Kaya[1], S. Doğan[1], I. Dilek[1]

[1]Department of Hematology, Yıldırım Beyazıt University, [2]Department of Hematology, Atatürk Education and Research Hospital, Ankara, Turkey

Background: Renal failure is a common initial presentation of multiple myeloma (MM) and causes significant morbidity and mortality.
Aims: This study aimed to investigate the factors associated with renal failure and renal recovery in MM.
Methods: The clinical features and prognostic factors were retrospectively analyzed for 169 newly diagnosed MM patients at single center. Statistical analyzes were performed using chi-square test using SPSS version 16.0 (SPSS

Inc., Chicago, IL, USA). A value of less than 0.05 was considered significant.The patients with renal failure (Cre ≥2mg/dl) at diagnosis were compared with the cases with normal renal function (Cre<2 mg/dl). Patients with renal failure at diagnosis were further analyzed with regards to renal function recovery after 2 and 4 cycles of anti-myeloma treatment.
Results: The median age of the patient population was 64.8 (39-88) years with male/female 98/71. Forty (23.7%) patients presented with renal failure and 19 patients required hemodialysis. According to the International Scoring System, 43(25.4%) patients had low (I), 46(27.2%) patients had intermediate (II), and 80(47.3%) patients had high (III) ISS score. There were no significant difference between the patients presenting with normal renal function (RN) and the patients presenting with renal failure (RF) in terms of age, gender, bone involvement, the ratio of first line bortezomib containing regimen. Compared with the RN group significantly more patients in RF group had light chain myeloma (p=0.028), high ISS (p=0.003), elevated serum lactate dehydrogenase value (p=0.001), initial hypercalcemia (p=0.001) and anemia (p=0.002). Response rates (≥partial response (PR)) after 2 cycles of anti-myeloma treatment and referral to high dose therapy and autologous transplantation were similar in both groups. However, in the RN group, the ratio of patients achieving ≥PR after 4 cycles of treatment was higher than RF group (p=0.019). Sixteen (42%) of the forty patients with renal failure at the time of initial diagnosis fully recovered after first line anti-myeloma treatment. Patients whose renal functions recovered (RFc) were compared with the patients whose renal functions did not recover (RFnc). There was no statistically significant difference between the RFc and RFnc groups in terms of age, gender, ISS, serum lactate dehydrogenase level, hypercalcemia, anemia, bone involvement and initial requirement for hemodialysis. Response (≥PR) to 2 cycles of anti-myeloma treatment was similar in each group. On the other hand, having light chain myeloma (p=0.012) and lambda light chain (p=0.002) had negative impact on renal function recovery. Fourteen of the 27 patients (51.9%) who received bortezomib containing first line treatment had renal function recovery. Renal function recovery was significantly associated with the use of bortezomib in first line therapy (p=0.004).
Summary/Conclusion: Initial presentation with renal failure is a poor prognostic feature and has negative impact on response to anti-myeloma treatment. On the other hand, renal function recovery is not always parallel to myeloma response. Along with sufficient supportive therapy, having a non-light chain myeloma and prompt initiaion of bortezomib based first line treatment seem to be best indicators of renal function recovery.

PB2198

DEGREE OF VULNERABILITY IN PATIENTS WITH MULTIPLE MYELOMA: A COMPARATIVE STUDY BETWEEN THE APPLICATION OF CLINICAL JUDGMENT AND THE SCALE OF ASSESSMENT (GA SCALE)

E. Abella*, F. García-Pallarols, R. Ben Lashen, A. Senín, L. Martinez-Serra, S. Montesdeoca, I. Párraga, E. Torres, D. Román, M. Ferraro, A. Angona, C. Besses

Hematology Department, Hospital del Mar/IMIM, Barcelona, Spain

Background: The International Myeloma Working Group (IMWG) has defined a frailty score (GA scale) based on comorbidity index, Charlson score and Katz basic activities of daily living scale for elderly myeloma patients. This score has demonstrated to be more sensitive for geriatric assessment and aids in choosing the most appropriate treatment for each patient. Although GA scale calculation is defined as easy, fast and effective, it is sometimes difficult, due to time constraints, to perform it during the pre-treatment visit. For this reason, the therapeutic decision is still often based on clinical judgment.
Aims: To compute the concordance between clinical judgment and GA scale. In discordant cases, to investigate whether the therapeutic decision has been adequate, assessing toxicity, tolerance and treatment discontinuation.
Methods: From 2015 to 2017, 47 evaluations in 43 patients were performed. The clinical judgment was established during the clinical visit considering age, ECOG, family support and cognitive evaluation and patients were classified as Fit, Unfit and Frail. The GA scale was calculated by the case manager before or during the first cycle of treatment except for 3 patients who did not finally receive treatment. Discordant cases were revised according to the clinical follow up. We defined as undervalued and overvalued, patients with a clinical judgment lower or greater than GA scale respectively.
Results: Twenty-five evaluations were done in patients between 65-75 years and 22 in patients >75 years. Discordant results have been found in 21/47 cases (44%) with a low concordance (Kappa= 0,338). Eleven cases were undervalued and 10 cases were overvalued. The treatment was discontinued in 3/11 (27%) cases of the undervalued group and 2/10 (20%) cases of the overvalued group. In both groups, toxicity was the main cause of treatment discontinuation. There were no treatment related deaths. There were no significant differences in number of discrepancies between age groups (p=0.96).
Summary/Conclusion: A low concordance between clinical judgment and GA scale was observed (Kappa=0.338).For discordant cases, discrepancies that led to treatment discontinuation were observed in more than 20% of the cases (20% in overvalued group and 27% in the undervalued group). Both the low concordance observed and the amount of significant discrepancies demonstrate once again that the application of the GA scale in elderly patients is more sensitive than the clinical assessment to establish the most appropriate treatment.

PB2199

IMPACT OF IMPROVEMENT IN RENAL FUNCTION AND WAITING TIME BEFORE INDUCTION THERAPY ON SURVIVAL IN NEWLY DIAGNOSED MULTIPLE MYELOMA

N. Wohner*, G. Varga, P. Farkas, L. Horvath, G. Szombath, E. Horvath, A. Balogh, A. Masszi, J. Varkonyi, T. Masszi

3rd Department of Internal Medicine, Semmelweis University, Budapest, Hungary

Background: Multiple myeloma (MM) is the second most common haematological malignancy among adults in Hungary. Renal impairment is frequent in MM patients and has fundamental impact on overall survival (OS).
Aims: Our research question was how long the waiting time of patients is from the detection of renal impairment (GFR <40 mL/min) until the start of induction therapy and how this waiting time influences OS. We also studied if reversibility/irreversibility of renal failure has an impact on OS.
Methods: We analyzed the medical history of 212 MM patients at Semmelweis University 3rd Department of Internal Medicine, Budapest, Hungary from 2007 to 2017. We studied if renal impairment (GFR <40 mL/min) was reversible (GFR >40 mL/min) or irreversible, as well as how long the patients waited from the diagnosis of renal disease until the first induction therapy for MM. We also compared ISS and FISH data and determined how all these factors influence the OS.
Results: One-third of the patients (74/212) had renal impairment at diagnosis, and in half of these cases (36/74) the renal function was reversible. Before 2012 the renal function was not reparable in 80% of patients, however after 2012 the ratio decreased to 53%, most probably due to the introduction of new generation drugs. OS was significantly lower in patients with irreversible renal failure compared to those without renal impairment (15 *vs* 55 months, p=0.013), however we did not find similar significant difference in patients whose renal impairment was reversible (55 *vs* 47 months, p=0.32). Importantly, the waiting time of those whose renal failure became irreversible was significantly longer compared to reversibly affected patients (7 weeks *vs* 2.5 weeks, p<0.0001).
Summary/Conclusion: Our results point out the importance of speed in the diagnosis of MM. Any delay in the diagnosis and start of the induction therapy worsens the outcome of patients with MM and renal failure. Despite the positive tendency that we detected in the last few years we still have to improve the interdisciplinary cooperation in order to diagnose and treat MM patients as soon as possible.

COMPARING EFFICACY OF INITIAL INDUCTION IN NEWLY DIAGNOSED MULTIPLE MYELOMA. A VALUABLE INFORMATION IN POPULATION-BASED REGISTRIES

R. Ríos-Tamayo[1,*], M.J. Sánchez Pérez[2], D. Sánchez-Rodríguez[3], A. Martín García[4], Y.-L. Chang-Chan[2], S. Sequera[5], J.L. García de Veas Silva[6], J. Sainz Pérez[7], A.B. Rivera Ginés[1], M.E. Clavero Sánchez[1], C. Alarcón Payer[6], M. Jurado Chacón[7]

[1]Monoclonal Gammopathies Unit, University Hospital Virgen de las Nieves, [2]Granada Cancer Registry, Andalusian School of Public Health, [3]Monoclonal Gammopathies Unit, FIBAO, [4]Clinical Trials Unit, [5]Pharmacy, [6]Immunology, [7]Hematology, University Hospital Virgen de las Nieves, Granada, Spain

Background: Prognosis in multiple myeloma (MM) depends on specific patient and disease characteristics, staging and response. Strong evidence supports the quality and duration of the response, in accordance with IMWG criteria, as a key prognostic factor. Therefore, a careful monthly monitoring of response is mandatory, as well as a global evaluation after

each phase of the treatment. Outside clinical trials (ct), heterogeneity remains in relation to response evaluation of real-life patients. Even in the setting of population-based MM registries, the response is rarely reported.
Aims: Assessing the evolution of the response to old and current induction regimens.
Methods: The Granada MM Registry is the second largest single-institution population-based registry (Ríos-Tamayo R *et al.*2015), working since 1985. Evaluation of the response was prospectively recorded since 2012, and retrospectively during the previous period. IMWG criteria have been used, including imaging (PET/CT) and flow minimal residual disease (MRD)(Kumar S *et al.*2016). All consecutive newly diagnosed MM (NDMM) patients with residence in our reference area, which were considered fit to receive the standard induction regimen at the moment of diagnosis, were included. Overall response rate (ORR) and complete response (CR) rate have been pointed out. When information was not available, the response was informed as unknown/not valuable.

Table 1.

REGIMEN	n	ORR %	CR %	MRD NEG%	UNKNOWN	CLINICAL TRIAL
MP	25	20	4	-	44	N
VAD	74	50.1	4.1	-	33.8	N
VCMPVBAD	6	66.6	33.3	-	16.7	N
VD	58	58.6	19	3.5	22.4	N
VMP	53	52.9	18.9	-	35.8	N
VCD	97	79.3	24.7	2.1	8.3	N
VRD	20	95	70	35	5	Y(18)
VTD	3	100	33.3	-	0	N
PAD	4	75	25	-	25	N
RD	9	66.7	55.6	22.2	22.2	Y(3)
RDC	4	100	25	25	0	Y
KRD	6	100	66.7	33.3	0	Y

Results: 359 NDMM patients have been evaluated in relation to 12 regimens, including two or more drugs: melphalan-prednisone (MP), vincristine-adriamycin-dexamethasone (VAD), V-BCNU-M-cyclophosphamide-P/V-BCNU-A-D (VBMCP/VBAD), bortezomib-D (VD), VMP, VCD, V-lenalidomide-D (VRD), V-thalidomide-D (VTD), bortezomib-A-D (PAD), RD, R-D-clarithromycin (RDC), carfilzomib-R-D (KRD). Table 1 shows the number (n) of patients in each combination, ORR and CR rates. If the regimen has been used in the context of a ct, it has been indicated.
Summary/Conclusion: The information about response should be prospectively recorded in MM population-based registries. The retrospective evaluation of response in old regimens is inconclusive due to a high proportion of unknown response. The new triplets, particularly VRD and KRD, whose approval in real-life is still pending, are highly effective as induction. Triplets are more effective than doublets. However, selected patients treated with doublets can achieve CR with MRD negativity. The heterogeneity in response highlights the need to implement a risk-adapted, individualized, and patient-centered therapy.

PB2202

EFFICACY OF NEW DRUGS PRIOR TO SINGLE OR TANDEM AUTOLOGOUS STEM CELL TRANSPLANTATION IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS. A SINGLE CENTER EXPERIENCE

S. Grammatico[1,*], E. Lisi[1], F. Vozella[1], L. Cesini[1], A. Piciocchi[2], S. Capria[1], R. Foà[1], M.T. Petrucci[1]

[1]Department of Cellular Biotechnologies and Hematology, Policlinico Umberto I, [2]GIMEMA Foundation Data Center, Roma, Italy

Background: In the last decade numerous studies have shown that proteasome inhibitors and immunomodulatory drugs lead to notable advancements over conventional chemotherapy in multiple myeloma patients. Indeed, a 3-drug regimen with these novel agents is the best induction treatment for young newly diagnosed multiple myeloma (YNDMM) patients before autologous stem cell transplantation (ASCT).
Aims: To compare the data reported in the literature with the "real-life" clinical practice at a single Center. We report our experience over the last 25 years comparing the efficacy of old drugs *vs* novel agents. In addition, the responses obtained with a single *vs* double ASCT in this cohort of patients were also evaluated.
Methods: We retrospectively analyzed 258 YNDMM patients treated at our Center between October 1988 and November 2014. All patients received old or novel agents as induction treatment, followed by stem cell mobilization with high-dose cyclophosphamide plus filgrastim and conditioning chemotherapy with melphalan at 200 mg/m^2. Tandem ASCT was performed sequentially 3-6 months after the first transplant. The primary endpoint was overall survival (OS) and the secondary end point progression-free survival (PFS).
Results: Between October 1988 and October 2008, 173/258 patients received as induction treatment old drugs, *i.e.* VAD-vincristine, doxorubicin and dexamethasone (n=167) or MP- melphalan and prednisone (n=6), while, between February 2005 and November 2013, 85/258 patients were treated with novel agents, *i.e.* bortezomib-based (n=67) or IMiD-based regimens (n=18). All 258 patients received high-dose melphalan and a single (n=153) or tandem (n=105) ASCT. Patients treated with old drugs obtained a CR/nCR/VGPR in 17.9% of cases after induction, in 28.9% after a single ASCT and in 34.5% after a tandem ASCT. Patients treated with new drugs obtained a CR/nCR/VGPR in 42.3% of cases after induction, in 42.3% after a single ASCT and in 54% after a tandem ASCT. The contribution of the second ASCT was statistically significant for patients treated with both old and new drugs (p=0.005 *vs* p=0.001).Patients in CR/nCR/VGPR after induction showed a better OS and PFS at 10 years (62.1% *vs* 40.7%; p=0.0632 and 36.2% *vs* 17.2%; p=0.0685).Patients treated with new drugs had a slightly better OS than patients treated with old drugs (66.1% *vs* 51.5%, p=0.26) and a significantly better PFS (55% *vs* 25.3%, p=0.0047). Among our 258 patients, 144 presented a first relapse. They had been treated as follows:1) 51 patients (35.4%) received old agents as first and second line therapy; 2) 79 patients old agents for first line therapy and novel agents for second line therapy (54.9%); 3) 2 patients novel agents for first line therapy and old agents for second line therapy (1.4%); 4) 12 patients novel agents both as first and second line treatment (8.3%). Our analysis focused on groups 1 and 2. OS and PFS at 10 years were better for patients of group 2 (20.4 *vs* 2.4%; p <0.0001 and 10% *vs* 2.3%; p=0.02). PFS2 (the interval from treatment start at the onset to the second relapse) at 10 years was also significantly better for group 2 (25.7% *vs* 9.2%; p=0.0002).
Summary/Conclusion: Our real-life experience confirms that novel agents have replaced the old drugs as induction treatment prior to ASCT in YNDMM patients. Moreover, according to our results, tandem ASCT still maintains an important role even in the era of novel agents. Novel agents have also a significant impact in the subsequent lines of treatments.

PB2203

BENDAMUSTINE-BORTEZOMIB-DEXAMETHASONE (BVD) IN HEAVILY PRETREATED MULTIPLE MYELOMA

C. Cerchione[1,*], L. Catalano[1], D. Nappi[1], A.E. Pareto[1], S. Basile[1], L. Marano[1], I. Peluso[1], L. Simeone[1], O. Vitagliano[1], S. Palmieri[2], S. Rocco[2], G. Monaco[2], A. Romano[3], F. Pane[1], F. Ferrara[2]

[1]Hematology - Department of Clinical Medicine and Surgery, University Federico II, Naples, [2]Hematology, A.O.R.N. Cardarelli, Napoli, [3]Department of General Surgery and Medical-Surgical Specialties, Haematology Section, University of Catania, Catania, Italy

Background: Bendamustine is a bifunctional alkylating agent, with low toxicity, proved to be effective in relapsed, refractory and in new diagnosed Multiple Myeloma (MM).
Aims: It has been evaluated efficacy and tolerance of Bendamustine, in combination with bortezomib-dexamethasone (BVD) in patients with relapsed and refractory MM (rrMM), whose prognosis is particularly severe. A regional retrospective real-life analysis of patients with rrMM who had been treated with BVD as salvage therapy has been performed.
Methods: 56 patients (31 M/25 F), with rrMM, median age at diagnosis 57.3 years (r. 36-82), median age at start of treatment 61.8 years (r.37-83) treated with several lines of treatments (median 6, r. 2-11), every refractory to all the drugs previously received (also Bortezomib), received BVD (Bendamustine 90 mg/sqm days 1,2; Bortezomib 1.3 mg/sqm days 1,4,8,11, Dexamethasone 20 mg days 1,2,4,5,8,9,11,12, Pegfilgrastim day +4) every 28 days, until progression. ISS was equally distributed, and cytogenetic was evaluable in 12 patients, and in particular one del13q and one t(11;14). All the patients had previously been treated with schedule containing bortezomib and IMIDs, and 30% had also received radiotherapy. 67% of them had undergone at least to a single auSCT. All patients were relapsed and refractory to last therapies received before BVD.
Results: Bendamustine was well tolerated, with grade 3 transfusion-dependent anemia in 41% of patients, and 37% grade 3 neutropenia (no ospedalization was required, no septic shocks were observed). No severe extrahematologic toxicity was observed, only grade 1 gastrointestinal side effect (nausea), treated by common antiemetic drugs. According to IMWG, after a median follow-up of 14 months (r.2-36), ORR was 64% (36/56: 4 CR, 7 VGPR, 16 PR, 9 MR) with 8 PD and 12 patients in SD, which can be considered as an impressive result in this subset of rrMM patients. In particular, for 11 patients, BVD was, after having achieved at least a PR, a bridge to second auSCT, and for two patients a bridge to alloSCT. Three patients have shown a notable PR after failure of novel agents (*i.e.* Carfilzomib and Pomalidomide). Median time to response was 1.2 months (r.1-3), median OS from diagnosis was 62.7 months (range 6-151), median OS from start of Bendamustine was 9.8 months (range 2-36).

Summary/Conclusion: The triplet Bendamustine-Bortezomib-Dexamethasone has shown significant efficacy in a particularly severe setting of patients, relapsed and refractory to all available therapeutic resources, and, in particular cases, it could be considered as a bridge to a second autologous or allogenic SCT.

PB2204

EFFICACY OF RETREATMENT WITH IMMUNOMODULATORY DRUGS AND PROTEASOME INHIBITORS FOLLOWING DARATUMUMAB MONOTHERAPY IN RELAPSED AND REFRACTORY MULTIPLE MYELOMA PATIENTS

R. Oostvogels*, M. Jak, R. Raijmakers, R. Mous, M. Minnema

Hematology, University Medical Center Utrecht, Utrecht, Netherlands

Background: Patients with relapsed and/or refractory multiple myeloma represent a major clinical challenge as data on optimal treatment regimens in this group are limited and trials of new drugs are often difficult to compare. Responses are generally limited and short-lived and their prognosis remains unfavorable.
Aims: In a single-center retrospective observational study we analysed the efficacy of retreatment with immunomodulatory agents (IMiDs) and/or proteasome inhibitors (PIs) after treatment with daratumumab monotherapy in patients with relapsed and/or refractory multiple myeloma (RRMM).
Methods: In total 55 patients were treated with daratumumab monotherapy between 2010 and 2017. From this group 29 (53%) IMiD-refractory patients were retreated with an IMiD after daratumumab treatment and 6 (11%) PI-refractory patients were retreated with a PI-based regimen.
Results: From the IMiD-refractory patients 20/29 (69%) showed an improved response (defined as stable disease or better) upon IMiD retreatment compared to their previous IMiD-response before daratumumab treatment. In the PI-refractory group 5/6 patients (83%) had a superior response to PI retreatment compared to the pre-daratumumab PI-response. In many patients, variable regimens and/or doses were used, precluding an exact comparison between pre- and post-daratumumab. However, in 3 lenalidomide-refractory patients retreatment with the same lenalidomide dose in a similar schedule resulted in improvement of response compared to the pre-daratumumab treatment. The immunomodulatory effects of daratumumab treatment leading to an altered balance between immunosuppressive cell subsets and effector T cells may play a role in the observed high response rates in previously refractory patients. Furthermore, the excellent tolerability of daratumumab treatment may enable patients to recover from prior lines of treatment and receive full dosing of subsequent therapies.
Summary/Conclusion: In conclusion, a high proportion of RRMM patients benefitted from retreatment with IMiDs and PIs after daratumumab treatment. These retreatment options should therefore be explored in relapsed refractory patients progressing on daratumumab monotherapy.

PB2205

THE EFFECT OF SURGICAL INTERVENTION IN THE TREATMENT OF SOLITARY PLASMACYTOMA OF THE BONE

M.T. Koning[1,*], I. Noordhoek[2], P.A. von dem Borne[1], L.A. Daniëls[3], W. Pondaag[4], A.H. Cleven[5], H. Veelken[1], S. Dijkstra[6]

[1]Department of Hematology, [2]Department of Surgery, [3]Department of Radiotherapy, [4]Department of Neurosurgery, [5]Department of Pathology, [6]Department of Orthopedic Surgery, Leiden University Medical Center, Leiden, Netherlands

Background: Solitary plasmacytomas of the bone (SPB) are malignant, intramedullary, monoclonal plasma cell expansions in absence of systemic myelomatous disease. Left untreated, many SPB progress to systemic multiple myeloma (MM). Adequate and timely treatment is vital, since SPB represent a window of curative opportunity that is lost with progression to MM. The current gold standard for SPB treatment is radiotherapy (RT). However, a recent population study (Thumallapally *et al*., 2017), suggested that additional surgical treatment improves patient survival.
Aims: We reviewed the literature and performed a meta-analysis to assess the use and effect of surgery in SPB.
Methods: We searched PubMed, EMBASE and Web of Science for papers describing cases of surgically treated SPB. We included original reports from clinical practise written in Dutch or English from 1990 or later describing ≥1 case of surgically treated SPB without evidence of systemic myelomatous disease at the time of diagnosis. Individually described cases for which intervention and follow-up data were available, were analysed in Kaplan-Meier plots.

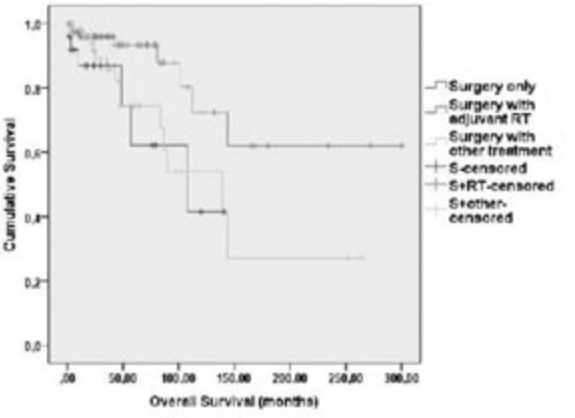

Figure 1.

Results: From 709 results, we included 113 suitable papers describing 700 SPB cases in total (skull and facial bones: 98; spine: 300; chest wall: 98; pelvis: 69; extremities: 86; unspecified: 49). Intriguingly, only 4 authors stated that their surgical intervention was driven by consideration for the patient's prognosis. More commonly, surgical intervention was performed due to initial misdiagnosis of the lesion or the need for acute intervention. In the skull, many authors performed craniotomies expecting to find meningiomas, spinal SPB was mostly operated upon for decompression and stabilisation and SPB of the extremities often presented as a pathological fracture with a need for stabilisation with osteosynthetic material. 195 cases were described in adequate detail to be included in a survival analysis. The male to female ratio was 2,2:1 and median age at diagnosis 53 years (range: 5-82), in line with previously published population data. Skull SPB cases were disproportionally often female (p=0,016). No other sex or age preference was observed between SPB localisations. Kaplan-Meier survival analysis showed better overall survival for combined treatment with surgery and RT (n=79) over surgery alone (n=25)(p=0,020) or surgery in combination with other treatment (n=53)(p=0,021). Progression-free survival was not significantly different between treatments. Our cohort had too few cases treated by RT alone to yield significant results.
Summary/Conclusion: Although surgical intervention with adjuvant RT was shown to confer the best survival in population studies, the choice for surgical intervention is rarely made for the benefit of long-term patient survival. Our findings warrant consideration of additional surgical excision to the treatment plan of patients otherwise treated by RT alone. Moreover, SPB patients who undergo surgical intervention for stabilisation, central nervous system decompression, diagnostic excision etc., may clearly benefit from adjuvant RT. Comprising only case reports, case series and retrospective cohorts, the papers included in this study are at a high risk for selection bias. Therefore we recommend validating these results in a prospective clinical trial. Additionally, these outcomes may be compared with patients treated by RT alone, and the research question may be extended to solitary extramedullary plasmacytomas and plasmacytomas in the context of MM.

PB2206

UNINVOLVED IGA SUPPRESSION PREDICTS EVOLUTION TO SYMPTOMATIC MYELOMA IN CONTEMPORARY DIAGNOSED SMM; PRELIMINARY RESULTS

P. Papaioannou[1], A. Gkioka[1], K. Tsalimalma[2], A. Koudouna[1,*], S. Kotsanti[1], K. Bitsani[1], D. Maltezas[1], T. Iliakis[1], M. Dimou[1], ?. Kafassi[2], P. Sfikakis[1], P. Panayiotidis[1], M. Kyrtsonis[1]

[1]Hematology Section - [1]st Department Of Propaedeutic Internal Medicine, [2]Immunology Laboratory, Laikon Hospital Athens, Athens, Greece

Background: Smoldering Myeloma (SMM) is an asymptomatic form of Multiple Myeloma (MM) that might have a course as indolent as monoclonal gammopathy of undetermined significance (MGUS), especially after the first 5 years. Some patients however may insidiously rapidly become symptomatic and as follow-up visits are less frequents in SMM, end organ damage may occur. To avoid such events, three biomarkers (FLCR>100, ≥1 osteolysis and ≥60% plasma cell bone marrow infiltration) were recently established to discriminate asymptomatic MM patients at increased risk of quick evolution, characterizing them, when present, as symptomatic and in need of immediate treatment (ref.1). In spite of the usage of the new IMWG definition criteria, there are still patients evolving relatively early and the actual notion of High risk SMM is quite subjective among scientific groups.

The Ig heavy chain can be accurately determined with the Heavy/Light Chain (HLC) 'Hevylite' method that measures separately HLC-IgA, -G, -M kappa or lambda, thus allowing exact quantification of the amount of pure monoclonal fraction but also the degree of suppression of uninvolved polyclonal Igs, both being reflected by the corresponding ratios (HLCR). HLCR values in MM (ref.2) and of the uninvolved isotype-specific heavy / light chain (HLC-pair suppression) in MGUS (ref.3) were shown to constitute independent risk factors for progression.
Aims: The aim of this study was to investigate weather involved and uninvolved HLCs values or their ratio can identify accurately SMM patients at risk to progress to symptomatic MM.
Methods: We studied 59 patients with SMM from whom 20 were men and 39 women, with median age 65 (31-84), immunoglobulin type consisted IgG in 51 patients (86,4%) and IgA in 8 patients (13,6%). None of the patients FLCR>100, ≥1 osteolysis or ≥60% plasma cell bone marrow infiltration. Patients were regularly followed (each 3 months) since SMM diagnosis and for a long period (median 98 months). "HevyLite" assay measurements were performed by nephelometry according to the manufacturer's instructions in frozen sera sample drawn at the time of diagnosis. Statistical analysis was performed by standard methods using the SPSS v24.0. software.
Results: HLCR measurements failed to add prognostic information; the same was true for uninvolved IgG and IgM values. However the summated uninvolved IgA kappa plus IgA lambda (SUAKL) values in IgG SMM and uninvolved isotype-specific IgA alone in IgA patients were significantly prognostic of evolution to MM (p<0,01). Time to evolution was 30,5 months in the 12 patients that progressed; their median SUAKL was 0,95g/L *versus* 1,8 g/L in the rest (p<0,01).
Summary/Conclusion: SUAKL will probably prove to be useful as a marker of high-risk SMM; its value should indeed be confirmed in a larger series

COMPARISON OF TWO MOBILIZATION REGIMENS FOR NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

E. Mariggiò[1,*], L. Lombardi[1], F. Vozella[1], F. Fazio[1], A. Piciocchi[2], R. Foà[1], M.T. Petrucci [1]

[1]Hematology, Sapienza University of Rome, [2]Gimema Data Center, Rome, Italy

Background: Induction therapy with novel agents followed by autologous stem cell transplantation (ASTC) is the worldwide gold standard for frontline treatment of younger patients with multiple myeloma (MM). Notwithstanding, a variable proportion of these patients fail to mobilize CD34+ peripheral blood stem cells (PBSC) at all or to collect an adequate number for a safe ASTC or sufficient for tandem or savage procedures ("poor mobilizer").
Aims: The use of lenalidomide and hematological toxicity developed during induction were taken into account as possible factors associated with poor mobilization. The use of Plerixafor with G-CSF for PBSC mobilization significantly improves the chances of a successful mobilization.
Methods: We report the unicentric experience of the Department of Cellular Biotechnologies and Hematology, "Sapienza" University, Rome in 48 patients (pts) with newly diagnosed MM treated as induction therapy with Bortezomib, Thalidomide, dexamethasone (VTd; 33 pts 68,7%) or Carfilzomib, Lenalidomide-dexamethasone (KRd; 15 pts 31,3%). The median age was 55,4 years (range 48-61), 28 men (58,3%) and 20 women (41,7%). In all cases the mobilizing regimen was cyclophosphamide (3g/m^2) associated to G-CSF (10mcg/Kg). International Staging System (ISS) was I-II-III in 25 (52,1%), 19 (39,6%) and 4 (8,3%) patients respectively. After induction, 7 pts (14,6%) achieved complete response (CR), 27 pts (56,3%) achieved a very good partial response (VGPR), and 14 (29,2%) partial response (PR). Filgrastim was used as G-CSF in 38 pts (79,2%) and Lenograstim in 10 pts (20,8%). The use of Plerixafor was necessary in 7 cases (46,7%) for patients treated with KRD induction regimen, in 3 cases (9%) for VTD.
Results: The use of Plerixafor (yes or not) has been compared with the following variables: sex, age, ISS, type of G-CSF, Induction Regimen, type of monoclonal component, time between mobilization date and therapy end. In univariate analysis type of induction regimen was the only statistically significant factor (KRd 7 cases used Plerixafor *vs* 3 VTd); p=0.003. CD34+ cell median final collection (x10^6 /Kg) was 8,60x10^6 /Kg (range 4.40-17) for KRd and 10,38x10^6 /Kg (range 1.49-18.8) for VTd respectively; the difference is statistically significant, p=0,047.
Summary/Conclusion: Our data though revealing a possible negative effect of lenalidomide-based regimens on PBSC mobilization used also with carfilzomib association. Lenalidomide is myelosuppressive and alters the stromal milieu thereby suppressing stem cell mobilization. Plerixafor with G-CSF has been shown to improve successful stem cell mobilization rates in patients receiving Lenalidmide based induction therapy.

PB2208

IMPACT OF NOVEL AGENTS ON AGGRESSIVE RELAPSE OF MULTIPLE MYELOMA: A SINGLE CENTER EXPERIENCE

E. Martino*, V. Calafiore, M.S. Parisi, V. Del Fabro, G. Sapienza, A. Romano, C. Conticello, F. Di Raimondo

Division of Hematology, A.O. "Policlinico-Vittorio Emanuele", University of Catania, Via Citelli [6], [95124] Catania, Italy, Division of Hematology, A.O. "Policlinico-Vittorio Emanuele", University of Catania, Via Citelli [6], [95124] Catania, Italy, Catania, Italy

Background: Therapeutic advances, notably the development of regimens that incorporate immune-modulatory drugs (lenalidomide and pomalidomide) and proteasome inhibitors (*e.g.* bortezomib and carfilzomib), have improved survival outcome in multiple myeloma (MM). However, MM remains largely incurable and patients invariable develop relapsed or refractory (R/R) disease, a new unmet clinical challenge for hematologists. Relapse can be characterized according to disease aggressiveness and the presence of clinical symptoms. Aggressive disease relapse can occur at biochemical level, due to rapid and relevant increase of monoclonal component or LDH, or at clinical level it can be defined by the presence of extramedullary disease, acute renal injury or progression to secondary plasma cell leukemia.
Aims: In this retrospective study we evaluated 76 patients who relapsed after a front-line regimen containing lenalidomide or bortezomib to identify the rate of biochemical and clinical aggressive relapses and clinical outcome upon treatment with second generation novel agents (pomalidomide and carfilzomib).
Methods: From July 2014 we evaluated 76 R/R patients (41 males and 35 females, median age 62 years, range 45-78). Median number of previous line was 3 (1-6), half of them (43/76) underwent ASCT. Pd consisted of pomalidomide 4 mg daily given orally on Days 1–21 of each 28-day cycle and dexamethasone 40 mg weekly. KRd consisted of Carfilzomib 20mg/m^2 IV on days 1 and 2 of the first cycle, then 27mg/m^2 on days 8, 9, 15 16 of the first cycle and days 1, 2, 8, 9, 15 and 16 of the subsequent cycles, Dexamethasone 20 mg on days 1, 2, 8, 9, 15, 16 and lenalidomide 25 mg daily given orally on days 1-21 of each 28-day cycle.
Results: 51 patients were both bortezomib and/or lenalidomide refractory and received Pd according to Italian Health System. 7 of them further progressed and received KRd, the remain 25 received KRd as second and third line therapy. 53 patients had a non aggressive relapse, while the remain 23 experienced an aggressive relapse of disease. 43 patients experiencing relapse after ASCT, 44% had asymptomatic serological relapse or progression, 66% experienced symptomatic relapse (with 38% high risk cytogenetic detected by FISH) and one-third experienced relapse featuring extramedullary disease, plasma cell leukemia or severe renal failure. In the remaining 33 patients not eligible to ASCT, 78% had not aggressive relapse. As expected median PFS obtained in Pd patients was higher for NA group (6 *vs* 4 months). Even if the majority of KRd patients are still under treatment, the OR was 90% with greater PFS in NA than in A group (8 *vs* 6 months).
Summary/Conclusion: In our community setting data, heavily pretreated patients achieved improvement of outcome obtaining a median PFS >4 months, using KRd and Pd as salvage therapies. We found that an aggressive relapse was more frequent in young patients and that earlier treatment at biochemical asymptomatic relapse is associated to better outcome.

PB2209

REAL WORLD DATA OF AGE RELATED CYTOGENETIC ABNORMALITY DISTRIBUTION IN MULTIPLE MYELOMA PATIENTS AT DIAGNOSIS: SINGLE CENTRE EXPERIENCE FROM THE UNITED KINGDOM

J. Tam*, R. Krishna, K. Marshall, L. Cresswell, C. Morrow, L. Barton, G. Asagba, M. Garg

Haematology, University Hospitals of Leicester, Leicester, United Kingdom

Background: Cytogenetic study/ Fluorescence *in situ* Hybridization (FISH) has become an essential tool in assessing prognosis and survival in patients newly diagnosed with multiple myeloma. Cytogenetic abnormalities have various implications in terms of treatment response. It would be useful to

identify patients with a higher incidence of high risk cytogenetic abnormalities in order to target further research in the vulnerable population.
Aims: To review distribution of cytogenetics abnormalities by FISH testing in different age groups of newly diagnosed multiple myeloma patients seen in the University Hospitals of Leicester NHS Trust between 2015-2018.
Methods: Data was collected from hospital computer-based patient records and the database of the cytogenetics department. All newly diagnosed patients with multiple myeloma who underwent a bone marrow biopsy were included in this analysis.. The bone marrow aspirates were screened morphologically. If there were ≥10% of plasma cells, the sample was referred for cytogenetics testing. The FISH panels consist of t (4;14), t (14;16), t (14;20), Del 17p, 1q amplification, and deletion 1p.

Table 1.

Abnormalities		Age group		
Type	No.	<45	45 to 65	>65
t (4;14)	4	0	1	3
t (14;16)	1	0	0	1
t (14; 20)	0	0	0	0
Del 17p	8	0	2	6
Amp1q	30	0	6	24
Del 1p	0	0	0	0
Not analysed	39	2	7	30
No ab detected	59	0	14	45
>1 abnormalities	16	0	2	14
Subtotal		*2*	*32*	*123*
Total	**157**		**157**	

Results: 157 patients (92 male and 65 female) with newly diagnosed multiple myeloma underwent bone marrow biopsy over the three-year period. 39/157 were not analysed as either the plasma cells on the screening sample was insufficient or the number of cells cultured were inadequate for analysis. 59/157 did not have any FISH abnormality. 59/ 157 patients were tested positive for FISH abnormalities, out of which 16/59 had more than one FISH abnormality. The results were categorised under three age groups (<45 years, 45-65 years and >65 years). None of the patients under 45 had an abnormal FISH result while 11/32 patients between the ages of 45-65 and 48 /123 in the >65 year-old age group were identified with FISH abnormalities. The most common FISH anomalies were amplification 1q followed by del 17P in both the intermediate age group and the older age population.
Summary/Conclusion: In our study it was observed that there was an increasing frequency of high risk mutations with increasing age. There is also a significantly higher proportion of del 1q seen in this UK cohort, this being a well known poor prognostic indicator. Cancer research UK data shows poorer patient survival ,shorter time to progression and poorer outcomes in this age group. More research needs to be targeted at the elderly population which may not be suited for more intensive therapies, to overcome high risk cytogenetics; but may benefit from targeted therapies given as maintenance treatment which may prevent progression and ensure better quality of life.

HIGH IMPLEMENTATION ADHERENCE TO LENALIDOMIDE IN MULTIPLE MYELOMA

I. Amitai[1,*], H. Magen[2,3], A. Rozenthal[1], S. De Geest[4,5], E. Tousset[6], I. Vaxman[1,2], P. Raanani[1,2], A. Nagler[3], A. Leader[1,2]

[1]Institute of Hematology, Davidoff Cancer Center, Rabin Medical Center, Petah-Tikva, [2]Sackler School of Medicine, Tel Aviv University, Tel Aviv, [3]Division of Hematology, Chaim Sheba Medical Center, Tel Hashomer, Israel, [4]Institute of Nursing Science, Department Public Health, University of Basel, Basel, Switzerland, [5]Department Public Health and Primary Care, Academic Centre of Nursing and Midwifery, KU, Leuven, [6]AARDEX Group, Visé, Belgium

IA and HM contributed equally; AL and AN contributed equally.

Background: Lenalidomide (LEN) is an important backbone of regimens in the multiple myeloma (MM) treatment arsenal. Non-adherence (NA) to anticancer therapy occurs in approximately 30% of cancer patients and is generally associated with adverse outcomes. A recent study used pharmacy refill data to show LEN implementation NA in 14.5% of MM patients (defined as medication possession ratio <80%), but ON-OFF cycling with LEN can affect the reliability of such data. Electronic methods of measuring adherence provide richer sampling and better reliability. There is no prior prospective longitudinal data on LEN adherence, and specifically no reports on electronically measured (EM) LEN implementation adherence.
Aims: (1) To determine the period prevalence of EM implementation adherence to LEN; (2) To delineate patterns of ON-OFF cycling.

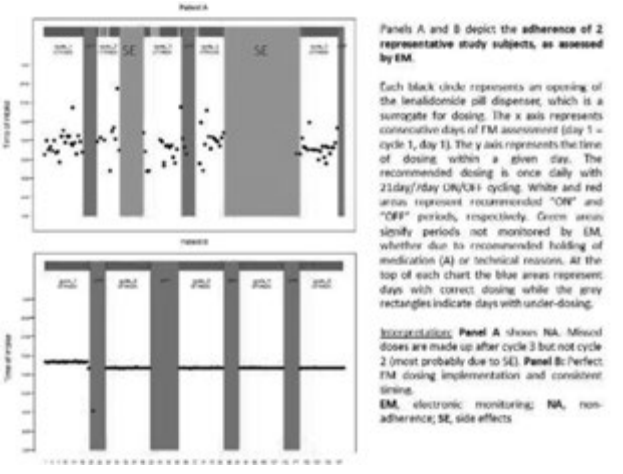

Figure 1.

Methods: Methods: We report on an ad-hoc interim analysis of a prospective observational pilot cohort study of LEN-naïve adult patients receiving LEN-based regimens for treatment of MM. Patients completing follow-up by Feb 1, 2018 were included in this analysis. Convenience sampling was used to enroll 37 patients cared for in the hematology outpatient clinic (all from 1 tertiary center), 34 of whom were included in this analysis (3 excluded due to technical defects or inability to use the EM device). *Sample characteristics* were as follows: median age, 64.5 years [interquartile range (IQR) 58-74]; 35% female; median no. of medications, 5 [IQR 3-6]; median ISS, 2 [IQR 2-3]; median prior disease duration, 22.5 months [IQR 6.5-56]; LEN regimen: 71% LEN-dexamethasone; line of treatment: 1st=6%, 2nd=73%, 3rd=21%. Implementation adherence to once daily LEN in 21day/7day (ON/OFF) cycles was monitored using EM (MEMS®, AARDEX) from study index (*i.e.* LEN cycle1, day1) until the end of cycle 5. This provided data on daily dosing (Figure 1). Adherence was expressed as the percentage of days with LEN taken as prescribed during ON cycling, independent of dosing timing. Descriptive statistics were used to show the median [IQR] for continuous variables and percentages for categorical data.
Results: Median LEN implementation adherence was 98.9% (IQR 93.1-100%; min 51.7%), while the mean was 93.8% (*i.e.*% of days with correct dosing during ON cycling). Representative cases of suboptimal and perfect adherers are shown in Figure 1. The median duration of follow-up was 132 days (IQR 76-138), while the median no. of cycles was 4.5 (IQR 2-5). The reasons for completing less than 5 LEN cycles with EM (n=17) were as follows: treatment change (n=7) mostly due to side effects (n=4); withdrawal of consent (n=5); death (n=1); others (n=4). 41% of patients had no adjustment in ON cycle length, while 53% had ≥1 shortened cycles. 80% (24/30) of evaluable patients achieved partial response or more at 6 months.
Summary/Conclusion: LEN implementation adherence was remarkably high yet showed large variability in this pilot study. Most patients had adjustments in cycle length, emphasizing the limitations of adherence analyses assuming fixed 21/7day cycling and the importance of rich sampling (e.g. EM). Importantly, a quarter of patients had correct dosing on less than 93% of days, which may be suboptimal. These patients may be candidates for adherence enhancing interventions. Thus, future research should focus on strategies for identifying this small subgroup of non-adherers.

PB2212

LONG TERM DISEASE CONTROL WITH POMALIDOMIDE AND DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS: A REAL LIFE EXPERIENCE

M.S. Parisi*, V. Calafiore, E. Martino, S. Leotta, M.C. Pirosa, G. Sapienza, V. Del Fabro, A. Romano, C. Conticello, F. Di Raimondo

Division of Hematology, A.O. "Policlinico-Vittorio Emanuele", University of Catania, Via Citelli [6], [95124] Catania, Italy, Division of Hematology, A.O. "Policlinico-Vittorio Emanuele", University of Catania, Via Citelli [6], [95124] Catania, Italy, Catania, Italy

Background: Pomalidomide is currently utilized in relapsed/refractory multiple myeloma (RRMM) patients that have experienced bortezomib and

lenalidomide treatment. In this setting the drug has shown in clinical trials improved survival and good tolerability.Since its approval in Italy, data on real life are still poor.
Aims: We conducted an analysis of RR MM patients treated with pomalidomide and dexamethasone (PomaD) in real life, previously enrolled in an interventional (STRATUS, MM-010) or currently enrolled in an observational study (MM-015) to provide further insights on this salvage therapy.
Methods: Between January 2016 and July 2017, 41 RR MM patients were treated with pomalidomide 4 mg daily po on days 1–21 of each 28-day cycle and dexamethasone 40 mg weekly (≤75 years) and 20 mg weekly (>75 years). Among patients 14 were enrolled in MM-015 study (an observational study) whereas additional 15 come from MM-010 study (a single-arm phase 3b study).
Results: We describe a total of 56 patients (median age 68 years, range 42-78). Median number of prior therapies was 4 (range 2-7). 29 (51%) patients had pre-existing severe anemia, 5 (9%) thrombocytopenia, 14 (25%) had renal impairment, 10 (18%) extramedullary myeloma;14 (25%) was high risk patients (r-ISS), 7 (12%) previously allo-transplanted. Median number of 8 (range 1-21) PomaD cycles were given. Overall treatment duration mean was 7.7 months. A half of the patients responded after at least one cycle. After a median follow-up of 12 months, median PFS and OS for patients were 6,7 and 9,9 months, respectively. At enrollment, 29 (51%) of patients were anemic, 15 (27%) neutropenic. The regimen was well tolerated with grade 3-4 haematological and non-haematological adverse events in 10 (18%) and 27 (48%) patients respectively. Grade 3-4 non-haematological AEs occurred in 48% of patients [most common: fatigue (7, 12,5%), pneumonia (6, 11%), diarrhea (3, 5%), glucose metabolism alteration (3, 5%), thromboembolism (2, 3,5%), diffuse erythema (2, 3,5%), hyponatremia (2, 3,5%), atrial flutter (1, 2%), acute renal failure (1, 2%)]. In case of serious AE, pomalidomide dose reduction (7, 12,5%) and discontinuation (11, 20%) were applied. All patients responded to treatment at the I/II cycle. Mostly PR and SD were observed. After a median time of 8 months (range 2-21) all patients relapsed. Data on 6-Months control of disease are favorable and related to Durie and Salmon stage. Almost 50% of patients obtained a control of disease with clinical benefit lasting 6 months. Moreover, patients with Stage I-IIA at PomaD-beginning had better probabilities of obtaining control of disease lasting almost 6 months. An unexpected data was the comparison between PFS obtained with the treatment before pomalidomide (previous treatment PFS, pPFS) and the PFS obtained with PomaD treatment (poPFS). 17 patients (30%) obtained a PFS longer than the precedent one. Among these patients, 6 were from STRATUS protocol and treatment was stopped at biochemical progression (25% increase in protein M) according to protocol indication. Difference between poPFS and pPFS was not statistically significant (log-rank p value 0.5).
Summary/Conclusion: Real life PomaD is well tolerated in RR MM patients prolonging PFS and OS with acceptable toxicity. Notably PFS could be superior to that obtained with precedent treatment and treatment may induce almost 6 months disease control in most patients intensively pretreated.

PB2213

THE DETERMINATION OF FACTORS AFFECTING ON THE PROGRESSION-FREE SURVIVAL OF MULTIPLE MYELOMA PATIENTS

A. Garifullin[1,*], S. Voloshin[1], A. Kuvshinov[1], A. Kuzyaeva[1], A. Schmidt[1], Z. Chubukina[1], V. Shuvaev[1], E. Krasnikov[2], S. Bessmeltsev[1]

[1]Russian Research Institute of Hematology and Transfusiology, [2]City Hospital N 40, Saint-Petersburg, Russian Federation

Background: The progression-free and overall survival are key indicators that reflect the effective therapy in patients with hematological disease. The use of different prognostic models based on various factors and their combinations allows to determine the optimal strategy for treating patients, including patients with multiple myeloma (MM) and improve survival. There are quantitative factors and qualitative signs which are determined before and after the induction therapy, and after autologous stem cells transplantation (AutoSCT), if this option was available. However, the advantage of each prognostic parameter should be revised when using new drugs and their combinations.
Aims: To define the factors influencing on progression-free survival (PFS) by means of one-factor and multifactor analyses.
Methods: We analyzed 72 patients with MM (median age 59 years, male/female – 1.25:1). The induction therapy with Bortezomib-based regimens (VD, CVD, VMP, PAD) was used in 48/72 (66.7%) patients, Immunomodulator-based regimens (Thal+D, RD, VRD, PomD) – in 20/72 (27.8%), chemotherapy – in 4/72 (5.5%). Autologous stem cell transplantation (ASCT) is carried out 48 (66.7%) patients. We used the sex, age, the variant induction antimyeloma therapy, response after treatment, MFC MRD status, PET-CT status, tumor load, AutoSCT, variant of maintenance therapy as prognostic factors. The MFC MRD status and PET-CT status were evaluated after 4-6 cycles of induction therapy and after ASCT, if it (AutoSCT) was performed. For definition of MRD we used 5-color flow cytometry with CD38, CD138, CD45, CD19, CD20, CD27, CD56 and CD117 antibodies. The MFC MRD– ($<10^{-4}$) response was stated at identification less than 0.01% of clonal plasma cells and MFC MRD– ($<10^{-5}$) – less than 0.001%. The PET-CT was done in 30 patients only. The PET-CT– status was established if specific accumulation of 18-FDG was absent.
Results: The general regression models (one-factor analysis) show reliable influence of complete response (CR) (p=.0004) and tumor load in bone marrow (p=.000006) on PFS. The multifactor analysis among these parameters shows the CR above the non-CR (VGPR, PR, SD), MFC MRD– status (MRD $<10^{-4}$) above MFC MRD+ (p<0.05). Simultaneous use of factors (achievement of CR and MRD $<10^{-4}$) show reliable impact on PFS (p=.0006). The MFC MRD– ($<10^{-4}$) was reached in 25% (18/72), The MFC MRD– ($<10^{-5}$) – in 9.7% (7/72). The PFS median in MFC MRD+ ($>10^{-4}$) group was 23 months, in the MFC MRD– ($<10^{-4}$) was 65 months (p=.0004). The reliable MFC MRD– ($<10^{-5}$) above MFC MRD– ($<10^{-4}$) and MFC MRD+ ($>10^{-5}$) was not achieved (p>.05). The PFS median in MFC MRD– ($<10^{-5}$) group was 67 months, in the MFC MRD+ ($>10^{-5}$) was 47 months (p>.05). It is probably caused that small number of patients with MFC MRD– ($<10^{-5}$) and short period of observation. The sex, age, variant of induction antimyeloma, PET-CT status, AutoSCT and variant of maintenance therapy were not impact on PFS (p>.05).

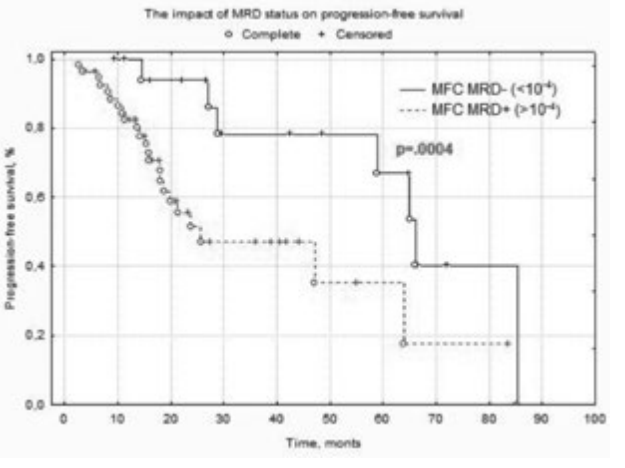

Figure 1.

Summary/Conclusion: The presence of MFC MRD is unfavorable prognostic factor. Achievement CR and MRD– ($<10^{-4}$) status are favorably influence on duration of PFS in MM patients.

PB2214

PHASE 2 STUDY FOR CARFILZOMIB PLUS ELOTUZUMAB PLUS DEXAMETHASONE FOR MYELOMA PATIENTS RELAPSED AFTER 1-3 PRIOR TREATMENT LINES

R. Silvennoinen[1,2,3,*], H. Nahi[4], P. Anttila[1], P. Koskenvesa[1], J. Lievonen[1], S. Luoma[1], A. Räsänen[5], V. Varmavuo[5], A. Sikiö[6], M. Nurmi[6], M. Säily[7], M. Sankelo[8], E. Jantunen[2,9,10], T.-T. Pelliniemi[11], S. Ilveskero[12], M.M. Majumder[13], C. Heckman[13]

[1]Comprehensive Cancer Center Hematology, Helsinki University Hospital, Helsinki, [2]Medicine, Kuopio University Hospital, Kuopio, [3]University of Helsinki, Helsinki, Finland, [4]Medicine, Karolinska Institutet Huddinge, Stockholm, Sweden, [5]Medicine, Kymenlaakso Central Hospital, Kotka, [6]Medicine, Central Finland Central Hospital, Jyväskylä, [7]Hematology, Oulu University Hospital, Oulu, [8]Hematology, Tampere University Hospital, Tampere, [9]Clinical Medicine, University of Eastern Finland, Kuopio, [10]Medicine, North Carelia Central Hospital, Joensuu, [11]Fimlab Laboratories Ltd, Tampere, [12]Clinical Chemistry and Hematology, HUSLAB Helsinki University Hospital, [13]Institute for Molecular Medicine Finland (FIMM), Helsinki Institute of Life Science, University of Helsinki, Helsinki, Finland

Background: The median progression free survival (PFS) and overall survival (OS) of multiple myeloma (MM) patients have prolonged due to novel agents combined with ASCT. However, the vast majority of patients will

progress after a median of 2-3 years with median OS of 7-8 years. Thus, the possible benefit of new combinations and dosing of available agents has to be investigated. The first proteasome inhibitor (PI), bortezomib (B), combined with elotuzumab and dexamethasone (d) showed superiority to Bd resulting in PFS of 9.7 *vs.* 6.9 months, respectively, without excessive toxicity (Jakubowiak *et al.* Blood 2016;127:2833-40[1]).
Aims: The aim of this study is to investigate the safety, feasibility and initial efficacy of a second generation PI carfilzomib plus a SLAMF7 antibody elotuzumab plus dexamethasone (KEd) in relapsed MM patients.
Methods: Forty patients with relapsed MM after 1-3 prior lines will be included in this phase 2 study after written informed consent. The primary endpoint is overall response rate. In patients achieving at least very good partial remission (VGPR) the quality of response and bone marrow lymphocyte subgroups will be assessed with high-sensitivity multicolour flow cytometry according to the 8-colour EuroFlow protocol. Carfilzomib (K) is given once weekly 20mg/m^2 on D1C1 and thereafter 70mg/m^2 in 28 day cycles on days 1, 8 and 15 in cycles 1-8 and on days 1 and 15 thereafter combined with weekly elotuzumab (E) 10 mg/kg on days 1, 8 and 15 in cycles 1-2, thereafter on days 1 and 15; dexamethasone (d) on days 1, 8, 15 and 22 on cycles 1-8, thereafter on days 1 and 15. Treatment will continue until progression or excessive toxicity. Carfilzomib dose was 20/56mg/m^2 for the first two cycles for the first five patients to evaluate the safety. Follow-up samples will be stored for later response analysis of elotuzumab interference on IgG-kappa paraprotein. Additionally, patient samples collected prior to treatment will be comprehensively profiled by whole exome and RNA sequencing and evaluated for *ex vivo* response to the agents. Furthermore, the previously described[1] association of FcγRIIIa polymorphism with response will be measured. Together, the study addresses clinical response, *ex vivo-in vivo* translation, identifies molecular biomarkers for the KEd combination and facilitates precision guided clinical trials for relapsed refractory MM.
Results: By the end of Feb 2018 eight patients have been enrolled. After a median of four cycles one patient is in VGPR, four patients are in PR, one in MR, and two that are too early to assess. One patient had grade 2 infusion reaction after premedication. One patient developed autoimmune hemolytic anemia (AIHA) possibly related to elotuzumab and recovered with steroids. She continued on Kd without reappearance of AIHA, while elotuzumab was permanently discontinued. A grade 3 adverse event with asymptomatic elevation of liver transaminase was detected in another patient who recovered with dose reduction of dexamethasone to 12mg and carfilzomib to 56mg/m^2 without any change in elotuzumab dose.
Summary/Conclusion: To the best of our knowledge this is the first study evaluating the carfilzomib plus elotuzumab plus dexamethasone combination in relapsed MM with comprehensive molecular annotations. Preliminary results of KEd treatment with weekly dosing of 70mg/m^2 resulted with at least PR response in 5/6 patients. We noticed an unexpected severe adverse event of AIHA in one study patient. AIHA should be excluded if unexpected anemia will appear during elotuzumab treatment.

PB2215

THE TREATMENT WITH PEGYLATED LIPOSOMAL DOXORUBICIN, CYCLOPHOSPHAMIDE AND DEXAMETHASINE (CED) FOR RELAPSED AND REFRACTORY MULTIPLE MYELOMA

M. Ionita[1], I. Ionita[2], F. Ghilezan[3], D. Calamar[2], V. Todorescu[2], C. Ionita[4], D. Oros[2], C. Sorica[2], H. Ionita[2,*]

[1]Internal Medicine, [2]Hematology, University of Medicine and Pharmacy Victor Babes Timisoara, [3]Hematology, Clinical County Hospital, [4]Surgery, University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania

Background: Multiple myeloma is a malignant plasma cell disorder. It is the second most frequent haematological malignancy and characterized by malignant plasma infiltration or the bone marrow and is associated with an increased level of monoclonal protein in the blood and/or urine. Patients affected by multiple myeloma become chemo-resistant : hence, one of the main topics in clinical research is the quest for therapeutic alternatives to overcome refractory disease.
Aims: Since 2012, we have treated patients affected by Multiple Myeloma, relapsed and refractory to most of the therapeutic options available, with a chemotherapy based on a combination of pegylated liposomal doxorubicin, cyclophosphamide and dexamethasone (CED), at monthly doses respectively of 35mg/m^2 on day 1800mg/m^2 on day 1 and 20mg/ m^2 on days 1-4.
Methods: Twenty (20) patients (11men, 9 women), with a median age of 62 years, (range: 40-74) affected by advanced, relapsed and progressive multiple myeloma, whose median number of previous treatments was 3 lines (range 2-5) were treated with monthly CED courses (median number of courses: 3; rage: 3-10).
Results: Three patients (15%) had a complete remission (CR), in 11 patients (55%) there was a partial response (PR); the disease remained stable in two patients (10%) and four patients (20%) did not benefit from CED treatment. Median response duration was 9 months (range: 4-25). The toxicity profile of CED was satisfactory: hematological toxicity (WHO grade 2) was observed in 6 patients (30%).There was 2 patients with gastrointestinal disturbances, one patient with infections, an episode of acute renal failure in one patient. One toxic death due to sepsis was noted.
Summary/Conclusion: These results can encourage further studies as they have been obtained in patient with severely advanced disease stage, previously not exposed to anthracyclines. The preliminary data point to a significant results in 50% of patients with particularly advanced disease.

PB2216

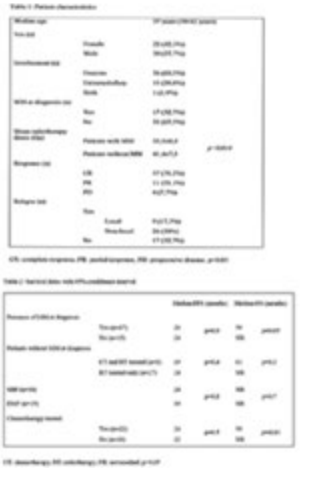
CLINICAL FEATURES AND OUTCOMES OF SOLITARY PLASMACYTOMAS: SINGLE-CENTER EXPERIENCE FROM TURKEY

Y. Ulusoy[1,*], E. Arslan Davulcu[1], F. Sahin[1], N. Soyer[1], E.S. Kamer[2], N. Ozsan[3], M. Hekimgil[3], G. Saydam[1]

[1]Hematology, [2]Radiation Oncology, [3]Pathology, Ege University Hospital, Izmir, Turkey

Background: Solitary plasmacytoma (SP) is a plasma cell dyscrasia that presents as a mass lesion consists of plasma cells that produces monoclonal immunoglobulins without any systemic involvement. SP accounts for approximately 5% of all plasma cell dyscrasias and mostly occurs in osseous tissue, however one third of patients have extramedullary plasmacytoma.
Aims: In this paper, we analyzed our patients and aimed to reveal patient characteristics and outcomes.
Methods: A total of 52 patients who were referred to our clinics of hematology and radiation oncology with the diagnosis of SP from January 2006 to March 2017, were evaluated retrospectively. Age, sex, treatment procedures, radiotherapy doses, involved tissue datas, relapse and response status, death times were recorded from hospital registries.

Table 1.



Results: Median age at the diagnosis was 57 years (30-82 years), 57,7% of them (n=30) were male. Seventeen patients were diagnosed as concurrent multiple myeloma (MM) and 15 of those treated with radiotherapy and chemotherapy both. Patients without MM at the diagnosis (n=35) were irradiated and followed periodically after completion of radiotherapy, 8 of those were treated with chemotherapy adjacent to radiotherapy due to widespread disease. Solitary bone plasmacytoma (SBP) was the most common diagnosis with a rate of 69,2% (n=36), one patient was diagnosed with SBP and extramedullary plasmacytoma (EMP) at the same time. Patients those whom had concurrent MM was irradiated palliatively with a dose of 20 to 45 Gray (Gy), curative radiotherapy was performed to all other patients at a dose of 45 to 54 Gy. Median duration of follow-up for patients was 45 months (0-144 months). Local recurrence defined as relapse from the affected site at the diagnosis was detected in 9 patients (17,3%), all relapsing patients (67,3%, n=35) were received mean 38,2±9,0 Gy dose of irradiation while patients with no recurrence were treated with mean 42,2±5,8 Gy dose of irradiation during diagnosis. Local recurrence was not related with the dose of radiotherapy (p=0,5). Patients responded well to all therapies, partial and complete response were achieved in 92,3% of patients (n=48). During

follow-up MM was diagnosed in 7 of all 35 patients without MM at the time of diagnosis, five of them had SBP. Median progression time to MM for those patients was 29 months (14-104 months). Median overall survival (OS) was not achieved, progression free survival (PFS) was median 26 months. The presence of MM at the diagnosis was not a risk factor for progressive disease (p=0,9). Median OS for patients with MM at the diagnosis was 59 months and was not reached in patients without MM. There were no significant PFS and OS differences between SBP and EMP groups (p=0,8, p=0,7, respectively). The outcomes of patients without concurrent MM treated with chemo-radiotherapy and treated with radiotherapy alone were not different also (Table 2).
Summary/Conclusion: This registry-based study represents our experience on SP and provides the data showing that radiotherapy as a single regimen results in good outcomes. Due to limited number of patient, it is difficult to hypothesize that radiotherapy is the golden standard, but radiotherapy alone to involved area seems to be adequate and safe treatment option. Our findings is consistent with literature, however there is no prospective or large patient group of retrospective analysis in the literature.

PB2217

BORTEZOMIB-CYCLOPHOSPHAMIDE-DEXAMETHASONE INDUCTION THERAPY IS COMPARABLE TO BORTEZOMIB-THALIDOMIDE-DEX AMETHASONE IN NEWLY DIAGNOSED MYELOMA: A SINGLE CENTRE EXPERIENCE

F. Al-Kaisi*, D. Smith, F. Wadelin, E. Das-Gupta, S. Henshaw, S. Adams, C. Williams

Clinical Haematology, Nottingham University Hospitals, Nottingham, United Kingdom

Background: Bortezomib-based triplet therapy is the current standard of care for induction treatment in myeloma prior to autologous stem cell transplant (ASCT) in combination with dexamethasone and an IMiD such as thalidomide (VTD) or an alkylator such as cyclophosphamide (VCD). Induction therapy aims to achieve the deepest remission whilst limiting treatment toxicity. Peripheral neuropathy secondary to bortezomib and thalidomide can result in dose reduction or treatment discontinuation and potentially poorer response. Substituting thalidomide for cyclophosphamide may limit neuropathy but could theoretically reduce efficacy due to losing the synergistic effect between bortezomib and thalidomide.
Aims: To compare the response to treatment, incidence of neuropathy and rate of bortezomib and thalidomide dose reduction or discontinuation in patients who received VTD *vs* VCD induction for newly diagnosed myeloma prior to ASCT.
Methods: Patients were treated in 2 consecutive cohorts. Response rates were assessed prior to ASCT using IMWG criteria.

Table 1.

	VTD (n=39)	VCD (n=30)
Median age	62	63
Cytogenetics		
Standard Risk	16	14
High Risk	4	5
Unknown	19	11
Median Bortezomib dose	20.8 (mg/m²)	24 (mg/m²)
Median bortezomib cycles	4	5
PFS (1 year)	87%	76.5%
Response Rate		
ORR	86.8 %	96.5 %
≥ VGPR	24 (61.5 %)	16 (53.3%)
PR	9 (23%)	12 (40%)
SD	1 (2.56%)	0
PD	4 (10.25%)	1 (3.3%)
Unknown	2 (5.1%)	1 (3.3%)
Peripheral Neuropathy	14 (35.8%)	13 (43.3%)
Grade 1	5 (12.8%)	2 (6.6%)
Grade 1 plus pain	3 (7.6%)	3 (10%)
Grade 2	3 (7.69)	7 (23.3%)
Grade 3	2 (5.12%)	1 (3.3%)

Results: Between 2014 and 2017, 39 patients were treated with VTD and subsequently, a further 30 were treated with VCD. Median age at diagnosis was 62 years and 63 years and the median performance status was 1 and 0, respectively. ORR was 86.8% with VTD and 96.5% with VCD. The rate of VGPR or better was higher in the VTD group (61.5% *vs* 53%). 4 patients (10.25%) in the VTD group and 1 patient (3.3%) in the VCD group progressed during treatment, with 3 of 4 in the VTD group having high-risk cytogenetics. More patients treated with VTD proceeded to ASCT (84.6% *vs* 70%). Median follow up was 16 months. The 1-year PFS was 87% for VTD *vs* 76.5% for VCD. Comparing VTD to VCD, the median total cumulative bortezomib dose was 20.8mg/m^2 *vs* 24 mg/m^2 and the median number of cycles given was 4 and 5 respectively. 14 patients (35.9%) with VTD developed neuropathy of any grade compared to 13 (43.3%) with VCD leading to dose reduction in 20.5% and 43.3% respectively. Median cumulative bortezomib dose prior to the first bortezomib dose reduction was 12.45mg/m^2 with VTD and 16.1mg/m^2 with VCD. The rate of bortezomib discontinuation due to neuropathy (all grades) was 10% in each group. 15 patients (38.5%) treated with VTD had thalidomide dose reduction and 13 (33.3%) discontinued it after a median of 4 cycles. Median bortezomib dose per patient before discontinuation was 10.63mg/m^2 for VTD and 19.43mg/m^2 for VCD.
Summary/Conclusion: ORR was higher in patients treated with VCD, with 96.5% achieving remission. Patients treated with VTD required earlier dose reductions of bortezomib and received a lower median dose. Whilst patients treated with VTD achieved a higher rate of VGPR or better, VCD still resulted in an impressive 53% VGPR or above. VGPR rate for VCD is higher than that seen in some previous studies and comparable to that in the IFM2013-04 trial although our results were achieved using a lower dose of cyclophosphamide (500mg weekly). 1-year PFS was higher in the VTD group but more patients in this arm proceeded to ASCT so the PFS data may not accurately reflect the efficacy of induction therapy. Interestingly the rate of neuropathy was higher with VCD. This may reflect the need for more active dose reduction of bortezomib in the VTD group, discontinuation of thalidomide in around one-third of VTD patients and the higher cumulative bortezomib dose in VCD patients. Our findings suggest VCD is effective, delivers a higher bortezomib dose and is a viable alternative to VTD for induction therapy in myeloma.

PB2218

RETROSPECTIVE AUDIT OF BISPHOSPHONATE USE IN MULTIPLE MYELOMA PATIENTS IN TWO DISTRICT GENERAL HOSPITALS AND FRACTURE CONSENSUS

Z. Saleem[1,*], R. Allam[2], T. Hui[2], A. Bebb[2], A. Danga[1], T. Sugai[1]

[1]Haematology, Hillingdon Hospital, [2]Haematology, west middlesex hospital, London, United Kingdom

Background: Bisphosphonates are specific inhibitors of osteoclastic activity and form a cornerstone in the treatment of Patients with multiple myeloma to reduce the incidence of Skeletal related events. They are shown to be effective in reducing the incidence of Pathological fractures and pain.Skletal related events in multiple myeloma patients are associated with adverse outcomes in the form of increased morbidity, more hospital admissions and poor quality of life.We conducted a retrospective audit of bisphosphonates use in multiple myeloma patients in two district general hospitals against the UK NICE guidelines. NICE published guidelines in February, 2016 regarding management of Multiple Myeloma Patients, recommending the use of Intravenous bisphosphonates in all multiple myeloma patients soon after diagnosis
Aims: Our Primary objectives were: 1: To assess our compliance with the NICE guideline, 2: To assess the efficacy of I/V Bisphosphonates in reducing the incidence of Pathological fractures in multiple myeloma patients. Our secondary objective was to assess the incidence of osteonecrosis of Jaw in patients receiving I/V Bisphosphonates.
Methods: We collected the data for newly diagnosed multiple myeloma patients between January, 2010 to December, 2017 at the Hillingdon and west Middlesex hospiatals from the clinic letters, medical notes and radiology reports.
Results: There were 110 patient diagnosed with multiuple myeloma during this period. 102 (92.7%) of the patients received I/V bisphosphonates, out of these 62 pateints received Zolendronic acid and 40 patients received Pamidronate.Only 8(7.2%) Patients did not receive Bisphosphonates, 2 of these patients were intolerant of the treatment, for the rest of the 6 patients no reason was identified from the medical notes. Mean Duration of treatment was 24 months(range 12-36 months), 56(50%) of the patients had pathological fractures at the time of Diagnoses. Only 16(14%) of the patients receiving bisphosphonates were found to have a new pathological fracture. On the other hand the incidence of pathological fracture was much higher in patients who did not receive any bisphosphonate, 3 (37.5%) patients not recieving bisphosphonates were found to have a new pathological fracture. None of the patients treated with I/V bisphosphonates were found to have osteonecrosis of jaw.
Summary/Conclusion: Although our data is relatively small but clearly demonstrates, our compliance with NICE guidelines regarding the use of

I/V Bisphosphonates in multiple myeloma patients, reduction in the incidence of Pathological fractures in multiple myeloma patients receiving bisphonates(14% *vs* 37.5% in treated and untreated groups respectively), none of the patients were identified to have developed osteonecrosis of jaw with I/V bisphonate treatment, (International consensus is 1 in 1000 patient being treated with I/V Bisphosphonates will develop osteonecrosis of jaw).

PB2219

PROGNOSTIC SIGNIFICANCE OF THE CHROMOSOME 1 ABNORMALITIES IN PATIENTS WITH MULTIPLE MYELOMA

J. Bila[1,*], V. Djurasinovic[1], A. Sretenovic[2], J. Jelicic[2], M. Dencic Fekete[2], M. Perunicic Jovanovic[2], D. Antic[1], B. Mihaljevic[1]

[1]Clinic of Hematology, Clinical Center of Serbia, Medical Faculty, University of Belgrade, [2]Clinic of Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background: For the past two decades, several chromosomal abnormalities (CA) of high-risk significance on the course of multiple myeloma (MM) were defined, aiming to establish different prognostic groups.
Aims: The aim of this study was to analyze the prognostic significance of the chromosome 1 molecular abnormalities in MM patients.
Methods: A total of 104 newly diagnosed MM transplant-ineligible (median age 68 years, range 65-80 years; 56 male/48 female), were analyzed in the study, with following distribution: IgG myeloma had 68 patients (65.4%), IgA 17 (16.3%), IgD 1 patients (1%), light chains 16 (15.4%), and non-secretory 2 (1.9%). According to the clinical stage (CS, Durie&Salmon), advanced III CS was found in 82 patients (78.8%), II in 14 (13.5%), and symptomatic I CS in 8 (7.7%) patients. The ISS score 1 had 30 (28.8%) patients, 40 (38.5%) ISS 2, and 34 patients (32.7%) had ISS 3. Renal impairment existed in 29 patients (27.9%). According to the Revised ISS core (R-ISS), the distribution was as follows: RSS I 43 patients (41.3%), II 37 (35.6%), and III 24 patients (23.1%). Applying interphase fluorescent in-situ hybridization (iFISH) with probe 1p32/1q21 (CDKN2C/CKS1B), chromosome 1 abnomalities were identified in 54 (59.3%) patients: del1p32 in 16 patients (29.6%); and +1q21 in 38 patients (70.4%). Thalidomide based combinations were applied in 86 patients (82.7%), while bortezomib based combinations were applied in 18 patients (17.3%) with high-risk features.
Results: The overall treatment response (CR/VGPR/PR, IMWG criteria) with chr1 abnormalities, was achieved in 32 patients (51.9%): in 10/32 patients (31.3%) with del1p32; and 22/32 patients with +1q21 (68.7%). The median follow up of analyzed group was 22 months (range 6-100 months). Patients with chromosome 1 abnormalities had shorter PFS, still without statistical significance (Breslow 2.499; p=0.114), and statistically significant shortness of OS (Breslow 5.344; p=0.016). However, statistical analysis did not confirm the prognostic impact of +1q21 (PFS: Breslow 2.123, p=0.145; OS: Breslow 1.833, p=0.176), or del1p32 (PFS: Breslow 0.366, p=0.545; OS: Breslow 0.505, p=0.477). In addition, Cox regression analysis indicated R-ISS3 as the most important prognostic parameter that influenced OS (95% CI, 1.760-7.1429; p=0.006).
Summary/Conclusion: Molecular abnormalities of the chromosome 1 are of the negative prognostic significance in the MM patients. Still, it seems that R-ISS score 3 is of major impact on the course of disease with subsequent implications on the treatment approach.

PB2220

PROGNOSTIC SIGNIFICANCE OF THE REVISED INTERNATIONAL STAGING SYSTEM IN TRANSPLANT-ELIGIBLE PATIENTS WITH MULTIPLE MYELOMA

J. Bila[1,*], M. Todorovic Balint[1], D. Antic[1], V. Djurasinovic[1], A. Sretenovic[2], J. Jelicic[2], M. Dencic Fekete[2], M. Perunicic Jovanovic[2], B. Mihaljevic[1]

[1]Clinic of Hematology, Clinical Center of Serbia, Medical Faculty, University of Belgrade, [2]Clinic of Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background: In attempt to define different prognostic groups, with a final goal to personalize optimal approach in treatment of patients with multiple myeloma (MM), Revised International Staging System (R-ISS) was established.
Aims: The aim of study was to analyze the prognostic significance of the R-ISS score in MM patients eligible for autologous stem cell transplantation (ASCT).
Methods: A total of 112 newly diagnosed MM patients (median age 54 years, range 22-65years; 63 male/49 female), were analyzed in the study, with following distribution: IgG myeloma had 72 patients (64.2%), IgA 19 (17.0%), IgD 3 patients (2.7%), light chains 14 (12.5%), and non-secretory 4 (3.6%), and. According to the clinical stage (CS, Durie&Salmon), advanced III CS was found in 87 patients (77.7%), II in 15 (13.4%), and symptomatic I CS in 10 (8.9%) patients. The ISS score 1 had 56 (50.0%) patients, 21 (18.7%) ISS 2, and 35 patients (31.3%) had ISS 3. Renal impairment existed in 14 patients (12.5%). According to the R-ISS score, the distribution was as follows: RSS I 58 patients (51.8%), II 39 (34.8%), and III 15 patients (13.4%). Patients were treated with induction therapy based on triple combinations with thalidomide and/or bortezomib, followed with high-doses of Melphalan (HDT, 200mg/m^2), and supported with ASCT.
Results: The overall treatment response (CR/VGPR/PR, IMWG criteria), analyzed on +100. day after HDT+ASCT, was achieved in 108 patients (96.4%). According to the R-ISS score, overall treatment response was achieved in all of 58 patients with R-ISS I; in 38/39 (97.4%) with R-ISS II; and in 32/35 (91.4%) with R-ISS III. The median follow up of analyzed group was 52 months (range 12-143 months). The R-ISS was highly statistically relevant regarding both EFS (Log Rank=13.729, p=0.001) and OS (Log Rank=10.486, p= 0.001). Cox regression analysis confirmed that R-ISS was the most important prognostic parameter that influenced OS. (95% CI, 1.056-7.120; p=0.038).
Summary/Conclusion: The R-ISS score is highly significant prognostic factor in transplant eligible myeloma patients. It represents currently most sensitive prognostic tool in multiple myeloma with consequent implications to personalized treatment approach.

PB2221

EFFECT OF BISPHOSPHONATE AND ANTI-MYELOMA THERAPY ON BONE TURNOVER MARKERS IN MULTIPLE MYELOMA

A. Jandial[1,*], S.H. J.[1], K. Mishra[1], S. Bhadada[2], A. Sood[3], D. Lad[1], R. Aggarwal[4], M. Prakash[5], G. Prakash[1], V. Suri[1], A. Khadwal[1], S. Kumari[1], N. Varma[6], P. Malhotra[1]

[1]Department of Internal Medicine, [2]Department of Endocrinology, [3]Department of Nuclear Medicine, [4]Department of Immunopathology, [5]Department of Radiodiagnosis, [6]Department of Hematology, PGIMER, Chandigarh, India

Background: Bone involvement is one of the defining features of symptomatic multiple myeloma (MM). There is little information on changes in bone mineral metabolism that occur with bisphosphonates and anti-myeloma medication.
Aims: Assessment of bone mineral metabolism in MM patients at diagnosis and three months after treatment with antimyeloma drugs and bisphosphonates.
Methods: Newly-diagnosed MM patients were prospectively enrolled from January 2017 to December 2017. Besides standard myeloma work-up (including skeletal survey), baseline evaluation included estimation of serum bone turnover markers [carboxy-terminal cross-linking telopeptide of type I collagen (CTX), aminoterminal propeptide of type 1 procollagen (P1NP), and Osteocalcin (OC)], DEXA scan, and Tc99 bone scintigraphy. Patients were treated as per institutional protocol with antimyeloma drugs and monthly bisphosphonates. Skeletal survey and bone turnover markers were re-assessed after 3 months.
Results: Twenty-four newly-diagnosed MM patients were enrolled. Median age was 55 years (range 35 – 76 years); 79.16% were males. Majority had bone pains (83.3%) and anemia (83.3%); renal failure (45.8%) and hypercalcemia (45.8%) were not uncommon. IgG subtype was most common (52%), followed by IgA (21%) and light chain myeloma (16%). Majority (83.3%) had ISS stage III disease; mean value of β-2 microglobulin was 17.81 (± 25.16) mg/mL. 17 patients (70.83%) had multiple lytic lesions and seven (29.16%) fracture at baseline (pathological 4, traumatic 3). On DEXA scan, 10 patients (41.67%) had osteopenia and three (12.5%) had osteoporosis. Bone scintigraphy revealed meaningful uptake at baseline in 19 patients (79.16%); mainly in axial skeleton. All bone markers [CTX, P1NP, and OC] showed a graded but statistically insignificant correlation with the extent of bone involvement on baseline skeletal survey, P >0.05. Baseline CTX levels in patients with pathological fractures were significantly higher than those without fracture (P=0.041). Baseline β-2 microglobulin significantly correlated with CTX (r=0.44) and P1NP (r=0.43) levels; OC showed no correlation with β-2 microglobulin. After 3 months, significant decline was observed only in CTX levels [0.46 (±0.84) *v* 1.16 (±1.19), P=0.001]; minimal upsurge was observed in P1NP and OC levels (P >0.05). Fall in CTX levels among patients receiving VTD [bortezomib, thalidomide plus dexamethasone; n=5] was significantly greater than those receiving VCD [bortezomib, cyclophosphamide plus dexamethasone; n=19], P=0.012. Decline in CTX among patients exclusively treated with zoledronate [n=17] was significantly larger than those who received initial ibandronate (due to renal failure) followed by zoledronate [n=7], P=0.017. After 3 months, overall response rate was 75% [CR 16.7%, VGPR 50%, PR 33.3%].

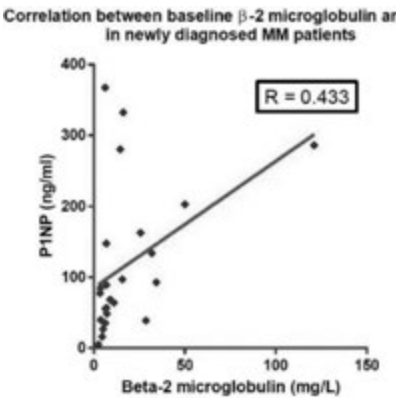


Figure 1.

Summary/Conclusion: We observed that bone turnover markers significantly correlated with myeloma disease burden (β-2 microglobulin). Their relationship with the severity of skeletal involvement was graded albeit inconsequential. Bisphosphonates and anti-myeloma medications considerably reduced CTX (bone resorption marker) but had trivial impact on P1NP and OC (bone formation markers). Predominance of ISS stage III patients, small study cohort and mitigation by concomitant unapparent factors (e.g., senile osteoporosis) shall be the possible explanations for these results. Larger prospective studies with longer follow up shall be required to interpret dynamics of bone turnover markers in myeloma.

CARFILZOMIB-LENALIDOMIDE-DEXAMETHASONE IN THE MANAGEMENT OF LENALIDOMIDE-REFRACTORY MULTIPLE MYELOMA

C. Cerchione[1,*], K. Ferrara[1], I. Peluso[1], M. Di Perna[1], I. Zacheo[1], D. Nappi[1], A. E. Pareto[1], A. Romano[2], F. Pane[1], L. Catalano[1]

[1]Hematology - Department of Clinical Medicine and Surgery, University Federico II, Naples, Napoli, [2]Department of General Surgery and Medical-Surgical Specialties, Haematology Section, University of Catania, Catania, Italy

Background: Carfilzomib is an epoxyketone proteasome inhibitor of second generation, proved to be effective and safe in relapsed and refractory Multiple Myeloma (rrMM), in combination with dexamethasone or lenalidomide and dexamethasone.
Aims: In this retrospective observational trial, it has been evaluated efficacy and safety of carfilzomib, in combination with lenalidomide-dexamethasone (KRD) as salvage regimen in patients with rrMM, refractory to lenalidomide, whose prognosis is particularly severe.
Methods: 27 patients (16 M/11 F), with rrMM, median age at diagnosis 63 years (r. 47-79), median age at start of treatment 66 years (r. 53-83) treated with several lines of treatments (median 3, r. 2-11), underwent to KRD regimen (ASPIRE trial schedule) for a median treatment cycles of 4 (r 1-12). ISS was equally distributed, and cytogenetic was evaluable in 8 patients, and in particular one del13q14 1q gain, one del13q14 and one t(11;14). All patients had previously been treated with bortezomib and IMIDs, and were refractory to this agents. 59% (16/27) of them had undergone at least to a single autologous SCT.
Results: According to IMWG criteria, after a median follow-up of 3 months (r.1-13), ORR was 66,7% (14/21: 8 VGPR, 6 PR) with 3 progressive diseases (PD) and 2 patients in stable disease (SD): this can be considered as an impressive result in this subset of rrMM patients, refractory to lenalidomide. In particular, for 1 patient, KRD was, after having achieved at least a PR, a bridge to second autologous SCT. Median time to response was 2 months (r.1-4), median OS from diagnosis was 51 months (r. 9-170), median OS from start of Carfilzomib was 3 months (r. 1-13). Carfilzomib was well tolerated, with grade 2 anemia in 33% (9/27) of patients, successfully managed by ESAs, without necessity of blood transfusions; 18% (5/27) grade 3-4 neutropenia (pegfilgrastim in primary prophylaxis was given, no ospedalization was required, no septic shocks were observed); 29% (8/27) grade 2, 18% (5/27) grade 3 and 7% (2/27) grade 4 thrombocytopenia, without hemorrhagic events and necessity of transfusions. Concerning severe extra-hematologic toxicity, it was observed pneumonia in 44% (12/27) of patients, treated by common antibiotic drugs; hypertension (grade 2-3) in 33% (9/27) of patients; arrhythmias in 7% (2/27) of patients; dyspnea in 11% (3/27) of patients; fatigue in 29% (8/27) of patients. All patients were carefully monitored by expert cardiologists of our deparment.
Summary/Conclusion: KRD has shown significant efficacy in a particularly severe setting of patients, relapsed and refractory to all available therapeutic resources, also lenalidomide, and, in particular cases, it could be considered as a bridge to a second autologous or allogenic SCT.

PB2224

FREQUENCY AND CAUSES OF NOT RECEIVING SUCCESSIVE LINES OF TREATMENT IN REFRACTORY MULTIPLE MYELOMA: A CROSS-SECTIONAL STUDY

A. Senín*, F. García-Pallarols, R. Ben Lashen, L. Martínez-Serra, S. Montesdeoca, D. Román, M. Ferraro, I. Párraga, C. Besses, E. Abella

Hematology Department, Hospital del Mar-IMIM, Barcelona, Spain

Background: The introduction of novel agents during the last decade has improved the clinical outcome in patients with recurrent/refractory multiple myeloma (R/R MM), which has allowed to increase the number of lines and the types of treatment received. Nevertheless, most studies are performed within clinical trials and there are few data on sequential treatments in real-world clinical practice, where treatments are not completed.
Aims: To study the frequency and reasons for not receiving next line of treatment in a real-life cohort of patients with R/R MM.
Methods: Main clinical-biological characteristics of 108 patients diagnosed of MM between 2010 and 2016 in a tertiary centre were collected. Patients were categorized according to the last line of treatment received, including palliative treatment with cyclophosphamide as a line.The reasons for not receiving a subsequent treatment in each line were defined as: response (not needing further therapy), treatment-related toxicity and death (due to toxicity, disease progression or other causes).Overall survival and time to next treatment curves were calculated by kaplan meier method. A competitive risk analysis was carried out to estimate the projected proportion of patients receiving second and third lines considering death, toxicity disqualifying for further therapy or loss of follow-up as competitive events.

Table 1.

Table 1. Reasons for not receiving a next line of treatment

Patients who do not receive a next line	1st line n=35	2nd line n=29	3rd line n=21	4th line n=13	5th line n=10
Response	11 (31)	4 (14)	2 (8)	0	0
On going	7 (20)	10 (35)	7 (33)	5 (38)	5 (50)
Exitus due to progression of MM	5 (14)	5 (17)	8 (40)	5 (41)	4 (40)
Exitus due to treatment-related complications	4 (11.5)	5 (17)	3 (14)	2 (16)	1 (10)
Exitus due to others Causes	4 (11.5)	2 (7)	0	0	0
Exitus due to another neoplasia	3 (9)	3 (10)	0	0	0
Toxicity by treatment	1 (3)	0	1 (5)	1 (5)	0

Results: The reasons for not receiving a next line of treatment, at the time of the analysis, are summarized in Table1.Thirty-five out of 108 patients (32%) received only a first line. Thirty-one percent of them (11/35) remained in response without requiring rescue treatment. Fourteen percent (5/35) discontinued treatment due to death in the context of progression and 11.5% (4/35) due to toxicity-related death. Twenty percent (7/35) died due to causes not related to MM, as other neoplasms (9%; 3/35). Only 3% of patients could not receive further treatment due to serious toxicities that did not result in death.Twenty-seven percent of patients (n=29) received only treatment up to the second line. The discontinuation due to death by progression and death by toxicity was 17% (5/29), in both cases.Twenty percent of patients (n=21) received treatment only up to the third line. Death by progression was the most frequent cause of not receiving successive lines (40%; 8/21), whereas severe toxicity and death by treatment-related com-

plications were the reason in 5% and 14% of patients, respectively.Only 12 patients received treatment up to fourth line, 7 up to fifth line and 1 up to sixth line. The cause of not continuing treatment was mainly death by progression (41% and 40% in fourth and fifth lines, respectively). No responses were observed in these lines.The median overall survival of the series was 25 months. Median of time to next treatment were 16, 15 and 13 months in first, second and third line, respectively. The projected probability of receiving a second line of treatment at 60 months was 78% whereas probability of receiving third line at 60 months was 53% by competitive-risk analysis (68% of the 78% remaining).
Summary/Conclusion: -In our series, 78% of patients were estimated, by competitive risk analysis, to receive a second line of therapy at 60 months. Patients do not access a second line mainly due to death. While the main reason for discontinuation in the first line was not needing further therapy, the main cause in successive lines was death by progression (25% of the global series) increasing its frequency according to the number of lines received.

PB2225

AUTOLOGOUS STEM CELL TRANSPLANTATION IN NEWLY DIAGNOSED ELDERLY MULTIPLE MYELOMA PATIENTS: A SINGLE CENTRE EXPERIENCE

T. Berno*, M. Riva, L. Ammirati, A. Visentin, C. Gurrieri, A. Branca, L. Checuz, A. Lico, G. Barilà, M. Leoncin, S. Imbergamo, F. Piazza, L. Trentin, G. Semenzato, R. Zambello

Department of Medicine, Hematology and Clinical Immunology Unit, University Hospital, Padua, Italy

Background: Multiple myeloma (MM) is a plasma cell malignancy that affects older adults with a median age at diagnosis of 70 years. Autologous stem cell transplantation (ASCT) is the standard of care for young newly diagnosed MM patients. The safety and efficacy of High Dose Therapy (HDT) as upfront treatment in elderly patients remain still uncertain, because elderly age is frequently associated with increased comorbidities and suspected increased treatment-related toxicity.
Aims: In our centre we analyzed the outcome and toxicities in a homogeneous cohort of newly diagnosed elderly MM patients treated with HDT approach.
Methods: We retrospectively evaluated 24 newly diagnosed elderly MM patients, according to International Myeloma Working Group (IMWG). All of them were fit/low-risk according to revised Myeloma Comorbidity Index (R-MCI). Median age at diagnosis was 66 years (range 65-68 years), and at transplantation 66.5 years (range 65-69). The revised International Staging System (R-ISS) stage was: I in 12 patients (50%), II in 8 cases (33%), III in 3 patients (12.5%) and unknown in 1 patient (4%). FISH analysis were performed at diagnosis in all patients, and we found standard-risk in 11 patients (46%), intermediate-risk in 4 cases (16%), high-risk in 3 cases (12.5%) and not assessable in 6 patients. Immunoparesis occurred in 19 patients (80%) at diagnosis. The induction therapy was bortezomib-based in association with dexamethasone (VD) with or without thalidomide (VTD). The mobilization regimen included cyclophosphamide followed by G-CSF. The conditioning regimen consisted of melphalan 140 mg/mq or 200 mg/mq given over two days.
Results: As induction therapy 10 patients (41.5%) received VD, 11 patients (46%) VDT and 3 patients received bortezomib-based therapy plus infusional chemotherapy regimens (12.5%). Melphalan 140 mg/mq conditioning regimen was administered in 14 patients (60%) and 200 mg/mq in 10 patients (40%). The overall response rate (ORR) to induction therapy (≥PR) was 91.6% including 5 CR (21%), 10 VGPR (41.5%), 7 PR (29%) and 2 SD (8.5%). The ORR after ASCT increased to 96%: 5 CR (21%), 14 VGPR (58.5%), 4 PR (16.5%) with 1 death. Immunoglobulin recovery 1 year after ASCT occurred in 15 patients (62.3%) out of 19 with immunoparesis at diagnosis. Median time to neutrophil and platelet engraftment was 10 days (range 6-18 days). No significant difference in toxicity was found among the two groups (MEL140 *vs* MEL200). The non-hematological toxicities after ASCT (G3-G4) included infections in 12 patients (50%) and gastrointestinal disorders in 10 cases (41.5%). In 1 patient we observed cardiac toxicity (G2). The day-100 post ASCT treatment-related mortality (TRM) was 4% (1 patients died after conditioning regimen). During follow up we reported secondary malignancies in 2 cases (8%) and one therapy-related myeloid neoplasm (t-MDS). The mean PFS was 30 months in MEL140 group *vs* 53 months in MEL200 (p=0.11), no significant difference in OS was observed (p=0.3).
Summary/Conclusion: Our results suggest that ASCT is a safe and well-tolerated procedure in our small cohort of elderly and fit patients. We detected among the two regimens (MEL140 and MEL200) a similar profile of toxicities. The dose of Melphalan (MEL200) seems to impact on the duration of response, with a statistically significant trend in PFS. We confirm that an accurate assessment of elderly patients performance status and comorbidities at diagnosis, can help to develop risk-adapted treatment strategies to improve outcome, in elderly MM patients.

PB2226

INCORPORATION OF TECHNOLOGY IN OUR MULTIPLE MYELOMA CONSULTATION: A YEAR OF EXPERIENCE

J.M. Sánchez-Raga*, A. Ortuño-Cabrero, A. Pérez-Montaña, N. Beltran, T. Ros, B. López-Andrade, M.D.C. Ballester-Ruiz, L. Lo Riso, L. Bento, L. García-Maño, M.A. Duran, A. Sampol-Mayol

Hospital Universitari Son Espases, Palma, Spain

Background: Multiple myeloma is a chronic pathology diagnosed usually in elderly patients. It often presents with systemic involvement (bone lesions, renal failure, anemia, infections) secondary to the pathology itself or as a treatment side effect. Patients often come to consult or the emergency department spotaneously for problems arising from this pathology. Thanks to the collaboration of Celgene we have developed a link project in our center, whereby a case management hematologist through a telematic medical consultation (telephone and via email), detects side effects of treatment, prescribes complementary tests or modifies adjuvant treatment and derives early to other specialists in the cases that it is necessary. With this, diagnostic and therapeutic delays have been avoided in patients affected by Multiple Myeloma, improving their quality of life and strengthening the doctor-patient relationship.
Aims: We summarize the activity of the first year of implementation of the telematic consultation and the benefits obtained from it.
Methods: In March 2017, the project was initiated and presented personally to each patient with multiple myeloma. In our center we have 104 patients in follow-up in this period of time, of which 80% have been included in the project for the time being.
Results: 51 patients have attended at least one telematic consultation (median 2, range 1-21). Tables 1 and 2 summarize the type of activity attended. We have save more than 135 spontaneous visits of the patients to our consultations or emergencies. We have also reduced the time until resolution of the reason for consultation. More detail information will be provided in the congress. 51 patients have performed at least one telematic consultation (median 2, range 1-21). Tables 1 and 2 summarize the type of activity attended in the consultation. With this consultation we have saved 137 spontaneous visits of the patient to consultations or emergencies. We have also reduced waiting times until resolution of the reason for consultation. More detailed information will be provided in the congres.

Table 1.

REASONS FOR CONSULTATION	Number of consultations	(%)
Medical consultation	75	36.8%
Claim citations / tests	51	25%
Information	31	15.2%
Referral specialists	20	9.8%
Prescription of medicines	16	7.8%

REASONS FOR MEDICAL CONSULTATION	Number of consultations
Digestive: Nausea, diarrhea, constipation	21
Respiratory: Respiratory infection, dyspnea	15
Pain	13
Cardio-vascular	9
Psychological:Anxiety, depression	6
Skin	5
Urological	3
Others	2

Summary/Conclusion: The telematic consultation can save hospital visits, reduce attention time, and improve the monitoring and quality of life of our patients. In an increasingly technological society, the incorporation of mobile phone, email and other tools will be more common in our clinical practice.

PB2227

TREATMENT WITH IXAZOMIB IN HEAVILY PRETREATED PATIENTS WITH MULTIPLE MYELOMA IN SLOVENIA: REAL LIFE DATA

A. Čebokli, N. Zima, S. Zver*

Hematology, University clinical center Ljubljana, Ljubljana, Slovenia

Background: Based on the TOURMALINE-MM1 trial, Ixazomib (Ixa) is a novel oral proteasome inhibitor (PI), which in combination with lenalidomide and dexamethasone (IxaRD) prolongs progression free survival and increases the overall response rate over RD alone.
Aims: To evaluate the efficacy and safety of IxaRd in the real-world clinical practice in Slovenia.
Methods: We retrospectivelly analysed data on heavily pretreated patients with RRMM, treated with IxaRD regimen from July 2016 to January 2018, that were included in the compassionate ixazomib use Named-Patient Program in Slovenia. We compared our data with significantly less pretreated patients in Tourmaline MM1 study. Primary end point was overall response rate (ORR). Secondary endpoints included duration of treatment, number of patients experiencing adverse effects (AE) and treatment discontinuation reasons.
Results: We treated 47 patients; Female/Male ratio was 30%/70%, median age at enrollment was 68 (46-82), median age at diagnosis 62, ISS I or II 59% and ISS III 41%. They were previously treated with median 5 (1-11) lines of therapy. 94% of patients were previously treated with bortezomib based regimens, 11% were primarily refractory. 69% of patients received lenalidomide based regimen (24% were refractory), and 13% received pomalidomide. At diagnosis, cytogenetics was not assessed in 47% (22/47) of patients: 15% (7/47) had high risk cytogenetics, 23% (11/47) intermediate risk and 15% (7/47) standard risk. Translocation (4;14) and gaining of (1q21) were determined as intermediate risk. 45 patients (96%) were treated with the IxaRD combination, 5 of those (10%) have continued without lenalidomide due to side effects. Two patients (4%) started treatment with ixazomib-dexamethasone regimen. Median number of cycles administered was 4,5 and 12 patients are still receiving treatment. Response rate was assesed according to IMWG criteria. ORR in these patients was 33%; 5 patients (10%) achieved CR, 5 (10%) VGPR, 6 (13%) PR. In addition we observed minimal response or at least stable disease in 17% of patients. In 27% of patients disease progressed. In 23% of patients we were not able to evaluate the response rate due to the short period of treatment. In 5 patients refractory to bortezomib, 1 VGPR and 1PR were observed. There were no AE reported amog 62% of patients. 6% of patients had polyneuropathy, 16% had cytopenias, 2% dizziness, 4% infection, 2% generalized skin rash, and 2% acute renal impairment, leading to treatment discontinuation in 8 patients.
Summary/Conclusion: The dataset from this real life study describes results of IxaRD regimen in our heavily pretreated and high risk patients. It also emphasises the difference between real life data and clinical trials. Namely our patients received many more lines of therapy and had more often unfavorable disease markers. The overal response rate, including MR and SD patients, was 50%, which is significantly less than the ORR published in Tourmaline study (78%). Clinical benefit rate was much lower in patients treated beyond 5th treatment line, including bortezomib and lenalidomide refractory patietns. We noticed that resistance to bortezomib doesn't always mean, that the patient is ixazomib resistant too; 40% of bortezomib refractory pts responded to ixazomib. It would be interesting to find out how it is with cross resistance interactions between karfilzomib and ixazomib and vice versa. During the observational period there were no ixazomib related deaths. IxaRd appears to be a reasonablly safe and effective treatment option.

PB2228

SERVICE DELIVERY OF APPROVED DARATUMUMAB TREATMENT FOR RELAPSED MYELOMA; CHALLENGES OF NORMAL IMMUNOGLOBULIN AND UNAFFECTED FREE LIGHT CHAIN SUPPRESSION, ESPECIALLY WHEN ASCT IS INCLUDED

R. Powles[1,*], L. Little[1], J. Sheldon[2], R. Wheeler[2]

[1]Myeloma Unit, Cancer Centre London, [2]Immunology, St Georges Hospital, London, United Kingdom

Background: The anti-CD38+ monoclonal antibody Daratumumab (dara) is established as part of the treatment pathway for MM, along with autologous stem cell transplantation (ASCT) (IMWG 2017). Patients who have previously received, or are receiving Daratumumab have altered cellular inmmunological status (ASH 2017 abstract 3148).
Aims: To review suppression of normal serum immunoglogulins in dara treated patients, and possible increased infection risk (EBMT 2018 Powles *et al.* Abstract B232), and whether this impinges on the safety of ASCT. To determine if in ASCT patients, this altered immune status, results in poor stem cell harvesting, delayed engraftment, infections, possible autologous GVHD, and dara infusion- related reactions when re-challenged post ASCT. We also look to see if suppression of normal Free Light Chain (FLC) levels occurs on dara, which may effect interpretation of FLC ratio.
Methods: In this study 26 patients with progressive MM (1-13 prior lines of therapy) aged 65y(36-83); IgG: 13, IgA: 8, BJ: 4, NS 1, were treated with dara plus/minus velcade or revlimid at our institution; 21 with minimum follow-up 6 months. Three patients underwent ASCT.
Results: Of 26 patients with progressive MM at baseline, 24 responded (MRD-ve 35%, VGPR 35%, PR 19%, SD 4%, PD 8%) **Immunoglogulin suppression;** There was profound suppression of normal unaffected Ig levels at 6 months in 25/26pts inc those in CR; *e.g.* 7 patients with IgG myeloma on dara monotherapy ≥6 months; at 1 month normal IgA was reduced by 30-86% (m 80%); IgM by 25-86% (m 66%). this pattern occurred in non-IgG patients. **Infections**; there were 95 infection events seen including 27% URTIs (grade 3) & 1 grade 4 influenza associated death. **Unaffected FLC Suppression;** in 24 (of 26) patients unaffected FLCs dropped at 1 month (2 were stable), *e.g.* in 7 IgGk patients λ light chains had dropped from 1.3mg/L to 0.7; 6.3 to 4.9; 13.6 to 5.3; 5.9 to 1.2; 17.1 to 7.9, 10 to 6.6; 9.7 to 7.0 at 1 month. This was compared with a rise in unaffected λ light chains in 6 (of 7) of these patients 1 month into a prior (non-dara) MM therapy. **ASCTs** Three patients received planned ASCTs; two had PBSCs harvested following dara treatment. **Pt1.** F 72, IgAλ. 13 previous lines (9 yrs) treatment, 6 cycles dara pre ASCT; 10 post. ANC engraftment; 12 days. Inpatient stay (los): 14 days. Pre ASCT: MRD+ve (PP14g/L) post ASCT: MRD-ve. **Pt 2.** F 49, IgGk. 4 previous lines (9 yrs) treatment. 7 cycles Dara pre ASCT; 10 post. ANC engraftment 13 days. los: 15 days. MDR+ve status (BMB IP+iv) pre SCT. post MRD-ve. **Pt 3.** M 63 IgAλ /AL. 2 previous lines (2yrs) treatment. 7 cycles Dara pre ASCT; 10 post. ANC engraftment: 13 days. los: 22 days. MRD-ve status pre SCT; post MRD-ve. All three had serum dara levels at time of ASCT.
Summary/Conclusion: We describe profound normal immunoglogulin suppression with associated infection for patients on dara, with or without serum dara levels present. Three ASCT patients engrafted and were discharged from hospital promptly. They mobilized standard stem cell yields, had no evidence of autologous GVHD, unexpected infections, or an IRR with their next infusion of dara. The effect of dara in suppressing the unaffected FLC requires consideration when monitoring FLC ratios in these patients.

PB2229

MONOCLONAL GAMMOPATHY AND TRANSTHYRETIN AMYLOIDOSIS

A. Alarcon Tomas[1,*], C. Salas[2], I. Zegrí[3], P. García-Pavia[3], J. Vázquez Cobos[4], P. Massó[5], I. Krsnik[1]

[1]Hematología, [2]Pathology, [3]Cardiology, Hospital Universitario Puerta de Hierro, [4]Hematología, Hospital Reina Sofía, [5]Hematología, CNIC, Madrid, Spain

Background: Amyloidosis is a rare disease characterized by tissue deposition of insoluble fibrils created by the aggregation of misfolded proteins. Cardiac involvement is common and associated with an increased risk of morbidity and mortality. The most frequent types of amyloidosis are light-chain (AL) and mutant or wild-type transthyretin (TTR). AL amyloidosis caused by the deposition of misfolded kappa or lambda light chains in patients with an underlying plasma cell malignancy. Differential diagnosis between AL and TTR cardiac amyloidosis is mandatory because prognosis and therapy are different, but it is not always easy as non-invasive techniques are not specific.
Aims: We report three patients with a monoclonal gammopathy and wild-type TTR amyloidosis.
Methods: Case reports, Patient 1. A 66-year old men was sent for haematological evaluation after an ischemic stroke. He was otherwise asymptomatic. An echocardiogram showed a concentric left ventricular hypertrophy suggesting cardiac amyloidosis. Blood tests showed normal counts, a monoclonal component and an increase in free light chains (FLC). A cardiac biopsy showed Congo Red positive deposits. Immunohystochemistry (IHC) was not diagnostic. Mass spectrometry (MS) confirmed the diagnosis of TTR amyloidosis. Fifty months from diagnosis, he remains asymptomatic with stable FLC and NT-proBNP. Patient 2. A 87 year old men was admitted to our Hospital with a two-month history of cough, edemas, and dyspnea. He had anemia, thrombopenia, a biclonal component and an increase in FLC. A cardiac biopsy with IHC and MS confirmed the diagnosis of TTR amyloidosis. He was begun on cyclophosphamide, prednisone and thalidomide with improvement of the blood counts and decrease of the M-spike. Thirteen months from diagnosis, he remains alive with cardiological support. Patient 3. A 75-year-old male was evaluated at our centre with a three-

month history of edemas and shortness of breath. A diagnosis of monoclonal gammopathy of unknown significance (MGUS) had been made elsewhere nine years before. Echocardiography showed a severe concentric left ventricular hypertrophy. A cardiac biopsy with IHC and MS confirmed the diagnosis of TTR amyloidosis. Ten months from diagnosis he remains stable with diuretic therapy. MGUS remains also stable.
Results: Our three patients are elderly males with a MGUS and a positive SC. Although IHC studies showed TTR deposition in the heart, a faint positive staining with anti-TTR can be seen in AL specimens. In the three cases, MS confirmed the presence of TTR and ruled out deposition of light chains.

Table 1.

	Patient 1	Patient 2	Patient 3
Age	66	87	75
Sex	Male	Male	Male
TTR gene Wild Type (WT)/Mutant	WT	WT	WT
MS (cardiac biopsy)	TTR	TTR	TTR
IHC	TTR expression +++, Amiloid A -, Kappa+, Lambda +	TTR expression +++, Amiloid A -, Kappa-, Lambda -	TTR expression ++, Amiloid A -, Kappa+, Lambda +
99mTechnetium-DPD scintigraphy	Score 2	Score 3	Score 3
Echo: LVEF/IVS	55%/21mm	50%/15mm	60%/18mm
NYHA stage	1	2	2
NT-proBNP, pg/ml	483	1557	3867
M-spike (g/dl)	IgG λ (1.2)	Biclonal λ (2.1)	IgG λ (1.3)
Proteinuria	Negative	Negative	Negative
% plasma cells in BM	35%	9%	1%
FLC κ/λ(mg/l)	14.9/147.5	35.2/272.8	31.3/23.9
Plasma Cell disorder	Asymptomatic MM	MM	MGUS

Table 1: clinical data and biochemical data, imaging techniques and biopsy results

Summary/Conclusion: Most cardiac amyloidosis are either due to TTR or light chain deposition. AL cardiac amyloidosis has a worse prognosis and the underlying neoplastic clone can be treated with anti-myeloma drugs. Differential diagnosis between AL and TTR amyloidosis may be complicated. Firstly, wild-type TTR amyloidosis may be more prevalent among elderly patients than previously thought. Secondly, many elderly patients have monoclonal gammopathies so the presence of a MGUS does not mean that amyloidosis is AL. Echocardiography or MRI of the heart cannot differentiate between the two types. Scintigraphy (SC) with 99Tc is always positive in patients with cardiac TTR-amyloidosis but up to 10% of AL cases may show a positive score. Immuno-electronic microscopy is not available in most centres. Differential diagnosis between cardiac AL and TTR amyloidosis is mandatory because subtyping of the amyloid has significant implications in the management of patients and prognosis. MS might be essential.

PB2230

DOES ASYMPTOMATIC D-DIMER ELEVATION PREDICT THROMBOSIS IN PATIENTS ON IMMUNOMODULATORY DRUGS IN MULTIPLE MYELOMA: REAL-LIFE DATA

M.S. Aydın[1,*], S.C. Yazgan[2], E. Karakulak[1], R. Çiftçiler[1], E. Kelkitli[3], M. Turgut[3], H. Goker[1], H. Demiroglu[1], O. Ozcebe[1], I. Haznedaroglu[1], S. Aksu[1], F. Tekin[1]

[1]Hematology, [2]Internal Medicine, Hacettepe University Faculty of Medicine, Ankara, [3]Hematology, [19] Mayıs University, Samsun, Turkey

Background: Immunomodulatory drugs (IMiDs) bring the risk of venous thromboembolism (VTE) in patients with Multiple Myeloma (MM). Prophylactic measures such as asetylsalicylic acid (ASA), low-molecular heparins (LMWH) or warfarin usage are routine but there are no well-defined criteria in which patients which measure will be taken. Risk assessment models with disease-related, treatment-related and patient-related risk factors help in decision process. Routine D-dimer monitoring in asymptomatic patients on IMiDs may help early diagnosis of VTE.
Aims: To evaluate if routine D-dimer monitoring on IMiD usage will detect asymptomatic VTE.
Methods: Retrospective data from a total of 55 MM patients on IMiD-containing regimens diagnosed between 01.01.2001 and 01.06.2017 were analyzed. D-dimer values and radiologically or pathologically diagnosed thromboses events were recorded. Univariate analyses were done by Chi-square test for categorical and by t-test for numerical variables, respectively.
Results: Median age of diagnosis was 58 (range, 33-79 years) and median age was significantly high in thrombosis group (n=8) with respect to patients without thrombosis (n=47) (p=0.040). Thromboprophylaxis regimens were recorded in 40 patients; 19 patients with ASA and 21 patients with LMWH. Of these, 50 patients were monitored with plasma D-dimer levels during IMiD usage. 23 patients (46%) showed an elevation of D-dimer (≥1 mg/L), and there were 32 patients in whom D-dimer was <1 mg/L or was not monitored. There were 8 thromboses events (3 deep venous thromboses and 5 pulmonary venous embolisms). All thromboses events were symptomatic. Of 11 patients with asymptomatic D-dimer elevation, all were investigated radiologically for possible thrombosis and none had thromboses. There was no median D-dimer value difference between symptomatically and asymptomatically D-dimer elevated patient groups (p=0.178). There was no thromboprophylaxis regimen choice difference between thrombosis and no-thrombosis groups (p=0.664).
Summary/Conclusion: VTE events may occur despite thromboprophylaxis in IMiD using patients. In this study, symptoms suggesting thrombosis seem more important with respect to D-dimer elevation in diagnosing VTE. But there is no enough data for foregoing serial plasma D-dimer monitoring because early intervention may help to prevent symptomatic or lethal VTE events.

PB2231

RENAL SALVAGE WITH BORTEZOMIB/CYCLOPHOSPHAMIDE/DEXAMETHASONE INDUCTION THERAPY IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS WITH RENAL INSUFFICIENCY: A SINGLE-CENTER STUDY FROM NORTH INDIA

U. Nath*, R. Chetia, J. Nanda, A. Baveja

Medical Oncology Haematology, All India Institute of Medical Sciences (AIIMS), Rishikesh, Rishikesh, India

Background: Renal impairment is a common and potentially life-threatening complication of multiple myeloma. Among newly diagnosed myeloma patients, 20-50% have acute kidney injury at the time of diagnosis. The commonest form of myeloma-related acute kidney injury is light chain cast nephropathy. Bortezomib/Cyclophosphamide/Dexamethasone (CyBorD) regimen is the preferred initial induction therapy in newly diagnosed myeloma patients with acute renal insufficiency.
Aims: Our study reports the renal salvage response to CyBorD induction therapy in newly diagnosed multiple myeloma patients with renal insufficiency in a tertiary hematology center in north India.
Methods: The study included 34 newly diagnosed patients of multiple myeloma with renal insufficiency (RI) between March 2016 & January 2018. RI was defined as either serum creatinine >2 mg/dL or creatinine clearance (CrCl) <40 mL/min related to myeloma.[1] Baseline tests of renal function included serum creatinine & estimation of CrCl, serum electrolyes, calcium, phosphorus & uric acid. The investigations done for myeloma diagnosis included bone marrow aspiration+biopsy, serum protein electrophoresis, serum immunofixation & free light chain assay, β2 microglobulin & X-ray skeletal survey. Renal biopsy could be performed in two patients only. Renal insufficiency was aggressively managed with intravenous hydration (3 liters/m^2/day, unless oliguric with volume overload) and intravenous dexamethasone. Induction therapy with CyBorD was initiated immediately after confirmation of myeloma diagnosis (21 days' cycle: Bortezomib 1.3 mg/m^2 intravenously on days 1,4,8,11; Cyclophosphamide 300 mg/m^2 orally on days 1,8,15; and Dexamethasone 40 mg/day orally on days 1,4,8 & 11 of each cycle). Hemodialysis was performed in patients with oliguric renal failure, volume overload, or severe hyperphosphatemia unresponsive to treatment. Plasmapheresis was not performed in any of the patients. Zoledronate was deferred till normalization of renal function. Renal response to anti-myeloma therapy was defined as per International Myeloma Working Group (IMWG) criteria [Complete renal response: CrCl >60 mL/min; Partial renal response: CrCl 30-59 mL/min].[1]
Results: The median patient age was 61 years (22-76 years). Majority (72%) of the patients had kappa light chain paraprotein (either kappa light chain myeloma or IgG/IgA kappa myeloma). Median serum creatinine & calcium levels at presentation were 3.1 mg/dl (2.1-11 mg/dl) & 11.2 mg/dl (8.1-15.4 mg/dl) respectively. Four patients (12%) required hemodialysis initially as per indication. Complete renal response was achieved in 94% (32/34) patients, including those who required dialysis. Two patients discontinued treatment & were lost to follow up. The median time from initiation of treatment to achievement of renal response was days (range 3 - 35 days).
Summary/Conclusion: Myeloma-related acute renal insufficiency is a medical emergency. Aggressive supportive treatment and prompt initiation of Bortezomib-based anti-myeloma therapy are the cornerstones of management. Hemodialysis is indicated in a minority of patients but can be life-saving. Bortezomib/Cyclophosphamide/dexamethasone induction regimen is associated with excellent renal salvage response in myeloma-related acute renal insufficiency.

PB2232

CLINICAL EFFICACY AND SAFETY OF LENALIDOMIDE IN NHS GREATER GLASGOW & CLYDE

L. Doherty[1,*], R. Soutar[1], K. MacLure[2]

[1]Haematology, Beatson West of Scotland Cancer Centre, Glasgow, [2]Robert Gordon University, Aberdeen, United Kingdom

Background: Lenalidomide in combination with dexamethasone is accepted for use in Scotland as 1st line therapy in transplant ineligible patients who are unsuitable for thalidomide treatment, 2nd line in patients who are unsuitable for thalidomide treatment and unrestricted use as 3rd line treatment.
Aims: This retrospective Real World Data (RWD) study examined the clinical efficacy and safety of lenalidomide in the treatment of multiple myeloma patients in NHS Greater Glasgow and Clyde (GG&C), with an approximate population of 1.2million.
Methods: All multiple myeloma patients treated in GG&C with lenalidomide from 01/01/2013 to 01/01/2016 were eligible for inclusion. Exclusion criteria were any patients with myeloma associated amyloidosis, those treated as part of a novel combination therapy or as part of maintenance therapy post-transplant. 131 patients met the criteria. Data were censored for 01/01/18. Patient characteristics including disease stage, ECOG status and renal function were determined. Clinical efficacy was evaluated using International Myeloma Working Group criteria for Time to Progression (TTP) and Progression Free Survival (PFS). Overall survival data were immature. Adverse effects and reasons for discontinuation were assessed.
Results: The overall median TTP was 90 weeks compared to the TTP of 58 weeks in the Pooled Pivotal Study[1] (PPS) of the MM-009 and MM-010 trials. PFS was 71 weeks, compared to 48 weeks in the PPS. The improved PFS/TTP was despite patients being older and having poorer performance status and renal function to the PPS. The results compare favourably to Spanish[2], Korean[3], Dutch[4] and Polish[5] RWD studies (see table). TTP was found to be significantly higher than PFS. The TTP metric creates a less robust endpoint as it censors deaths that have not been positively attributed to disease progression. This challenges the applicability of TTP in myeloma patients, a primarily elderly group, who have higher mortality rates irrespective of their underlying malignancy. In total, 22% (n=29) of patients either discontinued lenalidomide due to adverse effects (n=18) or died (not attributable to progression) while on lenalidomide (n=11). Although generally higher, rates of discontinuation due to adverse effects and deaths were comparable to those in published literature.

Table 1.

	GG&C	PPS	Spanish RWD	Korean RWD	Dutch RWD	Polish RWD
Median Age	71	63	66.5	62	61	60.5
ECOG Status 0 1 2 3 4	25% 31% 41% 4% 0	44% 44% 11% 0 0	NA	76.4 (0-1) 17.2 (2-4)	NA	Only 0-2 included
Median Previous Therapies	2 (0-5) 1 = 2.2% 2 = 15.2% 3≥ = 82.4%	1 = 18.4% 2 ≥ =81.6%	3	3.5	3.5	1-2 Lines =31% 3-5 Lines =56% ≥ 6 Lines =13%
Previous ASCT	45%	58%	35%	67%	66%	60%
Renal Impairment CrCl = Creatinine Clearance	CrCl>90 = 21% CrCl60-89 =21% CrCl30-59 =44% CrCl15-29 =12% CrCl<15 =2%	Patients with Creatinine > 221 μmol/L were excluded	Creatinine > 177 μmol/L = 12.6%	CrCl< 30 =9%	Cr Cl<50= 7%	Creatinine > 177 μmol/l = 7.5%
TTP weeks	90	58	56	35	39	87
PFS weeks	71	48	NA	NA	43	NA

Summary/Conclusion: This is the first study of lenalidomide use in unselected patients with a median age over 70 years and better reflects those treated in actual clinical practice. Despite the older age, poorer ECOG status and renal function, TTP/PFS were better than those seen in the PPS/RWD and confirms lenalidomide's efficacy in an elderly and pre-treated patient group.

MINIMAL RESIDUAL DISEASE NEGATIVITY AFTER MOLECULARLY TARGETED VENETOCLAX THERAPY OF SECONDARY PLASMA CELL LEUKEMIA WITH TRANSLOCATION T(11;14)

G. Mikala*, A. Cegledi, O. Csacsovszki, M. Peto, Z. Szemlaky, M. Udvardy, S. Tasnady, A. Kozma, P. Remenyi, I. Valyi-Nagy

Hematology and Stem Cell Transplantation, South-Pest Central Hospital, National Inst. Hematology & Infectology, Budapest, Hungary

Background: Secondary plasma cell leukemia presenting as a myeloma relapse after multiple prior lines of therapy is a condition with dismal prognosis and a usual survival of only a few weeks. Recently, it has been shown that multiple myeloma with translocation t(11;14) may be exquisitely sensitive to the bcl-2 inhibitor venetoclax.
Aims: Here we report the highly successful therapeutic result of a myeloma patient diagnosed 11 years ago who received 8 prior lines of therapy that included all available therapeutic agents (including thalidomide, lenalidomide, bortezomib, carfilzomib, bendamustine, daratumumab and twice high-dose melphalan with autologous stem cell transplantation). The patient presented at our institution with hypercalcaemia (3.01 mmol/l), cytopenias, ECOG 3 physical condition due to profuse bone pain. Blood smear indicated plasma cell leukemia, flow cytometry analysis confirmed plasma cell leukemia with circulating plasma cells at the level of 14 G/l.
Methods: We are reporting on a clinical case documented with clinical laboratory, FISH and flow cytometry analysis.
Results: Since the patient was known to have broad resistance to available myeloma therapies, however had translocation t(11;14) since diagnosis, after initial zoledronic acid infusion, we elected to administer bortezomib-dexamethason-bendamustine combination with the addition of clarithromycine 500 mg BID and 400 mg daily dose of venetoclax orally. On day 3, the circulatory plasma cells disappeared and grade II tumor lysis syndrome developed (LDH max at 3107 U/l, with manageable hyperuricaemia, hyperkalemia, and hyperphosphatemia). The overall clinical state of the patient was steadily improving, he currently continues to receive venetoclax in monotherapy at the dose level of 400 mg daily. As CYP3A4 inhibition, initially clarithromycine was administered, but after 1 month due to GI symptoms, clarithromycine was switched to fluconazole 100 mg daily that was well tolerated. After 5 month of venetoclax 400 mg OD (only) in this pharmacologically enhanced monotherapy, the patient is ECOG 0, his M-protein is detectable only by immunofixation, free light chains and their ratio are normal, blood counts are in the normal range. Bone marrow aspiration indicated pathological plasma cells below the level of detection of available flow cytometry.
Summary/Conclusion: Our case indicates that in secondary plasma cell leukaemia refractory to available prior therapies and exhibiting translocation t(11;14), venetoclax may be a potentially effective salvage therapy. Additionally, pharmacological enhancement of 400 mg daily dose of venetoclax - with CYP3A4 inhibitors clarithromycine or azole antifungal agents may provide a cost effective alternative to the generally recommended 1200 mg daily dose of this expensive novel medication.

SALVAGE THERAPY WITH POMALIDOMIDE-BASED REGIMEN IN RELAPSED/REFRACTORY MYELOMA. EFFICACY, AND SAFETY RESULTS

M. Sirvent Auzmendi[1,*], S. Herraez Rodriguez[2], E. Perez Persona[3], N. Caminos Altuna[1], I. Urreta Barallobre[4], E. Perez Santaolalla[1], I. Ceberio Echechipia[1], M. Araiz Ramirez[1]

[1]Hospital Universitario Donostia, San Sebastian, [2]Hospital Basurto, Bilbao, [3]Hospital Txagorritxu, Vitoria, [4]Epydemiology, San Sebastian, Spain

Background: The combination of pomalidomide and low-dose dexamethasone has proved to be effective and safe in patients with end-stage relapsed/refractory multiple myeloma (RRMM), otherwise characterized by a very poor outcome. MM remains an incurable disease with unavoidable relapses. However, with the new therapeutic approaches available to date, prolonged survival of patients has been demostrated. Pomalidomide is a distinct immunomodulatory drug with potent antimyeloma activity, and has demonstrated efficacy even in patients that are refractory to Lenalidomide. In order to increase response rate, commonly it is used in combination.
Aims: We analize retrospectively, in a real-worl clinical practice setting, the efficacy, and safety of a pomalidomide-based regimens in patients with RRMM, treated in 3 centers. We evaluated the efficacy either when given with dexamethasone in 23 patients or in combination with oral cyclophsphamide +/- claritromycin in 25 patients. We evaluated the impact of adverse prognostic factors of cytogenetics and refractoriness to previous lenalidomide.
Methods: This multicenter estudy included fourty eight patients treated with Pomalidomide-based regimen for RRMM, between 2013-2017.
Results: Overall response rate (ORR) was 55.4% including CR 4.4%, VGPR in 24.4%, and PR in 26.6% patients. 13.3% showed stable disease, and 31% progression. There was no significant difference in patients who received pomalidomide in combination *vs* alone with dexamethasone, in terms of ORR (66.6% *vs* 71.43%, p 0.75) and PFS (mean 7.2 *vs* 8.5 months, p 0.55). If the treatment was given early (at second, third or four line) there was a trend towars improved PFS (mean 8.6 *vs* 5.8 months at ≥5 lines), but was not statistically significant (p 0.24). Lenalidomide refractory patients present disease progression in 38.24% and ORR in 50%. In patients whithout refractoriness, all of them had response (p0.043). The mean PFS was 10 months in the non-refractory *vs* 5 month in the refractory group (p 0.11).There was no significant difference in ORR and mean PFS was 8.4 *vs* 7.1 months in standar *vs* high risk citogenetic groups (p0.62). The most common adverse events were infections (19.1%), cytopenias (10.6%) and inestability (6.4%). 12 patients (25%) need dose reduction and 5 (10.4%) had to discontinued because of AEs.
Summary/Conclusion: Pomalidomide-based treatment is effective, even in heavily treated RRMM, and adverse citogenetic group. In our study there was no benefit from using pomalidomide in combination with oral cyclophosphamide +/- claritromycin, but this should be confirmed in further studies. Lenalidomide refractory patients had shorter progressión free survival.

PB2235

RISK FACTORS FOR EARLY MORTALITY IN MULTIPLE MYELOMA WITH DIFFERENT SURVIVAL TIME CUT-OFF POINTS: REAL-LIFE DATA

M.S. Aydın[1,*], E. Karakulak[1], R. Çiftçiler[1], H. Demiroğlu[1], H. Goker[1], M. Turgut[2], E. Kelkitli[2], N. Sayinalp[1], Y. Buyukasik[1], F. Tekin[1]

[1]Hematology, Hacettepe University Faculty of Medicine, Ankara, [2]Hematology, 19 Mayıs University, Samsun, Turkey

Background: Overall survival in Multiple Myeloma (MM) improved in last decades with the introduction of newer agents and broader use of autologous hematopoietic stem cell transplantation. Besides this, early mortality (EM) is still a concern in newly diagnosed MM. Data for EM comes from large prospective trials of selected MM populations and different time cut-off points are used in different studies.
Aims: To evaluate most common causes of EM in MM, risk factors for EM and to flash on do's and don'ts in high risk cases.
Methods: Retrospective data from 37 newly diagnosed MM patients between 01.01.2003-30.10.2017 and died within 12 months of diagnosis and as control group 52 newly diagnosed MM patients who lived longer than 12 months were analyzed. Four different cut-off time points for early mortality was defined as 1 month (EM1), 3 months (EM3), 6 months (EM6) and 12 months (EM12). Univariate analyses were done by Chi-square test for categorical and by t-test for numerical variables, respectively. Multivariate analyses were done by Cox regression analysis.
Results: Median age was 59 (range, 45-82 years) and was not different from cases lived longer than 12 months (p=0,822). Males and females were 56.8% and 43.2% respectively. Disease characteristics and comorbidities are summarized in Figure 1. Most common cause of mortality was acute renal injury (86.5%). Median survival was 3.8 months for EM12. Multivariate analysis showed anemia (HR: 4.20, p: 0.003), and hypercalcemia (HR: 2.44, p: 0.012) as independent risk factors for EM12; anemia (HR: 3.79, p: 0,015) and hypercalcemia (HR: 2.39, p: 0.029) for EM6, anemia (HR: 4.69, p: 0.041) for EM3. Renal failure was also more frequent in EM12 (p=0,200). Congestive heart failure was associated with increased mortality in EM12 (HR: 3.10, p: 0.005) and EM6 (HR: 3.46, p: 0.005). Bortezomib based induction regimens were less frequently associated with mortality in EM12 (HR: 0.23, p<0.001), EM6 (HR: 0.22, p: 0,003) and EM3 (HR: 0.14, p: 0.01) in multivariate analysis. Types of paraprotein, extramedullary disease, adjusted Charlson Comorbidity Score were not statistically different between early mortality groups at any cut-off point of survival times. Response to induction regimen was not included in analysis due to missing data.

Table 1.

Figure 1. Disease characteristics and comorbidities

	Cases survived less than 12 months (n=37) (%)	Cases survived more than 12 months (n=52) (%)	p
Disease characteristics			
ISS III	14 (56.0)	22 (45.8)	p=0.465
Anemia	27 (72.9)	24 (48.0)	p=0.001
Bone morbidity	29 (93.0)	37 (78.7)	p=0.110
Hypercalcemia	16 (50.0)	11 (21.5)	p=0.009
Renal failure	14 (43.8)	15 (29.0)	p=0.238
Common Comorbidities			
Chronic renal disease	8 (21.6)	18 (34.6)	p=0.239
Congestive heart failure	8 (21.6)	2 (3.8)	p=0.015
Liver disease	4 (10.8)	0 (0)	p=0.027
Coronary artery disease	4 (10.8)	10 (19.2)	p=0.380
Chronic lung disease	3 (8.1)	2 (3.8)	p=0.645

Summary/Conclusion: Our study was first to detect anemia as a risk factor for EM in MM. Congestive heart failure was a risk factor as a comorbidity. Renal failure was also a risk factor for EM although not significant but there are studies showing renal failure as a risk factor for EM. These high risk patients should be treated with newer, less toxic agents.

PB2236

SPLENIC INVOLVEMENT IN AL AMYLOIDOSIS: A CAUSE FOR PANCYTOSIS

A. Jercan[1,*], S.N. Badelita[1], C. Dobrea[1], M. Popescu[1], D. Vasilache[1], S. Iacob[2], D. Coriu[1]

[1]Hematology and Bone Marrow Transplantation, [2]Gastroenerology, Fundeni Clinical Institute, Bucharest, Romania

Background: Light Chain Amyloidosis (AL) is a systemic disease which causes extracellular deposition of amyloid fibrils composed of immunoglobulin light chains secreted by monoclonal plasma cells. Splenic involvement is defined by functional hyposplenism identified by the presence of Howell-Jolly bodies in the red cells on peripheral blood smear in patients without splenectomy. Prevalence of hyposplenism in AL patients is 24%. Hyposplenism was identified in patients with AL and FX deficit. Splenomegaly is not a useful sign for the diagnosis of functional hyposplenism in amyloidosis. Hyposplenic patients had a worse survival compared to normosplenic amyloidosis patients, probably due to the extensive body burden of amyloid.
Aims: The aim was to study the presence of hyposplenism and it's association with pancytosis in light chain amyloidosis.
Methods: We studied the patients diagnosed with AL in the Hematology Department of Fundeni Clinical Institute, Bucharest, Romania, between 2007 and 2017. Functional hyposplenism was identified by the presence of Howell-Jolly bodies in the red cells on the peripheral blood smear. We evaluated CBC, age, sex, AL type, FX level and involved organs.
Results: In the last 10 years, there were diagnosed 124 patients with AL, 40 patients (32%) had Howell-Jolly bodies in the red cells and 13 patients (10%) had leukocytosis +/- thrombocytosis. Median age of patients with functional hyposplenism was 62 years, M:F ratio was 1:1 and 38% were κ

AL and 62% λ AL. The association of leukocytosis and presence of Howell-Jolly bodies in the red cells on peripheral blood smear was present in 6 patients, of which 4 had cardiac and kidney involvement and 4 had liver and peripheral nervous system involvement. Hepatomegaly was seen in 4 of the 6 patients. The average FX level was 69% (min. 30% and max 110%), but without clinically significant bleeding, except amyloid vasculitis.
Case presentation. A 47 years old male diagnosed in 2014 with pancytosis (WBC 14 310/μL; PLT 906 000/μL, HB 19.4 g/dl; Ht 56.4%) and hepatomegaly. Bone marrow aspirate and biopsy were performed and he was diagnosed, in another Hematology Department, with chronic myeloproliferative disease for which he received 4 phlebotomies and hydroxyurea for 6 months. In October 2014 he is diagnosed with nephrotic syndrome and has a renal biopsy that shows amyloid deposits (kappa light chain). In November 2014 he was admitted to our Clinic and was diagnosed with kappa light chain amyloidosis with systemic involvement: kidney (nephrotic syndrome), liver (massive hepatomegaly, Stiffness of 75 KPa on Fibroscan), splenic (pancytosis, Howell-Jolly bodies in the red cells, splenomegaly). We started treatment with CyBorD (Cyclophosphamide, Bortezomib and Dexamethasone), but the patient wasn't compliant and was lost from treatment and follow up for about 1 year. In this period, he developed severe kidney disease and started hemodialysis. He came back to our Clinic in November 2015 and received 7 cycles of CyBorD. Involved free light chain decreased from 519 mg/l to 44 mg/l, there was an impressive improvement in Fibroscan stiffness (75->13.8 KPa) and maintained a slight leukocytosis and thrombocytosis. He is without treatment since June 2016, in excellent clinical condition, normal blood count, but he is still on hemodialysis.
Summary/Conclusion: Amyloidosis with splenic involvement and secondary hyposplenism can be the cause of pancytosis and so it should be considered, especially if Howell-Jolly bodies in the red cells are present on the peripheral blood smear.

PB2237

MAINTENANCE TREATMENT WITH THALIDOMIDE AFTER FRONTLINE BORTEZOMIB-BASED REGIMENS IN TRANSPLANTATION INELIGIBLE PATIENTS WITH MYELOMA MULTIPLE (MM). EXPERIENCE OF REAL LIFE

D. De Miguel Llorente[1,*], A. Gil[2], H. Guillen[3], A. Vazquez[2], N. Golbano[4], A. Pérez[5], D. Subira[4], J. Arbeteta[4], S. Herrero[6], D. Morales[7]

[1]Hematologia, Hospital Universitario de Guadalajara, [2]H. U. Guadalajara, [3]H.U. Guadalajara, [4]H.U.G, [5]H.U.G., Guadalajara, [6]H.U.G, Gyadalajara, [7]HUG, Guadalajara, Spain

Background: Phase IIIB UPFRONT trial was designed to compare three frontline bortezomib-based regimens in transplantation ineligible patients with Myeloma Multiple (MM) (Niesvizky R, *et al.* JCO 2015;33:3921-3929. Median progression free survival (PFS) with VD, VTD and VMP was 14.7, 15.4 and 17.3 months, respectively; median overall survival was 49.8, 51.5 and 53.1 months. Nowadays, lenalidomide continuous frontline therapy in elderly MM patients has showed better results in PSF and OS in this group of patients.
Aims: The aim of our review was to evaluate the efficacy and clinical outcome of initial bortezomib-based therapies and the maintenance treatment with thalidomide in elderly MM patients.

Table 1.

	PFS (months, median)	OS (months, median)
VMP	44.5	69.5
VD	25	35
VCD	31	31

Methods: we report a total number of 30 elderly MM patients (age median 80 years old, range 66-89; 19 females) since January 2008 to December 2017. 18 patients were treated in frontline with Bortezomib and Dexamethasone (VD), 8 patients with Bortezomib. Melphalan and prednisone (VMP) and 5 patients with Bortezomib. Cyclophosphamide and dexamethasone (VCD). The patients after completed the planned cycles of Bortezomib (median 7 cycles, range 3-14), received maintenance therapy with oral thalidomide (50mg/d) until disease progression or toxicity. Response rate, progression-free survival (PFS) and overall survival (OS) were the outcome measures.
Results: Nowadays, 6 patients are ongoing with thalidomide therapy. 11 (36.6%) patients had to stopped the thalidomide due to progression of disease. Only one patient (3,3%) had discontinued thalidomide therapy by tolerability. In overall group, we reported a PFS of 33,5 median months, and 35 median months of OS. In the table 1, we described the results of PFS and OS, in the patient's different subgroup.
Summary/Conclusion: 1) Thalidomide maintenance offer an advantage in PFS and OS in all bortezomib containing regimens (VTD; VD; VCD) in transplantation ineligible patients with MM; 2) Thalidomide maintenance was feasible without producing cumulative toxicity. 3) The continuous treatment with thalidomide (low dosage, 50mg/d) is efficacious, tolerable and low cost, and it should be taken into consideration.

PB2238

EFFICACY AND SAFETY OF TREATMENT WITH BORTEZOMIB, CYCLOPHOSPHAMIDE, DEXAMETHASONE (VCD) VERSUS BORTEZOMIB, DEXAMETHASONE (VD) REGIMENS IN NEWLY DIAGNOSED PATIENTS WITH MULTIPLE MYELOMA (NDMM)

M. Liangming*

Hematology, Shan Xi Da Yi Hospital, Taiyuan, China

Background: Bortezomib (BTZ) represents an important progress in the treatment of multiple myeloma MM. BTZ combined with other agents is becoming a standard care.The combination of BTZ with dexamethasone previously shown the superior to VAD.
Aims: To observe the efficacy and safety of bortezomib cyclophosphamide dexamethasone VCD) versus bortezomib dexamethasone (VD) regimens in treatment of patients with newly diagnosed multiple myeloma (NDMM).
Methods: To retrospective analysis of the 73 patients with NDMM from January 2013 to January 2016 in Department of Hematology Dayi Hospital.they were divided into VCD arm and VD arm, The outcomes of two different regimens were analyzed, including response and adverse events
Results: He overall response rate was 80.5% (33/41) with VCD arm and 78.1% (25/32) with VD arm,with no statistically significant difierences (P=0.804). However,complete response was 36.6% (15/41) with VCD arm and 15.6% (5/32) with VD arm,and differences were statistically significant (P=0.046), The median progression free survival (PFS) was 27 and 24 months in VCD arm and VD arm, the median overall survival (OS) was 35 and 33 months in VCD arm and VD arm,with no statistically significant difierences (P>0.05). Peripheral neuritis (PN), thrombocytopenia,diarrhea and constipation are the most common adverse events in two groups. There was no statistically significant difference between the two groups (P>0.05). Most adverse events were in grade 1 and 2.
Summary/Conclusion: Both VCD and VD regimens are effective induction chemotherapy choices for NDMM. VCD is preferable to VD terms of achieving complete remission.

PB2239

THE AUTOPHAGY INHIBITOR HYDROXYCHLOROQUINE ADDED TO THALIDOMIDE BASED THERAPY FOR MULTIPLE MYELOMA DEEPENS RESPONSE AND PROLONGS REMISSION IN PATIENTS PREVIOUSLY TREATED WITH THALIDOMIDE

S. O'Mara[1,2,3,*]

[1]Haematology, Laverty pathology, [2]Tamara Hospital, [3]New England Northwest Haematology, Tamworth, Australia

Background: Autophagy inhibitors are being tested in clinical trials for the treatment of malignancy. In multiple myeloma the autophagy inhibitor plaquenil has been tested with bortezomib *in vitro* with mixed results as well as a clinical trial with disappointing outcomes. Recently the antibiotic clarithromycin has been shown to be an autophagy inhibitor and has also been shown to synergistically increase the response to thalidomide in vitro. There have been previous single cohort studies using thalidomide/ clarithromycin combinations in multiple myeloma. At the time of that study, it was not known that clarithromycin was an autophagy inhibitor. Clarithromycin when trialled with Bortezomib in a clinical trial lead to unacceptable gastrointestinal toxicity without clear benefit. Does the addition of an autophagy inhibitor Hydroxychloroquine when added to an IMID such as thalidomide lead to an improvement over thalidomide alone as suggested by the *in vitro* studies. A longnitudinal crossover study was undertaken on the effect of adding hydroxychloroquine to patients who had previously been given thalidomide therapy previously. It would be expected

that patients would have an inferior response and duration of response the second time they were given thalidomide.
Aims: To determine whether the autophagy inhibitor Hydroxychloroquine when added to thalidomide based therapy improves the response to thalidomide based treatment.
Methods: Three patients received the CTD regimen for a period of 6 months. Thalidomide 100mg a day, Cyclophosphamide 100mg a day orally and Dexamethasone 20mg orally once weekly. One had a partial response 5g/L lasting 16 months from 2014. The second patient had a VGPR 2g/L lasting 17 months 2014. The third patient had no response to either thalidomide or lenalidamide in 2008 at 14g/L. She subsequently underwent bortezomib based therapy and stem cell transplant. All three relapsed with bone pain and increasing paraprotein level >20% from plateau level. The patients again received CTD at the same dose and duration. Hydroxychloroquine (plaquenil) was added at 200mg twice a day. This dose is a dose used to treat common rheumatological diseases and is safe even in combination with other agents. The absolute response in paraprotein level was documented and the duration of response has been measured every three months.
Results: All patients symptoms of bone pain have resolved. Two patients have achieved a complete remission of 0 g/L paraprotein measured at the end of 6 months therapy with CTD and Hydroxychloroquine. The third patient achieved a Partial remission at 3g/l a 70% reduction. Two patients response duration has already been maintained for a longer period than in their first remission with CTD and the third continues. There has been no grade two or higher toxicity.
Summary/Conclusion: Hydroxychlroquine when used with thalidomide based therapy is a cheap non toxic addition to myeloma therapy that appears to deepen the response in all patients tested. It has also increased the response duration in 2 treated patient with the others not progressing. Although the clinical trials have focused on adding autophagy inhibitors to poteasome inhibitors, it appears that they may be more useful when used with IMIDS.

PB2240

CT AND MRI MAY RESULT IN OVERDIAGNOSIS OF SKELETAL DISEASE IN MULTIPLE MYELOMA

A.E.A. Dahm[1,*], V. Dalen[2], A.-S. Vegsgaard Olsen[2], C.-P. Jerome[3], J.-T. Geitung[3]

[1]Haematology, Akershus University Hospital, Lørenskog, [2]University of Oslo, Oslo, [3]Radiology, Akershus University Hospital, Lørenskog, Norway

Background: Investigations for skeletal disease is essential in the diagnostic work-up of multiple myeloma. According to international guidelines, low dose CT, MRI or PET-CT are the preferred choices of modality.
Aims: To compare the ability of MRI and CT to detect of skeletal disease in multiple myeloma. To investigate the inter-observer agreement between two radiologists in the interpretation of the images.
Methods: A retrospective, comparative study of multiple myeloma patients that that had taken MRI and CT within four months between 2007 and 2015. We included only patients where the entire vertebral column was portrayed and ended up with 12 patients. The radiologists looked at the images independently blinded for the colleague's' previous descriptions. The images were assessed for malignant fracture, osteoporotic fracture, malignant infiltration and osteoporosis. Later they sat down together, to make up a gold standard, using all pictures and information available to them.
Results: Radiologist 1 diagnosed 20 malignant fractures in the vertebral column on CT, and 26 on MRI, while Radiologist 2 diagnosed 12 fractures on CT and 22 on MRI. The gold standard, however, showed 10 fractures. The two radiologists agreed that 1 patient had no malignant fractures on CT, while the gold standard showed that 6 of 12 patients did not have malignant fractures. The radiologists had a total of 24 different diagnostic assessments of malignant fractures on CT and 18 on MRI. Radiologist 1 diagnosed 9 osteoporotic fractures on CT and 23 on MRI, and Radiologist 2 diagnosed 9 fractures on CT and 24 on MRI. The gold standard showed 14 osteoporotic fractures. The sensitivity for radiologist 1 to discover malignant fractures on CT was 0.83, specificity 0.5. For radiologist 2, the sensitivity for malignant fracture on CT was 0.5 and the specificity 0.67. On MRI, the sensitivity of Radiologist 1 for detecting malignant fractures was 0.83, specificity 0.17. Radiologist 2 had sensitivity of 1 on MRI, but specificity of 0.17. The inter-observer agreement for detection of malignant fractures showed a Cohen's kappa of 0.42.
Summary/Conclusion: Both radiologists diagnosed malignant and osteoporotic fractures when the gold standard showed that there was none. MRI was not better than CT. Furthermore, the agreement between the radiologists was unsatisfactory. Our study shows that the current guidelines for skeleton imaging in multiple myeloma may result in overdiagnosis of skeletal disease.

PB2241

BORTEZOMIB INDUCTION AND MAINTENANCE THERAPY IN MULTIPLE MYELOMA PATIENTS INELIGIBLE FOR TRANSPLANTATION

K. Milcheva[1,*], D. Todorieva[2], I. Kindekov[3], E. Naseva[4], B. Spasov[1]

[1]Clinic of Hematology, National Specialised Hospital for Active Treatment of Haematological Diseases, Sofia, [2]Clinic of Hematology, University Hospital "St.Stransky", Pleven, [3]Clinic of Hematology, [4]Department of Health Economics, Medical University - Sofia, Sofia, Bulgaria

Background: The current report represents the interim results of clinical observation, estimating the efficiency and safety of Bortezomib based induction and maintenance therapy in transplant ineligible patients.
Aims: The aim of the current investigation includes assessment of progression free survival (PFS), treatment response rates, overall survival (OS) and adverse events.
Methods: The analysis includes 20 patients, 9 male and 11 female, who received treatment in the hematology clinics of the Military Medical Academy and UMPHAT "G.Stranski" -Pleven. Inclusion criteria: patients with multiple myeloma, who received Bortezomib-based first line treatment and Bortezomib maintenance for two years or till progression/toxicity; transplants ineligible; Exclusion criteria: polyneuropathy Grade >=2 or heavy comorbidity. Patients were assessed by laboratory exanimations, including FBC, biochemistry, β2-microglobulin, and serum and urine electrophoresis with immune fixation. Patients' diagnose, stage and response were evaluated according to the IMWC 2010 recommendations. Bortezomib-induced hematology and non-hematology toxicity was graded according to the CTCAE v.4.03 criteria. Methods of descriptive statistics were applied. The survival rate was assessed by the Kaplan-Meyer method. The survival in the individual groups was compared with the Log Rank test (Mantel-Cox) and the follow up time - by Kaplan-Meyer's inverted method. Results were accepted significant at $p < 0.05$.
Results: After 27 months median follow up, the OS had not yet been reached, the PFS was 24 months. At 32 month, 61, 1% of patients were still alive. The two year survival was 76%. The majority of the patients were stage II-III ISS- 8 (80,0%) and Ig G type - 11(55%). After a median follow-up time of 24 months, the PFS was 24 months. The OS has not yet been reached. At 32-month, 61,1%of patients were still alive. The two-year survival was 76%. Median time to first response was 4 month (2-8), with predominant response rate (PR) in 75% of the patients. Median time to best response was 2 months (2-31), with predominant response rate CR in 45% of the patients. During the follow-up, 9 patients experienced loss of response. At the last visit, 11 patients continue their treatment. In the course of treatment, the safety of the drug was also monitored. In 20% (n=4) of patients, reversible Bortezomib-related toxicity was recorded and only one patient required dose reduction due to painful neuropathy. There were no serious CTCAE Grade 3-4 events, death or discontinuation of therapy due to Bortezomib.
Summary/Conclusion: Despite the small number of patients, the obtained results are comparable to those from the UPFRONT Phase 3 trial. Bortezomib (Velcade®) -based therapy, including induction and maintenance phase, in patients with multiple myeloma, unsuitable for transplantation, is an effective and safe therapeutic strategy.

PB2242

INCIDENCE AND PREVALENCE OF MULTIPLE MYELOMA IN A LARGE NATIONWIDE HEALTH PLAN IN ISRAEL

C. Weil[1,*], S. Gelerstein[2], G. Chodick[3], S. Sharman Moser[1], N. Barit Ben-David[2], V. Shalev[3], D. Meytes[4]

[1]Epidemiology & Database Research, Maccabi Healthcare Services, Tel Aviv, [2]Janssen Israel, J-C Health Care Ltd., Kibbutz Shefayim, [3]Epidemiology and Database Research & Sackler Faculty of Medicine, Maccabi Healthcare Services & Tel Aviv University, [4]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

Background: Multiple myeloma (MM) is the second most common hematologic malignancy.
Aims: This study aims to describe the real-world incidence and prevalence of MM in Israel.
Methods: A retrospective database study was conducted in Maccabi Healthcare Services (MHS), a 2-million-member health payer-provider in Israel. MM was defined by cross-linking ICD-9 diagnoses with dispensed MM treatments and free light chain assays. MM prevalence (31/12/2016) and incidence (2012-2016) rates were calculated and age-adjusted to the WHO World standard population. Prevalent patients were characterized in terms of socio-demographic characteristics, comorbidities, and medication use.
Results: The crude and age-standardized prevalence of MM was 3.2 and

2.6 per 10,000 population, respectively. The mean (± SD) age was 68.1±11.0 years (55% male). The prevalence of cardiovascular disease, diabetes, hypertension, chronic kidney disease (eGFR <60) and osteoporosis were 32%, 25%, 59%, 59%, and 38%, respectively. Overall, 88.5% ever had a record of dispensed MM treatment. Among patients treated in 2016 (N=427), their last purchase consisted of 43% first line, 30% second line, 18% third line, and 9% fourth line or more. The crude and age-standardized annual incidence rate was 5.1 and 4.7 per 100,000 population, respectively. The mean age at diagnosis was 68.5±11.4 (58% male). Adjusting to the Israeli population, there were an estimated 485 new cases of MM in Israel in 2016.
Summary/Conclusion: These results indicate a substantial burden of MM in Israel, in line with international estimates. This study serves as the basis for further research on MM patient outcomes.

PB2243

BORTEZOMIB, LENALIDOMIDE AND DEXAMETHASONE IN THE MANAGEMENT OF RELAPSED AND REFRACTORY MULTIPLE MYELOMA: A REAL-LIFE EXPERIENCE

C. Cerchione[1,*], A.E. Pareto[1], I. Zacheo[1], M. Di Perna[1], D. Nappi[1], I. Peluso[1], K. Ferrara[1], A. Romano[2], F. Pane[1], L. Catalano[1]

[1]Hematology - Department of Clinical Medicine and Surgery, University Federico II, Naples, Napoli, [2]Department of General Surgery and Medical-Surgical Specialties, Haematology Section, University of Catania, Catania, Italy

Background: Bortezomib, Lenalidomide and Dexamethasone is one of the best option for frontline treatment, approved in USA but not available in Italy. However, it can show interesting results also in relapsed and refractory patients, thanks to the synergistic effect of these agents.
Aims: In this retrospective observational study, it has been evaluated the safety and efficacy of the combination of bortezomib plus lenalidomide plus dexamethasone (VRD) in patients with relapsed and refractory Multiple Myeloma (rrMM).
Methods: 29 patients (19 M, 10 F), with rrMM, median age 64 years (range 38-79), were treated with the VRD regimen (Bortezomib 1.3 mg/sqm days 1,4,8,11; dexamethasone 20 mg days 1, 2, 4, 5, 8, 9, 11, 12 and oral lenalidomide 25 mg daily on days 1-21), with a median of 6 cycles (range 1-21). Patients had previously received 3 median (range 1-6) lines of therapy. 83% (24/29) of them had undergone to autologous SCT.
Results: According to IMWG, ORR was 79.3% (23/29: 6 CR, 5 VGPR, 7 PR, 5 SD). Median time to response was 3 months (range 1-6), median OS from diagnosis was 56 months (range 12-221). Bortezomib-lenalidomide-dexamethasone was well tolerated, with grade 1-2 anemia in 5 patients, successfully managed with ESAs, and, thanks to the way of administration, also compliance is good. Peripheral neuropathy was seen in 48% (14/29) patients.
Summary/Conclusion: Bortezomib-lenalidomide-dexamethasone triplet, thanks to a notable proved synergistic mechanism of action between bortezomib and lenalidomide, had shown significant efficacy in severe setting of heavily pretreated patients, relapsed and refractory to bortezomib and lenalidomide.

PB2244

OUTCOME OF PATIENTS WITH MULTIPLE MYELOMA AND RENAL FAILURE IN ERA OF NOVEL AGENTS- EXPERIENCE OF A TERTIARY CARE CENTRE FROM NORTHERN INDIA

N. Gupta*, F. Naim, A. Garg, K. Purohit, M. Mulam

Clinical Hematology and bone marrow/stem cell department, Sir Ganga Ram Hospital, New Delhi, India

Background: Renal involvement in myeloma is a serious complication which occurs in 20-30% of patients. In 10% of patients, it is severe enough to require dialysis. Historically outcome to patients with myeloma and renal failure have been poor with median survival of less than 1 year. Prognosis depends upon the reversibility of renal function with a survival similar to other patients in whom creatinine returns to normal. With the advent of novel agents like bortezomib and thalidomide, which can be safely given in these patients, remission rates and renal recovery rates have significantly improved.
Aims: To study the outcomes in patients of multiple myeloma presenting with renal failure treated with bortezomib based triple drug regimens treated at our centre.
Methods: This is a retrospective study in which 20 patients treated at the Sir Ganga Ram hospital, New Delhi, India with diagnosis of MM and renal dysfunction and at least six months of follow up were enrolled from January 2015 to June 2017. Demographic data, baseline serum creatinine, hemoglobin, serum calcium level, M protein type and level, bone marrow plasma cells, need for dialysis were recorded. Bortezomib plus Thalidomide plus dexamethasone (BTD) and Cyclophosphamide plus Bortezomib plus dexamethasone (CyBorD) were the two regimens employed in non-random fashion on treating physician's discretion.
Results: The mean age of the patients was 53.9 years. The median baseline serum creatinine was 5.05 mg/dL (2.79–15.39). Anemia (hemoglobin <10 g/dL) was noted in 70% and hypercalcemia (calcium >11mg/dL) in 40% of patients. Immunofixation revealed myeloma to be Ig G in 10/20 (50%), Ig A in 7/20 (35%) and light chain only myeloma in 3/20 (15%) patients. BTD and CyBorD were used in 12 (60%) and 8 (40%) of patients respectively with high dose dexamethasone (40mg/day for 4 days) given in first cycle to all patients. Hemodialysis was performed in 10 patients (50%) and two of them underwent high cut off (HCO) dialysis. Serum free light chain levels returned to normal after 4 sessions of 8 hours each of HCO dialysis. Serum creatinine came to normal level in all (80%) patients except four patients after 4 cycles of chemotherapy. Two (10%) of them remained dialysis dependant. Six patients (30%), who achieved a very good partial response (VGPR) after 4 cycles of bortezomib based chemotherapy but then suffered early relapse and died of progressive disease. The median progression free survival has not reached after 18 months of follow up (range 6-32 months). Six patients (30%) underwent autologous stem cell transplantation and continue to be complete remission. Median progression free survival in patients who underwent transplant (not reached after 25 months of follow up) *vs* non- transplanted group is (10.5 months).
Summary/Conclusion: In our patients with the incorporation of novel agents including bortezomib and thalidomide, outcome of patients with myeloma with renal failure has improved. Moreover, autologous transplant can further improve outcome in carefully selected patients. Longer follow up is needed to determine exact benefit of these agents in improving overall survival of these patients.

PB2245

YOUNG ADULTS WITH MULTIPLE MYELOMA – UNVEILING A DIFFERENT SPECTRUM IN A RESOURCE CONSTRAINED SETTING

S. Mirgh*, M. Mahapatra, T. Seth, R. Saxena, H.P. Pati, S. Tyagi, M. Aggarwal, R. Dhawan, R. Halder, S. Kothari, R. Chauhan

Hematology, All India Institute of Medical Sciences, New Delhi, New Delhi, India

Background: Traditionally, Multiple Myeloma (MM) has been considered a disease of the elderly with peak incidence at 60-70 years of age. However, there exists a certain subset of extremely young patients. Data on young adults with MM is scarce. We present the disease characteristics for this unique age group.
Aims: 1. To understand the frequency of patients with young myeloma (<=40 years), their clinical profile and response to therapy. 2. To compare with older population in terms of clinical profile.
Methods: Retrospective single-centre study conducted at a single tertiary care centre from New Delhi, North India. Records of all young patients (18-40 years) with MM managed in our department in the last 6 years (January 2012 – December 2017) were reviewed.
Results: A total of 112 evaluable patients were included in the study. Interestingly, the frequency of young MM patients was 27.6% (31/112), 3 of whom were less than 30 years of age at diagnosis. Unlike elderly, females almost equated the males in this age group (male:female : 1.06:1). Main presenting manifestations were back pain (64.5%), fatigue (58%) and referral for renal dysfunction (19.3%). Other presenting features included plasmacytomas (13%), weight loss (6%), bleeding manifestations (3%) and cord compression (3%). Hypercalcemia, renal dysfunction, anemia and lytic lesions were present in 19.3%, 35.4%, 71% and 77.4% patients respectively. Of these, one-fourth patients (25.8%) underwent autologous stem-cell transplant. Baseline beta-2-microglobulin levels were available in 23 patients. 82.6% patients were in high risk group as per ISS – 3 (International Staging System) staging. Almost one-third cases (n=10) (32.2%) were relapsed-refractory. FISH panel was done in 8 patients, 2 (25%) of whom revealed 13q deletion.
Summary/Conclusion: Our study shows a trend towards gender equality in young patients with MM, a higher prevalence of high-risk (ISS-3) disease, higher prevalence of appendicular skeleton lesions and good response to therapy.

PB2246

NON-MYELOMA KIDNEY DISEASE AND MANAGEMENT ALGORITHM IN MYELOMA PATIENTS

K. Westwood[1,*], S. Natarajan[1], S. Elhanash[1], I. Ali[2], S. Watt[1]

[1]Haematology, [2]Renal Medicine, Manchester Foundation NHS Trust, Manchester, United Kingdom

Background: In multiple myeloma, the kidney is a major organ that can be affected during the disease process resulting in 40% of patients developing renal impairment. In an ageing population, there are multiple comorbidities that can have a negative impact on renal function and hence non-paraprotein related disease has previously been described in up to 25% of myeloma patients. Declining renal function in myeloma results in difficulties giving optimum chemotherapy and worse outcomes for patients.
Aims: To optimise management of renal impairment from none myeloma causes.
Methods: We reviewed an unselected group of 34 patients, median age 75 (53-87), attending our unit with multiple myeloma and graded their renal function using a combination of glomerular filtration rate (GFR) and Albumin Creatinine Ratio (ACR).
Results: Findings show that 54.8% of the patients have a mild to moderate decrease in renal function and 32.3% show a moderate to severe decrease. 58% of patients had an ACR outside of the normal range (<3mg/ml). See Table. This leaves only 12.9% of patients had no markers of chronic kidney disease (CKD). We identified 12% of the patients are pre-diabetic (HBA1c 42-47 mmol/mol) and 5.9% of patients are known to be diabetic, but had HBA1C greater than 58 mmol/mol. 24% of patients were identified as having a systolic blood pressure ≥140 mmHg.
Summary/Conclusion: In patients who have myeloma at least partial remission we follow our algorithm summarised below for monitoring and intervention to preserve renal function, 1. Clinical testing of Blood pressure, HBA1C, ACR, EGFR at least 12 monthly; 2. Patients with stage 3b renal failure are referred for a renal opinion; 3. If the patient is diabetic and poorly controlled despite GP management we refer to endocrinology for intervention; 4. If they are pre-diabetic or newly diagnoses diabetic then we refer to GP for intervention; 5. We ask GPs to review for patients with a systolic BP over 140 or diastolic over 90. Initially with ambulatory BP monitoring and pharmaceutical intervention if confirmed; 6. If ACR >30 we advise an ACE inhibitor at a dose tolerated by the patient; 7. We consider addition of a statin if eGFR <60 due to increased cardiovascular risk. The full algorithm defines the frequency of CKD, diabetic and blood pressure monitoring needed for specific patient groups within the multiple myeloma population. In conclusion, the aim of our patient review and algorithm is to identify, target and manage all possible reversible causes of CKD in the multiple myeloma cohort. We believe this is a cheap and effective intervention to improve quality of life and may have an impact in the overall survival in multiple myeloma by preserving renal function. We intend to monitor our patient cohort longitudinally, but further studies would be useful to prove the effectiveness of these interventions in patients with multiple myeloma.

THE MYELOMA CANADA RESEARCH NETWORK CANADIAN MULTIPLE MYELOMA DATABASE (MCRN CMM-DB): MULTI INSTITUTIONAL SHARING OF CLINICAL DATA FOR RESEARCH

C.P. Venner[1,*], E. Masih-Kahn[2], T. Truaon[3], V. Jimenez-Zepeda[4], A. McCurdy[5], M. Sebag[6], K. Song[7], T. Reiman[8], R. LeBlanc[9], J. Stakiw[10], M. Louzada[11], R. Kotb[12], D. White[13], M. Aslam[14], A. Del Col[15], S. Tavoularis[15], E. Gul[16], D. Reece[2]

[1]Medical Oncology, Cross Cancer Institute, University of Alberta, Edmonton, [2]Medical Oncology and Hematology, [3]Health Informatics, Princess Margaret Cancer Centre, Toronto, [4]Tom Baker Cancer Centre, Calgary, [5]The Ottawa Hospital, Ottawa, [6]McGill University, Montreal, [7]The Leukemia and Bone Marrow Transplant Program of British Columbia, Vancouver General Hospital, Vancouver, [8]Horizon Health Network, Saint John, [9]The Maisonneuve-Rosemont Hospital Research Centre, Montreal, [10]Saskatchewan Cancer Agency, Saskatoon, [11]London Regional Cancer Centre, London, [12]Cancer Care Manitoba, Winnipeg, [13]Nova Scotia Health Authority, Halifax, [14]Allan Blair Cancer Centre, Regina, [15]Myeloma Canada, Montreal, [16]Myeloma Canada Research Network, Vaughn, Canada

Background: We have seen dramatic improvements in survival for patients living with multiple myeloma (MM). To better understand the current national landscape for patients with MM the Myeloma Canada Research Network (MCRN) developed a centralized Canadian Multiple Myeloma Database (MCRN CMM-DB) aimed at collecting all disease specific outcomes-based endpoints.
Aims: The goals of the MCRN CMM-DB are to: 1) benchmark current outcomes of MM patients treated with available treatment strategies in Canada; 2) identify regional therapeutic differences across the country; 3) inform future care strategies with evolving funded novel treatment approaches and 4) better inform future trial initiatives and national translational programs.
Methods: Sites with recognized expertise in treating MM across Canada were invited to participate in data collection. Capitalizing on existing local disease specific databases, endpoints were identified to determine the final data dictionary and mandatory data elements used in the MCRN CMM-DB. Given broad representation across multiple regions and institutions a governance structure was developed, which included Operations and Steering Committees. This was essential to ensure the development of a representative data collection platform, data quality and integrity, protection of patients' privacy, financial sustainability, guide data access, prioritize data usage and disseminate findings to the broader MM community nationally and internationally. The aim is to enroll all newly diagnosed patients from participating sites over the next 10 years. Where available, legacy data on previously diagnosed patients going back to 2007 will also be uploaded to represent the patient experience through the novel agent era.
Results: To date, 13 sites representing the major MM treating and academic centres across Canada have committed to the initiative. After user acceptance testing was completed the final MCRN-MM-DB was built according to agreed specifications approved by the organizing and steering committees. Using the eCancerCare platform a user-friendly web-based interface was developed to facilitate the entry of anonymized data to a secure centralized data repository. In parallel to the system build, each participating site obtained research ethics approval consistent with local requirements. Institutions signed a data sharing agreement with MCRN to facilitate ease of data transfer across jurisdictions. Access to the MCRN-MM-DB was deployed to sites with ethics approval, a signed data sharing agreement and with designated data coordinators to consent patients and enter data. Six sites that had existing data registries obtained REB approval to migrate legacy data. The first site was activated in July 2017. Thirteen sites representing the provinces of Ontario, Quebec, Alberta, Nova Scotia, Manitoba, Saskatchewan, British Columbia and New Brunswick are now contributing data. 20 users across sites have received formal training and were provided with Case Report Form Completion Guidelines. A total of 50 records from different sites have been audited centrally. Prospective data on 102 patients have been entered. The legacy dataset is estimated at 4000 patients. An aggregate summary of pooled data available in the MCRN-MM-DB will be presented at the meeting.
Summary/Conclusion: We anticipate that the MCRN CMM-DB will be one of the largest, most comprehensive nation-wide disease specific repositories. It will provide locally and nationally relevant benchmarks for current outcomes and better inform future clinical and academic ventures.

PB2248

BULKY EXTRAMEDULLARY SOFT-TISSUE PLASMACYTOMAS IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS: A SINGLE CENTER EXPERIENCE FROM NORTH INDIA

U. Nath*, R. Chetia, J. Nanda, A. Baveja

Medical Oncology Haematology, All India Institute of Medical Sciences (AIIMS), Rishikesh, Rishikesh, India

Background: Multiple myeloma (MM) is a clonal plasma cell neoplasm typically confined to the bone marrow and skeleton. In addition, a number of patients develop extramedullary disease, which may sometimes present as the leading clinical manifestation. The incidence of extramedullary plasmacytomas has been reported in the western literature as 7% - 18% at the time of multiple myeloma diagnosis and up to 20% at myeloma relapse. However, there is very little data regarding the same in the Indian scenario.
Aims: The present abstract reports the high incidence of bulky extramedullary soft-tissue plasmacytomas in newly diagnosed multiple myeloma patients hailing from the western parts of Uttar Pradesh and adjoining Haridwar district of Uttarakhand, who attended AIIMS Rishikesh for diagnosis & treatment.

Table 1.

Sl	Age/Sex	Diagnosis	Plasmacytoma site	Treatment & outcome
1	68 y / M	IgA Kappa MM	Bulky retroperitoneal mass; Multiple left cervical & supraclavicular lymphadenopathy (Biopsy+IHC: Plasmacytoma)	CyBorD x 2 cycles: No response. Bortezomib+ Bendamustine+ Dexa x 4 cycles: CR
2	62 y / F	Kappa Light Chain MM	Plasmacytoma involving left lung & adjacent thoracic wall (10.8 x 7.9 x 5.6 cm)	CyBorD x 4 cycles. Partial response.
3	60 y / M	Kappa Light Chain MM	Soft-tissue plasmacytomas on chest wall. Sphenoid bone plasmacytoma, adjacent to sphenoid sinus (24x13mm). Right Facial nerve palsy	Refractory to CyBorD. RVD started. Lost to follow up.
4	75 y / M	IgG Lambda MM	Multiple, large soft-tissue plasmacytomas in paraspinal region & on scapula	CyBorD x 3 cycle: Progressive disease. Lost to follow up.
5	39 y / F	Non-secretory MM	Presented with Left lumbar region mass & paraplegia. Biopsy: plasmacytoma. (25 x 14 cm) with intra-abdominal & intra-spinal extension	Bortezomib+ PegLiposomal Doxorubicin + Dexa x 2 cycles. Radiation (40Gy).
6	47 y / M	IgG Kappa MM, del17p13	D3-D4 paraspinal soft-tissue plasmacytoma with intraspinal extension. Large soft-tissue plasmacytoma in sacral region	Bortezomib + Lenalidomide + Dexa (RVD) started - February 2018.

Methods: The study included 32 newly diagnosed patients of multiple myeloma between March 2016 & December 2017. The investigations done for confirmation of myeloma diagnosis included bone marrow aspiration+biopsy, serum protein electrophoresis+immunofixation, serum

free light chain assay, and X-ray skeletal survey. MRI was done for imaging of the soft-tissue masses. Diagnosis of extramedullary soft-tissue plasmacytoma was confirmed by core biopsy/excision biopsy & immunohistochemistry (IHC) in all cases. PET-CT imaging facilities were not available at the institution. All the six patients were treated with Bortezomib-containing triple-drug regimens. Local radiation therapy was administered for compressive symptoms.
Results: Six patients (18.7%) out of total 32 consecutive newly diagnosed myeloma patients had one or more extramedullary soft-tissue plasmacytomas at presentation. The median age of these patients was 61 years (range 39-75 years). The patient characteristics & treatment outcomes are given in Table 1.
Summary/Conclusion: The frequent finding of bulky extramedullary soft-tissue plasmacytomas in newly diagnosed multiple myeloma patients in the western districts of Uttar Pradesh & adjacent Uttarakhand state in India could be the manifestation of unique myeloma disease biology. Possible association of aggressive plasmacytomas with kappa light chain paraprotein also needs to be explored in larger number of patients.

PB2249

POMALIDOMIDE-DEXAMETHASONE IN THE MANAGEMENT OF HEAVILY PRETREATED MULTIPLE MYELOMA

C. Cerchione[1,*], D. Nappi[1], A.E. Pareto[1], I. Migliaccio[1], I. Zacheo[1], M. Di Perna[1], I. Peluso[1], K. Ferrara[1], A. Romano[2], F. Pane[1], L. Catalano[1]

[1]Hematology - Department of Clinical Medicine and Surgery, University Federico II, Naples, Napoli, [2]Department of General Surgery and Medical-Surgical Specialties, Haematology Section, University of Catania, Catania, Italy

Background: Pomalidomide is a new generation IMID, with a very good compliance, thanks to oral administration, which can be used also in heavily pretreated patients, in a domestic setting.
Aims: In this retrospective observational trial, It has been evaluated efficacy and tolerance of pomalidomide plus dexamethasone (PD) as salvage regimen in heavily pretreated patients with relapsed and refractory MM (rrMM), whose prognosis is particularly severe.
Methods: 26 patients (14 M/12 F), with rrMM, median age at diagnosis 69 years (r. 52-84), and median age at start of treatment 73 years (r.56-87) treated with several lines of treatments (median 6, r. 2-9), every refractory to all the drugs previously received (also Bortezomib, Thalidomide and Lenalidomide), received PD (Pomalidomide 4 mg for 21 days, dexamethasone 40 mg days 1,8,15,22, pegfilgrastim day +8) every 28 days, until progression. ISS was equally distributed, and cytogenetic was evaluable in 12 patients, and in particular three del13q and one t(11;14) were present. All the patients had previously been treated with schedule containing bortezomib and IMIDs. 57% (15/26) of them had undergone at least to a single ASCT. All patients were relapsed and refractory to last therapies received before PD.
Results: Pomalidomide was well tolerated, with grade 3 anemia in 46% (12/26) of patients, 34% (9/26) grade 3 neutropenia (pegfilgrastim in primary prophylaxis was given, no hospitalization was required, no septic shocks were observed), 23% (6/26) grade 3-4 thrombocytopenia without hemorrhagic events and transfusion-dependence. No severe extra-hematologic toxicity was observed. According to IMWG, ORR1 (≥PR) was 42% (11/26: 2 CR, 3 VGPR, 6 PR), but, considering that we are evaluating a cohort of heavily pretreated patients without any other alternative treatment, with really poor prognosis, another parameter should be considered, ORR2 (≥SD), considering stable disease as a successful result in progressive MM. ORR2 was 73% (19/26: 2 CR, 3 VGPR, 6 PR, 8 SD). These can be considered as impressive result in this subset of patients. Oral treatment gives a really good compliance, in frail and unfit patients, and response, when present, is always really fast (median time to response: 2 months (r.1-6)), median OS from diagnosis was 87 months (range 21-228), median OS from start of pomalidomide was 8 months (range 1-14).
Summary/Conclusion: Pomalidomide-dexamethasone has shown significant efficacy and a very good compliance, thanks to oral administration, in a particularly severe setting of heavily pretreated patients, relapsed and refractory to all available therapeutic resources.

PB2250

PROGNOSTIC SIGNIFICANCE OF HEAVY/LIGHT CHAIN RATIO IN INTACT IMMUNOGLOBULIN MULTIPLE MYELOMA PATIENTS PRELIMINARY RESULTS

I. Kakkas[1,*], I. Konstantellos[2], S. Delimbasi[2], K. Papageorgiou[1], N. Harhalakis[2], A. Tsirogianni[1]

[1]Immunology and Histocompatibility, [2]Hematology and Lymphoma, Evangelismos Hospital, Athens, Greece

Background: During 2009, Bradwell *et al.* presented a new technique for intact Immunoglobulin Multiple Myeloma (IIMM) and Waldenstrom's Macroglobulinemia (WM) monitoring. They developed and validated a method for the separate quantification of the kappa and lambda bounded amounts of circulating IgG, IgA and IgM (Heavy/Light Chain-HLC assay). This was achieved by developing antisera with specificity for unique epitopes present at the junction between the heavy and light chains constant regions of each immunoglobulin molecule. This assay allows the quantification of the absolute value of the involved IgGκ, IgGλ, IgAκ, IgAλ, IgMκ and IgMλ along with their deriving ratios (IgGκ/IgGλ etc, Heavy/Light Chain ratio, HLC ratio). According to the literature, these measurements have been proven sensitive and specific for the monitoring of patients with IIMM. Additionally, the prognostic significance of HLC measurements for symptomatic IIMM patients (before treatment initiation) has been investigated. According to the results of two relatively recent studies (Bradwell 2013, Ludwig 2013), extreme low or high HLC ratios (<0.01 or >200) were associated with decreased overall survival of symptomatic IIMM patients.
Aims: The investigation for existence of any prognostic significance of HLC measurements for symptomatic IIMM patients (before treatment initiation) diagnosed and treated in our Hospital's Hematology and Lymphoma Department.
Methods: Forty-one newly diagnosed symptomatic IIMM patients were studied. Twenty-five of them were men and 16 women. Their median age was 68 years (range: 43-83). The isotype of paraprotein was in 31 cases IgG and in 10 cases IgA. Twenty-four patients were ISS stage I, 13 stage II and four stage III. Patients median follow-up was 16 months (range: 6-24). HLC ratio was determined in all patients before treatment initiation. HLC measurements were performed by using the Hevylite™ assays (The Binding Site Group Ltd, UK) on a SPA PLUS turbidometer.
Results: Statistical analysis was done by using the x^2 test. At the time of last evaluation, 36 patients were alive. Five patients had died due to disease progression and their median survival was seven months (range: 2-14). Extreme HLC ratios (<0.01 or >200) emerged in 14 patients (7/31 IgG and 7/10 IgA, $p<0.05$). Two out of five deceased patients were IgG and three IgA. Also, four out of the five deceased patients had extreme HLC ratios ($p<0.05$). It is noted that all three IgA deceased patients emerged extreme HLC ratios ($p<0.01$).
Summary/Conclusion: Despite the limited number of patients in our study, it is clear from the above-mentioned that there is a statistically significant correlation between IgA isotype of paraprotein and HLC ratio extreme values (<0.01 or >200). Also, there is a statistically significant correlation between mortality and HLC ratio extreme values, especially for IgA patients.

PB2251

RESPONSE TO INDUCTION THERAPY IN MULTIPLE MYELOMA PATIENTS; A SINGLE CENTRE EXPERIENCE

M. Borhany[1,*], M. Afzal[2], A. Hayee[2], U. Zaidi[2], T. Shamsi[2]

[1]Haematology and Blood Bank, [2]National Institute of Blood Disease and Bone Marrow Transplantation, Karachi, Pakistan

Background: Multiple myeloma is a clonal B-cell disorder which is characterized by proliferation and accumulation of plasma cells in the bone marrow. The disease accounts for 13% of all hematologic malignancies.
Aims: To determine clinical presentation and compare response to induction treatment of multiple myeloma (MM) in newly diagnosed patients registered with the National Institute of Blood Disease (NIBD), Karachi.
Methods: Prospective, observational study was done from January 2013 to June 17 at our hospital in newly diagnosed MM patients and treatment was followed in study patients. Remission was documented after 4 cycles of treatment according to the standard response criteria of International Myeloma working group (IMWG).
Results: Eighty seven MM patients were included in the study. There were 52 males and 35 females. The median age was 57.26 (ranged from 40-65 years). The male to female ratio was 1.4:1. The main presenting complains included backache in 57% (n=50), pain in the legs 46% (n=40) and generalized weakness 63% (n=55). Anemia with hemoglobin level <10 g/dl was found in 71% (n=62) patients. The mean hemoglobin value was 8.9±2.1g/dl. Renal impairment was present in 49.4% (n=43) patients while 29% (n=25) patients had hypercalcemia. Patients were staged according to International staging system; 49% of the patients (n=43) were in stage II, 30% (n=26) patients in stage I and 21% (n=18) in stage III disease. About 48% (n=42) patients received thalidomide/melphalan/dexa (TMD), out of which 43%

(n=18) achieved complete remission (CR) after 4 cycles while 57% (n=24) had partial response (PR). Thirty patients (34%) received lenalidomide/melphalan/dexa (LMD) of which 77% (n=23) achieved CR while 23% (n=7) patients had PR. Fifteen patients received lenalidomide/bortezomib/dexa (LBD), out of which 93% achieved CR. Chi square was applied to observe the association in treatment response and it was found statistically significant that treatment B and C had higher percentage of CR compared to treatment A (p-value = >0.05). However no significant results were found when treatment B and C was compared (p-value = <0.05). Twenty eight partial responders of treatment A and B received LBD, out of which 90% achieved remission. Overall survival at 3 years was 59%. Management related toxicities included weakness, constipation, diarrhea, nausea, vomiting and peripheral neuropathy.

Summary/Conclusion: Treatment with lenalidomide/melphalan/dexa and bortezomib combination was superior to the thalidomide group. Moreover, bortezomib addition results in complete remission in non-responders at induction and was well tolerated.

ADDRESSING UNMET MEDICAL NEEDS IN MAINTENANCE TREATMENT FOR NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM): CURRENT TREATMENT LANDSCAPE AND EMERGING THERAPEUTIC OPTIONS

W.J. Chng[1,*], M. Beksac[2], R. Hajek[3], K. Weisel[4], M.-V. Mateos[5], A. Spencer[6], S. Iida[7], D. de Farias[8], R. Labotka[9], T. Skacel[9], A. Palumbo[9], S. Lonial[10], S. Kumar[11], M. Dimopoulos[12]

[1]Department of Hematology-Oncology, National University Cancer Institute, Singapore, Singapore, [2]Department of Hematology, Ankara University, Ankara, Turkey, [3]Department of Hematooncology, University Hospital Ostrava, Ostrava, Czech Republic, [4]Department of Hematology, University of Tuebingen, Tuebingen, Germany, [5]Hospital Universitario de Salamanca, Instituto Biosanitario de Salamanca (IBSAL), Salamanca, Spain, [6]Australian Centre for Blood Diseases, Monash University, Malignant Haematology & Stem Cell Transplantation, Alfred Hospital and Department of Clinical Haematology, Monash University, Melbourne, Australia, [7]Department of Hematology & Oncology, Nagoya City University, Nagoya, Japan, [8]Hospital das Clinicas, Universidade Federal de Goiás (UFG), Goiânia Goiás, Brazil, [9]Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [10]Department of Hematology and Medical Oncology, Winship Cancer Institute, Emory University, Atlanta, GA, [11]Division of Hematology, Mayo Clinic, Rochester, MN, United States, [12]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

Background: In NDMM, following response to primary therapy, maintenance therapy prolongs progression-free survival (PFS) and overall survival (OS) (McCarthy *et al*, J Clin Oncol 2017; Ludwig *et al*, Blood 2012). However, although multiple drugs have been investigated, maintenance is not yet an established treatment option worldwide; lenalidomide is the only approved agent, and only as post-autologous stem cell transplant (ASCT) maintenance.

Aims: We reviewed published/ongoing phase 3 trials of current and emerging maintenance treatment options to evaluate the treatment landscape and identify unmet medical needs and how these needs might be addressed.

Methods: A focused literature review and a search of clinical trial registries were conducted to identify publications and ongoing phase 3 studies of maintenance treatment approaches in NDMM.

Results: Maintenance with lenalidomide, bortezomib, or thalidomide has been well-studied and offers differential benefit, leaving unmet needs in some populations. Lenalidomide maintenance post-ASCT prolongs PFS and OS *versus* placebo/observation (McCarthy *et al*, J Clin Oncol 2017) but increases risk of second primary malignancies and has a less pronounced benefit in some subgroups, including patients with high-risk cytogenetics and those with high ISS stage. Lenalidomide has shown improved PFS, but not OS, in the non-ASCT setting (Palumbo *et al*, N Engl J Med 2012). Thalidomide maintenance demonstrates a significant risk reduction for PFS, but not in patients with high-risk cytogenetics (Ludwig *et al*, Blood 2012), and with notable toxicity. Although both lenalidomide and thalidomide have shown OS benefits, these benefits are not consistent across all individual studies. Bortezomib has activity post-ASCT, including in patients with high-risk cytogenetics (Sonneveld *et al*, J Clin Oncol 2012), and in the non-ASCT setting (Palumbo *et al*, J Clin Oncol 2010; Mateos *et al*, Lancet Oncol 2010), but has not been studied in a placebo-controlled setting. Long-term use of bortezomib and thalidomide may be limited by short- and long-term toxicity, such as peripheral neuropathy, as well as by the treatment burden associated with repeated parenteral administration. Although these agents are being used for maintenance, several unmet medical needs still remain, including the need for a therapy that can be dosed for an extended time without cumulative or late-onset toxicity or the emergence of resistant clones at relapse. Further, there is a need for a maintenance therapy offering extended benefit in all patients, including subgroups with high-risk disease (advanced stage, high tumor burden, high-risk cytogenetics, comorbidities). Ideally, maintenance should deepen patient responses instead of just sustaining an existing response. There are several ongoing phase 3 studies of ixazomib, carfilzomib, and daratumumab as maintenance (Table) that may address some of the unmet needs. Long-term treatment with regimens containing these agents results in deepening responses and improved outcomes, including in multiple high-risk patient subgroups. Oral ixazomib potentially offers a convenient and feasible approach to long-term proteasome inhibitor therapy, with a manageable toxicity profile.

Table 1.

Table. Ongoing phase 3 maintenance trials

Agent	Study	Design	NCT number
Ixazomib	TOURMALINE-MM3 NCT02181413	Ixazomib vs placebo in post-ASCT NDMM	NCT02181413
	TOURMALINE-MM4 NCT02312258	Ixazomib vs placebo in post-induction, non-ASCT NDMM	NCT02312258
	GEM2014MAIN NCT02406144	Ixazomib-lenalidomide vs lenalidomide in post-ASCT NDMM	NCT02406144
Carfilzomib	University of Chicago NCT02659293	KRd vs lenalidomide in post-ASCT NDMM	NCT02659293
Daratumumab	Cassiopeia NCT02541383	Daratumumab vs observation post-ASCT	NCT02541383

Summary/Conclusion: Current maintenance therapies for NDMM have resulted in improved long-term outcomes but are associated with some limitations. Emerging therapies may offer a feasible approach due to manageable long-term toxicity profiles and convenience, especially oral agents.

PB2253

POSSIBLE FACTORS OF PROGRESSION IN MONOCLONAL GAMMOPATHY IN PATIENTS OF GOMEL REGION IN BELARUS

Z. Kozich[1,*], V. Martinkov[2], Z. Pugacheva[3], L. Smirnova[4]

[1]Hematology, [2]Molecular genetics, [3]Laboratory diagnostics, The Republican Research Center for Radiation Medicine and Human Ecology, Gomel, [4]Hematology, BelMAPO, Minsk, Belarus

Background: Monoclonal gammopathy of undetermined significance (MGUS) is a group of diseases with the proliferation of cells of lymphoid or plasmocyte nature <10% secreting various pathological immunoglobulins in blood serum and / or urine <30 g/l with no foci of lysis, kidney damage, hypercalcemia and risk of progression of 1% in a year

Aims: to detect possible risks of progression of monoclonal gammopathy in patients of Gomel region.

Methods: The material for the study was samples of whole venous blood and bone marrow from 28 patients with pathological paraprotein who underwent examination and treatment during the period 2014-2017 in the SI "RRCRM&HE" in Gomel (Belarus). The diagnosis was confirmed by the presence of pathological immunoglobulin in the blood and / or urine and tumor immunophenotype of plasma or lymphoid cells of bone marrow. Antigen expression was determined by flow cytometry. The results were estimated at the time of determination of the pathological protein. The number of clonal plasma cells in the bone marrow was 4.6% (1.2-15%) on an average. Monoclonal gammopathy was more common in women (62.9% were female). The median age was 64 years (46-80 years).

Results: In our study pathological paroprotein was represented by IgG (50.0%), IgA (17.9%), IgM (7.1%), Bens-Jones protein (14.3%) and absence of secretion of Ig (10.7%%). Monoclonal gammapathy with the presence of IgG and Bence-Jones protein progressed to multiple myeloma during the first year of follow-up in 9 (32.1%) patients. In one patient, the disease was transformed into Waldenstrom's macroglobulinemia within three years. During this period of time, a significant increase in CD20 expression was detected proportionally to the increase in the M-protein index. Two patients from this group showed a significant increase in CD117 expres-

sion (p=0.052) along with a high level of pathological M-protein. A high risk of progression was associated with the M-protein with IgM secretion. Excess of lactate dehydrogenase (LDH) indices was also significant (p=0.05) in patients with a high risk of progression, changes in B2-microglobulin (possibly due to a small percentage of plasma cells in the bone marrow) were not detected.
Summary/Conclusion: Monoclonal gammopathy of undetermined significance (MGUS) is a premalignant proliferation of B-lymphocytes with a high risk of progression to multiple myeloma, Waldenstrom's macroglobulinemia. Despite a very short observation period, during our study we detected a significant increase in CD117 and CD20 expression in patients who progressed to multiple myeloma and Waldenstrom's macroglobulinemia, which may be an unfavorable prognostic factor. Perhaps this will help to identify patients at high risk for progression initially, which is important in determining the time of the start of specific therapy.

PB2254

DARATUMUMAB-IXAZOMIB-DEXAMETHASONE: A NEW THERAPEUTIC REGIMEN FOR RELAPSED MULTIPLE MYELOMA?

S. Martín-Batista[1,*], M. Moreno-Vega[1], P. Hernández-Hernández[1], A. Martín-Martín[2], P. Machado-Machado[2], S. Lakwhani[2], C. De Bonis-Braun[2], B. González-González[2], M.J. Rodriguez-Salazar[2], B. Soria-Santabárbara[2], S. Iraheta-Reyes[2], T. Martín-Santos[2], M.R. Arcas-Vega[2], K. Mayani[2], J.M. Raya[2], M.T. Hernández[2]

[1]Hematology, [2]Universitary Hospital of Canary Islands, La Laguna. Canarias, Spain

Background: Patients with relapsed and refractory multiple myeloma (MM) have poor prognosis. Life expectancy is increasing because of a rising number of agents with various mechanisms of action. However, MM remains incurable because of the emergence of resistant clones. Among these drugs, Daratumumab (DARA) is the first-in-class human monoclonal antibody against CD38 cells showing an overall response rate of 36% and a median overall survival (OS) of 17 months in monotherapy, now it can be used in combination with lenalidomide and dexamethasone, or bortezomib and dexamethasone, for the treatment of patients who have received at least one prior therapy. Ixazomib is a boron-containing selective proteasome inhibitor that demonstrated antimyeloma activity with excellent safety profile. Ixazomib is a proteasome inhibitor approved in combination with lenalidomide and dexamethasone for the treatment of patients who received at least one prior therapy.
Aims: We report two cases of relapsed MM treated with DARA-Ixazomib-Dexamethasone as rescue treatment, to our knowledge, the first study reporting this combination.
Methods: Description of two case reports about patients treated on our Unit.

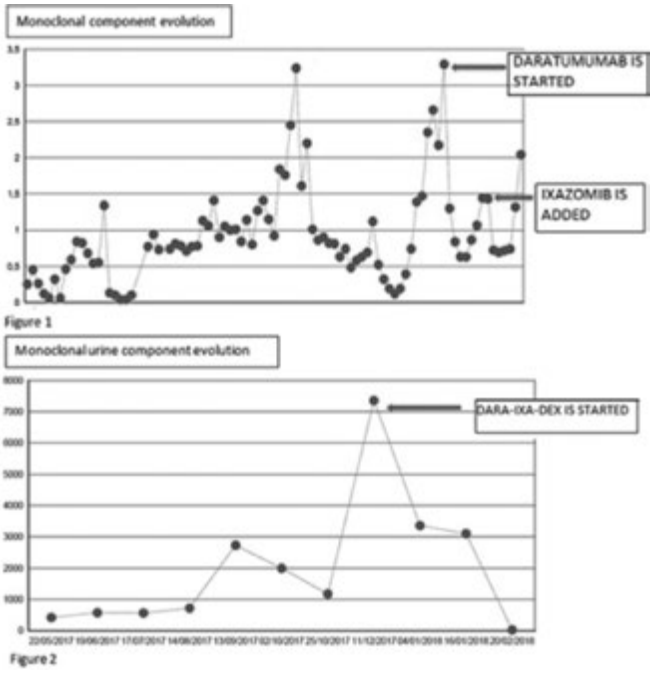

Figure 1.

Results: A 67-years-old woman with a known diagnosis of IgA lambda MM presented with relapsed MM. She first presented in 1999, was started on VBMCP/VBAD followed by auto transplant (ASCT), achieving a complete response (CR) but relapsed five years later, so she received bortezomib achieving a second CR. In 2007, a second relapsed was detected and she experimented a large sequence of treatment-relapsed consisting of VMP, Lenalidomide-dexamethasone, Bendamustine and Elotuzumab-thalidomide-dexamethasone. While the 13th cycle, she suffered a severe lung infection and was admitted in the critical care unit. Fortunately, she recovered well and was started on Carfilzomib. Next year, the disease progressed so we restarted Carfilzomib adding Dexamethasone (Kd), achieving a VGPR. Later, the disease progressed so the treatment was restarted but MM was refractory; in February 2017 a treatment based on DARA-bortezomib was initiated, but we stopped bortezomib because of severe neuropathy. After an optimal response, it got worse and Ixazomib was added; the disease evolution was optimal (Figure 1). After 12 cycles IgA levels increased slowly. At present, MM is in progression. Our second case is a 60-years-old woman whose kappa light chain MM was detected in 2016, and was started on VTD achieving a good response, because of many complications, we stopped the treatment. After few months, she progressed so we started bortezomib-cyclofosphamide-dexamethasone (VCD) without response, so Rd was initiated. It was interrupted due to vertebral fractures. Promptly, she was started on Kd, but she debuted with a sepsis. After recovering, she received dexamethasone-cyclophosphamide-etoposide-cisplatin, but after one cycle she was diagnosed with a spinal cord compression. In December 2017, a regimen consisting of DARA 16mg/kg/week -Ixazomib 4 mg/week -dexamethasone was initiated. As striking decrease of the protein M in urine was observed (Figure 2), but a pancreatic plasmacytoma was detected. An ASCT was made and currently, after two months, MM is in a VGPR.
Summary/Conclusion: Daratumumab has shown benefit in patients who have progressed, and whose combination with other drugs just started to investigate. We combined this drug with Ixazomib in an attempt to control the disease, the response was good. However, optimization of the regimen could prolong response duration and improve patients' outcomes.

Myeloproliferative neoplasms – Biology & Translational Research

PB2255

HIGHER SCLEROSTIN/SOST EXPRESSION IS ASSOCIATED WITH LOWER PERCENTAGE OF CIRCULATORY BLASTS AND BETTER PROGNOSIS IN PATIENTS WITH MYELOFIBROSIS

M. Lucijanic[1,*], A. Livun[2], K.M. Tupek[3], T. Stoos-Veic[4], G. Aralica[5], V. Pejsa[1], R. Kusec[1]

[1]Hematology Department, [2]Clinical Department of Laboratory Diagnostics, University Hospital Dubrava, [3]Clinical Department of Laboratory Diagnostics, Clinical Hospital Dubrava, [4]Cytology and Cytometry Department, [5]Pathology Department, University Hospital Dubrava, Zagreb, Croatia

Background: Sclerostin, a product of *SOST* gene, is a main negative regulator of bone metabolism which exerts its properties through inhibition of WNT signaling pathway in osteoblasts. WNT signaling pathway is implicated in pathogenesis of Philadelphia chromosome negative myeloproliferative neoplasms (Ph- MPNs). These diseases are characterized by remodelling of bone marrow (BM) stroma and development of BM fibrosis/osteosclerosis during course of the disease.
Aims: We aimed to investigate Sclerostin/*SOST* expression in BM tissue of patients with primary (PMF) and secondary myelofibrosis (SMF) and to assess its clinical correlations.
Methods: Using immunohistochemistry (IHC) and real-time-polymerase-chain-reaction (RT-PCR) we investigated Sclerostin/*SOST* expression in totally 66 diseased (51 PMF, 15 SMF) and 18 control BM samples. Sclerostin expression measured by IHC was expressed as a percentage of positive cells. *SOST* expression measured by RT-PCR was normalized to *Abl* and expressed as a ΔCT value. Samples were collected retrospectively in period from 2006 to 2016. Correlations with clinical parameters were made. The Mann Whitney U test, the Spearman rank correlation, the log-rank test and the Cox regression analysis were used. The ROC curve analysis was used to define optimal cut-off values for survival. *P* values <0.05 were considered to be statistically significant.

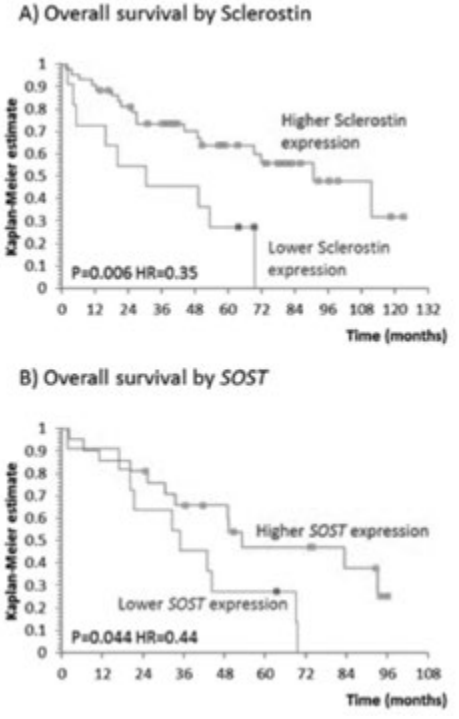

Figure 1.

Results: Median age of patients was 67 years, 59.2% were males. Median follow up of our cohort was 74 months. Sclerostin/*SOST* expression did not significantly differ between healthy and diseased patients, nor between PMF and SMF. However, higher Sclerostin expression in myelofibrosis patients was significantly correlated with lower percentage of circulatory blasts (Rho -0.28, P=0.042) and transfusion dependency (P=0.049). Higher *SOST* expression in diseased patients was similarly significantly correlated to lower percentage of circulatory blasts (Rho -0.44, P=0.042), but also higher platelets (Rho 0.4, P=0.031) and smaller spleen size (Rho -0.6, P=0.001). We found no significant association of Sclerostin/SOST expression with driver mutations or degree of bone marrow fibrosis. Patients with higher Sclerostin expression measured by IHC (HR=0.35, P=0.006) and *SOST* expression measured by RT-PCR (HR=0.44, P=0.044) had better overall survival than patients presenting with lower Sclerostin/*SOST* expression as shown in a Figure. This association remained significant for *SOST* (HR=0.21, P=0.025) after adjusting for age, gender and circulatory blasts (HR=1.06, P=0.002).
Summary/Conclusion: Sclerostin expression might affect stem cell mobilization. Patients with higher Sclerostin/*SOST* expression experienced improved survival, effect which might be prognostically independent of reduction in circulatory blasts and which is probably mediated through canonical WNT inhibition. Our findings emphasize the role of bone metabolism regulating cytokines, such as Sclerostin, in pathogenesis of Ph- MPNs and suggest that WNT inhibition might be an interesting therapeutic approach in myelofibrosis patients.

PB2256

HOW RUXOLITINIB IMPACTS ON DRIVER AND ADDITIVE MUTATIONS IN PATIENTS WITH MYELOFIBROSIS

S. galimberti[1,*], S. Balducci[2], F. Guerrini[2], S. Grassi[3], D. Cattaneo[4], A. Iurlo[5], P. Vigneri[6], M. Petrini[2], G.A. Palumbo[7], C. Baratè[8]

[1]clinical and experimental medicine, university of Pisa, [2]hematology, university of Pisa, pisa, [3]GENOMEC, university of Siena, siena, [4]policlinico ca' granda, hematology, [5]IRCCS ca' granda, hematology, Milano, [6]oncology, university of Catania, [7]hematology university of Catania, catania, [8]hematology pisa, pisa, Italy

Background: Introduction of ruxolitinib in the clinical practice has changed the outcome of patients with myelofibrosis (MF), offering longer survivals and improvement of the quality of life. Nevertheless, about 50% of patients loss clinical response, and some authors ascribed this phenomenon to driver and non-driver mutations: Patel *et al.* (Blood 2015) reported that having more than 3 mutations well correlated with shorter time to discontinuation and shorter overall survival (OS), but other investigators in the COMFORT-II trial reported that non-driver mutations did not correlate with response or survival (Guglielmelli, Blood 2014).
Aims: in order to further investigate if ruxolitinib could play any role in changing the mutational landscape in MF patients, we assessed the 3 driver and 8 non-driver mutations in 36 MF patients at diagnosis; 19 were tested also after 12 months of ruxolitinib, and compared with 4 cases receiving hydroxyurea.
Methods: JAK2, CALR, and MPL mutations were screened by qualitative/quantitative PCR. For the non-driver mutations, we designed a PCR plate with pre-spotted primers able to amplify ASXL1, EZH2, DNMT3A, IDH1, IDH2, SRSF2, TET2, TP53, for total 38 hot-spot sites (*Custom qBiomarker Somatic Mutation PCR Array®* - Qiagen, Italy). These genes were chosen because already included in the high molecular risk subgroup (*ASXL1*, *EZH2*, *SRSF2*, *IDH1/2*) or for their prognostic negative role in myeloid hematological neoplasias (DNMT3A, TP53).
Results: JAK2 was mutated in 70% of cases, CALR in 20%, whereas 10% were triple-negative. The median OS was significantly longer for primary MF (160 months) *vs* post-ET (80 months) or post-PV MF (35 months)(p=0.03), and for CALR- *vs* JAK2-mutated patients. At the last follow-up, 4 patients (11%) progressed to AML, and 12 (33%) died. The non-driver mutations were found at diagnosis in 33% of cases receiving ruxolitinib and in one/4 patients treated with hydroxyurea. Considering both driver and non-driver mutations, 24 cases (67%) were mutated, with 16 carrying one mutation, and 10 two mutations. The most frequently detected mutations belonged to the methylation pathway (DNMT3A, IDH, TET2=75%), followed by TP53 (17%), SRSF2 (8%), ASXL1 (8%), and EZH2 (8%). During treatment, JAK2 VAF remained stable, whereas non-driver mutations changed in 13 cases: 9 acquired a new mutation, while 4 lost the previously detected mutations. Acquisition of DNMT3A mutation was found in 5 patients, of IDH2 in one, and of TP53 in another one. None of the CALR-mutated cases carried non-driver mutations. In the 4 cases treated with hydroxyurea, during treatment one acquired TP53 and another one DNMT3A mutation. On the other hand, 4 cases lost mutations previously present at diagnosis (TP53, IDH2, ASXL1, DNMT3A) in the group of ruxolitinib, but nobody in the group of hydroxyurea. Presence/absence of non-driver mutations, their number (>1), the molecular subgroup (methylation, splicing, chromatin) did not significantly condition OS.
Summary/Conclusion: In this work, even if on a small series of patients, we showed that during ruxolitinib about the half of cases develops non-driver mutations, a percentage overlapping to that observed in cases receiving

hydroxyurea. Interestingly, ruxolitinib allowed disappearance of mutations in one third of cases. Acquisition of new mutations or the type of non-driver mutations did not correlate with higher rate of death or ruxolitinib failure.

PB2257

TUMOR-SPECIFIC METHYLATION OF THE CANDIDATE TUMOR SUPPRESSOR GENE HLS5 IS AN EPIGENETIC BIOMARKER FOR ACUTE MYELOID LEUKEMIA(AML) AND MYELOPROLIFERATIVE NEOPLASM(MPN)

J. Huang*, X. Ye

Hematology, the Fourth Affiliated Hospital, College of Medicine ,Zhejiang University, Yiwu, China

Background: Aberrant promoter methylation is an epigenetic mechanism for silencing tumor suppressor genes (TSG), and is also a biomarker for early cancer diagnosis and prognosis prediction. HLS5 belongs to the RBCC (Ring-finger, B-box, coiled-coil) family, a family of tumor suppressive genes including Pm, Tif1-α,Herf and Rfp, it has been reported to regulate erythroid differentiation, to be activated during the conversion of J2E erythroleukemic cells to monocytoid cells, and assumed to be a tumor supresor.However, the role of HLS5 in acute myeloid leukemia and myeloproliferative neoplasms has never been explored.
Aims: the role of HLS5 in acute myeloid leukemia and myeloproliferative neoplasms.
Methods: Bone marrow of 35 *de novo* AML-M2, 20 *de novo* AML-M5 and 68 JAK2/V617F mutation positive MPN patients were collected, the mononucleated cells separated, RNA extracted and the HLS5 expression level detected using real-time quantitative PCR and MSP. SPSS 16.0 used for data analysis.
Results: We identified HLS5 as a functional tumor suppressor gene frequently methylated in multiple myeloid neoplasms. We further uncovered HLS5 as one of the up regulated genes in myeloid neoplasm cell lines after pharmacologic demethylation with 5 aza 2' deoxycytidine (Aza). Methylation of HLS5 was detected in most acute myeloid leukemia cell lines, including KG1, Kasumi-1, U937, THP, HL60 cell lines and JAK2/V617F mutation positive cells. Aza treatment led to HLS5 promoter demethylation and transcriptional reactivation in silenced cell lines, indicating a methylation mediated silencing. Aberrant methylation was further detected in 40% (14/35) AML-M2, 60% (12/20) AML-M5 and 60-80% of various types of JAK2/V617F mutation positive MPN, but not in any normal PBMC sample, and is thus tumor specific. Moreover, HLS5 methylation was detected in 3/10 (30%) serum samples from MF patients.
Summary/Conclusion: Our results indicate that HLS5 methylation is a frequent event in multiple myeloid neoplasms, especially for AML and MPN, but the exact mechanism needs further investigation.

PB2258

BONE MARROW TRYPTASE LEVEL EVALUATION IN SISTEMIC MASTOCYTOSIS: ROLE IN DIAGNOSIS AND CLASSIFICATION OF DISEASE

M. Rondoni[1,*], G. Poletti[2], V. Cova[3], A. Pezzi[4], G. Cortellini[5], E. Massari[2], C. Zingaretti[6], M. Rosetti[2], F. Monti[2], C. Conti[3], S. Soverini[7], M. Mancini[7], L. Riccioni[8], L. Cardinale[9], G. Martinelli[6], F. Lanza[1]

[1]Section of Hematology & SCT Unit, AUSL Romagna, Ravenna, [2]Hematology Unit. Laboratory of Clinical pathology, [3]Allergology Unit. Laboratory of Clinical Pathology, AUSL Romagna, Pievesestina (FC), [4]AUSL Romagna, Ravenna, [5]Internal medicine and Allergology, AUSL Romagna, Rimini, [6]Hematology/Oncology, IRST IRCCS, Meldola(FC), [7]Department of Experimental Diagnostic and Specialty Medicine-University of Bologna, Institute of Hematology "L. e A. Seràgnoli", Bologna, [8]Pathology Unit, AUSL Romagna, Cesena, [9]Pathology Unit, AUSL Romagna, Ravenna, Italy

Background: Systemic Mastocytosis (SM) is a complex disorder characterized by the accumulation of abnormal mast cells (MCs) in different organs and a wide spectrum of symptoms, derived from abnormal MCs degranulation. The diagnosis is based on serum baseline tryptase (sBT) level, histopathological, morphologic and immunophenotypic evaluation of MCs and D816V mutation. Diagnosis and cure of SM is peculiar, and patients have to be referred to specialized centers. In some cases, with a very small percentage of MCs in bone marrow (BM), diagnosis is difficult, because major diagnostic criteria (MDC) are often missing, sBT may be <20ug/L, and very sensitive methods for detection of D816V mutation are required to avoid false negative results. Once a diagnosis of SM is made, it is mandatory to assess the burden of the disease, its activity, subtype and prognosis, and the appropriate therapy. Evaluation of sBT levels have been associated with the burden of disease, especially in ISM, whereas in ASM and MCL sBT level varies. Tryptase can be easily measured in many laboratories, in contrast to FC and high sensitive molecular methods.
Aims: to explore the utility of bone marrow tryptase (bmT) level for predicting disease diagnosis and behavior.
Methods: We systematically explored the bmT level in 39 patients with suspected SM, with sBT level, histopathological, morphologic and immunophenotypic evaluation of MCs and molecular analysis. The commercial technique Immuno CAP Tryptase System was used. To exclude lower level of bmT due to hemodilution of the sample, we performed the tryptase assay on the same sample used for the FC analysis considering eventual increased T-lymphocyte count. Moreover we evaluated bmT level in 16 BM samples analysed with FC for other hematological/suspected hematological diseases. bmT levels were correlated with all the others diagnostic parameters, including an accurate morphologic examination, and with the final diagnosis and classification according to WHO.
Results: the median bmT level was 230 ug/L in patients with SM diagnosis (IQR 123-471), whereas 14.95 in normal BM (IQR 6.52-26,30) ; p 0.0001. The bmT level is different in the categories of disease (ISM, SSM, ASM and LMC), with low significance (p= 0.0244), due to the predominance of ISM, but importantly this difference is lost considering together ASM and MCL forms *versus* the ISM. bmT level is elevated in patients without MDC (histopathological, presence of aggregates with more than 15 elements) as in the patients with the MDC, with 190.5 ug/L (IQR 95-345) in the first group and 230 (IQR 169-473) in the former, instead of 17.75 (IQR 14.6-19.10) *versus* 34 (IQR 20.6-105) for sBT level (p=0.0073). There is a correlation between bmT Level and percentage of MCs in BM, although less strong than in the case of sBT level. Correlations between bmT Level and morphological aspects of the BM smears show an higher median value in cases with mature forms of MCs (387ug/L *versus* 135.5ug/L, with p=0.0878), but without significance. No correlations were found with CD2 or CD25 expression.
Summary/Conclusion: high bmT level is closely associated with diagnosis of SM. Evaluation of bmT level can be integrated in the diagnostic process of SM due to its feasibility, in particular in ISM, where it can identify ISM with very low percentage of MCs. The variability of bmT Level in advanced forms highlights the need of different parameters for the disease characterization of MCL, ASM, and probably a subset of SSM, as the maturation markers of MCs in FC, or new Molecular alterations.

PB2259

A NOVEL GERMLINE CARL MUTATION AFFECTING AN EVOLUTIONARY CONSERVED REGION OF 3'UTR IN JAK2-NEGATIVE SIBLINGS WITH POLYCYTHEMIA VERA

A. Quattrocchi[1,*], S. Tomassini[2], M.C. Scerpa[1], N. Cenfra[2], A. Ceccherelli[1], S. Pisanò[1], E. De Marinis[1], M. Gentile[1], C. Maiorca[1], G. Cimino[2], C. Nervi[1]

[1]Department of Medical-Surgical Sciences and Biotechnologies, [2]Department of Cellular Biotechnology and Hematology, University La Sapienza - Rome, Latina, Italy

Background: The principal phenotypic driver mutations of MPNs, occurring on JAK2, MPL and Calreticulin (CALR) genes, cause a direct or indirect deregulation of JAK/STAT signalling. Recurrent exon 9 CARL mutants, associated almost exclusively with ETs and PMFs, activate JAK/STAT by interacting with TPO-receptor. CALR mutations generally arise from a +1 frameshift that generates a common novel peptide lacking of KDEL ER-retrieval signal, converting the first 31 bases of CALR 3'UTR into coding sequence. However, the hematopoietic and regulative functions of this 3'UTR region are still unknown.
Aims: We aimed to analyse in 2 siblings the clinical and biological consequences of an unusual deletion of 3'UTR, designated c.1254+10_+33del24, occurring 10 bp downstream the stop codon, thus not altering the coding sequence. Interestingly, both these patients were diagnosed with JAK2-negative PV.
Methods: CALR mutations and mutant allele burden were detected by PCR screening, identified by Sanger sequencing and confirmed by fragment analysis on DNA from granulocytes, CD34+-hematopoietic progenitor cells (HPC) isolated from peripheral blood (PB) and saliva epithelium. CALR mRNA levels was measured by quantitative RT-PCR (ABI-PRISM-7000). CALR, STAT-3/-5 and phopho-STAT-3/-5 protein levels were assessed by immunoblotting both in PB cells and in myeloid cell lines. The colony assays were performed using PB mononuclear cells isolated by Ficoll.

Results: CALR 3'UTR deletion c.1254+10_+33del24 was found in two sibling PV patients. This deletion is located within an evolutionarily conserved region at nucleotides 10-33 of 3'UTR, thus not altering the KDEL domain. Such mutation was detected in granulocytes, $CD34^+$-HPCs and oral epithelial cells from saliva samples, suggesting that the mutation is germline. In all samples, the mutant allele burden was >50%. Both siblings showed an enhanced erythropoiesis, also assessed by BFU-E growth at low erythropoietin conditions. Moreover, these patients and other MPNs cases affected by canonical CALR mutations showed increased CALR mRNA/protein levels and an aberrant activation of the JAK/STAT pathway, respect to healthy donors.
Summary/Conclusion: CALR mutations in MPNs have hitherto been observed only in ETs and PMFs, with a pathogenesis relying on TPO-receptor activation by the mutated novel peptide. Here we report that the mutation c.1254+10_+33del24, deleting 24 bp of CALR 3'UTR, is associated with PV. JAK/STAT signalling activation correlates with increased CALR expression and 3'UTR alteration. Our results suggest that CALR 3'UTR functional impairment, not altering KDEL sequence and operating for instance on RNA intracellular localization, miRNA binding, translational efficiency and mRNA editing, may affect erythropoiesis.

PB2260

INFLAMMATION THROUGH MATRIX METALLOPROTEINASE IN MYELOPROLIFERATIVE NEOPLASM

M. Kovacic[1,*], S. Bjelica[1], B. Beleslin-Čokić[2], D. Djikić[1], D. Leković[3], M. Gotić[3], V. Čokić[1]

[1]Department of molecular oncology, Institute for Medical Research, [2]Clinical for Endocrinology, Diabetes and Metabolic Diseases, Genetic laboratory, [3]Clinical of Hematology, Cliical Center of Serbia, Belgrade, Serbia

Background: Matrix metalloproteinases (MMPs) are a family of zinc-dependent endopeptidases involved in remodeling of the extracellular matrix. MMPs have multiple roles in cancer cell proliferation and inflammation, including myeloproliferative neoplasm (MPN).
Aims: The goal of our study is to explore the MMPs level in essential thrombocythemia (ET) and primary myelofibrosis (PMF), during inflammation.
Methods: Using zymography, we analyzed expression of MMP2,3,9 and 13 in plasma of healthy controls (n=5), ET (n=17) and PMF (n=17), according to JAK2V617F, calreticulin (CALR) and thrombopoietin receptor (MPL) mutation status by DNA sequencing. In addition, we determined the level of MMP2 in JAK2V617F mutated human erythroleukemia cell line (HEL) treated with pro-inflammatory IL6 and anti-inflammatory IL10. Also, MMP2 levels were determined in peripherial blood mesenchymal stromal cells of healthy controls, with or without mononuclear cells of PMF origin, treated with IL6 and JAK1/2 inhibitor Ruxolitinib. We divide ET and PMF patients per three groups: *JAK2*V617F positive (JAK2+, n=6), *CALR* positive (CALR+, n=6), and triple (*JAK2*V617F / CALR / MPL) negative (n=5).
Results: The levels of MMP3 and MMP13 were significantly higher in all three groups of PMF patients ($p<0.001$) compared to control and moreover the level of MMP3 and MMP2 were significantly lower ($p<0.01$) in triple negative ET/PMF compared to JAK2+ and CALR+ ET/PMF patients. The MMP9 was significantly higher in triple negative and JAK2+ patients with PMF compared to control ($p<0.01$). The level of MMP2 was significantly higher and in ET JAK2+ and CALR+ compared to control ($p<0.001$). The level of MMP3 was statistically lower in ET triple negative and JAK2+ patients compared to healthy controls ($p<0.01$), in opposite to MMP9 levels. The MMP13 levels were significantly higher and in ET JAK2+ and CALR+ compared to control ($p<0.001$) and triple negative ET ($p<0.01$). IL-6 induced expression of MMP2 in HEL cells after 6 hours ($p<0.01$), but not IL-10. IL-6 induced expression of MMP2 in mesenchymal stromal cells ($p<0.01$), while Ruxolitinib inhibited MMP2 in PMF mononuclear cells in co-culture with mesenchymal stromal cells after 48 hours.
Summary/Conclusion: The examined MMP levels were increased in plasma of ET and PMF patients, with predominance in JAK2+ and CALR+ patients. Inflammation increased MMP2 levels demonstrating JAK1/2 dependence. These observed MMP result may be a potential diagnostic marker of MPN.

PB2261

CALRETICULIN AND CD47 EXPRESSION IN A MDS/MPN CELL LINE MODEL K562: A MODEL FOR OUTCOME OF THERAPEUTIC RESPONSE

K. Boasman*, M.J. Simmonds, C.R. Rinaldi

Life Sciences, University of Lincoln, Lincoln, United Kingdom

Background: Myelodysplastic syndromes (MDS) and Myeloproliferative neoplasms (MPN) are a group of bone marrow neoplasms arising from clonal disorders of haematopoietic stem cells, with the tendency to progress into acute leukaemia. In solid tumours, calreticulin (CALR) overexpression produces a pro-phagocytic signal and is counteracted by concomitant expression of anti-phagocytic CD47, reflecting an apoptosis *vs* survival mechanism in response to chemotherapy. To investigate the role of CALR and CD47 expression during treatment for MDS and MPN we used the intermediate MDS/MPN cell line K562.
Aims: To investigate CALR and CD47 protein expression and location after treatment. Protein expression was analysed within an intermediate MDS/MPN cell line model (K562)
Methods: CALR and CD47 gene expression was measured by Real Time PCR and protein expression by western blotting, before and after treatment with azacytidine (AZA) and ruxolitinib (RUXO). Cells were incubated with 0.05μM/ml drug, re-dosed at 24 hours and harvested at 48 hours. Cell were also fractionised into 4 compartments: membrane, cytoplasm, cytosol and nucleus and CALR and CD47 expression measured in those compartments before and after treatment.
Results: We demonstrated upregulation of both genes, CALR and CD47 and the concomitant overexpression of both CALR and CD47 protein, after incubation with AZA or RUXO. When we analysed the cell fractions, we observed in untreated cells, the highest CALR protein expression is in the cytosol and nucleus (48.4% and 25.4%, respectively) comparing with the membrane and cytoplasm (13.3% and 12.9% respectively). CD47 expression in untreated cells is higher in the membrane and cytoplasm (43.1% and 33.4% respectively) and lower in the nucleus and cytosol (21.3% and 2.2% respectively). Possibly during fractionation CD47 protein residing on the nuclear envelope have been included not representing a common CD47 location. After incubation, cell survival rates were 81.6% in AZA and 89% in RUXO treated cells respectively, comparing with untreated cells, suggesting a slight more cytotoxic effect of AZA. Both drugs reduced CALR expression in the membrane (AZA 8.1%; RUXO 8.2% *vs* untreated 13.3%), but increased its expression in cytosol (AZA 54%; RUXO 51% *vs* untreated 48.4%) and in the cytoplasm (AZA 15.3%; RUXO 13.5% *vs* untreated 12.9%), indicating that pro-phagocytic CALR moves away from the membrane back into the cell. In contrast, CD47 expression significantly increased on the membrane (64.4% *vs* 43.1%) and decrease in the cytoplasm (0.9% *vs* 33.4%) when treated with AZA, while the expression remains virtually unmodified on the membrane (40.4% *vs* 43.1%) and in the cytoplasm (34.5% *vs* 32.5%) after treatment with RUXO.
Summary/Conclusion: In this study, we observed changes in CALR and CD47 localization after exposure to drugs. We identified a very similar pattern of CALR localization which internalised away from the membrane. This opposes previous studies in solid tumours, which show an increase of both CALR and CD47 on the cell membrane in response to chemotherapy. Interestingly the CD47 expression on the cell surface seems to follow a more drug specific trait, increasing significantly when exposed to AZA but decreasing when exposed to RUXO suggesting different ways of priming the immune-response. Further work is now required in MDS and MPN patient's cells to confirm our *in vitro* findings and to evaluate whether the different patterns of CALR and CD47 expression result in different treatment outcomes.

GENE EXPRESSION PROFILE IN ESSENTIAL THROMBOCYTHEMIA: FINDING NEW MARKERS FOR TRIPLE NEGATIVE CASES

S. Sánchez Sosa[1,2,*], C. Bilbao Sieyro[1,3], Y. Florido Ortega[1], E. González Pérez[1], M.D.L.N. Sáez Perdomo[1,2], J.M. González Martín[4], R. Stuckey[1], M.Á. Perera-Álvarez[1,2], G. Santana Santana[1], M.D.C. Galindo Rodríguez[1], M.T. Molero Labarta[1,5], J.F. Loro Ferrer[6], M.T. Gómez Casares[1]

[1]Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, [2]Universidad de Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain, [3]Morfology, Universidad de Las Palmas de Gran Canaria, [4]Unidad de Investigación, Hospital Universitario de Gran Canaria Dr. Negrín, [5]Ciencias médicas, Universidad de Las Palmas de Gran Canaria, [6]Ciencias clínicas, Universidad de Las Palmas de Gran Canaira, Las Palmas de Gran Canaria, Spain

Background: Essential thrombocythemia (ET) is a BCR-ABL1-negative myeloproliferative neoplasm characterized by JAK2, CALR and MPL mutations which trigger the cytokine receptor/JAK2 pathway. Whole exome sequencing studies have shown that in most ET cases, just one mutation in one of the three MPN driver genes is found. In approximately 15% of chronic thrombocytosis cases classified as ET, the genetic cause remains unknown and, since they do not present mutations in any of the three driver genes, they are known as triple negative. Therefore, epigenetic or other transcrip-

tion modulation mechanisms may be implicated. New molecular markers are needed to characterize triple negative cases, for that reason we studied the expression levels of genes related to MPN pathogenesis and evolution such as RB1, ASXL1, TET2, and EZH2.
Aims: To analyze the mRNA expression profiles of CALR, ASXL1, RB1 and TET2 genes in a series of ET patients with known mutational status of JAK2V617F, CALR and MPL.
Methods: Our series consisted of 73 ET patients, 53 females and 20 males, with a mean age of 61 years (range 45–77) diagnosed and treated between 1996–2017 at the Hospital Universitario de Gran Canaria Dr. Negrín. mRNA expression levels were determined by real time PCR in a LightCycler 480 Instrument II (Roche) using ABL as a control gene. Results were normalized with a cDNA pool from the peripheral blood of 10 healthy donors, which was introduced as an internal control in each experiment. The R Core Team software (2017) was used for statistical analyses.
Results: There was a positive, marginally significant, association between EZH2 and ASXL1 expression levels (p= 0.057). EZH2 expression levels were significantly lower in triple negative cases compared to those with mutations in any of the three driver genes (mean 0.75±0.3 SD *vs* 1.03±0.53 SD, respectively; p=0.003, t Student test). Levels of platelets were significantly higher in patients with mutations in any of the three driver genes compared to triple negative cases (777.82±302.48 SD and 652.31±231.4 SD, respectively; p=0.03, Mann–Whitney U test). Levels of hemoglobin were also higher in mutated patients compared to triple negative ET patients (134.91±31.7 SD and 134.03±11.1 respectively, p=0.04, Mann–Whitney U test).
Summary/Conclusion: The positive association between EZH2 and ASXL1 expression could be explained by their collaborative role in H3K27 methylation activity. A low expression level of EZH2 in triple negative cases indicates that EZH2 deficiency may be involved in the pathogenesis of a portion of triple negative cases. Finally, lower levels of platelet/hemoglobin in triple negative cases could reflect a subgroup of ET patients misclassified as triple negative while they may have reactive thrombocytosis.

PB2263

MOLECULAR CHARACTERIZATION OF MYELOPROLIFERATIVE NEOPLASMS IN RUSSIAN COHORT OF PEDIATRIC PATIENTS

M. Gaskova*, A. Panfyorova, N. Ershov, O. Soldatkina, A. Kazakova, A. Maschan, Y. Olshanskaya, N. Smetanina

Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background: Myeloproliferative neoplasms (MPNs) are a group of clonal hematopoietic stem cell disorders, which are exceedingly rare and poorly understood in children. The reported frequency of *JAK2* (V617F), *MPL*, *CALR* mutations is much lower in pediatric patients than in adults and the underlying genetics remain largely unknown.
Aims: The aim of our study was to characterize mutational profile of pediatric MPNs using next-generation sequencing (NGS).
Methods: The study included 19 patients diagnosed as Ph-negative MPN (11 boys and 8 girls). Essential thrombocythemia (ET) was diagnosed in 12 patients, polycythemia vera (PV) in 7 patients. The median manifestation age was 7.5 years (ranged from 3 months to 21 years). Next-generation sequencing (NGS) was performed using MiSeq (Illumina, USA). Amplicon library was prepared using Human Myeloid Neoplasms Panel, DHS-003Z (Qiagen, Germany), which included 141 genes. Fragment analysis of *CALR* gene exon 9 was performed for the detection of indels using ABI PRISM 3500 (Applied Biosystems).
Results: Classical *JAK2*(V617F) mutation was found in 9 patients: six patients with PV (86%) and two with ET (17%). Also *JAK2* c.1613_1616delACAAinsT in exon 12 was found in one case with PV. Mutations in *CALR* gene exon 9 were identified in four patients with ET (33%). Type 1 *CALR* frameshift mutation, a 52-bp del (p.L367fs*46) was found in two cases and one patient carried type 2 mutation, a 5-bp TTGTC insertion (p.K385fs*47), one patient harbored complex mutation c.1149-1154_delGGACAAinsTCCTTGTC(p.E383fs*48). No additional somatic mutation in epigenetic regulators (*ASXL1, IDH1/2, DMT3A*) specific for adult MPN were observed in our group. Investigation of 22 matched germline and somatic samples in 11 cases revealed the germline nature of the majority of additional mutation in epigenetic regulators (*IDH2, TET2, EZH2, EP300, BCOR, CREBBP*), in JAK-STAT negative regulators (*SH2B3*) and recurrent mismatch repair gene (*MSH6*), annotated as "possibly pathogenic" by predictive software. One JAK2(V617F) positive PV patient carried germline mutation *BLM* c.1642C>T, which was described as the breast and prostate cancer predisposal mutation. This patient also had somatic mutation in *BCOR* c.4934C>G and *MSH2* c.815C>T genes. In triple negative MPN cases additional mutations were very rare. Two patients had germline mutations *ANKRD26* c.2480T>C and *RELN* c.3651C>G and in one patient *TET2* c.5152G>T was found.
Summary/Conclusion: In our study frequency of *JAK2* and *CALR* mutations consisted 47% and 21%, respectively. Mutations in *MPL* gene were not observed. Thus, 32% patients were triple negative. The value of germline mutations in development of MPN should be further evaluated.

PB2264

THE UTILITY OF SERUM TRYPTASE LEVELS FOR THE INDICATION OF BONE MARROW BIOPSY IN THE DIAGNOSIS OF SYSTEMIC MASTOCYTOSIS. EXPERIENCE IN OUR CENTRE

C. Muñoz-Novas*, I. González, M. Infante, C. Heras, M.A. Foncillas, J.-A. Hernandez

Hematology, Hospital Infanta Leonor, Madrid, Spain

Background: Mastocytosis is a rare disease, classically included in the myeloproliferative diseases, and characterized by clonal proliferation of mast cells (MCs) in one or more organs. In the WHO classification of 2016 it is a separate entity. There are two types, cutaneous mastocytosis (CM), affecting exclusively the skin, and systemic mastocytosis (SM), affecting mainly the bone marrow, among other organs. Clinical expressions are due to the anomalous release of mast cell mediators (MCMs) or to the infiltration of MCs into the tissues. MCs release a large amount of mediators during their activation, tryptase, histamine and heparin being the most specific elements which are also measurable in the conventional laboratory. Tryptase is produced almost exclusively by MCs, although it can also be increased in anaphylaxis, myeloid neoplasms and severe renal failure. Normal levels of it are almost undetectable in healthy individuals, up to 11.4 µg/L being normal. Levels >20 µg/L are one of the WHO's minor criteria for the SM diagnosis.
Aims: To evaluate the diagnostic utility of increased levels of typtase as an independent marker in the diagnosis of SM.
Methods: We retrospectively reviewed the 2.877 requests for bone marrow biopsy (BMB) addressed to the Department of Hematology in our hospital between March, 2009 and February, 2017, we selected those whose reason for request was elevated levels of tryptase.

Table 1.

Age	Sex	Tryptase (µg/l)	BMA	BMB
40	woman	22.6	-	-
58	woman	18.4	+	+
84	man	27	-	-
44	man	15	-	-
60	woman	13	-	-
49	man	14	-	-
54	woman	22.9	-	-
77	man	47.6	-	-
44	woman	31	-	-
55	woman	21	-	-
51	man	156	+	+
70	woman	21	-	-
50	woman	13.5	-	-
60	man	36	-	+

Table 1. Clinical and laboratory characteristics of the patients

Symtoms	Pruritu	Allergy	Skin lesions	Cytopenias	Others organs	Asyntomatics
Percentage	71%	65%	64%	7%	7%	35%

Table 2. Symtoms

Results: BMB were performed in 14 patients to rule out SM because of increase of tryptase levels. All these requests came from the Department of Allergy. Of the 14 cases 6 were male and 8 females, with a median age of 57 years old (Table 1). A review of medical records showed that 35% of the patients (5/14) did not present any other indication suggesting SM. The remaining 65% had a past history of allergy: medication (4), chronic urticaria (1), hymenoptera (1), food (1), sun allergy (1), metal (1). In addition, these patients presented different types of skin lesions (Table 2). Serum tryptase levels ranged between 13.5-156 µg/L (mean 32.7), and 10/14 (71%) showed levels >20 µg/L. The BMB was diagnostic of SM in 3/14 (21%). In these cases, atypical MCs were observed in the bone marrow aspirate (BMA), and they were positive for the KIT D816V mutation with an inmunophenotype CD59+, CD25+ and/or CD2+ by flow cytometry. Only 2/3 had tryptase levels >20 µg/L. These 3 cases, in addition to the elevated tryptase levels, had monoclonal IgG kappa and bone lesions. One case had diagnosis of CM before SM and another case had abnormal blood count.

SM was not diagnosed in any case with elevated tryptase levels as the only abnormal parameter.
Summary/Conclusion: In the light of our results, we can conclude that tryptase is a sensitive but not a specific marker for the diagnosis of SM. In the absence of any other clinical evidence, and with slightly elevated tryptase levels, the risk of having SM is very low, so the study of BMB is not useful and could be avoided, while the association of other data suggestive of SM or an increase of other MSMs confers a high risk of suffering SM.

PB2265

TET2 MUTATION IN CELLULAR REPROGRAMMING AND HEMATOPOIETIC DIFFERENTIATION

C.E.G. Limia[1], R. Reis[1], C. Solza[2], A.H.D. Gabriel[3], I.R. Zalcberg[1], A. Di Stefano[4], I. Plo[4], S. Rehen[5], M.H. Bonamino[1,6], B. Monte Mor[1,*]

[1]Brazilian National Cancer Institute, [2]Hospital Universitário Pedro Ernesto, UERJ, Rio de Janeiro, [3]Hospital Universitário Antônio Pedro, Niterói, Brazil, [4]Institute Gustave Roussy, INSERM UMR[1170], Paris, France, [5]Laboratório Nacional de Células Tronco (LANCE), UFRJ, Instituto IDor, [6]Vice Presidência de Pesquisa e Coleções Biológicas (VPPCB), FIOCRUZ, Rio de Janeiro, Brazil

Background: Primary myelofibrosis (PMF) is a myeloproliferative neoplasm characterized by an clonal myeloproliferation, bone marrow fibrosis and extramedular hematopoiesis. In PMF, driver somatic mutations occur in *JAK2*, *MPL* or *CALR* genes. Mutations in epigenetic regulators as *TET2* and *ASXL1* that could lead to loss-of-function were frequently identified. In this context, induced pluripotent stem cells (iPSC) could be used to study clonal heterogeneity and to recapitulate *in vitro* some hematological features of PMF. Tet2 deletion in mouse embryonic fibroblast was shown to reduce cellular reprograming efficiency. Therefore, we asked if it would be possible to obtain iPSC from a *TET2* mutated PMF patient.
Aims: The main goal of this work was to assess the impact of somatic mutations in *CALR* and *TET2* in both cellular reprogramming and hematopoietic differentiation using iPSC.
Methods: This work was approved by INCA Ethics committee and patients signed informed consent. We used next generation sequencing to screen a cohort of Brazilian PMF patients for myeloid somatic mutations. One of the patients granulocytes (P1) were shown by Sanger sequencing to harbor $CALR^{ins5}$ and $TET2^{G898X}$ mutations. CD34+ primary cells were isolated from P1 or a healthy donor control and erythroblasts were differentiated *in vitro*. We generated iPS cells from P1 erytroblasts (P1-iPS) or from the control erytroblasts (C1-iPS) using the Sendai virus system. The pluripotency was confirmed in iPSC colonies by the expression of embryonic stem cells markers (Oct-3/4, Sox-2, SSEA-4, and TRA-1-81). The capacity to form germ layers was evaluated by embryonic body formation and layer specific markers detection by immunohystochemistry. Hematopoietic differentiation was performed on feeder-free culture supplemented with cytokines and $CD43^+CD34^+$ progenitors sorted at day 10-14. Myeloid Colony-Forming Units (CFU) were quantified in methylcellulose assays, under microscopic evaluation on day 12. CFU-Megakaryocytes were scored in plasma clots assays, after 9 days of culture and labeling with anti-CD41a antibody and alkaline phosphatase staining. Granulocytes were differentiated from $CD34^+CD43^+$ progenitors in liquid culture during 20 days.
Results: After cellular reprogramming, 32 P1-iPSC clones were obtained, 20 $CALR^{ins5}$ /*TET2wt* and 12 $CALR^{ins5}$/$TET2^{G898X}$ *homozygous*. The different genotypes observed for iPSC reflect the clonal diversity present in the PMF primary sample. We confirmed that *TET2* WT as well as *TET2* mutated iPSCs displayed pluripotency markers and were able to generate all three germ layers in EB assays, indicating that the G898X mutation did not impair cellular reprogramming. We next sought to study the role of these mutations in the hematopoietic differentiation. We observed that all type of myeloid colonies were generated in methylcellulose assays for P1-iPSC and C1-iPSC. Our preliminary results show that an increased number of granulocyte colonies derived from $CD34^+CD43^+$ progenitors of P1-*TET2* mutated iPSC, when compared both with iPSC P1-*TET2* WT and C1-iPSC. Using plasma clot assay, we observed higher numbers of large CFU-MK colonies derived from P1-iPSC *versus* C1-iPSC.
Summary/Conclusion: Our results suggest that the $TET2^{G898X}$ did not impair cellular reprogramming, since iPSC harboring this mutation displayed all the features of *bona fide* iPS and that mutations in *CALR and TET2* have an impact on hematopoietic differentiation of iPSC.

PB2266

CD271+ MSCS IN MYELOPROLIFERATIVE NEOPLASMS PH-NEGATIVE

M. Sobas[1,*], K. Zduniak[2], T. Wróbel[3], P. Ziółkowski[2]

[1]Hematology, Blood Neoplasms and Bone Marrow Transplantation, [2]Department of Pathology, [3]Department of Hematology, Blood Neoplasms and Bone Marrow Transplantation,, Medical University, Wroclaw, Poland

Background: Myeloproliferative neoplasms Ph-negative (MPN Ph-) are clinically heterogenous group of malignancies, characterized by presence of JAK2 or CALR or MPL mutation in most of the cases. Beside their clinical differences, these neoplasms differ significantly on histological grounds, not only in hematopoietic cells morphology and architecture, but also their microenviroment features. Mesenchymal stromal cells (MSCs) CD271-positive play a major role in hematopoietic stem cells renewal, and have been analysed previously in context of solid tumor propagation and some hematological cancers development.
Aims: To analyse quantity and architecture of CD271-postive MSCs in MPN Ph-.
Methods: We have analysed bone marrow trephine biopsies from 22 MPN Ph- patients: essential thrombocythemia (ET; n=7), polycythemia vera (PV; n=3), myelofibrosis (MF; n=11), prefibrotic myelofibrosis (prePMF; n=1) and 4 with non MPN diagnosis: chronic lymphocytic leukemia (n=1) and reactive disorders (n=3). Clinical, analytical and molecular data were collected. Histological sections were stained immunohistochemically using anti-CD271 antibody. Extension of staining was assesed semiquantitatively in a 3-grade (1-3) manner and correlated with diagnosis and several clinical and laboratory parameters.
Results: Here we present a very preliminary results. The CD271 staining grade 3 was observed in 6 from 11 MF (54.5%), grade 2 was observed in 5 from 11 MF (45.5%) and in 1 from 1 prePMF. The CD271 staining grade 1 was observed only in 1 MF and in all PV, ET and in non-MPN patients. There was no significant relation between CD271 and mutational status (JAK2, CALR), white blood cells, platelet counts, haemoglobin level, LDH level. There was no significant relation between CD271 and IPSS, DIPSS and DIPSS plus risk score.
Summary/Conclusion: Although we have analyzed a very small group of patients, a strong relationship between MF and high CD271+ cells density in bone marrow is visible. It surely requires further investigations, but CD271+ cells density assessment might be helpful in diagnosis of high-grade MPNs. It may also show novel insight into MPNs development and pathology.

PB2267

MUTATIONAL PROFILES AND PHENOTYPIC FEATURES IN JAK2 V617F-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS – A SINGLE CENTRE EXPERIENCE

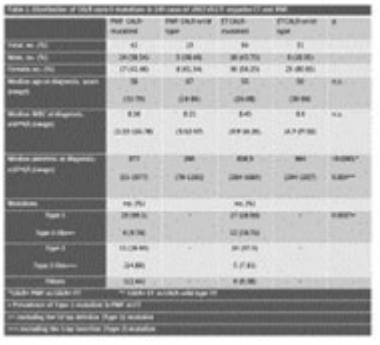
G.F. How*, S.J. Khoo, P.J. Kwok, C. Chuah

Haematology, Singapore General Hospital, Singapore, Singapore

Background: Since the discovery of CALR exon 9 mutations in 2013, the molecular diagnostic of ET and PMF has increased from approximately 60% (with diagnostic markers of JAK2 exon 14 and MPL exon 10 mutations) up to 90%. Generally, patients with mutant CALR exon 9 appear to have a prognostic advantage over those with wild type CALR. However, detection of ASXL1 mutations may enable more accurate assessment of risk stratification of PMF as these mutations are also frequently detected in PMF and appear to have a detrimental prognostic impact.
Aims: The aim of this study was to analyse CALR exon 9 mutation profiles of patients with ET and PMF and their association with ASXL1 exon 12 mutations in PMF.
Methods: For detection of mutations in CALR and ASXL1, CALR exon 9 and ASXL1 exon 12 respectively were PCR-amplified and direct sequencing of the amplicons was performed.
Results: A cohort of 92 (56 females, 36 males) JAK2 V617F-negative ET and PMF patients from a single centre was first screened for CALR mutations. A total of 61% (20/33) of PMF and 47% (28/59) of ET patients were identified with CALR frameshift indel mutations. More than 10 different mutations including several other novel ones were observed whilst Type 1(n=21) and Type 2(n=12) were the common variants detected. There was also an apparent biased incidence of Type 1/Type 1-like mutations in PMF. Overall, CALR mutations occurred more frequently in males than in females (p=0.010). For correlation studies of clinical data with mutation profiles, another 57 CALR-mutated patients (ET, n=36; PMF, n=21) were included. In 105 CALR-mutated patients (64 ET, 41 MF) studied, no significant difference was observed in the white blood cell counts or age between CALR-mutated and CALR-wild type patients within both ET and PMF cohorts. However, platelet count was significantly higher in CALR+ ET patients compared to the wild type cohort (p=0.004) and CALR+ PMF cohort ($p<0.0001$). The higher frequency of Type 1 (CALR1) mutations in PMF than in ET (56% *vs* 27%, p=0.0037) were confirmed in this bigger cohort.

Within PMF, platelet count was statistically higher in patients with Type 2-like (CALR2) mutations than those with CALR1. All CALR+ PMF patients were also screened for ASXL1 exon 12 mutations. Of 41 patients analysed, 7 patients were positive with frameshift mutations and 3 with nonsense mutations. The most frequent mutation was c.1934dupG, which constituted 40% of mutations. Although the study cohort size was small, the patients with ASXL1 mutations had significantly higher white blood cell count than those without (p=0.0035). Age, gender, platelet count and CALR mutation profile did not show any differences between different ASXL1 mutation status.

Table 1.



Summary/Conclusion: Like other studies which reported higher CALR1 prevalence in non-Asian populations, our cohort which comprised mostly Asians also showed similar profile. However, ASXL1 exon 12 mutations which were detected at a frequency of approximately 25% in CALR+ PMF in this study, did not appear to be associated with CALR1 or CALR2. It has been shown in large series that ASXL1 mutations compromised the survival of PMF patients while CALR mutations appearing to attenuate the effect. The interaction of CALR and ASXL1 mutations provides strong evidence for the prognostic relevance of performing *CALR* and *ASXL1* mutation determination in all patients with PMF. This study can also be further expanded to a larger study population with survival analysis of patients based on mutational status and other risk factors.

PB2268

THE MOLECULAR PATHOGENESIS AND THE HEMATOLOGICAL AND CLINICAL ASPECTS OF DRIVER AND SPLICEOSOME MUTATIONS IN POLISH PATIENTS WITH PRIMARY MYELOFIBROSIS

A. Bartoszewska-Kubiak[1,*], K. Matiakowska[2], M. Morgut-Klimkowska[1], E. Bielińska[1], O. Haus[1]

[1]Department of Clinical Genetics, Nicolaus Copernicus University, Faculty of Medicine, [2]Department of Clinical Genetics, Nicolaus Copernicus University, Bydgoszcz, Poland

Background: Primary myelofibrosis (PMF) is a *BCR-ABL1*-negative myeloproliferative neoplasm (MPN). PMF has the most heterogeneous clinical course among MPNs and is characterized by increased proliferation of megakaryocytes, progressive bone marrow fibrosis, extramodullary hematopoiesis, leukoerythroblastosis and shortened survival. Mutations in primary myelofibrosis (PMF) are operationally classified into 2 categories: drivers (*JAK2, MPL, CALR*) and others. Mutations in *JAK2* and *MPL* genes lead to constitutive activation of *JAK2/STAT* signaling pathway that results in increased proliferation of myeloid and magakaryocytic progenitors in absence of TPO and EPO. *CALR* gene encodes calreticulin, a protein which plays role in intracellular signaling, Ca^{2+} storage, regulation of gene expression, cell adhesion, apoptosis and autoimmune response. Mutations of these three genes are reciprocally exclusive. "Triple negative" PMF cases with any of them are associated with poor prognosis. Driver mutations might be accompanied by other mutations whose pathogenetic relevance is even less clear (*ASXL1, SRSF2, IDH1/2, EZH2, TET2, DNMT3A*, and *CBL*). *SRSF2* spliceosome mutations play a crucial role during RNA splicing pathway. Hotspot mutations in the exon 2 have been identified in PMF (3-17%).
Aims: The aim of the study was to evaluate and relate mutational status of *JAK2*, *MPL*, *CALR* genes and splicing factor *SRSF2* in Polish group of PMF patients and find associations between mutated and nonmutated cases.
Methods: *JAK2*V617F and *MPL*W515K/L mutation status were assessed using AS-PCR. Direct sequencing was performed to detect insertion/deletion of exon 9 of *CALR* gene and mutations of exon 2 of *SRSF2* gene. Relationship between the presence or absence ("triple negative") of these mutations and hematological and clinical data of patients was analyzed with Mann Whitney U Test.
Results: Out of the 98 patients, 36 (37%) carried *JAK2*V617F, 25 (26%) *CALR* exon 9 indel, 12 (13%) mutation of exon 2 *SRSF2* gene, 3 (3%) *MPL*W515 mutation and 22 (21%) were "triple negative". Among the three *MPL*-mutated cases 2 samples exhibited splice factor gene mutations *SRSF2* (66%). *JAK2*/V617F was accompanied by *SRSF2* mutation in 4 cases (11%), while *CALR* was rarely combined with splice factor gene mutations (4%). We found significant correlation (0,005) between high plateled (PLT) count and the presence of any mutation (median 207,5) in comparison to PLT in patients without mutation (median 74). An analogical association was detected between patients *CALR*(+) mutation (median PLT 333), and *CALR*(-) mutation (102,5), p=0,018. We have not found any significant relationship between clinical parameters and the presence of analyzed mutations.
Summary/Conclusion: Obtained result may suggest a clinical importance of simultaneous analysis of driver and spliceosome mutations, like *SRSF2*.

PB2269

TYPES OF CALRETICULIN (CALR) MUTATIONS IN MYELOPROLIFERATIVE NEOPLASMS: A COHORT OF PATIENTS FROM PAKISTAN

R.Z Ahmed, M. Rashid*, T. Shamsi

National Institute of Blood Diseases & Bone Marrow Transplantation, Karachi, Pakistan, Karachi, Pakistan

Background: Polycythemia vera (PV), essential thrombocythemia (ET), and primary myelofibrosis (PMF) are classic *BCR-ABL*-negative myeloproliferative Neoplasm (MPNs). In December 2013, somatic mutations in exon 9 of Calreticulin (*CALR*) gene were first time identified as the second most prevalent acquired nucleotide changes in *JAK*2 mutation negative ET and PMF patients. *CALR* mutations have important diagnostic and prognostic significance in ET and PMF patients.
Aims: To screen *CALR* mutations in local Pakistani population suspected of having MPNs.
Methods: Clinical and haematological features were obtained from 51 MPN patients (PV=10, ET=17, MF=12 and Undifferentiated MPN=9). *JAK*2V617F mutation was analyzed by ARMS-PCR. *CALR* mutations were identified by bi-directional Sanger sequencing.
Results: *CALR* mutations were detected in 13.7% patients, of which one patient was positive for *JAK*2V617F as well. All those who showed positive results for *CALR* mutations were ET patients (41.17%). Type I mutation was found in 42.8% and among them 2 had two new scattered point mutations (c.1081C>G and c.1086C>G) as well, Type II in 28.5%, and others in 28.5%. Among those patients with other than Type I or Type II mutation, one had novel double deletion of 10bp (c.1130_1139del) and 28bp (1195_1222) and one had reported CALR 12bp deletion (c.1214_1225del). When *CALR* positive and negative ET patients were statistically compared, no differences were observed in haemoglobin, white blood cell, platelet counts, hepatomegaly, and splenomegaly at p-value >0.05.
Summary/Conclusion: In our cohort *CALR* mutations were found associated with ET only. This difference emphasizes to conduct studies with large sample in this region.

PB2270

DOUBLE DELETION IN CALRETICULIN GENE: REPORTING NOVEL CALRETICULIN MUTATIONS IN A PAKISTANI PATIENT WITH ESSENTIAL THROMBOCYTHEMIA

M. Rashid*, R.Z. Ahmed, S. Ahmed, T. Shamsi

National Institute of Blood Diseases & Bone Marrow Transplantation, Karachi, Pakistan, Karachi, Pakistan

Background: The Calreticulin (*CALR*) identification as a recurrently mutated gene in primary myelofibrosis (PMF) and essential thrombocythemia (ET) took several years longer because its mutations were small insertion and deletions and its function in myeloid cell signalling had been less well understood. While 52bp deletions (Type 1) and 5bp insertions (Type 2) constitute >80% of *CALR* mutations, a variety of other insertion-deletion mutations have been reported.
Aims: Here we present *CALR* mutations in one patient with ET that is not reported before. Patient: This is a case of 60 years old, referred with increased platelets count. On physical examination. the liver was palpable 2 fingers and spleen 4 fingers below the costal margin. His platelet count were: $2318x10^9$/L, other parameters were; Hb:7.6 g/dl and TLC count was

13.29x10^9/L. Bone marrow aspirate and trephine biopsy were highly suggestive of MPN most likely ET. Platelet count fluctuates throughout the disease. He took Hydrea (high dose) and also received plateletpheresis.
Methods: For *CALR* exon 9 Traditional polymerase chain reaction was performed on DNA previously extracted from peripheral blood. The amplified product was purified and bidirectionally sequenced.
Results: Electropherogram of *CALR* exon 9 show double deletions, 10bp and 28 bp deletion
Summary/Conclusion: The identification of new *CALR* mutation will improve our understanding of the pathophysiology of MPN and will help to find new therapeutic targets. Still, there is question are those mutations monoclonal? If yes then in cis or Trans configuration? For resolving these issues there need to clone the PCR product in vector and do indirect sequencing.

PB2271

CLINICAL EXOME SEQUENCING REVEALS HOMOZYGOUS VARIANT IN THE RASOPATHY GENE CBL IN A PEDIATRIC PATIENT WITH JUVENILE MYELO-MONOCYTIC LEUKEMIA: A CASE REPORT WITH COMPLEX GENETIC SPECTRUM

A.A. Peer Zada*, M. Samman, H. AlHomaidani

Molecular Pathology, King Fahad Medical City, Riyadh, Saudi Arabia

Background: Juvenile myelomonocytic leukemia (JMML) is a rare clonal myelodysplastic/myeloproliferative neoplasm that occurs in infancy and early childhood, characterized by persistent monocytosis, no Philedelphia chromosome or BCR-ABL1 fusion gene, less than 20% myelo-monoblasts in the marrow and granulocyte-macrophage colony-stimulating factor hypersensitivity among other diagnostic criteria. The median age at presentation is 2 years (range 0.1-11.4) with an incidence of 1.2 per million child per year. Clinical and laboratory diagnostic criteria for JMML have recently incorporated molecular genetic analyses in the form of somatic and/or germline mutations in canonical RAS pathway genes (e.g., PTPN11, NF1, NRAS, KRAS, and CBL).
Aims: We sought to unravel a comprehensive genetic picture using clinical exome sequencing in an 18-month-old Saudi female child from a non-consanguineous marriage who presented with a JMML pathology and showed hematogones with 1% myeloblasts by flow cytometry.
Methods: Diagnostic work-up included pathology including cytomorphology, multicolour flow cytometry, chromosomal and FISH analyses, and array CGH for duplication and deletion analyses. For unraveling genetic etiology, exome sequencing was performed.
Results: Cytomorphology and radiology revealed JMML pathology with hepatosplenomegaly. Immunophenotyping of bone marrow lymphocytes by flow cytometry revealed hematogones with 1% myeloblasts positive for CD34, CD33 and CD13. Multicolour flow revealed T, B and NK lymphocytosis with intact expression of MHC classII antigens on B-cells, 12.6% activated T-cells (CD3+DR+) and intact expression of adhesion molecules. Chromosomal analyses revealed a normal female karyotype with no apparent numerical or structural abnormalities, and FISH analyses for comprehensive AML panel was normal. Deletion and duplication analyses of the Rasopathy panel genes vias aCGH revealed negative results. However, clinical exome sequencing in this patient revealed homozygous and/or heterozygous mutations in canonical RAS pathway genes in addition to gene variants related to acute myeloid leukemia.
Summary/Conclusion: This is a first report from Saudi Arabia and a second only report in the literature using clinical exome sequencing in JMML showing homozygous mutaion in the rasopathy gene CBL and suggests that exome sequencing holds great promise as a diagnostic tool in these patients who have the potential to transform to AML and therefore may warrants quick clinical intervention.

PB2272

CURCUMIN: A NEW THERAPEUTIC STRATEGY FOR JAK2 V617F MUTATED CELLS

J. Petiti*, V. Rosso, C. Panuzzo, D. Cilloni

Clinical and Biological Sciences, University of Turin, Orbassano, Italy

Background: The myeloproliferative neoplasms (MPNs) are chronic myeloid cancers divided in Philadelphia (Ph) positive, chronic myeloid leukemia, or negative: polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF). Mutations in *JAK2*, *MPL* and *CALR* genes are the biological markers in the most of Ph negative patients. The single base *JAK2 V617F* mutation is most common, with an incidence of 95% in PV and 50-55% in ET and PMF patients. The JAK2 protein has tyrosine kinase activity and the gain-of-function V617F mutation results in a constitutive activation of the JAK/STAT pathway, conferring a proliferative advantage and apoptosis inhibitions. The understanding of the molecular pathogenesis of MPNs has prompted the development of targeted agents, such as JAK inhibitors. Curcumin is the active phytochemical component isolated from the rhizome of the *Curcuma longa* plant. Curcumin is a highly pleiotropic molecule with multiple pharmacological effects, such as anti-inflammatory, anti-microbial, anti-oxidative and anti-proliferative activities. Extensive preclinical trials have indicated curcumin's therapeutic potential against a wide range of human diseases. Furthermore, previous studies showed that curcumin can suppress JAK2/STAT3 signaling pathways in different type of cancer and injuries.
Aims: The purpose of the present study was to investigate anti-proliferative and pro-apoptotic effects of curcumin in MPNs, in particular in *JAK2 V617F* cell lines.
Methods: HEL cell line, JAK2 V617F mutated in homozygosis, has been incubated with different concentrations of curcumin at different time points. Then, apoptosis, proliferation and cell cycle were evaluated. Subsequently, fragmentation of DNA, JAK2/STAT and AKT/mTOR pathways were investigated at both RNA and protein levels.
Results: We identified that curcumin induced apoptosis, cells cycle arrest and inhibition of proliferation in HEL cell lines. Furthermore, we showed JAK2/STAT and AKT/mTOR pathways are affected by curcumin treatments.
Summary/Conclusion: This study evaluates curcumin treatment in JAK2 mutated cell line, suggesting that it could be useful in the future for treatment of *JAK2 V617F* mutated patients.

Myeloproliferative neoplasms – Clinical

PB2273

IMMATURE PLATELET PARAMETERS FOR PREDICTION OF POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA IN PATIENTS WITH ELEVATED PLATELET COUNTS

J. Yoon*, B.K. Jung, J.A. Kwon, C.S. Lim, S.-Y. Yoon

Korea University, Seoul, Korea, Republic Of

Background: Elevated platelet count is characteristic features observed in myeloproliferative disorders, such as Polycythemia vera (PV) and Essential thrombocythemia (ET) but also could be observed in other reactive conditions. Several studies reported elevated numbers of immature platelet population in PV and ET compared to the normal control and yet studies comparing the patients with reactive thrombocytosis have not been performed.
Aims: In this study, we analyzed platelet related parameters including immature platelet fraction (IPF) for prediction of PV and ET in patients with thrombocytosis.
Methods: A retrospective study of IPF, immature platelet count (platelet count x IPF) and other platelet related parameters, such as plateletcrit (PCT), mean platelet volume (MPV) and platelet distribution width (PDW) were conducted using hematology analyzer XE-5000 (Sysmex, Kobe, Japan). A total of 100 whole blood samples from patients with thrombocytosis (platelet count ≥450x10^9/L) were included and among these, 11 were from PV, 13 from ET and 76 were from reactive thrombocytosis.
Results: IPF and immature platelet count were significantly higher in both PV and ET groups compared to the reactive thrombocytosis group. Moreover, PCT, PDW and MPV were also significantly elevated in both groups. Using ROC curve analysis, immature platelet count and PDW showed highest area under curve (both 0.86). In case of immature platelet count and PDW, with cut-off level of 10,243/μL and 10.75 fL, the sensitivities were 91.7% and 83.3%, respectively and specificities were 66.7% and 76.9%, respectively.
Summary/Conclusion: Identification of patients with possibility of PV and ET among the patients with thrombocytosis would allow prompt work up and appropriate treatment. Among the platelet associated parameter, immature platelet count and PDW were the most valuable in discriminating PV and ET from reactive thrombocytosis and would be useful for the differential diagnosis of patients with thrombocytosis.

Galeazzi[2]

[1]Hematologia, [2]Subcomision de Mieloproliferativo SAH, Buenos Aires, Argentina

Background: Hydroxyurea (HU) is the first-line agent recommended as a cytoreductive agent in the treatment of Phi-negative MPNs. The indication is based on the effectiveness in reducing the risk of vascular events in the short term and the risk of transformation to AML and MF in the long term. Its use continues to be controversial in published works regarding the prevention of thrombosis, prolongation of survival and transformation to MF and AML. Being a drug of simple handling in clinical practice, 11-20% of cases of intolerance have been reported and between 13-20% of resistance according to established criteria.
Aims: Describe population of patients with HU, criteria of treatment initiation, vascular complications, remission rate, rates of intolerance, resistance to HU and progression in MPN treated in Argentina in the daily practice.
Methods: Members of the Argentine Society of Hematology (SAH) reported the data obtained from clinical histories of patients with NMP treated with HU. We analyzed, reason for treatment initiation, response, frequency of thrombosis, intolerance rate, resistance and mortality with descriptive statistics. Complete remission was considered for those patients with PV with Hto <45% and with TE with platelets <400000/mm^3 sustained for 12 weeks.
Results: We included 419 patients referred by members of the SAH, diagnosed from 1986 to 2017, of which 417 were analysable, with a median follow-up of 67 (1-372) months; 63% female, mean age 63 years (SD 13.67), 206 patients with PV (49%), 180 TE (43%) and 31 FM (7.4%) Bone marrow biopsy was performed at 81%. Mutations were studied in 80.2%: JAK2V617F POS in PV (90.7%), TE (80%), MF (64%). Of 22 pac JAK2V617F NEG: 9 were CALR type 1 and 6 type 2, 4 MPL POS and 9 triple NEG. Splenomegaly was found in 43.2%. They received aspirin 81.3%. The reason for starting treatment was age (51%), followed by the presence of vascular risk factors (26.6%), thrombocytosis (24.7%) and previous thrombosis (16.8%). 62 patients had venous thrombosis, 48 prior to HU, 8 patients with 2 or more events, 16 had thrombosis with HU. 58 had arterial thrombosis (CVA, TIA, AMI) 48 were previous to HU, 11 during the treatment. 22 patients (20.2%) with major bleeding during HU treatment. Among the patients with PV, 61% maintained Hto less than 45%, and 66% of patients with ET achieved platelets less than 400,000 / mm3. A total of 136 patients (32.6%) with adverse events were reported, the most frequent were cutaneous, cytopenias and gastrointestinal symptoms. The incidence of neoplasms was 1.9%,t refractoriness 5% and 3.8% were intolerant. Progression to AML in 1.6% and to MF 2.6%. The progression-free survival was 282 months. The mortality was 4.8%. The overall survival was 295 months.
Summary/Conclusion: We can conclude that HU was effective in obtaining complete remissions in PV and ET, in reducing the risk of thrombosis. There were frequent side effects, mainly cutaneous ulcers, and a low rate of resistance / intolerance, progression and development of secondary neoplasia. The results obtained show that the evolution and complications of patients with PV JAK2 and JAK2 positive TE are similar and that the low rate of progression is probably related to the follow-up time, since this is directly proportional to the course of each decade of the disease and treatment. The active participation of the members of the SAH in the collection of data provides the basis for the creation of a prospective registry of MNP and the accomplishment of collaborative works within the framework of the SAH in the country and eventually in the region.

PB2275

CONDITIONAL PROBABILITY OF DELAYED RESPONSE IN SYMPTOM AMELIORATION DURING RUXOLITINIB TREATMENT OF PATIENTS WITH MYELOFIBROSIS

S. Koschmieder[1], L. Jacobasch[2], T. Geer[3], C. Schulte[4], J. Wehmeyer[5], B. Gröschl[6], S. Großer[6], R.A. Mesa[7], H.L. Pahl[8,*]

[1]Hematology / Oncology, University Hospital Aachen, Aachen, [2]Onkologische Schwerpunktpraxis, Dresden, [3]Medizinische Klinik III, Diakonie-Klinikum Schwäbisch Hall, Schwäbisch Hall, [4]Gemeinschaftspraxis für Hämatologie & Onkologie, Dortmund, [5]Gemeinschaftspraxis für Hämatologie und Onkologie, Münster, [6]Novartis Pharma GmbH, Nürnberg, Germany, [7]Mays Cancer Center, UT Health San Antonio MD Anderson, San Antonio, United States, [8]Hematology / Oncology, University Hospital Freiburg, Freiburg, Germany

Background: In patients with myelofibrosis (MF), ruxolitinib has proven effective in ameliorating symptoms such as night sweats, itching and abdominal discomfort. Responses are frequently seen within the first month of treatment. To date, however, data on symptom improvement has been reported as decreasing means of symptom scores over time in large patient cohorts. By nature, these data cannot address critical questions arising in clinical practice: if a patient fails to show symptom improvement within the first month or the first three months of treatment, what are the chances that he or she will still respond if treatment is continued?
Aims: Therapeutic decisions for individual patients may therefore be better informed by knowledge of conditional probabilities.
Methods: We thus used conditional probability algorithms to analyze symptom improvement in patients enrolled in the JaKoMo trial, a phase IV prospective, non-interventional study of MF patients receiving ruxolitinib therapy. Symptom burden was measured by the Total Symptom Score (TSS) of the MPN-SAF (Myeloproliferative Neoplasm - Symptom Assesment Form), a scale that measures 10 items and can range from 0-100.
Results: Data at baseline, one month, three and six months follow up were available for 192 MF patients. At baseline, JaKoMo patients reported a TSS of 29.9. Two separate response analyses were conducted. In a first study, response was defined as a change of at least 5 points in the TSS. Following a month of ruxolitinib treatment, 105 (55%) of patients responded by decreasing the total symptom score by 5 points or more. Importantly, of the remaining 87 patients, 23 patients (26.4%) responded during the fol-

lowing 2 months, and these responses were maintained for at least the following 3 months. Of the 64 of patients that had not responded by 3 months, a further 8 (13%) responded at 6 months. We subsequently used a more stringent criterium to define response, a decrease of at least 50% in the TSS of an individual patient. By this criterion, 62 patients (32%) responded following 1 month of treatment, while 130 patients (68%) did not. Of these 130 patients, 26 (20%) responded following two more months of treatment. Likewise, of the 104 remaining patients without a response until 3 months, 17 (16%) responded during the following 3 months. An important strength of our study is that the JaKoMo patient cohort is recruited largely from office-based hematologists, which renders the data more broadly applicable than studies conducted in selected, academic hospital settings.
Summary/Conclusion: Our data demonstrate that a subset of MF patients will experience relief from symptoms under continued ruxolitinib therapy, even if improvement was initially not observed during the first 4 to 12 weeks of treatment. Given the potential myelosuppressive effect of ruxolitinib, these data may be used to weigh risks and benefits in informing therapeutic decisions.

PB2276

IMMUNOHISTOCHEMISTRY AS A TOOL TO DETECT CALRETICULIN MUTATION IN PATIENTS OF PRIMARY MYELOFIBROSIS AND ESSENTIAL THROMBOCYTHEMIA AND ITS COMPARISON WITH POLYMERASE CHAIN REACTION

A. Gupta*, S. Sazawal, M. Mahapatra, H. Pati, S. Tyagi, R. Saxena

Haematology, All India Institute of Medical Sciences, New Delhi, New Delhi, India

Background: Philadelphia negative myeloproliferative neoplasms pose a significant diagnostic challenge. About 30-45% patients of Primary Myelofibrosis (PMF) and Essential Thrombocythemia(ET) are also negative for JAK2 mutation. In recent times calreticulin (CALR) mutations have been identified which can characterise about 50-80% of such patients. However, the heterogeneity of calreticulin mutations demand extensive molecular testing which are not widely available, labour intensive, costly and time consuming. To overcome these limitations immunostaining by immunohistochemistry(IHC) was developed to detect calreticulin mutations.
Aims: 1. Detection of calreticulin mutation by allele specific oligonucleotide (ASO) PCR and IHC in patients of JAK2 negative primary myelofibrosis and essential thrombocythemia; 2. To determine the sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of IHC when compared to PCR.
Methods: This is a prospective observational study. We included all suspected cases of PMF and ET both clinically and on bone marrow examination. Cases with positive BCR-ABL and JAK2 V617F mutation were excluded. Eligible cases were screened for CALR mutation by ASO-PCR for type 1 and type 2 mutations. Interpretation was done by comparing bands on gel electrophoresis to the expected product size (wild type CALR: 357bp, CALR type 1 mutation: 302bp and CALR type 2 mutation: 272 bp). For all these cases IHC was simultaneously done on the bone marrow biopsy section using monoclonal CAL2 antibody. Those cases with more than 90% strongly labelled megakaryocytes were taken as positive.
Results: A total of 61 patients were suspected to have PMF or ET on clinical and bone marrow examination. All these patients were negative for BCR-ABL fusion transcript. On further analysis 36 patients were found to have JAK2V617F mutation and were excluded from the study. Remaining 25 cases were analysed for CALR mutation by PCR and IHC. Amongst the 14 cases with positive CALR mutation, 12 were positive by both PCR and IHC. However, two patients who were CALR positive by PCR showed negative immunostaining by IHC. Remaining 11 cases reported negative for CALR mutation by both PCR and IHC. On statistical analysis of IHC performance, we found a sensitivity of 85.71% and specificity of 100% at 95% confidence interval. The positive predictive value (PPV) and negative predictive value (NPV) were 100% and 84.62% respectively.
Summary/Conclusion: IHC is a readily available and less labour-intensive method to identify CALR mutations in patients with PMF and ET with high sensitivity and specificity. In resource limited settings, immunostaining with CAL2 monoclonal antibody may serve as a valuable tool for diagnosing patients with PMF and ET. Limitation of study: The two cases with positive PCR result and negative IHC need to be evaluated by sanger sequencing to exclude the possibility of false positive PCR.

PB2277

COEXISTENCE OF JAK2V617F AND CALR MUTATIONS IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA IN A SINGLE CENTER

M. Saez-Perdomo[1,2,*], E. González Pérez[2], S. Sánchez Sosa[1,2], Y. Florido Ortega[2], C. Bilbao Sieyro[2,3], R. Stuckey[2], S. de la Iglesia Iñigo[2], A. Sáez Salinas[2], G. Santana Santana[2], A. Segura Diaz[2], M.T. Molero Labarta[2,4], M.T. Gómez Casares[2]

[1]Universidad de Las Palmas de Gran Canaria, [2]Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, [3]Morfology, [4]Ciencias médicas, Universidad de Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain

Background: Classic BCR-ABL1-negative MPNs include PV, ET, and PMF with JAK2V617F as the most common mutation. JAK2V617F can be detected in about 95% of patients with PV while the remaining 5% of PV patients carry a somatic mutation of JAK2 exon 12. Approximately one-third of patients with ET or PMF do not carry any mutation in JAK2 or MPL. In December 2013, mutations were described in CALR in 67–71 and 56–88% of JAK2 and MPL negative patients with ET and PMF, respectively. Various studies have found differences in the clinical features of patients with CALR mutations compared with those harboring JAK2 mutations, such as a lower risk of thrombosis, lower hemoglobin and leukocyte counts, higher platelet count and longer survival for CALR-mutated ET patients. CALR mutations have been reported to be mutually exclusive with JAK2V617F or MPL mutations. However, recently, a few studies have reported the coexistence of JAK2 and CALR mutations in MPN.
Aims: The aim of the study is to evaluate the coexistence of CALR and JAK2 in our center.
Methods: Our series consisted of 122 ET patients, 88 females and 34 males, diagnosed between 1996 and 2017 with a mean age at diagnosis of 56.62±17.65. JAK2 mutation screening was carried out using real time PCR with FRET probes and CALR and MPL analysis using high resolution melting. Mutations were confirmed by Sanger sequencing (ABI 3130 Thermo Fisher).
Results: Among the 115 ET patients studied for the presence of the 3 mutations we found 40.9% (n=47) JAK2+/MPL-/CALR-, 12.2% (n=14) JAK2-/MPL-/CALR+, 44.4% (n=51) JAK2-/MPL-/CALR-, 1.7% (n=2) JAK2+/MPL-/CALR+ and 0.8% (n=1) JAK2-/MPL+/CALR-. Both patients JAK2+/CALR+ presented clinical features similar to the others patients with ET due to a history of gradual elevation of platelet counts. These 2 patients had no associated symptoms, splenomegaly or previous hemorrhagic or thrombotic episodes. The peripheral blood count for one of these patients had a plt count of $1018x10^6$/L, hgb 13.7g/dl, WBC count $12.22x10^9$/L and was considered IP low risk; the other patient had a plt count of $523x10^6$/L, hgb 12.5g/dl and WBC count $6.05x10^9$/L, with a recent diagnosis as IP high risk. Both patients were treated with acetylsalicylic acid. One of them progressed to MF after 7 years of being diagnosed and both are still alive.
Summary/Conclusion: Since CALR mutations discovery, their presence has been proposed to be mutually exclusive with JAK2 and MPL mutations. However, CALR and JAK2 co-mutations have been reported in a few MPN cases across different ethnic groups with a frequency of around 1%, which agrees with the incidence of our series (1.64%), although 2 groups have reported frequencies higher than 4% in Asian patients. To date, we have not observed the coexistence of MPL and CALR/JAK mutations in any MPN patient. This discrepancy could either be due to differences in methodology for the detection of *CALR* mutations, a different mutational spectrum in Caucasian and Asian populations, or the fact that the majority of groups follow a diagnostic workup flow for MPN with the assumption that mutations are mutually exclusive. Co-mutated patients might represent a new subtype in MPNs; in fact, many groups have suggested that *JAK2/CALR* double positive might have a different phenotype and clinical course, distinct from *JAK2*-positive or *CALR*-positive subgroups. Thus identification of the true frequency of these patients is important for defining the prognosis, risk factors and outcomes of these MPN subgroups. Our results suggest that these mutations should be analyzed independently and simultaneously at diagnosis in all MPN patients.

PB2278

INTRODUCTION OF AN NGS GENE PANEL INTO CLINICAL SERVICE FOR MYELOPROLIFERATIVE NEOPLASMS

A. Skowronska*, J. Bryon, S. Clokie, Y. Wallis, J. Mason, K. Reay, C. Corbett, M. Griffiths

West Midlands Regional Genetics Laboratory, Birmingham Women's and Children's NHS Foundation Trust, Birmingham, United Kingdom

Background: In the West Midlands region of the UK, all patients with a suspected myeloproliferative neoplasm (MPN) have access to quantitative analysis of *JAK2* V617F by droplet digital PCR as standard of care. The British Committee for Standards in Haematology recommends that suspected MPN cases have investigation of *JAK2* exon 12, *CALR* and *MPL* genes if *JAK2* V617F is negative.

Aims: The aim of the project was to improve the MPN service by substituting sequential analysis of individual target regions within the *JAK2, CALR* and *MPL* genes with a single assay, and to increase the number of genes available for analysis.
Methods: A commercial next generation sequencing (NGS) gene panel (Oxford Gene Technology, SureSeq Myeloid Panel), coupled with the Illumina MiSeq platform was validated and implemented. The gene panel utilises hybridization based enrichment technology and consists of 25 MPN–related genes. During the validation stage the following were enriched and analysed: 29 positive control samples with 30 known pathogenic variants, 30 negative control samples without known pathogenic variants in the *JAK2, CALR and MPL* genes, and 24 MPN samples of unknown mutational status. Thus so far over 1500 clinical samples have been analysed and reported since the service was introduced in October 2016.
Results: The panel has successfully identified: a large range of known pathogenic variants at high sensitivity (*JAK2* V617F variant allele frequency 1%, *CALR* Type I frameshift variant allele frequency 3%), a potential alternative driver mutation in a known low level *JAK2* V617F positive patient, a rare *MPL* exon 4 pathogenic variant and also the detection of low level *CALR* pathogenic variants, which would not have been detected by Sanger sequencing analysis. In one patient the panel identified the presence of two different *JAK2* exon 14 pathogenic variants in cis (*JAK2* V617F and *JAK2* C618R). The *JAK2* C618R prevented the hybridization of the probe binding site of the *JAK2* V617F ddPCR assay which had led to a false negative result by ddPCR. The validation procedure also explored coverage and limits of sensitivity, potential chemistry specific artefacts and identified common polymorphisms for all 25 genes.
Summary/Conclusion: The panel has replaced the current sequential analysis of *CALR, MPL* and *JAK2* exon 12 in *JAK2* V617F negative patients and reduced turn-around-times with increased accuracy and sensitivity compared to Sanger sequencing and fragment analysis. Our current clinical service operates on a two tier system whereby clinicians can request analysis of the full 25 gene panel or a 4 gene subset (*JAK2, CALR, MPL, CBL* as an *in silico* analysis).

ADULT ONSET LANGERHANS CELL HISTIYOCYTOSIS: A SINGLE CENTER EXPERIENCE

E. Arslan Davulcu[1,*], Y. Ulusoy[1], H. Bülbül[1], N. Soyer[1], S. Kamer[2], F. Şahin[1], F. Vural[1], M. Tobu[1], N. Özsan[3], M. Hekimgil[3], M. Tombuloğlu[1], G. Saydam[1]

[1]Hematology, Ege University Medical Faculty Hematology Department, [2]Radiation Oncology, Ege University Medical Faculty Radiation Oncology Department, [3]Pathology, Ege University Medical Faculty Pathology Department, İzmir, Turkey

Background: Langerhans cell histiyocytosis (LCH) is a rare disease of histiocytes that is more prevalent in childhood. The etiology is unknown. Any organ or system may be affected in LCH. Bones, skin, and pituitary gland are frequently involved. Clinical presentation may be diverse according to the organ affected. Treatment modality depends on the extent of the disease. With mild symptoms and no risk organ involvement methotraxate, azathiopurin, thalidomide can be used or patient can be carefully observed without therapy. Symptomatic and mutisystemic LCH with or without risk organ involvement require chemotherapy.
Aims: Our aim is to evaluate clinical characteristics and outcome of adult onset LCH patients in our instutition.
Methods: We retrospectively evaluated adult patients diagnosed as LCH at Ege University Hospital between 2000-2017. All patients were screened by total bone X-ray survey and/or bone scintigraphy, abdominal and chest computerized tomography, cranial magnetic resonance imaging and some of the patients by positron emission tomography. Bone marrow aspiration and biopsy were performed in all patients in order to evaluate the possible bone marrow infiltration. Complete blood count, blood chemistry, erythrocyte sedimentation rate, coagulation studies, thyroid stimulating hormone and free T4, other pituitary gland hormones if pituitary gland is involved, and urine strip test were analyzed. Patients were stratified according to extent of the disease:Single system LCH (SS-LCH): One organ or system involved. It may be uni- or multifocal,Multisystem LCH (MS-LCH): Two or more organs/systems involved.Choice of treatment, dose and duration of drugs, radiotherapy fields and dosage, side effects of the treatment modalities were recorded. Outcome of the patients were evaluated.
Results: A total of 27 patients were diagnosed and treated in our hospital. Mean age at diagnosis was 38.3 years, 19 of them were male. There were 8 patients with MS-LCH, 13 with unifocal SS-LCH, and 6 with multifocal SS-LCH. Patients' characteristics were summarized in the tables 1, 2 and 3. All of our patients are alive. There was only one treatment toxicity, diabetes insipidus, in a patient with pons and mastoid lesion after radiotherapy. Most of MS-LCH and multifocal SS-LCH patients received systemic treatment, whereas unifocal SS-LCH.

Table 1. Patient characteristics with MS-LCH.

Patient No	Gender	Age	Involved organ/tissue	Chemotherapy	Radiotherapy	Treatment toxicity	Follow-up period (years)	Outcome
1	M	36	Lung, Skin	Cladribine (6 courses)	-	-	4	Alive
2	M	40	Thyroid, Gum	Chemotherapy for concomitant thyroidpapillary carcinoma	-	-	3	Alive
3	M	32	Skin, Gum	Cladribine (6 courses)	-	-	12	Alive
4	M	38	Bone (parietal), Lung	Cladribine (5 courses)	-	-	1	Alive
5	F	47	Bone (left mandible, left tibia), Pons,Lung	-	Pons-mastoid 10x2 gy,tibia 10x2 gy	Diabetes insipidus	8	Alive
6	F	47	Bone (left parietal, left femur), Skin	Cladribine (6 courses)	-	-	6	Alive
7	F	24	Bone (right femur), External ear (right)	-	10 GY for femur,10 gy for ear	-	6	Alive
8	M	24	Bone (Right frontal, right femur), Lung	Cladribine (6 courses)	5x190 cgy for frontal bone,1080 gy for femur	-	3	Alive

Table 2.

Summary/Conclusion: LCH is a rare and heterogeneous disease of adult patients. Systemic evaluation is crucial because treatment desicion depends on organ-tissue involvement. Treatment should be individualized and multi-disciplinary in order to reach good outcome.

PB2280

MORBIDITY AND MORTALITY OF PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS: A TERTIARY CENTER EXPERIENCE

E. Papadakis, V. Papadopoulos*, K. Kokoviadou, A. Banti, A. Kioumi

Hematology Department, Papageorgiou General Hospital, Thessaloniki, Greece

Background: The main causes of morbidity and mortality in patients with myeloproliferative neoplasms are thrombohemorrhagic events in polycycthemia vera (PV) and essential thrombocythemia (ET) and transformation to acute leukemia (most frequent in primary myelofibrosis – PMF) (Frederiksen *et al.* Blood 2011;118:6515). The introduction of tyrosine kinase inhibitors (TKIs) has changed the clinical course of chronic myeloid leukemia (CML) from a slowly progressive disease into a chronic one with near-normal life expectancy (Bower *et al.* JCO 2016;34:2851). Moreover the cardiovascular complications of TKIs have raised concerns about their effect on hemostasis (Moslehi *et al.* JCO 2015;33:4210).
Aims: The aim of the study is to assess the incidence of the main causes of morbidity and mortality collectively in patients with MPNs.
Methods: A retrospective study was conducted in patients with MPNs in a tertiary center. Mortality rates were calculated, as well as incidence rates for thrombotic and hemorrhagic events, transformation to acute leukemia and occurrence of solid tumors.

Results: A total of 224 patients, with median age at diagnosis 64.5 years (range 17-92) were included in the analysis. The initial diagnosis was CML (13%), ET (51%), PV (28%), PMF (5%) and myeloproliferative/myelodysplastic syndrom in 2%. Mean duration of follow-up was 8 years. In 20% of patients the presenting symptom was a thrombotic episode (arterial, venous or splenic infarct). During the follow-up, 83 events of interest were recorded. In the whole cohort, the incidence rate (in events per 100 patients per 10 years) of thrombosis was 13.42, hemorrhage 1.68, transformation to another hematologic malignancy 11.74, occurrence of solid tumor 5.59 and other events 13.98. Other events for which patients received medical attention included atypical chest pain, joint pain, arrythmias, pleural effusion and infections. Incidence of major events per diagnosis are presented in table 1. Cumulative incidence of thrombotic complications is illustrated in figure 1.

Table 1. Incidence rate (per 100 patient-years) and 95% confidence interval (CI) for the major events during follow up for different myeloproliferative neoplasms.

	CML	ET	PV	PMF
Thrombosis	2.39 (0.9-6.3)	1.27 (0.75-2.13)	1.29 (0.58-2.85)	0
Hemorrhage	0	0.27 (0.09-0.84)	0	0
Hematological malignancy	0.6 (0.08-4.2)	0.82 (0.43-1.56)	1.07 (0.45-2.57)	2.21 (0.32-15.37)
Solid tumor	0.6 (0.08-4.2)	0.36 (0.14-0.96)	1.07 (0.45-2.57)	0

All-cause mortality rates in deaths per 100 patient-years (95% CI) were for CML 1.8 (0.6-5.5), ET 0.9 (0.5-1.7), PV 1.9 (1-3.7), PMF 6.6 (2.2-19.8). Transformation to acute leukemia accounted for 46.7% of all deaths, solid tumors for 16.7% and other causes (cardiac death, sepsis) for 33.3% of deaths. All patients with atypical CML or other myeloproliferative/myelodysplastic syndrom died at a median of 16.4 months from diagnosis, while their disease had transformed to AML at a median of 14 months from initial diagnosis.

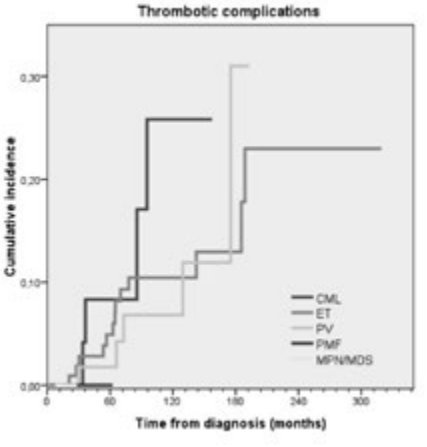

Figure 1.

Summary/Conclusion: Thrombotic complications account for the main burden of morbidity not only in patients with ET and PV, but also for CML patients on TKIs. Transformation to acute leukemia is the leading cause of death. It is crucial that future studies incorporate cardiovascular risk factors and estimate the effect of therapeutic interventions in both the thrombotic risk and the progression free survival.

PB2281

HETEROGENEITY AMONG DIFFERENT MYELOPROLIFERATIVE NEOPLASMS ASSOCIATED WITH SPLANCHNIC VEIN THROMBOSIS

D. Cattaneo[1,*], N. Orofino[1], C. Bucelli[1], V. Mattiello[1], P. Bianchi[1], U. Gianelli[2], A. Cortelezzi[1], A. Iurlo[3]

[1]Hematology, IRCCS Ca' Granda - Maggiore Policlinico Hospital Foundation, [2]Pathophysiology and Transplantation, University of Milan, and IRCCS Ca' Granda Maggiore Policlinico Hospital Foundation, [3]Hematology, IRCCS Ca' Granda Maggiore Policlinico Hospital Foundation, Milano, Italy

Background: In *BCR-ABL1*-negative myeloproliferative neoplasms (MPNs) incidence of major thrombotic events ranges from 1.75 to 5.5% events patient-years according to the specific MPN subtype. Venous thrombosis account for about 30-40% of these complications and can occur also at unusual sites, including the splanchnic circulation (SVT) with a prevalence ranging between 1 and 23%.
Aims: To evaluate differences in MPNs associated with SVT.
Methods: We reported a consecutive monocentric series of 38 patients with a diagnosis of *BCR-ABL1*-negative MPN, who developed a SVT at diagnosis or during the follow-up between 1979 and 2016.
Results: We identified 18.4% of PV, 26.3% of ET, 34.2% of MF and 21.1% of MPN-U. The latter were all diagnosed at the time of SVT onset, and characterized most frequently by a PV- or PMF-like bone marrow morphology but lacked the clinical phenotype required for a complete diagnosis. The majority of the cases (81.5%) bear *JAK2*V617F mutation; however, five patients were characterized by other molecular markers, *i.e. MPL* mutations in three patients, and *CALR* type 1 mutation in the remaining two cases. Among patients with a previous diagnosis of MPN who developed SVT during the follow-up, a cytoreductive treatment was already on-going in 53.8% of the cases, whereas it was then started in all but four of the remaining cases, due to young age and a blood cell count in the normal range or even below. After thrombotic index event, anticoagulants were started in 29 patients (76.3%), including six cases (15.8%) with direct oral anticoagulants (DOACs). At a median follow-up from MPN diagnosis of 12.3 years, six deaths were recorded: it was due to leukemic transformation in four patients, intracranial bleeding and infectious complication in one patient each. According to the literature, 44.7% of the patients in our series suffered from recurrent vascular events, either involving the arterial (21.1%), or the venous district (23.7%): in particular, five patients experienced a recurrent SVT.
Summary/Conclusion: In this report patients with a diagnosis of MPN-U seem to represent a distinct clinical entity when compared to the other MPN subtypes. In particular, in all MPN-U cases, SVT was the initial manifestation which led to the diagnosis of the underlying MPN. They were all characterized by the presence of *JAK2*V617F mutation, except one case which bear an *MPL*W515L mutation, and showed a normal karyotype. In addition, any of these patients neither developed clinical features which could enable physicians to re-classify them among one of the so-called classical MPN subtype even according to the WHO 2017 classification, nor experienced a leukemic evolution. Being aware of the limits of the present study, we can speculate that SVT associated with MPN-U represents a disease with a more indolent course as compared with other cases associated with full-diagnosed MPNs which more frequently developed during the follow-up. Notably, all the cases of leukemic transformation were reported among patients with a previous MF diagnosis after a median follow-up of 17.9 years. Furthermore, about half of our patients developed recurrent vascular events, confirming the limited efficacy of conventional therapeutic approach in these particular patients. However, it is interesting to underline that none of the six patients treated with DOACs developed another thrombotic complication, so probably representing a more valid strategy in this setting.

PB2282

THE EPIDEMIOLOGY AND PRESENTING CLINICAL CHARACTERISTICS OF MYELOPROLIFERATIVE NEOPLASMS IN MALAYSIA

Y.Y. Yap[1,*], J. Sathar[1], K.B. Law[2], S.C. Edmund[2]

[1]Department of Haematology in Ampang Hospital, [2]Clinical Research Centre, Ministry of Health, Ampang, Malaysia

Background: The evolution of molecular studies in myeloproliferative neoplasms (MPN) has enlightened us the understanding of this complex disease consisting of polycythaemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF). The epidemiology is well described in the western world but not in Asian countries like Malaysia.
Aims: To research the epidemiology of MPN in Malaysia in correlation with the clinical parameters and molecular studies.
Methods: This national registry of MPN was conducted from year 2009 to 2015 in Malaysia with description of clinical demographic in correlation to JAK2 V617F mutation, thrombosis, haemorrhagic complications and blood counts.
Results: A total of 1010 patients were registered over a period of 5 years. The mean age was 54 years with male predominance. The ethnic distribution revealed that Chinese had a relatively high weighted incidence proportion (43.2%), followed by Indian (23.8%), Malay (15.8%) and other ethnic groups (17.2%). The types of MPN reported were 40.4% of ET (n=408), 38.1% of PV (n=385), 9.2% of PMF (n=93), 3.1% of hypereosinophilic syndrome (HES) (n=31) and 7.9% of unclassifiable MPN (MPN-U) (n=80). Splenomegaly was only palpable clinically in 32.2% of patients. The positive JAK2 V617F mutation was present in 644 patients with 46.6% in PV, 36.0% in ET, 9.0% in PMF, and 7.4% in MPN-U, and had significantly

lower haemoglobin (p<0.001), haematocrit (p<0.001) and white blood cells (WBC) (p<0.001) than those with negative mutation. Significant differences in platelet and WBC count were detected in ethnic groups and MPN subtypes. There were more arterial thrombosis events seen in those with JAK2 V617F mutation as compared to venous thrombosis events (23.1% *vs* 4.4%). The bleeding rate was only 6.6%. Among the risk factors, previous thrombosis, old age (≥60 years) and hypertension were significantly correlated to positive JAK2 V617F mutation. The arterial thrombosis event is associated with higher presenting HB, HCT and PLT while the bleeding event is associated with lower presenting HB, HCT but higher PLT. The presence of JAK2 V617F mutation is associated with higher risk of arterial thrombosis.

Summary/Conclusion: Chinese ethnicity is associated with higher rates of MPN. The previous history of thrombosis, old age (≥60 years) and hypertension are risk factors that can be corelated to JAK2 V617F mutation in MPN patients. This study is instrumental for policy makers and funding agencies to ensure preventive strategies can be implemented in future.

PB2283

THE EVALUATION OF OXIDATIVE STRESS IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA AND VASCULAR EVENTS

M.-A. Gaman[1,*], C. Moisa[2], A.M. Gaman[3,4]

[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Bucharest, [2]Hematology, Emergency County Hospital Slatina, Slatina, [3]Pathophysiology, University of Medicine and Pharmacy of Craiova, [4]Hematology, Filantropia City Hospital of Craiova, Craiova, Romania

Background: Essential thrombocythemia (ET) is characterized by stem cell-derived clonal myeloproliferation with mutually exclusive "driver" mutations (JAK2, CALR, and MPL). Patients with ET have a high risk of thrombotic and hemorrhagic complications, and also a high risk of leukemic transformation. Increased levels of oxidative stress have been reported in patients with hematological disorders, including essential thrombocythemia. We previously reported that JAK2V617F-positive cases registered higher values of reactive oxygen species than healthy controls. Higher levels of oxidative stress markers have also been found in patients with essential thrombocythemia that also associated vascular events.[1-9]

Aims: To evaluate the antioxidant capacity in patients with ET and to observe if JAK2V617F-positive cases associate a lower antioxidant capacity and a higher risk for vascular events.

Methods: We evaluated 27 Romanian patients diagnosed with ET according to the 2016 revised WHO criteria. Informed consent was obtained from all patients enrolled. JAK2V617F mutation was detected by allele specific PCR testing. The antioxidant capacity was measured using a multidetection microplate reader FLUOstar Omega and a Sigma-Aldrich detection assay kit. Results were compared both to healthy controls and to each other. We compared the parameters of patients with ET and vascular events *versus* patients with ET and no vascular events. The exclusion criteria of this study were the presence of any condition associated with an increased oxidative stress status or the use of exogenous antioxidants. Statistical data analysis was performed using the student T-test (p-value ≤0.05 considered statistically significant).

Results: The study group involved 15 females and 12 males (median age=54 years). Eight patients had vascular events: six patients had arterial or venous thrombosis (one of them associated thrombophilia) and two patients had hemorrhage. Fourteen patients were JAK2V617F-positive. All patients with vascular events were JAK2V617F-positive. All patients with ET had a lower antioxidant capacity compared to healthy controls (p≤0.05). The antioxidant capacity was significantly decreased in patients with ET and vascular events compared to patients with ET and no vascular events (p≤0.05). The patients with arterial thrombosis associated the presence of JAK2V617F, older age at diagnosis, leukocytosis, higher hemoglobin levels, and a lower antioxidant capacity (p≤0.05).

Summary/Conclusion: In our study group, ET patients had a lower antioxidant capacity than healthy controls. The history of vascular in ET patients was associated with a lower antioxidant capacity than ET patients with no previous vascular events or healthy controls. We may hypothesize that, via a decreased antioxidant capacity, oxidative stress is related to vascular events in ET in addition to the JAK2V617F status.

IDENTIFICATION OF NEW CALR AND ASXL1 MUTATIONS IN PATIENTS WITH MYELOFIBROSIS BY TARGETED NGS PANEL

T. Subbotina[1,2,*], P. Nicolaeva[1], M. Mikhalev[3,4], M. Smelyanskaya[5], N. Oreshkova[1,6], R. Shaikhutdinova[1], E. Dunaeva[7], K. Mironov[7], G. Shipulin[7], V. Khorzhevskyi[4,8], A. Petkevich[9], V. Govorovskiy[10], V. Lutynskiy[10]

[1]Siberian Federal University, [2]The Federal State-Financed Institution Federal Siberian Research Clinical Centre under the Federal Medical Biological Agency, [3]Municipal Budget Health Service Institution «City Clinical Hospital № 7», [4]Krasnoyarsk branch of the Federal State budgetary Institution «National Research Center for Hematology» Department of Health, [5]Krasnoyarsk regional hospital, [6]Sukachev Institute of Forest, Siberian Branch of Russian Academy of Sciences, Krasnoyarsk, [7]Federal Budget Institute of Science «Central Research Institute for Epidemiology», Moscow, [8]Krasnoyarsk State Regional Bureau of Pathology, Krasnoyarsk, [9]N. N. Blokhin Russian Cancer Research Center, [10]Algimed Ltd, Moscow, Russian Federation

Background: There are well-known somatic driver mutations in genes JAK2, MPL, CALR associated with Ph-negative myeloproliferative neoplasms (MPN). Also somatic mutations in other genes (ASXL1, TET2, etc) are involved in the formation of the disease phenotype. Probably, there are some new mutations associated with MPN.

Aims: To carry out an advanced search for mutations in JAK2, MPL, CALR and ASXL1 using a next-generation sequencing–based method, with a MYELOID TUMOR SOLUTIONTM BY SOPHiA GENETICS panel for the patients with primary myelofibrosis (PMF).

Methods: 4 patients with PMF were included in this study, their written informed consent for scientific evaluations were obtained. The diagnosis of all patients was confirmed by bone marrow trephine biopsies histological examination. Amplicon libraries were prepared by Myeloid Solution sequencing panel (SOPHiA GENETICS, Switzeland) and paired-end sequencing runs were performed on a MiSeq (Illumina, USA). MiSeq Reagent Kit v3 (600-cycle, Illumina) was used for direct sequencing. Dry bench was performed by SOPHiA DDM. In order to confirm the variants in ROI Sanger or pyrosequencing were performed.

Table 1.

Table 1. Characteristics of 4 patients with PMF

№	Age of manifestation (years)	Sex	Disease	HU	Duration of the disease (mo)	Driver MPN mutations (allele burden, %)	ASXL1 mutations (allele burden, %)
1	63	M	PMF	Yes	24	MPL c.1544G>T; p.W515L (75%)	New Mutation: c. 2445_2449 del GTCTC; p.L815fs*5 (24%)
2	44	F	PMF	Yes	168	New CALR Mutations: 52nt 1128_1129insCTTTGCCTC; p.Lys377 Leu fs*5 (24%) 2) c. 1031_1133 del AGA; p. Glu 341 del (24%)	c. 1934_1935 ins G; p. G646 fs*12 (35%)
3	43	F	PMF	Yes	107	JAK2 (V617F) From 40% (2014) to 80% (2017)	New Mutation: c. 1772_1773 ins AA; p. Y591 fs*1 (31%)
4	56	M	PMF→ CMML	Yes	36	JAK2 (V617F) before the burden was up to 60%, now the mutation is not detected	c. 1934_1935 ins G; p. G646 fs*12 (46%)

Results: Characteristics of 4 patients with PMF are reported in Table 1. Patient 1 carries a known driver somatic mutation of MPL and new (here and below: not yet included in the COSMIC website) mutation in ASXL1. As a result of this mutation, there is a 5-bp deletion and a 2-bp frameshift that results in a mutant protein with a novel short C-terminus. Two new monoallelic driver mutations in oncogenic region of CALR gene were found in patient 2. The new mutant CALR fragment contains all the mutant amino acid sequence of the type I mutant L367fs*46 and nine altered and mainly positively charged amino acids LCLRRRRQR, therefore this new sequence has at least the same importance for oncogenicity as the type I CALR mutation. Also this patient carries ASXL1 mutation. Patient 2 suffers from PMF during 14 years without severe complications, which possibly means that mutation in ASXL1 simultaneously with new identified CALR mutation does not influence on survival rates. Patient 3 has V617F mutation and new mutation in ASXL1. There is a 2-bp insertion and a 2-bp frameshift that results in a mutant protein with a novel short C-terminus. The patient 4 had V617F mutation before October 2017. Currently, this mutation is not

detected, which is probably due to the replacement of the V617F clone by another pathological clone. There are also somatic and germline mutations in genes KIT, SETBP1, TET, CBL, EZH2, SRSF2, which may be associated with chronic and acute leucosis (Greenman, 2007; Makishima, 2013; Hirsch, 2016) and ASXL1 mutation. Since August 2017 there is a worsening of the patient`s state and in the same time decreasing of allele burden of V617F mutation following complete extinction. There is a pathomorphologic data for transformaition of PMF into chronic meylomonocytic leucosis (CMML). Mentioned transformation is possibly intermediate step between PMF and acute leucosis partly due to epigenetic status caused by ASXL1 mutation.
Summary/Conclusion: Newly identified mutations in CALR and ASXL1 with high probability have diagnostic and prognostic meaning for patients with MPN.

PB2285

THE MPN-10 SCORE AND DRIVER MUTATIONS IN THAI MYELOPROLIFERATIVE NEOPLASMS PATIENTS

N. Cherdchoo*, S. Kongkiatkamon, C. Polprasert, P. Rojnuckarin

Department of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand

Background: Recent advances in molecular diagnostics found that the majority of classic myeloproliferative neoplasms (MPNs) harbor characteristic driver mutations. The JAK2 protein transmits signals of various cytokine receptors, while CALR and MPL are involved only in the thrombopoietin receptor signaling. This may contribute to different cytokines-related symptoms that impact quality of life. The MPN Symptom Assessment Form total symptom score (MPN-SAF TSS) or MPN-10 score is a useful tool to assess symptom burden. However, the score has not been applied to clinical practice in Thailand.
Aims: To determine the MPN-10 scores and correlate them with clinical characteristics, genetic mutations and outcomes of MPNs patients.
Methods: The baseline characteristics, MPN-10 score and outcomes of MPNs patients diagnosed according to the WHO criteria at King Chulalongkorn Memorial Hospital, Thailand between 2014 and 2017 were reviewed.

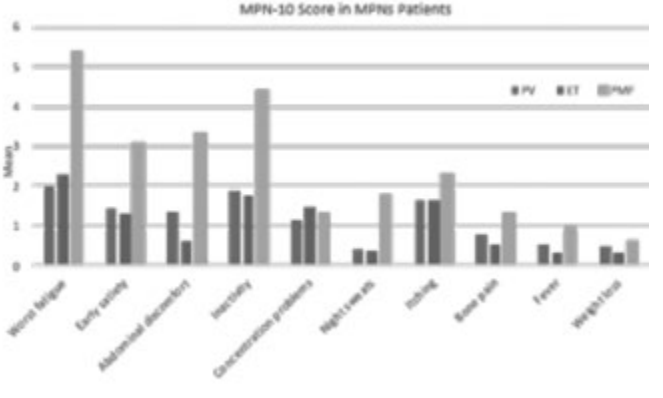

Figure 1.

Results: There were 146 patients enrolled. Forty-seven patients were diagnosed as polycythemia vera (PV), 72 as essential thrombocythemia (ET), and 27 as primary myelofibrosis (PMF). One hundred and thirty-two patients (90%) had driver mutations. PV patients harbored *JAK2V617F* mutation in 46 (97.8%) and *JAK2exon12* mutation in 1 (2.1%). ET patients had *JAK2V617F* mutation in 41 (56.9%), *CALR* mutation in 17 (23.6%), *MPL* mutation in 1 (1.3%) and triple negative mutation in 11 (15.2%), while PMF harbored *JAK2V617F* mutation in 20 (74.0%), *CALR* mutation in 4 (14.8%) and triple negative mutation in 3 (11.1%). Interestingly, the mean MPN-10 score of Thai PV and ET patients were significantly lower than those of Western population 11.7±11.4 *vs* 21.8±16.3, p=0.002, and 10.7±9.7 *vs* 18.7±15.3, p=0.0014 for PV and ET respectively. The mean MPN-10 score of Thai patients *vs* Western MF patients was 24.4±12.5 *vs* 25.3±17.2, respectively, p=0.862. In ET, the MPN-10 scores were not different between cases with *JAK2* vs. *CALR* mutations. In addition, a MPN-10 score is not associated with survival (p=0.643).
Summary/Conclusion: PMF had a higher symptom burden than PV and ET. MPN-10 scores in Thai PV and ET were significantly lower than those of Western patients. MPN-10 scores were not associated with driver mutations and could not predict survival in Thai MPNs patients.

RUXOLITINIB IN MYELOFIBROSIS: THE NORTHERN IRELAND EXPERIENCE

J. Russell[1,*], A. Daly[2], C. Arnold[2], M. Bowers[3], K. Boyd[4], R. Cuthbert[2], M. El-Agnaf[3], P. Elder[5], H. Eswedi[4], D. Finnegan[2], J. Hamilton[3], D. Hull[4], S. McCloskey[6], C. McConville[4], F. McNicholl[5], Y.-L. Ong[3], P. Windrum[6], M.F. McMullin[2]

[1]Cambridge University Hospitals NHS Foundation Trust, Cambridge, [2]Belfast City Hospital, Belfast, [3]Ulster Hospital, Dundonald, [4]Craigavon Area Hospital, Portadown, [5]Altnagelvin Area Hospital, Derry, [6]Antrim Area Hospital, Antrim, United Kingdom

Background: Ruxolitinib (RUX), the oral Janus kinase (JAK)1/2 inhibitor, is approved for treating disease-related splenomegaly or symptoms in adults with primary myelofibrosis (PMF), post-essential thrombocythaemia (PET)-MF, or post-polycythaemia vera (PPV)-MF. In March 2016, RUX was commissioned in Northern Ireland (NI) for higher-risk MF patients (IPSS 2+) and had only been available through clinical trials or special funding requests before then.
Aims: To assess the clinical outcomes of MF patients treated in NI and to compare the efficacy and safety of RUX with best alternative therapy (BAT) in the 'real-world' setting.
Methods: We performed a multicentre retrospective analysis of MF patients referred to a large tertiary cancer centre, from 1996 to 2017. Clinical data were obtained from electronic care records, laboratory and pharmacy databases. Survival analysis was estimated using the Kaplan-Meier method and standard log-rank test.
Results: We identified 47 patients, 46 of which were included in the whole cohort analysis (1 was excluded due to insufficient data). The median age at diagnosis was 65 years (35–83) and 63% were male. There were 24 (52%) PMF, 9 (20%) PET-MF, 11 (24%) PPV- MF, 2 (4%) post-myeloproliferative neoplasm-unclassified (PMPN)-MF patients, comprising 35% high-risk, 28% intermediate-2 (int- 2), 35% intermediate-1 (int-1) and 2% low risk patients. A driver mutation was detected in 89% (78% JAK 2+; 11% CALR+). The whole cohort median survival was 8.5 years (0.5–21.5). Of the 46 patients, 28 (61%) received RUX. Five were excluded from further analysis (2 had received another JAK inhibitor; 3 had stem cell transplantation). Of the remaining 41, 24 (59%) received RUX; 10 (24%) as first-line therapy. Baseline demographics were similar between patients treated with RUX or BAT. The RUX group comprised 29% high-, 38% int-2 and 33% int-1 risk patients, and had a significant 5-year overall survival (OS) advantage from time of diagnosis *vs* BAT; 77% (95% CI 53–90) *vs* 57% (95% CI 27–79); p=0.044. Median survival in the BAT group was 6.3 years for int-1, 1.4 years for int-2, and 2.1 years for high-risk patients. Median survival in the RUX group was 1.8 years for high-risk and was not reached for int-1 and int-2 risk patients. There was no survival difference between int-1 and int-2 risk RUX patients; however, int-1 risk RUX patients had a notable survival advantage *vs* int-1 risk BAT patients; 5y OS 100% *vs* 86% (95% CI 33–98); p=0.045. In the RUX group, 1y OS was 82% (58–93) with median follow-up of 14 months (1-50). The estimated discontinuation rate was 31% (95% CI 16–55) at 1 year. At the time of analysis, 10 patients had stopped RUX; 5 died, 4 progressed/no response, and 1 due to adverse effects (AE). Two (8%) transformed to acute myeloid leukaemia. The most common grade 3/4 AEs were thrombocytopaenia (25%) and anaemia (54%), with 33% requiring dose reduction or interruption. The most common non-haematological AEs were infection (42%). Data collection of spleen response and symptom control is underway but incomplete.
Summary/Conclusion: In summary, our whole cohort data demonstrate similar outcomes for MF patients treated in NI compared with contemporary clinical trials. Notably, there was a significant survival advantage for patients treated with RUX *vs* BAT in all risk groups, including intermediate-1 risk patients who at present do not meet funding criteria to receive RUX. This data must be interpreted with caution due to the limited follow-up but it suggests a potentially unmet clinical need in lower-risk MF patients that requires further study.

PB2287

THE RELEVANCE, EFFICACY AND SAFETY OF ERYTHROPOIETIC STIMULATING AGENTS (ESAS) IN ANEMIA CONTROL: A RETRO SPECTIVE ANALYSIS IN MYELOFIBROSIS PATIENTS IN A SINGLE HOSPITAL

H.N. Fernandez-Leyva[1,*], J. Arnold[1], N. Sargant[2], N. Rayman[2], R. Ashok[2]

[1]Haematology, Basingstoke and North Hampshire Hospital, winchester, [2]Haematology, Basingstoke and North Hampshire Hospital, Basingstoke, United Kingdom

Background: Primary myelofibrosis (PMF) is characterized by the dysregulated proliferation of myeloid cells including megakaryocytes and myeloid and erythroid progenitors in the bone marrow (BM), resulting in ineffective erythropoiesis and the reactive deposition of fibrous connective tissue (reticulin/collagen) often with osteosclerosis. The related myeloproliferative neoplasms essential thrombocythemia (ET) and polycythemia vera (PV) can both undergo delayed disease transformation into a fibrotic state: post-ET myelofibrosis (post-ET MF) or post- PV MF, respectively. Individuals affected by MF face unique challenges, even compared to other MPN patients.
Aims: The main aim of this study is to evaluate clinical features and hematological parameters, of patients with PMF on ESAs. The secondary aim is to assess response rates and duration of response in terms of IWG-MRT.
Methods: This is a retrospective analysis of clinical and laboratory features, ESAs treatment modalities, and outcomes of PMF patients evaluated between July 2015 until December 2017. Continuous and categorical variables were tested as SPSS Statistics analysis: We conducted a review of the medical data of the patient on ESAs Respondents were recruited via pharmacy software data. In total, **11** patients with primary MF or MF post-thrombocythemia / polycythemia vera (post-ET/PV: n=**6**) received ESAs in monotherapy for anemia (Hb <10g/dL). The concomitant use of cytoreduces treatment was allowed. According to criteria of the IWG-MRT, a favorable response is considered the cessation of the transfusion requirements in patients with transfusional dependence or the increase in Hb>2g/dL in those who were not transfused, maintained for at least 12 weeks.
Results: Patients had a diagnosed of PMF approximately 2.5 years ago. Most (59.1%) were male and predominant Caucasian population (97.6%). A total of 11 patients (64.7%) obtained clinical improvement of the anemia, after a median of 3.8 months of treatment. In the univariate analysis, the baseline factors associated with a higher probability of response were: female gender, MF post-ET/PV, leukocytes >10x10^9/L, EPO levels <125U/L, serum ferritin levels <200ng/mL, grade 1-2 marrow fibrosis and absence of cytogenetic alterations or previous transfusions. Based on the binary logistic regression analysis, the clinical factors with independent prognostic significance associated with the response were the patient's gender, the number of leukocytes and the ferritin levels. The median duration of the response was 18.2 months (IQR]: 9.5-21.4). After a median follow-up from the start of the 24-month treatment, 5 patients (29.4%) had discontinued ESAs.
Summary/Conclusion: The results of the study demonstrated that ESAs significantly improved the anaemia in about half of patients with MF and induced a durable response rates [risk ratio (RR): 2.77, 95% confidence interval (CI): 2.01–3.86, P=0.03; RR: 7.52, 95% CI: 3.81-6.2, P=0.05; respectively]. Some clinical factors can help predict the likelihood of response to treatment. An early initiation of ESAs could offer better results. The potential benefit is more significant in transfusion independent patient with baseline Haemoglobin levels of 90 g/L. A specific educational program needs to develop specifically for this population. The results of the research promote a development of comprehensive local guidelines.

PB2288

EXPRESSION OF CALRETICULIN AND CD47 IN MYELOPROLIFERATIVE NEOPLASMS

K. Boasman*, M.J. Simmonds, C.R. Rinaldi

Life Sciences, University of Lincoln, Lincoln, United Kingdom

Background: Myeloproliferative neoplasms (MPN) are chronic myeloid cancers that are characterized by the overproduction of mature blood cells, and that may evolve into acute myeloid leukaemia. In solid tumours, calreticulin (CALR) overexpression produces a pro-phagocytic signal and is counteracted by concomitant expression of anti- phagocytic CD47, reflecting an apoptosis *vs* survival mechanism.
Aims: To investigate the expression and cellular location of CALR and CD47 in patients with MPN in comparison with healthy controls.
Methods: Mononuclear cells were obtained from peripheral blood of 6 MPN patient samples (2 Polycythaemia Vera, 1 Myelofibrosis, 3 Essential Thrombocythemia), along with 3 healthy controls by FICOLL separation.Cells were fractionised into 4 compartments: Membrane, cytoplasm, cytosol and nucleus. Proteins were extracted using TRIzol extraction andCALR and CD47 protein expression was analysed by western blotting.
Results: Overall CALR expression was unchanged in MPN samples comparing with controls (3.23 *vs* 2.95 fold, respectively) (Fold changes are seen through normalization against the housekeeping protein). In contrast, CD47 significantly increased in MPN samples *vs* controls (3.66 *vs* 0.06 fold, respectively). CALR and CD47 showed similar patterns of cellular localization in controls: membrane (51% and 58.7%, respectively), cytosol (38.4% and 36.2%, respectively), cytoplasm (9.6% and 4.5%, respectively), and nucleus (1% and 0.7%, respectively). In MPN samples CALR and CD47 moved into the membrane (CALR=77.2%; CD47=66.6%) and cytoplasm (CALR=12.5%; CD47=14.8%), reducing in cytosol (CALR=5.4%; CD47=16.4%) and no changes in nuclear expression (CALR=1.3%; CD47=2.2%) were observed.
Summary/Conclusion: CD47, but not CALR, is overexpressed in patients with MPN comparing with controls. This opposes previous studies in solid tumours, which show significant increases of both CALR and CD47, suggesting a role for CD47 as a strong anti-phagocytic signal responsible for immune survival in MPN. We have also shown that in contrast to cells from healthy controls, MPN cells mainly express CALR and CD47 on the cell surface with possibly a slightly higher relative CALR expression. No differences in CALR and CD47 expression was noted in different MPN subtypes however a larger cohort of patients, treated and untreated, is required to confirm our findings and identify CALR/CD47 pattern changes in response to therapies.

FUNCTIONAL IRON DEFICIENCY AND INFLAMMATION IS COMMON IN MYELOFIBROSIS AND CONTRIBUTES TO ANAEMIA AND IMPAIRMENT OF QUALITY OF LIFE

G. Birgegård[1,*], E. Ahlstrand[2], E. Ejerblad[3], W. Ghanima[4], H. Hasselbalch[5], C. Nielsen[6], H. Knutsen[7], J. Samuelsson[8], A. Lindholm Sörensen[6,9], B. Andreasson[10]

[1]Inst for Medical Sciences, Uppsala University, Uppsala, [2]Department of Haematology, Örebro University Hospital, örebro, [3]Dept of Medical Sciences,, Uppsala University, Uppsala, Sweden, [4]Department of Research, Østfold hospital,, Østfold, Norway, [5]Department of Haematology, Zealand University Hospital, Roskilde, Roskilde, [6]Institute for Inflammation Research, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark, [7]Department of Haematology, Oslo University, Oslo, Norway, [8]Department of Haematology, University Hospital, Linköping, Sweden, [9]Department of Haematology, Zealand University Hospital, Roskilde, Denmark, [10]Department of Haematology, Specialistmedicin, Uddevalla Sjukhus, Uddevalla, Sweden

Background: Anaemia is a major problem in myelofibrosis (MF). The cause of anaemia is not completely understood. Recent studies have shown inflammatory activity in myelofibrosis. Inflammation influences iron metabolism. Cytokines upregulate hepcidin, causing a retention of iron in macrophages. This leads to sequestration of iron in the macrophages, a lowered transferrin saturation and reduced availability of iron for erythropoiesis. This is named functional iron deficiency (FID) and in malignancy is characterized by transferrin saturation (TSAT) <20% and a normal or elevated S-ferritin. FID is common in malignancies and is treatable with intravenous iron.
Aims: We aimed to investigate if FID and inflammation are common in MF and whether they may contribute to anaemia and influence Quality of life (QoL).
Methods: We recruited 80 patients with MF, 22 with ET (JAK2V617 was found in 60 and 61% in MF and ET, respectively) from 6 centers in the Nordic area. Blood values, iron variables and inflammatory markers were analyzed. Quality of life was investigated with MPN-SAF.
Results: MF 53 of the 80 MF patients were anaemic (Hb <120g/L in women, <130g/L in men). 14 of these were transfusion dependent with haemosiderosis (S-ferritin >500mg/L). These were excluded from the analysis of FID. Among the rest of the anaemic patients (n=39) FID (TSAT <20%, S-ferritin <500ug/L) was found in 35% *vs* 23.8% of non-anaemic (NS). In MF patients with FID, 70.6% were anaemic, *vs* 29.4% in patients with TSAT >20 (p=0.3). Among non-anaemic MF patients, 23.8% had a TSAT <20%, *vs* 35.3% of the anaemic patients. Hepcidin was significantly higher in patients with anaemia, 50.6 *vs* 24,4mg/L (p=0,01). 51% of women with MF had increased hepcidin levels *vs* 9% in men. There was a significant negative correlation between Hb and inflammatory markers in MF patients: TNFα, IL-6 and CRP(p<0.01 to 0.02), also LD (p=0.004) and Hepcidin (p=0.03). TSAT correlated with CRP (p<0.001). In all MF patients, hepcidin was higher in patients with S-ferritin >500mg/L (p<0.001), as was IL-6 (p=0.02), IL-2 (p=0.03), and CRP(p=0.001). For the whole group (MF+ET) there was a correlation between TSAT and QoL scores (Brief fatigue inventory (BFI) p=0.03, Total symptom score (TSS) p=0.002) as well as between inflammatory markers IL-6 and CRP and QoL scores(p=0.002-0.02 for BFI, overall QoL and TSS). Cytokine levels (IL-2, IL-6, TNFα and CRP) correlated positively with hepcidin (p values <0.001 to 0.01) in the whole group (MF+ET). **ET** In ET patients, TSAT was below 20% in 4 patients, but 3/4 had S-ferritin in the low range, indicating iron deficiency. The one ET patient with anaemia had a true iron deficiency with low S-ferritin. Only one ET patient with low TSAT could be classified as FID.
Summary/Conclusion: FID is common in MF but not in ET and patients with FID are more likely to be anaemic. MF is an inflammatory state and Hb correlated negatively with cytokine and hepcidin levels. Cytokine levels

correlated positively with hepcidin. The inflammatory activity and TSAT correlated with QoL. Our results indicate that the inflammatory state of MF disturbs iron turnover and contributes to anaemia development and impairment of QoL. FID should be sought for in anaemic MF patients. It is possible that MF patients with FID like other cancer patients may respond to IV iron.

PB2290

ESSENTIAL THROMBOCYTHEMIA AND SECONDARY THROMBOCYTOSIS IN CHILDREN OF BELARUS

T. Kozarezova*, N. Klimkovich

Department of pediatric oncology and hematology, Byelorussian Medical Academy of Post-Graduate Education, Minsk, Belarus

Background: Essential thrombocythemia (ET) is a disorder of adult-aged patients. The incidence in adults is 2/100 000 per year, but is approximately 1/10 000 000 per year in children. The low incidence recorded in children suggests that the biology of the disease could be different compared with the adult forms. Furthermore, ET can present in pediatric age as sporadic or familial diseases.
Aims: Analysis of etiology and clinical course of primary and secondary thrombocytosis in children.
Methods: Retrospective analysis was performed in 127 children (68 boys and 59 girls at the age of 5-10 years) with a diagnosis of thrombocytosis, observed between 2013 and 2017 at the Belarusian Research Center for pediatric oncology, hematology and immunology. The study was participated by all patients who were found thrombocytosis over 500x10^9/L (platelet count 680-1200x10^9/L).
Results: Among all patients, 122 children (96%) had secondary thrombocytosis (median platelet count 774 (680...940) x10^9/L), which is a result of excessive megacariopoyesis and thrombopoiesis in the course of various disorders, both hematologic and non-hematologic. The most common causes of secondary thrombocytosis were infections: viral (cytomegalovirus, parvovirus B19, herpesvirus type VI) and bacterial (Staphylococcus aureus, Proteus mirabilis, Escherichia coli, Klebsiella pneumoniae, Proteus vulgaris, Haemophilus influenzae, Streptococcus pyogenes, Streptococcus pneumoniae, Pseudomonas aeruginosa), bleeding (Crohn's disease, gastric and intestinal ulcers) and iron deficiency anemia. In all cases of secondary thrombocytosis, the platelet number normalized after curing the underlying diseases during the 2-14 month period. Other 5 patients (4%) after elimination of the relationship of thrombocytosis with taken medication and after elimination of the foci of infection in case of suspicion of primary thrombocytosis (median platelet count 1027 (925...1200) x10^9/L), performed myelogram, cytogenetic and molecular examination of bone marrow. Cytological study of the bone marrow: hypercellular bone marrow, increased proliferation of megakaryocytes (MK), with an increase in the number of large mature cells. Cells of the erythroid and myeloid lines are within normal limits. There is no shift towards unripe forms. Histological examination of the bone marrow showed an increase in the number of MK, large MK with excessive cytoplasm and a hyperbular nucleus. Molecular examination of bone marrow found a JAK2 V617F mutation in all 5 children with ET. Other types of mutations, characteristic of myeloproliferative diseases, are not identified. All patients with ET had not familial MPD. Because criteria for the treatment of ET are not specific for children, therapeutic choices are highly heterogeneous. Specific treatment included interferon alfa and hydroxyurea, and low-dose aspirin. In all the analyzed cases of ET in children, no clinical symptoms of disorders of hemostasis were ound. No patient experienced thromboembolic complications associated with thrombocytosis.
Summary/Conclusion: Myeloproliferative marker a JAK2 V617F mutation, and clonal hemopoiesis assay, are useful diagnostic tests in children with sporadic forms ET. Larger samples are obviously needed and of biologic markers to conclusions for diagnosis and treatment of ET in children.

PB2291

LONG TERM CLINICAL OUTCOMES OF MPN PATIENTS WITH JAK2, CALR AND MPL MUTATIONS IN BOSNIA AND HERZEGOVINA: 17 YEARS FOLLOW-UP

E. Islamagic[1,*], H. Komic[1], I. Eminovic[1], S. Kurtovic[2], A. Hasic[1], L. Mehinovic[1], Z. Halilovic[2], E. Suljovic Hadzimesic[2], A. Kurtovic-Kozaric[2]

[1]Faculty of Science, University of Sarajevo, [2]Clinical Center of the University of Sarajevo, Sarajevo, Bosnia and Herzegovina

Background: Philadelphia-negative classical myeloproliferative neoplasms (MPNs) are a heterogenous group of disorders characterized by cellular proliferation of one or more hematopoietic cell lines. In 2016, after revision of the *WHO Classification of Tumours of Haematopoietic and Lymphoid Tissues,* the detection of somatic mutations in three driver genes, *JAK2*, *CALR* and *MPL* was introduced as the major diagnostic criteria for MPN patients. Molecular profiling in combination with morphological and hematologic abnormalities will allow accurate evaluation of MPN subtypes and monitoring of response to the treatment.
Aims: In this study we analyzed clinical outcomes of MPN patients with detected *JAK2, CALR* and *MPL* mutations from Bosnia and Herzegovina as well as the correlation between clinical parameters, presence of the mutation and disease severity.
Methods: MPN patients (n=90) who were diagnosed in the period from January 2000 to September 2017 and treated at the Clinical Center of the University of Sarajevo Bosnia and Herzegovina, were included in this study. Patients were categorized according to four different MPN subtypes: polycythemia vera (PV, n=29), essential thrombocythemia (ET, n=40), primary myelofibrosis (PMF, n=3) and MPN-unclassifiable (n=18). Standard patients' variables were collected including full blood count, bone marrow characteristics, hepato/splenomegaly, and overall survival. qPCR was performed for *JAK2*^{V617F} detection. PCR and agarose gel electrophoresis were used for detection of *CALR* mutation including wild-type *CALR* (product: 357 bp), type 1 (product: 305 bp) and type 2 (product: 272 bp) mutations. Detection of *MPL* mutation was performed using capillary sequencing, to detect type 1 (W515L) and type 2 (W515K) mutations. Survival probabilities were estimated with the Kaplan-Meier method and compared using the log-rank test.
Results: Ninety MPN patients were enrolled in this study (50% were males). Median follow-up period was 63 months, and the median age at diagnosis was 61 years. Regarding clinical characteristics of studied cohort, 10% of patients had hypercellular bone marrow, while splenomegaly and hepatomegaly were detected in 16% (14/90) and 7% (6/90) of patients, respectively. The overall *JAK2*, *CALR* and *MPL* mutation frequencies in our cohort were 60%, 10%, and 3%, respectively. For PV patients (n=29), 76% carried *JAK2*^{V617F} mutation. For ET patients (n=29), 59% of patients were positive for *JAK2*^{V617F}, 24% of patients carried *CALR* type 1 or 2 mutation, and 3% carried *MPL* type 2 mutation, while 14% of patients were triple negative. *CALR* type 2 mutation was slightly more predominant than *CALR* type 1. In PMF patients (n=3), 33% of patients carried *JAK2*^{V617F}, 33% of patients carried *CALR* and 33% of patients carried *MPL* type 1 mutation. In the group of MPN-unclassifiable patients, 44% (8/18) carried *JAK2*^{V617F} mutation. Out of 90 patients, 18 died during the observed period of time (PV n=8, ET n= 3; PMF n=0, MPN-u n=7). In all MPN subtypes, Kaplan-Meier survival analysis showed that there were no statistically significant differences in overall survival between patients with and without detected driver mutation (p>0.05).
Summary/Conclusion: Determination of the mutational status of *JAK2, CALR* and *MPL* is important for diagnosis and treatment. We found that overall survival did not depend on the presence of the tested mutations in MPN patients.

PB2292

OXIDATIVE STRESS IN PRIMARY AND SECONDARY MYELOFIBROSIS: IS THERE A ROLE FOR THE JAK2V617F MUTATION OR EXTRAMEDULLARY HEMATOPOIESIS SITES?

M.-A. Gaman[1,*], A.M. Gaman[2,3]

[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Bucharest, [2]Pathophysiology, University of Medicine and Pharmacy of Craiova, [3]Hematology, Filantropia City Hospital of Craiova, Craiova, Romania

Background: Several studies have suggested the involvement of oxidative stress in aging and in many hematological disorders, including BCR-ABL1-negative myeloproliferative neoplasms. However, information is scarce about the oxidative status of patients with primary myelofibrosis (PMF) or myelofibrosis secondary to polycythemia vera (PV) or essential thrombocythemia (ET)[1-9].
Aims: The major aim of this study is to evaluate the levels of reactive oxygen species and the total antioxidant capacity in patients with PMF and post-ET or post-PV myelofibrosis compared to healthy volunteers (control group). The minor aim is to observe whether the presence of the JAK2V617F mutation or of extramedullary hematopoiesis (EH) sites influenced the oxidative status of the study group.
Methods: We enrolled 10 patients with PMF or post-ET/post-PV myelofibrosis, hospitalized in the Clinic of Hematology, Filantropia City Hospital Craiova, and 20 healthy volunteers (control group). Informed consent was obtained from all subjects involved. Oxidative stress was evaluated using a

CR3000 analyzer from a single drop of capillary blood. Reactive oxygen species were evaluated by FORT (Free Oxygen Radicals Testing) and the total antioxidant capacity by the FORD (Free Oxygen Radicals Defense) assays. The normal range for the FORT assay is <2.3mmol/L H_2O_2 and the normal range for the FORD assay is 1.07-1.53mmol/L. The JAK2V617F mutation was detected by amplification refractory mutation system–polymerase chain reaction. EH sites were detected using computed tomography (CT), magnetic resonance imaging (MRI), cutaneous biopsy or scintigraphy. Statistical data analysis was performed using the student T-test and a p-value ≤0.05 was considered significant.

Results: The study group involved 10 patients (median age =63.0±11.61 years, male-to-female ratio =3:7) and 20 healthy controls (median age =64.1±2.26 years). Three patients had been diagnosed with PMF and seven patients developed post-PV or post-ET myelofibrosis. In PMF, scintigraphy revealed one lienal and one renal EH site and skin biopsy revealed one cutaneous EH site. In post-PV or post-ET myelofibrosis, CT detected one osseous EH site, MRI detected one lienal EH site and both CT and MRI confirmed a hepatic EH site. Data regarding the oxidative status are presented as mean value ± standard deviation in the attached table.

Table 1.

Group	FORT	p-value	FORD	p-value
Normal range	≤ 2.300		1.07 – 1.53	
Control group	2.162 ± 0.375	p<0.05	1.405 ± 0.439	p<0.05
Study group	3.080 ± 0.553		0.535 ± 0.272	
PMF	2.567 ± 0.250	p<0.05	0.777 ± 0.232	p<0.05
Secondary MF	3.300 ± 0.500		0.431 ± 0.217	
EH +	3.150 ± 0.621	NS	0.532 ± 0.296	NS
EH –	2.975 ± 0.409		0.540 ± 0.233	
JAK2V617F +	3.433 ± 0.354	p<0.05	0.348 ± 0.072	p<0.05
JAK2V617F –	2.550 ± 0.328		0.815 ± 0.217	

Summary/Conclusion: We found an unbalanced oxidative status in the study population compared to controls: levels of FORT were increased, whereas FORD levels were decreased. Post-PV or post-ET myelofibrosis cases and JAK2V617F-positive cases had higher FORT and lower FORD values than PMF cases and JAK2V617F-negative cases (p≤0.05). The presence of EH sites did not have an impact of oxidative stress status. We may hypothesize that oxidative stress is involved in the pathogenesis of PMF and post-PV or post-ET myelofibrosis and that the presence of the JAK2V617F mutation plays a role in the increase in oxidative stress levels.

Medical Faculty, Malatya, [13]Hematology, Dr Ersin Arslan Research and Training Hospital, Gaziantep, [14]Hematology, AMU Internal Medicine, Aydin, Turkey

Background: Ruxolitinib has been approved for the treatment of patients with high- or intermediate-risk myelofibrosis with symptomatic splenomegaly. The aim of this study is to assess the efficacy and safety of ruxolitinib in patients with chronic myeloproliferative neoplasms.

Aims: The aim of this study is to assess the efficacy and safety of ruxolitinib in patients with chronic myeloproliferative neoplasms and clarify the existing treatment strategies of these patients.

Methods: Across all of Turkey, 14 centers were enrolled in the study. We retrospectively evaluated 132 patients who treated with ruxolitinib. Ethical committee aproval was obtained.

Results: Among 132 MPN patients, 72 (54.5%) of them were male, 60 (45.5%) cases were female. The median age of the patients at the time of diagnosis was 58 (26- 83). Twenty (15.2%) of the patients were post- ET MF, 32 were (24.2%) post-PV MF and 80 (60.6%) were diagnosed as PMF. There was thrombosis and bleeding history before diagnosis in 15.2% and 8.3% of the patients, respectively. Only two patients had concomitant cancer history. Antiplatelet, androgen, steroid and erythrocyte stimulating agent treatments were present in 59.9%, 12.1%, 7.6% and 2.3% patients, respectively. Splenectomy was performed only in 3.8% of the patients. There was JAK2 mutation and MPL mutation positivity in 66.9% and 14.6% of patients, respectively. Conventional cytogenetic analysis was applied in 31 patients. Twenty three patients had normal karyotype and 8 patients had complex karyotype. Leukemic transformation was observed in 6 (4.5%) patients. Only one patient was undergone hematopoietic stem cell transplantation. The median white blood cell, platelet and hemoglobin ($x10^3$/µl) counts were 10.75 (0.8- 61.3), 346 (42- 1920) and 10.8 (6. 6- 20.7), respectively. All patients had first line cytoreductive treatment. Hydroxyurea (85.2%) was the most common drug as first line treatment. Anagrelide (n=18) and interferon (n=14) were the most common drugs as second line treatment. Eight patients were used third line treatment. Interferon was the most common drug. Twenty patients were lost. Exitus reasons were pneumonia/sepsis in 10 patients, myocardial infarction (n=1), acute respiratory distress syndrome (n=1), bleeding (n=1), and cholangiocellular carcinoma (n=1) in other patients. The median dose of ruxolitinib was 30 (10- 40) mg at the beginning of the therapy. Dose change was made in 39 (43.8%) of 89 patients. Forty one (39%) of 105 patients had adverse events. Thirty five (33.3%) of 105 had hematological adverse events (n=21, anemia and n=19, thrombocytopenia). Eighteen (17.1%) of 105 patients had non-hematological adverse events. The most common events were infection (n=4), elevated liver enzymes (n=4) and fatigue (n=4). Others were zona zoster (n=2), abdominal discomfort (n=2), rash (n=1) and dizziness (n=1). Eighty eight (82.2%) of 107 patients who had constitutional symptoms were improved. The median spleen sizes before and after ruxolitinib treatment were 220 (110-350) mm *versus* 193 (110-270), respectively.

Summary/Conclusion: We observed a reduction in spleen size after ruxolitinib treatment in Turkish patients with MPN and constitutional symptoms were improved. Ruxolitinib is both safe and efficacious in Turkish patients with MPNs.

PB2294

DECITABINE AS SALVAGE TREATMENT FOR AML TRANSFORMATION OF CHRONIC MYELOPROLIFERATIVE NEOPLASM IN ELDERLY AND UNFIT PATIENTS

P. Niscola*, E. Abruzzese, A. Tendas, B. Neri, M.M. Trawinska, L. Cupelli, M. Palombi, L. Scaramucci, M. Giovannini, G. Catalano, P. de Fabritiis

Hematology Unit, S.Eugenio Hospital, Rome, Italy

Background: Myelodysplastic /myeloproliferative neoplasms, such as chronic myelomonocytic leukemia (CMML), and Philadelphia-chromosome negative chronic myeloproliferative neoplasms (MPNs) transformed to acute myeloid leukemia (AML) are associated with a poor response to available therapeutic options and a very dismal outcome, being only a minority of patients suitable for intensive chemotherapy and allogenic stem cell transplantation. Although a beneficial clinical activity by hypomethylating compounds have been suggested by some clinical studies, the role of these agents in this difficult setting has not been clearly established.

Aims: To report the outcome of 4 patients with AML transformation from essential thrombocytemia (1), polycythemia Vera (1) and JAK-2 positive CMML with bone marrow (BM) fibrosis, who were started on decitabine (25 mg/m2, 5 days every 4 weeks) at our institution between January 2015 and February 2018.

Methods: Clinical parameters, treatment and follow-up data were retrospectively collected and analyzed. There were 4 (3 male) patients with a median age of 71 (67-75). All patients were transfusion-dependent at the start of hypomethylating therapy. Abnormal karyotype (-7) were detected

in one patients whereas the remaining three showed no cytogenetic abnormalities. Previous therapies included phlebotomy (1), hydroxyurea (3) and pipobroman (1); 1 patient was treatment-naïve. The time interval from the MPNs and CMML diagnoses to AML transformation was of 10 (2-27) years.The median number of decitabine courses was 14 (11-24). Other than expected therapy related cytopenias, which were well manageable with conventional measures, treatment was well-tolerated and no remarkable side effects were recorded. Broad spectrum antibacterial and anti-fungal agents were given according to the duration and the degree of neutropenia.
Results: Responses were assessed according to 2006 IWG criteria after almost 4 courses of decitabine, Out of the 4 patients, 2 (50%) achieved complete remission (CR) and 2 (50%) a partial remissions (PR); in one of latter PR patients, the disappearance of extramedullary (nodal and lung) AML involvements was observed by six cycles of epigenetic courses. After a median follow-up of 12 (11-28) months, 2 patients, both having obtained CR and including that presenting the -7 abnormal karyotype, are still alive: overall survivals from the start of decitabine were of 11,+15,18 and + 28 respectively. Two patients progressed from the achieved PR and deceased because of clinical complications of overt AML.
Summary/Conclusion: Despite the limited number of cases, our experience reflected a real-life treatment scenario with encouraging results, given that all patients responded to decitabine which was tolerable and efficacious in elderly, comorbid and pretreated AML patients with an unfavorable prognostic profile long disease history of chronic MPNs and CMML with BM fibrosis. The efficacy of decitabine in this difficult to treat setting, although not durable in our patients who have achieved a PR, may represent an useful clinical basis for potential applications of this agent with other clinically active synergistic compounds, such as JAK2 inhibitors, are needed to improve overall outcome into future clinical trials which should include molecular profiling tools for an accurate selection of suitable patients.

PB2295

ASSESSMENT OF THE EFFICACY OF LOW-DOSE ASPIRIN BY THROMBOELASTOMETRY IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

E. Cacciola[1,*], E. Gentilini Cacciola[2], V. Vecchio[2], R. Cacciola[3]

[1]Medical and Surgical Science and ADvanced Technologies, [2]Institute of Haemostasis, Catania, Italy, [3]Experimental and Clinical Medicine, Institute of Haemostasis, Catania, Italy

Background: The essential thrombocythemia (ET) is a myeloid neoplasm characterized by platelet hyperreactivity and thrombosis. The daily low-dose aspirin (ASA) is a cornerstone in the prevention of the thrombotic events. In the ET an accelerated platelet turnover translates in a renewal of the drug target shortening the duration of cyclooxygenase (COX-1) inhibition and may dictate new dosing strategies particularly in ASA "low-responders" patients.
Aims: Therefore, we evaluated platelet count, β-thromboglobulin (β-TG) and platelet factor 4 (PF4), as markers of platelet activation, the clotting time (CT), clot formation time (CFT) and maximum clot firmness (MCF), as indicators of aspirinated platelet contribution to clot formation/firmness.
Methods: We studied 60 patients (20 men, 40 women; mean age 51 years, range 32-70) with ET according to WHO criteria. The mean duration of disease was 11 years. All patients were on ASA 100 mg once daily. Of the 60 patients, 45 were on anagrelide hydrochloride (daily dose 1.5 mg) (10 men, 35 women), 15 were on hydroxyurea (daily dose 2 mg) (10 men 5 women). None had inherited or acquired thrombotic risk factors. Sixty subjects served as controls. Platelets were measured by automated analyzer. β-TG and PF4 were determined by ELISA. CT, CFT and MCF were measured by ROTEM delta.
Results: The mean platelet count was 455±200x10^9/L. All patients had normal β-TG and PF4 (12±5 IU/ml and 4±1 IU/ml), normal CT (CT, unit: s. n.v. 100-240 s) (110±20 s), normal CFT (CFT, unit: s, n.v. 30-110 s) (45±5s) and normal MCF (MCF, unit: mm, n.v. 50-72mm) (61±2mm).
Summary/Conclusion: These findings suggest that in ET patients the daily low-dose ASA represents an optimal dosing strategy and that thromboelastometry may be an useful tool to confirm the efficacy of the low-dose ASA in ET patients.

PB2296

ESSENTIAL THROMBOCYTOSIS IN CHILDREN

C. Albayrak*, D. Albayrak

Pediatric Hematology Department, Ondokuz Mayis University Medical Faculty, Samsun, Turkey

Background: In childhood age, sporadic essential thrombocytosis is a very rare disease and its frequency has been reported as 1/1,000,000. WHO 2008 Essential Thrombocytosis Diagnostic Criteria; (iron deficiency, megaloblastic anemia, acute phase reactors, trauma, operation), absence of myeloproliferative neoplasm and thrombocytosis in the family, and the presence of thrombocytosis in WHO the absence of myeloid neoplasm criteria.
Aims: Seven cases of sporadic essential thrombocytosis diagnosed in our Pediatric Hematology Clinic were presented in this study.
Methods: Six of the patients are girls, one is a boy. Median referral age was 13 years (minimum 5 months, maximum 15 years). Application complaints; adolescent boys were found incidentally, with headache, dizziness, and tinnitus while young children had no complaints. No thrombus was detected in any patient. The median platelet count was 1442x10^9/L (963 lowest, 2438 highest).
Results: There was an increase in megakaryocytes in bone marrow aspiration, no cytogenetic abnormality. In one case Jak-2 (V617F) mutation, in two cases CALR mutation was detected. There was no mutation of MPL (W515L) in any case. One type 2 mutation known to one of the CALR mutation cases, and a new mutation that was not previously defined. No clonality was detected in the other four cases. Three cases of mutation detection and two cases of undetectable disease are followed by hydroxyurea treatment. Two other cases use low-dose aspirin. Follow-up is between six months and nine years. No complications developed.
Summary/Conclusion: Thrombocytosis is a common problem in childhood age group. Generally, reactive and secondary causes are detected. Essential thrombocytosis is a diagnosis that should come to our mind after other causes have been ruled out. Mutation studies should be carried out in children with WHO 2008 criteria. In adults, Jak-2 (V617F), CALR and MPL (W515L) mutations occur in 90% of cases, whereas in childhood, these three mutations occur only in 25% of cases. The high number of cases in which no mutation is detected indicates that new candidate genes must be searched and studied.

PB2297

THE MORTALITY OUTCOMES AND SURVIVAL PATTERNS OF MPN REGISTRY IN MALAYSIA

Y.Y. Yap[1,*], J. Sathar[1], K.B. Law[2], S.C. Edmund[2]

[1]Department of Haematology in Ampang Hospital, [2]Clinical Research Centre, Ministry of Health, Ampang, Malaysia

Background: The prognostication of myeloproliferative neoplasm (MPN) has been always challenging even in the advent of Janus kinase 2 (JAK2 V617F) molecular studies. The survival pattern of MPN in developing country like Malaysia is still awaiting discovery.
Aims: To investigate the mortality outcome in relation to demographic, clinical presentation and clinical blood parameters.
Methods: This was a retrospective national registry conducted from year 2009 to 2015 in Malaysia with description of mortality outcome in correlation to demographic, MPN subtypes, JAK2 V617F mutation, thrombosis, haemorrhagic events and blood parameters.
Results: A total of 865 patients were included for survival analysis. The mean survival duration was estimated to be 23.2 years (95% CI:20.739, 25.684). There were 154 deaths with 57.8% of males and 42.2% of females. The ethnic distribution among the decease were 50% of Malay, 40.9% of Chinese, 7.1% of Indian and 1.9% of others. JAK2 V617F was present in 61.1% while absent in 14.9% of mortality cases. The causes of death were mainly non-haematological related (55.2%) while haematological related was only 23.4%. The MPN sub-types like essential thrombocythemia (ET) had the best mortality outcome followed by polycythemia vera (PV), hypereosinophilia syndrome (HES), MPN-unclassifiable (MPN-U) and primary myelofibrosis (PMF) which was associated with odds of death of 1.2 times in comparison to others, p<0.001. The JAK2 V617F mutation had no influence in the overall survival (OS). The haemoglobin <12g/dL, haematocrit <35%, platelet <150 x10^9/dL and white blood count <5 x10^9/dL were significantly associated with the inferior OS (p<0.001). The arterial or venous thrombosis had no effect on the OS while those with bleeding events had a marginally significant better outcome (p=0.04). The grade 2 and above bone marrow fibrosis had a worse OS compared to the grade 1 and below bone marrow fibrosis. Patients presented with vasomotor symptoms were found to do better than those patients without (p=0.003).
Summary/Conclusion: The ET had the best OS while PMF had the worst OS. This is in conjunction with low blood counts, worsening bone marrow fibrosis and without vasomotor symptoms. The survival outcome of the MPN registry is instrumental for future policy development of effective healthcare in Malaysia.

PB2298

INDIVIDUALIZING PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS BY INTEGRATING GENETICS, AND CELLS COUNTS

M. Rashid*, R.Z Ahmed, U. Zaidi, T. Shamsi

National Institute of Blood Diseases & Bone Marrow Transplantation, Karachi, Pakistan, Karachi, Pakistan

Background: When evaluating classical myeloproliferative neoplasms (MPNs), the detection of Janus Kinase 2 (*JAK*2), Calreticulin (*CALR*), or Myeloproliferative Leukemia Virus Oncogene (*MPL*) mutations confirms the presence of an underlying MPN but their absence does not rule out the possibility.
Aims: The current study was to analyze the prevalence of *JAK*2 and *CALR* gene mutations in patients with MPN; secondary was to evaluate the impact of gene mutations on cell counts of MPN at diagnosis.
Methods: Our study population consisted of 90 patients with clinically suspected as MPN, 30 polycythemia (PV), 36 essential thrombocythemia (ET), 4 primary myelofibrosis (PMF) and 9 unclassified myeloproliferative neoplasms (U-MPN). Male predominance was found in PV patients 76.6%, ET patients were found in young age group (mean 45 years) and more splenomegaly was observed in PMF patients. *JAK*2V617F mutation was analyzed by ARMS-PCR while *CALR* mutations were identified by bi-directional Sanger sequencing.
Results: *CALR* mutations was not found in PV, in ET group frequency of *CALR* and *JAK*2 mutations were same 24.2%. *CALR* mutant ET was associated with younger age (mean 45 year), higher platelet counts (mean= 1251x10^9/L), lower leukocyte counts (mean= 11.x10^9/L) and also lower haemoglobin (median =1.7 g/dL) in comparison with *JAK2* V617F-positive ET. More splenomegaly was also observed in *CALR* mutated ET.

Table 1.

Total MPN patients 90				
	PV (30)	ET (36)	PMF (15)	U-MPN (9)
Gender Male, no. (%)	23 (76.6)	20 (55)	8 (53.3)	6 (66.6)

CALR mutation, Tested (n)	29	33	15	9
mutation-positive n (%)	0 (0%)	8 (24.2)	3 (20)	1 (11.1)
*BCR-ABL*1 mutation, Tested n (%)	15	19	13	6
mutation-positive	2 (13.3)	1 (5.2)	2 (15.3)	0 (0)

1. One patient had both coexistence of *CALR* exon 9 mutation with *JAK*2V617F in ET. 2. One patient's marrow status show myelofibrosis, *BCR/ABL* gene fusion by FISH was positive in 20% cells and *CALR* sequenced show 52bp deletion. 3. One patient with pancytopenia, show a novel homozygous mutation c.1139delA;p.E380fs50*. 4. One patient of ET shows 10 bp deletion (c.1 120_1129del) along with 28bp deletion.
Summary/Conclusion: *CALR* positive patients are phenotypically distinct from *JAK*2 positive patients. There is need to include a wide variety of bioinformatics assessments.

PB2299

SPLANCHNIC THROMBOSES IN MYELOPROLIFERATIVE DISORDERS EXPERIENCE OF THE HEMATOLOGY CENTER OF FUNDENI CLINICAL INSTITUTE

I. Ursuleac[1,2,*], R. Dragan[2], A. Bardas[2], C. Constantin[2], C. Dobrea[1,2], D. Coriu[1,2]

[1]'Carol Davila' University of Medicine and Pharmacy, [2]Hematology, Fundeni Clinical Institute, Bucharest, Romania

Background: Myeloproliferative disorders are known to cause splanchnic thromboses. Risk factors for thromboses in myeloproliferative neoplasms are: age >60years, previous thromboses, JAK2V617F mutation positivity, associated thrombophilic status, pancytosis, and classical risk factors (obesity, dislipidemia, diabetes, smoking, use of oral contraceptives).
Aims: Evaluating risk factors for splanchnic thromboses in a group of pacients with myeloproliferative neoplasms, unicentric analysis over 7 years (2010-2017) in Fundeni Hematology Clinic.
Methods: Clinical and epidemiological retrospective study of 20 cases of patients diagnosed with myeloproliferative neoplasms and visceral thromboses.
Results: Clinical and epidemiological data: 20 patients diagnosed with myeloproliferative neoplasms and visceral thromboses (14 women, 6 men) of median age 34.5 years (20-55 years): 4 cases of polycythemia vera, 7 essential thrombocytemia, 7 myelofibrosis, 2 unclassified myeloproliferative disorder. In 18 cases JAK2V617F mutation was present, 1 case negative and 1 was not tested. 10 patients with suprahepatic vein thrombosis, the majority positive for JAK2V617F mutation (9 cases). Portal vein thrombosis was found in 3 cases, all of them positive for JAK2V617F mutation, and associations of suprahepatic vein thrombosis with portal vein thrombosis was found in 7 cases. Pancytosis (Ht>44%, Le>11.000/mmc, Tr>450.000/mmc) was found in 5 cases, association of Ht>44% and Tr>450.000/mmc in 4 cases. Association between Ht>44% and leucocytosis over 11.000/mmc was found in 1 case. Normal blood cell counts values were detected in 4 cases. We identified the following as additional risk factors for thrombosis: smoking (6 cases), dislipidemia (3), use of oral contraceptives (2), thrombophilia (5). Two or more risk factors were present in 5 cases. Anticoagulant therapy was associated with cytoreductive therapy in 18 cases and 2 patients required only anticoagulant therapy. Recurrent thromboses were found in 2 cases. Death caused by progression of hematological disease occurred in 3 cases; all other patiens are hematologically stable under specific treatment. Due to progressive hepatic disease, 3 patients received liver transplants and 2 patients underwent transjugular intrahepatic portosystemic shunt.
Summary/Conclusion: Presence of splanchnic thrombosis is highly suggestive for the diagnosis of myeloproliferative neoplasms - 12 of our patients were diagnosed simultaneously for both pathologies, and in 8 patients the thrombotic episode occurred after the diagnosis of hematological disease. In the studied group of 20 cases, JAK2V617F mutation was identified in 18 cases. Most frequent myeloproliferative neoplasms were essential thrombocytemia and myelofibrosis, 7 cases each. Cytoreductive therapy associated with anticoagulant therapy represented therapeutical option for 18 cases. The evolution of thrombosis depends on the therapeutical response of the hematological disorder and also on the possibility for correcting the associated risk factors.

PB2300

A SINGLE-CENTER RETROSPECTIVE ANALYSIS OF AUTOIMMUNE MYELOFIBROSIS (AIMF). AIMF ASSOCIATED WITH COMMON VARIABLE IMMUNODEFICIENCY AND RELAPSING-REMITTING MULTIPLE SCLEROSIS

M. García-Recio[1,*], L. Lo Riso[1], A.M. Quintero[2], A. Formica[1], S.A. Jimenez[1], A. Ortuño[1], B. Lopez[1], R. Ramos[2], J. Ginés[3], M.A. Durán[1]

[1]Hematology, [2]Pathology, [3]Pharmacy, HUSE, Palma, Spain

Background: Autoimmune myelofibrosis (AIMF) is a rare cause of marrow fibrosis. It has been reported in association with autoimmune disorders, like systemic lupus erythematosus among others (Vergara-Lluiri *et al.* 2014). Our study presents two cases of common variable immunodeficiency (CVID) associated AIMF and one case of relapsing-remitting multiple sclerosis (RRMS) associated AIMF. Autoimmunity in the context of CVID occur in 20–30% of patients being cytopenias the most common autoimmune condition (Xiao *et al.* 2014).
Aims: To review the incidence and evolution of patients diagnosed with AIMF in our center.
Methods: We retrospectively reviewed patients from the Pathology service data base and medical histories.
Results: From 2000 to 2018, 34 patients were newly diagnosed of MF. Three (8.8%) were AIMF: two women (66%) diagnosed with CVID and one male (33%) diagnosed with RRMS. Median age at diagnosis was 38. One patient (33%) died due to an infection. Patients evolution and pathology (Table 1). Case A: A 25-year-old female diagnosed with CVID in 2010 in the setting of severe bicytopenia (600 neutrophils/uL and 6.000 platelets/uL), and mild/moderate infections. Despite autoimmunity tests were negative, direct coombs test was positive and has remained so ever since. Bone marrow biopsy (BMB) was compatible with AIMF. Immunoglobulins (Ig) 0,5g/Kg/21 days were given with CBC normalization. Corticoids were added and slowly tapered. Interestingly, while before each cycle platelets dropped under 10.000/uL, neutrophils sustainably normalized. Eltrombopag was iniciated in April/2011 with good results (>50.000 platelets/uL pre-Ig). Six years later, pre-Ig platelets account dropped to <10.000/uL. We switched to Romiplostim (raised to 4mcg/kg in the last visit) and increased Ig to 1g/kg with encouraging results (11.000 platelets/uL pre-Ig in the last visit). Case B: A 43-year-old female diagnosed in 2003 CVID and receiving Ig 0,5g/kg/21 days and corticosteroids, was sent to our clinic in 2010 due to grade IV neutropenia and severe infections. Neutrophils oscillated between 300/uL and 1000/uL and platelets progressively dropped to 25-30.000/uL. The patient presented with positive antibodies

anti-parietal cell (1/160), vitamin B12 in normal range. BMB was compatible with AIMF. In August/2017 due to grade IV bicytopenia, Ig were increased to every 14 days and mycophenolate was started maintaining neutrophils >600/uL and platelets >40.000/uL. Case C: A 38-year-old male diagnosed with RRME in 2008, last treatment alemtuzumab (June/2016) presented with asymptomatic grade IV thrombocytopenia in May/2017. Dexamethasone 40mg for 4 days (2 cycles) was started raising platelets to 253.000/uL. However, within a month, he presented with severe pancytopenia. Positive anti-neutrophil cytoplasmic antibodies were detected. BMB was compatible with AIMF. He received rituximab (2 doses) and Ig 1g/Kg/2days with no response. In September/2017 erythropoietin and plasma exchange was initiated with normalization of the platelet account (1 plasma volume was replaced with 0.5% human albumin diary (x4), then once a week). Neutrophils oscillated between 20 and 2.000/uL (good response to G-CSF and plasma exchange intensification). On February/2018 he presented with sepsis (gripeA) and died in the intensive care unit.

Table 1.

Table 1. Patients characteristics, pathology findings and evolution.

	Case A	Case B	Case C
Patients Characteristics			
Age at diagnosis	25	43	38
Sex	Female	Female	Male
Associated conditions	Common variable immunodeficiency	Common variable immunodeficiency	Relapsing-remitting multiple sclerosis
Autoimmunity tests	Negative[1]. Direct coombs: +++	Positive antibodies anti-parietal cell (1/160).	Positive anti-neutrophil cytoplasmic antibody.
Peripheral Blood Smear			
WBCs	Decreased	Decreased	Decreased
RBCs	Rare teardrop cells	Rare teardrop cells	Rare teardrop cells
Platelets	Decreased Giant forms	Decreased Giant forms	Decreased Normal
Bone Marrow Biopsy			
Cellularity	Augmented	Augmented	Augmented
Megakaryocytes	Augmented	Augmented	Slightly Augmented
Megakaryocytes morphology	Normal, no clustered	Normal, no clustered	Normal, no clustered
Myeloid precursors	Augmented	Augmented	Augmented
Erythroid precursors	Augmented	Slightly Augmented	Decreased
Lymphoid aggregates	Isolated interstitial, predominance LT	Paratrabecular, intratrabecular, predominance of T lymphocytes.	Nodular interstitial, predominance of T lymphocytes.
Plasma Cells	Isolated	Slightly Augmented	Augmented
Dysplasia	Absent	Absent	Mild
Intratrabecular hematopoiesis	Observed	Observed	Absent
Reticulin fibrosis	Grade 1-2	Grade 2	Grade 1 - 2
Treatment and follow-up			
Frontline	Corticosteroids and immunoglobulins	Corticosteroids and immunoglobulins	Corticosteroids and immunoglobulins
Response to frontline	WBCs: Normal. Platelets: No response.	WBCs: >600 Platelets: >40.000	No response.
Second line	Eltrombopag	Not required.	Plasma Exchange

Summary/Conclusion: AIMF is a rare disease of which we present previously unreported cases associated with CVID and RRMS. Thrombopoietin agonists can be considered as a therapeutic option for these patients.

PLASMA CONCENTRATIONS OF INTERLEUKIN 6 AND INTER LEUKIN 8 MAY BE RELATED TO POOR SURVIVAL AND ARE NOT AFFECTED BY CYTOSTATIC THERAPY IN PATIENTS WITH PRIMARY MYELOFIBROSIS FROM UKRAINE

R. Lozynskyy[1,*], O. Danysh[2], M. Voronyak[3], M. Lozynska[4], K. Susida[5], M. Kokoruz[6], Y. Vyhovska[7], Z. Maslyak[2], V. Orel[8], O. Abrahamovych[1]

[1]Internal Medicine #1, Danylo Halytsky Lviv National Medical University, [2]Hematology, Institute of Blood Pathology and Transfusion Medicine of National Academy of Medical Sciences, [3]Molecular Genetic Laboratory, Institute of Blood Pathology and Transfusion Medicine of National Academy of Medical Sciences of Ukraine, [4]Diagnostics of Hereditary Pathology, Institute of Hereditary Pathology of National Academy of Medical Sciences of Ukraine, [5]Hematology, Institute of Blood Pathology and Transfusion Medicine of National Academy of Medical Sciences of Ukraine, [6]Molecular Genetic Laboratory, Institute of Blood Pathology and Transfusion Medicine of National Academy of Medical Sciences, [7]Hematology, Danylo Halytsky Lviv National Medical University, [8]Consulting Polyclinic, Lviv Regional Clinical Hospital, Lviv, Ukraine

Background: The levels of different cytokines including VEGF, interleukin (IL) 6, IL-8 (CXCL8), and other molecules involved in inflammation were shown to be elevated in patients with primary myelofibrosis (PMF), a myeloproliferative neoplasm that still remains incurable without allogeneic hematopoietic stem cell transplantation. However, most of the studies give scarce data about clinical and genetic correlations with cytokine levels. So, the prognostic significance of cytokine concentrations is still unclear, especially under different palliative treatment strategies, including hydroxyurea and interferon-alpha, and in different populations.
Aims: To evaluate the plasma levels and clinical correlations of VEGF, IL-8, IL-6 and TNF-alpha and in patients with primary myelofibrosis from Ukraine.
Methods: The total of 45 patients clinically diagnosed with PMF were examined for plasma levels of VEGF, IL-8, IL-6 and TNF-alpha levels using ELISA on admission and after a year of follow-up. Control group consisted of 35 healthy persons. The study group included 21 patients with early PMF, the others had overt PMF according to WHO 2016 classification. Histological, cytogenetic and molecular genetic studies were performed for PMF patients. All the PMF patients received treatment with either hydroxyurea or interferon-alpha. Statistical differences were analyzed by the Mann-Whitney test.
Results: The upper quartile level of all studied cytokines in the group of patients with PMF exceeded the maximal levels of healthy donors. However, only VEGF and IL-8 levels of the patients from the study group were significantly increased (p=0.016 and p=0.044 respectively) comparing to the controls. Moreover, the levels of VEGF and IL-8 were higher than maximal for control group in only 37.8% and 46.7% of the patients with PMF. There were no differences found in the levels of the cytokines in patients with and without *JAK2*V617F mutation, but the TNF-alpha levels were significantly increased (p=0.001) in the patients bearing either *MPL*515L or *MPL*515K mutations. The level of IL-8 was significantly higher (p=0.048) in patients with cytogenetic abnormalities. There were no statistically significant differences in the cytokine levels between early and overt PMF groups. The levels of the cytokines had no significant differences between Dynamic International Prognostic Scoring System Plus risk groups. However, all 5 patients that died during the follow-up had significantly higher level of both IL-8 (p=0.0004) and IL-6 (p=0.02). The VEGF level was decreased at the follow-up on either hydroxyurea or interferon-alpha treatment in 93.3% of patients respectively, and the TNF-alpha levels increased in 88.9% of the patients, even if they were within the control group range at presentation. At the same time the IL-8 and IL-6 levels were not significantly changed under the same treatment during the follow-up.
Summary/Conclusion: The levels of VEGF and IL-8 may be increased in some patients with PMF, but this is not a disease specific feature, because most of the patients have the level of the cytokines within the range of values observed in healthy individuals. It is possible that the treatment with hydroxyurea and interferon-alpha could change the levels of VEGF and TNF-alpha, however the IL-8 and IL-6 levels do not change significantly after the year of follow-up on the same therapy and may be related with inferior prognosis. As the higher IL-8 level correlates with the presence of cytogenetic abnormalities, it is possible to suppose that cytogenetically abnormal cells may cause more intensive production of this cytokine.

PB2302

EPIDEMIOLOGICAL DATA ON POLYCYTHEMIA VERA IN ALBANIA (1999-2014)

A. Perolla[1,*], T. Caja[1], P. Pulluqi[2], E. Calliku[3], A. Ivanaj[4], A. Cili[4], A. Pushi[5]

[1]Internal Medicine, Hematology, [2]internal Medicine, [3]Internal Medicine ,Hematology, [4]internal Medicine Hematology, UHC " Mother Teresa", [5]Internal Medicine Hematology, UHC" Mother Teresa", Tirana, Albania

Background: Polycythemia Vera (PV) is a chronic myeloproliferative disease characterized by the elevation of the number of red blood cells. It is more common in males over 60 years old, but it can be present in every age group. An uncontrolled PV can induce a large number of thrombotic events putting in a high risk the lives of those patients.
Aims: To evaluate the incidence and sex-related incidence of PV in Albanian population during the period of time from 1999-2014 and to assess the emergency events at the moment of the diagnosis.
Methods: We collected and studied the data of all the patients more than 18 years old hospitalised and diagnosed with PV in the UHC "Mother Teresa" during the period from 1999-2014. SSPS 20.0 was used for the statistical analyses.
Results: According to the data collected and analyzed in the period from 1999-2014, the total number of the patients diagnosed with PV was 119 patients. From all the patients diagnosed with PV, 71 (60%) were males and 48 (40%) females. Only 23% of them have been presented in the Emergency Unit. 61% of all those patients presented in the Emergency Unit presented cardiovascular diseases (arterial hypertension, CAD, myocardial infarction), 12% neurological complications (stroke, convulsions etc..) 12% VTE (pulmonary, portal system, etc), 8% diabetes mellitus untreated (only one patient presented in the emergency with primary hypothyreosis) and 7% melena. The annual incidence of PV in Albania results in about 0,24

new cases per 100,000 inhabitants with an augmentation during 2006 (0,56 new cases per 100,000 inhabitants). The incidence was higher in males compared to females with a ratio 1,51/1. The annual incidence for males and females was respectively 0,29 new cases/100 000 inhabitants and 0,19 new PV cases/100000 inhabitants.
Summary/Conclusion: PV is a disease presented in Albania with about 7,4new cases per 100.000 inhabitants and with an incidence of around 0,24 new cases per 100,000 inhabitants affecting more males than females with a ratio 1,51/1. Mostly the patients went to the haematologist through the consultations and only 23% of them was diagnosed after presenting in the Emergency Unit predominantly with cardiovascular complications, before being diagnosed with PV. The correct diagnosis and management of those patients reduces the risk of thrombotic events and improves the prognosis.

PB2303

MLPA ASSAY USED FOR VERIFICATION OF RARE FINDING: SPORADIC PRESENCE OF TWO CALR MUTATIONS IN ONE PMF PATIENT

H. Drimalova[1,*], R. Sitkova[1], A. Buricova[2], D. Adamova[2], L. Stejskal[2], K. Horka[1]

[1]Department of medical genetics, Laboratory of molecular biology, AGEL Laboratories, Novy Jicin, [2]Hematology and Transfusion Departement, Silesian Hospital in Opava, Czech Republic

Background: Recently, somatic mutations in *CALR* gene have been demonstrated to be the second most common driver mutations in essential thrombocythemia (ET) and primary myelofibrosis (PMF). Approximately 50 different indels have been found in exon 9 of the *CALR* gene but more than 80% of *CALR* mutated patients possess one of the two most frequent variants: a 52-bp deletion (p.Leu367fs*46; type 1) and a 5-bp insertion (p.Lys385fs*47; type 2 mutation). An 80-year-old male patient with thrombocythemia was investigated for *CALR* mutation to confirm his clinical diagnosis of primary myelofibrosis. The patient carried both of the two most frequent types of *CALR* mutations (type 1 and type 2).

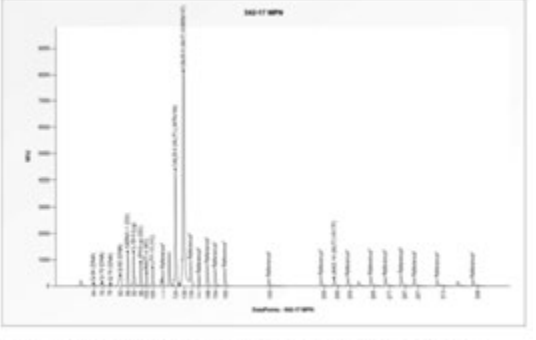

Figure 1. Capillary electrophoresis pattern of the patient DNA analysed with SALSA MLPA probemix P520-A2 MPN mix 2. |

Figure 1.

Aims: Verification of rare findings in *CALR* gene by MLPA assay and their interpretation considering the recent studies and clinical data of the patient.
Methods: In our laboratory the routine detection of the *CALR* mutations is performed by a fragment analysis on capillary electrophoresis. Positive results are confirmed by Sanger sequencing. However, sequencing data were not clear in this case (presence of deletion and insertion in one amplicon). Therefore we chose SALSA MLPA probemix P520-A2 MPN mix 2 for successfull verification of our findings (Figure 1).
Results: Presence of *CALR* mutation was one of the three major WHO diagnostic criteria of prePMF for this patient. Mostly, ET and PMF patients carry only one *CALR* mutation. Suprisingly, we found a patient with two variants: type 1 and type 2 mutation. MLPA and Sanger sequencing were used to verify our findings gained from fragment analysis, but only MLPA assay clearly confirmed the presence of two mutations. In our patient anamnesis the several diseases of urinary system were mentioned (subglandular hypospadia, kidney cysts, carcinoma of kidney) and the patient underwent radiotherapy due to carcinoma of prostate gland in 2010. The PMF diagnosis was established in 2017 with subsequent moderate progress.
Summary/Conclusion: The moderate progress of PMF is associated with prognostic benefit, which is described in patients with *CALR* mutation, particularly with type 1 cases. Both types of *CALR* mutaions in one patient have been already mentioned but without any clarification of its development or impact on the PMF prognosis. In the case of our patient, it seems to be moderate progress of PMF yet. As generally known, radioactivity increased a risk of myeloproliferative neoplasms. Therefore we suppose that the radiotherapy could influenced the development of PMF with the sporadic presence of two *CALR* mutations.

PB2304

A RETROSPECTIVE STUDY OF PATIENTS WITH POLYCYTHEMIA PRESENTING TO A COMMUNITY HAEMATOLOGIST: NOT ALL INCREASED HEMOGLOBIN IS POLYCYTHEMIA VERA

N. Gupta*, A. Garg, F. Naim

Clinical Hematology and bone marrow/stem cell department, Sir Ganga Ram Hospital, New Delhi, India

Background: As per new WHO 2016 classification, polycythemia vera (PV) is suspected once hemoglobin is above 16.5gm/Dl (HCT >49%) in males and 16gm/dL (HCT 48%) in females. JAK 2 V617F mutation or similar mutations in JAK 2 gene are seen in almost all of the patients with polycythemia vera. Bone marrow examination is required to make a diagnosis of PV and to differentiate it from other myeloproliferative neoplasms. High hemoglobin values more than the above ranges are commonly seen in clinical haematology practice.
Aims: Aim of present study was to evaluate patients presenting with raised hemoglobin and differentiate ideopathic polycythemia and its clinical course from polycythemia vera.
Methods: Retrospective review of patients referred to the haematologist in Sir Ganga Ram Hospital, New Delhi, India, for high hemoglobin levels from January 2015 to December 2017 was performed. Demographic characteristics, history (including smoking and alcohol) and general physical examination were noted. All patients were tested for JAK 2 V617F mutation, erythropoietin levels (EPO) and ultrasound whole abdomen for splenohepatomegaly. Patients with PV were treated with phlebotomy, low dose aspirin and cytoreductive therapy with hydroxyurea as per standard guidelines.
Results: A total of 70 patients were found, 65 males: 5 females, 14/70 (20%) were JAK2 V617F positive and rest 56/70 (80%) were negative (table 1). JAK 2 Exon 12 mutations were done in 31 of 56 JAK 2 V617F negative patients and all were negative. Bone marrow examination was done in 28 of 56 JAK 2 V617F negative patients and was normal in all except 2 patients in which panmyelosis was seen. Palpable splenomegaly was seen in 9/14() patients with JAK 2 V617F positive patients while splenomegaly was absent in all JAK2 negative patients. Phlebotomy was done if Hemoglobin was more than 17g/dL in JAK 2 negative patients and low dose aspirin was given if hypertension/hypercholesterolemia/diabetes was present. None of JAK 2 negative patient developed thromboembolism or AML/myelofibrosis during study period with a median follow up of 13.5 months while 2 patients died in JAK 2 positive group (one due to cerebrovasucular accident and other due to development of myelofibrosis.

Table 1. Comparision of jak2 positive and jak 2 negative patients with polycythemia.

	JAK 2 POSITIVE	JAK 2 NEGATIVE
PATIENTS- 70	14/70 (20%)	56 (80%)
MALE :FEMALE	54:2	11:3
AGE; MEDIAN (RANGE) YEARS	59.5 (25-76)	36 (20-67)
HYPERTENSION	8/14 (57%)	30/56 (53%)
SPLENOMEGALY	9/14	0/56
HISTORY OTHROMBOSIS (ARTERIAL AND VENOUS)	4/14 (28.5%)	3/56 (5.35%)
FOLLOW UP IN MONTHS; MEDIAN (RANGE)	13.5 (3-36)	13.5 (3-36)

Summary/Conclusion: Most of the patients referred for isolated increase in hemoglobin were young males without splenomegaly, had high prevalence of hypertension and were JAK 2 negative. Bone marrow examination was not performed in most of these patients and were treated as idiopathic erythrocytosis and managed conservatively with optimal clinical outcomes. There is a need to review the requirement of doing bone marrow examination in such patients.

PB2305

MANAGEMENT OF SYSTEMIC MASTOCYTOSIS IN A SINGLE CENTER EXPERIENCE

M. Criscuolo[1,*], L. Fianchi[1], A. Maraglino[1], A. Buonomo[2], P. Chiusolo[1], A. Bacigalupo[1], L. Pagano[1]

[1]Hematology, [2]Allergology, Catholic University of Sacred Heart Fondazione Policlinico Universitario A. Gemelli, Rome, Italy

Background: Mastocytosis is an extremely rare neoplasm originating from abnormal proliferation and tissue infiltration of clonal mast cells. The WHO classification recognizes cutaneous and systemic mastocitosis (SM), the former localized to skin and the latter further classified as indolent or aggressive, based on organ infiltration. Moreover, SM can be associated to another clonal hematological disease (SM-AHD), typically myelodysplastic syndromes (MDS) or acute myeloid leukemia (AML): in these cases the prognosis is similar to the predominant neoplasm.
Aims: The aim of the study is to analyze the characteristics of patients with both indolent and aggressive systemic mastocytosis (SM) and the triggering factors for treatment. We also reviewed the clinical course and treatment of patients with SM-AHD.
Methods: We retrospectively reviewed the charts and collected clinical and laboratory data of 20 patients diagnosed with SM and 9 patients diagnosed with SM-AHD from January 2008 through December 2017. We focused on onset symptoms, clinical characteristics, organ damage and indication to treatment.
Results: SM: Eighteen patients (90%) sought medical evaluation because of cutaneous lesions or anaphylaxis, and 2 (10%) because of bone pain or fractures. In 12 patients (60%) SM was diagnosed after a skin and bone marrow biopsy revealed mast cell infiltration. Six patients (30%) presented with anaphylaxis and high triptase levels: as reported in literature, both characteristics are strongly associated with SM, and both underwent a bone marrow examination. While bone marrow biopsy was always positive for mast cell infiltration, CKIT D816V mutation was detected in 12 patients only. Skeleton X-ray and 18F-FDG PET/CT were performed in 16 patients: 9 (56%) presented a radiological bone involvement but only 4 of them (25%) showed increased glucose uptake. Ten patients were diagnosed with indolent SM, and did not need systemic treatment: they were given antihistamines to control symptoms. Ten patients were diagnosed with aggressive SM: 3 started tirosin kinase inhibitors (TKI) for uncontrolled degranulation causing anaphylaxis and flushing; 5 started Interferon α (IFNα) considering bone pain due to fractures or severe osteoporosis; 2 started cladribine for diffuse bone and systemic involvement. Four patients needed further therapy for transient benefit or primarily poor control of clinical conditions. Of these 20 patients, 18 are surviving at 0.5-89.5 months. SM-AHD: These patients were all diagnosed after performing bone marrow evaluation for cytopenia. Two patients were diagnosed with AML: considering age >65 y.o., they were both treated with intermediate dose citarabine associated to TKI, and died after a median of 3 months. The other 7 patients were diagnosed with MDS: 3 had skin lesion and few symptoms related to uncontrolled degranulation, none presented with bone pain or skeleton alteration at X-ray. Regarding treatment, 2 patients were treated with TKI and 1 with IFNα for underlying SM, and 4 patients with best supportive care for low risk MDS; median overall survival was 23.9 months.
Summary/Conclusion: SM is difficult to recognize because it presents with generic symptoms, as anaphylaxis, osteoporosis and fractures, or flushing and gastritis. Nonetheless, it is important to investigate unexplained bone fragility, wasp venom anaphylaxis or non-catecholamine associated flushing, possibly suggesting an underlying mastocytosis. SM-AHD are mainly treated for the predominant non-mast cell disease, associated with antihistamines for symptoms control in few cases.

PB2306

CHARACTERISTICS OF PATIENTS WITH JAK2 EXON 12 MUTATED POLYCYTHEMIA VERA

T. Subbotina[1,2,*], E. Dunaeva[3], K. Mironov[3], A. Kharsekina[1], E. Vasiyliev[4], M. Mikhalev[5], M. Osadchaya[6], M. Smelyanskaya[4], V. Khorzhevskyi[7], G. Shipulin[3]

[1]Siberian Federal University, [2]The Federal State-Financed Institution Federal Siberian Research Clinical Centre under the Federal Medical Biological Agency, Krasnoyarsk, [3]Federal Budget Institute of Science «Central Research Institute for Epidemiology», Moscow, [4]Krasnoyarsk regional hospital, [5]Municipal Budget Health Service Institution «City Clinical Hospital № [7]», [6]Krasnoyarsk Territory Department of Health Regional state budget health facility «Krasnoyarsk interdistrict clinic №[1]», [7]Krasnoyarsk State Regional Bureau of Pathology, Krasnoyarsk, Russian Federation

Background: JAK2 exon 12 somatic mutations are highly specific to confirm the diagnosis of polycythemia vera (PV) (Pardanani A *et al.*, Leukemia, 2007). It is known patients with JAK2 exon 12 mutated PV have isolated erythrocytosis and a younger age than patients with JAK2 V617F mutated PV (Scott L *et al.*, N Engl J Med, 2007; Passamonti F *et al.*, Blood, 2011).
Aims: This study aims to assess the clinical and molecular characteristics of patients with JAK2 exon 12 mutated PV from Krasnoyarsk region, Russia.
Methods: 6 patients with JAK2 exon 12 mutated PV were involved in this study. The informed consents of these patients were obtained. The PV diagnosis of 1, 2, 3, 5 and 6th patient was confirmed by bone marrow trephine biopsies histological examination. JAK2 exon 12 mutation analysis was performed by heteroduplex analysis with separation of the PCR product by electrophoresis on non-denaturing PAGE (Subbotina T *et al.*, Haematologica 2017). The identification of the JAK2 exon 12 mutation types and allele burden measurement was carried out by pyrosequencing (Subbotina T *et al.*, Haematologica 2014). Clinical and laboratory data were collected from the time of initial diagnosis to the present. JAK2 exon 12 variance^{MUT} was calculated as a measure of relative changes in allele burden between the baseline and follow-up sample (Theocharides A *et al.*, Haematologica, 2008).
Results: Some clinical and laboratory characteristics of 6 patients with JAK2 exon 12 mutated PV are reported in Table 1. The subjects were both men and women. Age of disease onset in subjects was from 28 to 72 year. Three out of these patients became ill before the age of 30 years. Duration of the disease is different: from 3 to 12 years. All 6 patients have an increased number of red blood cells, along with an accompanying increase in the concentration of hemoglobin and hematocrit level in the peripheral blood. Some of them had moderate increase number of leukocytes and platelets in the disease dynamics. All 6 patients have different mutation variant in the 12 exon of the JAK2: N542-E543del (c.1624_1629delAATGAA); I540-E543delinsKK (.1619_1627 TCAgAAATg>AAA); N542_E543del (c.1623_1628delAAATGA); R541_E543>K (c.1622_1627delGAAATG); F537_K539>L (c.1611_1616delTCACAA); H538_K539>L (c.1612_1616CACAA>TT), accordingly. These mutations have been already described and included in the COSMIC website. Two out of six patients also have a mutation JAK2V617. JAK2 exon 12 allele burdens in the sample from 1 patient are significantly increased in the disease dynamics. N°1,2,5 patients in the anamnesis had splenomegaly. N°2,4,5 patients in the anamnesis had any thrombotic events. N°2-4 patients were treated phlebotomy only and did not receive any cytoreductive treatment to date. 5 and 6 patients receive hydroxyurea (HU). N°1 patient was treated only with phlebotomy until 2016. Since 2017 cytoreductive therapy with HU has been started, but this causes to the development of hydroxyurea-induced thrombocytopenia to I-II degree. Carrying out of bone marrow trephine biopsies histological examination in 2015 years was confirmed PV and in 2017 – fibrosis manifestations. Thus, in N°1 patient simultaneously with the allele burden increase develops disease progression – the initial manifestations of the transition of the PV to myelofibrosis. Thrombotic events have not been identified.

Table 1.

Table 1. Characteristics of 6 patients with JAK2 exon 12-mutated PV

№	Age of manifestation (years)	Sex	Disease Duration of the disease (mo)	HU	JAK2 V617F	JAK2 12 exon	% JAK2 12 exon mutation baseline	% JAK2 12 exon mutation last sample	JAK2 12 exon variance MUT	Time between two acute events (mo)
1	61	M	PV*/33	Yes	20g	N542_E543 del	15	50	+233	33
2	48	M	PV*/38	No	<1%	I540_E543 delinsKK	13	8	0,5	27
3	27	M	PV/132	No	20g	N542_E543 del	15	19	0,5	84
4	~72	F	PV/64	No	30g	R541_E543 >K	33	25	0,5	42
5	29	M	PV/132	Yes	<1%	F537_K539 >L	31	26	0,5	7
6	28	F	PV/84	Yes	30g	H538_K53 9 >L	10	11	0,5	4

* – The allele burden was determined at the primary address to the doctor with MPN symptoms

Summary/Conclusion: We confirm an earlier age of disease onset, as well as the presence of isolated erythrocytosis in patients with JAK2 exon 12 mutated PV. The increase of the allele burden level detected in one patient is accompanied with disease progression.

PB2307

JAK2V617F MUTATION AS A RISK FACTOR FOR INCIDENCE OF THROMBOTIC COMPLICATIONS IN PATIENTS WITH PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

E. Simonovic*, V. Colic

Internal Medicine, General Hospital Leskovac, Leskovac, Serbia

Background: Myeloproliferative neoplasms (MPN) are the group of clonal, malignant hematopoietic stem cell disorders, characterized by the proliferation of one or more blood lines with normal or nearly normal maturing in the bone marrow and in extramedullar hematopoietic organs. The following factors give contribution to the incidence of thrombosis: increasing level of products that are formed in the activation of platelets (thromboxane, p-selectin); increased production of microparticles that are parts of various cell membrane structures of platelet origin; JAK2V617F mutation. In

patients with MPN there is increased activity of the coagulation system due to the resistance to the anticoagulant function of thrombomodulin.
Aims: The aim of this study is to monitor JAK2V617F mutation as a potential risk factor for the incidence of thrombotic complications in patients with Philadelphia negative myeloproliferative neoplasms.
Methods: During the six-year period we monitored the occurrence of thrombotic complications in 157 patients of both sexes, aged between 30 and 87 years, being diagnosed with Ph-myeloproliferative neoplasm. Patients were classified into the following groups: 1. Group with polycythemia vera (PV) (68); 2. Group with essential thrombocythemia (ET) (36); 3. Group with idiopathic myelofibrosis (IMF) (26); 4. Group with unclassified myeloproliferative neoplasm (MPNs) (27). Among possible risk factors, we monitored the presence of JAK2V617F mutation, as well as the age of patients, deviations in counts of leukocytes, the presence of cardiovascular comorbidity, and the presence of diabetes mellitus. We used methods of clinical, laboratory, endoscopy, ultrasound and CT scans.
Results: JAK2V617F mutation was statistically more significantly present in patients with PV (about 81%). In patients with ET it was noticed 58%, in patients with IMF about 38%, and in group of patients with MPNs about 48%. The highest percentage of thrombotic complications (arterial and venous) was found in the group of patients with ET, which was statistically more significant relative to PV. Thrombotic complications were in both groups more frequent in percentage with JAK2V617F positive patients, but without statistical significance. It is believed that activated neutrophils bind to platelets by influencing the increased expression of tissue factor activity, as well as the activation and damage of the endothelial cells, especially with JAK2V617F positive patients. In patients with IMF, thrombotic complications were statistically more significantly present in JAK2V617F positive patients. In patients with MPNs, thrombotic complications were more common in JAK2V617F positive patients, but with significant deviations reported in the count of leukocytes in terms of leukocytosis. Thrombotic complications in all groups, except in the IMF group, were more commonly present in patients with cardiovascular comorbidity and diabetes mellitus, but the statistical significance was present only in the group with PV and ET.
Summary/Conclusion: JAK2V617F mutation can be considered as potential risk factors for thrombosis in patients with Philadelphia negative myeloproliferative disorders. Other risk factors must be also considered, like leukocytosis populations, cardiovascular diseases and diabetes mellitus. Further monitoring of those patients and a larger number of subjects is needed.

PB2308

A NATURAL LANGUAGE PROCESSING ALGORITHM TO AUTOMATICALLY CATEGORIZE DISEASE TYPE AND STATUS FROM FREE-TEXT BONE MARROW MORPHOLOGY REPORTS

Y.-F. Wang[1,*], J.-L. Li[2], B.-S. Ko[3], C.-C. Lee[2], J.-L. Tang[1,3]

[1]Tai-Cheng Stem Cell Therapy Center, National Taiwan University, Taipei, [2]Electrical Engineering, National Tsing Hua University, Hsinchu, [3]Hematology Division, Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan, Republic of China

Background: Bone marrow (BM) aspiration is a standard diagnostic and evaluation tool utilized by physicians together with other exams to make clinical decisions for all major hematologic diseases. The morphology report includes many important morphological features of the specimens. However, these findings are often documented in an unstructured free-text format, making it extremely difficult to extract and compare information from different reports. Recently, successful applications of natural language processing (NLP) techniques for automatic categorizations of findings on pathology or electronic medical reports have been shown for diseases such as breast cancer diagnoses.
Aims: We aim to develop NLP algorithms to automatically extract key clinical information to support physicians in the clinical decision and further research for hematologic malignancies.
Methods: A total of 12549 free-text BM morphology reports dated from 2007 to 2016 were collected from the National Taiwan University Hospital. Each report consists of information on the following key clinical classifications in a free-text format: specimen quality, disease types and disease status. We first achieved word normalization of these reports through a series lexical pre-processing using Wordnet lexicon corpus. We then derived a document vector as a summary representation of each report. This vector includes a fixed dimension equals to the sum total of unique *uni- bi- tri-*gram word count in our BM dataset, and each i^{th} element reflects the importance weighting for each word in the given report. The importance weighting is computed based on term-frequency inverse-document frequency (tf(t,d)*idf(d,t)). Term frequency, tf(t,d), is the number of occurrences of i^{th} word in the d^{th} report. And, idf(d,t)=log(n/(df(d,t)+1) where df(d,t) indicates the total number of report containing i^{th} word and n is the total number of reports. We finally trained machine learning algorithms to automatically learn to extract key clinical information using class-balanced support vector machine (SVM) with this tf-idf document vectors. We evaluated our approach using a three-fold cross-validation. That is, for each fold, 9790 reports were used as training set and the remaining 2759 reports were used as the blind testing set and we iterated this for three times. The accuracy was measured by comparing the concordance rate between the algorithm categorization and the expert categorization on the testing set.
Results: All three NLP algorithms achieved high categorization performance. The disease type classification achieved 0.95 accuracies in 9 out of 11 types of categories (Figure 1). In addition, the other two algorithms achieved overall 0.98 accuracies in specimen quality classification and 0.95 in disease status classification (data not shown). Among the 11 disease type classification tasks, the algorithm achieved accuracy lower than 0.95 in 3 categories: "Lymphoma", "Other" and "Unsure Diagnosis". The relatively lower accuracy of the "Lymphoma" class may be attributed to the fact that it was used to include all subtypes of lymphoma. Similarly, the "Others" class was used as the "garbage" class where multiple diagnostics decision other than malignancies could be made, and the "Unsure Diagnosis" reflect uncertain clinical diagnostic decisions.

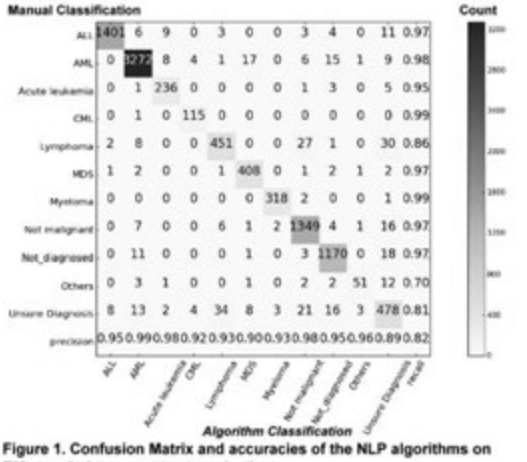

Figure 1. Confusion Matrix and accuracies of the NLP algorithms on BM morphology report categorization
Confusion matrix, precision and recall of 11-class disease type categorization.
Precision: Positive predictive value, Recall: True Positive Rate. The overall accuracy was 0.82.
Abbreviation: ALL: Acute Lymphoblastic Leukemia; AML: Acute Myeloid Leukemia; CML: Chronic Myeloid Leukemia; MDS: Myelodysplastic Syndrome; CR: Complete Response

Figure 1.

Summary/Conclusion: Our NLP algorithms could efficiently and accurately extract important information with high accuracy from a large scale free-text bone marrow morphology reports. Further research is needed to evaluate the algorithm performance on reports from other centers.

PB2309

THE INCIDENCE OF EARLY AND RECURRENT THROMBOTIC EVENTS IN EGYPTIAN MYELOPROLIFERATIVE NEOPLASMS (MPN) PATIENTS

T.E.E. Abouzeid[1,*], S. Elashwah[1], T. El- Gohary[2], R. Farag[3], R. Ghonaim[4]

[1]Hematology, Mansoura oncology center, Mansoura, [2]Oncology, Zagazig university, Zagazig, [3]Ophalmology, mansoura ophthalmic center, mansoura, [4]Clinical pathology, Zagazig university, Zagazig, Egypt

Background: Thrombotic events are considered a major complication in the follow-up, and treatment of Philadelphia negative Myeloproliferative Neoplasms (MPN), particularly polycythemia vera and essential thrombocythemia, associated with high morbidity and mortality, as reported in several retrospective studies.
Aims: To study the incidence of thrombotic events at diagnosis and during follow up of Egyptian MPN patients.
Methods: We studied 102 adult Egyptian patients diagnosed with Ph (-) ve MPN (M/F 49/53, mean age 50.13 ±12.1 years), at Mansoura Oncology center during the period from May 2012 till December 2017. Of them 47(46.1%) had Polycythemia Vera(PV), 27(26.5%) Essential Thrombocytosis(ET),22(21.6%) Myelofibrosis(MF), and 6(5.9%) Unclassified.
Results: Out of the 102 patient observed during the period of the study 32(31.45) patients was having thrombotic episodes, out of these 26 (25.5%) at diagnosis, 6 (5.9%) patient at follow up and 4 (3.9%) is said to have

recurrent thrombotic events. These thrombotic events were 15 arterial (6 cereberal.3 lower limb, 2 upper limbs. 2 hepatic, and I coronary), 13 venous (7 portal, 4splenis, and 2 lower limbs), and 4 patients were having combined arterio-venous thrombosis. As to the incidence of early thrombosis in the different MPNs, they were 14/47 (29.8%) in PV patients,8/27 (29.6%) in ET patients and 7/22 (31.8%) in PMF patients and 3/6(50%) unclassified patients. The median time from diagnosis to thrombotic event was also similar in the different MPNs (p=0.311). Several clinical features at diagnosis (age, gender, Hb levels, WBC and PLT counts, JAK-2 V617F mutation and previous thrombotic events) were evaluated for a role in predicting thrombotic events: only age and previous thrombotic events were significant. The overall survival was affected significantly with the presence of thrombosis (**P=0.097**), while the JAKII V617F positivity has no survival affection.
Summary/Conclusion: The incidence of early and recurrent thrombosis seems to be without any difference among ET, PV and PMF. Only age and previous thrombotic events had a predictive role, affecting the overall survival.

PB2310

BLOOD AND BONE MARROW CULTURES FOR THE DIAGNOSIS AND MANAGEMENT OF PRIMARY MYELOFIBROSIS

T. Saralidze[1,*], I. Mamatsashvili[1], T. Svanidze[2], T. Saralidze[3], T. Shvelidze[4], N. Gogokhia[5]

[1]Department of Internal Medicine, Tbilisi State Medical University, [2]I.Chavchavadze Av.[41]. Flat [16], Tbilisi State Medical University, department of Internal Medicine, [3]Department of Medicine, David Tvildiani Medical University, [4]Clinical laboratory, IUNONA Medical Center, [5]Clinical Laboratory, Tbilisi State Medical University, Tbilisi, Georgia

Background: Though WHO criteria for the prefibrotic and overt fibrotic stages of primary myelofibrosis (PMF) is well established, diagnosis and management of this disease often remains a challenging problem. Pathogenesis of anemia or cytopenia, that accompanies PMF, or development of post MF acute myeloid leukemia (AML) is also frequently unclear.
Aims: Our aim was to reveal peculiarities of hematopoiesis and main reasons of cytopenia in patients with PMF.
Methods: We studied blood and bone marrow cell (BMC) cultures of 7 patients with PMF in fibrotic stage using the method worked out by us. This method enables to observe hematopoiesis and detect proliferating clone in patients with hematological malignances during 3-5-7-14-21-days of cultivation of BMC. In 3-day-blood leukocyte cultures we studied macrophage-lymphocyte rosettes (MLRos) formation that reflects immune reactivity of organism. Increase of the amount of MLRos *in vitro* points to immune sensitization or immune conflict, while its decrease points to low immune reactivity of organism.

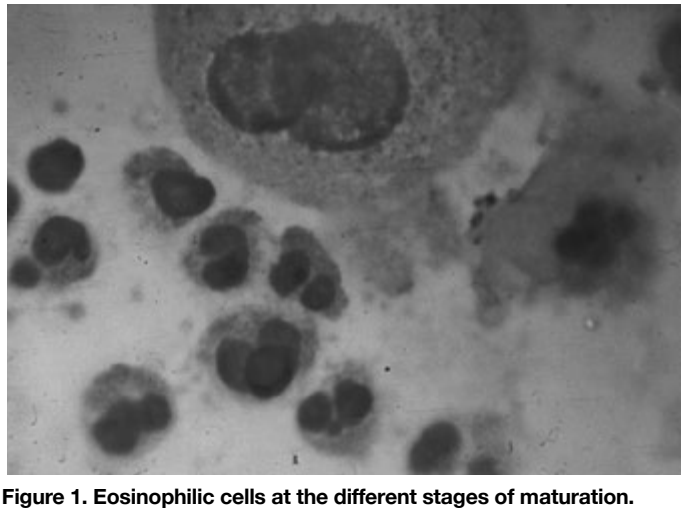

Figure 1. Eosinophilic cells at the different stages of maturation. Hypolobulated megakaryocyte (above) sequestrating platelets. 21-day-culture of bone marrow aspirate of a patient with primary myelofibrosis.

Results: Patients age was in the range of 40-70, 4- men, 3- women, all had anemia with reticolocytosis, 4 had thrombocytopenia, 1- leukopenia, except the last patient leukocytes were in the range of 8-12x10^9/L with moderate neutrophil leukocytosis and left shift to myelocytes and promyelocytes. All patients had splenomegaly (from 5-7 up to 15-18 cm), 5 had hepatomegaly (up to 5cm). BM biopsy showed megakaryocytic proliferation with reticulin and collagen fibrosis grades 2 or 3. Spleen aspirate showed myeloid metaplasia. In 3-5-days BMC cultures poor growth of myeloid cells, atypical megacaryocytes with hypolobulated nuclei and decreased erythropoiesis was observed; In 7-14-21-day cultures mainly growth of reticular stromal cells was seen, besides in one case growth of eosinophilic cells was observed (Fig.1). In 5 cases anti-erythrocyte and in 3 cases antiplatelet antibodies were also detected. In blood cultures of all patients amount of MLRos was increased significantly up to 75-85%, showing autoimmune character of cytopenia, while in norm it equals 37,4±2,2%. As above mentioned patients didn't have high leukocytosis and prominently progressive hepatosplenomegaly, they were effectively treated with prednisone 30-60mg/day. Because of frequent recurrence of cytopenia in 2 cases was done splenectomy. 1patient died after operation because of sepsis, second one was in remission for 5 years. 4 patients are alive more than 6 years and receive low dosage of steroids in case of cytopenia recurrence. 2 patients died because of disease progression. One of them developed post MF AML. Notable that in BMC culture of this patient proliferation of myeloid blast cells was revealed a month before clinical onset of AML.
Summary/Conclusion: Results of our data show that MLRos formation *in vitro* can be successfully applied for the detection of immune conflict in the pathogenesis of cytopenia in patients with PMF while use of BMC cultures is reasonable for observation and estimation of hematopoiesis *in vitro* that will help to precise diagnosis and hold tailored treatment in each case. Growth of eosinophilic cells in long-term culture confirm myeloproliferative nature of the PMF, while clonal expansion of blast cells *in vitro* predicts development of post MF AML.

PB2311

EVALUATION OF THROMBOTIC RISK IN CHRONIC MYELOPROLIFERATIVE NEOPLASMS PATIENTS

V. Popov[1,*], M. Andreescu[1], M. Omer[1], A. Trifa[2], O. Patrinoiu[1], F. Raicu[3], H. Bumbea[1]

[1]Hematology, Colentina Clinical Hospital, Bucharest, [2]Genetics, UMF Iuliu Hatieganu, Cluj Napoca, [3]Genetics, UMF Carol Davila, Bucharest, Romania

Background: Patients with chronic myeloproliferative neoplasms (MPNs) have thrombotic complications. Many reports showed that JAK2 mutation is involved in thrombosis pathogenesis. Genetic thrombophilia characterized by presence of more than 1 mutation PAI-1 4G-4G, MTHFR 677TT, V Leiden 506Q, and prothrombin 20210A could be an important risk factor.
Aims: The aim of our study was to evaluate the frequencies of these mutation in MPNs patients and association with thrombosis risk
Methods: This retrospective study included 75 patients with MPNs (36 female and 39 male), median age 65.1 (female-61.7, male 67.1). Mutational analyses identified in 52 patients presence of JAK2 mutation,14 patients have CALR mutation presence and 9 patients have no mutation. Thrombophilia testing was performed including mutations: PAI-1, MTHFR 677TT, V Leiden and prothrombin 20210A. The group of patients was splitted in group with thrombotic complications (heart infarct, pulmonary embolia, stroke, splanhnic thrombosis) represented by 21 patients and without thrombosis – 54 patients
Results: Thrombosis was present in MPNs patients JAK2 positive. Patients with CALR mutation had not thrombosis in their medical history, although they have higher count of platelet compared with MPNs patient with JAK2 mutation present (CALR group PLT 1036 x 109/L *vs* JAK2 group 847 x 109/L). Patients with thrombotic complication have not more frequent association with genetic mutations MTHFR, prothrombin or V Leiden mutations, 17/21 patients compared with 21/54 patients.
Summary/Conclusion: JAK2V617F mutation is an important risk factor for the pathogenesis of thrombosis in MPN. Association with another genetic mutations like V Leiden factor, PAI1 or prothrombin 20210A mutation could increased the risk of thrombosis but in our study we did not obtained this. We have to check these findings in a higher lot of patients

PB2312

THE SPECTRUM OF THROMBOSIS IN POLYCYTHEMIA VERA: EXPERIENCE OF A TERTIARY HOSPITAL

M. Arcas-Vega, S. Lakhwani*, A. Martín-Martín, P. Machado, S. Martín-Batista, M.T. Hernández, J.M. Raya

Hematology, Hosp. Univ de Canarias, Santa Cruz Tenerife, Spain

Background: Thrombosis is one of the most important complication among

patients with polycythemia vera (PV) and, in the bibliography, roughly one-fifth of patients with PV are diagnosed with an arterial or venous thrombotic event as a presenting feature. Fatal cardiovascular events contribute to the increased mortality rate among patients with PV and thrombotic events are so inextricably tied to the pathogenesis of PV that they are used in guiding patient risk stratification and treatment recommendations. In addition to several conventional risk factors for thrombosis, clinical data have implicated increased hematocrit and red blood cell adhesiveness, activated platelets, leukocytosis, and elevated *JAK2V617F* allele burden.
Aims: The goal of our study was to analyze the incidence and the different moment and form of presentation of thrombosis in patients with PV in our centre.
Methods: A retrospective analysis was conducted based on the review of medical records of the adult patients diagnosed of polycythemia vera in our centre from 1986 to 2017. Clinical and biological data were recorded.
Results: A total of 51 patients were analyzed (28 men and 23 women). Mean age at diagnosis was 61 years old (range 28-83). We found a total of 19 patients (37,2%) who suffered a thrombosis before or after PV diagnosis. Among patients with thrombosis before the diagnosis of PV different scenarios have been found: 1) Two patients developed a thrombotic phenomena that led to diagnosis of PV. Both suffered a stroke and one had heterozygous JAK2 mutation while the other one had mutation of exon2-JAK2. 2) Seven patients developed a thrombosis prior to PV diagnosis and without erythrocytosis [4 strokes, 1 acute myocardial infarction (AMI) and 2 pulmonary embolisms]. All of them had heterozygous JAK2 mutation except one that had homozygous mutation. 3) Four patients had a thrombosis before PV diagnosis but after the evidence of erythrocytosis (2 strokes and 2 AMI). Time from thrombosis until hematologist evaluation range from 1 to 29 months (mean 14,5 months). Time from evidence of polycythemia until hematologist evaluation range from 2 to 123 months (mean 43 months). All these patients had heterocygous JAK2 mutation. On other hand, six patients developed a thrombotic phenomenon after diagnosis (3 strokes, 2 AMI and 1 deep venous thrombosis). Two patients presented homozygous mutation for JAK2 and four heterozygous mutation. Four patients had leukocitosis at diagnosis also. About treatment, three patients were receiving hydroxyurea and two patients phlebotomy when thrombosis occurred, but two male patients had an hematocrit above 45%. Of note, five of these patients were without aspirin prophilaxis when developed the thrombosis .
Summary/Conclusion: In our series 37,2% of patients with PV developed thrombosis, especially before the diagnosis. All of them had *JAK2-V617F* mutation except one who had exon12-JAK2 mutation. Four thrombosis (21%) developed after erythrocytosis was observed but before the patient was evaluated by an hematologist. We wonder if they could have been avoided. After diagnosis, the suspension of aspirin prophylaxis by any reason, seems to be an important factor to develop thrombosis.

PB2313

SECONDARY MALIGNANCIES IN BCR-ABL NEGATIVE CHRONIC MYELOPROLIFERATIVE DISEASES

E. Arslan Davulcu*, H. Bülbül, Y. Ulusoy, F.D. Atilla, N. Soyer, F. Sahin, F. Vural, M. Tobu, M. Tombuloglu, G. Saydam

Hematology, Ege University Medical Faculty Hematology Department, Izmir, Turkey

Background: Myelofibrosis (MF), polycytemia vera (PV), and essential thrombocytosis (ET) are BCR-ABL negative chronic myeloproliferative diseases (CMPD) which may transform to acute myeloid leukemia or myelodysplastic syndrome. Furthermore, lymphoid malignancies are more prevalent in CMPD than normal population. Non-hematological malignancies are also increased in CMPD and those are related to several different etiologic factors.
Aims: Our aim is to evaluate secondary malignancies in our CMPD patients.
Methods: BCR-ABL negative CMPD patients diagnosed and followed up in Ege University Hematology department between 2000 and 2017 are retrospectively evaluated. Patients diagnosis, time of diagnosis, age, gender, mutational status regarding JAK-2, MPL and calreticulin, treatment, treatment side effects, physical examination findings, follow-up time and outcome are recorded. Patients who developed secondary malignancy are evaluated about their cancer treatment and outcome.
Results: There are 264 CMPD (138 female, 126 male) patients investigated. Distribution according to diseases are: 153 ET, 77 PV, 26 MF and 8 other CMPD. During follow-up, secondary malignancy occurred in 5 of our patients (1.89%): **Patient 1**: A male post-polycytemia MF patient, diagnosed at the age of 68. JAK-2 mutation is positive. He has been followed up since 10 years and receiving hydroxyurea 500-1500 mg per day. At the seventh year of CMPD, he was diagnosed as squamous cell skin cancer. After surgical resection, he is still in remission. **Patient 2**: A male ET patient, diagnosed at the age of 63. JAK-2, MPL and calreticulin mutations are negative. He has been followed up since 7 years. He received only hydroxyurea 1000-1500 mg per day for 6 years, hydroxyurea and anagrelide 1 mg per day combination for the last 1 year. At the fifth year of CMPD, he was diagnosed as squamous cell skin cancer on his ear. He treated only with cryotherapy and still in remission. **Patient 3**: A female ET patient, diagnosed at the age of 54. JAK-2, MPL and calreticulin mutations are negative. She has never received cytoreductive treatment. She has been followed up since 7 years. At the fifth year of CMPD, she was diagnosed as licen planus and after local therapies, her lesion is still stable. **Patient 4**: A male ET patient, diagnosed at the age of 54. JAK-2 mutation is positive. He has been followed up since 12 years. He received hydroxyurea for sometime after diagnosis but than swithced to anagrelide 2-4 mg per day since 10 years. At the eleventh year of CMPD, he was diagnosed as thyroid papillary carcinoma. After surgery,he was treated with radioactive iodine and now in remission. **Patient 5**: A female ET patient, diagnosed at the age of 43 after ischaemic cerebrovascular event. JAK-2, MPL and calreticulin mutations are negative. She has been followed up since 14 years. One year after diagnosis she received only hydroxyurea but during last 13 years she has switched to anagrelide 0.5-2 mg per day treatment. At the sixth year of CMPD, she was diagnosed as invaziveductal carcinoma and after mastectomy she received hormonotherapy. She is still in remission.
Summary/Conclusion: There are a number of evidences supporting that secondary malignancies are increased in CMPD patients compared to normal population. Although several factors, such as hydroxiurea, are blamed for that increase, the etiologic connection is yet unclear. Skin cancers have been the leading secondary malignancy (60%) in our study group. It is wise to keep in mind the reality of secondary cancers, during CMPD patients hematological management.

PB2314

RUXOLITINIB AND VITAMIN K ANTAGONISTS(VKA) IS SAFE AND EFFECTIVE AND SHOWS A FASTER RECANALIZATION AND AN ANTINFLAMMATORY EFFECT IN PRIMARY MYELOFIBROSIS(PMF) WITH SPLANCHNIC VEIN THROMBOSIS(SVT)

G. Giordano[1,*], A. Parente[2], D. Berardi[3], D. Castaldi[2], M.A. Cinotti[2], F. Vedruccio[2], V. Susca[4], L. Petrella[4], G. Berardi[5], M. Magri[6], G. Niro[6], R. Gigli[6]

[1]Medicine, Regional Hospital "A. Cardarelli", [2]Medicine, General Medicine, Campobasso, [3]Medicine, University La Sapienza, Rome, [4]Medicine, University of Molise, [5]Family Medicine, General Medicine, [6]Laboratory Medicine, Regional Hospital "A. Cardarelli", Campobasso, Italy

Background: PMF often causes SVT. Data regarding outcome of this subset of patients, mainly if treated with VKA plus ruxolitinib, are very few.
Aims: Aim of this case series is to analyze if use of ruxolitinib +VKA is safe and effective in treatment of patients with PMF with IPSS INT-2.
Methods: This study is a retrospective study. 4female patients, median age47 (R35-55), with PMF INT-2 and with SVT (2portal, 2mesenteric +splenic +portal), median Hb11.5g/dl (R11-12.5), PLT90000/mcl (R70000-100000), WBC10000/mcl (R4000-11000), peripheral blood blasts 1%(R1-2), 1 patient heterozygous for factor V Leiden received ruxolitinib 20mg/day +warfarin. All patients were Jak-2 mutated (GROUP1). In an historical cohort 6patients 2male, 4female median age60 (R45-65), 3PV, 1ET, 1PMF, 1 paroxysmal nocturnal hemoglobinuria and with SVT (4portal, 2splenic +portal), median Hb12.5g/dl (R10-13.5), PLT 150000/mcl (R110000-200000), WBC 8000/mcl (R6000-10000), peripheral blood blasts 0%(R0-1), 1 patient heterozygous for factor V Leiden, 1 for prothrombin G20210, received Hydroxyurea 1000mg (R500-1500)/day +warfarin. 3 patients were Jak-2 mutated (GROUP2). In an other historical cohort 6patients 4male, 2female median age60 (R55-70), 3liver cirrhosis, 3solid cancer and with SVT (5portal, 1splenic +portal), median Hb11.5g/dl (R9-12.5), PLT 100000/mcl (R90000-130000), WBC 4000/mcl (R2000-9000), peripheral blood blasts 0%,received only warfarin. 1 patient was Jak-2 mutated (GROUP3). All patients received an abdominal vascular doppler echography, C reactive protein(CRP) and D-Dimers(DD) mesuration at0, 3and6 months of follow-up. In patients receiving ruxolitinib circulating endothelial cells(CEC) were measured at same time (in flow cytometry with BDantibody CD146).
Results: Patients of GROUP1 showed a complete resolution of SVT in 2 cases and a partial portal recanalization in 2 cases after 3 months, without any thrombosis relapse or progression after 6 months; patients of GROUP2 showed a complete resolution of SVT in 2 cases, a partial portal recanalization in 2 cases and no resolution in 2 cases only after 6 months; patients

of GROUP3 showed a partial portal recanalization in 3 cases, no resolution in 2 cases and 1 progression only after 6 months.MedianCRP after0, 3and6 months(mg/l) was respectively inGROUP1 27(R18-33),8(R3-10),6(R3-7),inGROUP2 30(R20-35),18(R12-22),10(R7-15),in GROUP3 38(R28-40),35(R27-42),33(R22-35). MedianDD after0, 3and6 months(ng/ml) were respectively in GROUP1 6000(R4500-7000), 500(R300-1000), 130(R200-300), inGROUP2 4500(R3200-5500), 900(R850-2100), 400(R350-800), in GROUP3 2800 (R1300-3200), 4700(R3700-4900), 3500(R3000-4800). MedianCEC/ml inGROUP1 after0, 3and6 months(mg/l) were respectively 1500(R800-5500), 800(R600-1800), 500(R400-1200). InGROUP1 all patients showed reduction of spleen dimension and improuvement of systemic symptoms, InGROUP2 3 patients showed reduction of spleen dimension and0 improuvement of systemic symptoms, InGROUP3 no patients showed reduction of spleen dimension and improuvement of systemic symptoms. No patient showed side effects treatment related.
Summary/Conclusion: Ruxolitinib and VKA is safe and effective and shows a faster recanalization and an antinflammatory effect in patients with PMF with SVT. These results needs confirmation on a larger cohort of patients.

PB2315

ESSENTIAL THROMBOCYTHEMIA ASSOCIATED WITH MASTOCYTOSIS

E. Cosi*, M. Pizzi, M. Cancian, I. Bertozzi, C. Santarossa, F. Fabris, M.L. Randi

Department of Medicine, University of Padua, Padova, Italy

Background: Systemic mastocytosis with an associated hematological neoplasm (SM-AHN) is the second most common subtype of SM (estimated frequency 21-44%). In the majority of patients with SM-AHN, a myeloid stem cell malignancy is diagnosed but association of essential thrombocythemia (ET) and SM is anecdotal
Aims: In this work we described a case of Essential Thrmobocythemia associated with Mastocytosis completely diagnosed according to the more recent WHO 2016 criteria and we performed a review of all reported cases in literature about this association.

Table 1.

Sex/Age	Plts x10^9/L	Clinical findings at presentation	Molecular biology	Treatment	FU	Reference
F/65	1373	Maculo-papular skin lesions Bone lesions	-	HU	Normal plts	Krsnik (1991)
F/55	900	Bone lesions	-	none	Stable	Le Tourneau (1991)
M/64	900	Superficial adenopathy	-	HU	NO SM (3y)	
F/22	1000	Maculo-papular skin lesions	-	HU	NO SM (3y)	
M/60	1000	Bone lesions	-	HU	Normal plts. Stable 6 y	
M/68	940	Mild SM	-	HU	Normal plts. Stable 3 y	
F/31	820	Mild spleen enlargement	*JAK2V617F cKITD816V*	IFN-a	Normal plts. Stable BM after 3 y	Dobrea (2012)

Methods: We describe a 62 years-old man with thrombocytosis (600-750x10^9/L), longstanding hepato-splenomegaly and skin lesions compatible with maculopapular lesions at arms and legs roots (urticaria pigmentosa) treated with phototherapy. The patient had no lymphadenopathy. An abdomen ultrasound revealed fatty liver and splenomegaly (largest dimension 18.7cm); in addition, lateral X-ray pictures of the thoraco-lumbar spine showed multiple moderate vertebral fractures. Hemoglobin and white cells count were normal; despite a normal ferritin, homozygosity for *HFE H63D* mutation was detected. We searched for and found *JAK2V617F* mutation (allele burden 9.3%). The bone marrow (BM) biopsy, showing normal cellularity with normal M:E ratio (3:1), preserved myeloid and erythroid maturation, increased megakaryopoiesis (6-7 megakaryocytes/HPF), large/giant megakaryocytes with hypersegmented nuclei disposed in loose clusters, confirmed the hypothesis of ET. Perivascular and paratrabecular aggregates of spindle-shaped mast cells (MCs) were also present. These cells featured fine metachromatic granules and were intermingled with eosinophils and mature-looking lymphocytes. By immunohistochemistry, MCs were positive for triptase and CD117, with aberrant expression of CD25 and CD2. An increase in bone marrow reticulin fibers (MF grade 2) was present in MC-infiltrated areas. Cytogenetic analysis disclosed a normal male karyotype (46, XY). Elevated serum triptase level (123ng/mL) and oncogenic *KIT D816V mutation* definitely established the diagnosis of SM. No mutation in *TET2, ASXL1, SRSF2, RUNX1* and *CBL* genes was found. Treatment with low-dose Aspirin and Hydroxycarbamide (HU) was started and the platelets count rapidly falls to normal values. Two years after diagnosis our patient is alive and in good clinical conditions.
Results: Only seven other patients are described in English literature with ET-SM.
Summary/Conclusion: This is the first reported case of ET-SM diagnosed in agreement with the WHO 2016 criteria. Although SM-AHN are considered risk factor for reduced survival, mainly in patients older than 60 years of age, when SM coexists with ET, the less aggressive form among Myeloproliferative Neoplasms (MPN) that does not reduce the patients' expected survival, prognosis may be doubtful and the absence of mutation in other genes seems to confirm this observation. In the few ET-SM described cases as in our one, HU resulted an efficient and safety treatment.

PB2316

THERAPY OF PATIENTS WITH PREFIBROTIC STAGE OF PRIMARY MYELOFIBROSIS: LONG-TERM EFFECTS

E. Burnasheva[1,*], Y. Shatokhin[1], I. Snezhko[1], O. Matveeva[2], E. Grankina[1], A. Matsuga[3], A. Zeltser[4], E. Kuzub[1], O. Shatokhina[5], I. Eliseev[1], E. Osipyan[1]

[1]Hematology, Rostov State Medical University, [2]Out-patient department, Clinical and Diagnostic Centre "Health", [3]Hematology, City Hospital №7, [4]Laboratory of Medical Genetics, Rostov State Medical University, [5]Oncohematology, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation

Background: The use of ruxolitinib, interferon alfa and cytostatic agents is aimed at improving quality of life, prevention of progression and complications in patients with primary myelofibrosis (PMF). It is quite difficult to identify what kind of therapy is the most efective in patients with prefibrotic stage of PMF.
Aims: To assess the effect of different therapy regimens on the course of the disease in patients with prefibrotic stage of PMF.
Methods: We analyzed 32 Jak-positive patients with PMF (diagnosed according to the World Health Organisation Classification 2016). A total of 32 patients were included in this study. The age of subject ranged from 32 to 64 years. 8 patients were males and 24 - females. The mean follow-up was 42±9 month. Bone marrow biopsy control was performed in all the patients in 31±7 month. Estimation of spleen and liver size with ultrasound was made every 6 month. Patients were divided into three groups: 8 received 6±2 courses of cladribine and then interferon alfa, 10 were treated by interferon alfa and 14 received monotherapy by hydroxycarbamid.
Results: Bone marrow biopsy control showed fibrotic stage of PMF in all groups of patients. However there was difference in spleen size. Initially there was no significant difference in spleen size in all groups of patients (range 257±34 by 109±31 mm). By the end of follow-up average size of spleen were 157±24 by 64±12 mm, 167±33 by 79±27 mm and 199±21 by 92±29 in first, second and third group respectively.
Summary/Conclusion: Therapy with cladribine, hydroxycarbamide and interferon alfa doesn't influence the evolution of PMF. Cladribinein patients with prefibrotic stage of PMF significantly improves the quality of life due to more effective reduction of splenomegaly.

PB2317

RISK FACTORS FOR INCIDENCE OF HEMORRHAGIC COMPLICATIONS IN PATIENTS WITH POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA

E. Simonovic[1,*], V. Colic[1], L. Macukanovic-Golubovic[2]

[1]Internal Medicine, General Hospital Leskovac, Leskovac, [2]Internal Medicine, Clinic of Haematology, Niš, Serbia

Background: Polycythemia vera (PV) is a clonal chronic, progressive myeloproliferative disease, resulting from transformation of pluripotent hematopoietic stem cell. Essential thrombocythemia (ET) is a clonal disorder of unknown aetiology that involves multipotent hematopoietic stem cell, and it is characterized by increased formation of megakaryocytes in the bone marrow and distinctively increased platelet counts in peripheral blood without apparent cause. Hemorrhagic syndrome is the kind of complications occurring in about a quarter of patients with PV and reaching even 60% in patients with ET. Bleeding occurs due to ineffective megakaryocytopoiesis, retention of platelets in the large spleen, qualitative platelet disorders, acquired deficiency of factors V and vWF, disseminated intravascular coagulation.
Aims: The aim of this study is to monitor the count of erythrocytes, leukocytes and platelets, as well as hemoglobin and hematocrit values, as well as the presence of JAK2V617F mutation as potential risk factors for the incidence of hemorrhagic complications in patients with polycythemia vera and essential thrombocythemia.

Methods: During the five-year period we monitored the occurrence of hemorrhagic complications in 66 patients (of both sexes, aged between 30 and 78 years), being diagnosed with PV and 28 patients (of both sexes, aged between 38 and 79 years), being diagnosed with ET. We used methods of clinical, laboratory, ultrasound and CT scans. The following possible risk factors were monitored: counts of erythrocytes, leukocytes and platelets, hemoglobin and hematocrit values, as well as the presence of JAK2V617F mutation. Aspirin administration was also monitored for prophylaxis of thrombotic complications.
Results: The highest percentage of hemorrhagic complications were in the group of patients with ET and then in the group with PV. In both groups, the incidence of hemorrhagic complications in patients older than 65 years of age was higher. The highest erythrocyte count, the highest hemoglobin and hematocrit values, as well as the highest leukocyte count was recorded in the group of patients with PV. The highest platelet count was found in the group of patients with ET. Hemorrhagic complications were more frequent in patients with platelet count over $1000x10^9$/L. JAK2V617F mutation was more commonly reported in patients with PV (89%). In those patients, the hemorrhagic complications were also slightly more frequent than in the group of JAK2 negative patients. In patients with ET, the percentage of JAK2V617F positive patients was 48. There was no statistical significance regarding the occurrence of hemorrhagic complications between JAK2 positive and JAK2 negative patients. About 70% of patients with PV and ET were put on prophylactic administration of Aspirin. Studies have shown that statistically significant number of patients from both groups, who were on the prophylactic administration of Aspirin, showed some of the hemorrhagic complications.
Summary/Conclusion: The platelet count can be considered as a significant parameter for monitoring the risk of hemorrhagic complications in patients with ET and PV. The presence of JAK2V617F mutation as a risk factor for the development of hemorrhagic complications can be considered in the context of other risk factors. Monitoring of patients who were on the prophylactic administration of Aspirin had special importance, particularly when other risk factors for prevalence of hemorrhagic complications were present.

PB2318

REAL-LIFE EXPERIENCE WITH RUXOLITINIB IN POLYCYTHEMIA VERA PATIENTS RESISTANT OR INTOLERANT TO HYDROXYUREA

E. González Pérez*, M.D.L.N. Sáez Perdomo, R. Stuckey, M.D.M. Perera Álvarez, S. Sánchez Sosa, C. Bilbao Sieyro, Y. Florido Ortega, A. Segura Díaz, M.T. Molero Labarta, M.T. Gómez Casares

Hematology Service, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Spain

Background: Polycythemia vera (PV) is a Philadelphia chromosome-negative chronic myeloproliferative neoplasm characterized by mutation in Janus Kinase 2 (JAK2V617F), which is present in 95%–97% of PV patients. The most commonly used first-line cytoreductive agent is hydroxyurea (HU), although 1 in 4 patients become intolerant or resistant to HU. Until 2016, interferon was the main second line treatment. However, the discovery of JAK2V617F mutation and the realization of the critical role that the JAK-STAT pathway has in the pathogenesis of the disease led to the development of the JAK1/2 inhibitor ruxolitinib. Use of ruxolitinib as a second line therapy has been shown to be efficacious in clinical trials; however, few real-life experiences have been reported to date.
Aims: The main aim of this study was a preliminary analysis of the effects of ruxolitinib treatment in HU-resistant or intolerant PV patients in a single center.
Methods: Five PV patients at our hematology service were hydroxyurea resistant or intolerant and were not currently included in clinical trials. Their date of diagnosis ranged from 1999 to 2014. Analytical parameters were extracted from routine analysis. The presence of the JAK2V617F mutation was detected by RT-PCR.
Results: Of the 5 PV patients resistant or intolerant to hydroxyurea, 3 were women (60%). Three (60%) were aged 60 years and over at the date of diagnosis (mean age at diagnosis 60.4±1.67 years). Of the 5 PV patients, 3 (60%) were resistant to HU and 2 (40%) were intolerant. All patients presented the JAK2V617F mutation, with a mean allelic burden of 54.75±31.76%. Maximum HU doses were 2 g/24 h (mean range 1.5±0.71 g/24 h), and mean time with HU treatment was 6.4±6.19 years. The mean hematological parameters of the PV patients at diagnosis, at time of commencement with ruxolitinib, and date of last analysis is shown in Table 1. In general, adverse effects after commencement with ruxolitinib treatment reported were grade 1 or 2. Most common nonheamatological adverse events were asthenia, headache and pruritus. No patients has suffered any infections after of commencement with ruxolitinib treatment. With ruxolitinib, pruritus and asthenia symptoms improved for all patients, except in one patient who suffered a worsering of asthenia after commencement with ruxolitinib, but also an improvement of it after few months of treatment.. At the hematological level, there was a generalized recovery to normal levels with ruxolitinib treatment, especially platelet concentration. At the last analysis, no patients had progressed to secondary myelofibrosis and all patients were still alive.

Table 1.

	Hematocrit (%)	Hemoglobin (g/dL)	Platelets (10^3/µL)	Leukocytes (10^3/µL)	Spleen (cm)
Diagnosis date	53.4±9.79	16.94±3.25	509.8±108.20	11.76±6.28	0±0
Commencement with ruxolitinib	41.16±2,79	12.74±1.11	291.66±351.54	19.21±15.58	0.96±2.14
Last analysis	36,2±4,26	12.14±1.01	234.2±141.49	9.63±4.11	0±0

Summary/Conclusion: Five HU-resistant or intolerant PV patients treated with ruxolitinib had a generalized improvement at the hematological level and an improvement of pruritus and asthenia symptoms. The outcomes of the outlined studies suggest that ruxolitinib is generally well tolerated as a second line treatment HU-resistant or intolerant PV patients. This preliminary study will be extended to include further patients to confirm these results.

PB2319

TREATMENT WITH RUXOLITINIB FOR MYELOID MYELOFIBROSIS THE EXPERIENCE OF SINGLE CENTRE

A.-M. Moldovianu*, R. Stoia, D. Coriu

Hematology, Institutul Clinic Fundeni, Bucharest, Romania

Background: Myeloid myelofibrosis is a malignant hematologic disease characterized by clonal transformation of the stem cell precursors resulting in medullary myelofibrosis and extramedullary hematopoiesis. Ruxolitinib is a current therapeutic option for patients presenting with splenomegaly and constitutional symptoms.
Aims: The objectives of our work is to analize the results of ruxolitinib treated MF patients in Fundeni Clinical Institute.
Methods: Between January 2014 and December 2017 in our institution, 39 patients diagnosed with primary or secondary myelofibrosis were treated with ruxolitinib. Patients were stratified into risk groups according to the dynamic international prognostic scoring system. We analized the patient data regarding the dose of ruxolitinib, required support treatment including transfusions, required concomitant medication, treatment tolerance, side effects and causes of death. The response evaluation was done by assessing the evolution of constitutional symptoms and splenomegaly.
Results: From 39 MF patients treated with ruxolitinib, 37 were considered evaluable. Median follow-up period was 17 months (3-34 months). 27 (72,97%) patients are still on treatment. There were 10 (27,02%) cases of treatment stop due to: death in 6 (16,21%) patients and treatment failure in 4 (10.81%) patients. The main benefit from ruxolitinib treatment was, as our results showed, the improvement of constitutional symptoms in 31 (83,78%) of the patients. The effects on splenomegaly were similar to those described in the literature. 27 (72,92%) of the patients had a reduction of the spleen size more than 30% at one time in the follow-up period. The toxicities were especially hematologic and the majority were non-severe (grade 1-2). Dose reduction was necesary most frequently due to thrombocytopenia. There were 6 deaths, 4 of them possibly treatment related: 3 cases of respiratory infection and one case of urosepsis. Two patients had acute leukemia transformation of the disease.
Summary/Conclusion: Even there are no studies demonstrating the impact of ruxolitinib treatment on overall survival in myelofibrosis patients, its benefits on reducing splenomegaly and improving the constitutional symptoms make ruxolitinib the best available therapy as a symptomatic treatment.

PB2320

A HITHERTO UNDESCRIBED VHL SINGLE NUCLEOTIDE POLYMORPHISM INDUCED/RELATED POLYCYTHAEMIA ENTITY, CLINICAL FEATURES AND FAMILIAR CHARACTERISTICS. CLINICAL APPROACH

M. Udvardy*, G. Remenyi, Z. Simon, A. Illes

Department of Haematology, Bone Marrow and Cell Therapy Unit, Debrecen Medical University, Debrecen, Hungary

Background: At our outpatient we recorded 5 cases of young patients (tweens or tweens) who had remarkably high hemoglobin levels (175-200g/l range) and had mutation of Jak2, Jak exon 12,mpl W 515. None of them were heavy smoker. Their erythropoietin levels were in the lower normal range. Their erythrocytosis was isolated, no splenomegaly, minimal skin signs were detected. Interestingly a strong familiarity documented high heaemoglobin levels in young relatives were also detected along more frequent other oncological disorders.
Aims: Our aims were: 1. To find aetiologic factors for this unusually early polycthaemia syndroma, familiarity and oncologiaval associations; 2. try to characterise clinically this unusual cases and the clinical course; 3. try to establish therapy and followup for this peculiar clinical settings.
Methods: Considering oilycytheaemia, familiarity and oncogical disease associated cases we performed von Hippel Lindau gene (VHL) sequenations form tha plasmna of patients of some of first degree relatives. VHL sequenations were performed PCR amplification of VHL gene coding regions Intron sequences followed by direct fluorescent sequenation. This work had been performed by Dr Istvan Balogh, University Lab. Medicine institute, his work is kindly acknowledged None of the samples so far sequenced revealed any of the true, classical VHL gene mutation, but a polymorphism of the intron (IVS1-195-nt) before the 1st exon: namely rs779805 G>A, similar to what had been described in chinese population without blood count abnormalities (RCC, prostatic ,large bowel cancer association.
Results: In all proband cases, and 1st degree relatives we have found the same VHL gene single nucleotide polymorphism in homozygous or heterozagous form, namely rs779805 G>A. We were able to document high isolated hemoglobin levels in parents, siblings, nephiew, grandson, etc. Some of them had clear renal cell cancer (which also aoccurs in true VHL syndrome), melanoma, large bowel cancer, benign osteoclastomoa, Hodgkin. Leukocytosis, high platelet counts were not observed. Splenomegaly or skin signs were mild or absent. Due to the short observation period we did not find vascular complications, or MPN type transformations. Our treatment was cautious phlebotomy.
Summary/Conclusion: A Chinese survey clearly documented that rs779805 G>A, VHL gene single nucleotide polymorphism can be morre frequently associared with renal,large bowel, or skin cancer. They found this polymorphism much less in caucasians. none of these surves mention polycythemia or any other haematological abnormalities. So our findings might be considered as new ones. We do suggest to perform VHL sequenation in young peorple with otherwise unexplained polycythemia, especially with familiarity. We are going to open avenues cooperative efforts, how to proceed clinically with this cohort of oatients, and perform in depth genetical background analysis.

THIOL – DISULPHIDE HOMEOSTASIS IN POLYCYTHEMIA VERA

A. Senturk Yikilmaz[1,*], S. Akinci[2], S.M. Bakanay[1], F. Mustafayev[3], M. Alışık[4], S. Maral[2], Ö. Erel[4], I. Dilek[1]

[1]Department of Hematology, Yıldırım Beyazıt University,, [2]Department of Hematology, [3]Department of Internal Medicine, atatürk education and research hospital, [4]Department of Medical Biochemistry, Yıldırım Beyazıt University,, ANKARA, Turkey

Background: The balance of the thiol-disulphide homeostasis shifted to reductive thiol side in the Polycythemia Vera (PV).
Aims: This study aims to demonstrate in PV patients the thiol disulphide homeostasis which is known to play a role in cell proliferation, apoptosis and various steps of cell cycle.
Methods: Forty-two PV patients and 47 healthy controls were included in the study. Serum total (–SH + –S–S–) and native (–SH) thiol levels were measured in all subjects. The amount of dynamic disulphide bonds and, the ratio of (–S–S–) and (–S–S–) × 100/(–SH), (–S–S–) × 100/(–SH + –S–S), and –SH ×100/(–SH + –S–S–) were calculated with automatic method. The data obtained from the patient group were compared with the control group.
Results: Both groups were similar in terms of age and gender distribution. Compared with the control group, PV group had significantly higher native thiol, total thiol and nativ/total thiol levels.
Summary/Conclusion: In accordance with the nature of the disease, thiol balance in PV patients was in favor of proliferation. Increased total thiol (–SH + –S–S), native thiol (–SH) levels and native thiol/total thiol ratio might be associated with uncontrolled proliferation. his change can provocate proliferation status of the disease and/or may be secondary to the disease.

NEW POTENTIAL CANDIDATE GENES IN MANTLE CELL LYMPHOMA

O. Cédile[1,2,*], M.C. Hansen[1,2], L.H. Ebbesen[3], H.H.N. Bentzen[3], M. Thomassen[4], T.A. Kruse[4], S. Kavan[4], M.B. Møller[2,5], T.K. Kristensen[2,5], J. Haaber[1], N. Abildgaard[1], C.G. Nyvold[1,2]

[1]Department of Haematology, [2]Haematology-Pathology Research Laboratory, Odense University Hospital, Odense C, [3]Department of Haematology, Aarhus University Hospital, Aarhus, [4]Department of Clinical Genetics, [5]Department of Pathology, Odense University Hospital, Odense C, Denmark

Background: Mantle cell lymphoma (MCL) is a B cell non-Hodgkin lymphoma characterized by the translocation of the cell cycle regulator cyclin D1 (CCND1) under control of the immunoglobulin heavy chain (IGH) locus leading to the constitutive overexpression of CCND1 and cell cycle deregulation. The survival of MCL patients is still poor, especially for patients resistant to frontline therapy. Despite the remissions observed in patients, relapses often occur with disseminated lymphoma and are often more difficult to treat. There is a need for a better understanding of the clonal heterogeneity in MCL and to identify new genes, which could be targeted by novel drugs or be used as biomarkers to predict response to treatment.
Aims: We previously showed the genetic complexity and clonal evolution in MCL by exome analysis in paired samples at diagnosis and relapse and identified new mutations in genes involved in B-cell signaling pathways. In the current study, we have investigated the heterogeneity in gene expression in the same cohort of patients.
Methods: Malignant B cells at diagnosis and relapse from 4 MCL patients were sorted as presented at the EHA meeting in 2017 and subjected to total RNA sequencing together with CD19+ enriched B cells from 3 healthy donors. Six genes aberrantly expressed in MCL samples compared to healthy CD19+ B cells were selected and validated by qPCR in independent cohorts of diagnostic samples from MCL and chronic lymphocytic leukemia (CLL) patients. Peripheral blood mononuclear cells from 20 MCL and 20 CLL patients as well as CD19+ enriched B cells from 10 healthy donors were included. Exemption from informed consent was approved by the National Ethical Committee.
Results: The transcriptome analysis pointed to 19 upregulated genes. The expression of these genes varied between patients but also between paired diagnosis and relapse samples. This suggested clonal evolution or malignant progression and inter-patient heterogeneity, supporting our previous study. We selected 6 upregulated genes that were mainly associated to B cell signaling (CD1c, BLNK, MAP4K1, CCDC50, LILRA4 and PTPRJ) and explored the expression levels in MCL, CLL and healthy CD19+ B cells. While BLNK and CCDC50 were previously reported as highly expressed in MCL, we showed that BLNK expression was similar in MCL and CLL but slightly decreased compared to healthy CD19+ B cells. No difference was observed between MCL, CLL and healthy CD19+ B cells for the CCDC50 or MAP4K1 genes. CD1c was detected in MCL and CLL, although downregulated compared to healthy CD19+ B cells, with a lower expression in CLL than in MCL. This supports its expression in malignant B cells. Few studies detected PTPRJ and LILRA4 in MCL. We showed that PTPRJ was upregulated in MCL and CLL compared to healthy CD19+ B cells with a higher expression in MCL than in CLL. Interestingly, both MCL and CLL displayed 2 clear and different LILRA4 expression levels where the expression in healthy CD19+ B cells displayed an intermediate level.
Summary/Conclusion: Our transcriptome analysis supports the genetic complexity and the clonal evolution in MCL. It also identifies the genes CD1c, PTPRJ and LILRA4 to be aberrantly expressed in MCL with differential regulation of CD1c and PTPRJ in MCL and CLL. This study proposes new candidate genes to target with drugs or to use as biomarkers in MCL.

PB2323

THE ROLE OF MULTIPARAMETER FLOW CYTOMETRY IN THE WORK-UP OF IGM-MONOCLONAL GAMMOPATHIES

A. Mestice*, P. Curci, A. Vitucci, M. Urbano, V. Carluccio, S. Zucano, P. Carluccio, T. Perrone, A. Giordano, G. Specchia, R. Rizzi

Hematology Section, Dept. of Emergencies and Organ Transplantation, Bari University Medical School, Bari, Italy

Background: IgM-Monoclonal Gammopathy of Undetermined Significance (MGUS) accounts for 15 to 20% of all MGUS cases and it poses a unique diagnostic challenge as it can be associated with a broad spectrum of pathological processes including both B-cell lymphoproliferative disorders (LPD), and monoclonal-IgM related-disorders (IgM-RD). Among all, IgM-MGUS mostly progresses into Waldenström's macroglobulinemia (WM). According to the II International Workshop on WM (IWWM), IgM-MGUS and WM can be differentiated by absence *versus* presence of marrow infiltration by malignant B-cells, while smoldering WM (sWM) from sympomatic WM are differentiated by presence *versus* absence of clinical findings due to bone marrow (BM) infiltration.
Aims: Based on previous literature data, we aimed to evaluate the contribute of multiparameter flow cytometry (MFC) to discriminate between IgM-MGUS and WM by searching for clonal B-lymphocytes in BM and PB samples.
Methods: A total of 102 patients (64/38, M/F) with a median age of 70 yrs (36-89) were investigated. They were selected among patients with an IgM monoclonal gammopathy not associated with B-cell LPD other than WM. Median serum monoclonal (M)-protein level was 1.0 g/dl (0.2-3.9) and light-chain was kappa in 75% of cases. According to the II IWWM criteria, 52 patients were diagnosed as having MGUS, 23 sWM, and 27 WM. Fifty-one BM aspirates and 85 PB samples were immunophenotyped for evaluation of lymphocyte subsets and detection of clonal restriction by Ig K and λ light chain analyses on B-cell surface, irrespectively from B-cell proportion; all PB samples resulted positive for clonal restriction, and all BM aspirates were further analyzed with a large panel of MoAbs; data acquisition was performed on a Beckman Coulter Navios flow cytometer and analyses were performed by using Kaluza software.
Results: The median percentage of mature B-cells was found 1.8 (0-50) in PB, and 16 (1.3-50) in BM samples. Overall, in 56 out of 104 patients, clonal B-cells were detected; in particular, clonal restriction was demonstrated in 79% of BM and 40% of PB samples. The FCM results are summarized in the following table with regard to the different diagnosis. Of note, the identification of clonal populations required accurate gating strategies in 5 PB and 1 BM samples because of the presence of low clonal B-cell number within total B-lymphocytes.

Table 1.

	MGUS		sWM		WM	
	PB	BM	PB	BM	PB	BM
Number	47	12	16	15	32	24
Median lymphocytes % (range)	25 (12-38)	24 (8-41)	28 (7-51)	21 (12-34)	29 (10-65)	39 (13-61)
Median B-lymphocytes % (range)	3 (0-14)	3 (1-16)	1.5 (0-25)	4 (1-7)	1.4 (0-50)	26 (4-50)
Cases with clonal restriction (%)	9 (19)	5 (42)	10 (62)	12 (80)	15 (68)	24 (100)
Cases with involved/uninvolved light chain >10	3 (6)	4 (33)	3 (19)	5 (33)	7 (32)	21 (87)

Summary/Conclusion: Our results suggest a pivotal role of MFC in the diagnostic work-up of patients with IgM monoclonal gammopathies. Despite in most cases malignant cells display a non-specific phenotype, accurate gating strategies can enable to identify low-sized clonal populations within normal B-cell background in BM as well as in PB samples. In addition, further studies could establish a possible role of PB FCM studies in the management of patients with IgM monoclonal gammopathies.

PB2324

SARCOPENIA IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA IS CAUSED BY THE DEFICIENCY OF ESSENTIAL AMINO ACID TRYPTOPHAN

S. Ninomiya[1,*], N. Nakamura[1], H. Nakamura[1], J. Kitagawa[1], T. Hara[1], K. Saito[2], M. Shimizu[1], H. Tsurumi[1,3]

[1]Hematology, Gifu University Graduate School Of Medicine, [2]Internal Medicine, Gihoku Kosei Hospital, Gifu, [3]Hematology, Matsunami General Hospital, Hashima, Japan

Background: Sarcopenia, which is defined as the depletion of skeletal muscle, is associated with unfavorable outcomes in patients with some types of cancer including hematological malignancies. We previously reported that sarcopenia was a poor prognostic factor in patients with diffuse large B-cell lymphoma (DLBCL). However, the mechanism of development of sarcopenia has not been fully understood. Essential amino acid tryptophan is metabolized by indoleamine 2,3-dioxygenase (IDO) via kynurenine pathway. IDO is one of the immunosuppressive factor in tumor microenvironment. IDO was expressed in DLBCL tumor sites, and high IDO expression was a poor prognostic factor.
Aims: We hypothesized that the sarcopenia could be caused by the deficiency of essential amino acid tryptophan.

Methods: We retrospectively analyzed patients with DLBCL who treated in Gifu University Hospital. Skeletal muscle was measured by the analysis of CT images at the L3 level when they were diagnosed. The surface of muscular tissues was selected according to the CT Hounsfield unit. This value was normalized for stature in order to calculate the L3 skeletal muscle index (L3 SMI, cm2/m2). Serum concentrations of tryptophan and tryptophan metabolites, such as kynurenine were measured by HPLC. C2C12 myoblast cells and IDO-expressed lymphoma cell line (Raji-IDO) were used for investigating the effect of IDO on muscle.
Results: The value of L3 SMI was ranged from 27.2 to 52.2 cm^2/m^2. The levels of serum tryptophan was ranged from 20.2 to 105.7 μM, and serum kynurenine was ranged from 0.678 to 6.78 μM. We found that there was a positive correlation between the value of L3 SMI and the serum tryptophan level in DLBCL patients (p=0.015). These results indicated that tryptophan could be involved in clinically maintaining muscle mass. Therefore, we examined the effect of tryptophan and kynurenine on proliferation and myotube formation of C2C12 myoblast cells. We found that tryptophan depletion and kynurenine supplementation significantly reduced diameter of myotube from 248 to 110 μm and the number of myotube from 24.8 to 3.5 per field during 7 days. Interestingly, the depletion of leucine did not inhibit the proliferation and differentiation of C2C12 cells. Next, C2C12 were co-cultured with Raji cells expressing IDO for 7 days. The proliferation of C2C12 cells were inhibited by IDO-expressing cells, which metabolite tryptophan and produced kynurenines.
Summary/Conclusion: Sarcopenia in patients with DLBCL was caused by deficiency of tryptophan, which is metabolized by IDO. The reason why IDO positive DLBCL have poor prognosis might be not only tumor immunosuppression but also sarcopenia. Tryptophan supplementation and IDO inhibitors may prevent sarcopenia and improve the prognosis of DLBCL patients.

DETECTION OF MINOR BLOOD INVOLVEMENT IN MYCOSIS FUNGOIDES: PROGNOSTIC IMPLICATIONS

M.T. Cedena*, F. Mirás, L. Montejano, R. Sánchez, R. Ayala, J. Martínez-López

Hematology, H. 12 Octubre, Madrid, Spain

Background: Mycosis fungoides (MF) is the most frequent cutaneous T-cell lymphoma, generally with indolent course. It is accepted as a marker of poor prognosis a tumor load in peripheral blood of more than 1,000 cells/microL or more than 20% of the lymphocytes (B2), and equivalent to the nodal involvement (1). Less evidence exists on whether the detection of a lower tumor load in peripheral blood (B1<1,000 cel/microL) may have prognostic implications. In these cases of low tumor load, the manual Sézary count is difficult and requires a high experience. Techniques such as flow cytometry (FCM) and PCR (TCR gamma rearrangement) can help us to detect the presence of peripheral blood disease. Recently, the EORTC lymphoma cutaneous task force has recommended the FCM definition of blood-class even in patch/plaque/tumor MF (2), although the clinical implication of this minor blood involvement is to be defined.
Aims: To assess the degree of agreement between the results in the detection of Sézary cells in peripheral blood between FCM and PCR and the prognostic significance of the detection of low tumor load (stage B1).
Methods: The results obtained from 49 patients diagnosed of MF were retrospectively studied. The presence of circulating Sézary cells was analyzed by two techniques. For FCM, according to EORTC recommendations (1), presence of circulating Sézary cells was considered when the CD4/CD8 ratio was ≥10, or when the percentage of CD4 T negative for CD7>40% and/or for CD26>30%. The TCR gamma rearrangement was performed in parallel to identify clonal T cells. In addition, staging and survival data were collected.
Results: We identified 49 patients with MF, a median age 62 (19-88) years and 60% males. Samples of peripheral blood were sent in parallel for analysis by both techniques, at different times of the disease. Samples of 22/49 patients (45%) presented circulating Sézary cells according to FCM: in 7/22 sample with lymphocytes CD4 T>5,000/uL; in 6/22 samples, ratio CD4/CD8>10; in 10/22, CD3dim o negative; in 16/22, CD7dim or negative; in 21/22 samples, CD26 was negative. In 27/49 (55%) peripheral involvement was detected by either or both methods, FCM or PCR. The degree of agreement was moderate (kappa =0.457, p=0.001). There were discrepancies in results in 13/49 (27%) patients (8 positive exclusively for FCM and 5 positive only for PCR). All patients but one with positive samples only by FCM presented CD4 T<5,000/microL, ratio CD4/CD8<10, and CD7 or CD26 negativity were between 35-60%. It is known that a subtype of central memory CD4 T cells shows similar phenotype (CD2dim, CD7dim or negative, CD3dim, CD26negative) and certain overlap between normal T cells and Sézary cells could exit. With a median follow-up of 16.5 (1-48) months after the study, there were significant differences in survival between the group of peripheral blood involvement B2 with respect to the other two groups, without involvement (B0) or with low tumor burden (B1) (p= 0.039) (Figure 1). No significant differences were found in survival between stage B0 and stage B1.

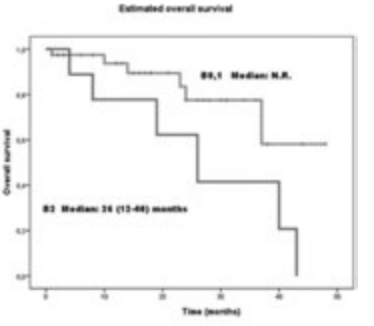

Figure 1.

Summary/Conclusion: FCM is a useful tool for detection of low load of circulating Sézary cells, being CD26 negative the more sensitive marker to discriminate them. Because its phenotyping overlaps with normal cells, false positive could be discarded with an additional assay, such as PCR. The detection of a minimal expression in peripheral blood (<1,000 cells/microL) does not seem to impact the survival of these patients in our series.

POTENT MYC AND RUNX COLLABORATION IN LYMPHOMA PERTURBS T-CELL RECEPTOR SIGNALLING AND ATTENUATES P53 TRANSACTIVATION

J. Hay[1,2,*], K. Gilroy[2,3], C. Huser[2], A. Kilbey[2,4], A. McCallum[2], E. Cameron[5], J. Neil[2]

[1]Paul O'Gorman Leukaemia Research Centre, [2]Molecular Oncology Laboratory, Centre for Virus Research, [3]Institute of Cancer Sciences, [4]Beatson Institute for Cancer Research, [5]School of Veterinary Medicine, University of Glasgow, Glasgow, United Kingdom

Background: Over-expression of MYC and RUNX family members collaborates strongly to drive lymphoma development, through their ability to neutralize their fail-safe methods of growth arrest and apoptosis. Although transgenic *Runx2* and *Myc* can independently collaborate with mutational loss of *p53* to induce T-cell lymphomas, their oncogenic cooperation overcomes the need to lose *p53* function.
Aims: To further investigate the potent oncogenic collaboration of *Runx2* and *Myc* and its mechanisms of neutralizing pressure for mutational loss of the *p53* pathway in vivo.
Methods: This oncogene collaboration has been studied further through gene expression array analysis of premalignant thymic tissue from a *Runx2/Myc* transgenic mouse model (GIM). Gene expression in 10 day old pre-lymphomatous *Runx2/Myc* thymus was examined compared to normal age-matched controls.
Results: The transcriptome of *Runx2/Myc* thymus shows predominantly gene up-regulation, and the most significantly altered genes are enriched for Myc and Runx binding motifs in the promoter proximal and enhancer regions respectively, suggesting indirect co-regulation of key target genes. Notably, screening of known post-translational modifiers of *p53* function reveals that the most significantly up-regulated gene is *Smyd2*. A role for SMYD2, a lysine methyltransferase, was further supported by its ability to block RUNX-induced senescence in primary fibroblasts. *Runx2/Myc* lymphoma lines lacking *p53* are resistant to a potent SMYD2 inhibitor (BAY-598) but our findings do not exclude an essential role for SMYD2 *in vivo*.
Summary/Conclusion: We have previously observed potent collaboration of *Runx2* and *Myc* in lymphoma development, and their ability to bypass the need for genetic loss of the *p53* pathway. To better understand this collaboration, we employed a gene expression microarray approach. This study showed a predominance of up-regulated genes in the *Runx2/Myc* (GIM)

mice compared to controls. Analysis of a panel of established *p53* modifiers showed up-regulation of several genes, including *Smyd2* and *Prmt5*. A role for SMYD2, a lysine methyltransferase, was further supported by its ability to block RUNX-induced senescence in primary fibroblasts. *Runx2/Myc* lymphoma lines lacking *p53* are resistant to a potent SMYD2 inhibitor (BAY-598) but our findings do not exclude an essential role for SMYD2 *in vivo*.

PB2327

THREE-DIMENSIONAL CULTURING INDUCES CHEMORESISTANCE AND INVASIVE CAPACITY OF MOUSE LYMPHOMA CELLS BY UPREGULATION TIAM-1/NOTCH

M. Ikram*

Anatomy, Pusan National University, Swat, Pakistan

Background: Lymphomas are a heterogeneous group of lymphoproliferative disorders of B and T cell origin that are treated with chemotherapy drugs with variable success rate that has virtually not changed over decades due to their more complex nature than solid malignancies. Till date new classes of chemotherapy and metabolic drugs have emerged, however durable responses to these conventional and new therapies are achieved in a limited number of cancer patients, with many individuals experiencing resistance to the drugs.
Aims: The paucity in our understanding of what regulates the drug resistance phenotype and establishing a predictive indicator is, in great part, due to the lack of adequate *ex vivo* lymphoma organoids models to accurately study the effect of microenvironmental signaling in which Non Hodgkin lymphomas cells arise and properly studied. Therefore, is a need to develop 3D tissues models that mimic the NHL microenvironment model for NHL biology and drug responses.
Methods: 3D cells culture methods including hydrogel, viability assay like WST based analysis, Annexin/PI staining, RT-PCRs for genes analysis, confocal microscopy and western blot analysis for protein expression analysis, Flow cytometric analysis for single cells sorting and cancer stem cell analysis, knock down effects by using specific inhibitions or designing siRNA of specific signaling molecule.
Results: we explored strategies to enhance chemosensitivity to doxorubicin, an important chemotherapeutic drug widely used for the treatment of hematological malignancies. Lymphoma cells grown in this model exhibited excellent biomimetic properties compared to conventional 2D culture including (1) enhanced chemotherapy resistance, (2) suppressed rate of apoptosis, (3) upregulated expression of drug resistance genes (MDR1, MRP1, BCRP and HIF- 1α), (4) elevated levels of tumor aggressiveness factors including Notch (Notch-1, -2, -3, and -4) and its downstream molecules (Hes-1 and Hey-1), VEGF and MMPs (MMP-2 and MMP-9), and (5) enrichment of a lymphoma stem cell population. Tiam1, a potential biomarker of tumor progression, metastasis, and chemoresistance, was activated in our 3D lymphoma model. Remarkably, we identified two synergistic therapeutic oncotargets, Tiam1 and Notch, as a strategy to combat resistance against doxorubicin in EL4 T and A20 B lymphoma.
Summary/Conclusion: Therefore, our data suggest that our 3D lymphoma model is a promising *in vitro* research platform for studying lymphoma biology and therapeutic approaches.

PB2328

FUNCTIONAL SCREEN FOR 177LU-LILOTOMAB SATETRAXETAN DRUG COMBINATIONS FOR TREATMENT OF AGGRESSIVE DIFFUSE LARGE B-CELL LYMPHOMA

G.E. Rødland[1], K. Melhus[2], J. Dahle[2], R. Syljuåsen[1], S. Patzke[2,*]

[1]Radiation Biology, OUH Norwegian Radium Hospital, [2]Research and Development, Nordic Nanovector ASA, Oslo, Norway

Background: CD37 is an internalizing transmembrane glycoprotein widely expressed on mature B-cells and B-cell malignancies. The next generation anti-CD37 radioimmunoconjugate (RIC) ^{177}Lu-lilotomab satetraxetan (Betalutin®), containing the beta-emitting radionuclide lutetium-177, is currently being tested as one-time injection therapy in a clinical phase 2b trial for follicular lymphoma (FL) and phase 1 trial for diffuse large B-cell (DLBCL) non-Hodgkin B-cell lymphomas.
Aims: The present work is to identify proliferation inhibiting drug combinations with ^{177}Lu-lilotomab satetraxetan in radioimmunotherapy resistant DLBCL cell lines.
Methods: Cell cycle progression and DNA damage induction in response to ^{177}Lu-lilotomab satetraxetan treatment was studied by flow cytometry in six human DLBCL cell lines. Two identified treatment resistant cell lines were treated for 18 hours with ^{177}Lu-lilotomab satetraxetan (600 MBq/mg; 1 or 0.5µg/ml), washed, and seeded on micro-well plates pre-printed with a drug library of 384 approved anti-cancer compounds at 10, 100, and 1000 nM f.c. (Selleck). Cell viability was monitored at days 3 to 6 post seeding using a RealTime-Glo™ MT Cell Viability Assay (Promega). Drug combinations were scored by effect size compared to drug or ^{177}Lu-lilotomab satetraxetan treatment alone.
Results: We identify two aggressive activated B-cell like DLBCL cell lines, U-2932 and RIVA, as resistant to treatment with ^{177}Lu-lilotomab satetraxetan (1 µg/ml) *in vitro*. Both cell lines arrest in G_2-phase with high amount of DNA damage (γH2AX staining) 18h after treatment, but display more than 80% viability six days post treatment. Two independent consecutive screens identify both cell line specific and shared compounds, which in combination with ^{177}Lu-lilotomab satetraxetan result in growth inhibition greater than the additive effect of single treatments alone. Compounds scoring as hit in both investigated cell lines are considered candidates for combination therapy with ^{177}Lu-lilotomab satetraxetan. Redundant hits are enriched in inhibitors targeting cell cycle kinases that regulate transition through mitosis, such as CDK1/2, AURKA, PLK1, as well as enzymes with important roles in DNA integrity surveillance and repair, such as Topoisomerases. Several identified compounds are in clinical trials for treatment of non-Hodgkin's lymphomas. Selected hits, comprising antimitotic small molecule kinase inhibitors, are currently under further functional characterization.
Summary/Conclusion: ^{177}Lu-lilotomab satetraxetan shows promising activity against different DLBCL cell lines, but treatment resistance in an *in vitro* assay is evident for triple hit lymphoma cell lines U-2932 and RIVA. Combinatorial drug screening identifies ^{177}Lu-lilotomab satetraxetan resistance reversing targets. Candidate compounds under clinical development for lymphoma treatment present particularly interesting leads for further functional characterization in mouse xenograft models of human lymphoma and new avenues for future radioimmuno-combination therapy.

STRONG PD-1 EXPRESSION ON TUMOR-INFILTRATING T-CELLS IN DIFFUSE LARGE B CELL AND FOLLICULAR LYMPHOMA

S. Bellesi[1,*], F. Corrente[1], A. Cuccaro[1], F. D'Alò[1], P.L. Puggioni[1], E. Maiolo[1], M. Martini[2], L.M. Larocca[2], V. De Stefano[1], S. Hohaus[1]

[1]Istituto di Ematologia, Università Cattolica del Sacro Cuore, [2]Istituto di Anatomia Patologica, Università Cattolica del Sacro Cuore, ROME, Italy

Background: Blocking the PD-1 immune checkpoint is a therapeutic strategy with unprecedented clinical efficacy in the treatment of advanced cancers including hematological malignancies. Evaluation of PD1 expression in lymphoma biopsies has been studied using immunohistochemistry.
Aims: The aim of the present study was to assess the expression of PD-1 in lymph node suspensions of 67 patients with lymphomas compared to reactive and metastatic lymph nodes using flow cytometry (FCM).

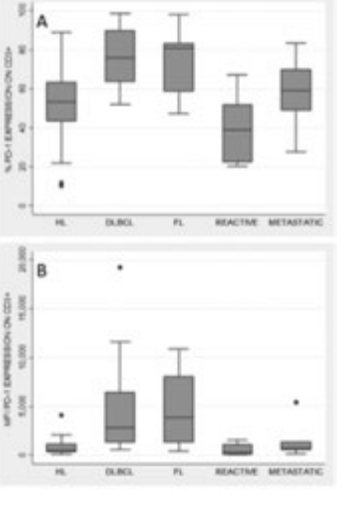

Figure 1.

Methods: Lymph node biopsies were obtained at diagnosis from 16 patients with diffuse large B-cell lymphoma (DLBCL), 11 patients with follicular

lymphoma (FL), 27 patients with Hodgkin lymphoma (HL), 6 patients with metastatic carcinomas and 7 patients with reactive lymph nodes. Lymph node suspensions were prepared by mechanical disaggregation of solid tissue using the Medimachine system (BD Biosciences). PD-1 (CD279, clone EH1 2.1, BD Biosciences) expression was assessed on CD3+, CD4+ and CD8+ T-lymphocytes. Fluorescence Minus One (FMO) was used in setting the gate for positive events. Data were acquired on BD FACSCantoII flow cytometer (BD Biosciences) and analyzed using BD FACSDiva software (BD Biosciences). Data were expressed as percentage of expressing cells and median fluorescence intensity (MFI).

Results: PD-1 was expressed on 53% (median, range: 10% to 89%) of tumor-infiltrating T cells in HL, which was not statistically different from PD1 expression on T cells from reactive (39%, p=0.149) and metastatic lymph nodes (59%, p=0.241). In contrast, T cells from lymph node biopsies from both DLBCL (n=16) and FL (n=11) showed higher expression of PD-1 on CD3+ T-cells (76% and 81%, respectively), when compared to both HL (53%, p<0.01) and to reactive lymph nodes (39%, p<0.01) (Fig. A). The higher PD-1 expression on CD3+ population of DLBCL and FL was also confirmed when analyzing the median fluorescence intensity. MFI on tumor-infiltrating T cells was 2855 (median, range: 582 to 19238) in DLBCL and 3889 (median, range: 451 to 10895) in FL, while it was only 536 (median, range: 88 to 4085) in HL and 339 (median, range: 69 to 1573) in reactive lymph nodes (p<0.001) (Fig. B). The pattern of PD1 expression on the CD3+ T cells was stable across CD4+ and CD8+ T-cells subpopulations in all samples. No significant difference was observed in PD1 expression on tumor-infiltrating T cells between DLBCL and FL.

Summary/Conclusion: Flow cytometric evaluation yields rapid and quantifiable information on PD1 expression of tumor-infiltrating T cells. We found strong PD1 expression on tumor-infiltrating T cells in lymph node biopsies of patients with newly diagnosed B-cell Non-Hodgkin lymphomas, both of diffuse large B cell and follicular type. This expression was stronger than on T cells from HL biopsies and reactive lymph nodes. Further studies are needed to assess the utility of flow cytometric evaluation of PD1 expression as a biomarker for immune checkpoint inhibition.

PB2330

BONE MARROW STROMAL MICROENVIRONMENT PRECURSOR CELLS IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA WITHOUT BONE MARROW INVOLVEMENT

E. Fastova*, N. Petinati, N. Sats, N. Drize, A. Magomedova, S. Kravchenko, V. Savchenko

National Research Center for Hematology, Moscow, Russian Federation

Background: Bone marrow (BM) is not affected in most patients with Diffuse Large B-cell Lymphoma (DLBCL). In the onset of the disease, histological examination shows no changes in the BM stroma. Patients, depending on IPI, are treated either by R±CHOP courses or by the program R±mNHL-BFM-90. Immediately after the course of treatment and in the distant periods (6-12 years), changes in the bone marrow stroma are observed. There is no data about alterations in stromal precursor cells (multipotent mesenchymal stromal cells /MSCs/ and colony forming unit fibroblasts /CFU-F/).

Aims: The aim of the study was to investigate the changes in MSCs and CFU-F from the BM of patients with DLBCL at the onset of the disease and 6-12 years after treatment.

Methods: The study included 10 patients at the onset of the disease, 20 after treatment with R±mNHL-BFM-90 and 11 with R±CHOP. In all patients BM was taken after informed consent. From the BM, MSCs were isolated by the standard method and the concentration of CFU-F was determined. The relative expression level (REL) of various genes in MSCs was determined by real-time PCR. As a control 31 MSC samples from the BM of healthy donors selected for each group of patients according to age were used.

Results: DLBCL patients' stromal progenitor cells differ from those of donors. In primary patients, the concentration of CFU-F in the BM is reduced by 30%. After R±CHOP, it is 2 times reduced compared with donors and 1.6 times with primary patients. After R±mNHL-BFM-90 it is 1.5 times higher than that of donors and 2 times higher than in patients after R±CHOP. The total cellular production of MSCs in primary patients is 2.3 times higher than that of donors. Many years after R±CHOP, it almost reaches the level of donors, after R±mNHL-BFM-90, it remains 1.7 times higher. Activation of the stromal microenvironment occurs. The expression of *FGF2* in MSCs is reduced in primary patients and years after treatment. The REL of *FGFR1* is also lower in patients compared to donors. The REL of *FGFR2* is doubled in primary patients compared to donors and remains significantly increased years after the treatment. The REL of *ICAM1* and *MMP2*, involved in the adhesion of hematopoietic cells, are reduced by 2 times, which indicates irreversible changes in the ability to maintain hematopoiesis irrespective of the treatment. Osteopontin (*SPP1)* regulates the quiescent state of hematopoietic stem cells (HSC) in a niche. In primary patients, the REL of this gene is increased almost 3 times in comparison with donors. In patients after R±CHOP, it decreases, and after treatment with R±mNHL-BFM-90, it rises even more. Apparently patients MSCs react to the lymphoid tumor and use the mechanisms of HSCs protection. The level of osteocalcin (*BGLAP)* expression is reduced in primary patients and remains low for years regardless of the treatment. Patients bone tissue suffers and these changes are not restored. The REL of interleukin 6 (IL6) is reduced in primary patients by 3.5 times in comparison with donors. Years after chemotherapy, it remains reduced 2 times regardless of the treatment. IL6 is a growth factor for lymphoid cells and simultaneously a pro-inflammatory cytokine. Its decrease can also be attributed to the protective mechanisms used by the MSCs.

Summary/Conclusion: Stromal BM precursor cells respond to a lymphoid tumor even if there is no BM involvement. Analysis of all factors shows that many years after treatment, the characteristics of MSCs are only partially restored. Supported by grant from the Russian Foundation for Basic Research, Project 17-00-00170.

FINE-NEEDLE-ASPIRATION: IS IT A USEFUL DIAGNOSTIC TOOL?

Á. Gil[1,*], D. Subirá[2], F. Barriopedro[1], R. Martínez[1], T. Miguel[3], A. Rosell[4], H. Guillén[1], A. Pérez[1], A. Vázquez[1], S. Herrero[1], J. Arbeteta[1], N. Golbano[1], D. Morales[1], L.M. Juárez[1], D. de Miguel[1]

[1]Hematology, [2]Immunology, [3]Internal Medicine, [4]Pathology, Hospital de Guadalajara, Guadalajara, Spain

Background: The diagnosis of NHL is based on histological findings from biopsies, but clinicians often perform fine-needle aspirations (FNA). This rapid and cost-effective procedure provides material for both cytology (Cy) and flow cytometry immunophenotyping (FCI) studies.

Aims: To determine the accuracy of the combined use of Cy and FCI in samples obtained by FNA to discriminate between reactive/benign processes (RP) and neoplasia (N). For this purpose, FNA report was correlated with clinical follow-up and histology from patients submitted to excisional biopsies to achieve the definitive diagnosis (Image 1).

Methods: From March 2010 to December 2016, 380 FNA specimens from 357 patients were obtained from lymphoid tissues (n=219), transbronchial aspirations (n=95) and extranodal sites (n=66). Median follow-up from the time of FNA study was 35.5 months (0-95.4). Conventional cytological techniques were applied. For FCI, a stabilisating reagent was added to fresh samples (≥16 hours) before using a standard stain-lyse-wash protocol. For screening, mAbs against CD45, CD3, CD4, CD8, CD19, CD20, CD22, CD56, kappa and lambda were used. Additional reagents were only included if the screening test showed data of malignancy. Results from Cy&FCI were considered as concordant when they matched together with their discrimination between RP and N, further classified as lymphoma, carcinoma, other hematological (OHN), and other neoplasms (ON).

Table 1.

			Results from FNA samples							
			Concordant Cy&FCI		Only one technique Cy		Only one technique FCI		Misdiagnosed Cy&FCI	
Definitive diagnosis	n	%	n	%	n	%	n	%	n	%
Reactive/ Benign	229	63.97	185	80.8	29	12.66	12	5.24	3	1.31
NHL	43	12.01	35	81.4	2	4.65	3	6.98	3	6.98
Hodgkin lymphoma	9	2.51	0		8	88.89	0		1	11.11
OHN	7	1.96	5	71.4	0		2	28.57	0	
Carcinoma	66	18.44	20	30.3	30	45.45	1	1.52	15	22.73
ON	2	0.56	1	50.0	0		0		1	50.0
Others*	2	0.56	2	100.0	0		0		0	
TOTAL	358		248	69.27	69	19.27	18	5.03	23	6.42

Results: Twenty-two samples were discarded because loss of patient s follow-up (n=7), or necrosis/insufficient material for study (n=15). In 30 of the remaining 358 samples, material was adequate for either Cy or FCI, and 328 samples (91.6%) were properly evaluated by both methods. A concordant result between Cy&FCI correlated with the definitive diagnosis in 69.3% of samples, mostly RP (80.8%) (Image 1). Within RP, 3 double Cy&FCI false positive results were reported (1.3%); in contrast, 16/68 solid tumors (23.5%) were misdiagnosed by both techniques. Regarding the hematological diseases, an exact identification was done by Cy&FCI in 81.4% of all NHL (n=35) and 71.4% of OHN. Interestingly, 33 out of 35 NHL (94.3%) were new

diagnosis, and FCI data were concordant with the definitive histological subclassification in 26/33 NHL (78.8%). In contrast, both Cy&FCI reported a false negative result in 1 Hodgkin lymphoma (HL) and 3 NHL (6.98%). Thirteen samples (3.6%) had discrepant Cy&FCI results: Cy correctly identified 2 carcinoma, 2 NHL and 3 RP; FCI correctly identified 3 low-grade NHL and 3 RP. The sensitivity, specificity, and positive and negative predictive values of concordant Cy&FCI results were 81.2%, 98.4%, 95.4% and 92.9% respectively for all type of malignancies as compared to 90.9%, 98.9%, 93% and 98.5% for hematological neoplasms only.
Summary/Conclusion: Adequate material for both Cy&FCI studies was obtained in most samples of our series. Their combined use didn t preclude discrepant results, but the high correlation between a concordant negative Cy&FCI result and RP may avoid unnecessary biopsies. Regarding neoplasms, there was a much better correlation between the results of Cy&FCI in hematological diseases than in carcinomas. The diagnosis of HL relied on Cy only, but the feasibility of FCI for grading NHL allows a prompt start-up of extension studies until achievement of definitive diagnosis with a second diagnostic procedure.

IGVH GENES IN SPLENIC MARGINAL ZONE LYMPHOMA COMPLICATED WITH AUTOIMMUNE HEMOLYTIC ANEMIA

H.L. Julhakyan*, B. Biderman, A. Sudarikov

National Research Center for Hematology, Russian Federation, Moscow, Russian Federation

Background: Splenic marginal zone lymphoma (SMZL) is an indolent B-cell lymphoma frequently associated with monoclonal gammopathy and autoimmune disorders. Therefore, whereas it is well known that the prevalence of autoimmune hemolytic anemia (AIHA) is highest in the more advanced stages of the disease and may depend on the type of treatment administered.
Aims: The ame of this study was to investigate association between autoimmune hemolytic anemia (AIHA) and IgVH genes status.
Methods: We searched in our database of 118 SMZL patients consecutively referred from 2005 to 2017. We identified 9 SMZL patients (7,6%) who developed overt AIHA. All patients met the SMZL WHO diagnostic criteria. AIHA was defined with standard criteria: a fall in hemoglobin level of at least 2 g/dL, associated with a positive direct Coombs test and/or increased reticulocyte count, and a rise in indirect bilirubin with no other causes of anemia identified. *IGHV* mutational status was determined by Sanger sequencing. Cases with 98% or higher *IGHV* gene homology to germinal sequences were considered unmutated. We performed a case-control study comparing the 9 patients with SMZL and AIHA with 10 SMZL patients without AIHA.
Results: A higher prevalence of unmutated *IgVH* was found in patients with AIHA (7 of 9, 77,8%). In comparison only 1 of 10 (10%) controls showed unmutated *IgVH*, as expected in an unselected cohort. The Pirson criteria significant in cases with unmutated *IgVH* in SMZL with AIHA (p<0,05). No significant difference was observed in VH family distribution between the two groups. There was a tendency towards more common tumor progression in patients with unmutated *IgVH* genes with AIHA than in those with mutated ones without AIHA. In all cases SMZL with AIHA were present monoclonal secretion of paraprotein.
Summary/Conclusion: Our data show that AIHA is associated with unmutated status in SMZL patients and that patients with early onset of AIHA have a shorter survival. Larger prospective cohorts are needed in order to verify this observation, and to tell us whether the association is directly causal or whether it reflects an increased tumor bulk at the time of AIHA development.

PB2333

IGHV GENES AND STEREOTYPIC RECEPTORS IN DIFFERENT B-CELL MALIGNANCIES

B. Biderman[1,*], H. Julakyan[1], L. Al-Radi[1], T. Trishkina[1], E. Nikitin[2], P. Butylin[3], A. Rumyantsev[3], E. Stadnik[3], S. Kulikov[1], A. Sudarikov[1]

[1]National Research Center for Hematology, [2]S.P.Botkin Clinical Hospital, Moscow, [3]V.A.Almazov North-West Federal Medical Research Center, Saint Petersburg, Russian Federation

Background: Immunoglobulin heavy chain V-gene (IGHV) mutational status is known to be a key factor for the long-term prognosis in B-cell chronic lymphocytic leukemia (B-CLL). In addition, the diversity of rearranged IGHV genes in B-CLL cells is very limited and significantly different from that of normal B cells. Recent data obtained suggest narrowing of the IGHV repertoire not only in B-CLL but also in other B-cell lymphomas (such as hairy cell leukemia, marginal zone lymphoma, etc.).
Aims: To compare the sequences of IGHV genes in patients with various B-cell malignancies.
Methods: The study included 790 patients with B-CLL, 45 with splenic marginal zone lymphoma (SMZL) and 33 with hairy cell leukemia (HCL). Rearranged IGHV genes for 683 patients observed at the National Research Center for Hematology (2006-2017) and for 185 patients observed at Almazov North-West Federal Medical Research Center (2012-2016) were sequenced according to Sanger procedure and analyzed as described in [Biderman *et al*., 2012].
Results: Rearranged IGHV gene repertoire for B-cell malignancies was compared. V-gene family usage was different for B-CLL, HCL and SMZL. For example, VH3 genes are most often (60%) expressed in HCL, VH4 and VH1 genes are less common - 21% and 12%, respectively. In SMZL, half of all cases represent VH1 genes (51%), 27% - VH3 genes and 15% - VH4. In the case of B-CLL, 45% are VH3, 30% and 17.5% are VH1 and VH4 respectively. While typical distribution for normal B cells is VH3 - 57%, VH1 - 20%, VH4 - 18% [Fais *et al*., 1998]. Other VH genes usage was also rare for the cases investigated (1% -2%), similar to that for normal B cells. For SMZL patients from our sample with VH1 family genes all cases (with the exception of one) represent IGHV1-2 gene (49% of the total sample). In addition, there is a very high similarity of the nucleotide sequences of the CDR3 region for several of these cases (Pic. 1). On the other hand, in B-CLL this gene is relatively rare and occurs in 5% of cases. Furthermore in B-CLL this gene is preferably unmutated (84%), while in SMZL the frequencies of mutated and unmutated cases are similar. It should be noted that IGHV1-2 gene usage was not detected for HCL patients in our sample. In B-CLL, the most common gene was IGHV1-69 (18%), it also participates in the formation of the most common stereotypic antigenic receptors (CLL # 3, 5, 6). Two cases (6%) with IGHV1-69 gene usage were detected in HCL patients, and none in SMZL patients. No stereotypic antigenic receptors described for B-CLL so far were found in our sample of SMZL and HCL patients.

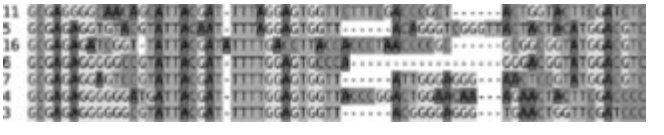

Figure 1.

Summary/Conclusion: The narrowing of the IGHV gene repertoire in B-CLL, HCL and SMZL suggests antigen stimulation of B-cells could play an important role in the development of these diseases. At the same time differences in IGHV gene repertoire between these B-cell malignancies may indicate that different antigens may be involved. Unfortunately, our sample of patients with SMZL and HCL are much smaller than that for B-CLL. Further studies with extended samples of SMZL and HCL may be beneficial to reveal possible prognostic factors and probably CDR3 stereotype data for these diseases.

PB2334

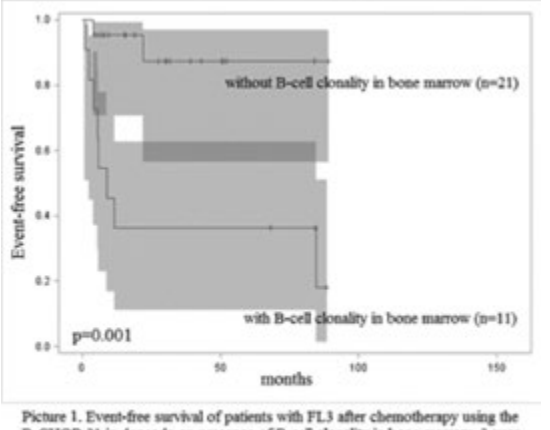
HISTOLOGICAL AND MOLECULAR BONE MARROW INVOLVEMENT IN FOLLICULAR LYMPHOMA 3 GRADE

L.V. Plastinina*, A.M. Kovrigina, E.S. Nesterova, F.A. Babayeva, K.A. Sychevskaia, A.B. Sudarikov, S.M. Kulikov, S.K. Kravchenko

National Research Center for Hematology, Moscow, Russian Federation

Background: Bone marrow (BM) is one of the most frequent extranodal sites of follicular lymphoma (FL). BM involvement is an unfavorable prognostic factor in FL included in FLIPI2. Detection of B-cell clonality in the BM suggests a specific BM involvement, but is not sufficient to confirm of the BM involvement in a tumor process.
Aims: To characterize morphological and molecular (B-cell clonality) features of BM involvement in FL 3 grade and assess their prognostic value in patients who received chemotherapy with R-CHOP-21.
Methods: In this retrospective analysis 89 primary patients with FL3 (median age was 54 years, range 21-78 years, f:m=1:1,5) were observed in the «National Research Center for Hematology» Moscow, Russian Federation (2001-2016) were included. B involvement in FL3 was studied by histological slides of bone marrow biopsy (BMC) with staining H&E in 48 patients. Three variants of the tumor lymphoid cells in the BM were determined in 46 available speciments: a) small-cell (BM infiltration predomi-

nantly centrocytes); b) large-cell (BM infiltration predominantly centroblasts); c) mixed-cell (BM infiltration by centrocytes and centroblasts in different ratios). B-cell clonality was studied in 49 patients. A multivariate analysis was performed in groups of patients with R-CHOP-21 chemotherapy. The analysis included a number of clinical and laboratory parameters - age, gender, stage by Ann-Arbor, FLIPI and others, including histological (n=54) or molecular (n=32) BM involvement.
Results: B involvement in FL3 was detected by BMB in 48 (54%) of 89 patients – 54% in FL3A, 39% in FL3B, 56% in FL 3(A+B) grade. Small-cell BM involvement detected in 22 (48%) patients, large-cell – in 14 (30%) patients, mixed-cell – in 10 (22%). Large-cell BM involvement was more common in FL3B in comparison with FL3A (57% *vs.* 20%, p=0,06). Patients with BM involvement had more often involvement of other extranodal sites besides BM (79% *vs.* 54%, p=0,01), three times more often had thrombocytopenia (p=0,07), four times more often had monoclonal secretion of paraprotein (in blood and/or urine, p=0,06) than patients without BM involvement. By multivariate analysis we did not reveal an unfavorable prognostic value of BM involvement by histological study (p=0,058). B-cell clonality was detected in 21 (43%) of 49 patients. According to the multivariate analysis the detection of B-cell clonality in the BM had an independent unfavorable prognostic value for the overall (HR-10,367, p=0,001) and event-free survival (HR-8,0, p=0,001) (picture 1), Me 30 MEC.



Picture 1. Event-free survival of patients with FL3 after chemotherapy using the R-CHOP-21 in depends on presence of B-cell clonality in bone marrow. 3-year EFS in the group with B-cell clonality is 36% vs. 87% in the group without B-cell clonality (p=0,001).

Figure 1.

Summary/Conclusion: There are 3 morphological variants of BM involvement in FL3. BM involvement in FL3 is associated with other extranodal sites tumor involvement. Detection of B-cell clonality in the BM is independent unfavorable prognostic factor for the overall and event-free survival (on R-CHOP-21 therapy).

PB2335

ACTIVATION INDUCED CYTIDINE DEAMINASE IN PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA

L. Vanhinsbergh[1,*], P. Patten[2], S. Kassam[2], A. Ramsay[2], S. Al Sarraj[3], C. Shah[2]

[1]Haematology, NHS, [2]Haematology, [3]Histopathology, Kings College, London, United Kingdom

Background: Primary Central Nervous System Lymphoma (PCNSL) is a distinct subtype of extranodal non-Hodgkin lymphoma (NHL) confined to the brain, leptomeninges, eyes and spinal cord. It accounts for approximately 1% of all lymphomas and 3% of all brain tumours and has a dichotomous, frequently poor outcome despite recent novel treatment approaches. Specific antigen (Ag) recognition by PCNSL tumour cells through their B cell receptors (BCR) has recently been reported. Further, evidence for Ag selection and drive of the BCR of PCNSL cells is shown by marked restricted immunoglobulin heavy chain variable gene (*IGHV*) usage. Activation induced deaminase (AID), required for both class switching and somatic hypermutation (SHM) of the BCR, is oncogenic in NHL. Evidence for AID activity in PCNSL is demonstrated by marked and ongoing SHM of the BCR and mutations in oncogenes that show aberrant SHM mutation patterns.
Aims: Investigate the role of AID in PCNSL.
Methods: We have reviewed AID expression by immunohistochemistry (IHC) in 38 PCNSL biopsies. Additionally we successfully analysed the *IGHV* of some of these biopsies using the LymphoTrack® Dx IGH FR1 assay (Invivoscribe).
Results: We have demonstrated ongoing expression (positive/focal) in 24 of which 23 also express MYC protein (>30% positive cells). AID negative biopsies lack MYC positivity in 9 of 14 of cases, overall showing a strong correlation between AID and MYC (p=0.0001, Fischer's exact test). In three PCNSL biopsies further analysed we have found that transition mutations in or near WRCY motifs, typical of an AID mutation footprint, predominate (80% mutations found, n=10).
Summary/Conclusion: This data supports a role for AID mediated antigenic drive in the pathogenesis of PCNSL with a strong correlation to MYC, a recognised tumour driver. Further work is required to explore the role of the tumour microenvironment and potential antigens.

PB2336

IGVH SOMATIC MUTATION PROFILE IN SPLENIC LYMPHOMAS

H.L. Julhakyan*, B. Biderman, L. Al-Radi, I. Yakutik, A. Sudarikov

National Research Center for Hematology, Russian Federation, Moscow, Russian Federation

Background: Splenic Lymphomas are rare diseases often misdiagnosed as hairy cell leukemia (HCL), splenic diffuse red pulp lymphoma (SDRPL) and splenic marginal zone lymphoma (SMZL). Criteria for differential diagnosis of these diseases are still controversial and require further elaboration.
Aims: The aim of our study is to determine the immunoglobulin variable heavy chain (IGHV) gene usage and somatic mutation patterns in a series of SDRPL and SMZL patients.
Methods: We studied 10 patients with SDRPL and 24 patients with SMZL (2014-2017 years). Diagnosis was based on standard WHO criteria. In all patients, the diagnosis was based on peripheral blood and BM findings. The baseline clinical and laboratory features as well as follow-up and outcome were recorded for every patient. IGHV mutational status was determined by Sanger sequencing. Cases with 98% or higher IGHV gene homology to germinal sequences were considered unmutated.
Results: Two cases (20%) of SDRPL were shown to bear unmutated IGHV genes whereas 8 (80%) - mutated. In 5 cases (50%) genes of VH3 family were found; in other 5 (50%) - genes of VH4 family. No preference for certain VH genes (from families 3 or 4) were observed. VH1 gene usage was not detected. In 9 cases (37.5%) of SMZL unmutated IGHV genes were detected and in 15 (62,5%) - mutated. VH1 gene family usage was found in 14 (58%) SMZL patients; most of them (12 patients, 86%) carrying IGHV1-2 gene (unmutated in 6 cases and mutated also in 6 cases). VH3 gene family usage was found in 7 SMZL patients (3 cases represent distinct IGHV3-7 gene) and 3 cases had different genes from VH4 family.
Summary/Conclusion: Despite the limited number of cases analyzed it should be concluded that IGHV mutational status may not be used to distinguish between SDRPL and SMZL since both diseases are shown to be associated with mutated as well as unmutated IGHV genes. However IGHV1-2 gene usage may strongly indicate SMZL. These findings have to be confirmed on extended sets of disease cases.

PB2337

MICROVASCULAR DENSITY, CD68 AND TRYPTASE EXPRESSION IN HUMAN DIFFUSE LARGE B-CELL LYMPHOMA

D. Ribatti[1,*], G. Ingravallo[2], F. Gaudio[2], T. Perrone[2], R. Tamma[1], B. Nico[1], E. Maiorano[2], G. Specchia[2]

[1]Department of Basic Medical Sciences, Neurosciences and Sensory Organs, [2]DETO, University of Bari Medical School, BARI, Italy

Background: Diffuse Large B-cell Lymphoma (DLBCL) is the most common form of Non-Hodgkin lymphoma characterized by clinical and biological heterogeneity attributable both to the tumor cells and the complex tumor-microenvironment surrounding them. Tumor-associated macrophages (TAMs) and mast cells are two major components of the tumor inflammatory infiltrate with a definite role in enhancing tumor angiogenesis.
Aims: In this study, we have investigated CD68 and tryptase expression and their relationship with microvascular density (MVD) in chemo-resistant and chemo-sensitive patients affected by DLBCL.
Methods: This retrospective study reviewed data from 29 patients diagnosed with DLBCL. Paraffin-embedded tissues representatives of the DLBCL cases were sectioned and the slides were then incubated with antibodies against CD68, tryptase and CD31. For each case, three slides stained for CD68, tryptase and CD31 expression were scanned using the whole-slide scanning platform Aperio Scanscope CS. CD68 and tryptase expression were assessed

with the Positive Pixel Count algorithm embedded in the Aperio ImageScope software and reported as a percentage of positivity, defined as the number of positively stained pixels on the total of pixels of the image. Fields were selected in areas with the most intensive CD68 and tryptase expression.To quantify MVD, the microvessel analysis algorithm embedded in the Aperio ImageScope software was used. Fields were selected in the areas of highest vascularization and only vessels with defined shape and lumen were considered. Statistical significance of CD68, tryptase and CD31 expression between responders and non-responders groups was assessed with the unpaired t-test. Correlation analysis between CD68 and MVD and tryptase and MVD was performed with the Spearman non parametric correlation test.
Results: CD68 and tryptase expression as well as MVD were increased in chemo-resistant patients when compared with chemo-sensitive patients. Tryptase expression showed a positive correlation with MVD, supporting a role for mast cell in DLBCL tumor angiogenesis, while CD68 correlation with MVD was not significant, indicating a different role for TAMs than angiogenesis in DLBCL.
Summary/Conclusion: Overall, this study is one of the first to compare the expression levels of CD68 and tryptase to MVD in DLBCL. Our results show that although CD68 expression is increased in non-responder DLBCL cases, this increased expression is not correlated with the increase in MVD, while tryptase increased expression in non-responders group appear to be correlated significantly with MVD, strengthening the association between mast cells and tumor angiogenesis.

PB2338

LOW CONCENTRATION OF VENETOCLAX INDUCES APOPTOSIS OF HIGH-GRADE B-CELL LYMPHOMA CELLS

A. Uchida*, Y. Isobe, Y. Uemura, J. Asano, I. Miura

Division of Hematology and Oncology, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan

Background: High-grade B-cell lymphoma with recurrent chromosomal translocations of 8q24/*MYC* and 18q21/*BCL2* (HGBL-MBR) is a subtype of aggressive lymphoma with poor prognosis in spite of showing germinal center B-cell (GCB) phenotype. New therapeutic strategies against HGBL-MBR are needed due to the resistance to conventional chemoimmunotherapy.
Aims: We examined *in vitro* sensitivity of HGBL-MBR cells to topo-II inhibitor doxorubicin, bromodomain inhibitor JQ-1, BH3 mimetics venetoclax, and Mcl-1 inhibitor S63845.
Methods: Three GCB-type cell lines (Karpas231, OCI-Ly8, and BJAB) were used. The translocations were confirmed by FISH analysis, and the expressions of Myc and Bcl-2 family proteins were assessed by Western blot analysis. At 24 and 48 hours after treatment with each drug, the cell count and viability were evaluated by dye exclusion test. Annexin V binding assay was also performed to detect apoptotic changes.
Results: FISH analyses confirmed that Karpas231 and OCI-Ly8 have both *IGH-BCL2* fusion and a split of *MYC* and that BJAB has only *IGH-MYC* fusion. Although the expression levels of Myc and Bcl-xL were varied, those of Bcl-2 were similarly high in the three lines. Compared with BJAB, Karpas231 and OCI-Ly8 showed the minimal expression of Mcl-1. Doxorubicin and JQ-1 suppressed the proliferation in a dose-dependent manner in the three lines. Although venetoclax showed growth suppression in both HGBL-MBR cell lines but not in BJAB, S63845 had the minimal effect only in BJAB. After treatment with 200 nM of venetoclax, annexin V-positive cells increased above 70% of total cells in Karpas231 and OCI-ly8, while apoptotic changes were hardly detected in BJAB (1.3%). After treatment with venetoclax, dephosphorylation of Bcl-2 rapidly occurred in both HGBL-MBR cell lines. Furthermore, the sensitivity of BJAB to venetoclax was restored in combination with 100 nM of S63845, suggesting that the resistance to venetoclax in BJAB seemed to be attributed to Mcl-1.
Summary/Conclusion: Our data indicate that the anti-apoptotic activity of both HGBL-MBR cell lines more strongly depends on Bcl-2 than Mcl-1, and that venetoclax may be a promising agent to overcome the resistance to conventional chemoimmunotherapy in HGBL-MBR.

PB2339

INTEGRATION OF BIOINFORMATICS AND EXPERIMENTS TO IDENTIFY TP53 AS A POTENTIAL TARGET IN EMODIN INHIBITING NON–HODGKIN'S LYMPHOMA

J. Hu*, Y. Chen, M. Lin, Y. Cao, Z. Wu

Department of Hematology, Fujian Institute of Hematology, Fujian Medical University Union Hospital, Fuzhou, China

Background: Non–Hodgkin's Lymphoma (NHL) was a group of lymphoid malignancies with unsatisfactory treatment effect in some aggressive subtypes. Emodin was an anthraquinone with potent anti-cancer activities. However, the molecular mechanism of Emodin repressing aggressive NHL remains to be revealed in detail.
Aims: To explore the active mechanisms of Emodin in aggressive NHL using a bioinformatics method-Functional-activity network (FAN) analysis and subsequently to verify those bioinformatics findings by *in vitro* cell experiments.
Methods: The initial target of Emodin, DPTs were acquired by DrugBank. Protein Interaction Network Analysis Platform (PINA) was employed to predict the DPT-protein interaction. Protein interaction chart and network derived from the integrated data was forecasted using String JAVA consortium. Top 10 pathways in Emodin associated network were validated and those which were associated with NHL were investigated by KEGG website and selected for further analysis. The cBio Cancer Genomics Portal was applied to investigate the connection of Emodin related-genes in NHL studies. Subsequently, effect of E35, a novel derivative of emodin were investigated on the diffuse large B cell lymphoma (DLBCL) cell lines SU-DHL4. The effect of E35 on SU-DHL4 cell vitality was tested by 3-(4,5-dimethylthiazol-2-yl)-2,5 diphenyltetra-zolium bromide (MTT) and Colony formation assay. Cell apoptosis following E35 treatment was assessed by Annexin V 7-AAD and PE staining. Western blot analysis was used to confirm those molecular targets predicted by FAN analysis.
Results: Emodin was queried on Drugbank database and 4 of its primary direct protein targets (DPT) were identified. Then the 489 DPTs-associated proteins were predicted on Protein Interaction Network Analysis Platform (PINA). Emodin-DPTs and DPTs-targeted proteins/genes were categorized as Emodin-related proteins/genes and submitted to String database for expanding the protein network and KEGG pathways analysis. 3 signal pathways, Pathway in cancer, Viral carcinogenesis and Transcriptional misregulation in cancer, were identified as significant association with Emodin treatment in NHL. Advanced integrated analysis exhibited the bridging that functionally connected Emodin action to key target protein TP53 in NHL. Subsequently, treatment of E35 on SU-DHL4 cells suppressed cell proliferation and induced apoptosis in a time- and dose-dependent manner, with an IC50 of 0.87±0.10μM at 48h. Annenxin-V PE and 7-AAD staining indicated raised apoptosis phenomenon with the increasing dose of E35. Apoptotic cells without intervention were 7.70%±1.55%, while 5μM and 10μM E35 treatment for 24h brought them up to 23.01±2.70% 50.23±1.90%. E35 declined TP53 protein expression and inhibited PI3K/AKT pathway in a dose-dependent manner.

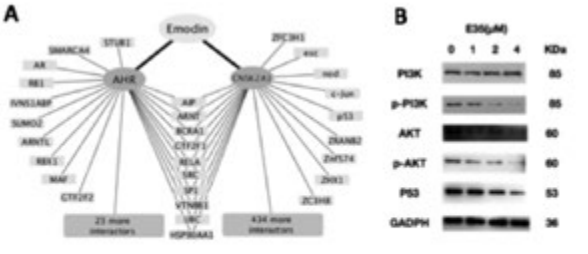


Figure. (A)Emodin-targeted protein interaction network. Drug: Emodin (color in yellow), primary direct protein targets (DPT): CSNK2A1, AHR (color in green) and secondary DPT-targeted protein: color in pastel orange and blue. **(B) Effect of E35 on SU-DHL-4 cells.** Detection of the TP53 protein and PI3K/AKT pathway.

Figure 1.

Summary/Conclusion: Bioinformatics tool FAN analysis could predict key target protein TP53 in Emodin intervention in DLBCL. Further experiments confirmed the bioinformatics findings. All of above showed that combined bioinformatics analysis and experiments offered a novel approach for understanding of mechanisms of Emodin and its derivative action in NHL with convenience and integrity.

PB2340

NOVEL THIENOPYRIDINES AS POTENT INDUCERS OF CELL CYCLE ARREST IN MATURE B-CELL NEOPLASMS

C. Broughton[1,*], M. El Mohtadi[1], C. Graham[1], J. Ashworth[1], K. Whitehead[1], M. van Rensburg[2], L. Pilkington[2], D. Barker[2], N. Dempsey-Hibbert[1]

[1]School of Healthcare Science, Manchester Metropolitan University, Manchester

Metropolitan Univesity, Manchester, United Kingdom, [2]School of Chemical Sciences, University of Auckland, Auckland, New Zealand

Background: Thienopyridines are a family of compounds well known for their anti-platelet activity, and are commonly used to prevent thrombotic events. However, attention has recently turned to their anti-cancer properties. Mechanistic investigations have explored their mode of action, with PLCγ, Jak2 and also Lck suggested as direct targets, while mitotic spindle inhibition via micro-tubule de-stabilisation has also been demonstrated. Mature B-cell malignancies are infamously difficult to treat. Traditionally, treatment approaches have included Microtubule Target Agents (MTA) such as vincristine and vinblastine that bind to tubulin and disrupt microtubule dynamics. MTA have been hugely successful and are among the most important anti-cancer drugs. However, neurotoxicity, neutropenia and the development of drug resistance can be limiting factors. A greater understanding of the mechanisms of action of MTAs will enhance their use and effectiveness and aid in the identification of newer compounds with this action.
Aims: The aim of this study was to assess the effects of six novel thienopyridine derivatives synthesized by our group on B-cell apoptosis, cell cycle arrest and mitotic disruption with the intention of identifying a new family of compound for use in the treatment of mature B-cell neoplasms
Methods: The Burkitt lymphoma mature B-cell line, Daudi, was used in this study. Cells were seeded at a standard density dependent on the downstream assay to be performed and treated with varying concentrations (1-100μM) of thienopyridine derivative (DJ0081, DJ0199, DJ0206, DJ0209, DJ0014 and DJ0021) for varying culture times. Cellular biochemical activity was assessed using the MTS assay, while apoptosis and necrosis were observed using the Annexin V/Propidium Iodide flow cytometry assay. Cell cycle arrest was determined by flow cytometric Propidium Iodide cell cycle assay, and alpha-tubulin expression was visualised using confocal microscopy.
Results: Five of the novel compounds demonstrated a significant reduction in biochemical activity after 48h and 72h of treatment at 10μM with three of the compounds having affects at 1μM, indicating cytostasis/cell death. As expected, compound DJ0021 (synthesised as the control compound) did not significantly affect cell viability. At these same concentrations and time points, significant apoptosis was induced, with very few necrotic events observed by flow cytometry. Cell cycle analysis demonstrated a significant G2 arrest and tetraploidy following just 24h treatment with 10μM, and more marked G2 arrest at 48 and 72h treatment, while microtubule formation was found to be disrupted by all five compounds.
Summary/Conclusion: The study demonstrates the anti-mitotic activity of these thienopyridine derivatives and their potential for use in the treatment of mature B-cell malignancies.

PB2341

LYMPH NODE ASSESSMENT BY CYTOLOGY AND MULTIPARAMETRIC FLOW CYTOMETRY: A PROSPECTIVE STUDY OF 176 SAMPLES

Z. Diez Gallarreta*, F. Marco De Lucas, P. Isusi Gorbea, Á. Blanco González, J. Uriarte Elguezábal, B. Dávila De Las Fuentes, S. Herráez Rodríguez, I. Leal Martínez, C. Alonso Caballero

Hematology, Hospital Universitario Basurto, Bilbao, Spain

Background: Histopathologic study is considered nowadays the technique of choice for the diagnosis of pathology in lymph nodes. However, it has limitations: subjective analysis, limited reproducibility, reduced amount of reagents for determining antigenic expression and considerable consumption of time and human resources. Cytomorphologic examination and multiparametric flow citometry (C-FCM) may solve some of these obstacles: faster diagnosis and multiparametric analysis with qualitative and quantitative characterization of different cell antigens expression. Limitations of this technique are: impossibility to evaluate lymph node architecture and cellular damage during processing.
Aims: Our aim was to evaluate in our centre the diagnostic value of C-FCM for oncohematologic diseases in lymphoid tissues and its accuracy in subclassifying Non Hodgkin Lymphomas (NHL), apart from indicating in which circumstances this technique was insufficient.
Methods: From 2015 to 2017, we prospectively analyzed by C-FCM 176 lymph tissue biopsy specimens, mainly obtained (76.7% (135/176)) by large needle biopsy of lymph node. Every sample was evaluated by cytomorphology of touch imprints stained with May-Grümwald-Giemsa and by FCM. Likewise, a part of the same sample was evaluated by histopathology. Median age was 60 years (1-91): 94 male (53.4%) and 82 female (46.6%). 54 (31%) had previous lymphoma history. Statistical analysis was performed employing G-STAT program (version 2.0.1, Biometrics Department of GlaxoSmithKline).
Results: C-FMC detected neoplastic disorders in 120 (68.2%) samples: 82 NHL (67.8%), 11 Hodgkin Lymphomas (HL, 9%), 26 malignant non hematologic neoplasms (NHN 21.5%) and 1 Acute Myeloid Leukemia (0.8%). Sensitivity and specificity were 85% and 83%. Positive predictive value (PPV) and negative predictive value (NPV) were 94.2% and 63.6%, respectively. Sensitivity and NPV increased to 93% and 86% when HL, NHN and T-cell / histiocyte-rich-B-cell lymphomas (TCRBL) were excluded from the analysis. 71/82 LNH (86.6%) were defined according to the 2008 World Health Organization (WHO) classification of hematolymphoid neoplasms, with a concordance of 78% with respect to the histopathological study.

Table 1.

Concordance Between C-CFM and Histopathologic Study in B-NHL According to the WHO Classification

WHO Classification	C-FCM	Histopathologic Confirmation	Concordance (%)	Discordance
Diffuse Large B Cell Lymphoma (DLBCL)	30	22	73.4	7 FL[1], 1 unspecified B-NHL
Burkitt Lymphoma	3	3	100	None
Small Lymphocytic Lymphoma (SLL)	10	7	70	1 HL[2], 1 MZL, 1 Follicular hyperplasia[3]
Follicular Lymphoma (FL)	19	14	73.7	4 DLBCL, 1 Follicular hyperplasia
Mantle Cell Lymphoma	4	4	100	None
Marginal Zone Lymphoma (MZL)	3	3	100	None
Angioimmunoblastic T Lymphoma	2	2	100	None

[1]There are 4 out of 7 FL in which the diagnosis of DLBCL was confirmed afterwards by other techniques (PET with high SUV)
[2]Richter Syndrome Hodgkin Variant [3]SLL was confirmed later in another sample

Summary/Conclusion: C-FCM provides very valuable information regarding diagnosis of pathology in lymph nodes, showing high sensitivity and specificity. C-FCM is especially useful in NHL, allowing their sub-classification according to WHO criteria with a concordance of 78%. Moreover, being a faster technique compared to histopathology, while keeping a high PPV, it makes it easier to take quick therapeutic decisions, which is relevant in aggressive diseases. However, in NHN, HL and TCRBL, the utility of this technique relies on excluding the most usual NHL diagnosis, remaining histopathology the gold standard for diagnosis.

THE UTILITY OF THE FORWARD SCATTER PARAMETER IN THE FLOW-CYTOMETRIC EVALUATION OF LYMPH NODE CELL SUSPENSION TO IDENTIFY B CELL LYMPHOMAS

F. Corrente[1,*], S. Bellesi[1], P.L. Puggioni[1], F. D'Alò[1], A. Cuccaro[1], E. Maiolo[1], F. Attili[2], E. Meacci[3], E. Scarano[4], C. Lodoli[5], F. Pacelli[5], L.M. Larocca[6], V. De Stefano[1], S. Hohaus[1]

[1]Istituto di Ematologia, Università Cattolica del Sacro Cuore, [2]Istituto di Gastroenterologia, Università Cattolica del Sacro Cuore, [3]Istituto di Chirurgia Toracica, Università Cattolica del Sacro Cuore, [4]Istituto di Otorinolaringoiatria, Università Cattolica del Sacro Cuore, [5]Istituto di Chirurgia Generale, Università Cattolica del Sacro Cuore, [6]Istituto di Anatomia Patologica, Università Cattolica del Sacro Cuore, Rome, Italy

Background: Flow-cytometric assessment on lymph node biopsies has been reported to be useful in the diagnosis of non-Hodgkin lymphomas (NHL). Diffuse large B-cell lymphoma (DLBCL) is the most common form of B-NHL among adults. The forward-scatter is a useful flow-cytometric parameter to study the lymphoma cell size.
Aims: The aim of the present study was to assess the diagnostic relevance of forward-scatter in identification of DLBCL on lymph node suspension samples.
Methods: Lymph node suspensions were prepared from biopsies obtained by surgical resection or by ultrasound-guided endoscopic core biopsies. We used the Medimachine system (BD Biosciences) for mechanical disaggregation of the solid tissue. The screening panel included CD19, CD20, CD10, Kappa, Lambda, CD5, CD3, CD4 and CD8. For B-cells the normal range of Kappa/Lambda ratio was >0.8 or <3.0. A clear clonality, CD10+ or CD5+ expression on B cell populations or absence of surface immunoglobulin light chain were suggestive of B-NHL. The Forward-scatter Area (FSC-A) was evaluated on B- and T-cells of lymph node suspensions and expressed as

median value. Data were acquired on BD FACSCantoII flow cytometer (BD Biosciences) and analyzed by BD FACSDiva software (BD Biosciences). We defined the ratio between FSC-A of the pathological B-cell population and the FCS-A of CD3+ T-cells as FSC ratio.
Results: In this study we included 41 lymph node suspensions with a pathological B cell population. Immunohistochemical diagnosis was DLBCL in 23 patients, follicular lymphoma (FL) in 12 patients, mantle cell lymphoma (MCL) in 3 patients, marginal zone lymphoma (MZL) in 2 patients and small lymphocytic lymphoma (SLL) in 1 patients. Subsequent immunohistochemical analysis proved that all B-NHL were correctly identified (100% sensitivity) by flow-cytometry analysis. B-cell pathological populations were CD19 and CD20 positive and presented a clear clonal light chain restriction in 33/41 cases, while 8/41 (6 DLBCL, 1 FL, 1 MZL) did not show any light chain expression. CD10 was expressed in all FL cases and in 4/23 DLBCL. CD5 was present in the patients with MCL and in 1 case of DLBCL. DLBCL cases showed a higher FSC ratio (see fig. 1) compared to other B-NHL (1.60 *vs* 1.04, P <0.001). By calculating the receiver operating characteristic (ROC) curve, the best cut-off for FSC ratio was 1.23, with an AUC=0.94 (95% CI 0.85 to 1.00). This cut-off value provided a sensitivity of 96%, a specificity of 79%. The positive predictive value was 86% and a negative predictive value of 96%.

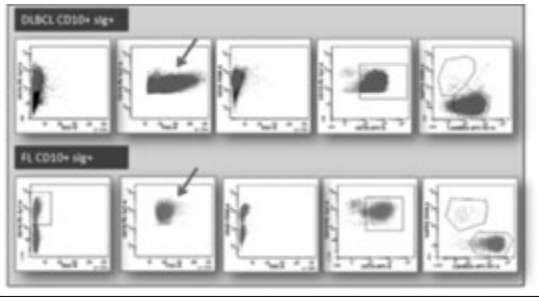

Figure 1.

Summary/Conclusion: The FSC ratio between the pathological B lymphoma cell population to the normal CD3+ T cells is a simple parameter, that is routinely acquired during flow cytometry and can be helpful in discerning between DLBCL and low-grade lymphomas and mantle cell lymphoma. This information may be helpful to direct the immunohistochemical work-up.

PB2343

THE COMPREHENSIVE DESCRIPTION OF TP53 GENE ABERRATIONS IN DLBCL

E. Voropaeva[1,*], T. Pospelova[2], M. Voevoda[1], V. Maximov[1]

[1]"Research Institute of Internal and Preventive Medicine" - Branch of IC&G SB RAS., [2]Novosibirsk State Madical University, Novosibirsk, Russian Federation

Background: At present, there is no comprehensive description of aberrations in the *TP53* gene in DLBCL. *TP53* mutations is the most studied aspect. A comparative analysis of *TP53* mutations presented in the special databases shows that their frequency and spectrum can vary for the same type of the tumor depending on the study population. Information about the Russian population in the current version of the IARC *TP53* mutation database is not provided.
Aims: The purpose of the present study was to carry out a complex analysis of the frequency and spectrum of mutations in 5-8 exons, the frequency of loss heterozygosity and methylation of the promoter of the *TP53* gene in DLBCL.
Methods: Genomic DNA was isolated from formalin-embedded paraffin blocks of lymph nodes and extranodal tumor lesions biopsies of 92 patients with DLBCL by phenol-chloroform extraction method using guanidine. The tissue sections containing at least 70-80% of the tumor cells were taken. Direct Sequencing by Sanger of the *TP53* gene was performed according to the IARC protocol. Analysis of the methylation status of the *TP53* gene was performed by methyl-specific PCR. Estimation of loss of heterozygosity (LOH) in the gene *TP53* was carried out at the microsatellite locus D17S796.
Results: A quarter (24.3%) of patients had mutations in the coding sequences of the gene, which is consistent with the literature data. Four patients had multiple mutations. The distribution of the mutations was as follows: 1 (3%) mutation leading to splicing failure, 11 (33%) intron with an unknown effect, 12 (37%) missense, 6 (18%) - synonymous, 2 (6%) - nonsense type, 1 (3%) - a mutation leading to a shift in the reading frame in the *TP53* gene. 5 (15.6%) of substitutions was GC AT substitutions in CpG islets. In 9 tumor samples, rs78378222 was detected, which leads to a violation of the polyadenylation signal and disruption of mRNA translation. According to the IARC *TP53* mutation database, the codons 248, 273, 175, 245, 281, 244, 305, 249 and 297 are the "hot spots" in the *TP53* gene in DLBCL. In the samples of patients from Russian cohort, only a mutation in 244 codons was identified (p.G244S). However, mutations p.W146R, p.T155I, p.V272E, p.R213X was verified in two cases of each. The frequency of methylation of the *TP53* gene promoter was 4/69 (5.8%), and the LOH frequency was 10/74 (13.5%).
Summary/Conclusion: In total 32.4% of DLBCL samples had *TP53* aberrations with proven oncogenic potential. Complex analysis made it possible to clarify that the insufficiency of the function of the *TP53* gene in DLBCL can be formed according to the classical "two-stroke" mechanism: almost all cases of LOH were combined either with somatic mutations, germ-line marker rs78378222 or methylation of the *TP53* gene promoter.

PB2344

THE IMPAIRED PRODUCTION OF TNF, TGF BETA 1 AS AN IMPORTANT REASON OF DEFECTIVE NATURAL KILLER ABILITY IN NON-HODGKIN LYMPHOMA PATIENTS WITH SPLEEN AFFECTION

V. Barilka[1,*], V. Matlan[2], O. Shalay[1], Y. Yevstachevych[1], S. Prymak[1], V. Loginsky[1]

[1]Immunology and Genetics of Blood Neoplasms Lviv, Ukraine, SI Institute of Blood Pathology and Transfusion Medicine of the NAMS of Ukraine, [2]Department of Hematology and Transfusiology, Danylo Halytsky National Medical University, Lviv, Ministry of Health of Ukraine, Lviv, Ukraine

Background: The microenvironment of non-Hodgkin lymphoma (NHL) may assists to distribution and survival of neoplastic cells with simultaneous development of immune tolerance of natural killer (NK) by broken secretion of tumor necrosis factor (TNF) and transforming growth factor beta 1 (TGFβ1).
Aims: o detect the cytotoxicity ability (CA) of NK from mononuclear cells (MN) of peripheral blood (MNPB), MN of lymphatic nodes from the gate of spleen (MNLNs), MN from spleen tissue (MNS) of 10 NHL patients (pts) with spleen affections. To detect the CA NK from peripheral blood (as an effector cells) of NHL pts *vs.* autological MNS, MNLNs (as a target). To prepare supernatants (Sp) of the MNPB, MNLN and MNS after 24 h incubation cells in RPMI 1640 and to detect the concentration of cytokines in Sp and plasma.
Methods: The peripheral blood gained before breakfast. The tissues both of lymph nodes and spleen obtained after surgical remover. The concentrations of TNF and TGFβ1 were determinatend by biological methods. The CA of NK was estimated vs. K562 and autological NHL cells marked with ^{3}H-methylthymidine. Control group consisted of 15 healthy persons and 8 pts with reactive hyperplasia of spleen (RHS) and 7 pts - with non-specific reactive lymphadenitis (nSRL).
Results: The level of TNF in both plasma and Sp MNPB of NHL pts were higher, than in the plasma and Sp MNPB of the healthy donors (p<0,001). The TNF levels in both Sp of MNS (0,23±0,12 ng/ml) and MNLNs (0,19±0,07 ng/ml) of NHL pts did not differ statistically and were exceeded by analogical data in RHS pts and nSRL. The level of TGF β1 in plasma (3,68±0,73 ng/ml) NHL pts was higher (3,730±0,900 ng/ml) than in control group (p<0,05). TGFβ1 in Sp of MNPB was two times lower that of control (p<0,05). The level of TGFβ1 in Sp of MCS of NHL pts was for certain below (4,860±0,610 ng/ml), than in Sp of MCS of RHS pts (8,330±0,531 ng/ml; p<0,05). The CA of NK from NS *vs* K562 was higher (29,27±7,92%) than in both NLNs (15,85±3,80%; p<0,05) and NPB in NHL pts (16,69±2,26%; p<0,05). The CA of NK from peripheral blood of NHL pts was for certain below (14,695±2,26%) than in healthy donors (22,241±0,84%; p<0,05). The CA of NK from NLNs was lower *vs* 562 cells line, than CA of NK from MNS of NHL pts with spleen affections. The of NK from blood *vs* the autological NLNs and MNS were in both cases for certain below, than CA of NK *vs* the of 562 cell lines (p<0,01). The CA of NK from blood NHL pts *vs* autological of MNS (5,36±1,64%) and CLNs (7,26±1,60%) were statisticall below, than data of autological CA of NK in the RHS pts (30,175±2,94; p<0,001). The CA of NK from blood of NHL pts negatively correlated with the ncentration of TNF in both plasma (r= - 0,50) and Sp of MNPB (r= - 0,55). It should be noted that the level of TNF in plasma of pts with RHS positively correlated with CA of NK from NS (r=0,40). The CA of NK from MNPB of NHL pts negatively correlated with the concentration of TGF β1 in plasma (r=-0,619) and negatively with the TGF β1 in Sp from MNS (r=-0,620).

Summary/Conclusion: Concentration of TNF and TGFβ1 in plasma of NHL pts with spleen affection for certain higher, than in the healthy persons. NK from blood of NHL pts *vs* own neoplastic cells was lower than stranger 562. These results could specify on tolerance of cellular immunity in the NHL pts. Thus, impaired secretion of TNF and TGF β1 may has an important role in the regulation of ability NK vs. neoplastics cells and can be important markers for modulation of immune responses in NHL pts with spleen affection.

PB2345

CLONAL EVOLUTION OF FOLLICULAR LYMPHOMA CELLS FROM ONSET TO RELAPSE

K. Sychevskaia*, B. Biderman, S. Kravchenko, L. Plastinina, S. Smirnova, F. Babayeva, E. Nikulina, J. Mangasarova, A. Sudarikov

National Research Center for Hematology, Moscow, Russian Federation

Background: Though complete clinical remissions could be induced in Follicular lymphoma (FL) early and late relapses are relatively often. Key events in tumorogenesis in FL while predecessors of tumor cells migrate from bone marrow to the germinal center of the lymph node follicle include V(D)J-recombination, overexpression of the BCL-2 gene and somatic hypermutation. However, the origin of residual cells that may contribute to the development of relapses in FL still not known.
Aims: To compare FL clonal tumor cells in disease onset and relapse by means of sequencing and mutational analysis of clonally rearranged genes of immunoglobulins heavy chains (IGHV).

Table 1.

Table1. Clinical and laboratory data of FL patients

	Onset	1st relapse	2nd relapse
Patient C	08/2014 10 mutations	07/2016 12 mutations (+2)	-
Patient K	06/2010 10 mutations	12/2013 13 mutations (+3)	-
Patient R	03/2007 18 mutations	05/2009 20 mutations (+2)	-
Patient H	08/2012 10 mutations	03/2013 10 mutations	08/2013 10 mutations

Methods: Four FL patients diagnosed and treated at the National Research Center for Hematology, who subsequently relapsed were included in the study. Clinical and laboratory data are summarized in Table 1. B-cell clonality testing and IGHV sequencing was performed according to BIOMED-2 protocol. Fragment analysis and Sanger sequencing was performed on ABI PRISM 3100 genetic analyzer, followed by comparison with the germinal sequence databases www.imgt.org and www.ncbi.nlm.nih.gov/igblast.
Results: B-cell clonality testing and IGHV sequencing at diagnosis and in relapse were done for all 4 patients. Clonal peaks of identical length at diagnosis and in relapse were identified in all 4 cases. Somatic mutations were identified in all cases (90-95% homology with germinal sequence). In three cases additional somatic mutations (from 2 to 3) were identified in relapse while preserving those found in the debut of disease (Table 1). In 3 cases of acquisition of new somatic mutations, patients had late relapses (from 13 months to 21), whereas in one patient with early relapse the nucleotide sequence of the tumor clone remained the same. The data obtained indicate that the tumor cells in relapse originate from the mature clonal cells found in disease onset, and not from the earlier progenitor cell during parallel development.
Summary/Conclusion: The data obtained strongly indicate that the late relapse substrate is a mature tumor cell of the debut, which repeatedly passes the differentiation stage in the germinal center of the follicle, acquiring new somatic mutations. The possibility of tumor cells migration between the lymph node and the bone marrow had been shown for FL. One can speculate that the cells of the primary tumor clone may survive chemotherapy in the bone marrow niches and in recurrence return to the lymph node under the influence of an unknown stimulus, while entering a new cycle of somatic hypermutation. In contrast to the late, the development of early relapses may be due to incomplete eradication of FL cells in the sites of primary tumor lesion, as indicated by the stability of the nucleotide sequence. Further studies with extended samples of FL patients are required to obtain data of more statistical power.

PB2346

EZH2 GENE UPREGULATION IN PRIMARY TESTICULAR AND CENTRAL NERVOUS SYSTEM DIFFUSE LARGE B-CELL LYMPHOMA: A POTENTIAL TARGET FOR TREATMENT IN IMMUNE-PRIVILEGED SITES?

G. Koenig[1], B.V. Chakravarthi[1], J. Gordetsky[1], G. Netto[1], M. Rodriguez-Pena[1], D. Correia-Salles[2], L. Schwartz[3], J. Jorns[4], S. Varambally[1], D. Peker[1,*]

[1]University of Alabama at Birmingham, Birmingham, [2]Johns Hopkins University, Baltimore, [3]University of Pennsylvania, Philadelphia, [4]Medical College of Wisconsin, Madison, United States

Background: Upregulation of the enhancer of zeste homolog-2 (*EZH2*), a histone N-methyltransferase, is a well-established in cancer development through various mechanisms. *EZH2* has recently become a major target in cancer treatment. Primary central nervous system (CNS) and testicular diffuse large B-cell lymphomas (DLBCL) are rare but aggressive diseases with poor outcome due to therapeutic challenges.
Aims: In the present study, we investigated the EZH2 expression status in these two distinct variants.
Methods: A retrospective chart review, from 2003 to 2013, identified cases with a diagnosis of primary testicular and CNS DLBCL. Immunodeficiency-related, EBV-associated, and MYC gene positive LBCL were excluded from the analysis. A formalin-fixed-paraffin-embedded tissue samples were analyzed using quantitative real-time PCR (Taqman assay) for RNA expression levels of EZH2, using custom designed primers in commercially available kits. Control samples included three benign lymph nodes free of any neoplastic processes.
Results: Twenty-seven cases had adequate RNA extracted for analysis and PCR results were available in 18 cases; testis (n=11) and primary central nervous system (n=7). The median age was 65 years (range 41- 71 years), with a male to female ratio of 6 (M=15, F=3). Median overall survival (MOS) was 27months (2 to 74 months). Immunophenotypic cell-of-origin subtype was determined in 15 cases using Han's algorithm, six cases were germinal center B-cell (GCB) type (33%) and nine cases were non-GCB type (50%). Eleven cases showed higher expression of EZH2 when compared to normal lymph nodes. Five of these cases were testicular lymphoma (45%) while six cases were CNS origin (85%). The remaining seven cases did not show increased expression of EZH2.
Summary/Conclusion: Results suggest that EZH2 gene upregulation might be playing an important role, particularly in primary CNS DLBCL and possibly in testicular DLBCL; therefore might be a potential target of treatment. Larger studies are needed to establish the prognostic and therapeutic utility of RNA expression level of the EZH2 in these aggressive forms of DLBCL.

PB2347

CORRELATION BETWEEN CLINICAL ANT PATHOLOGICAL VARIABLES WITH IMMUNOHISTOCHEMICALLY DIFFERENTIATED MOLECULAR SUBTYPES OF DIFFUSE LARGE B-CELL LYMPHOMA

E. Hadzimesic Suljovic[1,*], S. Radovic[2], N. Obralic[1], A. Kozaric[1], N. Bilalovic[1], A. Sofo-Hafizović[1]

[1]Clinical Center University of Sarajevo, Hematology Clinic, [2]Medical Faculty University of Sarajevo, Sarajevo, Bosnia and Herzegovina

Background: Gene expression profiling has made a distinction between the two pathological entities of the DLBCL, ABC DLBCL and GCB-DLBCL. Genetic profiling is still far from routine clinical practice, so using immunohistochemical methods, identification of GCB and ABC phenotype has been translated into clinically feasible approach by developing algorithms for defining the molecular subtypes based on the expression of immunohistochemical markers defining subgroups as GCB and non-GCB. *I*PI (International Prognostic Index) remains the most accurate prognostic model due to inconsistent results of prognostic models based on biomarkers, and research focus is directed to upgrading the IPI models and to correlations between clinical parameters and biomarkers with biological characteristics of the disease.
Aims: To determine the correlation between clinical and pathological variables with immunohistochemically differentiated molecular subtypes of DLBCL.
Methods: We have analyzed 50 patients with DLBCL for the expression of bcl-2, bcl-6, CD10, MUM1 and Ki-67 Patients were divided into two groups, the non-GCB, GCB group or favorable group 1 and unfavorable group 2, according to Hans's algorithm and Muris's algorithm. Clinical-pathological, biochemical parameters of disease have been correlated with

subgroups of DLBCL and biomarkers individually. The impact of the expression of bcl-2, bcl-6, CD10, MUM1 and Ki67 on IPI-highest score in multiple regression analysis, afterwards in regression equation and variance analyse.
Results: Patients younger than 60 years are significantly more non-GCB subtype, avarage age 46.29 years. CD10 and MUM1 are significantly more present in non-GCB subtype and in Group2. Positive correlation between bcl6 and extranodal localisation was proved (p>0.05). In the analysis of correlation of pathological variables and immunohistohemically determined molecular subtypes, difference in the size of the nucleus as well as the correlation between the subtypes to Hans (p<0.05), but not Muris (p>0.05) was demonstrated. 91.7% of non-GCB patients had the size of nucleus II. Difference in the incidence rate of more than one extranodal site in non-GCB groups per Hans was found (p=0.045). POsitive correlation was found between increased values of lactat dehidrogenase and beta2mikcroglobulin and Group2. GCB phenotype showed positive correlation with good-risk patients identified by IPI. Multiple regressional analysis proved impact of biomarkers on IPI. The mutual impact of bcl-2, bcl-6, MUM1, Ki67 is significantlyrelated to poor-risk IPI patients
Summary/Conclusion: A more aggressive type of the disease and more severe clinical features are significantly more common among patients in the subgroup of non-GCB or group 2, DLBCL. Non-GCB subgroup and group 2 were associated with a higher clinical stage (III / IV), lower Karnofsky index or higher ECOG performance status, number of extranodal localization of more than one locus, elevated lactate dehydrogenase value, increased value of Ki67 and increased value of beta2microglobulin.

Platelets disorders

PB2348

GENETIC MUTATION WITH BAT SCORING ASSESSMENT IN GLANZMANN THROMBASTHENIA PATIENTS

M. Abid*, M. Borhany, N. Fatima, S. Ahmed, T. Shamsi

Hematology department, National Institute of Blood Disease and Bone Marrow Transplantation, Karachi, Pakistan

Background: Glanzmann thrombasthenia is a platelet function disorder that is caused by an abnormality in the genes for glycoprotein IIb/IIIa receptor. The receptor is either absent or does not function properly as a result of which the platelets do not have the ability to attract each other and the coagulation factors and thus leads to impaired clot formation. A number of bleeding assessment tools (BATs) has been developed to standardize the bleeding history. To improve the diagnostic accuracy and sensitivity by predicting the future risk of bleeding.
Aims: To evaluate the genetic mutation and BAT scoring assessment of diagnosed GT patients.
Methods: This was an observational study, conducted at the National Institute of Blood disease Karachi. Diagnosed GT patients of all age group of either gender were included in this study. Polymerase chain reaction (PCR) was used to amplify all coding regions of the *ITGA2B* and *ITGB3* genes (using reference sequences NM_000419 and NM_000212, respectively). ABI-3500 was used for genomic analysis. ISTH-BAT questionnaire assessment was applied to evaluate bleeding score.
Results: A total of 11 patients were included in this study. At diagnosis, female to male ratio was 7:4. The median age was 7 years with range of 2-17 years. Consanguineous marriages with positive family history were reported in the study. Missense, nonsense, deletion, insertion and splice site were the types of mutations observed in our study. Of these mutations, missense (54.5%) was the most common. The study was assessed in the GT patients with respect to ISTH-BAT scoring with mean BAT score of the patient at diagnosis was 9.27±4.1. The clinical manifestations observed in our study were epistaxis and gums bleed (82%) each, GI bleed (27%), menorrhgia (18%) and hematoma and hemarthrosis (9%).
Summary/Conclusion: Mutational analysis is a key component of a complete diagnosis of GT with respect to The ISTH-BAT is a useful tool for documenting bleeding symptoms.

Background: ITP is a heterogeneous autoimmune disorder mediated by platelet (PLT) antibodies thought to accelerate PLT destruction while inhibiting also their production. ITP features in the general Greek population have not been properly investigated.
Aims: To access systematically, for the first time, the characteristics of adult patients (pts) receiving thrombopoietin receptor agonists (TPO-RAs), *i.e.* Romiplostim (R) and Eltrombopag (E), using data from the national database (ITP registry) operated under the auspices of the Hellenic Society of Hematology.
Methods: The greek ITP registry recruits pts (n=1167, to date) nationally through a network of 19 centers. In the present study we retrospectively analyzed data from adult ITP pts diagnosed from 1979 to 2017, who received R and E.
Results: The total number of evaluable adult pts was 69 (29 M; 40F) and the median age at diagnosis was 54 years (20-88). R was administered in 27 pts and E in 42 pts, with a median age of 59.8 years and 58.6 years, respectively. 94% of the pts started R from 2009 to 2013 and 95% started E from 2012 to 2016. The median time from ITP diagnosis to R and E administration was 12 months (0.5-360) and 8 months (0.4-265) respectively. The mean number of prior ITP therapies was 2.3 (1-5) in the R- and 2 (1-7) in the E-cohort (P=0.061). Similar proportions of pts in the R- and E-cohort, respectively, had received corticosteroids (26/27 & 4/42), intravenous immunoglobulin (20/27 & 24/42), rituximab (5/27 & 3/42), vinblastine (3/27 & 2/42), immunosuppressants (2/27 & 2/42), vincristine (1/27 & 1/42) and had undergone splenectomy (3/27 & 2/42). Anti-RhD immunoglobulin was administered in 1/27 pts in the R-cohort and Danazol in 1/42 pts in the E-cohort. The median PLT number at R or E initiation was 20.42x10^9/L and 25.03x10^9/L respectively, P=0.254. Similar PLT counts were observed between pts receiving R and E at 6 months (163.9x10^9/L & 151x10^9/L, respectively, P= 0.8937) and at 12 months (166.5x10^9/L & 157.4x10^9/L respectively, P=0.7236). Patients remained on R and E treatment for a median of 23.5 months (0.5-106) and 15.5 months (0.4-75), respectively. There was no difference in complete response (CR, ie PLT count above 100x10^9/L) to R and E (62% & 59%, respectively, P=0.192) or partial response, *i.e.* PLT count 30-100x10^9/L, (19% & 22%, respectively, P=0,7264). 14(52%) pts in the R-cohort discontinued R: 2 in CR stopped R maintaining a sustained remission after discontinuation, 6 had no response, 2 due to adverse effects (gastrointestinal disorders, headache) and 4 underwent splenectomy. After R discontinuation, 10 pts received E, 8 of whom responded. In 2 non-responders additional therapies included corticosteroids, vinblastine, intravenous IgG and Rituximab. 14 (33%) pts in the E-cohort discontinued E: 4 in CR stopped E obtaining a sustained remission after discontinuation, 5 had no response, 4 due to adverse effects (hepatotoxicity, pulmonary embolism, retinal artery thrombosis) & 1 underwent splenectomy. Following E discontinuation 4 pts received R, 1 of whom responded. Other treatments included intravenous immunoglobulin, danazol, splenectomy and corticosteroids.
Summary/Conclusion: Our real-life multicenter retrospective analysis on the use of TPO-RAs suggests that both R and E have acceptable toxicity profiles and are highly effective in adult ITP pts failing 1 or more lines of therapy. TPO-RA switch is a feasible strategy that can be beneficial, at least in some cases.

PB2350

PERIOPERATIVE USE OF ELTROMBOPAG IN PATIENTS WITH CHRONIC THROMBOCYTOPENIA. A SINGLE-CENTER EXPERIENCE

E. Landete[1,*], A. Domingo[1], G. Pérez-Rus[1], A.M. Rodríguez-Huerta[1], D. Carbonell[1,2], A.M. Pérez-Corral[1,2], J. Anguita[1,2], J.L. Díez-Martín[1,2], C. Pascual[1,2]

[1]Department of Hematology, Gregorio Marañón General University Hospital (HGUGM), [2]Gregorio Marañón Health Research Institute (IiSGM), Madrid, Spain

Background: Patients with moderate-severe chronic thrombocytopenia have an increased risk of bleeding during surgical procedures. Perioperative management of these patients may be difficult. Eltrombopag is a well established treatment for chronic immune thrombocytopenia (ITP). During the last years, new indications for this agent have been proposed. Eltrombopag may be an interesting option for patients with different thrombocytopenic disorders requiring surgical interventions.
Aims: The aim of this study was to evaluate the efficacy and safety of perioperative use of Eltrombopag in thrombocytopenic patients undergoing invasive interventions.
Methods: We retrospectively analyzed a total of 12 procedures carried out in 10 patients with chronic thrombocytopenia who received Eltrombopag. One patient was Jehovah's Witness. We included patients with chronic ITP and thrombocytopenia due to liver disease. The data was obtained from the hospital computer records. Patients and procedure characteristics are shown at table 1. Eltrombopag was administered at a median initial dose of 25mg/day (IQR, 25-50). To evaluate treatment efectiveness based on platelet response we used the International Working Group Consensus Criteria for ITP, defyning "Partial Response" and "Response" as platelet count ≥30x10^9 or ≥100x10^9/L in absence of bleeding, respectively, and "Non response" as platelet count <30x10^9/L or less than 2-fold increase of baseline platelet count or bleeding. Statistic analysis was performed using SPSS software, version 21.0.
Results: Median platelet count at initiation of Eltrombopag was 32x10^9/L (IQR, 28-56x10^9/L). All patients achieved response over a median of 12 days (IQR, 7-14). Median platelet count before intervention was 116x10^9/L (IQR, 104-126x10^9/L). There were no procedure cancellations due to thrombocytopenia. No patient needed rescue treatments or platelet transfusion during procedures. No several bleeding or thromboembolic event was recorded. No adverse effect was registered in our cohort. After surgical intervention, all patients discontinued Eltrombopag progressively with no rebound effect.

Table 1.

Summary/Conclusion: Eltrombopag may be an effective perioperative treatment for patients with thrombocytopenia of a variety of etiologies. This agent increases platelet count in a short period of time, what may reduce the risk of bleeding of patients undergoing elective invasive interventions. It is a good alternative for patients with ITP who are not candidates to classical therapies as corticoids or immunoglobulins and its use may avoid perioperative platelet transfusion. Treatment with Eltrombopag may be discontinued safely after procedures in patients not requiring chronic treatment. Properly designed clinical trials are needed to verify these findings.

PB2351

INCIDENCE OF THROMBOTIC MICROANGIOPATHY IN HOSPITAL UNIVERSITARIO SON ESPASES. THE ROLE OF THE HEMATOLOGY LABORATORY AND THE MULTIDISCIPLINARY TEAM IN THE TMA EARLY DIAGNOSIS

B. Lopez-Andrade[1,*], M.C. Ballester[1], M.A. Duran[1], L. Lo Riso[1], J.M. Sanchez-Raga[1], A. Perez[1], M. Uriol[2], S. Cabello[2], M. Garcia-Recio[1], G. Aspas[1], A. Sampol[1]

[1]Haematology, [2]Nephrology, H. Universitario Son Espases, Palma mallorca, Spain

Background: Thrombotic microangiopathy (TMA) is a rare and life-threatening condition that can arise secondary to different diseases or mechanisms. The best known is the thrombotic thrombocytopenic purpura (TTP) a severe deficiency of ADAMTS13 in which an early treatment associates good prognosis, Hemolytic uremic syndrome (HUS) and Secondary TMA were the potential multiple etiologies can further delay diagnosis and treatment. The early detection of TMA can be done by both the clinical physician and hematology laboratory. In May of 2016 we started the implementation of the multidisciplinary team (MDT) in our center, in which the laboratory

screens for early detection and works with the MDT when a TMA is suspected either by clinical or laboratory findings; decreasing the time for the diagnosis and treatment.
Aims: Retrospectively evaluate the improvement in the response time and detection of TMA cases with the joint effort of the MDT and the Hematology laboratory, in a single center.
Methods: The MDT working group takes in physicians from Intensive care unit, Nephrology, Hematology, Farmacy, Immunology, and other services who follow the criteria for the diagnostic of TMA and discuss all potential TMA cases via a smartphone chat App, to elaborate the differential diagnoses and to recommend the best treatment option at every case. The screening evaluation is performed by a hematologist present in full time in the laboratory since 2015, either by critical results or a call from a suspected TMA case from the MDT. The laboratory screening and team workflow is described in figure 1. We report 44 cases from 2010-2017 (Including adults and children) with a median age 40-year-old. (1-76) from before and after the MDT group (table 1). The Response time (RT) was retrospectively evaluated from the laboratory records, from the first day that a TMA diagnosis was feasible up to the day it was diagnosed.
Results: In the cohort of 44 cases there has been a dramatic increase in the detection of cases after the MDT group and screening was stablished, 2010 to Apr16 (15cases) *versus* >May16-Feb18 (29 cases) an increase of 65% of the diagnosis after the MDT. The median response time decreased from 11 days (1.5-12) before the MDT to 0 days (0-2) (*P*=0.03) after the MDT. (table 1).

Table 1. Overall TMA diagnosis before and after MDT.

Cases	TMA	Atypical HUS	HUS	TTP	TMA transplant related	Mean Response time
2010– Apr 2016	15	10	0	2	3	11 days (1.5 – 12)
May 2016 – Feb 2018	29	10	11	4	4	0 days (0-2)
TOTAL	44	20	11	6	7	----------

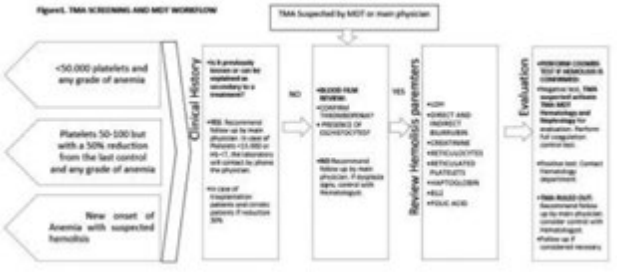

Figure 1.

Summary/Conclusion: The MDT communication with the laboratory and vice versa increases the awareness and detection of TMA, in which is fundamental to have a hematologist present in the laboratory and a trained staff to early recognize these alterations. The implementation of the MDT has improved the probability to early detect a TMA at our center. We believe that the Increase in the number of cases is probably related to missed or not diagnosed cases in the pre MDT era.

PB2352

ACCURACY EVALUATION OF LOW PLATELET COUNTS ON A NOVEL SLIDE-BASED INTEGRATED HEMATOLOGY ANALYZER

V.H. van der Velden[1,*], K. Ropar[2], D. Bracco[2], T. Allen[2], H. Russcher[1]

[1]Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands, [2]Roche Diagnostics, Westborough, United States

Background: The **cobas m** 511 integrated hematology analyzer is a novel slide-based system that performs a CBC, WBC differential, reticulocyte count, and nucleated RBC count using digital analysis of a microscope slide.
Aims: To assess the accuracy of low platelet (PLT) counts on the **cobas m** 511 compared with the Sysmex® XN-10 Automated Hematology Analyzer and BD FACSCanto™ Flow Cytometer in a single-center study.
Methods: Residual whole blood samples (n=115) in the PLT range 1-505 x10^3/µL (based on flow cytometery using CD61, CD41a, and CD42b antibodies) were randomly processed on each system. Sysmex samples were set to automatically reflex to PLT-F function, which is marketed as more reliable for thrombocytic or problematic samples than the standard impedance PLT-I function. Three analyses were performed: **cobas m** 511 and Sysmex Analyzer *versus* flow cytometer (reference), and **cobas m** 511 *versus* Sysmex Analyzer (reference). Data were compared using three thresholds and results included if a valid PLT result was obtained on both systems.
Results: All low PLT samples had valid results with the **cobas m** 511 and flow cytometry. Two (1.7%) samples were flagged with the Sysmex Analyzer (PLT-F) indicating unreliable results. The **cobas m** 511 demonstrated excellent accuracy compared with flow cytometry, with ≥93.6% sensitivity, specificity, and agreement, and good accuracy compared with Sysmex Analyzer (**Table 1**). Attempts were made to also study results for the Sysmex Analyzer PLT-I function; however, the vast majority of samples (100% for PLT counts ≤10, 80% for PLT 11-20, and 28% for PLT 21-50 x10^3/µL) had flags indicating unreliable values using this function which prevented any further comparison.

Table 1. Accuracy analyses.

	PLT threshold (10^3/µL)	Sensitivity (%)	Specificity (%)	Agreement (%)
cobas m 511 vs. flow cytometer (N = 115)	10	95.5	96.8	96.5
	20	93.6	94.1	93.9
	50	98.6	97.6	98.3
Sysmex Analyzer (PLT-F) vs. flow cytometer (N = 113)	10	100.0	96.7	97.3
	20	100.0	92.5	95.6
	50	100.0	97.6	99.1
cobas m 511 vs. Sysmex Analyzer (PLT-F) (N = 113)	10	88.0	97.7	95.6
	20	94.1	100.0	97.3
	50	100.0	100.0	100.0

Summary/Conclusion: These data demonstrate the robustness and accuracy of platelet counts reported by the **cobas m** 511 system. Many samples were flagged using the Sysmex PLT-I function that, in routine use, would have reflexed to the PLT-F function. All samples on the **cobas m** 511 system had valid PLT results.

PB2353

FREQUENCY OF AUTOIMMUNE THYROIDITIS IN CHILDREN WITH CHRONIC IMMUNE THROMBOCYTOPENIC PURPURA

T.N. Tahtakesen Güçer*, E. Yılmaz, G. Aydoğan, N.N. Ozdemir

Pediatric Hematology Oncology, Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey

Background: Chronic immune trombocytopenic purpura (ITP) is defined as an unexplained isolated thrombocytopenia that persists more than 12 months. Rheumatologic diseases, immunodeficiencies and thyroid diseases may coexist with chronic ITP due to immune dysregulation.
Aims: To investigate the frequency of autoimmune thyroiditis in patients with chronic ITP.
Methods: A total of 142 patients with chronic ITP with a follow up period of more than one year between 1995-2018 were included. Thyroid function tests, thyroid autoantibodies, thyroid ultrasonography were investigated.
Results: Seventy-three were female (51.4%) and 69 were male (48.6%). Mean age of patients was 13.2±5.4 years (range 2.4-28.1 years) and the mean age at diagnosis was 89±51 months (range 2.1-200 months). Thyroid function tests and thyroid autoantibodies were investigated in 129 patients. There was no clinical findings of either hypo / hyperthyroidism in any patient however, at least one value of fT4, TSH, anti TPO,or anti TG values was abnormal in 40 (31%) of investigated cases. Twentynine patients (22.4%) were put on follow-up by pediatric endocrinology department with a diagnosis of Hashimoto thyroiditis. Thyroid hormone replacement therapy was started in one patient. Anti TPO values of 22 patients (15.5%) and Anti-TG values of 18 patients (12.7%) were high. The majority of patients with high thyroid autoantibodies were female (67.5%).
Summary/Conclusion: We found that thyroid autoantibody positivity without clinical findings was a common finding in children with chronic ITP. According to a comprehensive study conducted in the USA, AntiTPO positivity is 10.4% and AntiTG positivity is 11.3% in general population. When compared with these rates, the frequency of thyroid autoantibody positivity and autoimmune thyroiditis was higher in children with chronic ITP in our study. As a conclusion hematologists managing children with chronic ITP should be vigilant about the regular evaluation with thyroid function tests and thyroid autoantibodies.

WASP MUTATIONS: A SINGLE GENE DEFECT, LEADING TO VARIOUS CLINICAL AND HEMATOLOGICAL PHENOTYPES

K. Kiaras[1,2,*], H. Farajifard[3,4], Z. Aryan[3,4], B.S. Shamsian[5], R. Sherkat[6], I. Mohammadzadeh[7], J. Ghaffari[8], M.T. Arzanian[3], M. Sadeghi Shabestari[9], R. Molatefi[10,11], N. Rezaei[1,3,4]

[1]Network of Immunity in Infection, Malignancy and Autoimmunity (NIIMA), Universal Scientific Education and Research Network (USERN), [2]Research Center for Immunodeficiencies, Children's Medical Center, [3]Department of Immunology, School of Medicine, [4]Research Center for Immunodeficiencies, Children's Medical Center, Tehran University of Medical Sciences, [5]Pediatric Congenital Hematologic Disorders Research Center, Mofid Children's Hospital, Shahid Beheshti University of Medical Sciences, Tehran, [6]Acquired Immunodeficiency Research Center, Al-Zahra Hospital, Isfahan University of Medical Sciences, Isfahan, [7]Noncommunicable Pediatric Diseases Research Center, Amirkola Hospital, Babol University of Medical Sciences, Babol, [8]Department of Pediatrics, Mazandaran University of Medical Sciences, Sari, [9]Department of Pediatrics, Children's Hospital, Tabriz University of Medical Sciences, Tabriz, [10]Department of Allergy and Clinical Immunology, Rasool e Akram Hospital, Iran University of Medical Sciences, Tehran, [11]Department of Pediatrics, Bo-Ali children's Hospital, Ardabil University of Medical Sciences, Ardabil, Iran, Islamic Republic Of

Background: Wiskott-Aldrich Syndrome (WAS) is an inherited x-linked defect, with characteristic features of thrombocytopenia, eczema and recurrent infections that result from ineffectiveness of the immune system. Mutations in *WASP* gene lead to WAS; however, mutations in that gene could also be seen in non-syndromic conditions such as isolated thrombocytopenia or neutropenia.
Aims: This study was performed to highlight the importance of Wiskott-Aldrich syndrome and to emphasize the need to have this diagnosis in mind if encountering a patient with microthrombocytopenia and eczema.
Methods: Herein, four patients with mutations in WASP gene are presented, who were referred to the Primary Immunodeficiency Diseases Referral Clinic of Children's Medical Center. Although direct sequencing of WASP gene was performed for three patients with classical phenotype of WAS, exome sequencing method was carried out for the remaining one, as his clinical phenotypes did not fulfil WAS criteria.
Results: One of the patients had initial signs of dysentery, eczema and petechiae at the age of 4 months; the diagnosis was immediately made, as his uncle had the diagnosis of WAS. He is under treatment with intravenous immunoglobulin (IVIG) and is awaiting a matching donor for hematopoietic stem cell transplantation (HSCT). Another one, who unfortunately passed away four months after HSCT, because of EBV infection of pharynx, had had the same initial presentations at the age of 6 months, but there had been a diagnosis lag of two and a half years before the confirmation of WAS diagnosis. The other two patients, on the other hand, did not initially have any clinical presentations and low platelet count was discovered during a routine check-up. They were diagnosed with autoimmune thrombocytopenia (ITP) at first and there was a 1.5 and a 9 year diagnosis lag. They are also under treatment with IVIG since diagnosis. The first recorded platelet count for these four patients varied from under 10,000 to 90,000. The mutations found in 3 of the patients were already known mutations in *WASP* gene, including c.121 C>T, c.91G>A, c.397 G>A. However, a novel mutation was detected in the 4th patient.
Summary/Conclusion: We wish to call attention to this uncommon, yet highly important disease. Although small size platelets and thrombocytopenia associated with recurrent infections and eczema make a suspicion of WAS, mutations in *WASP* gene should also be considered in those with isolated thrombocytopenia as well. It seems that there is still a long way from fully comprehending the genetics underlying the disease and there is plenty of scope for more research on therapeutic approached.

PB2355

IMMUNE MEDIATED THROMBOCYTOPAENIA IN CHILDREN: WHAT HAPPENS AFTER THE REFERRAL? A 7 YEAR RETROSPECTIVE REVIEW IN A TERTIARY PAEDIATRIC HAEMATOLOGY CENTRE

R. Koshy*, B. Nolan

Paediatric Haematology, Our Lady's Hospital For Sick Children, Dublin, Ireland

Background: Immune thrombocytopaenia (ITP) develops secondary to the production of auto-antibodies against platelets leading to isolated thrombocytopaenia. The cause is unknown in most cases, although ITP may be triggered by a viral illness. It is characterised by spontaneous bruising, petechiae and mucosal bleeding. ITP resolves in approximately 90% of children without intervention. However, a minority will continue to have low platelet counts for over 1 year (chronic ITP). Treatment is indicated for severe or prolonged bleeding. The majority of children do not require treatment. This condition can result in considerable concern from diagnosing clinicians and parents alike in both acute and chronic settings.
Aims: This study aims to perform a retrospective review of all children referred /attending our haematology department with a diagnosis of ITP and report on outcomes, treatment tolerability and describe the relationship, if any, between chronic ITP and the progression to development of auto-immune disease in a cohort of paediatric patients.
Methods: A retrospective review of patients referred to the Haematology Department between 2010-2017 with a platelet count <100x10^9 platelets per litre. Demographics, disease-related data, relevant auto-immune history and laboratory results were collected from medical records entered and analysed using Excel.
Results: Demographics: 140 patients were identified, 71 male and 69 female. At diagnosis, 78 were between 0 and 4 years of age, 35 between 5 and 10 years and 27 between 10 and 15 years. **Preceding events:** 3 patients had history of recent vaccinations. 6 patients had Epstein Barr Virus associated ITP. **Course of thrombocytopenia**: In 79 patients, platelet count recovered in less than 6 months. 43 patients had chronic ITP : 19/78 between 0 and 4 years of age, 13 / 35 between 5 and 9 years of age, and 11 / 27 between 10 and 15 years of age. Platelet count returned to normal in 17 patients who had ITP for more than 12 months. 3 patients developed recurrent ITP after initial recovery of platelet count. **Bleeding:** 27 patients received treatment for bleeding : 24 for epistaxis, 1 for haematuria, 2 for GI bleeds. 4 patients received precautionary treatment following trauma, 7 received treatment for dental/surgical procedures. 7 of 37 patients who received intravenous immunoglobulin developed signs and symptoms suggestive of aseptic meningitis. Two patient received platelets (one: Poland, one: Letterkenny) No patients received red cells. **Treatment of thrombocytopenia.** 8 patients received Prednisolone with non sustained increase in platelet count. 3/8 received Rituximab treatment. **Auto-immune disease.** 5 patients had co-existing / progression to autoimmune conditions : 1 hyperthyroidism, 1 mixed connective tissue disease and auto-immune hepatitis, 1 systemic lupus erythematosus ,1 autoimmune neutropaenia, IgA deficiency and coeliac disease and 1 evolving connective tissue disease/SICCA syndrome.
Summary/Conclusion: In conclusion, this data illustrates the diversity of ITP in children. Data here may not reflect the true history of ITP. Data may be skewed to chronic or atypical patients referred to one tertiary centre. We would recommend that a national registry be established to capture data on all children presenting with ITP in Ireland.

PB2356

LONG-TERM ELTROMBOPAG IN PEDIATRIC PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (CITP): AN EXTENSION STUDY OF RUSSIAN PATIENTS FROM PETIT2

E. Donyush[1,*], A. Petrova[2], N. Schedrova[3], M. Goldbrunner[4], O. Ocak Arikan[4], J. Maier[4], V. Lebedev[5]

[1]Izmaylovskaya Children's City Clinical Hospital, Moscow, [2]Children City Hospital #[1], Saint-Petersburg, [3]Novartis Pharma LLC, Moscow, Russian Federation, [4]Novartis Pharma AG, Basel, Switzerland, [5]GUZ Regional Children's Clinical Hospital, Krasnodar, Russian Federation

Background: cITP is an acquired autoimmune disorder defined by low platelet counts for >12 months from diagnosis, resulting in an ongoing risk of significant bleeding (Rodeghiero *et al. Blood* 2009). Common therapy includes immunosuppression with corticosteroids; however, associated complications may be problematic, particularly for young children. The randomized, multicenter, placebo-controlled PETIT (Bussel *et al. Lancet Haematol* 2015) and PETIT2 (Grainger *et al. Lancet* 2015) trials in patients 1-17 years old demonstrated eltrombopag (EPAG), an oral thrombopoietin receptor agonist, as a therapeutic option for children with previously treated cITP. However, long-term data in pediatric patients are limited. Here we report outcomes from an open-label, Phase III extension study of pediatric patients who completed PETIT2 from four centers in Russia.
Aims: To evaluate the long-term safety and tolerability of EPAG in pediatric patients with previously treated cITP.
Methods: Patients aged ≥1-18 years previously enrolled in PETIT2 with clinical benefit from EPAG, were enrolled in the extension. Patients/guardians provided written informed consent. Screening was followed by a single-arm treatment period. Starting EPAG dose was based on the patient's dose at the end of PETIT2, and adjusted according to platelet count and the investigator's clinical judgement (max 75 mg/day) to maintain a safe hemostatic range (~50–200x10^9/L). Frequency and severity of adverse events (AEs) were recorded (graded using CTCAE version 4.03), and hematology and blood chemistry regularly monitored. Patients were considered to have completed the study and EPAG discontinued within 3 months once the patient reached 18 years of age or EPAG received local regulatory approval for pediatric cITP.
Results: Of nine patients enrolled (4 female, 5 male; median 9 [range 4-15] years old), four (44.4%) completed the study and five (55.6%) discontinued (patient decision, n=2; lack of efficacy, n=2; AE [autoimmune hepatitis], n=1). Median duration of exposure in the extension was 24.6 (range 3-48) months; all nine patients received EPAG for ≥3 months. 8/9 patients started

on or were escalated to 75 mg/day. AEs were reported in eight (88.9%) patients (Table), most commonly nasopharyngitis (n=3), epistaxis (n=2), and headache (n=2). No AE was considered EPAG related by the investigator. Serious AEs were reported in three (33.3%) patients: autoimmune hepatitis (n=1), epistaxis (n=1), and scleral hemorrhage (n=1); none were considered treatment related by the investigator. The autoimmune hepatitis case occurred in a 6 year old after ~3 months on EPAG, while on 75 mg/day; assessments at the time revealed Grade 3 alanine and aspartate aminotransferase (ALT/AST) elevations with normal bilirubin, ALT/AST normalized over the next 3 weeks following discontinuation. Overall, platelet counts fluctuated, but were generally maintained within a safe hemostatic range; patient numbers per timepoint were low.

Table 1.

Table. Adverse events (AEs) by preferred term and maximum severity

Preferred term	All grades, n (%)	Grade ≥3, n (%)
Nasopharyngitis	3 (33.3)	0
Epistaxis	2 (22.2)	0
Headache	2 (22.2)	0
Autoimmune hepatitis	1 (11.1)	1 (11.1)
Blood bilirubin increased	1 (11.1)	0
Iron deficiency	1 (11.1)	0
Pharyngitis	1 (11.1)	0
Scleral hemorrhage	1 (11.1)	0
Tonsillitis	1 (11.1)	0

A patient with multiple severity grades for an AE is only counted under the maximum grade

Only AEs occurring during treatment or within 30 days of the last study treatment are reported

Summary/Conclusion: This open-label, Phase III extension study evaluated the long-term safety of EPAG in pediatric cITP patients who previously participated in PETIT2. Patients continued to receive benefit from EPAG with a safety profile consistent with that observed in the PETIT studies and the known safety profile for EPAG. Only one patient discontinued treatment because of an AE (autoimmune hepatitis), considered unrelated to EPAG by the investigator. There were no unexpected safety findings, indicating a favorable benefit–risk profile for EPAG in the long-term treatment of pediatric cITP patients.

PB2358

THE USEFULNESS OF THE IMMATURE PLATELET FRACTION IN THE DIAGNOSIS OF ITP AND OTHER HEMATOLOGIC DISEASES

D.J. Park[1,*], S. Kim[1], Y. Kim[1], J.-A. Kim[2], Y.H. Park[2]

[1]Laboratory Medicine, [2]Division of Hematology, Department of Internal medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: The immature platelet fraction (IPF) is a predictive factor in increased platelet production associated with platelet immunomediated consumption or platelet destruction which results from the suppression of bone marrow production.
Aims: We evaluated the value of immature platelet fraction (IPF) in distinguish between immune thrombocytopenic purpura (ITP) and aplastic anemia (AA). Additionally, in order to evaluate its potential usefulness as a diagnostic marker, we detected IPF in other hematologic diseases including myelodysplastic syndrome (MDS) and myeloproliferative neoplasms such as polycythemia vera (PV), essential thrombocythemia (ET) and chronic myelogenous leukemia (CML).
Methods: 10 patients with ITP were compared with 12 patients with AA, 8 patients with MDS, 6 patients with ET, 4 patients with PV, 8 patients with CML and 80 age- and sex- matched healthy controls. Complete blood count tests including IPF, platelet distribution width (PDW), mean platelet volume (MPV), platelet large cell ratio (P-LCR), plateletcrit (PCT) were performed using Sysmex XN-2000 (Sysmex, Kobe, Japan).
Results: Mean IPF was 16.1% in patients with ITP, 4.0% in patients with AA, 11.2% in patients with MDS, 2.5% in patients with ET, 3.2% in patients with PV, 7.2% in patients with CML and 3.1% in the control group ($p<0.05$). ITP patients showed high IPF, PDW, MPV, and P-LCR compared with other groups, while PCT was lower in ITP patients than other groups.
Summary/Conclusion: We found highly elevated IPF in disorders related to increased platelet production, particularly associated with platelet destruction such as ITP. Especially in thrombocytopenic patients, IPF showed significant differences between ITP and AA. MDS patients resulting from the decreased platelet production associated with bone marrow suppression showed slightly increased IPF rather than healthy controls. ET and PV showed normal ITP comparing with healthy controls. Interestingly, CML with fibrosis 2 cases revealed significantly higher IPF (mean:15.1%) than CML without fibrosis 6 cases (mean:4.6%). Besides ITP, we found elevated IPF in MDS and CML. The IPF is highly recommended to evaluate the thrombopoietic status of bone marrow in thrombocytopenia patients.

PB2359

EVALUATION OF PLATELET RECEPTOR EXPRESSION IN CHRONIC LYMPHOID LEUKEMIA TREATED WITH IBRUTINIB

V. Popov[1], I. Dumitru[2], C.O. Matei[3], B.M. Matei[4], M. Omer[1], R. Leu[5], M.G. Moisescu[4], T. Savopol[6], E. Kovacs[5], H. Bumbea[7,*]

[1]Hematology, Colentina Clinical Hospital, [2]Hematology, Emergency University Hospital, [3]Biophysics and Cellular Biotechnology, [4]Biophysics and Cellular Biotechnology, UMF Carol Davila, [5]Biophysics and Cellular Biotechnology, Carol Davila University of Medicine and Pharmacy, [6]Biophysics and Cellular Biotechnology, Carol Davila University of Medicine and Pharmacy, [7]Hematology Emergency University Hospital, UMF Carol Davila, Bucharest, Romania

Background: Patients with chronic lymphoid leukemia (CLL) treated with Ibrutinib have increased bleeding risk. This complication is associated to platelets abnormalities. Platelet aggregation induced by different reagents is significantly decreased compared to controls. Ibrutinib inhibits platelet integrin αIIbβ3, outside-in signaling and thrombus stability. Membrane fluidity (MF) has an important role in the expression of platelet receptors and in modulating the activity of membrane proteins.
Aims: The aim of our study was to determine whether treatment with Ibrutinib influences the platelet MF and platelet receptor expression.
Methods: We present a retrospective study on 12 cases of CLL patients treated with Ibrutinib who were admitted in Colentina Clinical Hospital Bucharest, compared to a control group consisting in 10 untreated CLL patients. Platelet MF was measured by fluorescence anisotropy using TMA-DPH marker. Expression of platelet receptor was assessed by flowcytometry. We evaluated CD41/CD61 and CD42a/CD42b expression.
Results: Patients with CLL treated with Ibrutinib had a a higher platelet MF than in control group ($p=0.001$). 3 CLL patients associated 17p mutation. In this group the level of MF was lower than in patients who had no 17p mutation, without statistical significance. The expression of CD41/CD61 and CD 42a/CD42b was lower in CLL group treated with Ibrutinib compared to untreated CLL patients group ($p=0.04$). We also assessed the variation coefficient that represents the spread of intensity of fluorescence signal. This was higher in CLL patients group treated with Ibrutinib compared to control, for both types of analyzed receptors (CD41/CD61 and CD42a/CD42b). Our results confirm that MF and platelet receptors expression are influenced by Ibrutinib.
Summary/Conclusion: Administration of Ibrutinib in CLL patients is associated with higher MF and lower expression of platelet receptor with high spread of fluorescence. The modification of fluidity of platelet membrane probably could influence the expression of platelet receptors and quality of signaling. We have to check these findings on a larger group of CLL patients treated with Ibrutinib.

PB2360

IMMUNE THROMBOCYTOPENIA AND VITAMIN D DEFICIENCY

C. Tham*, A. Luqmani, M. Atta, D. Paul, C. Vladescu, E. Lucchini, A. Sayed, N. Cooper

Department of Clinical Haematology, Hammersmith Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom

Background: In our practice we have observed a number of patients with immune thrombocytopenia (ITP) whose platelet count has increased after vitamin D replacement alone, prompting us to investigate this further. Vitamin D deficiency has been linked with the development of autoimmune disease. This pathophysiological mechanism may also apply to patients with ITP, in which case, correcting vitamin D deficiency would be a safe way of aiding treatment.
Aims: Assess whether there is a relationship between ITP and vitamin D deficiency in both adults and children.
Methods: Adult and pediatric ITP patient cohorts were retrospectively analysed, comprising of 148 and 34 patients respectively. The pediatric

cohort was further divided into acute (11) and chronic (23) groups. Vitamin D laboratory tests were reviewed and classified as – replete (>70nmol/L), insufficient (40-70nmol/L) or deficient (<40nmol/L). Platelet counts taken at the same time as vitamin D testing were also recorded. Thrombocytopenias were categorised as mild (>30x10^9/L), moderate (10-30x10^9/L) or severe (<10x10^9/L). Those with repeat vitamin D tests were categorised as – increased, unchanged or decreased vitamin D level, based on category (replete, insufficient or deficient) rather than numerical value.
Results: In the pediatric chronic ITP group, of the 20 patients tested, the mean vitamin D level was 46.4nmol/L (SD ±25.8). 40% of these were deficient and 35% insufficient. In the acute ITP group 6 patients were tested, the mean vitamin D level was 47.5 nmol/L (SD ±29.6). Overall, 83.3% of those tested were either deficient or insufficient and this did not correlate with severity of thrombocytopenia. In the adult cohort of 148 patients, 117 (mean age 45 years) had vitamin D levels and platelet counts tested. The mean level was 53.8nmol/L (SD ±31.7). Of these, 35% were deficient, 41% insufficient and 24% replete. When stratified by severity of thrombocytopenia, there was no significant difference between groups. There were significantly more patients deficient in winter and spring compared to in summer and autumn. Plotting numerical values of vitamin D level against platelet count showed little correlation, with a Pearson R value of -0.0048. 47 patients underwent repeat testing for vitamin D levels. Vitamin D levels increased in 17, remained unchanged in 24 and decreased in 6 patients. When stratified by change in platelet count (by category, rather than numerical value), 5 patients showed an increase in both vitamin D and platelet count, 2 of which were on no other treatment for ITP. This was not a consistent change with others having a fall in platelet count despite an increase in vitamin D levels.

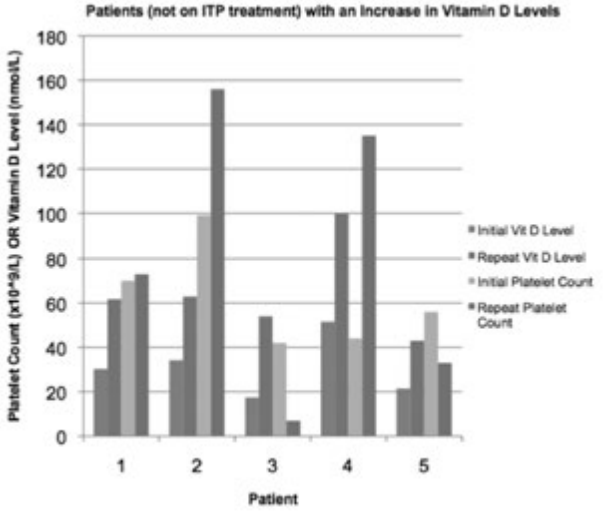

Figure 1.

Summary/Conclusion: From our data, a small number of patients had an increase in their platelet count with vitamin D replacement alone. However, this was not a consistent effect and there was no overall correlation between vitamin D deficiency and thrombocytopenia. Nonetheless, this is a heterogeneous group of patients, on a variety of treatments which were not accounted for. Vitamin D deficiency is a significant problem in our cohort of children and adults with ITP. Vitamin D is of clear importance in regulation of the immune system with an apparent protective effect against infections. The role of vitamin D in autoimmune conditions is harder to establish given the heterogeneity of disease and the variability of clinical trials performed in this area. However, given the low sunlight in the UK and the importance of vitamin D for overall immunity, we recommend testing for and replacing vitamin D, particularly over winter months.

PB2361

DISCONTINUATION OF TREATMENT WITH TROMBOPOIETIN RECEPTOR ANALOGS IN PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA (ITP): IS IT POSSIBLE?

M. Yuste Platero[1,*], L. Bermejo Martínez[2], D. Morillo Giles[1], R. Martos Martínez[1], E. González Arias[1], P. Beltrán Álvarez[2], A. Pascual Martínez[2], P. Llamas Sillero[3]

[1]Hospital General de Villalba, Hematology, Collado Villalba, [2]Hospital Infanta Elena, Hematology, Valdemoro, [3]Hospital Fundación Jiménez Díaz, Hematology, Madrid, Spain

Background: Primary immune thrombocytopenia (ITP) is an autoimmune disease in which, along with a greater destruction of platelets, an insufficient marrow production is observed. This second mechanism confirms the existence of thrombopoietin levels (TPO); which reinforces the hypothesis that thrombopoietin levels were elevated in this population group. To improve the number of platelets in ITP, a group of drugs, the thrombopoietin receptor agonists (TPO-RA), were developed. Two clinical trials led to the approval of eltrombopag (RAISE and EXTEND studies), without determining the time of treatment, as well as the possibility of temporary interruptions of those patients who reached platelet numbers in stable ranges.
Aims: To analyze if the successful suspension of the drug is possible, for those patients who reach adequate platelet counts.
Methods: Prospective study conducted between January/2017 and February/2018, in which 2 patients diagnosed with primary immune thrombocytopenia are included. We analyze the time of active treatment, as well as the period of suspension of therapy. The cut-off point of the platelet count was considered optimal was 100x10^9/mm^3, and was defined by recommendations of clinical guidelines and patient safety and validated according to the laboratory standards of our center (Range of normality: 150x10^9/mm^3-450x10^9/mm^3).
Results: Two patients diagnosed with ITP on treatment with thrombopoietin analogues were included. The first case is a 75-year-old woman, with comorbidities that made difficult the treatment with corticosteroids at full doses (diabetes mellitus and recurrent infections). At diagnosis 15x10^9/mm^3 platelets. First-line treatment with poor tolerance is started, suspending it and starting in May 2017 second-line treatment with eltrombopag. The treatment was maintained for 10 weeks at standard doses with very good tolerance and progressive rise in platelet counts, reaching stable numbers in the different analytical controls. Given the stability, it was decided to suspend treatment and close clinical and analytical follow-up, maintaining platelet numbers above 100x10^9/mm^3 to date. The current period without treatment is 7 months. The second case is an 80-year-old woman with a diagnosis of ITP that debuted with severe thrombocytopenia and associated clinical bleeding. First-line treatment with corticosteroids was initiated at high doses and IVIGs cycle, being refractory without reaching adequate platelet counts. In August/2017, second-line treatment with thromboprotein receptor agonists (eltrombopag) was started until October 2017, with analytical and clinical stability. On that date it was decided to suspend treatment by stable platelet counts. The patient continues without active treatment and asymptomatic from the point of view of bleeding complications. The current period without treatment is 4 months.
Summary/Conclusion: Currently there is published data on the interruption of the TPO-RA, but objective data and standardized recommendations have not yet been provided. It has not been possible to identify the predictive factors related to the response and maintenance or withdrawal of the drug. These two cases demonstrate and support that not only a stable response can be achieved in patients diagnosed with ITP, but that the withdrawal of the drug, once adequate platelet ranges have been reached, is possible, but always with the need for a clinical and analytical follow-up close of these patients.

PB2362

CLINICAL AND LABORATORY PARAMETERS IN CHILDREN WITH ITP

O. Tanous[1,*], A. Koren[2], T. Dujovny[3], H. Eitam[4], R. Colodner[4], C. Levin[3]

[1]Ward A, [2]hematology unit, [3]pediatric hematology unit, [4]yetzhak rabin [20], Emek Medical Center, Afula, Israel

Background: Immune Thrombocytopenia (ITP) is one of the most common hematological abnormalities in children; despite the extremely low platelet count the symptoms are generally mild. Some studies have argued that a compensatory pro-coagulant plasmatic state with a protective effect exist in these patients. Our study aims to investigate this pro-coagulant state in pediatric ITP patients.
Aims: Our study aims to investigate the bleeding tendency and pro-coagulant state in pediatric thrombocytopenic patients.
Methods: Pediatric ITP patients treated at Emek Medical Center were included. Bleeding score and laboratory parameters including platelet (Plt) count, PT- aPTT, von Willebrand factor (vWF) and Factor VIII activity at 2 different points, disease onset and during follow-up, were assessed.
Results: Thirty seven patients were included (24M/13F); median age was 3.3 (0.7-22.7) yr. Eight pts (22%) had a bleeding score of 3 (more than skin) or more. Five patients were treated with steroids or IVIG. Patients with an acute disease (12 mo), (p<0.025). The severity of bleeding was lower

in Arab pts than in Jewish ones (p<0.02). Seventeen pts were evaluated at two time-points. The mean Plt count and vWF were 25.3 K/µl, 165.6% at point 1 and 199.1K/µl, 146.6% at point 2; respectively. Platelet count significantly increased and vWF significantly decreased between time points 1 and 2 among our patients (Z=-3.41, p<0.001; Z=2.23, p<0.03). A compensatory pro-coagulant state with increased vWF was found in our cohort at enrollment and declined when platelet count increased. This might explain the scarcity of severe bleeding in pediatric ITP patients.
Summary/Conclusion: A compensatory pro-coagulant state with increased vWF was found in our cohort at enrollment and declined when platelet count increased. This might explain the scarcity of severe bleeding in pediatric ITP patients.

PB2363

NON –CATHATER THROMBOEMBOLIC EVENTS IN CHILDREN

Z. Salcioglu*, G. Aydoğan, F. Akıcı, E. Yılmaz, G.N. Özdemir, E. Uysalol, C. Bayram

[1]Pediatric Hematology-Oncology, Kanuni Sultan Suleyman Education And Research Hospital, Istanbul, Turkey

Background: Although the incidence of thromboembolic events has increased over the last decade, non catheter-related thromboembolism is uncommanly seen in childhood.
Aims: This study was aimed to analyze the data of 93 thromboembolic events in children who were followed up in our hematology–oncology clinic between 2000-2017, retrospectively.
Methods: Information of 93 patients were retrieved from patient files and from the records contained in the electronic information processing environment created after 2005.
Results: Fifthy four of the patients were males and 39 were females. The age range was between four months-16 years. Presenting ages of the patients were changing from one day to 12 years. Of the children 11 (11.8%) of the cases were neonates, 23 (24.7%) were infants less than 1 year old, and 59 (63.5%) were children over than one year old. Thromboembolic events were mostly located in central nervous system 54 (58.1%), deep venous system of the limbs 20 (21.6%), portal vein 9(9.8%), renal vein 2 (2.1%), intracardiac 2 (2.1%), inferior vena cava 2 (2.1%), peripheral artery 2 (2.1%) and pulmonary embolism 2 (2.1%). Inherited risk factors were present in 55 (48.4%) of the children. Twenty of the patients carried two risk factors (21.5%). FV Leiden heterozygosity was the most common inherited risk factor. Acquired risk factors were present in 35 (37.6%) of the children. Systemic infection was the most common underlying risk factor. Acquired and inherited risk factors were present simultaneously in 20 (21.5%) of the patients. Treatment included low-molecular-weight heparin (n=67), coumadin (n=12), heparin (n=8), aspirin(n=6).
Summary/Conclusion: Thrombosis in children is an important complication with high morbidity and mortality. Thrombosis in children is gaining increased awareness, as advanced medical care has increased treatment intensity of hospitalized pediatric patients. Better predictors of prognosis in relation to risk factors, treatment and prophylaxis are therefore urgently needed. Future respective studies may help to assess the risk profile and therapy.

PB2364

THE IMPACT OF GESTATIONAL THROMBOCYTOPENIA IN NEWBORNS

S. Cristina[1,*], P. Monica[1], B. Ema[1], C. Sonia[1], L. Diana[1], S. Miruna[2], G. Alexandru[1], P. Ovidiu[1]

[1]Hematology, University of Medicine and Pharmacy "Victor Babes" Timisoara, [2]Hematology, Municipality Emergency Hospital of Timisoara, Timisoara, Romania

Background: Thrombocytopenia develops rarely during pregnancy or in the immediate postpartum period. It may develop secondary as a biomarker of a coexisting disorder or it may be also idiopathic.
Aims: The aim of this study was to determine the impact that gestational thrombocytopenia (GT) has on the pregnancy evolution as well as on the newborn's health.
Methods: This is a retrospective study on 40 women who developed thrombocytopenia during pregnancy. Data was obtained from their medical files. We selected data from when they were at least 30 weeks of pregnancy.
Results: From the total of 40 women, 26 (65%) developed mild thrombocytopenia (platelets over 100.000) and 14 (35%) developed mild thrombocytopenia (platelets between 50.000 and 100.000). From the total of patients who developed mild thrombocytopenia, 73,07% presented a very mild oscilation in the platelets values before giving birth while 26,93% presented a significant decrease in platelets count with about 50.000. The situation was different in case of women who developed moderate anemia. The majority of them (71,42%) developed severe thrombocytopenia and cortison therapy was given. What concerns the newborns of mothers presenting mild anemia, only 15,38% of them presented thrombocytopenia and it recovered in a few weeks without therapy. On the other hand, the majority of newborns (57,14%) whose mothers presented moderate thrombocytopenia developed persistent thrombocytopenia with platelets in continuous decrease and further investigations were performed.
Summary/Conclusion: This study reveals that newborns from mothers who developed moderate gestational thrombocytopenia have better chances to develop thrombocytopenia.

Quality of life, palliative care, ethics and health economics

PB2365

MONTELUKAST AND GEMFIBROZIL IMPROVES SYMPTOM CONTROL AND ENHANCES THE RESPONSE TO ORAL CHEMOTHERAPY IN HAEMATOLOGICAL MALIGNANCIES WITH A POOR PROGNOSIS

S. O'Mara[1,2,3,*]

[1]Haematology, Laverty Pathology, [2]Tamara Hospital, [3]New England Northwest Haematology, Tamworth, Australia

Background: Many malignancies occur in elderly and unfit patients who are not suitable for agressive chemotherapy due to side effects, poor response and poor survival with standard therapies. These patients often receive some benefit from orally administered palliative treatment regimens. A phase 1/2 clinical trial (MOM trial ANZCTR) was undertaken using Montelukast and Gemfibrozil to enhance the response to existing chemotherapy in Multiple Myeloma (reported elsewhere). One of the observations was that the patients felt significantly better on montelukast treatment and appeared to have less chemotherapy toxicity. Montelukast and Gemfibrozil was added to a number of oral treatment regimens administered with palliative intent to see whether side effects of treatment as well as the disease symptoms would improve.
Aims: To test whether the addition of Montelukast and Gemfibrozil to palliative treatment regimens improved the disease response, symptoms, treatment side effects and functional performance status.
Methods: All patients gave informed consent. Age range 67 -92. Median 84 yo. 14 patients on palliative oral treatment regimens for a variety of haematological malignancies(AML, CLL, NHL, Richters) were given Montelukast 30mg twice daily as well as 600mg Gemfibrozil twice daily. The effect on transfusions, admissions to hospital, clinical response as well as general well being was measured. Treatment regimens included low dose oral chlorambucil in CLL. Single agent 6-TG or busulphan in non responsive AML. Oral prednisolone, cyclophosphamide and etoposide in agressive nhl. Two patients with solid tumours received no additional chemotherapy.
Results: 2/4 patients on palliative AML treatment have responded. Patient 1 became transfusion independent after 1 month. Patient 2 has had a response in peripheral blood after failing 6 months treatment with Azacytidine. 5/5 patients with CLL on 2 mg of oral chlorambucil per day have had a marked improvement in lymphocyte counts. 1/1 patient with waldenstroms macroglobulinaemia has become transfusion independent and shown response after previously having no resopnse to single agent chlorambucil. 1/1 patients with Richters transformation of CLL has had complete resoloution of B symptoms and complete resoloution on PET scan measured at 2 months. 1/1 patient with myeloma with bone marrow failure has become transfusion independent, improved white cell counts and improved performance status from 4 to 2. 1/1 with progressive disease following chemotherapy for lung cancer has had an improvement in performance status from 3 to1 as well as a reduction in tumour size. 2/2 patients with agressive lymphoma have had a complete response in less than 4 weeks with transformed lymphoma and angioimmunoblastic nhl. 1/1 patient with end stage airways disease and advanced non responsive GIST tumour went from ECOG 4 to ECOG 2 after 3 weeks of treatment. Fourteen of sixteen patients have shown demonstrable benefit.
Summary/Conclusion: Montelukast and Gemfibrozil both given alone and when added to palliative chemotherapy appears to improve the response to treatment and symptoms in the majority of patients. It appears to reduce transfusion dependency. There has been a marked improvement in performance status. There have also been some highly significant responses in otherwise incurable poor prognosis malignancies. As these improvements are ongoing, it is planned to update the results at the congress.

PB2366

METABOLIC PROFILE OF CHILDREN AND ADOLESCENTS FOLLOWING TREATMENT FOR HEMATOLOGIC MALIGNANCIES

D. Apostolaki[1,*], K. Katsibardi[2], V. Efhymiou[1], F. Bacopoulou[1], G. Avgerinou[2], A. Kattamis[2]

[1]Center for Adolescent Medicine and UNESCO Chair on Adolescent Health Care, First Department of Pediatrics, National and Kapodistrian University of Athens, Aghia Sophia Children's Hospital, [2]Hematology-Oncology Unit, First Department of Pediatrics, "Aghia Sophia" Children's Hospital, University of Athens, Athens, Greece

Background: Metabolic disorders have been increasingly recognized in childhood cancer survivors. Dyslipidemia, glucose intolerance, hyperinsulinism and insulin resistance may play a role in the development of metabolic syndrome and later cardiovascular disease in these patients. Contributing factors to metabolic disturbances include cancer type and treatment, associated hormonal disorders, disturbed energy intake and/or physical inactivity as well as family history of metabolic disorders and obesity.
Aims: To assess the metabolic profile of children and adolescents after completing their treatment for hematologic malignancies.
Methods: Children and adolescents with hematologic malignancies (2 groups: leukemia or lymphoma), at least 6 months post-treatment, underwent measurement of height and weight, Tanner staging for sexual maturity, liver ultrasonography and fasting blood lipid profile assessment for cholesterol (C), triglycerides (TG), high-density lipoprotein cholesterol (HDL), low-density lipoprotein cholesterol (LDL), apolipoproteins A_1 (apoA_1) and B (apoB), lipoprotein a (Lpa) and uric acid (UA). Body mass index (BMI) and homeostatic model assessment for insulin resistance (HOMA-IR) were calculated for each patient.
Results: A total of 30 patients, 18 with acute lymphoblastic or acute myelogenous leukemia (15 and 3, respectively), (mean age±SD; 12.7±3.8 years) and 12 with Hodgkin or non-Hodgkin lymphoma (10 and 2, respectively) (mean age±SD, 14.5±3.3 years) participated in the study. Patients had completed treatment for leukemia before 21.6±13.6 months and for lymphoma before 19.3±11.5 months. Among patients with leukemia 23.5% had normal weight and 76.5% were overweight or obese, whereas among patients with lymphoma, 58.3% had normal weight and 41.7% were overweight or obese. Serum concentrations (mean±SD) of lipids in patients with leukemia were C 168.5±32.1 mg/dl, LDL 95.6±26.8 mg/dl, HDL 57.5±13 mg/dl, TG 76.9±30.5 mg/dl, apoA_1 148.5±29.2 mg/dl, apoB 86.9±21.7 mg/dl, UA 4.8±1.7 mg/dl and for Lpa median (interquartile range): 4.7 (37.5) mg/dl. Respective concentrations for patients with lymphoma were C 166±27.6 mg/dl, LDL 89.3±21.4 mg/dl, HDL 63.3±14.7 mg/dl, TG 67.1±26 mg/dl, apoA_1 127.2±45.4 mg/dl, apoB 78.0±11.6 mg/dl, UA 4.5±1.5 mg/dl and Lpa 2.9 (6.4) mg/dl. HOMA-IR (mean±SD) was 2.1±1.5 or 3.1±1.9, for patients with leukemia or lymphoma respectively. There was no statistically significant difference in the metabolic profile between the 2 groups. Among patients with leukemia, serum TG were significantly higher (P=0.011) in those with fatty infiltration of liver (100.8±32 mg/dl) than patients without fatty liver (63.8±21.2 mg/dl). In patients with lymphoma, UA concentrations and HOMA-IR were higher (P=0.042 and P=0.031 respectively) in overweight or obese patients (5.5±1.4 mg/dl and 4.4±1.6 respectively) than in normal weight patients (3.8±1.2 mg/dl and 1.5±0.2 respectively). There were no statistically significant differences in the lipid profile between genders for both groups.
Summary/Conclusion: Serum TG were associated with fatty infiltration of the liver in patients with leukemia whereas UA and HOMA-IR were associated with BMI-category in patients with lymphoma. Larger studies are needed to fully elucidate the metabolic disturbances in young survivors of hematologic malignancies.

PB2367

QUALITY OF LIFE OF TRANSFUSION DEPENDENT THALASSEMIA PATIENTS IN GREECE. A MULTICENTRE STUDY

P. Klonizakis[1,*], C. Apostolou[1], I. Christodoulou[1], D. Andriopoulos[1], K. Kafantari[1], D. Pantelidou[2], S. Kokkota[2], M. Diamantidis[3], A. Kourakli[4], M. Sarigianni[1], R. Klaassen[5], E. Vlachaki[1]

[1]Aristotle University of Thessaloniki, [2]Thalassemia Unit, AXEPA General Hospital, Thessaloniki, [3]Thalassemia Unit, General Hospital of Larisa, Larisa, [4]Thalassemia and Hemoglobinopathies' Center, University Hospital of Patras, Patra, Greece, [5]University of Ottawa Children's Hospital of Eastern Ontario, Ontario, Canada

Background: In Greece, the Quality of Life (QoL) in Transfusion-Dependent Thalassemia (TDT) has been studied in only small groups of patients and all assessments involved the administration of generic QoL questionnaires. TranQol, is a novel, disease-specific QoL questionnaire for TDT patients that has been recently validated and will be administered in this study.
Aims: The aim of this study is to evaluate the QoL of TDT patients in Greece using a novel, disease-specific QoL questionnaire (TranQol) in combination with a generic QoL questionnaire (SF-36).
Methods: In this multicentre study, we recruited 288 consecutive adult TDT patients from four Thalassemia Centers in Greece, according to specific inclusion and exclusion criteria. The participants had a mean age of 32±7 years, 42% were male and 58% were female. Demographic and clinical characteristics were retrieved from the patients' medical records. All participants completed a set of two QoL questionnaires, the generic SF-36v2 and the disease-specific TranQol, during their scheduled transfusion visits. The

data from SF-36v2 were used in order to compare the QoL of TDT patients with the healthy population in Greece. The more sensitive TranQol was used to describe possible differences in QoL between the following subgroups of TDT patients 1) type of iron chelation therapy 2) presence of comorbidities 3) level of liver hemosiderosis. Parametric and non-parametric tests will be used to compare data with or without normal distribution, respectively. Statistical significance is defined as $p<0.05$.

Results: Compared to the available data from the healthy population in Greece, the SF-36 scores of TDT patients were lower in all Qol domains which involved Physical Functioning (81% *vs* 50%), Role Physical (79% *vs* 50%), Bodily Pain (73% *vs* 52%), General Health (67% *vs* 47%), Vitality (66% *vs* 55%), Social Functioning (82% *vs* 50%), Role Emotional (82% *vs* 47%) and Mental Health (68% *vs* 49%). The mean summary score of TranQol was 71%±15, whereas the scores of the domains physical health, emotional health, sexuality, family functioning and school/career where 71%±15, 67%±17, 77%±23, 74%±19 and 75%±21 respectively. The mean TranQol summary score was lower for patients treated with Deferiprone compared to patients treated with Deferoxamine (mean difference=11%, 95% C.I: 2-21), Deferasirox (mean difference=12%, 95% C.I: 15-21) or with the combination of Deferiprone-Deferoxamine (mean difference=12%, 95% C.I :15-21). Assessment of comorbidities revealed that patients with osteoporosis have significantly lower TranQol scores (70%±14 *vs* 74%±13). The TranQol mean scores did not differ between groups with different levels of liver iron but patients with mild liver hemosiderosis had lower physical health scores compared to patients with normal levels of liver iron (mean difference=7%, 95% C.I: 6-14).

Summary/Conclusion: This is the first QoL study in a representative sample of the TDT population in Greece. Compared to the healthy population, TDT patients have a lower QoL. The use of a disease-specific QoL questionnaire revealed distinct groups of TDT patients with worse QoL. Our findings could help the physicians to early recognize these groups of TDT patients and help them improve their QoL. In the era of novel treatments for TDT patients, each new drug should be evaluated in terms of both clinical efficacy and improvement in health-related QoL. Our results may provide a baseline index score of QoL in TDT patients to be compared with relevant outcomes from future clinical trials.

PB2368

COST OF HEMATOLOGIC CANCERS IN INDIA: A HOSPITAL INPATIENT CARE ANALYSIS

C. Cherian Philip[1,*], S. Singh[1], A. Mathew[1], A. Jindal[2], N. Kakkar[3], M.J. John[1]

[1]Clinical Haematology, [2]Immunohematology and Blood Transfusion, [3]Laboratory Haematology, Christian Medical College & Hospital, Ludhiana, India

Background: Health care expenditure in India remains a challenge. Majorly dependent on out of pocket expenditure and private health care, these expenses are now a leading cause of poverty in India and reason to abstain from treatment(1,2). Despite an acknowledged increase in burden of cancers in India, data on the costs of care are lacking. This information is essential for national health care planning and resource allocation. In identifying with this goal we analysed the inpatient hospital care costs for the four most common hematologic cancers from our centre.

Aims: To estimate the inpatient hospital care costs for ALL, AML, NHL and Multiple Myeloma at a tertiary care centre In India.

Methods: Cost data was collected for each hospital inpatient admission beginning July 2015 through January 2018. This was obtained from a prospectively maintained registry which also included baseline demographic information. Hematologic cancers were defined by the WHO classification of tumors of hematopoietic and lymphoid tissues. Inpatient stay was categorized as private room and general ward. The General Ward accommodates five patients in a room with a shared amenities and piped oxygen, suction facility. Private rooms accommodate a single patient and furnished with additional amenities. Patients who were moved to an intensive care unit were not included in this analysis. Standard chemotherapy protocols, antibiotics and antifungal policies with standard of care diagnostic tests were adhered and administered to all patients in an inpatient ward without specialized air handling facilities. The trigger for component transfusion was platelet count of $<10x10^9$/l and Hb<7g/dL.

Results: A total of 461 patients were admitted in this period. Characteristics of these patients are detailed in table1. The median distance from home to hospital was 61 km (range: 10-78) and 73(15.8%) patients travelled from another state. Acute Lymphoblastic leukemia was the most frequent diagnosis for admission in 163 (35.4%) patients followed by Non Hodgkin Lymphoma in 144(31.2%). Patients in the private ward were more likely to have availed a health insurance (6.38% *vs* 2.1%, P<0.01). The median cost of care per inpatient stay was 46027.50 (€575) [€ 260-€1369].

Table 1.

Table 1. Characteristics of patients with hematologic cancers		
Variable	**N (461) n (%)/ Median (IQR)/Mean (±SD)**	
Age	47 (21-60)	
Durations of admission (days)	4 (2-8)	
Payment (Out of pocket)	394(85.5)	
Gender(Male)	285(61.8)	
Comparison across admission categories		
-	**General N (284)**	**Private N (177)**
Age~	46 (20-59)	49 (24-63)
Durations of admission (days)~	4 (1-7)	5 (2-11)
Disease-wise inpatient expenditure (Mean)*		
Multiple Myeloma	₹ 108546 (€1356)	₹ 119646 (€1495)
AML	₹ 99636 (€1245)	₹ 341782 (€4272)
ALL	₹ 74580 (€932)	₹ 209160 (€2614)
NHL	₹ 37476 (€468)	₹ 142473 (€1780)

*₹ 80= €1; ~ P>0.05; # inpatient expenditure included the cost of drugs, antibiotic usage, supportive care with component transfusion and growth factors, hospital room charges, investigation charges and consultation fees.

Summary/Conclusion: In our analysis, the majority of inpatient hospital expenses are borne out-of-pocket. With a GNI per capita of €1346 and multiple admissions required for chemotherapy administration or complications in hematological cancers; the costs of inpatient care places a high burden on patients. This is despite reduced costs of care when compared globally(3). Variations in treatment protocols across treatment centres in different countries limit the generalization of our findings. However, it is likely that this data is broadly representative of the experience of many tertiary centres within India and also likely to represent many developing countries from where there is limited data. Universal health coverage and better allocation of resources is needed for patients with hematological cancers in India.

Policlinico Giaccone, [9]Hematology Unit, Ospedale Civile Cervello, Palermo, [10]Hematology Unit, Benevento, [11]Hematology Unit, Ospedale Civile S. Vincenzo, Taormina, [12]Eubea, Naples, [13]Hematology Unit, P.O. S. Giuseppe Moscati, Avellino, [14]Hematology Unit, A.O. S. Carlo, Potenza, [15]Hematology and BMT Unit, University of Bari, Bari, [16]Hematology Department, II University Federico II, Naples, Italy

Background: The outstanding availability and clinical success of tyrosine kinase inhibitors has turned CML into a chronic disease in which patients need to both tolerate and adhere to continuing treatment for many years. Nonetheless this great clinical achievement has not been paralleled by a full understanding of the impact of the CML disease from the patient viewpoint. This new scenario changed both physician's behaviour and patient's perceptions about the disease and influence clinical decision-making. There is now evidence that patient-reported outcomes, including self-reported symptoms, might provide useful information beyond traditional disease factors.

Aims: Aim of the SOLARIS project was both to develop and investigate a simplified health-related quality-of-life (QoL) assessment to detect real-life information from the patient about the symptom burden and on the administered treatment.

Methods: Therefore 244 CML patients in chronic phase (M 60%, F 40%, median age 61yrs) were enrolled: 175 of them were on Imatinib (IM) therapy and 69 on Dasatinib (DAS), either as first or second line treatment. All patients provided written informed consent. More than 45% of them received concomitant medications; elderly patients (over 65yrs) represented 41.4% of the total population. A simplified and easy to use QoL questionnaire with 9 single-item and another with 14 single-item was given to patients receiving IM- or DAS-therapy respectively. A small cohort of patients (19) shifted from IM-therapy to DAS. Fisher exact test was performed to evaluate any possible differences between the two treatment groups (IM *vs* DAS).

Results: CML patients treated with IM reported a high incidence of periorbital edemas with ocular side effects (70%), muscle cramps (79%), bone and joint pain (51%), fatigue (61%). Interestingly, most of the patients receiving DAS-therapy reported fatigue as the main symptom (70%). When compared, we found that diarrhea (p=0.001), periorbital edemas with ocular side effects (p=0.00007) and muscle cramps (p=0.000006) clearly emerged among the treatment symptom burden as main differences favouring DAS, whereas no other difference among symptoms was detected. Moreover, those patients who changed to DAS showed an improvement of most of the side effects with the exception of fatigue.
Summary/Conclusion: In conclusion we are aware that our questionnaire is not validated and that some items are missing, however we believe that a short and easy to use questionnaire and real-life spontaneous questions might be helpful in understanding patients' perception on symptom burden and treatment in CML.

PB2370

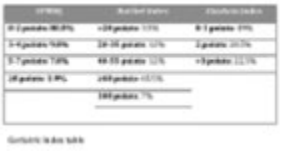
PROFILE OF "OLDEST OLD" PATIENTS WITH ANEMIA IN A HEMATOLOGY-GERIATRIC INTERDISCIPLINARY CONSULTATION

L. Lacalle[1,*], N. Fernández[2], N. Espinosa[3], S. Pinzon[4], M.P. Olier[5], M.J. Agustín[5], M. Clerencia[2], M.P. Delgado[4], M.Á. Montañés[4], M.V. Recasens[4]

[1]Hematology, Hospital San Jorge, Huesca, [2]Geriatrics, Hospital Universitario Miguel Servet, Zaragoza, [3]Hematology, Instituto de Investigación Biomédica de Salamanca, Salamanca, [4]Hematology, [5]Pharmacy, Hospital Universitario Miguel Servet, Zaragoza, Spain

Background: Anemia is a frequent entity arising with age, mainly in people over 85 years old, known as "oldest old". Nowadays, this segment of the population is growing, and consequently it will increase along next decades. In our center (Miguel Servet Universitary Hospital), an interdisciplinary Hematology-Geriatrics consultation has been created in order to attend these patients.
Aims: To analyze, in a 15 months follow-up, the profile of elderly patients with anemia in order to optimize their treatment and improve their life quality.
Methods: It is a descriptive, observational and prospective analysis of patients assessed in Hematology-Geriatrics consultation in a tertiary hospital. Period of study: from October 2016 to January 2018. Functional status was determined by Barthel Index. Comorbidity was measured by Charlson Index. Cognitive function was measured by Pfeiffer questionnaire (SPMSQ). Nutrional risk was evaluated by a Mini-Nutritional short version (Mini-MNA).Data collection was included in a SPSS base for clinical parameters and epidemiological variables.
Results: 69 patients were analyzed (47%male-53% female), with a mean age of 86 years old. 208 consecutive consultations have been attended with a mean of 3 reviews per patient. All of them had multi-pathological requirements and were polymedicated. Geriatric syndrome was detected in 80% of patients, and only 53.2% of them required treatment. 19.5% of the patients showed cognitive impairment. 15% of the patients had severe or complete dependence for activities of daily living (ADL), 12.5% had moderate dependence, and 72.5% of them had mild dependence. Through the brief Charlson Index, we have objectified high comorbidity (>3points) in 22.5% of our patients. The most frequent causes of anemia were iron deficiency (71%), vitamin B_{12} deficiency (52%), renal failure (52%) and most of them presented multifactorial causes of anemia (68%). The percentage of patients requiring transfusion support was 34.8% and erythropoiesis-stimulating agents, as subcutaneous erythropoietin, were prescribed in 33% of them (alpha: 88%, beta: 12%).

Table 1.



Summary/Conclusion: Our patient profile is a 86-year-old female, multipathological and polymelicated with multifactorial anemia, that presents mild dependency and moderate comorbidity, with no cognitive impairment. Carrying out a comprehensive geriatric assessment to these elderly patients with anemia, has allowed us to optimize their treatment, by reducing invasive tests and by avoiding refer them to other hospital services.

PB2371

EVALUATION OF FERRIC MALTOL AS ALTERNATIVE TO PARENTERAL IRON THERAPY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE (IBD) IN TERMS OF COSTS REDUCTIONS AND HEALTHCARE HUMAN RESOURCE UTILISATION

S. Lovato[1,2,*], P. Oppong[3], A. Akbar[3]

[1]Imperial College London, [2]Postgraduate, [3]Gastroenterology, London North West University Healthcare NHS Trust, London, United Kingdom

Background: In 2016 Ferric maltol (Feraccru), was approved, as alternative to parenteral iron, as second line treatment for iron deficiency anaemia (IDA) in patients with inflammatory bowel diseases (IBD) non responsive or intolerant to oral iron. Two clinical trials (AEGIS-1 & AEGIS-2), showed a statistically significant improvement in haemoglobin (Hb) with good tolerability.Both oral and parenteral iron are effective in correcting IDA, however parenteral iron is often used in IBD patients as oral iron is poorly tolerated. Parenteral iron is more expensive, and the cost of administration in a healthcare setting and nursing time required must also be considered.
Aims: We wanted to assess impact of the introduction of ferric maltol in our NHS Trust on the hospital budget and the nursing time.
Methods: We consider the following costs: 3 months of ferric maltol £168.78, iron infusion (drug plus appointment cost) £570.68. Nursing time for each infusion was estimated as 75 minutes. First we analysed how many of our patients who were prescribed ferric maltol needed to switch to parenteral iron. For these patients we calculated the cost of both therapies as £739.46.We calculated how many parenteral iron infusions were administered to IBD patients in a period of 12 months before the introduction of ferric maltol. As last we calculated the potential savings, if ferric maltol prescription was extended to any patients with IDA.
Results: In a period of 9 months we prescribed ferric maltol for 28 patients. If all the patients were treated with parenteral iron the total expense would have been £15960. As 4 (14%) of these had to stop the drug and have parenteral iron the cost have been calculated as £7005 with a saving of £8955 and 56% of cost reduction. In addition there was saving of 30 hours or 3.75 days in nursing time. If these savings were projected to a period of 12 months the calculation would be of £11940 and 5 days. In a period of 12 months IBD patients received 169 iron infusions at a total cost of £99.445. If all these patients were started on ferric maltol and only 14% of them needed parenteral iron the total cost would have been £42.220. The nursing time would decrease from 221 hours to 30 hours with a saving of 22.5 days. If we apply the same considerations to all the parenteral iron infusion, we estimated that in a 12 months period were issued around 800 parenteral iron prescriptions, the estimated saving with ferric maltol would have been £257.604 and 107.7 days.

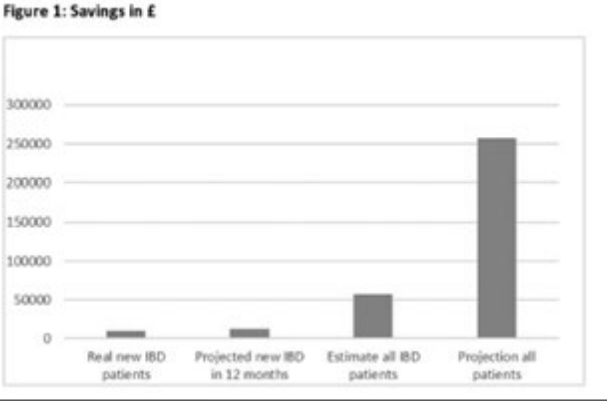


Figure 1.

Summary/Conclusion: Using Ferric maltol in our NHS Trust has been cost effective reducing costs and saving nursing time. Only new patients with IDA were prescribed ferric maltol, the patients who were already on IV iron maintenance continued with the parenteral therapy. The cost effectiveness will improve if we could switch to ferric maltol all the patients who were on parenteral iron maintenance and if ferric maltol was approved for treatment of any cause of iron deficiency. We recognise some limitation of this analysis. First the percentage of patients who had to stop the drug and needed parenteral iron could be underestimated because as patients prescribed ferric maltol towards the end of the study period had shorter follow up. Second, the number of appointments for iron infusion could have been overestimated as some of the patients could have been admitted. Last not all the patients, particularly those with active IBD could qualify for oral therapy

and some could refuse it. Further data are needed to clarify these points and better estimate the real impact of this intervention.

PB2372

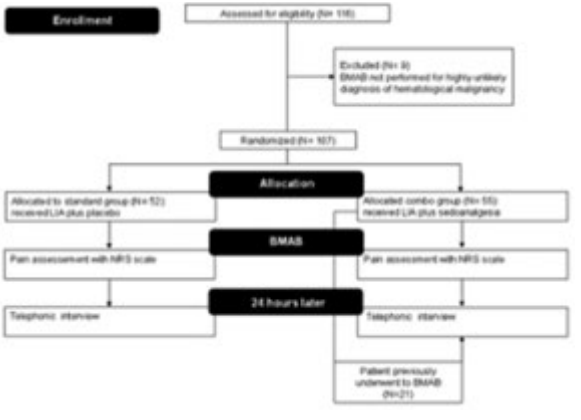
COMBINED ORAL ADMINISTRATION OF ANALGESIA AND ANXIOLYSIS FOR PAIN ASSOCIATED WITH BONE MARROW ASPIRATION AND BIOPSY

C. Cerchione*, M. Picardi, N. Pugliese, R. Della Pepa, A. Gravetti, A. Casoria, D. Nappi, G. Ciancia, F. Pane, V. Martinelli

Hematology - Department of Clinical Medicine and Surgery, University Federico II, Naples, Napoli, Italy

Background: Bone marrow aspiration and biopsy (BMAB) is a painful procedure, and the commonly adopted local infiltration anesthesia (LIA) with lidocaine is unable to relieve the pain during the most uncomfortable phases, or the anticipatory anxiety related to pain recalling thereafter. As there are no formal guidelines for adding a sedoanalgesic premedication before beginning the BMAB, many combinations have been adopted by several authors.
Aims: Our randomized and patient blinded trial aimed to evaluate, as primary end point, the efficacy and safety of opioid and benzodiazepine agent combination plus LIA in patients who underwent BMAB for hematological malignancies. Two secondary end points were: 1) to define if patients who already underwent to BMAB without LIA prefer sedoanalgesia; 2) to demonstrate if sedoanalgesia can influence the quality of the biological specimen harvested.
Methods: Patients were randomly assigned into two arms for receiving either placebo plus LIA (standard group, 48,6%) or oral fentanyl citrate 200 mcg plus oral midazolam 5 mg in addition to LIA (combo-group, 51,4%) during BMAB. Pre-procedural anxiety and procedural pain were assessed according to the Numered Rating Scale (NRS: 0-10), dividing the time of the procedure into five intervals (T0, T1, T2a, T2b, and T3) and evaluating discomfort grade during each moment of procedure in both groups. Cognitive function was measured before and 30 minutes after the procedure. Possible side effects were recorded, as well as the adequacy of tissue samples harvested. A telephone interview was performed 24 hours later. A total number of one-hundred-sixteen (n=116) were enrolled in the study. Nine (n=9) patients did not meet inclusion criteria and were excluded. Fifty-two (n=52) patients were randomized and assigned to standard group and fifty-five (n=55) to combo group (Figure 1).
Results: At T2b and T3 (corresponding to the biopsy time and time after the biopsy, respectively) there was a significantly lower (p<0.05) perception of pain in the patients who received sedoanalgesia (combo-group) compared to those who did not (standard group). Moreover, 100% of the patients in combo group who had previously undergone this procedure without premedication reported that they would prefer sedoanalgesia for the subsequent procedures, thus confirming the effectiveness of this combination also in relieving anticipatory anxiety. Finally, the histological specimen was found to be high in quality, as defined by standards.

Table 1.



Summary/Conclusion: Administration of oral analgesia and anxiolysis is a safe and feasible option to be used in outpatient setting; sedoanalgesia is very effective in reducing pain during the biopsy and it diminishes the anticipatory anxiety related to a painful procedure. Patients should have the possibility to choose between local anesthesia alone or sedoanalgesia plus local anesthesia.

PB2373

RESULTS OF A MULTICENTER UNIVERSAL NEWBORN SCREENING PROGRAM FOR SICKLE CELL DISEASE IN ITALY: A CALL TO ACTION

R. Colombatti[1,*], M. Martella[1], L. Cattaneo[2], G. Viola[1], A. Cappellari[1], C. Bergamo[1], S. Azzena[1], E. Baraldi[3], B. Dalla Barba[3], U. Trafojer[3], P. Corti[2], M. Uggeri[2], A. Biondi[2], G. Basso[1], C. Zorloni[2], P. Tagliabue[2], M. Bracchi[2], N. Masera[2], L. Sainati[1]

[1]Clinic of Pediatric Hematology Oncology, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, Italy, Padova, [2]Clinica Pediatrica, Università degli studi Milano-Bicocca-Fondazione MBBM, Monza, [3]Neonatal Care Unit, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, Italy, Padova, Italy

Background: Sickle Cell Disease (SCD) is a chronic and complex multisystem disorder requiring comprehensive care with newborn screening (NBS), health education, management of acute and chronic complications. Early diagnosis through NBS programs allows timely implementation of preventive measures such as penicillin prophylaxis, adequate health care measures (i.e spleen palpation), stroke prevention programs and hydroxyurea treatment. In spite of evidence of the above benefits of NBS for SCD and the inclusion of NBS as first step for comprehensive care in international guidelines, Italy still lacks a national SCD NBS program and policy on blood disorders. Pilot single center screening programs and a regional targeted screening have been implemented so far, but more evidence is needed to impact health policies.
Aims: To evaluate feasibility and efficacy of a multi center universal newborn screening for SCD in the frame work of a public-private partnership; to determine SCD epidemiology in the areas of Padova and Monza (North Italy) as rationale to support the need for a national universal SCD NBS.
Methods: Two public tertiary care university hospitals, Reference Centers for Pediatric Hematologic Disorders- including SCD, partnered with local charities to organize the NBS program. Guthrie cards for HPLC analysis were collected for newborns in both centers' nursery and NICU, after informed consent from the mothers. The analysis were done in the Padova lab. Confirmation test with molecular genetics was performed for HPLC positive samples. SCD patients were enrolled in comprehensive care programs; S carriers were offered genetic counseling extended to the family.

Table 1. The incidence of SCD patients, traits and other Hb abnormalities.

	Newborn	Positive test	Newborn SCD	Newborn S carriers	Other hemoglobinopathies
Padova (PD)	2821	37 (1.27%)	3 (0.10%)	28 (0.99%)	6 (0.21%)
Monza (MZ)	2618	23 (0.88%)	1 (0.038%)	9 (0.34%)	13 (0.5%)
MZ + PD	5439	60 (1.1%)	4 (0.07%)	37 (0.68%)	19 (0.34%)

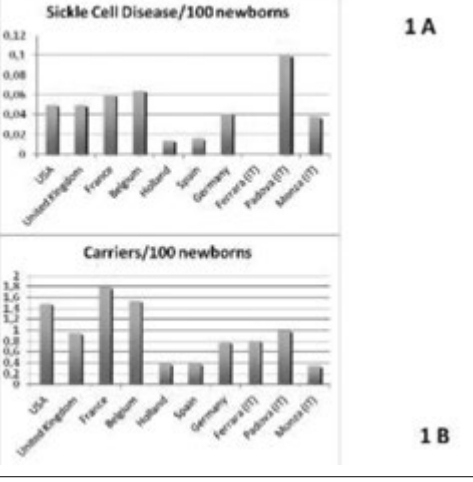


Figure 1.

Results: 5466 newborns were enrolled and for 5439 informed consents were obtained. All the samples were adequate for analysis. A similar families origin was seen in the two centers (65% Italians, 9% Mixed Couples, 26% Immigrants), but Padova had higher percentage of immigrants (>60%) coming from areas at high risk of hemoglobinopathies. The incidence of SCD patients, traits and other Hb abnormalities are showed in Table 1. Compared to other SCD NBS programs in USA and Europe, our results show similar incidence of SCD patients and carriers (Figures 1 A and B). SCD patients were all Sub-Saharian Africans, while HbS and other variants car-

riers were: 15% and 23% Caucasians (Italian and Albanians); 10% and 47% from North Africa-India-South America respectively.
Summary/Conclusion: Our results demonstrate the feasibility of a multicentric NBS program for SCD; give information on HbS epidemiology in two Northern Italian Areas and support previous European recommendation for a universal NBS program for SCD in Italy: a high incidence of patients and carriers was detected, with high percentage of carriers of non Sub-Saharian African origin, impossible to identify in a targeted NBS which is therefore not not adequate in our context.

PB2374

TIME FROM SYMPTOM ONSET TO DIAGNOSIS AND TREATMENT AMONG HEMATOLOGICAL MALIGNANCIES: DISEASE, PATIENT AND HEALTH SYSTEM RELATED INFLUENCING FACTORS

A. Dapkevičiūtė[1,2,*], L. Griškevičius[1,2], V. Šapoka[1,2], E. Martynova[3], V. Pečeliūnas[1,2]

[1]Vilnius university hospital Santaros klinikos, [2]Vilnius University, Faculty of medicine, Vilnius, Lithuania, [3]Quantitative psychology program, Arizona State University, Arizona, United States

Background: Diagnostic delay causes unfavourable outcomes among cancer patients. This subject has been widely analysed in solid tumours. However, data regarding haematological malignancies diagnostic delay is scarce worldwide and has never been analysed in Lithuania.
Aims: We aimed to evaluate diagnostic intervals, factors influencing their duration and prolonged time to diagnosis negative effect on clinical outcomes among multiple myeloma and lymphoma patients.
Methods: Patients were asked to participate in the study during their scheduled visits in outpatient clinic at a single institution if they had multiple myeloma or lymphoma diagnosis (ICD codes - C90, C81-C84). All participants signed Informed consent form. Following time intervals were evaluated: A - time from symptom onset to registration for a medical consultation, B - from registration to first medical consultation, C - from first medical consultation to diagnosis, D - from diagnosis to treatment initiation, E - from symptom onset to diagnosis, F - time from symptom onset to treatment initiation. Interval durations and majority of influencing factors were assessed based on face-to-face questionnaire. Data of disease characteristics was collected from medical records.

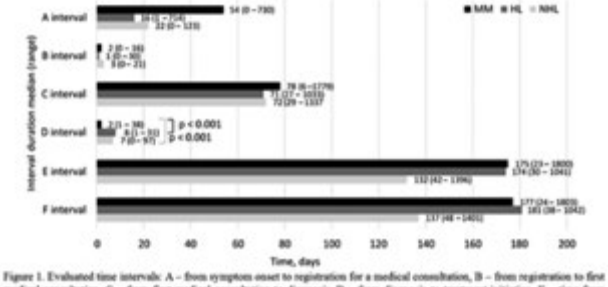

Figure 1. Evaluated time intervals: A – from symptom onset to registration for a medical consultation, B – from registration to first medical consultation, C – from first medical consultation to diagnosis, D – from diagnosis to treatment initiation, E – time from symptom onset to diagnosis, F – time from symptom onset to treatment initiation. MM – multiple myeloma, HL – Hodgkin lymphoma, NHL – non Hodgkin lymphoma.

Figure 1.

Results: 100 patients diagnosed with multiple myeloma (n=53) and lymphomas (n=47) were included. Median interval from symptom onset to registration for a medical consultation (A interval) was 30 (0-730) days, from registration to consultation (B interval) 2 (0-30) days, from first consultation to diagnosis (C interval) 73 (6-1779) days, from diagnosis to treatment (D interval) 5 (0-97) days. Overall time to diagnosis (E interval) was 151 (23-1800) days and did not differ statistically significantly for lymphoma and myeloma patients. Major factors influencing overall diagnostic E interval in multiple linear regression were living in big cities (p=0.008), anxiety and depression (p=0.002), self-medication (p=0.019), more specialists seen before diagnosis (p=0.022). Longer overall time to diagnosis resulted in higher incidence of multiple myeloma complications (p=0.024) and more advanced Durie-Salmon stage (p=0.049) when corrected for age, gender and CIRS comorbidity score. However, longer E interval was not associated with higher ISS stage for myeloma and increased Ann-Arbor stage for lymphomas.
Summary/Conclusion: The most important factors causing delay were living in big cities, anxiety and depression, self-medication, more specialists seen before diagnosis. Diagnostic delay may have negative influence on clinical outcomes for multiple myeloma patients. Median time from symptom onset to diagnosis was nearly 5 months indicating that there is space for improvement. Further studies are needed in order to prepare recommendations directed at shortening time to diagnosis and providing clinical benefits for patients with haematological malignancies.

PB2375

THE RUSSIAN NATIONAL GAUCHER REGISTRY

S. Kulikov[1,*], R. Ponomarev[2], K. Lukina[2], E. Sysoeva[2], E. Lukina[2]

[1]Department of Biostatistics, [2]Department of Orphan Diseases, National Research Center for Hematology, Moscow, Russian Federation

Background: The Department of Orphan diseases of the National Research Center for Hematology has gained a unique experience of treating patients (pts) with Gaucher disease (GD) in the last 10 years. A total of 286 Gaucher pts have been examined and are under follow-up in the Department which constitutes 94,4% of all diagnosed pts in the Russian Federation. Establishment of the national Gaucher registry is crucial for ensuring data integrity, enabling systematization and analysis of clinical data as well as continuous monitoring and long-term follow-up of the pts.
Aims: Demonstrate advantages of the centralized approach to management and monitoring of the pts with orphan diseases.
Methods: GD is an autosomal recessive lysosomal storage disease, caused by deficiency of the enzyme glucocerebrosidase (GBA), required for the degradation of glycosphingolipids. GBA deficiency results in accumulation of its immediate substrates, glucosylceramide and glucosylsphingosine, predominately in lysosomes of cells of the reticuloendothelial system. Clinical manifestations include hepatosplenomegaly, cytopenias and bone involvement. Historically managed by splenectomy, transfusions and orthopaedic surgery, the development of specific therapy in the form of intravenous enzyme replacement therapy (ERT) in the 1990s has resulted in dramatic improvements in hematologic and visceral disease and provided the possibility to prevent the development of debilitating bone complications. GD is an extremely heterogeneous condition with severe early manifestations in some patients, whereas others may exhibit a lifelong asymptomatic course. Thus, an individualized approach and a multidisciplinary team of specialists are needed to assess the severity of the disease and provide an adequate treatment and monitoring. Therefore, all adult Gaucher pts are examined and followed up in the National Research Center for Hematology. From 2007 to 2018, a total of 286 Gaucher pts have been examined and are under follow-up in the Department of Orphan diseases of the National Research Center for Hematology. 99% of these pts have been receiving pathogenetic treatment for the period of 1 – 15 yrs. The development and implementation of the national registry allowed us to create a platform for the registration of the whole population of adult Gaucher pts in the Russian Federation. The registry captures detailed laboratory, clinical and radiological data of all pts obtained both before the initiation of the treatment and on treatment, thus representing a convenient tool for comprehensive data analysis.
Results: The data accumulated in the national Gaucher registry allowed us to analyze the long-term results of splenectomy in Gaucher pts which was the primary treatment option in the pre-ERT era. It was demonstrated that splenectomy leads to a regress of cytopenia, however, at the same time it is the risk factor for severe bone involvement. The priority field of our further research is the development of optimal, scientifically and economically justified treatment regimen in Gaucher pts who achieved treatment goals.
Summary/Conclusion: Centralized examination and management of Gaucher pts in the Federal Research Center enabled us to accumulate, organize and systematize all available data on the patient population of the Russian Federation. The national registry represents a valuable tool for epidemiological research and provides a data source to carry out the analysis of both short and long-term results of the pathogenetic treatment.

PB2376

A REVIEW OF CLINICAL PRACTICE REGARDING DNACPR DECISION MAKING, DISCUSSION AND IMPLEMENTATION

A. Burge[1,*], J. de Vos[2]

[1]Acute Medicine, [2]Haematology, Royal Surrey County Hospital, Guildford, United Kingdom

Background: Cardiopulmonary resuscitation (CPR) was introduced in the 1960's as a treatment in the context of sudden cardiac arrest due to arrhythmias, most commonly due to acute Myocardial Infarction. As awareness spread and equipment improved it became more common in other situations, and it has become increasingly recognised that this is not always appropriate. In fact, it can even expose patients to invasive and intensive physical treat-

ment which may at best be briefly successful. Anticipatory decisions are a way to prevent palliative patients from being subjected to the trauma and indignity of CPR where there is no real prospect of benefit. However it is clearly a difficult and potentially distressing topic for patients, families and healthcare professionals alike. Guidance exists in the UK in the form of 'Decisions relating to cardiopulmonary resuscitation guidance 2016' which states 'Whenever possible making specific anticipatory decisions about whether or not to attempt CPR is an important part of good-quality care for any person who is approaching the end of life and/or is at risk of cardiorespiratory arrest. This is a highly important aspect of patient care, and is an area of continual improvement for in order to ensure ensuring the best care for dying patients and their families.

Aims: To analyse the DNACPR discussions taking place in the context of acute admissions to a tertiary oncology and haematology centre in order to try and improve clinical practice. Areas included were: intent of current treatment, reason for acute admission, evidence of previous resuscitation discussions in out-patient clinics or the community, the timing of DNACPR decisions in the context of the acute admission and time of death, grade of doctors carrying out discussions and the clinical context in which this was taking place.

Methods: Retrospective analysis of 41 sets of notes of deceased Haemato-Oncology and Oncology patients, identified through monthly divisional mortality and morbidity meetings.

Results: 66% of patients identified were undergoing palliative treatment at the time of admission, and the most common reasons for admission included general decline/disease progression (29%)and infection (32%). Overall 15% of patients had evidence of previous DNACPR decisions *or* end of life discussions prior to admission. 51% of patients who passed away had DNACPR decisions made within 3 days of admission and 49% of patients died within one week of admission. In 61% of patients this discussion was carried out by a junior doctor and 56% of patients were acutely or critically unwell at the time of discussion.

Summary/Conclusion: DNACPR are a key element of good and patient-centred care, allowing patients to die with dignity and have input into their end of life care. This review shows that significant changes in practice are required in order to improve the care delivered to patients with incurable malignant diagnoses. It highlights the importance of the early recognition of the palliative patient or patients in whom CPR would be unlikely to be successful. Equally important is the understanding and recognition by physicians as well as the communication to patients and relatives, that DNACPR decisions do not affect ongoing cancer treatment; ideally these discussions are carried out by a senior member of the team who knows the patient well. This review has increased DNACPR awareness, discussions and trasparency in our department. In this era of ever-developing and increasing lines of often palliative treatments these discussions and decisions are more relevant than ever.

PB2377

NEPA (NETUPITANT PLUS PALONOSETRON) FOR THE PREVENTION OF CHEMOTHERAPY INDUCED NAUSEA AND VOMITING IN PATIENTS RECEIVING STEM CELL TRANSPLANTATION

M. Corrochano[1,*], M.E. Moreno[2], I. Garcia-Cadenas[1], A. Barata[3], A. Feliu[2], A. Esquirol[1], E. Rodriguez[2], R. Martino[1], J. Sierra[1]

[1]Hematology, [2]Pharmacy, [3]Clinical psychology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Chemotherapy-induced nausea and vomiting (CINV) is a significant side effect during stem cell transplantation (SCT) despite prophylactic therapy. NEPA (Netupitant plus palonosetron) has proven to be highly effective in controlling these symptoms in patients with solid tumors; however, data are scarce in SCT recipients.

Aims: To evaluate the efficacy and safety of NEPA in two different cohorts of SCT patients.

Methods: Two cohorts of patients were analysed: those undergoing high emetogenic conditioning regimens before SCT and those receiving high doses of cyclophosphamide as graft *vs* host disease (GVHD) prophylaxis.

On the first day of chemotherapy (CT), the cohort of patients receiving high emetogenic conditioning regimens (group number 1) were prescribed an oral fixed-dose combination of NEPA (300 mg netupitant, 0.5mg palonosetron) together with 8 mg of dexamethasone (DXM) followed by daily DXM at a dose of 8 mg whilst receiving CT and 4 mg in the subsequent 48 hours. On the other hand, the cohort of patients being prescribed GVHD prophylaxis based on high dose cyclophosphamide (group number 2), were given NEPA on day +3 after infusion (first day of cyclophosphamide) and DXM was not administered before day +5.

Results: Twenty-one patients were included in the study: 13 in group number 1 and 8 in group number 2. Baseline characteristics are detailed in Table 1. In regard to patients in group number 1, during the acute phase of treatment (days in which patients receive CT), 6 (46%) out of the 13 patients achieved complete response (CR, defined as no emesis or no need for antiemetic rescue) and 4 (31%) partial response (PR, defined as presence of mild to moderate nausea but no emesis). The maximum number of emetic episodes experienced per day was of 2 in two patients. Six patients required additional treatment for breakthrough emesis and were all successfully controlled with single standard doses of olanzapine (n=2), metoclopramide (n=3) or lorazepam (n=1). Responses improved during the delayed phase (up to 72 hours after the last dose of chemotherapy) where 9 patients (69%) achieved CR and 3 patients (23%) achieved PR. In respect to patients in group number 2, during the acute phase (period of time whilst receiving cychophosphamide postSCT), 4 patients (57%) achieved CR and 5 patients (71%) PR. Four patients were successfully controlled for breakthrough emesis during this time with single standard doses of metoclopramide. Regarding the delayed phase, 5 patients achieved CR (62.5%) and 4 (50%) PR. 4 patients required single standard doses of metoclopramide (n=2) and olanzapine (n=2) for breakthrough emesis with appropriate response. Of the 21 patients evaluated, 11 (52%) had a history of significant nausea and emesis with prior chemotherapies, 7 (33, 3%) of which did not develop emesis with the NEPA regimen. Non-hematologic adverse effects attributed to the study medications were minor (hiccups n=3, somnolence n=3, hyperglycemia n=10, constipation n=3); all of which gave no further complications.

Table 1.

	Group 1/N=13 (100%)	Group 2/N=8 (100%)
Gender: Male	8 (61,5%)	5 (62,5%)

Allogenic	5 (38,4%)	8 (100%)

CyTBI: cyclophosphamide and total body irradiation; BEAM: carmustine, etoposide, cytarabine and melphalan; CBV: cyclophosphamide, carmustine and etoposide; BuCy: busulfan and cyclophosphamide; Flu-TBI: fludarabine and total body irradiation; Flu-Bu: fludarabine and busulfan; Flu-Mel: fludarabine and melphalan; TBF: thiotepa, busulfan and fludarabine.

Summary/Conclusion: NEPA-based antiemetic regimens seem to offer encouraging results in terms of prophylaxis of CINV in the SCT setting, including different procedures (autologous and allogeneic transplants) and new options such as Cy-post for GVHD prevention. Based on these promising results in terms of efficacy and safety, enrolment of new patients is currently ongoing.

PB2378

REFERRALS TO HEMATOLOGICAL CONSULTATIONS FOR EOSINOPHILIA – DIFFERENCES BETWEEN GENERAL AND UNIVERSITY HOSPITAL PATIENTS.

H. Holik[1,*], B. Coha[1], I. Vučinić Ljubičić[1], I. Radman-Livaja[2], S. Bašić-Kinda[2], P. Rončević[2], B. Miklaušić[3], I. Franić Šimić[4], I. Horvat[4], R. Zadro[4,5], I. Aurer[2,6]

[1]Department of Hematology and Oncology, General Hospital Dr. Josip Benčević, Slavonski Brod, [2]Division of Hematology, Department of Internal Medicine, University Hospital Centre Zagreb, Zagreb, [3]Department of Infectious Diseases, General Hospital Dr. Josip Benčević, Slavonski Brod, [4]Department of Laboratory Diagnostics, University Hospital Centre Zagreb, [5]Faculty of Pharmacy and

Biochemistry, [6]Medical School, University of Zagreb, Zagreb, Croatia

Background: Eosinophilia is mostly caused by allergic or infectious disorders. Only a small proportion are primary clonal needing hematological treatment. Despite that, patients with eosinophilia are frequently referred to hematologists for diagnostic evaluation.
Aims: Analyze characteristics of patients with eosinophilia referred for hematologic evaluation in different hospital types.
Methods: Patients referred to hematologic evaluation for eosinophilia in 2016 were identified by searching electronic data bases of a general and a university hospital. Individual patient data were then extracted from their respective files.
Results: We identified 75 patients fulfilling entry criteria, 20 in the general and 55 in the university hospital. Median age was 58; 36 were male and 39 female. Seven had severe eosinophilia, 30 moderate and 38 mild eosinophilia. Ten patients (13%) had myeloid neoplasms, one with PDGFRA and one with PDGFRB rearrangement; 6 had other myeloproliferative neoplasms and 2 myelodysplasia. Twenty-three patients (31%) had allergic and autoimmune disorders (e.g. asthma, rheumatoid arthritis, polyarteritis nodosa, bullosus pemphigoid, psoriasis, coeliac disease, discoid lupus erythematosus, eosinophilic fasciitis and other), 6 (8%) paraneoplastic syndrome, (metastatic lung, ovarian, gastric cancer, lymphoma), 12 (16%) parasitosis (strongyloidiasis, ascariasis, toxoplasmosis, trichinellosis, echinococcosis) 12 (16%) had drug-induced or postinfectious eosinophilia (reaction to lenalidomide, rituximab, phenoxymethylpenicillin, vancomycin which presented with drug rash with eosinophilia and systemic symptoms syndrome (DRESS)) and in 12 (16%) the cause remained unknown. Patients referred to the general and university hospital had similar demographic characteristics and severity but different causes of eosinophilia with the most pronounced differences in frequency of parasitosis (35% *vs* 9%), allergic and autoimmune disorders (20% *vs* 35%) and unknown causes (10% *vs* 18%).
Summary/Conclusion: Less than 20% of patients referred to hematologic evaluation for eosinophilia have primary hematological disorders. Most have other underlying disorders, including autoimmune diseases and cancer. However, a significant proportion, especially in patients living in less urbanized areas, have parasitic infestations which must be excluded before treatment with steroids is initiated. Finally, in a significant proportion of patients the cause remains unknown, more frequently in a university hospital setting.

PB2379

PAIN AND SERIOUS ADVERSE EVENT WITH BONE MARROW ASPIRATION AND BIOPSY: A SINGLE CENTRE EXPERIENCE FROM INDIA

C. Cherian Philip[1,*], S. Singh[1], A. Mathew[1], A. Jindal[2], N. Kakkar[3], M.J. John[1]

[1]Clinical Haematology, [2]Immunohematology and Blood Transfusion, [3]Laboratory Haematology, Christian Medical College & Hospital, Ludhiana, India

Background: The bone marrow aspiration and biopsy (BMAB) is an important and frequent investigative tool for hematological disorders. It serves an important role in establishing diagnosis and prognosis. Although thought to be safe and well tolerated; little is known about the complications and degree of pain experienced by patients undergoing BMAB.
Aims: We attempted to estimate the frequency of serious adverse events and level of pain and experienced by patients undergoing BMAB at our centre.
Methods: We conducted a prospective analysis on patients who underwent BMAB from January 2015 through December 2017 at our tertiary care centre. An informed consent was taken pre-procedure. The procedure was performed by variable operators namely; consultant, residents and physician assistants. All patients where premedicated with tramadol intravenous pre procedure and the preferred approach was from the posterior superior iliac (PSIS) approach through a left lateral approach. Post procedure each patient was asked to define the pain by the Wong-Baker grimace scale. In the day care setting; the patient was observed for upto 60 minutes prior to being sent home. A serious adverse event was considered as one requiring a prolonged observation beyond routine practice or leading to or extending of admission to manage adverse events following and related to the BMAB.
Results: A total of 665 BMAB procedures were performed in this period (Table1). The most frequent indication was for staging of lymphoma in 171(26.2%) patients. Sixteen patients (2.4%) did not report any pain. Four serious adverse events were reported, representing 0.6% of total reported procedures. The major serious adverse event was haemorrhage, which comprised 2 of the 4 serious adverse events. Both the haemorrhage event related to a posterior Ilial Artery psedoaneurysm. One was managed conservatively while the second one required surgical excision of the retroperitoneal hematoma and ligation of right internal iliac artery. Remainder events related to persistent vomiting and severe aching pain in the ipsilateral leg. There was no difference in pain levels [2 (1-10)] or significant complications when performed by variable operators, P>0.05. Patients who experienced greater pain (Pain score >3) had a longer duration and more than two attempts to complete the BMAB.

Table 1.

Table 1: Baseline features of patients undergoing BMAB

Variable	Patients (N=665) n (%) Median (IQR)/Mean ±SD
Age	50 (30-62)
Gender (male)	415(62.4)
Pain score	3 (2-4)
Duration of procedure (mins)	24.6 (± 9.8)
Number of attempts to complete the BMAB	2 (1-2)
Operator (Physician Assistant)	459 (69.0)

Summary/Conclusion: In our analysis BMAB is associated with a low level of perceived pain and complications. The procedure appears relatively safe and the level of pain and attempts do not appear related to the operator. Current strategy appears effective and the further attempts to control pain for this procedure may not be indicated.Serious adverse events following BMAB though rare, but nevertheless can have considerable impact on individual patients.There is a potential for dangerous adverse events following BMAB.

PB2380

PREVALENCE OF METABOLIC SYNDROME AND SARCOPENIA AS LONG-TERM LATE EFFECTS IN LYMPHOMA SURVIVORS

A. Daniele*, C. Minoia, G. Lerario, S. Ciavarella, I. Abbate, R. Divella, E. Savino, A. Guarini

IRCCs National Centre Institute "Giovanni Paolo II, Bari, Italy

Background: Metabolic syndrome and sarcopenia could often occur in long-term cancer survivors. The first is characterized by a set of cardiovascular risk factors defined by the Cholesterol Education Program Adult Treatment Panel III, which requires simultaneous presence of at least 3, abdominal obesity, hypertension, hyperglycemia, hypertriglyceridemia and low to high density lipoprotein cholesterol (HDL-C), sarcopenia is characterized by a progressive lean mass loss that causes asthenia and malnutrition.
Aims: The aim of this study was to evaluate the prevalence of metabolic syndrome and sarcopenia in lymphoma survivors and provide adequate nutritional support according to Mediterranean Diet.
Methods: Since November 2016 to March 2017, we enrolled 41 consecutive patients (19 women and 22 men) aged between 24 and 76 years in continuous remission of lymphoma for at least 3 years and in current follow-up at our Institutionwithin the "CCM2014 project supported by the Italian Ministry of Health. Nutritional status was assessment by anthropometry (arm, wrist, waist, thigh and calf circumference), plicometry (according to Durnin Womerslay) and body mass index, while glucose, HDL-cholesterol, triglycerides were tested by immunometric assay; For each patient, a customized food plan has been developed based the Mediterranean Diet and they were followed every four weeks.
Results: 16/41 (39.0%) of patients of both gender presented a status of obesity (mild, moderate and severe),12/41 (29,2%) were overweight, 11/41 (26,8%) were normal weight and 2/41(4.8%) were underweight; In the women the waist circumference mean was 60.4 cm (range:70-116), while for men the mean was 90.27 cm (range: 69-142). Considering the parameters that characterize the metabolic syndrome, 15/41 patients (36,5%) had at least 3 of these, significantly associated with status of obesity or overweight ($p<0.001$); Regarding the evaluation of the compartments by plicometry, a significant loss of lean mass and consequent increase in fat mass was and malnutrition observed in the obese and overweight patients respect to normal weight ($p <0.001$).
Summary/Conclusion: More than 60% of long-term lymphoma survivors have a moderate or severe weight gain and 36% have metabolic syndrome associated to sarcopenia; these preliminary data suggest that an early nutritional intervention associated with adequate physical activity could reduce the risk of onset of both complications in lymphoma survivors.

PB2381

TEACHING HAEMATOLOGY TO MEDICAL STUDENTS: WHAT DO WE TEACH AND WHAT THEY WANT TO BE TAUGHT

S. Lovato[1,2,*], B. Bhatkal[1,2], J. Arnold[1,2]

[1]Imperial College London, [2]Postgraduate, London North West University Healthcare NHS Trust, London, United Kingdom

Background: In the UK Haematology is part of medical school curriculum, yeaching is delivered through lectures but in some cases a "clinical attachment" in Haematology will be part of their clinical experience. In 2017 we piloted a project on 24 third year medical students to understand if they were able to interpret full blood count results and to recognise some haematological conditions. We found that the understanding of general haematology conditions was greater that haemato-oncology conditions. Using a "Team Based Learning" (TBL) approach, where students could discuss the cases in small groups, did improve their knowledge.
Aims: We wanted to validate the results of the pilot study extending the teaching session to more students. We also wanted to understand what they thought was the most important thing they learnt.
Methods: Four teaching session were conducted for 83 students in total. The teaching session consisted in 10 multiple choice questions on clinical cases including full blood count results. The students first completed the test individually, then they discussed the answers in small groups. At the end of the session students were asked to complete a feedback form.
Results: This study confirmed that students have better knowledge of non-malignant condition, haemato-oncology is poorly understood. The specific results for each topic are shown in Figure 1. Anaemias due to iron deficiency, thalassemia trait and B12 or folate deficiency and MDS were correctly diagnosed by more than 50% of the students, the only non-malignant condition that confused the students was reactive lymphocytosis due to viral infection. Less than half of the students could recognise malignant conditions except for AML. When the cases were discussed in small groups the percentage improved significantly, with the exception of AML, but still less than half of the students could recognise reactive lymphocytosis due to viral infection, CML, Lymphoma and Multiple Myeloma. Students were asked in the feedback form what was the most useful topic they learnt, the results are shown in Table 1. Most of the students appreciated the practical aspect of the session: interpreting blood results in a clinical scenario context; they also appreciated revising topics covered by the course attended during the previous year and they found the teaching on lymphomas and leukaemia the most useful.

Figure 1: percentage of correct answers for each topic

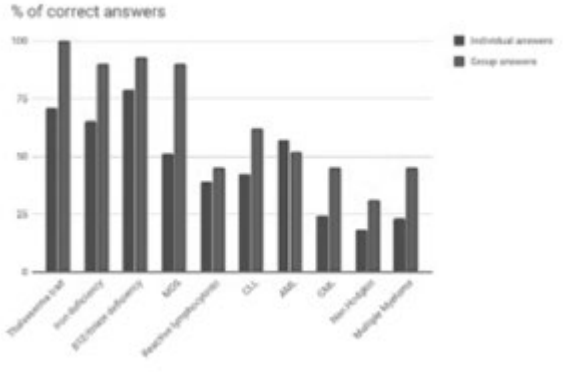

Figure 1.

Table 1.

Table 1: What was the most useful thing students learnt?

Students' answer	Number of students
Lymphomas	16
Interpreting full blood count results	13
Revision of haematology course	13
Differential of Leukaemias	8
Blood test results applied to clinical scenarios	6
CRAB criteria in Multiple Myeloma	5
Differential of Anaemias	3
Myelodysplastic Syndrome	3

Summary/Conclusion: This study confirmed what we found last year in the pilot study, medical students have a satisfactory understanding of non malignant haematology conditions but knowledge in haemato-oncology is often poor. What students appreciated is to be able to apply their theoretical knowledge to practical scenario, this reflect an understanding of the fact that interpreting blood results is an essential skill for doctors. The conditions that most of the students could not recognise where also indicated as the most appreciated topics of the teaching session. Using TBL session as revision was useful to improve students' performance. We are planning to continue this project to confirm the results.

PB2382

MYELOPROLIFERATIVE NEOPLASMS AND ACCEPTANCE AND COMMITMENT THERAPY: AN ONGOING FEASIBILITY STUDY AIMED AT SYMPTOM MITIGATION AND QUALITY OF LIFE

L. Padrnos[1,*], M. Buras[1], H. Kosiorek[1], R. Scherber[2], E. Knight[1], A. Cuc[1], C. Stonnington[1], A. Dueck[1], Y. Geda[1], R. Mesa[2]

[1]Mayo Clinic Hospital Arizona, Scottsdale, [2]UT Health San Antonio, San Antonio, United States

Background: Patients with myeloproliferative neoplasms experience significant symptom burden, including fatigue, pruritus and pain. The high symptom burden has been shown to be associated with decreased quality of life, sleep difficulties and mood disturbances. Acceptance and Commitment Therapy (ACT) is an evidence based psychological intervention targeting emotions, thoughts and behavior. ACT employs 6 core psychological processes to attain psychological flexibility: acceptance, flexible attention to the present moment, values clarification, committed action, self as context and defusion. Several Randomized Clinical Trials have reported the efficacy of ACT targeting mood, pain, and medical conditions such as Diabetes Mellitus, but it has never been investigated in patients with MPN. We launched a feasibility study to the ACT intervention among MPN patients to assess the ability to improve symptom burden, physical function and mitigate decreased QOL.
Aims: To evaluate the impact of Acceptance and Commitment Therapy in MPN patients.
Methods: 10 participant intervention includes 6 one-hour, in person therapy sessions with an ACT-certified psychologist. Assessments are based on validated questionnaires to assess MPN specific symptoms, global health, perceived stress, fatigue and degree of acceptance.
Results: We enrolled 5 MPN patients to date, the 4 patients who completed the pre and post surveys were evaluable for review. Most of the patients (N=3) were female and with an average age of 63.5 years. Two were actively working outside of the home and two were retired. One patient's MPN diagnosis came 1-3 years ago, the remaining 3 patients were diagnosed more than 5 years ago. Most of the patients endorsed constitutional symptoms (N=3), with fatigue being the most bothersome (N=3). At baseline, at least half of participants (≥2) reported feeling not able to control worrying, lack of interest or pleasure in activities, feeling depressed or hopeless, feeling bad about themselves, trouble concentrating several days a week, feeling nervous, worrying "too much", trouble relaxing, irritability, trouble falling asleep, and feeling tired several days a week. After the intervention, there was a decrease in degree of fatigue experienced at the time of documentation (median change (MC) -2.0) and over the past 24 hours (MC -1.5). In the post-intervention setting, there was a decrease in frequency of participant reported negative experiences including distress, negative emotions, difficulty with handling situations. Additionally, there was an improvement in patient reported assessment of quality of life, mental health and satisfaction with social roles and activities.
Summary/Conclusion: Patients with MPNs have a high degree of physical stress from their disease, psychological distress from the impact of their disease on their ability to function within their social network, and emotional stress of having a hematologic malignancy. ACT may be a feasible option to improve patient experience with predominantly incurable myeloproliferative neoplasm. In addition to developing disease modifying pharmaceutical interventions, the health care system must also develop innovative methods of addressing symptoms and the psychological distress of a hematologic malignancy.

PB2383

REAL-WORLD UTILIZATION OF MULTIPLE MYELOMA TREATMENTS IN THE ERA OF NOVEL THERAPIES: WHAT IS THE CURRENT STANDARD OF CARE?

D. Singer[1], E. Thiel[2], D. Irwin[2], M. Moynihan[2], C. McKay[1], E. Maiese[1,*]

[1]Janssen Scientific Affairs LLC, Horsham, PA, [2]IBM Watson Health, Ann Arbor, MI, United States

Background: Historically, few FDA approved treatments for multiple myeloma (MM) were available, with bortezomib and lenalidomide considered the standard of care. Recently, several new treatments for MM have been approved by FDA. With only a short time on the market, little is known about how the new MM treatments are being utilized in routine clinical practice and how the standard of care may be evolving.
Aims: To address this gap in understanding, this real-world study described the characteristics of patients initiating a new line of therapy (LOT) and characteristics of the new LOTs.
Methods: This retrospective study utilized data from IBM Explorys Research Database to identify MM patients with no record of stem cell transplant and ≥1 record for MM treatment between 11/2015 - 9/2017 (study period). An algorithm was used to identify new LOTs based on MM therapies (excluding corticosteroids) initiated during the study period. Descriptive analyses characterized utilization of all MM therapies and combinations.
Results: A total of 2615 patients started a new LOT during the study period. 1753 (67.0%) patients who started a new LOT were ≥65 years and 1169 (44.7%) were female. 1629 (62.3%) patients started 1st LOT, 426 (16.3%) started 2nd LOT, 235 (9.0%) started 3rd LOT, and 325 (12.4%) started 4th or more LOT. Among the new LOTs, the most common regimens were lenalidomide (n=733 (28.0%)), bortezomib (n=463 (17.7%)), bortezomib +lenalidomide (n=345 (13.2%)), daratumumab (n=219 (8.4%)), and bortezomib+cyclophosphamide (n=187 (7.2%)). Less common regimens included pomalidomide (n=75 (2.8%)) and carfilzomib (n=44 (1.7%)).
Summary/Conclusion: This real-world study suggests that the MM treatment paradigm is evolving to include newer therapies, however, bortezomib and lenalidomide remain common regimens. As disease recurrence is often more aggressive and survival shorter with each subsequent LOT, critical research is in progress to understand the real-world effectiveness of new treatments and how use in earlier LOTs *vs* later LOTs may impact effectiveness.

PB2384

PREVALENCE OF ANXIETY AND DEPRESSION AMONG CAREGIVERS OF CANCER PATIENTS IN MALAYSIA

K. Tey[1,*], R. Abdul Malik[2], M. Saad[2], G.F. Ho[2], J. Paul[2], G.G. Gan[3]

[1]Pharmacology, [2]Oncology, [3]Haematology, University Malaya Medical Centre, Kuala Lumpur, Malaysia

Background: Cancer is the third most common cause of death in Malaysia according to the National Cancer Registry in 2007. It is well documented that many cancer patients experienced significant symptoms of anxiety and depression. The shift of cancer patients' care is now mainly towards home care and outpatient treatment and hence increasingly, family members are becoming more involved in the care of these patients. Good social support from close relationship especially from spouse or family members is one of the important factors which have a protective effect on risk of anxiety and depression. Many studies had reported that caregivers also experience psychological distress. It was reported that as high as 38.1% of caregivers had anxiety and 82.2% had depression. However, there is limited information available in Malaysia which specifically report on the prevalence of psychological distress of the caregivers.
Aims: This study aims to determine the prevalence of anxiety and depression of all cancer patients and their caregivers in a teaching institution in Malaysia.
Methods: This is a cross-sectional study where family caregivers and patients who had been diagnosed with cancers within the last 12 months were recruited in University Malaya Medical Centre. Their psychological symptoms were assessed using Hospital Anxiety and Depression scale (HADS) and scores of >7 was used to demonstrate symptoms of anxiety or depression. Multi-dimensional Scale of Perceived Social Support (MSPSS) was used to identify the social support factors perceived by the patients.
Results: A total of 109 patients with underlying diagnosis of cancer and their caregivers (109) were recruited from September 2016 to December 2017. The age of patient's ranges from 18 years to 91 years (mean 52.94±SD 16.49), while the mean age of caregivers is 47.3 years (ranges 17 to 80). Majority of the patients (52%) were male, while most of the caregivers (64%) were female. Majority of patients were Chinese (56%), followed by Malay (32%) and Indian (10%). There were almost equal proportion of patients interviewed who had solid tumors and haematological malignancies. The prevalence rate of patients with symptoms of anxiety and depression was 33.9% and 39.4% respectively. The prevalence rate of caregivers with symptoms of anxiety and depression was 38.5% and 27.5% respectively. There was no significant association of anxiety and depression with the demographic factors of patients. Greater proportion of the female caregivers (45%) reported symptoms of anxiety compared to male caregivers (25.6%), P<0.05. There was significantly higher prevalence of anxiety if the caregivers are the only person providing care to patients, 51.0% *vs* 29.7%, P<0.05. There was significant correlation of anxiety and depression of patients and caregivers, P<0.05. The mean total scores of perceived social support of the patients were relatively high is 69.64; the mean score of significant others subscale was 24.27, family subscale was 25 and friends subscale was 20.39. There was no significant association of the perceived support with risk of anxiety or depression in patients.
Summary/Conclusion: This study demonstrated that family caregivers experienced high prevalence of anxiety and depression. It would appear that there was a correlation between patients and caregivers' psychological distress. Therefore, it is important to ensure adequate support be provided to caregivers.

PB2385

HEALTH-RELATED QUALITY OF LIFE IN CAREGIVER OF HEMOPHILIA PATIENTS

G. Ferrer Garrido*, J.M. Calvo Villas, N. Fernández Mosteirin, P. Delgado Beltrán

Hematología clínica, Hospital Universitario Miguel Servet, Zaragoza, Spain

Background: The care demands of children with chronic diseases can affect caregivers' health by imposing caregiving burden to them. In regard to caregiving burden of hemophilia, the levels of overload are high due to the frequent hospital dependence as well as the home management of bleeding. The development of inhibitors is related to a greater effect on the caregiver.
Aims: To analyze caregiving burden in hemophilia patients aged <25 years in a Reference Centre of Congenital Coagulopathies.
Methods: A questionnaire on health and quality of life for adults was given to both caregivers of hemophila patients <25 years of age controlled in our centre and a control group of caregivers of healthy children. The validated questionnaire used was the Short Form Health Survey (SF-36) of 36 items. This form includes 8 dimensions of health and quality of life: physical health, physical role, corporal pain, general health, vitality, social function, emotional role and mental health. The score is from 0% (worst quality) to 100% (best quality).
Results: The results of questionnaire of three groups of caregivers are shown in table and graph below: 1) Caregivers of children with severe hemophilia (SH); 2) Caregivers of children with mild hemophilia (MH); 3) Caregivers of healthy children (Control). The groups were homogeneous in their demographic characteristics. No relevant differences were observed neither the 3 main groups nor among the parents of each group.

Participating caregivers	Number both sexes	Number mothers	Number fathers	Participating children	Number
Total number	35	20	15	Total number	31
Caregivers of healthy children (control)	13	8	5	Healthy children Median 13 years (range 3-24)	17
Caregivers of hemophiliac children	22	12	10	Hemophiliac children Median 9,5 years (range 1-24)	14
Caregivers of children with MH	9	5	4	Children with MH	6
Caregivers of children with SH	13	7	6	Children with SH (on prophylaxis)	8 (2 with inhibitors presence)

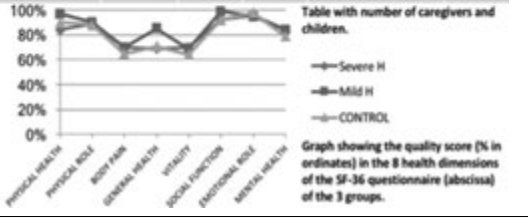

Table with number of caregivers and children.

Graph showing the quality score (% in ordinates) in the 8 health dimensions of the SF-36 questionnaire (abscissa) of the 3 groups.

Figure 1.

Summary/Conclusion: 1. We have not found significant impact on the health related quality of life of caregivers of hemophilia children in relation to controls. 2. Mild clinical hemophilia profile, capable monitoring and compliance with the prophylaxis regimens have a positive impact on both health and quality of life of caregivers. 3. It is advisable to enlarge the sample size in futher studies to validate our results.

PB2386

ACTIONS THAT MAKE ANTICOAGULANT THERAPY SAFER: 10 YEARS ON - DO WE COMPLY? EVALUATING WARFARIN USE AND APPROPRIATENESS AT A LONDON ACUTE HOSPITAL

D. Harding[1,*], J. Kotecha[1], S. Patel[2]

[1]General Internal Medicine, Chelsea and Westminster Hospital NHS Foundation Trust, [2]Pharmacy, Chelsea andWestminster Hospital NHS Foundation Trust, London, United Kingdom

Background: Anticoagulant prescribing, dispensing and administration continue to be a source of preventable near misses and harmful events in healthcare settings. Patients often have complex comorbidities and polypharmacy; which can mean they are more vulnerable to potential over- or under- anticoagulation and the resulting adverse effects. Breakdowns in communication between staff or confusion about warfarin prescribing, monitoring and administration have been cited as a major factor in adverse events.
Aims: The National Patient Safety Agency (NPSA) issued guidance aimed at preventing harm as a result of anticoagulant use in 2007 - this project assesses how well this hospital adheres to this guidance ten years on from its release.
Methods: A literature review was performed and audit standards were agreed with the multi-disciplinary team. Data was collected from electronic patient and prescribing records as well as patient notes, during April-May 2017. Approval was granted by the local governance department.
Results: 84% of patients on warfarin had a documented indication and target INR range. 39% of patients had significantly deranged INR; appropriate action was taken in 67% of cases. Prescription times varied greatly; 49% were prescribed on time (before 2pm), 17% were prescribed after 5pm. Administration times varied; 47% were administered before 4pm, 4.5% administered after 8pm.
Summary/Conclusion: There are still improvements to be made. The variation in standards are undoubtedly multifactorial; late return of INR results, heavy workload of ward teams, failure to handover to on-call teams, and the use of agency nursing staff (without e-prescription access) are some of the contributory factors postulated at this hospital. A plan is in place to change practice and improve compliance with NPSA. The audit highlighted the requirement to maintain training for all medical staff, especially as the introduction of direct oral anticoagulants means junior staff are perhaps less familiar with warfarin use nowadays.

PB2387

STRONG ASSOCIATION BETWEEN HERPES SIMPLEX VIRUS AND CHEMOTHERAPY-INDUCED ORAL MUCOSITIS IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES UNDERGOING INTENSIVE CHEMOTHERAPY OR STEM CELL TRANSPLANTATION

J. Hong[1,*], H.-K. Park[2], H. Park[3], D.-Y. Shin[1], Y. Koh[1], S.-S. Yoon[1], J.-Y. Choi[4], Y. Choi[5], I. Kim[1]

[1]Department of Internal Medicine, Seoul National University Hospital, [2]Department of Oral Medicine and Oral Diagnosis, Seoul National University Dental Hospital, Seoul, [3]Department of Internal Medicine, Inha University Hospital, Incheon, [4]Department of Preventive Medicine, Seoul National University College of Medicine, [5]Department of Immunology and Molecular Microbiology, School of Dentistry and Dental Research Institute, Seoul National University, Seoul, Korea, Republic Of

Background: A link between oral cavity infections and chemotherapy-induced oral mucositis (CIOM) in patients with hematological malignancies (HMs) undergoing intensive chemotherapy (IC) or hematopoietic stem cell transplantation (HSCT) has been suggested. However, conclusive data are lacking, and there are no current guidelines for the prophylactic use of antimicrobials to prevent CIOM in these populations.
Aims: The aim of the current study was to prospectively determine the prevalence of HSV reactivation and colonization with *Candida* as well as the relationship between such oral microbial factors and CIOM development in patients with HM undergoing IC or HSCT.
Methods: Patients aged ≥19 years with HM undergoing IC or HSCT were enrolled. Each patient was evaluated for HSV and *Candida* in the oral cavity along with CIOM at baseline as well as the second, third, and fourth weeks. To evaluate the reactivation of HSV-1 and -2 in oral keratinocytes, a sample was obtained by placing a sterilized Transfer Membrane on the buccal mucosa. If CIOM developed, the sampling site included the CIOM lesions. DNA was isolated from the sampled membrane and reactivation of HSV-1 and -2 was determined by PCR using the HSV 1/2 PCR kit. At every evaluation (baseline, week 2, week 3, and week 4), CIOM presence was estimated and graded according to the WHO oral toxicity scale and the NCI-CTCAE), version 3.0. For the semiquantitative evaluation of the severity of CIOM, the reticulation, erythema, and ulceration (REU) scoring method for oral lichen planus or oral lichenoid lesions was applied.
Results: Seventy presentations among 56 patients were analyzed. CIOM was observed in 23 presentations (32.9%), with a higher incidence associated with HSCT (17 of 35 presentations, 48.6%) than with IC (6 of 35 presentations, 8.6%). Reactivation of HSV-1 was significantly associated with an increased incidence of CIOM and a higher 'reticulation, erythema, and ulceration' score after adjusting for age, sex, type of disease, and treatment stage. A higher HSV-1 viral load was associated with increased and more severe incidents of CIOM. The presence of *Candida* was not associated with CIOM.
Summary/Conclusion: HSV reactivation in the oral cavity is highly associated with CIOM in patients with HM undergoing high-dose chemotherapy, independent of age, sex, treatment stage, and type of disease. A prospective trial to evaluate the effect of prophylactic acyclovir on CIOM prevention in HM patients receiving induction chemotherapy or autologous HSCT is therefore warranted.

PB2388

QUALITY OF LIFE OF PATIENTS WITH TYPE 1 GAUCHER DISEASE AFTER LONG-TERM ENZYME REPLACEMENT THERAPY

H. Li*, Z. Long, Y. Du, M. Chen, B. Han

Hematology, Peking Union Medical College Hospital,China, Beijing, China

Background: Chronic condition and weakening clinical manifestations of type 1 Gaucher disease (GD1) can significantly affect patients' quality of life (QOL). Given the extraordinary cost and degree of uncertainty in predicting the course of condition, understanding the potential benefits of ERT pertaining to improvements in psychosocial parameters and observable symptoms is important.
Aims: This study investigates survival status and QOL in GD1 patients who underwent long-term imiglucerase enzyme replacement therapy (ERT) and identifies possible relevant factors affecting QOL.
Methods: Factors affecting QOL were analyzed based on clinical data, survey of living conditions, and SF-36 questionnaires of GD1 patients receiving ERT (20–40 U/kg intravenously, twice a week).
Results: Median age of onset, start of ERT, and current median age of the 22 GD1 patients (13 men, 9 women) were 6 (1–38), 26 (6–41), and 40.5 (24–52) years, respectively. Of these, 68.2% lived in developing cities, 86.4% did not receive college education, and 77.3% were with annual income <$4500. Median ERT duration was 15.75 (7–22) years. All dimensions but mental health (MH) of QOL in GD1 patients were significantly poor ($P<0.05$) compared with that of normal Chinese population based on SF-36 scores. History of splenectomy before treatment was an adverse factor affecting patients' physical health ($P<0.05$) but not mental health ($P>0.05$). ERT at early ages was beneficial in increasing patients' physical and mental health ($P<0.05$). Presence of splenomegaly and bone involvement despite ERT had no effect ($P>0.05$).
Summary/Conclusion: Compared with normal Chinese population, GD1 patients were associated with reduced QOL, which is consistent with their current living condition, poor education, and income status. History of splenectomy and age at the beginning of ERT are key factors affecting QOL.

PB2389

THE CHANGE OF QUALITY OF LIFE IN 52 NON-SEVERE APLASTIC ANEMIA PATIENTS AFTER CYCLOSPORINE A THERAPY

F. Chen[1,*], Z. Guo[1], L. Zhang[2], F. Ye[2], H. Li[1], Z. Long[1], C. Yang[1], M. Chen[1], B. Han[1]

[1]Hematology, Peking Union Medical College Hospital, [2]Hematology, Chuiyangliu Hospital affiliated to Tsinghua University, Beijing, China

Background: Aplastic anemia is an immune-mediated bone marrow failure syndrome that impairs the quality of patients' life greatly and immunosuppressive therapy is one of the effective treatment. Few studies have been conducted on the quality of life of AA patients.
Aims: To explore the change of quality of life (QoL) in non-severe aplastic anemia (nSAA) patients before and after 2 years of cyclosporine A therapy, and the possible factors which may affect the QoL.
Methods: Patients with *de novo* non-severe AA from Jan,2014 to Jan, 2016 who had been treated with only cyclosporine A (CsA) for at least 2 years in the out clinic of Peking Union Medical College Hospital were asked to fill-

in the SF36 form before and after CsA treatment. Data from nSAA were compared with those of normal controls and patients' information like age, sex, education, annual income, insurance type, compliance were collected, disease severity and treatment effect were also evaluated.
Results: 52 patients were included in our study with 27 51.9% males and 25 48.1% females. The medium age were 48-year-old 21 ~85 year-old . After two years of treatment, 15 28.8% patients achieved CR 25 48.1% achieve PR and 12 23.1% patients had no effects (NR) The overall response ORR were 76.9% Before therapy, the scores of SF36 in nSAA patients were significantly lower than that of normal controls either in physical or mental component summaries P 0.05 . After 2 years of therapy, however, nSAA patients had significant improvement of mental component summaries and recovered to normal with even higher score in VT and MH compared with normal controls, although they still had lower scores in physical component summaries compared with normal ones. No associations were found between QoL and age, sex, education level, family income, type of payment, adherence of patients, or severity of disease onset. Patients with CR and PR had shown significant improvement in QoL.
Summary/Conclusion: Patients wih nCAA had impaired QoL compared with normal. Treatment of CsA can improved the QoL, especially in mental component summaries. Patients can benefit from the treatment regardless of their social statues or severity of disease and patients need to achieve at least PR to see significant improvement.

PHARMACOECONOMIC EVALUATION OF MANAGEMENT OF DASATINIB AND IMATINIB THERAPY SIDE EFFECTS IN CHRONIC MYELOID LEUKEMIA. MULTICENTRIC RETROSPECTIVE STUDY

G. Giordano[1,*], A. Parente[2], D. Berardi[3], D. Castaldi[2], M.A. Cinotti[2], F. Vedruccio[2], V. Susca[4], L. Petrella[4], G. Berardi[5], M. Magri[6], G. Niro[6], R. Gigli[6]

[1]Medicine, Regional Hospital "A. Cardarelli", [2]Medicine, General Medicine, Campobasso, [3]Medicine, University La Sapienza, Rome, [4]Medicine, University Of Molise, [5]Family Medicine, General Medicine, [6]Laboratory Medicine, Regional Hospital "A. Cardarelli", Campobasso, Italy

Background: About10% of patients with chronic myeloid leukemia(CML) treated with thyrosine kinase inhibitor(TKI) show side effects.
Aims: Aim of this study is to evaluate the side effects management expense in patients receiving imatinib or dasatinib.
Methods: This study is a retrospective multicentric study. 13patients, M/F:8/5,median age75(R60-78) received imatinib 400mg/day and 15patients, M/F:9/6,median age68(R50-72) received dasatinib100mg/day. During an observation period of 7years 3imatinib patients showed 1acute heart failure and hepatotoxicityG4,1chronic diarrheaG3, 1acute recurrent abdominal painG4 and 3dasatinib patient showed 1osteomuscular painG4, 1gastrointestinal bleedingG4, 1pleural effusion. For each patient, the overall cost of side effects management during the entire follow-up period was calculated. This cost was then divided by the days of hospital admission, in order to give an average daily patient treatment cost. Then in each group the median of average daily costs was performed. Cost for each diagnostic and therapeutic intervention was considered in conformity of Italian National Health Service.
Results: In imatinib group the median days of hospitalization were30(R7-60), with a median daily expense of366€(R330-461),a median complication management cost of€10980and a median hospitalization cost for each patient of€22500. In dasatinib group the median days of hospitalization were15(R3-30), with a median daily expense of275€(R195-370),a median complication management cost of€4125and a median hospitalization cost for each patient of€11250. For each patient the median saving in dasatinib side effect management respect to imatinib group is €11250for hospitalization and €6855for complication management. In dasatinib group the saving is about €90/day. All imatinib patient with side effects changed therapy with a IInd generation TKI with an increase in follow-up test expense of about€13/day for the first 6months.
Summary/Conclusion: Management of side effects of dasatinib seems to be cheaper than imatinib. These data need confirmation on a larger cohort of patients.

PB2391

SINGLE WEIGHT-BASED DOSE OF RASBURICASE FOLLOWED BY ALLOPURINOL FOR SPONTANEOUS TUMOR LYSIS SYNDROME IN HEMATOLOGICAL MALIGNANCIES – A SUCCESSFUL AND COST SAVING COMBINATION

F. Mousinho[1,*], T. Mendes[1], P. Sousa e Santos[1], E. Viegas[2], B. Madureira[3], F. Falcão[2], F. Lima[1]

[1]Clinical Hematology, [2]Pharmacy Department; Faculty of Pharmacy - Universidade de Lisboa, [3]Pharmacy Department, Hospital de São Francisco Xavier, Centro Hospitalar de Lisboa Ocidental, Lisboa, Portugal

Background: Allopurinol, an inhibitor of xanthine oxidase, has long been considered the standard agent for the management of hyperuricemia in patients with preexisting hyperuricemia from spontaneous tumor lysis syndrome (TLS), or patients at high risk for developing TLS during chemotherapy (CT). Rasburicase is a recombinant urate oxidase enzyme which represent an effective alternative to allopurinol in rapidly reducing uric acid (UA) levels, improving patients electrolyte status, and reversing renal impairment, and the recommended dose is 0.2 mg/kg/day administered intravenously for up to five days, with a very high cost.
Aims: To evaluate and characterize a single weight-based dose of rasburicase followed by oral allopurinol for treatment of preexisting hyperuricemia related with TLS and in patients at high-risk for TLS, as well as to determine the effect on serum creatinine (Cr).
Methods: Retrospective medical record review, between February 2012 to August 2017, from patients with *de novo* or relapse/progressive hematological malignancies who received a single weight-based dose of rasburicase (0.2mg/kg, intravenously). Subsequent control of UA and Cr were recorded at baseline and monitored daily after initial rasburicase administration.
Results: A total of 32 administrations in 30 adult patients with *de novo* disease (19) and with relapse/progressive disease (13), and rasburicase was started the day before of CT protocol. Two patients received 2 administrations, but at different phases of the disease. At the time of administration 96.9% of the cases had hyperuricemia (>6.0 mg/dL), and 3.1% had a high-risk of TLS. The median baseline UA and Cr levels were 11.0 mg/dL (3.6-22.3) and 1.57 mg/dL (0.65-5.67), respectively. All patients responded to rasburicase presenting undetectable UA levels (<0.2-0.5 mg/dL) 24 hours after rasburicase administration, and detectable UA levels from the 5th day and at that time successfully started allopurinol 300mg daily. The 7th day median of UA and Cr levels in the available patients was 3.65 mg/dL (0.7-9.7) and 1.15 mg/dL (0.41-3.52), respectively. No patient needed additional dose of rasburicase, as no one required renal replacement therapy TLS related, during CT. The use of rasburicase in single weight-based dose led to a saving of € 72891,88 compared to 5 days of administration.
Summary/Conclusion: According to our results, the use of a single weight-based dose of rasburicase has demonstrated to be well tolerated, and seems to be an effective and inexpensive therapeutic strategy in managing hyperuricemia secondary to TLS, which should be considered in an era of high health costs due to innovatory therapies directed at molecular targets.

PB2392

A 4-YEAR EXPERIENCE IN PALLIATIVE CARE OF THE ONCO-HEMATOLOGY PATIENT

M. Couto[1,*], I. Oliveira[1], N. Domingues[1], M. Mariz[1], J. Ferraz-Gonçalves[2]

[1]Onco-Hematology, [2]Palliative Care, Instituto Português de Oncologia do Porto, F.G., E.P.E., Porto, Portugal

Background: Most Palliative Care (PC) patients have oncologic disease, being liquid tumors a part of it (around 7%). According to the literature, the latter should be individualized from solid tumors: they usually have more advanced stages of disease at diagnosis, more symptomatology expressed along their course and there is a shorter interval between the last treatment and the referral date or even death. There are few PC units in Europe with significant number of Onco-hematology (OH) patients admitted and characterized.
Aims: Review of all OH patients referred to the PC Service of one oncologic institution along four years, to understand their profile, the invasive medical decisions prescribed in their last month of life and how PC referral and care could be improved.
Methods: Clinical records of all OH patients referred to PC between 2014 and 2017 were reviewed and characterized (demography and disease, treatments, relevant medical decisions taken in the last month of life by PC and survival).
Results: A sample of 179 patients was reviewed and characterized: 94 males (52.5%), median age of 71 years [19-99]; 48.6% had Non-Hodgkin Lymphoma, 26.3% had Multiple Myeloma, 10.6% had Acute leukemia, 14.5% had other OH diseases. For those who were treated for their OH disease (n=158, median number of 2 lines [1-8]), 96.2% underwent chemotherapy, 28.5% radiotherapy and 21.5% underwent hematopoietic stem cell transplant. The referral was heterogeneous among physicians (27.4% from one physician). Most patients were observed first inpatient (55.3%), 17.9% in PC outpatient consult, 1.7% refused PC, 1.1% were transferred to another unit, one had home care and 23.5% died before being observed. At the end of this study, 98.3% died (89.2% in the hospital, 10.8% outside the hospi-

tal). The median time between the end of treatment and referral do PC was 45 days and between referral and death was 17 days. Medical prescription of PC patients in the last month of life was reviewed in the 176 patients who died: 39 patients were blood transfused (22 erythrocyte units and 17 platelets concentrates), 7 were prescribed with antibiotics and 3 with antifungal agents, 3 did a Computerized Tomography, 2 went through thoracentesis, 2 did PC radiotherapy, 2 were intervened surgically in the operation room; some procedures were done only once in the population studied, as echography, paracentesis, central venous catheterization, cystostomy and catheter positioning, hemodialysis, parenteral nutrition, nasogastric tube placed, Percutaneous Endoscopic Gastrostomy placement.
Summary/Conclusion: OH patients should be referred earlier to PC in order to better benefit from this planned and specialized care, preferentially followed in the out-patient consult. This decision requires a more integrative work between PC and OH physicians since diagnosis. In the last month of life a variety of invasive procedures were done, which should be minimized (for the lack of benefit and negative impact in patient's quality of life).

PB2393

TREATMENT PATTERN AND UNMET NEED IN ADULTS WITH PHILADELPHIA POSITIVE (PH+) RELAPSED OR REFRACTORY (R/R) B-CELL PRECURSOR (BCP) ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) IN EU-5 COUNTRIES

X. Zhang[1,*], L. Zhang[2], M. Gijsen[2], Z. Cong[1]

[1]Global Health Economics, Amgen Inc., Thousand Oaks, United States, [2]PRMA Consulting, Fleet, United Kingdom

Background: Ph+ R/R BCP ALL is a rare disease with poor prognosis. Tyrosine kinase inhibitors (TKIs) are usually recommended for these patients but exact treatment patterns are unclear.
Aims: This study was aimed to understand the current treatment pattern and unmet need in adults with Ph+ R/R BCP ALL in EU-5 countries.
Methods: A Delphi-based methodology was employed: a survey sent to clinicians and a country-specific panel were used to discuss the survey results to generate point estimates. Physicians must be board certified with at least 5 years' experience in R/R ALL. The percentage of using each treatment was estimated for patients who were relapsed/refractory to at least one 2nd-generation TKI or were intolerant to 2nd-generation TKIs and intolerant/refractory to imatinib. Limitations of the current treatments for Ph+ R/R ALL were examined.
Results: Four physicians from the UK, 4 from Germany, and 3 from each of the remaining 3 countries were enrolled with a median of 10 years' experience in R/R ALL. Regimens are widely distributed in each country and across the countries (Table). TKI (mainly ponatinib) combined with chemotherapy is the most commonly used regimen. Most physicians agree or strongly agree with these limitations of the current treatments: The risk of developing resistance to TKIs is very high; Survival is short, particularly once the disease becomes resistant to TKIs; Chemotherapy alone does not significantly extend overall survival; Patients may experience different adverse events (AEs) with each TKI.

Table 1.

Regimen	Proportion of Patients (%)				
	France	Germany	Italy	Spain	UK
TKI only		15	86	17	10
TKI + Clofarabine based chemo				1	15
TKI + FLAG-IDA based chemo			2	10	50
TKI + Hyper-CVAD	20		7	10	
TKI + Other chemo (e.g. vincristine + steroids)	67	35		17	25
TKI + Blinatumomab	7	7			
Blinatumomab		29		22	
Inotuzumab	6	14		5	
Chemo only			5		
Best supportive care only				18	
TKI					
Ponatinib	60	71	100	90	100
Dasatinib	7	15		10	
Nilotinib	33	14.5			

Summary/Conclusion: TKI plus chemotherapy is the most commonly used regimen for adults with Ph+ R/R BCP ALL in the EU-5 countries. There remains significant unmet need due to limited survival, resistance to TKIs and AEs associated with the current treatments.

PB2394

QUALITATIVE STUDY INVESTIGATING THE PERCEPTIONS OF MYELOPROLIFERATIVE NEOPLASM PATIENTS PARTICIPATING IN AN ONLINE YOGA INTERVENTION

J. Huberty[1,*], R. Eckert[2], L. Larkey[3], K. Gowin[4], J. Mitchell[5], R. Mesa[2]

[1]School of Nutrition and Health Promotion, Arizona State university, Phoenix, [2]Mays Cancer Center, University of Texas San Antonio, San Antonio, [3]College of Nursing and Health Innovation, Arizona State university, [4]Division of Hematology and Oncology, Mayo Clinic, Phoenix, [5]Jules Mitchell Yoga, Hermosa Beach, United States

Background: Myeloproliferative neoplasms (MPNs) are rare hematological malignancies with a significant symptom burden (e.g., fatigue, sleep disturbances, depressive symptoms, anxiety, etc.) that is often left unresolved despite the recent advances in pharmacologic therapy. Yoga is a non-pharmacologic strategy that has been shown to improve symptom burden in other cancers, with preliminary evidence that online yoga may be effective for improving fatigue, sleep disturbance, anxiety, depression, and total symptom burden in MPN patients. Online yoga helps to address many of the commonly reported barriers of cancer patients to in-person interventions and may make yoga more accessible to MPN patients due to the rarity of the disease and limited in-person opportunities for MPN patients. An exploration of MPN patient perceptions of participation in online yoga is needed to tailor interventions to patient needs and inform future studies.
Aims: The purpose of this study was to explore the perceptions of MPN patients participating in a 12-week online yoga intervention.
Methods: This paper represents the combined qualitative interview data gathered from two studies. Participants were asked to complete 60 min/week of online, home-based yoga (via Udaya.com) for 12 weeks. Participants were also asked to participate in a 15-20 min phone interview at post-intervention. The interview consisted of 10 open-ended questions aimed at identifying patient perceptions, attitudes, and feelings towards the yoga intervention. The qualitative data was coded in NVivo 11 for content analysis.
Results: The total sample included 39 MPN patients, of which 87% (n=34/39) were female and the mean age was 60.3+/-7.3 years. Online yoga was well-accepted and liked among MPN patients. MPN patients reported physical and mental health benefits, including improved physical activity levels (n=27/39), reduced fatigue (n=20/39), improved sleep (n=16/39), and reduced stress (n=14/39). Participants liked the convenience and flexibility of being able to do yoga at home (n=21/39). MPN patients also cited some negative aspects of the yoga intervention, including the perceived difficulty of the yoga classes (n=9/39), the lack of feedback and accountability associated with home-based yoga (n=16/39), and some minor technical issues with the streaming of online yoga videos (n=11/39). The majority of MPN patients (n=24/39) had some intention to continue participating in yoga of some form (*i.e.*, online or in-person) and nearly all (n=35/39) would recommend yoga for other MPN patients.
Summary/Conclusion: Online yoga provides a feasible and attractive format through which to deliver a non-pharmacologic intervention for symptom management among MPN patients. Although the overall yoga intervention was perceived positively by MPN patient participants, opportunities for improvements in the delivery were identified. Randomized controlled trials are needed to confirm the effects of online yoga on MPN patient symptom burden. The qualitative findings presented here may help to inform the development and design of future trials.

PB2395

PEDIATRIC REFERENCE RANGES FOR A NOVEL SLIDE-BASED INTEGRATED HEMATOLOGY ANALYZER

J. Tabor*, D. Bracco, T. Allen, D. Zahniser

Roche Diagnostics, Westborough, United States

Background: The **cobas m** 511 system is a novel slide-based automated hematology analyzer that performs a CBC, WBC differential, reticulocyte count, and nucleated RBC count using automated digital microscopy.
Aims: To determine pediatric reference ranges for the 26 parameters measured by the system in a single-center study.
Methods: Residual EDTA whole blood samples were obtained from 245 healthy subjects covering four age ranges (6–≤24 months, 2–≤6 years, 6–≤12 years, and, separately for males and females, 12–≤18 years). A hematologist reviewed the subjects' medical records to rule out the presence of pathologies or therapies known to affect blood cell counts. Samples were analyzed on the **cobas m** 511 system and reference ranges were calculated as the central 95% of values obtained for each parameter according to CLSI guideline EP28-A3c.
Results: Reference ranges for each pediatric cohort for the 26 blood count parameters measured by the system are presented in **Table 1**.
Summary/Conclusion: The observed reference range for the 26 parameters analyzed on the **cobas m** 511 Hematology Analyzer, and the age and sex differences, are consistent with reference ranges determined for other automated hematology analyzers.

Table 1. Pediatric reference ranges.

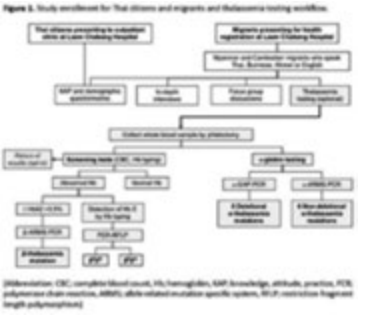
KNOWLEDGE, CULTURAL, AND STRUCTURAL BARRIERS TO THALASSEMIA SCREENING IN MIGRANT POPULATIONS IN THAILAND

J. Xu[1,*], W. Tanongsaksakul[2], T. Suksangpleng[3], S. Ekwattanakit[3], S. Riolueang[3], B. Kaiser[4], N. Thielman[1,4], M. Telen[1], V. Viprakasit[3,5]

[1]Department of Medicine, Duke University, Durham, United States, [2]Department of Paediatrics, Laem Chabang Hospital, Laem Chabang, [3]Siriraj-Thalassaemia Center, Mahidol University, Bangkok, Thailand, [4]Duke Global Health Institute, Duke University, Durham, United States, [5]Department of Paediatrics, Mahidol University, Bangkok, Thailand

Background: Thalassemia is an inherited disorder characterized by reduced α and/or β globin chains, leading to severe anemia, ineffective erythropoiesis, and other complications. Although originally prevalent in the malaria belt region, thalassemia has become a global problem due to population migration, including in Europe and North America. Thailand has one of the highest burdens of thalassemia in the world, and in response, has developed a national thalassemia prevention and control program. Using public education, genetic counseling, and prenatal screening and diagnosis, the program has achieved moderate success in lowering the incidence of new severe thalassemia cases. However, it excludes nearly 4 million largely low-skilled migrant workers from neighboring Myanmar, Cambodia, and Laos, where thalassemia is also prevalent. Thus, increasing migration may worsen the burden of severe thalassemia in Thailand, as well as in other regions of the world. It is of global interest, therefore, to identify strategies for thalassemia prevention and control in migrants. Nevertheless, few studies have explored barriers to thalassemia screening among Southeast Asian migrants. Both quantitative and qualitative methods are needed to investigate how migrants' knowledge, attitudes, beliefs, and behaviors may affect the success of interventions targeted to this population. We have designed and are currently conducting a mixed-methods study of barriers to thalassemia screening in Myanmar and Cambodian migrant workers in the industrial region of Laem Chabang, Chonburi, Thailand.
Aims: To compare levels of awareness and knowledge of thalassemia in migrants and Thai citizens; to characterize migrant attitudes and beliefs surrounding thalassemia screening; and to determine the feasibility of large-scale thalassemia screening in migrant communities in Thailand.
Methods: Written informed consent is being obtained from 200 Myanmar or Cambodian migrants and 200 Thai citizens (age 18-49 years) residing in Chonburi. Subjects are sampled for demographic and KAP (knowledge, attitudes, and practices) surveys on thalassemia. Myanmar or Cambodian subjects fluent in Thai, Burmese, or Khmer, presenting for routine health registration, and Thai subjects presenting for outpatient visits are included. Pregnant women and their partners are excluded. Descriptive statistics, tabulations and Chi-Square analysis will be used to compare socio-demographic variables and levels of thalassemia awareness between migrant and Thai subjects. Thai-speaking migrants will also be sampled purposively for in-depth interviews (IDI) and focus group discussions (FGD) to explore beliefs underlying migrant attitudes, as well as sensitive topics such as prenatal screening, termination of pregnancy, stigma, and access to healthcare. FGD will be stratified by gender and country of origin. Qualitative data will be coded and inductive thematic analysis used to identify relevant recurrent themes. Finally, as a feasibility study, migrants will be offered comprehensive thalassemia testing (Figure 1), providing preliminary estimates of thalassemia prevalence and screening uptake among migrants.
Results: This mixed-methods study will evaluate knowledge of thalassemia and identify key barriers to implementing thalassemia screening in migrant populations.

Table 1.



Summary/Conclusion: Novel insights gained may inform future thalassemia education and screening efforts for migrants in Thailand and have broader implications for the screening and care of migrants with thalassemia. This is an emerging issue that requires a global solution.

PB2397

INFLUENCE OF ABO BLOOD GROUP ON VON WILLEBRAND FACTOR TESTS IN HEALTHY SAUDI BLOOD DONORS

A. Alharbi[1], S. Bakr[2,3,*], A.-K. Al-Momen[4], K. Al-Saleh[5], R. Nasr[6], H. Kohgear[6], T. Owaidah[6]

[1]Department of Pathology and Laboratory Medicine, King Faisal Specialist Hospital & RC, [2]College of Medicine, Princess Nourah bint Abdulrahman University, Riyadh, Saudi Arabia, [3]College of Medicine, Fayoum University, Fayoum, Egypt, [4]College of Medicine, King Saud University[4], [5]College of Medicine, King Saud University, [6]Department of Pathology and Laboratory Medicine, King Faisal Specialist Hospital & RC, Riyadh, Saudi Arabia

Background: Von Willebrand disease is a common bleeding disorder. The wide variation in VWF levels between and within normal individuals highlights the clinical challenge of defining its cutoff value. Although studies on the influence of ethnicity on ABO phenotypes and the levels of VWF have been carried out on different ethnicities, there is a lack of such data among Arab population.
Aims: We aimed to evaluate the correlation of ABO phenotypes with all the parameters of the minimal test panel of VWF including (VWF:Ag, VWF:RCo, VWF:CB and FVIII:C), tested in a normal Arab population, and to estimate ABO specific normal reference range.
Methods: Blood samples were collected from 87 healthy donors in Riyadh to determine levels of factor VIII and VWF panel between the various ABO phenotypes.
Results: The highest mean values of factor VIII:C (128 U/dL), VWF:Ag (125 U/dL), VWF:RCo (109 U/dL), and VWF:CB (91 U/dL) were observed with type AB and the lowest mean values of factor VIII:C (81 U/dL), VWF:Ag (85 U/dL), VWF:RCo (73 U/dL), and VWF:CB (70 U/dL) corresponded to type O.
Summary/Conclusion: ABO phenotypes significantly influence plasma levels of VWF parameters in Arab nations as seen with other ethnicity. Hence, ABO specific normal ranges of the minimal test panel of VWFand factor VIII:C are essential for the appropriate prediction of mild VWD. Further study including a larger categorized sample size is required to generalize the test panel on the Arab population.

PB2398

OBSERVATIONAL STUDY TO DEVELOP A TREATMENT–RELATED PATIENT-REPORTED OUTCOME MEASURE IN GAUCHER DISEASE (QOL-ONE PRO1G)

Città della Salute e della Scienza di Torino - Ospedale Regina Margherita, Turin, [12]U.O.C. Malattie Metaboliche e Genetiche; D.A.I. Pediatria, Ospedale Pediatrico Giovanni XXIII, Bari, [13]Center for Bleeding Disorders and Coagulation, Careggi University Hospital, Florence, Italy, [14]School of Life and Medical Sciences, University of Hertfordshire, Hatfield, United Kingdom, [15]National Medical Surgical Centre and Multinational Centre for Quality of Life Research, University Clinic, St.Petersburg State Universit, St. Petersburg, Rwanda, [16]Grande Ospedale Metropolitano Bianchi Melacrino Morelli, REGGIO CALABRIA, Italy

Background: Gaucher disease (GD) is a rare autosomal recessive lysosomal disorder that results in the accumulation of sphingolipids in the body's tissues due to glucocerebrosidase enzyme deficiency. GD manifests with vast clinical heterogeneity. Type 1 is the most common form (non neurophatic) with a wide spectrum of signs and symptoms at presentation: some are very mild, others may present variably enlarged liver and spleen which may cause abdominal discomfort. Trombocytopenia and anemia are very common at diagnosis and may be associated with signs and symptoms (bruising and bleeding, tiredness, vertigo, dyspnea and reduced physical functioning). Over 20% of patients experience bone pain or fractures. Treatment is indicated for patients with type 1 GD who exhibit clinical signs and symptoms of the disease, including anemia, thrombocytopenia, skeletal disease, or visceromegaly. Assessment of the impact of illness on physical, mental, and social functioning is an essential element of clinical diagnosis, a major determinant of therapeutic choices and efficacy, and a guide to longer-term care. Furthermore, it is known that patient reported outcomes (PROs) may influence various changes in intervention. There are many generic instruments available to measure the impact of disease on patient's health-related quality of life (HRQoL). However, there is no PRO measure that has been developed specifically for the use in GD. Such a measure would help clinicians to gain a more in-depth understanding of the impact of GD on patients and inform clinical decision making, leading to better patient care and compliance.
Aims: The aim of this study is to develop and validate an instrument designed to measure the impact of GD and treatment on individual patients' PROs. Primary endpoints are the generation of items to construct a PRO instrument for patients with GD and its psychometric evaluation.
Methods: This is an observational multicentre study. Participants will be GD patients aged ≥18 years attending referral centers. The study will be divided in 6 stages: Stage 1 - conceptualisation of PROs in GD patients before the data collection, in order to lay a conceptual foundation for the new instrument; Stage 2 - qualitative interviews; Stage 3 - item generation; Stage 4 - pre-testing; Stage 5 - item reduction; Stage 6 - validation of the final questionnaire. The total number of patients estimated to be assessed is approximately 100.
Results: The results of first stages of the study will be presented. The issues related to PROs of patients with GD will be researched and conceptualized. The interview guidance on HRQoL and symptom issues related to disease and its treatment will be developed and the interviewer will conduct interviews in accordance with this guidance. Emerging themes on HRQoL and symptoms from the interviews will be reported and are expected to fall into the four main HRQoL domains - physical, social, environmental and psychological. Outcomes of qualitative interviews will be analyzed.
Summary/Conclusion: The user-friendly questionnaire to evaluate impact and symptoms of GD will meet the minimum standards set out by the FDA for PROs and HRQoL instruments that include intrinsic characteristics (reliability and validity), responsiveness, sensitivity to change in health states and adequate sample size (*FDA Guidance, 2006; https://www.fda.gov/downloads/drugs/guidances/ucm193282.pdf*). The instructions on the questionnaire will be easy to use, and the instrument will be short in length, self-explanatory, take a short time to complete, be easy to use and put minimal burden on the patient.

PB2399

NEW HEMATOLOGICAL RESEARCH PAPER TO DEVELOP AN INTERNATIONAL PROSPECTIVE REGISTRY FOR GD THAT CAN BE USED TO PROVIDE A CLEAR PICTURE OF THE CURRENT WORLD-WIDE MANAGEMENT OF GD

S. Salek[1,*], A. Symeonidis[2], C. Bradley[3]

[1]Institute of Medicines Development, University of Hertfordshire, Hartford, United Kingdom, [2]Hematology, university of patras, patras, Greece, [3]Dacro research group, university of glasgow, glasgow, United Kingdom

Background: Gaucher Disease (GD) is a rare disease, with 75% of GD patients being diagnosed and managed by hematologists. In the majority of cases the appropriate diagnosis is established incidentally, following a bone marrow examination, as part of the investigation process for unexplained splenomegaly, thrombocytopenia or anemia. Despite this, many of the common causes of misdiagnosis of GD when a bone marrow examination is not performed, are hematological in nature, with hematological malignancy, idiopathic thrombocytopenia and anemia of chronic disease being the more likely misdiagnosis.
Aims: If we are to truly find out what is happening in GD and address any possible GD health disparities world-wide, we need to know and understand where we are with regards to current treatment and care services for GD. If these services fall short, how can we improve their effectiveness and thus improve the quality of service that is given.
Methods: This new research initiative will provide a real-world picture of treatment and outcomes by studying clinical characteristics, disease-management and relevant clinical outcomes *i.e.* determine what is happening in the countries surveyed and pinpoint reasons for this. Moreover, by integrating the essential data from all resources we will create recommendations for the appropriate patient data collection even for local registries outside Europe, thus harmonizing diagnostic and registration strategies and contributing to better scientific communication and collaboration worldwide. This research initiative will be devised and conducted, in order to determine whether consecutive patients with known or suspected GD during a hospital admission were being investigated and treated in accordance with guidelines. It will also provides an opportunity to obtain comparative data on the characteristics and outcome of patients with GD, in terms of comparative data about GD rates, morbidity, mortality and survival data after treatment.
Current local and national registries will be used as a platform to collect detailed clinical information relevant to clinical practice and thus create a more clinically orientated International GD Registry.
Results: This future important research initiative will help us develop a truly International Prospective Registry for GD that can be used to provide a clear picture of the current world-wide management of GD. This will help us to: Promote research of GD and Develop both practical and clinical research recommendations in GD. Develop educational initiatives to allow the sharing of knowledge and best practice. Create a dataset of preserved biological material, potentially available for research purposes.
Summary/Conclusion: We aim to remove any world-wide GD health disparities by building up a partnership of all sectors involved in GD care *i.e.* multi-disciplinary teams, medical societies and co-op groups, politicians, the pharmaceutical industry, GD patient groups, the private sector and the wider community of people involved in the multifaceted aspects and phases of GD care.

PB2400

TERTIARY PREVENTION FOR PATIENTS WITH MULTIPLE MYELOMA

P. Kotoucek[1,*], R. Bezergianov[2], R. Enright[3], W. Nagi[1], Z. Ondrusova[4], A. Orfao[5], Z. Stefanikova[4], J. Sedlak[6]

[1]Haematology, Broomfield Hospital, Chelmsford, United Kingdom, [2]Counseling Services, Arizona State University, Arizona, [3]Educational Sciences, University of Wisconsin-Madison, Madison, United States, [4]Slovak Myeloma Society, Bratislava, Slovakia, [5]Salamanca Cancer Centre, Salamanca, Spain, [6]Biomedical Centre, Slovak Academy of Sciences, Bratislava, Slovakia

Background: Myeloma (MM) is a cancer derived from the immune system. The immune system is a part of the Psycho-neuro-endocrine-immune system (PNI) (Adler and Cohen, 1975). The noetic dimension has been defined and described as the highest level of the psychological function (Frankl, 2014) so influences the whole PNI. Present research in understanding the biology of myeloma is focused mainly on pre-myeloma disorder, monoclonal gammopathy of undetermined significance (MGUS). Interactions of MGUS cells with the immune system, bone cells, and others in the bone marrow niche may be key regulators of malignant transformation. These interactions involve a bi-directional crosstalk leading to both growth-supporting and inhibitory signals (Dhodapkar, 2016). Over-saturation of antigen-presenting cells by bioactive lipid antigens can be one of the intrinsic mechanisms in patients with myeloma with high BMI or Gaucher disease, an inherited metabolic disorder. One of the extrinsic mechanisms promoting myeloma development is suppression of the immune system via inhibitory signals from PNI during long term stress or conflicts, such as loss of a family member, long term resentment or long term deprivation of acceptance or a lack of meaning of life, ie existential emptiness (Enright, 2012, Frankl, 2014).

Aims: We have organised psycho-immunology research in the Slovak Myeloma Society based on case reports of patients and/or family members, correlating psychological factors and responses to chemotherapy, including autologous stem cell transplant.
Methods: We have examined the relationship between responses to a phenomenology questionnaire, particularly about the meaning of life, and the response to chemotherapy of patients from the national conference of the Slovak Myeloma Society (SMyS) in September 2014. 46 patients responded to an anonymous questionnaire which consisted of 7 questions concerning: 1) Age, 2) Gender, 3) Status of MM disease, 4) Status and timing of the most recent chemotherapy, 5) Meaning of life before myeloma, 6) Meaning of life with myeloma, 7) Qualitative changes of meaning of life before and after being diagnosed with MM.
Results: Results: N=46 patients; Female n=28; median age 62 years, age range 30-70 years; Male n=18; median age 64.5 years, age range 45-79 years. 57% of the patients had MM in CR (complete remission) or responding to chemotherapy with improving the parameters of meaning of their life (MoL). 4% of the patients had progressing MM with worsening MoL parameters. 22% of the patients had progressive MM but with improving MoL parameters. 17% of the patients had MM in CR or responding to chemotherapy but with deteriorating MoL parameters.
Summary/Conclusion: Results above raise an important question about implementing efficient integrative treatments, like logotherapy (Frankl, 2014) or Forgiveness Therapy (Enright, 2012) targeting PNI into treatment of patients with multiple myeloma (Rosenthal and Dean-Clower, 2005) and their tertiary prevention. There is clear evidence that patients living with myeloma more than 13 years without chemotherapy have a constellation of unique immune changes favouring both immune cytotoxicity and recovery of B-cell production and homing, suggesting improved immune surveillance. (Pessoa de Magalhães *et al*., 2013). Tertiary prevention for patients with myeloma should target both intrinsic and extrinsic factors with the intention of keeping efficient immune surveillance even better than in healthy volunteers to prevent recurrence of disease (Chang *et al*., 2016, Tariman *et al.* 2016, Demark-Wahnefried *et al.* 2008).

PB2401

GENERAL HEALTH IN OLDER ADULTS WITH NON-HODGKIN LYMPHOMA USING A COMPREHENSIVE GERIATRIC ASSESSMENT

D. Mercante[1,*], J. Musacchio[2], Y. Hökerberg[1], I. Mattos[1]

[1]Escola Nacional de Saúde Pública, FIOCRUZ, [2]Instituto de Pesquisa, Oncoclínicas, Rio de Janeiro, Brazil

Background: Older adults develop their aging process in a very heterogeneous way and so, considering only chronological age to decide for the best treatment is not effective. To assist in these decisions, Oncogeriatric specialists suggest the use of the Comprehensive Geriatric Assessment (CGA) that classifies this group in terms of general health assessment. The patients recognized as fit by CGA could be referred to an intensive therapy, whereas the unfit should have their impairments identified and reverted, as possible, to get hold of a better treatment, improving prognosis.
Aims: The aim was assess the general health in older adults with non-Hodgkin Lymphoma (LNH) using CGA and analyze her association with endpoints related to medical therapy decisions.
Methods: A cross-sectional study was carried out using data of older adults diagnosed with NHL who were submitted to a structured survey while in an appointment in National Cancer Institute, between February and July 2013. After applying inclusion and exclusion criteria, 125 patients comprised the study sample. Sociodemographic, clinical, pathological and related to treatment variables were analyzed, after classification in fit or unfit health condition, using three different criteria of CGA. The elements included in CGA were the assessments of functionality, comorbidity, emotional and cognitive function, nutrition, medication use and social support.
Results: Patients had a median of 68 years. There was a slight predominance of the female gender and of aggressive lymphomas in advanced stage. The prevalence of fit patients ranged from 25 to 76%, according to the criteria of CGA chosen, with age and education being factors that affected this result. With regard to treatment, 76% were submitted to an intensive therapy, using anthracycline agents, but 26% of those had to decrease dose or discontinue treatment. In relation to these outcomes, CGA categorization showed a stronger association than age, although none were statistically significant.
Summary/Conclusion: A careful review of the literature and exploration of the present data leads to the conclusion that general health assessment, using CGA, and its domains in the approach of older adults with cancer, has a well-established role. On account of this being a cross-sectional study, with incident and prevalent cases and a small sample size, further studies will be required to reach better conclusions.

Sickle cell disease

GLYCERYL TRINITRATE FOR THE TREATMENT OF SICKLE CELL LEG ULCERS

M. Boustani[1,2], C. Roignant[2], B. Kuk[2], G. De Luna[2], A. Habibi[2,3], E. Foïs[2], K. Ezzedine[4,5], F. Galactéros[1,2,3], P. Bartolucci[1,2,3,*]

[1]Université Paris Est Créteil, Faculté de médecine, [2]Unité des Maladies Génétiques du Globule Rouge, centre de référence « syndromes drépanocytaires majeurs », médecine interne, Hôpital Universitaire Henri Mondor, [3]Institut Mondor de Recherche Biomédicale (IMRB), Institut National de la Santé et de le Recherche Médicale (INSERM) U[955], DHU A-TVB, F-[94010], [4]Service de dermatologie, Hôpital Universitaire Henri Mondor, [5]Université Paris Est Créteil, Faculté de médecine, EpiDermE, Créteil, France

Background: Sickle cell disease is the most frequent genetic disorder in France with an incidence of 1/2364 birth in 2010. It is a multisystemic disease with various clinical presentations, with the vaso-occlusive crisis being the most common. Several therapeutic strategies have already been tested, such as the use of hydroxycarbamide, red cell exchange, bone marrow transplantation, and recently, gene therapy. All the progress made, contributed to lower the morbimortality of the disease. Sickle cell leg ulcer (SCLU) is a common complication affecting almost 1/5th of patients Europe and has a major impact on patients' quality of life, mainly due to the chronic pain it induces and its slow healing process, leading eventually to social marginalization and occupational deprivation. However, there is no clear recommendation regarding the specific treatment of SCLU. Hemolytic anemia-induced phenotypes, tend to have low nitric oxide bioavailability which alters vasoreactivity, and thus encourages endothelial activation and the development of an ischemic vasculopathy.
Aims: The purpose of our study was to evaluate Glyceryl Trinitrate efficacy in the treatment of leg ulcers.
Methods: We conducted a retrospective study in adult patients with sickle cell disease, presenting a SCLU of more than 1 cm^2, treated in our center from January 2015 till December 2017. Patients with other potential causes of leg ulcers (Diabetes, arterial insufficiency, systemic diseases, venous insufficiency) were excluded. Ulcers were either treated using a regular dressing or with an additional puff of Trinitrate 0.30 mg sprayed on the ulcer on a weekly basis, at each wound dressing change, and photographic follow up was implemented for and was analyzed with Pictzar software. Our primary endpoint was healing speed (decrease of ulcer surface/day) and secondary endpoint was the total duration of healing. Mann-Withney test was used to compare medians.
Results: Seventeen patients were included: 16 had homozygous Sickle cell disease (SS) and 1 heterozygous patient (Sβ0 thalassemia). Six SS patients (2 men et 4 women) with a mean age of 47 years old received Trinitrate spray. Ten homozygous and one heterozygous patients (10 men) with a mean age of 47 years old, didn't receive topical Trinitrate. There was no significant difference (*p value*=0.3) between median leg ulcer size at the inclusion (5.75 *vs* 2.4 cm^2). Faster healing was seen in the Trinitrate group but did not attain statistical significance (0.11 cm^2/day *vs* 0.005 cm^2/day; *p value*=0.08,). Median duration of ulcer healing was 100 days in the control group, and 56 days in the Trinitrate group, although one patient still had a persistent ulcer by the end of the follow-up.
Summary/Conclusion: Our retrospective study, on a small number of patients, shows a tendency towards leg healing hastening when spraying Trinitrate on the ulcer during wound care. A randomized controlled study on a larger scale of patient is necessary to confirm this result. Other vasodilatory treatments may also be tested following a similar methodology.

INTERLEUKIN-1B AND INTERLEUKIN-6 GENETIC POLYMORPHISMS AND SICKLE CELL DISEASE: AN EGYPTIAN STUDY

M. El-Ghamrawy[1,*], M. Khorsheid[2], O. Ibrahim[3], A. Gad[2]

[1]Pediatrics, Pediatric Hematology and BMT Unit, [2]Clinical Pathology Department, Faculty of Medicine, Cairo University, [3]Child Health Department, National Research Center, Cairo, Egypt

Background: Sickle cell disease (SCD) is one of the most common monogenic red cell disorders worldwide. IL-1 and IL-6 have pivotal role in pathogenesis of many acute and chronic diseases, their genetic alterations have been considered as molecular contributors for several inflammatory disorders.
Aims: To detect the frequency of Interleukin-1ß (IL-1ß +3954 C/T) and Interleukin-6 (IL-6-174 G/C) polymorphisms in a cohort of Egyptian SCD patients and to study their possible impact on the clinical course of the disease in a cohort of pediatric SCD patients.
Methods: Eighty four pediatric Egyptian SCD patients (54 males) with a mean age of 11.08±5.9 years followed up at Pediatric Hematology and BMT Unit, Children Hospital, Cairo University were enrolled. Hundred age and sex matched unrelated healthy children were included in as a control group. Genotyping of IL-1β +3954 C/T and IL-6 -174 G/C polymorphisms was performed by PCR-RFLP assay. Informed consents were obtained from the parents or legal guardians of patients before enrollment and the study was approved by the Research Ethics Committee of Faculty of Medicine, Cairo University.
Results: Genotypic frequencies of IL-1β +3954 C/ T in studied group (n=84) were 38.1% for the heteromutant genotype and 15.5% for homomutant genotype. For IL-6-174 G/C, 58.2% and 12% of SCD patients had heteromutant and homomutant genotypes respectively. There was no statistical difference in the distribution of polymorphic genotypes between SCD and controls Polymorphic genotypes of IL-6-174 G/C were associated with frequent and severe attacks of vaso-occlusion (VOC) requiring hospitalization (p=0.023 and 0.03 respectively), while there was no statistical difference between SCD patients harboring wild or polymorphic genotypes of IL-1β +3954 C/T regarding gender, frequency and severity of VOC or disease-related complications.
Summary/Conclusion: Our study provides evidence of the possible role of IL-6, as an inflammatory marker, in the vaso-occlusive subphenotype of SCD and marking a more unfavorable disease phenotype. IL-6 -174 G/C polymorphism could be considered as a molecular predictor for recurrent, severe attacks of VOC in Egyptian SCD patients. Further investigations with larger cohorts are recommended for better characterization of patients prone for complications and for identification of novel molecular markers that could modulate disease morbidity and mortality.

HBS/BETA+ THALASSEMIA PATIENTS LIVING IN ITALY: A SURVEY OF "MILD" SCD PATIENTS

L.D. Notarangelo[1], A. Agostini[1], P. Samperi[2], A. Barone[3], F. Arcioni[4], A. Pegoraro[5], B. Filippini[6], M. Nardi[7], G.C. Del Vecchio[8], L. Sainati[9], N. Masera[10], T. Casini[11], P. Giordano[8], R. Colombatti[9], G. Russo[2,12,*]

[1]Paediatric Onco-haematology Unit, Children's Hospital, Spedali Civili, Brescia, [2]Pediatric Onco-Hematology Unit, AOU Policlinico Vittorio Emanuele, Catania, [3]Department of Pediatric Onco-Hematology, University Hospital, Parma, [4]Pediatric Onco-Hematology Unit, S. Maria Della Misericordia Hospital, Perugia, [5]Pediatric Hematology Oncology Unit, Ospedale Donna Bambino, Verona, [6]Pediatric Unit, Hospital, Rimini, [7]Department of Pediatrics, University of Pisa, Pisa, [8]Department of Paediatrics "B. Trambusti", Azienda Policlinico-Giovanni XXIII, Bari, [9]Department of Child and Maternal Health, Clinic of Pediatric Hematology Oncology, Azienda Ospedaliera-Universita` di Padova, Padova, [10]Department of Pediatric Clinic, San Gerardo Hospital, University of Milano-Bicocca, Monza, [11]Department of Pediatric Oncology-Hematology, Meyer Children's Hospital, Firenze, [12]Clinical and Experimental Medicine, University of Catania, Catania, Italy

Background: HbS/beta+ thalassemia (S/beta+ th) patients usually suffer from a mild form of the disease; nevertheless, there are many grey areas concerning the clinical decision-making process, since most evidence is derived from SS and S/beta0 patients who suffer from a severe clinical condition. Specific protocols of care are lacking. We started our project on the observation of a patient with S/beta+ th, who experienced a moderate/severe form of the disease, with unexpected high number of vaso-occlusive crise (VOC) episodes.
Aims: To report on a subpopulation of Sickle Cell Disease (SCD) patients, *i.e.* S/beta+ th.
Methods: We prepared an excel database in order to collect essential clinical data from such patients. The file has been used in 11 centres which are part of the AIEOP (Associazione Italiana di Ematologia ed Oncologia Pediatrica).
Results: We collected data from 34 patients (20 males), aged 1.7-55 years (median 11.6). Country of parents' origin were Albania (21), Italy (18), Ivory Coast (6), Senegal (4), Burkina Faso (4), Brasil, Santo Domingo, India, Tanzania and Ghana (2 each). The most frequent thalassemia mutations were IVS-6 T>C (7 patients) and IVS-I-110 G>A (6 patients). Diagnosis of SCD was obtained as prenatal diagnosis in 5 patients, for the remaining 31, median age at diagnosis was 3.1 years; the event that lead to diagnosis was a clinical occurrence related to SCD in 16/32 patients; for 16/32 diagnosis was either fortuitous or due to familiarity, unknown in the remaining 2 patients. Anaemia was mild, median Hb concentration being 9.5 g/dl. Current clinical appearance was related mainly to VOC, with a median 0.5 episodes/year (range 0-6); other manifestations included splenic sequestration in 3/32 patients, acute chest syndrome in 2/34, osteomyelitis ind 1/34 and stroke in 1/30. Out of 26 patients screened for Transcranial Doppler (TCD), it was reported 1 conditional and 1 abnormal pattern, respectively. 10/33 patients were on hydroxyurea; 4/28 on regular transfusion regimen. Antibiotic prophylaxis was prescribed to 19/33 patients. No genotype-phenotype correlation was found.
Summary/Conclusion: Our "real-life" data show a heterogeneous clinical spectrum, with different policies regarding therapy (none, hydroxyurea, transfusion) and antibiotic prophylaxis in the various centres. Clinical data reveal a subgroup of patients with a more severe clinical phenotype, requiring disease modifying treatments, like the severe genotypes, and raise the need to reconsider the routine follow up clinical protocol currently applied to S/beta+ th patients, including TCD.

PB2406

TRANSFER FROM PEDIATRIC TO ADULT CARE IN THE SETTING OF HAEMOGLOBINOPATHIES IN ANTWERP, BELGIUM

K. Saevels[1,*], A. Devos[2], M. Philippe[2], V.D.V. Ann[1]

[1]Haematology, [2]Pediatrics, UZA, Edegem, Belgium

Background: The complexity of haemoglobinopathies, resulting in multi-organ dysfunction, necessitates a carefully integrated care regimen. Unlike normal red cells, diseased cells tend to form clumps and obstruct blood flow. This results in extreme pain crises, severe haemolytic anaemia and chronic damage to vital organs due to oxygen deficiency, infections and iron overload. Today, because of early preventive screening and treatment in red blood cell clinics, more than ninety percent of patients reach adulthood. With increased life span, patients encounter multiple transitional care episodes. These are particularly challenging since they increase morbidity and mortality. Good transition and access to primary care coupled with a comprehensive care in red blood cell diseases can improve outcomes.
Aims: To understand and to promote successful transfer from pediatric to adult care in the setting of hemoglobinopathies in the Antwerp region.
Methods: Patient demographics: At the University Hospital of Antwerp a total of 80 patients with severe haemoglobinopathies were followed on a routinely base in 2017 on a paediatric ward (n=50) and an adult ward (n=30). Haemoglobinopathies were divided in sickle cell disease (HbSS (n=56); HbSC (n=10) and HbS/β-thalassemia (n=7) (n=73) and β-thalassemia major (n=7).
Methods: We did a survey amongst 5 adolescents (15 to 18 years) and 5 young adults (18 to 30 years) during their transition to adult care. All patients were asked what has to be improved in the current protocol of transititional care to enhance their quality of self-care.
Results: All patients asked for a mobile medical card and an illustrated booklet with crucial information to help them to communicate their physical, psychological and social needs. This card with medical history, chronic medication, transplant related topics and hematology contact information improves communication with caregivers and healthcare professionals worldwide. Also the card has to expanded with a personal pain plan, sport advice and information on specific situations at school and professional environments. To make sure that the information is valuable we collaborate intensively with some of the dedicated young patients, to move forward with this patient-centered care project.
Summary/Conclusion: Successful transfer from paediatric to adult care has its foundation in a strong collaboration amongst the adolescents and young adults, their family and friends and the health care system to support building skills and positive disease management. Patients are encouraged to become empowered about their health and appropriate medical care. This is especially important in the new and rapidly evolving era of new therapies like T-cell depleted haplo-identical haematopoietic stem cell transplantation for severe and advanced stage sickle cell disease and gene therapy for β-thalassaemia. Incorporation in daily medical practice of patient-centered care evolves quickly and helps future clinical trials for haemoglobinopathies in Belgium.

PB2407

ASSOCIATION BETWEEN BCL11A, HSB1L-MYB AND XMNI ГG-158 (C/T) GENETIC POLYMORPHISMS AND HEMOGLOBIN F IN EGYPTIAN SICKLE CELL DISEASE PATIENTS

M. El-Ghamrawy[1,*], M. Khorsheid[2], M. Abdel-Hady[1], E. Michael[3]

[1]Pediatrics, Pediatric Hematology and BMT Unit, [2]Clinical Pathology Department, [3]Pediatrics, Faculty of Medicine, Cairo University, Cairo, Egypt

Background: Sickle cell disease (SCD) is a monogenic disease associated with multisystem morbidity. Clinical severity of SCD is extremely variable, and reasons for this heterogeneity are not fully understood. Inter-individual variation in hemoglobin F (HbF) level is likely one of the main modifiers that contribute to the clinical heterogeneity observed in SCD patients as it inhibits HbS polymerization and reduces the mean corpuscular HbS concentration. Previous studies showed association of variants at 3 major genomic loci with HbF levels.
Aims: To investigate the prevalence of BCL11A (rs11886868), HSB1L-MYB (rs9382268) and *Xmn*I γG-158 (C/T) genetic polymorphisms in a cohort of Egyptian SCD patients and to clarify the possible association between these polymorphisms and HbF level before and after hydroxyurea (HU) therapy.
Methods: One hundred Egyptian SCD patients (53 females) with a mean age of 13.68±8.91 years followed up at Pediatric Hematology and BMT Unit, Children Hospital, Cairo University were enrolled. Hundred age and sex matched unrelated healthy children were included as a control group. Genotyping of the studied single nucleotide polymorphisms (SNPs) was performed by polymerase chain reaction restriction fragment length polymorphism (PCR-RFLP) assay. Informed consents were obtained from the parents or legal guardians of patients before enrollment and the study was approved by the Research Ethics Committee of Faculty of Medicine, Cairo University.
Results: The distribution of the studied SNPs did not differ between SCD patients and controls except for the heteromutant genotypes of BCL11A which was significantly higher in SCD patients (p=0.13). For the HSB1L-MYB, BCL11A and Xmn1, baseline HbF level was higher in patients having the polymorphic genotypes than those with the wild genotypes, yet the difference between them did not reach a statistically significant level (p=0.47, 0.95 and 0.19 respectively). Fold change of HbF after HU therapy did not differ between patients harboring the wild or the variant genotypes for each SNP either alone or when more than one SNP co-existed (p=0.12, 0.91 and 1 for HSB1L-MYB, BCL11A and Xmn1 respectively). for HSB1L-MYB, BCL11A and Xmn1 respectively for base line HbF level and p=0.15, 0.14 and 0.35 for HSB1L-MYB, BCL11A and Xmn1 respectively for steady state HbF level).
Summary/Conclusion: *HSB1L and BCL11A* genetic polymorphisms had no positive impact on HbF level. Identification of regulators of HbF expression might be promising and mechanisms mediating this switching process could lead to better, less toxic, and more effective strategies for HbF induction.

PB2408

DISTRIBUTION OF IL4 VNTR POLYMORPHISMS AMONG SUDANESE PATIENTS WITH SICKLE CELL DIEASE

T. Alabid*

Heamatology and immuneheamatology, University of Khartoum, Khartoum, Sudan

Background: : Sickle cell disease (SCD) is an inherited disease associated with the chronic inflammatory condition indicated by elevated levels of inflammatory cytokines and increased Th17 response. These inflammatory pathways may be directly regulated by genetic polymorphisms and could be associated with different outcomes of the disease. Interleukin-4 (IL-4) is the main cytokine of T helper 2 lymphocytes, which has a key role in the regulation of humoral immune responses. The expression level of IL-4 gene could change by the 70 bp variable number of tandem repeat (VNTR) polymorphism that found in its third intron. In Africa (SCD) is one of the most common inherited disorders of hemoglobin and varies in frequency between different areas in Sudan.

Table. IL-4 VNTR genotypes and alleles distributions among SCD patients and controls.

Genotype	Patients N (%)	Control N (%)	P-value	OR(95% CI)
RP1/RP1	53(53.0)	59(59.0)	0.393	0.78(0.48 - 1.37)
RP1/RP2	31(31.0)	0	0.000**	-
RP2/RP2	16(16.0)	41(41.0)	0.000**	0.27(0.14 - 0.53)
Alleles RP1	137(68.5)	63(31.5)	0.048*	1.511(1.002 - 2.278)
Alleles RP2	118(59.0)	82(41.0)		

** P-value<0.05 statistical significantly **P-value<0.001 highly significantly different, OR=Odd Ratio, CI= Confident interval.*

Aims: The aim of this study was to detect the distribution of IL-4(VNTR) alleles among Sudanese patients with SCA and to investigate the possible associations with the development of stroke among these patients.
Methods: One hundred patients (50 male and 50 female; 8.34±6.67 years) with SCD and one hundred (47 male and 53 female; 8.64±4.99 years) healthy blood donors were evaluated. The polymorphisms were performed by PCR analysis and described as genotype frequencies.
Results: The entire RP1/RP2 genotype carriers were SCD patients. A significant difference in the distribution of RP2/RP2 genotype was found among patients (16%) and controls (41%) (P =0. 000) and it was only found among western Sudan tribes .RP1/RP1 genotype frequency was almost the same between (patients: controls), (53%: 59%). RP1 allele can be considered as risk factor for SCD as it was found 1.5 fold time to be in SCD patients than in controls (O.R =1.51).
Summary/Conclusion: In this study, there were three main genotypes of IL-4 identified (RP1/RP1, RP1/RP2, RP2/RP2) in the patients and controls. The risk of sickle cell patients was higher in individuals with RP1/RP2 genotype than controls. In addition, the frequency of allele 1 was higher in sickle cell anemia patients (68.5%), but this difference was weak evidence, therefore, this allele could be a risk factor for sickle cell patients (O.R =1.5).The distribution of SCD among Sudanese population directly affect the frequency of IL4 VNTR among different tribes. Studies in Sudan reported the presence of SCD in western tribes mainly. The RP1 allele could be a risk factor for sickle cell anemia patients. No statistically significant difference between tribes in VNTR allele's distribution, but Darfour and Kordofan tribes showed high frequency of RP2 allele.

PB2409

GENDER-RELATED DIFFERENCES IN SICKLE CELL DISEASE: A RETROSPECTIVE STUDY IN A PEDIATRIC POPULATION

G. Ceglie[1,*], I. Tarissi de Jacobis[1], F. de Gennaro[1], M. Di Mauro[1], M. Quaranta[1], C. Baronci[2], A. Villani[1], G. Palumbo[2]

[1]University Department of Pediatrics (DPUO), [2]Department of Oncohematology, Ospedale Pediatrico Bambino Gesù, Rome, Italy

Background: Sickle cell disease (SCD) is the most common monogenic disease worldwide. The disease mainly affects people of African, Caribbean, Middle Eastern, Eastern Mediterranean and Asian origin, but its prevalence is increasing in Europe, probably as a result of human migration. The incidence of SCD is not gender related, since it is transmitted as an autosomal recessive disorder. However, there have been reports of sex related differences in SCD mortality and morbility in adult patients. No studies are currently available about gender heterogeneity in the pediatric population.
Aims: The aim of this study is to find gender-related differences in the clinical course of SCD in a pediatric population.
Methods: In our study, we retrospectively analyzed the clinical records of 39 pediatric patients with a diagnosis of SCD (hemoglobin SS genotype), 23 males (59%) and 16 females (41%). We studied the gender differences analyzing the frequencies of the pain crisis per year, the number of blood transfusion per year, cardiac sequelae and severe complications (e.g. infectious, cardiovascular).
Results: Pain crisis frequency per year were significantly increased in the male population with a mean number of crisis per year of 1.6 *versus* 0.6 in the female population (p=0.04). Also, severe complications were mostly found in the male population; in fact, in 4 cases of osteomyelitis, 3 occurred in male patients and 1 in female patient. Moreover, we observed one case of transient ischemic attack and one of portal vein thrombosis, both of them occurred in male subjects. To evaluate cardiac complications of the disease, we analyzed the echocardiographic findings, available in 31 patients (17 males and 14 females). SCD-related cardiac complications were observed mainly in the male population: among 13 patients with echocardiographic alterations, 10 of them were boys (77%) and 3 were girls (23%) (p=0.04, Fisher's test). The number of blood transfusions per year was not different in males and females. The age at diagnosis was lower in males (median age of 2 years) than in girls (median age of 4 years), without reaching statistical significance (p=0.08).
Summary/Conclusion: Our data support the hypothesis that gender could play a role in determining the clinical course of SCD. The higher morbility in males is a well-known feature of SCD in adults but this is, to our knowledge, the first study that confirms this finding in a pediatric population. In our cohort both pain crisis frequency and severe complications of the disease were found to be more frequent in males than in females. We also found that the median age at diagnosis is higher in girls, probably explaining the lower total number of females in our population. These two findings support the hypothesis of a less severe clinical phenotype occurring in girls, so that the milder course of the disease leads to a later diagnosis in this group of

patients. These sex-related differences, in part observed in the adult population, have, until now, been attributed to hormonal variations that are physiologically found in the two sexes after puberty. On the other hand, in a pediatric population, other factors must be responsible for these differences and should be addressed to in further studies. These findings might also be valuable to integrate gender as a factor in the risk assessment of these patients at diagnosis, and possibly guide therapeutic decisions, with the aim of personalizing the therapy.

NEWBORN SCREENING FOR SICKLE CELL DISEASE: EXPERIENCE IN BALEARIC ISLANDS 2 YEARS AFTER OF THE IMPLEMENTATION OF THE SCREENING PROGRAM

L. Lo Riso[1], A. Ortuño Cabrero[1,*], J. Robles Bauza[2], M. Garcia-Recio[1], B. Robredo Rodriguez[1], B. Lopez Andrade[1], J.M. Sanchez-Raga[1], A. Sampol Mayol[1], M.A. Duran Pastor[1]

[1]Hematology and hemotherapy, [2]Clinical analysis laboratory, Hospital Universitario Son Espases, Palma, Spain

Background: Migratory flows changed the distribution of the incidence of hemoglobinopathies. Nowadays Sickle cell disease (SCD) is more frequent en the mediterranean area than beta or alpha thalassemia, until now typical in this area. The increase in the incidence of SCD and the need of an early treatment due to frequent and severe complications in the firsts years of life, have determined, by the National Health System, the inclusion of the deteccion of hemoglobinopathies as part of the newborn's mandatory screening for endocrinal and metabolic pathologies.
Aims: This study presents data obtained after 23 months since this screening program in the Balearic islands.
Methods: Blood samples are obtained by newborn's heel-pricks between the 2nd and 5th day of life, and they are analyzed in Son Espases Hospital's Clinical Analysis Laboratory by high performance liquid chromatography (HPLC) with VARIANT system (BioRad). Positive cases for hemoglobin (Hb) variants were confirmed by peripheral blood samples from both parents (in case of FAS, FAC, FAX) or from both parents and newborn (in case of homozygous for FS or double heterozygous FSC or FSb). Samples were analyzed in the Eritropathology Laboratory in Son Espases Hospital by HPLC (Biorad-10) and Capillary Electrophoresis (Sebia Minicup).After checking results, an appointment is scheduled for the affected family with Hematology department, and there they are given information about the pathology, genetic counseling and a recommendations guide from the Spanish Society of Pediatric Hematology and Oncology. In homozygous cases, antibiotic prophylaxis is prescribed and a follow-up visit is scheduled. Data from this screening program are filed in a registry controlled by the Balearic Islands Ministry of Health.
Results: 19197 samples were analyzed from Balearic Autonomous Community obtained between 25/04/2016 and 28/02/18. 105 cases were detected with some Hb variant (Table 1), with 3 of them homozygous for HbS.Due to the family hemoglobinopathy study another two cases (1 homozygous HbS, 1homozygous HbC), and 3 families were both parents were either heterozygous HbS or HbC were detected.

Table1. Hemoglobinopathy incidence in Balearic islands 25/04/2016 and 28/02/2018.

Number of samples analyzed 19.197		
	Number of cases	1 every…
FAS	79	243,00
FAC	20	959.85
FAD	2	9599.50
Hb Burt	1	19197.00
FS	3	6399.00
Total	105	182.83

Summary/Conclusion: Incidence of homozygous HbS in Balearic islands is similar to the one calculated in other observational studies among different Spanish territories, although we were able to detect a greater number of heterozygous Hb variants than in those other regions.The screening for hemoglobinopathies has been useful in the detection of cases affected of sickle cells disease in newborn and family members not yet diagnosed, and the instauration of early treatment.

PB2411

SICKLE CELL SYNDROMES (SCS) IN SOUTHERN TUNISIA: A COHORT OF 76 CASES

K. Faten[1,*], H. sondes[1], L. lamia[2], M. Abir[1], M. Ghorbel[1], F. Safi[3], M. Naifar[4], H. Mnif[5], F. Makni[4], M. Hachicha[2], A. Mahfoudh[3], E. Moez[1]

[1]Hematology Department, [2]pediatric Department, [3]pediatric resucitation department, CHU Hédi Chaker Sfax Tunisia, [4]biochemestry department, chu habibi bourguiba, [5]blood transfusion center, Chu Hbib Bourguiba, sfax, Tunisia

Background: Hemoglobin sickle cell disease is one of the most frequent hemoglobinopathies in Tunisia.The sickle cell syndromes (SCS) representing by patients with homozygosity for HbS, patients with hemoglobin SC(HbSC, combined heterozygosity for hemoglobins S and C) and patients with sickle cell-beta thalassemia, is still a health problem because of their severe clinical manifestations and their complications.
Aims: The objective of this study is to describe the clinical profile, treatment and complications of these patients in the south Tunisian.
Methods: Our study is retrospective having interested the patients with SCS diagnosed and taken care in three centers of the university hospital Hedi chaker of Sfax: Pediatrics Department, Pediatrics Emergency Resuscitation (PUR) and the Hematology Department of CHU Hedi Chaker of Sfax for a period of 35 years (from 1979 to 2014). The diagnosis and classification of the type of SCS is based on clinic data, hemogram, hemoglobin electrophoresis and the family survey.
Results: We collected 76 cases of SCS: 44 cases followed in hematology department, 23 cases in pediatric center and 9 patients in pediatric intensive care unit. The mean age at diagnosis was 8 years (extremes: 1month - 49 years). Sixty-five of our patients (85.5%) were white, 11 (14.5%) were black. Inbreeding (consanguinity) was observed in 37 cases (48.7%). SS homozygous sickle cell disease was noted in 68.4%, hemoglobin SC in one patient (1.3%) and Sß thalassemia in 9 patients.SCS diagnosis was made following anemic syndrome in 46% of cases, a vasoocclusive crisis in 34% of cases, a complication in 4% of cases and hand-foot syndrome in 1.3% of cases.The main acute complications observed in our patients were vaso-occlusive attacks (67%), infections (44.2%) and aggravation of anemia (24.7%). chronic complications were vesicular lithiasis in 20 patients with osteonecrosis of the femoral head in 5 patients.The symptomatic treatment consisted of antibioticprophylaxis in 85% of the patients, hyperhydration performed in 47 cases (hospitalized for vaso-occlusive attacks), blood transfusion in 40 patients and transfusion exchange in 11 patients(a preoperative preparation in 6 cases,pregnant women in 2 cases and a serious vasoocclusive accident in 3 patients.the background treatment consisted of a transfusion exchange program in 9 patients and Hydroxyurea in 17 patients.
Summary/Conclusion: Homozygous sickle cell disease was the most common type of sickle cell disease in our series (68.4%), as also described in most of the series in the literature. The diagnosis of major sickle cell syndrome remains relatively late in our series (8 year) compared to literature. The frequency of vaso-occlusive seizures is the same as that reported in the series, while the infections are a little less due to antibiotic prophylaxis.The rate of anemia, however, remains more important than in the series. Vesicular lithiasis was the most frequently described chronic complication in our study, a little more common than in the literature. Background treatment has improved treatment outcomes and decreased the incidence of vasoconstriction and hospitalization. The bone marrow allograft, not made in our patients remains a pillar in the process that should be introduced in our institution.

PB2412

IMPACT OF SICKLE CELL DISEASE ON WORK, SCHOOL, RELATION SHIPS, AND SOCIAL LIFE: RESULTS FROM IN-DEPTH INTERVIEWS WITH PATIENTS

P. Stebbins[1], C. Saucier[1], M. Bailey[2,*], D. D'Alessio[2], A. Mitchell[1], M. White[1], K. Raymond[1]

[1]Optum, Johnston, [2]Novartis Pharmaceuticals Corporation, East Hanover, United States

Background: Sickle cell disease (SCD) affects approximately 100,000 individuals in the US. There are few published studies which document the impact SCD has on patients' day to day activities and relationships. Qualitative research methods are ideal to gain an in-depth understanding of the ways in which SCD symptoms impact patients' lives.
Aims: To describe SCD patients' self-reported impacts of SCD symptoms/pain crises on their work, school, relationships, and social life.
Methods: Twelve patients (aged >=12) who experienced one or more sickle cell-related pain crises in the past year were interviewed either in person

(n=9) or by telephone (n=3) using a qualitative, exploratory interview approach.
Results: Of the eight adult (aged >=18) patients interviewed, five reported having left the workforce due to the effects of their SCD and three remained employed. Three of the eight patients described having worked during pain crises despite pain and fatigue; two reported needing to make accommodations during their work day. Of the five currently unemployed, three had voluntarily retired and two had been displaced as a direct result of SCD. Of the three currently employed patients, two reported being restricted in their ability to perform their duties. Of the adolescent patients interviewed (n=4, age ranged from 12-16), all reported one or more pain crisis episodes in which he or she missed between one and four days of school, and all reported experiencing presenteeism. Two reported that symptoms and absences due to crises resulted in getting behind on school work. All four reported missing gym and other physical activities at school to manage symptoms. All 12 patients reported family and social relationships as either sources of stress, support, or both during pain crises. Seven of 12 described having one or more close friends or family members who did not understand pain crises, and labelled patients as "lazy" or "a crybaby." Four of 12 patients reported minimizing contact with others during a pain crisis. Three of the eight adult patients reported experiencing anxiety at having to cancel plans at the last moment either due to the onset of a pain crisis or to prevent being exposed to a sick loved one for fear of the exposure triggering a crisis. Six of 8 adult patients reported having friends, family, and neighbors who offered support, planned recreational outings, and assisted with childcare, transportation, and errands. Adolescents did not report direct impacts on their relationships; however, three of the four reported envy of siblings and peers who could participate in activities such as sports and field trips while they could not due to SCD.
Summary/Conclusion: Living with SCD has a significant impact on patient's physical and emotional well-being and social functioning for both adults and adolescents. Absenteeism and job loss due to SCD was common among the adult patients interviewed. Missing school and having difficulty completing schoolwork due to symptoms and crises may have future consequences for adolescents. The tendency to self-isolate due to a lack of understanding about SCD and the debilitating nature of pain crises amongst friends and family members further add to the social and economic consequences of SCD. Having a better understanding of patients' experiences can help improve treatment for SCD and reduce its impact on a patient's day to day life.

PB2413

BARRIERS TO TREATMENT FOR PATIENTS WITH SICKLE CELL DISEASE: RESULTS FROM IN-DEPTH INTERVIEWS WITH PATIENTS AND CAREGIVERS

P. Stebbins[1], M. Bailey[2,*], D. D'Alessio[2], C. Saucier[1], K. Raymond[1], M. White[1]

[1]Optum, Johnston, [2]Novartis Pharmaceuticals Corporation, East Hanover, United States

Background: Previously published research on sickle cell disease (SCD) demonstrates that patients experiencing a SCD-related pain crisis often treat themselves at home rather than seek medical care outside the home (e.g. medical professional such as a physician's office or walk-in clinic, or by emergency services). Rapid initiation of treatment outside the home for patients experiencing a SCD-related pain crisis can be critical to minimize the risk of organ damage and reduce overall pain. What are the perceptions and treatment experiences that shape the decision to seek treatment outside the home for a SCD-related pain crisis?
Aims: To describe SCD patient and caregiver self-reported perceptions of barriers to seeking treatment outside the home for SCD-related pain crises.
Methods: Twelve patients (>=12 years of age) and six caregivers of patients <12 years of age with SCD were interviewed either in person (n=14) or by telephone (n=4) using a qualitative, exploratory interview approach. Patients had all experienced one or more sickle cell-related pain crisis in the past year.
Results: All patients interviewed (n=12) and one-third of caregivers (n=2) reported deliberately delaying seeking treatment outside the home when experiencing a SCD-related pain crisis. They also reported using a variety of pain crisis prevention and minimization strategies to delay care outside the home as long as possible. Strategies included: rest, hydration, music, meditation, and increased medication use. All patients described seeking treatment outside the home as typically the last resort; while the majority of caregivers of pediatric patients were more likely to initiate care inside the home, but seek care outside the home as pain levels escalated. Of the subset of study participants who shared reasons for delaying seeking treatment outside the home (n=7), the most commonly reported reasons to delay or avoid treatment outside the home were: receiving stigmatizing attitudes from doctors and other treatment professionals or not being believed about pain levels (n=6) and long wait times in emergency rooms (n=4; participants could report more than one reason). Additional factors included: inadequate or ineffective treatment options (n=3), a lack of knowledge on SCD-related pain crises and SCD in general amongst (non-specialist) clinicians (n=2), and perceived racial discrimination (n=2). Most caregivers (n=4) reported a lack of education and/or knowledge about how to identify and mitigate a pain crisis, which delayed their ability to seek treatment outside the home.
Summary/Conclusion: Although this study was conducted with a small sample in the US, the findings emphasized the importance of understanding patient and caregiver perceptions of barriers and treatment experienced outside the home for SCD-related pain crises. Educating medical professionals, particularly non-specialists and emergency care personnel, about SCD may help reduce some of the barriers experienced by these patients and caregivers, ultimately helping patients by providing appropriate and timely pain relief and minimizing potential organ damage and other complications. In addition, it is important to ensure patients and caregivers are making treatment related decisions, about when to seek treatment outside the home, based on medical need rather than perceptions of medical professionals.

PB2414

IMPACT OF HYDROXYUREA ON NEPHROTIC SYNDROME SECONDARY TO DREPANOCYTOSIS - A CASE REPORT

I. Oliveira[1,*], J. de Amaral Melo[2], M.J. Palaré[3], A. Ferrão[3], C. Simão[4], A. Morais[3]

[1]Serviço de Pediatria, Hospital de São Bernardo, [2]Serviço de Hematologia e Transplantação de Medula, Departamento de Pediatria, Centro Hospitalar de Lisboa Norte E.P.E., [3]Unidade de Hematologia, [4]Unidade Pluriassistencial, Departamento de Pediatria, Centro Hospitalar de Lisboa Norte E.P.E, Lisboa, Portugal

Background: Nephropathy is a common complication of sickle cell anemia (SCA) and an important poor prognostic factor among these patients. It can rarely present as a nephrotic syndrome.
Aims: We aimed to describe the impact of hydroxyureia on nephrotic syndrome secondary to drepanocytosis in an adolescent.
Methods: Clinical case presentation.
Results: A 12-year-old African girl from São Tomé and Príncipe was diagnosed with sickle cell disease 6 years earlier. She remained asymptomatic and without any organ involvement up until the age of 11 when she moved to Portugal and presented with an inaugural nephrotic syndrome. Her initial urinary protein/creatinine ratio was 18,3mg/dL (normal <0,15) and she was started on prednisolone 60mg/m^2/day. A renal biopsy was done which revealed a membranoproliferative glomerulonephritis with hemosiderin deposits in the tubular epithelium. However, she maintained a nephrotic proteinuria with episodic but exuberant malleolar swelling which brought her great discomfort and motivated frequent school absences. A minimum urine protein/creatinine ratio of 8mg/dL was reached while on prednisolone and enalapril. After the discontinuation of corticosteroid, she maintained a clinical and laboratory deterioration. Nine months after the inaugural episode, she was started on hydroxyurea to delay the progression of the renal disease. Since then, she showed regression of the edema, her serum albumin normalized and her urinary protein/creatinine ratio decreased (16,5mg/dL at the beginning of the treatment with hydroxyurea and 6,7mg/dL after 6 months). There was an increase in the fetal hemoglobin from 9% to 18%. She remains on both enalapril and hydroxyurea with no further complications. Ophthalmic and cardiac evaluations were normal and she has a normal middle cerebral artery flow velocity on the transcranial doppler.
Summary/Conclusion: The best approach to prevent the progression of nephropathy in patients with sickle cell disease remains to be determined. In this case, the use of corticosteroids and a renin-angiotensin-aldosterone inhibitor reduced the urinary protein/creatinine ratio, but the patient maintained a nephrotic proteinuria with episodes of severe edema. The initiation of hydroxyurea was effective in controlling the progression of the secondary nephropathy. We believe this was a result of limiting intraparenchymal sickling and thus decreasing the glomerular dysfunction. Starting treatment with hydroxyurea early on should therefore be considered in the treatment of renal disease in children with SCA.

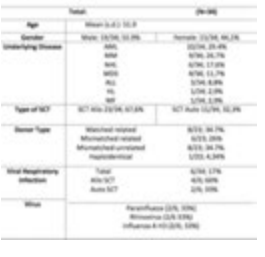
T CELL EXHAUSTION PROFILE (CD4+/CD28- CD8+/CD28-) IN BONE MARROW TRANSPLANTATION. CLINICO-EPIDEMIOLOGICAL FINDINGS

M. Villanueva[1,*], A. Figuera[1], Y. Perez[2], C. Cuellar[1], J.M. Galvan[3], G. Silva[1], M.C. Marcos[4], J.C. Nazario[5], L. Cardenoso[6], R. De La Camara[1], C. Munoz[2]

[1]Hematology, [2]Immunology, [3]Internal Medicine, [4]Pneumology, Hospital Univesitario de La Princesa, [5]Innovation Unit, Hospital Clínico San Carlos, [6]Microbiology, Hospital Univesitario de La Princesa, Madrid, Spain

Background: Recipients of allogeneic stem cells grafts have clonally expanded CD8+/CD28- and CD4+/CD28- T lymphocytes during the early period after SCT, this cellular dynamic is probably associated with the acquisition of a toxic phenotype who over produce granzime and perforin. This scenario predisposes to continuous inflammation, increase T cell cytotoxic, NK activity (NK Per+ Gran+) and favor the appearance of senescent lymphocytes. On the other hand, viruses are recognized as the predominant pathogens leading to pneumonia after allo SCT (lack data in auto SCT). The direct consequences of respiratory viral infection (RVI), subsequent cellular injury and altered host immunity could also initiate a cascade of immunologic events (T cell exhaustion, inflammation).
Aims: The present study aimed to evaluate the dynamics of T cell exhaustion profile CD4+/CD28- Per+/Gran+, CD8+/CD28- Per+/Gran+ NK Per+ Gran+ during the first 100 days after SCT recipients (autologous, allogenic and patients with RVI).
Methods: Informed consent was obtained from all the patients before blood samples were collected. In a prospective study, peripheral blood samples were obtained previous BMT and at day +100 post BMT from 34 patients (11 autologous, 23 allogenic). To evaluate the expression of CD4+/CD28- Per+/Gran+, CD8+/CD28- Per+/Gran+, flow cytometry analysis was performed: 100µL of PB was labeled, with a panel of 8 monoclonal antibodies: PERFORIN FITC, GRANZIME PE, CD4 PerCP, CD28 APC, CD8 APC-H7, CD16/56 V450 and CD45 V500.The molecular detection of RV were tested with the CLART® Pneumovir assay (Clinical Array Technology, Genomica, Spain) based on the principle of multiplex polymerase chain reaction and DNA microarray.Statistical analysis was performed with IBM SPSS v24.
Results: Thirty-four patients were evaluated from November 2016 to December 2017 at the University Hospital of La Princesa, Madrid Spain. The patients characteristics are shown in Table 1.The median percentages of baseline CD8+/CD28- cell line was 9,09% (range, 4,1-14,7) and the median percentages of CD8+/CD28-cell line at +100d were 29,2% (range, 13,3 -38,9). Likewise, significant differences were found (p=0.001). We compared between the group of patients who had a RVI and the group without RVI: We found differences between patients with VRI and those who did not have VRI in the CD8+/CD28- +100d cell line, the median percentages of the RVI patients were 58.43% (range, 42.72-68.43) and the median percentages in the uninfected were 29.26% (range, 13.26-38.94) (p=0.002). In the other cell lines, we did not find any statistically significant association.

Table1.



Summary/Conclusion: In the present work, we show a dynamic change in the exhausted phenotype of T cell lymphocytes CD8+/CD28- throughout the SCT. There are a statistically significant differences when analyzing patients infected with RV *vs* non-infected patients (baseline *vs* + 100d). In agreement wtih previous reports, there was a marked increased od CD8+/CD28- cell fraction early after SCT. Exposure to certain VR in the first 100 days after TPH may contribute the appearance of populations of exhausted T lymphocytes CD8+/CD28- favoring a sustained inflammatory environment and probably works as a trigger in certain immunological complications (immune-disregulation). It is necessary to evaluate these patients over time and see their correlation with other clinico-epidemiological variables in the SCT (aGVHD, cGVHD, pulmonary functional tests, bronchiolitis obliterans, CMV reactivations).

[1]Pusan National University Hospital, Busan, [2]Korea University School of Medicine, Seoul, [3]Chonnam National University Hwasun Hospital, Hwasun, [4]Seoul National University Hospital, Seoul, [5]Chonbuk National University Hospital, Jeonju, [6]Busan Paik Hospital, Busan, [7]Kyungpook National University Hospital, Daegu, [8]Korea Cancer Center Hospital, Seoul, [9]Dong-A University College of Medicine, Busan, [10]Ulsan University Hospital, Ulsan, [11]Kosin University College of Medicine, Busan, [12]Asan Medical Center, [13]Hanyang University College of Medicine, Seoul, [14]Dongsan Medical Center, Daegu, [15]Yonsei University College of Medicine, Seoul, Korea, Republic Of

Background: The role of upfront ASCT in patients with diffuse large B cell lymphoma is still controversial.
Aims: We evaluated the effectiveness and safety profiles of upfront ASCT with 194 patients of DLBCL.
Methods: Total 151 patients (77.80%) achieved complete remission after ASCT and overall response rate was 84.0%.
Results: Treatment related mortality was 3.6% and 66 patients (34.0%) had progression or relapse. The 5-year overall survival rates and progression free survival rates were 72.3% and 54.6%. There were no significant differences in OS (p=0.371) and PFS (p=0.572) between BCNU conditioning group (BEAM) and busulfan conditioning groups (BuCyE or BuMelE). Neutrophil engraftment was significantly faster in busulfan group than in BCNU group (p=0.011). But, the frequency of mucositis was higher in busulfan groups than in BCNU group (p=0.03). Among the busulfan group, BuMelE group showed lower recurrence rate and higher rate of achievement of CR after ASCT than BuCyE group. Multivariate analysis for OS showed that performance status ≥2 (p<.001), non-rituximab induction therapy (p=0.011) and BuCyE conditioning (p=0.016) were poor prognostic factors. In addition, PS ≥2 (p=0.018), non-rituximab induction therapy (p=0.003) and non-CR status before ASCT (p=0.029) were significantly associated with poor prognosis in PFS. The following factors; stage, bulky disease, high LDH, bone marrow involvement and high risk IPI did not affect survival significantly.
Summary/Conclusion: In conclusion, it is considered that upfront ASCT can overcome the poor prognosis of high risk DLBCL patients. And busulfan based conditioning, especially BuMelE, is an effective conditioning regimen, showing similar efficacy and safety profile as BEAM conditioning.

PB2417

EFFICIENCY OF CD34+-SELECTED STEM CELL BOOSTS FOR PRIMARY POOR GRAFT FUNCTION AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH APLASTIC ANEMIA

R. Bogdanov*, N.K. Steckel, D.W. Beelen

Department of Bone Marrow Transplantation, University Hospital of Essen, Essen, Germany

Background: An important point for success of allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a sufficient and durable reconstitution of hematopoietic donor stem cells. Primary poor graft function (PPGF) after allo-HSCT is characterized by persistent pancytopenia, immunodeficiency and dependence on blood transfusions, despite of a complete donor chimerism. Absence of a regulatory effect of bone marrow stromal microenvironment in patients with aplastic anemia, even in case of using bone marrow as a source of stem cells, increases the probability of development of PPGF.
Aims: The purpose of this analysis is to assess safety, efficacy and survival after CD34+-selected stem cell boost in patients (pts) with PPGF after allo-HSCT for aplastic anemia.

Methods: The analysis comprises data of 13 pts with aplastic anemia after allo-HSCT from HLA-matched sibling (n=7) or unrelated (n= 6) donors, who underwent allo-HSCT between 2008 and 2017. The median age of the 10 male and 3 female pts was 32 years (range, 17 to 66). The immunoablative conditioning regimen consisting of 4x50mg/kg cyclophosphamide and 3x30mg/kg rabbit ATG was performed in all pts before allo-HSCT. In case of unrelated donors, 2 Gy total nodal irradiation was additionaly administerd. Bone marrow (n=12) or peripheral blood stem cells (n=1) with the a median of $2.65x10^6$ $CD34^+$ cells/kg bodyweight (BW)(range, 1.5 to 4.7) were transplanted. PPGF was defined as transfusion-dependent thrombocytopenia with platelet counts <20.000/µl, or transfusion-dependent anemia or leucopenia with neutrophil counts <1.000/µl. PPGF was diagnosed at a median of 47 days (range, 22 to 100) after allo-HSCT by bone marrow biopsy. The median neutrophil count at time of stem cell boost administration was $0.3x10^9$/L (range, 0.14 to 1.8), the median platelet count $15x10^9$/L (range, 7 to 30), and the median hemoglobin concentration 8 g/dL (range, 7 to 9), respectively. Immunomagnetically selected $CD34^+$ stem cells from original donors were used without further immunosuppressive prophylaxis. Cell counts were as follows: $5.48x10^6$ $CD34^+$ cells/kg BW (range, 0.95 to 13.2), $0.22x10^4$ $CD3^+$ cells/kg BW (range, 0.16 to 0.8), $2,12x10^4$ $CD20^+$ cells/kg BW (range, 0.55 to 3.55). Hematological engraftment was defined as an increase of neutrophils by 1.000/µl, of platelets by 50.000/µl, and hemoglobin by 8.5g/dL.
Results: The rate of complete hematological engraftment was 85% (11 of 13 pts). A partial response in 1 or 2 hematopoietic cell lines was noted in 2 pts (15%). The median time to hematological engraftment was 17 days after stem cells boost. The current actuarial 9-year survival rate is 76% (Fig.1). In only one case, 8 months after stem cell boost, a relapse of aplastic anemia developed, requiring a second allo-HSCT. Three pts died as a result of infectious complications. Acute graft-versus-host disease was diagnosed in 3 pts (23%): grade I (skin, liver) and chronic GvHD in 5 pts (38%) (limited n=4, extensive n=1).

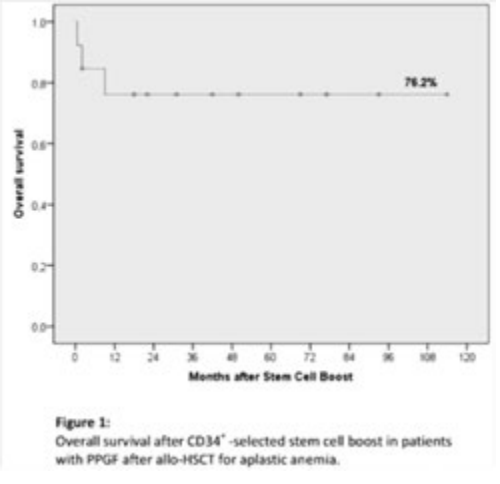

Figure 1.

Summary/Conclusion: The use of $CD34^+$-selected peripheral blood stem cell boosts from the original donor allows a rapid regeneration of hematopoiesis in the majority of aplastic anemia patients with PPGF after allo-HSCT. Infectious complications might be decreased by deciding on early stem cell boost and improved anti-infectious prophylaxis in pts with PPGF.

PB2418

ALLOGENEIC TRANSPLANTATION FOR HODGKIN'S LYMPHOMA IN THE BRENTUXIMAB VEDOTIN ERA: A RETROSPECTIVE ANALYSIS OF THE RETE EMATOLOGICA PUGLIESE (REP) EXPERIENCE

F. Gaudio[1,*], P. Mazza[2], A.M. Carella[3], D. Pastore[4], A. Mele[5], G. Palazzo[2], P. Carluccio[1], G. Pisapia[2], N. Cascavilla[3], G. Specchia[1]

[1]Hematology, Bari, [2]Hematology, Taranto, [3]Hematology, San giovanni Rotondo (FG), [4]Hematology, Brindisi, [5]Hematology, Tricase (LE), Italy

Background: Patients with Hodgkin's lymphoma (HL) progression after autologous stem cell transplantation (SCT) have a very poor outcome. Brentuximab vedotin (BV), an anti-CD30 targeting antibody-drug conjugate, has been studied in this patients setting. Allogeneic SCT is the only strategy with a curative potential.
Aims: This study reports a retrospective analysis of the multicenter experience of the Rete Ematologica Pugliese (REP) over the past 16 years with the aim of comparing the patient characteristics and outcomes of 22 BV pretreated patients with those of 45 patients who received reduced intensity conditioning (RIC) allogeneic SCT without prior BV, in the time period fetore the drug was available (pre-BV era).
Methods: 67 patients with a histologically confirmed diagnosis of HL who underwent allogeneic SCT from 2000 to 2016 were retrospectively studied. The median age was 34 years (range 16-57 years) and 36 (54%) were male. At the time of allogeneic SCT, 28 (42%) patients had chemosensitive disease and 39 (58%) were chemorefractory. All the patients received reduced-intensity conditioning, 52% received matched sibling donor and 48% matched-unrelated donor grafts.
Results: Of the 26 patients with chemosensitive disease, 18 (70%) achieved CR, 7 (27%) had PR or stable disease and 1 (3%) had progressive disease. Of the 36 patients with chemorefractory disease 7 achieved CR (20%), 26 had PR or stable disease (72%) and 3 (8%) had progressive disease. Following transplantation, 40 patients relapsed or progressed at a median time of 6.3 months (range 1- 59 months) post-transplant. After a median follow-up of 38 months (range 3-195 months) 41 patients remain alive and 26 have died. There were no significant differences between groups in terms of engraftment or acute/chronic GVHD incidence. For the BV-treated group, the 2-year PFS was 59%, 2-year OS was 72%, 1-year NRM was 10%, and the 2-year relapse/progression incidence was 24%. In the no-BV group the 2-year PFS was 42%, 2-year OS was 60%, 1-year NRM was 18%. The cumulative incidence of relapse/progression at two years was 58%. Patients in the BV group had a lower median SCT-CI score, higher percentages of patients in CR and fewer peri-transplant toxicities.
Summary/Conclusion: Allogeneic SCT may be an effective salvage strategy for patients who suffer relapse after autologous SCT. Use of the salvage treatment BV yields improved responses over conventional multi-agent chemotherapy with less toxicity, thereby providing better candidates for allogeneic SCT. The impressive activity of novel regimens, such as PD1 inhibitors, has the potential to further enhance responses and survival in HL patient.

PB2419

POST HARVEST PRODUCT HPC AS A COST-EFFECTIVE SURROGATE MARKER FOR CD34+ CELL COUNT IN ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANT SETTING

A. Jamal[1,*], M.T. Khan[2], S. Parveen[3], Q. Rizvi[1], T. Farzana[1], U. Zaidi[1], M. Borhany[1], S. Munzir[4], I. Ghafoor[5], M. Saud[4], S. Ansari[1], T. Shamsi[1,5]

[1]Clinical Haematology & BMT, National Institute of Blood Disease and Bone Marrow Transplantation, [2]School of Public Health, Dow University of Health Sciences, [3]Research and Development, [4]Transplant Immunology, [5]Apheresis and Stem Cells, National Institute of Blood Disease and Bone Marrow Transplantation, Karachi, Pakistan

Background: Allogeneic haematopoietic stem cells transplant provides the only chance of cure for various haematological disorders. Success of bone marrow transplant relies on the infusion of appropriate dose of haematopoietic progenitor cells (HPC) *i.e.* a minimum CD34+ cell count of $>2x10^6$ CD34+ cells/kg of recipient's body weight. Enumeration of CD34+ cells by flowcytometry is a universally accepted reliable indicator of HPC. However, it is an operator-dependent costly procedure with a turnaround time of few hours. Sysmex automated haematology analyzers (XN-1000) segregate an immature myeloid population referred to as haematopoietic progenitor cells (XN-HPC).It is a non-operator dependent cost-effective procedure with a turnaround time of 90 seconds. Incipient statistics of various studies have suggested good correlation between XN-HPC and CD34+ cell count.
Aims: To elucidate the role of XN-HPC as a reliable and cost-effective surrogate of CD34+ cells in post-harvest products in allogeneic bone marrow transplant setting.
Methods: A cross sectional analytical study was conducted at the National Institute of Blood Disease & Bone Marrow Transplantation from Dec'2012 - Dec'2016. Eighty four patients, with various benign and malignant haematological diseases, and their matched related donors were recruited in the study. Donors were primed with injection GCSF 10ug/kg body weight subcutaneously for 4 days to mobilize stem cells. Peripheral blood apheresis was performed on day 5 to achieve the minimum target of $>2x10^6$ CD34+ cells/kg of recipient's body weight. HPC, and CD34+ cell count of peripheral blood apheresis (post-harvest) product was performed by Sysmex XN-1000, and BD FACSCalibur respectively. Statistical analyses were performed using STATA version 11. Spearman's rank correlation coefficient (p) and Receiver Operating Characteristic (ROC) curve were plotted to identify HPC value to optimally distinguish the cut-off of ≥2million CD34+ cells/kg of recipient's body weight.

Results: Eighty-four healthy donors underwent peripheral blood stem cell harvest. Median age of the donors was 21 years. The most common benign and malignant diseases were Aplastic anemia (27%) and Acute myeloid leukemia (11%) respectively. Multiple XN-HPC cut-off values were computed for the CD34+ cell count of ≥2 × 10^6/kg of recipient's body weight to establish evaluable sensitivity and specificity of XN-HPC. The XN-HPC cut-off of 0.049×10^3/ul has a sensitivity and specificity of 96.3% and 09% respectively, whereas the HPC cut-off of 0.87×10^3/ul has a sensitivity and specificity of 47.5% and 82% respectively. Despite a weak correlation between HPC and CD34 (p=0.18, p-value=0.104), the ROC curve analysis showed area under the curve (AUC) of 0.71 (95% CI; 0.58-0.84, p-value=0.023) highlighting the possible potential of XN-HPC to serve as a cost effective surrogate for CD34+ cell count.

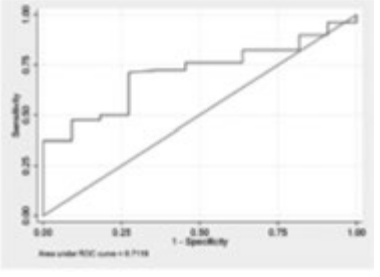

Figure 1.

Summary/Conclusion: Our results demonstrated a statistically significant p value of <0.05 that points towards the possible prognostication potential of XN-HPC for CD34+ cell count, in post-harvest products, in allogenic bone marrow transplant setting. A larger sample size will help in further elucidating the relationship of post-harvest product XN-HPC and CD34+ cell counts.

PB2420

INFLUENCE OF RABBIT ANTI THYMOCYTE GLOBULIN (ATG) AS PART OF CONDITIONING REGIMEN ON CMV REACTIVATION IN ALLOGENEIC STEM CELL TRANSPLANT RECIPIENTS

U. Zaidi*, S.H. Ansari, S. Parveen, D. Zahid, T. Farzana, T. Shamsi

National institute of blood disease and bone marrow transplantation, Karachi, Pakistan

Background: Anti thymocyte globulin (polyclonal anti T cell antibody preparation) is used in pre transplant conditioning regimen to reduce the risk of GvHD and graft rejection emanating from allo-reactivity of donor and recipient, which is reduced by CD34+ lymphocyte depletion. ATG has improved overall survival due to better GvHD prophylaxis. On the other hand, T-cell depletion regimen (ATG) increases the risk of opportunistic infections and hence increase transplant related mortality. Cytomegalovirus (CMV) infection or antigenemia is a significant risk factor in transplant related morbidity and mortality.
Aims: To determine if GvHD prophylaxis with r-ATG increased CMV reactivation 100 days post-transplant in allogeneic stem cell transplant recipients. The primary outcome will be the incidence of CMV at 100 days.
Methods: This retrospective study evaluated patients who received an allogeneic stem cell transplant for malignant and non malignant hematological disorders from June 2015 to 2017, at National Institute of Blood Disease and Bone Marrow Transplantation. Pre Transplant CMV serology was performed in all donors and recipients. All recipients received leucodepleted blood products and oral Acyclovir for CMV prophylaxis. CMV antigen by PCR was routinely done twice weekly in all patients. For preemptive treatment of CMV ganciclovir was offered to all patients with >100copies/ml.
Results: 100 patients with hematological disorders included: Thalasemia major (n=44), Aplastic anemia (n=30), Fanconi Anemia (n=8), Acute myeloid leukemia (n=7), Chronic myelogenous leukemia (n=2), Paroxysmal nocturnal hemoglobinuria (n=2),acute lymphoblastic leukemia (n=1), Gaucher's Disease (n=1) and Myelodysplastic syndrome (n=1), PRCA (n=1), Sideroblastic Anemia(n=1), severe combined immunodeficiency (n=1), Hemophagocytic lymphohistiocytosis (n=1). Mean age of patient at time of transplantation was 10.45±9.2years, 9 patients underwent haplo-identical and 91 were full matched allergenic bone marrow transplantation. Neutrophil and platelet engraftments were achieved in median days of 13(10-29) and 16(10-42) respectively. CMV reactivation was observed in 38/64(59%) patients who received ATG based conditioning regimen *versus* 14/36(39%) patients who did not receive ATG which was clinically and statistically significant. Median duration of CMV reactivation was 13(range=1-42) days post transplant. Treatment related neutropenia (grade II-III) was observed in 7 patients after ganciclovir therapy.CMV infection (Pneumonitis) was documented in 1 patient. Acute GvHD of gut and skin was observed in 7 and 1 patient respectively. Secondary graft failure was observed in 3/52(5.7%) CMV positive and 2/48 (4.2%) in patients with negative CMV.
Summary/Conclusion: CMV reactivation is increased when r-ATG is used as part of the conditioning regimen for GvHD prophylaxis. Large number of patients and follow-up over longer period of time data is still needed to establish CMV as a risk factor for secondary graft failure in allogeneic transplant recipients.

PB2421

AUTOLOGOUS HEMATOPOIETIC STEM CELLL TRANSPLANTATION AS A SALVAGE THERAPY IN RELAPSED/REFRACTORY DLBCL PATIENTS – A SINGLE CENTRE EXPERIENCE

M. Wach*, M. Cioch, D. Jawniak, J. Manko, A. Walter-Croneck, W. Legiec, E. Wasik-Szczepanek, O. Czabak, A. Szczepanek, M. Hus

Klinika Hematoonkologii i Transplantacji Szpiku, SPSK [1], Lublin, Poland

Background: Diffuse large B-cell lymphoma (DLBCL) is one of the most frequent non-Hodgkin lymphpmas (NHL) accounting for about 30% of all newly diagnosed cases and more than 80% out of aggressive lymphomas. Outcome of initial therapy has improved over the last decade but approximately 10-15% of patients present primary refractory disease and additionally 20-25% out of them will relapse. Salvage chemotherapy followed by autologous hematopoietic stem cell transplantation (AHSCT) is still the standard second-line treatment for refractory/relapsed DLBCL.
Aims: The aim of the study is to present chemosensitive patients with relapsed/refractory DLBCL who underwent AHSCT at our centre between December 1997 and October 2017.
Methods: We evaluated 81 patients; there were 35 male and 46 female. Median age was 42.6 years (range; 18.0-69.7) .Most patients were diagnosed as DLBCL NOS-63 pts. (78%), as Primary Mediastinal Large B-cell Lymphoma-12 pts. (15%), as Primary DLBCL of central nervous system-2 pts. (2%), T-cell /histiocyte –rich large B-cell lymphoma -1 pt.(1%) and as Anaplastic ALK+ large B-cell lymphoma-3 pts. (2%). They received median 2 lines of induction therapies (range; 1-4); most were treated with R-CHOP and R+/R-/-DHAP. 34% patients achieved complete (CR), 53.2% partial remission(PR) and 12.8% had progression before transplantation.
Results: In all 81 patients stem cell collection was performed from peripheral blood (100%). The standard conditioning regimen BEAM(BCNU, Etoposide ,Ara-C and Melphalan) was given to 80 patients, 1 received CBV (BCNU,Cyclophosphamide, Etoposode). A median number of 3.8 CD34+ cells/kg (range; 1.6-8.0) were infused. All patients were engrafted with a median time to achieve an absolute neutrophil count>0.5x109/L of 12 days (range; 8-36) and to platelets>20x10/9/L of 13 days (range: 7-36). The complications grade 3 and 4 seen in transplanted patients inculded; mucositis (n=69), bacterial infection (n=5), viral infection (n=4), hemorrhage of CNS in 2 patients (they alive). Transplant related mortality (TRM) was 6.3%. The overall response rate(OS) was 90%. 62% patients achieved CR, 28% PR and 10% stayed in progrssion after AHSCT.The median overall survival (OS) was 47,1 months (median: 3.13-237.9). The median of disease free survival (DFS) was 40.1 months (median; 2.97-237.9).
Summary/Conclusion: Conclusion: AHSCT is highly effective and safe procedure for refractory/relapsed DLBCL patients .Novel agents incorporated in AHSCT programm will be helpful in every part of it; as an induction chemotherapy, preparative regimen and maintenace therapy to improve the results of DLBCL patients, refractory even to AHSCT.

PB2422

BEAC (CARMUSTINE, ETOPOSIDE, CYTARABINE, AND CYCLOPHOSPHAMIDE) IS A SAFE AND EFFECTIVE CONDITIONING REGIMEN IN AUTOLOGOUS HEMATOPOIETIC CELL TRANSPLANTATION FOR LYMPHOMA

I. Sakellari*, S. Bouziana, E. Gavriilaki, V. Constantinou, D. Mallouri, M. Iskas, A. Vardi, A. Marvaki, I. Batsis, D. Sotiropoulos, A. Anagnostopoulos

Hematology Department - BMT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece

Background: Melphalan and Carmustine (BCNU) are key components of

the gold standard conditioning regimen (BEAM) for autologous hematopoietic cell transplantation (AHCT) in Hodgkin (HL) and Non-Hodgkin (NHL) lymphoma patients. However, given their limited availability over the last decade, we have administered alternative conditioning regimens including intravenous Busulfan (BuEM) instead of BCNU and then, Cyclophosphamide (BEAC) instead of Melphalan. Although BuEM has been well tolerated and highly efficacious compared to the gold standard BEAM regimen, BEAC has not been extensively studied.
Aims: We aimed to determine the safety, toxicity and efficacy of BEAC in AHCT for lymphoma.
Methods: We enrolled consecutive lymphoma patients that received BEAC (Carmustine 300mg/m^2, Etoposide 800mg/m^2, Cytarabine 800mg/m^2, and Cyclophosphamide 140mg/kg) between 2016 and 2017. As a control group, we studied consecutive lymphoma patients that had been transplanted using BuEM (Busilvex 9.6mg/kg, Etoposide 800mg/m^2 and Melphalan 140mg/m^2) in our center between 2011 and 2013.
Results: In total, 33 patients received BEAC and 67 BuEM with no significant difference in baseline characteristics (Table).

Table 1.

	BEAC	BuEM	p-value
Age (years)	42 (17-64)	34 (18-65)	0.146
Hodgkin Lymphoma (%)	64	61	0.813
Relapsed/refractory disease (%)	21	21	0.998
Chemosensitive disease (%)	69	52	0.140
Infused CD34 (x10^6/kg)	6.3±3.7	6.4±3.4	0.900

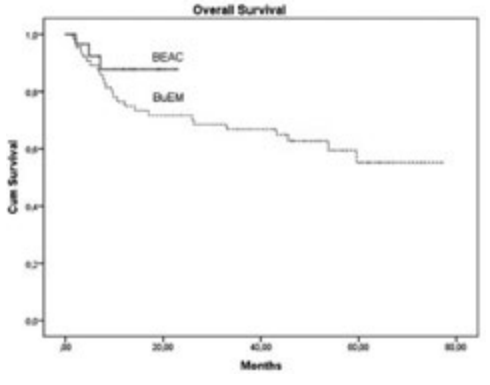

Figure 1.

Days of neutrophil (p=0.657) and platelet (p=0.572) engraftment or transfusion needs (p=0.114 for red blood cell units and p=0.135 for platelets transfused) were also similar between BEAC and BuEM patients. BEAC resulted in significantly lower toxicity regarding infection rate (51.5% *versus* 91%, p<0.001) and WHO grade 3-4 mucositis (p<0.001), gastrointestinal (p=0.025) and liver toxicity (p=0.013). Regarding outcomes, there was no difference in disease status at +100 or at last follow-up. Furthermore, no significant difference was found in the percentage of patients receiving adjuvant therapy post-transplant (p=0.492). Among them, BuEM patients received only radiation; whereas 6 BEAC patients received also adjuvant therapy with brentuximab according to current indications. With a median follow-up of 7.2 (0.8-22.9) months for BEAC and 44.9 (2.3-77.1) for BuEM, relapse mortality was similar between regimens (p=0.626). 1-year overall survival (OS) was 92.4% and 87.6% respectively (Figure, p=0.186). In the multivariate model, OS was significantly associated with diagnosis of HL (p=0.001) and chemosensitive disease (p=0.005).
Summary/Conclusion: BEAC resulted in lower toxicity and similar outcomes compared to BuEM regimen in lymphoma patients with similar pre-transplant characteristics. Outcomes were also comparable to our previously published experience with the gold standard BEAM regimen. Therefore, BEAC emerges as a feasible alternative conditioning regimen in AHCT for lymphoma.

PB2423

MESENCHYMAL STEM CELLS CAN BE DEMONSTRATED BY FLOW CYTOMETRY IN THE G-CSF MOBILISED PERIPHERAL BLOOD OF PATIENTS UNDERGOING PERIPHERAL BLOOD STEM CELL TRANSPLANTATION

A. Jain[1,*], A. Khadwal[1], M.S. Sachdeva[2], P. Malhotra[1], N. Varma[2], S. varma[1], G. Prakash[1], D. Lad[1]

[1]Internal medicine, [2]Haematology, Postgraduate institute of medical education and research, Chandigarh, India

Background: Mesenchymal stem cells (MSCs) possess unique properties of self-renewal, wide differentiation potential and an immunosuppressive effect, are enriched in the bone marrow and their isolation relies on culture in special media.
Aims: Present study aimed to demonstrate MSCs in the peripheral blood (PB) of individuals undergoing hematopoietic stem cell transplant (HSCT) using flow cytometry and correlate their counts with the post-transplant outcomes.
Methods: A total of 33 subjects which included autologous arm (n=25) [patients of MM (n=20), lymphoma (n=5)] and allogeneic arm (n=8) [healthy donors of patients undergoing allogeneic HSCT] during the period extending from 1-1-2016 to 30-06-2017 were prospectively included in the study. Baseline PB sample of the eligible subjects was analyzed for MSCs by flow cytometry. Stem cell mobilization of the subjects was done using granulocyte-colony stimulating growth factor (G-CSF, given for 4 days @ 10mcg/kg/day). Two milliliters of PB sample was analyzed for CD34 and MSC counts using a panel of monoclonal antibodies (CD34-APC, CD45-APC H7, CD73-PE, CD90-FITC and CD105-PE-Cy7) immediately prior to the apheresis. MSCs were defined by an absence of CD34/CD45 and any dual positivity for CD90/73/105. Mononuclear cells were harvested using cell separator and 3 ml of sample from the apheresis product (AP) was analyzed for CD34 and MSC by flow cytometry. Subjects with inadequate CD34 count after the first apheresis (<2x10^6/kg) underwent a second procedure next day after receiving G-CSF (10 mcg/kg/day) and a single dose of plerixafor (0.24mg/kg, given 8 hours prior to the procedure). CD34 and MSC were analyzed by flow cytometry at day 6 (both PB and AP). AP with a minimum of 2.0x10^6/kg CD34 dose was infused to the patient following conditioning. Patients were followed up for a minimum of 100 days post-HSCT and complications in the post-transplant period were recorded till the last follow up. Analyses were conducted using IBM SPSS statistics (version 22.0).
Results: Baseline MSCs were seen in 14 (42%) subjects. The mean baseline MSC (PB) (x10^{-4})% in the autologous and allogeneic group was 19.7±41.83 and 7.9±9.95 respectively (p-0.852). Patients with baseline MSC (PB) had a higher mean MSC (PB) at D5 and D6 (p-<0.001 and 0.030 respectively). Overall 19 (58%) subjects had MSCs at D5 (PB). Administration of more chemotherapy cycles was associated with an absence of D5 MSCs (PB) in patients of MM (p-0.045). A total of 17 (52%) subjects had D5 MSC (AP). Mean D5 MSC (AP) (x10^{-4}%) in the autologous and allogeneic groups was 5.4±8.7 and 25±39 respectively (p-0.019). Patients with D5 MSC (AP) had a trend towards requiring anti-fungal drugs for a greater duration (p-0.051). Only 6 (18%) patients had detectable D6 MSC (PB). Patients with D6 MSC (PB) required anti-fungal drugs for a greater duration (p-0.041) and had a lesser duration of GI mucositis (p-0.015). A total of 6 (18%) subjects had D6 MSC (AP). Post-HSCT events were not associated with the D6 MSC (AP) except for a greater duration of anti-fungal drug requirement (p-0.041). Day-100 outcome of MM patients was significantly associated with D5 MSC (AP) and D6 MSC (PB) (p-0.043 and 0.046 respectively). No significant difference was found between the type of chemotherapy received by MM and lymphoma patients and baseline, D5 (PB/AP) and D6 (PB/AP) MSC.
Summary/Conclusion: MSCs can be demonstrated by flow cytometry in the PB and AP of individuals undergoing HSCT. MSC count in the PB and AP correlates with post-HSCT events.

PB2424

THE PROGNOSTIC ROLE OF E2A-PBX1 EXPRESSION DETECTED BY RQ-PCR IN B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Y. Hong*, X. Zhao, Y. Qin, S. Zhou, Y. Chang, Y. Wang, X. Zhang, L. Xu, X. Huang

Peking University People's Hospital, Beijing, China

Background: The *E2A-PBX1* rearrangement is common in B-cell acute lymphoblastic leukemia (B-ALL). However, whether this fusion gene can be used as a reliable marker for minimal residual disease (MRD) following allogeneic hematopoietic stem cell transplantation (allo-HSCT) remains unknown.
Aims: The aim of this study was to investigate the clinical characteristics of *E2A-PBX1*(immunoglobulin enhancer binding factor-pre-B leukemia) fusion gene in patients with acute lymphoblastic leukemia (ALL) after allogeneic stem cell transplantation (allo- HSCT).
Methods: Clinical data were collected from 28 consecutive B-ALL patients who received allo-HSCT. The *E2A-PBX1* gene was examined by real-time

quantitative polymerase chain reaction (RQ- PCR). The correlation between its expression level and the disease status was analyzed.
Results: The median follow-up was 374d (55-2342d). Of the enrolled patients, 7 (25%) patients died of leukemia relapse. A total of 9 (32.1%) patients experienced relapse at a median of 164d (75-559d) after transplantation. The median expression level in the first positive sample was 0.14% (0.0071-902.4%). The duration from *E2A-PBX1*-positive results to hematological relapse was 74d (30-469d). *E2A-PBX1* expression generally became positive prior to flow cytometry. Patients with positive *E2A-PBX1* gene expression pre-transplantation were more likely to have positive *E2A-PBX1* expression after transplantation.

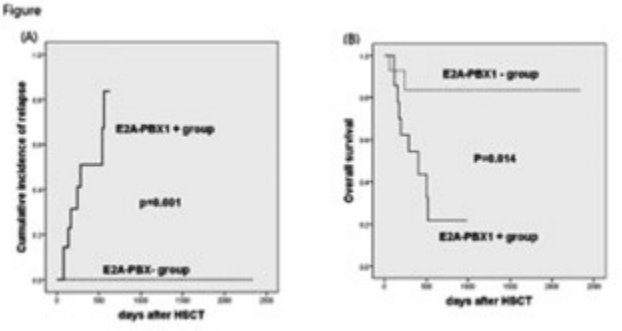

Figure 1.

Summary/Conclusion: *E2A-PBX1* expression determined by real-time quantitative reverse-transcriptase polymerase chain reaction (RQ-PCR) could be used to evaluate MRD status after allo-HSCT. Patients with positive *E2A-PBX1* expression after transplant will have a poor prognosis.

PB2425

HIGH DOSE THERAPY AND AUTOLOGOUS PERIPHERAL BLOOD STEM CELL TRANSPLANTATION FOR NON-HODGKIN LYMPHOMA MALAYSIAN HOSPITALS EXPERIENCE

N.A. Anuar[1,*], K. Tey[1], A. Teh[2], M.H.F. Abdul Rahman[2], S.C. Ng[2], P.C. Bee[1], G.G. Gan[1]

[1]Haematology, University of Malaya Medical Centre, Kuala Lumpur, [2]Haematology, Sime Darby Medical Centre, Subang Jaya, Malaysia

Background: High dose therapy (HDT) followed by autologous hematopoietic stem cell transplantation (AHSCT) is recognized as a standard of care for relapsed/refractory Non-Hodgkin Lymphoma (NHL).There are many studies which have demonstrated improved disease free survival(DFS) and overall survival(OS) with AHSCT in these patients. There have been also several studies which reported better outcome in patients with high risk NHL who had upfront AHSCT.
Aims: This study aims to determine if upfront AHSCT do improve patients' clinical outcome in Malaysia.
Methods: This is a retrospective study where patients who had undergone AHSCT from October 1997 to September 2017 in 2 major hospitals in Malaysia were included. Patients' demographic data and clinical information were collected. The risk groups were categorized into 2 groups; whereby IPI score of 0-2 were defined as low risk and IPI score of 3-5 were considered as high risk.
Results: A total of 169 patients (male: female 105:64) were included. Majority of patients had B cell lymphoma (85.8%) while the rest had T cell lymphoma (14.2%). The median age at diagnosis was 46 (ranges from 15-69) years. The median period of diagnosis to AHSCT was 10 (range 3-111) months. Majority of patients (89.3%) were transplanted in complete remission (CR) and the remaining (10.7%) in partial remission (PR). Majority of patients (61%) who were transplanted were in first CR. 68% of patients were categorized as low risk and 32% patients were categorized as high risk. Conditioning regimens used were: BEAM (n=107), Benda-EAM (n=17), BEAC (n=12), TEAM (n=11), TBI-Cyclo (n=6), Thiotepa-BuCy (n=5), CBV (n=4), BuCy (n=4) and C/L-EAM (n=3). The mean CD34+ cell dose infused was $8.8x10^6$/kg (ranges 1.53 to $72.3x10^6$/kg). The median duration of platelet count remaining <$30x10^6$/L and white cell <$1.0x10^9$/L were both 8 days respectively. The mortality rate during follow up was 28%; 3% were due to transplant related mortality and the remaining were from progressive disease. The two years OS for patients transplanted in first CR, second CR, and PR were 87%, 67.8%, 29.4% respectively, (p≤0.0001). The two years event free survival (EFS) for patient transplanted in first CR, second CR, and PR is 81.5%, 52.5%, 17.6% respectively, (p≤0.0001). Using Cox regression analysis, remission status at transplantation was shown to have a significant effect on OS and EFS. Patients who were transplanted at first CR regardless of their IPI risk status had a significantly better OS and EFS compared to the others, p<0.001. The IPI risk status did not demonstrate any significant effect in OS and EFS.
Summary/Conclusion: This study demonstrated that upfront AHSCT should be considered in patients with NHL regardless of their IPI risk status.

PB2426

CYTARABINE IS MORE EFFECTIVE THAN CYCLOPHOSPHAMIDE AS A STEM CELL MOBILIZATION REGIMEN IN MULTIPLE MYELOMA

L. Adamusová[1,2], T. Jelínek[1,2,3,*], M. Šimíček[1,2,3], M. Navrátil[1], M. Kaščák[1], H. Plonková[1], J. Mihályová[1], J. Ďuraš[1], I. Tvrdá[1], Z. Kořístek[1,3], R. Hájek[1,3]

[1]Department of Haematooncology, University Hospital Ostrava, [2]Faculty of Science, [3]Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic

Background: High dose melphalan followed by autologous hematopoietic stem cell transplantation (HSCT) was established as a standard of care for patients under the age of 65 with newly diagnosed multiple myeloma (MM). Current hematopoietic stem cell (HSC) mobilization strategies in patients with MM are based on administration of granulocyte-colony stimulating factor (G-CSF). Intermediate doses (1-5g/m^2) of cyclophosphamide (Cy) are given prior G-CSF in most European transplant centers in order to increase the yield of HSC collection. Nevertheless, mobilization with intermediate doses of cytarabine (AraC) followed by G-CSF was shown to be very effective alternative mobilization regimen (Giebel 2013).
Aims: To retrospectively compare the efficacy and toxicity of two mobilization regimens, Cy+G-CSF and AraC+G-CSF, used in patients with newly diagnosed MM.
Methods: 70 consecutive patients with MM (46 males, 24 females, median age of 62 years, from 37 to 71) mobilized between July 2014 and August 2017 either by Cy+G-CSF (n=30), or by AraC + G-CSF (n=40) were included in the analysis. Cy group: Cy 2,5g/m^2 day 1 followed by G-CSF. AraC group: AraC 400mg/m^2/12h day 1-2 followed by G-CSF. In both regimens the G-CSF was given from day 5 until the end of apheresis at the dose of 10µg/kg/day divided into two daily doses (rounded to the whole ampoules). HSC collections were performed using Spectra Optia cell separator (Terumo BCT, USA). Standard mobilization efficacy (complete blood count, CD34$^+$ cells) and apheresis product quality controls (complete blood count, CD34$^+$ cells, CFU-GM) were performed. The primary endpoint for HSC collection was to harvest ≥$10x10^6$ CD34$^+$/kg, which was considered to have enough HSC for 4 high-dose chemotherapies followed by autologous HSCT.
Results: Peak levels of circulating CD34$^+$ cells in peripheral blood were significantly higher in the AraC group compared to Cy group (368 *vs* 99 CD34$^+$ cells/µL, means, p<0.0001). Mean number of apheresis per patient was 1.2 in AraC group compared to 2.1 in Cy group. Single apheresis was sufficient to collect target amount of CD34$^+$ cells (≥$10x10^6$/kg) in 83% of patients in the AraC group compared to 17% of patients in the Cy group, and ≥$10x10^6$ CD34$^+$/kg was collected in 98% patients in the AraC group compared to 57% of patients in Cy group. CD34$^+$ cell yield was significantly higher in the AraC group compared to Cy group ($27x10^6$ *vs* $5x10^6$ CD34+/kg, means, p<0.0001). Numbers of collected CFU-GM were also significantly higher in the AraC group ($404x10^4$/kg *vs* $109x10^4$/kg, means, p<0.0001). Mobilizations with AraC were well tolerated. It should be emphasized that 50% of patients from AraC group developed Gr.4 thrombocytopenia compared to 7% in Cy group. This resulted into the higher need of platelet transfusions in the AraC group (48% *vs* 10% of patients), however no serious hemorrhagic complications were observed. Times to engraftment after transplantations did not differ between both groups of patients.
Summary/Conclusion: Mobilization regimen AraC + G-CSF was significantly more efficient compared to commonly used mobilization regimen Cy + G-CSF. Safety profile of AraC is acceptable, except of higher rate of Gr. 4 thrombocytopenia, which resulted in need of platelet transfusions in half of patients mobilized by AraC + G-CSF. We conclude, that mobilization with AraC could be considered as a safe and very efficacious alternative to Cy in patients with MM when more than 2 autologous HSCT are anticipated.

PB2427

REDUCED RISK OF SINUSOIDAL OBSTRUCTION SYNDROME OF THE LIVER AFTER BU-CY CONDITIONING BEFORE ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION, A RESULT OF PERSONALIZED DOSE ADJUSTMENT

M. Remberger[1], I. El-Serafi[1,2,3,*], P. Ljungman[4], O. Ringdèn[5],

J.K. Törlén[1], M. Sundin[6], A. Björklund[4], J. Winiarski[6], J. Mattsson[1,7]

[1]Oncology-Pathology, Karolinska Institutet, Stockholm, Sweden, [2]Biochemistry, Port-Said University, Port-Said, Egypt, [3]Clinical and Experimental Medicine, Linköping University, Linköping, [4]Medicine, Huddinge, [5]Laboratory Medicine, [6]Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden, [7]Hematology, Oslo University Hospital, Oslo, Norway

Background: Sinusoidal obstruction syndrome/veno-occlusive disease of the liver (SOS/VOD) has been a common and potentially life-threatening complication after allogeneic hematopoietic stem cell transplantation (HSCT).
Aims: To study the effect of busulfan dose adjustment during conditioning prior to HSCT on the patients' risk for developing SOS/VOD and the clinical outcome.
Methods: We focused on patients undergoing myeloablative conditioning with oral busulfan (16mg/kg) and cyclophosphamide (120mg/kg) (Bu-Cy) before allogeneic HSCT during 1990-2015. Since the end of 1990's dose adjustment based on pharmacokinetic analysis has been performed for busulfan. Norethisterone therapy was discontinued in 1998. Most patients had a hematological malignancy. Median age was 34 years (<1-61). A matched related donor was used in 164 patients, a matched unrelated donor was in 166 and a mismatched donor was in 42 patients. Stem cell source was bone marrow (BM) (n=157), peripheral blood stem cells (PBSC) (n=195) and cord blood (CB) (n=20). The majority of patients received cyclosporine and methotrexate as GVHD prophylaxis. SOS was diagnosed according to the Baltimore criteria.
Results: SOS/VOD of the liver was diagnosed in 26 patients (7.0%). Patients receiving PBSC had a SOS/VOD incidence of 3.1% compared to 10.8% and 15.0% in patients given BM and CB, respectively (P=0.006). The incidence of SOS/VOD decreased gradually over time with the highest incidence 1995-99, 14.7% compared to 2.3% during 2010-2014. In multivariate analysis, use of PBSC (P=0.01) and patients in CR1/CP1 (P=0.027) was protective. Overall survival at one year was 46% *vs* 77% in patients with or without SOS/VOD (P<0.001).
Summary/Conclusion: With appropriate management steps the incidence of SOS/VOD may be decreased.

PB2428

MODIFIED BUCY VERSUS BEAM FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANTATION IN LYMPHOMA: CASE PAIR COMPARATIVE ANALYSIS ON TOXICITY AND EFFICACY

H. Huang[1,*], L. Zhang[1], Y. Jiang[1], Z. Jin[1], C. Li[1], J. Ruan[2], D. Wu[1]

[1]Department of Hematology, The First Affiliated Hospital of Soochow University, Suzhou, China, [2]Division of Hematology and Medical Oncology, Weill Cornell Medical College, New York-Presbyterian Hospital, New York, United States

Background: High-dose chemotherapy (HDC) followed by autologous stem cell transplantation (auto-SCT) is superior to conventional chemotherapy in a subgroup of newly diagnosed and relapsed/refractory lymphomas. And BEAM (semustine, etoposide, cytarabine, and melphalan) is one of the most commonly used conditioning regimens. However, the source of melphalan is restricted in China. The conditioning regimen of modified BuCy (busulfan, cyclophosphamide, semustine and cytarabine, mBuCy) has been widely used as the myeloablative regimen for AML and is well tolerated and has shown good efficacy. However, there are limited datum on the efficacy and safety of the mBuCy conditioning regimen in lymphoma auto-SCT. And whether this mBuCy conditioning regimen can be safely used as an alternative to BEAM in lymphoma was uncertain.
Aims: To evaluate the efficacy and toxicity of mBuCy and BEAM regimens.
Methods: From February 2014 to November 2017, a total of 70 Hodgkin's lymphoma (HL) and non-Hodgkin's lymphoma (NHL) patients underwent HDC with mBuCy (n=27) or BEAM (n=43), followed by auto-SCT in our center. As far as the patient's disease status at time of auto-SCT is concerned, we made a 1:1 match. In total, 27 pairs of patients were analyzed.
Results: In our study, we found that there were no significant differences in median number of infused CD34+ cells/kg, hospitalization duration, and median units of transfused red blood cells and platelets, as well as the time of platelet engraftment between the two groups. However, neutrophil engraftment was somewhat faster in mBuCy group than that in the BEAM group (median days: 9 days *vs* 9.5 days, p=0.038). When it comes to toxicity, the incidence of nausea/vomiting, hepatic impairment, renal impairment, pulmonary infection and treatment-related mortality was found to be similar in the two groups. However, compared with patients conditioned with mBuCy, patients conditioned with BEAM were more likely to develop mucositis and diarrhea (p=0.029; p=0.040). For grade III-IV mucositis and diarrhea, the incidence rate was higher in BEAM (25.9% *vs* 3.7%; 18.5% *vs* 0%). With a median follow-up of 15.2 months (range, 3.0 - 41.3 months) in the mBuCy group and 34.9 months (range, 4.6 - 48.0 months) in the BEAM group, we compared the 2-year PFS (72.0% *vs* 72.0%, p=0.761) and 2-year OS (84.0% *vs* 77.0%, p=0.783) of the regimens mBuCy and BEAM respectively, which indicated that the two groups were equivalent. Univariate analysis revealed that the International Prognostic Index (IPI) at diagnosis (p=0.046) and the level of serum LDH at transplantation (p=0.002) were the variables associated with PFS. For OS, only the level of serum LDH at transplantation (p=0.010) remained significant. In multivariate analysis, only the level of serum LDH was significantly associated with PFS (p= 0.029, HR: 4.52; 95% CI: 1.17-17.56).

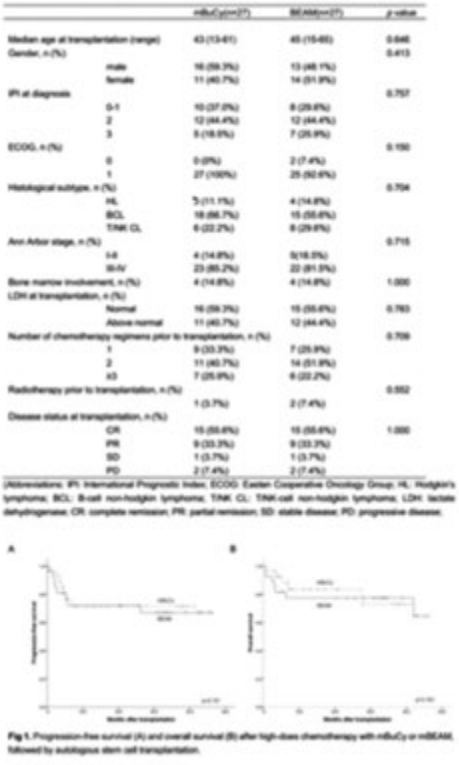

Figure 1.

Summary/Conclusion: Conditioning regimen of mBuCy was found to be well tolerated with acceptable nonhematological toxicity. Patients who underwent auto-SCT after mBuCy had similar survival outcomes and faster neutrophil engraftment than a matched pairs-cohort who underwent auto-SCT after BEAM, indicating that mBuCy can be considered a valid alternative to BEAM.

PB2429

ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION FOR PRIMARY REFRACTORY ACUTE LEUKEMIA PATIENTS: A RETROSPECTIVE GITMO SCORE BASED ANALYSIS

I. Cutini*, C. Nozzoli, A. Gozzini, S. Guidi, I. Donnini, R. Saccardi

Cellular Therapies and Transfusional Medicine Unit, University Hospital, Florence, Florence, Italy

Background: Patients with acute leukemia (AL) who fail to achieve complete remission (CR) have a dismal prognosis. Only few of them can be rescue after allogeneic hematopoietic cell transplantation (HCT). We retrospectively applied the GITMO score for PIF AL patients, that divides patients in 3 different categories; low, intermediate and high risk (Todisco E, BMT 2017).
Aims: Retrospective GITMO score based analysis.
Methods: The study population included 25 patients with AL presented as primary induction failure (PIF) who had received an allogeneic HCT between 1 March 2014 and 30 September 2017 at our institution. Median age was 51 yo. Disease characteristics and prior history of hematological diseased and gender are summarized in Table 1. Patients received myeloablative (n=16) or reduced-intensity conditioning (RIC) regimens (n=9). Median time from diagnosis to transplant was 7 months, (range 0-9 months).
Results: Among PIF AL population 16 belong to low risk group; 7 to intermediate group and 2 to high risk group respectfully. 18 out of 25 were

evaluable on +30 days from transplant: 16 patients achieved complete hematological remission (CHR), 2 patients shown refractory disease. 7 patients died within 2 months (range 0-4 months) from transplant due to multiorgan failure (2 pts), sepsis (3 pts) and engraftment failure (2pts). 12 out of 25 (35%) died due to TRM. Mean OS was 521 days, median OS was 331 days. Only 7 out of 25 patients (28%) are still alive without active disease, mean follow up was 337 days (79-1348 days). Among the three GITMO categories, the mean and median OS was 527 and 364 days, 581 and 341 days, and 262 days for low, intermediate and high risk group respectively (p=0.126). 8 patients experienced aGVHD and 7 patients cGVHD. All patients had received corticosteroids as frontline treatment. Those unresponsive were treated with second-line immunosuppressors. Mean time for developing GVHD was 2 and 4 months for aGVHD and cGVHD respectively. GVHD characteristic was shown in table 1. A trend to a better OS was shown in patients who developed aGVHD (p=0.380) and cGVHD (p=0.219). No impact was shown for CMV sierological status. (p=0,651). No impact was shown for myeloablative *versus* RIC regimens (p=0.983).

Table 2

Summary/Conclusion: The clinical outcome of PIF AL patients is poor and only a minor proportion of patients is rescued by HSCT. GITMO score can be used to create a risk score that helps to identify patients who most likely benefit from the procedure. The availability of reliable prognostic factor is particularly important in the era of alternative donor, such as haploidentical source. The small sample size may prevent to assess more significant differences across the population.

PB2430

OUTCOME OF SECOND ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN ACUTE LEUKEMIA: A SINGLE CENTER EXPERIENCE

T.N. Yigenoglu*, H. Batgi, B. Uncu Ulu, A. Merdin, S. Bascı, M. Bakırtas, J.V. Yıldız, M.S. Dal, M.K. Cakar, D.K. İskender, A.I.E. Tekgunduz, F. Altuntas

Hematology, Dr. Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Ankara, Turkey

Background: Patients with acute leukemia who relapse after their first allogeneic hematopoietic stem cell transplantation (allo-HSCT1) have poor prognosis. Second allo-HSCT (allo-HSCT2) from matched related or unrelated donor or haplo-identical transplantation has been already used as a potentially curative treatment for patients who relapsed after their first allogeneic stem cell transplantation. There is still limited information about alternative donor sources on the efficacy of allo-HSCT2.
Aims: To identify prognostic factors affecting the outcome of second HSCT, we performed a retrospective study on our patients with acute leukemia.
Methods: Data from Dr. Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Stem Cell Transplantation Unit database were retrospectively analyzed.
Results: A total of 319 patients with acute leukemia had received allo-HSCT1 at our center between March 2009 and May 2017. 78 of them relapsed after their first allogeneic stem cell transplantation and 13 of them underwent their second allogeneic stem cell transplantation. The median interval between allo-HSCT1 and allo-HSCT2 was 240 days (range: 120-1800). Patients had acute myeloid leukemia (AML, n=4), T cell acute lymphoblastic leukemia (T ALL, n=4), Philedelphia positive B cell acute lymphoblastic leukemia (Ph+ B ALL, n=3), Philedelphia negative B cell acute lymphoblastic leukemia (Ph neg ALL, n=2). All of the patients received myeloablative conditioning regimen. Donors at allo-HSCT2 were HLA-matched or 1 antigen HLA-mismatched related donor (MRD, n=11) and unrelated donor (URD, n=2). 7 patients were transplanted from the same donor used in their first transplantation while in 6 patients transplantation was performed from alternative donors.Among 13 patients, 1-year overall survival (OS) and progression-free survival (PFS) rate were 46.1% and 23% respectively. Overall survival rates did not differ between patients with varying age, diagnosis, times of relapse, durations between the first transplantation and the relapse, GVHD grade, donor type(same or different, related or unrelated) and EBMT score.
Summary/Conclusion: The outcome of allo-HSCT2 has been still unsatisfactory because of the high rate of TRM and relapse. Outcome of second allogeneic transplantation from an alternative donor is comparable with the second transplantations performed from the same donor.

PB2431

AUTOLOGOUS STEM CELL TRANSPLANTATION OUTCOME IN NEWLY DIAGNOSED TRANSPLANT-ELIGIBLE MULTIPLE MYELOMA IN SIRIRAJ HOSPITAL, BANGKOK, THAILAND: AN 18-YEAR FOLLOW-UP

N. Tungsuksomboon*, C. Kunacheewa, E. Karoopongse

Division of Hematology, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Treatments for multiple myeloma (MM) with induction chemotherapy followed by autologous stem cell transplantation (ASCT) and maintenance therapy have been recommended as the standard approach. Long term follow-up after transplantation and factors associated with progression-free survival (PFS) and overall survival (OS) are not yet elucidated.
Aims: To investigate long term transplantation outcome including OS, PFS and related prognostic factors in patients with newly diagnosed MM who underwent ASCT in a referral university hospital in Thailand.
Methods: A cohort of patients older than 18 years with first diagnosed MM treated with ASCT from 2000 to 2015 were reviewed. We used IMWG criteria to classify the depth of response. All patients received induction regimen(s) comprising 2 or 3 drugs followed by high-dose melphalan before undergoing ASCT. Factors affecting survival were explored using Cox proportional hazard models.
Results: One hundred and twenty-two patients were included. The median follow-up time was 39 (2-115) months. The median age of the cohort was 56 (31-68) years with 45.1% of male. IgG Kappa was the most common type of paraprotein identified. Majority of patients were in ISS stage III (34.4%) followed by stage II and I at 21.3 and 14.8%, respectively. Approximately half of patients (48%) received only 1-drug regimen before ASCT. Most patients (92%) received novel agent(s) for which bortezomib was the most commonly used drug (87%), either as a single agent or in combination. Thalidomide or lenalidomide was used 30% and 18%, respectively. Prior to ASCT; 63.1%, 5.7%, 26.2% and 4.9% of subjects achieved sCR, CR, VGPR and PR, respectively. After ASCT; 68.9%, 4.9%, 23.7% and 3.3% of subjects achieved sCR, CR, VGPR and PR, respectively. There was no transplantation-related mortality. ASCT improved disease response in 22/45(49%) patients who achieved less than sCR before ASCT. After ASCT, 24.6% received consolidation and 52.5% received maintenance therapy. Median OS was 111.3 months while 3-yr OS, 5-yr OS and 10-yr OS were 91%, 74%, and 45% respectively. Median PFS was 53.4 months while 3-yr PFS, 5-yr PFS, and 10-yr PFS were 75%, 43% and 16% respectively. Factors affecting PFS included presence of plasma cells ≥5% in BMA after induction chemotherapy (HR 3.53, 95% CI 1.25-9.93, p=0.017), or after ASCT (HR 4.29, 95% CI 1.23-14.99, p=0.022), achieving less than CR after ASCT (HR 2.32, 95% CI 1.35-3.98, p=0.002), and receiving maintenance therapy (HR 0.35, 95% CI 0.21-0.59, p <0.001). While male (HR 2.10, 95% CI 1.01-4.37, p=0.047) and achieving less than VGPR after ASCT (HR 5.72, 95% CI 1.03-31.67, p=0.046) were affected patients' OS.

Subgroup analysis showed that maintenance therapy had significant benefit for both OS and PFS only in the patients who achieved VGPR after ASCT (OS_HR 0.115, 95% CI 0.03-0.43, p=0.001, PFS_HR 0.12, 95% CI 0.05-0.30, p <0.001). Maintenance with lenalidomide or thalidomide didn't alter PFS (HR 0.71, 95% CI 0.35-2.06, p=0.844). Abnormal SFLC had significantly impacted on PFS (HR 2.15, 95% CI 1.24-3.74, p=0.006).

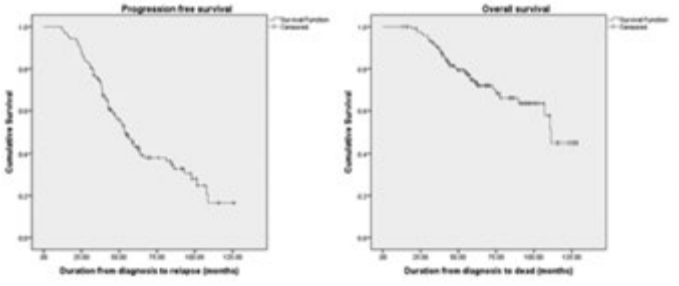

Figure 1.

Summary/Conclusion: We reported almost 10-year overall survival in newly diagnosed multiple myeloma treated with upfront autologous stem cell transplantation. Depth of response, either pre or post stem cell transplantation, determines patients' survival. Moreover, our data revealed that maintenance therapy post transplantation improved clinical outcome, particularly among patients who achieved less than complete response after stem cell transplantation.

PB2432

SEQUENTIAL CLOFARABINE CONTAINING CHEMOTHERAPY WITH REDUCED THIOTEPA BASED CONDITIONING AND T CELL REPLETE HAPLOIDENTICAL STEM CELL TRANSPLANT FOR REFRACTORY MALIGNANCIES: A SINGLE CENTRE EXPERIENCE

A. Garcia Sola*, A. Gallardo, O. Benítez, C. Díaz, M. Ortiz, A. Pascual, A. Rodríguez, M. Pascual

Hospital Regional Universitario de Malaga, Malaga, Spain

Background: A sequential conditioning provides promissing results that has not, otherwise, been validated in haploidentical setting. Only 10-20% of refractory acute myeloid leukaemia (AML) achieve complete remission (CR) with another course of chemotherapy, and less than 20% of OS is reached after a year in this high risk population, this approach could be meant to obtain the best outcome. With similar chemotherapy schemes it has been obtained a 40% OS but still unsatisfactory results due to toxicity.
Aims: We show our experience with clofarabine-based sequential chemotherapy in haploidentical SCT followed by TBF reduced intensity conditioning (RIC-TBF) (thiotepa, busulfan, fludarabine) and post transplant cyclophosphamide (PTCy) plus tacrolimus as graft *versus* host disease prophylaxis (GvHD).
Methods: We collected data retrospectively of 15 cases of refractory/relapsed/progressive haematological malignancies who received clofarabine based sequential conditioning followed by RIC-TBF. As a standard, we have used clofarabine at the dose of 40mg/m^2/day from days -13 to -9 (5 doses), alongside cytarabine 2000 mg/m^2/day. Once the disease burden was reduced, thiotepa 5 mg/Kg/day on days -5 and -4, fludarabine 50 mg/m^2 on days -3 and -2, and busulfan 3.2mg/Kg on day -2 were administered. Only one patient received fludarabine instead of clofarabine for burden mass reducing. As GvHD prophylaxis we combined PTCy 50 mg/Kg/day on days +3 and +4 with tacrolimus in all cases, adding sirolimus in one patient, or mycophenolate mofetil in other two cases. Given the clinical situation, and because all patients lacked a suitable HLA matched donor, an haploidentical donor was selected with a median age of 36 years old (16-62) and a sex ratio male-female of 60%>40%. From our N of 15 patients (median age 39 yrs (6-66), male/female 7/8), the underlying conditions were AML 46.6%, ALL 33.3% and MDS 20%, with disease status pre-transplant of refractoriness in 73.3%, 13.3% relapsed and 13.3% progressed. Sorror HCT -CI scoring was 40%, 40% and 20% for 0, 1 and ≥3 respectively. Disease scoring risk of high/very high (86.7%).
Results: With a median follow up among survivor of 19.3 months an estimated OS and RFS at 13 months of 58.2% and 43.6% respectively. A CR at day +90 was achieved in 80% of the cases (12). In two patients, the test could not be assessed due to early death at days +48 and +57. Four patients (26.7%) relapsed at a median period time of 6 months (range 2-9) and 2 of these died. All together (6 patients) died while 4 of these cases were non leukaemia related. Transplant related mortality of the entire cohort was 26,7%. We had 53.3% of grade ≥3 aGvHD with a median onset at D+55 and cGvHD (at least moderate) in 3 cases (20%) with a median onset of D+302.
Summary/Conclusion: With promising results, even though presenting a small N of 15 patients, a significant reduced disease burden and limited toxicity due to RIC with thiotepa T cell replete haplo SCT, allows to show feasibility with significant OS, RFS rates and a good quality of life (QoL) for patients with a presumed very poor outcome. There are still several challenging goals to achieve, that we need to work on, especially on considering to reduce the incidence of GvHD without incrementing the relapse rate, thus, overall means to improve a QoL, which would be the ultimate target.

PB2433

THE USE OF THE ANTI-EMETIC AKYNZEO FOR AUTOLOGOUS STEM CELL TRANSPLANT PATIENTS RECEIVING HIGH DOSE MELPHALAN : RESULTS OF PILOT STUDY SHOW REDUCTION IN EMESIS, NAUSEA AND LENGTH OF HOSPITAL STAY

R. Hall[1,*], R. Brooks[1], L. Hammond[1], R. Hudson[2]

[1]Haematology, [2]Pharmacy, The Royal Bournemouth Hospital, Bournemouth, United Kingdom

Background: High dose Melphalan is standard conditioning chemotherapy for patients with Myeloma and Lymphoma for autologous stem cell transplant (ASCT). This is a highly emetic regimen and despite the use of the 5-HT3 receptor antagonists, nausea and vomiting continues to be a problem. During 2016 we noticed a high use of subcutaneous infusion of levopromethazine in this patient group. This anti-emetic can result in patient drowsiness, potential injection site infection and demands on nursing time. We performed a pilot study using the new antiemetic Akynzeo (netupitant and palonosetron hydrochloride 300mg/0.5mg) given prior to high dose Melphalan.
Aims: The study aimed to reduce the incidence of nausea and vomiting associated with high dose melphalan chemotherapy using a novel antiemetic regimen. We hope to demonstrate a resultant improvement in nutritional intake and a reduction in length of hospital admission.

Table 1.

Average number days	nausea overall	nausea grade 1	nausea grade 2	vomiting grade1	reduced nutritional intake	sc levo pump use	sc pump inflammation	ondansetron use	metaclopramide use	length hospital admission
standard antiemetic regimen	4.9	2.85	2.9	2.6	8.5	8.33	0.83	17.21	14.13	19.83
Akynzeo antiemetic regimen	0.79	1.5	0.08	0.08	1.84	0	0	0.83	12.69	17.67

Methods: From 29/12/15 to 4/1/17, 24 consecutive patients were treated with high dose Melphalan as part of an ASCT protocol (22 Myeloma patients and 2 lymphoma patients). The first 12 patients were treated using our standard anti-emetic protocol of regular Ondansetron 8mg bd and metaclopromide 10mg tds from D1 chemotherapy. In addition as required doses and continuous sc infusions of Levopromethazine were used as needed. The subsequent 12 patients were given a novel anti-emetic protocol of Akynzeo single dose on D1 chemo with dexamethasone 12mg orally D1 and 8mg orally D2-4 as per Akynzeo product specification. No other regular anti-emetics were used during the ASCT admission period. As required doses of metaclopromide and as required doses and continuous sc infusions of Levopromethazine were utilised. Retrospective analysis was made of all 24 patients. Factors analysed were: number of days of nausea and vomiting documented in medical notes with CTCAE grade. Number of days of reduced nutritional intake, all antiemetic drugs used, use of subcutaneous infusion Levopromethazine, duration of inpatient admission. Results from the 2 cohorts of patients were compared. Anti-emetic drug costs and nursing time required were also considered.
Results: There was a significant reduction seen in days of recorded nausea, vomiting, poor nutritional intake, subcutaneous levopromethazine pump usage and overall length of hospital stay in the pilot study group receiving the novel anti-emetic Akynzeo (see table).
Summary/Conclusion: The anti-emetic regimen of single dose Akynzeo with dexamethasone resulted in a reduction in nausea and vomiting. Cessation of subcutaneous levopromethazine infusion usage and a reduction in length of hospital admission was seen in the Akynzeo group. The Akynzeo anti-emetic regimen drug cost was higher (average £78 *vs* £24 in the standard regimen group) but the saving in length of hospital stay, nursing time and positive patient experience is significant. We now use the Akynzeo regimen as our anti-emetic protocol for all ASCT conditioning regimens.

PB2434

EVALUATION OF THE MEASUREMENT ERROR IN THE CALCULATION OF CHIMERISM FROM THE RATIO OF TANDEM REPEATS (STR) CONTAINING STUTTER PEAKS

U. Chabaeva[1,*], N. Risinskaya[2], N. Kostritsa[2], A. Sudarikov[2], S. Kulikov[1]

[1]Department of biostatistics, [2]Lab of Molecular Hematology, National Research Center for Hematology, Moscow, Russian Federation (Russia), Moscow, Russian Federation

Background: Chimerism analysis plays a key role in the detection of bone marrow engraftment after allogeneic bone marrow transplantation (BMT). The analysis of short tandem repeats (STR) loci from the donor and the recipient DNA and calculation of individual STR markers percentage is one of routine test for chimerism monitoring. One of most often complications are the stutter PCR peaks appearance due to polymerase slippage during amplification of target STRs. The stutter peak may concur with an informative recipient`s marker hindering chimerism estimation based on that locus. This problem seems to be especially serious in case of a sex-matched sibling bone marrow transplantation. Thereby, the absence of "stutter-peaks free" markers hinders mixed chimerism estimation at the point of low recipient hematopoiesis output. Previously we demonstrated the possibility of the universal formulas correction for the chimerism calculation excluding stutter percentage.
Aims: Detection of low levels of mixed chimerism is possible if only recipient peak is greater then expected donor stutter peak plus some threshold because of error of measurement. The aim of this work was to evaluate the portions of variation of peak level caused by person (donor), locus and noise of measurements and then to calculate the threshold according given type II error of stutter-complicated chimerism detection.
Methods: Data includes measurements of stutter peaks (SP) percentage in 10 loci in DNA samples of 23 donor/recipient sets. In each donor/patient set first measurement was done for donor then further stutter percentage was calculated on the DNA samples of patients with verified complete donor chimerism in 6 up to 14 time points. Additionally we made measurements in parallel probes – 8 aliquots for 8 donors in 7 loci in the most recent time point samples. The UNIVARIATE and GLM SAS procedures were used to calculate simple statistics and run analysis of variance.
Results: Relative levels of stutter peaks by locus types for 23 donor/patient sets is shown on Fig.1, multiple points means repeated measurements. The analysis of variance shows that the main sources of variation are the person (F=5.4, p<.0001) and locus(F=12.8, p<.0001) but not time (number) of measurement (F=0.77, p=0.6). We also compared the variance of repeated measurement of SP of donor/patient set and variance in aliquots of last patient's measurements. At that case the analysis of variance shows that the main sources of variation are the person (F=49.45, p<.0001) and locus type (F=45.16, p<.0001) but not aliquots (number of the parallel probes) (F=1.93, p=0.08). The deviations in repeated measurement and in aliquots are close (0.73 *vs* 0.54) and we can regard them as measurement errors. Then we estimate the distribution of errors, for this we take regression residuals (RR) after fitting by donors and locus types. The mean of RR is zero by definition, the standard deviation is 0.73, 95% percentile is 0.86. The threshold for chimerism detection with 5% of type II error can be calculated by formula: Th5=SP+0.86, where SP is value of stutter peak percentage of donor.

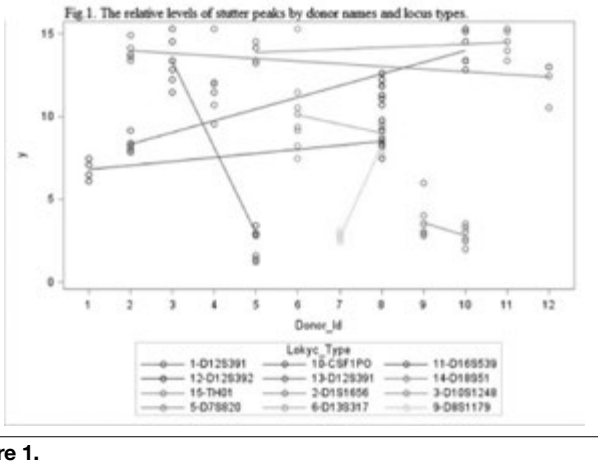

Figure 1.

Summary/Conclusion: We recognized that the stutter peaks are variated mostly by locus type and by person but rather stable in series of measurements in different time points and in several aliquots for the same locus. That means that we can construct the individual chimerism detection rule using donor SP and measurement error which we have evaluated.

PB2435

THE EXPERIENCE USING OF ELTROMBOPAG FOR TREATMENT OF THROMBOCYTOPENIA AFTER ALLOGENEIC HEMATOPOETIC STEM CELL TRANSPLANTATION IN PEDIATRIC PATIENTS

I. Sasmaz[1,2,*], B. Antmen[2], B. Karagun[2], M. Serbest[2]

[1]Pediatric Hematology, Cukurova University, [2]Department of Pediatric Hematology, Bone Marrow Transplantation Unit, Adana Acıbadem Hospital, Adana, Turkey

Background: Thrombocytopenia after allogeneic hematopoetic cell transplantation is a common complication. The underlying causes are often multifactorial in this patient population including impaired platelet production, increased platelet destruction and combination of these mechanisms. Eltrombopag is an oral thrombopoietin receptor agonist which interacts with the transmembrane domain of the receptor on bone marrow megakartocytes and upstream progenitor stem cells. Eltrombopag use has been suggested chronic idiopathic thrombocytopenic purpura and aplastic anemia. There are few reports eltrombopag treatment after allogeneic hematopoetic cell transplantation.
Aims: We aim to report our eltrombopag experiences with 7 pediatric patients treated with eltrombopag for severe thrombocytopenia after allogeneic hematopoetic cell transplantation at our center.
Methods: A total of 198 allogeneic hematopoetic cell transplantation were performed at Acıbadem Adana Hospital Pediatric Bone Marrow Transplantation Unit in Turkey from 2013 to 2017. Seven cases of 198 patients were treated eltrombopag for persistan thrombocytopenia after allogeneic hematopoetic cell transplantation. Bone marrow aspiration and biyopsy were performed in all patients before starting eltrombopag treatment. Medical records and treatment modalities were evaluated retrospectively.
Results: In this study, 7 patients were treated with eltrombopag, age ranging from 5 to 17 years with a average of 12 years. There were 3 patients with thalassemia major, 2 patients with acute lymphoblastic leukemia, one patients with aplastic anemia and one patient with myelodysplastic syndrome. Four patients were males, three were female. Five patients had HCT from an unrelated donor. Two patients had haploidentical transplantation from mother. Five patients had bone marrow transplantation,2 had peripheral blood stem cell transplantation. Eltrombopag was started in 6 patients with prolonged isolated thrombocytopenia and one patient with secondary failure of platelet recovery. The number of megacaryocytes was decreased in 6 patients and was within the normal range in one patient. Before starting eltrombopag treatment 7 patients were dependent on platelet transfusions weekly. Eltrombopag was started at a median 228 days after HSCT (range, 77 to 582 days) in patients with PIT. Eltrombopag were started at the dose of 25-50 mg once daily. Median duration for treatment was 177 days. No serious side effects were seen. The incidence rate of successful platelet recovery to >50000/mikrolitre without transfusion support was 71% (5 of 7 patients).
Summary/Conclusion: Eltrombopag is currently available oral thrombopoietin receptor agonist. We showed that our experience using of eltrombopag is very effective with minimal side effects for persistent thrombocytopenia after allogeneic hematopoetic cell transplantation in pediatric patients who had depended on platelet transfusion.

PB2436

COMPARISON OF MYELOABLATIVE AND REDUCED-INTENSITY CONDITIONING REGIMENS FOR ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

R. Çiftçiler, M. Okay, E. Aladağ, Y. Büyükaşık, H. Göker, H. Demiroğlu*

[1]Hematology, Hacettepe Universty, ankara, Turkey

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is an e ective therapy for a variety of malignant and non-malignant hematologic disorders. Myeloablative conditioning (MAC) and reduced-intensity conditioning (RIC) regimens may have different clinical outcomes. Several investigators have reported a dose-response relationship between the pretransplant conditioning regimen and long-term outcome after allogeneic hematopoietic transplantation in acute leukemia. MAC regimens are associated with a reduced risk of relapse after HSCT, but it's doubtful. That it translates into prolongation of overall survival due to the increased treatment-related and

nonrelapse mortality. In many studies, RIC has been shown to have similar overall survival (OS) but higher relapse rates compared with MAC regimens in patients with myeloid malignancies undergoing allogeneic HSCT.
Aims: To evaluate long-term outcome of MAC *versus* RIC regimens in patients with acute myeloid leukemia (AML) patients undergoing allogeneic HSCT.
Methods: This study is a retrospective single-center analysis. We retrospectively compared the long term outcome with MAC and RIC regimens in patients who underwent allo-HSCT for AML at Hacettepe University between 2001 and 2017.
Results: We analyzed the survival outcomes after MAC-HSCT *versus* RIC-HSCT among 107 adult patients with AML diagnosed from 2001 through 2017. Of these, 44 patients received a MAC regimen and 63 patients received a fludarabine-based RIC regimen in AML. Median follow-up of 95 months (range, 7-213) for the RIC-HCT group and 34 months (range, 6-153) for the MAC-HCT group. The 6-month estimated survival was found to be higher in RIC patients as compared to MAC patients (93% *versus* 82%), but no statistically significant difference was observed (p: 0,5). The 3-year estimated survival for RIC and MAC patients were 67% and 60%, respectively. In multivariate analysis, the type of conditioning regimen (RIC *vs* MAC) did not influence the progression free survival (p: 0,24). Five of the RIC patients and 9 of the MAC patients developed acute graft *versus* host disease (GvHD). Sixteen of the RIC patients and 6 of the MAC patients developed chronic GvHD. There was no significant difference between two groups in terms of acute and chronic GvHD (p:0,089).

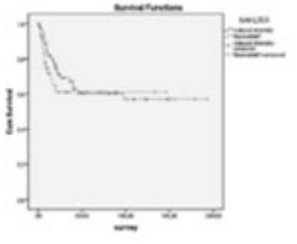

Figure 1.

Summary/Conclusion: This retrospective analysis confirmed that MAC and RIC regimens had a consistently equivalent rate of overall and disease free survival in AML patients with allogeneic HSCT.

RELAPSE AFTER ALLOGENIC STEM CELL TRANSPLANT. CAN AZACITIDINE PROLONG SURVIVAL? EXPERIENCE IN OUR CENTER

I.G. García García*, A. Chinea Rodríguez, F. Martín Moro, B.M. Michael Fernández, K. Velázquez Kennedy, C. Martínez Geijo, A. Sanz Ruipérez, J. Marquet Palomares, F.J. López Jiménez

Hematology, Hospital Universitario Ramón y Cajal, Madrid, Spain

Background: Relapse after allogeneic stem cell transplantation (post-allo-SCT) is the main cause of treatment failure. Currently, the incidence of relapse in patients with acute myeloid leukemia (AML) is between 30-40%. The mean overall survival is 3 to 4 months and the overall survival at two years is less than 20%.
Aims: The aim of this study was to define the benefits of Azacitidine (AZA) in relapsed patients post-allo-SCT, looking for an association between the post-relapse overall survival and the response rate to AZA. We also examined FBC values (increase in hemoglobin, neutrophil or platelet counts), cytogenetic abnormalities present at relapse, and variations in chimerism.
Methods: This is a retrospective single-center study, which analyzed 14 patients who received AZA from January 2013 to January 2018 at a dose of 75mg / m². The cytogenetic risk groups were established according to the European Leukemia Net classification. We used the Kaplan-Meier statistical analysis to estimate the postrelapse overall survival, and we analyzed the impact with the Log-Rank and Breslow tests.
Results: The patient's characteristics are shown in Table 1. The mean age was 54 (±12) years. The mean time to relapse post-transplant was 7.4 (±4.9) months. The mean treatment time with AZA was 4 (±2.5) months, with an average of 4 (±2) cycles, and a mean cycle length of 6 (±1) days per cycle. A decrease in the blast percentage occurred in 4 patients, one of them reached a complete remission. We found a statistically significant association ($p<0.05$) between the treatment response measured by blast count decrease, and the overall survival (graph 1). The average duration of the response was 12 months. One of these 4 patients presented a hematological response with an increase in the hemoglobin level, another showed an increase in platelet count, and a third presented an increase in both hemoglobin and in the neutrophil count. Two patients presented a cytogenetic response with post-AZA negativization of high-risk genetic markers: Del (5q) and del (7q) in one patient, and inv (3) (q21q26) in the other. Changes in chimerism occurred in four patients, two of them achieved a complete chimerism. The median overall survival was 7 (3-14) months. However, even patients who presented a hematological response, a decrease in the percentage of blasts, normalization of cytogenetic abnormalities or who achieved a complete chimerism, lost those responses with the progression of the underlying disease. Table1.

Table 1.

Characteristics		N	%	Results postAZA		N	%
Sex	Female	9	64	Blast	Descent without RC	3	21
	Male	5	36		Descent with RC	1	7
					Progressión	10	72
Cytogenetics in AML	Good	0	0	Cytogenetic response	Yes	2	14
	Intermediate	1	7		No	12	86
	Adverse	13	93				
Conditioning	Haploidentical	10	72	Change chimerism	Yes	4	29
	MAC	2	14		No	10	71
	RIC	2	14				
AZA indication	Frank relapse	12	86				
	EMR+	1	2				
	Genetic marker+	1	2				
Early relapse (≤6 months)	Yes	8	57				
	No	6	43				

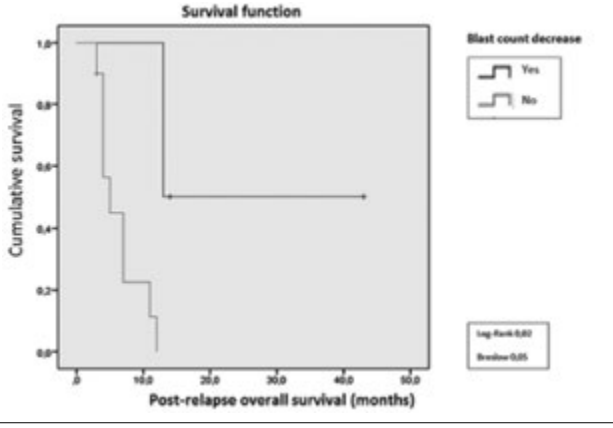

Figure 1.

Summary/Conclusion: AZA is a therapeutic option in post allo-SCT relapsed patients. In our study, the median overall survival was 7 (3-14) months, which is longer than expected in this group of patients. In addition, AZA can modify characteristics of the disease, such as genetic markers of poor prognosis and chimerism. Althought many patients present an initial response, this is then lost with disease progression. The development of new therapeutic strategies is needed in this cohort of patients, to offer a better prognosis in post allo-SCT relapse.

IMPACT OF A MULTI-FACETED INTERVENTION BUNDLE ON THE COLONIZATION RATES OF MULTIDRUG RESISTANT BACTERIA IN HAEMATO-ONCOLOGY PATIENTS

N. Denny[1,*], N. Martinez-Cibrian[1], R.J. Shorten[2], E. Tholouli[1], F. Dignan[1], A. Dodgson[3], M. Saif[1]

[1]Department of Haematology, Manchester University Foundation Trust, [2]Public Health Laboratory, Public Health England, [3]Department of Microbiology, Manchester University Foundation Trust, Manchester, United Kingdom

Background: The growing threat of colonization by multidrug resistant organisms (MDRO) presents a particular challenge to haemato-oncology patients receiving chemotherapy or undergoing a haematopoietic stem cell transplantation (HSCT) as they are heavily reliant on antimicrobial agents to prevent and treat overwhelming infection. MDRO include carbapenem producing Enterobacteriaceae (CPE) and vancomycin-resistant Enterococci (VRE) and both can colonise the bowel. Haemato-oncology patients often develop prolonged neutropenia and gastrointestinal mucositis which creates the perfect means for translocation of these MDRO and can lead to systemic infection. There are few studies examining the impact of multi-faceted infec-

tion prevention and control bundles on MDRO colonisation and infection in haemato-oncology patients.
Aims: To assess the impact of the introduction of a bundle of infection prevention and control measures on CPE and VRE colonisation and infection rates in haemato-oncology patients.
Methods: Data on MDRO colonisation and infection of consecutive patients receiving treatment in our haematology ward between April 2012 and December 2017 was collected. An intervention consisting of 15 infection prevention and control measures, such as patient and staff cohorting and the use of a vapourised hydrogen peroxide system was introduced in November 2014. Patients were divided into pre and post intervention cohorts and the incidence of new CPE and VRE colonisation compared. Secondary outcomes include the incidence of MDRO infection and hand hygiene compliance. Statistical analysis was carried out using SPSS version 22 and Mann Whitney U test was used to compare colonisation and infection incidence between pre and post intervention periods.
Results: During the 69 month period of the study, there were 41,594 patient days; 20,768 in the pre-intervention period and 20,826 in the post intervention period. Monthly acquisition of CPE and VRE colonisation for the two study periods is shown in figure 1. The total number of CPE colonisation acquisitions over the whole study period was 105; 82 in the pre-intervention period and 23 in the post intervention period. The incidence density of CPE colonisation acquisition in the pre-intervention period was 3.95 cases per 1000 patient days compared to 1.1 cases per 1000 patient days in the post intervention period (p=0.0001). The total number of VRE colonisation acquisitions over the study period was 279; 157 in the pre-intervention period and 122 in the post-intervention period. The incidence density of VRE colonisation acquisition in the pre-intervention period was 7.6 cases per 1000 patient days compared to 5.9 cases per 1000 patient days in the post intervention period (p=0.12).

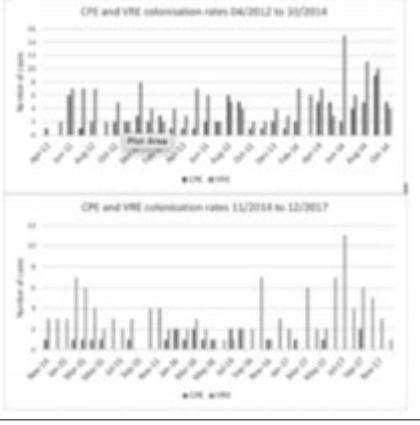

Figure 1.

Summary/Conclusion: The implementation of a multi-faceted bundle of infection prevention and control measures led to a significant reduction in new colonisation with CPE in our haemato-oncology cohort. In contrast, the incidence density of new VRE colonisation showed no statistically significant decrease. This may reflect differences between CPE and VRE in mode of transmission and susceptibility to particular infection control measures. Since the main source of MDRO infection in this cohort is thought to be mucositis related, we expect the significant reduction in CPE colonisation to be matched by a similar reduction in CPE infection. This emphasises the importance of rigorous infection prevention and control measures in protecting our patients in the age of the superbug.

PB2439

OVERALL SURVIVAL AND NON-RELAPSE MORTALITY OF PATIENTS WITH CHRONIC GRAFT VERSUS HOST DISEASE: A SYSTEMATIC LITERATURE REVIEW

T. Ágh[1], M. Csanádi[1], B. Elezbawy[1], T. Webb[2,*], M. Mahler[3], N. Sengupta[3], A. Tordai[4]

[1]Syreon Research Institute, Budapest, Hungary, [2]Janssen Research & Development, High Wycombe, United Kingdom, [3]Janssen Research and Development, Raritan, NJ, United States, [4]Institute of Pathophysiology, Semmelweis University, Budapest, Hungary

Background: Chronic graft-versus-host disease (cGVHD) is a serious and life-threatening complication of allogeneic hematopoietic stem cell transplantation (HSCT) affecting 30% to 70% of patients. It is characterized by systemic inflammation and fibrosis with a heterogeneous presentations affecting a wide range of tissues and organs. cGVHD is the leading cause of non-relapse mortality (NRM) following HSCT, also contributing to morbidity and a decrease in quality of life.
Aims: To perform a systematic literature review of evidence (1) on overall survival (OS) and NRM among cGVHD patients and (2) on the effect of cGVHD on OS and NRM compared to patients without cGVHD.
Methods: A systematic review of English-language articles was conducted in PubMed. Literature search was limited to studies that applied the National Institute of Health (NIH) Consensus Criteria for the diagnosis and staging of cGVHD, published between 2007 and 2017, studied human subjects with a cohort size of at least 100 patients. Included studies were assessed for quality with a NIH quality assessment tool. NRM and OS values measured among cGVHD patients were extracted from the articles. In the evaluation of cGVHD-effect on OR and NRM we extracted data only from those analyses that applied a multivariate study design.
Results: From the screened 1682 publications, 38 studies were included. From the onset of cGVHD, the 1 and 2 year NRM rates ranged from 10% to 26%, and from 10% to 32%, respectively. The 1 and 2 year OS rates from the onset of cGVHD ranged from 66% to 75% and from 59% to 81%, respectively. Studies found that patients with cGVHD had better OS (range of hazard ratio [RoHR]: 0.09 - 0.38), but increased NRM (RoHR: 2.4 - 4.8) compared to patients without cGVHD. Studies where cGVHD was included as a time-dependent covariate in the multivariate analysis found that the improved OS was primarily due to differences in relapse rate (RR). These results showed that patients with cGVHD had significantly lower RR than patients without cGVHD: no cGVHD *vs* classic cGVHD, HR: 0.46; and no cGVHD *vs* mild / moderate / severe cGVHD, RoHR: 0.12 - 0.26. However, higher NRM was observed in several sub-groups of cGVHD patients when they were compared to those without cGVHD: cGVHD after acute GVHD, HR: 4.83; *de novo* cGVHD, HR: 3.52; classic cGVHD, HR: 2.4; and overlap cGVHD, HR: 2.5. Furthermore, higher cGVHD severity was reported to be associated with worse NRM (severe *vs* mild/moderate, RoHR: 3.04 - 3.07). Four studies found a significant association between OS and cGVHD severity and 3 indicated better OS in case of lower cGVHD severity. Overlap GVHD was associated with worse OS (HR: 2.1) and higher NRM (HR: 2.8) compared with classic cGVHD.
Summary/Conclusion: Evidence suggests that the improved OS in cGVHD patients is due to lower risk of relapse, which can be explained with the presence of a potent graft *versus* tumor (GVT) effect. However, NRM was found to be higher in patients with cGVHD and studies indicated an increased risk in the presence of more severe disease. A delicate balance is thought to exist between cGVHD severity as a source of NRM and a favorable effect on decreased RR in the presence of less severe cGVHD. Considering the importance of the GVT effect and higher risk of NRM associated with more severe disease, there exists an unmet medical need for novel approaches to ameliorate the severity of cGVHD whilst preserving the benefits of the GVT effect.

PB2440

IN MULTIPLE MYELOMA, AFTER CTX-BASED PBSC MOBILIZATION, THE USE OF HIGH DOSE G-CSF (10 MCG/KG) IS MORE EFFECTIVE IN RESPECT TO LOW DOSE G-CSF(5 MCG/KG) BUT ONLY IF PLERIXAFOR ON DEMAND IS NOT USED

S. Leotta[1], A. Cupri[1], A. Spadaro[1], G. Sapienza[1], L. Scalise[1], M.G. Michieli[2], G. Milone[1,*]

[1]Hematology, BMT UNIT, Catania, [2]Oncology, BMT UNIT, Aviano, Italy

Background: The use of algorithms to administer PLX has increased the success rate of the PBSC mobilization treatments. However also the increase of the dose of G-CSF from 5 mcg/Kg to 10 mcg/Kg could be important to the end of harvesting an optimal amount of CD34+ cells. It is not known if "high dose G-CSF" and "on demand PLX" show a synergistic effect so that their combined used may be of additive usefulness or, on the contrary, if these two measures do not have a synergy.
Aims: Determine, in Multiple myeloma patients mobilized with cyclophosphamide 2-4 gr/sqm, if the use of high dose G-CSF (10 mcg/Kg) is more effective than lower dose (5 mcg/Kg) and if the possible increase of effectiveness of G-CSF high dose is influenced by the concomitant use of on demand Plerixafor.
Methods: 404 patients were retrospectively studied, all were affected by MM and were in first mobilization attempt. All 404 patients received CTX at 2-4gr/sqm, 180/404 patients were enrolled in on demand PLX (PLX GROUP) and 224/404 were not (NO PLX GROUP). In NO PLX GROUP

112 patients received G-CSF at 10mcg/Kg and 68 received it at dose of 5mcg/Kg. In PLX GROUP 153 received G-CSF at dose of 10mcg/Kg and 71 at dose of 5mcg/Kg.
Results: In NO PLX GROUP, percentage of patients failing to harvest the minimum CD34+ of $2x10^6$/Kg was 19% in patients receiving 5mcg/Kg *versus* 8.8% in patients receiving G-CSF at 10mcg/Kg (p=0.04). Patients receiving G-CSF at dose of 5mcg/Kg reached a harvest $>6x10^6$ CD34+ cells in 42% of cases while this outcome was reached in 72% of patients receiving G-CSF at dose of 10mcg/Kg (p=0.0001). Mean harvested CD34+ cells was $6.3x10^6$/Kg *versus* $13.0x10^6$/Kg (p=0.0001). In PLX GROUP, patients failing the minimum CD34 harvest ($2x10^6$/Kg) was 5.0% and 1.7% in the two groups treated, respectively, with 5 mcg/Kg and in 10mcg/Kg (p=0.08) the optimal threshold of $6x10^6$/Kg was reached In 67% of those receiving G-CSF at 5mcg/Kg and in 73% of patients treated with G-CSF at 10 mcg/Kg (p=not significant). The mean number of harvested CD34+ cells was $10.4x10^6$/Kg *versus* $11.2x10^6$/Kg, respectively in 5mcg/Kg and in 10mcg/Kg groups (p=NS). Thus, high dose G-CSF seems more advantageous when PLX on demand is not used while its efficacy is less evident when PLX on demand is programmed. We therefore wished to study the existence of an interaction between these two factors. In ANOVA test the amount of CD34 cells harvested was used as dependent variable and "dose of G-CSF" and "to be enrolled in a PLX ON DEMAND study" were evaluated. Interaction between the two factors was significant (F=14.1; p=0.0002).
Summary/Conclusion: After CTX based mobilization, a dose of G-CSF of 10 mcg/Kg allows to reach an optimal amount of CD34+ cells ($>6x10^6$/Kg) more frequently in respect to the dose of 5 mcg/Kg. However, this hold true only when PLX is not used. In fact, in patients enrolled in PLX studies, there is no evidence that a higher dose of G-CSF determines further improvement in respect of that obtained with the use of the on demand PLX. Thus, we can conclude that if PLX on demand is used there is no need to increase dose of G-CSF.

PATIENTS NON-COMPLIANCE LEADS TO HIGHER RISK OF ACUTE GVHD

E. Mikhaltsova[1,*], M. Drokov[1], L. Kuzmina[1], O. Pokrovskaya[1], V. Vasilyeva[1], N. Popova[1], D. Dubnyak[1], O. Koroleva[1], A. Sidorova[1], E. Usikova[1], S. Khrushchev[2], Z. Konova[1], A. Dmitrova[1], D. Vybornykh[2], E. Parovichnikova[1], V. Savchenko[1]

[1]BMT department, [2]Laboratory studying Mental and Neurological Disorders in Patients with Hematological Diseases Moscow, National Research Center for Hematology, Moscow, Russian Federation

Background: Non-effective medical therapy is like a "worldwide problem of striking magnitude". Sometimes ineffective medical therapy closely relates with non-compliance with medical recommendations. First 3-4 months after allogeneic stem cell transplantation (allo-HSCT) are crucial for acute graft *versus* host disease (GVHD) developing in patients after allo-HSCT. Here we report the data about an impact of patient non-compliance on aGVHD incidence after allo-HSCT.
Aims: to assess the impact of patient non-compliance with medical recommendations on aGVHD incidence.

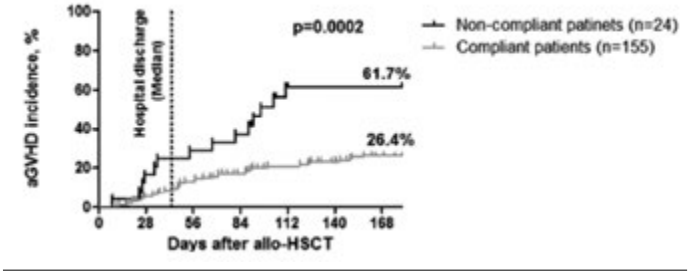

Figure 1.

Methods: We analyzed the data of 179 patients who underwent allo-HSCT between 2009-2017 in National Research Center for Hematology. All patients had an acute leukemia (59- ALL and 120 – AML) and were in complete remission (CR) before allo-HSCT. Physician expert opinion (based on physician-patient interactions and/or clinical interview with mental health specialist) was used to assess patient non-complaince with medical recommendations. Exact Fisher's test was used to analyze the 2 × 2 contingency tables. Kaplan–Meier analysis with log-rank test was used for aGVHD probability analysis and group comparison. A p-value less than 0.05 was considered as significant.
Results: 13% patients were non-compliant with medical recommendations. The groups of compliant and non-compliant patients were absolutely comparable based on various characteristics (diagnosis, sex, age, disease status, transplant source, type of donor). According to our data aGVHD occurred in "non- compliant" group more frequently than in "compliant" group - 61.7% and 26.4% respectively (p=0.0002). All other factors that could affect aGVHD incidence (graft source, HLA-disparity, disease status) were balanced.
Summary/Conclusion: Patient non-compliance with medical recommendations is strongly associate with developing of aGVHD. We are convinced that patient non-compliance an reduce to zero previously conducted the best aGVHD prophylaxis. This study reinforces the importance of this problem for each transplant center and needs to be continued together with clinical psychologists and psychiatrists.

DONOR AND RECIPIENT CCR5-DELTA 32, CCR2-64I, SDF1-3'A, IL6 -572 C/G POLYMORPHISMS AND TRANSPLANTATION OUTCOME

N. Risinskaya*, I. Fevraleva, U. Chabaeva, N. Petinati, S. Kulikov, A. Sudarikov, L. Kuzmina, E. Parovichnikova, V. Savchenko

National Research Center for Hematology, Moscow, Russian Federation

Background: Immunological tolerance after bone marrow transplantation (BMT) depends on complex interaction between graft and host cells and includes cytokine production and reception. Both host and graft cells may carry different polymorphic alleles in appropriate genes that may alter these processes. Possible impact of cytokine gene polymorphisms on the BMT outcome have not been thoroughly studied yet.
Aims: To measure possible correlation of overall survival, reconstitution time and level of GVHD with CCR5-delta 32 (rs333), CCR2-64I (rs1799864), SDF1-3'A (rs1801157), IL6 -572 C/G (rs1800796) polymorphisms in host and graft cells.

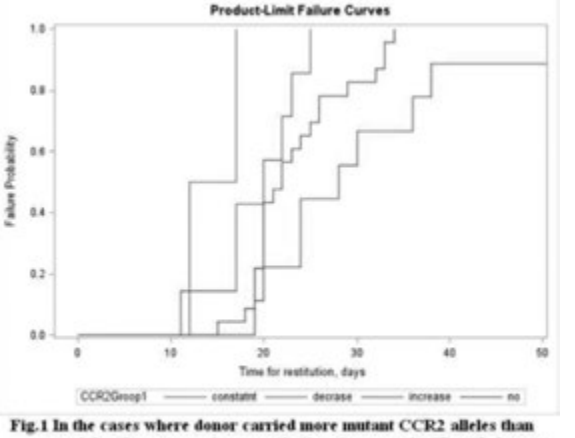

Fig.1 In the cases where donor carried more mutant CCR2 alleles than recipient hematopoesis reconstitution time was significantly longer than in other cases (p<0.0001)

Figure 1.

Methods: Forty three patients 18 to 64 years old (median age 32), 13 males and 30 females who received allogeneic hematopoietic transplantation in the National Research Center for Hematology were included in the study. Stem cell source was bone marrow in 14 cases and mobilized peripheral stem cells in 29 cases. 26 patients were diagnosed with AML, 9 with ALL, 3 with AA, 2 with MDS, 2 with CML and 1 with MPN/CLL. DNA of donors and recipients were analyzed for CCR5-delta 32(rs333), CCR2-64I(rs1799864), SDF1-3'A(rs1801157), IL6 -572 C/G (rs1800796) polymorphisms by means of allele-specific PCR. Genetic data were correlated with overall survival, reconstitution time, frequency of acute or chronic GVHD after BMT. Infectious complications where analyzed at days 0-30 and at days 30-120 after transplantation. SAS software was used for statistical analysis. Kaplan-Meier estimates, Log-Rank test and chi-square were used for group comparison.

Results: Patients were divided according to each polimorphysm issue into 4 groups: 1/ no mutant alleles in both recipient and donor; 2/ equal number of mutant alleles in recipient and donor; 3/ donor has less mutant alleles than recipient (0 *vs* 1, 0 *vs* 2, 1 *vs* 2); 4/ donor has more mutant alleles than recipient. All groups were equal in graft source, diagnosis, disease stage, gender and age. No correlations of most polymorphic alleles with overall survival, reconstitution time, frequency of a GVHD and infectious complications at day 30 were found. In the cases where donor carried more mutant CCR2 alleles than recipient hematopoesis reconstitution time was significantly longer than in other cases (p<0.0001) (Fig 1). Infectious complications were also more frequent at day 30-120 (p<0,0016): 10 of 11 patients who received transplant from a donor carrying more mutant CCR2 alleles than recipient (91%) *vs* 8 of 32 patients in other groups (22-50%).
Summary/Conclusion: Cytokine polymorphic alleles of donors and recipients may alter bone marrow transplantation outcome. Decreased reconstitution rate and increased levels of infectious complications could be registed in patients who received transplant from donors carrying mutant CCR2 alleles. More patient samples and extended cytokine gene panels are required for further studies.

CONDITIONING REGIMENS FOR AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN LYMPHOMA: COMPARISON BEAM / BEAC-BUCY-GEMBUMEL

E. Colombo*, S. Jarchum, E. Mas, M. Alvarez, M. Balseiro, D. Minoldo, M. Lavarda, M. Rizzi, G. Jarchum

Sanatorio Allende, Cordoba, Argentina

Background: Hematopoietic progenitor cell transplantation (HSCT) represents a potentially curative therapy for certain hematological diseases. Improving conditioning regimen (CR)efficacy and safety is the major variable for results and is an important area of research. Also the world shortage and expense of carmustine has promoted the use of alternative conditioning regimens to the classical BEAM/CBV. Recently at MD Anderson Cancer Center, Dr. Nieto demonstrated that GEMBUMEL improves PFS and OS in patients with HL R/R. GEMBUMEL combines the alkylating activity with the inhibition of DNA repair, producing an additive or synergistic effect. We present here a comparative study of the CR: BUCY, BEAM-BEAC and GEMBUMEL in patients (P) with diagnosis of Lymphoma subjected to autologous HSCT.
Aims: To evaluate the safety and efficacy of these regimens in our experience.
Methods: Retrospective, observational and descriptive work. Patients with diagnosis of Hodgkin's Lymphoma (HL) and non-Hodgkin's Lymphoma (NHL) undergoing autologous HSCT in the 2010-2017 period were included. CR were (all the medication was done intravenous): BEAC (Carmustine 300mg/m^2, Etoposide 1200mg/m^2, Cytarabine 800mg/m^2 Cyclophosphamide 140mg/kg IV) BEAM (Carmustine 300mg/m^2, Etoposide 800mg/m^2, Cytarabine 1600mg/m^2, Melphalan 140mg/m^2) BUCY (Busulfan 12.8mg/kg Cyclophosphamide 120mg/kg) GEMBUMEL (Busulfan 420mg/m^2, Melphalan 120mg/m^2, Gemcitabine 5500mg/m^2). Safety was analyzed assessing: toxicity (according to CTCAE), haematological recovery and transfusional requirement. Progression Free Survival (PFS) and Overall Survival (OS) was evaluated for the efficacy analysis. Descriptive statistics were used for the numerical variables, ANOVA for the categorical ones, Chi-Square test for comparison of proportions and the analysis of PFS and OS by Kaplan Meier curves. A p <0.05 was considered statistically significant.
Results: We analyzed 70 P, with the following distribution according to CR: 1-BUCY (n=16), 2-BEAM / BEAC (n=35) and 3-GEMBUMEL (n=19). Only a statistically significant difference was observed in the relationship between men and women, within their baseline. When grade III-IV of Toxicity was evaluated between the groups, there were statistically significant with p <0.001, mucositis (50% *vs* 54.2% *vs* 100%), hepatitis (0% *vs* 0% *vs* 73.7%) and dermatitis (0% *vs* 0% 36.8%), with no difference in transplantation related mortality. When Efficacy was compared, neutrophil recovery was achieved with a mean of 13, 13.8 and 11 days (p 0.169) and platelets 33, 20 and 18 days (p 0.008), and there were no differences in transfusion requirements. The 12-month PFS was 75, 80 and 78.95% and the OS at 12 months was 87, 94.2 and 94.7%, with no significant statistical differences. The comparison according to disease (HL *vs* NHL) also showed no difference in terms of OS.
Summary/Conclusion: GEMBUMEL CR presented more toxicity, evidencing a higher incidence of mucositis, hepatitis and dermatitis, while BUCY showed late recovery of platelets. There were no differences in PFS or OS between the CR.

PB2445

CLINICAL RESPONSE TO SYSTEMIC TREATMENTS FOR STEROID-REFRACTORY CHRONIC GRAFT VERSUS HOST DISEASE: A SYSTEMATIC LITERATURE REVIEW

T. Ágh[1], M. Csanádi[1], B. Elezbawy[1], T. Webb[2,*], M. Mahler[3], N. Sengupta[3], Z. Vokó[1]

[1]Syreon Research Institute, Budapest, Hungary, [2]Janssen Research & Development, High Wycombe, United Kingdom, [3]Janssen Research and Development, Raritan, NJ, United States

Background: Chronic graft-versus-host disease (cGVHD) is a serious complication of allogeneic hematopoietic stem cell transplantation affecting 30% to 70% of patients. It is the leading cause of late non-relapse mortality, contributes to morbidity and impairs quality of life of transplant patients. Corticosteroids are standard first-line therapy for cGVHD, but around 50% of patients do not respond adequately. Evidence on the comparative efficacy of second-line treatments is limited, partly because, until the 2005 National Institutes of Health (NIH) Consensus Conference (revised in 2014) no uniform criteria for the diagnosis of cGVHD and response were available.
Aims: To systematically review the available clinical trials to investigate the efficacy of systemic treatments on response in patients with steroid-refractory (SR) cGVHD.
Methods: A systematic review of English-language publications was performed using Scopus and Cochrane Central Register of Controlled Trials databases. Literature was searched from 2005 to October 2017. The review was limited to phase 2 to 4 clinical trials that used the NIH Consensus Criteria for diagnosing cGVHD and determining response, and included >25 patients per study arm. Data on response were extracted from the included trials. Overall response rate [ORR] was defined as: (number of patients with complete response [CR] + number of patients with partial response [PR]) / total number of patients treated.
Results: Four phase 2, single arm trials were included. These investigated the efficacy of ibrutinib (n=1), interleukin-2 (IL-2; n=1), imatinib (n=1), and rituximab (n=1). Most trials failed to report response at a fixed time point and reported best response at any time during the follow-up, thus CR and PR data presented below are maximum response rates. At median follow-up of 13.9 months, CR with ibrutinib was 21% and PR was 45% (ORR: 67%; 28/42 patients); 71% (20/28 patients) and 48% (12/25 patients) responders showed a sustained response of ≥20 and ≥32 weeks, respectively. With ibrutinib, 56% of patients with ≥2 involved organs showed a response in ≥2 organs, and 42% of patients with ≥3 involved organs showed a response in ≥3 organs. During 1 year follow-up, CR with rituximab was 22% and PR was 65% (ORR: 87%; 32/37 patients); 21 patients maintained their response for 1 year. Response rates with rituximab were higher in the musculoskeletal system (ORR: 100%), skin (ORR: 77%) and oral cavity (ORR: 71%) than those in the liver (ORR: 44%), eyes (ORR: 43%), gut (ORR: 33%), and lungs (ORR: 9%). Patients treated with IL-2 or imatinib had no CR. By week 12, 61% of patients (20/33 patients) treated with IL-2 had PR; response sites included skin (PR: 27%), joint/fascia (PR: 17%), lung (PR: 15%), liver (PR: 13%), and gastrointestinal tract (PR: 10%). During 6 months, PR with imatinib was 51% (20/39 patients); the best response rates were observed in the gut (PR: 50%), lungs (PR: 35%) and skin (PR: 32%). The definitions of SR cGVHD varied in the included clinical trials.
Summary/Conclusion: Findings suggest that patients with SR cGVHD treated with ibrutinib and rituximab can reach CR. However, none of the included clinical trials reported comparative data demonstrating superior efficacy in response for one particular agent over others. Heterogeneity in the definition of SR cGVHD and follow-up time did not allow direct comparison of results. Further controlled clinical trials with larger cohorts are needed.

PB2446

PATIENTS HAPLOTYPE, DONORS KIR ALLELE AND POSTHSCT EVOLUTION

D. Bratu[1,*], A. Moise[2], I. Constantinescu[3]

[1]Haematology, [2]Department of Immunogenetics and Virusology, Fundeni Clinical Institute, [3]Department of Immunogenetics and Virusology, Fundeni Clinical Institute, Bucharest, Romania

Background: Some new consideration about haplotype of patients with acute leukemia and their binding with genoidentical donors KIR allele in HSCT try to explain few aspects in postHSCT evolution.
Aims: Some new consideration about haplotype of patients with acute leukemia and their binding with genoidentical donors KIR allele in HSCT try to explain few aspects in postHSCT evolution.

Methods: Patients with acute leukemia,lymphoblastic and non-lymphoblastic,aplastic anemia and their genoidentical donors are evaluated(eighteen paars). Haplotype HLA sistematisation follow IPD/ KIR : HLA- A3/A11, HLA-Bw4, HLA-Bw6(Bw4 negative) HLA-C1/C1 homozygot, HLA-C1/C2 heterozygot, HLA-C2/C2 homozygot.

Table 1.

Ligand	Activatory allele	Inhibitory allele
HLA A3/A11	KIR3DL2	KIR2DS4
HLA Bw4	KIR3DL1	KIR3DS1
HLA C1	KIR2DL2, KIR2DL3	KIR2DS4
HLA C2	KIR2DL1	KIR2DS1

The source of HSCT was PBSC.The method used was PCR-SSP (Innotrain DIAGNOSTIK GMBH, Dynal BIOTECH PEL-FREEZE) The complications like graft *versus* host disease acute and chronic, relapse, TMA and the recovery with leucocytes and thrombocytes are followed.
Results: HLA-Bw6 haplotype(7) with 85,71% overall survival, HLA-A3/A11(15) with 53,33%, HLA-C2/Cx(17) with 50.00% and presence of all these haplotype at same patient(6) with 83,33% overall survival demonstrate the protective effect and cumulative effect of some categories of HLA haplotype. Donors KIR haplotype are AB, protective ,evident effect at patients with KIR haplotype AA(4:2 AML,1ALL,1AA) but also with favorable HLA. Patients with HLA-Bw6, HLA-C2/C2,HLA-A3/A11(6) don't develop aGVHD, relapse, TMA, a single patient with HLA-Bw4 develop aGVHD; positive effect also about leucocyte and trombocyte recovery,especially in the presence of actiatory allele (sig, 0,5%). HLA-Bw6 haplotype (Bw4 negative) with donor inhibitory KIR3DL1, confirm missing ligand theory, (83% OS, sig<0,05); with donor activatory KIR3DS1,OS is 100% (sig<0,05).
Summary/Conclusion: Cumulative effect of some patient HLA haplotype with donor KIR haplotype (also patient KIR haplotype)improve overall survival and protect again most complication after HSCT.

IMPACT OF PROCALCITONIN IN THE DIFFERENTIAL DIAGNOSIS OF FEBRILE COMPLICATIONS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

S. Butera[1,2], A. Evangelista[3], L. Giaccone[1,2], C. Dellacasa[2], D. Faraci[1,2], L. Brunello[1,2], G. Ciccone[3], G. Mengozzi[4], A. Busca[2], B. Bruno[1,2,*]

[1]Department of Molecular Biotechnology and Health Sciences, University of Torino, [2]Department of Oncology, SSD Trapianto Allogenico di Cellule Staminali, [3]Clinical Epidemiology, [4]Department of Clinical Chemistry, SC Baldi Riberi, A.O.U Città della Salute e della Scienza di Torino, Torino, Italy

Background: Serum procalcitonin (PCT) has been proposed as a promising diagnostic biomarker for severe bacterial infections in patients with febrile episodes following allogeneic haematopoietic stem cell transplantation (allo-HSCT). A reliable biomarker may be particularly helpful during neutropenic fever.
Aims: The purpose of this study was to determine the potential role of PCT in the differential diagnosis of febrile complications in allo-HSCT recipients.
Methods: Febrile episodes and PCT values were retrospectively reviewed in 553 consecutive allografts performed at our Centre, from January 2007 to December 2016. Biomarkers (PCT and C reactive protein) were assessed in correspondence of the febrile event. Fever work-up also included complete blood counts, haemocultures and chest X-ray. Other imaging studies and/or bronchoalveolar lavage were performed as clinically indicated. A total of 3430 determinations of PCT on 355 patients were analysed. Donors were HLA-identical siblings (no.101); haploidentical (no.58); or unrelated (no.209). Association between PCT and clinical outcomes were evaluated by generalized linear model with Gamma distribution and link-log.
Results: Frequency of PCT determinations was higher in the first 36 days after transplantation, with a median at +16 days (IQR: 8-36). Overall 210 PCT determinations (6,1%) were performed at the onset and within the first 48 hours of a documented bacterial infection. PCT values were significantly higher in patients with documented gram negative bacteraemia (mean 8.85 ng/ml) compared to patients with no documented infections, with a mean difference of PCT levels of 6.93 ng/ml (95%CI: 1.62, 12.24; p<0.01). PCT showed a promising diagnostic accuracy for Gram negative infections, as compared with inflammatory fever or Gram positive proven bacteraemia. PCT showed a high negative predictive value for bacteraemia regardless of Gram stain, ranging from 97% at cut off value of 2 ng/ml to 96.9% at a cut off value of 0.5 ng/ml. PCT levels superior to 2 ng/ml can be considered specific of bacteraemia with a specificity of 89,5% for gram positive bacteraemia and of 89.7% for gram negative proven infection. PCT elevations were not significant in patients with documented invasive fungal infections defined by EORTC/MSG criteria (p=0.618), and in patients developing cytokine release syndrome (CRS) after haplo-identical allografts (p=0.207). A mean difference of PCT levels of 6.37 ng/ml was found if anti-thymocyte globulin (ATG) treatment was included as graft-versus-host disease prophylaxis, compared to patients that did not receive ATG. (95%CI: 2.67-10.06; p<0.001). Multi organ failure was significantly associated with an elevation of PCT values with a mean rise of 3.27 ng/ml in the last 96 hours before death. (95%CI: 1.35, 5.18; p<0.001).
Summary/Conclusion: Despite the limitations of the retrospective design of our study and of the low prevalence of proven bacteraemia in correspondence of a PCT determination in our population, PCT may be considered a helpful tool in the differential diagnosis of febrile complications after allo-HSCT. Our findings form the basis for the prospective assessment (in the contest of a clinical trial) of a diagnostic algorithm and scoring system that include PCT determination to evaluate risk of gram negative sepsis and of early mortality in febrile episodes after allografting.

SUFU RS17114808 (C>T) POLYMORPHISM DOES NOT INFLUENCE THE OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN ADULTS

N. Meggyesi[1,*], P. Kovy[1], K. Balassa[2], L. Varga[3], A. Bors[1], A. Batai[4], E. Torbagyi[4], L. Gopcsa[4], L. Lengyel[4], A. Barta[4], A. Tordai[5], I. Valyi-Nagy[4], T. Masszi[6], H. Andrikovics[1], P. Remenyi[4]

[1]Laboratory of Molecular Genetics, Central Hospital of Southern Pest, National Institute of Hematology and Infectious Diseases, [2]School of PhD Studies, Semmelweis University, [3]Hungarian National Blood Transfusion Service, [4]Department of Hematology and Stem Cell Transplantation, Central Hospital of Southern Pest, National Institute of Hematology and Infectious Diseases, [5]Department of Pathophysiology, [63]rd Department of Internal Medicine, Semmelweis University, Budapest, Hungary

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the most effective treatment option for certain hematological malignancies. Suppressor of fused (SUFU) is a negative regulator of the hedgehog signaling pathway which is involved in cell proliferation and differentiation, and it interacts with the Glioma transcription factors. Recently, correlation has been shown between the SUFU polymorphism rs17114808 and the incidence of acute graft *versus* host disease (aGvHD).
Aims: The aim of this study was to investigate the role of SUFU rs17114808 (C>T) polymorphism in the outcome of HSCT.
Methods: We examined the association of recipient and donor SUFU rs17114808 C>T and allo-HSCT outcome in a cohort of 407 adult patients who underwent first allo-HSCT between January 2007 and December 2013 at our single center. 208 patients received stem cells from their siblings, 199 patients from matched unrelated donors (MUD). 227 patients was diagnosed with AML (n=155) or ALL (n=72) and 180 patients with other (MDS [n=31], CML [n=22], MPN [n=20], MM [n=25], CLL [n=25], NHL [39], HL [18]) diseases. In 260 cases myeloablative conditioning (MAC), while in 147 cases reduced intensity conditioning (RIC) was applied. For identification of SUFU rs17114808 from genomic DNA LightCycler melting curve analysis (LightCycler 480II, Roche Diagnostics) was performed.
Results: We did not find any association between recipients' SUFU rs17114808 C>T polymorphism and HSCT outcome on the whole cohort. In patients with SUFU rs17114808 CT or TT genotype, aGvHD grade II-IV occurred in 68% (67/99), compared to 32% (98/307) in patients with CC genotype (p=1). Relapse occurred in 29% (29/99) T carrier patients and in 25% (76/307) of patients with CC genotype (p=0.428). Similar findings were observed in case of SUFU rs17114808 C>T polymorphism in donors. The frequency of aGvHD was 29% (22/76) in case of T allele carrier donors and 32% (107/336) in patients with wild type (CC) donor (p=0.682). Donors' SUFU genotype did not influence the relapse rate (22% [17/76] in patients with donors bearing at least one T variant *vs* 27% [91/336] for wild type donors). Overall survival did not differ in subgroups with different genotypes of recipients and donors. Based on tests for interaction, subgroup analysis was performed according to diagnosis (acute leukemia *vs* other) and conditioning regimen (MAC *vs* RIC), but we did not find significant association in the subgroups.
Summary/Conclusion: In contrast with a previous study performed in pediatric HSCT patients, our findings suggest that SUFU rs17114808 C>T polymorphism in adult HSCT recipients and donors does not influence the outcome of HSCT.

PB2449

IMPACT OF AB0 INCOMPATIBILITY ON ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION OUTCOME: A SINGLE-CENTER RETROSPECTIVE STUDY

A. Busani, G. Saporiti, T. Zollner, E. Tagliaferri, F. Grifoni, F.G. Rossi, C. Manera, N.S. Fracchiolla, A. Cortelezzi, F. Onida*

Ematologia - Centro Trapianti Midollo - Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico - University of Milan, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico - University of Milan, MILANO, Italy

Background: Hematopoietic stem cell transplantation (HSCT) is used to treat a range of hematological malignant and non-malignant conditions including autoimmune, metabolic and immunodeficiency diseases. Because major histocompatibility genes are inherited independently of blood group system genes, approximately 40-50% of all allogeneic HSCTs are performed across the AB0-blood group barrier. Due to the widespread expression of AB0 antigens on a variety of human tissues other than erythrocytes, AB0 incompatibility may have an impact on the outcome of allogeneic HSCT that goes beyond the well-known immune-hematological complications such as immediate hemolysis due to the presence of isoagglutinins and delayed hemolysis due to passenger B lymphocytes.
Aims: With this retrospective study, we aimed to assess the impact of AB0 mismatch on allogeneic HSCT outcomes, including non-relapse mortality, overall and relapse-free survival, post-transplant PRC transfusion requirement, as well as relapse rate and incidence of graft- failure and acute GvHD.
Methods: Retrospectively collected data from 169 consecutive patients undergoing allogeneic HSCT between 01/2008 and 10/2017 at the Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico Hospital in Milan, Italy, were analyzed. Kaplan Meier estimates were used for survival outcomes while cumulative incidences were analyzed by competing risk analysis.
Results: The patient series included 98 AB0-identical, 29 major incompatible, 32 minor AB0-mismatched and 10 bidirectionally incompatible transplants. Mean overall survival for groups of patients undergoing AB0-identical, major AB0 mismatch and minor AB0 mismatch HSCT were 66 months (95% CI [55 ;77]), 47 months (95% CI [28; 65) and 46 months (95% CI [31; 61]), respectively. Non-relapse mortality in the three groups were significantly different by Gray's test with point estimates of 12%, 29% and 26% at 5 years, respectively, whereas no significant differences were observed for relapse rate and graft failure incidence. Although not statistically different, incidence of acute grade III-IV GvHD was twice as high in patients transplanted from minor AB0-mismatched donors than in the AB0 identical group (16% *vs* 8%). Following transplantation, PRC transfusion requirement was significantly higher in the major AB0 mismatch then in the AB0-identical transplanted patients (median 14 *vs* 7, p=0.01). Of note, a weak positive correlation was found between the anti-donor A/B IgG titers measured prior HSCT and the total number of RBC transfusions administered one year after HSCT. One case of PRCA occurred in one 0+ 50-year-old woman who received peripheral blood-derived hematopoietic stem cells from an A+ HLA-identical 32-year-old male sibling after myeloablative conditioning for AML in first complete remission. Anti-A IgG isoagglutinin titers prior to transplantation were 1:256. The patient received a total of 46 RBC products in the year following transplantation and resolution occurred during danazole treatment.
Summary/Conclusion: In our patient cohort, both major and minor AB0 mismatching were associated with a significantly higher NRM. Major ABO mismatching associated to higher PRC transfusion requirement. Possible more frequent occurrence of severe acute GvHD is also suggested in minor AB0-mismatched transplants.

PB2450

AUTOLOGOUS HEMATOPOIETIC CELL TRANSPLANTATION FOR HIV-RELATED LYMPHOMA: A SINGLE CENTER MATCHED CASE-CONTROL STUDY

M.O. Popova*, Y. Rogacheva, A. Nekrasova, I. Tsygankov, K. Lepik, O. Pirogova, E. Darskaya, Y. Zalylov, L. Stelmah, I. Moiseev, S. Bondarenko, N. Mikhaylova, B. Afanasyev

Raisa Gorbacheva Memorial Institute of Children Oncology, Hematology and Transplantation, First Pavlov State Medical University of Saint-Petersburg, Saint-Petersburg, Russian Federation

Background: Human immunodeficiency virus (HIV) infection is associated with an increased incidence of non-Hodgkin lymphoma (NHL) and Hodgkin lymphoma (HL). Throughout the HAART era, autologous stem cell transplantation (ASCT) has been reported as a feasible approach to either rescue or consolidate HIV-related lymphoma patients. However, the number of published comparative studies according to the HIV status is limited.
Aims: An observational prospective study was designed to assess the safety and tolerability of intensive chemotherapy and ASCT for the treatment of HIV-related NHL and HL.
Methods: Since the Jan 2016 nine patients with HIV-related lymphoma who have undergone ASCT were included in prospective singe centre study (study group - HIV group, n=9). The data of the non-HIV-infected patients with lymphoma who have undergone ASCT at the same period of time (control group, n=36) were collected to compare the efficacy and safety of the procedure (1:4). Median follow up time was 12 (2-20) months. The primary end points were overall survival (OS) and relapse rate at 12 months after ASCT. Secondary end points were time to hematopoietic recovery and organ toxicity. Common Terminology Criteria for Adverse Events (CTCAE 4.0) for the toxicity analyse have been used. The underlying diseases in HIV-group were HL n=6 (67%) and NHL n=3 (33%). Conditioning regimen was BEAM with BCNU replacement by Bendamustine 160 mg/m2/day at D-7, D-6. HIV viral load was undetectable (100%); the median number of CD4+ cells was 265 cells/mcl; all patients were on HAART. An assessment of potential differences in patients, disease and treatment characteristics between the 2 groups showed no significant differences.
Results: Overall survival (OS) at 12 months for all patients (n=45) was 93,3%. OS at 12 months was 88,9% in HIV-group *vs* 94,4% (p=0,3) in control group. One patient died later on engraftment in HIV group (cerebral hemorrhage) and two in control group within 1.5 years after ASCT (lymphoma progression). Relapse rate of the underlying disease at 12 months was 14% in HIV-group, in control group – 11% (p=0,8). The median time of leukocytes, neutrophils, and platelets recovery was D+13, D+15, D+15 respectively in HIV-group and D+13, D+16, D+14 in control group. There were no differences in rate of organ (Nephrotoxicity, Hepatotoxicity, Enteropathy and Mucositis) toxicity according to CTCAE.
Summary/Conclusion: One-year overall survival in patients with HIV-related lymphoma was 88,9%, relapse rate – 14% and did not differ from the control group. There were no found significant differences between two groups in hematopoietic recovery and toxicity rate. Preliminary data provide further evidence that HIV status does not affect the outcome of ASCT for lymphoma. Patients with HIV-related lymphoma should be considered candidates for ASCT if they meet standard transplant criteria.

PB2451

IMPACT OF MIXED CHIMERISM IN T REGULATORY CELLS ON RELAPSE RATE IN ACUTE LEUKEMIA PATIENTS AFTER ALLO-HSCT

D. Dubnyak[1,*], N. Risinskaya[2], M. Drokov[1], N. Kostritsa[3], J. Davydova[4], L. Kuzmina[1], N. Kapranov[4], V. Vasilyeva[1], N. Popova[1], E. Mikhaltsova[1], O. Koroleva[1], A. Sidorova[1], E. Usikova[1], Z. Konova[1], I. Galtseva[4], A. Sudarikov[2], E. Parovichnikova[1], V. Savchenko[1]

[1]Bone marrow transplant, [2]Molecular biology laboratory, National Research Center for Hematology, Moscow, Russian Federation, [3]School of Medicine, Lomonosov Moscow State University, [4]Immunophenotyping laboratory, National Research Center for Hematology, Moscow, Russian Federation, Moscow, Russian Federation

Background: It is known that T-regulatory cells (Treg) play an important role in maintaining tolerance after allo-HSCT. Tregs prevent the development of acute graft-versus-host disease (aGVHD) (Beres & Drobyski, 2013). At the same time these T-cell populations can limit the antitumor response (graft-versus-leukemia, GVL) and that limitation may cause relapses. Here we report the analysis of mixed chimerism in T-reg population and the frequency of relapse in patients with acute leukemia (ALL and AML) after allo-HSCT with comparable levels of donor chimerism.
Aims: To evaluate a possible relationship between the mixed chimerism in Treg cells and the rate of relapses in acute leukemia patients after allo-HSCT.
Methods: The study included 31 patients after allo-HSCT (ALL n=6, AML n=25). The median age was 38 years (19-66). Peripheral blood samples for analysis were taken on day 30 after transplantation. Immunomagnetic separation (Miltenyi Biotec, Germany) was used to isolate population with CD4+CD25+ phenotype which is predominantly associated with Treg cells. Extraction of DNA was performed from the obtained cells. Chimerism in DNA samples was determined using the STR-PCR method. The percentage of donor chimerism was calculated using standard procedures (Nollet *et al.*, 2001) Statistical analysis of the data was carried out using SPSS ver 23. (IBM, Chicago, Ill., USA). Exact Fisher's test was used to analyze the 2x2 contingency tables.
Results: In the patients group with less than 11% of cells with host genotype (more than 89% of cells of donor origin) the relapse rate was significantly

higher - 52.6% (10 of 19) than in the other group of patients with 11% and more cells with host genotype - 8.3% (1 of 12), (p=0.02). At the same time donor chimerism in the unselected bone marrow did not significantly differ between the groups (p=0.36) and amounted to 100% (75-100%) and 97.5% (90-100%). The study groups were balanced for all other factors that could affect the relapse rate: disease status, graft source, GVHD.

Table 1.

Cells with host genotype	Relapse	No relapse	p-value
<11%	52.6% (n=10)	47.4% (n=9)	0.02*
≥11%	8.3% (n=1)	91.7% (n=11)	

Table 1. Relapse rate depending number of Treg cells with host genotype

Summary/Conclusion: According to our data we proposed that host's Treg cells are not capable of suppressing GVL that explains significant differences in the frequency of relapses in patients with acute leukemia after allo-HSCT. Predominance of host's Treg cells may serve as a favorable prognostic sign but this hypothesis needs to be confirmed in the largest cohort of patients.

PB2452

HAPLO-IDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) IN HIGH-RISK HEMATOLOGICAL MALIGNANCIES WITH COMBINATION OF UNMANIPULATED BONE MARROW AND PERIPHERAL BLOOD STEM CELLS

D. Ait Ouali*, M. Benakli, F. Mehdid, N. Rahmoune, M. Baazizi, S. Zerkout, K. Tarhi, H. Bouarab, R. Belhadj, F. Harieche, R.-M. Hamladji, R. Ahmed Nacer

Hematology and Bone Marrow Transplantation, Pierre and Marie Curie Center, Algiers, Algeria

Background: The haplo-identical HSCT is currently a rescue procedure in patients (pts) with high risk hematological malignancies when identical HLA donor is not available. This procedure without T-depletion appears to allow rapid immune reconstitution and reduced incidence of graft-versus-host disease (GVHD) and good survivals.
Aims: We propose a retrospective study of 35 pts who benefited from this procedure.
Methods: From May 2013 to January 2017, 36 haplo-identical HSCT were used in 35 pts with hematological malignancies (7 AML, 19 ALL, 5 CML in blast crisis, 1 lymphoblastic NHL, 2 AL biphenotypic, 1 MDS). Median age was 24 years (5-55) and sex-ratio (M/F):2.8. The diagnosis-transplant delay is 32 months (6-138). At the time of the transplant, 21 pts were in second complete remission and 5 pts in active disease. The donors used were parent (father: 17, mother: 3) or siblings (brother: 11, sister: 4) or offsprings (daughter 1). The median age for donors is 39 years (13 -65). The degree of compatibility (HLA A, B and DR) is 3/6 (24 cases), 4/6 (10 cases) and 5/6 (2 cases). CMV status between donor/recipient was high risk in 35 cases. The ABO incompatibility is major in 5 cases, minor in 4 cases. The conditioning regimen associated Busilvex 9.6 mg/kg; Aracytine 8 g/m^2; Cyclophosphamide 3.6 g/m^2 for all pts. The GVHD prophylaxis included the combination Ciclosporin-Methotrexate, Mycophenolate mofetil and Thymoglobulin (10 mg/kg) in 35 pts. Thirty-five pts received an unmanipulated bone marrow (BM) transplant and Peripheral blood stem cells (PBSC) with a median dose infused CD34+ cells: 8.89 10^6/kg (1.43-32), mononuclear cells: 7.67.10^8/kg (0.59-19.2), CD3+ cells: 2.99 10^8/kg (0.04-14.2), CD4+ cells: 1.62 10^8/kg (0.02-7.53), CD8+ cells: 1.46 10^8/kg (0.36-7.53). At September 2017, the minimal follow-up delay was 8 months and maximal 52 months.
Results: Aplasia was observed in all pts with median duration of 20 days (13-32). The median day of neutrophils engraftment was 13 days (11-27). No cases of VOD were observed. One pt presented an early rejection and benefited from a second haplo-identical transplant with another donor. Acute GVHD occurred in 17 pts (48%) including 14 (40%) grade II-IV. Chronic GVHD was seen in 11 pts (39%) with extensive form in 4 pts. Seventeen pts (43%) showed CMV reactivation on average at day 44 (35-67). Eight cases of haemorrhagic cystitis (22%) (one grade 4) are observed on average at day 47 (26-119). Nine pts (25%) relapsed, of which 5 pts were blast crisis at the time of the transplant. After follow-up of 15 months (8-52), 19 pts (54%) are alive and 16 pts (45%) died within 10 pts (28%) from TRM (GVHA digestive: 3, severe infection: 5, haemorrhagic cystitis: 1, TRALI syndrome: 1) and 6 pts from relapse. The overall survival (OS) and disease free survival (DFS) are 51.5% and 41.6% respectively.
Summary/Conclusion: Haplo-identical allograft is, currently, a well-validated procedure in pts with high-risk haematological malignancies who do not have sibling HLA donor as our results show. However GVHD, CMV reactivation and TRM are relatively high with this procedure using combination of primed BM and PBSC.

PB2453

IMPACT OF IFN LAMBA 3/4 SINGLE NUCLEOTIDE POLYMORPHISMS (SNPS) ON THE CYTOMEGALOVIRUS (CMV) REACTIVATION IN AUTOLOGOUS STEM CELL TRANSPLANT (AUTO-SCT) PATIENTS

O. Annibali[1,*], E. Riva[2], L. Piccioni[3], V. Tomarchio[1], E. Circhetta[1], C. Sarlo[1], L. Franeschini[4], M. Cantonetti[4], M. Rizzo[4], S. Angeletti[5], G. Avvisati[1]

[1]University Campus Bio-Medico, Hematology stem cell transplantation, [2]University Campus Bio Medico,Virology Unit, [3]University Campus Bio Medico,Virology Unit, [4]University Tor vergata, Hematology, [5]University Campus Bio Medico,[4]Laboratory of Pathology and Microbiology, Rome, Italy

Background: CMV infection represents one of the main cause mortality after SCT. Recently, a protective effect of the T allele of rs12979860 IL-28B SNP against CMV infection in the allogenic stem cell transplantation was suggested. We investigate whether the rs12979860 and rs368234815 (IFNl4) SNPs might affect the incidence of active CMV infection in Autologous stem cell transplantation (Auto-SCT) setting.CMV infection represents one of the main cause mortality after SCT. Recently, a protective effect of the T allele of rs12979860 IL-28B SNP against CMV infection in the allogenic stem cell transplantation was suggested.
Aims: We investigate whether the rs12979860 and rs368234815 (IFNl4) SNPs might affect the incidence of active CMV infection in Autologous stem cell transplantation (Auto-SCT) setting.
Methods: The study included 99 patients who underwent to Auto-SCT. IL28 and IFNl4 SNPs were correlated with CMV reactivation along with other clinical and treatment parameters. CMV reactivation by CMV DNAemia was evaluated once a week until day 100 from Auto-SCT.
Results: CMV reactivation was documented in 50% (TT-DG/DG), 35% (CC-TT/TT) and 29.2% (CT-TT/DG) of the patients respectively. No differences in CMV copies number were recorded at reactivation between different IL28/IFNl4 genotypes. The analysis of patients older than 60 years showed a significantly higher incidence of active CMV infection in the TT-DG/DG (83%) population with respect to CC-TT/TT (21%) and CT-TT/DG (40%) patients.
Summary/Conclusion: Our data suggest a negative role of TT-DG/DG genotype in the CMV reactivation in Auto-SCT. The exposure to rituximab and the pre infusion presence of anti CMV IgG also significantly influenced CMV reactivation.

PB2454

BUSULFAN VS MELPHALAN IN REDUCED INTENSITY CONDITIONING ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION FOR HIGH RISK MDS/AML: OUTCOMES OF A SINGLE UK CENTRE

N. Borges*, L. Duncan, E. Hurst

Northern Centre for Cancer Care, Newcastle upon Tyne, United Kingdom

Background: Reduced intensity conditioning (RIC) allogeneic haematopoietic stem cell transplantation (allo-HSCT) is an effective treatment for high risk MDS and AML, but the optimal conditioning regimen remains debatable. FluMel (Fludarabine 150mg/m^2, melphalan 140mg/m^2) replaced FluBu (Fludarabine 150mg/m^2, Busulfan 9.6mg/kg IV) as the standard RIC regimen for myeloid malignancy in our centre due to perceived elevated transplant-related mortality. All RIC transplants are T-cell depleted with standard doses of alemtuzumab.
Aims: To determine whether the use of busulfan or melphalan with fludarabine in RIC allo-HSCT for MDS/AML had a significant impact on outcomes in our centre.
Methods: Outcomes pertaining to consecutive MDS/AML patients transplanted with fludarabine and either busulfan (FluBu) or melphalan (FluMel) based RIC over a 2-year period in a single centre were retrospectively analysed, including demographics, Karnofsky performance status (KPS), engraftment, graft-versus-host disease (GVHD), and mortality. Statistical analysis was conducted using Student's t-test and Fisher's exact test.
Results: Between May 2015 and May 2017, 44 patients underwent RIC allo-HSCT for MDS/AML. Twenty-two (50%) patients received FluBu and 22 patients received FluMel. In the FluBu group, 9 (41%) patients were male, with an average age of 56 years (range 31-71) and KPS range of 90-100. Ten

(45%) patients died, 5 (50%) of which due to relapse and the remainder (50%) due to infection, within an average of 255 days from transplant (range 37-608). In the FluMel group, 13 (59%) patients were male, with an average age of 57 years (range 40-69), and KPS range of 80-100. Seven (32%) patients died, 2 (29%) of which due to relapse, and the remainder (71%) due to infection, within an average of 198 days from transplant (range 44-428). Average time to engraftment was 15.1 and 15.5 days in the FluBu and FluMel groups, respectively. Eleven (50%) patients in the FluBu group and 9 (41%) in the FluMel group developed GVHD (grades II-IV). There was no significant difference in survival or non-relapse mortality (NRM) between both groups (p=0.5365 and p=0.6221, respectively).
Summary/Conclusion: In a uniform MDS/AML cohort, we have demonstrated no significant difference in outcomes between T-cell depleted fludarabine/busulfan and fludarabine/melphalan RIC allo-HSCT. However, more studies are needed with larger samples and longer follow-up times.

PB2455

RELATIONSHIP BETWEEN THE CONTENT OF CD34 + CELLS AND THEIR COLONY-FORMING CAPACITY IN PATIENTS WITH MULTIPLE MYELOMA IN THE PROCESS OF PREPARING A LEUKAPERESIS PRODUCT FOR AUTOLOGOUS TRANSPLANTATION

J. Chubukina[1,*], V. Balashova[2], V. Rugal[3], N. Semenova[3], I. Kostroma[2], S. Gritsaev[4], T. Glazanova[1], L. Bubnova[1], S. Voloshin[2], S. Bessmeltsev[2]

[1]Laboratory Of Immunohematology, [2]Hematological Department, [3]Laboratory For Study Of Leukemia, [4]Department Of Bone Marrow Transplantation, Russian Research Institute Of Hematology And Transfusiology, Saint-Petesburg, Russian Federation

Background: Restoration of normal hematopoiesis after autologous transplantation of peripheral hematopoietic stem cells (PHSC) depends on a number of factors, including the colony-forming capacity (CFC) of CD34+ cells. The number of colony forming units (CFU) per unit volume of the test material is a characteristic of the functional activity of the product harvested for transplantation.
Aims: To study the correlation between the number of CD34+ cells and the number of CFUs in cell culture in the same samples of the peripheral blood leukapheresis product before and after cryopreservation in patients with multiple myeloma (MM). vity of the product harvested for transplantation.
Methods: Samples of peripheral blood apheresis product before and after cryopreservation in 32 patients with MM who underwent autotransplantation of PHSC have been studied. CFU was studied by culturing cells in a semi-solid culture medium MethoCultH4435 based on methylcellulose. The CD34+ cell count was determined by a standard flow cytometry method. Both indicators were calculated for 10,000 nuclear cells.
Results: In MM patients, the number of CD34+ cells in the apheresis product prior to cryopreservation was on average 1697,0±206,1x10^5 (230,0-4710,0). After thawing of the cellular suspension, the number of CD34+ cells increased almost 1.5-fold and amounted to an average 2473,0±294,7x10^5 (255,0-7500,0). The number of CFUs in the cell culture prior to cryopreservation was on average 396,6±21,5x10^5 (146,0-636,0 colonies). After the transplant was thawed, the number of CFUs decreased to 238,3±19,4x10^5, which is 1,7-fold less then prior to cryopreservation. Comparison of the number of CD34+ cells and CFU in the transplant prior to cryopreservation showed that the number of CD34+ cells was more than 4 times higher than the number of CFUs and, therefore, only about 25% of CD34+ cells were capable to form the colonies. After cryopreservation, there was a significant decrease in CFC of PHSC, whereas the number of CD34+ cells increased in comparison with baseline (due to granulocyte destruction), and was 10 times higher than the number of CFUs. At the same time, the correlation between CD34+ cells and CFU in culture in MM patients both before and after cryopreservation was absent; there was a great variability in these parameters. A correlation was found only between the number of CD34+ cells and CFU-GM before cryopreservation (r=+0,302, p<0,05).
Summary/Conclusion: Thus, to evaluate the effectiveness of cell mobilization and transplant quality, it is expedient to simultaneously use two indicators characterizing PHSC – the content of CD34+ and the colony-forming capacity. Probably, the further study of the immunophenotypic characteristics of CD34+ cells, reflecting the degree of differentiation of PHSC, will help to explain the differences in their functional activity.

PB2456

VINORELBINE FOR STEM CELL MOBILIZATON IN HODGKIN'S LYMPHOMA

A. Kuzyaeva[1,*], V. Shuvaev[2], J. Schubukina[2], M. Mikhaleva[2], A. Garifullin[1], A. Kuvshinov[2], A. Shmidt[2], A. Seltser[2], A. Chechetkin[2], S. Voloshin[2]

[1]Haematology, [2]Federal State Budget Institution Russian Scientific and Research Institute of Hematology and Transfusiology of Federal Medical Biological Agency, St-Petersburg, Russian Federation

Background: Currently high-dose chemotherapy with autologous hematopoietic stem cell transplantation is the standard of treatment for patients with Hodgkin's Lymphoma (HL) who has the first chemosensitive relapse of the disease. At our center, most of the patients with HL are mobilized PBSC when they achieve complete or partial remission after the first line of therapy to have adequate stem cells reserve in case of autologous transplantation. There are many studies devoted to the non-myelosuppressive regimens of mobilization with vinorelbine in patients with multiple myeloma, who showed its efficacy, low toxicity and reduced costs for the preparation of PBSC. Therefore, our center performed study for adaptation of this regimen in patients with other hematological malignancies, like HL. We present a comparison of mobilization regimens using vinorelbine at dose 35mg/m^2 and cyclophosphamide at dose 1.5g/m^2 in homogeneous groups of patients with HL in remission after the first line of chemotherapy.
Aims: To assess the efficacy of mobilization with vinorelbine in patients with HL.
Methods: We have analyzed the data of 18 patients with HL, with similar parameters of the median age and status of the disease, in the complete remission who received first line of therapy and underwent PBSC mobilization. Patients were divided into 2 groups according to the mobilization regimens: group 1 - vinorelbine (n=6), group 2 - cyclophosphamide (n=12). In group 1, the following scheme was used: Day 1 - vinorelbine 35mg/m^2, IV; from Day 4 - filgrastim 10 mg/kg, SC daily. In group 2: Day 1 - cyclophosphamide 1.5 mg/kg, IV; from Day 2 - filgrastim 10 mg/kg SC, daily. The first day of apheresis was initiated at $CD34^+$ cells level of more than 20/μL in peripheral blood.
Results: The median of $CD34^+$ cells in peripheral blood (PB) on the first day of harvest was: 193.5/μL in group 1 and 105/μL in group 2. On the first day of harvest, adequate number of PBSC (>2.0x10^6/kg) was achieved in 100% of patients in group 1 (range 2.4-7.1x10^6/kg, the median 4.85x10^6/kg) and 50% patients from group 2 (range 0.7-7.0x10^6/kg, the median 2.89x10^6/kg). There were need from 1 to 3 harvest (the median 1.5) in order to yield the minimum amount of CD34+ in group 2 patients. The length of hospital stay for patients in group 1 was 9-10 days (median 9), and 9 to 13 days (median 11) for group 2. Neutropenia grade 4 developed in 33% of patients in group 2 and was not noted in any patient in group 1. Significant differences were found between the harvests (p=0.04) and days in hospital (p=0.009) between groups 1 and 2. The number of $CD34^+$ cell/kg harvested in first day had tendency (p=0.06) favor to vinorelbine. There were no statistically significant differences between the groups of patients according to the level of $CD34^+$ cells in the PB on the first day of harvest, the number of $CD34^+$ cells/kg collected on the first day of harvest and the total number of collected $CD34^+$ cells/kg.
Summary/Conclusion: Our results demonstrate that vinorelbine for PBSC mobilization i has comparable efficacy with intermediate doses of cyclophosphamide in patients with HL. At the same time, less hospital days and the number of harvest makes this regimen more cost attractive. Continuation of study vinorelbine in mobilization in hematolgical patients will reduce the frequency of "waste harvest", the costs of collection PBSC and the risk of complications.

PB2457

HAPLOIDENTICAL STEM CELL TRANSPLANTATION IN HIGH RISK HEMATOLOGIC MALIGNANCIES: RISK FACTOR AND OUTCOME ANALYSES IN OUR CENTER

M. Perera Alvarez[1,*], M. Saez-Perdomo[2,3], C. Acosta Fleitas[2], C. Rodríguez Medina[1], E. González Pérez[1], L. Guerra[1], M. Torres Ochando[1], S. Jiménez Bravo de Laguna[1]

[1]Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, [2]Hematology, Hospital Universitario de Gran Canaria Dr Negrín, [3]Universidad de las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain

Background: The allogenic stem cell transplantation (Allo-HSCT) is an efficient treatment for patients with high risk hematologic malignancies. Over the past decades new modalities of Allo-HSCT as Haploidentical stem cell transplantation (Haplo-HSCT) allowed us to offer this therapy to patients who for race reasons, presence of rare haplotypes or rapidly progressive disease course can't find a compatible unrelated donor.
Aims: The aim of this study is to assess the efficacy of Haplo-HSCT on our series evaluating the survival (S), overall mortality (OM) at 100 days and transplant related mortality (TRM).

Methods: We analyzed all the consecutive Haplo-HSCT performed in our center since 2013. The conditioning regimens were decided regarding age, comorbidities and pre-Haplo-HSCT disease status. All patients received high doses of Cy (50 mg/kg on days 3 and 4 posttransplantation) cyclosporine and MMF as CGvHD prophylaxis. We classified the patients before the Haplo-HSCT according to performance status (ECOG), comorbidities (Sorror), disease status (DRI and EBMT). We used SPSS V.23 to calculate the S and OM by the KM test and Chi squared tests.
Results: We performed 43 haplo-HSCT, 25 were males and 18 females with a mean age of 43 (range 16- 68). Diagnosis: Acute myeloid leukemia (24), Acute lymphoid leukemia (3), Hodgkin disease (65), Non Hodgkin lymphoma (2), severe aplastic anemia (2) Chronic lymphoproliferative disease (3). 23/43 patients died throughout the follow-up period with 31% OM at day +100 (fig. 1a). 15/23 patients died due to TRM. 7/8 of the remaining patients died due to disease progression and 5 out of these 7 patients had an active disease pre-Haplo-HSCT. For the analysis of the prognostic indexes we only observed a statistically significant difference by chi squared p=0.004 for TRM between patients with ECOG >2 (100% died due to TRM) and patients <2 (28.2% died due to TRM). Among the patients with acute leukemia (27/43) the overall mortality at day +100 was 28.5%. 16 out of the 27 deceased were in CR pre-Haplo-HSCT and 11/27 had an active disease. Comparing the survival of both groups by KM we observed 48% survival for the patients receiving the Haplo-HSCT with CR against 22% for the patients receiving Haplo-HSCT with active disease (figure 1b) at 12 months, which was mantained through the third year (p=0.1 not statistically significant due to the small sample size).

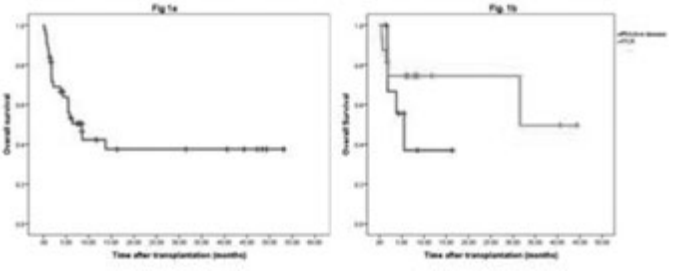

Figure 1.

Summary/Conclusion: Our results revealed ECOG >2 as an independent variable for TRM with statistical signification. Regarding acute leukemias, we were able to rescue 22% patients with refractory disease at 3 years, which agrees with the results previously published, and rises to 50% for patients receiving the Haplo-HSCT with CR.

PB2458

DURATION OF IMIPENEM-CILASTATIN AND/OR PIPERACILLIN TAZOBACTAM IS PREDICTIVE FOR ACUTE GRAFT VS HOST DISEASE AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

N. Ben Abdeljelil*, W. Chanbeh, A. Barhoumi, L. Essakly, C. Ellouz, O. Ben Dhia, R. El Fatmi, A. Lakhal, D. Belloumi, L. Torjemane, S. Ladeb, T. Ben Othman

Centre National de Greffe de Moelle Osseuse de Tunis, Tunis, Tunisia

Background: Allogeneic stem cell transplantation (ASCT) is associated with a high risk for developing graft-versus-host disease (GVHD).
Aims: The aim of the study is to determine if duration of imipenem-cilastatin and/or piperacillin-tazobactam exposure is an independent risk factor for grade II-IV acute GVHD.
Methods: A retrospective study was conducted in adults patients who underwent ASCT from HLA-identical sibling donors between January 2014 and December 2016 to evaluate the impact of duration of imipenem-cilastatin or piperacillin-tazobactam exposure on grade II-IV acute GVHD. Patients with lymphoid malignancy were conditioned with fludarabine/busulfex/cyclophosphamide or TBI/etoposide. Myeloid malignancies were conditioned with busulfex/cyclophophamide. Patients with aplastic anemia received ATGAM/cyclophosphamide or fludarabine/thymoglobulin/cyclophosphamide regimens. Gut decontamination with polymixin E, gentamicin and amphotericin B was used in all recipients. Graft-versus-host disease prophylaxis consisted of cyclosporine and a short course of methotrexate. No patient received antibiotic prophylaxis. GVHD was confirmed by biopsy and classified according to Glucksberg criteria. Patients who did not receive imipenem-cilastatin or piperacillin-tazobatam or received them less than 24 hours were excluded. The odds ratios and 95% confidence intervals as determined by multivariate analysis for 7 variables (selected based on a P value <0.15 in univariate analysis).
Results: Seventy-nine patients underwent ASCT (47men and 32 women). Median age was 35 years (range, 18-56y). Diagnosis included AML (n=27, 34.2%), ALL (n=23, 29.1%), Aplastic anemia (n=18, 22.8%), other hematologic malignancies (n=11, 13.9%). Stem cell source were BM in 34 patients (43%) and PBSC in 45 patients (57%). Twenty-four patients received piperacillin-tazobactam only (30.4%, group 1), 23 patients received imipenem-cilastatin only (29.1%, group 2) and 32 patients received both (40.5%, group 3).The median duration of antibiotic exposure was 17days (range, 4-64 days). One patient experienced primary graft failure. Non-relapse mortality (NRM) was 17.4%. One patient had early NRM. Twenty-six patients (32.9%) developed grade II-IV acute GVHD at a median of 23 days (range, 14-100 d). The frequency of grade II-IV acute GVHD was comparable in the three groups (33.3%, 23.8% and 40.6% in groups 1, 2 and 3, respectively, p=0.45). Acute gut GVHD occurred in 16 patients (20.7%). Three-year overall survival was 66%. In univariate and multivariate analysis, the risk of acute grade II-IV GVHD increased significantly with duration of antibiotic exposure. Exposure for ≥25 days increases the risk by nearly six times (OR=5.8, 95% CI: 1.8- 18.68, p= 0.003).
Summary/Conclusion: Duration of broad-spectrum antibiotics exposure is associated with an increased risk of acute GVHD. Limiting the use of antibiotics post-ASCT may reduce the occurrence of acute GVHD.

PB2459

ESTIMATED ENERGY REQUIREMENT AND ACTUAL INTAKE IN PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION – A PROSPECTIVE STUDY FROM TERTIARY CARE CENTRE IN NORTH INDIA

K. Mishra*, A. Jandial, B. Barwal, D. Lad, G. Prakash, P. Malhotra, N. Varma, S. Varma, A. Khadwal

Pgimer,Chandigarh, Chandigarh, India

Background: Nutritional status is significantly compromised during the hematopoietic stem cell transplantation (HSCT), which not only postpones the period of engraftment but also plays a role in graft *versus* host disease (GVHD), veno-occlusive disease (VOD) and hospitalization in the ICU. Moreover, given conditioning regimen composed of high-dose chemotherapy or total body irradiation (TBI) triggering various side effects that disturb nutritional intake, such as stomatitis, nausea, vomiting, loss of appetite and diarrhea, it's a challenging task to maintain healthy nutritional status. However, less literature is available regarding nutrition status compromise (average amount and duration of inadequate intake of nutrients) in patients undergoing HSCT which hampers with planning during HSCT. The need for similar data is even more pertinent in developing countries where the average nutritional status of the citizen is poor.
Aims: To assess and compare Estimated Energy Requirement, dietary intake and weight changes from the day of the start of conditioning regimen to 14 days after transplantation or discharge.
Methods: This prospective observational study carried out in the Department of Internal Medicine in association with department of Dietetics PGIMER, Chandigarh. A total of 20 patients (12 auto and 8 allo) undergoing HSCT were included between 2016-2017. Body mass index (BMI) and Mid upper arm circumference (MUAC) was measured daily, and recording of all foods and fluid taken by patients was done using diet chart performa. Based on daily food consumption Calorie, protein, carbohydrate, and fat intake were calculated. The Estimated Energy Requirement (EER) for Maintenance is the dietary energy intake that is predicted to maintain energy balance in healthy individuals or groups of individuals at current levels of body size and level of physical activity. EER was calculated for each patient according to their physical activity level, based on dietary reference intakes (DRI) equations and was compared with actual calorie intake. The Transplantation period was divided into four phases; phase 1(start of conditioning to D-1), phase 2 (D0 to D+7), phase 3(iD+8 to D+14) and phase 4 (at the time of discharge).
Results: The median age was 45.5 years (Range 10-64). The average calories, carbohydrates, protein, and fats intake by all patients undergoing HSCT had decreasing trend during all phases except for the time of discharge. There was a significant effect of duration on weight (p=0.002), BMI (p=0.000), calorie intake (p=0.002) and fats intake during different phases (p <=0.001). There was no significant effect of duration on protein (p=0.128) and carbohydrates intake (p=0.051). None (0%) of the patients met 100% of EER in any phase of transplant duration. Two (10%) at phase 1, eight (40%) at phase 2, 15 (75%) at phase 3 and three (15%) at discharge did not meet even 50% of EER (image).

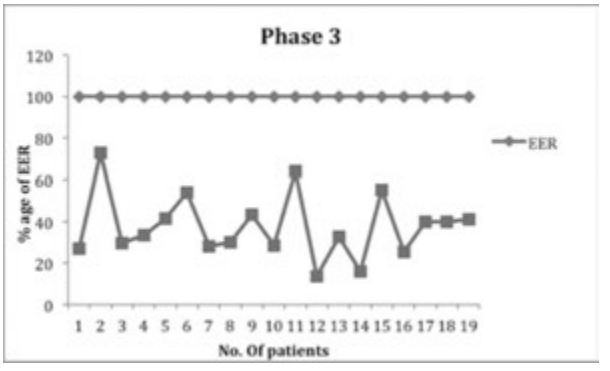

Figure 1.

Summary/Conclusion: There is a significant compromise in nutrients intake in patients undergoing HSCT. The nutritional status continues to worsen unless patient recovers fully and is fit for discharge. Therefore, there is a need to step up our effort to supplement nutrition by giving oral and parenteral supplements. Further study can be done in HSCT patients not meeting EER, analyzing the effect on engraftment, GVHD, VOD and hospitalization stay.

PB2460

DESIGN OF PHASE 3, RANDOMIZED TRIAL OF DEFIBROTIDE FOR PREVENTION OF HEPATIC VENO-OCCLUSIVE DISEASE/ SINUSOIDAL OBSTRUCTION SYNDROME

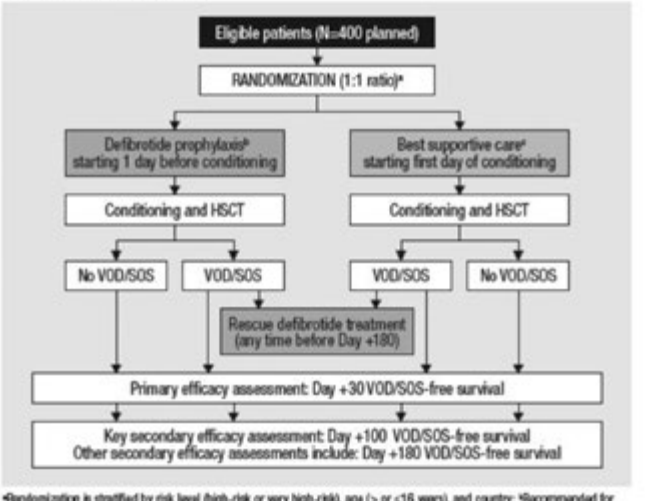
S. Grupp[1,*], A. Pagliuca[2], S. Corbacioglu[3], R. Hume[4], W. Liang[4], W. Tappe[4], P. Richardson[5]

[1]Pediatric Oncology, The Children's Hospital of Philadelphia, Philadelphia, United States, [2]King's College Hospital, London, United Kingdom, [3]University of Regensburg, Regensburg, Germany, [4]Jazz Pharmaceuticals, Palo Alto, [5]Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States

Background: Hepatic veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) is a potentially life-threatening complication of hematopoietic stem cell transplant (HSCT); VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved for treatment of severe VOD/SOS post-HSCT in the European Union in patients aged >1 month and for VOD/SOS with renal or pulmonary dysfunction post-HSCT in the United States and Canada, but no drug is approved for VOD/SOS prevention. VOD/SOS risk factors include receiving myeloablative conditioning (MAC) or calicheamicin antibody conjugates. Defibrotide as prophylaxis reduced VOD/SOS incidence in high-risk pediatric patients (Corbacioglu *et al.*, *Lancet*, 2012); data are more limited for adults. A new randomized, parallel group study of defibrotide for prevention of VOD/SOS in high-risk, post-HSCT patients of all ages (≥1 month) is underway (NCT02851407).
Aims: To assess the efficacy and safety of defibrotide prophylaxis plus best supportive care compared with best supportive care alone for prevention of VOD/SOS in adult and pediatric post-HSCT patients at high or very high risk for VOD/SOS.
Methods: HARMONY is a phase 3, multicenter, randomized study being conducted at ~100 sites worldwide (**Figure**). High/Very high-risk patients receive defibrotide prophylaxis with best supportive care or best supportive care alone. VOD/SOS is diagnosed according to modified Seattle criteria, or biopsy; a blinded endpoint adjudication committee validates each diagnosis. Patients in either arm who develop VOD/SOS will receive defibrotide rescue treatment. The planned sample size of 400 provides 90% power to detect a 0.46 hazard ratio for the primary endpoint of VOD/SOS-free survival by Day +30. Study eligibility criteria include: scheduled HSCT and high/very high risk of VOD/SOS. High-risk criteria are MAC plus ≥1 additional risk factor: transaminase >2.5× upper limit of normal (ULN), serum total bilirubin >1.5× ULN, cirrhosis, hepatic fibrosis on biopsy, viral hepatitis within 1 year, prior hepatic irradiation, iron overload, or high-risk stage IV neuroblastoma. Very high-risk criteria are ≥1 of the following: osteopetrosis, familial hemophagocytic lymphohistiocytosis or predefined related disorders undergoing MAC, prior gemtuzumab (dose ≥9 mg/m^2) or inotuzumab (≥1.5 mg/m^2 over 28 days), or Class III high-risk thalassemia. Key exclusion criteria are hemodynamic instability, clinically significant bleeding (or from life-threatening site), or use of medication <24 hours that increases bleeding risk (heparin ≤100 U/kg/day is permitted). The recommended defibrotide dosage is 25 mg/kg/day (in 4 divided doses) for ≥21 days starting the day before conditioning and ending no later than Day +30 post-HSCT. The key secondary outcome is VOD/SOS-free survival by Day +100; other secondary assessments include VOD/SOS-free survival by Day +180, VOD/SOS incidence, disease relapse, and MOD onset and resolution.
Results: As of February 2018, 107 sites are active and 164 patients have been randomized. Enrollment is ongoing.

Table 1.

Figure 1. Study Design



*Randomization is stratified by risk level (high-risk or very high-risk), age (> or ≤16 years), and country; †Recommended for ≥21 days and ending no later than Day +30 post-HSCT, with best supportive care; ‡Given according to institutional guidelines until Day +30 post-HSCT or hospital discharge, whichever is sooner, or diagnosis of VOD/SOS, if applicable.
HSCT, hematopoietic stem cell transplantation; VOD/SOS, veno-occlusive disease/sinusoidal obstruction syndrome.

Summary/Conclusion: HARMONY will provide phase 3, randomized study data on the efficacy and safety of defibrotide for the prevention of VOD/SOS in HSCT patients at high/very high risk for VOD/SOS. These findings will extend previous pediatric study data and provide new evidence in adults.

PB2461

A SINGLE-CENTRE DATA FOR BACTERIAL AND VIRAL INFECTION RATES IN ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANT RECIPIENTS DURING THE FIRST 180 DAYS POST-NEUTROPHIL ENGRAFTMENT

M. Khalifa[1,*], S. Atanze[1], D. Partridge[2], S. Thomas[1], S. Francis[1], S. Stanworth[3], J. Snowden[1], H. Kaur[1]

[1]Haematology, [2]Microbiology, Sheffield Teaching Hospitals, Sheffield, [3]NHS blood and Transplant, John Radcliffe Hospital, Oxford, United Kingdom

Background: Infections are the most common complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT). They are associated with significant morbidity and mortality. In the early post-engraftment bacterial infections and reactivation of latent viruses is frequently seen due to immunosuppressive therapy. There is lack of literature on infection incidence and description of causative pathogens which would be of interest towards any future studies looking at prophylaxis strategies.
Aims: To identify the rates of bacterial and viral infections in allo-HSCT recipients during the first 180 days post-neutrophil engraftment. To compare the infection rates between matched unrelated donors (MUD) and sibling allo-HSCTs.To compare infection rates between myeloablative and reduced intensity conditioning (RIC) allo-HSCTs. To describe the common bacterial and viral organisms causing infection.
Methods: Data was collected retrospectively for all patients that underwent an allo-HSCT from January 2015 to December 2017. All positive blood cultures and viral specimens for each patient were identified for the time period specified using the laboratory database systems. Data was analysed using Prism (Graphpad). Student's t test was used for comparing medians and chi squared for proportions. A p value ≤0.5 was considered significant.
Results: 113 patients received an allo-HSCT during the study period. The median age was 54 (SD 15 years, range 19-72). The majority of donors were matched unrelated donors (MUDs), 64%, with 29% of allograft from sibling donors, 5% haploidentical and 2% with cord blood stem cells. Myeloablative conditioning was used in 19% of allografts whereas (RIC) was used in 81% of transplants. There was no difference in the number of episodes of viral infection in MUD allografts compared to sibling allografts

(MUD median 2, SD 1.4, sibling median 2, SD 1.6.) (p >0.05, unpaired t test). The commonest viral infection was EBV, occurring in 55% of patients overall. EBV infection was significantly more common in sibling allografts at 78% than MUD allografts at 47% (p≤0.05). Infections with respiratory viruses were significantly more common following myeloablative conditioning, with adenovirus and respiratory syncytial virus both seen in 23% of myeloablative allografts, compared to 5% and 3% respectively of RIC allografts (p ≤0.05).Data on p 54% of patients had at least one positive blood culture. There was no difference in the proportion of patients with a positive blood culture in MUD allografts compared to sibling allografts (MUD 50%, sibling 55%) (p>0.05) The organisms isolated were diverse, with a total of 25 different genera/species isolated. The commonest were coagulase negative staphylococci or mixed coagulase negative staphylococci 49% *Pseudomonas sp* in 14%, *Escherichia coli* in 8% and *Klebsiella sp* and *Enterococcus sp* each in 7%.

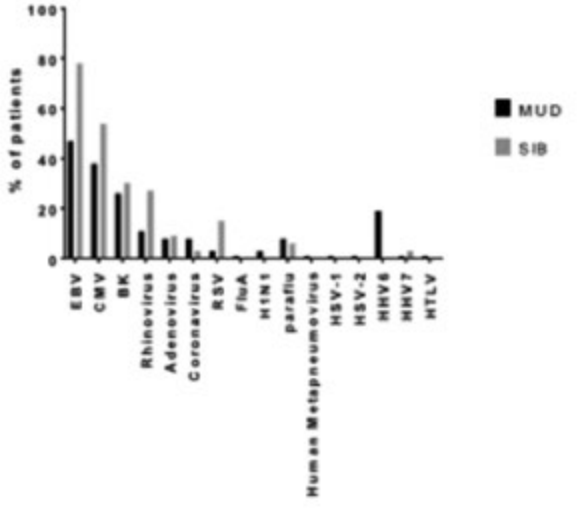


Figure 1.

Summary/Conclusion: We present a comprehensive description of the types and frequencies of bacterial and viral infections in allo-HSCT recipients during the first 180 days post neutrophil engraftment. There are statistically significant differences in patterns of viral reactivation according to donor and conditioning regimen, which may have implications for surveillance, prophylaxis and empirical treatment in these patient groups.

PB2462

COULD THE OUTPATIENT-BASED AUTOLOGOUS STEM CELL TRANSPLANTATION REDUCE THE "FINANCIAL TOXITY" WITHOUT WITHOUT ADVERSELY AFFECTING THE EFFECTIVENESS AND SAFETY OF THE METHOD?

P. Kaloyannidis*, E. Shaibani, N. Al Mokhtar, F. Aburahman, E. Mutahar, M. Al Darweesh, O. Abduljalil, A. Estanislao, B. Jenifer, R. Khalili, J. Apostolidis, K. Al Anezi, H. Al Hashmi

Adult Hematology and Stem Cell Translantation Department, King Fahad Specialist Hospital, Dammam, Saudi Arabia

Background: Given the improvements in the supportive care, autologous hematopoietic stem cell transplantation (AHSCT) could be performed in outpatient basis, for selected patients (pts), offering the benefit of shorter hospitalization, less exposure to hospital pathogens, saving nosocomial beds, demonstrating thus not only a safe but also a cost effective profile.
Aims: To evaluate the feasibility and safety of the outpatient-basis AHSCT approach.
Methods: We retrospectively analyzed outcome of 34 AHSCTs performed on outpatient basis, in a total of 27 pts, previously diagnosed with Hodgkins lymphoma (n=6) or Multiple Myeloma (n=21); 7 pts with MM underwent tandem-AHSCT in the context of the scheduled treatment plan. Nine were females and 18 males aged of a median of 48 (25-68) ys. The eligibility criteria for the outpatient AHSCT, were the standard clinical and laboratory tests, plus psychosocial evaluation, patient's compliance assessment, 24 hours caregiver availability, timely access to the hospital and signed informed consent. The conditioning regimen consisted from single agent Melphalan of 200 (n=25) or 140mg/m^2 (n=9), graft infusion and supportive care were given in an allocated room. The antimicrobial, antifungal and antiviral prophylaxis was administered from day -2 and filgrastim 5mcg/kg from day +5 till neutrophils recovery. If no infection was documented the antimicrobial and antifungal prophylaxis were discontinued upon stable neutrophils recovery while antiviral prophylaxis was continued for 10-12 months. Patients were evaluated daily or every 2 days in the outpatient clinic. The criteria for admission were fever >38^{o}C, intractable nausea/vomiting or diarrhea, mucositis needing total parenteral nutrition and any other toxicity WHO>grade 3.
Results: The median day for neutrohils >1000/mm^3 was 11 (9-18) and for platelets >20000/mm^3 was 11 (0-21); in 2 pts platelets never dropped lower than 25000/mm^3. Totally, 15 admissions were required, 10 for inability for food/fluid uptake due to severe mucositis, 4 for febrile neutropenia and 1 for engraftment syndrome. The infections successfully treated with broad spectrum antibiotics and no pt was admitted to intensive care unit. For the whole 34 ASCTs, the total hospitalization days were 77 (median:1, range 0-12) ,while for the 15 admissions the median hospitalization days were 5 (1-12), which favorably compares with the average of 14 hospitalization days for a single "conventional" ASCT. No other toxicities (WHO>3) were observed. Currently 26/27 pts are alive 9(1-37) months post AHSCT. Foe pts with MM the 2-years overall and progression free survival are 93% and 65% respectively. All six patients with HL are alive 3-12 months post AHSCT.
Summary/Conclusion: Our data indicate that the outpatient-ASCT is a feasible and safe approach provided a caregiver availability, close pts evaluation and adequate supportive care. Keeping in mind the nosocomial complications and the potential high cost of the prolonged hospitalization, it seems that the outpatient ASCT offers lower risk of infections and significant cost saving compared to the "convetional" inpatient ASCT approach.

PB2463

AUTOLOGOUS HEMATOPOIETIC CELL TRANSPLANTATION FOR LYMPHOID MALIGNANCIES IN PATIENTS OF 65 YEARS OLD AND BEYOND. A SINGLE CENTER FEASIBILITY EXPERIENCE

S. Desilets[1], E. Nicolas-Virelizier[1], F. Subtil[2], L. Gilis[1], L. Lebras[1], S. Assaad[1], Y. Guillermin[1], P. Rey[1], M. Michallet[1], A. Belhabri[1], A.-S. Michallet[1,*]

[1]Hematology, Centre Léon Bérard, Lyon, [2]Université Lyon [1], Villeurbanne, France

Background: Autologous hematopoietic cell transplant (auto-HCT) remains a cornerstone consolidation strategy in the front line treatment of Multiple Myeloma (MM) and Lymphomas in young and fit patients. However, with the better toxicity profile of new drugs used in induction phase and in conditioning, as well as the improvement in their management, auto-HCT is more often considered in older patients.
Aims: The aim of this retrospective study was to assess the feasibility and efficacy of consolidation auto-HCT for lymphoid malignancies in patients of 65 years old and beyond.
Methods: Between years 2012 and 2016, 54 patients aged 65 years and beyond, received auto-HCT, median age at transplantation was 67 years (range: 65-71), 23 (43%) were female. Diagnosis was MM in 45 (83%) patients and lymphoma in 9 (17%) patients (2 Diffuse B Cell, 4 mantle cell, 1 follicular, 1 Hodgkin and 1 T cell). Performance status (PS) at transplantation was 0 in 16% of patients, 1 in 78% and 2 in 6%. Auto-HCT was used in first line strategy for the majority of patients (N=45, 83%). For the multiple myeloma patients, the induction treatment was mostly bortezomib-based regimen [VTD (56%), VCD (15%), VRD (5%), VD (5%)] and 5% received lenalidomide and dexamethasone. The lymphoma patients received RDHAP (6 patients), DHAP (1), Brentuximab (1), RCHOP (1). The majority of patients were easily collected for HC without the need of mobilization with plerixafor (78%), the median number of CD34 collected cells was 3.99 million/kg (range 2.04 to 10.96). One MM patient received a tandem auto-HCT. Disease response at transplantation was as follow: in MM patients, 9 (20%) CR, 14 (30%) VGPR, 20 PR and 2 less than PR; in lymphoma patients, 5 (56%) were in complete radiological response and 4 (44%) were in PR. MM patients received Melphalan-based conditioning, 24 (53%) received the standard dose of 200mg/m^2, 12 (27%) received 140mg/m^2 and 9 (20%) received 100mg/m^2. The lymphoma patients were conditioned with either BEAM (N=6), RBEAM (N=2) or TEAM (N=1).
Results: After transplantation, the median time to neutrophils recovery (neutrophils >0.5x10^9/L) was 11 days (range: 9-20) and the median time to platelets recovery (platelet >50x10^9/) was 15 days (range: 10-29). The median duration of hospitalization after transplantation was 17 days (range: 9-28), at hospital discharge 28 (53%) patients had a PS of 1. Main toxicities were gastro-intestinal and febrile neutropenia, 34 (63%) patients had mucitis, of those, 23 (68%) grade 1-2 and 10 (%) grade 3-4. Forty patients had

nausea and vomiting, 21 (52%) were of grade 3-4; 37 patients had diarrhea, 22 (60%) were grade 1-2. Febrile neutropenia was observed in most patients (N=45, 82%). After a median follow up of 32 months, the median progression-free survival rate was 22 months and median overall survival was not reached. At the last follow-up, 45 patients were alive, 9 patients died, all of them had progressive disease (6 were MM), 2 died of septic shock after a chemotherapy treatment.
Summary/Conclusion: We showed that auto-HCT is a feasible and well tolerated treatment option for patient with lymphoid malignancies with 65 years old and beyond, no death related to this procedure, this was mainly due to the good patient selection and the better prevention and management of the procedure-related toxicities and complications.

PB2464

THE EFFECT OF GEOGRAPHICAL DISTANCE BETWEEN A TRANSPLANT CENTER AND PATIENT RESIDENCE WHO UNDERWENT ALLOGENEIC STEM CELL TRANSPLANTATION: A RETROSPECTIVE, UNICENTRIC STUDY

B. Haffar*, R. Massoud, N. Moukalled, A. Zahrelddine, R. Nehme, A. Bazerbachi, J. El Cheikh

Internal Medicine, American University of Beirut, Beirut, Lebanon

Background: Several factors affect the outcome of allogeneic stem cell transplantation (Allo-SCT) in hematologic malignancies patients. Proximity to the transplant center could be an independent factor that affects overall survival (OS). This study has been conducted at American University of Beirut Medical Center (AUBMC), a referral center for the Middle East located in Lebanon.
Aims: Our aim was to determine the differences in the survival between patients residing in Lebanon and those referred from abroad.
Methods: We identified 161 consecutive adults patients who underwent allo-SCT between January 2007 and December 2016. One hundred and three patients (64%) were residing in Lebanon, and 58 patients (36%) were referred from abroad. Follow up on patients residing in Lebanon was done mainly via regular clinic visits, while those residing outside Lebanon was either by clinic appointment, and/or phone calls in case they could not travel to Lebanon. All patients and transplant characteristics are listed in table 1.

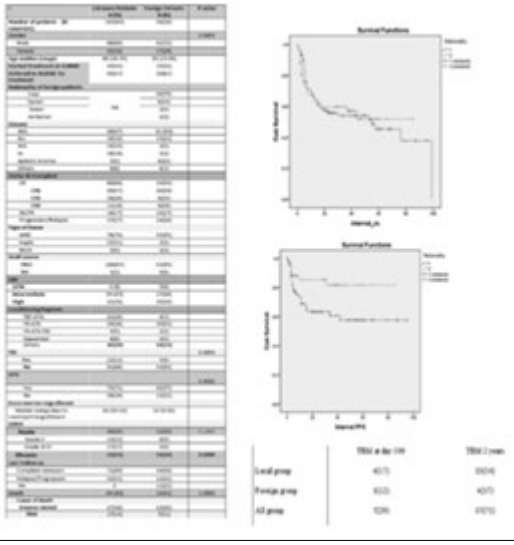

Figure 1.

Results: All patients engrafted. The median time to neutrophil engraftment was 15 days in both groups but with different ranges (10-23) and (9-35) days in local and foreign groups respectively. In Local group 68 (66%) patients were in Complete remission (CR) at transplant, from those 39 (57) were in first CR (CR1), 18 (26) were in second CR (CR2), and 11(16) were third CR (CR3). *vs* 35 (34%) were in progression disease/relapsed disease (PR/RD) and Stable disease/partial response(SD/PR) at transplant, in foreign group 34 (59%) patients were at CR at time of transplant, from those 20 (59) were in CR1, 8(23) were in CR2, and 6(18) were in CR3, while 24 (41%) patients were in PR/RD and (SD/PR) at time of transplant. The incidence of acute graft *versus* host disease (aGVHD) was higher in local group with 30 cases (29%) and 11 cases (19%) in foreign group (P= 0.188). Similarly, the incidence of chronic graft *versus* host disease (cGVHD) in local group was superior to foreign group, with 23 (22%) patients *vs* 11 (19%) patients respectively (P=0.6904). After a median follow up of 16 months (range, 1-99), 59 (57%) and 34 (59%) patients were alive in the local and foreign group respectively. The median OS was 55 months in local groups, but it has not been reached in foreign group. The median progression free survival (PFS) has not been reached in both groups. The cause of death was classified into two categories, disease related and TRM. In the local group, 44 (43%) patients died, from those, 27 (26%) were disease related and 17 (14%) due to TRM. Whereas 24 (41%) patients died in foreign group, from those 12 (21%) deaths were disease related, while 7 (12%) deaths were TRM.
Summary/Conclusion: Our results imply that the geographical distance has no impact on the OS, however, we have found that it might have impact on the PFS, but we should take into consideration that more patients in local group underwent Haploidentical bone marrow transplant. These findings need to be verified in larger scale studies.

PB2465

PROGNOSTIC IMPACT OF MINIMAL RESIDUAL DISEASE IN AML PATIENTS BEFORE ALLOGENEIC STEM CELL TRANSPLANTATION ON DISEASE FREE SURVIVAL

O. Koroleva[1,*], J. Davydova[2], E. Parovichnikova[1], L. Kuzmina[1], I. Galtseva[2], V. Troitskay[3], N. Kapranov[2], E. Mikhaltsova[1], V. Vasilieva[1], D. Dubnyak[1], N. Popova[1], Z. Konova[1], A. Sidorova[1], E. Usikova[1], T. Lobanova[3], M. Drokov[1], V. Savchenko[1]

[1]BMT department, [2]Immunophenotype laboratory, [3]Hematology department, National Research Center for Hematology, Moscow, Russian Federation

Background: It's well known that the disease status before allogeneic stem cell transplantation (allo-HSCT) affects the outcome in adults with acute myeloid leukemia (AML). Multicolor flow cytometry (MFC) is one of the most applicable diagnostic methods to evaluate minimal residual disease (MRD). However, a primary immunophenotype of leukemia cells is often unknown, so the "different from normal" approach to assess MRD could be used in this situation before allo-HSCT.
Aims: To evaluate an impact of MRD by MFC on disease free survival in AML patients after allo-HSCT.

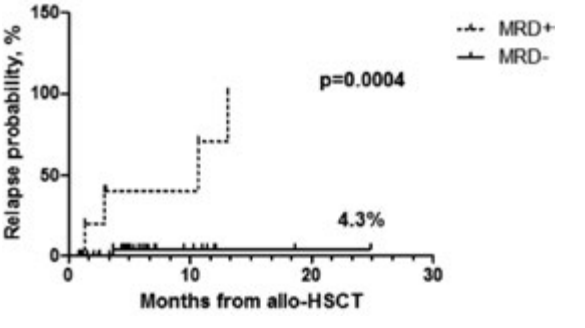

Figure 1.

Methods: MRD status was evaluated in 37 patients with AML. All patients received allo-HSCT in National research center for Hematology between September 2015 and December 2017. A median age was 40 years old (19-66 years). There were 14 males and 23 females. All patients had first complete remission (CR1) confirmed by bone marrow morphology. Patients received allo-HSCT from related (n=16) or unrelated (n=21) donors. The intensity of conditioning was mainly reduced (n=23) rather than myeloablative conditioning (n=14). Bone marrow (BM) as a graft source was used in 25, PBSC – in 12 pts. MRD was measured before allo-HSCT (2 weeks before conditioning) in bone marrow by 6-color flow cytometry (BD FACS Canto II). The panel of monoclonal antibodies included 4 tubes with core 3 markers (CD33, CD34, CD45) and the set of other markers - CD38, CD13, CD117, CD11b, CD99, CD14, CD16, CD66b, CD65, CD56, HLA-DR. The analysis of MRD was performed based on "different from normal" approach without primary immunophenotype of blast cells. Sensitivity of MFC was 0.01% (50 cells with abnormal immunophenotype from total 500 000 cells). MRD >0,01% was considered as "positive".
Results: MRD "positivity" before allo-HSCT was detected in 5 patients, MRD "negativity" - in 32. Leukemia relapse was installed in 1 pt in MRD negativity group, 4 in MRD positivity group. Disease free survival in the MRD negativity group was 77,7% *versus* 32,3% in the MRD "positivity" group, p=0,008. Probability of relapse in MRD "negativity" and in MRD "positivity" groups was 76,6% and 4,3%, respectively, p=0,0004 (Fig1).

Summary/Conclusion: According to our data MRD analysis based on "different from normal" approach is an effective method for AML patients in CR. Moreover, MRD status before allo-HSCT is an important prognostic factor for detection of a minimal population of blast cells for disease-free survival and can be considered as a discriminator for preemptive or preventive therapy.

TREATMENTS FOR STEROID-REFRACTORY ACUTE GRAFT *VERSUS* HOST DISEASE: A SYSTEMATIC LITERATURE REVIEW

A. Taylor[1,*], E. Wissinger[2], S. Cadarette[2], K. Ruiz[2], J. Jansson[3], M. Akbari[3]

[1]Takeda Pharmaceuticals International, London, United Kingdom, [2]Xcenda L.L.C, Palm Harbor, [3]Takeda Pharmaceuticals International, Cambridge, United States

Background: Approximately half of patients who develop acute graft-versus-host disease (aGvHD) after an allogeneic hematopoietic stem cell transplant will respond to first-line corticosteroid therapy. Steroid-refractory (SR)-aGvHD has high 6-month mortality rates of up to 80%, particularly when there is gastrointestinal (GI) involvement. There are no approved treatments for SR-aGvHD and success with off-label interventions has been limited and variably reported. There is a high degree of heterogeneity among studies regarding the definitions of SR disease, treatment response, and the timing of assessment of responses. Considering these limitations and the high burden of morbidity in SR-aGvHD, it is important to evaluate the efficacy of treatments currently used in clinical practice, to better understand the factors that may influence clinical outcomes.
Aims: To assess the clinical outcomes of interventions used off-label to treat SR-aGvHD.
Methods: A systematic literature review (SLR) was conducted using MEDLINE and Embase databases to identify studies published in English from January 2006 to August 2017, describing overall survival (OS) or treatment response rates in patients with SR-aGvHD. Any pharmacological intervention(s), including best supportive care, were included; non-pharmacological interventions such as extracorporeal photopheresis and stem cell infusions were excluded.

Table 1.

Results: Sixty-one publications describing treatment of patients with SR-aGvHD and reporting relevant clinical outcomes data were included in the SLR. Interventions utilized in these studies included monoclonal antibodies originally licensed in autoimmune disease such as alemtuzumab, basiliximab, infliximab, tocilizumab, vedolizumab, and combinations thereof, as well as other immunosuppressive agents such as etanercept, mycophenolate mofetil, pentostatin, and ruxolitinib. There was a high degree of heterogeneity in study design, patient population and size, and length of follow-up reported among the publications included in the SLR. Most studies were retrospective chart reviews, and all but 3 were conducted in a single country, most frequently the United States. Most studies focused on patients with Grade II-IV SR-aGvHD, but some investigations included patients with less severe disease, and the proportion of patients with GI involvement reported at baseline was heterogeneous. Data for OS were highly variable across the included publications. Among larger (N>50) studies reporting 1-year OS, rates ranged from 27% in patients treated with thymoglobulin to 62% among those given basiliximab and etanercept in combination. OS rates for patients with GI involvement at baseline, described in a few studies with smaller numbers of patients, were generally lower than for the overall population, 25% *versus* 34%>79% at 6 months, and only 24%>33% at 1 year. Due to limited publications, small numbers of included patients, variability in study designs, and limited reporting of outcomes, no other clear trends for OS could be identified.
Summary/Conclusion: A considerable number of potential off-label treatments has been reported for use in patients with SR-aGvHD. Results are highly variable for clinical outcomes including OS, and long-term survival rates remain disappointingly low, particularly for patients with GI involvement. There remains a need for further research to identify effective treatments for patients with SR-aGvHD.

PB2467

COMPARISON OF PERIPHERAL STEM CELL MOBILIZATION OF PATIENTS WITH MULTIPLE MYELOMA AND LYMPHOMA IN LATE MIDDLE AGE (55-64 YEARS) VERSUS OLD AGE (OLDER THAN 65 YEARS): A SINGLE CENTER EXPERIENCE

Z. Gulbas[1,*], D. Çekdemir[2], I. Dora[1], Ç. Eren[2]

[1]Hematologic oncology and Bone Marrow trssplantation, [2]Anadolu Health Cener, Kocaeli, Turkey

Background: In patients with myeloma and lymphoma, stem cell mobilization can be unsuccessful in 5-30% of the cases. The underlying mechanisms may include qualitative and quantitative differences among hematopoietic stem cells in the bone marrow, differences in the migration ability of hematopoietic stem cells or weakened response to G-CSF.
Aims: to compare of results of peripheral stem cell mobilization of patients with multiple myeloma and lymphoma in late middle age (55-64 years) *versus* old age (older than 65 years).
Methods: Patients were divided into two groups as middle age (55-64 years) (n=101), and old age (older than 65 years) (n=102).We retrospectively reviewed the data of 159 multiple myeloma patients and 44 lymphoma patients who have been mobilized between September 2010 and June 2016 in the bone marrow transplantation center
Results: The median number of peripheral blood CD34+ cell was 24.3×10^9 CD34+ cells/L in the middle age group, 20.0×10^9 CD34+ cells/L in the old age group, and there was no significant difference between the two groups. Two groups do not differ from each other in the terms of neutrophil and platelet engraftment times (p=0.702, and 0.113, respectively). The median number of CD34+ cells collected was 9.55×10^9 CD34+ cells/L in the middle age group, 9.20×10^9 CD34+ cells/L in the old age group, and there was no significant difference between the two groups. Even if the quantity of CD34+ cells collected in elderly patients was lower than in younger patients, this quantity does not reach significance.
Summary/Conclusion: the analysis of our data showed that the age of the patients has no impact on the mobilization of stem cells in lymphoma and myeloma patients. Even if the quantity of CD34+ cells collected in elderly patients was lower than in younger patients, this quantity does not reach significant difference.

PB2468

PRE-TRANSPLANT DISEASE STATUS AS A RESPONSE PREDICTOR IN AGGRESSIVE LYMPHOMAS

S. Marini[1,*], A. Ribeiro[1,2], D. Mota[1], C. Geraldes[1,2], L. Ribeiro[1,3]

[1]Hematology, Centro Hospitalar e Universitário de Coimbra, [2]Faculdade de Medicina, [3]Centro de Investigação em Meio Ambiente, Genética e Oncobiologia, Universidade de Coimbra, Coimbra, Portugal

Background: Autologous stem cell transplantation (ASCT) is currently an important therapeutic strategy. It is used as a consolidation therapy after high-dose chemotherapy in patients with aggressive non-Hodgkin's lymphoma (aNHL). The timing for transplantation depends not only on the lymphoma subtype but also on the disease status prior to the transplant, being indicated in patients with first chemosensitive relapse of aNHL after reaching partial (PR) or complete (CR) responses. However, clinical experience seems to show a worst *outcome* in patients with PR prior to ASCT, wondering wether the intensification of the chemotherapy regimen (until achieving CR) should be an option.
Aims: To compare the outcome of patients with aNHL in PR *versus* CR prior to autologous stem cell transplantation.
Methods: Retrospective longitudinal observational study of patients submitted to ASCT, from january 2007 to july 2017, in a single Portuguese institution. Statistical analysis was performed recurring to descriptive sta-

tistics and survival analysis using the Kaplan-Meier method, stratified by Log-Rank.
Results: We analyzed a sample of 76 patients with a median age at diagnosis of 46 years (17-64 years) and 53 (69.7%) were male. This population included several types of aNHL particularly Diffuse large B-cell lymphoma (DLBCL) n=46 (60.5%), High grade B-cell lymphomas, NOS n=3 (3.9%), Mantle cell lymphoma (MCL) n=22 (28.9%) and T-cell lymphomas n=5 (6.6%). Patients were treated with a median of 2 therapeutic lines (range 1-4) and had a ECOG ≤1, prior to ASCT. The response assessments after day 100, was statistically significant (p<0.001) favoured the transplant, from the 17 patients with PR prior to ASCT, 12 achieved CR. With a median follow-up of 74 months, we observed no statistically significant difference in the median overall survival (OS) of the entire study population, however, in subgroup analysis by lymphoma subtype there was a significant difference in the OS of patients with DLBCL (PR *vs* CR: 106m *vs* NR; p=0.003). Twenty patients relapsed after ASCT, the median time until relapse was 46 months. Progression-free survival (PFS) of the entire cohort, defined from the time of ASCT to the time of relapse, revealed lower time to relapse in patients with PR prior to ASCT compared to patients in CR (86 months *vs* 135 months; p=0.01).
Summary/Conclusion: Patients with DLBCL transplanted in PR after high dose chemotherapy, had a lower overall survival compared to the CR group. This suboptimal prognosis raises the issue whether chemotherapy should be optimized prior to consolidation with ASCT.

A STUDY OF UPFRONT AUTOGRAFT FOLLOWING 3 TO 4 CYCLES OF BORTEZOMIB, LENALIDOMIDE AND DEXAMETHASONE BASED CHEMOTHERAPY IN 52 INDIAN MYELOMA PATIENTS – A TERTIARY CENTRE EXPERIENCE FROM CHENNAI,INDIA

K. Kumar*, C. Subash

Haematology and BMT, Miot Chennai, Chennai, India

Background: In the era of newer immune-modulatory drugs, lot of debate is there on role and timing of Autologous bone marrow Transplantation. We conducted this study to look at the efficacy of RVD combination chemotherapy followed by an Autologous bone marrow transplant in 52 eligible Indian Myeloma patients.
Aims: We conducted this study to look at the efficacy of RVD combination chemotherapy followed by an Autologous bone marrow transplant in 52 eligible Indian Myeloma patients.
Methods: Eligible patients were treated according to this protocol. RVD q 21 days (3 cycles) Lenalidomide 10mg x 14 days every 21 day cycle, Bortezomib 2mg 1,4,8,11, Dexa 20mg 1,2,4,5,8,9,11,12. Then Collection of peripheral blood stem cells (PBSCs) using GCSF+/-Plerixafor. Autologous stem cell transplant: Melphalan 200mg/m^2: Day -1, Re-infusion of PBSCs. Then maintenance Lenalidomide 10mg 21 days every 28 days till progression.
Results: Results: 75% entered the transplant after three cycles of RVD after achieving a minimum of VGPR. The response rated to RVD were more than 95%. All entered the maintenance phase. The median followup was 24 months. In the transplantation group, 8 patients had disease progression, and symptomatic patients received a second-line therapy. Of the patients who were treated for disease progression, three underwent a second transplantation at the time of progression and one underwent Allogeneic transplantation.
Summary/Conclusion: Conclusions: In conclusion, we found that early consolidation therapy with high-dose chemotherapy plus transplantation was associated with longer progression-free survival. This benefit must be weighed against the increased risk of toxic effects associated with high-dose chemotherapy plus transplantation. This is a feasible option in Indian patients both in response rates as well as finances.

REVIEW OF THE MANAGEMENT OF HYPOMAGNESAEMIA AND HYPOKALAEMIA IN ALLOGENEIC STEM CELL TRANSPLANT INPATIENTS AT A MAJOR LONDON CENTRE

A. Dervin, O. Tomkins*, K. Thomson

UCLH - University College London Hospitals NHS Foundation Trust, London, United Kingdom

Background: Electrolyte imbalances are common in allogeneic transplant patients, often secondary to gastrointestinal loss and widespread use of calcineurin inhibitors. Hypokalaemia and hypomagnesaemia puts the patient at risk of cardiac arrythmias. There is often variation in the approach taken to electrolyte replacement. At our transplant unit, there is currently no guideline in place to guide prescribing and administration of magnesium and potassium replacement. This leads to apprehension among junior medical staff and nurses, and may lead to prolonged electrolyte derangement through insufficient replacement. There is also signficiant cost associated with repeated electrolyte replacement and monitoring of serum magnesium and potassium.
Aims: We aimed to review current practice of magnesium and potassium replacement at a major London transplant centre. We also aimed to assess the increment rate for low *versus* high concentrations of magnesium and potassium replacement, and to draft a departmental guideline.
Methods: We audited prescriptions of magnesium and potassium for allogenic transplant patients between October and December 2017. Historic medication charts and our pathology results system were accessed. Serum levels pre- and post-replacement were recorded and the 24-hour increment calculated.
Results: Prescription charts for 52 patients were reviewed. Ninety-eight prescriptions of intravenous magnesium were found: nine prescriptions (39.8%) of 8mmol, 7 (7.1%) of 16mmol and 51 (52.0%) of 20mmol. Average serum increment was 0.08, 0.174 and 0.26mmol/L respectively. There was no significant difference in the serum levels pre-replacement between groups, ranging from 0.44 to 0.77 mmol/L. Oral magnesium replacement was not used. For intravenous potassium chloride, 138 prescriptions were found. Patients had pre-replacement levels between 2.4 and 3.9mmol/L. Oral potassium replacement was concomitantly prescribed in 40 cases (28.99%). There were 102 prescriptions for 40mmol potassium, one for 60mmol, 29 for 80 mmol, four for 120mmol and one for 160mmol. The average serum potassium increment at 24 hours was 0.259mmol/L with 40mmol, 0.3 with 60mmol, 0.6 with 80 mmol, 0.85 with 120mmol and 1.1 with 160 mmol. Post-replacement serum potassium was never higher than 4.9mmol/L. Serum magnesium level was checked in 100 of the cases requiring intravenous potassium replacement (72.5%); 75 of these also required magnesium replacement, 30.7% were prescribed only 8mmol.
Summary/Conclusion: We demonstrate that the approach to treatment of hypomagnaesaemia and hypokalaemia at our transplant unit varies significatly. There is a limited increase in serum magnesium level with intravenous doses less than 20mmol, yet lower doses than this are frequently administered. Correction of hypomagnesaemia is also often inadequate in patients with concomitant hypokalaemia. We also demonstrate that increment in serum potassium is limited with doses lower than 80mmol and that it is safe to administer this amount of potassium in hypokalaemic patients without risk of iatrogenic hyperkalaemia. We propose creating a guideline that recommends immediate administration of these higher doses of magnesium sulfate and potassium chloride. We recommend immediate use of 20mmol intravenous magnesium indeficient patients. We also recommed administration of 80mmol potassium if serum concentration is less than 3.0mmol/L. This would minimise risk of arrhythmias and lower the cost of repeated monitoring and administration.

PB2472

ALLOGENEIC BONE MARROW TRANSPLANTATION IN THREE CASES WITH DOCK 8 DEFICIENCY

T. Patiroglu[1,*], M. Cansever[2], M. Karakukcu[1], E. Unal[1], A. Ozcan[1]

[1]Pediatric Hematology, [2]Pediatric Immunology, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Combined immunodeficiency due to dedicator of cytokinesis 8 protein (DOCK8) deficiency is a form of T and B cell immunodeficiency characterized by recurrent cutaneous and sinopulmonary viral infections and susceptibility to cancer. Laboratory findings include elevated IgE level in serum and eosinophilia. T cell lymphopenia and reduced T cell function have been reported. Patients can also have NK and B cell lymphopenia. IgG levels may elevated but specific antibody responses are impaired. IgM and IgA levels may be reduced in DOCK8 immunodeficiency syndrome was called autosomal recessive hyper IgE syndrome (AR-HIES) and considered a rare form of HIES.
Aims: Therefore, we present three cases with DOCK8 immunodeficiency syndrome who they received an HLA-identical sibling donor bone marrow transplant (BMT).

Table 1.

	Case 1	Case 2	Case 3
WBC (mm3)	13100	21450	15940
ANC (mm3)	2150	6010	5500
ALC (mm3)	2490	5860	3810
AEC (mm3)	7356	5860	8607
Ig G (mg/dl)	1670	644	960
IgA(mg/dl)	126	42	109
Ig M(mg/dl)	334	18.9	46.7
IgE(IU/ml)	10300	3080	8080
CD3 (mm3)	1520	10610	1836
CD4(mm3)	470	5960	393
CD8(mm3)	920	2910	721
CD19(mm3)	670	8530	567
CD16+56(mm3)	250	1560	656

Methods: First (age:12 years) and second boys (age:1 year) were sibling and their parents were first cousins. All 3 cases had recurrent pulmonary infection, erythematous and eczematous rash on the whole body and hepatosplenomegaly. Furthermore, first case had bilateral chronic supurative otitis and a mass in left auricula and third female patient (age:10 years) also had the clitoral vegetative mass. Therapeutic measures included antiviral and antibacterial prophylaxis, immunoglobulin replacement and allogeneic BMT. The auricular and clitoral masses after ABMT regressed spontaneously and they are follow-up in our clinic. Laboratory findings of 3 cases are demonstrated in the table 1.
Summary/Conclusion: Early BMT should be strongly considered as a potential curative therapy in DOCK8 immunodeficiency syndrome.

PB2473

HAPLOIDENTICAL TRANSPLANTATION OF HEMATOPOIETIC STEM CELLS IN ADULT PATIENTS WITH HEMOBLASTOSES IN THE REPUBLIC OF KAZAKHSTAN

A. Olifirovich[1,*], V. Kemaikin[2], O. Gainutdinova[2], N. Tabynbaev[2], A. Suleymenova[2], M. Ospanova[2]

[1]Отдел онкогематологии и трансплантации костного мозга, Национальный научный центр онкологии и трансплантологии, Астана, [2]Oncohematology and Bone Marrow Transplantation Department, National Scientific Center for Oncology and Transplantology, Astana, Kazakhstan

Background: A comprehensive analysis of the results of haploidentical hematopoietic stem cell transplantation in adult patients have been performed for the first time during the period from October 2011 to July 2017. The incidence of acute and chronic graft *versus* host disease, overall survival and mortality were assessed.
Aims: To assess the total and relapse-free survival in patients after haploidentical transplantation of hematopoietic stem cells.
Methods: Considering the absence of generally recognized protocol on the date of beginning of haploidentical transplantation of hematopoietic stem cells to be used in the Republic of Kazakhstan, different conditioning and prevention regimens for acute and chronic graft *versus* host disease were used.
Results: At this time, 23 of 64 patients are alive amounting to 36%. The follow-up period is within 4 to 7 days. The median overall survival of the patients followed up is 2.58 months. The curve of overall survival contains tow plateaus. The 1st plateau is patients with relatively short follow-up period equal to 12-20 months. However, the median overall survival was reached in these patients. The 2nd plateau is the group of patients with follow-up period within 22 to 47 months. The cumulative survival percentage is 27%. The median overall survival of the patients followed up is 4.1 months. The cumulative survival percentage is 39%. Despite insignificant differences in the overall survival between the two groups of patients, the percentage and overall survival length are higher in the group of patients with their haploSCT in the 1st complete remission. The follow-up period is not long enough to analyze 5-years overall and relapse-free survival. At present, however, we note the significant difference in the median OS – 2.58 in the general group *vs* 4.1 months in the group of patients with acute leukemias in the 1st remission.
Summary/Conclusion: The obtained results are comparable to those that presented in foreign studies. The frequency of acute GVHD of Grades II-IV was 26.6%, *i.e.* practically comparable to this parameters of 21.9% presented in the study performed by Long H. *et al.* [4]. In relation to chronic GVHD, the parameter observed in our Department is significantly lower than the frequency reported in the above study – 11% *vs* 24.1%. However, at this stage of follow-up we could not conclude that development of chronic GVHD in haploSCT recipients in our Department is significantly more rare. This is explained by the fact that the follow-up period is still insufficient to a valid analysis of this parameter, a part of patients is followed up for less than 100 days. Also, a rather high mortality in the early posttransplantation period was observed. The equivalent comparison of the frequency of chronic GVHD requires a longer follow-up period. The parameter of OS in the general group of patients is lower than this parameter in foreign studies – 29% *vs* 52.6%. This is provided by unfavorable disease status on the date of transplantation and development of severe complications in the early post-transplantation period. However, the analysis of more homogeneous group of recipients with acute leukemias in the 1st complete remission shows a higher OS – 39%.Based on the results of our clinical analysis, the following may be concluded:Considering certain difficulties with organization of non-sibling transplantation of bone marrow in the Republic of Kazakhstan, one of the main tasks at this stage of development of hematological practice in the Republic is developing the haploidentical bone marrow transplantation

PB2474

ELTROMBOPAG FOR THE TREATMENT OF REFRACTORY PURE RED CELL APLASIA (PRCA) AFTER MAJOR ABO INCOMPATIBLE HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT)

C.M. Dellacasa[1,*], A. Busca[1], S. Aydin[2], G. Iovino[2], L. Giaccone[1], L. Brunello[2], V. Tassi[3], T. Francisci[3], C. Pecoraro[3], S. Manetta[2], L. Godio[4], B. Bruno[1]

[1]Stem Cell Transplant Unit, [2]Hematology, [3]Transfusion Unit, [4]Pathology, AOU Città della Salute e Della Scienza di Torino, Torino, Italy

Background: Pure red cell aplasia (PRCA) occurs in 7,5% to 16% of AB0 major mismatched allogeneic HSCT recipients. Several treatments have been applied but their results are largely variable.
Aims: To describe the use of eltrombopag for the treatment of refractory PRCA after HSCT.
Methods: We describe two PRCA patients resistant to multiple therapeutic options, treated with thrombopoietin mimetic eltrombopag (used off label) at the dose of 75 mg qd for the first two weeks and then increased to 150 mg qd. Both patients received a major ABO-incompatible HSCT (donor A pos, recipient O pos) after myeloablative conditioning regimen. In both cases RBC reduction of the apheretic stem cell product was not performed due to the low hematocrit value.
Results: Patient 1: A 48-year old male with high risk acute myeloid leukemia underwent matched unrelated donor (MUD) HSCT. Pre-transplant anti-A isohemoagglutinin titer was 1:512. Neutrophil engraftment occurred on day + 16; subsequently the patient developed transfusion dependent anemia, and on day +100 the bone marrow biopsy documented the presence of a PRCA with full donor chimerism. The patient was treated with theta-erythropoietin (rHuEPO) 40000 U per week and subsequently received 5 plasma exchange (PEX) procedures without significant response; from day + 234, 4 weekly doses of Rituximab 375 mg/m2/week were administered without any beneficial effect. At 6 months post-HSCT, iron chelation therapy (ICT) with deferasirox (DFX) was started and discontinued after 3 months due to grade III neutropenia. At 14 months post-HSCT, eltrombopag (ETP) was started due to persistent transfusion dependent anemia along with mild leukopenia and thrombocytopenia, leading to rapid improvement of blood cell counts. After 4 months of treatment, ETP was discontinued with an haemoglobin value of 15,4 gr/dl. At the present, the patient is off treatment since 6 months with normal haemoglobin levels and neutrophil counts. The bone marrow biopsy shows a normal cellularity (80%) with good trilinear representation and no evidence of clonal evolution. Patient 2: A 47-year old female with biphenotypic acute leukemia received a MUD HSCT. Patient's anti-A isohemoagglutitin pre transplant titer was 1:256. After engraftment, on day +47 treatment with rHuEPO 40000 U per week was started due to transfusion dependent anemia, with no remarkable response. A bone marrow biopsy on day + 100 was consistent with the diagnosis of PRCA. Chimerism was full donor. PEX procedures were discontinued due to a severe anaphylactic reaction to plasmatic proteins. Rituximab (375 mg/sqm/week for 4 weeks) and 4 doses of Bortezomib (1,4 mg/mq once a week) followed by one dose of Cyclophosphamide (1 gr) were administered without any significant response. At 5 months post HSCT ICT with DFX was started, but stopped after six months due to neutropenia, and replaced by DFO. At 30 months post transplant ETP was started. After 5 weeks the patient became transfusion independent. ETP dose was reduced due to mild thrombocytosis. After 5 months of treatment the bone marrow biopsy showed a moderate trilinear hyperplasia with no evidence of clonal evolution. After 6 months of treatment, ETP was stopped, and the patient mantains normal blood cell counts.
Summary/Conclusion: Our results, even if restricted to a very small proportion of patients, may be considered indicative of a favorable effect of ETP on post transplant unilineage cytopenias such as PRCA. Additional studies are mandatory to confirm our preliminary data.

PB2475

THE OUTCOMES OF HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR THALASSEMIA MAJOR BASED ON A FBCA CONDITIONING REGIMEN

B. Wu[1,*], R. Dong[2], Q. Su[3], J. Xu[4]

[1]Hematology, Shunde Hospital of Southern Medical University, Shunde, [2]Hematology, Shunde Hospital of Southern Medical University, Shunde Hospital of Southern Medical University, [3]Hematology, The first people hospital of Guangzhou, [4]Hematology, Zhujiang hospital of Southern medical university, Guangzhou, China

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is the sole available curative therapy for patients with thalassemia major. With the progress human leukocyte antigen (HLA) antigen typing technology and supportive care, the outcome of thalassemia major have greatly improved in recent years, even in high risk patients. However, the problem of finding a suitable donor was still a major limit to cure these patients. In the past decades, haploidentical donor was more and more used in hematologic malignancies HSCT. Here, we explored the outcome of haploidentical donor (HD) HSCT to thalassemia major children based on a FBCA conditioning regimen.
Aims: To anlysis the outcomes of haploidentical hematopoietic stem cell transplantation for thalassemia major based on a FBCA conditioning regimen.
Methods: Eghit patients with thalassemia major (age 3-14 year old, meidan 5.5 year old) underwent haploidentical hematopoietic stem cell transplantation. The conditioning regimen was consists of fludarabin(Flu), busulfan(Bu), cyclophosphamide(Cy) and antithymocyte globulin(ATG). All donors were HLA mismatched family members including fathers mothers and sister. ABO blood type between donor and receipt were incompatible in three patients.GVHD prophylaxis included cyclosporine (CSA), and short course of methotrexate (MTX). Chimerism studies were performed with blood nucleated cells whth STR-PCR.
Results: The median of nucleated cell and CD34+ cell dose in the infused product were 9.7×10^8/kg (range, $6.9\text{-}26.7\times10^8$/kg) and 10.1×10^6/kg (range, $8.2\text{-}27.2\times10^6$/Kg), respectively. The median time to achieve absolute neutrophil recovery was in 10 days (range,10 to 15 days), and platelet recovery was in 13 days (range,10 to 102 days).Four patients (50%) have experienced grade I-II acute GVHD; Two patients suffered from grade III-IV (25%) acute GVHD and one of which turned into local chronic GVHD (skin).Chimerism studies were performed for all patients after transplantation. The data showing all patients have achieved full donor chimerism (100%) at post-transplantation +30 day and mixed chimerism status was not observed in all eight patients with the mdeian one year follow up. So far, all of the patients have a stable engraftment and were transfusion independent in daily life.
Summary/Conclusion: The acute and chronic GVHD of haploidentical hematopoietic stem cell transplantation for thalassemia major based on this FBCA conditioning regimen is accpitable and the outcome prompt us to study further.

PB2476

AUTOLOGOUS STEM-CELL TRANSPLANTATION AS FIRST-LINE TREATMENT OF ELDERLY PATIENTS WITH A NEWLY DIAGNOSED MULTIPLE MYELOMA IN THE ERA OF THE NOVEL DRUGS

V. Cabanas Perianes*, M. Moya, B. Navarro, M.J. Moreno, A. Martinez Marin, E. Fernandez Poveda, M. Berenguer, J.J. Cerezo, R. Perez Lopez, A. Sanchez Salinas, A.M. Garcia Hernandez, J. Monserrat, M. Blanquer, J.M. Moraleda

Hematology, Hospital Universitario Virgen De La Arrixaca, Murcia, Spain

Background: We analyzed 24 symptomatic newly diagnosed Multiple Myeloma (NDMM) patients who were 65 years or older receiving induction therapy with novel agents plus ASCT.
Aims: The objectives were to assess the toxicity and efficacy in two cohorts: elderly patients (≥70 years or older) *versus* a younger group (65-69 years).
Methods: The endpoints were: overall response rate (ORR), progression free survival (PFS) and overall survival (OS), adverse effects, time to platelet and neutrophils engraftment and time to discharge. The dose of melphalan conditioning employed were 200 or reduced doses (140, 100 or 70mg/m^2 in tandem) if age ≥70 years, renal failure or Hematopoietic Cell Transplantation-Comorbidity Index over 2 were presented at ASCT moment.
Results: 14 patients ≥70 y and 10 patients between 65-69 years were reported. ORR an OS rate at 1 year was 100%. No differences were observed in terms of time to reach platelets and neutrophils engraphtments, time to discharge and adverse effects. After a median follow-up of 23.5 months, the median PFS was 32 months in the older group, as compared with 43 months in the group down 70 years underwent ASCT (p=0.97).

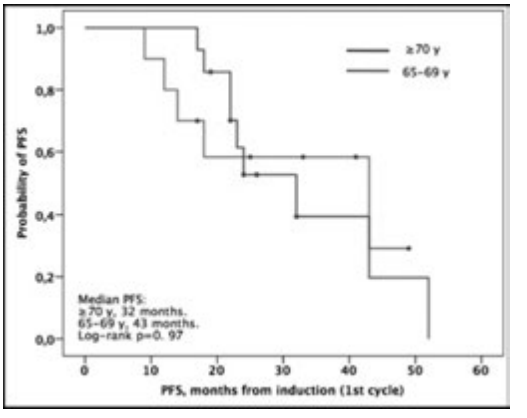

Figure 1.

Summary/Conclusion: ASCT is feasible and safe in NDMM patients aged ≥70 years if an individualized approach is performed.

PB2477

INFLUENCE OF LENALIDOMIDE USED IN INDUCTION PERIOD AND INTENSITY OF MOBILIZATION REGIMEN ON THE NUMBER OF CD34+ CELLS HARVESTED IN PATIENTS WITH MULTIPLE MYELOMA

I. Kostroma[1,*], A. Zhernaykova[1], Z. Chubukina[2], I. Zapreeva[1], N. Semenova[3], S. Bessmeltsev[4], A. Chechetkin[4], S. Gritsaev[1]

[1]Bone marrow transplantation department, [2]Immunologic laboratory, [3]Research laboratory of leukemia, [4]Hematological clinic, Russian Institute of Hematology and Transfusiology, St.Petersburg, Russian Federation

Background: Recovery of hematopoiesis after autologous stem cell transplantation (AutoSCT) depends on the count of the harvested CD34+ cells. It is supposed that count and proliferative capacity of mobilized stem cells are influenced by the kind of previous therapy and variety of chemotherapy agents used in the mobilization regimen.
Aims: The aim of the study was to determine prognostic significance of premobilization lenalidomide apply and the sort of mobilizatrion regimen (cyclophosphomide or vinorelbine) on the number of CD34+ cells in the autotransplant of multiple myeloma (MM) patients.
Methods: We examined the data of autotransplant harvesting in 68 patients retrospectively. Mobilization regimens with vinorelbine 35mg/m^2 (23 patients) and cyclophosphamide 3.0g/m^2 (45 patients) were used. 21 patients (30.9%) were treated with lenalidomide previously. In the group of patients treated with lenalidomide 14 patients were mobilized with vinorelbine and 7 patients with cyclophospamide.
Results: Mobilization failure with the number of CD34+ cells less than $2\text{x}10^6$/kg was fixed in 5 patients (7.4%). There was no any difference in CD34+ cells number in groups of patients according to the age and MM variant. We found the trend with decreasing of CD34+ cells number in patients treated with lenalidomide: $4.1\text{x}10^6$/kg (0.27-23.29) *vs* $6.76\text{x}10^6$/kg (0.58-29.13) in patients who were not treated with lenalidomide; p=0.066. There was significant difference in the count of CD34+ cells harvested after cyclophospomide plus G-CSF and vinorelbine plus G-CSF: $6.8\text{x}10^6$/kg (0.53-29.13) *vs* $3.96\text{x}10^6$/kg (0.27-9.66) accordingly; p=0.022.
Summary/Conclusion: We conclude that vinorelbine plus G-CSF is a mobilization regimen of choice for older patients who were not treated with lenalidomide aggressively in the premobilization period and for whom the single AutoSCT is planned.

PB2478

AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH AGGRESSIVE NON-HODGKIN'S LYMPHOMA

N. Zorina[1,*], N. Minaeva[2], M. Khorobrykh[1], P. Sherstnev[3], S. Utyomov[4], N. Isaeva[5], A. Luchinin[6]

[1]Bone marrow transplantation, [2]Hematologic clinic, [3]Transfusiology, [4]Cryopreservation of blood and tissues, [5]Immunohematology, [6] Clinical research department, Federal State Institute of Science "Kirov Research Institute of

Hematology and Blood Transfusion of the Federal Medical and Biological Agency of Russia", Kirov, Russian Federation, Kirov, Russian Federation

Background: High dose chemotherapy with autologous hematopoietic stem cell transplantation (autoHSCT) in combination with targeted medications is widely used in prognostically unfavorable variants of non-Hodgkin's lymphoma (NHL) treatment.
Aims: To estimate the results of autoHSCT in patients with NHL with unfavorable course.
Methods: 48 autoHSCT to 42 NHL patients (18 – female, 25 – male, age 22-69 years, median 37,5 years) were performed from 1999 till February 2018. Of them: diffuse large B-cell lymphoma (DBCL) in PR1/CR2 – 21 patient, mantle cell lymphoma (MCL) in PR 1/2 – 8, follicular lymphoma (FL) 3B type in CR2 – 4 patients, rimary mediastinal lymphoma – 6 patients,peripheral T-cell lymphoma – 5 patients. Patients were treated with more, than 2 lines of chemotherapy. Hematopoietic stem cells (HSC) were harvested after the second line therapy with G-CSF stimulation. Six patients received 2 autoHSCTs (DBCL 4B in PR1 – 4, FL type 3 in PR2 FLIPI2 -1, primary mediastinal lymphoma – 1). Conditioning regimen BendaEAM was used in 39% of cases, BEAM - in 37,25%, CVB - in 10%, ICE - in 13,75% (plus rituximab in 69,6% autoHSCTs). Transplant – cryopreserved HSCs, counting (2-21)x10^6/kg body weight CD34+ cells, (2,8-5,1)x10^8/kg myelokaryocytes. Leukocyte recovery more, than 1x10^9/l was achieved on 14 day, platelet count more, than 30x10^9/l – on day 17. Most of patients with B-cell lymphomas received 2 year rituximab maintenance therapy after autoHSCT.
Results: At time point February 2018 29 patients were alive, 10 died due to lymphoma progression, 3 – because of infection complications. Transplant failure was revealed in 5,4% of patients, 100 days mortality was 5.4%. Overall 3-year survival (OS) was 73%, 5 – year survival – 67%, 10– year survival – 58%. Overall survival median was 12,7 years. Relapse free 3 – year survival (RFS) was 73%. Median relapse free survival was 98 months. DBCL patients had 3 – year OS 75%, 5 – year OS – 70%, 10-year OS – 63% and median OS 12,7 years. MCL patients had 3-year OS of 75%, 5 year OS – 75%, median OS was not achieved. All patients, who received repeated autoHSCT are alive, in PET-negative CR with surveillance median of 40 months. The most common complications in post-transplant period were 1-2 grade mucositis – 81% of patients. Septic complications were revealed in 8.1% of cases, pulmonary aspergilosis – in 4%. Frequency of infections did not increase after repeated autoHSCT, engraftment occurred at usual time point.
Summary/Conclusion: AutoHSCT method is an effective therapeutic option for patients with high risk NHL.

PB2479

INITIAL THERAPY AND OUTCOMES AFTER STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA PATIENTS

S. Franco*, J. Borras, R. Del Campo, A. Cladera, J.M. Guerra, D. Gómez, I. Herraez, N. Amer, M. Mascaró, J. Bargay

Hematology, Hospital Son Llàtzer, Palma de Mallorca, Spain

Background: Infections are a major cause of morbidity and mortality in patients with Multiple Myeloma (MM). MM related immunodeficiency involves B-cell dysfunction as well as T-cell, dendritic cell, and NK-cell abnormalities. In addition to the immunodeficiency related to myeloma, the type of anti-myeloma therapy used plays a role in the development of infections.
Aims: To compare transplant outcome in terms of risk of infection between MM patients treated with 2 different frontline therapies.
Methods: Out of 87 MM patients from Hospital Son Llàtzer who underwent ASCT from March 2003 to February 2017, we performed a retrospective observational study involving 35 of them. Exclusion criteria: patients with Plasma cell leukemia, concomitant diagnosis of Amyloidosis AL and those who received Busulfan-Melfalan as conditioning regimen. Patients were separated into two groups depending on its frontline therapy (arm A: VBCMP/VBAD *vs* arm B: novel agent combinations). Molecular cytogenetic alterations were not included because data for these were not available in all patients. Hematologic recovery was defined as an absolute neutrophil count ≥500/mm^3 and platelets ≥20,000/mm^3. We analyzed all infections occurred within the first year post-ASCT. In all patients the intensive regimen consisted of Melphalan 200mg/m^2. Data were collected from electronic medical records. Quantitative variables were expressed as median and interquartile range, and the qualitative variables as percentages ($p<0.05$ was considered statistically significant). Differences between groups were analyzed with the Mann-Whitney U test and Chi-square.
Results: Out of 35 patients analyzed, 19 received poly-chemotherapy as frontline treatment, and 16 patients received combinations of novel agents. No differences were observed between groups in regard to age at the time of transplantation (60.9 years old for group A *vs* 59 years old for group B) and HCT-CI. In regards to response before ASCT, the rate of very good partial response or better was slightly higher for group B (86.6% *vs* 63.2%), *p=0.122.* Median CD34+ infused cells was also similar between groups A and B (3.4.10^6/kg *vs* 3.5. 10^6/kg, respectively. There was no significant difference in hematological recovery (12 *vs* 11.5 days) or development of mucositis (94.7% *vs* 100%). Of 35 patients, 19 (54.3%) developed at least one infectious complication. Although not statistically significant, the frequency of infections was higher in group A (68.4%) than in group B (37.5%), *p=0.067.* Median time to first infectious episode was 152 days in group A and 79.5 days in group B, *p=0.282.* Respiratory infections were the most common infections in both groups (33% *vs* 45.5%), *p=0.236.* Of note, 3 patients (16.7%) in group A required hospitalization during the first infectious episode *vs* none in group B, *p=0.153.*
Summary/Conclusion: Infection is a significant cause of morbidity and death in patients with MM. In this analysis, out of 35 patients, 19 (54.3%) developed at least one infectious complication during the first year after ASCT. Although not statistically significant, the frequency of infections and hospitalization was higher in the group that received poly-chemotherapy, suggesting that poly-chemotherapy might induce more immunosuppression. These results are limited because of the small number of patients included.

Table 1.

Table 1. Baseline and outcomes

Parameter	Both groups N=35	Group A N=19	Group B N=16	p value
Sex	Male: 21(60%) Female:14(40%)			
Durie-Salmon		I-3 (15,8%) II-3 (15,8%) III-13 (68,4%)	I-0 II-6 (37,5%) III-10 (62,5%)	0.125

THE ROLE OF MYELOID-DERIVED SUPPRESSOR CELLS IN AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION

A. Betsch[1,*], O. Rutgeerts[1], S. Fevery[1], B. Sprangers[2], D. Dierickx[2], M. Beckers[2]

[1]KU Leuven, [2]University Hospitals of Leuven, Leuven, Belgium

Background: Myeloid-derived suppressor cells (MDSC) are a heterogeneous group of immature, immunosuppressive cells that play a role in cancer induction, progression and immune evasion. Two major MDSC subsets exist: polymorphonuclear (PMN-MDSC) and monocytic MDSC (M-MDSC). Recent studies indicated that the immune reconstitution after autologous hematopoietic stem cell transplantation (ASCT) is associated with outcome. Since MDSC are immunosuppressive cells, we hypothesize that they play a role in the immune reconstitution and outcome after ASCT.
Aims: The aim of this study is to define the presence and function of MDSC in ASCT. Therefore, we will phenotypically and functionally analyze different MDSC subsets. Since the content of the peripheral blood stem cell (PBSC) graft is less defined, we will analyze MDSC and other immune cells in the PBSC graft. In addition, the immune reconstitution after ASCT will be studied in relation to the amount of MDSC infused and the kinetics of MDSC after ASCT will be assessed.
Methods: Flow cytometry is used to study the presence of MDSC in peripheral blood mononuclear cells (PBMC) and in the PBSC graft of multiple myeloma and lymphoma patients, undergoing ASCT.
Results: The kinetics of MDSC levels are similar between M-MDSC and PMN-MDSC during the transplantation period. MDSC levels in PBMC and

in the PBSC graft increased after G-CSF mobilization, together with an increased IL-4Rα expression on MDSC. At the time of ASCT, following high-dose chemotherapy, MDSC levels had decreased. After ASCT, MDSC levels recovered again. Interestingly, the PMN-MDSC/M-MDSC ratio was lower in the PBSC graft, compared to PBMC.
Summary/Conclusion: Recent findings have provided proof that immune reconstitution plays a key role in the therapeutic effect of ASCT. Since MDSC are known to be immunosuppressive cells that accumulate after G-CSF mobilization protocols, they may play a role in the immune reconstitution and outcome after ASCT. Indeed, after G-CSF mobilization, both M-MDSC and PMN-levels were increased. Interestingly, IL-4Rα expression on MDSC increased, suggesting a higher immunosuppressive activity of MDSC. In addition, the PMN-MDSC/M-MDSC ratio was decreased in the PBSC graft as compared to PBMC. This may suggest that in the PBSC graft less PMN-MDSC and/or more M-MDSC, which are considered to be the most immunosuppressive population, are present. Further *ex vivo* assays will be performed to study the immunosuppressive capacity of MDSC in PBMC and in the PBSC graft. Moreover, more patients will be included to further study the role of MDSC in ASCT.

ABO INCOMPATIBLE BONE MARROW TRANSPLANTS – A TERTIARY CENTRE EXPERIENCE

S. Sen[1,*], S. Tulpule[2], S. Gupta[2], K. Mullanfiroze[1], R. Sawant[3]

[1]Dept of Paediatric Oncology & BMT, [2]Dept of Oncology & BMT, [3]Dept of Transfusion Medicine, Kokilaben Dhirubhai Ambani Hospital, Mumbai, India

Background: Though ABO incompatibility is not a contraindication for BMT, it can be a factor responsible for lower overall survival.
Aims: We present our data on ABO incompatible transplants and their outcomes.
Methods: Of the 87 BMT's done at our centre, 14 were ABO incompatible. The indications for BMT were malignancies like refractory AML or relapsed B ALL and benign haematological conditions like Aplastic Anaemia and Thalassemia Major. Among the ABO incompatible BMTs, 9 were major incompatibility, 5 were minor. For all major and bidirectional blood group incompatibility, we determined the recipient antibody titres, and in all cases where the recipient isoagglutinin titre was more than 1:64, repeated plasma exchange was done till antibody titres were less than 1:16. IVIG in a dose of 0.5 gm/kg was also given to the recipient on Day -1. Red cell depletion of the graft by centrifugation was also undertaken in all cases of major ABO incompatibility.
Results: One patient with major ABO incompatibility had a severe haemolytic reaction following infusion of bone marrow stem cells and transplant had to be aborted. The baseline isoagglutinin level was 1;64 and repeat plasma depletion of the patient was done to reduce the isoagglutinin levels to below 1:4. Peripheral blood stem cells were harvested from the donor which was red cell depleted by centrifugation and this was infused without incident. None of the other cases had any immediate or delayed haemolytic reaction. However 1 patient subsequently died due to graft failure and 2 from sepsis.
Summary/Conclusion: In our series, ABO incompatibility did not seem to have been a major factor behind poor outcome. The mortality in our limited series is possibly due to the aggressive nature of the primary disease like refractory AML and patient condition rather than blood group mismatch per se.

PB2482

THE ROLE OF AUTOLOGOUS STEM-CELL TRANSPLANTATION IN RELAPSED MULTIPLE MYELOMA. OUR SIX YEAR EXPERIENCE

B. Navarro Almenzar*, V. Cabañas Perianes, M. Blanquer Blanquer, M. J. Moreno Belmonte, J.J. Cerezo Manchado, R. Pérez López, M. Berenguer-Piqueras, F. Labbadia, E. Fernández Poveda, A. Martínez Marín, M. Moya Arnao, J.M. Moraleda Jiménez

Hematology, Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, Spain

Background: The role of autologous stem-cell transplantation (ASCT) in relapsed multiple myeloma has not been fully defined and more data are needed.
Aims: To assess the effycacy of second ASCT in patients with relapsed multiple myeloma (MM).
Methods: In this retrospective analysis, we reviewed the charts of the patients who underwent a second ASCT at least 12 months after their first ASCT for relapsed MM at our institution between March 2011 and July 2017. Progression free survival after ASCT, progression free survival after chemotherapy and overall survival were analyzed by the Kaplan-Meier method.
Results: Twenty patients (12 male, 8 female) with a median age of 62 years (48-73) were included. Patients were classified according to the type of myeloma: IgG 8 (40%); IgA 6 (30%); Bence-Jones 5 (25%); IgD 1 (5%). Adverse cytogenetics were present in 10% of the patients, including delp53, t(4; 14) and t(14; 16). HCT-CI was low (<3) in 74% of them: 0 (63%), 1 (11%), 3 (21%), 4 (5%). The median time from the diagnosis of multiple myeloma to the second transplant was 54 months (25-127). The median time from the first transplant to disase was 32.5 months (12-103). The progression-free survival after the first ASCT was <24 months in 30% of patients. PET-CT at the relapse was positive in 14 (71%) patients, and 7 patients (35%) had plasmacytomas. The median number of previous lines of treatment before second ASCT was 2 (2-4). Bortezomib had been administered to 95% of the patients, and immunomodulators to 60%. The last treatment received before the transplant included Lenalidomide in 50% of the cases. The response after salvage therapy prior to transplantation was: stringent complete response 3 (15%); complete response 3 (15%); very good partial response 8 (40%); partial response 6 (30%). Conditioning regimen was Melphalan in 15 patients (75%) and Busulfan-Melfalan in 5 patients (25%). Transplant related mortality was 5%. The second transplantation significantly improved the stringent complete response rate (from 15% to 55%) (p=0.008).). With a median follow up of 33,5 months, the median progression free survival after the second ASCT was 30 months, and 37 months after progression. The progression free survival benefit of the second ASCT was confirmed in all risk subgroups: high risk cytogenetic, time from the first ASCT to relapse <24 m, plasmacytoma at relapse, or response after second ASCT.
Summary/Conclusion: Our results confirm that second ASCT significantly increases the number of stringent complete responses in multiple myeloma patients relapsed after a first ASCT. Studies with larger sample of patients are needed in the era of the novel drugs.

PB2483

HAPLOIDENTICAL BONE MARROW TRANSPLANTS – A TERTIARY CENTRE EXPERIENCE FROM THE DEVELOPING WORLD

S. Sen[1,*], S. Tulpule[2], S. Gupta[2], K. Mullanfiroze[1]

[1]Dept of Paediatric Oncology & BMT, [2]Dept of Oncology & BMT, Kokilaben Dhirubhai Ambani Hospital, Mumbai, India

Background: Bone Marrow Transplantation (BMT) can be a life saving procedure in many conditions, however the lack of a HLA matched sibling or fully matched unrelated donor can be an impediment to proceed for a transplant. Haploidentical transplants using stem cells from familial donors who are only half matched to the recipients has become increasing popular in this context. This is especially relevant in the Indian subcontinent due to the lack of any large stem cell registries and costs associated with obtaining cells from overseas registries.
Aims: Here we report on our experience of haploidentical BMT in our tertiary BMT centre.
Methods: From February 2014 to September 2017, 20 haploidentical bone marrow transplantations were done in 19 patients. The age range was 5 months to 27 years with a median of 9 yrs. 14 male and 5 female patients underwent haploidentical BMT for indications ranging from malignant diseases such as relapsed AML or ALL, CML to benign diseases like Thalassemia Major, Chronic Granulomatous Disease and Aplastic Anaemia. The donors were parents or immediate siblings who were haploidentical to the recipients.
Results: 3 of the 19 died due to transplant related toxicity. 1 child with aplastic anaemia had a first transplant from the father had a graft rejection and a second successful haploidentical BMT was done with the mother as the donor. All received T cell replete stem cells with Post Transplant Cyclophosphamide, MMF and a calcineurin inhibitor for GVHD prophylaxis. All but one (who received bone marrow stem cells) were transfused GCSF stimulated peripheral blood stem cells.
Summary/Conclusion: With a median follow up period of 8 months our data is still young, however, with an overall survival of 84%, haploidentical bone marrow transplant is a promising new option available for those who lack other appropriate donors.

PB2484

MECHANISTIC ANALYSIS OF CYTOKINE RELEASE SYNDROME AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION FOLLOWING IMMUNE CHECKPOINT BLOCKADE; ABERRANT ACTIVATION OF CD8 CTL BEYOND CONTROL OF REGULATORY T CELL

Y. Usui*, Y. Meguri, M. Iwamoto, Y. Sando, M. Sakamoto, Y. Fujiwara,

T. Kondo, K. Tani, K. Saeki, S. Okamoto, N. Asada, H. Nishimori, N. Fujii, E. Kondo, Y. Maeda, K.-I. Matsuoka

Department of Hematology and Oncology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceuticals Sciences, Okayama, Japan

Background: Cytokine release syndrome (CRS) is a severe toxicity which is associated with the elevation of inflammatory cytokines and presumably with the activation of T cells. PD-1 is one of immune checkpoint molecules expressed on activated T cells and its immune regulation is thought to be the important target for anticancer therapy. Recent studies reported that patients received allogeneic stem cell transplantation (Allo-SCT) after PD-1 blockade often developed severe CRS followed by refractory GVHD. However, the safety of the treatment sequence of PD-1 blockade and autologous stem cell transplantation (Auto-SCT) has not been reported so far.
Aims: We demonstrate a case study about severe CRS after Auto-SCT with pretreatment by Nivolumab to characterize the abnormality of lymphoid immune reaction and clinical findings after the therapeutic combination.
Methods: A 63-year-old man was diagnosed with classical Hodgkin lymphoma (HD). His disease was resistant to several lines of chemotherapies including ABVD, DHAP, IDEA (Ifosphamide, Dexamethasone Etoposide and Cytarabine) and Brentuximab Vedotin. However, the disease was progressed with the enlargement of left subclavian lymph node. He received 22 courses of Nivolumab and achieved PR again. Consequently, he received Auto-SCT with LEED. On Day 5, he became febrile to 38.5 and was administered anti-biotics as febrile neutropenia. On Day 6, body temperature rise of up to 40 , erythema of the whole body appeared, and vasopressor was administered due to low blood pressure. On Day 7, since there were few findings suggestive of infection from cultural examinations and imaging tests, it was considered to be a non - infectious fever and we diagnosed as CRS. Symptoms included decreased oxygenation, decreased urine volume, declined renal function (creatinine 2.03mg/dl), increased CRP (21.49mg/dL), increased procalcitonin (63.6ng/mL). Corticosteroid could not improve severe CRS, therefore, on Day 9, Tocilizumab 4mg/kg was administered as CRS. An antipyretic effect was observed immediately after administration, and general condition was gradually improved. On Day 11, neutrophil engraftment was achieved.
Results: We examined the lymphocyte subset of CD4 T, CD8 T, $Foxp3^{+}Helios^{+}$Treg and their expressions of CD62L and CD45RA. The CD8/CD4 ratio was increased at the peak of CRS (68.4%/15.3% of lymphocytes) as compared to the baseline (18.5%/42.2%). Both CD4 and CD8 T cells at CRS dominantly consisted of $CD62L^{-}CD45RA^{-}$Effector-memory phenotype but it was more evident in CD8 T cells (52.3% in CD4 T, 79.5% in CD8 T). After the treatment with Tocilizumab, CD8/CD4 ratio decreased (26.6%/14.9%) and $CD62L^{-}CD45RA^{-}$ Effector-memory phenotype also decreased (22.7% in CD4 T, 64.7% in CD8 T).%$Foxp3^{+}Helios^{+}$Tregs of CD4 T cells was stable in the peritransplant period (9.1% before SCT, 8.3% at the point of CRS and 8.3% 1 month after SCT).
Summary/Conclusion: These results suggested that the sequence of PD-1 blockade and Auto-SCT could induce the aberrant enhancement of CD8-positive effector-memory cytotoxic T cells regardless of the adequate amount of Tregs leading to severe CRS and anti-IL-6 therapy can restore the abnormal lymphocyte activation and CRS symptoms. The careful monitoring of early T cell reconstitution after Auto-SCT following PD-1 blockade might provide a novel strategy to predict and control excessive immune reaction leading to severe CRS.

PB2485

RESCUE HAPLOIDENTICAL STEM CELL TRANSPLANTATION FOR APLASTIC ANAEMIA FOLLOWING PRIMARY GRAFT FAILURE

S. Sen[1,*], S. Tulpule[2], S. Gupta[2], K. Mullanfiroze[1]

[1]Dept of Paediatric Oncology & BMT, [2]Dept of Oncology & BMT, Kokilaben Dhirubhai Ambani Hospital, Mumbai, India

Background: Primary graft failure remains one the important causes of mortality and morbidity in cases of stem cell transplantation. We report on a case of Aplastic Anaemia where an immediate rescue haploidentical stem cell transplantation from a different donor resulted in a successful engraftment.
Aims: To determine whether an immediate transplantation with repeat conditioning chemo-radiation therapy can result in a successful engraftment in a case of primary graft failure.
Methods: A 3yr old male child was diagnosed to have Severe Aplastic Anemia. Unfortunately there were no matched sibling donors and hence a haploidentical transplant using his fathers stem cells was undertaken. He was conditioned with Fludarabine, Cyclophosphamide, ATG and TBI and Post Transplant Cyclophosphamide was used for GVHD prophylaxis. Unfortunately he failed to engraft, and at day +21 we undertook a second rescue haploidentical transplant for the primary graft failure. As he had rejected his fathers stem cells, we decided not to use father the second time around as a donor re-transplant him using his mother stem cells. Though he was profoundly neutropenic with a WBC count of 20, we decided to give him full repeat conditioning with the same protocol as we surmised that he still had a active immune system that had rejected the primary graft. Repeat conditioning using the same protocol was started from Day + 22 and mother's stem cells was infused on Day +28.
Results: He engrafted successfully by Day +12 of the second transplant and though the transplant was complicated by a cutaneous fungal infection and CMV reactivation, child was discharged home with 100% donor engraftment.
Summary/Conclusion: A second haploidentical transplant using repeat conditioning can be used successfully in cases of primary graft failure.

Stem cell transplantation – Experimental

Background: Salvage immune-chemotherapy followed by autologous stem cell transplantation (ASCT) is the standard second line treatment for relapsed and refractory Diffuse Large B Cell Lymphoma (DLBCL). Second line immune-chemotherapy, rituximab plus platinum compound or rituximab plus ifosfamide containing regimens, were able to obtain response and permit sufficient harvest of peripheral stem cell.
Aims: The aim of this phase II study (GIOTTO study, Eudract: 2013-004014-17) was to evaluate the efficacy and safety of new anti-CD20 antibody (Obinutuzumab) in association with DHAP as induction therapy before high dose chemotherapy with ASCT in patients with relapsed/refractory DLBCL. One of the secondary objective of this study was to demonstrate the capacity of hematopoietic cell mobilization of this new immune-chemotherapic regimen.
Methods: Obinutuzumab was administered on day 1,8,15 in association with DHAP in the first cycle and on day 1 in association with DHAP for the other three cycles. Peripheral stem cell collection (PBSCC) had to be performed after the second or third cycle between 12 and 14 days.
Results: From June 2014 to June 2017 29 patients were enrolled, according to clinical characteristics 17 patients were refractory to first line therapy and 12 relapsed after first line treatment. Seventeen patients underwent peripheral blood stem cell (PBSC) mobilization while 12 did not because of disease progression during salvage therapy. Eight out 17 underwent PBSCC after the second cycle and 9 after third cycle. The median number of harvested CD34 positive cells was 5,8x10^6/Kg (range 2-12,24x10^6/Kg) and the median number of aphereses was 2 (range 1-4). No patients needed plerixafor administration. Eight patients were transplanted with a median number of 3,85x10^6/Kg CD34 positive cells and no engraftment failures were reported.
Summary/Conclusion: The use of Obinutuzumab did not impair peripheral stem cell harvest after salvage therapy in relapsed/refractory non Hodgkin's lymphoma.

PB2487

PRE-ANALYTICAL INVESTIGATIONS FOR ESTABLISHING A PROTOCOL FOR TREOSULFAN HANDLING AND ACTIVATION

I. El-Serafi[1,2,*], O. Loy[3], Y. Zhao[3], S. Oerther[3], J. Mattsson[2,4]

[1]Clinical and Experimental Medicine, Linköping University, Linköping, [2]Oncology-Pathology, [3]Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden, [4]Hematology, Oslo University Hospital, Oslo, Norway

Background: Treosulfan is an alkylating agent that is used for the treatment of ovarian cancer and for conditioning prior to stem cell transplantation. It is a prodrug that is activated non-enzymatically to two active metabolites.
Aims: To optimize a protocol for both *in vivo* samples handling and *in vitro* drug preparation.
Methods: Treosulfan stability was tested in biological fluids at different conditions as well as for plasma binding and drug cytotoxicity on cell lines.
Results: Plasma samples can be safely frozen for short period up to 8h, however; for longer periods, samples should be acidified. Urine samples and cell culture media can be safely frozen regardless the pH. For *in vitro* investigations, incubation of treosulfan at 37°C for 24h activated 100% of the drug. Treosulfan binding to plasma proteins was 10% and it was safe to separate the plasma from whole blood without affecting treosulfan concentrations. Whole blood acidification should be avoided for the risk of hemolysis. Finally, the HL-60 cell line was more sensitive to treosulfan compared to K562 cell line and the drug cytotoxicity increased following pre-incubation for 24h at 37°C.
Summary/Conclusion: The stability profiling of treosulfan provided a valuable reference for proper handling of biological samples for both *in vivo* and *in vitro* studies. These results can be utilized as a corner stone for further investigations that will enable better understanding for the drug kinetics and dynamics. Such studies are required in order to personalize treosulfan treatment, reduce its toxicity and improve the clinical outcome.

PB2488

HLA ANTIGEN AND HAPLOTYPE DISTRIBUTION IN MALAYSIAN CANDIDATES FOR HEMATOPOIETIC STEM CELL TRANSPLANTATION

K. Tey[1,*], P.C. Bee[2], Z. Mohamed[1], S. Mohd Zain[1], H.S. Eng[1]

[1]Pharmacology, University of Malaya, [2]Haematology, University of Malaya Medical Centre, Kuala Lumpur, Malaysia

Background: Histocompatibility matching of human leukocyte antigens (HLA) between recipient and their family members is essential to identify suitable donors for allogeneic hematopoietic stem cell transplant (AHSCT). Data on HLA antigen and haplotype frequencies may allow better prediction of the probability of finding HLA-matched donors and consequently enhance the donor search strategy. To our knowledge this is the first haplotype frequency report in Malaysia.
Aims: This study aims to determine the distribution of HLA antigens and haplotypes in patients who had undergone HLA typing for AHSCT in University of Malaya Medical Centre and to review the outcome of the transplant. This study aims to determine the prevalence of anxiety and depression of all cancer patients and their caregivers in a teaching institution in Malaysia.
Methods: This retrospective study involves the analysis of HLA typing results of patients and their potential donors who had undergone HLA matching in University of Malaya Medical Centre from 2003 to 2017. The patients and donors' HLA typing results were collected through their laboratory reports. The Centre routinely tests for HLA antigen/allele group by intermediate resolution solid phase assay. Only the siblings of the patients were tested in view of the patient require full HLA matched donor for transplantation. HLA typing for HLA-A, -B, -DR, and -DQ from each patient and potential donor were collected to derive the haplotype present in the patient's family. The frequency of recurring haplotype was then directly counted and recorded.
Results: A total of 143 patients and their family members (mean no. of siblings=2.7, SD±1.4) were recruited for this study. Majority of the patients were Chinese (62.9%), followed by Malay (29.4%), and Indian (4.9%). While 81 (56.6%) patients found HLA-matched donors, only 42 (29.4%) patients proceeded with AHSCT. Majority of the Malays found a match within their family (69%), followed by Indians (57%), and Chinese (52%). 53.2%, 51.7%, and 25% of Chinese, Malays, and Indians respectively from the matched group proceeded with transplant. No significant association was found between number of siblings screened and number of HLA-matched siblings (p=0.71). Of the 42 patients who proceeded for AHSCT, 47 haplotypes were successfully derived from 11 patients and their families. Of the 47 haplotypes determined, 12.8% were haplotype HLA-A*33-B*58-DRB1*17-DQB1*02, while HLA-A*01-B*27-DRB1*12-DQB1*05:01, HLA-A*02-B*13-DRB1*15-DQB1*06, HLA-A*02-B*46-DRB1*08-DQB1*06, HLA-A*02-B*60-DRB1*09-DQB1*09, HLA-A*11-B*39-DRB1*08-DQB1*06, HLA-A*24-B*15-DRB1*12-DQB1*07 were each 4.26% respectively. No disease relapse occurred within the haplotype determined group, however one death was reported post-transplant. The most frequent antigens observed from the patients and their families of the transplanted group was HLA-A*11 (31.9%), HLA-B*58 (23.4%), HLA-DRB1*12 (19.1%), and HLA-DRB1*15 (19.1%), and HLA-DQB1*6 (27.7%).
Summary/Conclusion: Malaysia is comprised of a multi-ethnic population in which the haplotype distribution may vary among ethnic groups. Though the results suggested the seven most common haplotypes, a larger scale study in healthy population shall be performed to validate the findings.

Thalassemias

GLOMERULAR DYSFUNCTION IN ADULT PATIENTS WITH B-THALASSEMIA MAJOR

A.E. Abdelhamid*, S. Shoeib, M. Abdelahafez, H. Elkholy

Internal medicine, Menoufia University, Shebin Alkom, Egypt

Background: β thalassemia major associated nephropathy has recently been a growing matter of concern affecting most aging thalassemia major patients. Serum creatinine is alone an unreliable indicator of renal functions.
Aims: The aim of the present study is to investigate the presence of glomerular dysfunctions in adults with β thalassemia major (β-TM), using early biomarkers of glomerular dysfunctions.
Methods: 50 patients with β-TM were subjected to history taking and clinical examination. Urinary albumin/creatinine ratio (ACR), Serum cystatin-C (SCys-C) levels were measured and CKD-EPI-CysC equation for estimated glomerular filtration rate (eGFR) were calculated. Presence of ACR>300mg/g and/or decreased eGFR cys were considered as glomerular dysfunction.
Results: Cases with HCV infection or diabetes were excluded from our analysis for possible risk factors for glomerular dysfunction, In the 43 patients with β-thalassemia major there were 18 patients with glomerular dysfunction (41.9%). There were significant differences between patients with and patients without glomerular dysfunction as regards age, urine albumin to creatinine ratio, serum Cyst-C, Serum creatinine, estimated GFRcys, hemoglobin and insignificant differences as regads sex, weight, height, BMI, splenectomy, using iron chelators or drugs for osteoporosis, blood requirement (ml/Kg/year) or ferritin level more than 1000.
Summary/Conclusion: our study revealed presence of glomerular dysfunctions in about (41.9%) of adult β-TM patients, age and pretransfusion hemoglobin level are predictors for glomerular dysfunctions. CKD-EPI-CysC equation for eGFR can detect early renal damage in these patients.

PB2490

DO VENTRICULAR DEPOLARIZATION AND REPOLARIZATION DIFFER IN B-THALASSEMIA CARRIERS?

S. Akarsu[1,*], T. Kasar[2]

[1]University of Firat, Faculty of Medicine, Department of Pediatric Haematology, Elazig, [2]Ordu University, Faculty of Medicine, Department of Pediatric Cardiology, Ordu, Turkey

Background: In our population the incidence of β-thalassemia minor (TM) is 2.1 percent. These cases are frequently evaluated as iron deficiency anemia (IDA) and receive iron containing medications. In cases with IDA, and β-thalassemia major, electrocardiographic (ECG) signs reflecting cardiac autonomic dysfunction, and changes in depolarization, and repolarization differ widely.
Aims: We haven't encountered any study related to changes in ECG signs in the literature. So we wanted to investigate corrected QT (QTc), and QTc dispersion (QTcd) in cases with TM which demonstrate clinical manifestations in between IDA, and β-thalassemia major.
Methods: Study population consisted of Group 1 (TM; n:15), Group 2 (IDA; n:17), and Group 3 (healthy control; n:13). Mean ages of Groups 1, 2 and 3 were 10.2±17.4, 13.2±14.5, and 13.5±2.5 months, respectively. In all cases whole blood cell counts, levels of serum iron, iron binding capacity, and ferritin were evaluated, and hemoglobin electrophoresis was performed. Peak heart rate, RR, PR, QRS, QT, QTc and QTcd were calculated using 12-lead ECG. Groups in all 3 groups were compared as for all ECG variables.
Results: QTc intervals were estimated for TM (383.7±40.7 ms), IDA (399.1±20.4 ms), and healthy control (403.8±20.6 ms) groups as indicated. QTc intervals in cases diagnosed as TM were shorter relative to IDA, and healthy control groups. A statistically significant difference was detected between TM, and healthy control groups ($p<0.05$). QTc interval was statistically significantly longer in cases diagnosed as TM (84.6±34.5) ms when compared with cases with IDA (61.7±37.0 ms) ($p<0.05$). The other parametres did not differ between groups.
Summary/Conclusion: Changes in ECG tracings may occur not only in heart diseases, but also it may become manifest as a sign of myocardial ischemia due to anemia. In order to be able to explain some electrocardiographic changes in cases diagnosed as TM caused by etiological factors other than myocardial ischemia, and accumulation of iron, further studies should be carried out with greater number of patients.

PB2491

LONGITUDINAL TREND ANALYSIS OF SERUM TRANSFERRIN RECEPTOR-1 LEVEL IN A COHORT OF 104 PATIENTS AFFECTED BY NON TRANSFUSION-DEPENDENT THALASSEMIA

P. Ricchi*, B. Gargiulo, M. Ammirabile, S. Costantini, A. Spasiano, P. Cinque, A. Filosa

Oncoematologia, AORN Cardarelli, Naples, Italy

Background: Non-transfusion-dependent thalassemias (NTDT) are a wide group of inherited disorders grouped together only by the fact that their phenotypic expression rarely or occasionally requires regular transfusions. The soluble transferrin receptor-1 (sTfR1), that fully reflects the marrow erythropoietic activity, had not only a striking diagnostic accuracy in predicting the risk of extramedullary hematopoiesis (EMH), but also in scoring disease severity. Our prospective data in NTDT patients showed previously that sTfR1 levels were unchanged following iron chelation therapy when ferritin level was clearly and significantly decreased.
Aims: Our aim was to explore the longitudinal trend of sTfR1 levels in a wide cohort of patients with NTDT followed at U.O.S.D. Rare Red Blood Cells Diseases of Ospedale Cardarelli (Naples, Italy).
Methods: Until today, 104 NTDT patients have been undergoing since 2007 the measurement of the sTfR1 levels about twice a year. During the observation period, based on several complications treatment and/or prevention, such as extramedullary hematopoiesis, cardiomiopathy, pulmonary hypertension and fatigue, 16 patients were started on regular blood transfusion (BT) therapy and 12 on hydroxyurea (HU) and 76 have never been treated (controls). Basal and final values were considered those at the first and last assessment for controls (CTRLs), respectively. For patients who were started on transfusion or HU, basal and final values were considered those assessed just before and following about 12 months of both treatments.
Results: Patients treated with BT were older than CTRLs (median value 48.3 *vs* 38.2 years old, $p=0.005$). Patients treated with BT and HU at baseline had higher sTfR1 median levels as compared to CTRLs (11.8 and 8.7 *vs* 5.1 mg/ml; $p<0.001$ and $p<0.001$, respectively). sTfR1 median levels were unchanged (median observation time: 5.78 years) among CTRLs: 5.1 *vs* 4.9 mg/ml (median reduction=-0.2, $p=0.55$). sTfR1 median levels were also unmodified among BT and HU groups, before the start of treatments. Conversely, following the start of treatments, we observed a statistically significant reduction in STfr1 levels in both population. In patients treated with BT, the median levels dropped of 5.6 mg/ml from a median value of 8.1 to a median value of 5.9 mg/ml ($p=0.00023$) with a median 50% of reduction with respect to baseline ($p=0.00003$). Whereas, in patients treated with HU, the median levels dropped of 4 mg/ml to a median value of 8.35 mg/ml ($p=0.005$) with a median 32% of reduction with respect to baseline ($p=0.003$).
Summary/Conclusion: Our data among CTRLs show that the sTfR1 level remains unchanged over a long period of observation and suggest that it could be a reliable marker of the disease since its first measurement. But, in a prospective evaluation, these data highlight that increased sTfR1 levels are associated with the risk of undergoing BT and HU treatment. We found also that these fundamental treatments for the management of patients with NTDT are able to significantly reduce sTfR1 levels. Further studies are needed to evaluate if, consistently with our previous findings, such a conspicuous drop in sTfR1 levels following both treatments could be also predictive of reduction and/or prevention of the complications typical of NTDT patients.

PB2492

HB PALENCIA A NOVEL BETA DELTA GLOBIN GENE FUSION WITH OVEREXPRESSION OF BETA GLOBIN CHAIN

P. Ropero[1,*], J.M. Nieto[1], F.A. González[1], A. Villegas[1], R.B. Martínez[1], C. Vicente[1], J.M. Alonso[2], A.M. Bobes[1], P.A. Velasco[1], A.M. González[1], M.M. Ibarra[1], R.O. Trelles[1], E. Golvano[2], L. Guerrero[2], B. Albarrán[2]

[1]Hematology, Hospital Clínico San Carlos, Madrid, [2]Hematology, Complejo Asistencial Universitario, Palencia, Spain

Background: Non homologous crossing-over between d and β globin genes results in a family of fusion genes that produce the Lepore and anti Lepore type hemoglobins. The Lepore hemoglobins are characterized by globins chains with a δ-amino terminus, a β-carboxyl terminus, and reduced synthesis, resembling that seen in normal δ synthesis. The reciprocal products of the Lepore genes, the anti Lepore type hemoglobins (Miyada, Hong Kong, CHORI…), have β-amino and δ carboxyl terminal and also exhibit reduced synthesis. In other hand the hemoglobin Parchman is a rare variant that hybrid globin chain had a δ-amino terminus, an internal β-chain fragment, and a δ-carboxyl terminus.

Aims: We present a new hemoglobin, the result of a double cross-linking of the δ and β genes or an unequal cross-linking between a Lepore type gene and the β gene. The new fused globin chain has the β-amino end, an internal δ chain fragment and the β carboxy terminus and its synthesis is similar to that of β-globin.
Methods: The propositus was an 80-year-old white man for the hemoglobinopathies study, because to rule out type 2 diabetes, Hb A1c was quantified by ion exchange HPLC (Variant II turbo) and an abnormal peak appeared in a retention time (RT) of 1.15 min which constituted 43.9%. Analysis of hemoglobins was made by HPLC exchange ionic (Variant II), electrophoresis capillary (Sebia Capillarys Flex) and the DNA analysis using PCR; MLPA and automatic sequencing of Sanger of δ and β genes.
Results: Sequencing showed that the 5 'end belongs to the HBB gene up to CD8, from CD9 and up to CD31 to the HBD gene and since the reverse sequencing of the β gene established that from the 3' UTR region and up to CD32 it belonged to the gene HBB, an unequal crossover between the HBD and HBB genes should have been carried out, causing a crossover gene reversion of at least 196 bp and a maximum of 225 bp of the HBD gene in the HBB gene which would give rise to a βδβ hybrid gene. This uncertainty would be due to the fact that although the sequence up to +21 from Cap belongs to the HBB gene, from this position and up to CD8 it could correspond to both the HBB gene and the HBD since this sequence is completely the same in both genes. This recombination probably took place during meiosis.
Summary/Conclusion: In the case of this new variant (Hb Palencia), it is probably the result of a cross-linking between a Lepore type gene (Baltimore or Washington-Boston) and a HBB gene, since the probability of a double cross-linking of the genes HBD and HBB in a region that covers less than 200 bp is extremely low. The normal levels of Hb A2 (2.9%) suggest that in both chromosomes the HBD gene would be intact, allowing a correct synthesis of the δ-globin chain. On the other hand, the percentage of Hb Palencia, around 40%, is similar to that of Hb A, therefore, the synthesis of the βδβ-globin chain should be controlled in a similar way to that of β-globin. And since the propositus does not have a thalassemia phenotype, consequently the β cluster of one chromosome would be strictly normal and that of the other allele would have a normal HBD gene and the β would correspond to the hybrid (βδβ).This Hb Palencia is the first variant due to a hybrid gene, constituted in the 3 'and 5' UTR ends by the sequences and machinery of the HBB gene and a part of the interior by sequences of the HBD gene. This structure would confirm that the sequences of the promoter regions as well as those of the IVS-II are necessary and essential for the synthesis of the β-globin type chain.

PB2493

LABORATORY DIAGNOSIS FOR THALASSAEMIA INTERMEDIA: ARE WE THERE YET?

S. Ansari*, N. Rashid, A. Hanifa, S. Munzir, B. Kaleem, A. Naz, K. Perveen, Z. Hussain, I. Ansari, Q. Jabbar, T. Khan, M. Nadeem, T.S. Shamsi

National Institute of Blood Disease & Bone Marrow Transplantation, Karachi, Pakistan

Background: Differentiation between thalassaemia major and thalassaemia intermedia at presentation is not uniformly characterized, for which an absolute criteria needs to be developed.
Aims: This study investigated the primary and secondary genetic modifiers to develop a laboratory finding by forming different genetic mutational combinations seen among thalassaemia intermedia patients and comparing them with thalassaemia major.
Methods: This cross sectional study analyzed 315thalassaemia intermedia patients. Selection primarily based with hemoglobin between 3-10gm/dl after 2 years of age. 105thalassaemia major patients were recruited on the basis of documented evidence of diagnosis and were receiving blood transfusion therapy regularly. Mutations were identified and various mutational combinations were formed and comparison was done between thalassemia intermedia and major using statistical software STATA 11.1.
Results: The mean age of the total population was 5.9 +/-5.32 years of which 165 (52%) were males and 150 (48%) were females. Of the two groups (thalassemia intermedia and thalassemia major), *IVSI-5, IVSI-1 and Fr 8-9* are more prevalent among the thalassemia intermedia cohort. When comparison was done between the thalassemia intermedia and thalassemia major patients, it showed significant results (p-*value*<0.001) for the presence of *Xmn-1* polymorphism.
Summary/Conclusion: The presence of IVSI-5 homozygous with Xmn-1, IVSI-5 heterozygous with Xmn-1, Cd30 homozygous with or without Xmn-1 and IVSI-1 homozygous or heterozygous either with or without Xmn-1 prove to be strong indicators towards diagnosis of thalassemia intermedia.

PB2494

NOVEL NONSENSE MUTATION IN A1 GLOBIN GENE [HBA1:C.49A>T] RESPONSIBLES FOR A-THALASSEMIA NON DELETION

P. Ropero*, F.A. González, J.M. Nieto, A. Villegas, R.B. Martínez, A.M. Bobes, C. Vicente, P.A. Velasco, A.M. González, M.M. Ibarra, R.O. Trelles

Hematology, Hospital Clínico San Carlos, Madrid, Spain

Background: α-thalasemia is a common disease charcterized mainly deletions of one or several α genes which is known as α-thalassemia deletion. On the other hand, point mutations are also observed in critical regions of the α genes such as the consensus zones of the introns or in the polyadenylation sequences, which can alter the processes of transcription, translation or in the posttradutional processing of the mRNA, originating the so-called α-thalassemia no deletion. So far, more than 100 mutations have been described. One of the least frequent mechanisms is the nonsense mutations, those that generate the substitution of a triplet coding for an amino acid by a stop codon and therefore the protein synthesis stops prematurely. At present 9 mutations of this type have been documented, 6 that affect the HBA2 gene and 3 that affect the HBA1 gene.
Aims: We present a new mutation in CD16 of the HBA1 gene, where the change AAG>TAG generates a stop codon.
Methods: The propositus, a 48-year-old woman from Madrid, was studied because she had maintained microcytosis without iron deficiency. The Hb A_2 and Hb F levels were measured by ion exchange HPLC (VARIANT II). Hemoglobin was studied by capillary zone electrophoresis and ionic exchange HPLC (β-thalassemia Short Program). The most frequent α globin mutations were discarded by multiplex PCR (Alpha-Globin StripAssay ki) and molecular characterization was undertaken using automatic sequencing.
Results: The propositus presented microcytosis with hypochromia and with normal reticulocytes. No abnormal hemoglobins were detected and Hb A2 and Hb F levels were within normality. Molecular characterization of the α1-globin gene by automatic sequencing identified the novel transversion mutation HBA1:c.49A>T, which resulted in an amino acid change from Lys>Stop at codon 16 of exon 1 in the heterozygous state [$\alpha_1$16(A14)Lys>Stop; HBA1:c.49A>T]. This was confirmed by sequencing of the other strand.
Summary/Conclusion: This type of mechanism is very rare among the globin genes, in fact, between the γ genes (A and G) has not been detected, in the β globin gene (HBB) has been identified 18 times (18/913), in the δ gene only in three (3/126) and in the α globin 9 genes (9/799). This new mutation is the fourth described in the HBA1 gene and the tenth nonsense among the alpha globin genes. The first nonsense mutation described in the alpha globin genes was in 1987 in a black family in the USA, since then and until the current 21st century no other had been described, probably as a result of advances and refinement of biology techniques as the automation of genetic sequencing, which has allowed an increase in the ability of analysis. This new mutation has a mild phenotype in the heterozygous state. Short gene products might eventually undergo nonsense mediated decay, while any anomalous short protein will be removed through the ubiquitin mediated proteolytic pathway resulting in the mild phenotype of an α-thal (αTα/αα) genotype. Probably the severe end of the clinical spectrum, when it is inherited with a deletion mutation of two genes.

PB2495

GLOMERULAR AND TUBULAR FUNCTION IN THALASSEMIA PATIENTS

G. Aydogan*, D. Doganci, N. Ozdemir, F. Akici, Z. Salcioglu

Pediatric Hematology, Kanuni Sultan Suleyman Education And Research Hospital, Istanbul, Turkey

Background: Thalassemia is a hereditary hemolytic anemia resulting from defects in globin chains. Transfusion-dependent thalassemia patients are prone to develop renal dysfunction due to iron overload, chronic anemia, and/or chelation therapy.
Aims: The aim of this study was to analyze renal tubular and glomerular function in patients with beta thalasemia major (β-TM).
Methods: Thirty-eight transfusion dependant (β-TM) patients were recruited. Patients were divided into three groups based on serum ferritin levels. Glomerular functions [serum urea, creatinine, cystatin-c, estimated glomerular filtration rate (eGFR) and urinary protein excretion] and tubular functions [serum electrolytes, fractional sodium excretion (FeNa), fractional potassium excretion (FeK), tubular phosphorus reabsorption (TPR), urinary calcium excretion] were assesed in all patients.

Results: In all patients serum urea, creatinine and electrolytes were normal. Cystatin-c was increased in 5.3% of patients, GFR was increased in 28.9% and decreased in 18.4% of patients. Proteinuria (4-40 mg/m2/h) was detected in 36.8%. Protein/creatinine ratio was over 0.2 in 50% of patients. Microalbuminuria (30-300mg/day) was detected in 10.5% of the patients, albumin/creatinine ratio was above 30 mg /gr 18.4% of patients. Calcium excretion over 4mg/kg/day was found in 42.1%, and high calcium/creatinine ratio in 28.9% of the patients. FeNa was detected in 18.4% over 1%, while TPR was found to be decreased in 7.8%. Between β-TM patient groups with ferritin levels below 1000 ng/ml, between 1000-2000 ng/ml, above 2000 ng/ml, glomerular and tubular functions were not significantly different. Also there was no correlation between kidney function tests and ferritin. GFR was found to be significantly lower in patients aged 18 years and older, than patients aged 10-18 years and under 10 years according to age specific references. Creatinine was significantly lower and protein/creatinine ratio was significantly higher in patients younger than 10 years of age.
Summary/Conclusion: Different levels of renal tubular and / or glomerular dysfunction were encountered in this study. Findings suggest that renal injury is associated with increased age. In our study, serum ferritin did not correlated with renal tubular and glomerular functions.

GENE SPECTRUM ANALYSIS OF THALASSEMIA CARRIERS RESIDING IN NORTHERN CHINA

W. Zhou[1,*], Z. Yang[2], Q. Cui[1], L. Qiu[2], B. Han[1]

[1]Peking Union Medical Collage, Chinese Academe of Medical Science, [2]Department of clinical laboratory, Peking Union Medical Collage, Chinese Academe of Medical Science, Beijing, China

Background: Thalassemia is one of the most pervasive monogenic diseases worldwide. In China, southern provinces were known as high incidence areas of thalassemia. But thalassemia is now becoming increasingly common in northern China because of continued migration.
Aims: We compared gene spectrum of α and β-thalassemia in northern and southern China, and compared our data in provinces of different elevations. The results may help to understand the similarities and differences of people who reside in the north China but originate from different areas.
Methods: Positive patients or carriers were analyzed from 2136 suspected α and β-thalassemia carriers who were referred to Peking Union Medical College Hospital from 2012 to 2017 for diagnosis. Gap-PCR and RDB (reverse dot blot) analysis were applied for detections of common α and β-thalassemia gene mutations. Basic clinical data from these patients or carriers were collected. Telephone follow-up survey was conducted on their ancestral information, to confirm whether these northerners have southern lineage.
Results: A total of 1059 carriers (male 299, female 760, age range from 0 to 82 years, mean age 30.2 years) were selected from north dweller, 183 (17.3%) of them with pure northern descent in three generations and the rest 876 (82.7%) carriers with south descent. Most of our people with positive thalassemia gene findings had no or mild symptoms. People who originated from the north origin had higher percentage of β-thalassemia gene mutations compared with people from the south origin (72.8% *vs* 62.4%, χ^2=9.92, P=0.001). Analysis of the individual gene distribution of the south and north did not show significant difference either in α-thalassemia (P=0.221) or β-thalassemia (P=0.979). Differences between gene distributions in provinces with similar average altitudes were relatively small. No significant statistical differences in the frequency of α mutation were found in different altitude levels. But in β thalassemia, the frequency of 6 most common mutations were significantly different in provinces with altitude below 500 meters, about 500-1000 meters, and above 1000 meters (χ^2 test, P<0.05).
Summary/Conclusion: Most of people with positive thalassemia gene findings who reside in the north China are thalassemia carriers. People with north lineage may have higher frequency of β mutation than those originated from the south, but they had similar spectrum of α and β mutations. People lived at different level of altitudes may have different spectrum of β mutations.

PB2498

SERUM FERRITIN TREND AS A PREDICTOR OF LIVER AND CARDIAC IRON OVERLOAD AMONG CHILDREN WITH TRANSFUSION DEPENDENT THALASSEMIA AND SICKLE CELL DISEASE

S. Sahmoud[1,*], M. Azzam[2], S. Elfiky[3], I. Alnasser[4], I. Elghamry[5], A. Gobarah[2], A. Almanea[6]

[1]Pediatric Hematology department, Suez Canal University, [2]Pediatric Departement, [3]Pediatric Hematology department, Faculty of Medicine, Suez Canal University, Ismailia, Egypt, [4]Radiology department, King Fahd Armed Forces Hospital, Jeddah, Saudi Arabia, [5]Pediatric Hematology and Oncology department, Ain Shams University, Cairo, Egypt, [6]Pediatric Hematology and Oncology department, King Fahd Forced Arm Hospital, Jeddah, Saudi Arabia

Background: Chronic blood transfusion cause inevitable iron overload. Conflicting results were found regarding how much serum ferritin can predict tissue iron overload among chronically transfused patients and how much it differs by age.
Aims: to evaluate cardiac (CIO) and liver Iron overload (LIO) in children with sickle cell disease (SCD) and Transfusion dependent thalassemia (TDT) and testing their predictability by using the serum ferritin trend.
Methods: 3 Serum ferritin levels were tested at interval of 6 months, the last one was at the time of MRI T2* examination of both liver and heart. Increasing values of serum ferritin over time was considered an increasing trend.
Results: 90 (43 male, 9.9+/_4.4 year) TDT and 47 (32 male, 11.85 +/_3.82 year) SCD children were included. LIO was higher among TDT children with liver iron concentration of 11.87 mg/g, and 6.58 mg/g (p: 0.0001). Similarly, there was a higher level of CIO in TDT (T2*: 24.38 m/sec) than in SCD (31.97 m/sec) (p: 0.001). Age didn't increase the risk of LIO (OR 0.81, CI 0.46-1.42, p: 0.47), or CIO (OR 1.23, CI 0.74-2.03, p: 0.43) in TDT neither did of LIO (OR 1.054, CI 0.86-1.28, p: 0.61) nor CIO (OR 0.722, CI 0.41-1.28, p: 0.27) in SCD. Percentage of children with increasing trend of serum ferritin was 50% in TDT and 30% in SCD children (p: 0.31). The relationship between serum ferritin trend and CIO/ LIO in TDT (p: 1.0/0.67) and CIO/LIO in SCD (p: 1.0/0.66) was insignificant. In TDT, Serum ferritin at a level of >4036 µg/l could differentiate mod/severe CIO from those with none/mild one (AUC 0.872, p: 0.001). Similar discrimination could be achieved regarding LIO in TDT at a lower level of >2294 µg/l (AUC 0.879, p: 0.001). In SCD Mod/severe LIO could be discriminated from none/mild LIO at a level of >1892 µg/l serum ferritin (AUC 0.822, p: 0.001).
Summary/Conclusion: Serum ferritin level could predict both LIO and CIO in TDT cases, and LIO in SCD. Ferritin trend had no relation to tissue iron overload in both groups.

PB2499

HEMOGLOBINOPATHIES SCREENING IN A EUROPEAN CENTRAL HOSPITAL- RETROSPECTIVE STUDY OF THE LAST 10 YEARS

D. Fonseca E Silva[1,2], C. Sousa Neves[1,*], M. Lima[3,4], M.I. Freitas[1]

[1]Laboratorial Hematology Department, Centro Hospitalar do Porto, [2]Instituto de Ciências Biomédicas Abel Salazar, University of Porto (ICBAS/UP), [3]Unit for Multidisciplinary Research in Biomedicine, Instituto de Ciências Biomédicas Abel Salazar, University of Porto (UMIB/ICBAS/UP), [4]Cytometry Laboratory, Clinical Hematology Department, Centro Hospitalar do Porto, Porto, Portugal

Background: The hemoglobinopathies (HGP) are a group of hereditary disorders in which there is abnormal production or abnormal structure of the hemoglobin (Hb) molecule. These are the most frequent group of genetic disorders worldwide. They are broadly categorized into two major groups: thalassemias and structural variants of hemoglobin. HGP have become much more common recently in northern and central Europe, including Portugal, due to immigration.
Aims: The aim of this study was to analyze the incidence of HGP in all samples screened for HGP in a central hospital during the last 10 years.
Methods: Retrospective study performed in a central and university hospital of Porto, Portugal. A total of 4131 samples of 3886 patients, studied from January 2007 to December 2016, were included. These samples were collected in EDTA-K3 tubes and were analyzed in an automatic hematological counter to obtain red blood cell count with erythrocyte indices. The next step of diagnosis workout consisted on Hb tests: high performance liquid chromatography, electrophoresis and, sometimes solubility test. When detected abnormal structural Hb, samples were tested by molecular biology to identify the Hb variant.
Results: From all the patients studied (n=3886), 19.8% (n=771) had Hb genetic disorders and were subdivided into two main groups: β-thalassemia syndromes (71.5%; n=551) and structural Hb variants (28.5%; n=220). The most frequent HGP were β-thalassemia (n=550 β-thalassemia minor and n=1 β-thalassemia major) and Hb AS (14.5%; n=112), followed by Hb Lepore (5.1%; n=39), Hb SS (2.9%; n=22), Hb AD (2.2%; n=17) and Hb AC (1.0%; n=8). Other rare Hb variants detected were: Hb AE (0.5%; n=4), Hb Indianopolis (0.5%; n=4), Hb Koln (0.4%; n=3), Hb SC (0.4%; n=3), ∅-chain variant Hb A2 (0.3%; n=2), Hb Himeji (0.1%; n=1), Hb Setif

(0.1%; n=1), Hb Strasbourg (0.1%; n=1) and Hb Porto Alegre (0.1%; n=1). Concomitant β-thalassemia and Hb AS was also present in two of our patients (0.3%; n=2).
Summary/Conclusion: Our data are concordant with previous epidemiological studies. It is noteworthy that our sampling included HGP screening samples and not the whole population and therefore we found higher levels of genetic Hb disorders. The α-thalassemia syndromes were not detected by our methods, as characterization of these diseases requires DNA-based α-globin gene testing. For this reason, some of the samples studied for HGP screening may have gone undetected. HGP are a public health issue and therefore early detection and characterization of the HGP is crucial so that appropriate counselling and treatment can be provided to couples through prenatal screening and families who may be at risk of having HGP. The reinforcement of these measures can lead to the reduction of incidence and morbidity associated with these disorders.

PB2500

THE PHENOTYPIC MANIFESTATIONS OF BETA-THALASSEMIC MUTATIONS IN AZERBAIJAN

C. Asadov*, T. Mammadova, E. Abdulalimov, G. Aliyeva, S. Gafarova

Pathology of hemopoesis, Institute of Hematology and Transfusiology, Baku, Azerbaijan

Background: Azerbaijan is one of the countries with the highest prevalence of thalassemias. β-Thalassemia is known for its extremely diverse clinical manifestations. Therefore, determination of factors causing such a diverse clinical presentation has clinical significance, and the major reason for such diversity is the variety of mutations. A number of studies revealed genotype-to-phenotype correlations of β-thalassemia mutations in various populations, and we hereby report the first one conducted in an Azerbaijani population.
Aims: The aim of our study was to reveal genotype-to-phenotype correlations of the most common β-thalassemia mutations in an Azerbaijani population.
Methods: 48 patients (23 heterozygous, 23 homozygous, 2 compound heterozygous β-thalassemia) with known genotypes were included in the study. Evaluations of RBC count, hemoglobin concentration, hematocrit, MCV, MCH, and MCHC were performed with a Sysmex XT2000i hematology analyzer. All samples were tested for hemoglobin fractions by high-performance liquid chromatography via the VARIANT II Hemoglobin Testing System (Bio-Rad). DNA amplification was performed on a C-1000 thermocycler (Bio-Rad). Detection of mutations by reverse dot-blot hybridization was performed with commercial test kits (β-Globin StripAssay Kit, ViennaLab) according to the manufacturer's instructions. One-way ANOVA followed by Tukey's honestly significant difference test was used to analyze between-group differences.
Results: The classical β-thalassemia carrier pattern of increased RBC count and low hemoglobin and erythrocyte indices (MCV, MCH, and MCHC) was observed in almost all patients. Increased HbA_2 concentrations and fetal hemoglobin within the normal range (<2%) were observed in most cases. There was a statistically significant difference ($p<0.05$) in RBC, MCV, and MCH parameters of IVS-I-6 patients compared to the groups with codon 8 and IVS-II-1. The former was associated with comparably lower RBC and higher MCV and MCH mean values. Based on this pattern of hematologic data, it can be concluded that IVS-I-6 presents a milder phenotype compared to codon 8 and IVS-II-1 mutations. No statistically significant difference was obtained between codon 8 and IVS-II-1 mutations ($p>0.05$). The data of homozygous individuals were also observed to correlate with the type of the mutation. Statistically significant between-group differences ($p<0.05$) were observed for MCV, MCH, and MCHC. Contrary to the heterozygous individuals, lower mean values of these parameters were observed in the group of homozygous IVS-I-6 patients, possibly due to their less frequent transfusions, compared to codon 8 and IVS-II-1 patients. The results obtained indicate that clinical presentation varies between different β-globin gene mutations: individuals with IVS-I-6 (T>C) mutations showed milder presentation than those with codon 8 (-AA) and IVS-II-1 (G>A), which is associated with the molecular basis of the mutations.
Summary/Conclusion: Our study revealed genotype-to-phenotype correlations of the most prevalent β-thalassemia mutations of the Azerbaijani population. According to our data, hematologic parameters and consequently the clinical presentation are closely related to the type of the mutation, especially in homozygous patients. Our findings can provide a better prediction of clinical manifestation by early identification of the type of the β-thalassemia mutations.

PB2501

THE MAIN ENDOCRINE HEMOCHROMATOSIS COMPLICATIONS DURING HOMOZYGOUS B-THALASSEMIAS: 18 YEARS SINGLE ALGERIAN EXPERIENCE

G. Yamina*, D. Malika, A. Mohamed Rafik, S. Mohamed, B. Salah Eddine

Hématology, hospital dr Mohamed Seghir Nekkache, ALGIERS, Algeria

Background: Endocrine abnormalities are common in thalassemia patients, despite the initiation of an early adapted chelation treatment, the main complications that can occur, hypothyroidism, diabetes, growth retardation, hypogonadism, hypoparathyroidism, adrenal insufficiency.
Aims: Clinical, biological and evolutionary evaluation of the main endocrine complications of polytransfused homozygous β-thalassemia patients over a period of 18 years.
Methods: This is a retrospective study over 18 years [January 1999 - December 2016], we collected 35 homozygous thalassemic β : major form (MF)=17 cases, intermediate form (IF)=18 cases. The search for endocrine complications is done on a regular basis: clinical examination, biological assessment, hormonal assessment, radiological assessment. Then the patient will be referred to the endocrinologist for proper treatment.
Results: The average age of diagnosis of β thalassemia in major form was 11 months [6 to 46 months], in the Intermediate form was 28 months [6 to 78 months]. The current median age was 17 years [30 months to 47 years], with a sex-ratio=1.05 (18 males/17 females). Endocrine complications are found in 40% of cases (MF=10, IF=4): (hypothyroidism n=5, hypogonadism n=5, diabetes n=4), these various complications are detailed below: **Hypothyroidism**: it is infra-clinical in 5 cases (MF=3, IF=2), the average age of discovery is 24 years [13 to 33 years], the thyroid balance: average TSH of 5.73 mIU / ml [4.96 to 6.61], average FT4 of 81 µg /l [77 to 88], these patients are monitored regularly and there is a stabilization of thyroid status. **Hypogonadism**: n=5 (MF=4, IF=1), the average age is 26 years [17 to 32 years], primary amenorrhea is noted in 3 cases, the hormone balance found: GH average of 1.38µUI / ml [0.88 to 1.86], average FSH of 0.26 IU / l [0.18 to 0.68], average oestradiol of 53 ng / l [33 to 72], 2 patients are treated by patch estrogen with a good evolution in a patient after 12 months of hormonal treatment. **Diabetes:** n=4 (FM=3, FI=1), average age of 32 years [22 to 47 years], average Hb A1c of 8.1% [7.5 to 8.9], these patients are on a low-carbohydrate diet combined with insulin therapy with regular monitoring in diabetology. Note that all our patients are under a deferasirox chelator treatment at the dosage of 20 to 30 mg / kg / day with regular monitoring of ferritin levels. The median follow-up of our patients is 16 years [13 to 47 years].
Summary/Conclusion: Endocrine complications during β-thalassemia are manifestations mainly associated with haemochromatosis resulting from direct involvement of the glandular parenchyma or the hypothalamic-pituitary axis. The frequency of these complications increases with age of patients, they are the most common complications, noted in 40% of cases. When complications are established, management should focus on interrupting the evolutionary process and treating symptoms. It is for this reason that the realization of an early detection in endocrine environment is essential in order to diagnose the beginning endocrinous attacks (intolerance to sugar, rough hypothyroidism) and to intensify the chelating treatment

PB2502

EVALUATION OF THE EFFECTIVENESS OF EXJADE IN PATIENTS WITH B-THALASSEMIA MAJOR DURING 3 YEARS IN GEORGIA

Z. Mtvarelidze*, M. Kvezereli-Kopadze

Hematology, Children s New Clinic, Tbilisi, Georgia

Background: B-Thalassemia is the most common hemoglobinophaty in Georgia. Carrier rate is 3,79%, and annual affected births of homozygote β-thalassemia are **about 20 new births per year.** One of the most important problems of treatment of this pathology is excretion excess iron with iron chelator therapy. In recent years for this purpose, usage of Exjade, but its efficiency criteria's and distant results not known yet.
Aims: This study was undertaken to evaluate the effectiveness of Exjade in patients with transfusion-dependent β-thalassemia major during 3 years in Georgia.
Methods: 16 children, aged 3 to 17 years, with transfusion-dependent β-thalassemia phenotype, were enrolled in a trial. The starting dose of Exjade was 20-30mg/kg per day given orally once a day. Baseline and serial laboratory tests were performed: detailed history and physical examination, complete blood count with red blood cell indices, reticulocyte count, hemoglobin electrophoresis, and ferritin level measurement monthly, liver and

renal function tests, bilirubin, urine analysis. Response to therapy was evaluated after 6 month, 1, 2, 3 years of treatment.
Results: No adverse effects were observed at a dose of 20-30mg/kg day. Positive clinical-laboratory effect was noticed in 13 patients: the general condition of children improved, increased intervals between hemotransfusions after 6 month of treatment. The decrease in ferritin levels started in 4-5 months of treatment. Taking into account the ferritin level, in some cases, treatment was temporarily stopped, or, dose of Exjade was decreased after a year of treatment. In 3 cases, the treatment was ineffective, despite Exjade dose was increased.
Summary/Conclusion: Accurate assessment of excessive iron stores is essential to optimal therapy. In our cases the Exjade is safe and effective in 81,2% of patients with transfusion-dependent β-thalassemia major. It is noted, that the result is achieved with continuous, regular Exjade therapy and such patients are under monthly monitoring of serum ferritin level. We also should consider that Exjade is characterized by a later effect (after 4-5 months of treatment). Exjade therapy should start as soon as the patient becomes significantly iron overloaded, this correlates with the serum ferritin>1,000 ng/ml. In some cases, his ineffectiveness is due by irregular/late start of treatment (the level of ferritin exceeds 2,000 ng/ml).Combination chelation may be an effective treatment strategy for patients with insufficient response to monotherapy. In rare cases, determining the causes of Exjade inefficiency is very difficult, that's why further studies in this direction are needed.

[1]Hematology, Hospital Universitario Miguel Servet, zaragoza, [2]Hematology, Hospital Clínico San Carlos, Madrid, [3]Pediatrician, Hospital Universitario Miguel Servet, zaragoza, [4]Hematology, Hospital Universitario Miguel Servet, Madrid, Spain

Background: Hemoglobinopathies are the most common, potentially deadly monogenic disorders in the world. It is estimated that 7% of the world population are carriers. Global migration in the modern period has led to a continual spread of these anomalies so that they are rapidly becoming more common in the industrialized regions of Europe.
Aims: Description of the mutational spectrum of thalassemias and other hemoglobinopathies in a third hospital level
Methods: A cross-sectional study of patients diagnosed of hemoglobinopathies in a tertiary hospital. Period of study: January 2016- December 2017. Hemoglobin fractions were determined by capillary electrophoresis techniques Minicap® CDT (Sebia, Lisses, France). Molecular study was carried out in selected cases at the Hospital Clínico San Carlos in Madrid. The study of thalassemia was carried out on the most prevalent mutations by Gap-PCR and in those without detected mutation, genetic screening of the HBA1 / HBA2 or HBB genes was performed and the MLPA technique allowing the study of the exons of the HBB and HBA1 / HBA2 genes.
Results: Based on this series of patients, α-thalassemia is identified as the most prevalent hemoglobinopathy in our patients and -α , deletion the most frequent deletion found in these patients. In our series prevalence demonstrates great variability, and the mutations expose big differences with respect to other prevalence studies. The study of these mutations is important for diagnosis, individual clinical prognosis and future planning of the management of possible complications and epidemiological records, these records being the way to develop future cohort studies and the possibility of comparison or integration with other registries because hemoglobin defects are of widely diverse genetic and clinical types, specialized laboratory analysis is needed to diagnose them correctly and provide a basis for proper therapeutic decisions.
Summary/Conclusion: Based on this series of patients, α-thalassemia is identified as the most prevalent hemoglobinopathy in our patients and -α , deletion the most frequent deletion found in these patients. In our series prevalence demonstrates great variability, and the mutations expose big differences with respect to other prevalence studies. The study of these mutations is important for diagnosis, individual clinical prognosis and future planning of the management of possible complications and epidemiological records, these records being the way to develop future cohort studies and the possibility of comparison or integration with other registries because hemoglobin defects are of widely diverse genetic and clinical types, specialized laboratory analysis is needed to diagnose them correctly and provide a basis for proper therapeutic decisions.

Table 1.

HEMOGLOBINOPATIES	FREQUENCY

COMPARISON OF GENE MUTATION SPECTRUM OF THALASSEMIA IN DIFFERENT PART OF CHINA AND SOUTHEAST ASIA

Y. Zhuo[1], C. Quexuan[2,*], Z. Wenzhe[2], Q. Ling[1], H. Bing[2]

[1]Clinical laboratory, [2]Hematology, Peking Union Medical Collage Hospital, Beijing, China

Background: Thalassemia is a common genetic disorder. High prevalence of thalassemia is found in South China, Southeast Asia, India, Middle East and Mediterranean. Thalassemia is usually thought to exist only in southern China, but more and more cases from northern China have been reported recently.
Aims: We compared gene spectrum of α and β-thalassemia in northern and southern China in our group, and compared our data with the largest meta-analysis in southern China, and data from Southeast Asian countries. The results may help to understand the similarities and differences of people from different area and different ethnic groups.
Methods: During 2012 to 2017, suspected thalassemia people were detected for common α and β-thalassemia mutations by gap-PCR and reverse dot blot (RDB) analysis in Peking Union Medical College hospital (PUMCH). 1059 people who carried thalassemia genes were analyzed retrospectively. We picked mutated individuals with northern identity card numbers and conducted telephone follow-up survey in order to collect their ancestral information. Besides, we used 'thalassemia', 'mutation', and Southeast Asian countries as keywords to search potential related studies in PubMed and EMbase.
Results: All carriers included in our study resided in northern China. Among them, 17.3% were native northerners and 82.7% were immigrants from southern China. Although significant difference was found between our data and data from the meta-analysis literature of southern China in both α and β-thalassemia, we also found some similarities between them. Similar gene mutation spectrum were found between Malaysia Chinese and Guangdong people, while other ethnic people in Southeast Asia had totally different gene spectrum from that of Chinese people.
Summary/Conclusion: Chinese People originated from north may have lower percentage of α-thalassemia mutations. Chinese people in different area had similar gene mutation profile and Chinese people had significantly different gene spectrum from other ethnic people in Southeast Asia.

EVALUATION OF CARDIAC IRON ACCUMULATION IN THE PATIENTS WITH BETA-THALASSEMIA MAJOR AND ITS CORRELATION WITH SERUM FERRITIN LEVEL:SINGLE-CENTRE RESULTS FROM TURKEY

S. Erdinc[1], M. Söker[2,*], A. Gözü Pirincciogluu[3], H. Uzel[2], K. Yılmaz[3], F. Karakoç[4], S. Söker[5]

[1]Pediatrics, Ergani Public Hospital, [2]Pediatric Hematology and Oncology, [3]Pediatrics, Dicle University Medical Faculty, [4]Pediatrics, Sbu Gazi Yasargil Research And Training Hospital, [5]histology And Embriology, Dicle University Medical Faculty, Diyarbakır, Turkey

Background: Cardiac complications due to iron accumulation in the patients with beta-thalassemia major (B-TM) are the main causes of death.
Aims: The study aims to demonstrate the relationship between cardiac T2* MRI and serum ferritin accumulation in children with B-TM.
Methods: The study involves 27 patients (11 females, 40.7% and 16 males, 59.3%). The ages of the patients range from 9 to 19 years (13.5±3). All of

the patients included in the study received the chelation treatment.
Results: The mean value of ferritin was 2794±2162 ng/ml (509-10795 ng/ml). The mean cardiac T2* MRI value was 28.2±9.9 ms (5.42-41.9 ms) while the mean liver T2* MRI value was 5.2±6.6 ms. The mean value of pre-transfusion hemoglobin was 8.8±0.7 g/dl. Statistical significance was found between the cardiac T2* value and age (p=0.019). Five patients with the cardiac iron accumulation had relatively higher ferritin levels but with no significant correlation.
Summary/Conclusion: In conclusion, it was seen that the cardiac iron accumulation in the patients with B-TM was age-related. Serum ferritin levels were not found to be useful enough to show cardiac iron accumulation.

PB2506

ZINC DEFECIENCY AND INSULIN RESISTANCE IN THALASSEMIA CHILDREN IN ISMAILIA, EGYPT

S. Sahmoud[1,*], S. El Sharkawy[2], A. Atef[2]

[1]Pediatric Hematology department, Suez Canal University, [2]Pediatric Department, Faculty of Medicine, Suez Canal University, Ismailia, Egypt

Background: In Egypt there are 10,000 registered thalassemia (thal) cases and more than 20,000 non-registered cases. In patients without thal the diabetogenic effects of altered zinc status had been observed while almost 9% of the Egyptian population at risk of zinc deficiency.
Aims: This study aimed at finding out the relationship between the zinc status and insulin resistance in thal children.
Methods: 40 thal children (21 males, 9.9 +/_3.9 years) and 40 healthy ones (20 males, 11.4 +/_ 3.1 years) where tested for serum zinc level, oral glucose tolerance test, fasting blood glucose and serum insulin with calculation of HOMA-IR.
Results: Mean zinc level wasn't significantly different between thal (74.63+/-19.37) and non thal children (81.03+/-15.44) (p=0.106), but zinc deficiency were more prevalent in thal children than the healthy ones with 32.5, and 15% respectively (p=0.023). Only insignificant percentage of the study (8%) and the control groups (2%) had impaired glucose tolerance test (p=0.087). Using HOMA-IR test 20 and 22.5% of thal children had intermediate and resistant levels compared to only 12.5 and 2.5% of non thal children (p=0.01). No significant correlation was found between the serum zinc level and HOMA- IR (r -0.023, p=0.86).
Summary/Conclusion: zinc deficiency and insulin resistance were more common in thal children, but zinc deficiency didn't significantly increase the risk of insulin resistance.

PB2507

THE USE OF RED BLOOD CELL INDICES FOR SCREENING B-THALASSEMIA

Y. Zhilenkova*

Clinical chemistry, The North-West State Medical University n. a. I. I. Mechnikov, Saint-Petersburg, Russian Federation

Background: Microcytic anemia is frequently due to iron deficiency anemia (IDA) or thalassemia. The differentiation between thalassemia and IDA has important clinical implications.
Aims: To study the possibility of using erythrocyte indices as laboratory markers for screening thalassemia.
Methods: The study included 48 patients with a beta-thalassemia minor (26 male and 22 female, 2 to 58 years old) and 50 patients with IDA with Hb>90 g/l (22 male and 28 female, 2 to 54 years). The Sysmex XN-2000 analyzer was used to determine: Hb, RBC, MCV, MCH, RDW,% Micro,% Hypo-He. The erythrocyte indices were calculated: E=MCV - (10xRBC), E&F=MCV - RBC - 5xHb - 3.4, G&K=MCV_2×RDW/100 × Hb; M=MCV/RBC; Si=MCV-RBC-3xHb; S=MCH/RBC; RDWDI=MCV × RDW/RBC; M-H =%MicroR -%Hypo-He; M-H-RDW =%MicroR -%Hypo-He - RDW-CV. The concentration of iron and serum ferritin was determined using a Cobas-6000 analyzer. Thalassemia was confirmed by determining hemoglobin fractions (HbA_2>3.2%) by capillary electrophoresis (Minicap, Sebia).
Results: The most sensitive were M-H-RDW (97.8%) and M-H (95.4%), G&K (90.1%) and Si (90.1%), specificity - M (97.5%), Si (97.5) and MH-RDW (96.5%). The best Youden index, which combines information on sensitivity and specificity, were in the indices M-H-RDW (94.3) and M-H (89.9).
Summary/Conclusion: The M-H-RDW and M-H indices, which are calculated using the new hematological parameters available on Sysmex analyzers, can be highly reliable for thalassemia screening.

GENETIC POLYMORPHISMS AS RISK FACTORS OF ENDOTHELIAL DYSFUNCTION IN PREGNANT WOMEN

N. Korsakova[1,*], S. Kapustin[1], N. Silina[1], O. Matvienko[1], O. Golovina[1], A. Nikolaeva[2], L. Papayan[1]

[1]Russian Research Institute of Hematology and Transfusiology, [2]Antenatal clinic 22, Saint-Petersburg, Russian Federation

Background: Normal vascular system function is of highest importance in pregnancy. Endothelial dysfunction (ED) is an early nonspecific vascular trouble mark, leading eventually to various pathologies including thrombotic disorders. At present, technology of noninvasive quantitative ED evaluation by means of EndoPAT device is developed, that gives the value of Reactive Hyperemia Index (RHI). Allelic polymorphisms of genes participating in vascular tone, lipid metabolism and thromboresistance regulation might influence ED development, predisposing progression of states involved in ED pathogenesis, *e.g.* arterial hypertension and dyslipidemia.
Aims: To evaluate genetic polymorphisms impact in ED development in pregnant women.
Methods: The study included 18 pregnant women with confirmed diagnosis of arterial hypertension, gestational or type II diabetes mellitus, and/or obesity. ED evaluation was performed with use of EndoPAT 2000 device, RHI value of ≤1,67 was considered as ED mark. Control group consisted of 200 healthy persons. Molecular genetic typing was performed by PCR for following genetic polymorphisms: angiotensinogen (AGT) T704C, angiotensin-converting enzyme (ACE) Ins/Del, angiotensin II receptor type 1 (ATGR1) A1166C, G-protein β3 subunit (GNB3) C825T, apolipoprotein E (ApoE) E2/E3/E4 and endothelial NO-sinthase (eNOS) T786C. STATISTICA 6.0 was used. Median (Me) and 95% confidence interval (CI) for RHI were calculated. Fisher exact test was used to assess the differences in genotype frequencies. Odds ratios (OR) and their 95% CI were calculated.
Results: The patients had the following RHI values: Me 1,4, 95% CI 1,1-1,8, that confirms ED presence. Genotype frequencies in pregnant women with ED are represented in Table 1.

Table 1. Genotype frequencies in pregnant women with ED.

	Pregnants with ED,% (n=18)	Controls,% (n=200)	OR; 95%CI		Pregnants with ED,% (n=18)	Controls,% (n=200)	OR; 95%CI
AGT 704 C/C	38,9	25,5	1,9; 0,7-5,1	**Apo E3/E4**	**38,9***	17,0	**3,1; 1,1-8,6**
AGT 704 T/C	33,3	46,0	0,6; 0,2-1,6	Apo E2/E4	5,6	1,0	5,8; 0,5-67,6
AGT 704 T/T	27,8	28,5	1,0; 0,3-2,8	Apo E3/E3	50,0	61,0	0,6; 0,2-1,7
ACE Del/Del	**50,0***	26,5	**2,8; 1,0-7,4**	Apo E2/E3	5,6	18,5	0,3; 0,03-2,0
ACE Ins/Del	27,8	48,5	0,4; 0,1-1,2	Apo E2/E2	0	0,5	0
ACE Ins/Ins	22,2	25,0	0,9; 0,3-2,7	Apo E4/E4	0	2,0	0
ATGR1 1166 C/C	5,6	7,0	0,8; 0,1-6,3	eNOS 786 C/C	11,1	13,0	0,8; 0,2-3,9
ATGR1 1166 A/C	38,9	37,0	1,1; 0,4-2,9	eNOS 786 T/C	27,8	47,0	0,4; 0,1-1,3
ATGR1 1166 A/A	55,6	56,0	1,0; 0,4-2,6	eNOS 786 T/T	61,1	40.0	2,4; 0,9-6,3
GNB3 82 5 T/T	11,1	11,0	1,0; 0,2-4,7				
GNB3 82 5 C/T	66,7	44,5	2,5; 0,9-6,9	* significant difference, p<0,05.			
GNB3 82 5 C/C	22,2	44,5	0,4; 0,1-1,1				

Summary/Conclusion: Pregnant women with ED had significantly higher ACE Del/Del and Apo E3/E4 genotypes frequencies, OR values indicate the direct correlation of these genotypes with ED development in pregnants. Unexpectedly homozygous and heterozygous eNOS 786 C allelle carriers as a tendency were found less frequently among pregnant women with ED, whereas eNOS 786 T/T genotype frequency had a tendency to be higher in pregnants with ED, showing invert correlation (not statistically significant) of eNOS 786 C allelle carriage with ED development in pregnancy.

PB2509

MULTI-ORGAN THROMBOSIS AS A MANIFESTATION OF IDIOPATHIC HYPEREOSINOPHILIC SYNDROME IN A CHILD – A CASE REPORT

S. Oberoi*, T. Brown, I. Vanan

Pediatric Hematology Oncology, Cancer Care Manitoba, Winnipeg, Canada

Background: Idiopathic hypereosinophilic syndrome (HES) is a disease characterized by an absolute eosinophil count (AEC) greater than 1500/mm^3 lasting for more than 6 months in the absence of any other known cause of eosinophilia and with the evidence of eosinophil mediated tissue damage. HES presenting as multi-organ thrombosis is rare in children.
Aims: To report a pediatric case with idiopathic HES who presented with pulmonary embolism and deep venous thrombosis of lower limbs.
Methods: A retrospective review of patient's electronic chart was conducted to retrieve clinical and laboratory data.
Results: A 14-year-old boy presented with shortness of breath, chest pain and swelling of the left leg to pediatric emergency. A Doppler ultrasound of lower limbs revealed thrombosis of the left femoral vein extending in to the left popliteal vein. A chest CT scan demonstrated segmental pulmonary embolism along with pleural effusion. He was started on Dalteparin and antibiotics. A complete blood count showed an AEC of 7770/mm^3 and a platelet count of 79,000/mm^3. The patient subsequently developed persistent fever along with worsening respiratory distress. His right lower limb became swollen and tender. A repeat Doppler ultrasound of lower limbs showed a new extensive occlusive clot of right femoral vein and popliteal vein. A worsening pleural effusion was noted on chest imaging. Marked eosinophilia was detected in pleural fluid (eosinophils-21%). His AEC was persistently elevated (Range: 6020/mm^3-8250/mm^3). A full diagnostic work up for infectious, immunological and rheumatolgical causes of eosinophilia came back negative. Bone marrow aspirate and biopsy were normocellular with marked non-dysplastic eosinophilia (23%). Bone marrow cytogenetics and flow cytometry were normal. BCR/ABL and JAK2 V617F mutations were negative by polymerase chain reaction (PCR). FIP1L1, CHIC2, PDGFRA and PDGFRB gene regions were normal by PCR. No evidence of B- or T-cell clonality was seen. He was started on methylprednisolone at a dose of 30mg/kg for 3 days with the working diagnosis of idiopathic HES. His clinical status improved significantly within 24 hours of starting steroids. Peripheral blood AEC normalized (AEC-60/mm3) within 3 days. Due to persistently sub-therapeutic anti-Xa levels, Dalteparin was changed to Apixaban. Oral prednisolone was started at dose of 2mg/kg/day following the pulse dose of methylprednisolone and was tapered based on his clinical status and AEC. Assessments done three months in to treatment showed resolving pulmonary emboli with normal pulmonary function and persistence of old thrombus in right and left leg with minimal collaterals. Clinically, he continues to do well on Apixaban and minimum doses of prednisolone.
Summary/Conclusion: Hypereosinophilic syndrome can present as multiple life-threatening thromboses in children. One should be aware of the thromboembolic complications of HES.

PB2510

DEEP VEIN THROMBOSIS IN THE INPATIENT : A TERTIARY CARE ANALYSIS FROM INDIA

C. Cherian Philip[1,*], S. Rathore[2], S. Singh[1], A. Mathew[1], A. Jindal[3], N. Kakkar[4], M.J. John[1]

[1]Clinical Haematology, [2]Radiodiagnosis, [3]Immunohematology and Blood Transfusion, [4]Laboratory Haematology, Christian Medical College & Hospital, Ludhiana, India

Background: Venous thromboembolism and DVT is recognized as the most common cause of inpatient death in the west and there exists established guidelines to direct its management. The incidence of Deep Vein Thrombosis however has been traditionally considered low in Asia. There exists no definitive scientific explanation to this and recent data challenge this concept. The limited data on the prevalence of deep vein thrombosis in India is both conflicting and scarce. This information is important to sensitize health care professionals and influence treatment strategies. In identifying with this goal we analysed the inpatient burden of DVT from our centre.
Aims: We attempted to estimate the prevalence of DVT among inpatients in our tertiary care centre.
Methods: We conducted a retrospective analysis of patients hospitalized between January 2014 through December 2016 to our academic hospital with 700 beds. Patients with potential venous thromboembolism were identified as those who underwent duplex ultrasound and CT Pulmonary angiogram (CTPA) examinations during that period. The diagnosis was confirmed by a review of the patients' inpatient records. Major bleed was defined as one requiring transfusions. Death and repeat thrombosis were defined as events.
Results: A total of 106074 patients were admitted in these period and184 examinations (duplex of the leg and CTPA) were done. Of these 26 patients were excluded (16- arterial thrombus and 10 – no details on type of thrombus) for this analysis. Characteristics of the included patients are detailed in table1. The prevalence of DVT was 158 of 106074 patients (0.15%). The median length of hospitalization was 10 (5-15) days. Four (2.6%) patients had a pulmonary embolism. While hospitalized and diagnosed with a DVT; 18 (11.4%) had undergone a major surgery; 25 (15.8%) patients were diagnosed with a malignancy; 16 (10.1%) were related to their central line and 11 (7%) patients were on pharmacological prophylaxis. A thrombosis workup was done in 10 (6.3%) patients and swelling of the leg was the major complaint in 91 (82.0%). The patients [55 (45.8%)] were mostly treated by a Vitamin K antagonist bridged with a LMWH.Seven (4.4%) patients required an IVC filter or embolectomy. There was one documented history of major bleed (Upper gastrointestinal bleed) and 20 deaths. The Overall (OS) and Event-free survival (EFS) at one year were 83.2%±3.9% and 74.1%±5.0% respectively.

Table 1.

Table 1. Characteristics of patients with DVT	
Variable	**N (158) n (%)/ Median (IQR)/Mean (±SD)**
Age	55(42-66)
Gender(Male)	95 (60.1)
Durations of admission (days)	10 (5-15)
Hb(g/dL)	10.7 (±2.6)
TLC (x 10^9/L)	10.0 (6.7 - 15.2)
Platelets (x 10^9/L)	228 (157 - 327)
Comorbidities (Hypertension)	39 (24.7)
Pregnancy (Yes)	5 (3.2)
Smoking (Yes)	5 (3.2)
Family History of Thrombosis (Yes)	4 (2.5)
Recent trauma (Yes)	7 (4.4)

Summary/Conclusion: Our analysis supports the belief that the prevalence of DVT in the Indian setting is low. An underlying malignancy is the most commonly identifiable cause of a DVT. Major bleed post treatment and primary prophylaxis are infrequent in inpatients. Racial differences and low levels of suspicion with resulting investigations might account for this variation in prevalence. Multicentric ,prospective data collection along with biological studies within India is needed to establish and explain this difference.

PB2511

PLASMA LEVELS OF SOME HEMOSTATIC MARKERS IN PATIENTS WITH ACUTE CORONARY SYNDROMES

Y. Tyravska[1,*], T. Vovk[2], N. Raksha[2], V. Lizogub[1]

[1]Internal medicine#4, Bogomolets National Medical University, [2]Department of Biochemistry, Educational and Scientific Center 'Institute of Biology and medicine', Taras Shevchenko National University of Kyiv, Kyiv, Ukraine

Background: Disturbances in the plasma levels of tissue plasminogen activator (t-PA) and its inhibitor (PAI-1) as well as in fibrinolysis have been implicated in the pathogenesis and development of ischemic heart disease, particularly acute coronary syndrome.
Aims: The main goal of the current study was to compare some hemostasis parameters of the patients with acute myocardial infarction and patients with unstable angina.
Methods: Blood plasma was taken from 35 healthy donors and 9 patients with acute myocardial infarction (AMI), 14 patients with new onset unstable angina (NOUA), 21 patients with progressive unstable angina (PUA). Plasma levels of tissue-type plasminogen activator (t-PA), plasminogen activator inhibitor-1 (PAI-1) and von Willebrand factor (vWF) were measured by enzyme-linked immunosorbent assays. Soluble fibrin monomer complex (SFMC) was determined using the phosphate method with 0.1 M phosphate-buffered saline containing sodium citrate and 0.2% 6-aminohexanoic acid with following determination (Zaichko N.V., 2006).
Results: Tissue-type plasminogen activator is an enzyme that converts the inactive proenzyme plasminogen to the active protease plasmin – the main executer of fibrinolysis. The obtained data showed that the plasma concentration of t-PA was in 1.43 times lower in the patients with AMI and NOUA than in the group of the healthy donors. The decreased of plasma level of t-PA may reduce fibrinolytic activity and attenuate removal of the thrombus and may ultimately lead to acute myocardial infarction in some patients with unstable angina. On the other hand, the t-PA level in patients of PAU group was at the control level. The catalytic activity of t-PA in the bloodstream is mainly regulated by the binding with some inhibitors. Therefore,

the plasma level of the primarily inhibitor PAI-1 was also estimated. There were significant elevations of PAI-1 in patients with AMI, NOUA and PUA. According to the obtained results the level of PAI-1 was in 16 times higher than the control value for 30% of patients with NOUA and for 70% of patients with PUA. For all the patients of AMI group PAI-1level was in 11 times higher than this in the group of the healthy donors. The elevated level of PAI-1 results in deficient plasminogen activation and is strongly associated with a predisposition to thrombosis. To estimate the thrombotic conditions and the degree of blood coagulation system activation SFMC concentration was determined. SFMC is formed in the early-activated state of blood coagulation and its appearance is expected to be a parameter for the diagnosis of thrombus formation. The conducted study revealed significant elevation of SFMC level in all patients of AMI group (in 10.6 times), NOUA group (in 12.6 times) and in 60% of the patients with PUA (in 11.5 times). Despite the well-known fact the involvement of endothelial dysfunction in the pathogenesis of cardiovascular disease no significant differences of the vWF's concentration in patients with AMI and NOUA have been detected. In contrast, about 60% of the patients with PUA have plasma level of vWF in 1.36 times higher comparing to the group of healthy donors.
Summary/Conclusion: The obtained findings suggest the strong impairment of the hemostasis balance in patients with acute coronary syndromes that appears as elevation of level of PAI-1, depletion of level of t-PA and accumulation of SFMC.

THROMBOLYTİC TREATMENT IN A CHILD WITH OF DIFFUSE VENOUS THROMBOSIS: BEHCET'S DISEASE

D. Seven Karaman[1], E. Zengin[2], B. Özoğlu[1], A. Tekin Yılmaz[3], N. Uyar[4], S. Aylan Gelen[2,*], A. Sakarya Güneş[5], K. Babaoğlu[6], A. Uncuoğlu[4], N. Sarper[2]

[1]Kocaeli University Medical School Pediatry, [2]Kocaeli University Medical School Pediatric Haematology, [3]Kocaeli University Medical School Pediatric Infection, [4]Kocaeli University Medical School Pediatric Gastroenterohepatology, [5]Kocaeli University Medical School Pediatric Neurology, [6]Kocaeli University Medical School Pediatric Cardiology, Kocaeli, Turkey

Background: Behçet's disease is characterized by recurrent oral aphthous ulcers, genital ulcers, and uveitis. Involvement of large vessels, central nervous system, and gastrointestinal tract, and thrombotic events are less frequent but can be life threatening.
Aims: Here we report the therapeutic process as a case report of an 12 years old male patient presenting with neurological symptoms and diffuse venous thrombosis with Behçet's disease..
Methods: A 12 years old male patient with three days of fever was referred to our center, because of hepatomegaly, pleural effusion and persistent fever. In history; 3 years ago he applied to a hospital with double vision, inward shift in both eyes and bilateral papillary edema. Pseudotumor cerebri was diagnosed. Cranial MRI was re-evaluated, right sinus venous thrombosis was detected, thrombophilia screening was normal. Anticoagulant treatment was used for 1 year. In last 5 years, painful aphthous lesions occurred 3-10 times a year and were healing in 3-5 days. There was no similar disease in the family history. In physical examination; he had fever and tachypne. The skin was pale, right lung baseline respiratory sounds were decreased, and there was 1/6 systolic murmur on mesocardiac region. Superficial veins on the abdomen were apparent, liver was 5 cm palpable. Ampicillin sulbactam and clarithromycin was started for pneumonia-parapneumonic effusion. Abdominal USG was found normal except hepatomegaly. On the 10th day, pleural effusion was reduced, the fever persisted, the liver continued to grow, and the anemia deepened. After the diagnosis of thrombus in right atrium and vena cava inferior, treatment was changed to ceftriaxone and gentamicin with the diagnosis of infective endocarditis and unfractionated heparin was started. Abdominal and thoracic CT angiography was performed in terms of thromboembolism. Bilateral pulmonary embolism, infarct in parenchyma, filling defect in right atrium was observed. Vena cava inferior, bilateral iliac veins, vena porta, vena hepatica were obliterated. Liver perfusion deterioration and gall bladder hydrops were observed.
Results: The tissue plasminogen activator (tPA) was started at a dose of 0.3 mg/kg/h in addition to heparin upon approval from his family. Due to nosebleed dose was reduced to 0.25 mg/kg/hour, when the nosebleed stopped the dose was increased to 0.3 mg/kg/hour again. At the end of 16th hour, Doppler USG revealed normal in the portal vein, hepatic vein and vena cava inferior. At the 19th hour of tPA therapy, the thrombus in the right atrium was narrowed, but the thrombus continued in the vena cava inferior. On the second day of tPA treatment, upper gastrointestinal tract bleeding was observed in the patient. Erythrocyte suspension transfused, antacid and proton pump inhibitor started. On the 46th hour of the therapy thrombus in both the right atrium and the vena cava inferior was dissolved and then tPA and unfractionated heparin was terminated. The abdominal tendency disappeared, the veins on the abdominal wall have become silky and the liver has become smaller. Enoxiparin 1 mg/kg/dose was started at 12 hours interval. Methylprednisolone and azathioprine initiated. Anticoagulant treatment was changed to Coumadin.
Summary/Conclusion: In pediatric patients, tPA is the agent for thrombolytic upon approval from the parents. There is minimal experience with thrombolytic therapy in children. A survey showed no consensus in indications for thrombolysis, dose, mode of delivery, or duration of therapy. Thrombolytic therapy in patients is life saving for life or limb threatening diffuse thrombosis.

PB2513

RESULTS OF USING IDARUCIZUMAB IN SIX PATIENTS

E. Morente Constantín[1,*], C. Ferrer Chaves[2], P. Romero Garcia[3], A. Biedma López[2], J. Berruga Oñate[2], M.A. Garcia Ruiz[1], M. Rivas Luque[1], M. Jurado Chacón[1]

[1]Servicio de Hematología y Hemoterapia, Hospital Universitario Virgen de las Nieves, Granada, [2]Servicio de Hematología y Hemoterapia, Hospital San Juan de la Cruz, Úbeda, [3]UCI, Hospital de Santa Barbara, Soria, Spain

Background: Patients who are receiving oral anticoagulant therapy may benefit from anticoagulant reversal if they present life-threatening bleeding or undergoing urgent intervention. Idarucizumab (Praxbind, Boehringer Ingelheim) is a specific reversal agent for dabigatran. It is a humanized monoclonal antibody fragment that binds dabigatran and it is indicated in adult patients when a rapid reversal of its anticoagulant effect is required.
Aims: This is a descriptive study to determine whether idarucizumab would be able to reverse the anticoagulant effect of dabigatran in patients who are about to undergo an urgent procedure.
Methods: The six clinical cases of patients treated with idarucizumab are described. **CASE 1**: A 70-year-old woman receiving Dabigatran 150mg/12h who comes to the emergency due to postoperative metrorrhagia. Due to the need of urgent surgery, idarazizumab was given. Hysterectomy with a double annexectomy was made. 20 days later, Dabigatran 150mg/12h was reintroduced without further complications. **CASE 2:** A 55-year-old male receiving anticoagulant Dabigatran 150mg/12h, who came to the emergency with complicated renal colic. It was decided to implant double J-catheter, for which we administered idarazizumab. Dabigatran was restarted in 24h at its usual dose, with no new complications thus far. **CASE 3:** A 77-year-old woman treated with Dabigatran 110mg/12h goes to the emergency room with urinary tract infection and rectal bleeding. She was treated with Idarucizumab. 1h after its administration, the diarrhoea continues without evidence of bleeding. 24h later, she died due to multi-organ failure but without evidence of bleeding. **CASE 4:** A 88-year-old woman treated with Dabigatran 110mg/12h goes to the emergency room with 24-hours rectal bleeding. Given the persistence of rectal bleeding 13h after admission, it was started reversal treatment with Idarucizumab. After 1 hour of administration, there is no evidence of bleeding and there is evidence of normalization of clotting times. **CASO 5:** A 86-year-old woman treated with Dabigatran 110mg/12h comes to the emergency room with 48-hours rectorragia. Given the situation of severity with active bleeding, in addition to establishing measures of hydration and transfusion, it was decided to start reversal treatment with Idarucizumab. Improving her general condition progressively, 16h after its administration, there was an increase in the coagulation times, recovered gradually. **CASE 6:** A 76-year-old male, treated with Dabigatran 150mg/12h comes to the emergency room with dizziness and melenic depositions of 3 days of evolution. Although rectal bleeding was not present at this time, it was decided to start reversal treatment with Idarucizumab 2h after admission. 3h later, there was no evidence of bleeding and the clotting times were normal. 12h later, there was an increase in coagulation times. Gastrointestinal endoscopy was performed with no evidence of blood remnants or apparent lesions.
Results: The use of idarucizumab permitted rapid and safe intervention of patients. They had normal hemostasis during the procedure. 5 g dose of idarucizumab was sufficient and reversal was maintained for 24 hours.
Summary/Conclusion: Idarucizumab is integrated into protocol for the emergency management of patients on dabigatran. Idarucizumab is effective for dabigatran reversal among patients who have uncontrolled bleeding or will be undergoing urgent surgery.

PB2514

MAY-THURNER SYNDROME AND RECURRENT DEEP VENOUS THROMBOSIS IN TWO PEDIATRIC CASE TREATED WITH DABIGATRAN ETEXILATE

M. Cetin, S. Aytac*

Pediatric Hematology, Hacettepe University, Ankara, Turkey

Background: May-Thurner Syndrome (MTS) also known as iliac vein compression syndrome is a predisposition factor for venous thromboembolism. It occurs as a result of compression of the left common iliac vein between the right common iliac artery and the vertebrae. As a result of venous congestion deep venous thrombosis develop in the left lower extremity. MTS is diagnosed in 2-5% of all patients being evaluated for chronic venous insufficiency of the lower extremity. It is reported that MTS was more common in women and the mean age at presentation is 42.6±16.9 years.
Aims: Here, we present two adolescent girl who was initially diagnosed as lower extremity DVT and received LMWH however their symptomps were progress under the treatment of LMWH, they both experience recurrence. Because of swelling and pain of the leg they were both re-evaluated and diagnosed as postthrombotic syndrome. However their symptomps did not resolve and PO dabigatran etexilate was given.
Methods: Two adolescent girl(15 and 16 years old) who were initially diagnosed as left lower extremity DVT with postphylebitic syndrome, treated with dabigatran etexilate and their distinctive symptomps eventually disappear with this treatment however MR angiography did show MTS. Althogh they both had a history of recurrence since PO dabigatran etexilate treatment they had neither recurrence nor aggravation of symptomps for 2 years.
Results: Several treatment modalities have been used to treat MTS mostly based on surgical and/or endovascular interventions in the past. More recently medical treatment approaches especially for patients with DVT were considered.
Summary/Conclusion: In conclusion leg swelling and pain in adolescent girls with left lower extremities DVT should be evaluated for MTS.

PB2515

EXPERIENCE IN REAL-LIFE ANTICOAGULANT TREATMENT WITH EDOXABAN IN PATIENTS WITH ATRIAL FIBRILLATION AND SECONDARY PREVENTION OF DEEP VEIN THROMBOSIS WITH A FOLLOW-UP OF LAST YEAR

M.A. Garcia Ruiz[1,*], M. Rivas Luque[1], P. Romero Garcia[2], E. Morente Constantín[1], P. Garrido Collado[1], M. Jurado Chacon[1]

[1]Servicio de Hematología y Hemoterapia, Hospital Universitario Virgen de las Nieves, Granada, [2]UCI, Hospital de Santa Barbara, Soria, Spain

Background: Atrial fibrillation (AF) is associated with the risk of ischemic stroke. Oral anticoagulation therapy is a well-established treatment for preventing strokes in patients with moderate to high risk. Non-vitamin K antagonist oral anticoagulants (NOACs) have been recommended as alternatives to Anti-Vitamin K (AVK) for stroke prevention in patients with non-valvular AF (NVAF) and Deep Vein Thrombosis (DVT). Edoxaban (Lixiana®, Daiichi-Sankyo) is an oral, reversible, direct factor Xa. The dose consists of 60mg/24h and 30mg/24h (reduced dose) for estimated creatinine clearance of 15-50mL/min, body weight <60 kg or concomitant use of P-glycoprotein inhibitors.
Aims: Primary Objective: To evaluate the efficacy of Edoxaban in the prevention of stroke and Embolism Systemic. Secondary objective: To assess the safety, in function of the major bleeding largest defined according to the criteria of the International Society of Thrombosis and Hemostasis.
Methods: This is a descriptive study. We have included a total of 211 patients with NVAF (199 patients) and DVT (12 patients). The mean CHA2DS2-VASc (risk of stroke) of patients studied was of 3.74 in the total population and 4.18 in reduced dosage population. The mean HAS-BLED (risk of bleeding) of the studied patients was 3.01 in the total population and 3.25 in the reduced dosage population. We have included 163 cases with doses of 60mg/24h and 48 cases at a dose of 30mg/24h (22,7% of total patients. It was about 109 women (51,66%) and 102 men (48,34%), aged between 42 and 95 years old (mean age 72.5). The main reason of suspension of AVK and replacement by Edoxaban was poor control of INR (199 patients) and diathesis bleeding (12 patients). Of the total number of included patients, 41 had presented a previous stroke under treatment with AVK. The treatment time has been between 3 and 13 months, with an average of 7.65 months of follow-up.
Results: It has not been reported any case of Stroke, Systemic Embolism, or Major during the follow-up time of the patients treated. Only one case of non-major clinically relevant bleeding (rectal bleed) which required changing to another NOAC. One case of small bruise in a patient treated with a 60 mg dose /24h which had a creatinine clearance of 44ml/min, so the dose was reduced to 30mg/24h. One patient presented self-limited hemoptysis that did not require suspension of the treatment. One patient with a subdural hematoma, after traumatic brain injury, which treatment was suspended. During the study, a patient was diagnosed with lung cancer and was discontinued anticoagulant treatment, and replaced by low molecular weight heparin. The patient died later by this pathology oncology. Three patients died due to respiratory disease (Influenza and respiratory insufficiency), not being related to the anticoagulant medication.
Summary/Conclusion: The results obtained confirm the efficacy and safety of Edoxaban in the prevention of stroke in the NVAF and DVT. This is a good sample of 211 patients and more than seven months of follow-up, despite the short period of time since the use approval of the drug in our country (18 months). The results support the results of the trials. We believe that there is a good alternative to oral anticoagulation in patients with NVAF with efficacy in the prevention of stroke and Systemic Embolism, and with a good safety profile with a clinical benefit net at the expense of mainly absence of bleeding. Subsequent studies will provide data confirmation.

PB2516

RITUXIMAB FOR REFRACTORY THROMBOTIC THROMBOCY TOPENIC PURPURA IN CRITICALLY ILL PATIENT

S. Mohamed[1,*], M. Yassin[1], A. El Buzidi[2], M. Abdelaty[2], A. Akkari[2], A. Nashwa[1]

[1]Hematology, [2]MICU, HGH, DOHA, Qatar

Background: Thrombotic thrombocytopenic purpura (TTP) is characterized by thrombocytopenia and microangiopathic hemolytic anemia (MAHA) without an obvious cause, and may include fever, mild renal failure, and neurologic deficits. Refractory TTP defined by some authors as any one of the following: 1-TTP for which treatment with plasma exchange (PEX) and glucocorticoids fails to produce a satisfactory response. 2-new neurologic abnormalities during PEX that are not attributable to another cause such as bleeding or infection. 3- Exacerbation of symptoms or laboratory findings occurs during PEX or within the first 30 days of stopping PEX.
Aims: To show outcome of two difficult cases of refractory TTP to daily PEX plus rituximab twice weekly.
Methods: The first case is a 32 years old male patient, known case of ulcerative colitis, the second case is a 26 years old male healthy before both, diagnosed him with of TTP based on clinical and laboratory findings and started on PEX and prednisolone.They were not responding initially and their hospital stay complicated with renal failure, ARDS and seizures so both patients intubated and admitted in intensive care unit. We added rituximab to the treatment, and as desperate measures we made rituximab twice weekly. After several weeks improve gradually. Both of them were extubated, and later sent to the medical word for further rehabilitation.
Results: The pathophysiology is lack of protease which cleavage von willbrand large multimeric. The protease called ADAMT- 13 and it could be absent congenitally or acquired. Severe deficiency of ADAMT-13 less than 5% specific for idiopathic TTP. The established management is plasma exchange (PE) along with steroids 80% of patients to survive, however, the result is still there are refractory and relapse cases. There is increase of usage of Rituximab as salvage therapy in cases of TTP. Mischelle *et al*., reported four cases and systemic review of literature. The found patient who received Rituximab in relapse or refractory, their median age is 42, most were females 78%, median doses 4, given once weekly and dose was 375mg/m^2. Complete remission achieved in 95% within 11- 35 days. According to our knowledge rituximab twice weekly agents was never used before. Our two patients were refectory to PE although it was going on daily for more than 2-3 weeks along with steroids.
Summary/Conclusion: TTP is a serious hematological malignancy with considerable amount of refractory cases. Rituximab addition to PE and steroids is good strategy. We suggest it can be used twice weekly safely, although further studies needed to proof efficacy Young patients and healthy deserves all extraordinary measures, which include not only rituximab but continue PE daily with giving up on patient.

PB2517

THE ELEVATION OF VON WILLEBRAND FACTOR (VWF) IN THE PATIENTS WITH MALIGNANT LYMPHOMA TREATED WITH RITUXIMAB (R)-CHOP THERAPY

N. Shimizu[1,*], R. Oka[1], S. Nakamura[1], Y. Watanabe[1], S. Tanaka[1], Y. Sato[1], H. Imamura[1], H. Kawana[1], T. Yamaguchi[1], M. Ohira[1], A. Saiki[1], H. Bujo[2], K. Shirai[3], I. Tatsuno[1]

[1]Center for Diabetes, Metabolism and Endocrinology, [2]Department of Clinical Laboratory Medicine, Toho University Sakura Medical Center, Sakura City, [3]Department of Internal Medicine, Mihama Hospital, Chiba, Japan

Background: An increased incidence of atherosclerosis has been noted in

cancer survivors. In past, there only were a few reports on the relation between atherosclerosis and chemotherapy. As a mechanism for the progression of atherosclerosis with chemotherapy, the reduction of nitric oxide from endothelial cells has been reported apart from complications of metabolic diseases. We have also reported a case who was 68-year-old female with follicular lymphoma, clinical stage IVA showing the plaque formation of carotid artery and the elevation of cardio-ankle vascular index (CAVI) after the eight courses of R-CHOP therapy (rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisolone) without complication of diabetes mellitus and hyperlipidemia.
Aims: So, herein we evaluate the risk for the development of atherosclerosis with chemotherapy using an arterial stiffness parameter, the CAVI, the findings of carotid artery ultrasonography and the value of von Willebrand factor (vWF) as an endothelial damage in the patients with malignant lymphoma who were treated with R-CHOP therapy.
Methods: We enrolled eight patients who were diagnosed B-cell malignant lymphoma and finished with treating with R-CHOP therapy from December of 2016 to August of 2017. We evaluated the atherosclerosis with CAVI index, carotid artery ultrasonography and the value of vWF during each consecutive chemotherapy. The Ethics Committee in Toho University approved this study, and we obtained informed consent.
Results: Seven men and one woman were registered (the median age, 72.5 years old). Every eight patients achieved complete remission after chemotherapy. Two patients were treated with 6th course, one patient with 7th course and the other patients were with 8th course of R-CHOP therapy. Two patients had not evaluated the vWF after final therapy, and we missed to check the value of vWF in some patients during the treatment, so evaluable number of patients were shown as in Figure. Almost all patients showed elevation of the vWF with the progression of treatment. The value of vWF of pretreatment (132.5±44.4) elevated significantly (p=0.0227) to 186±44.5 at just before second treatment. Comparing the value of vWF of pretreatment and another point, vWF elevated significantly as follows (just before 4th treatment;184.5±40.8, p=0.0117, just before 6th treatment;189.5±31.5, p=0.0117). After the treatment, the value decreased in all the patients, however there was not significant difference (p=0.0796). Six patients out of eight patients showed the progression of atherosclerosis, new plaque formation or progression of intima-media thickness by carotid artery ultrasonography. In evaluation of CAVI index, some patients showed the elevation of index with the progression of treatment. However, there was not significant elevation at all during the treatment.

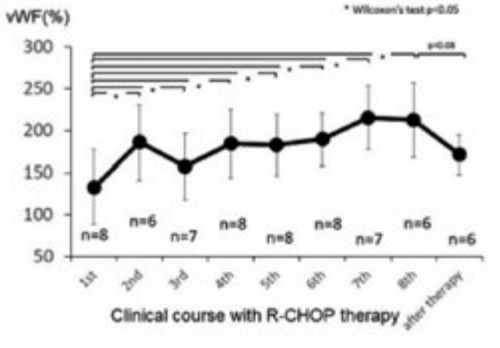

Figure 1.

Summary/Conclusion: We reported that malignant lymphoma patients showed the significant elevation of vWF during the R-CHOP therapy. We speculate that this therapy may be the risk of progression of atherosclerosis via vascular endothelial damage. Further study will be required to clarify the relationship between chemotherapy and arteriosclerosis.

PB2518

LEICINE-CONTAINING REGULATORY PEPTIDES PREVENT THE DEVELOPMENT OF TROMBOSIS

L. Lyapina*, M. Grigorjeva, T. Obergan

Moscow Lomonosov State University, Biological faculty, Moscow, Russian Federation

Background: It is known that glucine-containing peptides (glyprolines) have anticoagulant, antiplatelet and fibrindepolymerizing effects *in vitro* and *in vivo* in normal (Ashmarin *et al.*, 2008) and pathological conditions, complicated by thrombosis (metabolic disorders of fat and carbohydrate, including hyperholesterinemia, metabolic syndrome, diabetes mellitus).
Aims: To improve anticoagulation and create antithrombotic effects of glyprolines peptides by inclusion in their structure of leucine molecule from the N- or C-end in conditions of the depression of the function of the anticoagulation system in the development of metabplic syndrome, enhanced by the introduction of thromboplastin into the bloodstream.
Methods: The following methods were used in this study: registration of platelet aggregation, anticoagulant activity by test of activated partial thromboplastin time, total fibrinolytic activity (TFA), enzymatic fibrinolysis (EF), fibrindepolymerization activity (FDPA). The proline- and glycine-containing oligopeptides having a base Pro-Gly-Pro (PGP) with the addition of the amino acid leucine to N- and C- end of peptide molecule were used. All experiments were carried out on rats in accordance with the Helsinki Declaration about humane treatment of animals. The development of metabolic syndrome was modeled by keeping all animals on a high-calorie diet (HCD) for 2 months. Scheme of experiments: the experimental group of rats were intranasally administrated the peptides every 24 h for 5 days at a doses of 500μg/kg. At the same time the control group of rats were received 0.85% saline instead peptides. 18 h after the last administration of peptides rats intravenously injected 1% thromboplastin in the amount of 0.4 ml to generate thrombin in the bloodstream. Blood samples were taken 6-8 min after injection of thromboplastin.
Results: It was found that PGPL and LPGP inhibit the formation of fibrin clots in the provocation of venous thrombosis. When comparing the antithrombotic action of two peptides, it was found that the process of fibrin polymerization took place more slowly under the action of PGPL than LPGP in these conditions. The blood of animals was analyzed after the action of thromboplastin in the preliminary administration of oligopeptides PGPL and LPGP. The increase in TFA-1.7-1.6 times, EF-1.5-1.4 times, FDPA-1.9-2.7 times compared with control rats contained on the HCD and did not receive peptides were found in the blood. In these experimental conditions, in the case of the fibrin clots formation in the bloodstream, they are rapidly subjected to not only enzymatic (plasmin action), but also non-enzymatic (the action of the peptides themselves) lysis. We have shown that oligopeptides exhibit anticoagulant activity in the bloodstream. The action of PGPL is more pronounced (1.6 times increase), than anticoagulant plasma activity of LPGP (1.36 times increase). Both peptide provided in the blood antiplatelet effect (the most significant after LPGP administration). Thus, platelet aggregation decreased by 55% and 65% under the action of PGPL and LPGP respectively.
Summary/Conclusion: Thus, glyproline peptides with leucine included in their structure at both ends of the molecule activate or normalize the function of the blood anticoagulation system. They are involved in the prevention of venous thrombosis processes and contribute to the manifestation of thrombolytic effects of plasmin. They have antiplatelet effect, protecting the organism from the initial stages of thrombosis. Peptide LPGP has the most effective anticoagulant and antithrombotic action.

PB2519

ACTIVATION OF PLATELET HAEMOSTASIS AND ITS CORRECTION BY PROLINE-CONTAINING PEPTIDES IN METABOLIC DISORDERS

M. Grigorjeva*, L. Lyapina

Biology, Lomonosov Moscow State University, Moscow, Russian Federation

Background: Metabolic syndrome (MS) is characterized by dyslipidemia, hyperglycemia, insulin resistance. This pathology lead to the development of atherosclerotic changes in blood vessels and haemostasis disorders. The hyperactivity of platelets is the most important among the mechanisms involved in the processes of atherothrombosis. Also the development of MS lead to formation of large hyperactive platelets and increase of red blood cells hemolysis, which results an enhancement of the erythrocyte ADP release. This contributes to increased platelet aggregation, hypercoagulation and formation of prothrombogenic status of the organism. Directed influence of pharmacology agents may to reduce pathologically increased platelet aggregation. Earlier it was shown that regulatory oligopeptides exhibit anticoagulant and antiplatelet effects in the organism. Recently, special attention has been paid to proline-containing peptides with the addition of various amino acids to their molecules.
Aims: To study the increase of platelets aggregation function in rats with experimental metabolic syndrome and the possibility of its correction by short regulatory proline- and glycine-containing (glyproline) peptides Pro-Gly-Pro (PGP), Arg-Pro-Gly-Pro (RPGP), Pro-Gly-Pro-Leu (PGPL) and Pro-Gly-Pro-Val (PGPV).
Methods: The experiments were carried out on male adult (4 months of age) Wistar rats (350-400 g body weight). All experimental procedures were performed in accordance with the ethical principles of the Helsinki Decla-

ration. Experimental MS was induced by feeding the rats a fat-rich high-caloric diet (HCD) during 6 weeks. At the same time rats received 10% glucose ad libitum. Than MS-rats were intranasally administered peptides PGP, RPGP, PGPL and PGPV at doses 200μg/kg body weight once a day for 7 days (treated groups) and saline (control group) by simultaneous HCD continuation. ADP-induced platelet aggregation were measured in rich platelet blood plasma (Born method). Blood were collected from the jugular vena 20h and 7 days after the last peptides administration.
Results: Experiments showed that consumption of HCD by the rats over 6 weeks lead to development of lipid and carbohydrate metabolism disorders and marked hypercoagulation. First of all, platelet aggregation increased more than twofold relative to those of normal rats. The intranasal administration of PGP, RPGP, PGPL and PGPV to MS-rats resulted a reduction of ADP-induced platelet aggregation respectively by 33%, 34%, 30% and 58% compared with control group 20h after the last peptides injection. These effects were observed 7 days after peptides withdrawal too: ADP-induced platelet aggregation was decreased by 30%, 50%, 30% and 33% respectively. RPGP and PGPV had the most pronounced and stable antiplatelet effects in rats with experimental MS and these effects were long lasting.
Summary/Conclusion: Thus the presented study indicate that proline- and glycine-containing peptides have significant antithrombotis effects in rats with disorders of lipid and carbohydrate metabolism. They have antiplatelet effect and protect the organism from enhanced platelet aggregation, decrease activation of platelet haemostasis and thrombus formation. We assume that regulatory glyproline oligopeptides can be attributed to antithrombotic agents with anticoagulant and antiplatelet properties in metabolism disorders.

PB2520

EFFICIENCY OF PGPV PEPTIDE APPLICATION IN THE EVENT OF THROMBOSIS OF DANGEROUS SITUATIONS IN THE CONDITIONS OF METABOLIC SYNDROME IN RATS

T. Shubina*, L. Lyapina

Biology Department, Moscow Lomonosov State University, Biological faculty, Moscow, Russian Federation

Background: Disorders of lipid metabolism in metabolic syndrome leads to atherothrombosis, accompanied by an increase in blood clotting and a decrease in fibrinolysis. It is known that the amino acids proline, arginine, methionine, leucine and regulatory peptides Pro-Gly-Pro, Pro-Gly, Pro-Gly-Pro-Arg have hypocholesterol effect, thereby reducing the risk of developing the disease, and atherosclerosis. Endogenous tripeptide Pro-Gly-Pro has antithrombotic activity, but it is unstable in the body. Also, the essential amino acid valine is required for the growth and synthesis of body tissues. It is necessary for the normal exchange of nitrogen in the organism and is actively involved in the biosynthesis of cholesterol.
Aims: The aim of this work was to assess anticoagulant-fibrinolytic and antiplatelet effects of the peptide Pro-Gly-Pro-Val (PGPV) on the model of rats with experimental metabolic syndrome (MS).
Methods: White male rats (450-600 g) were used in the study. All experiments were conducted in accordance with ethical principles of the Helsinki Declaration. Inducing metabolic disorders caused a high-calorie diet (HCD), the energy value 130% of the standard diet and 32% fat caloric. The content of rats for 6 weeks on HCD led to the development obesity and increased blood glucose. After 1.5 months, rats were divided into groups (in each group n=10): Group 1-HCD rats treated with PGPV in dose 200 μg/kg body weight; Group 2 – untreated HCD rats were given 0.85% saline; Group 3 - healthy rats without treatment on standard feed. PGPV or saline were injected by intranasal way for 20 μl per rat once daily for 10 days. Blood samples were obtained 1 h after the last administration of drugs, after 7 and 14 days after discontinuation of the drug with continuing content on HCD (on 10^{th}, 17^{th} and 24^{th} days of experiments, respectively). ADP-induced platelet aggregation, total fibrinolytic activity (TFA), enzymatic (EFA) and non-enzymatic (NFA) fibrinolytic activity on plates of non-stabilized fibrin and anticoagulant activity (APTT test) were determined in blood plasma.
Results: It was found that the 10-fold intranasal treatment of rats with PGPV peptide led to a significant lengthening of the clot formation time by 2.2 times (by APTT test), an increase in TFA by 89% is due to the growth of EFA by 2.7 times and NFA by 1.6 times compared to the Group 2. Platelet aggregation in Group 1 was lower by 58% compared to HCD rats, but was higher than in healthy animals. 7 days after termination of treatment, the significant increase in anticoagulant and fibrinolytic properties of the plasma remained in the Group 1, compared with the values in the 2nd and 3rd Groups. Thus, the APTT increased 2.6 times, TFA – 2.3 times, EFA 2 times, NFA – 1.6 times. Attention is drawn to the fact of a sharp increase in APTT and TFA, *i.e.* the ability of the drug to provide anticoagulation effect in the long-term. 24 days after the cancellation of the PGPV anticoagulant and fibrinolytic blood activity in rats of the Group1 remained significantly higher than in the 2nd. Platelets aggregation in Group 1 corresponded to normal values and were lower than in the 2nd Group.
Summary/Conclusion: Clear evidence was obtained of the benefits of the introduction of PGPV intranasal rats with metabolic disorders as a therapeutic agent that contributes to the normalization of the hemostatic system and reduces thrombotic complications, namely, reducing the increased ability of platelets to aggregate and increase anticoagulant-fibrinolytic activity.

PB2521

CHANGE OF FIBRINOGEN LEVEL AND ACTIVITY OF FXIII UNDER THE INFLUENCE OF THE REGULATORY PEPTIDES PRO-GLY-PRO AND PRO-GLY-ARG

T. Obergan*, M. Grigorjeva

Department of Biology, M.V. Lomonosov Moscow State University, Moscow, Russian Federation

Background: Fibrin, which is the basis of the blood clot, is formed from fibrinogen plasma upon the activation by the enzyme thrombin. Stabilization of fibrin in the final stage of coagulation is provided by the factor of the blood coagulation system – transglutaminase, FXIII. Increased fibrinogen concentrations, as well as elevated FXIII activity in the blood, can create dangerous thrombosis situations in the human body. In earlier studies, it was shown that short regulatory peptides, containing proline and glycine (glyprolines) exhibit antithrombotic effects in the organism. In our studies on the model of Wessler thrombosis it was shown that repeated administration of peptides Pro-Gly and Pro-Gly-Pro led to a decrease in the weight of fresh fibrin clots and a decrease in the number of cases of thrombosis. Also, glyprolines have antiplatelet, anticoagulant and fibrinolytic activity *in vitro* and in vivo, impeding the thrombus formation and slowing blood clotting. However, these effects are short-lived due to the low stability of glyprolines. Adding to the peptide molecule of the amino acid arginine increases its resistance and antithrombotic properties. Herewith the influence of glyprolines on blood coagulation factors such as fibrinogen and fibrinase (FXIIIa) has not been studied enough.
Aims: The aim of this study was to evaluate the effect of the peptides Pro-Gly-Pro (PGP) and Pro-Gly-Arg (PGR) on activity of factor XIII, fibrinogen level and anticoagulant activity of blood and their ability to prevent thrombus formation in healthy organism.
Methods: Experiments were carried out on thirty healthy male rats of Wistar strain (200–220 g body weight) in accordance with ethical principles of the Helsinki Declaration. Three groups of animals were used (in each group n=10): untreated rats as control (Group 1), PGP-treated rats (Group 2) and PGR-treated rats (Group 3). Peptide-treated rats received PGP or PGR by intranasal way daily during 5 days in doses 1 mg/kg of the body weight in the amount of 20 μL per rat. Untreated rats (control) received 0.85% saline as vehicle in the same volume by intranasal way. Blood samples were obtained 1 h after 5^{rd} administration of drugs. Anticoagulant activity (by APTT test), activity of factor FXIII and levels of fibrinogen were estimated in blood plasma by standard methods using standard assay kits (Technology Standard, Russia).
Results: The multiple 5-fold intranasal administration of PGP led to a decrease in the activity of FXIII by 15% (P <0.05), and PGR – by 25% (P <0.01) compared to control. The use of both peptides caused a reduction in fibrinogen levels almost equally by 20% and 25%, respectively, compared to values in the control group (P <0.05 in both cases). This was accompanied by an increase of anticoagulant activity in the animal blood, since APTT raised by 21% (PGP) and 27% (PGR), respectively (P <0.01 in both cases). It is noted that the effects of the peptide PGR were more pronounced.
Summary/Conclusion: The study demonstrated the inhibitory effect of peptides PGP and PGR on blood coagulation factors due to reduce the level of fibrinogen and decrease of activity of FXIII. Thus, the peptides of the glyproline family, when they appear in the bloodstream, contribute to loosen the strength of fibrin clots in case of their emergence, reduce the prothrombotic potential of the blood and restrict the probability of thrombus formation.

PB2522

ANTITHROMBOTIC ACTIVITY OF PEPTIDE SELANK AGAINST THE BACKGROUND OF EXPERIMENTALLY INDUCED ENDOTHELIAL DYSFUNCTION IN RATS

E. Rogozinskaya*

M.V. Lomonosow Moscow State University, Moscow, Russian Federation

Background: Peptides of a glyproline series, including tripeptides PRO-GLY-PRO (PGP), are formed in the body during the hydrolysis of collagen and elastin. They carry out peptidergic regulation in the body. Multiple studies have shown that glyiprolines are effective and have antiplatelet and anticoagulant properties. Recent experimental data indicate an increase in the effects of glyiprolines when different amino acids are added to the protein structure. Thus, the amino acid arginine ARG (R) increases antithrombotic effects in the body due to the release into the bloodstream of NO.
Aims: Study an influence of arginine-containing peptide Selank on the parameters of the hemostasis system against the background of endothelial dysfunction.
Methods: Endothelial dysfunction was caused by repeated administration of a solution of NO-synthase inhibitor - L-name at a concentration of 10 mg/kg. As the drug, Selank peptide THR-LYS-PRO-ARG-PRO-GLY-PRO (TKPRPGP) was intranasal used at a concentration of 100 μg/kg. All animal experiments were conducted in accordance with ethical principles and documents of the European Convention for the Protection of Vertebrates. White Wistar rats (300 g) were divided into 4 groups: 3 test groups (rats receiving Selank; L-name; Selank + L-name); 1 group - control (NaCl). The substances were administered for 7 days daily every 24 hours. On the 8th day, blood was taken from the jugular vein and a series of experiments was conducted to determine the effect of drugs on the parameters of hemostasis. After the cancellation of Selank, but the continued introduction of L-name, after 7 days, a series of experiments were repeated. The studies were performed on the APTT test (activated partial thromboplastin time) and the parameters of thromboelastogram (TEG).
Results: It was found that the intranasal administration of Selank to rats showed the presence of anticoagulant and antiplatelet activity in blood plasma under conditions of endothelial dysfunction according to APTTV and TEG parameters. So Selank increased the APTT by 30% compared with that in rats with dysfunction of the endothelium, Selank + L-name returned this parameter to the control level. After the subsequent withdrawal of the drug against the background of L-name, a similar pattern was observed: Selank increased the APTT by 20%.
Summary/Conclusion: So, arginine-containing glyprolin Selank showed anticoagulant and antiplatelet activity, and in the presence of Selank there was no endothelial dysfunction caused by L-name. Under conditions of cancellation of the oligopeptide, but continuing dysfunction, its trace positive effects on the parameters of the hemostatic system were noted.

PB2523

A CASE-CONTROLLED STUDY OF VASOVAGAL REACTIONS IN BLOOD DONORS: INFLUENCE OF SEX, AGE, DONATION STATUS, WEIGHT, BLOOD PRESSURE, AND PULSE

T. Faiza[1,*], D. Djamel[2], N. Rachid[3]

[1]Hematology, central hospital of the army, [2]Medecine, blood transfusion station, [3]Epidemiology, Mayo Hospital, ALGER, Algeria

Background: Vasovagal reactions occur in a small, but significant number of blood donors. These reactions may decrease return donation and disrupt blood collection activities.
Aims: The purpose of this study was to define the contributory role of sex, age, weight, blood pressure in vasovagal reactions with syncope in blood donors.
Methods: Delayed adverse reactions to blood donation occur after the donor left donation site. Their intrinsic gravity and possible complications can be increased by the fact the donor is alone. on this study was to define the contributory role of sex, age, weight, blood pressure, and pulse in vasovagal reactions with syncope in blood donors. Case controls and random population controls were used in a logistic regression analysis to determine the significance of individual variables to syncopal reactions.
Results: Female donors (RR= 0.41IC (0.23-0.72, p=0.002), Young donors; <30 years: RR=1,45 IC (1.22-1.69) P=0.013 (s), first-time donors (p<.000), low-weight donors <75Kg: RR=1.22 IC (1.06-1.58, p=0.01), and donors with low predonation blood pressure (HR=0.36, p=0.001) had higher absolute donation reaction rates than other donors. as well as the amount of blood taken (fig.1): p=0.013(S)When each variable was adjusted for other variables by regression analysis, age, weight, and donation status (first-time or repeat donor), the most important variableis volume of blood (p=.000). Whenwe compare two periods: 2008-2012 then 2008-2017, we we have noted a net decrease of this type of complications over time, which suggests a better control of the sampling techniques and in particular of the measures of more rigorous selection of the donors (RR=0.45: IC (0.30-0.723), p=0.002.

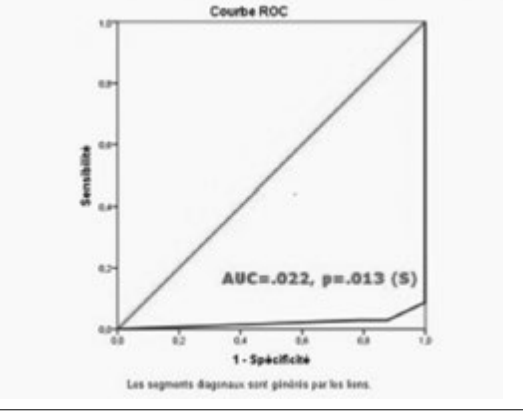

Figure 1.

Summary/Conclusion: Donation-related vasovagal syncopal reactions are a multifactorial process determined largely by age, weight, volume delayted and first-time donor status. Occurrence of a delayed donor reaction is clearly underrated in standard haemovigilance. It remains to be seen whether it have the same impact on donor return as immediate reactions. Considering that delayed reactions are much larger, it might be interesting to take them into account in the evaluation of strategies dedicated to lower immediate reactions.

PB2524

DEFERRAL FOR MALARIA RISK: AN INCREASING CONCERN ON BLOOD AVAILABILITY IN OMAN

K. Al Habsi*, A. Elkashif, S. Al Hashami, Z. Alarimi, T. Ashraf

Blood Banks Services, Ministry of Health, Muscat, Oman

Background: Malaria is an increasing concern to blood transfusion services

in non-endemic areas. Many blood donors travel to and from malaria endemic areas making it more difficult to ensure blood safety. Therefore, donor selection and deferral strategies are crucial to identify donors at risk of malaria exposure. Generally, these deferral strategies are not sensitive nor specific and can result in negative impact on the blood availability. Oman is a very low risk for malaria after an eradication program launched successfully in the 1990s. However, due to its location and historical connections with Asia and Africa many blood donors are deferred for malaria risk.
Aims: Our study aim to assess the impact of malaria deferrals on blood availability in Oman.
Methods: Records of all blood donors at the Central Blood Bank in Oman between November 2014 and October 2015 were reviewed. Archived donor forms, daily worksheets and the Information Technology "IT" system were used to collect rates of attending donors, total donations, total deferrals, positive serology and malaria-related deferrals. The percentage of donors deferred due to travel to malaria risk area, their country of origin, the areas of exposure and the duration of deferral were calculated.
Results: The total number of blood donors attended during the study period was 40285 donors. The total number of pre-donation deferrals was 12287 (30.5%) in addition to 2128 (5.3%) post-donation deferrals mainly due to reactive serology markers. The malaria risk related deferrals were 4578 donor (37.3% of total deferrals and 11.4% of total attending donors). Approximately 40% of those deferred for malaria risk were Omani nationals. The remaining 60% non-Omani deferrals were mainly Indians (79%) followed by donors from Pakistan (9%), Bangladesh (3.5%), Philippine (2%) and other nationalities. The common malaria endemic areas of exposure include India (60.1%) followed by Thailand (8%), Malaysia (7.6%), Pakistan (6.8%), Tanzania (4.1%) and several other Asian and African countries. The duration of deferral was ≥6 months in 67.1% (3074/4578) of deferred donors including 261 (5.7%) donors with permanent deferral due to previous history of malaria infection.
Summary/Conclusion: A significant number of blood donors in Oman are deferred because of travel to malaria-endemic areas. This negative impact on the blood availability requires a change in the current deferral strategy to ensure blood availability while maintaining the safety of blood products. Targeted malaria screening approach for blood donors at risk is required.

PB2525

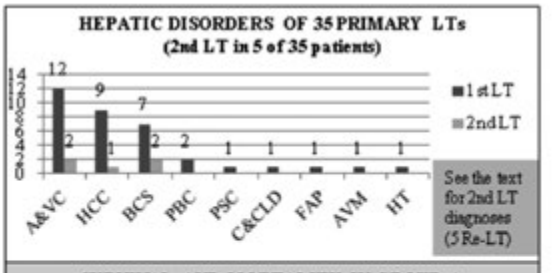
HEMATOLOGICAL DISORDERS AND LIVER TRANSPLANTATION DO PATIENTS HAVE A GOOD OUTCOME?

M.M. Campos[1,*], V. Oliveira[2], C. Gaspar[3], M.J. Marques[1], A.I. Fernandes[1], A.C. Silva[1], M.H. Alves [1]

[1]Dept of Immunohemotherapy (Head: D. Espírito Santo), Centro Hospitalar Lisboa Central, EPE (CHLC), Lisboa, [2]Dept of Transfusion Medicine, Hospital Prof. Doutor Fernando Fonseca, EPE, Amadora, [3]Dept of Clinical Hematology, Centro Hospitalar Lisboa Central, EPE (CHLC), Lisboa, Portugal

Background: In this survey we included patients with clinical indications for liver transplant (LT) and concomitant hematological disorders. End-stage liver diseases were alcoholic and viral cirrhoses (A&VC), hepatocellular carcinoma (HCC), Budd-Chiari syndrome (BCS), primary biliary cirrhosis (PBC), primary sclerosing cholangitis (PSC), cirrhosis and cholestatic liver disease (C&CLD), familial amyloid polyneuropathy (FAP), arteriovenous malformations (AVM), and hepatic toxicity (HT). Blood disorders were hemochromatosis, Osler-Weber-Rendu disease (OWRD), hemophilia B, myeloproliferative syndromes (MPS) including chronic myeloid leukemia (CML) submitted to bone marrow transplantation (BMT), polycythemia vera (PV) and essential thrombocythemia (ET), myelodysplastic syndrome (MDS), β-thalassemia minor, sickle cell disease (SCD), immune thrombocytopenic purpura (ITP), and acute myeloid leukemia subtype M2 (AML-M2) treated with BMT in childhood.
Aims: A series of 35 consecutive patients with hematological diseases submitted to LT was retrospectively analyzed (group A). In this set of patients, 35 primary transplants were done with grafts from different sources: cadaveric (32), related healthy living-donor (1), non-related healthy living-donor (1) and FAP carrier donor (1). A total of 5 re-transplants (all from cadaver) were performed. Main goals were to detect differences in transfusion supply comparing 127 patients with A&VC and/or HCC only (group B) with 21 hematological patients with the same liver diagnoses (group C) and their mortality rates. Consumptions and overall survival were also considered in group A.
Methods: A review of electronic clinical records was carried out in patients whose LT were comprised between 1 February 2010 and 31 January 2017 (one or more years following patient's last LT) in CHLC. Specific archives of the Department of Immunohemotherapy were assessed.
Results: The enrolled hematological patients (group A) were 21 males and 14 females (mean: 49.9; SD: 10.2 years-old). From group A and concerning A&VC and/or HCC, 18 males and 3 females (mean: 54.1; SD: 7.4 years-old) corresponded to group C which were compared to 109 males and 18 females (mean: 55.7; SD: 8.3 years-old) identified as group B during corresponding months of LT. In hematological patients, the distribution of hepatic disorders related to the 1st LT is displayed (figure 1). Diagnoses for the 2nd LT were arterial and venous thrombosis, graft fibrosing cholestatic hepatitis and acute graft failure. A&VC without HCC were clustered in one column and HCC (alone/associated with cirrhoses) in another column. Hematological diagnoses, survival and mortality are presented (figure 1). All-causes mortality rates were 25.2% and 19.0% in groups B and C respectively. Consumption medians in group B were 6 red blood cell units and 20 plasma units *versus* 3 and 14 units in group C and 4 and 18 units in group A, respectively. More products were also provided for bleeding control.

Table 1.



SURVIVAL AND MORTALITY IN GROUP A

HEMATOLOGICAL DISEASES (n = number of patients)	Patients (n)	Alive (n)	Deceased (n)
Hemochromatosis	15	11	4
MPS (PV: n=5; ET: n=3; CML: n=1)	9	4	5
OWRD (1 with ITP)	4	2	2
Hemophilia B	2	2	0
MDS	1	1	0
β-Thalassemia minor	2	1	1
SCD + β-Thalassemia minor	1	1	0
Resulted AML-M2	1	1	0
Total	35	23	12

Summary/Conclusion: Overall survival in group A corresponded to 65.7% and mortality rate reached 34.3% which was related to hepatic disorder in the majority of patients. The leading causes of death were hemorrhagic shock (all groups) followed by severe infection (group B); one case of CML relapse and another of sepsis occurred in group A. The hematological patients showed a lower blood transfusion support. MPS were associated with BCS in 7 patients. Severe diseases can be treated by a multidisciplinary management with net clinical benefits. Creating new synergies could improve outcomes of hematological patients needing LT.

PB2526

DARATUMUMAB AND BLOOD-COMPATIBILITY TESTING: EXPERIENCE IN OUR CENTER

E. Morente Constantin[1], P. Romero Garcia[2], M.P. Garrido Collado[1], A. Garcia Ruiz[1,*], E. Clavero Sanchez[1], M. Jurado Chacon[1], R. Rios Tamayo[1]

[1]Servicio de Hematología y Hemoterapia, Hospital Universitario Virgen de Las Nieves, Granada, [2]Complejo Hospitalario Soria, Soria, Spain

Background: Daratumumab is a monoclonal antibody (mAb) antiCD38, which is used in the treatment of patients with multiple myeloma. It binds to CD38, which multiple myeloma cells overexpress. Therefore, the plasma of these patients reacts with the red blood cells (RBCs) producing a panreactivity and interfering in the transfusion compatibility testing. Plasma of patients treated with daratumumab agglutinate in the Indirect Antiglobulin Test in all potentiating reagents that accelerates antibody coating on the red cells and this reaction may persist for up to 6 months after the treatment has ended.
Aims: To validate the procedure to resolve the interference of daratumumab in transfusion compatibility testing using red cells treated with Dithiothreitol (DTT), which will allow us to identify a clinically significant antibody that has been initially masked by the presence of daratumumab.
Methods: The study has been conducted in 8 patients diagnosed with multiple myeloma who have been treated with daratumumab in monotherapy. Irregular antibody screening tests and CrossMatching were performed on

all of them, being positive in the 6 cases with active treatment, and negative in the 2 in which more than six months have passed since its finalisation. We performed the technique to eliminate reactivity by treating the red cells used in compatibility tests with DTT, which negates the binding of daratumumab to CD38 on the RBC surface, but it also denatures Kell antigens, while preserving the E antigen. The material used was phosphate buffered saline (PBS) (pH 8.0), 0.2 M DTT, cells for Irregular antibody screening tests, K + and E + control cells, monospecific reagent AntiIgG and AntiIgG-C3d polyspecific. We performed the method in tubes, Biovue Column Agglutination Technology and Micro Typing System (Bio-Red).
Results: After performing the technique, we were able to eliminate panreactivity in both Irregular antibody screening tests and CrossMatching. Therefore, we consider it a very useful technique to resolve interferences produced by daratumumb with blood compatibility testing. After the treatment with DTT, Kell antigen disappears.
Summary/Conclusion: DARA causes pan reactivity *in vitro* by binding to CD38 on reagent RBCs. It is necessary to do a baseline antibody screen and Rh and Kell phenotyping (type and screen) before starting the treatment with daratumumab. Treating reagent RBCs with DTT is a useful method to mitigate the interference created by antiCD38 mAbs in pretransfusion testing, although it is not free from limitations that, in some cases, may compromise transfusion safety. Treatment with DTT leads to denaturation of the Kell protein, so that antiKell antibodies cannot be identified when the target red cells have been previously treated with DTT. It is not always possible to have RBCs of the same phenotype. We believe that it is essential to have a validated technique to resolve these discrepancies.

PB2527

SINGLE CENTRE EXPERIENCE OF THERAPEUTIC PLASMA EXCHANGE IN RENAL PATIENTS

R. Kohli[1,*], G.D. Young[2], S. Forbes[2], R. Rajakariar[2], R. Thuraisingham[2], P. MacCallum[3], L. Green[4]

[1]Haematology, Queen Mary, University of London, [2]Renal Medicine, Barts Health NHS Trust, [3]Haematology, Queen Mary, University of London; Barts Health NHS Trust, [4]Haematology, Barts Health NHS Trust; NHSBT; Queen Mary, University of London, London, United Kingdom

Background: Therapeutic plasma exchange (TPE) involves removal of plasma containing pathological circulating auto-antibodies and immune complexes from the patient and artificial replacement with a colloid solution (e.g albumin and/or plasma) or a combination with a crystalloid solution to maintain euvolaemia. Many renal disorders have an immune-mediated pathogenesis and the ability of TPE to rapidly lower serum immunoglobulins makes this treatment a first line option. The type of fluid used for performing TPE varies significantly between hospitals and clinicians due to the lack of robust evidence on optimal fluid type.
Aims: To understand TPE practice by reviewing the indications for TPE, fluid type used and number of exchange sessions and to determine if variabilities in type of fluid used in patients with similar renal conditions exist.
Methods: Four year retrospective single centre study of TPE practice between February 2014 and December 2017, at the renal unit at Barts Health NHS Trust.
Results: 134 patients underwent TPE between February 2014 and December 2017 (50% were male). The median age was 52 years (age range 19-89), and of the total, 89% received TPE for renal disease while the remainder had an underlying neurological diagnosis. The most common renal indications were vasculitis with pulmonary haemorrhage (13.4%), IgA nephropathy (7.6%), transplant rejection (6.7%) and HLA incompatibility (6.7%). The maximum number of TPE sessions received was 6 (sessions range 1-6). The majority of the patients, 53.7%, received human albumin solution (4.5% HAS) during their first session, while 29.9% received Octaplas (solvent detergent treated plasma) and 14.2% received a 50:50 mix of 4.5% HAS and Octaplas. Variability in fluid type used for patients with similar renal conditions was observed. 43.8% of patients with vasculitis and pulmonary haemorrhage received Octaplas in the first session, while 31% received 4.5% HAS and the remainder (25%) received a 50:50 mix of 4.5% HAS and Octaplas. 55.6% patients with IgA nephropathy received 4.5% HAS during their first session while 33.3% received Octaplas. In patients with HLA incompatibility, 62.5% received 4.5% HAS during session one and 37.5% received Octaplas. 50% of patients who required TPE for transplant rejection received Octaplas during the first session, 25% received 4.5% HAS and 12.5% received either a 50:50 mix or normal saline.
Summary/Conclusion: Although indications for TPE in our unit are similar to what is evidenced in literature, there is variability in type of fluid used per TPE session in patients with similar underlying renal pathology. Further prospective studies are therefore required to determine what optimal fluid type should be utilised

HAEMOGLOBIN AND SEVERITY OF ACUTE ISCHAEMIC STROKE: REVISITING TRANSFUSION THRESHOLDS

C. Cherian Philip[1,*], J. Pandian[2], H. Khatter[2], P.N. Sylaja[3], S. Kaul[4], D. Khurana[5], M.V. Padma[6], S. Singh[1], A. Jindal[7], M.J. John[1], D. Arora[2], A.B. Singhal[8]

[1]Clinical Haematology, [2]Neurology, Christian Medical College & Hospital, [3]Neurology, Sree Chitra Tirunal Institute of Medical Sciences and Technology, Ludhiana, [4]Neurology, Nizam's Institute of Medical Sciences, Hyderabad, Hyderabad, [5]Neurology, Postgraduate Institute of Medical Education and Research, Chandigarh, [6]Neurology, All India Institute of Medical Sciences, [7]Transfusion Medicine & Immunogenetics, Christian Medical College & Hospital, Ludhiana, India, [8]Neurology, Massachusetts General Hospital, Boston, United States

Background: There exists conflicting reports on the impact of hemoglobin in stroke. Physiological data suggest an adverse impact of anaemia on stroke. Also, it is noted that in Polycythemia; thrombotic events, in particular arterial thrombosis are increased and may contribute to a heightened mortality risk in patients with PV. Available guidance based on observational data suggests maintaining a hemoglobin level above 90g/L in patients with ischaemic stroke admitted to the ICU. However such recommendations are based on evaluation of specific patient populations and carry the potential risk to harm unexplored patient subsets if generalized. The best practice in patients with stroke is unclear and the impact of hemoglobin in stroke needs to be explored.
Aims: We attempted to determine the level of hemoglobin in patients with severe acute ischaemic stroke in our tertiary care centre.
Methods: We determined the impact of hemoglobin in a discovery case-control cohort in our hospital. We also performed a validation of the findings in an independent cohort of prospectively collected dataset of the Indo-US stroke registry and add to the evidence. The discovery cohort consisted of 570 patients with acute stroke who were admitted consecutively between January, 2012 to March, 2014 to our regional tertiary center in India, with a catchment population of ≈10, 00,000. The validation cohort consisted of patient enrolled into the prospective U.S. NIH and Indian Government funded Indo-US Stroke Registry and Infrastructure Development Project register; the methods of which have been detailed previously. Briefly, this registry enrolled consecutive adult patients admitted with imaging-confirmed ischemic stroke and at two weeks after symptom onset to five academic hospitals in geographically diverse centers across India. Data was entered into a central web-based electronic database. From January, 2012 to August, 2014, data was prospectively collected for 2066 patients.
Results: The patients in the discovery cohort were matched for gender, level of hemoglobin and proportion of anemics. In this cohort on a binary logistic regression analysis of stroke severity with hemoglobin quintiles in men we did not detect any significant relation. There was a trend noted with increasing severity of stroke with lower hemoglobin quintiles in women. We then explored this trend in the validation cohort. There was a significant association with increasing severity of stroke in both men (Hb <12) and women (Hb <12.7) based on the quintiles (Table 1).

Table 1.

Table 1: Binary logistic regression analysis of stroke severity with haemoglobin quintiles in entire validation cohort (n=2066)

Analysis of stroke severity with hemoglobin quintiles in males					
HB quintile	Coefficient	Odds ratio	p-value	95% C.I.	
				Lower	Upper
1	0.531	1.701	**0.007**	1.157	2.499
2	-0.113	0.893	0.583	0.596	1.338
3	-0.366	0.694	0.094	0.452	1.065
4	-	1.000	-	-	-
5	-0.186	0.830	0.387	0.545	1.265
Analysis of stroke severity with haemoglobin quintiles in females					
HB quintile	Coefficient	Odds ratio	p-value	95% C.I.	
				Lower	Upper
1	0.022	1.022	0.934	0.608	1.718
2	-0.748	0.473	**0.015**	0.259	0.865
3	-0.865	0.421	**0.004**	0.233	0.762
4	-	1.000	-	-	-
5	0.049	1.050	0.864	0.602	1.830

The cutoff points for the quintiles are as follows: male: 12, 13.3, 14.2, and 15.2 g/dL; female: 10.7, 11.7, 12.3, and 13.6 g/dL.

Summary/Conclusion: In our analysis there appears to be a trend towards increasing severity of stroke with lower levels of hemoglobin. This is more

significant in women. Current strategy of transfusion of red cells to maintain hemoglobin above 9g/dL in patients with acute ischaemic stroke might need to be revised to higher thresholds.

PB2529

PLATELET ALLOIMMUNIZATION IN MULTITRANSFUSED PATIENTS IN MOROCCO

Z. Ouabdelmoumene[1,*], L. Blouin[2], X. Lafarge[2], F. Zarati[3], H. Mifdal[3], N. Nourichafi[3], K. Bouisk[3], M. Benajiba[4], N. Habti[1,4]

[1]Laboratory of Hematology Cell and Genetic Engineering, Faculty of Medicine and Pharmacy Casablanca University Hassan II Morocco, Casablanca, Morocco, [2]Laboratoire d'histocompatibilité, EFS Aquitaine-Limousin, Bordeaux, France, Bordeaux, France, [3]Regional blood transfusion center of Casablanca Morocco, Casablanca, [4]National Blood Transfusion Centre of Rabat Morocco, Rabat, Morocco

Background: Platelet membrane carries a large number of glycoproteins, which express the platelet's specific antigens HPA (Human Platelet Antigen) on their surface. In transfusion, anti-HPA alloimmunization can lead to many serious complications, such as multi-platelet transfusion refractoriness. However, the implication of these antigens in platel*et al.*loimmunization was not studied before in Morocco.
Aims: The aim of this study is to determine the prevalence of the anti-HPA antibodies in serum of 90 multi-transfused patients in Morocco.
Methods: The serum of 90 multi-transfused patients who received leukocyte depleted red cells component, were included in this study, the detection of HPA antibodies was performed by a qualitative solid phase enzyme linked immunesorbent assay kit (PAKPLUS).
Results: A total of 6 out of 90 (6.66%) patients were found to be immunized to platelets. 1.1% patients were found to be alloimmunized to HPA-5a, 1.1% anti-GPIIb IIIa, 2.22% anti-GPIa IIa, and 2.22% anti- GPIa IIa.
Summary/Conclusion: Using a leukocyte depleted red cells component could reduce alloimmunization to platelets. To confirm these data, it's important to study the association between platelet antigens and their clinical consequences for the proper diagnosis and a better blood transfusion safety.

PB2530

PREVALENCE OF KELL, MNS, DUFFY, KIDD, P1PK, LEWIS, LUTHERAN BLOOD GROUP SYSTEMS IN THE POPULATION OF NORTH-EASTERN REGIONS OF RUSSIAN FEDERATION

E. Butina[1,*], E. Poponina[1], A. Yovdiy[1], N. Minaeva[2], I. Paramonov[3]

[1]Laboratory of Immunohaematology, [2]Haematology, [3]Director, Federal State Institute of Science "Kirov research Institute of Hematology and Blood Transfusion of the Federal Medical and Biological Agency of Russia", Kirov, Russian Federation

Background: A study of the frequency of phenotypes of red blood cell (RBC) in the inhabitants of the region is necessary for planning the preparation and storage of blood components, the organization of prevention of post-transfusion complications and hemolytic disease of the fetus and newborn.

Table 1. Prevalence of Kell, MNS, Duffy, Kidd, P1PK, Lewis, Lutheran Blood Group Systems in the population of north-eastern regions of Russian Federation.

Blood Group System	Phenotype	Prevalence (%)
Kell	K-k+	95.1
	K+k+	4.8
	K+k-	0.1
	Kp(a+b-)	0
	Kp(a+b+)	98.2
	Kp(a-b+)	1.8
MNS	M-N-	31.3
	M+N+	56.3
	M-N+	12.4
	S+s-	18.8
	S+s+	42.1
	S-s+	39.1
Duffy	Fy(a+b-)	18.8
	Fy(a-b+)	34.4
	Fy(a+b+)	46.8
	Fy(a-b-)	0
Kidd	Jk(a+b-)	19.0
	Jk(a-b+)	25.9
	Jk(a+b+)	55.1
	Jk(a-b-)	0
P1PK	P1+	63.0
	P1-	37.0
Lewis	Le(a+b-)	7.4
	Le(a-b+)	88.9
	Le(a-b-)	3.7
	Le(a+b+)	0
Lutheran	Lu(a+b-)	1.6
	Lu(a-b+)	82.3
	Lu(a+b+)	16.1
	Lu(a-b-)	0

Aims: Determine the distribution of the phenotypes of the Kell, MNS, Duffy, Kidd, P1PK, Lewis and Lutheran Blood Group systems in donors of blood components living in north-eastern regions of the Russian Federation.
Methods: Analysis of the results of typing of RBC antigens by gel agglutination assay (BioRad, USA) in 128 donors of blood components was carried out.
Results: Frequency of occurrence of phenotypes of red blood cells is presented in the table 1.
Summary/Conclusion: In the population of north-eastern regions of Russian Federation two times less often than in European countries, there are phenotypes K+k+, M-N+, Le(a+b-), more often - P1-.

PB2531

FREQUENCY OF HPA-15A AND HPA-15B HUMAN PLATELET ALLOANTIGENS IN MOROCCAN BLOOD DONORS

Z. Ouabdelmoumene[1,*], H. Elhousse[1], N. Nourichafi[2], K. Bouisk[2], M. Benajiba[3], N. Habti[1,3]

[1]Laboratory of Hematology Cell and Genetic Engineering, Faculty of Medicine and Pharmacy Casablanca University Hassan II Morocco, [2]Regional blood transfusion center of Casablanca Morocco, Casablanca, [3]National Blood Transfusion Centre of Rabat Morocco, Rabat, Morocco

Background: HPA (Human Platel *et al.* loantigens) are polymorphisms expressed on platelet membrane glycoproteins, several studies have shown the role of antibodies against human platelet antigen (HPA)-15 in platel*et al.*loimmunisation that may show clinical manifestations, such as neonatal alloimmune thrombocytopenia, post-transfusion purpura and platelet refractoriness. Typing of HPA-15a and HPA- 15b has not been carried on the Moroccan population. This is the first study of HPA-15 system in Morocco.
Aims: The aim of this study is to determine the genotypes and allele frequencies of HPA-15a and HPA-15b among Moroccan blood donors and to compare their allele frequencies with those reported in other populations
Methods: A total of 97 Moroccan blood donor samples randomly selected, were genotyped using the polymerase chain reaction with sequence-specific primers (PCR-SSP).
Results: The results showed that the most frequent genotypes were AA (43, 29%) followed by AB (29, 89%). Allele frequencies were 0,582 and 0.417 for HPA-15a and HPA-15b, respectively. Allele frequencies were similar to those found in North Africa (Algerian). However, the B allele was less frequent in HPA-15 systems when compared with Caucasians (French) and Arabs (Saudi).
Summary/Conclusion: Differences in the distribution of HPA-15 highlight the diversity in Moroccan population. Therefore it is advantageous to establish a compatible platelet concentrates, for patients who require multiple platelets transfusions and have a higher chance of becoming alloimmunised or refractory due to anti-HPA alloantibodies. This data obtained will form an addition to the literature in transfusion research.

PB2532

FREQUENCY OF ANEMIA IN LYMPHOPROLIFERATIVE DISORDERS PATIENTS DURING ANTITUMOR THERAPY

N. Romanenko[1,*], N. Potikhonova[1], A. Chechetkin[2], S. Voloshin[1], S. Bessmeltsev[1]

[1]Clinical Hematology, [2]Transfusiology, Russian research institute of hematology and transfusiology, Saint-Petersburg, Russian Federation

Background: The anemia in lymphoproliferative disorder's (LPD) patients is a frequent symptom and can decrease the efficacy of antitumor therapy (AT-therapy), overall survival and quality of life. Anemia's pathogenesis is based on suppression by proinflammatory cytokines and decreasing erythroid precursor's sensitivity to serum erythropoietin. More over AT-therapy can play significant role in increasing of frequency and severity of anemia - chemotherapy-induced anemia.
Aims: To definite of frequency of anemia in newly diagnosticated of LPD patients and evaluate the influence of antitumor therapy on frequency and severity of anemia.
Methods: We have examined the following patients in the age of 24-85 years: multiple myeloma (MM) in II and III st. (n=119), Non-Hodgkin's lymphoma (NHL) in III-IV st. (n=72) and chronic lymphocytic leukemia (CLL) in B or C st. (n=147). Clinical blood test (hemogram) was examined more then twice before AT-therapy and during 1-3 cycles of therapy. All patients were administrated different therapy: patients with multiple myeloma – VD, V P, VMP, PAD; patients with Non-Hodgkin's lymphoma – RB, VRB, R-FC, R-CHOP, R-CVP; patients with chronic lymphocytic leukemia – RB, FC-R, R-CHOP, R-Chlorambucil.
Results: We have accessed the rate of anemia in the group of patients with

MM (n=119) was 56.3% (n=67) but after AT-therapy it significantly increased to 79.0% (n=94; p<0.01); in the group of NHL (n=72) the rate of anemia increased from 38.9% (n=28) to 65.3% (n=47; p<0.01); in the group of CLL (n=147) the rate of anemia increased from 33.3% (n=49) to 68.7% (n=101; p<0.01). Besides the grade of anemia (by WHO hematological toxicity scale) also increased. So, the number of patients with anemia (grade 1) increased from 17.5% (n=59) to 27.2% (n=92; p<0.01); the number of patients with anemia (grade 2) increased from 13.6% (n=46) to 24.9% (n=84; p<0.01); the number of patients with anemia (grade 3) increased from 7.1% (n=24) to 11.8% (n=40; p<0.05); the number of patients with anemia (grade 4) increased from 4.4% (n=15) to 7.7% (n=26; p<0.05). Too impotent to emphasize that 20.4% (n=69) of patients were administrated 1-6 dosages of red blood cells transfusions.
Summary/Conclusion: In this study were revealed the high rate of chemotherapy-induced anemia in newly diagnosed LPD patients and increasing of it during the AT-therapy that might to need administration of RBC transfusions.

PB2533

IS THERE A CHANGE IN SEROLOGICAL STATUS IN BLOOD DONORS AT THE BOUFARIK BLOOD TRANSFUSION BANK DURING THE LAST TEN YEARS?

T. Faiza[1,*], D. djamel[2], N. Rachid[3], D. Khadidja[1]

[1]Hematology, Central Hospital of the Army, [2]Medecine, blood transfusion station, [3]Epidemiology, Mayo Hospital, ALGER, Algeria

Background: Screening for infectious agents is a vital step in the process of biological qualification of blood donations in virology, preventing the transmission of viral diseases following a blood transfusion or its derivatives.
Aims: The purpose of this study is to determine the seroprevalence of infectious markers in a descriptive, retrospective and monocentric study performed at the Boufarik PTS over a 10-year period (2008-2017).
Methods: This cohort onclude 10,300 donations of blood. Donors received an interview and clinical examination before being selected for a donation. Screening for HIV, HVB and C was performed by enzyme immunoassay based on the Elisa principle and indirect haemagglutination for syphilis.
Results: The prevalence of HIV, HBS, HCV and syphilis serological markers is 0%, 24%, 0.67 and 23%, respectively. By taking two comparative periods: 2008-2012 (n=4139 donations) and 2013-2017 (n=6161 donations): there is an increase in the number of positive cases for the hepatitis B virus: n=07 (2008- 2012) *versus* n=18 (2013-2017): RR=.69 (.37-1.30), p=.13 (NS) fig.1. An increase in the number of positive cases for hepatitis C virus: n=02 (2008-2012) *vs* n=05 (20132017): RR=.89 (.21-3.73), p=.45 (NS) fig.2. A stable number of positive cases for the syphilis virus: n=12 (2008-2012) *versus* n=12 (2013-2017): RR=1.49 (.663.31), p=.16 (NS) fig.3.
Summary/Conclusion: These results show that the prevalence of viral infections is stable over time among blood donors in our region. This is due to the introduction of a quality assurance system, the choice of the collection site, the selection of donors and finally the improvement of the quality of screening, which has helped to ensure optimal blood safety.

PB2534

THE SAFETY AND EFFICACY OF THE LEAST INCOMPATIBLE CROSS-MATCH TRANSFUSION USING *IN VIVO* COMPATIBILITY TESTS

S. Maral[1,*], I. Dilek[2], S.M. Bakanay[2], A. Yıkılmaz[2], S. Akıncı[2]

[1]Hematology, Dıskapı Research and Training Hospital, [2]Hematology, Ataturk Research and Training Hospital, Ankara, Turkey

Background: Pre-transfusion compatibility testing is performed to provide appropriate blood components. Compatibility testing certainly includes the determination of ABO and Rh types, antibody screening of the patient's plasma for any unexpected anti-RBC antibodies and a crossmatching test using the patient's plasma and the donor RBCs to determine if they are compatible.If no compatible cross-matched blood can be found, clinicians may avoid transfusion and consultation by the hematology department is generally required. The majority of clinicians usually choose to transfuse group O, Rh(D)-negative.Another option is to separate the most compatible or the least incompatible blood and start the transfusion with this. Nevertheless, it is not clear how safe the least incompatible transfusion is, and whether it provides the targeted hemoglobin increments. It has also not been fully clarified whether acute hemolytic transfusion reactions can be ignored.
Aims: The aim of this study was to determine the safety and efficacy of the least incompatible cross-matched blood transfusion, through the use of biological *in vivo* cross-match testing.
Methods: The study included 18 patients with incompatible cross-matching who were transfused RBC.A total of 55 units of RBC were transfused.Red blood cell concentrates were included in saline-adenine-glucose-mannitol (SAG-M). None of the patients had any premedication such as steroids or antihistamines before transfusion. From the selected incompatible unit, 20 ml blood was collected in a 20 cc syringe(Hayat®) and infused intravenously to the patient in 10 minutes via the antecubital vein. Patients were observed for any signs of acute hemolysis for 20 minutes before the initiation of the transfusion of the residual blood. The transfusions were started from another vascular access and were completed in 2 hours. Each transfusion was observed by medical professionals to identify any evidence of acute hemolysis. Possible acute transfusion reactions were listed on a form (Figure 1: patient transfusion form) including dyspnea, headache, hypotension, back pain, fever, tachycardia, and chills, and these were recorded together with the time of occurrence by the observer.If any symptoms indicating hemolysis were observed, the transfusion was stopped and another selected unit of blood was used. Pre- and post-transfusion hemoglobin and hematocrit levels were compared to determine the increase as a result of the transfusion. Biochemical markers indicating hemolysis, such as lactate dehydrogenase and total-indirect bilirubin levels were recorded to evaluate the hemolytic state. The laboratory test results were reported within 24 hours of the transfusion.
Results: A No complications or signs were observed in any of the 55 transfusions and all the transfusions were completed succesfully.An appropriate increase in hematocrit and hemoglobin was seen post-transfusion (p:0.001). As indicators of hemolysis, lactate dehydrogenase (LDH) and bilurubin levels were determined to have significantly increased post transfusion (p:0.035, p:0.001).
Summary/Conclusion: Acute hemolytic transfusion reactions are a serious situation which can result in mortality. When pre-transfusion tests result in ABO compatibilty and are cross-match incompatible, clinicians should not avoid transfusion if it is urgently required. The biological *in vivo* compatibility test seems to be a procedure which is safe, predictive, and can be feasibly applied at the bedside, and could be life-saving for many patients.

PB2535

ANALYSIS OF RED CELL AND PLATELET TRANSFUSION IN A TERCIARY HOSPITAL. A RETROSPECTIVE CASE STUDY

R.M. Rodriguez Nuñez*, C. Fonte Feal, A. Nieto Vázquez, C. Insua Vilas, P.M. García Cereijo, M.D.C. Albo López

Hematology, Hospital Alvaro Cunqueiro, Vigo, Spain

Background: Blood transfusion is an essential treatment, sometimes the only valid one, but it always involves certain risks. Physicians should weigh in the benefits and hazards of this treatment and follow the recommendations. Most studies demonstrate that in recent years, red cell transfusion has decreased, meanwhile platelet transfusion remains practically the same. This is because of the application of smarter blood transfusion protocols.
Aims: Make a retrospective study of red cell and platelet transfusion in our hospital. We analyzed hemoglobin levels and number of platelets before and after transfusion; we also analyzed the type of surgery, medical disorder and mortality, among other variables.
Methods: We collected data of red cell and platelet transfusion at Vigo hospital, from January to June 2016. We did a descriptive analysis, presenting qualitative variables as absolute frequency and percentage, and quantitative variables as mean and standard deviation. We used Chi square test to compare qualitative variables between types of surgery and also between the various medical disorders. We used one factor ANOVA to compare quantitative variables. Data were analyzed with IBM SPSS statistics 19.0. The accepted level of statistical significance was 0.05.
Results: We transfused 7787 blood products to 1575 patients; 6175 packed red cells and 1612 platelets. 51.4% of patients were male. Mean age was 69+/-19,6. Most of red cell transfusions were to patients with medical disorders, and among them, to patients with hematological ones. In patients with non hematological medical disorders, most of transfusions were to those with GI bleeding, followed by solid organ cancer. On the other hand, most platelet transfusions were to patients with solid organ malignancies, follow by patients with non hematological anemia (Graphics 1). Patients with hematological disorders which received the most red cell transfusions were, in order: MDS, NHL, acute myeloid leukemia and allogenic stem cell transplantation. Regarding platelet transfusions, the order is the following: acute myeloid leukemia, allogenic stem transplantation, NHL and autologous stem cell transplantation. Among surgical patients, the ones which received most of red cell transfusions were trauma patients, follow by cardiac and abdominal surgeries; platelet transfusions were received mostly by patients undergoing cardiac surgery, follow by vascular surgery. Other variables, such as anticoagulation or infection, didn't have clinical significance over transfusion.

Most deaths occurred in the group of patients with medical conditions (71,2%), and among those, the ones with solid organ malignancies, follow by non hematological anemias and GI bleeding. Regarding these results we could identified inadequate transfusion behaviors.

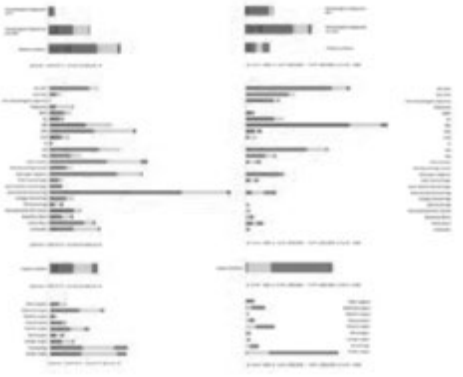

Figure 1.

Summary/Conclusion: In our hospital, we concluded that patients who received the most transfusions were those with medical conditions, and among them, the ones with hematological disorders. These results are similar to those published in other studies. Nevertheless, platelet transfusions were received in large numbers by patients with a number above 50.000, which is not what guidelines recommend. On the other hand, red cell transfusion, in our hospital, is closer to the recommendations, even if we have a liberal transfusion policy. These findings led us to apply some corrective actions in our hospital.

PB2536

HAEMOVIGILANCE REPORTS OF ADVERSE BLOOD DONOR REACTION AMONG VOLUNTARY BLOOD DONORS IN TERTIARY CARE HOSPITAL IN KATHMANDU, NEPAL

B. Nepal*

Blood Bank, Grande International Hospital, Kathmandu, Nepal

Background: Voluntary blood donation is widely considered to be safe with very minimum chance of adverse reaction, which may occur during or after the end of phlebotomy procedure.
Aims: To identify and understand the complication of adverse donor reactions though the incidence of reactions in the blood donors.
Methods: This is a prospective study done among voluntary blood donors at Grande International Hospital, Kathmandu, Nepal from February 2013 to March 2015. The outlines of reported and communicated adverse donor reaction were also collected after the blood donation from voluntary blood donors in different locations including outdoor and in-house blood donation drive.
Results: In the present study 6,955 whole blood donors were included, during the period of 2 years, 105 (1.50%) adverse donor reactions were reported. Majority 89(84.76%) of adverse donor reactions were mild in nature such as, sweating; 27(25.72%), Light headedness; 19(18.09%), nausea and vomiting; 15(14.28), allergy and bruises;11(10.47%), sore arm; 9(8.58%) and hematoma; 8(7.62%) while 16 (15.24%) were severe adverse reactions similarly, anaphylaxis;11(10.49%), loss of consciousness; 3(2.85%) and convulsive syncope;2(1.90%). Markers of the adverse donor reaction were age, sex, pulse, weight, blood pressure and donation status. Age and first time status were related with significantly higher risk of adverse reaction with 18-23 years old at higher risk compared to 24-55 years old. First time donors were at higher risk compared to repeated volunteer donors.
Summary/Conclusion: The results of the study are helpful to identify and understand the complication of adverse donor reactions though the incidence of reactions in the blood donors is lower than in other studies. Donor age and donation status were strong possibilities of complications.

PB2537

SAFE OF PLASMA EXCHANGE IN ACUTE RENAL FAILURE SECONDARY TO VASCULITIS

I.M. Parra Salinas[1,*], L. Arnaudas Casanova[2], A. Blasco Forcén[3], V.P. González Rodríguez[1], J.A. García-Erce[4]

[1]Hematology, Miguel Servet University Hospital, Zaragoza, [2]Nephrology, Reina Sofia Hospital, Tudela, [3]Nephrology, Miguel Servet University Hospital, Zaragoza, [4]Hematology, Navarra blood bank, Pamplona, Spain

Background: The benefit of Plasma Exchange (PE) in acute kidney injury secondary to vasculitis has been demonstrated both in the acute phase of these diseases, but also has been proved to decrease the dialysis-dependent rate at the first year.
Aims: The aim of this article is to evaluate the safe of PE in renal vasculitis, and secondarily the response (dialysis independence) at 30 days.
Methods: Unicentre descriptive and longitudinal study, with a prospective database of all patients with acute renal failure secondary to vasculitis treated with PE. severity of renal injury was classified according to AKIN (Acute Kidney Injury Network) scale and RIFLE (Risk, Injury, Failure, Loss y End Stage Kidney Disease risk, Injury) criteria.
Results: We analysed 13 cases, 7 women. The median age was 67.7 years, 30-day response rate were 38.5% and 92.3% had a high Charlson comorbidity index (>4). All patients needed dyalisis but only in 4 were performed before the onset of PE. Other clinical characteristics are exposed at table 1. Serum creatinine levels below 5.8 mg/dL were related with great responses (*p=0.032*). There were observed decreases of serum creatinine levels (*p=0.005*), glomerular filtrate (*p=0.003*) and random urine sample proteinuria (*p=0.045).* The devices used for PE were continous-flow cell separators. The standard replacement solution is 5% human albumin. To avoid hypocalcemia symptoms, intravenous calcium gluconate is administered as prophylaxis at the beginning of each session and is repeated if symptoms appear. In accordance with the local protocol to prevent dilutional coagulopathy, all patients receive intravenous vitamin K at the end of the procedure. A median of 6 (4-17) sessions were performed per patient and were initiated 10 (0-28) days after diagnosis. Out of the 96 sessions carried out, one (1.04%) presented a low access pressure and 4 (4.1%) clinical complications (itching in 3 and fever in 1), corresponding to two patients (table 2). None of them were serious and only one had to be suspended due to fever. Patients who experience more complications (clinical and technical) had a high number of leukocytes prior to PRT (*p=0.04*) and had undergone a higher number of sessions (*p=0.010*) as showed in table 2.

Table 1.

Summary/Conclusion: Global frequency of complications in our series was lower than published in the literature, it leads us to conclude that PRT is a safe therapeutic strategy in our centre and encourages us to postulate that our prophylactic measures. The finding of increased initial white blood cell count in patients with complications, might be investigated in studies with higher casuistry.

PB2538

FREQUENCY OF REACTIVE BLOOD DONORS IN A TERTIARY CARE HOSPITAL, KARACHI, PAKISTAN

B. Nepal*

Blood Bank, Grande International Hospital, Kathmandu, Nepal

Background: In recent years, number of patients infected with HBV or HCV or HIV or co-infected with either of the two viruses, has increased tremendously in Karachi population. IDUs (intravenous drug users), MSM (Men who have Sex with Men) and individuals having unsafe sex are among the

people who are identified as groups at higher risk of contracting these infections than others. But these studies does not give an exact picture of prevalence and frequency of these infection in Karachi's population as focus of most of these studies were individuals already involved in behaviours (intravenous drug use and unsafe sex) regarded as high risk behaviours.
Aims: To find the frequency of different types of reactive healthy blood donors at a tertiary care hospital, Karachi, Pakistan.
Methods: The retrospective observational study carried out on both male and female healthy blood donors. Data from complete blood screening from January 2013 to December 2014 were collected and frequency of various types of reactive blood donors was sorted out to get an actual picture. All the blood products were screened for HBV and HIV Using enzyme linked immunosorbent assay (Elisa plate washer version 3 and Elisa plate reader stat fax 3200). HCV screening was performed on Architect 2000 SR Chemiluminescent micro plate immune assay (CMIA). Malarial parasite tested by making thick and thin smear seen under microscope. Syphilis was tested by ICT method.
Results: A total number of 6996 healthy donors were received and about 624 were found to have blood screening positive in various combination. The highest numbers of isolates was HbsAg reactive 214, HCV 213, VDRL 170, HIV 26 and 1 case of malarial parasite. More prevalent in male population. In this study there were seven donors found with HCV –VDRL co infection and five co-infected with HCV and HbsAg two donors with HIV and HbsAg infected and two donors were HbsAg and VDRL reactive.
Summary/Conclusion: This study supports that HBV, HIV and syphilis prevalence is high and HIV prevalence is low in healthy blood donors.

PB2539

FIVE YEARS OF HEMOVIGILANCE REPORTS OF COMPLICATIONS OF THE BLOOD DONATION REPORTED AT A TERTIARY CARE CENTRE IN KARACHI

B. Nepal*

Blood Bank, Grande International Hospital, Kathmandu, Nepal

Background: There is a minor chance of risk among blood donors. Even though blood donors are usually screened for the presence of risk factors, sometimes blood donations can put a person at panic.
Aims: The safety of the blood supply depends on the actions to protect both; blood transfusion recipient and the blood donor. Hemovigilance practice of learning of complications of blood donation and protecting them from such complications is the best way to minimize the risk to blood donor.
Methods: Comprehensive blood donor hemovigilance program was studied at Dr. Ishratul Ebad Khan Institute of blood diseases, Karachi from 2010 to 2015. Outlines of reported and communicated complications were collected after whole blood donation. Analysis was done by general logistic regression.
Results: Complications after 30,000 Whole blood donation procedures calculated1620total .(54 per 1,000 donations). The majority of the complications were faint and pre-faint reaction with light headedness (58.6%), Sore arm (24%), Bruises and hematoma (14.4%). Minor complications were Agitation/sweating (2%) and arterial puncture(1%). Markers of the complications were age, sex, race, weight, blood pressure and donation status. All associated independently after whole blood donation. Age and first-time status were associated with a significantly higher risk of complications with 18-22 years old at higher risk compared to 23 to 50 years old. First-time donor were at higher risk compared to repeat donor.
Summary/Conclusion: The results of this study are helpful in identifying and understanding the promoter to complication of blood donation. Donor age and status were strong predictors of complications. The remedies and specific areas of care should be provided.

PB2540

KNOWLEDGE ATTITUDE AND PRACTICE OF BLOOD DONATION AMONGST MEDICAL STUDENTS IN NIGERIA

C. efobi[1,*], A.O. Ugwu[2], H.C. Okoye[2]

[1]Haematology, Chukwuemeka Odumegwu Ojukwu University, Awka, [2]Hematology, University of Nigeria Enugu Campus, Enugu, Nigeria

Background: There is currently a dire need for blood donors to meet the increasing demand for blood and blood products. Information on the perception and practice of blood donation among potential donors may help in designing policies for improved services in low income countries.
Aims: This study assesses the knowledge, attitude and practice of blood donation among medical students in Nigeria.
Methods: A descriptive cross sectional study carried out among different classes of medical students at two medical schools in south-eastern Nigeria in 2017. The sociodemographic characteristics, knowledge, attitude and practice of blood donation were sought from of the respondents.
Results: The age range was 19–46 years (mean=24.2±3.2) years with 169(43.7%) respondents having good knowledge and 37(9.6%) with poor knowledge of blood donation. There was a strong association between level of knowledge and respondents' year of study (p=0.001) but no significant association between knowledge and practice of blood donation (p=0.23). The donation rate was found to be 31.0% whereas 267 (69.0%) respondents had never donated blood. While a tenth (10.3%) of the respondents are regular blood donors, less than one third (31%) had ever donated blood. Majority of both the donors (85%) and non-donors (92.1%) opined that blood donation should be voluntary and non-remunerated.
Summary/Conclusion: Nigerian medical students have fair knowledge but a favourable attitude toward blood donation. Policy makers in the health sector could utilize this interesting observation in designing strategies for improving the quantity and quality of blood donation in Nigeria.

PB2541

REASONS FOR BLOOD DONOR DEFERRAL AMONG VOLUNTARY BLOOD DONORS IN A TERTIARY CARE HOSPITAL IN KATHMANDU, NEPAL

B. Nepal*

Blood Bank, Grande International Hospital, Kathmandu, Nepal

Background: Ensuring the wellness of the voluntary blood donor is the main purpose of the donor deferral. It also minimizes the unwanted symptoms that may appear among blood donor recipient.
Aims: To assess the Reasons for blood donor deferral among voluntary blood donors in a tertiary care hospital in Kathmandu, Nepal
Methods: This is the retrospective study carried out among voluntary blood donors at Grande International Hospital, a tertiary care hospital in Kathmandu, Nepal from January 2015 to January 2017.
Results: The data were collected from previous records of the blood donor history forms. From a total of 8,550 blood donations, 302(3.53%) blood donor were deferred due to various reasons. Among all the deferred blood donors 189(62.58%) were female where as 113(37.42%) were male. Furthermore, 289(95.69%) were temporarily deferred and 13(4.31%) were permanently deferred. The mean age of deferred blood donor was 35 years. Out of total blood donor deferral; 101(33.48%) donor were rejected because of bed side hypertension (*i.e.* blood pressure- systolic >140 and diastolic >90 mm hg) which was followed by anaemia(*i.e.* haemoglobin <12 gm/dl) 94(31.12%), vaccinations history 43(14.23%), hypotension (*i.e.* Systolic <90mm hg and diastolic <60 mm hg) 35(11.58%), dental examination 10(3.32%) and medication history 6(1.98%). Permanent deferral namely, risk factor involving transfusion transmitted infections and chronic disease were 5(1.65%) and 8(2.64%) respectively. The prime cause of permanent deferral was risk factor involving transfusion transmitted infections while the temporary deferral was bed side hypertension. Gender wise, the leading cause of donor deferral in male was bed side hypertension and anaemia was the major cause in female.
Summary/Conclusion: The findings of the survey aid to evaluate the significant causes of blood donor deferral. This study suggests that the restrictive criteria can be used for blood donor selection. This will in turn increase the blood supply of tertiary care hospital.

PB2542

DISTRIBUTION OF ABO AND RH BLOOD GROUP IN NEPALESE POPULATION

B. Nepal*

Blood Bank, Grande International Hospital, Kathmandu, Nepal

Background: ABO and RH are the major blood grouping system .which can effective transfusion compatibility .The distribution of blood group ABO and RH varies across the world according to the population
Aims: To get the knowledge of distribution of ABO and RH blood group for effective management of inventory
Methods: This is retrospective study conducted at Nepal Red Cross Society Central Blood Transfusion Service. Data from January 2010 to January 2016 were collected from donor management software .The data includes socio demographic data and Transfusion Transmissible infectious and other laboratory defects of blood donors.

Results: Out of 440720 blood donor, 384308 (87.20%) were male and 56412 (12.8%) were female. The commonest ABO blood group present was A (31.64%) followed by O (30.79%), B (25.94%) and AB (8.88%) in blood donors; while in Rhesus system, 428600 (97.25%) donors were Rh-Positive and 12120 (2.75%) donors were Rh-Negative.
Among the various ABO blood group "A" is the commonest and Rh Positive nearly equal to 97%.
Summary/Conclusion: Similarity of distribution of ABO and Rh blood group were reported in south Asian countries. This indicates the influence factor of genetic drift and ancestral link with Indian sub continent. These studies has a important proposition regarding the inventory management of blood bank and transfusion services.

DISTRIBUTION OF BLOOD DONOR IN DIFFERENT AGE GROUP IN KATHMANDU NEPAL

B. Nepal*

Blood Bank, Grande International Hospital, Kathmandu, Nepal

Background: Voluntary non-remunerated blood donor consists of 78% blood donor's population in Nepal. Therefore demographic about the distribution of blood donors according to the age group is important to achieve 100% Voluntary non-remunerated blood donors in Nepal.
Aims: To explore the demographic distribution of the blood donor in different age group in the Kathmandu Nepal.
Methods: This is retrospective study conducted at Nepal Red Cross Society Central Blood Transfusion Service. Data from January 2013 to January 2017 were collected from donor management software .The data includes socio demographic data .Data has been process with SPSS version -17
Results: During 4 years study period, total of 276,290 Blood donation happened from both mobile blood collection and in-house blood collection. Out of 276,290 Collection, 48351 (17.5%) are from 18-24 age group; 106924 (38.7%) are from 25-31 age group 53324 (19.3%) are from 32-38 age group; 34536 (12.5%) are from group 39-45 age group; 23761 (8.6%) are from age group 46-52 and 9394 (3.4%) from age group above 53 respectively.
Summary/Conclusion: The distribution of ABO blood group varies regionally and from one population to another. In Kathmandu, Nepal 18-38 years age group is the most common age group encountered donating blood. The data generated in the present study and several other studies of different geographical region of India will be useful to health planners and future health challenges in the region.

PLASMAPHERESIS: AN EXPERIENCE IN BLOOD BANK OF A TERTIARY CARE HOSPITAL IN PESHAWAR

H. Khan*

Hematology, Nowshera Medical colleg nowshera Pakistan, Nowshera, Pakistan

Background: plasmapheresis for therapeutic purposes is less practiced in Pakistan. It has a therapeutic as well as diagnostic importance and present study is a continuation of the above statement
Aims: To determine the frequency of major indications require plasmapheresis in blood bank of Lady Reading Hospital Peshawar.
Methods: This cross sectional study was conducted in blood bank of Lady Reading Hospital Peshawar from june 2010 to June 2012. Relevant information's were recorded on a pre-designed questionnaire prepared in accordance with the objectives of the study
Results: A total of 54 patients were enrolled in the trial. 23 (42.59%) were females, and 31(57.41%) were males. Males to females ration was 1.4:1. We received patients for plasmaphersis in age ranging from 15 to 74 years. Majority were young patients in age range 15 to 34 years age. We received majority of the patients for the subject procedure from ICU(Intensive care unit) 20(73%), followed by cardiothoracic unit 17(31.48%). We also receive two volunteers during study. The frequency of various indications for plasmapheresis were; myasthenia gravis 29(53.7%), Guillen barre syndrome 20(37.04%) and thrombocytopenic purpura 3(5.56%).
Summary/Conclusion: From this study we concluded that the autoimmune diseases are common in younger age which is a very serious concern for our society. Plasmapheresis is a therapeutic procedure as well and patients with autoimmune disorders get relieved with it symptomatically as autoimmune antibodies are removed. Myasthenia gravis was counted as major disease followed by GBS and thrombocytopenic purpura in our population.

we've BEEN PIONEERING CAR T CELL THERAPIES FOR OVER 20 YEARS AND WE'RE NOT STOPPING NOW.

It's a new day for research and patient care in CAR T cell therapies. City of Hope has been accelerating innovative CAR T research for more than 20 years, developing novel CAR T cell therapies for blood and solid tumors, as well as partnering with global biopharmaceutical companies for clinical trials.

- Over 180 patients currently being treated with CAR T cell therapies
- 14 open CAR T cell therapy trials with several more opening this year
- Authorized site for both tisagenlecluecel (Kymriah) and axicabtagene ciloleucel (Yescarta)

Find out more about City of Hope's CAR T cell therapies program. Go to **CityofHope.org/CAR-T** or call our dedicated CAR T cell therapy line: **+1 833-310-CART (2278)**
